### Noyes, Alfred 1880–1958

English poet

Night after night, among the gabled roofs,  
Climbing and creeping through a world unknown  
Save to the roosting stork, he learned to find  
The constellations, Cassiopeia's throne,  
The Plough still pointing to the Pole star,  
The Sword-belt of Orion. There he watched  
The movement of the planets, hours and hours,  
And wondered at the mystery of it all.

In the night sky, when the air is clear, there is a cosmic  
Rorschach test awaiting us. Thousands of stars, bright

peppered across the canopy of night. The eye, irritated  
by randomness, seeking order, tends to organize into pat-  
terns these separate and distinct points of light.

Indeed, "it is to mythology," says Sir John Herschel, "and to classic antiquity that I should be disposed to retreat, as to a neutral ground, on which to escape from vexatious and interminable discussions on this head." The view is correct: those who would sweep away the constellations altogether as incongruous absurdities, or wicked pagan allusions, seem rather reckless about the consequences of such a measure on astronomical history, chronology, and extra-observatorial practice.

## SOUTHERN CROSS

**Meredith, Owen (Edward Robert  
Bulwer-Lytton, First Earl Lytton)** 1831–91  
English statesman and poet

Then did I feel as one who, much perplexed,  
Led by strange legends and the light of stars

Over long regions of the midnight sand  
Beyond the red tract of the Pyramids,  
Is suddenly drawn to look upon the sky,  
From sense of unfamiliar light, and sees,  
Reveal’d against the constellated cope,  
The great cross of the South.

**Twain, Mark (Samuel Langhorne  
Clemens)** 1835–1910  
American author and humorist

We saw the Cross tonight, and it is not large. Not large,  
and not strikingly bright. But it was low down toward  
the horizon, and it may improve when it gets up higher  
in the sky. It is ingeniously named, for it looks just as a  
cross would look if it looked like something else. But that  
description does not describe; it is too vague, too general,  
too indefinite. It does after a fashion suggest a cross – a  
cross that is out of repair – or out of drawing; not cor-  
rectly shaped. It is long, with a short cross-bar, and the  
cross-bar is canted out of the straight line.

It consists of four large stars and one little one. The little  
one is out of line and further damages the shape. It should  
have been placed at the intersection of the stem and the  
cross-bar. If you do not draw an imaginary line from star  
to star it does not suggest a cross – nor anything in par-  
ticular.

One must ignore the little star, and leave it out of the  
combination – it confuses everything. If you leave it out,  
then you can make out of the four stars a sort of cross –  
out of true; or a sort of kite – out of true; or a sort of  
coffin – out of true.

**Kipling, Rudyard** 1865–1936

British writer and poet

After me cometh a Builder. Tell him, I too have known.  
When I was King and a Mason - a Master proven and skilled -

I cleared me ground for a Palace such as a King should build.

I decreed and dug down to my levels. Presently, under the silt,

I came on the wreck of a Palace such as a King had built...

...

Swift to my use in my trenches, where my well-planned ground-works grew,

I tumbled his quoins and his ashlar, and cut and reset them anew.

Lime I milled of his marbles; burned it, slacked it, and spread;

Taking and leaving at pleasure the gifts of the humble dead.

Yet I despised not nor gloried; yet as we wrenched them apart,

I read in the razed foundation the heart of that builder's heart.

As he had risen and pleaded, so did I understand

The form of the dream he had followed in the face of the thing he had planned.

**Grindal, Bruce** 1940–

American anthropologist

**Salamone, Frank**

American anthropologist

In the past twenty years, “doing” anthropology has become more and more complex. In the days when we traveled long distances to far-off places, our fieldwork stayed in the field. Now, the distances have been narrowed. Informants have become consultants. Consultants are our friends. As such, they can board a plane in their land and come to visit, spending long nights in earnest conversation about truth and meaning and enlightenment and expectations. In the days when we wrote only inscrutable manuscripts circulated among colleagues, there was no one to dispute the validity of our work except another “expert” in the area. Now, our consultant-friends are critics, editors of our written words, commentators of their lives, and ours.

## CONTEMPLATION

**von Humboldt, Alexander** 1769–1859  
German naturalist and explorer

In reflecting upon the different degrees of enjoyment presented to us in the contemplation of Nature, we find that the first place must be assigned to a sensation which is wholly independent of an intimate acquaintance with the physical phenomena presented to our view, or of the peculiar character of the region surrounding us. In the uniform plain bounded only by a distant horizon, where the lowly heather, the cistus, or waving grasses deck the soil; on the ocean shore, where the waves, softly rippling over the beach, leave a track, green with the weeds of the sea; everywhere, the mind is penetrated by the same sense of the grandeur and vast expanse of Nature, revealing to the soul, by a mysterious inspiration, the existence of laws that regulate the forces of the universe.

The mere accumulation of unconnected observations of details, devoid of generalization of ideas, may doubtlessly have tended to create and foster the deeply rooted prejudice, that the study of the exact sciences must necessarily chill the feelings, and diminish the nobler enjoyments attendant upon a contemplation of nature.

**Agassiz, Jean Louis Rodolphe** 1807–73  
Swiss-born American naturalist, geologist, and teacher

First-born among the Continents, though so much later in culture and civilization than some of more recent birth, America, so far as her physical history is concerned, has been falsely denominated the New World. Hers was the first dry land lifted out of the waters, hers the first shore

washed by the ocean that enveloped all the earth beside; and while Europe was represented only by islands rising here and there above the sea, America already stretched an unbroken line of land from Nova Scotia to the Far West.

If we imagine an observer to approach our planet from outer space, and, pushing aside the belts of red-brown clouds which obscure our atmosphere, to gaze for a

whole day on the surface of the earth as it rotates beneath him, the feature beyond all others most likely to arrest his attention would be the wedge-like outlines of the continents as they narrow away to the South.

This is indeed the most striking character presented by our map of the world, and has been so regarded ever since the chief features of our planet have become known to us.

[The geologist] will have to leave behind him – perhaps reluctantly – the dumbfounding spectacle of the present continental masses, firmly anchored to a plastic foundation yet remaining fixed in space; set thousands of kilometers apart, it may be, yet behaving in almost identical fashion from epoch to epoch and stage to stage like soldiers at drill; widely stretched in some quarters at various times and astoundingly compressed in others, yet retaining their general shapes, positions and orientations; remote from one another throughout history, yet showing in their fossil remains common or allied forms of terrestrial life; possessed during certain epochs of climates that may have ranged from glacial to torrid or pluvial to arid, though contrary to meteorological principles when their existing geographic positions are considered – to mention but a few such paradoxes.

A moving continent is as strange to us as a moving earth was to our ancestors, and we may be as prejudiced as they were. On the other hand, if continents have moved many former difficulties disappear, and we may be tempted to forget the difficulties of the theory itself and the imperfection of the evidence.

**Wheeler, John Archibald** 1911–

For the advancing army of physics, battling for many a decade with heat and sound, fields and particles, gravitation and spacetime geometry, the cavalry of mathematics, galloping out ahead, provided what it thought to be the rationale for the natural number system. Encounter with the quantum has taught us, however, that we acquire our knowledge in bits; that the continuum is forever beyond our reach. Yet for daily work the concept of the continuum has been and will continue to be as indispensable for physics as it is for mathematics.

...the corona is not a mass of foggy or milky light... but has a hairy structure, like long tufts of flax.... Of this appendage we may say with entire confidence that it cannot be an atmosphere...that is, a continuous mass of elastic gas held up by its own elasticity.... What, then, is the corona? Probably detached particles partially or wholly vaporized by the intense heat to which they are exposed.... The difficult question which we meet is, How are these particles held up? To this question only conjectural replies can be given.

The shaking fact was that they deteriorated so quickly. And why the sudden upswing in deaths. People weren’t indulging in vices more than they were a year ago. Maybe it was a kind of statistical equalizing. They’d been lucky and now the numbers were catching up to them.

The well-known virtue of the experimental method is that it brings situational variables under tight control. It thus permits rigorous tests of hypotheses and confidential

statements about causation. The correlational method, for its part, can study what man has not learned to control. Nature has been experimenting since the beginning of time, with a boldness and complexity far beyond the resources of science. The correlator's mission is to observe and organize the data of nature's experiments.

## COSMIC BALANCE

### Tesla, Nikola 1856–1943

Austrian-born Serbian American physicist and inventor

Every living being is an engine geared to the wheelwork of the universe. Though seemingly affected only by its immediate surroundings, the sphere of external influence extends to infinite distance. There is no constellation or nebula, no sun or planet, in all the depths of limitless space, no passing wander of the starry heavens, that does not exercise some control over its destiny – not in the vague and delusive sense of astrology, but in the rigid and positive meaning of physical science. More than this can be said. There is nothing endowed with life – from man,

who is enslaving the elements, to the humblest creature – in all this world that does not sway it in turn. Whenever action is born from force, though it be infinitesimal, the cosmic balance is upset and universal motion results.

That proposition is, that the whole world, living and not living, is the result of the mutual interaction, according to definite laws, of the forces possessed by the molecules of which the primitive nebulosity of the universe was composed. If this be true, it is no less certain that the existing world lay, potentially, in the cosmic vapour; and that a sufficient intelligence could, from a knowledge of the properties of the molecules of that vapour, have predicted, say the state of the Fauna of Britain in 1869, with as much certainty as one can say what will happen to the vapour of the breath in a cold winter's day.

**Jeans, Sir James Hopwood** 1877–1946

The cosmogonist has finished his task when he has described to the best of his ability the inevitable sequence of changes which constitute the history of the material universe. But the picture which he draws opens questions of the widest interest not only to science, but also to humanity. What is the significance of the vast processes it portrays? What is the meaning, if any there be which is intelligible to us, of the vast accumulations of matter which appear, on our present interpretations of space and time, to have been created only in order that they may destroy themselves?

## COSMOGONY

**Bridgman, Percy Williams** 1882–1961

American physicist

...the most striking thing about cosmogony is the perfectly hair raising extrapolations which it is necessary to make. We have to extend the times of the order of 1013 years and distances of the order of 109 light years [regarding] laws which have been checked in a range of not more than  $3 \times 10^2$  years, and certainly in distances not greater than the distance which the solar system has traveled in that time, or about  $4 \times 10^{-2}$  light years. It seems to me that one cannot take such extrapolations seriously unless one subscribes to a metaphysics that claims that laws of the necessary mathematical precision *really* control the actual physical universe.

The purpose of any cosmogonic theory is to seek out ideally simple conditions which could have initiated the world from which, by the play of recognized physical forces, that world, in all its complexity, may have resulted.

Only on the basis of the spectroscopic investigation of stars and the modern atomic physics, and only after well-founded opinions about spatial order of the stellar universe had been derived by analysis of vast observational material, could the astronomers undertake to draw a picture, first of the inner constitution and then also of the temporal development, of stars. Cosmogony still remains a rather problematic enterprise.

What is a big deal – the biggest deal of all – is how you get something out of nothing. Don't let the cosmologists try to kid you on this one. They have not got a clue either – despite the fact that they are doing a pretty good job of convincing themselves and others that this is really not a problem. "In the beginning," they will say, "there was nothing – no time, space, matter, or energy. Then there was a quantum fluctuation from which...." Whoa! Stop right there. You see what I mean? First there is nothing, then there is something. And the cosmologists try to bridge the two with a quantum flutter, a tremor of uncertainty that sparks it all off. Then they are away and before you know it, they have pulled a hundred billion galaxies out of their quantum hats.

So it seems reasonable to ask what cosmology, now that it is a science, can tell us about God.

Sadly, but in all earnestness, I must report that the answer as I see it is: Nothing. Cosmology presents us neither the face of God, nor the handwriting of God, nor such thoughts as may occupy the mind of God. This does not mean that God does not exist, or that he did not create the universe, or universes. It means that cosmology offers no resolution to such questions.

In cosmology the reliance on physical simplicity, pure thought and revealed knowledge is carried well beyond the fringe because we have so little else to go on. By this desperate course we have arrived at a few simple

pictures of what the Universe may be like. The great goal is now to become more familiar with the Universe, to learn whether any of these pictures may be a reasonable approximation, and if so how the approximation may be improved. The great excitement in cosmology is that the prospects for doing this seem to be excellent.

We have bravely tested the waters and have found the ocean to our liking, resonant with our nature. Something in us recognizes the Cosmos as home. We are made of stellar ash. Now these spots, as they are somewhat dark and of considerable size, are plain to everyone and every age has seen them, wherefore I will call them great or ancient spots, to distinguish them from other spots, smaller in size, but so thickly scattered that they sprinkle the whole surface of the Moon, but especially the brighter portion of it. These spots have never been observed by anyone before me; and from my observations of them, often repeated, I have been led to the opinion which I have expressed, namely, that I feel sure that the surface of the Moon is not perfectly smooth, free from inequalities and exactly spherical...but that, on

the contrary, it is full of inequalities, uneven, full of hollows and protuberances, just like the surface of the Earth itself, which is varied everywhere by lofty mountains and deep valleys.

How vast is creation! I see the planets rise and the stars hurry by, carried along with their light! What, then, is this hand which propels them? The sky broadens the more I ascend. Worlds revolve around me. And I am the center of this restless creation.

Oh, how great is my spirit! I feel superior to that miserable world lost in the immeasurable distance beneath me; planets frolic about me – comets pass by casting forth

their fiery tails, and centuries hence they will return, still running like horses on the field of space. How I am soothed by this immensity! Yes, this is indeed made for me; the infinite surrounds me on all sides. I am devouring it with ease.

There is no interruption in creation; no broken arch, no lapse; an action and its consequences embrace all nature; the chain may be longer or shorter, but never breaks. Climb this immense knotted cord, take one fact after another, and you will progress from the vibrio to the constellation. The immanent marvel has its own cohesion. Nothing is wasted; no effort is lost. The useless does not exist. The universe has what is necessary and only what is necessary.

Lecture Third (p. 156)

Gould & Lincoln. Boston, Massachusetts, USA. 1857

Who shall declare what, throughout these long ages, the history of creation has been? We see at wide intervals the mere fragments of successive floras; but know not how what seem the blank interspaces were filled, or how, as extinction overtook in succession one tribe of existences after another, and species, like individuals, yielded to the great law of death, yet other species were brought to the birth and ushered upon the scene, and the chain of being was maintained unbroken. We see only detached bits of that green web which has covered our earth ever since the dry land first appeared; but the web itself seems to have been continuous throughout all time; though ever, as breadth after breadth issued from the creative loom, the pattern has altered, and the sculpturesque and graceful forms that illustrated its first beginnings and its middle

spaces have yielded to flowers of richer colour and blow, and fruits of fairer shade and outline; and for gigantic club-mosses stretching forth their hirsute arms, goodly trees of the Lord have expanded their great boughs; and for the barren fern and the calamite, clustering in thickets beside the waters, or spreading on flowerless hill-slopes, luxuriant orchards have yielded their ruddy flush, and rich harvests their golden gleam.

### **Berra, Tim M.** 1943–

The proper place for the study of religious beliefs is in a church or temple, at home, or in a course on comparative religions, but not in a biology class. There is no place in our world for an ideology that seeks to close minds, force obedience, and return the world to a paradise that never was. Students should learn that the universe can be confronted and understood, that ideas and authority should be questioned, that an open mind is a good thing. *Education does not exist to confirm people's superstitions, and children do not learn to think when they are fed only dogma.*

The argument that the literal story of Genesis can qualify as science collapses on three major grounds: the creationists' need to invoke miracles in order to compress the events of the earth's history into the biblical span of a few thousand years; their unwillingness to abandon claims clearly disproved, including the assertion that all fossils are products of Noah's flood; and their reliance upon distortion, misquote, half-quote, and citation out of context to characterize the ideas of their opponents.

The Verdict on Creationism

*The Skeptical Inquirer*, Volume 12, Winter, 87/88 (p. 186)

Creation science has not entered the curriculum for a reason so simple and so basic that we often forget to mention it: because it is false, and because good teachers understand exactly why it is false. What could be more destructive of that most fragile yet most precious commodity in our entire intellectual heritage – good teaching – than a bill forcing honorable teachers to sully their sacred trust by granting equal treatment to a doctrine not only known to be false, but calculated to undermine any general understanding of science as an enterprise?

**Laudan, Larry** 1945–

Rather than taking on the creationists obliquely and in wholesale fashion by suggesting that what they are doing is "unscientific" tout court (which is doubly silly because few authors can even agree on what makes an activity scientific), we should confront their claims directly and in piecemeal fashion by asking what evidence and arguments can be marshaled for and against each of them. The core issue is not whether Creationism satisfies some undemanding and highly controversial definition of what is scientific; the real question is whether the existing evidence provides stronger arguments for evolutionary theory than for Creationism.

It becomes evermore important to understand what is science and what is not. Somehow we have failed to let our students in on that secret. We find as a consequence, that we have a large and effective group of creationists who seek to scuttle the basic concept of the science of biology – the science that is essential for medicine, agriculture, and life itself; a huge majority of citizens who, in "fairness," opt for presenting as equals the "science" of creation and the science of evolutionary biology; and a president who is so poorly informed that he believes that scientists are questioning that evolution ever occurred. It is hard to think of a more terrible indictment of the way we have taught science.

American creationist

Creationism is consistent with the innate thoughts and daily experiences of the child and thus is conducive to his

mental health. He knows, as part of his own experience of reality, that a house implies a builder and a watch a watchmaker. As he studies the still more intricately complex nature of, say, the human body, or the ecology of a forest, it is highly unnatural for him to be told to think of these systems as chance products of irrational processes.

*Scientific Creationism*

Chapter I (p. 14)

Creation-Life Publishers. San Diego, California, USA. 1974

It seems beyond all question that such complex systems as the DNA molecule could never arise by chance, no matter how big the universe or how long the time. The creation model faces this fact realistically and postulates a great Creator, by whom came life.

**Nelkin, Dorothy** 1933–2003

Creationism is a “gross perversion of scientific theory.” Scientific theory is derived from a vast mass of data and hypotheses, consistently analysed; creation theory is “God given and unquestioned”, based on an a priori commitment to a six-day creation. Creationists ignore the interplay between fact and theory, eagerly searching for facts to buttress their beliefs. Creationism cannot be submitted to independent testing and has no predictive value, for it is a belief system that must be accepted on faith.

According to the idealized principles of scientific discourse, the arousal of dormant issues should reflect fresh data that give renewed life to abandoned notions. Those outside the current debate may therefore be excused for suspecting that creationists have come up with something new, or that evolutionists have generated some serious internal trouble. But nothing has changed; the creationists have presented not a single new fact or argument. Darrow and Bryan were at least more entertaining than we lesser antagonists today. The rise of creationism is politics, pure and simple; it represents one issue (and by no means the major concern) of the resurgent evangelical right. Arguments that seemed kooky just a decade ago have reentered the mainstream.

*Hen’s Teeth and Horses Toes*

Evolution as Fact and Theory (p. 253)

W.W. Norton & Company, Inc. New York, New York, USA. 1983

The basic attack of modern creationists falls apart on two general counts before we even reach the supposed factual details of their assault against evolution. First, they play upon a vernacular misunderstanding of the word “theory” to convey the false impression that we evolutionists are covering up the rotten core of our edifice. Second, they misuse a popular philosophy of science to argue that they are behaving scientifically in attacking evolution. Yet the same philosophy demonstrates that their own belief is not science, and that “scientific creationism” is a meaningless and self-contradictory phrase, an example of what Orwell called “newspeak.”

Evolution as Fact and Theory (p. 254)

Our creationist detractors charge that evolution is an unproved and unprovable charade – a secular religion masquerading as science. They claim, above all, that evolution generates no predictions, never exposes itself to test, and therefore stands as dogma rather than disprovable science. This claim is nonsense. We make and test risky predictions all the time; our success is not dogma, but a highly probable indication of evolution’s basic truth.

Brazilian-born English zoologist

To be creative, scientists need libraries and laboratories and the company of other scientists; certainly a quiet and untroubled life is a help. A scientist's work is in no way deepened or made more cogent by privation, anxiety, distress, or emotional harassment. To be sure, the private lives of scientists may be strangely and even comically mixed up, but not in ways that have any special bearing on the nature and quality of their work. If a scientist were to cut off an ear, no one would interpret such an action as evidence of an unhappy torment of creativity; nor will a scientist be excused any bizzarerie, however extravagant, on the grounds that he is a scientist, however brilliant.

However, creativity is not simply originality and unlimited freedom. There is much more to it than that. Creativity also imposes restrictions. While it uses methods other than those of ordinary thinking, it must not be in disagreement with ordinary thinking – or rather, it must be something that, sooner or later, ordinary thinking will understand, accept, and appreciate. The real creative trick is to get the right answer when you have only half of the data in hand and half of it is wrong and you don't know which half is wrong. Let us assume that crises are a necessary precondition for the emergence of novel theories and ask next how scientists respond to their existence. Part of the answer, as obvious as it is important, can be discovered by noting first what scientists never do when confronted by even severe and prolonged anomalies. Though they may begin to lose faith and then to consider alternatives, they do not renounce the paradigm that has led them into crisis. They do not, that is, treat anomalies as counterinstances, though in the vocabulary of philosophy of science that is what they are.

The romantic view of the creative process of science as something cognate with poetic invention is often sneered at by people who pride themselves as shrewd, practical-minded men of the world with a sound sense of the value of money. But they don't do any better than the rest of us, and it is they, indeed – people who believe that there is a cut and dried scientific method and that they can buy scientific results by paying for them – who are the incurable daydreamers with their heads in the clouds and no real understanding of the way the mind works.

I know of no significant advance in science that did not require major inputs from both cerebral hemispheres. This is not true for art, where apparently there are no experiments by which capable, dedicated and unbiased observers can determine to their mutual satisfaction which works are great. As one of hundreds of examples, I might note that the principal French art critics, journals and museums of the late nineteenth and early twentieth centuries rejected French Impressionism in toto; today the same artists are widely held by the same institutions to have produced masterpieces. Perhaps a century hence the pendulum will reverse direction again.

It is often cited as an argument against teamwork that every great new concept originates in one brain. This is true, but tossing an idea around in a group discussion helps to formulate it clearly in the brain of one participant or the other. Some of my best ideas came when I was trying to explain to my students and associates something that I myself only sensed but did not yet fully understand.

All children are curious and I wonder by what process this trait becomes developed in some and suppressed in others. I suspect again that schools and colleges help in the suppression insofar as they meet curiosity by giving the answers, rather than by some method that leads from narrower questions to broader questions. It is hard to satisfy the curiosity of a child, and even harder to satisfy the curiosity of a scientist, and methods that meet curiosity with satisfaction are thus not apt to foster the development of the child into the scientist. I don't advocate turning all children into professional scientists, although I think there would be advantages if all adults retained something of the questioning attitude, if their curiosity were less easily satisfied by dogma, of whatever variety.

One can fool all the people some of the time, and some of the people all the time, but one cannot fool all the people all the time when the evidence is as clear as it can be in natural science. Nothing, by contrast, can force one person to agree with another about which approach to literary criticism is the best, right, or most fruitful; and we simply do not know what makes some children grow up curious and others uninterested; and we can and do argue and disagree over such matters without end.

Curiosity is one of our more primal appetites. It may at time go out of fashion, but it always commands respect. Timeless as well as artless in its enticement, it has stirred men since mankind's more hirsute, sniffingly inquisitive days. Certainly it is the prerequisite of knowledge, if not that rarer quality of wisdom itself.

To every investigator there come moments when his thought is baffled, when the limits of experimental possibility seem to have been reached and he faces a barrier which defies his curiosity. Then it is that imagination, like a glorious greyhound, comes bounding along, leaps the barrier, and a vision is flashed before the mind – a vision no doubt that is partly false, but a vision that may be partly true. It stirs up new ideas in the thoughts of the investigator, it fires him with a fresh enthusiasm and his curiosity spurs him on to further endeavors.

...I stand at the seashore, alone, and start to think: There are the rushing waves...mountains of molecules each stupidly minding its own business...trillions apart...yet forming white surf in unison.

Ages on ages...before any eyes could see...year after year...thunderously pounding the shore as now. For whom, for what? ...On a dead planet with no life to entertain.

Never at rest tortured by energy...wasted prodigiously by the sun...poured into space. A mite makes the sea roar.

Deep in the sea, all molecules repeat the patterns of one another till complex new ones are formed. They make others like themselves...and a new dance starts.

Growing in size and complexity...living things, masses of atoms, DNA, protein...dancing a pattern ever more intricate.

Out of the cradle, onto dry land...here it is standing...atoms with consciousness...matter with curiosity.

Stands at the sea...wonders at wondering...I...a universe of atoms...an atom in the universe.

**Lauden, Larry** 1945–

If a sound justification for most scientific activity is going to be found, it will eventually come perhaps from a recognition that man's sense of curiosity about the world and himself is every bit as compelling as his need for clothing and food.... Making sense of the world and one's place in that world has roots deep within the human psyche.... We can drop the dangerous pretense that science is legitimate only in so far as it contributes to our material well-being or to our store of perennial truths. Viewed in this light, the repudiation of theoretical scientific inquiry is tantamount to a denial of what may be our most characteristically human trait.

The value the world sets upon [scientists'] motives is often grossly unjust and inaccurate. Consider, for example, two of them: mere insatiable curiosity and the desire to do good. The latter is put high above the former, and yet it is the former that moves some of the greater men the human race has yet produced: the scientific investigators. What actually urges him on is not some brummagem idea of Service, but a boundless, almost pathological thirst to penetrate the unknown, to uncover the secret, to find out what has not been found out before. His prototype is not the liberator releasing slaves, the good Samaritan lifting up the fallen, but a dog sniffing tremendously at an infinite series of rat-holes.

What is the origin of the urge, the fascination that drives physicists, mathematicians, and presumably other scientists as well? Psychoanalysis suggests that it is sexual curiosity. But all that is left is a meandering line with little explanatory power; there is no way to predict how future points are likely to fall. Science is the search for neat, predictable curves, compact ways of summarizing the data. But there is always the danger that the curves we see are illusory, like pictures of animals in clouds.

Of all gifts to earth, the first and greatest was darkness. Darkness preceded light, you will remember, in Genesis. Perhaps that is why darkness seems to man natural and universal. It requires no explanation and no cause. We postulate it. Whereas light, being to our minds merely the cleansing vibration that dispels the black, requires some origin, some lamp whence to shine. From the appalling torch of the sun down to the pale belly of the glowworm we deem light a derivative miracle, proceeding from some conceivable source. We can conceive darkness without thought of light; but we cannot conceive light without darkness.

Almost no one is indifferent to Darwin, and no one should be. The Darwinian theory is a scientific theory, and a great one, but that is not all it is. The creationists who oppose it so bitterly are right about one thing: Darwin's dangerous idea cuts much deeper into the fabric of our most fundamental beliefs than many of its sophisticated apologists have yet admitted, even to themselves.

*Darwin's Dangerous Idea*

Chapter One, Section 1 (p. 18)

Simon & Schuster. New York, New York, USA. 1995

Let me lay my cards on the table. If I were to give an award for the single best idea anyone ever had, I'd give it to Darwin, ahead of even Newton or Einstein and everyone else. In a single stroke, the idea of evolution by natural selection unifies the realm of life, meaning and purpose with the realm of space and time, cause and effect, mechanism and physical law.

*Darwin's Dangerous Idea*

Chapter One, Section 1 (p. 21)

Simon & Schuster. New York, New York, USA. 1995

Do you believe, literally, in an anthropomorphic God? If not, then you must agree with me that the song is a beautiful, comforting falsehood. Is that simple song nevertheless a valuable meme? I certainly think it is. It is a

modest but beautiful part of our heritage, a treasure to be preserved. But we must face the fact that, just as there were times when tigers would not have been viable, times are coming when they will no longer be viable, except in zoos and other preserves, and the same is true of many of the treasures in our cultural heritage.

*Darwin's Dangerous Idea*

Chapter Eighteen, Section 1 (p. 514)

Simon & Schuster. New York, New York, USA. 1995

We cannot preserve all the features of the cultural world in which these treasures flourished. We wouldn't want to.

*Darwin's Dangerous Idea*

Chapter Eighteen, Section 1 (p. 514)

Simon & Schuster. New York, New York, USA. 1995

But hasn't there been a tremendous rebirth of fundamentalist faith in all these creeds? Yes, unfortunately, there has been, and I think that there are no forces on this planet more dangerous to us all than the fanaticisms of fundamentalism, of all the species: Protestantism, Catholicism, Judaism, Islam, Hinduism, and Buddhism, as well as countless smaller infections. Is there a conflict between science and religion here? There most certainly is.

*Darwin's Dangerous Idea*

Chapter Eighteen, Section 1 (p. 515)

Simon & Schuster. New York, New York, USA. 1995

I know, I know, the lion is beautiful but dangerous; if you let the lion roam free, it would kill me; safety demands that it be put in a cage. Safety demands that religions be put in cages, too – when absolutely necessary.

*Darwin's Dangerous Idea*

Chapter Eighteen, Section 1 (p. 515)

Simon & Schuster. New York, New York, USA. 1995

Save the Baptists! Yes, of course, but not by all means. Not if it means tolerating the deliberate misinforming of children about the natural world. According to a recent poll, 48% of the people in the USA today believe that the book of Genesis is literally true. And 70% believe that "creation science" should be taught in school alongside evolution. Some recent writers recommend a policy in which parents would be able to "opt out" of materials they didn't want their children taught. Should evolution be taught in the schools? Should arithmetic be taught? Should history? Misinforming a child is a terrible offense.

*Darwin's Dangerous Idea*

Chapter Eighteen, Section 1 (p. 516)

Simon & Schuster. New York, New York, USA. 1995

The message is clear: those who will not accommodate, who will not temper, who insist on keeping only the purest and wildest strain of their heritage alive, we will be obliged, reluctantly, to cage or disarm, and we will do our best to disable the memes they fight for.

*Darwin's Dangerous Idea*

Chapter Eighteen, Section 1 (p. 516)

Simon & Schuster. New York, New York, USA. 1995

If you insist on teaching your children falsehoods – that the Earth is flat, that "Man" is not a product of evolution by natural selection – then you must expect, at the very least, that those of us who have freedom of speech will feel free to describe your teaching as the spreading of falsehoods, and will attempt to demonstrate this to your children at our earliest opportunity. Our future well-being – the well-being of all of us on the planet – depends on the education of our descendants.

The Darwinian revolution knocked out the back wall, revealing eerie lighted landscapes as far back as we can see. Only a fool could deny the revolutionary impact of Darwinism on the outlook of the nineteenth century, when – as one biologist put it – the educated public was faced with the alternative "for Darwin or against evolution." But the narrow sectarianism of the neo-Darwinists of our own age is an altogether different matter; and in the not-too-distant future biologists may well wonder what kind of benightedness it was that held their elders in thrall.

[Darwinism] means that man must, for certain purposes of science, toe the line with the rest of living things. And at first, naturally enough, man did not like it. He was too lordly. For a long time, therefore, he pretended to be fighting for the Bible, when he was really fighting for his own dignity. This was rather hard on the Bible, which has nothing to do with the Aristotelian theory of the fixity of species; though it might seem possible to read back something of the kind into the primitive creation-stories preserved in Genesis. Now-a-days, however, we have mostly got over the first shock to our family pride. We are all Darwinians in a passive kind of way.

There is a hideous fatalism about it, a ghastly and damnable reduction of beauty and intelligence, of strength and purpose,

No data were taken at station D during the period 0830 to 1630 GST due to the presence of a red racer snake (*Coluber constrictor*) draped across the high-tension wires (33,000 V) serving the station. However, even though this snake, or rather a three-foot section of its remains, was caught in the act of causing an arc between the transmission lines, we do not consider it responsible for the loss of data. Rather we blame the incompetence of a red-tailed hawk (*Buteo borealis*) who had apparently built a defective nest that fell off the top of the nearby transmission tower, casting her nestlings to the ground, along with their entire food reserve consisting of a pack rat, a kangaroo rat, and several snakes, with the exception of the above-mentioned snake who had a somewhat higher destiny. No comparable loss of data occurred at the other antenna sites.

There is a tendency to mistake data for wisdom, just as there has always been a tendency to confuse logic with values, intelligence with insight. Unobstructed access to facts can produce unlimited good only if it is matched by the desire and ability to find out what they mean and where they lead. Facts are terrible things if left sprawling and unattended. They are too easily regarded as evaluated certainties rather than as the rawest of raw materials crying to be processed into the texture of logic.

Some of them are corpses, skeletons, mummies, twitching, tottering, animated by companions that have been damned alive. There are giants that will walk by, though sound asleep. There are things that are theorems and things that are rags: they’ll go by like Euclid arm in arm with the spirit of anarchy. Here and there will flit little harlots. Many are clowns. But many are of the highest respectability. Some are assassins. There are pale stenchers and gaunt superstitions and mere shadows and lively malices: whims and amiabilities. Sometimes there are heated arguments at meetings about how to interpret data. When you have very few facts, fully interpreting them can give rise to three or four interpretations – within the error bars, the uncertainties in the measurements. You get people adhering to one or the other interpretation for a while, and that's not based on fact because there are not enough facts. Eventually more facts are gathered and it becomes clear what the answer is, and everybody agrees. In the end you have a new result. That's the wonderful thing about science, that you can only find in science. There is a point when there is no doubt anymore. There is usually a lot of emotional stress before you get rid of some former idea. There may

be a few crackpots who fight it, but if the evidence is good, eventually all accept it. I think that's wonderful. One of the best things about science is that there are some objective answers.

When a man of science speaks of his “data,” he knows very well in practice what he means. Certain experiments have been conducted, and have yielded certain observed results, which have been recorded. But when we try to define a “datum” theoretically, the task is not altogether easy. A datum, obviously, must be a fact known by perception. But it is very difficult to arrive at a fact in which there is no element of inference, and yet it would seem improper to call something a “datum” if it involved inferences as well as observation. This constitutes a problem...

The individual source of the statistics may easily be the weakest link. Harold Cox tells a story of his life as a young man in India. He quoted some statistics to a Judge .... His friend said, "Cox, when you are a bit older, you will not quote Indian statistics with that assurance. The Government are very keen on amassing statistics – they collect them, and they raise them to the *n*th power, take the cube root and prepare wonderful diagrams. But what you must never forget is that everyone of those figures come in the first instance from the *chowty dar* (village watchman), who just puts down what he damn pleases."

We are, therefore, in danger of being overwhelmed by our data and of being unable to deal with the simpler problems

first and understand their connection. The continual heaping up of data is worse than useless if interpretation does not keep pace with it. In biology this is all the more deplorable because it leads us to slur over what is characteristically biological in order to reach hypothetical “causes.”

**Eldredge, Niles** 1943–

And this poses something of a problem: if we date the rocks by their fossils, how can we then turn around and talk about patterns of evolutionary change through time in the fossil record? We need an independent time frame to know that a trilobite in Ohio is roughly the same age as one in New York before we can talk about geographic variation; otherwise, their differences might as well be ascribed to the sort of process of gradual change that Darwin thought was inevitable with the simple passage of time.

There is nothing more unjust than the vulgar opinion, by which physicians are misrepresented as friends to death. On the contrary, if the number of those who recover by physic could be opposed to that of the martyrs to it, the former would rather exceed the latter. Nay, some are so cautious on this head, that, to avoid a possibility of killing the patient, they abstain from all method of curing, and prescribe nothing but what can neither do good nor harm. I have heard some of these, with great gravity, deliver it as a maxim that Nature should be left to do her own work, while the physician stands by as it were to clap her on the back and encourage her when she doth well.

## DECAY

**Hutton, James** 1726–97

Scottish geologist, chemist, and naturalist

We are thus led to see a circulation of the matter of this globe, and a system of beautiful economy in the works of nature. This earth, like the body of an animal, is wasted at the same time that it is repaired. It has a state of growth and augmentation; it has another state, which is that of diminution and decay. This world is thus destroyed in one part, but it is renewed in another; and the operations by which this world is thus constantly renewed are as evident to the scientific eye, as are those in which it is necessarily destroyed.

**Thoreau, Henry David** 1817–62

American essayist, poet, and practical philosopher

How much beauty in decay! I pick up a white oak leaf, dry and stiff, but yet mingled red and green, October-like, whose pulpy part some insect has eaten beneath, exposing the delicate network of its veins. It is very beautiful held up to the light, such work as only an insect eye could perform.... To rebuild the tortoise-shell is a far finer game than any geographical or other puzzle, for the pieces do not merely make part of a plane surface, but you have got to build a roof and a floor and the connecting walls. These are not only thus dovetailed and braced and knitted and bound together, but also held together by the skin and within. It is a band-box.

It is necessary for technical reasons that these warheads be stored upside down, that is, with the top at the bottom and the bottom at the top. In order that there may be no doubt as to which is the bottom and which is the top, it will be seen to it that the bottom of each warhead immediately be labeled with the word TOP.

Decisions are something more than factual propositions. To be sure, they are descriptive of a future state of affairs, and this description can be true or false in a strictly empirical sense; but they possess, in addition, an imperative quality – they select one future state of affairs in preference to another and direct behavior toward the chosen alternative. In short, they have an ethical as well as factual content.

It has long been my wish to make you the patron saint or tutelary divinity of some book of mine, and it has lately

occurred to me that it ought to be a book of the desultory and chatty sort that would remind you, in your present exile at the world's eastern rim, of the many quiet evenings of old, when, over a tankard of mellow October and pipe of fragrant Virginia, while Yule logs crackled blithely and the music of pattering sleet was upon the window-pane, we used to roam in fancy through the universe and give free utterance to such thoughts, sedate or frivolous, as seemed to us good.

Like all other arts, the Science of Deduction and Analysis is one which can only be acquired by long and patient study, nor is life long enough to allow any mortal to attain the highest possible perfection in it. Before turning to those moral and mental aspects of the matter which present the greatest difficulties, let the inquirer begin by mastering more elementary problems.

To give rules for deduction is like giving rules for firing a gun. You teach how to load the gun, and how to aim it when firing. These two points are like the premises, and their combination in deduction. In firing, the ball will take care of itself. If the charge and the aim be right, it will hit the mark. This is like the conclusion of a deductive syllogism. Take care of the premises, and the conclusion will take care of itself.

The question whether any branch of science can ever become purely deductive is easily answered. It cannot. If science deals with the external world, as we believe it does, and not merely with the relations of propositions then no branch of science can ever be purely deductive. Deductive reasoning by itself can never tell us about facts. The use of deduction in science is to serve as a calculus to make our observations go further, not to take the place of observation.

Mathematical reasoning is deductive in the sense that it is based upon definitions which, as far as the validity of the reasoning is concerned (apart from any existential import) needs only the test of self-consistency. Thus no external verification of definitions is required in mathematics, as long as it is considered merely as mathematics.

“Deeds” were never invented, they were done; thoughts, on the other hand, are a relatively late discovery of man. First he was moved to deeds by unconscious factors; it was only a long time afterward that he began to reflect upon the causes that had moved him; and it took him a very long time indeed to arrive at the preposterous idea that he must have moved himself – his mind being unable to identify any other motivating force than his own.

It is not the critic who counts; not the man who points out how the strong man stumbles, or where the doer of deeds could have done them better. The credit belongs to the man who is actually in the arena, whose face is marred by dust and sweat and blood; who strives valiantly; who errs, who comes short again and again, because there is no effort without error and shortcoming; but who does actually strive to do the deeds; who knows great enthusiasms, the great devotions; who spends himself in a worthy cause; who at the best knows in the end the triumph of high achievement, and who at the worst, if he fails, at least fails while daring greatly, so that his place shall

The reasoning of mathematicians is founded on certain and infallible principles. Every word they use, conveys a determinate idea, and by accurate definitions they excite the same ideas in the mind of the reader that were in the mind of the writer. When they have defined the terms they intend to make use of, they premise a few axioms, or self evident principles, that every man must assent to as soon as proposed. They then take for granted certain postulates, that no one can deny them, such as, that a right line may be drawn from one given point to another, and from these plain simple principles, they have raised most astonishing speculations, and proved the extent of the human mind to be more spacious and capable than any other science.

Definition is a metaphorical word, which literally signifies “laying down a boundary.” All definitions are of names, and of names only; but in some definitions, it is clearly apparent, that nothing is intended except to explain the meaning of the word; while in others, besides explaining the meaning of the word, it is also implied that there exists, or may exist, a *thing* corresponding to the word.

...there are terms which cannot be defined, such as number and quantity. Any attempt at a definition would only throw difficulty in the student's way, which is already done in geometry by the attempts at an explanation of the terms point, straight line, and others, which are to be found in treatise on that subject. A point is defined to be that “which has no parts and which has no magnitude”; a straight line is that which “lies evenly between its extreme points...” In this case the explanation is a great deal harder than the term to be explained, which must always happen when we are guilty of the absurdity of attempting to make the simplest ideas yet more simple.

A definition should be framed with reference to the thing defined, and not to any use to which either the term or the definition may be applied in some wider statement or system of thought. It should include everything that is essential, and exclude everything that is not essential, to a conception of the thing defined. In other words, the thing should be defined as it is – an “und fur sich” – “in itself, by itself, for its own sake.”

The most important of our duties, then, is to seek means by which we may destroy delusions that can never do more than mislead us. Thus, be it understood, to demonstrate a theorem, it is neither necessary nor even advantageous to know what it means. The geometer might be replaced by the logic piano imagined by Stanley Jevons; or, if you choose, a machine might be imagined where the assumptions were put in at one end, while the theorems came out at the other, like the legendary Chicago machine where the pigs go in alive and come out transformed into hams and sausages. No more than these machines need the mathematician know what he does.

Franken's first demonstration of nonlinear optical frequency conversion in 1961 employed a quartz crystal to double the frequency of 694-nm light from a ruby laser. Because that interaction was not phase matched, the ultraviolet output power was so small that the editors at Physical Review Letters mistook for a blemish the spot on Franken's spectrograph plate that demonstrated the new effect. They airbrushed it out of the published version, rendering the first evidence of nonlinear frequency conversion truly invisible.

When Nature lifted the ice-sheet from the mountains she may well be said not to have turned a new leaf, but to have made a new one of the old. Throughout the unnumbered seasons of the glacial epoch the range lay buried, crushed, and sunless. In the stupendous denudation to which it was then subjected, all its pre-glacial features disappeared. Plants, animals, and landscapes were wiped from its flanks like drawings from a blackboard, and the vast page left smooth and clean, to be repictured with young life and the varied and beautiful inscriptions of water, snow, and the atmosphere.

## DESCRIPTION

**Barrow, John D.** 1952–

English theoretical physicist

Just as our picture of the most elementary particles of matter as little billiard balls, or atoms as mini solar systems, breaks down if pushed far enough, so our most sophisticated scientific description in terms of particles, fields, or strings may well break down as well if pushed too far. Mathematics is also seen by many as an analogy. But, it is implicitly assumed to be the analogy that never breaks down. Our experience of the world has failed to reveal any physical phenomenon that cannot be described mathematically. That is not to say there are not things for which a description is wholly inappropriate or pointless. Rather, there has yet to be found any system in Nature so unusual that it cannot be fitted into one of the strait-jackets that mathematics provides.

Down the River (p. 219)

Ballantine Books. New York, New York, USA. 1968

The restless sea, the towering mountains, the silent desert – what do they have in common? and what are the essential differences? Grandeur, color, spaciousness, the power of the ancient and elemental, that which lies beyond the ability of man to wholly grasp or utilize, these qualities all three share. In each there is the sense of something ultimate, with mountains exemplifying the brute force of natural processes, the sea concealing the richness, complexity and fecundity of life beneath a surface of huge monotony, and the desert – what does the desert say? The desert says nothing. Completely passive, acted upon but never acting, the desert lies there like the bare skeleton of Being, spare, sparse, austere, utterly worthless,

inviting not love but contemplation. In its simplicity and order it suggests the classical, except that the desert is a realm beyond the human and in the classicist view only the human is regarded as significant or even recognized as real.

None other than this long brown land lays such a hold on the affections. The rainbow hills, the tender bluish mists, the luminous radiance of the spring, have the lotus charm. They trick the sense of time, so that once inhabiting there you always mean to go away without quite realizing that you have not done it.

I shall never be able to express clearly whence comes this pleasure men take from aridity, but always and everywhere I have seen men attach themselves more stubbornly to barren lands than to any other. Men will die for a calcined, leafless, stony mountain. The nomads will defend to the death their great store of sand as if it were a treasure of gold dust. Nature does not intentionally produce designs for her own delectation, or for man's admiration, as some child-like theologians assert. The object of nature, indeed, is not to produce a design, but a "something" whether it be a design or not. The design is a very secondary consideration to the "something." It is the "something" alone which is of importance.

Science first dawned in the genial climes of the East; but its warming rays were soon absorbed in the cheerless fog of despotism. The body of knowledge which had been created by the efforts of unfettered genius, became the exclusive property of the order of priesthood, who rendered it an engine of power, subservient to the purposes of a gloomy and debasing superstition. The discoveries of happier times were entombed in silence and darkness.

The archivist and the experimental scientist may with impunity select from their sources those facts which have for them a personal and immediate significance in terms of some special problem. Their libraries and experimental facilities may be expected to endure, so that in the future there may be access to the same or a similar body of data. If, however, it were certain that, after the archivist's first perusal, each document would be utterly and forever destroyed it would undoubtedly be required of him that he transcribe the entire record rather than just that portion which at the moment interests him. He would have difficulty in justifying his research if, knowingly, he caused the destruction of a unique record for the sake of abstracting only a narrowly selected part.

The gathering of data from archeological sites, in nearly every instance, involves the destruction of the original record.

German-born physicist

Everything is determined, the beginning as well as the end, by forces over which we have no control. It is determined for the insect as well as the star. Human beings, vegetables, or cosmic dust, we all dance to a mysterious tune, intoned in the distance by an invisible piper.

**Popper, Karl R.** 1902–94

Austrian/British philosopher of science

The intuitive idea of determinism may be summed up by saying that the world is like a motion-picture film: the picture or still which is just being projected is the present. Those parts of the film which have already been shown constitute the past. And those which have not yet been shown constitute the future.

In the film, the future co-exists with the past; and the future is fixed, in exactly the same sense as the past. Though the spectator may not know the future, every future event, without exception, might in principle be known with certainty, exactly like the past, since it exists in the same sense in which the past exists. In fact, the future will be known to the producer of the film – to the Creator of the world.

The basis of the vision of classical physics was the conviction that the future is determined by the present, and therefore a careful study of the present permits an

unveiling of the future. At no time, however, was this more than a theoretical possibility. Yet in some sense this unlimited predictability was an essential element to the scientific picture of the physical world. We may perhaps even call it the founding myth of classical science. The situation is greatly changed today...

When the scientist tells you he does not know the answer, he is an ignorant man. When he tells you he has a hunch about how it is going to work, he is uncertain about it. When he is pretty sure of how it is going to work, and he tells you, "This is the way it is going to work, I'll bet," he still is in some doubt. And it is of paramount importance, in order to make progress, that we recognize this ignorance and this doubt. Because we have the doubt, we then propose looking in new directions for new ideas. The rate of development in science is not the rate at which you make observations alone but, much more important, the rate at which you create new things to test.

It is rather he, who, with just discrimination, looks at a case in all its difficulties; who to habits of correct reasoning, adds the acquirements obtained from study and observation; who is trustworthy in common things for his common sense, and in professional things for his judgment, learning, and experience; who forms his opinion positive or approximate, according to the evidence; who looks at the necessary results of inevitable causes; who promptly does what man may do of good, and carefully avoids what he may do of evil.

Young doctors are particularly strong, as I understand, on what they call diagnosis – an excellent branch of the healing art, full of satisfaction to the curious practitioner who likes to give the right Latin name to one’s complaints; not quite so satisfactory to the patient, as it is not so very much pleasanter to be bitten by a dog with a collar round his neck telling you that he is called Snap or Teaser, than by a dog without a collar. Sometimes, in fact, one would a little rather not know the exact name of his complaint, as if he does he is pretty sure to look it out in a medical dictionary, and then if he reads, “This terrible disease is

attended with vast suffering and is inevitably mortal,” or any such statement, it is apt to affect him unpleasantly.

## DICE

**Cicero (Marcus Tullius Cicero)** 106 BCE–43 BCE

Roman orator, politician, and philosopher

Four dice are cast and a Venus throw results – that is chance; but do you think it would be chance, too, if in one hundred casts you made one hundred Venus throws? It is possible for paints flung at random on a canvas to form the outline of a face; but do you imagine that an accidental scattering of pigments could produce the beautiful portrait of Venus of Cos? Suppose that a hog should form a letter “A” on the ground with its snout; is that a reason for believing that it could write out Ennius’s poem *The Andromache*?

It is probably true quite generally that in the history of human thinking the most fruitful development frequently takes place at those points where two different lines of thought meet. These lines may have roots in quite different parts of human culture, in different times or different cultural environments or different religious traditions: hence if they actually meet, that is, if they are at least so much related to each other that a real interaction can take place, then one may hope that new and interesting developments may follow.

When I behold a fashionable table, set out in all its magnificence, I fancy that I see gout and dropsies, fevers and lethargies, with innumerable distempers, lying in ambuscade among the dishes. Nature delights in the most plain and simple diet. Every animal, but man, keeps to one dish. Herbs are the food of this species, fish of that, and flesh of a third. Man falls upon everything that comes his way; not the smallest fruit or excrescence of the earth, scarce a berry or mushroom can escape him.

**Foster, Sir Michael** 1836–1907

Man, unscientific man...is often content with "the nearly" and "the almost." Nature never is. It is not her way to call the same things which differ, though the difference may be measured by less than the thousandth of a milligramme or of a millimetre, or by any other like standard of minuteness. And the man who, carrying the ways of the world into the domain of science, thinks that he may treat Nature's differences in any other way than she treats them herself, will find that she resents his conduct; if he in carelessness or in disdain overlooks the minute difference which she holds out to him as a signal to guide him in his search, the projecting tip, as it were, of some buried treasure, he is bound to go astray, and, the more strenuously he struggles on, the farther will he find himself from his true goal.

Men have fallen in love with status and pictures. I find it easier to imagine a man falling in love with a differential equation, and I am inclined to think that some mathematicians have done so. Even in a nonmathematician like myself, some differential equations evoke fairly violent physical sensations to those described by Sappho and Catallus when viewing their mistresses. Personally, I obtain an even greater “kick” from finite difference equations, which are perhaps more like those which an up-to-date materialist would use to describe human behavior.

It seems to be the impression among students that mathematical physics consists in deriving a large number of partial differential equations and then solving them, individually, by an assortment of special mutually unrelated devices. It has not been made clear that there is any underlying unity of method and one has often been left entirely in the dark as to what first suggested a particular device to the mind of its inventor.

Among the splendid generalizations effected by modern mathematics, there is none more brilliant or more inspiring or more fruitful, and none more nearly commensurate with the limitless immensity of being itself, than that which produced the great concept variously designated by such equivalent terms as hyperspace, multidimensional space,  $n$ -space,  $n$ -fold or  $n$ -dimensional space, and space of  $n$  dimensions.

Let us assume that the three dimensions of space are visualized in the customary fashion, and let us substitute a color for the fourth dimension. Every physical object is liable to changes in color as well as in position. An object might, for example, be capable of going through all shades from red through violet to blue. A physical interaction between any two bodies is possible only if they are close to each other in space as well as in color. Bodies of

different colors would penetrate each other without interference.... If we lock a number of flies into a red glass globe, they may yet escape: they may change their color to blue and then able to penetrate the red globe.

Well, Diary Dear, eventually the Space Hopper managed to explain in what sense the Planiturthian People's Bicircle is Seven Dimensional. It's all to do with variables – quantities that can change. 'Dimension' is a geometric way of referring to a variable. Time is a nonspatial variable, so it provides a fourth dimension, but the same goes for temperature, wind-speed, or the number of termites in Tangentia. The position of a point in three: dimensional space depends on three variables – its distances East, North, and Upwards relative to some reference point. By analogy, anything that depends on four variables lives in a four dimensional space, and anything that depends on variables lives in a 101-dimensional space.

Mathematical theorists tell us that the only way in which the right and left sides of a solid body can be changed is by taking that body clean out of space as we know it – taking it out of ordinary existence, that is and turning it somewhere outside space.... Discoveries are like fruits.... [W]e must give them time to blossom, to form, and to ripen. When a man applies his whole mind to a research – takes advantage of all indications, all chances – when he makes, in a word, the idea he is pursuing the center of all his activity, there infallibly comes an hour of illumination, which reveals to him suddenly the so long-sought secret.

Nothing can be more puerile than the complaints sometimes made by certain cultivators of a science, that it is very difficult to make discoveries now that the soil has been exhausted, whereas they were so easily made when the ground was first broken. It is an error begotten by ignorance out of indolence. The first discovery did not drop upon the expectant idler who, with placid equanimity waited for the goods the gods might send, but was heavily obtained by patient, systematic, and intelligent labour; and, beyond all question, the same labour of the same mind which made the first discoveries in the new science, would now succeed in making many more, trampled though the field may be by the restless feet of those unmethodical inquirers who, running to and fro, anxiously exclaim, “Who will show us any good thing?”

Ardent desire for knowledge, in fact, is the one motive attracting and supporting investigators in their efforts; and just this knowledge, really grasped and yet always flying away before them, becomes at once their sole torment and sole happiness. Those who do not know the torment of the unknown cannot have the joy of discovery, which is certainly the liveliest that the mind of man can ever feel.

First, I should be clear about what the act of discovery entails. It is rarely, on the frontier of knowledge or elsewhere, that new facts are “discovered” in the sense of being encountered, as Newton suggested, in the form of islands of truth in an uncharted sea of ignorance. Or if they appear to be discovered in this way, it is almost always thanks to some happy hypothesis about where to navigate. Discovery, like surprise, favors the well-prepared mind.

Modern discoveries have not been made by large collections of facts, with subsequent discussion, separation, and resulting deduction of a truth thus rendered perceptible. A few facts have suggested an hypothesis which means a supposition proper to explain them. The discoveries of modern science lead us to infer that there is a great resemblance, in many particulars, between the greatest and the smallest bodies in creation; that atoms, like suns, are separated from each other by distances which are enormous when compared with their actual size; that the molecules composing a bar of iron waltz round and round in circlets or ovals, exactly as Mars, Jupiter, and the rest of us, whirl round Phoebus, and Phoebus himself and his fellow-stars revolve round some unknown central point.

Scientific discoveries seldom come singly. The mastering of one problem of nature commonly suggests new modes of attacking other problems, and often contains in itself the key to their solution. Perhaps it is quite

as frequently the case that new discoveries follow incidentally, it may be, in the researches for completing the original discovery, or in the revived interest in subjects previously supposed to be exhausted for research with known methods.

One of the most important qualifications of a scientific discoverer, viz., rapid scientific insight, depends essentially upon the possession of extensive knowledge, and especially upon a knowledge of great scientific principles and their relations to each other. The history of most efforts at discovery follows a common pattern, whether we consider the discovery of varieties of insects, the exploration of the oceans for continents and islands, or the search for oil reserves in the ground. There is an initial accelerating rise in the discovery rate as increasing numbers of explorers become attracted. New ideas and tools are brought to bear on the search, and the pace of discovery quickens. Soon, however, the number of discoveries remaining to be made dwindles, and the rate of discovery declines despite the high efficiency of the methods developed. The search is approaching an end. An occasional, previously overlooked feature can be found or a particular rare species encountered; but the rate of discovery begins to decline quickly and then diminishes to a trickle. Interest drops, researchers leave the field, and there is virtually no further activity.

I fell into a reverie, and lo, the atoms were gamboling before my eyes! Whenever, hitherto, these diminutive beings had appeared to me, they had always been in motion; but up to that time I had never been able to discern the nature of their motion. Now, however, I saw how, frequently, two smaller atoms united to form a pair; how a larger one embraced the two smaller ones; how still larger ones kept hold of three or even four of the smaller; whilst the whole kept whirling in a giddy dance. I saw how the larger ones formed a chain, dragging the smaller ones after them but only at the ends of the chain.

The road to discovery is not an easy one to travel.... There is to add to its forbiddingness no warm compensating reception at its end, except in one's own glow of attainment. For progress is first obstructed by the reticence of nature and then opposed by the denunciation of man. Nature does not help and humanity hinders. If nature abhors a vacuum, mankind abhors filling it. A really new idea is a foundling without friends. Indeed a doorstep acquisition is welcome compared with the gift of a brand new upsetting thought. The undesired outsider is ignored, pooh-poohed, denounced, or all three according to circumstances. A generation or more is needed to secure it a hearing and more time still before its worth is recognized.

True, his functions here are more those of the spy than the judge; but his object remains pretty much the same. Her hidden motives and laws of action is what nature must be made to confess. ...discovery in mathematics is not a matter of logic. It is rather the result of mysterious powers which no one understands, and in which the unconscious recognition of beauty must play an important part. Out of an infinity of designs a mathematician chooses one pattern for beauty’s sake, and pulls it down to earth, no one knows how. Afterwards the logic of words and of forms sets the pattern right. Only then can one tell someone else. The first pattern remains in the shadows of the mind.

A discovery in science, or a new theory, even where it appears most unitary and most all-embracing, deals with some immediate element of novelty or paradox within the framework of far vaster, unanalyzed, unarticulated reserves of knowledge, experience, faith, and presupposition. It is not in the nature of things for anyone man to make a sudden, violent discovery; science goes step by step and every man depends on the work of his predecessors. When you hear of a sudden unexpected discovery – a bolt from the blue, as it were – you can always be sure that it has grown up by the influence of one man or another, and it is the mutual influence which makes the enormous possibility of scientific advance. Scientists are not dependent on the ideas of a single man, but on the combined wisdom of thousands of men, all thinking of the same problem and each doing his little bit to add to the great structure of knowledge which is gradually being erected.

When one investigates carefully the genesis of any discovery, one finds that it was gradually prepared by a number of smaller ones, and the deeper one's investigation, the more intermediary stages are found. Our first impression of scientific progress is like that of gigantic stairs, each enormous step representing one of those essential discoveries which brought mankind almost suddenly up to a higher level, but that impression is imperceptibly obliterated as we pursue our analysis. The big steps are broken into smaller ones, and these into others still smaller, until finally the steps seem to vanish altogether – yet they never vanish.

The process of discovery in mathematics is one in which we are concerned with both the particular and the general. Induction and imagination are as important as purely deductive reasoning. Very often it is some simple insight into a particular fact at a particular level of abstraction that provides the illumination for an important advance. Later, from the heights newly won, the practiced eye may see the opportunity to broaden the advance all along a higher level of abstraction.

A great discovery is not a terminus, but an avenue leading to regions hitherto unknown. We climb to the top of the peak and find that it reveals to us another higher than any we have yet seen, and so it goes on. The additions to

our knowledge of physics made in a generation do not get smaller or less fundamental or less revolutionary, as one generation succeeds another. The sum of our knowledge is not like what mathematicians call a convergent series... where the study of a few terms may give the general properties of the whole.

No one can take from us the joy of the first becoming aware of something, the so-called discovery. But if we also demand the honor, it can be utterly spoiled for us, for we are usually not the first. What does discovery mean, and who can say that he has discovered this or that? After all it's pure idiocy to brag about priority; for it's simply unconscious conceit, not to admit frankly that one is a plagiarist.

As men contemplate the riches of nature, and see the mass of observations incessantly increasing before them, they become impressed with the intimate conviction that the surface and the interior of the earth, the depths of the ocean, and the regions of air will still, when thousands and thousands of years have passed away, open to the scientific observer untrodden paths of discovery.

Theories lead to experiments and investigations and he who investigates will scarcely ever fail of being rewarded by discoveries. Scientists have discovered many peculiar things, and many beautiful things. But perhaps the most beautiful and the most peculiar thing that they have discovered is the pattern of science itself. Our scientific discoveries are not

independent isolated facts; one scientific generalization finds its explanation in another, which is itself explained by yet another. By tracing these arrows of explanation back toward their source we have discovered a striking convergent pattern – perhaps the deepest thing we have yet learned about the universe.

I have difficulty in understanding the philosophical content that many people seem to find in discoveries in physics. It is true, of course, that many of the subjects of physics – space and time, causality, ultimate particles – have been the concern of philosophers since the earliest times. But in my view, when physicists make discoveries in these areas, they do not so much confirm or refute the speculation of philosophers as show that philosophers were out of their jurisdiction in speculating about these phenomena.

Whether we deal with such tentative explanations, or with the controversial protein nature of enzymes, I feel that it is not important for the scientist whether his own theory proves the right one in the end. Our experiments are not carried out to decide whether we are right, but to gain new knowledge. It is for knowledge's sake that we plow and sow. It is not inglorious at all to have erred in theories and hypotheses. Our hypotheses are intended for the present rather than for the future. They are indispensable to us in the explanation of the secured facts, to enliven and mobilize them and above all to blaze a trail into unknown regions toward new discoveries.

### **Jerome, Jerome K.** 1859–1927

English author

I remember going to the British Museum one day to read up the treatment for some slight ailment of which I had touch. I got down the book, and read all I came to read; and then, in an unthinking moment, I idly turned the leaves, and began to indolently study diseases. Bright's disease, I was relieved to find, I had only in a modified form, and so far as that was concerned, I might live for years. Cholera I had, with severe complications; and diphtheria I seemed to have been born with. I plodded conscientiously through the twenty-six letters, and the only malady I could conclude I had not got was housemaid's knee.

Disease is a series of new and extraordinary actions. Each link in the series is essentially to the integrity of the whole. Let one link be fairly broken, and this integrity is spoiled; and there is an end of the disease; and then the constitution is left to resume its old and accustomed actions, which are the actions of health.

You will discover which remedies have done no harm, and which have notably curtailed the duration of the disease; and thus for the future you will have a standard by which to measure the value of the medicine which you see employed to counteract the malady in question. What you have done in respect of one disease, you will be able to do in respect of many; and by proceeding in this way you will be able, on sure data, to pass judgment on the treatment pursued by your masters.

That disease over which science has since achieved a succession of glorious and beneficial victories was then the most terrible of all the ministers of death. The havoc of the plague had been far more rapid; but plague had visited our shores only once or twice within living memory, and the smallpox was always present, filling the churchyards with corpses, tormenting with constant fears all whom it had not yet stricken, leaving on those whose lives it spared the hideous traces of its power, turning the babe into a changeling at which the mother shuddered, and making the eyes and cheeks of the betrothed maiden objects of horror to the lover.

And this is the ultimate lesson that our knowledge of the mode of transmission of typhus has taught us: Man carries on his skin a parasite, the louse. Civilization rids him of it. **Zinsser, Hans** 1878–1940

US bacteriologist

Typhus is not dead. It will live on for centuries, and it will continue to break into the open whenever human-stupidity and brutality give it a chance, as most likely they occasionally will. But its freedom of action is being restricted, and more and more it will be confined, like other savage creatures, in the zoological gardens of controlled diseases.

So we now have to talk about what we mean by disorder and what we mean by order.... Suppose we divide the space into little volume elements. If we have black and white molecules, how many ways could we distribute them among the volume elements so that white is on one side and black is on the other? On the other hand, how many ways could we distribute them with no restriction on which goes where? Clearly, there are many more ways to arrange them in the latter case. We measure "disorder" by the number of ways that the insides can be arranged,

so that from the outside it looks the same. The logarithm of that number of ways is the entropy. The number of ways in the separated case is less, so the entropy is less, or the “disorder” is less.

So many continents and land bridges have been built in and across the Pacific by biologists that, were they all plotted on a map, there would be little space left for water. Whenever a particularly puzzling problem arises, the simplest thing seems to be to build a continent or bridge, rather than to admit defeat at the hands of nature, or to consider the data at hand inadequate for solving the

problem. Most of the land bridges suggested to account for the distribution of certain plants and animals in the Pacific create more problems than they solve. If the central and eastern Pacific ever included large land areas and land bridges, there should be some indication of the consequent peculiar development of the fauna and floras, but there is no such evidence.

Dissected the Sea Urchin (*Echinus esculentus*). Very excited over my first view of Aristotle’s Lantern. These complicated pieces of animal mechanism never smell of musty age – after aeons of evolution. When I open a Sea Urchin and see the Lantern, or dissect a Lamprey and cast eyes on the branchial basket, such structures strike me as being as finished and exquisite as if they had just a moment before [they had] been tossed me fresh from the hands of the Creator. They are fresh, young, they smell new.

**Berlinski, David** 1942–

Distance is a concept with a thousand florid faces – there is emotional distance, intellectual distance, biological distance, psychological distance, geographical distance, moral distance, aesthetic distance, sociological distance – but in mathematics distance is defined by a reference to a space of some sort and is thus a concept that requires, among other things, a fixed point, the question *how far?* Prompting in turn the inevitable further question *from where?*

## DISTILL

**Levi, Primo** 1919–87  
Italian writer and chemist

Distilling is beautiful. First of all, because it is a slow, philosophic, and silent occupation, which keeps you busy but gives you time to think of other things, somewhat like riding a bike. Then, because it involves a metamorphosis from liquid to vapor (invisible), and from this once again to liquid; but in this double journey, up and down, purity is attained, an ambiguous and fascinating

condition, which starts with chemistry and goes very far. And finally, when you set about distilling, you acquire the consciousness of repeating a ritual consecrated by the centuries, almost a religious act, in which from imperfect material you obtain the essence, the usia, the spirit, and in the first place alcohol, which gladdens the spirit and warms the heart.

I would therefore urge that people be introduced to [the logistic equation] early in their mathematical education. This equation can be studied phenomenologically by iterating it on a calculator, or even by hand. Its study does not involve as much conceptual sophistication as does elementary calculus. Such study would greatly enrich the student’s intuition about nonlinear systems. The general practitioner looks at it and says, "Looks

shoots at it but misses and the bird flies away.

The next bird flies overhead, and the pathologist looks

says, 'Hmmm...green wings, yellow bill, quacking  
sound...might be a duck.' He raises his gun to shoot it,

A third bird flies over. The surgeon raises his gun and  
shoots almost without looking, brings the bird down, and  
turns to the pathologist and says, 'Go see if that was a  
duck.'

...men possessed of vague preconceived ideas are strongly disposed to force facts to fit, defend, or explain them. And this tendency both interferes with the free search for truth and limits the good which can be extracted from such truth as is in its despite attained.

If the reader questions whether there is still war between science and dogma, I must reply that there always will be as long as knowledge is opposed to ignorance. To know requires exertion, and it is intellectually easiest to shirk effort altogether by accepting phrases which cloak the unknown in the undefinable.

This assemblage of imperfect dogmas bequeathed by one age to another – this physical philosophy, which is composed of popular prejudices – is not only injurious because it perpetuates error with the obstinacy engendered by the evidence of ill observed facts, but also because it hinders the mind from attaining to higher views of nature.

Dogmatism has no place in science, and dogmatism about the unknown is especially reprehensible. We live by, faith, faith in the order of nature, faith in ourselves, and faith in our fellow men. This faith is our most prevalent motivation, and it is a reliable guide for behavior just in so far as it is founded on knowledge. Where knowledge is lacking we may extrapolate with due regard for the uncertainties arising from the incompleteness of our knowledge.

## METEORIC DUST

**Geikie, Sir Archibald** 1835–1924  
English geologist

In tracts where the growth of silt upon the sea-floor is excessively tardy, the fine particles, scattered by the dissipation of these meteorites, may remain in appreciable quantity. In this case, again, it is not needful to suppose that meteorites have disappeared over these ocean depths more numerous than over other parts of the earth's surface. The iron granules have no doubt been as plentifully showered down elsewhere, though they cannot be so readily detected in accumulating sediment. I know no recent observation in physical geography more calculated to impress deeply the imagination than the testimony of this presumably meteoric iron from the most distant abysses of the ocean. To be told that mud gathers on the floor of these abysses at an extremely slow rate conveys but a

vague notion of the tardiness of the process. But to learn that it gathers so slowly, that the very star-dust which falls from outer space forms an appreciable part of it, brings home to us, as hardly anything else could do, the idea of undisturbed and excessively slow accumulation.

A distant morning, desolate and steamy (horns and oboes, low and melodic). Sunrise over an empty ocean. The earth stretches; it wiggles and breathes. Ocean floors begin to move and continents start to wander (woodwinds and trumpets have found their voices). Migrating continents and sliding oceans cause volcanic eruptions and earthquakes (hear the power of the pipe organ and the low, steady moan of the double basses). Volcanoes give birth to hot springs, geysers, and mineral waters (a lull for clarinets and flutes). These dynamics contribute to and help drive the earth's atmosphere, producing climatic change and ice ages (an interlude for French horns and cellos). This is earth music: earth rhythms from earth processes.

Scientists still do not appear to understand sufficiently that all earth sciences must contribute evidence toward unveiling the state of our planet in earlier times, and that the truth of the matter can only be reached by combing all this evidence.... It is only by combing the information furnished by all the earth sciences that we can hope to determine 'truth' here, that is to say, to find the picture that sets out all the known facts in the best arrangement and that therefore has the highest degree of probability. Further, we have to be prepared always for the possibility that each new discovery, no matter what science furnishes it, may modify the conclusions we draw.

English naturalist

[Consider] the view now held by most physicists, namely, that the sun with all the planets will in time grow too cold for life, unless indeed some great body dashes into the sun, and thus gives it fresh life. Believing as I do that man in the distant future will be a far more perfect creature than he now is, it is an intolerable thought that he and all other sentient beings are doomed to complete annihilation after such long-continued slow progress.

**Barrell, Joseph** 1869–1919

The history of the earth is read in the rocks which have been thrust up by internal forces and beveled across by erosion. The nearer events are clearly recorded in the sequence and nature of the sedimentary rocks and their fossils.

Genius and science have burst the limits of space; and observations, explained by just reasoning, have unveiled the mechanism of the universe. “Would it not also be glorious for man to burst the limits of time, and, by means of observations, to ascertain the history of this world, and the succession of events which preceded the birth of the human race?”

Preliminary Observations (p. 3)

It is my object, in the following work, to travel over ground which has as yet been little explored, and to make my reader acquainted with a species of Remains, which, though absolutely necessary for understanding the history of the globe, have been hitherto almost uniformly neglected.

*Essay on the Theory of the Earth*

Section 1 (p. 25)

Kirk & Mercein. New York, New York, USA. 1818

The ancient history of the globe, which is the ultimate object of all these researches, is also of itself one of the most curious subjects that can engage the attention of enlightened men; and if they take any interest in examining, in the infancy of our species, the almost obliterated traces of so many nations that have become extinct, they will doubtless take a similar interest in collecting, amidst the darkness which covers the infancy of the globe, the traces of those revolutions which took place anterior to the existence of all nations.

*Essay on the Theory of the Earth*

Section 1 (p. 27)

Kirk & Mercein. New York, New York, USA. 1818

We admire the power by which the human mind has measured the motions of globes which nature seemed to have concealed forever from our view: Genius and science have burst the limits of space, and a few observations, explained by just reasoning, have unveiled the mechanism of the universe. Would it not also be glorious for man to burst the limits of time, and, by a few observations, to ascertain the history of this world, and the series of events which preceded the birth of the human race?

*Essay on the Theory of the Earth*

Section 1 (p. 27)

Kirk & Mercein. New York, New York, USA. 1818

We now propose to examine those changes which still take place on our globe, investigating the causes which continue to operate on its surface.... This portion of the history of the earth is so much the more important, as it has been long considered possible to explain the more ancient revolutions on its surface by means of these still existing causes.... But we shall presently see that unfortunately this is not the case in physical history; the thread of operations is here broken, the march of nature is changed, and none of the agents that she now employs were sufficient for the production of her ancient works.

## EARTH, MOBILITY OF

**Copernicus, Nicolaus** 1473–1543

Polish astronomer

I began to consider the mobility of the Earth; and although the idea seemed absurd, yet because I knew that the liberty had been granted to others before me to postulate all sorts of little circles for explaining the phenomena of the stars, I thought I also might easily be permitted to try whether by postulating some motion of the Earth, more reliable conclusions could be reached regarding the revolution of the heavenly bodies, than those of my predecessors.

## EARTH, MODEL OF

**Bullen, K. E.**

Seismologist

The nether regions of the Earth are inaccessible in the ordinary sense. Before the time of Newton, when evidence about them was nearly totally lacking, it was not necessarily unreasonable to describe the Earth in terms of models involving say a Hell, or a subterranean monster shaking itself to cause earthquakes. The subsequent growth of evidence has lowered the plausibility of such models.

## EARTH, ORIGIN OF

**Smart, W. M.**

To many it may seem presumptuous of anyone to attempt to unravel the mysteries surrounding the origin of the Earth and, in a wider sense, of the Universe itself; to others it may even seem irreverent that the great act of Creation should be regarded as a field for scientific speculation. In his pursuit of knowledge of the external world the scientist, however, is not held within precise limits of time, past or future; for example, the measure of progress in astronomy through the ages can be expressed, in some respects at least, in terms of the increasing capacity of man to see still further into the future and to peer still more deeply into the mists of the past.

*Our Mobile Earth*

Chapter I (p. 5)

Charles Scribner's Sons. New York, New York, USA. 1926

Our earth is very old, an old warrior that has lived through many battles. Nevertheless, the face of it is still changing, and science sees no certain limit of time for its stately evolution. Our solid earth, apparently so stable, inert, and finished, is changing, mobile, and still evolving. Its major quakings are largely the echoes of that divine far-off event, the building of our noble mountains. The lava floods and intriguing volcanoes tell us of the plasticity, mobility, of the deep interior of the globe. The slow coming and going of ancient shallow seas on the continental plateaus tell us of the rhythmic distortion of the deep interior-deep-seated flow and changes of volume. Mountain chains prove the earth's solid crust itself to be mobile in high degree. And the secret of it all – the secret of the earthquake, the secret of the 'temple of fire,' the secret of the ocean basin, the secret of the highland – is in the heart of the earth, forever invisible to human eyes.

And these people fancy that earthquakes, volcanoes, and all such little escapades, will be over, will "cease and determine," as soon as our Earth reaches the age of maidenly bashfulness. Poor thing! It's quite natural, you know, in a healthy growing girl. A little overflow of vivacity, a pirouette more or less, an earthquake plus or minus, what harm should that do to any of us!

Human society is organized for a stable earth: its whole machinery supposes that while the other familiar elements of air and water are fluctuating and trustworthy, the earth affords a foundation which is firm. Now and then this implied compact with nature is broken, and the ground trembles beneath our feet. At such times we feel a painful sense of shipwrecked confidence: we learn how very precious to us was that trust in the earth which we gave without question. If the disturbance be of a momentary and unimportant kind, we may soon forget it, as we forget the rash word of a friend; if it be violent, we lose one of the substantial goods of life, our instinctive confidence in the earth beneath our feet.

There is something so mysterious in the nature and origin of that physical force that convulses the earth, and in a few moments buries thousands of human beings amidst the ruins of their proudest fabrics, that the slightest display of its power appalls the stoutest heart. In vain we invoke philosophy to our aid: reason accepts the postulate that “what has been may be again,” and the earthquake is a matter of fact after which philosophy gropes in obscurity, unable to say to the mighty commotion, “Thus far shall thou go, but no farther, and here shall thy proud waves be stayed.”

I will set it down here as a maxim that the operations of the human intellect are much accelerated by an earthquake. Usually I do not think rapidly – but I did upon this occasion. I thought rapidly, vividly, and distinctly. With the first shock of the five, I thought – “I recognize that motion – this is an earthquake.” With the second, I thought, “What a luxury this will be for the morning papers.” With the third shock, I thought, “Well my boy, you had better be getting out of this.” Each of these thoughts was only the hundredth part of a second in passing through my mind. There is no incentive to rapid reasoning like an earthquake. I then sidled out toward the middle of the street – and I may say that I sidled out with some degree of activity, too. There is nothing

like an earthquake to hurry a man when he starts to go anywhere.

The deep and peculiar impression left on the mind by the first earthquake which we experience... is not, in my opinion, the result of a recollection of those fearful pictures of devastation presented to our imaginations by the historical narratives of the past, but is rather due to the sudden revelation of the delusive nature of the inherent faith by which we had clung to a belief in the immobility of the solid parts of the earth.

*The Story of Eclipses*

Chapter X (p. 93)

S.S. McClure Co. New York, New York, USA. 1909

### Author undetermined

The sky is an immense place where everything moves in its own way. Some go faster than others, some turn around themselves while they are going around the sun and each other. Sometimes the fast ones catch up with the slow ones and that is an eclipse. Also, when the moon

gets in the way we can't see the sun, and that is an eclipse too and everybody talks about it.

That is an important eclipse.

Reported by little girl who visited the Hayden Planetarium

*The Sky*, Volume 3–4, December, 1939 (p. 25)

Working like a carefully rehearsed team, the sun and moon teamed up yesterday to put on a dramatic celestial show, the plot calling for the moon to cast its shadow over the sun to create a eclipse.

The thing the ecologically illiterate don't realize about an ecosystem... is that it's a system. A System! A system maintains a certain fluid stability that can be destroyed by a misstep in just one niche. A system has order, a flowing from point to point. If something dams that flow, order collapses. The untrained might miss that collapse until it was too late. That's why the highest function of ecology is the understanding of consequences.

Every genuine worker in science is an explorer, who is continually meeting fresh things and fresh situations, to which he has to adapt his material and mental equipment. If scientific education today is unsuited for those who are to make science their life work, it is even less suited for those to whom it is merely to be part of a general education. Men of science complain of the lack of a wide appreciation of scientific knowledge; what else can they expect if they offer to the world only the dry bones of knowledge from which the breath has departed? Nothing could be better adapted than the ordinary school course, with its tedious insistence on bare and uninspiring fact, to kill any rising enthusiasm. It is most important certainly, to impress the student with the nature of scientific truth and with the possibility of definite, positive knowledge concerning the material world.... But to insist on the truth of science and to neglect its meaning is to aggravate the evil which we seek to cure....

The great benefit which a scientific education bestows, whether as training or as knowledge, is dependent upon the extent to which the mind of the student is brought into immediate contact with the facts – upon the degree to which he learns the habit of appealing directly to Nature.

That man, I think, has had a liberal education who has been so trained in youth that his body is the ready servant of his will, and does with ease and pleasure all the work that, as a mechanism, it is capable of; whose intellect is a clear, cold, logic engine, with all its parts of equal strength and in smooth working order; ready, like a steam engine, to be turned to any kind of work, and spin the gossamers as well as forge the anchors of the mind; whose mind is stored with a knowledge of the great and fundamental truths of Nature and of the laws of her operations; one who, no stunted ascetic, is full of life and fire, but whose passions are trained to come to heel by a vigorous will, the servant of a tender conscience; who has learned to love all beauty, whether of Nature or of art, to hate all vileness, and to respect others as himself.

I am the last person to question the importance of genuine literary education, or to suppose that intellectual culture can be complete without it. I shall meet with no contradiction when I say that without at least an elementary mathematical and scientific education a man remains a total stranger in the world in which he lives, a stranger in the civilisation of the time

Education, in its larger sense, is one of the most inexhaustible of all topics. Though there is hardly any subject on which so much has been written, by so many of the wisest men, it is as fresh to those who come to it with a fresh mind, a mind not hopelessly filled full with other people's conclusions, as it was to the first explorers of it: and notwithstanding the great mass of excellent things which have been said respecting it, no thoughtful person finds any lack of things both great and small still waiting to be said, or waiting to be developed and followed out to their consequences.

What the world needs is a fusion of the sciences and the humanities. The humanities express the symbolic, poetic, and prophetic qualities of the human spirit. The sciences express the creative urge in man to construct a universe which is comprehensible in terms of the human intellect. Without them, mankind would find itself bewildered in a world of natural forces beyond comprehension, victims of ignorance, superstition and fear.

If they were only a towering mathematical structure in which the #'s shoot out their volutes in bewildering arabesques, with swan-neck integrals describing Louis XV patterns, they would have no interest whatever for the physicist, for the man who has to examine the nature of things before he talks about it.

Electricity is actually made up of extremely tiny particles, called electrons, that you cannot see with the naked eye unless you have been drinking. Electrons travel at the speed of light, which in most American homes is 110 volts per hour. This is very fast. In the time it has taken you to read this sentence so far, an electron could have traveled all the way from San Francisco to Hackensack, New Jersey, although God alone knows why it would want to. The five main kinds of electricity are alternating current, direct current, lightning, static, and European. Most American homes have alternating current, which means that the electricity goes in one direction for a while, then goes in the other direction. This prevents harmful electron buildup in the wires.

Chance has thrown my way another principle, more universal and remarkable... which casts a new Light on the subject of electricity. This principle is that there are two distinct Electricities, very different from each other; one of these I call vitreous Electricity; the other resinous Electricity. The first is that of Glass, Rock-Crystal, Precious Stones, Hair of Animals, Wool, and many other bodies. The second is that of Amber, Copal, Gum-Lac, Silk, Thread, Paper, and a vast number of other substances. The characteristic of these two Electricities is that a body of the Vitreous Electricity, for example, repels all such as are of the same Electricity; and on the contrary, attracts all those of the resinous electricity.... This Principle very naturally explains why the ends of Thread, of Silk or Wool recede from one another in the form of a Pencil or Broom when they have acquired an electric Quality.

Electricity is often called wonderful, beautiful; but it is so only in common with the other forces of nature. The beauty of electricity or of any other force is not that the power is mysterious, and unexpected, touching every sense at unawares in turn, but that it is under law, and that the taught intellect can even now govern it largely. The human mind is placed above, and not beneath it, and it is in such a point of view that the mental education afforded by science is rendered super-eminent in dignity, in practical application and utility; for by enabling the mind to apply the natural power through law, it conveys the gifts to God to man.

Much as a pitched baseball is given a spin about its axis, so also does the electron spin about. However, the microscopic quantum mechanical electron behaves very differently from a baseball. Baseballs can be old, new, clean, dirty, and can differ from one another in myriad ways. On the other hand, all electrons are absolutely identical to one another. There is a subtler difference as well. Baseballs may spin rapidly, slowly, or in the case of a knuckleball, not at all. Every electron in the universe (about 1080 of them!) is spinning at exactly the same rate. The magnitude of electron spin is an intrinsic and immutable characteristic of the electron. Only the axis about which the electron spins can be changed.

To argue whether the electron is really a wave or a particle is futile: an electron is an electron, and it behaves as an electron behaves. The observer may sometimes perceive wave properties in that behavior, and sometimes particle properties, and that, as Keats said, is all ye know, and all ye need to know. If we ask for more, what we are really asking for is a direct, metaphysical understanding of the nature of the electron, as if we could grasp its “true” nature with our minds and obtain some understanding of it beyond the scope of physical experimentation.

How can it be that electrons exhibit wave and particle properties at the same time?... The quantum state represents a novel state of matter that cannot be described in the old-fashioned way. It exhibits features that do not occur with objects in our ordinary experience. This is

why we must use more abstract terms when we describe atomic reality. It may seem incredible to the noninitiated that an electron behaves in certain situations like a wave and in others like a particle.

That an electron here has the same mass as an[other] electron... is also a triviality or a miracle. It is a triviality in quantum electrodynamics because it is assumed rather than derived. However, it is a miracle on any view that regards the universe as being from time to time “reprocessed.” How can electrons at different times and places in the present cycle of the universe have the same mass if the spectrum of particle masses differs between one cycle of the universe and another?...

Are particles of the same pattern identical in anyone cycle of the universe because they give identically patterned views of the same universe? No acceptable explanation for the miraculous identity of particles of the same type has ever been put forward. That identity must be regarded, not as a triviality, but as a central mystery of physics.

All that can be said upon the number and nature of elements is, in my opinion, confined to discussions entirely of a metaphysical nature. The subject only furnishes us with indefinite problems, which may be solved in a thousand different ways, not one of which, in all probability, is consistent with nature. I shall therefore only add upon this subject, that if, by the term elements, we mean to express those simple and indivisible atoms of which matter is composed, it is extremely probable we know nothing at all about them; but, if we apply the term elements, or principles of bodies, to express our idea of the last point which analysis is capable of reaching, we must admit, as elements, all the substances into which we are capable, by any means, to reduce bodies by decomposition.

...if, by the term elements we mean to express those simple and indivisible atoms of which matter is composed, it is extremely probable that we know nothing about them; but if we apply the term elements, or principles of bodies, to express our idea of the last point which analysis is capable of reaching, we must admit as elements all the substances into which we are capable, by any means, to reduce bodies by decomposition. Not that we are entitled to affirm that these substances we consider as simple may not be compounded of two, or even of a greater number of principles; but since these principles cannot be separated, or rather since we have not hitherto discovered the means of separating them, they act with regard to us as simple substances, and we ought never to suppose them compounded until experiment and observation have proved them to be so.

Newly liberated oxygen is like a boy newly released from school, active, aggressive, and up to mischief generally. Accordingly “nascent” oxygen, set free from water by chlorine, seizes instantly upon anything within reach that is oxidizable and – and marries it on the spot! Then self and spouse become a staid couple to whom the pranks of unmarried days are now forgotten and impossible.

If a small animal and a lighted candle be placed in a closed flask, so that no air can enter, in a short time the candle will go out, nor will the animal long survive.... The animal is not suffocated by the smoke of the candle.... The reason why the animal can live some time after the candle has gone out seems to be that the flame needs a continuous rapid and full supply of nitro-aereal particles.... For animals, a less aereal spirit is sufficient.... The movements of the lungs help not a little towards sucking in aereal particles which may remain in said flask and towards transferring them to the blood of the animal.

This, which can barely be distinguished from the discovery of perpetual motion, which it is an axiom of science to call impossible, has left every chemist and physicist in a state of bewilderment... It will, no doubt, be a matter of surprise, that in a treatise upon the elements of chemistry, there should be no chapter on the constituent and elementary parts of matter; but I shall take occasion, in this place, to remark, that the fondness for reducing all the bodies in nature to three or four elements, proceeds from a prejudice which has descended to us from the Greek Philosophers. The notion of four elements, which, by the variety of their proportions, compose all the known substances in nature, is a mere hypothesis, assumed long before the first principles of experimental philosophy or of chemistry had any existence. In those days, without possessing facts, they framed systems; while we, who have collected facts, seem determined to reject them, when they do not agree

with our prejudices. The authority of these fathers of human philosophy still carry great weight, and there is reason to fear that it will even bear hard upon generations yet to come.

Preface (pp. xxv–xxvi)

Printed for W. Creech. Edinburgh, Scotland. 1802

All that can be said upon the number and nature of elements is, in my opinion, confined to discussions entirely of a metaphysical nature. The subject only furnishes us with indefinite problems, which may be solved in a thousand different ways, not one of which, in all probability, is consistent with nature. I shall therefore only add upon this subject, that if, by the term *elements*, we mean to express those simple and indivisible atoms of which matter is composed, it is extremely probable we know nothing at all about them; but, if we apply the term *elements*, or , to express our idea of the last point which analysis is capable of reaching, we must admit, as elements, all the substances into which we are capable, by any means, to reduce bodies by decomposition.

But in Nature all this is different. Nature has no chips or fragments which she does not put to use; and as on the way to her apparent ends there are no incidents which she did not foresee, so beyond those ends there are no ulterior results which do not open out into new firmaments of Design.

The energy difference predicted by the effects of the vacuum on atoms is so small that it is only detectable as a transition at microwave frequencies. The precision of microwave measurements is so great that Lamb was able to measure the shift to five significant figures. He subsequently received the Nobel Prize for his work. No doubt remains that virtual particles are really there.

Even though we can't see them, we know that these virtual particles are "really there" in empty space because they leave a detectable trace of their activities. One effect of virtual photons, for example, is to produce a tiny shift in the energy levels of atoms. They also cause an equally tiny change in the magnetic moment of electrons. These minute but significant alterations have been very accurately measured using spectroscopic techniques.

We do not know how the scientists of the next century will define energy or in what strange jargon they will discuss it. But no matter what language the physicists use they will not come into contradiction with Blake. Energy will remain in some sense the lord and giver of life, a reality transcending our mathematical descriptions. Its nature lies at the heart of the mystery of our existence as animate beings in an inanimate universe.

One of the most impressive discoveries was the origin of the energy of the stars, that makes them continue to burn. One of the men who discovered this was out with his girl friend the night after he realized that nuclear reactions must be going on in the stars in order to make them shine. She said, “Look at how pretty the stars shine!” He said, “Yes, and right now I am the only man in the world who knows why they shine.” She merely laughed at him. She was not impressed with being out with the only man who, at that moment, knew why stars shine. Well, it is sad to be alone, but that is the way it is in this world.

There is a fact, or if you wish, a law governing all natural phenomena that are known to date. There is no known exception to this law – it is exact as far as we know. The law is called the conservation of energy. It states that there is a certain quantity, which we call energy, that does not change in the manifold changes which nature undergoes. That is a most abstract idea, because it is a mathematical principle; it says that there is a numerical quantity which does not change when something happens.

A point about solar energy that government planners seem to have trouble grasping is that it is fundamentally different from other energy sources. Solar energy is democratic. It falls on everyone and can be put to use by individuals and small groups of people. The public enthusiasm for solar is perhaps as much a reflection for this unusual accessibility as it is a vote for the environmental kindness and inherent renewability of energy from the sun.

And where did the energy come from to create this matter? The answer is that it was borrowed from the gravitational energy of the universe. During the inflationary period the universe borrowed heavily from its gravitational energy to finance the creation of more matter...The debt of gravitational energy will not have to be paid until the end of the universe.

You see, therefore, that living force may be converted into  
heat, and that heat may be converted into living force, or  
its equivalent attraction through space. All three, there-  
fore – namely, heat, living force, and attraction through  
space (to which I might also add light, were it consistent  
with the scope of the present lecture) – are mutually con-  
vertible into one another. In these conversions nothing  
is ever lost. The same quantity of heat will always be  
converted into the same quantity of living force. We can  
therefore express the equivalency in definite language  
applicable at all times and under all circumstances.

Of all the concepts or constructs of physics, energy, by

Energy really is only an integral; now, what we want  
to have is a substantial definition, like that of Leibniz,  
and this demand is justifiable to a certain degree, since  
our very conviction of the conservation of energy rests

in great part on this foundation.... And so the manuals of physics contain really two discordant definitions of energy, the first which is verbal, intelligible, capable of establishing our conviction, and false; and the second which is mathematical, exact, but lacking verbal expression.

The uncertainty principle implies that particles can come into existence for short periods of time even when there is not enough energy to create them. In effect, they are created from uncertainties in energy. One could say that they briefly “borrow” the energy required for their creation, and then, a short time later, they pay the “debt” back and disappear again. Since these particles do not have a permanent existence, they are called virtual particles.

Efforts have been made to look on energy as on something which can be labeled and identified through its various transformations. Thus we may feel a certain bit of energy radiating from a coal-fire, and if our knowledge was complete, we ought to be able to fix the time at which that identical bit of energy left the sun and arrived on the surface of the earth, setting up a chemical action in the leaves of the plant from which the coal has been derived. If we push this view to a logical conclusion, it seems to me that we must finally arrive at an atomic conception of energy, which some may consider an absurdity.

The greatest difference between engineers and other professionals is that engineers do not offer a person-to-person service, nor are their services a matter of life, freedom, or property, of deep personal concern. Most engineers thrive on promotion and expansion of business, new inventions, new buildings, and more consumption of goods. Obviously, then, they are tempted to whip up trade, advertise, seek out clients, and promote deals. This spirit leads to competition. Until this is recognized, I see no hope of solving the problem of engineering professional development.

A good engineer must be of inflexible integrity, sober, truthful, accurate, resolute, discrete, of cool and sound judgment; must have courage to resist and repeal attempts at intimidation, a firmness that is proof against solicitation, flattery, or improper bias of any kind; must take an interest in his work; must be energetic, quick to decide, prompt to act; must be as fair and impartial as a judge on the bench; must have experience in his work and in dealing with men, which implies some maturity of years; and must have business habits and knowledge of accounts.

Men who combine these qualities are not to be picked up every day. Still they can be found, and when found, they are worth their price; rather they are beyond price, and their value cannot be estimated by dollars.

To the engineer, all matter in the universe can be placed into one of two categories: (1) things that need to be fixed, and (2) things that will need to be fixed after you've had a few minutes to play with them. Engineers like to solve problems. If there are no problems handily available, they will create their own problems. Normal people don't understand this concept; they believe that if it ain't broke, don't fix it. Engineers believe that if it ain't broke, it doesn't have enough features yet.

Engineers are always honest in matters of technology and human relationships. That's why it's a good idea to keep engineers away from customers, romantic interests, and other people who can't handle the truth.

Even as when

In planning some steel-rutted road, long years

Dreamed of – where now the fire-horse ramps, steam-breath'd,

Sweating red coal-drops on his panting path –

The deep-eyed engineer his level lays

Inscrutable, and anon, the hills with men,

Brood of his brain swarm.

In many segments of industry, the young man is looked upon first as an engineer and second as an electrical engineer with specific knowledge. Industrial problems do not divide themselves neatly into the areas of electrical, mechanical, chemical, or civil engineering; rather, they are considered as general problems requiring a solution which the young engineer is expected to provide. In the majority of cases he must produce a physical device which will accomplish a desired result. This is not a “textbook” solution but an original, creative effort.

Civilization, as we know it today, owes its existence to the engineers. These are the men who, down the long centuries, have learned to exploit the properties of matter and the sources of power for the benefit of mankind. By an organized, rational effort to use the material world around them, engineers devised the myriad comforts and conveniences that mark the difference between our lives and those of our fore-fathers thousands of years ago. The story of civilization is, in a sense, the story of engineering – that long and arduous struggle to make the forces of nature work for man's good.

The Legislators are the Engineers,  
Who when 'tis out of Order make Repairs:  
The People are the Owners, 'twas for them  
The first Inventor drew the ancient Scheme.  
'Tis for their Benefit it works, and they  
The Charges of maintaining it defray:  
And if their Governours unfaithful prove,  
They, Engineers or Managers remove.  
Unkind Contention sometimes there appears  
Between the Managers and Engineers:  
Such Strife is always to the Owners wrong,

And once it made the Work stand still too long;  
Till William came, and loos'd the Fatal Chain,  
And set the Engineers to work again:  
And having made the wondrous thing complete,  
To Anne's unerring Hand he left the Helm of State.

It might be supposed that engineers, who are so largely responsible for the increase in the productive capacity of men and of nations, would be the first to enjoy, or at least to seek to enjoy, the benefits of their own accomplishments; that they would utilize, or seek to utilize in a prolonged period of education, the leisure time made possible by the improvement in productive efficiency which they brought about. That they do not do so is evidence of the need for the enrichment of their education: they don't know what they are missing.

Thus in many directions the engineers of the future, in my judgment, must of necessity deal with a much more certain and more intimate knowledge of the materials with which he works than we have been wont to deal with in the past. As a result of this more intimate knowledge his structures will be more refined and his factors of safety in many directions are bound to be less because the old elements of uncertainty will have in large measure disappeared.

The engineer is both a scientist and a businessman. Engineering is a scientific profession, yet the test of the engineer's work lies not in the laboratory, but in the marketplace.

*The Revolt of the Engineers*

Chapter 1 (p. 1)

The Press of Case Western University, Cleveland, Ohio, USA, 1971

Engineers, as a rule are not and do not pretend to be philosophers in the sense of building up consistent systems of thought following logically from certain premises. If anything, they pride themselves on being hard-headed practical men concerned only with facts, disdaining mere speculation or opinion. In practice, however, engineers do make many assumptions about the nature of the universe, of man, and of society.

*The Revolt of the Engineers* (p. 9)

The Press of Case Western University, Cleveland, Ohio, USA, 1971

The cement binding the engineer to his profession was scientific knowledge. All the themes leading toward a closer identification of the engineer with his profession rested on the assumption that the engineer was an applied scientist. It was the cumulative character of scientific knowledge that gave weight to engineers' claims to be the agents of progress and enlightenment.

Our engineers are healthy and virile, active and useful, balanced and happy in their work. Our architects are disillusioned and unemployed, boastful or peevish. This is because there will soon be nothing more for them to do. We no longer have the money to erect historical souvenirs. At the same time, we have got to wash!

Translated by Frederick Etchells

*Towards a New Architecture*

The Engineer's Aesthetic and Architecture (pp. 18–19)

The Architectural Press. London, England. 1965

Our engineers produce architecture, for they employ a mathematical calculation which derives from natural law, and their works give us the feeling of HARMONY. The engineer therefore has his own aesthetic, for he must, in making his calculations, qualify some of the terms of his equation; and it is here that taste intervenes. Now, in handling a mathematical problem, a man is regarding it from a purely abstract point of view, and in such a state, his taste must follow a sure and certain path.

to check the work of others.

many of the solutions were as satisfying and beautiful.  
Their instinct – perhaps sharpened in this country by the  
passion to find a new snobbism wherever possible, and to  
invent one if it doesn't exist – was to take it for granted  
that applied science was an occupation for second rate  
minds. I say this more sharply because thirty years ago

The engineer of today is confronted with a library of acquired results; tables and formulae to the value of folios full have been calculated and recorded; and the student finds everywhere in front of him the footprints of the pioneers. In the eighteenth century the field was largely unexplored; the engineer must read with his own eyes the face of nature.

*Records of a Family of Engineers*

Chapter I (p. 212)

Chatto & Windus. London, England. 1912

The seas into which his labours carried the new engineer were still scarce charted, the coasts still dark; his way on shore was often far beyond the convenience of any road; the isles in which he must sojourn were still partly savage. He must toss much in boats; he must often adventure on horseback by the dubious bridle-track through unfrequented wildernesses; he must sometimes plant his lighthouse in the very camp of wreckers; and he was continually enforced to the vicissitudes of outdoor life.

*Records of a Family of Engineers*

Chapter I (p. 213)

Chatto & Windus. London, England. 1912

The engineer was not only exposed to the hazards of the sea; he must often ford his way by land to remote and scarce accessible places, beyond reach of the mail or the post-chaise, even the tracery of the bridle-path, and guided by natives across bog and heather.

*Records of a Family of Engineers*

Chapter II, Part I (p. 241)

Chatto & Windus. London, England. 1912

With the civil engineer, more properly so called (if anything can be proper with this awkward coinage), the obligation starts with the beginning. He is always the practical man. The rains, the winds and the waves, the complexity and the fitfulness of nature, are always before him. He has to deal with the unpredictable, with those forces (in Smeaton's phrase) that "are subject to no calculation"; and still he must predict, still calculate them, at his peril.

Engineer

The creative engineer uses his three brains. He uses his intellectual brain as an applied scientist to understand the laws of science and to see that the things which he invents do not break these laws. He uses his emotional brain for the act of invention, and he uses his physical brain – his brain with his hands, feet and body – for the proper understanding of the design of things that will work.

Scientists and engineers may all study physical reality, but the scientist is usually considered successful if he or she has contributed to theory while the engineer is less interested in generating theory for its own sake than in doing whatever is necessary to design and produce useful artifacts. A scientist who does not understand a phenomenon has failed; but an engineer who does not fully understand a device may still be considered successful if the device works well enough. Scientists and engineers thus operate with different standards for success that affect the way they argue.

Engineers have traditionally been people who work toward the attainment of practical goals.... [I]f a particular task requires the use of some practical goals. If a particular task requires the use of some particular physical phenomenon, then the more he understands this particular phenomenon the better able he will be to reach his goal. However, as an engineer he could not care less about his understanding per se. In contrast, scientists have traditionally been people whose sole drive was to understand the world around them. They could not care less what use was made of this understanding.

Most young men when entering technical schools have no adequate conception of what the engineering profession really is. Many of them undertake the course either because their parents desire them to receive a useful education or because they think that engineering is a good calling in which to make a living; but very few of them enter on account of a heartfelt admiration of engineering as the profession of progress, to which are due practically all the wonderful developments of the world during the last one hundred years – developments that have so added to the comforts and conveniences of man as to make life truly worth living instead of a burden grievous to be borne.

Chemical engineering is that branch of engineering concerned with the development and application of manufacturing processes in which chemical or certain physical changes of material are involved. These processes may usually be resolved into a coordinated series of unit physical operations and unit chemical processes. The work of the chemical engineer is concerned primarily with the design, construction and operation of equipment and plants in which these unit operations and processes are applied. Chemistry, physics and mathematics are the underlying sciences of chemical engineering, and economics its guide in practice.

Chemical engineering as a science...is not a composite of chemistry and mechanical and civil engineering, but a science of itself, the basis of which is those unit operations which in their proper sequence and coordination constitute a chemical process as conducted on the industrial scale. These operations, as grinding, extracting, roasting, crystallizing, distilling, air-drying, separating, and so on, are not the subject matter of chemistry as such nor of mechanical engineering. Their treatment in the quantitative way...and...the materials and equipment concerned in them is the province of chemical engineering. It is this selective emphasis on the unit operations themselves in their quantitative aspects that differentiates chemical engineering from industrial chemistry, which is concerned primarily with general processes and products.

Engineering is the art of skillful approximation; the practice of gamesmanship in the highest form. In the end it is a method broad enough to tame the unknown, a means of combing disciplined judgment with intuition, courage with responsibility, and scientific competence within the practical aspects of time, of cost, and of talent. This is the exciting view of modern-day engineering that a vigorous profession can insist be the theme for education and training of its youth. It is an outlook that generates its strength and its grandeur not in the discovery of facts but in their application; not in receiving, but in giving. It is an outlook that requires many tools of science and the ability to manipulate them intelligently. In the end, it is a welding of theory and practice to build an early, strong, and useful result. Except as a valuable discipline of the mind, a formal education in technology is sterile until it is applied.

Professional Responsibility of Engineering  
*Mechanical Engineering*, Volume 86, Number 1, January, 1964

Engineering is a method and a philosophy for coping with that which is uncertain at the earliest possible moment and to the ultimate service to mankind. It is not a science struggling for a place in the sun. Engineering is science extrapolation from existing knowledge rather than interpolation between known points. Because engineering is science in action – the practice of decision making at the earliest moment – it has been defined as the art of skillful approximation. No situation in engineering is simple enough to be solved precisely, and none worth evaluating is solved exactly. Never are there sufficient facts, sufficient time, or sufficient money for an exact solution, for if by chance there were, the answer would be of academic and not economic interest to society. These are the circumstances that make engineering so vital and so creative.

Engineering is the science of economy, of conserving the energy, kinetic and potential, provided and stored up by nature for the use of man. It is the business of engineering to utilize this energy to the best advantage, so that there may be the least possible waste.

The scientist usually works – but very seldom under the pressure of a timetable – in a field of his special interest, in which he has generally chosen to stake out a narrow sector for his own specialization. The engineer, on the other hand, while also operating within the area of his

own competence, has to tackle a variety of problems, some of which may be new to him, but to which he has to apply his scientifically based knowledge and skill to produce workable and practical solutions; this work includes economics and involves both analysis and synthesis, generally within a rigid time limit. This is technology and engineering.

The roots of the tree are pure science...and a peculiar thing coming in here, called aesthetics, about which the architects and some other people are very concerned. The trunk of the tree is called human understanding and, in particular, applied mathematics. The branches of the tree are engineering and the extreme twigs are the growing new fields of engineering in which things are really happening...pure science is the roots which feed the tree but the actual growth of new life comes on the twigs of extremely specialized engineering. Some sort of scheme of knowledge like this is important.

Engineering is more closely akin to the arts than perhaps any other of the professions; first, because it requires the maximum of natural aptitude and of liking for the work in order to offset other factors; second, because it demands, like the arts, an almost selfless consecration to the job; and, third, because out of the hundreds who faithfully devote themselves to the task, only a few are destined to receive any significant reward – in either money or fame.

## ENGINEERING TERMS

### Author undetermined

A number of different approaches are being tried – We don't know where we're going, but we're moving.

Close project coordination – We should have asked someone else; or, let's spread the responsibility for this.

Customer satisfaction is believed assured – We are so far behind schedule that the customer was happy to get anything at all from us.

Developed after years of intensive research – It was discovered by accident.

Extensive effort is being applied on a fresh approach to the problem – We just hired three new guys; we'll let them kick it around for a while.

Major Technological Breakthrough – Back to the drawing board.

Modifications are underway to correct certain minor difficulties – We threw the whole thing out and are starting from scratch.

Preliminary operational tests are inconclusive – The darn thing blew up when we threw the switch.

Project slightly behind original schedule due to unforeseen difficulties – We are working on something else.

Test results were extremely gratifying – It works, and are we surprised!

The designs are well within allowable limits – We just made it, stretching a point or two.

The design will be finalized in the next reporting period – We haven't started this job yet, but we've got to say something.

The entire concept will have to be abandoned – The only guy who understood the thing quit.

## ENGINEER'S CREED

### Author undetermined

Engineers have different objectives when it comes to social interaction.

'Normal' people expect to accomplish several unrealistic things from social interaction:

Stimulating and thought-provoking conversation

Important social contacts

A feeling of connectedness with other humans

In contrast to 'normal' people, engineers have rational objectives for social interactions:

Get it over with as soon as possible.

Avoid getting invited to something unpleasant.

Demonstrate mental superiority and mastery of all subjects.

I take the vision which comes from dreams and apply the magic of science and mathematics, adding the heritage of my profession and my knowledge of nature's materials to create a design.

I organize the efforts and skills of my fellow workers employing the capital of the thrifty and the products of many industries, and together we work toward our goal undaunted by hazards and obstacles.

And when we have completed our task all can see that the dreams and plans have materialized for the comfort and welfare of all.

I am an Engineer. I serve mankind by making dreams come true.

When, hypocritically clad in dressing-gown and slippers, I stopped at my guest's inner door and Fontenette opened it just enough to let me enter, I saw, indeed, a wonderful sight. The entomologist had lighted up the room, and it was filled, filled! with gorgeous moths as large as my hand and all of a kind, dancing across one another's airy paths in a bewildering maze or alighting and quivering on this thing and that. The mosquito-net, draping almost from ceiling to floor, was beflowered with them majestically displaying in splendid alternation their upper and under colors, or, with wings lifted and vibrant, tipping to one side and another as they crept up the white mesh, like painted and gilded sails in a fairies' regatta.

There is a popular superstition to the effect that museum entomologists devote their time to the fabrication of mommets. These are small, artificially constructed images into which pins are stuck, mainly with a view to making life less tolerable for other entomologists. The museum entomologist calls them species, but they bear little resemblance to the species actually encountered in nature. Such a view is exaggerated, but it may contain a grain of truth. Most of us could probably do more to give our species reality by giving thought to the distributional data available to us than in fact we do.

For the present I will confine myself to announcing as a result of my argument that if we think of that quantity which with reference to a single body I have called its entropy, as formed in a consistent way, with consideration of all the circumstances, for the whole universe, and if we use in connection with it the other simpler concept of energy, we can express the fundamental laws of the universe which correspond to the two fundamental laws of the mechanical theory of heat in the following simple form. 1. The energy of the universe is constant. 2. The entropy of the universe tends toward a maximum.

It would be absurd to assume that the validity of the second law depends in any way on the skill of the physicist or chemist in observing or experimenting. The gist of the

second law has nothing to do with experiment; the law asserts briefly that there exists in nature a quantity which changes always in the same sense in all natural processes. The proposition stated in this general form may be correct or incorrect; but whichever it may be, it will remain so, irrespective of whether thinking and measuring beings exist on earth or not.... The limitations to the law, if any, must lie in the same province as its essential idea, in the observed Nature, and not in the Observer. That man's experience is called upon in the deduction of the law is of no consequence; for that is, in fact, our only way of arriving at knowledge of natural law. But the law once discovered must receive recognition of its independence, at least in so far as Natural Law can be said to exist independent of Mind. Whoever denies this must deny the possibility of natural science.

Mr. Krutch's contribution...has been his recognition and communication of the discovery that the natural world must be treated as an equal partner. That a world entirely conquered by technology, entirely dominated by industrial processes, entirely occupied by man and machine, would be a world unfit to live in. Perhaps impossible to live in.

### **Commoner, Barry** 1917–

American biologist, ecologist, and educator

The environment makes up a huge, enormously complex living machine that forms a thin dynamic layer on the

earth's surface, and every human activity depends on the integrity and the proper functioning of this machine. Without the photosynthetic activity of green plants, there would be no oxygen for our engines, smelters, and furnaces, let alone support for human and animal life. Without the action of the plants, animals, and microorganisms that live in them, we could have no pure water in our lakes and rivers. Without the biological processes that have gone on in the soil for thousands of years, we could have neither food crops, oil, nor coal. This machine is our biological capital, the basic apparatus on which our total productivity depends. If we destroy it, our most advanced technology will become useless and any economic and political system that depends on it will founder. The environmental crisis is a signal of this approaching catastrophe.

We must avoid here two complementary errors: on the one hand that the world has a unique, intrinsic, pre-existing structure awaiting our grasp; and on the other

hand that the world is in utter chaos. The first error is that of the student who marveled at how the astronomers could find out the true names of the distant constellations. The second error is that of Lewis Carroll's Walrus who grouped shoes with ships and sealing wax, and cabbages with kings...

It is of the utmost importance to your real advancement in science, to avoid every source of error, or whatever may lead you to form an erroneous judgment. Now a true judgment can only be obtained by a profound view of nature, and a strict examination into the mutual connections and dependencies of things; you will hence see the necessity of strict and accurate examination, of time to acquire the requisite knowledge, and of attention to comprehend it: for among the various sources of error, we may reckon the precipitation of our judgment and a presumptuous ignorance as the principal.

It is almost as difficult to make a man unlearn his errors, as his knowledge. Mal-information is more hopeless than non-information; for error is always more busy than ignorance. Ignorance is a blank sheet, on which we may write; but error is a scribbled one, from which we must first erase. Ignorance is contented to stand still with her back to the truth; but error is more presumptuous, and proceeds in the same direction. Ignorance has no light, but error follows a false one. The consequence is, that error, when she retraces her footsteps, has farther to go, before we can arrive at the truth, than ignorance.

It sounds paradoxical to say that the attainment of scientific truth has been effected, to a great extent, by the help of scientific errors. But the subject-matter of physical science is furnished by observation, which cannot extend beyond the limits of our faculties; while, even within those limits, we cannot be certain that any observation is absolutely exact and exhaustive. Hence it follows that

any given generalisation from observation may be true, within the limits of our powers of observation at a given time, and yet turn out to be untrue, when those powers of observation are directly or indirectly enlarged.

It may fairly be doubted whether any generalisation, or hypothesis, based upon physical data is absolutely true, in the sense that a mathematical proposition is so; but, if its errors can become apparent only outside the limits of practicable observation, it may be just as usefully adopted for one of the symbols of that algebra by which we interpret Nature, as if it were absolutely true.

Believe truth! Shun error! – these, we see, are two materially different laws; and by choosing between them we may end by colouring differently our whole intellectual life. We may regard the chase for truth as paramount, and the avoidance of error as secondary; or we may, on the other hand, treat the avoidance of error as more imperative, and let truth take its chance.... Our errors are surely not such awful solemn things. In a world where we are so certain to incur them in spite of all our caution, a certain lightness of heart seems healthier than this excessive nervousness on their behalf. At any rate, it seems the fittest thing for the empiricist philosopher.

The only method of preventing such errors from taking place, and of correcting them when formed, is to restrain and simplify our reasoning as much as possible. This depends entirely upon ourselves, and the neglect of it is the only source of our mistakes.

But any pride I might have felt in my conclusions was perceptibly lessened by the fact that I knew that the solution of these problems had almost always come to me as the gradual generalisation of favourable examples, by a series of fortunate conjectures, after many errors. I am fain to compare myself with a wanderer on the mountains who, not knowing the path, climbs slowly and painfully upwards and often has to retrace his steps because he can go no further – then, whether by taking thought or from luck, discovers a new track that leads him on a little till at length when he reaches the summit he finds to his shame that there is a royal road, by which he might have ascended, had he only had the wits to find the right approach to it. In my works, I naturally said nothing about my mistake to the reader, but only described the

The Wave Theory of Light (p. 317)

**Lodge, Sir Oliver** 1851–1940  
English physicist

For well nigh a century we have had a wave theory of  
light; and a wave theory of light is almost certainly true.  
It is directly demonstrable that light consists of waves of  
some kind or other, and that these waves travel at a cer-  
tain well-known velocity – achieving a distance equal to  
seven times the circumference of the Earth every second;  
from New York to London and back in the thirtieth part  
of a second; and taking only eight minutes on the journey  
from the Sun to the Earth. This propagation in time of an  
undulatory disturbance necessarily involves a medium. If  
waves setting out from the Sun exist in space eight min-  
utes before striking our eyes, there must necessarily be  
in space some medium which conveys them. Waves we  
cannot have, unless they be waves in something.

Indeed, one of the most important of our fundamental  
assumptions must be that the ether not only occupies all  
space between molecules, atoms, or electrons, but that it  
pervades all these particles. We shall add the hypothesis  
that, though the particles may move, the ether always  
remains at rest.

At first sight the idea that we are immersed in a medium

able; it is not so if we remember that in all probability  
matter is composed mainly of holes. We may, in fact,  
regard matter as possessing a bird-cage kind of structure,  
in which the volume of the ether disturbed by the wires  
when the structure is moved is infinitesimal in compari-  
son with the volume enclosed by them.

## ETHER SPACE

**Anaxagoras** ca. 500 BCE–428 BCE  
Greek philosopher of nature

The formation of the world began with a vortex, formed out of chaos by Energy. This vortex started at the center and gradually spread. It separated matter into two regions, the rare, hot, dry and light material, the aether, in the outer regions, and the heavier, cooler, moist material, the air, in the inner regions. The air condensed in the center of the vortex, and out of the air, the clouds, water and earth separated. But after the formation of earth, because of the growing violence of the rotary motion, the surrounding fiery aether tore stones away from the earth and kindled them to stars, just as stones in a whirlpool rush outward more than water. The sun, moon and all the stars are stones on fire, ...are moved round by the revolution of the aether.

All pieces of matter and all particles are connected together by the ether and by nothing else. In it they move freely and of it they may be composed. We must study the kind of connection between matter and ether. The particles embedded in the ether are not independent of it, they are closely connected with it, it is probable that they are formed out of it: they are not like grains of sand suspended in water, they seem more like minute crystals formed in a mother liquor.

## ETHICS

### Accreditation Board for Engineering and Technology

Engineers uphold and advance the integrity, honor, and dignity of the engineering profession by:

- I. using their knowledge and skill for the enhancement of human welfare;
  - II. being honest and impartial, and serving with fidelity the public, their employer;
  - III. striving to increase the competence and prestige of the engineering profession;
- and
- IV. supporting the professional and technical societies of their disciplines.

Scientific statements of facts and relations, indeed, cannot produce ethical derivatives. However, ethical derivatives can be made rational and coherent by logical thinking and empirical knowledge. If we can agree on some fundamental ethical propositions, then other ethical propositions can be derived from them, provided that the original premises are stated with sufficient precision. Such ethical premises play a similar role in ethics to that played by axioms in mathematics.

We do not know whether we shall succeed in once more expressing the spiritual form of our future communities in the old religious language. A rationalistic play with words and concepts is of very little assistance here; the most important preconditions are honesty and directness. But since ethics is the basis for the communal life of men, and ethics can only be derived from that fundamental human attitude which I have called the spiritual pattern of the community, we must bend all our efforts to reuniting ourselves, along with the younger generation, in a common human outlook. I am convinced that we can succeed in this if again, we can find the right balance between the two kinds of truth.

Events in the heavens happen in their own good time and not before, and they are often not repeatable. Astronomers

have learned to take what's an offer and make the best of it.

The cosmic drama is played out on a vast scale in time and space. The mind, moving “on wings as swift as meditation,” perceives today the events that were passing at the bounds of the observable universe several thousand million years ago – events of which the news has just reached us, carried with the speed of light. Some of these events seem foreign to us, like the customs of a distant land. They may stem from a different stage of development. We catch a glimpse of the drama that is being played out on the fringes of the world, and they carry a suggestion of the Theater of the Absurd.

We see that things which lack intelligence, such as natural bodies, act for an end, and this is evident from their acting always, or nearly always, in the same way, so as to obtain the best result. Hence it is plain that not fortuitously, but designedly, do they achieve their end. Now whatever lacks intelligence cannot move towards an end, unless it be directed by some being endowed with knowledge and intelligence; as the arrow is shot to its mark by the archer. Therefore some intelligent being exists by whom all natural things are directed to their end; and this being we call God.

If single acts [of creation] would evince design, how much more a vast universe, that by inherent laws gradually builded itself, and then created its own plants and animals, a universe so adjusted that it left by the way the poorest things, and steadily wrought toward more complex, ingenious, and beautiful results! Who designed this mighty machine, created matter, gave to it its laws, and impressed upon it that tendency which has brought forth the almost infinite results on the globe, and wrought them

into a perfect system? Design by wholesale is grander than design by retail.

By irreducibly complex I mean a single system composed of several well-matched, interacting parts that contribute to the basic function, wherein the removal of anyone of the parts causes the system to effectively cease functioning. An irreducibly complex system cannot be produced directly (that is, by continuously improving the initial function, which continues to work by the same mechanism) by slight, successive modification of a precursor, system, because any precursors to an irreducibly complex system that is missing a part is by definition nonfunctional.

They [Fundamentalists] long for the return of a more moral America, an America that may never have been. All around them they see what they perceive as declining morality and spirituality. They reason that if humans share ancestry with the other animals, we have no reason to behave as anything other than animals. This view neglects the fact that humans are the only known animals with the ability to contemplate the consequences of their own actions. It also fails to recognize that there is a great deal of good in the world, the nightly news notwithstanding. Crime existed long before the theory of evolution, even before the writing of the Bible, and biologists do not like crime anymore than the creationists do. Evolutionary theory is not a license to run amok, and neither is a belief in the literal interpretation of the Bible a guarantor of moral behavior.

It is true that I accept the theory of evolution as the most logical one that has ever been put forward to explain the development of living creatures on this earth. As far as I am concerned, however, there is absolutely no conflict between a belief in evolution and a belief in God as the creator. Believing as I do in evolution, I merely believe that is the method by which God created, and is still creating, life on earth. And it is a method so marvelously conceived that to study it in detail is to increase – and certainly never to diminish – one’s reverence and awe both for the Creator and the process.

The story of evolution is probably the most fascinating of all we have to tell because it reaches into our very fiber. It ties all forms of life together and provides us with a common bond to plants and animals. Basically, we are composed of the same substances and possess the same basic drives, making us all brothers in a cosmic experiment. Astronomers tell us that the earth should continue to exist another five billion years. Since life has only been around for three billion years, we are still in our youth. The insights gained through the study of evolution will assure us a future and allow us to determine our destiny.

Biologists must constantly keep in mind that what they see was not designed, but rather evolved. It might be thought, therefore, that evolutionary arguments would play a large part in guiding biological research, but this is far from the case. It is difficult enough to study what is happening now. To figure out exactly what happened in evolution is even more difficult. Thus evolutionary achievements can be used as hints to suggest possible lines of research, but it is highly dangerous to trust them too much.

Evolution is a cosmic game of Pussy wants a corner. Each creature has its eye on some snug corner where it would rest in peace. Each corner is occupied by some creature that is not altogether satisfied and that is on the lookout for a larger sphere. There is much beckoning between those who are desirous of making a change. Now and then some bold spirit gives up his assured position and scrambles for something better. The chances are that the adventurer finds it harder to attain the coveted place than he thought.

On the same principle, if a man were to make a machine for some special purpose but were to use old wheels, springs and pulleys, only slightly altered, the whole machine, with all its parts, might be said to be specially contrived for its present purpose. Thus throughout nature almost every part of each living being has probably served, in a slightly modified condition, for diverse purposes, and has acted in the living machinery of many ancient and distinct specific forms.

For if we would compare the Infinite, it would surely require a greater Infinite to cause the causes of effects than to produce the effects themselves.

Evolution is very possibly not, in actual fact, always gradual. But it must be gradual when it is being used to explain the coming into existence of complicated, apparently designed objects, like eyes. For if it is not gradual in these cases, it ceases to have any explanatory power at all. Without gradualness in these cases, we are back to miracle, which is simply a synonym for the total absence of explanation.

My argument will be that Darwinism is the only known theory that is in principle capable of explaining certain aspects of life. If I am right it means that, even if there were no actual evidence in favor of Darwinian theory (there is, of course) we should still be justified in preferring it over all rival theories.

One way to dramatize this point is to make a prediction. I predict that, if a form of life is ever discovered in another part of the universe, however outlandish and weirdly alien that form of life may be in detail, it will be found to resemble life on earth in one key respect: it will have evolved by some kind of Darwinian natural selection.

But Charles Darwin showed how it is possible for blind physical forces to mimic the effects of conscious design, and, by operating as a cumulative filter of chance variations, to lead eventual to organized and adaptive complexity, to mosquitoes and mammoths, to humans and therefore, indirectly, to books and computers. Darwin's theory is now supported by all the available relevant evidence, and its truth is not doubted by any serious modern biologist.

Protein molecules are the ultimate stuff of life. If we think of the cell as being analogous to a factory, then the proteins can be thought of as analogous to the machines on the factory floor which carry out individually or in groups of all the essential activities on which the life of the cell depends. Each protein is a sort of micro-miniaturized machine, so small that it must be magnified a million times before it is visible to the human eye. The structure and functioning of these fascinating work horses of the cell was a complete mystery until the 1950s.

The impossibility of gradual functional transformation is virtually self-evident in the case of proteins: mere causal observation reveals that a protein is an interacting whole, the function of every amino acid being more or less (like letters in a sentence or cogwheels in a watch) essential to the function of the entire system. To change, for example, the shape and function of the active site (like changing the verb in a sentence or an important cogwheel in a watch) in isolation throughout the molecule, destabilizing the whole system and rendering it useless.

When a number of enzymes are necessary for the assembly of a particular compound, they are arranged adjacent to each other so that, after each step in the operation, the partially completed compound can be conveniently passed to the next enzyme which performs the next chemical operation and so on until the compound is finally assembled. ### Nothing in Biology Makes Sense Except in the Light of Evolution

Title of article

*The American Biology Teacher*, Volume 35, March, 1973 (p. 125)

Seen in the light of evolution, biology is, perhaps, intellectually the most satisfying and inspiring science. Without that light it becomes a pile of sundry facts – some of them interesting or curious but making no meaningful picture as a whole.

Nothing in Biology Makes Sense Except in the Light of Evolution

*The American Biology Teacher*, Volume 35, March, 1973 (p. 129)

Evolution comprises all the stages of the development of the universe: the cosmic, biological, and the human or cultural developments. Attempts to restrict the concept of evolution to biology are gratuitous. Life is a product of the evolution of inorganic nature, and man is a product of the evolution of life.

Changing Man

*Science*, Volume 155, Number 3761, 27 January, 1967 (p. 409)

Evolution is a creative process, in precisely the same sense in which composing a poem or a symphony, carving a statue, or painting a picture are creative acts.... It renders possible formations of living systems that would otherwise be infinitely improbable. Nothing can be simpler and more ingenious than its mode of operation: gene constellations that fit the environment survive better and reproduce more often than those that fit less well.

*Genetics of the Evolutionary Process*

Chapter 12, Evolution as a Creative Process (pp. 430, 431)

Columbia University Press. New York, New York, USA. 1970

I venture another, and perhaps equally reckless generalization – nothing makes sense in biology except in the light of evolution, *sub specie evolutionism*. If the living world has not arisen from common ancestors by means of an evolutionary process, then the fundamental unity of living things is a hoax and their diversity, a joke.

As a paleontologist, I readily concede that my long dead fossils, lacking any traces of their soft anatomies or behaviors, are totally mute on the subject of reproduction and transmission of genetic information. And this is, I acknowledge, a major limitation to our data.

*Reinventing Darwin: The Great Debate at the High Table of Evolutionary Theory* (p. 2)

John Wiley & Sons, Inc. New York, New York, USA. 1995

Simple extrapolation does not work. I found that out back in the 1960s as I tried in vain to document examples of the kind of slow, steady directional change we all thought ought to be there, ever since Darwin told us that natural selection should leave precisely such a telltale signal as we collect our fossils up cliff faces. I found instead, that once species appear in the fossil record, they tend not to change much at all. Species remain imperturbably, implacably resistant to chance as a matter of course.

*Reinventing Darwin: The Great Debate at the High Table of Evolutionary Theory* (p. 3)

John Wiley & Sons, Inc. New York, New York, USA. 1995

Stasis is now abundantly well documented as the preeminent pale ontological pattern in the evolutionary history of species.

*Reinventing Darwin: The Great Debate at the High Table of Evolutionary Theory* (p. 77)

John Wiley & Sons, Inc. New York, New York, USA. 1995

No wonder paleontologists shied away from evolution for so long. It seems never to happen. Assiduous collecting of cliff faces yields zigzags, minor oscillations, and the very occasional slight accumulation of change – over millions of years, at a rate too slow to really account for all the prodigious change that has occurred in evolutionary history. When we do see the introduction of evolutionary novelty, it usually shows up with a bang and often with no firm evidence that the organisms did not evolve elsewhere! Evolution cannot forever be going on someplace else. Yet that's how the fossil record has struck many a forlorn paleontologist looking to learn something about evolution.

*Reinventing Darwin: The Great Debate at the High Table of Evolutionary Theory* (p. 95)

John Wiley & Sons, Inc. New York, New York, USA. 1995

But we saw – as did several pale ontological contemporaries of Darwin – that if you do collect a series of fossils up through a sequence of sedimentary rock, and if you don't see much evidence of anatomical change through that series, that is indeed evidence that substantial gradual evolutionary change has not occurred within that species lineage, no matter how guppy the record may be. That's why the evidence for stasis now appears so overwhelming.

*Reinventing Darwin: The Great Debate at the High Table of Evolutionary Theory* (p. 96)

John Wiley & Sons, Inc. New York, New York, USA. 1995

I needed to explain why evolution leaves an entirely different sort of pattern in the rock record than Darwin – and his long string of successors, including many paleontologists – had supposed.

John Wiley & Sons, Inc. New York, New York, USA. 1995

The persistent pattern of no change within samples, coupled with the abrupt appearance of new species – organisms marked with anatomical innovations – had to be telling us something about the way the evolutionary process works.

[Hypotheses] on the origin of species are an indication of our mental tendencies rather than the synthetic result of facts incontrovertibly ascertained. Science, surely, was always in the forefront of the fight against authoritarianism and superstition. It is to science that we owe our increased intellectual freedom *vis-à-vis* religious beliefs; it is to science that we owe the liberation of mankind from ancient and rigid forms of thought. Today these forms of thought are nothing but bad dreams – and this we learned from science. Science and enlightenment are one and the same thing – even the most radical critics of society believe this.

Chapter 8 (p. 181)  
Cambridge University Press. Cambridge, England. 1999

Will the laymen be able to come to a correct judgment? Most certainly, for the competence, the complications and the successes of science are vastly exaggerated. One of the most exhilarating experiences is to see how a lawyer, who is a layman, can find holes in the testimony, the technical testimony, of the most advanced expert and thus prepare the jury for its verdict. Science is not a closed book that is understood only after years of training. It is an intellectual discipline that can be examined and criticized by anyone who is interested and that looks difficult and profound only because of a systematic campaign of obfuscation carried out by many scientists (though, I am happy to say, not by all).

Three cheers for the fundamentalists in California who succeeded in having a dogmatic formulation of the theory of evolution removed from the text books and an account

Ideologies are marvelous when used in the companies of other ideologies. They become boring and doctrinaire as soon as their merits lead to the removal of their opponents.) The most important change, however, will have to occur in the field of education.

Using stories we may of course also introduce “scientific” accounts, say, of the origin of the world and thus make the children acquainted with science as well. But science must not be given any special position except for pointing out that there are lots of people who believe in it. Later on the stories which have been told will be supplemented with “reasons,” where by reasons I mean further accounts of the kind found in the tradition to which the story belongs. And, of course, there will also be contrary reasons. Both reasons and contrary reasons will be told by the experts in the fields and so the young generation becomes acquainted with all kinds of sermons and all types of wayfarers.

Evolution, a fact rather than mere hypothesis, is the central unifying concept in biology. By extension it affects almost all other fields of knowledge and thought and must be considered one of the most influential concepts in Western thought.

Though often brilliantly and ingeniously composed, his argument was based, in many instances, on new and often unsubstantiated hypotheses, sometimes fuzzy analogies and metaphors, the repudiation of compet-

ing explanations, and a frequent plea to complexity and general ignorance, rather than compelling, clearly incontrovertible evidence in its own support; and it is clear that Darwin knew this.

Yet even here, where Darwin's arguments are strongest, nagging questions remain. For example, a reader of the Origin might be justified in wondering what Creationist view Darwin is referring to. Perhaps this is a problem more for the present-day reader. Darwin's contemporaries may have known exactly what he meant, though I doubt it. Often the Creationist position seems merely a straw man – set up only to be knocked down. The constraints on space in the Origin, which led Darwin to abandon his original intention of arguing on both sides of the mutability issue, add to this feeling. The result is that the Creationist position is never clearly defined in the Origin.

The conditions that direct the order of the whole of the living world around us, are marked by their persistence in improving the birthright of successive generations. Yet ideas of unity amid diversity, of order amid change, have also long been growing, even finding expression, and this not merely, as sporadically in all ages, in impressions and speculations on decline or on better things; but in clearer and more comprehensive surveys of

the processes of change, even inquiries into its method. These, in fact, have gone towards making up that general idea we now more or less share, of the universe as not only orderly, but in the process of change. Changing order, orderly change, and this everywhere – in nature inorganic and organic, in individual and in social life – for this vast conception, now everywhere diffusing, often expressed, rarely as yet applied, we need some general term – and this is Evolution.

Well evolution is a theory. It is also a fact. And facts and theories are different things, not rungs in a hierarchy of increasing certainty. Facts are the world's data. Theories are structures of ideas that explain and interpret facts. Facts do not go away when scientists debate rival theories to explain them. Einstein's theory of gravitation replaced Newton's, but apples did not suspend themselves in mid-air, pending the outcome. And humans evolved from ape-like ancestors whether they did so by Darwin's proposed mechanism or by some other yet to be discovered.

Since we proposed punctuated equilibria to explain trends, it is infuriating to be quoted again and again by creationists – whether through design or stupidity, I do not know – as admitting that the fossil record includes no transitional forms. Transitional forms are generally lacking at the species level, but they are abundant between larger groups.

These shortest-term studies are elegant and important, but they cannot represent the general mode for building patterns in the history of life. The reason strikes most people as deeply paradoxical, even funny – but the argument truly cannot be gainsaid. Evolutionary rates of a moment, as measured for guppies and lizards, are vastly too rapid to represent the general modes of change that build life's history through geological ages.... These measured changes over years and decades are too fast by several orders of magnitude to build the history of life by simple cumulation. Reznick's guppy rates range from 3,700 to 45,000 darwins (a standard metric for evolution, expressed as change in units of standard deviation – a measure of variation around the mean value of a trait in a population – per million years). By contrast, rates for major trends in the fossil record generally range from 0.1 to 1.0 darwin. Reznick himself states that “the estimated rates [for guppies] are...four to seven orders of magnitude greater than those observed in the fossil record” (that is, ten thousand to ten million times faster!).

Orchids manufacture their intricate devices from the common components of ordinary flowers, parts usually fitted for very different functions. If God had designed a beautiful machine to reflect his wisdom and power, surely he would not have used a collection of parts generally fashioned for other purposes. Orchids were not made by an ideal engineer; they are jury-rigged from

a limited set of available components. Thus, they must have evolved from ordinary flowers.

I emphatically do not assert the general “truth” of this philosophy of punctuational change. Any attempt to support the exclusive validity of such a grandiose notion would border on the nonsensical.... Nonetheless, I will confess to a personal belief that a punctuational view may prove to map tempos of biological and geographic change more accurately and more often than any of its competitors – if only because complex systems in steady state are both common and highly resistant to change. As my colleague British geologist Derek V. Ager writes in supporting a punctuational view of geologic change: “The history of anyone part of the earth, like the life of a soldier, consists of long periods of boredom and short terror.”

Two organisms may maintain the same feature because both inherited it from a common ancestor. These are homologous similarities, and they indicate “propinquity of dissent,” to use Darwin's words. Forelimbs of people, porpoises, bats and horses provide the classic example of homology in most textbooks. They look different, and do different things, but are built of the same bones. No engineer, starting from scratch each time, would have built such disparate structures from the same parts. Therefore, the parts existed before the particular set of structures now housing them: they were, in short, inherited from a common ancestor.

We talk about the “march from monad to man” (old-style language again) as though evolution followed continuous pathways to progress along unbroken lineages. Nothing could be further from reality. I do not deny that, through time, the most “advanced” organism has tended to increase in complexity. But the sequence [allocated in most texts] from jellyfish to trilobite to nautiloid to armored fish to dinosaur to monkey to human is no lineage at all, but a chronological set of termini on unrelated evolutionary trunks. Moreover life shows no trend

to complexity in the usual sense – only an asymmetrical expansion of diversity around a starting point constrained to be simple.

Tires to Sandals (p. 322)

W.W. Norton & Company, Inc. New York, New York, USA. 1993

There is no progress in evolution. The fact of evolutionary change through time doesn't represent progress as we know it. Progress is not inevitable. Much of evolution is downward in terms of morphological complexity, rather than upward. We're not marching toward some greater thing. The actual history of life is awfully damn curious in the light of our usual expectation that there's some predictable drive toward a generally increasing complexity in time. If that's so, life certainly took its time about it: five-sixths of the history of life is the story of single-celled creatures only.

*The Third Culture*

The Pattern of Life's History (p. 52)

We cannot understand much of the history of late nineteenth- and early twentieth-century anthropology, with its plethora of taxonomic names proposed for nearly every scrap of fossil bone, unless we appreciate its obsession with the identification and ranking of races. For many schemes of classification sought to tag the various fossils as ancestors of modern races and to use their relative age and apishness as a criterion for racial superiority.

We are here because one odd group of fishes had a peculiar fin anatomy that could transform into legs for terrestrial creatures; because the earth never froze entirely during an ice age; because a small and tenuous species, arising in Africa a quarter of a million years ago, has managed, so far, to survive by hook and by crook. We may yearn for a "higher" answer – but none exists.

*Life magazine*, December, 1988

The absence of fossil evidence for intermediary stages between major transitions in organic design, indeed our inability, even in our imagination, to construct functional intermediates in many cases, has been a persistent and nagging problem for gradualistic accounts of evolution. Is a New and General Theory of Evolution Emerging?

*Paleobiology*, January, 1980 (p. 127)

The history of most fossil species includes two features particularly inconsistent with gradualism: 1. Stasis. Most species exhibit no directional change during their tenure on earth. They appear in the fossil record looking much the same as when they disappear; morphological change is usually limited and directionless. 2. Sudden appearance. In any local area, a species does not arise gradually by the steady transformation of its ancestors; it appears all at once and "fully formed."

Scientific claims must be testable; we must, in principal, be able to envision a set of observations that would render them false. Miracles cannot be judged by this criterion, as Whitcomb and Morris have admitted. But is all creationists' writing merely about untestable singularities? Are arguments never made in proper scientific form? Creationists do offer some testable statements, and these are amenable to scientific analysis. Why, then, do I continue to claim that creationism isn't science? Simply because these relatively few statements have been tested and conclusively refuted.

This View of Life, An Early Start

*Natural History*, Volume 87, Number 2, February, 1978 (p. 24)

All paleontologists know that the fossil record contains precious little in the way of intermediate forms; transitions between major groups are characteristically abrupt. Gradualists usually extract themselves from this dilemma by invoking the extreme imperfection of the fossil record – if only one step in a thousand survives as a fossil, geology will not record continuous change. Although I reject this argument...let us grant the traditional escape and ask a different question. Even though we have no direct evidence for smooth transitions, can we invent a reasonable sequence of intermediate forms – that is, viable, functioning organisms – between ancestors and descendants in major structural transitions? Of what possible use are the imperfect incipient stages of useful structures? What good is half a jaw or half a wing? The concept of preadaptation provides the conventional answer by permitting us to argue that incipient stages performed different functions. The half jaw worked

perfectly well as a series of gill-supporting bones; the half wing may have trapped prey or controlled body temperature. I regard preadaptation as an important, even an indispensable, concept. But a plausible story is not necessarily true. I do not doubt that preadaptation can save gradualism in some cases, but does it permit us to invent a tale of continuity in most or all cases? I submit, although it may only reflect my lack of imagination, that the answer is no...

Today, our duty is to destroy the myth of evolution, considered as a simple, understood, and explained phenomenon which keeps rapidly unfolding before us. Biologists must be encouraged to think about the weaknesses of the interpretations and extrapolations that theoreticians put forward or lay down as established truths. The deceit is sometimes unconscious, but not always, since some people, owing to their sectarianism, purposely overlook reality and refuse to acknowledge the inadequacies and the falsity of their beliefs.

It follows that any explanation of the mechanism in creative evolution of the fundamental structural plans is heavily burdened with hypotheses. This should appear as an epigraph to every book on evolution. The lack of direct evidence leads to the formation of pure conjectures as to the genesis of the phyla; we do not even have a

basis to determine the extent to which these opinions are correct.

Chapter III (p. 88)  
Academic Press. New York, New York, USA. 1977

Some contemporary biologists, as soon as they observe a mutation, talk about evolution. They are implicitly supporting the following syllogism: mutations are the only evolutionary variations, all living beings undergo mutations, therefore all living beings evolve. This logical scheme is, however, unacceptable: first, because its major premise is neither obvious nor general; second, because its conclusion does not agree with the facts. No matter how numerous they may be, mutations do not produce any kind of evolution.

*Evolution of Living Organisms: Evidence for a New Theory of Transformation*  
Chapter III (p. 88)

The opportune appearance of mutations permitting animals and plants to meet their needs seems hard to believe. Yet the Darwinian theory is even more demanding: a single plant, a single animal would require thousands and thousands of lucky, appropriate events. Thus, miracles would become the rule: events with an infinitesimal probability could not fail to occur.

It was obvious that both the general theory of evolution and its extension to man in particular must meet from the first with the most determined resistance on the part of the Churches. Both were in flagrant contradiction to the Mosaic story of creation, and other Biblical dogmas that were involved in it, and are still taught in our elementary schools. It is creditable to the shrewdness of the theologians and their associates, the metaphysicians, that they at once rejected Darwinism, and made a particularly energetic resistance in their writings to its chief consequence, the descent of man from ape. This resistance seemed the more justified and hopeful as, for seven or eight years after Darwin's appearance, few biologists accepted his theory, and the general attitude amongst them was one of cold skepticism.

*Evolution: The Modern Synthesis*

Chapter I (p. 13)

George Allen & Unwin Ltd. London, England. 1942

There is no more need to postulate an élan vital or a guiding purpose to account for evolutionary progress than to account for adaptation, for degeneration or any other form of specialization.... The purpose manifested in evolution, whether in adaptation, specialization, or biological progress, is only an apparent purpose. It is just as much a product of blind forces as is the falling of a stone to earth or the ebb and flow of the tides. It is we who have read purpose into evolution, as earlier men projected will and emotion into inorganic phenomena like storm or earthquake.

*Evolution: The Modern Synthesis*

Chapter 10 (pp. 568, 576)

George Allen & Unwin Ltd. London, England. 1942

The concept of evolution was soon extended into other than biological fields. Inorganic subjects such as the life-histories of stars and the formation of the chemical elements on the one hand, and on the other hand subjects like linguistics, social anthropology, and comparative law an religion, began to be studied for an evolutionary angle, until today we are enabled to see evolution as a universal and all pervading process.

Evolutionary science is a discipline or subject in its own right. But it is [also] the joint product of a number of separate branches of study and learning. Biology provides its central and largest component, but it has also received indispensable contributions from pure physics and chemistry, cosmogony and geology among the natural sciences, and among human studies from history and social science, archaeology and prehistory, psychology and anthropology. As a result, the present is the first period in which we have been able to grasp that the universe is a process in time and to get a first glimpse of our true relation with it. We can see ourselves as history, and can see that history in its proper relation with the history of the universe as a whole.

*Evolution in Action*

Chapter 1 (pp. 1–2)

Harper & Bothers. New York, New York, USA. 1953

Evolution in the extended sense can be defined as a directional and essentially irreversible process occurring in time, which in its course gives rise to an increase of variety and an increasingly high level of organization in its products. Our present knowledge indeed forces us to the view that the whole of reality is evolution – a single process of self-transformation.

Evolution and Genetics (p. 278)

Simon & Schuster. New York, New York, USA. 1955

As a result of a thousand million years of evolution, the universe is becoming conscious of itself, able to understand something of its past history and possible future.... It is as if man had been suddenly appointed managing director of the biggest business of all, the business of evolution – appointed without being asked if he wanted it, and without proper warning and preparation. What is more, he can't refuse the job. Whether he wants to or not, whether he is conscious of what he is doing or not, he is in point of fact determining the future direction of evolution on this earth. That is his inescapable destiny, and the sooner he realizes it and starts believing in it, the better for all concerned.

The hypothesis of special creation is not only a mere specious mask for our ignorance; its existence in Biology marks the youth and imperfection of the science. For what is the history of every science but the history of the elimination of the notion of creative, or other interferences, with the natural order of the phenomena? Harmonious order governing eternally continuous progress – the web and woof of matter and force interweaving by slow degrees, without a broken thread, that veil which lies between us and the Infinite – that universe which alone we know or can know; such is the picture which science draws of the world.

If the fundamental proposition of evolution is true, that the entire world, living and non-living, is the result of the mutual interaction, according to definite laws, of the forces possessed by the molecules of which the primitive nebulosity of the universe was composed, it is no less certain that the existing world lay, potentially, in the cosmic vapor, and that a sufficient intellect could, from a knowledge of the properties of the molecules of that vapor, have predicted, say the state of the Fauna of Great Britain in 1869, with as much certainty as one can say what will happen to the vapor of the breath in a cold winter's day.

At present, science has no satisfactory answer to the question of the origin of life on the earth. Perhaps the appearance of life on the earth is a miracle. Scientists are reluctant to accept that view, but their choices are limited; either life was created on the earth by the will of a being outside the grasp of scientific understanding, or it evolved on our planet spontaneously, through chemical reactions occurring in nonliving matter lying on the surface of the planet. The first theory places the question of the origin of life beyond the reach of scientific inquiry. It is a statement of faith in the power of a Supreme Being not subject to the laws of science. The second theory is also an act of faith. The act of faith consists in assuming that the scientific view of the origin of life is correct, without having concrete evidence to support that belief.

Persons who want naturalistic evolution to be accepted as unquestioned fact must therefore use their cultural authority to enact rules of discourse that protect the purported fact from the attacks of unbelievers. First, they can identify science with naturalism, which means that they insist as a matter of first principle that no consideration whatever be given to the possibility that mind or spirit preceded matter. Second, they can impose a rule of procedure that disqualifies purely negative argument, so that a theory which obtains some very modest degree of empirical support can become immune to disproof until and unless it is supplanted by a better naturalistic theory.

Evolution as Dogma: The Establishment of Naturalism

*First Things*, October, 1990

Darwinists believe that the mutation-selection mechanism accomplishes wonders of creativity not because the wonders can be demonstrated, but because they cannot think of a more plausible explanation for the existence of wonders that does not involve an unacceptable creator, *i.e.*, a being or force outside the world of nature.

Evolution as Dogma: The Establishment of Naturalism

*First Things*, October, 1990

The problem with scientific naturalism as a worldview is that it takes a sound methodological premise of natural science and transforms it into a dogmatic statement about the nature of the universe. Science is committed by definition to empiricism, by which I mean that scientists seek to find truth by observation, experiment, and calculation rather than by studying sacred books or achieving mystical states of mind. It may well be, however, that there are certain questions – important questions, ones to which we desperately want to know the answers – that cannot be answered by the methods available to our science. These may include not only broad philosophical issues such as whether the universe has a purpose, but also questions we have become accustomed to think of as empirical, such as how life first began or how complex biological systems were put together.

Evolution as Dogma: The Establishment of Naturalism

*First Things*, October, 1990

Creationists are disqualified from making a positive case, because science by definition is based upon naturalism. The rules of science also disqualify any purely negative argumentation designed to dilute the persuasiveness of the theory of evolution. Creationism is thus out of court and out of the classroom – before any consideration of evidence. Put yourself in the place of a creationist who has been silenced by that logic, and you may feel like a criminal defendant who has just been told that the law does not recognize so absurd a concept as "innocence."

Evolution as Dogma: The Establishment of Naturalism

*First Things*, October, 1990

For the scientific materialist the materialism comes first; the science comes thereafter. We might therefore more accurately term them "materialists employing science." And if materialism is true, then some materialistic theory of evolution has to be true simply as a matter of logical deduction, regardless of the evidence.

The fossil remains found at Piltdown by Mr. Dawson set students of man's evolution the most difficult task that has confronted them hitherto. In his characterization, Piltdown man was quite unlike any fossil type known to us. Sir Arthur Smith Woodward was impressed by his simian similarities; I, on the other hand, was impressed by those features which, as I thought then, were eminently human and modern. Hence arose those discrepancies between us – discrepancies of a quarter of a century ago. Since then, much has happened. Discoveries are being made which help to throw Piltdown man into his proper place in the crowded throng of evolving human forms. We now know that when the Piltdown type was being evolved in England – or at the western end of the Old World – a totally different type had come into being in the Eastern lands of the Old World.... So long as man is interested in his long past history, in the vicissitudes which our early forerunners passed through, and the varying fate which overtook them, the name of Charles Dawson is certain of remembrance.

We take the side of science in spite of the patent absurdity of some of its constructs, in spite of its failure to fulfill many of its extravagant promises of health and life, in spite of the tolerance of the scientific community for unsubstantiated just-so stories, because we have a prior commitment, a commitment to materialism. It is not that the methods and institutions of science somehow compel us to accept a material explanation of the phenomenal world, but, on the contrary, that we are forced by our a priori adherence to material causes to create an apparatus of investigation and a set of concepts that produce material explanations, no matter how counter-intuitive, no matter how mystifying to the uninitiated. Moreover, that materialism is an absolute, for we cannot allow a Divine Foot in the door.

*Billions and Billions of Demons*

The problem is to get [the creationists] to reject irrational and supernatural explanations of the world, the demons that exist only in their imaginations, and to accept a social and intellectual apparatus, Science, as the only begetter of truth. The reason that people do not have a correct view of nature is not that they are ignorant of this or that fact about the material world, but that they look to the wrong sources in their attempt to understand.

*Billions and Billions of Demons*

As to assertions without adequate evidence, the literature of science is filled with them, especially the literature of popular science writing. *Billions and Billions of Demons*

*New York Review of Books*, January 9, 1997

Given the immense extent, inherent complexity, and counterintuitive nature of scientific knowledge, it is impossible for anyone, including non-specialist scientists, to retrace the intellectual paths that lead to scientific conclusions about nature. In the end we must trust the experts and they, in turn, exploit their authority as experts and their rhetorical skills to secure our attention and our belief in things that we do not really understand.

*Billions and Billions of Demons*

It is said that there is no place for an argument from authority in science. The community of science is constantly self-critical.... It is certainly true that within each narrowly defined scientific field there is constant challenge to new technical claims and to old wisdom.... But when scientists transgress the bounds of their own specialty they have no choice but to accept the claims of authority, even though they do not know how solid the grounds of those claims may be. Who am I to believe... quantum physics if not Steven Weinberg, or about the solar system if not Carl Sagan? What worries me is that they may believe what Dawkins and Wilson tell them about evolution.

Billions and Billions of Demons

*New York Review of Books*, January 9, 1997

Creationists have capitalized on scientific disputes among biologists on the details of the evolutionary process by pretending that serious students of the subject are themselves in doubt about evolution. Evolutionary study is a living science; as such it is rich with controversy about particular issues of detail and mechanism. Creationists have extracted published statements in those controversies and used them dishonestly to suggest that biologists are in doubt about the fact of organic evolution. Local school boards and students must clearly be impressed that scientists in universities seem themselves to be denying evolution.

The only alternative is to say that they did arise from muck because God's finger went out and touched that muck. That is to say, there was a non-natural process. And that's really where the action is. Either you think that complex organisms arose by non-natural phenomena, or you think that they arose by natural phenomena. If they arose by natural phenomena, they had to evolve. And that's all there is to it.

[S]cience, like other productive activities, like the state, the family, sport, is a social institution completely integrated into and influenced by the structure of all our other social institutions. The problems that science deals with, the ideas that it uses in investigating those problems, even the so-called scientific results that come out of scientific investigation, are all deeply influenced by predispositions that derive from the society in which we live. Scientists do not begin life as scientists after all, but as social beings immersed in a family, a state, a productive structure, and they view nature through a lens that has been molded by their social experience.

As we examine ourselves as products of symbiosis over billions of years, the supporting evidence for our multimicrobe ancestry becomes overwhelming. Our bodies contain a veritable history of life on Earth. Our cells maintain an environment that is carbon- and hydrogen-rich, like that of the Earth when life began. They live in a medium of water and salts like the composition of the early seas. We became who we are by the coming together of bacterial partners in a watery environment. Although the evolutionary dynamics of DNA, genetic transfer, and

symbiosis were not discovered until almost a century after Charles Darwin's death in 1882, he had the shrewdness to write, "We cannot fathom the marvelous complexity of an organic being; but on the hypothesis here advanced this complexity is much increased. Each living creature must be looked at as a microcosm – a little universe, formed of a host of self-propagating organisms, inconceivably minute and as numerous as the stars in heaven."

Introduction (p. 18)

Summit Books. New York, New York, USA. 1986

Our bodies, like those of all life, preserve the environment of an earlier Earth. We coexist with present-day microbes and harbor remnants of others, symbiotically subsumed within our cells. In this way, the microcosm lives on in us and we in it.

Thus, horses have very stiff backbones, and a consequence of this is that people can ride them. However, we would not say that the function of a horse's backbone is to enable people to ride horses, because we do not think that horse's backbones evolved as they did so as to enable people, in the future, to ride.

Why did it take so long for evolution to be seriously proposed? And why did Darwinism face such an uphill battle after it was proposed? The reason is that Darwin challenged some of the basic beliefs of his age. Four of them were pillars of Christian dogma.

*One Long Argument: Charles Darwin and the Genesis of Modern Evolutionary Thought*  
 Chapter Four (p. 38)  
 Harvard University Press. Cambridge, Massachusetts, USA. 1991

There is indeed one belief that all true original Darwinians held in common, and that was their rejection of creationism, their rejection of special creation. This was the flag around which they assembled and under which they marched. When Hull claimed that “the Darwinians did not totally agree with each other, even over essentials”, he overlooked one essential on which all these Darwinians agreed. Nothing was more essential for them than to decide whether evolution is a natural phenomenon or something controlled by God. The conviction that the diversity of the natural world was the result of natural processes and not the work of God was the idea that brought all the so-called Darwinians together in spite of their disagreements on other of Darwin’s theories.

*One Long Argument: Charles Darwin and the Genesis of Modern Evolutionary Thought*  
 Chapter Seven (p. 99)  
 Harvard University Press. Cambridge, Massachusetts, USA. 1991

We live in an age that places great value on molecular biology. Let me emphasize the equal importance of evolutionary biology. The very survival of man on this globe may depend on a correct understanding of the evolutionary forces and their application to man. The meaning of race, of the impact of mutation, whether spontaneous or radiation-induced, of hybridization, of competition – all these evolutionary phenomena are of the utmost importance for the human species. Fortunately the large number of biologists who continue to cultivate the evolutionary vineyard is an indication of how many biologists realize this: we must acquire an understanding of the operation of the various factors of evolution not only for the sake of understanding our universe, but indeed very directly for the sake of the future of man.

The demarcation between science and theology is perhaps easiest, because scientists do not invoke the supernatural to explain how the natural world works, and they do not rely on divine revelation to understand it. When early humans tried to give explanations for natural phenomena, particularly for disasters, invariably they invoked supernatural beings and forces, and even today divine revelation is as legitimate a source of truth for many pious Christians as is science. Virtually all scientists known to me personally have religion in the best sense of this word, but scientists do not invoke supernatural or divine revelation.

The theory of evolution is quite rightly called the greatest unifying theory in biology.

*Populations, Species, and Evolution*  
 Chapter 1 (p. 1)  
 Harvard University Press. Cambridge, Massachusetts, USA. 1970

The basic framework of the theory is that evolution is a two-stage phenomenon: the production of variation and the sorting of the variants by natural selection. Yet agreement on this basic thesis does not mean that the work of the evolutionist is completed. The basic theory is in many instances hardly more than a postulate and its application raises numerous questions in almost every concrete case.

*Populations, Species, and Evolution*  
 Chapter 1 (p. 6)  
 Harvard University Press. Cambridge, Massachusetts, USA. 1970

The occurrence of genetic monstrosities by mutation, for instance the homeotic mutant in *Drosophila*, is well substantiated, but they are such evident freaks that these monsters can be designated only as “hopeless.” They are so utterly unbalanced that they would not have the slightest chance of escaping elimination through stabilizing selection. Giving a thrush the wings of a falcon does not make it a better flier. Indeed, having all the other equipment of a thrush, it would probably hardly be able to fly at all. It is a general rule, of which every geneticist and breeder can give numerous examples, that the more drastically a mutation affects the phenotype, the more likely it is to reduce fitness. To believe that such a drastic mutation would produce a viable new type, capable of occupying a new adaptive zone, is equivalent to believing in miracles.

*Populations, Species, and Evolution*  
 Chapter 15 (p. 253)  
 Harvard University Press. Cambridge, Massachusetts, USA. 1970

The finding of a suitable mate for the “hopeless monster” and the establishment of reproductive isolation from the

Chapter 15 (p. 253)

Harvard University Press. Cambridge, Massachusetts, USA. 1970

Every anti-evolutionist prior to 1859 allowed for the intermittent, if not constant, interference by the Creator. The natural causes postulated by the evolutionists completely separated God from his creation, for all practical purposes. The new explanatory model replaced planned teleology by the haphazard process of natural selection. This required a new concept of God and a new basis for religion.

*Science*, Volume 176, Number 4038, June 2, 1972 (p. 988)

Evolutionary biology, in contrast with physics and chemistry, is a historical science – the evolutionist attempts to explain events and processes that have already taken place. Laws and experiments are inappropriate techniques for the explication of such events and processes. Instead one constructs a historical narrative, consisting of a tentative reconstruction of the particular scenario that led to the events one is trying to explain.

Progressive evolution is the universal plan. Everything which we meet in the world around us, matter and mind, every individual and all congregated masses, begin their course as germs and unfold in slow progression.... The faculties of all intelligent creation, all that you call mind, all that you call heart, are framed for an interminable series of evolutions.... It is not mainly the mould of this mighty frame of things which establishes it, it is the fact that creation is eternally unfolding new resources and presenting itself under successive and amazing combinations of which no creature in the universe had imagined it capable.

We know from astronomy that the universe had a beginning, from physics that the future is both open and unpredictable, from geology and paleontology that the whole of life has been a process of change and transformation. From biology we know that our tissues are not impenetrable reservoirs of vital magic, but a stunning matrix of complex wonders, ultimately explicable in terms of

biochemistry and molecular biology. With such knowledge we can see, perhaps for the first time, why a Creator would have allowed our species to be fashioned by the process of evolution.

...we must ask first whether the theory of evolution by natural selection is scientific or pseudoscientific.... Taking the first part of the theory, that evolution has occurred, it says that the history of life is a single process of species-splitting and progression. This process must be unique and unrepeatable, like the history of England. This part of the theory is therefore a historical theory, about unique events, and unique events are, by definition, not part of science, for they are unrepeatable and so not subject to test.

They've seen their task as to elaborate his theory and to fill the gaps in it, to fill the trunk and twigs of the tree. But it seems to me that the theoretical framework has very little impact on the actual progress of the work in biological research. In a way some aspects of Darwinism and of neo-Darwinism seem to me to have held back the progress of science.

Organic evolution is one of the basic facts and characteristics of the objective world. From one point of view it is the basic thing about that world, because it is the process by which the universe's greatest complexities arise and systematic organization culminates. Being the process by which we ourselves came to be, it is crucial

for comprehension of our place in and relationship to the objective world.

Suppose that the most fundamental and general principle of a science had been known for over a century and had long since become a main basis for understanding and research by scientists in that field. You would surely assume that the principle would be taken as a matter of course by everyone with even a nodding acquaintance with the science. It would obviously be taught everywhere as basic to the science at any level of education. If you think that about biology, however, you are wrong. Evolution is such a principle in biology. Although almost everyone has heard of it, most Americans have only the scantest and most distorted idea of its real nature and significance.

The fact that theories are not subject to absolute and final proof has led to a serious vulgar misapprehension. Theory is contrasted with fact as if the two had no relationship or were antitheses: "Evolution is only a theory, not a fact." Of course, theories are not facts. They are generalizations about facts and explanations of facts, based on and tested by facts. As such they may be just as certain – merit just as much confidence – as what are popularly termed "facts." Belief that the sun will rise tomorrow is the confident application of a generalization. The theory that life has evolved is founded on much more evidence than supports the generalization that the sun rises every day. In the vernacular, we are justified in calling both "facts."

It has been said by some theorists that cases like that of the crocodile, virtually unchanged for 100 million years and more, represent a failure of the evolutionary force, a blind alley, a long senescence. As I gazed at my antagonist, it occurred to me how false this is. Here was no

failure but an adaptation so successful that once developed it has never needed to change. Is it, perhaps, not the success but the failure of adaptation that has forced evolving life onward to what we, at least, consider higher levels?

...The fossil record shows very clearly that there is no central line leading steadily, in a goal-directed way, from a protozoan to man. Instead there has been continual and extremely intricate branching, and whatever course we follow through the branches there are repeated changes both in the rate and in the direction of evolution. Man is the end of one ultimate twig... Even slight changes in earlier parts of the history would have profound cumulative effects on all descendent organisms through the succeeding millions of generations.... The existing species would surely have been different if the start had been different, and if any stage of the histories of organisms and their environments had been different. Thus the existence of our present species depends on a very precise sequence of causative events through some two billion years or more. Man cannot be an exception to this rule. If the causal chain had been different, *Homo sapiens* would not exist.

For the fittest will always survive,  
While the weakest go to the wall.

A Ballade of Evolution Stanza I

John W. Luce & Co. Boston, Massachusetts, USA. 1915

The theologians, who from the beginning of time have accredited themselves as the custodians of all fundamental truth having, by hasty discards of old dogmas, survived the shock of learning that the earth is round, and that the sun, moon and stars are held in place in the universe by the force of gravity, continued to hold as they had for some four thousand years to the theory of individual creation as set forth by the biblical authors. In the main this proposition had passed unchallenged even by scientists, though before Darwin, as he is at pains to record with all possible detail, some naturalists, to make use of a very general term, expressed the opinion that changed conditions of life had given rise to a sufficient differentiation in individual forms to create new species. Nor did Philosophy herself in those days steer her bark far enough from the shores of dogma to catch the broad sweeping current of the law of change.

Construed in terms of evolution, every kind of being is conceived as a product of modification wrought by insensible gradations upon a preexisting kind of being; and this holds as fully of the supposed “commencement of organic life” as of all subsequent developments of organic life.... Organic evolution may be likened to a mammoth, creeping, kaleidoscopic procession which began to move when life first appeared upon earth. In the beginning the procession was small. With the passing eons of time, there has been an ever increasing multitude, slowly, but steadily, moving forward. New forms have constantly joined the procession, and old forms have dropped out. We have not been able to look back into the distant past and learn from when the procession started; we are not able to look forward into the future and predict where the procession means to go; we are only trying to analyze and determine the nature of the factors responsible for the kaleidoscopic nature of the procession as it appears today.

Human beings use four times as much water to remove their excreta as they use for all other purposes, including drinking, cooking and washing. Is it pure, disinterested hygiene, or are we somehow washing away our sins? Although we take an obsessive interest in one activity and pretend the other does not exist, it is a fundamental equation that if you eat, you excrete ...

**Bergson, Henri** 1859–1941

...I pass from state to state. I am warm or cold, I am merry or sad, I work or I do nothing, I look at what is around me or I think of something else. Sensations, feelings, volitions, ideas – such are the changes into which my existence is divided and which color it in turns.

I change, then, without ceasing.

True, the universe is more than a collection of objective experimental data; more than the complexus of theories, abstractions, and special assumptions devised to hold the data together; more, indeed, than any construct modeled on this cold objectivity. For there is a deeper, more subjective world, a world of sensation and emotion, of aesthetic, moral, and religious values as yet beyond the grasp of objective science. And towering majestically over all, inscrutable and inescapable, is the awful mystery of Existence itself, to confound the mind with an eternal enigma.

Our experience hitherto justifies us in believing that  
nature is the realization of the simplest conceivable math-  
ematical ideas. I am convinced that we can discover by  
means of purely mathematical constructions the concepts  
and laws connecting them with each other, which fur-  
nish the key to the understanding of natural phenomena.  
Experience may suggest the appropriate mathematical  
concepts, but they most certainly cannot be deduced from  
it. Experience remains, of course, the sole criterion of

the physical utility of a mathematical construction. But the creative principle resides in mathematics. In a certain sense, therefore, I hold it true that pure thought can grasp reality, as the ancients dreamed.

When we merely note and record the phenomena which occur around us in the ordinary course of nature we are said to observe. When we change the course of nature by the intervention of our muscular powers, and thus produce unusual combinations and conditions of phenomena, we are said to experiment. Herschel justly remarked that we might properly call these two modes of experience passive and active observation. In both cases we must certainly employ our senses to observe, and an experiment differs from a mere observation in the fact that we more or less influence the character of the events which we observe.

Even the careful and sober testing of our ideas by experience is in its turn inspired by ideas: experiment is planned action in which every step is guided by theory. We do not stumble upon our experiences, nor do we let them flow over us like a stream. Rather, we have to be active: we have to "make" our experiences. It is we who always formulate the questions to be put to nature; it is we who try again and again to put these questions so as to elicit a clear-cut "yes" or "no" (for nature does not give an answer unless pressed for it). And in the end, it is again we who give the answer; it is we ourselves who, after severe scrutiny, decide upon the answer to the question which we put to nature – after protracted and earnest attempts to elicit from her an unequivocal 'no.'

In treating any particular subject I would first of all make some experiments, because my design is first to refer to experiments and then to demonstrate why bodies are constrained to act in such a manner. This is the method we ought to follow in investigating the phenomena of Nature. Theory is the general, experiments are the soldiers. Experiment is the interpreter of the artifices of Nature. It is never wrong; but our judgment is sometimes deceived because we are expecting results which experiment refuses to give. We must consult experiment and vary the circumstances, till we have deduced general laws, for it alone can furnish us with them.

Appearances in these things are most deceptive: in the theatre experiments are made for illustration, and are generally of a simple kind, and easily comprehended, and the minds of the audience are prepared by the lecturer to follow and understand them. In the laboratory, on the contrary, this aid is wanting when most necessary; and, in consequence, operations... of a very accurate kind, and carried on with a perfect design, may appear confused to the uninitiated, or to the uninitiated.

When we merely note and record the phenomena which occur around us in the ordinary course of nature we are said to observe. When we change the course of nature by the intervention of our will and muscular powers, and thus produce unusual combinations and conditions of phenomena, we are said to experiment. Sir John Herschel has justly remarked that we might properly call these two

modes of experience passive and active observation....

[A]n experiment differs from a mere observation in the fact that we more or less influence the character of the events which we observe.

When Galileo let balls of a particular weight, which he had determined himself, roll down an inclined plane; or when Torricelli made the air carry a weight, which he had previously determined to be equal to that of a certain column of water; when at a still later stage Stahl changed metal into calx, and calx back again into metal, by first withdrawing something and then restoring it; then a new light was flashed on all students of nature.... Reason, holding in one hand its principles according to which concordant phenomena alone can be admitted as laws of nature, and in the other hand the experiment which it has devised according to those principles, must approach nature for instruction; but not as a pupil, to be taught just what the master pleases, but as a judge, who forces the witnesses to answer the questions he puts to them.... Thus after many centuries of groping, the study of nature was first made to walk along the sure path of a science.

Experiment is like a man traveling to some far off place, and finding no place by the way where he can sit down and rest himself, and few or no guide posts to tell him whether he be in the right direction for it or not. Still he holds on. Perhaps he has been there before, and is pretty sure of this being the direction in which he found it. Or, perhaps he

has never been there, but some of his friends have, and they told him of this being the right road to it. And so it may be that, by his own sagacity and the help of well-informed friends, he reaches it at last. Or, after all his own pains, and all his friends can do for him, it may be that he never reaches it at all.

American Physicist

The instruments of modern science have provided us with greatly enhanced capabilities for gathering data about the universe. With our microscopes, telescopes, and particle detectors, we are no longer bound by the limitations of human sensory apparatus or of our confinement to this

tiny planet. And we have learned to rely more on the rational interpretation of the reading of these instruments than on preconceived notions based on everyday experience.

An experiment is an observation that can be repeated, isolated and varied. The more frequently you can repeat an observation, the more likely are you to see clearly what is there and to describe accurately what you have seen. The more strictly you can isolate an observation, the easier does your task of observation become, and the less danger is there of your being led astray by irrelevant circumstances, or of placing emphasis on the wrong point. The more widely you can vary an observation, the more clearly will be the uniformity of experience stand out, and the better is your chance of discovering laws.

Some things you can't find out; but you will never know you can't by guessing and supposing; no, you have to be patient and go on experimenting until you find out that you can't find out. And it is delightful to have it that way, it makes the world so interesting. If there wasn't anything to find out, it would be dull. Even trying to find out and not finding out is just as interesting as trying to find out and finding out; and I don't know but more so.

### Tyndall, John 1820–93

Irish-born English physicist

Experiments have two great uses – a use in discovery and verification, and a use in tuition. They were long ago defined as the investigator's language addressed to Nature, to which she sends intelligible replies. These replies, however, usually reach the questioner in whispers too feeble for the public ear.

*Six Lectures on Light Delivered in America in 1872–1873* (3rd edition)  
Lecture I (p. 3)  
D. Appleton & Co. New York, New York, USA. 1901

Experiment, as I have said, is the language by which we address Nature, and through which she sends her replies; in the use of this language a lack of straightforwardness is as possible and as prejudicial as in the spoken language of the tongue. If you wish to become acquainted with the truth of Nature, you must from the first resolve to deal with her sincerely.

*Fragments of Science for Unscientific People*  
Chapter XIII (p. 361)  
D. Appleton & Co. New York, New York, USA. 1875

Do not think the work dull; you are conversing with Nature, and must acquire over her language a certain grace and mastery, which practice can alone impart. Let every movement be made with care, and avoid slovenliness from the outset. Experiment...is the language by which we address Nature, and through which she sends her replies; in the use of this language a lack of straightforwardness is as possible, and as prejudicial, as in the

spoken language of the tongue. If, therefore, you wish to become acquainted with the truth of Nature, you must from the first resolve to deal with her sincerely.

From the time when man in interrogating nature began to experiment, or to produce phenomena under definite conditions, and to collect and record the fruits of experience, so that investigation might no longer be restricted by the short limits of a single life, the philosophy of nature laid aside the vague and poetic forms with which she had at first been clothed, and has adopted a more severe character – she now weighs the value of observations, and no longer divines, but combines and reasons.

I have often had cause to feel that my hands are cleverer than my head. That is a crude way of characterizing the dialectics of experimentation. An experiment is a device to make Nature speak intelligibly. After that one has only to listen.

The life of a student of any science is a constant series of frustrations. From his own observations and those of others, a trellis of theory is built up beyond the solid stakes of fact. The investigator tests these, perched on scaffoldings of experiment which break down again and again and are, as often, reconstructed with the weak points reinforced. Eventually, as soon as he has tied down an elusive shoot, he loses interest and is lured by the ones a little higher up. There is never an end, and never a complete satisfaction – as there may be in the arts, when a perfect sonnet or a good statue is, in itself, final and forever.

## EXPERIMENTAL ERROR

**Crookes, Sir William** 1832–1919

English chemist and physicist

A scientific man engaged in any special pursuit has much difficulty in making clear, to even the scientific public, the result of his experiments. The benefit of his research may be perfectly apparent; but if his experiments have been conducted with rigour there will be a certain individual departure from a general standard in the results, which, if he merely state his conclusions, will confuse the attentive reader. Perhaps certain of the experiments were performed under better test conditions, and their numerical results are therefore more nearly correct than the results of another series of experiments. Should this be the case, to take an average of the results would yield an empirical result, deviating considerably from the truth. Yet many of our most eminent experimentalists are satisfied with recording their experiments, and leave the student of their labours in an uncomfortable uncertainty as to the exact value of the entire system of experiment.

## EXPERIMENTER

**Bernard, Claude** 1813–78  
French physiologist

An experimenter facing natural phenomena is like a spectator watching a dumb show. He is in some sort the examining magistrate for nature; only instead of grappling with men who seek to deceive him by lying confessions or false witness, he is dealing with natural phenomena which for him are persons whose language and customs he does not know, persons living in the midst of circumstances unknown to him, yet persons whose designs he wishes to learn.

The illusions of an experimenter form a great part of his power. These are the preconceived ideas which serve to guide him. Many of them vanish in the long path which he must travel, but one fine day he discovers and proves that some of them are adequate to the truth. Then he finds himself master of facts and of new principles, the application of which sooner or later bestows their benefits.

The child grows, but is still an experimenter: he grasps at the moon, and his failure teaches him to respect distance. At length, his little fingers acquire sufficient mechanical tact to lay hold of a spoon. He thrusts the instrument into his mouth, hurts his gums and thus learns the impenetrability of matter. He lets the spoon fall, and jumps with delight to hear it rattle against the table. The experiment made by accident is repeated with intention, and thus the young student receives his first lesson upon sound and gravitation. There are pains and penalties, however, in the path of the enquirer: he is sure to go wrong, and Nature is just as sure to inform him of the fact. He falls downstairs, burns his fingers, cuts his hand, scalds his tongue, and in this way learns the conditions of his physical well being. This is Nature's way of proceeding, and it is wonderful what progress her pupil makes.

**Atkins, Peter William** 1940–

I shall take your mind on a journey. It is a journey of comprehension, taking us to the edge of space, time, and understanding. On it I shall argue that there is nothing that cannot be understood, that there is nothing that cannot be explained, and that everything is extraordinarily simple.

A great deal of the universe does not need any explanation. Elephants, for example. Once molecules have learnt to compete and to create other molecules in their own image, elephants, and things resembling elephants, will in due course be found roaming through the countryside.

We thus obtain a fictitious explanation by which we believe to have understood that which we cannot yet understand, and whereby the attention is diverted away from the matter to be explained which then remains all the longer unelucidated. I should like to repeat once again what I have stated so often before, namely that in Science fictitious, prematurely enunciated explanations invariably lead astray, and that the only method to obtain positive knowledge is to leave the incomprehensible unexplained until sooner or later the explanation emerges of its own accord from facts which are so plain that divided opinions about them can scarcely arise. Not to believe that there is more to be seen than can clearly and plainly be appreciated, and to regard the rest as material for further investigation, is a scientific principle which should not be violated but it is one which precisely those persons who are gifted with a lively mind and a fertile imagination find most difficult to follow.

...whatever an explanation actually does, in order to be called an explanation at all it must be capable of making clear something not preciously clear, *i.e.* of increasing or producing understanding of something. The difference between explaining and “merely” informing, does not, I shall argue, consist in explaining being something “more than” or even something intrinsically different from informing or describing, but in its being the appropriate piece of informing or describing, the appropriateness being a matter of its relation to a particular context.

The scientific community must be effective in communicating the results of its work to the public in a way that can be understood and used. The need for this is acute, for the complexity and difficulty of environmental and resource problems require full use of all the knowledge scientists can muster. The wisdom of the actions of both the government and private sectors depends in large part on their understanding of resource characteristics.

If we say there is a limit – the ultimate atom – then, as all size is comparative, we can imagine a being to whom this atom seems as large as an apple or even a house does to us; and we then find it quite unthinkable that this mass of matter should be in its nature absolutely indivisible even by an infinite force. It follows that all explanations of phenomena can only be partial explanations. They can inform us of the last change or the last series of changes which brought about the actual conditions now existing, and they can often enable us to predict future changes to a limited extent; but both the infinite past and the remote future are alike beyond our powers. Yet the explanations that the theory of evolution gives us are none the less real and none the less important, especially when we compare its teachings with the wild guesses or the total ignorance of the thinkers of earlier ages.

...the way I think of what we're doing is we're exploring, we're trying to find out as much as we can about the world. People say to me, “Are you looking for the ultimate laws of physics?” No, I'm not, I'm just looking to find out more about the world and if it turns out there is a simple ultimate law which explains everything, so be it, that would be very nice to discover. If it turns out it's like an onion with millions of layers and we're just sick and tired of looking at the layers, then that's the way it is, but whatever way it comes out its nature is there and she's going to come out the way she is, and therefore when we go to investigate it we shouldn't predecide what it is we're trying to do except to try to find out more about it. It is fascinating that the word “explore” does not apply to the searching aspect of the activity, but has its origins in the sounds we make while engaged in it. We like to think of exploring in science as a lonely, meditative business, and so it is in the first stages, but always, sooner or later, before the enterprise reaches completion, as we explore, we call to each other, communicate, publish, send letters to the editor, present papers, cry out on finding.

I am still doubtful whether the means adopted by nature to ensure the preservation of species or races have been so inadequate that entire races are now extinct or lost.

If there really are lost species, it can doubtless only be among the large animals that live on the dry parts of the earth; where man exercises absolute sway, and has compassed the destruction of all the individuals of some species which he has not wished to preserve or domesticate.

One must therefore never expect to find among living species all those which are found in the fossil state, and yet one may not assume that any species has really been lost or rendered extinct. It is certainly possible that among the largest animals some species have been extinguished as a consequence of the multiplication of man in the places which they inhabited. But this conjecture cannot be established from the consideration of fossils alone: we shall only be sure on this point when all the habitable globe is perfectly known.

To believe that the Earth was the only place where organic life was given and taken away – the only field where great physical revolutions were in play, would be to detract from the wisdom and beneficence of the Creator. To the laws of nature we dare not assign either limitation or locality. Wherever there is matter, we may predict its laws and its elements, and wherever are its elements, we may anticipate the existence of beings that are to use them. Wherever light shines, there must be an eye to welcome it; wherever air expands, there must be beings to breathe it; wherever heat vivifies, there must be life to be revived.

I do not believe we yet know enough about stars, planets, life and mind to give us a firm basis for deciding whether the presence of intelligence in the universe is probable or improbable. Many biologists and chemists have concluded from inadequate evidence that the development of intelligent life should be a frequent occurrence in our galaxy. Having examined their evidence and heard their arguments, I consider it just as likely that no intelligent species other than our own has ever existed. In a universe whose size is beyond human imagining, where our world floats like a dust mote in the void of night, men have grown inconceivably lonely. We scan the time scale and the mechanisms of life itself for portents and signs of the invisible. As the only thinking mammals on the planet – perhaps the only thinking animals in the entire sidereal universe – the burden of consciousness has grown heavy upon us. We watch the stars, but the signs are uncertain. We uncover the bones of the past and seek for our origins. There is a path there, but it appears to wander. ## Humanoid Progenitor

You're wondering who we are, why we have done this, how it has come that I stand before you, the image of a being from so long ago. Life evolved in my planet before all others in this part of the galaxy. We left our world, explored the stars, and found none like ourselves. Our civilization thrived for ages but what is the life of one race compared to the vast stretches of cosmic time? We knew that one day we would be gone – that nothing of us would survive. So, we left you. Our scientists seeded the primordial oceans of many worlds where life was in its infancy. The seed codes directed your evolution toward a physical form resembling ours. This body you see before you – which is of course shaped as yours is shaped. For you are the end result. The seed codes also contained this message, which was scattered in fragments on many different worlds. It was our hope that you would have to come together in fellowship and companionship to hear

this message. And if you can see and hear me, our hope has been fulfilled. You are a monument not to our greatness but to our existence. That was our wish – that you too would know life and would keep alive our memory. There is something of us in each of you. And so, something of you in each other. Remember us.

Scientists point out that there is nothing miraculous or unrepeatable about the appearance of life on earth. They believe it would happen again, given the same sufficient time and the same set of circumstances. It would even happen under very different circumstances. There is no reason to believe that conditions in the atmosphere and oceans of the primitive earth were modified by any outside power to make them favorable for the development of life. They just happened that way, and it is likely that life would have appeared even if conditions had been considerably different.

No one can yet show proof that there exists A single planet save the solar ones.

But space is wide and high, and time is long,  
 And there are millions more of other suns.  
 So men imagine why they do not know  
 And they assume that surely there must be  
 Some other planets, peopled like our own;  
 Some other worlds with creatures such as we.

Government Printing Office. Washington, D.C. 1965

We are like the inhabitants of an isolated valley in New Guinea who communicate with societies in neighboring valleys (quite different societies, I might add) by runner and by drum. When asked how a very advanced society will communicate, they might guess by an extremely rapid runner or by an improbably large drum. They might not guess a technology beyond their ken. And yet, all the while, a vast international cable and radio traffic passes over them, around them, and through them.... We will listen for the interstellar drums, but we will miss the interstellar cables. We are likely to receive our first messages from the drummers of the neighboring galactic

valleys – from civilizations only somewhat in our future. The civilizations vastly more advanced than [us], will be, for a long time, remote both in distance and in accessibility. At a future time of vigorous interstellar radio traffic, the very advanced civilizations may be, for us, still insubstantial legends.

Dell Publishing, Inc. New York, New York, USA. 1975

On some [planets], intelligent life may have evolved, reworking the planetary surface in some massive engineering enterprise. These are our brothers and sisters in the Cosmos. Are they very different from us? What is their form, biochemistry, neurobiology, history, politics, science, technology, art, music, religion, philosophy? Perhaps one day we will know them.

Chapter I (p. 11)

Random House, Inc. New York, New York, USA. 1980

Occasionally, I get a letter from someone who is in “contact” with extraterrestrials. I am invited to “ask them anything.” And over the years I’ve prepared a little list of questions. The extraterrestrials are very advanced, remember. So I ask things like, “Please provide a short proof of Fermat’s Last Theorem.” I write out the simple equation with the exponents.... It’s a stimulating exercise to think of questions to which no human today knows the answers, but where a correct answer would immediately be recognized as such. It’s even more challenging to formulate such questions in fields other than mathematics. Perhaps we should hold a contest and collect the best responses in “Ten Questions to Ask an Alien.”

Facts are the raw material of science – the bricks from which our model of the universe must be built – and we are rightly taught to search for sound and solid facts, for strong and heavy bricks that will serve us well in building foundations, for clean and polished bricks that will fit neatly into ornamental towers. But while accumulating the bricks may be a contribution to science, we must take care that the pile does not become a hopelessly discouraging jumble. For science itself is not brickmaking – it is, at the workaday and technical level, bricklaying; and at the creative and artistic level, architecture, the designing of an edifice that will utilize all the bricks to the very best of advantage.

Observed facts must be built up, woven together, ordered, arranged, systematized into conclusions and theories by reflection and reason, if they are to have full bearing on life and the universe. Knowledge is the accumulation of facts. Wisdom is the establishment of relations. And just because the latter process is delicate and perilous, it is all the more delightful. The lofty scorn of the true philosopher for mere perception is well shown in Royer Collard's remark: "There is nothing so despicable as a fact." Which does not prevent philosophers or any one else from making facts the essential basis of all discussion of relations.

There is a tendency to mistake data for wisdom, just as there has always been a tendency to confuse logic with values, intelligence with insight. Unobstructed access to facts can produce unlimited good only if it is matched by the desire and ability to find out what they mean and where they lead. Facts are terrible things if left sprawling and unattended. They are too easily regarded as evaluated certainties rather than as the rawest of raw materials crying to be processed into the texture of logic.

It is true that a controversy approaches its conclusion by the accumulation of facts that impinge upon it, it is only so provided these “facts” are without ambiguity in their implications. For otherwise, twisted by the rival hypotheses, and sometimes with so many more words that they convey less sense, these “facts” so multiply the extraneous questions that controversies become endless. Thus prejudice and imagination freely hold sway and logic is replaced by fashion.

You should consider your brain originally is like a little empty attic, and you have to stock it with furniture as you choose. A fool takes in all lumber of every sort that he comes across, so that the knowledge which might be useful to him gets crowded out, or at best is jumbled up with a lot of other things, so that he has difficulty in laying his hands upon it. Now the skilled workman is very careful indeed as to what he takes into his brain attic. He will have nothing but the tools which may help him in doing his work, but of these he has a large assortment and all in the most perfect order. It is a mistake to think that that a little room has elastic walls and can distend to any extent. Depend upon it there comes a time when for every addition of knowledge you forgot something that you knew before. It is of the highest importance, therefore, not to have useless facts elbowing out the useful ones.

But are we sure of our observational facts? Scientific men are rather fond of saying pontifically that one ought to be quite sure of one’s observational facts before embarking on theory. Fortunately those who give this advice do not practice what they preach. Observation and theory

get on best when they are mixed together, both helping one another in the pursuit of truth. It is a good rule not to put overmuch confidence in a theory until it has been confirmed by observation. I hope I shall not shock the experimental physicists too much if I add that it is also a good rule not to put overmuch confidence in the observational results that are put forward until they have been confirmed by theory.

...it is always safe and philosophic to distinguish, as much as is in our power, fact from theory; the experience of past ages is sufficient to show us the wisdom of such a course; and considering the constant tendency of the mind to rest on an assumption, and, when it answers every present purpose, to forget that it is an assumption, we ought to remember that it, in such cases, becomes a prejudice, and inevitably interferes, more or less, with a clear-sighted judgment. I cannot doubt but that he who, as a wise philosopher, has most power of penetrating the secrets of nature, and guessing by hypothesis at her mode of working, will also be most careful, for his own safe progress and that of others, to distinguish that knowledge which consists of assumption, by which I mean theory and hypothesis, from that which is the knowledge of facts and laws; never raising the former to the dignity or authority of the latter, nor confusing the latter more than is inevitable with the former.

Chapter 5 (p. 55)

Verso. London, England. 1978

...science is not sacrosanct. The restrictions it imposes (and there are many such restrictions though it is not easy to spell them out) are not necessary in order to have general coherent and successful views about the world. There are myths, there are the dogmas of theology, there is metaphysics, and there are many other ways of constructing a world-view. It is clear that a fruitful exchange between science and such “non-scientific” world-views will be in even greater need of anarchism than is science itself. Thus anarchism is not only possible, it is necessary both for the internal progress of science and for the development of our culture as a whole.

*Against Method: Outline of an Anarchistic Theory of Knowledge*

Chapter 15 (p. 180)

Verso. London, England. 1978

Facts contain ideological components, older views, natural interpretations, which have vanished from sight or perhaps never were formulated in an explicit manner. These components are highly suspicious, first because of their age, because of their archaic origin, and, secondly, because their very nature protects them from critical examination and always has protected them from such an examination.

A fact is not novel if it has an analogue which could have some interest. A fact which does not fit in with a series of known facts is a fact which deserves particular attention. If the mind had to retain all individual facts, it could not manage and science would not exist; but when these facts can be connected by general laws and by theories, when a large number of these facts can be represented by a single one, one can remember them more easily, one can generalise one's ideas, one can compare one general fact with another general fact and discoveries can succeed each other. It is only when laws can be introduced into a science that it assumes the true character of science.

The scientific study of any subject is a substitution of businesslike ways of "making sure" about it for the lazy habit of "taking it for granted" and the worse habit of making irresponsible assertions about it. To make sure it is necessary to have done with a careless "looking into it" and to undertake precise observations, many times repeated...[it] is necessary to make measurements and accountings, to substitute realistic thinking (an honest dealing with facts as they are) for wishful or fanciful thinking (a self-deceiving day-dreaming) and to carry on a systematic "checking up"...science is nothing more nor less than getting at facts, and trying to understand them...

To SIMPLIFY and personalize scientific facts and ideas without distorting them to some extent is practically impossible. Whoever is rash enough to attempt to do so at once finds himself daintily impaled on one or the other horn of a (dilemma: whether to strain the facts into all sorts of dubious analogies in an effort to make his presentation interesting, thereby incurring the righteous wrath of top-notch scientists; or to hew rigidly to the line of technical accuracy on all points, at the risk of being unintelligible to those who turn to his work for information). The one easy way to resolve this state of affairs is to be a minor genius, with a profound knowledge of science coupled with a flair for imparting its concepts correctly and clearly without being other than entertaining in the process. Short of this, the only solution is to decide which is more important – to secure the unqualified approval of experts, or to reward the intelligent curiosity of laymen with at least some measure of comprehensible explanation.

Facts are things made – *res gestae, facta*. They have the nature that is given to them by their Maker; and in knowing only the fact, there is no capability for knowing why their nature is thus and not otherwise. The Maker has so constituted the fact, but in our ignorance of what determined Him in the making, we can only find in experience that the fact is, and can by no means say why it is.

Facts are certainly stubborn things, as people say. But it is equally certain that they are the most slippery things to get a hold of. And even when you have got a hold of them, they can be used with such different designs – after such varying fashions, that no more unlike buildings can be constructed of the same bricks or hewn stones, than conclusions arrived at from precisely the same facts. And this because all the facts round about the known facts, and which keep those facts in their places, compelling them to combine after a certain fashion, are not known, or perhaps are all unknown.

As long as the pursuit of the facts of a given province of phenomena is in the hands of a few isolated investigators, as long as every experiment can be easily repeated, the fixing of the collected facts by provisional description is ordinarily sufficient. But the case is different when the whole world must make use of the results reached by many, as happens when the science acquires broader foundations and scope, and so particularly so when it begins to supply intellectual nourishment to an important branch of the practical arts, and to draw from that province in return stupendous empirical results.

Scientific facts accumulate rapidly, and give rise to theories with almost equal rapidity. These theories are often wonderfully enticing, and one is apt to pass from one to another, from theory to theory, without taking care to establish each before passing on to the next, without assuring oneself that the foundation on which one is building is secure. Then comes the crash; the last theory breaks down utterly, and on attempting to retrace our steps to firm ground and start anew, we may find too late that one of the cards, possibly at the very foundation of the pagoda, is either faultily placed or in itself defective, and that this blemish easily remedied if detected in time has, neglected, caused the collapse of the whole structure on whose erection so much skill and perseverance have been spent.

...the chief function which it [the digestive tract] has to perform in the living organism, maybe compared to a chemical factory, where the raw materials the food-stuffs are submitted to an essentially chemical process. In this factory the foods are brought into a condition in which they are capable of being absorbed into the body fluids and made use of for the maintenance of the processes of life. The factory consists of a series of compartments, in each of which the food, according to its properties, is either retained for a time or at once sent on to the next; and each single compartment is provided with suitable reagents. These reagents are either prepared in adjoining little workshops, burrowed into the walls of the laboratory itself, or else in distant and separate organs, connected, as in other large chemical factories, with the main workshop by a system of transmitting tubes. These latter

are the so-called secreting glands with their excretory ducts. Each of the workshops furnishes a special fluid, its own particular product, endowed with definite chemical properties which enable it to act on certain /portions of the food, this latter being ordinarily formed of a complex mixture of different ingredients.

Perhaps the greatest injustice that can be done to science is to regard it merely as a collection of facts, and the practice of science as little more than the routine accumulation of minutiae. It is true that science deals with hard, inflexible facts, but it has also to do with very general ideas and abstract principles; and it is the co-ordination of these ideas and observed facts that is the essence of modern science. Facts alone do not constitute a science. Nature Study is not the same as the study of nature.

One of the chief motivations behind the attempt to defend a distinction between theoretical and observational terms has been the desire to explain how a theory can be tested against the data of experience, and how one theory can be said to “account for the facts” better than another; that is, to give a precise characterization of the idea, almost universally accepted in modern times, that the sciences are “based on experience,” that they are “empirical.”

Facts mean nothing by themselves. All the people at present crowding the Strand are facts. Nobody can possibly know the facts. Naturalists collect a few. But an Englishman was not daunted by facts. To explain why all the lines in his rectilinear universe were bent, he invented a force called gravitation and thus erected a complete British universe and established it as a religion which was devoutly believed in for 300 years. The book of this Newtonian religion was not that oriental magic thing, the Bible. It was that British and matter-of-fact thing, a Bradshaw [a British railway timetable]. It gives the stations of all the heavenly bodies, their distances, the rates at which they are traveling, and the hour at which they reach eclipsing points or crash into the earth like Sirius. ...statistics need to be much more than the output of a battery of adding machines. The ideal collection of facts is the man who has spent years as a specialist in the work and in this way knows the reality behind the words and figures. Only the personal touch that comes from intimate familiarity with facts at their source can give life to statistics.

What are the Facts?

Facts that have aged in the course of their collection and preparation for consumption are likely to be too stale for practical use. Dating an egg doesn't keep it good.

What are the Facts?

*Civil Engineering*, Volume 2, Number 3, March, 1932 (p. 155)

In this partnership of engineer and economist, it will be the engineer's part to furnish most of the facts. The engineer calls them "plain" facts, because they do not lend themselves to display as readily as theoretical phrases. He uses facts, not pieces on a chessboard to be moved back and forth in a contest of wits, but rather as foundation stones to be assembled in orderly fashion to hold up the superstructure of conclusions.

We must never conceal from ourselves that our concepts are creations of the human mind which we impose on the facts of nature, that they are derived from incomplete knowledge, and therefore will never exactly fit the facts, and will require constant revision as knowledge increases.

All knowledge, we admit, is in the last resort “empirical,” in the sense that it arises out of *facts*, that is, out of experiences which we cannot altogether fashion as we please to suit our own convenience, or our own sense of what is fitting or desirable, but have largely to accept as they come to us.

Armchair philosophy, apart from actual work in the field, the laboratory, and the museum, is by no means to be commended. But the worship of fact, as fact, may easily be overdone. The number of discoverable facts is practically infinite, and it is therefore possible to get into such a condition as not to be able to see the wood for the trees, to lose the due sense of proportion, and to become mere machines for tabulating interminable trivialities.

Scientific facts are of little value in themselves. Their significance is their bearing upon other facts, enabling us to generalize and so to discover principles, just as the accurate measurement of the position of a star may be without value in itself, but in relation to other similar measurement of other stars may become the means of discovering their proper motions. We refine our instruments; we render more trustworthy our means

of observation; we extend our range of experimental inquiry, and thus lay the foundation for the future work, with the full knowledge that, although our researches can not extend beyond certain limits, the field itself is, even within those limits, inexhaustible.

Chapter XLIII (p. 396)

Harper & Brothers. New York, New York, USA. 1899

In the space of one hundred and seventy six years, the Lower Mississippi has shortened itself two hundred and forty two miles. That is an average of a trifle over one mile and a third per year. Therefore, any calm person, who is not blind or idiotic, can see that in the Old Oolitic Silurian Period, just a million years ago next November, the Lower Mississippi river was upwards of one million three hundred miles long, and stuck out over the Gulf of Mexico like a fishing rod. And by the same token any person can see that seven hundred forty two years from now the Lower Mississippi will be only a mile and three quarters long, and Cairo and New Orleans will have joined their streets together, and be plodding comfortably along under a single mayor and a mutual board of aldermen. There is something fascinating about science. One gets such wholesale returns of conjecture out of such a trifling investment of fact.

Coat it [a fact] over with the incrustations of criticism, the mould of age, and it must be fresh hewed to the point of losing its identity – its susceptibility of identification, I mean, – before it can be appreciated as a part of “the solid ground of nature – made solid of course by eyes, not really myopic or hypermetropic when they have their errors of refraction properly corrected, made solid in a word by the unfailing, unerring use of sense – a veritable fact, not an old fact, of course, but a new one.

The Evanescence of Facts

*The Popular Science Monthly The Popular Science Monthly*, Volume 86, Number 2, 1915 (p. 181)

It unfortunately has come to look a little suspicious in the secular press, but a new fact, really approved by the hierarchy of science, unsmirched by any touch of the imagination and free of any suspicion of deductive birth, is a thing of beauty if not a joy forever. The old facts, though they continue to sing:

*Duhast uns gepflanzt; Zu Tausenden kommen Wir, Vater, getanzt.*

are, I must confess, a pretty “poor run of shad.” It is true it does not seem just the way a fact should behave. Its vintage should improve with age. It is undeniable, however, that in really choice circles of science, the old facts are not looked on with favor.

The Evanescence of Facts

*The Popular Science Monthly The Popular Science Monthly*, Volume 86, Number 2, 1915 (p. 181)

They [facts] seem just a little tarnished; the mind is not tempted to gild them over or rub them up, the imagination refuses to endow them with those winged words which carry newly quarried facts bright and shining to the work table of the appreciative student, unhaunted by any shade of historical perspective. Evidently the time to work a fact into the masonry of science, “the solid ground of nature” upon which her trusting and unsuspecting, non-historical, scientific children love to build, is when it is fresh and when the mortar will cling to it.

The Evanescence of Facts

*The Popular Science Monthly The Popular Science Monthly*, Volume 86, Number 2, 1915 (p. 181)

The imagery of Shakespeare, the flowers of eloquence in Demosthenes, need no burnishing, no drapery to hide their age, but the atoms of Democritus and the spheres of Ptolemy need considerable correction, and the cloud of insect facts which swarm up from my old yellow sheets, if not simply disgusting, are at least uninspiring.

The Evanescence of Facts

*The Popular Science Monthly The Popular Science Monthly*, Volume 86, Number 2, 1915 (p. 181)

A fact, it is true, should lack nothing. It should stand alone unshamed in its nakedness – for is it not the truth? Is not the truth divine?

## FAITH OF SCIENCE

**Eddington, Sir Arthur Stanley** 1882–1944  
English astronomer, physicist, and mathematician

Reasoning leads us from premises to conclusion; it cannot start without premises.... [W]e...must believe that we have an inner sense of values which guides us as to what is to be heeded, otherwise we cannot start on our survey even of the physical world.... At the very beginning there is something which might be described as an act of faith – a belief that what our eyes have to show us is significant.

*Science and the Unseen World*

Chapter VI (pp. 73–74)

The Macmillan Company. New York, New York, USA. 1929

**Ferris, Timothy** 1944–  
American science writer

To say that nature is comprehensible to us, that science is not deluding itself, is an assertion of faith – ‘reason is one of the articles of faith,’ said Eddington – but there is nothing wrong with that. After all, we are part of the universe. And the faith of science – that the seamless wave of nature will reveal itself to our reasoned inquiry – that faith is part of the universe too.

Science demands also the believing spirit. Anybody who has been seriously engaged in scientific work of any kind realizes that over the entrance to the gates of the temple of science are written the words: Ye must have faith. It is the quality which the scientist cannot dispense with.

There cannot be any issue between faith and science, for science and faith mutually exclude one another; not in the sense that the one renders the other impossible, or vice versa, but rather that so far as science extends faith does not exist, and faith begins where science leaves off.

## FALLING

**Emerson, Ralph Waldo** 1803–82

American lecturer, poet, and essayist

Let us draw a lesson from nature, which always works by short ways. When the fruit is ripe, it falls. When the fruit is despatched, the leaf falls. The circuit of the waters is mere falling. The walking of man and all animals is a falling forward. All our manual labor and works of strength, as prying, splitting, digging, rowing, and so forth, are done by dint of continual falling, and the globe, earth, moon, comet, sun, star, fall forever and ever.

**White, Gilbert** 1720–93

English naturalist and cleric

Faunists, as you observe, are too apt to acquiesce in bare descriptions, and a few synonyms: the reason is plain: because all that may be done at home in a man's study;

I had this very rare privilege of being able to pursue in my adult life what had been my childhood dream. I know it's a rare privilege, but if you can tackle something in adult life that means that much to you, then it's more rewarding, than anything imaginable. Having solved this problem there's certainly a sense of loss, but at the same time there is this tremendous sense of freedom. I was so obsessed by this problem that for eight years I was thinking about it all the time – when I woke up in the morning to when I went to sleep at night. That's a long time to think about one thing. That particular odyssey is not over. My mind is at rest.

**Oppenheimer, James Robert** 1904–67

The principle point of difference for which one must allow from the beginning is this: that two like charges repel each other, whereas all masses attract each other.

Like children who are not permitted to do certain things, we are not permitted by nature to think in terms of infinity. We may think in terms of the universe, transcendent minds do that. We may think in terms of the world, the noble mind finds itself so engaged. One may think in terms of his country, a great mind does that. It is fine to think in terms of the state, commendable to think in terms of the town, and one may think in terms of himself if that is his best outlook, but we are not allowed by nature to think in terms of the finite.

When the spark or atom of fire lies hid in primary matter, it is dark, deformed, and in no ways promising such a fair contexture and life as it will be clothed with when it has built its house or body, in which it seems dormant awhile.

In this sense it was *Vulcan deformis*.

A fire is a delightful thing, a companion and an inspiration. If my room were kept warm by some wretched modern contrivance of water-pipes or heated air, would it be the same to me as that beautiful core of glowing fuel, which, if I sit and gaze into it, becomes a world of wonders? Let science warm the heaven-forsaken inhabitants of flats and hotels as effectually and economically as it may; if the choice were forced upon me, I had rather sit, like an Italian, wrapped in my mantle, softly stirring with a key the silver-grey surface of the brasier's charcoal.

## FLOWER NAME

**Gannett, William Channing**

The flower-names are often little poems in themselves. Those long, uncouth names, dreaded in botany, hide Nature-meanings in them. Heliotrope is “she who turns to the sun”; mesembryanthemum is “flower of the mid-day”; nasturtium carries its meaning of “bent-nose” in its face; geranium is “crane's-bill,” – let the seed-vessel grow and it will tell the reason why; saxifrage is – rock-cleaver, – named so from its birthplace in the clefts; anemone is – wind-flower.” These, you see, were but simple heart and eye names to the Greeks or Romans, just as we call the pets heart's-ease, day's-eye, morning-glory, honeysuckle, mignonette. Each people has its own. Other flower-names come down to us impearled with myth and story, – the hyacinth, narcissus, Solomon's-seal, arethusa, the passion-flower.

## FLUOROCHEMISTRY

**de Ment, J.**

No biographical data available

With the increasing number of researches and publications devoted to the applications of fluorescence to

chemistry, a need is rapidly arising to identify this new branch of science as distinct and apart from related and often confused fields. Therefore, it seems expedient to propose the name fluorochemistry as described in this branch of science. The term fluorochemistry is in order with other terms created to identify highly specialized fields which are still within the boundaries of chemistry and/or physics.

The Historian or the Antiquary may have traversed the fields of ancient or of modern battles; and may have pursued the line of march of triumphant Conquerors, whose armies trampled down the most mighty kingdoms of the world. The winds and storms have utterly obliterated the ephemeral impressions of their course. Not a track remains of a single foot, or a single hoof, of all the countless millions of men and beasts whose progress spread desolation over the earth. But the Reptiles, that crawled upon the half-finished surface of our infant planet, have left memorials of their passage, enduring and indelible. No history has recorded their creation or destruction; their very bones are found no more among the fossil relics of a former world. Centuries, and thousands of years, may have rolled away, between the time in which these footsteps were impressed by Tortoises upon the sands of their native Scotland, and the hour when they are again laid bare, and exposed to our curious and admiring eyes. Yet we behold them, stamped upon the rock, distinct as the track of the passing animal upon the recent snow; as if to show that thousands of years are but as nothing amidst Eternity – and, as it were, in mockery of the fleeting perishable course of the mightiest potentates among mankind.

Fundamentally considered, there are neither forces nor matter. Both are merely abstractions, assumed from different points of view, of things as they are. They supplement and presuppose each other. Separately they do not exist. Matter is not like a carriage, to which the force, like horses, can be put or again removed from. A particle of iron is, and remains, the same, whether it crosses the horizon in the meteoric stone, rushes along in the wheel of the steam-engine, or circulates in the blood through the temples of the poet. These qualities are eternal, inalienable, and untransferable.

I have long held an opinion, almost amounting to conviction, in common I believe with many other lovers of natural knowledge, that the various forms under which the forces of matter are made manifest have one common origin; or, in other words, are so directly related and mutually dependent, that they are convertible, as it were, one into another, and possess equivalents of power in their action.

The long and constant persuasion that all the forces of nature are mutually dependent, having one common

origin, or rather being different manifestations of one fundamental power, has made me often think upon the possibility of establishing, by experiment, a connexion between gravity and electricity, and so introducing the former into the group, the chain of which, including also magnetism, chemical force and heat, binds so many and such varied exhibitions of force together by common relations.

Whatever attempts have been made by metaphysical writers to reason away the connection of cause and effect, and fritter it down into the unsatisfactory relation of habitual sequence, it is certain that the conception of some more real and intimate connection is quite as strongly impressed upon the human mind as that of the existence of an external world, the vindication of whose reality has, strange to say, been regarded as an achievement of no common merit in the annals of this branch of philosophy. It is our own immediate consciousness of effort, when we exert a force to put matter in motion or to oppose and neutralize force, which gives us this internal conviction of power and causation, so far as it relates to the material world.

The parts of all homogeneous hard bodies which fully touch one another stick together very strongly. And for explaining how this may be, some have invented hooked atoms, which is begging the question; and others tell us that bodies are glued together by rest...and others, that they stick together by conspiring motions.... I had rather infer from their cohesion that their particles attract one another by some force, which in immediate contact is exceedingly strong, at small distances performs the chemical operations above mentioned, and reaches not far from the particle with any sensible effect.

A countless number of free forces (for nowhere is man freer than during a battle, where it is a question of life and death) influence the course taken by the fight, and that course never can be known in advance and never coincides with the direction of any one force. If many simultaneously and variously directed forces act on a given body, the direction of its motion cannot coincide with any one of those forces, but will always be a mean – what in mechanics is represented by the diagonal of a parallelogram of forces. If in the descriptions given by historians, especially French ones, we find their wars and battles carried out in accordance with previously formed plans, the only conclusion to be drawn is that those descriptions are false.

Forecasting in economics is an activity fully licensed in the City of Action and the City of Intellect. Sought and subsidized by executives in government and business, it is also recognized and accredited by the universities. For it to attain so remarkable a status, two suspicions had to be overcome: that of men of action "the speculative views of intellectuals who lack any experience of reality"; and that, even stronger, of men of learning about "intellectual adventurism which discredits science by going beyond the established facts."

Rather than projecting the shadow of Tomorrow's unknowable realities, I propose to ask whether it is imaginable – I stress this crucial word – to exercise effective control over the future-shaping forces of Today. This rescues us from the impossible attempt to predict the shape

of Tomorrow, and leaves us with the somewhat less futile effort of inquiring into the possibilities of changing or controlling the trends of the present... Can this intrusion of science and technology be bounded, confined to its needed applications, and kept from sucking the life out of our engagement with nature and with one another? I find that difficult to imagine.

## FORETHOUGHT

**Bronowski, Jacob** 1908–74  
 Polish-born British mathematician and polymath

We are all aware, although we rarely think about it, that all human forethought depends on our recognizing or putting some kind of order into the world. As much as book-keeping, government, and doing the week-end shopping...science is an activity of putting order into our experience... Science is to get rid of angels, blue fairies, and other agents whose intervention would reduce the explanation of physical events to other than physical terms... We must use science as it is, and that is an assembly of observations so ordered that they tell us what we may expect in the future. Science is not only rational; it is also empirical. Science is experiment, that is, orderly and reasoned activity. The essence of experiment and of all science is that it is active. It does not watch the world, it tackles it.

Mathematicians fancy that their formulas are infallible because they are drawn from mathematics, and they have a formula for everything: everything is classed, ticketed, and in such a way as to preclude discussion. How can one dispute with a formula?

Not one of them [formulae] can be shown to have any existence, so that the formula of one of the simplest of organic bodies is confused by the introduction of unexplained symbols for imaginary differences in the mode of combination of its elements.... It would be just as reasonable to describe an oak tree as composed of blocks and chips and shavings to which it may be reduced by the hatchet, as by Dr Kolbe's formula to describe acetic acid as containing the products which may be obtained from it by destructive influences. A Kolbe botanist would say that half the chips are united with some of the blocks by the force *parenthesis*; the other half joined to this group in a different way, described by a *buckle*; shavings stuck on to these in a third manner, *comma*; and finally, a compound of shavings and blocks united together by a fourth force, *juxtaposition*, is joined to the main body by a fifth force, *full stop*.

I can well remember how most of my western friends regarded the early fossil hunters and naturalists who came to do collecting. They were usually spoken of as bone- or bug-hunting idiots. For anyone to go chasing over the West hunting for petrified bones, or even bugs, was conclusive evidence of his lack of good horse sense, especially in sections of the West where Indians were still wild enough to want to stick their arrows into anything wearing a white skin.

The attention of naturalists was early directed to the investigation of the fossil organic remains so generally and abundantly distributed throughout the strata of which the crust of the earth is composed. It is not, as some writers now imagine, entirely a modern study; for even so early as the time of Leibnitz, we find that philosopher drawing and *Essay On the Theory of the Earth*

Life, therefore, has often been disturbed on this earth by terrible events. Numberless living beings have been the victims of these catastrophes; some, which inhabited the dry land, have been swallowed up by inundations; others, which peopled the waters, have been laid dry, from the bottom of the sea having been suddenly raised; their very

remains have been extinguished for ever, and have left no other memorial of their existence than some fragments, which the naturalist can scarcely recognize.

*An Essay on the Theory of the Earth*  
Section 1 (p. 25)  
Kirk & Mercein. New York, New York, USA. 1818

The importance of investigating the relations of extraneous fossils with the strata in which they are contained is quite obvious. It is to them alone that we owe the commencement even of the Theory of the Earth; as, but for them, we could never have even suspected that there had existed any successive epochs in the formation of our earth, and a series of different and consecutive operations in reducing it to its present state.  
*An Essay on the Theory of the Earth*  
Section 23 (p. 69)  
Kirk & Mercein. New York, New York, USA. 1818

It is also owing to these extraneous fossils, slight as is the knowledge we have hitherto acquired respecting them, that we have yet been enabled to discover the little that we yet know concerning the revolutions of our globe. From them we have learned that the strata, or at least those which contain their remains, have been quietly deposited in a fluid; that the variations of the several strata must have corresponded with the variations in the nature of the fluid; that they have been left bare by the transportation of this fluid to some other place; and that his fact must have happened more than once. Nothing of all this could have been known with certainty, without the aid of extraneous fossils.  
*An Essay on the Theory of the Earth*  
Section 23 (pp. 69–70)  
Kirk & Mercein. New York, New York, USA. 1818

We are ignorant even of the agents which may have held some of these substances in a state of solution; and it is still disputed respecting several of them, whether they have owed their origin to the agency of water or fire. After all, philosophers are only agreed on one point, which is, that the sea has changed its place; and this could have never been certainly known, but for the existence of extraneous fossils. These fossils, then, which have given rise to the theory of the earth, have at the same time furnished its principal illustrations – the only ones, indeed, that have as yet been generally received and acknowledged.

Now let us turn to our richest geological museums and what a paltry display we behold! That our collections are imperfect is admitted by everyone. Many fossil species are known from single and often broken specimens. Only a small portion of the earth has been geologically explored, and no part with sufficient care. Shells and bones decay and disappear when left of the bottom of the sea where sediment is not accumulating. We err when we assume that sediment is being deposited over the whole bed of the sea sufficiently quickly to embed fossil remains.

...every fossil on a museum shelf is a three-fold miracle. First, the plant had to die under the most exceptional conditions remote from the normal course of events, which is swift decay, dissolution, and reworking of the mold into new forms of life. Then, by a wildly fortuitous set of circumstances, the fossilized evidence must not be washed into the sea, or buried several miles under sedimentary rocks, but had to come to light, be bared by erosion, or deprived of its Stygian privacy in the course of mining or excavating. And then, as the most unlikely chance of all, a paleobotanist (a very rare fellow even in a densely packed congress of botanists) had to pass by

and collect the specimen before it was burned for coal, ground up for cement, washed away or otherwise hopelessly obliterated.

A very little attention to the phenomena of the mineral kingdom is sufficient to convince us that the conditions of the earth's surface has not been the same at all times that it is at the present moment. When we observe the impressions of plants in the heart of the hardest rocks; when we discover trees converted into flint, and entire beds of limestone or of marble composed of shells and corals; we see the same individual in two states, the most widely different from one another; and, in the latter instance, we have clear proof, that the present land was once deep immersed under the waters of the ocean.

The series of changes which fossil bodies are defined to undergo does not cease with their elevation above the level of the sea; it assumes, however, a new direction, and from the moment that they are raised up to the surface, is constantly exerted in reducing them again under the dominion of the ocean. The solidity is now destroyed which was acquired in the bowels of the earth; and as the bottom of the sea is the great laboratory, where loose materials are mineralized and formed into stone, the atmosphere is the region where stones are decomposed, and again resolved into earth.

Fossil hunting is by far the most fascinating of all sports. It has some danger, enough to give it zest and probably about as much as in the average modern engineered big-game hunt, and danger is wholly to the hunter. It has uncertainty and excitement and all the thrill of gambling with not of its vicious features. The hunter never knows what his bag may be, perhaps nothing, perhaps a creature never before seen by human eyes. It requires knowledge, skill, and some degree of hardihood. And its results are so much more important, more worthwhile than those of any other sport! The fossil hunter does not kill, he resurrects. And the result of this sport is to add to the sum of human pleasure and to the treasure of human knowledge.

And this has been done by Thousands who have never paid the least regard to that wonderful order & regularity with which Nature has disposed of these singular productions and assigned to each Class its peculiar Stratum.

There is not even a universally accepted definition of the term “fractal.” It seems that if one does not prove theorems (as, evidently, fractal geometers do not), then one does not need definitions. Man has mounted science, and is now run away with. I firmly believe that before many centuries more, science will be the master of man. The engines he will have invented will be beyond his strength to control. Some day science may have the existence of mankind in its power, and the human race commit suicide by blowing up the world. Not only shall we be able to cruize in space, but I see no reason why some future generation shouldn't walk off like a beetle with the world on its back, or give it another rotary motion so that every zone should receive in turn its due portion of heat and light.

Man has acquired the habit of going to the past because it was the line of least resistance for his mind. On the whole there is something sympathetic for the dupe of the fortune-teller in the spirit of modern science; it is one of the persuasions that come into one's mind, as

one assimilates the broad conception of science, that the adequacy of causation is universal; that in absolute fact – if not in that little bubble of relative fact which constitutes the individual life – in absolute fact the future is just as fixed and determinate, just as settled and inevitable, just as possible a matter of knowledge as the past.

Whether true or false, the hypothesis of external galaxies is certainly a sublime and magnificent one. Instead of a single star-system it presents us with thousands of them.... Our conclusions of Science must be based on evidence, and not on sentiment. But we may express the hope that this sublime conception may stand the test of further examination.

Ironically, our relatively peripheral position on the spiral arm of a rather ordinary galaxy is indeed rather fortunate. If we had been stationed in a more central position – say,

near the galactic hub – it is likely that our knowledge of the universe of other galaxies, for example, might not have been as extensive. Perhaps in such a position the light from surrounding stars could well have blocked our view of intergalactic space. Perhaps astronomy and cosmology as we know these subjects would never have developed.

The Free Press, New York, New York, USA. 1998

**Eddington, Sir Arthur Stanley** 1882–1944

English astronomer, physicist, and mathematician

Let us first understand what a galaxy is. The following is a recipe for making galaxies: Take about ten thousand million stars. Spread them so that on the average light takes three or four years to pass from one to the next. Add about the same amount of matter in the form of diffuse gas between the stars. Roll it all out flat. Set it spinning in its own plane. Then you will obtain an object which, viewed from a sufficient distance, will probably look more or less like a spiral nebula.

Since as the Creation is, so is the Creator also magnified, we may conclude in consequence of an infinity, and an infinite all-active power, that as the visible creation is supposed to be full of sidereal systems and planetary worlds, so on, in like similar manner, the endless immensity is an unlimited plenum of creations not unlike the known.... That this in all probability may be the real case, is in some degree made evident by the many cloudy spots, just perceivable by us, as far without our starry Regions, in which tho' visibly luminous spaces, no one star or particular constituent body can possibly be distinguished; those in all likelihood may be external creation, bordering upon the known one, too remote for even our telescopes to reach.

Consider now the Milky Way; there also we see an innumerable dust; only the grains of this dust are not atoms, they are stars; these grains move also with high velocities; they act at a distance one upon another, but this action is so slight at great distance that their trajectories are straight; and yet, from time to time, two of them may approach near enough to be deviated from their path, like a comet which had passed too near Jupiter. In a world, to the eyes of a giant for whom our suns would be as for us our atoms, the Milky Way would seem only a bubble of gas.

In my opinion it would be a great tragedy for science if the theory of gases were temporarily thrown into oblivion because of a momentary hostile attitude toward it, as for example was the wave theory because of Newton's authority.

I am conscious of being only one individual struggling weakly against the stream of time. But it still remains in my power to contribute in such a way that, when the theory of gases is again revived, not too much will have to be rediscovered.

At the time I formed the theory of mixed gases I had a confused idea, as many have, I suppose, at this time, that the particles of elastic fluids are all of the same size; that a given volume of oxygenous gas contains just as many particles as the same volume of hydrogenous.... But...I became convinced that different gases have not their particles of the same size: and that the following may be adopted as a maxim, till some reason appears to the contrary: namely – [t]hat every species of pure elastic fluid has its particles globular and all of a size; but that no two species agree in the size of their particles, the pressure and temperature being the same.

*A New System of Chemical Philosophy*

The greatest difficulty attending the mechanical hypothesis, arises from the different gases observing different laws. Why does water not admit its bulk of every kind of gas alike? – This question I have duly considered, and though I am not able yet to satisfy myself completely, I am nearly persuaded that the circumstance depends upon the weight and number of the ultimate particles of the several gases: those whose particles are lightest and single being least absorbable, and the others more according as they increase in weight and complexity.[5] An enquiry into the relative weights of the ultimate particles of bodies is a subject, as far as I know, entirely new: I have lately been prosecuting this enquiry with remarkable success. The principle cannot be entered upon in this paper; but I shall just subjoin the results, as far as they appear to be ascertained by my experiments.

So many of the properties of matter, especially when in the gaseous form, can be deduced from the hypothesis that their minute parts are in rapid motion, the velocity increasing with the temperature, that the precise nature of this motion becomes a subject of rational curiosity. Daniel Bernoulli, Herapath, Joule, Krönig, Clausius, etc. have shown that the relations between pressure, temperature, and density in a perfect gas can be explained by supposing the particles to move with uniform velocity in straight lines, striking against the sides of the containing vessel and thus producing pressure.

Therefore the rest, amounting to sixty-one pounds, is this *spiritus sylvestris*. This spirit, hitherto unknown, which can neither be contained in vessels nor reduced to a visible body, I call by a new name, *gas* (*hunc spiritum incognitum, hactenus, novo nomine gas voco*). There are bodies which enclose that spirit, and can be resolved almost wholly into it; therein it is as fixed or solidified, from which state it may be driven forth, as is seen in the fermentation of wine, bread, etc.

From time immemorial, man has desired to comprehend the complexity of nature in terms of as few elementary concepts as possible. Among his quests – in Feynman’s words – has been the one for “wheels within wheels”

– the task of natural philosophy being to discover the innermost wheels if any such exist. A second quest has concerned itself with the fundamental forces which make the wheels go round and enmesh with one another. The greatness of...of gauge field theories – is that they reduce these two quests to just one.

**Mayr, Ernst** 1904–2005

The genes within a gene pool form a harmonious whole which can evolve only as a whole. The first step, then, in the multiplication of species, is a physical separation of a portion of the species, permitting it to go its own way genetically. What happens after this isolation depends on the genetic contents of the isolated population, on the totality of selection forces working on it and on numerous chance phenomena (mutation, recombination, etc.).

For the general practitioner a well-used library is one of the few correctives of the premature senility which is so apt to overtake him. Self-centered, self-taught, he leads a solitary life, and unless his every-day experience is controlled by careful reading or by the attrition of a medical society it soon ceases to be of the slightest value and becomes a mere accretion of isolated facts, without correlation. It is astonishing with how little reading a doctor can practise medicine, but it is not astonishing how badly he may do it.

French chemist and physicist

In the natural sciences, and particularly in chemistry, generalities must come after the detailed knowledge of each fact and not before it. It is really only after having acquired this knowledge that one may see if the facts have anything in common...and only after that is it permissible to consider them in a general manner.

Science is nothing without generalisations.... The suggestion of a new idea, or the detection of a law, supersedes much that had previously been a burden upon the memory, and by introducing order and coherence facilitates the retention of the remainder in an available form.

When a man has studied the heavens for ten thousand nights, he is entitled to make certain generalizations. Space is without limit or definition. There is no east or west, no north or south, no down or up, no in or out. It is truly boundless and must be respected as such. It cannot be measured or comprehended. The Science Press. New York, New York, USA. 1905

Let us notice first of all, that every generalization implies in some measure the belief in the unity and simplicity of nature. As to the unity there can be no difficulty. If the different parts of the universe were not like the members of one body, they would not act on one another, they would know nothing of each other; and we in particular would know only one of these parts. We do not ask, then, if nature is one, but how it is one.

Genetics is the first biological science which got in the position in which physics has been in for many years. One can justifiably speak about such a thing as theoretical mathematical genetics, and experimental genetics, just as in physics. There are some mathematical geniuses who work out what to an ordinary person seems a fantastic kind of theory. This fantastic kind of theory nevertheless leads to experimentally verifiable prediction, which

an experimental physicist has to test the validity of. Since the times of Wright, Haldane, and Fisher, evolutionary genetics has been in a similar position.

Talent repeats; Genius creates. Talent is a cistern; Genius is a fountain. Talent deals with the actual, with discovered and realized truths, analyzing, arranging, combining, applying positive knowledge, and in action looking to precedents; Genius deals with the possible, creates new combinations, discovers new laws, and acts from an insight into principles. Talent jogs to conclusions to which Genius takes giant leaps. Talent accumulates knowledge, and has it packed up in the memory; Genius assimilates it with its own substance, grows with every new accession, and converts knowledge into power. Talent gives out what it has taken in; Genius what has risen from its unsounded wells of living thought. Talent, in difficult situations, strives to untie knots, which Genius instantly cuts with one swift decision. Talent is full of thoughts, Genius [is] of thought; one has definite acquisitions, the other indefinite power.

**GENOME**

**Ridley, Matt** 1958–  
English science writer

The truth is that nobody is in charge. It is the hardest thing for human beings to get used to, but the world is full of intricate, cleverly designed and interconnected systems that do not have control centers. The economy is such a system. The illusion that economies run better if somebody is put in charge of them – and decides what gets manufactured where and by whom – has done devastating harm to the wealth and health of people all over the world, not just in the former Soviet Union, but in the west as well.... It is the same with the body. You are not a brain running a body by switching on hormones. Nor are you a body running a genome by switching on hormone receptors. Nor are you a genome running a brain by switching on genes that switch on hormones. You are all of these at once.

This is the reality of genes for behavior. Do you see now how unthreatening it is to talk of genetic influences over behavior? How ridiculous to get carried away by one “personality gene” among 500? How absurd to think that, even in a future brave new world, some-body might abort a foetus because one of its personality genes is not up to scratch – and take the risk that on the next conception she would produce a foetus in which two or three other genes were of a kind she does not desire? Do you see now how futile it would be to practise eugenic selection for certain genetic personalities, even if somebody had the power to do so? You would have to check each of 500 genes one by one, deciding in each case to reject those with the “wrong” gene. At the end you would be left with nobody, not even if you started with a million candidates. We are all of us mutants. The best defense against designer babies is to find more genes and swamp people in too much knowledge.

The tree is known by its fruits, and the fruits of chance are incoherence, incompleteness, unsteadiness, the stammering utterance of blind, unreasoning force. A coherence that binds all the geological ages in one chain, a stability of purpose that completes in the beings born to-day an intention expressed in the first creatures that swam in the Silurian ocean or crept upon its shores, a steadfastness of thought, practically recognized by man, if not acknowledged by him, whenever he traces the intelligent connection between the facts of Nature and combines them into what he is pleased to call his system of geology, or zoology, or botany these things are not the fruits of chance or of an unreasoning force, but the legitimate results of intellectual power.

**Geikie, Sir Archibald** 1835–1924

What art effects upon the marble block, nature accomplishes upon the surface of the land. Her tools are many and varied – air, frost, rain, springs, torrents, rivers, avalanches, glaciers, and the sea – each producing its own characteristic traces in the sculpture. With these implements, out of the huge bulk of the land she cuts the valleys and ravines, scoops the lake-basins, hews with bold hand the colossal outlines of the mountains, carves out peak and crag, crest and cliff, chisels the courses of the torrents, splinters the sides of the precipices, spreads out the alluvium of the rivers, and piles up the moraines of the glaciers.

## GEOLOGICAL SCIENCE

**de La Beche, Henry Thomas** 1796–1855  
 English geologist

The advance of geological science has lately been so rapid, that it requires some exertion to keep pace with it. Hasty conclusions can no longer command attention, – there are too many observers in the field to permit errors to remain long uncontradicted, – and it is very desirable for the progress of science, that no deference for a name should cause them to remain uncontradicted. It surely can be no offence to state, that the progress of science has led to new views, and that the consequences that can be deduced from the knowledge of a hundred facts may be very different from those deducible from five. It is also possible that the facts first known may be the exceptions to a rule, and not the rule itself, and generalizations from these first-known facts, though useful at the time, may be highly mischievous, and impede the progress of the science if retained when it has made some advance.

**McPhee, John** 1931–

I used to sit in class and listen to the terms come floating down the room like paper airplanes. Geology was called a descriptive science, and with its pitted, outwash plains and drowned rivers, its hanging tributaries and starved coastlines, it was nothing if not descriptive.

Someone developed enough effrontery to call a piece of our earth an epieugeosyncline. A cactolith, according to the American Geological Institute Glossary of Geology and Related Sciences, was “quasi-horizontal chonolith composed of anastomosing ductoliths, whose distal ends curl like a harpolith, thin like a sphenolith, or bulge dscordantly like an akmolityh or ethmolith.”

## GEOLOGICAL THOUGHT

**Kemp, James Furman** 1859–1926  
 American geologist

We feel ourselves as it were upon some mountain summit looking ever away and away into regions beyond. And just as when standing amid such surroundings we have felt the ecstatic thrill brought by the expanding prospect and have burned with eagerness to penetrate the new lands further on, so in the realm of geological thought we look back over the periods of the past, over the course which we have come, over the problems solved, the lower summits climbed, and then turning ahead to the future, to the yet unknown, we burn with eagerness to push forward in our day and generation the boundaries of knowledge another stage.

Geologic time! How the striking of the great clock, whose hours are millions of years, reverberates out of the abyss of the past! Mountains fall, and the foundations of the earth shift, as it beats out the moments of terrestrial history.

*The Writings of John Burroughs* (Volume 19)  
 Chapter II (p. 40)  
 Houghton, Mifflin. Boston, Massachusetts, USA. 1916

How geologic time looks out from the ledges and walls of gray rocks unmindful of us human ephemera that pass! It has seen the mountains decay and the hills grow old. The huge drift boulders rest on the margin of meadows and fields, or stand sentry to the woods, and though races and kingdoms pass, scarcely the change of a wrinkle disturbs their calm stone faces. Yet time gets the better of them also. The frowning ledge melts as inevitably as a snowbank.

A great reform in geological speculation seems now to have become necessary. A very earnest effort was made by geologists, at the end of last century, to bring geology within the region of physical science, to emancipate it from the dictation of authority and from dogmatic hypotheses. The necessity for more time to account for geological phenomena than was then generally supposed to be necessary, became apparent to all who studied with candour and with accuracy the phenomena presented by the surface of the earth.

Geologic time – we know the earth is very old, but it occurs to me that the millions, nay billions, of years of geologic time, which geologists constantly remind us of, and impress us with, are not what an understanding of earth history should really be about. The span of geologic time is almost impossible to equate with the daily life of any of us. It is like our budget deficit – difficult to imagine, hard to comprehend, and seemingly impossible to control. Geologic time is simply not relevant to most of us.

Persons have been called Geologists who, gifted with prolific imaginations, have indulged in fanciful speculation concerning a former order of things, and have reared hypotheses respecting the origin of our planet upon foundations so flimsy and unsubstantial, as to deserve no other appellation than flighty excursions of a poetic mind. Others, by careful, diligent, and extended observations of the present state of the earth's surface, have endeavored, in the path of induction, to trace the nature of the agents which have once been active, to ascertain how far they are now operating, and to anticipate the results of their continuance. If they frame theories, they do so upon the results of actual research; if they indulge in speculation, they assign to it its proper place. These are really Geologists, and their aim is, not to imagine or suppose, but to discover the nature of all changes of the earth's surface and interior, and thence to arrive at the laws that regulate them.

The complacent manner in which geologists have produced their theories has been extremely amusing; for often, with knowledge (and that frequently inaccurate) not extending beyond a given province, they have described the formation of a world with all the detail and air of eye-witnesses. That much good ensues, and that the science is greatly advanced, by the collision of various theories, cannot be doubted. Each party is anxious to support opinions by facts. Thus, new countries are explored, and old districts re-examined; facts come to light that do not suit either party; new theories spring up; and, in the end, a greater insight into the real structure of the earth's surface is obtained.

What is the boasted communion which the vain poet holds with nature compared with conversation which the geologist perpetually carries on with the elemental world?

Gazing on the strata of the earth, he reads the fate of his species. In the undulations of the mountains is revealed to him the history of the past; and in the strength of rivers and the powers of the air he discovers the fortunes of the future. To him, indeed, that future, as well as the past and the present, are alike matter for meditation : for the geologist is the most satisfactory of antiquarians, the most interesting of philosophers, and the most inspired of prophets ; demonstrating that which has past by discovery, that which is occurring by observation, and that which is to come by induction.

In examining things which actually exist, and which have proceeded in a certain order, it is natural to look for that which had been first; man desires to know what had been the beginning of those things which now appear. ### **Author undetermined**

Geology is my major, I shall not want another.

It maketh me to go down in dark places;

It leadeth me into the running waters.

It ruineth my soles –

It leadeth me on the paths of the outcrops

For its name's sake.

Yea, though I search through the valleys,

I find the rocks on the hills.

I fear great evil when on the cliffs:

The hammers and chisels discomfort me.

It preparast a bedding plane for me in the

Presence of my brunton, it anointest my

Body with mud, my collecting sack runneth over.

Surely to goodness if I follow this vocation all

The days of my life. I shall be buried in a

Landslide forever.

## **GEOLOGIST'S WIFE**

### **Author undetermined**

then, my dear, to the highlands you go,

Geology calls you, you must not say no:

Alone in your absence I cannot but mourn.

And yet it were selfish to wish your return.

No, come not until you have searched through the gneiss,

And marked all the smoothings produced by the ice;

O'er granite-filled chinks felt Huttonian joy,

And measured the Parallel Roads of Glenroy.

Yet still, as from mountain to mountain you stride,

In visions I'll walk like a shade by your side;

Your bug and your hammer I'll carry with glee,

And climb the raised beaches, my own love, with thee.

Me, too, you'll remember, for love claims no less,

And all your proceedings a fondness confess;

Each level you take, be it not from the sea,

But above the dear place where your Susan may be.

Let everything mind you of tender relations –

Bee, even the hard rocks have their inclinations!

Oh, let me believe that, wherever you roam,

The axis of yours can be nowhere but – home!

Suppose that you find on the mountains of Lorn,

A boulder that long since from Nevis was torn,

'Twill seem like that fond one who left his own shore,

‘Perhaps to return to Lochaber no more.’

And if, in your wanderings, you chance to be led

To Ross-shire or Moray, to see the Old Rod,

Oh still, as its mail-covered fishes you view.

Remember the colour is love's proper hue.

Such being your feelings, I'll care not although  
 You're gone from my side – or a fortnight or so;  
 But know, if much longer you leave me alone,  
 You may find, coming back, you have two wives of  
 stone!

Geology does have a first authoritative book of facts – but  
 it is not in the library! It is in the rocks of the lithosphere.  
 No author's personal equation need be allowed for when  
 you read it; no emotional reactions warped the original  
 historian's selection of facts. Yet this unbiased book is  
 exceedingly difficult to read, for it is written in hiero-  
 glyphs and it is very fragmentary. Its deciphering is far  
 from complete, and many fragments previously unknown  
 are constantly being collected and pieced together.

Geology has been charged with failure to measure up to the intellectual standard of the so-called “exact” sciences. The reproach is no longer merited. It originated during a century when the power of the experimental method in science was first clearly appreciated. As usually the case with great discoveries, this was soon given exaggerated importance by many students of the logic of science. Now that the intoxication of early, magnificent success in the use of experiment is succeeded by more sober second thought, it has become clearer that this method of research is only one of several that are quite essential and are of coordinate value in scientific thought.

The movement of land waste is generally so slow that it is not noticed. But when one has learned that many land forms result from the removal of more or less rock waste, the reality and the importance of the movement are better understood. It is then possible to picture in the imagination a slow washing and creeping of the waste down the land slopes; not bodily or hastily, but grain by grain, inch by inch, yet so patiently that in the course of ages even mountains may be laid low.

Geology has its peculiar difficulties, from which all other sciences are exempt. Questions in chemistry may be settled in the laboratory by experiment. Mathematical and philosophical questions may be discussed, while the materials for discussion are ready furnished by our own intellectual reflections. Plants, animals and minerals, may be arranged in the museum, and all questions relating to their intrinsic principles may be discussed with facility. But the relative positions, the shades of difference, the peculiar complexions, whether continuous or in subordinate beds, are subjects of enquiry in settling the

characters of rocks, which can be judged of while they are in situ only.

Among the questions which disquieted pious souls in my younger days, but which have ceased to disquiet any of us, are those respecting the age and gradual development of the earth and of the solar system, which came in with geology and modern astronomy. I remember the time when it was a mooted question whether geology and orthodox Christianity were compatible...

A new geology was developing, and the Geological Society of London ushered in its birth. No more should observations be made through the distorting medium of preconceived fancies! No more should geology be inspired by that heedless spirit which cares not to distinguish between fancy and fact! With youthful vigor the new geology would have nothing to do with the search for cosmogonies and such like fancy foods, and the Geological Society of London should be nourished on unadulterated facts.

To some minds geology scarcely assumes the rank of a science, except where treated from a physical point of view. They consider the simplest physical law adequate to the explanation of the most stupendous phenomena. To them, mountain chains rise and are abraded, and the entire crust of the earth is folded and plicated in obedience to certain laws. They see no difficulty in the way of imagining torrents of water moving onward and upward, carrying masses of rocks over heights far above their origin by some simply gyratory force. The entire earth becomes with equal ease to them, either a pliable, elastic, or compressible mass, or a non-elastic body; sudden cataclysms, according to the fancy of the expounder. No wizard's wand ever played so many pranks as the poor earth in the hands of these theorizing geologists.

Geology, if we would let alone grand theorizing, is a simple and beautiful study, in which we see everything evolved naturally and harmoniously, without at any time great and sudden changes. We remark those changes as one who having viewed a city in its progress, should fall asleep for a century and afterwards behold the difference. But to one who could have seen stone laid upon stone, and each edifice completed singly, it would have had but the aspect of natural and quiet progress.

This statement is possibly surprising in view of the fact that almost any modern writer can produce a geologic timetable that gives precise datings and lengths of eras and systems and even of some of the smaller subdivisions....All other absolute ages have been derived from the three radioactive tie points by interpolation based on thickness of strata or by “reasoned guesses”...

In the study of the changes which the parts of that structure have undergone and are now undergoing it shades through the science of Meteorology into that of Physics. In the study of the successive surfaces of that structure it grades into the science of Geography. In the study of the stony relics of the vanished beings that once dwelt upon those surfaces it joins hands with the sciences of Zoology and Botany. In studying the phenomena presented by the sequence and inter-relations of the rock formations which go to the building up of that structure, it finds the means of reading the past history of the earth and its living inhabitants – a glory reserved for Geology alone.

*Principles of Geology* (Volume 1)

Chapter I (p. 1)

John Murray. London, England. 1830

Geology is intimately related to almost all the physical sciences, as history is to the moral. An historian should, if possible, be at once profoundly acquainted with ethics, politics, jurisprudence, the military art, theology; in a word, with all branches of knowledge by which any insight into human affairs, or into the moral and intellectual nature of man, can be obtained. It would be no less desirable that a geologist should be well versed in chemistry, natural philosophy, mineralogy, zoology, comparative anatomy, botany; in short, in every science relating to organic and inorganic nature. With these accomplishments, the historian and geologist would rarely fail to draw correct and philosophical conclusions from the various monuments transmitted to them of former occurrences.

...we are apprehensive lest zoological periods in geology, like artificial divisions in other branches of natural history, should acquire too much importance, from being supposed to be founded on some great interruptions in the regular series of events in the organic world, whereas... we ought to regard them as invented for the convenience of systematic arrangement, always expecting to discover intermediate gradations between the boundary lines we have first drawn.

For not only does it greatly add to the materials on which the natural theologian finds his deductions, by adding to the organisms, plant and animal, of the present creation the extinct organisms of the creations of the past, with all their extraordinary display of adaptation and design; but it affords him, besides, materials peculiar to itself, in the history which it furnishes both of the appearance of these organisms in time, and of the

wonderful order in which they were chronologically arranged.

Gould and Lincoln. Boston, Massachusetts, USA. 1857

Geology is the most poetical of all sciences; and its various facts, as they present themselves to the human mind, possess a more overpowering immensity than even those of Astronomy itself. For while the Astronomer can carry about with him in his imagination a little portable Orrery of the whole solar system, the Geologist is oppressed by a weight of rocks and mountains, and of strata piled over strata which all his diligence in forming theories has not yet enabled him completely to arrange. He is no mere intellectual mechanic, who calculates and reasons on the movements of a piece of natural clockwork; the objects with which he is chiefly conversant have no ascertained forms, or known proportions, that he may conceive of them as abstract figures, or substitute a set of models in their places; his province, in at least all its outer skirts, is still a terra incognita, which he cannot conceive of as a whole; and the walks which intersect it are so involved and irregular that, like those of an artificial wilderness, they seem to double its extent. The operations of his latest eras, as his science exists in time, terminate long before history begins; while, as it exists in space, he has to grapple with the immense globe itself, with all its oceans, and all its continents.

It is admitted, on all hands, that the Scriptures are not intended to resolve physical questions, or to explain matters in no way related to the morality of human actions; and if, in consequence of this principle, a considerable latitude of interpretation were not allowed, we should continue at this moment to believe that the earth is flat; that the sun moves around the earth; and that the circumference of a circle is not more than three times its diameter. It is but reasonable, therefore, that we should extend to the geologist the same liberty of speculation, which the astronomer and mathematicians are already in possession of; and this may be done, by supposing that the chronology of Moses relates only to the human race.

American statesman

Last year, I amused and probably alarmed and shocked our good neighbors across the street at the National Academy of Sciences by revealing that I am a scientist. I have a Bachelor of Science degree in geology from the City College of New York, and my great contribution to the field of geology is that I never entered it upon graduation.

Astronomy and Geology owe much of their charm to the fact that they suggest thoughts of other forms of life than those with which we are familiar. Geology teaches us of days when this earth was peopled with strange creatures such as now are found upon its surface. We turn our thoughts to the epochs when those monsters thrived and multiplied, and picture to ourselves the appearance which our earth then presented.

Geology has for its business a knowledge of the processes which are in continual or occasional operation within the limits of our planet, and the application of these laws to explain the appearances discovered by our Geognostical researches, so as from these materials to deduce conclusions as to the past history of the globe.

*Considerations on Volcanoes*

Preface (p. iv)

W. Phillips & George Yarp. London, England. 1825

If the business of Geology is the study of the structure of the accessible portion of the Earth, and of the changes it has undergone, there can be no more important branch of the science than that which examines the nature and mode of operation of the subterranean forces which have everywhere more or less broken up, disturbed, and altered the level of the superficial rocks, modified their internal texture and composition, and brought fresh material upon or towards the exterior of the globe.

Geology, like every other science when well interpreted, lends its aid to natural religion. It tells us, out of its own records, that man has been but a few years a dweller on the earth; for traces of himself and his works are confined to the last monuments of its history. Independently of every written testimony, we therefore believe that man with all his powers and appetencies, his marvelous structure and fitness for the world was called into being a few thousand years of the days in which we live.

*Discourse on the Studies of the University of Cambridge* (pp. 22–23)

But let us for a moment, suppose that there are some religious difficulties in the conclusions of Geology. How are we then to solve them? Not by making a world after a

pattern of our own – not by shifting and shuffling the solid strata of the earth, or dealing them out in such a way as to play the game of an ignorant and dishonest hypothesis – not by shutting our eyes to the facts, or denying the evidence of our senses: but by patient investigation carried on in the sincere love of truth and by learning to reject every consequence not warranted by direct physical evidence.

*Discourse on the Studies of the University of Cambridge*  
Appendix (p. 105)  
John W. Parker. London, England. 1850

We might expect...that as we come close upon living nature, the characters of our old records would grow legible and clear. But just where we begin to enter on the history of the physical changes going on before our eyes, and in which we ourselves bear a part, our chronicle seems to fail us; a leaf has been torn out from Nature's book, and the succession of events is almost hidden from our eyes.

I am convinced that, at its best, science is simple – that the simplest arrangement of facts that sets forth the truth best deserves the term scientific. So the geology I plead for is that which states facts in plain words – in language understood by the many rather than only by the few. Plain geology needs little defining, and I may state my case best by trying to set forth the reasons why we have strayed so far away from the simple type.

If from the discoveries of Astronomy and Geology we infer that the created universe, including our own globe, has existed through an unknown but unspeakably long period of time past; and IF, from the records of revelation, we draw the conclusion that the work of creation, or at least so far as respects our planet, took place not quite

six thousand years ago; it is evident that the two positions cannot stand: one destroys the other. One of them must be an error; both may be wrong; only one can be right.

The close of one century, the dawn of another, may naturally suggest some brief retrospective glance over the path along which our science has advanced, and some general survey of its present position from which we may gather hope of its future progress; but other connexion with geology the beginnings and endings of centuries have none. The great periods of movement have hitherto begun, as it were, in the early twilight hours, long before the dawn.

The science of geology becomes of infinite importance when we consider it as connected with our immortal hopes. These depend on the truth of revelation, and the whole system of revealed religion is ultimately connected with the veracity of Moses. The divine legation of Christ and of the Jewish lawgiver must stand or fall together. If the Mosaic account of the creation and of the deluge is true, and consequently the promises recorded by him well founded, we may retain our hopes; but, should the former be given up as false, we must renounce the latter.

Geology has revealed the fact that the crust of the earth is composed of five layers or strata. We exist on the surface of the fifth. Geology teaches, with scientific accuracy, that each of these layers was from ten thousand to two million years forming or cooling. (A disagreement as to a few hundred thousand years is a matter of little consequence to science.)

It may be said that the history of events, as shown by the rocks and fossils, does not necessarily require physical or chemical treatment. There is some truth in these statements, but on the other side it may be held that the facts are the results accomplished by physical and chemical works. These facts become important and significant mainly as they are interpreted in physical and chemical terms. The objects of the earth, – the complex results of chemical and physical work – if described without reference to the manner in which the results came about, have comparatively little interest.

...the study of Geology opens to us the spectacle of many groups of species which here, in the course of the earth's history, succeeded each other at vast intervals of time; one set of animals and plants disappearing, as it would seem, from the face of our planet, and others, which did not before exist, becoming the only occupants of the globe. And the dilemma then presents itself to us anew: – either we must accept the doctrine of the transmutation of species, and must suppose that the organized species of one geological epoch were transmuted into those of another by some long-continued agency of natural causes; or else, we must believe in many successive acts of creation and extinction of species, out of the common course of nature; acts which, therefore, we may properly call miraculous.

Geology has, for the earliest times, claimed the serious attention of mankind, by appealing to two entirely different sides of human character. In the first place, reverence for the mysterious in nature, which in untutored men amounts to worship, has always been excited by the secrets of the earth; while, in the second place, the cupidity of man has always led him to explore the rocks in quest of the mineral treasures which they contain.

Geology illustrates better than any other science, probably, the wide ramifications and the close inter-relations

of physical phenomena. There is scarcely a process, a product, or a principle in the whole range of physical science, from physics and chemistry up to astronomy and astrophysics, which is not fully illustrated in its uniqueness and in its diversity by actual operations still in progress on the earth, or by actual records preserved in her crust. The earth is thus at once the grandest of laboratories and the grandest of museums available to man.

How geologic time looks out from the ledges and walls of gray rocks unmindful of us human ephemera that pass! It has seen the mountains decay and the hills grow old. The huge drift boulders rest on the margin of meadows and fields, or stand sentry to the woods, and through races and kingdoms pass, scarcely the change of a wrinkle disturbs their calm stone faces. Yet time gets the better of them also. The frowning ledge melts as inevitably as a snow bank.

Whatever his method of approach, the geologist must take cognizance of the following facts...There is no place on the earth where a complete record of the rocks is present...To reconstruct the history of the earth, scattered bits of information from thousands of locations all over the world must be pieced together. The results will be at best only a very incomplete record. If the complete story of the earth is compared to an encyclopedia of thirty volumes, then we can seldom hope to find even one complete volume in a given area. Sometimes only a few chapters, perhaps only a paragraph or two, will be the total geological contribution of a region; indeed, we are often reduced to studying scattered bits of information more nearly comparable to a few words or characters.

### **Chalmers, Thomas** 1780–1847

Scottish theologian

There are prejudices...against the speculations of the geologist, which I am anxious to remove. It has been said that they nurture infidel propensities. It has been alleged that geology, by referring the origin of the globe to a higher antiquity than is assigned to it by the writings of Moses, undermines our faith in the inspiration of the Bible, and in all the animating prospects of the immortality which it unfolds. This is a false alarm. The writings of Moses do not fix the antiquity of the globe.

### **Chamberlin, Thomas Chrowder** 1843–1928

American geologist

The studies of the geologist are peculiarly complex. It is rare that his problem is a simple unitary phenomenon explicable by a single simple cause. Even when it happens to be so in a given instance, or at a given stage of work, the subject is quite sure, if pursued broadly, to

grade into some complications or undergo some transition. He must therefore ever be on the alert for mutations and for the insidious entrance of new factors. If, therefore, there are any advantages in any field in being armed with a full panoply of working hypotheses and in habitually employing them, it is doubtless the field of the geologist.

The geologist in the wilderness epitomizes man against nature. A tiny, transitory creature, whose life will be over in a mere second of geologic time, attempts to discern the life processes of Earth. Hammering at the rocks pregnant with data, the geologist is in physical contact and combat with the Earth, like a mosquito attacking Goliath. Ever so grudgingly, the Earth yields its life history.

We are voyagers on it through space, it has been said, as passengers on a ship, and many of us have never thought of any part of the vessel but the cabin where we are quartered. Some curious passengers (these are the geographers) have visited the steerage, and some (the geologists) have looked under the hatches, and yet it remains true that those in one part of our vessel know little, even now, of their fellow-voyagers in another. How much less, then, do most of us know of the ship itself, for we were all born on it, and have never once been off it to view it from the outside!

It is the nature of the history of the earth that a geologist has available to him only partial information. Occasional lines from disconnected paragraphs in obscurantist chapters are what can be read. Violence in the handling of the book through time has caused many of these chapters to be ripped and reassembled out of context. That the gist of the early chapters can be deciphered at all is a credit to the perseverance and imagination not always associated with other sciences. The geologist operates at all times in an environment characterized by a high degree of uncertainty and ornamented with end-products which are the outcomes of the interactions of many complex variables. He sees only the end, and has to induce the processes and the responses that filled the time since the beginning.

## GEOMETER

**Clifford, William Kingdon** 1845–79  
English mathematician

The geometer of to-day knows nothing about the nature of actually existing space at an infinite distance; he knows nothing about the properties of this present space in a past or a future eternity. He knows, indeed, that the laws assumed by Euclid are true with an accuracy that no direct experiment can approach, not only in this place where we are, but in places at a distance from us that no astronomer has conceived; but he knows this as of Here and Now; beyond his range is a There and Then of which he knows nothing at present, but may ultimately come to know more.

I do not find that geometers are mighty solicitous, whether their arguments be, in formula, compounded according to logical prescription; and yet there are none who demonstrate wither more precisely or with greater conviction. For they usually follow the guidance of nature; descending step by step, from the simpler and more general to the more complex, and defining every term, they leave no ambiguity in their language. Hence it is that they cannot err in the form of their syllogisms – for we seldom deviate from logical rules, except when we abuse the ambiguity of words, or attribute a different meaning to the middle term in the major and in the minor proposition. It is also the custom of geometers to prefix certain self-evident axioms or principles from which all that they are subsequently to demonstrate flow. Finally, their conclusions are deduced, either from definitions which cannot be called in question, or from those principles and propositions known by the light of nature, which are styled axioms, or from other already established conclusions, which now obtain the cogency of principles. They make not troublesome inquiry into the mood or figure of a syllogism, nor lavish attention on the rules of logic; for such attention, by averting their mind from more necessary objects, would be detrimental rather than advantageous.

Geometry, then, is the application of strict logic to those properties of space and figure which are self-evident, and which therefore cannot be disputed. The question is therefore to demonstrate all geometrical truths with the smallest possible number of assumptions.

There is (gentle reader) nothing (the works of God only set apart) which so much beautifies and adorns the soul and mind of man as does knowledge of the good arts and sciences.... Many...arts there are which beautify the mind of man; but of all none do more garnish and beautify it than those arts which are called mathematical, unto the knowledge of which no man can attain, without perfect knowledge and instruction of the principles, grounds, and Elements of Geometry.

Modern algebraic geometry has deservedly been considered for a long time as an exceedingly complex part of mathematics, drawing practically on every other part to build up its concepts and methods and increasingly becoming an indispensable tool in many seemingly remote theories. It shares with number theory the distinction of having one of the longest and most intricate histories among all branches of our science, of having always attracted the efforts of the best mathematicians in each generation, and of still being one of the most active areas of research.

Chapter I (pp. 14–15)

George Newnes, Ltd. London, England. 1902

The history of geometry is, as it were, a drama enacted through the centuries: therein is beheld the growth of a science from helpless birth and stumbling childhood, through the strenuous but rash vigour of youth, to the perfect wisdom and disciplined strength of manhood. In the life of a science a human life is but an insignificant moment, and from this point of view the history of geometry assumes a grandeur scarcely short of majestic.

Chapter I (p. 15)

George Newnes, Ltd. London, England. 1902

Geometry may be helpfully likened to a vast and intricate mountain region, in which each truth is a summit, unattainable without the putting forth of more or less effort. When once reached these summits furnish views which have in them something grand, although it may happen that their attainment conveys the greater reward. But each ascent is only the start of some fresh ascent of a loftier peak, and from no summit yet attained is it possible to

gaze all around with every truth of geometry below.

The mathematical process in the symbolical method (i.e., the algebraical) is like running a railroad through a tunneled mountain, ...in the ostensive (i.e., the geometrical) like crossing the mountain on foot. The former causes us, by a short and easy transit, to our destined point, but in miasma, darkness and torpidity, whereas the latter allows us to reach it only after time and trouble, but feasting us at each turn with glances of the earth and of the heavens, while we inhale the pleasant breeze, and gather new strength at every effort we put forth.

Modern pure geometry differs from the geometry of earlier times not so much in the subjects dealt with as in

the processes employed and the generality of the results obtained. Much of the material is old, but by utilizing the principle of projection and the theory of transversals, facts which were thought of as in no way related, prove to be simply different aspects of the same general truth. This generalizing tendency's the chief characteristic of modern geometry.

If geometry is to be regarded as a science born of direct and exact observation of nature, a science that seeks by purely inductive means to win from immediately observed simple phenomena the laws of complicated phenomena, then one is indeed compelled to reject many a traditional idea; but if we do so, the material to be worked up will be brought back to its proper domain and the ground for a whole series of controversies will be eliminated. No matter how many sorts of speculation may still be associated with geometry, its fruitful application in the natural sciences and in practical life rests upon the fact that its concepts originally correspond to empirical objects. As long as one limits himself from first to last to this empirical core, geometry retains the character of a natural science, distinguished from the other parts of science by the fact that it needs to derive very few of its concepts and laws immediately from experience.

The truths of Geometry are all necessarily connected with one another, and the system of such truths can never be rightly explained, unless that connection be accurately traced, wherever it exists. It is upon this that the beauty and peculiar excellence of the mathematical sciences depend: it is this, which, by preventing any one truth from being single and insulated, connects the different parts so firmly, that they must all stand or all fall together.

### **Russell, Bertrand Arthur William** 1872–1970

English philosopher, logician, and social reformer

It was formerly supposed that Geometry was the study of the nature of the space in which we live, and accordingly it was urged, by those who held that what exists can only be known empirically, that Geometry should really be regarded as belonging to applied mathematics. But it has gradually appeared, by the increase of non-Euclidean systems, that Geometry throws no more light upon the nature of space than Arithmetic throws upon the population of the United States.

*Mysticism and Logic and Other Essays*

Chapter V (p. 92)

Longmans, Green & Company. London, England. 1925

Geometry, throughout the 17th and 18th centuries, remained, in the war against empiricism, an impregnable fortress of the idealists. Those who held – as was generally held on the Continent – that certain knowledge, independent of experience, was possible about the real world, had only to point to Geometry: none but a madman, they said, would throw doubt on its validity, and none but a fool would deny its objective reference.

*An Essay on the Foundations of Geometry*

Introduction (p. 1)

Dover Publications, Inc. New York, New York, USA. 1956

How can a certain line, or a certain surface, form an impassable barrier to space, or have any mobility different in kind from that of all other lines or surfaces? The notion cannot, in philosophy, be permitted for a moment, since it destroys that most fundamental of all the axioms, the homogeneity of space.

*An Essay on the Foundations of Geometry*

Chapter Bisection 51 (p. 54)

Dover Publications, Inc. New York, New York, USA. 1956

All geometrical reasoning is, in the last resort, circular: if we start by assuming points, they can only be defined by the lines or planes which relate them; and if we start by assuming lines or planes, they can only be defined by the points through which they pass.

*An Essay on the Foundations of Geometry*

Chapter III, Section 108 (p. 120)

Dover Publications, Inc. New York, New York, USA. 1956

There is no logical implication of other entities in space. It does not follow, merely because there is space, that therefore there are things in it. If we are to believe this, we must believe it on new grounds, or rather on what is called the evidence of the senses. Thus we are taking an entirely new step.

Next to the science of number, the science of space is that which is at once the most abstract, and admits of the most universal application to the study of natural phenomena. Everything that takes place takes place in space; and thus Geometry, or the science of space, necessarily intervenes in all exact observation of events.

He who would know what geometry is must venture boldly into its depths and learn to think and feel as a geometer. I believe that it is impossible to do this, and to study geometry as it admits of being studied and am conscious it can be taught, without finding the reason invigorated, the invention quickened, the sentiment of the orderly and beautiful awakened and enhanced, and reverence for truth, the foundation of all integrity of character, converted into a fixed principle of the mental and moral constitution, according to the old and expressive adage “*abeunt studia*” in mores.

The branch of physics which is called Elementary Geometry was long ago delivered into the hands of mathematicians for the purposes of instruction. But, while mathematicians are often quite competent in their knowledge of the abstract structure of the subject, they are rarely so in their grasp of its physical meaning.

At the same time it will not be forgotten that the physical reality of geometry cannot be put in evidence with full clarity unless there is an abstract theory also.... Thus, for example, while the term electron may have more than one physical meaning, it is by no means such a protean object as a point or a triangle.

Geometry became one of the most powerful expressions of that sovereignty of the intellect that inspired the thought of those times. At a later epoch, when the

intellectual despotism of the church, which had been maintained through the middle ages, had crumbled, and a wave of skepticism threatened to sweep away all that had seemed most fixed, those who believed in truth clung to Geometry as to a rock, and it was the highest ideal of every scientist to carry on his science “more geometrico.”

This science, Geometry, is one of indispensable use and constant reference, for every student of the laws of nature; for the relations of space and number are the alphabet in which those laws are written. But besides the interest and importance of this kind which geometry possesses, it has a great and peculiar value for all who wish to understand the foundations of human knowledge, and the methods by which it is acquired. For the student of geometry acquires, with a degree of insight and clearness which the unmathematical reader can but feebly imagine, a conviction that there are necessary truths, many of them of a very complex and striking character; and that a few of the most simple and self-evident truths which

it is possible for the mind of man to apprehend, may, by systematic deduction, lead to the most remote and unexpected results.

## GEOMETRY, BOARDING-HOUSE

### **Leacock, Stephen** 1869–1944

Canadian humorist

All boarding-houses are the same boarding-house.

Boarders in the same boarding-house and on the same flat are equal to one another.

A single room is that which has no parts and no magnitude.

The landlady of a boarding-house is a parallelogram – that is, an oblong angular figure, which cannot be described, but which is equal to anything.

A wrangle is the disinclination of two boarders to each other that meet together but are not in the same line.

All the other rooms being taken, a single room is said to be a double room.

## POSTULATES AND PROPOSITIONS

A pie may be produced any number of times.

The landlady can be reduced to her lowest terms by a series of propositions.

A bee line may be made from any boarding-house to any other boarding-house.

The clothes of a boarding-house bed, though produced ever so far both ways, will not meet.

Any two meals at a boarding-house are together less than two square meals.

If from the opposite ends of a boarding-house a line be drawn passing through all the rooms in turn, then the stove-pipe which warms the boarders will lie within that line.

On the same bill and on the same side of it there should not be two charges for the same thing.

If there be two boarders on the same flat, and the amount of side of the one be equal to the amount of side of the other, each to each, and the wrangle between one boarder and the landlady be equal to the wrangle between the landlady and the other, then shall the weekly bills of the

two boarders be equal also, each to each.  
For if not, let one bill be the greater.  
Then the other bill is less than it might have been – which is absurd.

In our own lives we are the total of all our past experiences... we are ever growing older like the universe of the immortal Bergson. So too the germ-plasm; it is literally the heir of all the ages of germ-plasm experience, and the germ-plasm is living, is experiencing as much as we and in like manner. **Playfair, John** 1748–1819

Scottish geologist, physicist and mathematician

For the moving of large masses of rock, the most powerful engines without doubt which nature employs are the glaciers, those lakes or rivers of ice which are formed in the highest valleys of the Alps, and other mountains of the first order.

English poet

The glaciers creep

Like snakes that watch their prey, from their far fountains.

American author and humorist

...a man who keeps company with glaciers comes to feel tolerably insignificant by and by. The Alps and the glaciers together are able to take every bit of conceit out of a man and reduce his self-importance to zero if he will only remain within the influence of their sublime presence long enough to give it a fair and reasonable chance to do its work.

**von Helmholtz, Hermann** 1821–94

German scientist and philosopher

The world of ice and of eternal snow, as unfolded to us on the summits of the neighbouring Alpine chain, so stern, so solitary, so dangerous, it may be, has yet its own peculiar charm.

**Wright, George Frederick** 1838–1921

American geologist

To the ordinary man of science, water is a mineral and ice a rock; but to the glacialist both are fluids. The apparent solidity of ice is an illusion due to the dullness of our senses. The reason why its viscous or semi-fluid character remained unsuspected until a comparatively recent period is due to the fact that the ordinary movement of accessible glaciers was so slow that we could not by observation readily note their rate of progress.

My sweet pipet,  
Can I forget

The day we met – Pipet?  
 The day was drear and wet, how wet!  
 Your price was half a dollar net,  
 But shall I ever repay the debt, Pipet?  
 I think of what you held for me,  
 E'en though 'twas only 10 cc.,  
 (or 20 as the case may be),  
 And how in vain I tried to check  
 The water running down your neck – pipet.

Now if by chance we are missing a flask  
 We go to our neighbor, and timidly ask,  
 “Can you give us the low down – who stole our glass?”  
 With innocent surprise or utter dismay  
 He tell us that he has not seen it today.

So we give up our search, but the suspicion is strong  
 That our chemical neighbor has done us the wrong.
