BIOLOGICAL AND MEDICAL PHYSICS, BIOMEDICAL ENGINEERING

The fields of biological and medical physics and biomedical engineering are broad, multidisciplinary and dynamic. They lie at the crossroads of frontier research in physics, biology, chemistry, and medicine. The Biological and Medical Physics, Biomedical Engineering Series is intended to be comprehensive, covering a broad range of topics important to the study of the physical, chemical and biological sciences. Its goal is to provide scientists and engineers with textbooks, monographs, and reference works to address the growing need for information.

Books in the series emphasize established and emergent areas of science including molecular, membrane, and mathematical biophysics; photosynthetic energy harvesting and conversion; information processing; physical principles of genetics; sensory communications; automata networks, neural networks, and cellular automata. Equally important will be coverage of applied aspects of biological and medical physics and biomedical engineering such as molecular electronic components and devices, biosensors, medicine, imaging, physical principles of renewable energy production, advanced prostheses, and environmental control and engineering.

Preface

Protein molecules are one of the most important types of macromolecules of the living world. They perform many functions: enzymatic (catalytic), structural, contractile, etc. Each protein molecule is characterized by its native conformation, which is determined by the amino acid sequence, and staying in it allows it to fulfill its biological functions. The interaction between such protein molecules is carried out in certain areas, the structure of which is determined by their conformation. The determination of such active sites responsible for the binding of protein complexes at the present time is a difficult task since even the exact conformation of proteins is not always known. For this reason, it is very difficult for the experimenter to determine the affinity of the various regions of proteins, their reactivity and the stability of the formed biological complex, as well as the probability of participation of different domains in the formation of a biological complex. It is also worth noting that even for native proteins, there is always the possibility of partial disturbance of the native structure, especially under stress conditions (e.g., heat, oxidation, or osmotic). When the native structure is violated, the proteins stop performing their biological functions, become less stable, and may tend to aggregate, which can lead to a wide range of pathological states of the cell and the whole organism.

Note that for modern proteomics, research and prediction of protein interactions are very important tasks, since they determine the function of proteins at levels from the cell to the whole organism. For proteins whose structure is known, the search for intermolecular interactions according to known data on the conformation of their tertiary structure reduces to the problem of searching for geometric complementarity of the sections of two interacting molecular surfaces and modeling their contacts, the so-called molecular docking. The task of molecular docking is the task of a conformational search algorithm, which reduces to a search for the conformational space of the formed biological complex due to the variation of the torsion angles of protein molecules.

Modern conformational search algorithms in most cases find conformations that are generally close to the experimentally found structures in a relatively short time. However, there are factors that also have a significant impact on the success of the docking, which are often not taken into account in standard algorithms. One such

factor is the conformational mobility of the target protein. The mobility range can be different—beginning with a small ≪adjustment≫ of the side chains and ending with scale domain movements. These movements play an important role. At first glance, the most logical solution to this problem is to take into account the mobility of the protein in a docking program. Unfortunately, modern computational tools do not allow such modeling to be performed in an acceptable time frame since a protein molecule is very large, and allowing for mobility over all degrees of freedom can lead to a so-called combinatorial explosion (an astronomical increase in the number of possible variants). Only in some programs is there a limited mobility of protein-binding sites (usually at the level of a small adaptation of conformations of the side chains of the active center residues). Another approach to this problem consists in docking the same protein in several different conformations and then selecting the best solutions from each docking run. The third approach is to find a universal structure of the target protein in which docking would produce fairly good results for different classes of ligands. In this case, the number of ≪missed≫ (but correct) solutions decreases, but the number of incorrect options also increases significantly. It should also be noted that most programs for the theoretical docking of proteins work according to the following principle: One protein is fixed in space, and the second is rotated around it in a variety of ways.

At the same time, for each rotation configuration, estimates are made for the evaluation function. The evaluation function is based on surface complementarity (the mutual correspondence of complementary structures (macromolecules, radicals), determined by their chemical properties), electrostatic interactions, van der Waals repulsion, and so on. The problem with this approach is that calculations throughout the configuration space require a lot of time, rarely leading to a single solution, which in turn does not allow us to speak of the uniqueness of the target protein and ligand interaction variant.

So while modeling by the methods of molecular dynamics, from 200 to 10,000 possible combinations of the formation of a protein complex with a ligand were found (see Chap. 5).

Such a large number of modifications, along with the lack of a criterion for selecting the most probable variants of the bound structures of biological complexes (which would allow a radical reduction in their number), make it very difficult to interpret the theoretical results obtained for practical use, namely the finding of catalytic centers and a qualitative assessment of the dissociation constant of interacting substances.

The mathematical approach developed and physically substantiated in the monograph, in addition to the works on molecular dynamics, will allow theoretically predicting the passage of the biochemical reaction in the chosen direction with the given amino acid sequences, studying the behavior of dimers in vitro in solutions with different concentration of the monovalent salt in the formation of the nucleosome nucleus, the temperature on the stability of protein dimers, determining the regions of protein molecules responsible for the aggregate the effect of phosphorylation of the amino acid residues of the polypeptide chain on the formation of biological complexes, determining the presence of active regions of proteins and

detecting the stability of various regions of protein complexes by analyzing the matrix of the potential energy of electrostatic interaction between different sites of the biological complex, and also investigating the influence of point mutations in BH3 peptides on the stability of the biological one complex with pro-apoptotic proteins Bcl-2 family and accurately determine the dissociation constants in the binding of different BH3-peptides to proteins Bcl-2 and Bcl-xl.

In the future, this will help to solve fundamental and applied problems of medicine.

The monograph is addressed to researchers and specialists in biomedical physics, molecular biology interested in the development and application of mathematical methods in medical research.

The monograph consists of eight chapters.

In Chap. 1, we consider various experimental approaches for determining the structure of molecules, the mutual arrangement of domains in space, the identification of active protein centers, and their advantages and limitations in the study of various physical properties of biological complexes.

In Chap. 2, we construct a physical model of the interactions between protein molecules and study of their propensity to form biological complexes.

In Chap. 3, we discuss mathematical model of the temperature effect on the character of linking between monomeric proteins in aqueous solutions.

In Chap. 4, we construct mathematical model that will allow us to describe the behavior of biological complexes in vitro on the example of the formation of two histone dimers H2A–H2B and H3–H4 from the corresponding monomeric proteins H2A, H2B, H3, and H4 in solutions with different concentrations of monovalent salt.

In Chap. 5, two algorithms are developed: algorithm 1 and algorithm 2. Algorithm 1 was developed in order to search for the interaction site of a polypeptide chain of a full-length protein with short active region. Algorithm 2 was developed to determine the most active sites of interaction between full-length proteins when dimers are formed in the direction from the N-terminus to C-terminus

In Chap. 6, we construct a physical model of phosphorylation the amino acid residues of the polypeptide chain of a protein on the formation of biological complexes with other proteins.

In Chap. 7, we discuss a new method that allows one to qualitatively determine the effect of point mutations in peptides on the stability of the formed complex with full-length proteins. On the basis of the developed approach, a qualitative correlation of the obtained results with the dissociation constant was revealed using the example of the formation of the BH3 peptide biological complex of Bmf, Puma, Bad, Hrk, Bax, Bik, Noxa, Bid, Bim, and Bak proteins with the Bcl-xl protein and the BH3 peptides protein Bax with the Bcl-2 protein, taking into account the replacement of amino acid residues.

In Chap. 8, two algorithms have been developed, first was developed specifically for the selection of amino acid residues in peptides to improve their affinity in the interaction of peptides with whole proteins, and second was developed to search for scattered active regions of the protein when bound to the peptide.

Before closing, we want to acknowledge my sincere thanks to my colleague Prof. A. P. Golovitsky for a critical reading of the manuscript. Our thanks are to Springer Nature, in particular Dr. Habil. Claus E. Ascheron.

Note that Sect. 2.5 (Physical Interpretation of Condition Number) is written in cooperation with Prof. A. P. Golovitskii.

The results of the work were obtained using computational resources of Peter the Great Sainte-Petersburg Polytechnic University Supercomputing Center (www.spbstu.ru).

Note that when using different versions of MATLAB, the numerical estimates obtained may differ, however, their analysis will be of qualitative agreement.

The calculations were performed in MATLAB computing environment 2017a, operating system CentOS Linux 7.

Chapter 1
Physical Methods for Studying Proteins

Abstract This chapter discusses various experimental approaches for determining the structure of molecules, the mutual arrangement of domains in space, the identification of active protein centers, and their advantages and limitations in the study of various physical properties of biological complexes.

1.1 Electrophoresis Methods

The basis of the electrophoresis method is the motion of charged particles under the action of an electric field [1–7]. A large number of such important biological molecules as proteins, amino acids, nucleic and ribonucleic acids have different ionizable groups and therefore there are various electric charged particles in a solution, either as anions or as cations. These particles migrate either to the anode or to the cathode under the action of an applied electric field. Note that many complex biological molecules can have several different charged groups and will move in a medium with the applied electric field depending on the resultant charge.

Consider in more detail how the charged biological particles are separated in the process of electrophoresis.

To separate the selected biological objects in the medium, a potential difference (voltage) must be applied to the electrodes, which creates an electric field E, which corresponds to the applied voltage V and the distance d between the electrodes. Thus, when the electric field E acts on a molecule that has a charge q(C), the force Eq(H) arises. This force leads to the motion of the charged molecule to the electrode. During the movement, a friction force arises that delays the movement of the molecule. The friction force is hydrodynamic in nature and depends on the shape and size of the molecule and on the pore size of the medium in which the electrophoresis is carried out as well as the viscosity of the buffer. In practice, the most common concept of electrophoretic mobility of an ion is that of the ratio of the ion's velocity to the field strength. Molecules are divided according to their size even if they have the same total charge since they are affected by different frictional forces. Thus, molecules begin to move in the buffer at different rates and separate depending on their electrophoretic mobility when applying a potential difference to the electrodes.

T. Koshlan and K. Kulikov, *Mathematical Modeling of Protein Complexes*,

https://doi.org/10.1007/978-3-319-98304-2_1

When the electric field is turned off before all the molecules reach the electrodes, the components of the biological sample mixture are separated depending on their electrophoretic mobility. The determination and localization of the separated components of the biological mixture are determined by autoradiography or by staining with a suitable dye. Electrophoregrams of protein-enzymes make it possible to study changes in the activity and isoenzyme spectrum of proteins under the influence of external and internal factors in both humans and other organisms.

Electrophoresis is a convenient method that allows one to separate a mixture of proteins after various experiments and draw conclusions about the stability of biological complexes: homodimers, heterodimers, tetramers, oligopolymers, etc. During the electrophoresis, most of the generated power is dissipated as heat. Heating of the medium in which electrophoresis is performed has negative consequences, namely: -the decrease in the viscosity of the buffer with a decrease in the resistance of the medium, -the formation of convection currents, leading to the mixing of separated samples, -an increase in the diffusion rate of sample and buffer ions, leading to a broadening of the zones of the separated samples. -the thermal destruction of samples, which are quite often sensitive to heat. This can cause protein denaturation.

The electrophoresis method can only confirm or infirm the formation of a molecular complex or its dissociation, but does not tell us anything about the nature of the interaction or the causes of dissociation, nor about the structure of the complex formed [7]. It does not reveal the structure of the catalytic active centers of the molecule, nor does it make it possible to calculate the thermodynamic constants of molecules entering into interaction or to draw any conclusions about the stability of biological complexes.

1.2 Chromatographic Methods

The chromatographic method is a method of separation of substances [8–17] developed by the Russian botanist Mikhail Tsvetom.

The chromatographic method is based on the distribution of the analyzed substances between two immiscible phases, which is described by the distribution coefficient K_d. Two different phases A and B correspond to a coefficient of distribution at a given temperature, which is the value of the constant [18]

$$K_d = \frac{N_A}{N_B},$$

where N_A is the concentration in phase A, and N_B is the concentration in phase B.

In any chromatographic system, there is a fixed (stationary) phase and a mobile phase. The fixed phase can be a solid carrier, gel, liquid, or a mixture of solid and liquid. The mobile phase can be liquid or gaseous and penetrates through the stationary phase after applying the mixture to be separated. In the process of chromatography, substances come into contact with two phases and differences in the coefficient

of distribution of substances lead to separation of the mixture under study. At the moment, there are two basic options for carrying out chromatographic separations: thin-layered and columnar. Let's consider in more detail column chromatography. In this method, the stationary phase is in a metal or glass column. A mixture of substances to be analyzed is applied to the column and we then begin to pass a mobile phase through it, which is called an eluent. This method of column chromatography is most often used for analytical purposes in biochemistry. During the passage of the eluent through the column, the analyzed solutions are separated depending on their distribution coefficients and leave the column as a solution of the eluate. In a thin layer chromatography, a stationary phase on a suitable matrix is covered with a thin layer of glass, metal foil-plastic. The mixture to be separated is applied to the edge of the plate in the form of spots or stripes. Further, in the plate, located in a horizontal or vertical position, the mobile phase begins to act under the action of capillary forces, causing the substances to be analyzed to migrate to the opposite edge of the plate with determined velocity for each substance. The advantage of this method over column chromatography is the ability to analyze several samples at once. In order to improve the separation of the substances to be analyzed, the composition of the mobile phase can be changed, for example by modifying the salt concentration, the pH value, or the polarity. A successful chromatography yields all components of the mixture in their pure form. Let us consider in more detail the methods of analysis in chromatography, depending on the purpose of the experiment. Chromatographic separation of the samples under study is carried out at a qualitative or quantitative level. Qualitative analysis is performed to confirm the presence in the sample of a certain component. Quantitative analysis is carried out for the purpose of finding and confirming the presence in the sample of a certain substance and measuring its quantity. The quantitative analysis is based on determining and measuring the peak area and determining the substance using an appropriate calibration curve. The chromatographic method is suitable for determining the substances and their quantity in the mixture, but this method does not allow us to make any assumptions about the structural organization of the present molecules, about the presence in them of certain domains responsible for binding the protein complex or about the nature of their interaction. It does not reveal the structure of the catalytic active centers of the molecule. It also does not make it possible to calculate the thermodynamic constants of the molecules entering into interactions to draw any conclusions about the stability of biological complexes.

1.3 Mass Spectrometry

Mass spectrometry is a direct method that allows one to directly determine the following physical parameters of the studied substances: the molecular weight, the elemental composition of molecules, their fragments, the relationship between each other and their relative location, and to study the mechanisms of fragmentation [19]. Based on the data obtained during mass spectrometry, correlation dependences are

obtained between the structural characteristics of molecules and ions formed as a result of the decay of molecules upon ionization [20–23]. A mass-spectrometric experiment also studies the processes of energy transfer during the interaction of molecules with electrons ions, the processes of atom rearrangement in the formed ions and the influence of certain functional and structural groups on ionization and fragmentation processes.

1.3.1 Electron Impact

Electron impact is the main and most frequently used ionization method in mass spectrometry. It consists in the following: molecules in a gas phase are bombarded by a beam of electrons emitted by a cathode heated to a high temperature and accelerated to a given energy by a potential difference between the cathode and the anode. The cathode is usually made of tungsten or rhenium wire. The ionization process takes place in a vacuum. For most of the organic molecules studied, the ionization energy is 7–12 eV. The efficiency of ionization increases with increasing energy of ionizing electrons, reaching a maximum at 30–40 eV, then slowly decreases. During the ionization process, under the influence of ionizing electrons, the molecules begin to acquire excess energy, which causes the destruction of the molecular ion $[M]^+$ with the formation of fragmented and rearranged ions characterizing the structure of the substance under study. E-impact mass spectrometry is a compound research method that produces the most reproducible mass spectra of individual compounds. The main contribution to the average relative measurement error is low-intensity peaks of ions, which, as a rule, are not used for structural relationships. The average relative error in the values of the ion peaks recorded on different mass spectrometers under the same mode is approximately 15%. Mass spectrometry electron impact nevertheless has a significant drawback. Thermolabile compounds (mostly natural compounds), high molecular weight substances, organic salts, metal complex compounds and even some classes of organic compounds (hydrocarbons, aliphatic alcohols and amines, etc.) that do not give a peak in the mass spectrometry of electronic shock fall out of the scope of its application as a structural method.

1.3.2 Chemical Ionization

Another method of ionization is chemical ionization with the formation of positive and negative ions (positive and negative chemical ionization) and is based on the flow of ion-molecular reactions in a gas phase. The first mass spectra with chemical ionization of simple substances were obtained by Field and Manson in 1965. At present, this variant of mass spectrometry with chemical ionization has found wide application in the practice of scientific research, and also in analytical chemistry. The method of chemical ionization with the formation of positive ions can increase the

intensity of the peak of the molecular ion as in the case of labile molecules and more clearly trace the main directions of fragmentation. In order to obtain optimal mass spectra from the ratio of the peaks of molecular and fragment ions, it is necessary to select a reagent gas and ionization conditions. The sensitivity of this method with the use of chemical ionization depends on the nature of the substance and the ionization conditions but does not exceed the sensitivity of the method with ionization by electron impact. The advantage of the method of mass spectrometry with negative chemical ionization is very high sensitivity and selectivity to compounds that have a high affinity for the electron, for example, halogen-containing substances. However, in this method, just as in the method of positive chemical ionization, it is necessary to select a reagent gas and ionization conditions. The sensitivity of the method depends on the ionization conditions and on the structure of the molecules. It should be noted that it is not always possible to evaporate many organic substances without decomposition, and therefore, they cannot be ionized by electron impact and chemical ionization. The possibilities of electron and chemical ionization decrease dramatically in the transition from amino acids to peptides due to even lower volatility and increased thermolability of these compounds [24]. Such biological objects include most biological molecules (proteins, DNA, etc.), physiologically active substances, polymers, as well as many highly polar substances. Also, significant disadvantages can be attributed to the relatively large size and high cost of modern mass analyzers.

1.4 X-ray Analysis of Protein Crystals

X-ray analysis is one of the most important experimental methods that allow us to determine with atomic precision the spatial coordinates of all the atoms in the object [25]. After determining the position of each atom, the following parameters of the molecule structure can be calculated: interatomic distances, valence angles, rotation angles around bonds, and surface charge distribution. The data obtained by X-ray diffraction analysis are valuable information for chemists, biochemists, biophysicists and biologists who study the different relationships between the structural characteristics of the biological molecules and their functional properties, as well as for specialists studying the electronic structure of molecules and molecular interactions. Today, the structures of about 15 thousand proteins and their complexes with biologically important molecules are known. The method of X-ray structural analysis is based on the diffraction of X-rays on a crystal lattice, so it can be applied only to substances that are in a crystalline state. If the sample consists of a large number of randomly oriented identical molecules in solution, then the scattering pattern will be determined from the averaged directions, which will to a considerable extent prevent obtaining detailed information on the atomic structure. We note that this method is based on the phenomenon of X-ray diffraction on a three-dimensional crystal lattice. For a successful X-ray examination of the structure of a biological object, it is necessary to use monochromatic X-ray radiation. For this purpose, various filters and monochromators are used. To obtain a diffraction pattern, the object under study

is placed in an X-ray beam and the intensity of the radiation scattered in different directions is measured. The easiest way is to place the beam of the film on the way and judge the intensity of scattering in this direction by the degree of darkening of the spot after the exposition. At the output, a set of intensities of the rays scattered in different directions, or diffraction pattern, is obtained. The next stage is the analysis of the obtained diffraction pattern and obtaining information about the atomic structure of the object under study. One of the drawbacks of the method of X-ray structural analysis in the study of protein structures is that the proteins are in vitro and in vivo in solution, and, when tested, they are subjected to crystallization processes [18]. A logical question arises: is there any fundamental distortion of the structure of protein molecules during crystallization. It is considered that strong distortions don't occur after all. However, as evidenced by a number of experimental studies [26–28] in the field of investigation of various regions of protein binding of the histone chaperone Nap1, the results of the X-ray diffraction analysis are not fully consistent with the results obtained in the study of the thermodynamic properties of the same protein in solution. In particular, the results of the work contain conflicting data on the involvement of the flexible ends of the histone chaperone molecule when it binds to dimers of histone proteins H2A–H2B and H3–H4. The flexible ends of the histone-chaperone molecule, according to X-ray diffraction analysis data, do not interact with dimers of histone proteins, but experiments using targeted site-specific mutagenesis in solution showed that the ends of the histone chaperone can make a synergistic contribution to the interaction with histone dimers. Thus, despite the high accuracy of the X-ray structural method in the study of proteins, it must be supplemented with other physical methods for studying biological objects.

1.5 Methods of Spectral Analysis

Let us analyze the spectral nature of the interaction of electromagnetic radiation with matter. This interaction is of a quantum nature and depends on the radiation property, as well as on the material. The main physical characteristics of electromagnetic radiation are frequency, wavelength, and intensity. Let us consider the interaction of electromagnetic radiation with the energy levels of the substances under study. Electrons in atoms and molecules of the substances under study can be at different energy levels, but in principle, they tend to occupy the level with the lowest energy-the basic level. In order to effect the transition of an electron from a lower to a higher energy level (into an excited state), the system must transmit a certain amount of energy, and if the source of this energy is electromagnetic radiation, then an absorption spectrum appears. The molecule of the irradiated substance absorbs a strictly defined amount of energy, which corresponds to the difference in the energy levels that the electron occupies. In the transition of an atom or a molecule from a higher to a lower energy level, one quantum of energy is emitted, which in turn is accompanied by the appearance of a radiation spectrum. Thus, transitions in atoms and molecules, which are usually observed in the form of absorption spectrum,

emission spectrum or fluorescence spectrum in the ultraviolet or visible parts of the spectrum, are the cause of the appearance of electronic spectra.

1.5.1 Spectroscopy in the Ultraviolet and Visible Range

Consider the general law of light absorption by matter, the Bouguer–Lambert–Baer law. This law is based on two relationships: one of the relationships relates the absorption of light to the concentration of the absorbing substance, and the other relates the length of the light path or the thickness of the layer to the absorbing substances. The ratio of the intensity of the incident and transmitted light is called transmission T: $T = I/I_0$, where I_0 is the intensity of incident light, I is intensity of transmitted light. Note that intensity is the product of the photon energy by the number of photons colliding on a surface unit per time unit. At $T = 100\%$, the substance is absolutely transparent and does not absorb radiation, since the intensity of the incident light is equal to the intensity of the light passing through the substance, and at $T = 0$ the substance is completely opaque and completely absorbs the incident radiation. Substances with intermediate transmission values are characterized by the extinction of E [18]:

$$E = \lg\left[\frac{1}{T}\right] = \lg\left[\frac{I_0}{I}\right].$$

When performing spectrophotometric analysis, it is customary to prepare a series of standard solutions, with the help of which a calibration curve of the dependence of absorption on concentration is constructed [29, 30]. After that, the absorption of the analyzed solution is measured, and its concentration is found from the calibration curve by interpolation. The main advantage of the spectrophotometer is the ability to scan the full wavelength range of the ultraviolet and visible light regions and obtain absorption spectra [18]. These spectra obtained for each substance reflect the dependence of the absorption on the wavelength. Note that the wavelength of the absorbed light is determined by the corresponding electron and therefore specific absorption peaks can be attributed to known molecular fragments. Qualitative analysis in the ultraviolet and visible wavelength ranges allows identification of certain classes of compounds in pure form, as well as in mixtures, for example, proteins, nucleic acids, cytochromes, and chlorophylls. The method serves to identify changes in the chemical structure of compounds. The quantitative analysis is based on the fact that some chromophore groups, such as aromatic amino acids in proteins or heterocyclic bases of the nucleic acids, absorb light at a certain wavelength. Proteins can be analyzed at a wavelength of 280 nm, and nucleic acids-at 260 nm, although in any case, it is necessary to take into account the possibility of the influence of impurities from other substances if they are also present in the solution. To account for this effect, it is customary to measure the absorption of additional impurities at two wavelengths: at the wavelength at which the analyze is absorbed, and at the wavelengths at which it is not absorbed. This method allows one to make an assumption about changing

the structure of biological molecules in their binding and to draw conclusions about the presence or absence of interaction between the selected objects; if one knows in advance about the presence of the active center of the molecule, the method allows one to observe the presence of changes in the structure of this center. The method of spectroscopy in the ultraviolet and visible ranges can find good application in the study of already known biological molecules with a given structure and known catalytic centers. Usually, this method is used in conjunction with other physical methods of biological objects research to confirm or supplement the changes in the previously known absence or presence of interaction between biological objects in the solution, to make assumptions about their nature of binding, which must be supplemented and confirmed by additional physical methods of research [18].

1.6 Spectrofluorimetry

Fluorescence is the phenomenon of light emission by matter, i.e. when a molecule moves from a state with a higher energy level to a state with a lower energy level. This transition is recorded by the intensity of the emitted radiation. In order to carry out such a possibility of transitions from a higher to a lower energy level, it is necessary to excite the molecule by exposure to electromagnetic radiation. In this case, the wavelength of the emitted radiation is larger, and the energy, therefore, is less than the wavelength of the absorbed light. The difference between these two wavelengths is called the Stokes shift, and usually, the best results are obtained with those compounds in which the Stokes shift is greater. The fluorescence spectra provide information on events that occur within a time interval of less than 10^{-8} s. The quantum yield Q is determined by the expression [18]:

$$Q = \frac{Q_1}{Q_2}$$

where $Q_1$is the number of emitted quanta, Q_2 is the number of absorbed quanta. At low substance concentrations, the fluorescence intensity I_f depends on the incident light intensity I_0 [18]:

$$I_f = 2.3 I_0 \varepsilon_\lambda c d Q,$$

where c is the molar concentration of the fluorescent solution, d is length of light path in solution (cm), ε_λ is molar extinction coefficient of material at wavelength λ(dm/(mole·cm). Fluorescence analysis is widely used, despite the fact that only a few molecules are able to fluoresce. If it is necessary to identify the substance, the absorption and fluorescence spectra are compared. To clarify the known structure, an analysis of the effect of pH and solvent composition is performed, as well as fluorescence polarization. If the substance is non-fluorescent, fluorescent labels are attached to its molecules and the radiation of the attached label is monitored. Then, as with the natural fluorescence of proteins, the fluorescence of aromatic groups

in the side chains of amino acid residues is monitored. The label is used for both qualitative and quantitative analysis. The main application of fluorimetry is the quantitative determination of substances whose concentration is too low. Similarly, the fluorometry method is suitable for studying the kinetics of enzymatic processes. Since our work is devoted to the study of the interaction of proteins, we will consider in more detail what allows us to investigate the fluorometry method in this direction. The presence of tryptophan or flavin adenine dinucleotide in the protein amino acid molecule, which takes an active part in many redox biochemical processes as a cofactor, makes it possible to obtain the natural fluorescence of the biological objects under study. Binding and release of cofactors, inhibitors, and substrates near the fluorescent group lead to a change in the fluorescence spectrum, which allows obtaining information about the relative conformation changes, denaturation, and aggregation of molecules. The change in the conformation of the analyzed protein, which occurs when the ligand is bound, is reflected in the nature of the fluorescence. The method of fluorescence due to resonance energy transfer allows determining the localization of metals in metalloproteins, various conformational changes in enzymes and receptors when binding substrates to ligands, and the distance between different pairs of proteins on the ribosome. Thus, the method of spectrofluorimetry makes it possible to obtain accurate results when analyzing samples with very low concentrations. This method is also characterized by high selectivity since the Stokes shift allows the use of two monochromators-one for exciting light, the other for selective light. The disadvantages of the method are its high sensitivity to changes in temperature, pH, and polarity of the solvent; it is also impossible to predict the ability of a particular substance to fluoresce. The main disadvantage is the suppression of fluorescence [18]. The reason for this phenomenon is that the energy that could be released in the form of fluorescence is transmitted to other molecules during a collision.

1.7 Circular Dichroism

Circular dichroism is the effect of optical anisotropy which manifests itself in the difference between the absorption coefficients of light polarized in the right and left circles [31]. This method is based on measuring the angle of rotation of the polarization plane after the polarized light passes through the solution containing the chiral substance. We note that chirality is a property of a molecule that does not coincide in space with its mirror image. A plane polarized light can be represented as a sum of two circularly polarized rays with right and left polarization. Asymmetrical chiral molecules in their nature interact differently with these components, so the rays propagate in the sample at a different speed (they have different refractive indices). As a result, the plane of polarization of the light beam passing through the sample rotates relative to the plane of polarization of the initial beam. In the spectral regions where the substance absorbs light, circular dichroism is observed. The right and left rays are not only refracted in different ways by the chiral substance but are also absorbed to varying degrees. As a result, an initially plane polarized light becomes

elliptically polarized. Since it is difficult to measure the ellipticity, it is therefore measured separately for the absorption of the left and right rays. The CD spectrum represents the dependence of the ellipticity on the wavelength. This spectrum makes it possible to obtain information on the three-dimensional structure of molecules, the relative content of elements of the secondary structure of the protein (alpha helices, beta layers and irregular sequences) in solution, which becomes particularly relevant when studying the effect of denaturing agents or temperature on the three-dimensional structure of selected proteins. This method has proven itself in studies of protein denaturation in which there is a change in alpha and beta-structures in irregular sequences during protein denaturation. However, the application of CD to the analysis of spatial three-dimensional structures of biological molecules is limited due to a lack of understanding of the influence of individual parts of molecules on the formation of this level of structure. In due time, the CD spectra of poly-L-amino acids were obtained, which were used as standards in determining the content of each form of the secondary structure in proteins. For known proteins, the method of approximation of curves was used. An important advantage of the CD method is that it can be used to study the conformation changes of various substances when interacting with other proteins, DNA, and ligands. The drawbacks of the CD method are that it does not allow one to calculate the distance between different paramagnetic proteins or to reveal the structure of the catalytic active sites of the molecule and does not make it possible to calculate the thermodynamic constants of molecules entering into interaction or to draw any conclusions about the stability of biological complexes [18].

1.8 Conclusion

The main objective of this chapter, despite the fact that it is of an overview nature and contains a number of known facts, is to consider various experimental approaches associated with the study of the structure of molecules, the mutual arrangement of domains in space, and the detection of active protein centers: electrophoresis methods, chromatographic analysis methods, mass spectrometry, X-ray crystal analysis of proteins, spectral analysis methods, and circular dichroism. Their advantages and disadvantages are listed. It should be noted that most of the presented experimental approaches have significant limitations in the study of various physical properties of biological complexes. To study the whole variety of physical characteristics of protein complexes, it is necessary to combine a large number of different experimental approaches, each of which makes it possible to determine a narrow list of desired physical parameters. We also note that most of the biochemical reactions with the given chemical elements must be verified experimentally, which is a fairly labor-consuming and expensive method, requiring a large amount of time for its conduct. The above limitations, which involve the study of the physical characteristics of biological structures, require the development of a new mathematical approach that would allow:

- to theoretically predict the passage of a biochemical reaction in the chosen direction with given amino acid (a.a.) sequences;
- to study the behavior of dimers in vitro in solutions with different concentrations of monovalent salt for the production of nucleosome histone nucleus, to investigate the influence of temperature on the stability of protein dimers H2A–H2B H3–H4, some sections of amino acid sequences of the input solution, taking into account the contribution of hydrophobic amino acid residues in the formation of the structure of dimers;
- to determine the regions of protein molecules responsible for the aggregation of proteins in aqueous solution under different temperature regimes from 20–40 °C;
- to study the effect of phosphorylation of amino acid residues of polypeptide chain on the formation of biological complexes on the example of phosphorylated flexible n-end protein p53 for two amino acid residues;
- to determine the location of active protein sites and to detects the stability of different protein sites by analyzing the potential energy-electrostatic interaction matrix between different sites of the microbiological complex, such as histone chaperone Nap1-sNap1, protein heterodimer p53-Mdm2 and Mdm2-Mdm2 homodimer, which are responsible for the entry of an entire protein molecule into biochemical reactions;
- to study the effect of point mutations in BH3 peptides on the stability of the formed or biological complex with pro-apoptotic proteins of the Bcl-2 family, as well as the qualitative determination of the dissociation constant for binding different BH3 peptides to Bcl-2 and Bcl-xl proteins.

Chapter 2
Mathematical Simulation of Complex Formation of Protein Molecules Allowing for Their Domain Structure

Abstract This chapter we construct a physical model of the interactions between protein molecules and study of their propensity to form biological complexes. The reactivities of proteins have been studied using electrostatics methods based on the example of histones H2A, H2B, H3, H4. The capability of proteins to form stable biological complexes that allow for different segments of amino acid sequences has been analyzed. The ability of protein molecules to form compounds has been considered by calculating matrices of electrostatic potential energy of amino acid residues constituting the polypeptide chain. The method of matrices has been used in the analysis of the ability of protein molecules to form complex biological compounds.

2.1 Introduction

The present chapter is dedicated to developing a mathematical model that will be able to theoretically predict a biochemical reaction that occurs in a chosen direction that involves given proteins with known amino acid sequences. There are a number of papers that should be noted in which different amino acid sequences of the chosen proteins have been analyzed.

In [1] hydrogen–deuterium exchange in combination with mass-spectrometry was used to reveal binding sites of the H2A–H2B dimer with Nap1. Authors identify the interaction surface between H2A–H2B and Nap1, and confirm its relevance both in vitro and in vivo.

In [2] investigated contacts between histones H2A, H2B, H3 and H4 in the nucleosome. The authors used the experimental structures chromosome containing histones and calculated the number of contacts between different histones.

In this work the number of contacts between histone intrudes in the nucleosome was found that the H2A–H2B and H3–H4 heterodimers have the greatest number of contacts between pairs of heterodimers.

T. Koshlan and K. Kulikov, *Mathematical Modeling of Protein Complexes*,
Biological and Medical Physics, Biomedical Engineering,
https://doi.org/10.1007/978-3-319-98304-2_2

A quantitative method for studying the affinity of Nap1 to histones was developed in [3] The binding affinity between Nap1 and H2A–H2B was found to be on the nanomolar level. It was noted that each Nap1 dimer binds two H2A–H2B dimers; the termini of the Nap1 molecule were shown to give a synergetic contribution to binding with histones.

No clear criteria were given in the mentioned papers, which should allow one to determine the reactivities of different protein domains that are responsible for the participation of whole molecules in various biochemical reactions. Thus, the present work aims at developing a mathematical model that should facilitate the processing of existing experimental data, predict theoretically a biochemical reaction passing in a chosen direction involving given amino acid sequences, and reveal protein sites responsible for interactions between different protein molecules, which actually determines the importance of the task. The work consists of several parts. In the first section, basic principles of the nucleosome formation are given, the principles of the formation of histone heterodimers H2A–H2B and H3–H4. The second part is dedicated to developing a physical model of interactions between proteins with the formation of biological complexes based on electrostatic interactions of protein molecules allowing for their amino acid sequences. Biological systems are considered in detail in the third part, including the formation of H2A–H2B and H3–H4 heterodimers; the results of interaction simulations in the chosen biological systems are presented. All calculations were conducted in order to allow different amino acid sequences to participate in the studied protein reactions.

The developed algorithms allow to determine the interaction of different domains of proteins or whole proteins.

2.2 General Principles of the Formation of Biological Complexes

Consider general principles of biological complex formation in regard to our research. We will analyze protein interactions H2A, H2B, H3, H4 which actively participate in the nucleosome formation process. Chromatin assembly is a stepwise process that starts with the association of a tetramer of histone $(H3–H4)_2$ with the DNA, followed by the incorporation of two H2A–H2B dimers to form the nucleosome [4, 5].

The nucleosome assembly process is facilitated by several partially redundant pathways and is aided by histone chaperone proteins, such as nucleoplasmin, antisilencing factor 1 (Asf1), histone regulator (HIR), chromatin assembly factor 1 (CAF-1), and nucleosome assembly protein 1 (Nap1) [6, 7].

Fig. 2.1 Three-dimensional structure of histone H2A with indication of the N–terminus and C–terminus of the amino acid sequence [8]

2.2.1 Formation of Heterodimers (H3–H4) and (H2A–H2B)

Histones H2A, H2B, H3 and H4 are the basic proteins [7], which form dimers, the structure of which is called ≪handshake≫ in this structure, the formation of dimers H2A–H2B or H3–H4 occurs in opposite directions of each histone [5].

In Fig. 2.1 scheme of the H2A protein showing the N-tail and the C-tail of the protein is presented. In this chapter, we analyze different protein sequences and allow for their domain structure to determine possible compound formations (H2A–H2B), (H3–H4). Note that domains arise due to combination, alternation, and α-helices and β-sheets, between which less dense structure appear [9].

Amino acid sequences of histone proteins H2A, H2B, H3, H4, as well as their secondary structures were taken from [10]; entry numbers for proteins were P04911, A6ZKU6, P61830, P02309 respectively. In this chapter we have investigated yeast proteins.

2.3 Description of the Physical Model

Earlier experiments [11] revealed that the interaction of protein molecules is determined by the potential energy of the electrostatic interaction. For this reason, this study is devoted to a theoretical analysis of the electrostatic interactions between protein molecules.

Let us describe a physical model of the electrostatic interaction between the amino acid sequences of different proteins.

Each amino acid is represented as a uniformly charged sphere with its own radius value. The protein is represented as a free-articulated polyamino acid sequence [12].

When studying the interaction of charged protein molecules, a number of approximations were used:

1. the energy of protein interaction is determined only by the forces of electrostatic interaction;

2. a protein molecule is modeled as interconnected amino acid residues;

3. each amino acid residue of the protein is represented as a uniformly charged sphere.

The sphere radius size of each amino acid residue was taken from the work [13]:

$$R_A = 0.6\,\text{nm}, R_R = 0.809\,\text{nm}, R_N = 0.682\,\text{nm}, R_D = 0.665\,\text{nm}, R_C = 0.629\,\text{nm},$$

$$R_Q = 0.725\,\text{nm}, R_E = 0.714\,\text{nm}, R_G = 0.537\,\text{nm}, R_H = 0.732\,\text{nm}, R_I = 0.735\,\text{nm},$$

$$R_L = 0.734\,\text{nm}, R_K = 0.737\,\text{nm}, R_M = 0.741\,\text{nm}, R_F = 0.781\,\text{nm}, R_P = 0.672\,\text{nm},$$

$$R_S = 0.615\,\text{nm}, R_T = 0.659\,\text{nm}, R_W = 0.826\,\text{nm}, R_Y = 0.781\,\text{nm}, R_V = 0.654\,\text{nm}.$$

Note that the ability of molecules to interact with different amino acid residues strongly depends on their environment, which is due to their polar and non-polar parts.

Since in this chapter we are considering the problem of electrostatic interaction between histones, we make the following assumption: we divide interactions between 20 amino acid residues into 10 classes from $0.05e$ to $1e$ in accordance with [14].

Thus, we assign to the amino acid residues a charge that is less than or equal to the charge of the electron. Note that the square of the modulus of the wave function, which describes the state of an electron in a multi-center model, determines the probability density of an electron or the density of an electron cloud, which characterizes the unequal probability of finding an electron in a selected part of the volume of an electron cloud in a polyatomic amino acid residue. It follows that the redistribution of electron charges in polyatomic amino acid residues may well lead to the fact that the probability of finding a valence electron in the neighborhood of the residue is less than one, and the average value of the charge of the residue is less than the charge of the electron.

The distances between the two interacting amino acid residues of neighboring proteins were determined from the following assumptions [15, 16]:

1. the distance between the oppositely charged amino acid residues was 0.15 nm;

2. between like-charged ones, the distance was 0.4 nm;

3. The distance between the amino acid residues that form, presumably, one hydrogen bond was 0.35 nm;

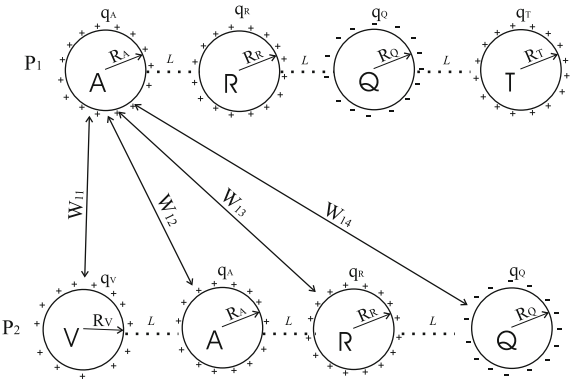

Fig. 2.2 Schema of the interaction of amino acid residues of two interacting proteins P_1 and P_2. Each amino acid is represented as a uniformly charged sphere of a given diameter

4. The distance between amino acid residues, which, presumably, can form more than one hydrogen bond, was set to 0.25 nm.

Below we have considered the problem of modelling the processes of electrostatic interaction of the formation of dimers from the complete amino acid sequences of selected proteins within the framework of the classical electrostatic theory (Fig. 2.2).

2.4 The Problem of the Electrostatic Interaction of Two Conducting Spheres

Let there be two conducting spheres with radii R_1, R_2 and charges Q_1 and Q_2, located at a distance L between the centers. Then, following the works [17–20] we can write the expression for the potential energy of the electrostatic interaction of the spheres between their centers:

$$W_q = \left[\frac{1+\gamma}{2\alpha}\right] \frac{\alpha^2 c_{11} - 2\alpha c_{12} + c_{22}}{c_{11}c_{22} - c_{12}^2}, \tag{2.1}$$

where Q_1 Q_2 are the charges of the first and second spheres, $\gamma = R_2/R_1$,$\alpha = Q_2/Q_1$, c_{11}, c_{12}, c_{22} are the capacitive coefficients [20]:

$$c_{11} = 4\pi\varepsilon_0\varepsilon R_1\gamma \sinh(\beta) \sum_{n=1}^{\infty} \left[\gamma \sinh(n\beta) + \sinh[(n-1)\beta)]\right]^{-1}, \tag{2.2}$$

$$c_{22} = 4\pi\varepsilon_0\varepsilon R_1\gamma \sinh(\beta) \sum_{n=1}^{\infty} \left[\sinh(n\beta) + \gamma \sinh[(n-1)\beta)]\right]^{-1}, \tag{2.3}$$

$$c_{12} = -4\pi\varepsilon_0\varepsilon R_1\gamma\frac{\sinh(\beta)}{(1+\gamma)h}\sum_{n=1}^{\infty}[\sinh(n\beta)]^{-1}, \tag{2.4}$$

where ε is the dielectric constant of the medium, ε_0 is the dielectric constant. In this case, $(R_1 + R_2)$ is chosen as a unit length, so that h is the dimensionless distance between the centers of the spheres, which is defined as $h = L/(R_1 + R_2)$, and β is associated with the distance between the centers of the spheres as follows [17–20]:

$$h = l/(R_1 + R_2)$$

The parameter β associated with the distance between the centers of the balls as follows [17–19]:

$$\cosh(\beta) = \frac{h^2(1+\gamma)^2 - (1+\gamma^2)}{2\gamma} \tag{2.5}$$

Note that the capacitive coefficients (2.2)–(2.4) are defined in units of R_1/k, $k = 1/4\pi\varepsilon_0$. Then, as the unit of energy measurement, we choose the value $kQ_1Q_2/(R_1 + R_2)$, in this case for the dimensionless energy of the electrostatic interaction of the spheres and, respectively, for the capacitive coefficients c_{11}, c_{12}, c_{22}, we obtain the following expressions:

$$\widetilde{W}_q = \left[\frac{1+\gamma}{2\alpha}\right]\frac{\alpha^2 c_{11} - 2\alpha c_{12} + c_{22}}{c_{11}c_{22} - c_{12}^2}, \tag{2.6}$$

$$c_{11} = \varepsilon\gamma\sinh(\beta)\sum_{n=1}^{\infty}\left[\gamma\sinh(n\beta) + \sinh[(n-1)\beta)]\right]^{-1}, \tag{2.7}$$

$$c_{22} = \varepsilon\gamma\sinh(\beta)\sum_{n=1}^{\infty}\left[\sinh(n\beta) + \gamma\sinh[(n-1)\beta)]\right]^{-1}, \tag{2.8}$$

$$c_{12} = -\varepsilon\gamma\frac{\sinh(\beta)}{(1+\gamma)h}\sum_{n=1}^{\infty}[\sinh(n\beta)]^{-1}. \tag{2.9}$$

We perform the following transformations for expressions (2.7)–(2.9). We introduce the variable $z = \exp(-\beta)$, then we obtain the following expressions:

$$c_{11} = 2\varepsilon\gamma\sqrt{\cosh(\beta)^2 - 1}\times$$

$$\times\sum_{n=1}^{\infty}\frac{z^n}{(1-z^{2n})[(\gamma+\cosh(\beta)) - \sqrt{\cosh(\beta)^2-1}(1+z^{2n})/(1-z^{2n})]},$$

$$c_{22} = 2\varepsilon\gamma\sqrt{\cosh(\beta)^2 - 1}\times$$

Fig. 2.3 Representation of the potential energy matrix of the electrostatic interaction $W_{i,j}$, $i = \overline{1,4}$, $j = \overline{1,4}$ of two proteins P_1 P_2

	A	R	Q	T
V	W_{11}	W_{12}	W_{13}	W_{14}
A	W_{21}	W_{22}	W_{23}	W_{24}
R	W_{31}	W_{32}	W_{33}	W_{34}
Q	W_{41}	W_{42}	W_{43}	W_{44}

$$\times \sum_{n=1}^{\infty} \frac{z^n}{(1-z^{2n})[(1-\gamma\cdot\cosh(\beta)) - \gamma\cdot\sqrt{\cosh(\beta)^2-1}(1+z^{2n})/(1-z^{2n})]},$$

$$c_{11} = -\varepsilon \frac{2\gamma\sqrt{\cosh(\beta)^2-1}}{h(1+\gamma)} \sum_{n=1}^{\infty}[(z^{2n})/(1-z^{2n})],$$

where $\cosh(\beta)$ is defined by the expression (2.5).

The resulting values of the potential energy of electrostatic interaction between the corresponding amino acid residues, which we represent as charged spheres, are written into the matrix (see Fig. 2.3).

In our model, we will assume that each amino acid residue of one protein molecule can interact with any other amino acid residue of another protein.

To analyze the biochemical processes we use the notion of condition number $\mathrm{cond}(W_0)$ of the matrix W_0: In order to analyze the relation between biochemical processes with histones, we use the condition number ($\mathrm{cond}(W_0)$) concept, which measures the degree of biochemical structures stability given the physical conditions.

$$\mathrm{cond}(W_0) = ||W_0|| \cdot ||W_0^{-1}||.$$

where $||W_0||$ is the norm of the matrix of the potential energy of the pair electrostatic interaction between peptides. For the calculation of the condition number we use the singular value decomposition (SVD) [21]. Then we have the following expression:

$$\mathrm{cond}(W_0) = \frac{\sigma_{\max}(W_0)}{\sigma_{\min}(W_0)}, \tag{2.10}$$

where $\sigma_{\max}(W_0)$, $\sigma_{\min}(W_0)$ are largest and smallest singular values of the potential energy matrix of pairwise electrostatic interaction between amino acid protein sequences.

In this physical formulation of the problem, it will characterize the degree of stability of the configuration of the biological complex. In order to choose a more stable biochemical compound between proteins, we select the matrix of potential energy of electrostatic interaction with the **smallest** value of the condition number.

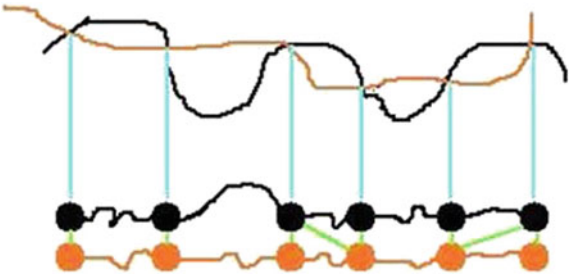

Fig. 2.4 A system modeling the formation of a biocomplex

2.5 Physical Interpretation of Condition Number

Consider the biological complex (see Fig. 2.4).

It can be represented as a polyatomic molecule. In this case, we assume that the chains themselves (black and red) under the external conditions under consideration are stable, having elastic, but strong links between the elements of each individual chain with high discontinuity energies. The newly formed links between individual elements of different chains will be considered less stable (green), i.e. their bond-dissociation energy is lower. Then we can consider the resulting formation (bio-complex) as a kind of quasi-molecule, consisting of bound undeformed amino acid residues (hereinafter called ≪fragments≫). Under external influence, i.e. upon impact with its ≪neighbors≫, a molecule receives energy of the order of kT(k is Boltzmann constant). In this case, vibrations develop in the molecule and a change in its structure (bond dissociation) can occur. But it is not a fact that the weakest bond will break: in a molecule, it can be connected with a strong one.

The wave function describing the entire quasi-molecule in the general case depends on the $3N$ variables of the geometric coordinates of each fragment. Since 6 of them describe the translational and rotational motion of a quasi-molecule as a whole, the wave function describing the oscillations inside the quasi-molecule $\Psi^{vib}(q)$ itself will depend on the $3N-6$ coordinates: $q = (q_1, q_2, \ldots, q_{3N-6})$, $q_i \equiv (x_i, y_i, z_i)$.

The Schrodinger equation for $\Psi^{vib}(q)$

$$\left[-\frac{\hbar}{2}\sum_{i,j}^{3N-6} a_{ij}\frac{\partial^2}{\partial q_i \partial q_j} + W(q)\right]\Psi^{vib}(q) = E^{vib}\Psi^{vib}(q),$$

where $W(q)$ is the coordinate dependence of the interaction potential between the fragments. The coefficients a_{ij}, generally speaking, depend on the coordinates, but for small oscillation amplitudes (quasi-harmonic oscillations) they can be assumed to be constant. We set the oscillation amplitudes to small and expand $W(q)$ in a neighborhood of the equilibrium coordinate q_0 in the Taylor series:

$$W(q) = W(q_0) + \frac{1}{2}\sum_{i,j}^{3N-6} \left.\frac{\partial^2 W(q)}{\partial q_i \partial q_j}\right|_{q_0} (q_i - q_i^{(0)})(q_j - q_j^{(0)}) + \cdots$$

First, let's move the coordinate to the point $q_0 = q_1^{(0)}, q_2^{(0)}, \ldots$, and the energy will be evaluated from its minimum value, i.e. from $W(q_0) = W(q_1^{(0)}, q_2^{(0)}, \ldots,)$.

$$W(q) = \frac{1}{2}\sum_{i,j}^{3N-6} \left.\frac{\partial^2 W(q)}{\partial q_i \partial q_j}\right|_{q_0} q_i q_j + \cdots \tag{2.11}$$

For small oscillations (2.11) is represented by the quadratic form

$$W(q) = \frac{1}{2}\sum_{i,j}^{3N-6} k_{ij} q_i q_j,$$

where

$$k_{ij} \equiv \left.\frac{\partial^2 W(q)}{\partial q_i \partial q_j}\right|_{q_0}$$

are power constants of bonds. They form a symmetric square matrix $K = (k_{ij})$. If this matrix is nondegenerate, then it is always possible to perform such an orthogonal coordinate transformation that only the diagonal elements in the new coordinates Q_i will be non-zero. In such coordinates, called normal, we get (for small oscillations).

$$W(Q) = \frac{1}{2}\sum_{i=1}^{3N-6} \widetilde{k}_i Q_i^2, \tag{2.12}$$

where

$$\widetilde{k}_i = \left.\frac{\partial^2 W(Q)}{\partial Q_i^2}\right|_{Q_0}$$

are power constants (hereinafter - PC) of the ith mode of the normal oscillation form the diagonal matrix $\widetilde{K}$. The observed lines of vibrational transitions in molecules correspond precisely to mode (and not interconnected) oscillations. We emphasize that the $\widetilde{k}_i$ do not coincide with the PC of the links between the fragments (forming the complete matrix K), but are elements of the diagonal matrix of the PC oscillation modes $\widetilde{K}$. Mathematically, the values of $\widetilde{k}_i$ are the roots of the characteristic polynomial, i.e. the eigenvalues of the matrix K. Since all $\widetilde{k}_i$ are positive, the matrix K is positive-definite and, moreover, square and symmetric. Hence it can be represented as $K = A^T A$, where A is a nondegenerate matrix [22, 23]. For matrices of this form, the eigenvalues coincide with its singular numbers [22, 23]; the latter can be found by performing a singular expansion of the matrix K.

After the transition to normal coordinates, the Schrodinger equation for small oscillations looks like as

$$\left[\sum_{i=1}^{3N-6}\left[-\frac{\hbar}{2\mu_i}\frac{\partial^2}{\partial Q_i^2}+\frac{1}{2}\widetilde{k}_i Q_i^2\right]\right]\Psi^{vib}(Q)=E^{vib}\Psi^{vib}(Q), \tag{2.13}$$

where μ_i are the values called reduced masses and are inverse to the diagonal elements of the matrix $\widetilde{A}$, into which the matrix a_{ij} passed after the coordinate transformation. Note that (2.13) makes it possible to represent the wave function $\Psi^{vib}(Q)$ as the product of individual wave functions for each ith mode

$$\Psi^{vib}(Q)=\Psi^{vib}(Q_1)\cdot\Psi^{vib}(Q_2)\cdot\Psi^{vib}(Q_3)\cdot\ldots\cdot\Psi^{vib}(Q_{3N-6}),$$

which depends on one variable Q_i. Then

$$\left[-\frac{\hbar}{2\mu_i}\frac{\partial^2}{\partial Q_i^2}+\frac{1}{2}\widetilde{k}_i Q_i^2\right]\Psi^{vib}(Q_i)=E_i^{vib}\Psi^{vib}(Q_i),\ i=1,2,\ldots,3N-6, \tag{2.14}$$

$$E_i^{vib}=\hbar\sqrt{\frac{\widetilde{k}_i}{\mu_i}}(n_i+1/2),\ n_i=1,2,\ldots \tag{2.15}$$

where E_i^{vib} are the values of the energies of (small) oscillations of the ith mode.

$$E_i^{vib}=\hbar\sum_{i=1}^{3N-6}\left[\sqrt{\frac{\widetilde{k}_i}{\mu_i}}(n_i+1/2)\right],\ n_i=1,2,\ldots \tag{2.16}$$

The expression (2.16) is the total energy of oscillations of the quasimolecule.

We associate the PC of the $\widetilde{k}_i$ with the parameters of the quasimolecular potential. We note that the Schredinger equation (2.14) for each of the modes is similar to that for a diatomic molecule. The Morse potential is a very successful and frequently used approximation for the interaction potential of atoms of diatomic molecules, which provides a good accuracy of the potential curves of real molecules. Therefore, we assume that the interaction potential for any ith mode of oscillations is described by the Morse potential (see Fig. 2.5):

$$W(Q_i)=W_i^0\left[1-e^{-\alpha_i(Q_i-Q_0)}\right]^2,$$

where W_i^0 is the stationary potential energy of the ith mode, which is equal to the dissociation energy of the ith mode, Q_0 is the equilibrium of the coordinate. For small values of Q_i-Q_0 we expand the expression $e^{-\alpha_i(Q_i-Q_0)}$ in a Taylor series near $Q_i=Q_0$ we get

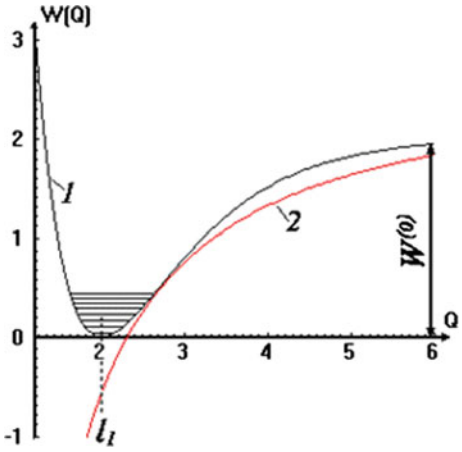

Fig. 2.5 Curves of the potential binding energy between the fragments biological complex: 1 is Morse potential, 2 is Coulomb potential

$$W(Q_i) \approx W_i^0[1 - [1 - \alpha_i(Q_i - Q_0)]]^2 = W_i^0\alpha_i^2[Q_i - Q_0]^2. \tag{2.17}$$

It follows that the expression (2.17) is a quadratic function of $(Q_i - Q_0)$, which coincides with the expression for the potential energy of a harmonic oscillator

$$W(Q_i) = \frac{1}{2}\widetilde{k}_i(Q_i - Q_0)^2.$$

Then

$$\frac{1}{2}\widetilde{k}_i(Q_i - Q_0)^2 = W_i^0\alpha_i^2(Q_i - Q_0)^2. \tag{2.18}$$

$$\widetilde{k}_i = 2W_i^0\alpha_i^2, \tag{2.19}$$

where $\widetilde{k}_i$ are PC of the ith mode.

Substitute (2.19) into the expression (2.16):

$$E_i^{vib} = \hbar \sum_{i=1}^{3N-6} \left[\sqrt{\alpha_i \frac{2W_i^0}{\mu_i}}(n_i + 1/2) \right], n_i = 1, 2, \ldots \tag{2.20}$$

To estimate the coefficients α_i, we represent the relationship between the constituent elements of an effective (in the sense of (2.14)) linear harmonic oscillator of an individual mode in the form of an attractive force F working against the repulsive force. The latter can be represented as a spring that is compressed by the force F and has a force constant of k (see Fig. 2.6). Due to its electrostatic nature, the force F will be determined as

$$F = \frac{|q_1 q_2|}{\kappa l_1^2}$$

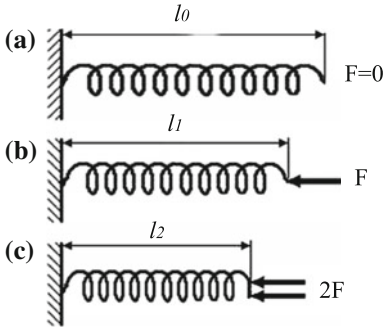

Fig. 2.6 Model of the forces and potential energies near the minimum of the potential curve

in absolute value, where $\kappa = 4\pi\varepsilon\varepsilon_0$, the l_0 is length of the uncompressed spring without affecting the compressive force (see Fig. 2.6).

In the equilibrium position, the values of the attractive and repulsive forces must be equal, i.e. $F = k(l_0 - l_1)$, and $2F = k(l_0 - l_2)$. Let $\Delta l = l_2 - l_1$, then we get

$$F = k\Delta l, \tag{2.21}$$

and also that

$$\Delta l = l_0 - l_1, \tag{2.22}$$

In equilibrium (see Fig. 2.6b) under the action of the force F, the expression (2.21) taking into account (2.22) will be rewritten as

$$\frac{|q_1 q_2|}{\kappa l_1^2} = k(l_0 - l_1) = k\Delta l, \tag{2.23}$$

taking into account (2.22) we get

$$W^0 = \frac{|q_1 q_2|}{\kappa l_1} - \frac{k\Delta l^2}{2},$$

Then

$$\frac{|q_1 q_2|}{\kappa l_1^2} = \frac{W^0}{l_1} + \frac{k\Delta l^2}{2l_1}.$$

Taking into account the expression (2.23), we get

$$k\Delta l = \frac{W^0}{l_1} + \frac{k\Delta l^2}{2l_1} \Rightarrow W^0 = k\Delta l\left[l_1 - \frac{\Delta l}{2}\right].$$

Taking into account the expression (2.19), we get

$$\alpha^2 = \frac{1}{\Delta l(2l_1 - \Delta l)}. \tag{2.24}$$

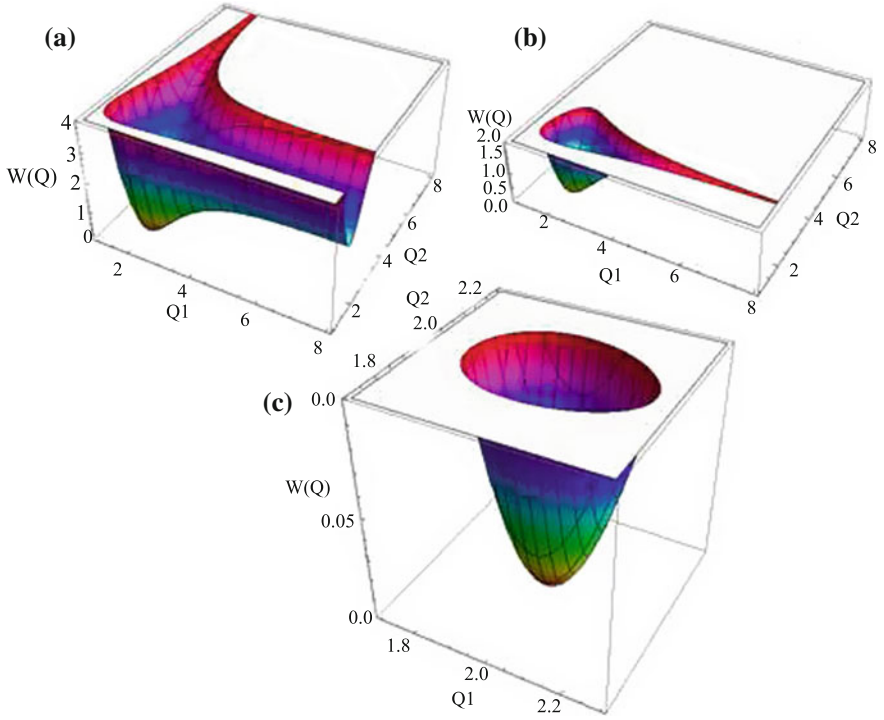

Fig. 2.7 Surface of the potential energy of the oscillator modes described by the two-dimensional Morse potential at ($W^0_{max}/W^0_{min} \approx 2$) and clipped at the top: **a**—at the level of greater dissociation energy, **b**—at the level of lower dissociation energy, with—at the level of applicability of the linear harmonic oscillator approximation

As is known from the literature, the bond lengths (both single l_1 and double l_2) between fragments in different biomolecules depend only slightly on the composition of the fragments [24]. In the first approximation, they can be made constant. Then, in accordance with (2.24), one can assume the practical constancy of the coefficients α.

For the thermodynamic equilibrium state in question, the most probable value of the quasimolecule vibration energy is kT (k is Boltzmann constant). Figure 2.7 shows the potential energy surface (PES) $W(Q)$ for the two-dimensional Morse potential. Consider the sections of the PES with the plane $w_t = kT$. Note that a real multidimensional case should be understood as ≪hyperplane≫.

If W_T exceeds or equals W_i^0 (the stationary potential energy of the ith mode) corresponding to the lowest horizontal asymptote of the potential energy surface, then the mode bond is severed, and the conformation of the quasimolecule breaks (see the Fig. 2.7b).

If $W_T \ll W_i^0$, then the PPE section of plane $W_T = kT$ will be an ellipse (hyperellipsoid) in the coordinates Q (see Fig. 2.7c). This hyperellipsoid will be the most extended along the direction Q_i corresponding to the ith oscillation mode, which has the lowest binding energy W_i^0.

The equation of this hyperellipsoid in accordance with (2.17) appears in an implicit form as

$$\sum_{i=1}^{3N-6} W_i^0 \alpha_i^2 (Q_i - Q_0)^2 - W_T = 0. \tag{2.25}$$

Thus, the strong elongation of the hyperellipsoid in some direction Q_i very likely means a greater tendency of the bio-complex to break the conformation in the sense of breaking the connection for the ith mode of oscillations (the weakest coupling is torn, and the weakest mode is torn). Therefore, the ratio of the maximum and minimum lengths of the axes of this hyperellipsoid

$$\left.\frac{\max(Q_i - Q_0)}{\min(Q_i - Q_0)}\right|_{W(Q_i - Q_0) = W_T}$$

equals

$$\sqrt{\frac{\max(\widetilde{k_i})}{\min(\widetilde{k_i})}} = \sqrt{\frac{\max(W_i^0 \alpha_i^2)}{\min(W_i^0 \alpha_i^2)}}$$

can serve as a qualitative indicator of the stability of the bio-complex (the greater this value, the worse the stability). Similarly, the stability indicator can be the ratio

$$\frac{\max(\widetilde{k_i})}{\min(\widetilde{k_i})}.$$

For the matrix $K = (k_{ij})$, which has the above properties, the condition number cond(K) coincides with the ratio of its maximal and minimal eigenvalues, i.e. the ratio of the maximal and minimal elements of the matrix $\widetilde{K}$:

$$\mathrm{cond(K)} = \frac{\max(\widetilde{k_i})}{\min(\widetilde{k_i})}$$

The PC of the ith mode is proportional to W_i^0 (the stationary potential binding energy of the mode). Assuming that the coefficients α_i, as shown above, depend weakly on i, we get

$$\frac{\max(\widetilde{k_i})}{\min(\widetilde{k_i})} = \frac{\max(W_i^0)}{\min(W_i^0)}$$

The last relation coincides with cond($\mathrm{W_0}$), where $(\mathrm{W_0}) = (\mathrm{W_{ij}})$ is the matrix of stationary potential binding energies between the fragments of the bio-complex (it is also symmetric and positive-definite).

So, the criterion for the stability of a biocomplex can be the value cond(W_0), where $\mathrm{W_0} = (\mathrm{W_{ij}})-$ is the matrix of stationary potential binding energies between fragments of the biocomplex.

2.6 Numerical Simulation of Interaction of Biological Systems. Conclusion

We simulated interactions of various sites of amino acid sequences that comprise secondary structures of different protein domains and analyzed the possibility of domain formation by different sites of the amino acid sequences as follows:

$$(1)\mathrm{H2A} + \mathrm{H2B} \rightarrow (\mathrm{H2A} - \mathrm{H2B}),$$

$$(2)\mathrm{H3} + \mathrm{H4} \rightarrow (\mathrm{H3} - \mathrm{H4}).$$

2.6.1 Heterodimer Formation H2A–H2B

We stimulated an interaction of histone proteins as they binded into the (H2A–H2B) dimer.

We used different sites of the proteins H2A and H2B and analyzed their ability to form stable biological complexes. Note that the (H2A–H2B) dimer is formed by ≪head-to-tail≫ joining of two histones into a ≪handshake≫ motif Fig. (2.8a) [5, 25].

Thus, interaction between different domains of the H2A and H2B proteins was calculated by analyzing the electrostatic interaction potential energy with allowance for the fact that, in the dimer, they are bound in the ≪head-to-tail≫ orientation.

To solve this problem, various segments of the amino acid sequences were taken and the analysis of conditioning numbers for the matrix of electrostatic interaction was performed. Each in the matrix is the matrix of potential energy of electrostatic interaction between two corresponding proteins: $\mathrm{H2A}_{(19-56)}$–$\mathrm{H2B}_{(91-124)}$, $\mathrm{H2A}_{(89-114)}$–$\mathrm{H2B}_{(31-57)}$, $\mathrm{H2A}_{(19-56)}$–$\mathrm{H2B}_{(31-57)}$ and $\mathrm{H2A}_{(89-114)}$–$\mathrm{H2B}_{(91-124)}$.

We considered central parts of the chains.

Tables 2.1 and 2.2 presents the calculation results for different domains of H2A and H2B proteins that allow for two analyzed binding patterns of the proteins to the dimer: ≪head-to-tail≫ and ≪head-to-head≫.

Figure 2.9a, b show the schemes of histone proteins H2A and H2B, sites areas of the amino acid chain, between which the interaction for two cases of formation

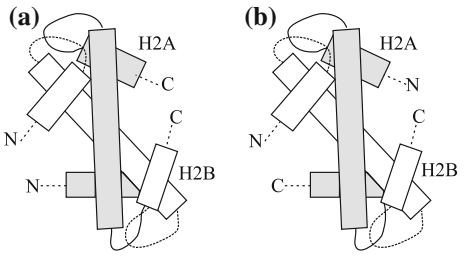

Fig. 2.8 Schematic representation of (H2A–H2B) dimer formation in the case of **a** the ≪tail-to-head≫ and **b** ≪head-to-head≫ structures. The polypeptide chain numbering is from the N-terminus to the C-terminus

4	$H2B_{(91-124)}$	STISAREIQTAVRLILPGELAKHAVSEGTRAVTK	17.880

lg(cond(W)) is common logarithm of condition number.

of heterodimers: ≪head-to-tail≫ (a) and ≪head-to-head≫ (b). The numbers in the rectangular boxes indicate the common logarithm of the conditioning number for the selected pair of amino acid sequences. The values of the lg(cond(W)) for model of histone binding in the dimer ≪head-to-tail≫ for amino acid sections $H2A_{(19-56)}$–$H2B_{(91-124)}$ and $H2A_{(89-114)}$–$H2B_{(31-57)}$ are 18.416 and 18.611, respectively. The values of the conditioning numbers for the second model of formation of the heterodimer ≪head-to-head≫ with the participation of sections $H2A_{(19-56)}$–$H2B_{(31-57)}$ and $H2A_{(89-114)}$–$H2B_{(91-124)}$ are 31.685 and 17.880 respectively.

A significant increase in the value of lg(cond(W)) for the site $H2A_{(18-56)}$–$H2B_{(31-57)}$ indicates a very small degree of stability of the configuration of the biological complex, which is formed by two histone proteins $H2A_{(18-56)}$–$H2B_{(31-57)}$.

Thus, the model of the formation of the histone dimer ≪head -to-head≫ with the participation of amino acid sequences $H2A_{(18-56)}$–$H2B_{(31-57)}$ and $H2A_{(89-114)}$–$H2B_{(91-124)}$ has a smaller number of stable configurations of interacting amino acid residues in comparison with the ≪head-to-tail≫ model. One stable biological segment in the ≪head-to-head≫ model can not provide the formation of a ≪head-to-head≫ complex.

Results of the performed calculations for amino acid sequences of the histones $H2A_{(18-56)}$, $H2B_{(91-124)}$, $H2A_{(89-114)}$, $H2B_{(31-57)}$ indicate, that histones are more inclined to form heterodimers in the direction of ≪head-to-tail≫, than ≪head-to-head≫.

Thus, with the participation of selected amino acid sequences of different sections of histone proteins H2A and H2B, we can conclude that the formation of a heterodimer in the direction of ≪head-to-tail≫ is more preferable in comparison with the direction of ≪head-to-head≫, since the formation of a heterodimer according to the first model (≪head-to-tail≫) is performed by two interacting proteins regions $H2A_{(19-56)}$–$H2B_{(91-124)}$, $H2A_{(89-114)}$–$H2B_{(31-57)}$.

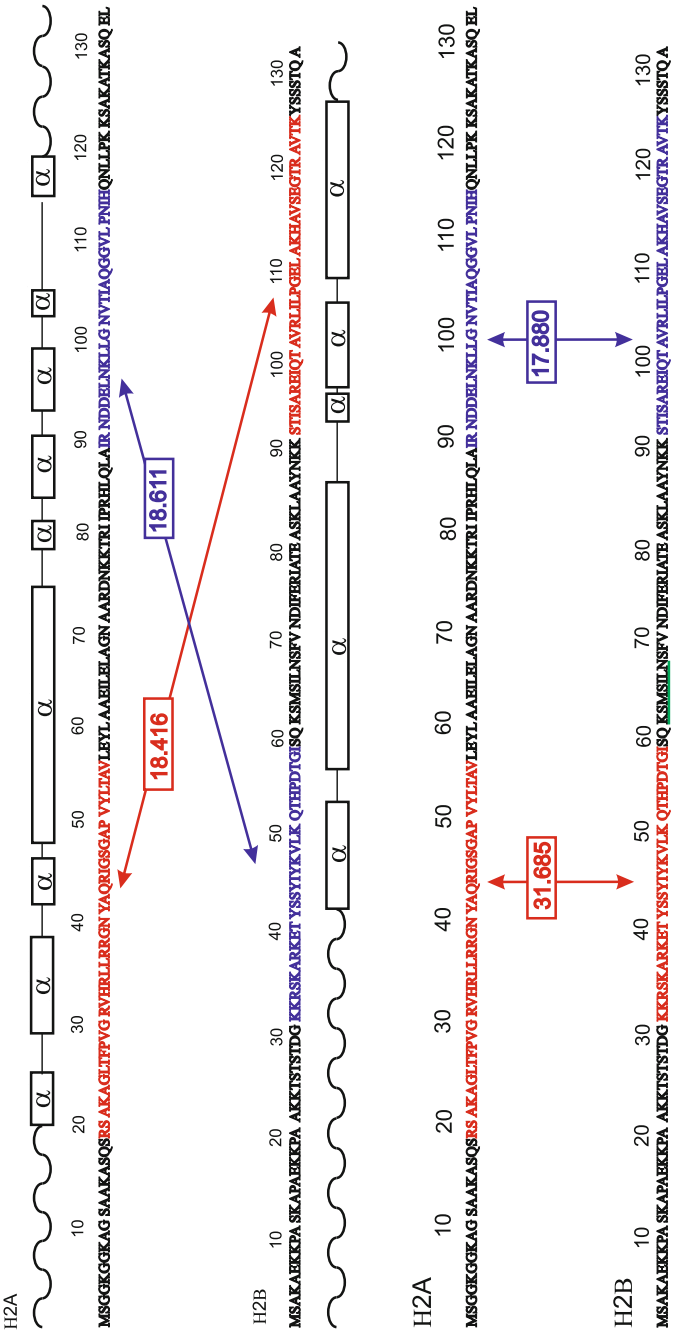

Fig. 2.9 Schemes of histone proteins H2A and H2B

Table 2.3 Common logarithm of condition numbers for the electrostatic interaction energy matrices for proteins (H3–H4) in the ≪head-to-tail≫ configuration

$N^{\underline{0}}$	Name of protein	Amino acid sequence	lg(cond(W))
1	$H3_{(84-127)}$	RFQSSAIGALQESVEAYLVSLFEDTNLAAIHAKRVTIQKKDIKL

3	$H3_{(50-75)}$	REIRRFQKSTELLIRKLPFQRLVREI	
4	$H4_{(76-103)}$	HAKRKTVTSLDVVYALKRQGRTLYGFGG	18.435

lg(cond(W)) is common logarithm of condition number.

In case ≪head-to-head≫, the stability of the heterodimer is realized by the interaction of only one region of histone proteins: $H2A_{(89-114)}$–$H2B_{(91-124)}$.

2.6.2 Heterodimer Formation H3–H4

Interaction of histone proteins upon binding into the (H3–H4) dimer allowing for their secondary structure was simulated.

Note that the (H3–H4) dimer is formed by ≪head-to-tail≫ joining of two histones into a ≪ *handshake* ≫ motif as well as the formation of the H2A−H2B heterodimer (see Fig. 2.8a) [5, 25].

Thus, interaction between different domains of the H3 and H4B proteins was calculated by analyzing the electrostatic interaction potential energy with allowance for the fact that, in the dimer, they are bound in the ≪head-to-tail≫ orientation. The possibility of the formation of a ≪head-to-head≫ dimer by the considered histones was also analyzed.

To solve this problem, various segments of the amino acid sequences histones H3, H4 were taken and the analysis of conditioning numbers for the matrix of electrostatic interaction was performed: $H3_{(50-75)}$, $H4_{(76-103)}$, $H3_{(84-127)}$ and $H4_{(25-50)}$.

Figure 2.10a shows the secondary structures of histone proteins H3 and H4 and scheme of interaction of different segments of amino acid sequences for model the dimer formation: ≪head-to-head≫.

Figure 2.10b shows the scheme of interaction between different sections of amino acid sequences for histone proteins H3 and H4, which models the dimer formation: ≪head-to-tail≫.

The numbers in the rectangular boxes indicate the common logarithm of the conditioning number (lg(cond(W))) for the selected pair of amino acid sequences.

Tables 2.3 and 2.4 present the calculation results for different domains of H3 and H4 proteins that allow for two analyzed binding patterns of the proteins to the dimer: ≪head-to-tail≫ and ≪head-to-head≫.

The results of the numerical simulation performed for the model ≪head-to-tail≫ when forming a histone heterodimer, H3–H4 demonstrates the set of values lg(cond(W)) smaller in value than the set of values for the formation model of the heterodimer ≪head-to-head≫. The values for the first model ≪head-to-tail≫ are 18.435 and 17.500, and for the second model, we got the values: 19.394 and 17.845.

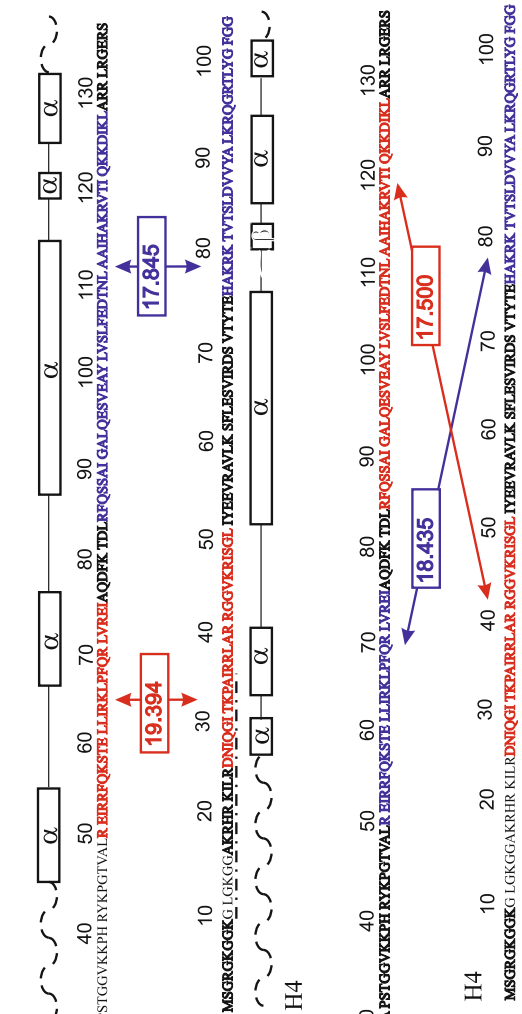

Fig. 2.10 Schemes of histone proteins H3 and H4

Table 2.4 Condition numbers of the for electrostatic interaction energy matrices for proteins (H3–H4) in the ≪head-to-head≫ configuration

$N^{\underline{0}}$	Name of protein	Amino acid sequence	lg(cond(W))
1	$H3_{(50-75)}$	REIRRFQKSTELLIRKLPFQRLVREI	
2	$H4_{(25-50)}$	DNIQGITKPAIRRLARRGGVKRISGL	19.394
3	$H3_{(84-127)}$	RFQSSAIGALQESVEAYLVSLFEDTNLAAIHAKRVTIQKKDIKL	
4	$H4_{(76-103)}$	HAKRKTVTSLDVVYALKRQGRTLYGFGG	17.845

lg(cond(W)) is common logarithm of condition number.

Thus, the numerical results model of histone heterodimer formation the ≪head-to-tail≫ with the participation between chosen amino acid sequences demonstrates a more stable interaction between amino acid sites of histones H3 and H4, than the model of formation histone heterodimer by the ≪head-to-head≫. These results are in good agreement with earlier experiments [5].

The results of numerical modeling made it possible to establish the most stable interactions between different domains.

Thus, the present study allows one to draw conclusions based on the fact that common logarithm condition number lg(cond(W)) which contains the interaction of different amino acid chains reveals which biological objects form the most stable compounds.

The model showed a remarkable sensitivity to the amino acid composition of the studied proteins.

It allows one to theoretically predict amino acid sequences with the given physical properties, facilitate experimental studies, and reduce their price by decreasing the number of measurements.

It is possible that some other sites of binding exist in the studied biological complexes; a separate simulation should be done if it is necessary to carry out an experiment with a given amino acid sequence.

2.7 MATLAB Script for Mathematical Simulation of Complex Formation of Protein Molecules Allowing for Their Domain Structure

Input parameters:

1. S_1, S_2 are amino acid sequences of biological complexes ($S_1 \geq S_2$). 2. epsilon is the dielectric constant of the medium.

Output parameters:

lg(cond(W)) is the common logarithm of the condition number of the matrix W, where its elements are composed of the electrostatic potential energy which is created based on the interaction between pair of amino acid residues of biological complexes.

Calculation:

lg(cond(W) is the common logarithm of the condition number of the matrix W, which will allow a prediction the reactivity of the studied biological complexes.

Chapter 3
Mathematical Modelling of the Temperature Effect on the Character of Linking Between Monomeric Proteins in Aqueous Solutions

Abstract The mathematical model was developed for taking into account the influence of the temperature of an aqueous salt-free solution on the character of dimer formation by different sections of small proteins: H2A–H2B and H3–H4 dimers, and the effect of temperature on various sections of the Bcl-xl protein were studied. The analysis of the numerical calculations obtained in the course of the developed mathematical model revealed a different behavior of the histone dimers H2B-H2A and H3–H4, as well as the Bcl-xl$_{(1-212)}$–Bcl-xl$_{(1-212)}$, Bcl-xl–Bcl-xl, Bcl-xl$_{(1-212)}$–Bcl-xl$_{(213-233)}$, Bcl-xl$_{(213-233)}$–Bcl-xl$_{(213-233)}$ with an increase of temperature from 20 °C to 40 °C, as well as the contribution of different sections of the Bcl-xl protein to the formation of the biological complex.

3.1 Introduction

This chapter presents a developed theoretical method that allows one to analyze the effect of the temperature of an aqueous solution on the character of the formation of protein dimers, as well as to determine the regions of protein molecules that make the greatest contribution to the stabilization of dimers. The maximum protein size was 233 a.a. (Bcl-xl). The behavior of protein complexes was studied in water at various temperatures, without the addition of salts. Note that for the analysis of longer proteins by the number of amino acid residues, it is necessary to cut such proteins into domains, as was done with the Bcl-xl protein, dividing it into two sections Bcl-xl$_{(1-212)}$ and Bcl-xl$_{(213-233)}$ in order to determine the interaction of these domains and their role in the formation of the Bcl-xl–Bcl-xl homodimer.

Note that we have developed a mathematical model to take into account the influence of the temperature of the aqueous solution on the nature of the binding of protein molecules.

The physical model developed by us makes it possible to determine the stability of protein complexes, as well as to predict the possible aggregation of proteins when the temperature of the aqueous solution changes.

Let us note that the study of protein aggregation is a topical trend in contemporary molecular biophysics. The aggregation of proteins is one of the processes that occur continuously in a cell. Each protein is characterized by its native conformation, which allows it to fulfill its prescribed biological functions. However, genetic mutations and errors in the synthesis of proteins on a ribosome may lead to the formation of misfolded protein structures. There is always the probability of a partial distortion in the native structure, even for native proteins, especially under stress conditions (thermal, oxidative, or osmotic). When the native structure is distorted, proteins cease to fulfill their biological functions, become less stable, and may exhibit a tendency to aggregate, which may lead to a broad spectrum of pathological states in a cell and the organism as a whole.

Hence, the approach developed in this work will make it possible to study and explain the pathological aspects associated with the structural transformation of proteins in the process of aggregation.

The chapter consists of several parts. In the first part, we describe the principal properties of proteins and the character of their behavior at an increasing temperature. The second part shows the physical characteristics of the formation of dimers, H2A–H2B, H3–H4 and protein complexes Bcl-xl–Bcl-xl in previously conducted in vitro experiments. The third part gives a detailed description of the physical model of accounting for the effect of the temperature of an aqueous solution on protein complexes. The fourth part is devoted to numerical calculations and analysis of the data obtained on the example of the formation of dimers H2B-H2A and H3-H4, Bcl-$xl_{(1-212)}$–Bcl-$xl_{(1-212)}$, Bcl-xl–Bcl-xl, Bcl-$xl_{(1-212)}$–Bcl-$xl_{(213-233)}$, Bcl-$xl_{(213-233)}$–Bcl-$xl_{(213-233)}$, the major conclusions drawn in this work are given.

3.2 The Main Properties of Proteins and the Nature of Their Behavior with Increasing Temperature

It is known that a slight increase in temperature may lead to both the aggregation of some proteins and the dissolution of others. Let us consider the hydrophobic interactions [1–3] responsible for the aggregation of proteins in more detail. It has been hypothesized previously that interactions between hydrophobic amino-acid residues intensify with increasing temperature and abate with decreasing temperature in a short range of values [2]. While an amino-acid sequence acquires a native structure, hydrophobic residues are generally located inside the globular structure of a protein far from the water environment. When the temperature is increased, the native structure of a protein sustains distortion exhibited as a loss of protein functions. Hydrophobic residues become exposed on the surface of a molecule and may begin to interact with the hydrophobic residues of other proteins. There are several interactions of different natures that govern the structure of a protein, such as hydrogen and hydrophobic interactions, interactions between charged amino acids, and covalent bonds between cysteine residues. In its native state, a protein molecule is usually

closely packed in such a way that the side groups located in the inner part of a molecule have restricted freedom of motion. The motion of the side groups that form the hydrophobic core of a molecule is especially restricted.

By increasing the temperature, it is possible to create ambient conditions under which the small-scale fluctuations of some groups of atoms become more intensive.

Since the hydrophobic residues are mainly inside the globular structure in the native state of the molecule, away from the water environment, then the temperature increase may lead to a violation of the native structure of protein [4], which is expressed in the loss of protein functions. Hydrophobic residues reach the surface of the molecule and can begin to interact with the hydrophobic residues of other proteins.

After hydrophobic amino-acid residues become exposed on the surface and begin to interact with other hydrophobic amino-acid residues, under certain conditions, a protein molecule is denaturated to form aggregates, e.g., of hydrophobic molecule parts.

Thus, the denaturation and rearrangement of the interacting amino acid residues with increasing temperature can lead to aggregation [5].

Let us note that denaturation is the destruction of the native special structure of a protein with the resulting loss of its bioactivity [3]. It is noteworthy that protein molecules do not necessarily form aggregates with increasing temperature, but may lose their native structure without forming any aggregates. The solubility of proteins of different kind is varied within broad ranges.

The solubility of a protein depends on the ratio between its polar and non-polar groups, their mutual arrangement, and the resulting dipole moment. A large number of polar groups must increase both the affinity of proteins to water and their solubility. However, ionic groups may have an inverse effect when they are bonded with oppositely charged groups and form intermolecular salt-like bonds. The formation of these intermolecular bonds always leads to dehydration and promotes the appearance of coarse insoluble aggregates, so the denaturation of proteins is also a function of the protein concentration in a solution. Electrostatic forces in water are reduced due to the high dielectric permeability, and interactions occur between the polar groups of a molecule and water. If the interaction between a protein and a solvent is stronger than between the amino acids of this protein, the protein is dissolved. Let us note that the capacity for water retention, as well as the solubility, simultaneously depends on the degree of both proteinwater and proteinprotein interactions and the conformation of a protein and its degree of denaturation. For this reason, thermal treatment has a strong effect on these physical properties [6–8]. In many cases, thermal treatment decreases the solubility of proteins and may increase the water-retention function under certain conditions. However, it is difficult to distinguish any general properties here. Each type of proteins exhibits its properties in different ways depending on its composition, structure, and conformation. Hence, in each case, the temperature effect on a protein requires careful study.

3.3 The Physical Properties of the Studied Proteins H2A, H2B, H3, H4, Bcl-xl

In this section, we consider previously published experimental studies of the physical properties of proteins H2A, H2B, H3, H4, Bcl-xl in vitro solutions with different physical characteristics.

In this section, we consider previously published experimental studies of the physical properties of proteins H2A, H2B, H3, H4, Bcl-xl in vitro in solutions with different physical characteristics. In [9] the thermal stability of the core histone dimer H2A–H2B has been studied by high-sensitivity differential scanning calorimetry and circular dichroism spectroscopy. The unfolding transition temperature of the 28kDa H2A–H2B dimer increases as a function of both the ionic strength of the solvent and the total protein concentration. At neutral pH and physiological ionic strength, the thermal denaturation is centered at about 50 °C. Analysis of the data shows that at low ionic strength and pH values between 6.5 and 8.5, the H2A–H2B dimer behaves as a highly cooperative system. The self-associative behavior of the $(H3–H4)_2$ in the absence of the H2A-H2B dimer, makes it very difficult to analyze its thermodynamic properties under conditions where its interaction with H2A–H2B dimer is particularly sensitive. The $(H3–H4)_2$ tetramer is responsive to changes in ionic strength. Extensive aggregation is promoted at higher protein concentrations, especially at high levels of NaCl.

Aggregation of the $(H3–H4)_2$ tetramer is prevented by the addition of the histone H2A-H2B dimer which acts as a molecular cap and regulates the assembly pathway toward the formation of octamers [10]. In [9] the H3–H4 dimer is thermally more stable than the H2A–H2B dimer. Comparison of corresponding data for the two dimeric proteins reveals that the unfolding temperature of the H3–H4 dimer is approximately 20 °C higher than that of the H2A–H2B dimer under similar experimental conditions. In [11] reported that at temperatures greater than 32 °C get aggregation of tetramer H3–H4.

Let us turn to the physical properties of the Bcl-xl protein in solutions.

In [12] reported that Bcl-xl irreversible aggregation and assembles into highly-ordered rope-like homogeneous fibrils under elevated temperatures. In [13] provide evidence that acidic pH promotes the assembly of Bcl-xl into a megadalton oligomer. Bcl-xl displays the propensity to oligomeriation in solution and that such oligomerization is driven by the intramolecular binding of its C–terminal TM domain to the canonical hydrophobic groove in a domain-swapped trans-fashion, whereby the TM domain of one monomer occupies the canonical groove within the other monomer and vise verse [14]. Bcl-xl exists in various associative [12] and can formation at 20 °C, ranging from monomer and dimer to higher-order oligomers. At 40 °C, the dimer and multimer conformers appear to shift in the direction of the polymeric conformation. The truncation of C–terminal TM domain completely abolished oligomerization of Bcl-xl under low temperatures 20 °C to 40 °C. A key role of TM domain is driving the intermolecular association of Bcl-xl into large aggregates in agreement with previous studies.

3.4 Description of the Physical Model

The mathematical model developed in this work is based on studies [15–17] and describes the temperature effect on the character of linking in protein dimers in an aqueous solution.The selected histone dimers H2A–H2B and H3–H4 as the model system, various sections of the Bcl-xl: Bcl-xl, Bcl-$xl_{(1-212)}$, Bcl-$xl_{(213-233)}$ protein, which form the Bcl-xl–Bcl-xl, Bcl-$xl_{(1-212)}$–Bcl-$xl_{(1-212)}$, Bcl-$xl_{(1-212)}$–Bcl-$xl_{(223-233)}$, Bcl-$xl_{(213-233)}$–Bcl-$xl_{(213-233)}$.

To analyze the stability of dimers in an aqueous solution while the temperature changes from 20 °C to 40 °C, we performed calculations of the matrix condition number, the elements of which are the potential energies of electrostatic interaction between pairwise taken amino acid residues. Several assumptions were made.

1. Each amino acid residue interacts with all other amino acid residues with a specific charge. Note, that the charge of each amino acid residue was obtained using the data from [2].

We took the data from [18], which shows changes in the volume of a protein with known amino acid sequences and using these data and calculated the order of magnitude δ on which the radius of each amino acid residue can vary with a temperature change of 5 °C. In the attached program, δ is denoted by Rt1.

2. The radius of hydrophobic amino-acid residues (A, I, L, M, F, P, W, Y, V) decreases by the value of δ for every 5 °C of temperature increase.

Let us note that different proteins demonstrate a complicated dependence of change in their volume with increasing temperature, as the process of heating may lead to different distortions in their three-dimensional structure and have diverse characters for different proteins [18, 19].

3. The radius of the other amino acid residues increases by the value of δ for every 5 °C of temperature increase.

4. When the temperature reaches 40 °C, we assume that there is a violation of the linear change in the parameters of physical quantities and the value of δ increases two-fold. Below is the general case of calculating the radii of amino acid residues at different temperatures of the aqueous solution.

$$R_a = r_a \cdot 10^{-9} - n\delta; \quad R_r = r_r \cdot 10^{-9} + n\delta; \quad R_n = r_n \cdot 10^{-9} + n\delta; \quad R_d = r_d \cdot 10^{-9} + n\delta;$$

$$R_c = r_c \cdot 10^{-9} + n\delta; \quad R_q = r_q \cdot 10^{-9} + n\delta; \quad R_e = r_e \cdot 10^{-9} + n\delta; \quad R_h = r_h \cdot 10^{-9} + n\delta;$$

$$R_i = r_i \cdot 10^{-9} - n\delta; \quad R_l = r_l \cdot 10^{-9} - n\delta; \quad R_g = r_g \cdot 10^{-9} + n\delta; \quad R_k = r_k \cdot 10^{-9} + n\delta;$$

$$R_m = r_m \cdot 10^{-9} - n\delta; \quad R_f = r_f \cdot 10^{-9} - n\delta; \quad R_p = r_p \cdot 10^{-9} - n\delta; \quad R_s = r_s \cdot 10^{-9} + n\delta;$$

$$R_t = r_t \cdot 10^{-9} + n\delta; \quad R_w = r_w \cdot 10^{-9} - n\delta; \quad R_y = r_y \cdot 10^{-9} - n\delta; \quad R_v = r_v \cdot 10^{-9} - n\delta,$$

where $\delta = 10^{-4}$ nm, r is the initial radius of the amino acid residue, R is the finite radius of the amino acid residue, n is an integer depending on the temperature of the aqueous solution (see Table 3.1).

Table 3.1 The value of the number n at different temperatures of the aqueous solution

Water temperature, °C	20°	25°	30°	35°	40°
n	1	1	2	3	8

Table 3.2 Relative dielectric permeability of water at different temperatures [20]

Water temperature, °C	20°	25°	30°	35°	40°
Dielectric permeability of water	80.103	78.304	76.546	74.828	73.151

5. The initial radii of amino acid residues are and the distances between the different amino acid residues are defined in Chap. 2.

Thus, every temperature corresponds to a certain set of 20 radii of amino-acid residues.

6. The distance between differently charged amino-acid residues is 0.15 nm.

7. The distance between the hydrophobic residues was taken at 0.36 nm.

8. The distance between identically charged amino acid residues is 0.4 nm.

9. We believe that the tendency of the values of lg(cond(W)) to decrease with a change in temperature of the aqueous solution may serve as an indicator of the possible aggregation of protein complexes.

In this case, the distances considered increased by a multiple of δ every 5 °C. In the program, this distance is represented by the sum of the distances between the boundaries of the spheres and the sum of the two mean radii of the spheres.

Since every temperature of an aqueous solution corresponds to a certain electrical permeability, its values for all temperatures used in our calculations were compiled in Table 3.2.

To analyze the temperature effect on the character of linking in protein dimers in aqueous solutions, we use the concept of the condition number (see Chap. 2) which will characterize the degree of stability in the configuration of a biocomplex in different temperature regimes in this physical formulation.

3.5 Numerical Modelling of the Effect of Temperature on the Character of Binding of Monomeric Proteins to Aqueous Solutions. Conclusion

To numerically model of the temperature effect on the character of the linking of monomeric proteins into dimers in aqueous solutions, we selected small proteins. We took the sequences of histone proteins H2A, H2B, H3,H4, and Bcl-xl from the database [21], where their numbers were P04911, P02293, P61830, P02309 and Q07817, respectively. Let us point out that the thermal motion energy will grow with increasing temperature, and this may lead to the destruction of solvate shells and, correspondingly, the aggregation of the system. We assume that the electrostatic

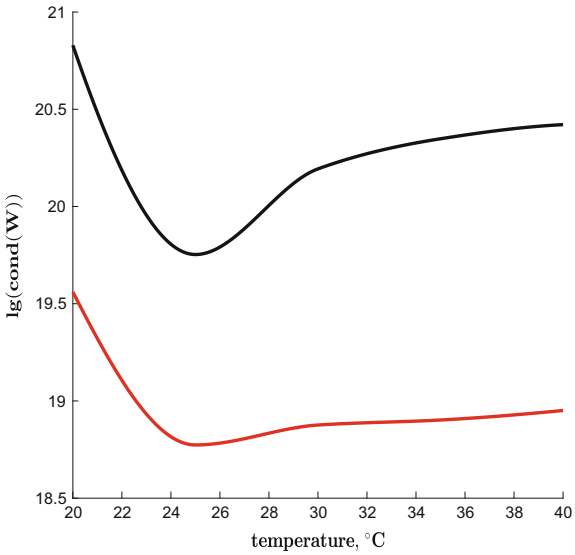

Fig. 3.1 lg(cond(W)) versus temperature for dimers H2A–H2B and H3–H4. The black color line for dimer H2A–H2B and red color line for dimer H3–H4

interaction between amino-acid residues in the process of aggregation is stronger, and this must lead to an decrease in lg(cond(W)), where cond(W)is the condition number of matrix of the potential energy of pairwise electrostatic interaction between the studied proteins (see expression 2.10). To select the most stable biochemical complex that links between proteins, we take the electrostatic potential energy matrix with the lowest condition number.

The results of numerical simulation of the interaction of histone dimers H2A–H2B and H3–H4 are presented in Fig. 3.1.

Numerical calculations were carried out for the whole Bcl-xl protein, as well as for the shortened Bcl-$xl_{(1-212)}$–Bcl-$xl_{(1-212)}$ protein, in which the TM domain was cut off from the C–terminus. A numerical calculation of the interaction of the shortened region of the protein Bcl-$xl_{(1-212)}$ with the TM domain of the protein Bcl-$xl_{(213-233)}$ was also performed. The results of numerical calculations for different regions of the Bcl-xl protein are shown in Fig. 3.2.

In Fig. 3.1 numerical calculations of the effect of temperature on the behavior of histone dimers in aqueous solutions in the range from 20° to 40° are presented. The values of lg(cond(W)) at 20° for the dimers H2A–H2B and H3–H4 were 20.828 and 19.560, respectively.

We also give the interaction values of the proteins H2A and H2B, H3 and H4, obtained in Chap. 2 at a temperature of 20°. In this case, the values of lg(cond(W)) corresponding to the formation of the dimers H2A–H2B and H3–H4 were 19.749 and 18.266, respectively.

We note that the developed thermal model makes it possible to analyze the stability of biological complexes in an aqueous solution when the temperature is changed by analyzing the curve lg(cond(W)). The numerical results obtained using the mathematical model from Chap. 2 allow one to directly compare the lg(cond(W))

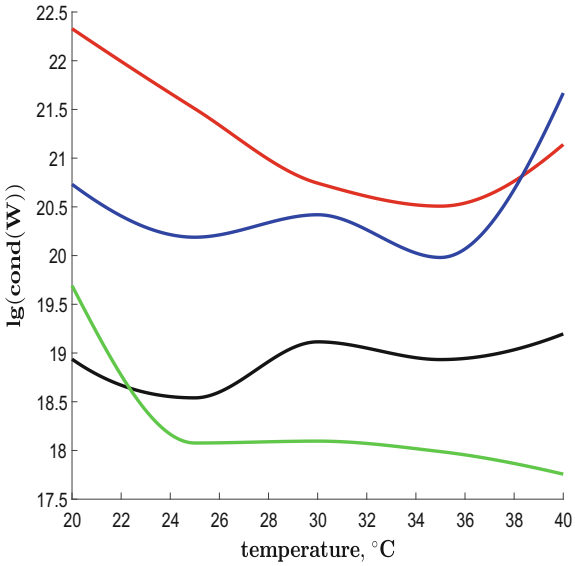

Fig. 3.2 lg(cond(W)) versus temperature Bcl-xl$_{(213-233)}$–Bcl-xl$_{(213-233)}$, Bcl-xl–Bcl-xl, Bcl-xl$_{(1-212)}$–Bcl-xl$_{(1-212)}$,Bcl-xl$_{(1-212)}$–Bcl-xl$_{(213-233)}$. The blue color line for Bcl-xl$_{(1-212)}$–Bcl-xl$_{(1-212)}$, red color line for Bcl-xl–Bcl-xl, black color line for Bcl-xl$_{(213-233)}$–Bcl-xl$_{(213-233)}$, green color line for Bcl-xl$_{(1-212)}$–Bcl-xl$_{(213-233)}$

values with the formation of different dimers for the analysis of the behavior of proteins.

Thus, from the obtained numerical data we see that the dimer H2A–H2B is less stable than the dimer H3–H4. This conclusion coincides with the numerical calculations obtained according to the thermal model.

The values of lg(cond(W)) in the interaction of H3 proteins with H4 are in a lower range of values than in the interaction of histones H2A and H2B. We assume that the effect of temperature in aqueous solutions leads to a more stable formation of a heterodimer involving H3 and H4 proteins than H2A and H2B, as well as to the possible aggregation of the H3–H4 dimer.

The formation of a pronounced minimum in the region 25 °C of the dimer H2A–H2B compared to the dimer H3–H4 can indicate structural changes in a given temperature range.

Let us now consider the numerical results of the interaction of different sections of the Bcl-xl protein. On the graph Fig. 3.2 are shown the results of numerical simulation of Bcl-xl$_{(213-233)}$–Bcl-xl$_{(213-233)}$, Bcl-xl–Bcl-xl, Bcl-xl$_{(1-212)}$–Bcl-xl$_{(1-212)}$,Bcl-xl$_{(1-212)}$–Bcl-xl$_{(213-233)}$.

We present the lg(cond(W)) values (see Table 3.3) obtained for these compounds using a mathematical model of the interactions between protein molecules and study of their propensity to form complex biological complexes (see Chap. 2).

Note that we will do the analysis of this table together with the obtained graphs for the selected pairs of proteins. We investigated the interaction of different regions of the Bcl-xl protein in order to determine the role of the selected sites in the formation of the whole homodimer Bcl-xl–Bcl-xl.

Table 3.3 Numerical results of the interaction of dimers Bcl-xl$_{(213-233)}$–Bcl-xl$_{(213-233)}$, Bcl-xl–Bcl-xl, Bcl-xl$_{(1-212)}$–Bcl-xl$_{(1-212)}$,Bcl-xl$_{(1-212)}$–Bcl-xl$_{(213-233)}$

Dimers	Bcl-xl–Bcl-xl	Bcl-xl$_{(1-212)}$– –Bcl-xl$_{(1-212)}$	Bcl-xl$_{(213-233)}$– –Bcl-xl$_{(213-233)}$	Bcl-xl$_{(1-212)}$– –Bcl-xl$_{(213-233)}$
lg(cond(w))	20.622	20.748	19.071	17.253

lg(cond(W)) is common logarithm of condition number

The results are shown in Fig. 3.2 and are described by the red and blue curves, respectively. As can be seen from Fig. 3.2, the homodimer (Bcl-xl)$_2$ is more stable than the homodimer of the cut off proteins Bcl-xl$_{(1-212)})_2$ as the temperature changes.

In this case, the homodimer (Bcl-xl)$_2$ demonstrates a gradual decrease in lg(cond(W)) values as the temperature changes from 20° to 40°, in contrast to Bcl-xl$_{(1-212)})_2$.

The curve of the values of lg(cond(W)) for the homodimer Bcl-xl$_{(1-212)})_2$ increases from 20.730 to 21.668 at a temperature from 20° to 40°, and the curve of the values of lg(cond(W)) for the homodimer Bcl-xl$_2$ decreases from 22.328 to 21.140, respectively. A similar change in lg(cond(W)) within the framework of the constructed model is interpreted as an indicator of a possible aggregation of the protein complex. Analysis of the numerical values of Table 3.3 obtained on the basis of the mathematical model from Chap. 2 allows us to assume that the dimer (Bcl-xl)$_2$ is initially a more stable complex than the truncated dimer Bcl-xl$_{(1-212)})_2$, since the values of lg(cond(W)) were 20.622 and 20.748, respectively.

Such differences in the behavior of protein dimers when the temperature varies from 20° to 40° are explained by the role of the TM domain of the protein Bcl-xl$_{(213-233)}$, which can take part in the formation of the dimer (Bcl-xl)$_2$.

To test this assumption, the interaction of the truncated Bcl-xl$_{(1-212)}$ protein with the TM domain of Bcl-xl$_{(213-233)}$ was studied. The results are shown in Fig. 3.2 and are described by a green curve. The numerical value of this interaction at a temperature of 20° is given in Table 3.3 and amounted to 17.253. Since this value is significantly smaller than the interaction of (Bcl-xl)$_2$ and Bcl-xl$_{(1-212)})_2$ according to Table 3.3, we can conclude that the formed biological complex (Bcl-xl)$_{(1-212)}$-Bcl-xl$_{(213-233)}$ is more stable than (Bcl-xl)$_2$ and Bcl-xl$_{(1-212)})_2$. This result correlates with the pattern of the curves in the Fig. 3.2.

Thus, the TM domain can play an essential role in the formation of the protein homodimer (Bcl-xl)$_2$, and its absence in the dimer Bcl-xl$_{(1-212)})_2$ can lead to destabilization of this truncated homodimer.

The interaction of the TM domain of Bcl-xl$_{(213-233)}$ with itself was investigated separately. The results shown in the graph Fig. 3.2 are described by a black curve.

The numerical results (see Table 3.3) demonstrate that the values of lg(cond(W)) for the formation of the complex Bcl-$xl_{(213-233)}$ are higher than the values of lg(cond(W)) corresponding to the interaction $(Bcl\text{-}xl)_{(1-212)}$- Bcl-$xl_{(213-233)}$ and are lower than the values of lg(cond(W)) that correspond to the interactions of $(Bcl\text{-}xl)_2$ and $Bcl\text{-}xl_{(1-212)})_2$. This result qualitatively coincides with the value of lg(cond(W)), which was obtained for a mathematical model of the temperature effect on the character of linking between monomeric proteins in aqueous solutions.

As can be seen from the presented graph Fig. 3.2, the values of lg(cond(W)) of the homodimer of $Bcl\text{-}xl_{(213-233)})_2$ proteins lie in a lower range than the values of lg(cond(W)) of the protein homodimer $(Bcl\text{-}xl)_2$.

The result obtained for $Bcl\text{-}xl_{(213-233)})_2$ can be interpreted as the formation of a biological complex, but with a temperature change it behaves less unstably than $Bcl\text{-}xl_{(1-212)}$–$Bcl\text{-}xl_{(213-233)}$.

The curve $Bcl\text{-}xl_{(213-233)})_2$ tends to increase the values of lg(cond(W)) from 20° to 40°, varying from the values 18.937–19.195, respectively.

Thus, we assume that the TM domain of the protein Bcl-$xl_{(213-233)}$ can form a complex with the same site Bcl-$xl_{(213-233)}$, but the interaction with the globular part of the protein Bcl-xl is preferable for the TM domain.

The constructed mathematical model allows to determine:

– the influence of temperature on the character of binding of monomeric proteins in aqueous solutions

– the contribution of different sections of the examined proteins to the formation of a stable biological complex in a given temperature range.

3.6 Matlab Script for Mathematical Modelling of the Temperature Effect on the Character of Linking Between Monomeric Proteins in Aqueous Solutions

Input parameters:

1. S_1, S_{20} are amino acid sequences of biological omplexes ($S_1 \geq S_{20}$)
2. $epsilon_1$ is the dielectric constant of the medium
3. t is the temperature of the medium

Output parameters:

lg(cond(W) is the common logarithm of the condition number of the matrix W, where its elements are composed of the electrostatic potential energy which is created based on the interaction between pair of amino acid residues of biological complexes.

Compute:

lg(cond(W) is the common logarithm of the condition number of the matrix W, which will allow a prediction the reactivity of the studied biological complexes.

Chapter 4
Mathematical Modelling of the Effect of a Monovalent Salt Solution on the Interaction of Protein Molecules

Abstract This chapter is devoted to the development of a mathematical model that will allow us to describe the behavior of biological complexes in vitro on the example of the formation of two histone dimers H2A−H2B and H3−H4 from the corresponding monomeric proteins H2A, H2B, H3, and H4 in solutions with different concentrations of monovalent salt. The calculations were performed taking into account the screening of the electrostatic charge of charged amino acids at different concentrations of monovalent salt using the Guy–Chapman theory. It should be noted that the screening of non-polar, polar, aromatic amino acids in solutions with different ionic strength was not taken into account in this chapter.

4.1 Introduction

In this chapter, a physical model is constructed that simulates the initial stage of the formation of a histone octamer, namely, the formation of H2A−H2B and H3−H4 dimers, taking into account the different concentrations of the monovalent salt solution. Since in the present chapter we consider the pairwise interaction of amino acid residues, which are represented as uniformly charged spheres, the article [1] should be mentioned, in which various pairs of amino acid residues were investigated for their ability to interact on the basis of physicochemical properties: size, charge, hydrophobic interactions. The results obtained in the study characterize the ability of an amino acid to bind to another amino acid. However, it should be noted that in the above work, no criterion is given for quantifying the electrostatic interaction forces between protein units leading to the assembly or dissociation of the histone octamer at different concentrations of monovalent salt.

Thus, the approach developed in this chapter will make it possible to quantify the electrostatic interaction between histone proteins in solutions with different concentrations of monovalent salt, taking into account the screening effect of charged amino acid residues, and also the criteria for the stability of various protein

T. Koshlan and K. Kulikov, *Mathematical Modeling of Protein Complexes*,
Biological and Medical Physics, Biomedical Engineering,
https://doi.org/10.1007/978-3-319-98304-2_4

compounds depending on the concentration of the salt solution. It should be noted that the stability of most biological complexes with given amino acid sequences must be checked experimentally method.

The chapter consists of several parts.The first part describes the structure of the histone core previously conducted experimental work on the effect of salt solutions on the nature of the interaction of the biological complexes. In the second part, the electrostatic problem of interaction of protein molecules is considered taking into account the screening effect in a salt solution of different concentrations. In the third part, a new algorithm is proposed for determining the formation of a biochemical complex from two compounds by analyzing the potential energy matrix of the pairwise electrostatic interaction of biological reagents. In the fourth part, numerical calculations of the formation of protein complexes in solutions with different concentrations and analysis of the data obtained are presented.

4.2 General Principles for the Formation of Dimers H2A−H2B, H3−H4 and the Behavior of These Compounds in Solutions with Different Concentrations of Monovalent Salt

To analyze the interaction of protein molecules, taking into account the effect of the concentration of the monovalent salt of the solution, we chose four histones H2A, H2B, H3, and H4, forming a histone octamer of DNA. Let us turn to a brief examination of the structure of DNA and histones.

In [2] the central histone octamer contains two copies of each of the core histone proteins, H2A, H2B, H3, and H4 as established 3.1 Å crystal structure of the histone octamer.

The core histones are assembled into four histone-fold heterodimers (two each of H2A/H2B and H3/H4). Each of the core histones contains the histone fold domain, composed of three α-helices connected by two loops, which allow heterodimeric interactions between core histones known as the handshake motif, more in detail with the structure of the histone domain can read in articles [3–5].

Let's move on to the behavior of selected protein complexes in solutions with different concentrations of monovalent salt.

In [6] reported that at low ionic strength, H3−H4 and $(H3-H4)_2$ crosslinked products are favored and, as the ionic strength is raised, increased aggregation is observed in the form of higher molecular weight products until, at 2 M NaCl, the products of the cross-linking reaction are too large to enter the gel. Association H2A−H2B with the $(H3-H4)_2$ tetramer indicates that the H2A−H2B dimer could prevent small-scale aggregation of H3 and H4 by serving as a molecular "cap", i.e., by binding to the sites available on either side of the $(H3-H4)_2$ tetramer, the H2A−H2B dimer may be blocking tetramer ≪sticky≫ regions responsible for self-aggregation.

In [7] authors examine the stability of the isolated H2A−H2B heterodimer using urea denaturation in the presence of a variety of salts. The results presented here show that the salt stabilization of the H2A−H2B dimer involves a combination of enhancing the hydrophobic effect (via the Hofmeister effect or preferential hydration) and screening of electrostatic repulsion. The most highly charged regions of the dimer are the N-terminal tails, sites of posttranslational modifications such as acetylation and phosphorylation. These modifications, which alter the charge density of the tails, are involved in regulation of nucleosome dynamics.

In [8] the thermodynamic properties $(H3-H4)_2$ can not be studied directly though, since its thermal denaturation is completely irreversible even at the lowest salt concentrations.

Below we have considered the problem of modelling the processes of electrostatic interaction of the formation of dimers from the complete amino acid sequences of selected histone proteins.

Note that the biological objects interact in a solution that may have different ionic strengths, i.e., that contains a variety of dissolved ions. In these biological systems, the interactions between the ions are of great importance, which strongly depend on the ionic strength of the solution. This value is a measure of the intensity of the electric field created by ions in solution. To consider the effect of the magnitude of the ionic strength in solution on the stability of the studied biological compounds, we used the Gouy–Chapman theory to calculate the screening potential of a charged amino acid sequence of the protein at various concentrations of monovalent salt in solution with biological objects.

4.3 Shielding Effect in a Salt Solution

To take into account the mechanism of formation of the compensating layer of ions in the solution (shielding effect), which is formed due to forces of electrostatic attraction to distributed surface charge, we used the Gouy–Chapman theory [9–11]. In this theory the ions of the electrolyte are described by point charges of both signs in a water medium with a certain dielectric permittivity. If the energy of the ions in the field of attraction to the surface charge is of the order of kT (where k is the Boltzmanns constant, T is the absolute temperature), then the thermal motion must make such layer diffusive. Thus, the spatial distribution of counterions (ions that have the opposite charge) is determined by the fact that they are in a state of thermal motion and, at the same time, are attracted to the surface charge, which results in the formation of a diffuse layer of a certain length. Note that the length at low concentrations of the electrolyte can be significant. The electric field in the double layer must monotonically decrease with distance from a charged surface because its charge is shielded by the charge of counterions located between the given remote point and the charged surface. At the outer boundary of the electric double layer the electric field has to vanish. Thus, the only variable on which the function of the potential decay depends is the distance from the charged surface. Note that the radius

of the particle is collinear with the vector of the distance from the charged surface. In accordance with this model, the functions of the electric potential and corresponding average charge distribution are computed in the neighborhood of a charged surface. The calculation of the electric double layer for the charged surface of the sphere was performed for the five charged amino acids, i.e., aspartic acid (D), glutamic acid (E), lysine (K), arginine (R), and histidine (H).

Let us write the Poisson equation for a flat surface

$$\frac{d^2\varphi(x)}{dx^2} = -\frac{\rho}{\varepsilon\varepsilon_0}, \tag{4.1}$$

where ρ is the charge density defined at a distance x from the surface and $\varphi(x)$ is the potential, ε is dielectric permittivity of the medium, and ε_0 is the electric constant. According to [9–11], we write the total charge density per unit volume for a particular ion:

$$\rho = \sum_{i=1}^{N} n_i z_i e = \sum_{i=1}^{N} n_i^0 z_i e \exp\left[\frac{-z_i e\varphi(x)}{kT}\right], \tag{4.2}$$

where n_i^0 is the concentration of the ions in solution, e is the charge of the electron, and z is the ion charge.

Combining (4.1) and (4.2), we get the Poisson–Boltzmann equation

$$\frac{d^2\varphi(x)}{dx^2} = -\frac{e}{\varepsilon\varepsilon_0}\sum_{i=1}^{N} n_i^0 z_i \exp\left[\frac{-z_i e\varphi(x)}{kT}\right]. \tag{4.3}$$

The equation must be supplemented by the boundary conditions [11]:

$$\varphi(0) = \varphi_0, \quad \varphi|_{x\to\infty} = 0. \tag{4.4}$$

Multiplying (4.3) by $\frac{d\varphi}{dx}$ on the left and right, we get

$$\frac{1}{2}\frac{d}{dx}\left(\frac{d\varphi}{dx}\right)^2 = -\frac{e}{\varepsilon\varepsilon_0}\sum_{i=1}^{N} n_i^0 z_i \exp\left[\frac{-z_i e\varphi(x)}{kT}\right]\left(\frac{d\varphi}{dx}\right),$$

$$\frac{1}{2}\frac{d}{dx}\left(\frac{d\varphi}{dx}\right)^2 = \frac{d}{dx}\frac{kT}{\varepsilon\varepsilon_0}\sum_{i=1}^{N} n_i^0 \exp\left[\frac{-z_i e\varphi(x)}{kT}\right]. \tag{4.5}$$

After integrating (4.5) and taking into account the conversion of the derivative of the potential far from the surface to zero (whereby the integration constant is determined), we have

$$\frac{1}{2}\left(\frac{d\varphi}{dx}\right)^2 = \frac{kT}{\varepsilon\varepsilon_0}\sum_{i=1}^{N} n_i^0 \exp\left[\left[\frac{-z_i e\varphi(x)}{kT}\right] - 1\right], \tag{4.6}$$

$$\frac{d\varphi}{dx} = \pm\left[\frac{2kT}{\varepsilon\varepsilon_0}\sum_{i=1}^{N} n_i^0 \exp\left[\left[\frac{-z_i e\varphi(x)}{kT}\right] - 1\right]\right]^{1/2}. \tag{4.7}$$

Note that the obtained (4.7) can be integrated in the case of arbitrary potentials of the surface, but only for a symmetric electrolyte as follows:

$$z_+ = -z_- = z,\ \ n_+^0 = n_-^0 = n^0.$$

We convert the expression included in the righthand side of (4.7)

$$\sum_{i=1}^{N} n_i^0 \exp\left[\left[\frac{-z_i e\varphi(x)}{kT}\right] - 1\right]$$

as follows:

$$\sum_{i=1}^{N} n_i^0 \exp\left[\left[\frac{-z_i e\varphi(x)}{kT}\right] - 1\right] = 2n^0\left[\mathrm{ch}\left[\frac{ze\varphi(x)}{kT}\right] - 1\right] = 4n^0\mathrm{sh}^2\left[\frac{ze\varphi(x)}{2kT}\right]. \tag{4.8}$$

Then, taking into account expressions (4.8), (4.7) takes the form

$$\frac{d\varphi}{dx} = -\sqrt{\frac{8n^0kT}{\varepsilon\varepsilon_0}}\,\mathrm{sh}\left[\frac{ze\varphi(x)}{2kT}\right]. \tag{4.9}$$

After integrating (4.9) taking into account the boundary conditions (4.4), we get

$$\varphi(x) = \frac{4kT}{ze}\mathrm{Arth}(\mathrm{th}(ze\varphi_0/4kT)\exp(-x\kappa)), \tag{4.10}$$

where κ is the characteristic length of the Debye radius. It is defined as follows [9]:

$$\kappa^{-1} = \left[\frac{\varepsilon\varepsilon_0 kT}{\sum_{i=1}^{N} n_i^0 z^2 e^2}\right]^{1/2}, \tag{4.11}$$

Note that, at this distance, the field of a charged particle is screened due to the accumulation of the charge of opposite sign around it. We assume that when a charged amino acid residue of the protein is placed in a solution with a given ionic strength, the shielding of a charge of its sphere occurs, i.e., its potential is reduced and its effective radius is increased due to the characteristic length of the Debye radius. Thus, from (4.10) we obtain the values of the potential of the sphere on the boundary of shielding, and from the expression (4.11) we obtain the Debye radius. Using these data, we find the new value of the charge for each sphere placed in a saline solution.

Table 4.1 Debye length at various concentrations of a monovalent salt at 20 °C configuration

$N^{\underline{0}}$	Ionic concentration, M	Debye length
1	0.1	0.479
2	0.2	0.336
3	0.4	0.234
4	0.6	0.188
5	0.9	0.157
6	1	0.141

4.3.1 Debye Length

The Debye length (κ^{-1}), is a measure of the electric double layer thickness, and is a property of the electrolyte solution. It should be noted that this parameter contains information about the dielectric permittivity of the solvent, as well as the valence, z, and bulk concentration, n_i^0, of the ions. However, no information regarding the properties of the charged surface is present in the Debye length. Although it is normally referred to as the thickness of the electric double layer, the actual thickness of a double layer extends well beyond κ^{-1}. Typically, the Debye length represents a characteristic distance from the charged surface to a point where the electric potential decays to approximately 33% of the surface potential [12].

Now, n_i^0, the ionic number concentration, is given by

$$n_i^0 = \left[\mathrm{M}\frac{\mathrm{mol}}{\mathrm{L}}\right] \times \left[1000\frac{\mathrm{L}}{\mathrm{m}^3}\right] \times \left[\mathrm{N_a}\frac{1}{\mathrm{mol}}\right]$$

or $n_i^0 = 1000\mathrm{N}_a\mathrm{M}$, with the Avogadro number $\mathrm{N}_a = 6.022 \times 10^{23}$ mol $^{-1}$ and M being the molar concentration (mol/L) of the electrolyte. The values of the Debye length, κ^{-1}, for different electrolyte concentrations for the case of z = 1 are shown in the following table. In this case, the ionic strength is equal to the molar concentration of the electrolyte. It is clear from the tabulated results that κ^{-1} decreases as the electrolyte concentration increases. At high molarity, the electric double-layer thickness becomes very small. In a non-electrolyte system, however, the double-layer thickness can be thought of as extending to infinity (i.e., a is equal to the molar concentration of the electrolyte. It is clear from the tabulated results that κ^{-1} decreases as the electrolyte concentration increases. The Table 4.1 shows the debye length at various concentrations of a monovalent salt at 20 °C.

As the concentration of the salt increases, the Debye length decreases. We calculated the charge at different distances 0.2, 0.25, 0.5, 0.75nm from the sphere boundary at different concentrations of saline solution 0.1 M, 0.2 M, 0.4 M, 0.6 M, 0.8 M, 1.0 M. The results are shown in Fig. 4.1. As can be seen in the graph, with an increase in the salt solution concentration, the coulomb charge decreases due to a screening of the sphere charge by salt counter-ions.

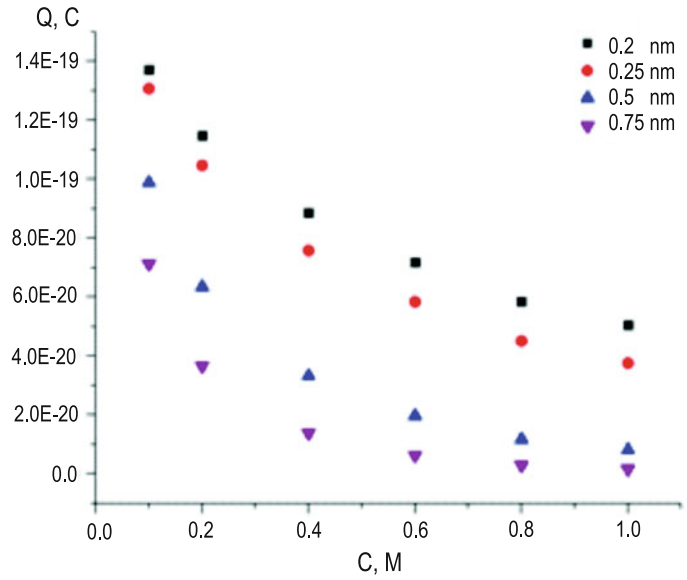

Fig. 4.1 Graph of the Coulomb charge decay with increasing salt solution concentration 0.1 M, 0.2 M, 0.4 M, 0.6 M, 0.8 M, 1.0 M at different distances from the sphere boundary 0.2, 0.25, 0.5, 0.75 nm

4.4 Description of the Physical Model

In this section, we turn to the description of the developed physical model for accounting for the effect of the concentration of a monovalent salt solution on the nature of selected histone proteins dimmers binding. In this physical model, we took into account the screening of the charged amino acid residues arginine (R), aspartic acid (D), phenylalanine (F), histidine (H), lysine (K) in an aqueous solution at various concentrations of a monovalent salt from 0.1 M to 0.8 M at a temperature of 20 °C. It was suggested that when the concentration of the monovalent salt of the aqueous solution increases, the interaction between charged amino acid residues decreases due to a screening of their charge by salt counter-ions in the aqueous solution.

At the same time, we suppose that:

1. the charge of charged amino acids is screened at a certain distance $delta_i$, ($i = \overline{1, 5}$) from the boundary of the amino acid residue, which we represent as a conducting sphere. This distance increases as the salt concentration in the solution increases and charges amino acids decrease as the salt concentration in the solution increases (see Table 4.2).

Table 4.2 The magnitude of the delta and the charges of the charged amino acid residues depending on the concentration of the salt solution

$N^{\underline{0}}$	Ionic concentration, M	delta, nm	$Q_D \times 10^{-19}$	$Q_E \times 10^{-19}$	$Q_R \times 10^{-19}$	$Q_H \times 10^{-19}$	$Q_K \times 10^{-19}$
1	0.2	0.003902	1.596	1.5954	1.59489	1.5955	1.59544
2	0.4	0.00702	1.583	1.589	1.580	1.582	1.581
3	0.6	0.00741	1.567	1.565	1.564	1.565	1.565
4	0.8	0.00780	1.553	1.551	1.569	1.551	1.551

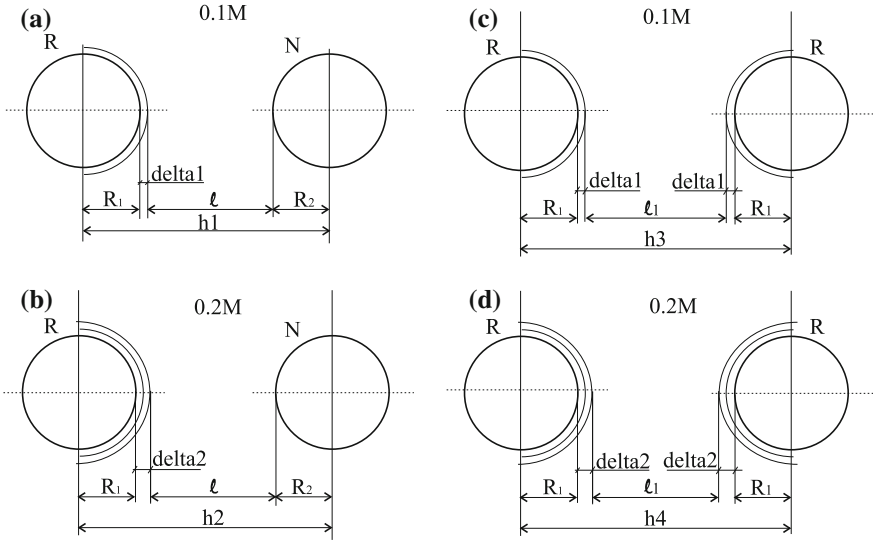

Fig. 4.2 Schema of increasing the distance between charged amino acids, as well as between charged amino acids and all other amino acids

2. Taking into account the increase in the concentration of the monovalent salt of the solution, the distance between the centers of the charged amino acid residues also increases, as well as between charged amino acids and all other amino acid residues, as shown in Fig. 4.2.

Thus, with an increase in the salt concentration in an aqueous solution at a constant temperature of 20 °C, the value of delta increases, as shown in Fig. 4.2. Between the charged amino acids, the distance increases from each side of each amino acid. The schema for calculating the distance between the amino acids R and N at a monovalent salt concentration 0.1 M is shown in Fig. 4.2a.

The schema for calculating distance between the amino acids R and N at a monovalent salt concentration of 0.2 M is shown in Fig. 4.2b.Thus, $h_1 < h_2$.

Table 4.3 Values of the dielectric constant of the medium from the concentration of the monovalent salt at temperatures 20 °C configuration

$N^{\underline{0}}$	Ionic concentration, M	Dielectric constant
1	0.1	79.800
2	0.2	78.602
3	0.3	77.409
4	0.4	76.223
5	0.5	75.045
6	0.6	73.878
7	0.7	72.724
8	0.8	71.584
9	0.9	70.460
10	1.0	69.354

A schema for calculating distance between two charged amino acid residues R and R at a monovalent salt concentration of 0.1 M is given in Fig. 4.2c.

In Fig. 4.2d, a schema for calculating distance between the charged amino acid residues R and R is shown with an increase in the concentration of the monovalent salt in the aqueous solution to 0.2 M. Thus $h_3 < h_4$.

With this, the values of l and l_1 remain constant. Since each concentration of the monovalent salt of the aqueous solution corresponds to its electrical permeability value, the value for concentrations from 0.1 M to1 M, we have combined these data in Table 4.3.

To analyze the biochemical processes we use the notion of condition number matrix of the potential energy of the pair electrostatic interaction between peptides. In this physical formulation of the problem, it will characterize the degree of stability of the configuration of the biological complex. In order to choose a more stable biochemical compound between proteins, we select the matrix of potential energy of electrostatic interaction with the **smallest** value of the condition number (see Chap. 2).

4.5 Results of Numerical Simulation. Conclusion

In this section, we present the numerical simulation results of the effect of the concentration of a monovalent salt solution on the nature of binding of protein complexes. Let us consider the behavior of the histone monomeric proteins H2A, H2B, H3 and H4 when they are bound to the H2A−H2B and H3−H4 dimers and the concentration of the monovalent salt in the aqueous solution increases.

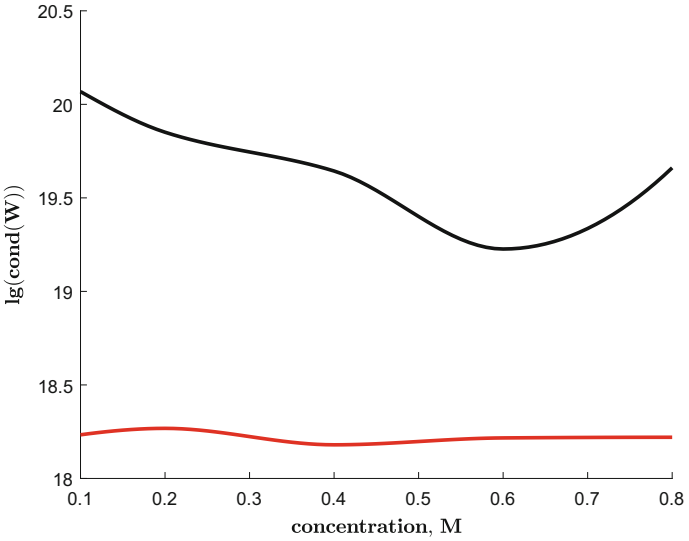

Fig. 4.3 influence of the concentration of a monovalent salt of an aqueous solution for the formation of histone dimer H2A−H2B and dimer H3−H4

Figure 4.3 shows the results of the influence of the concentration of a monovalent salt solution for the formation of histone dimer H2A−H2B and dimer H3−H4. Dimer H2A−H2B is described by the black curve and dimer H3−H4 is described by the red curve.

The first value of lg(cond(W)) for the interaction of H2A and H2B proteins at a concentration of 0.1 M was 20.068. All subsequent values of lg(cond(W)) do not rise above the first value. The curve obtained for the H3−H4 dimer is in the range of much lower values of lg(cond(W)). Note that the first value of lg(cond(W)) for the interaction of H3 and H4 monomers at 0.1 M is 18.233. Thus, from Fig. 4.3 it follows that when the dimer H2A−H2B is formed, an increase in the concentration of the monovalent salt leads to an increase the stabilization of the complex. At the same time, the analysis of the H3−H4 plot demonstrates a lower range of values of the lg(cond(W)) value compared to the values of lg(cond(W)) obtained by the interaction of H2A and H2B. The presence of a lower range of lg(cond(W)) values is interpreted as a possible propensity to aggregate of this biological complex, in this case, the H3−H4 dimer.

Thus, the mathematical modelling performed in this work on biological objects using histone proteins H2A, H2B, H3, and H4 has demonstrated the ability to predict the stability of the biological complex in the case of in vitro solutions with different ion strengths. An analysis of the calculations performed showed that different concentrations of the monovalent salt of the solutions correspond to the formation of more stable biological complexes. The introduced criterion lg(cond(W)) allows predicting a decrease or increase in the binding strength of histone proteins in the

formation of histone dimers, taking into account the charge screening of charged amino acid residues of proteins.

The effect of the concentration of a monovalent salt of an aqueous solution was studied on the same histone proteins at 20 °C. A comparison was made of the results obtained for the histone dimers H2A−H2B and H3−H4 with an increase in the concentration of the monovalent salt at a temperature of 20 °C and the behavior of the histone dimers in the salt-free aqueous solution at 20 °C. It should be noted that in the previous experimental article [13] the unfolding transition temperature of the 28kDa H2A−H2B dimer increases as a function of the ionic strength of the solvent.

It should be noted that we cannot at the moment interpret a specific concentration of monovalent salt on the achievement of which aggregation of protein complexes and their precipitation occurs. This requires additional experiments to study the behavior of biological complexes in solutions with different salt concentrations. In this chapter, screening of charged amino acid residues was taken into account, but we did not take into account how the other amino acid residues interact, in particular, how the charge of amino acid residues changes with increasing salt concentration, what changes occur with the volume of aa. and a possible change in other physical parameters of a.a. To obtain these additional data, further theoretical and experimental studies are required.

4.6 Matlab Script for Mathematical Modelling of the Effect of a Monovalent Salt Solution on the Interaction of Protein Molecules

Input parameters:

1. S_1, S_{20} are amino acid sequences of biological complexes ($S_1 \geq S_{20}$)
2. concentration of a monovalent solution
3. epsilon is the dielectric constant of the medium

Output parameters:

lg(cond(W) is the common logarithm of the condition number of the matrix W, where its elements are composed of the electrostatic potential energy which is created based on the interaction between pair of amino acid residues of biological complexes.

Compute:

lg(cond(W) is the common logarithm of the condition number of the matrix W, which will allow a prediction the reactivity of the studied biological complexes.

Chapter 5
Mathematical Modeling Identification of Active Sites Interaction of Protein Molecules

Abstract In this chapter, two algorithms are developed: Algorithm 1 and Algorithm 2. Algorithm 1 was developed in order to search for the interaction of a polypeptide chain of a full-length protein with short active region. Algorithm 2 was developed to determine the most active sites of interaction between full-length proteins when dimers are formed in the direction from the N-terminus to C-terminus. Numerical calculations were made using proteins Mdm2, Nap1, P53.

5.1 Introduction

For modern proteomics, research and prediction of protein interactions are very important tasks, since they determine the function of proteins at levels from the cell to the whole organism. For proteins whose structure is known, the search for intermolecular interactions according to known data on the conformation of their tertiary structure reduces to the problem of searching for geometric complementarity of the sections of two interacting molecular surfaces and modelling their contacts, the so-called molecular docking [1]. The task of molecular docking is the task of a conformational search algorithm, which reduces to a search for the conformational space of the formed biological complex due to the variation of the torsion angles of protein molecules.

Modern conformational search algorithms in most cases find conformations that are generally close to the experimentally found structures in a relatively short time. However, there are factors that also have a significant impact on the success of the docking, which are often not taken into account in standard algorithms. One such factor is the conformational mobility of the target protein. The mobility range can be different - beginning with a small ≪adjustment≫ of the side chains and ending with scale domain movements [2]. These movements play an important role. At first glance, the most logical solution to this problem is to take into account the mobility

T. Koshlan and K. Kulikov, *Mathematical Modeling of Protein Complexes*,
Biological and Medical Physics, Biomedical Engineering,
https://doi.org/10.1007/978-3-319-98304-2_5

of the protein in a docking program. Unfortunately, modern computational tools do not allow such modelling to be performed in an acceptable time frame since a protein molecule is very large, and allowing for mobility over all degrees of freedom can lead to a so-called ≪combinatorial explosion≫ (an astronomical increase in the number of possible variants). Only in some programs is there a limited mobility of protein binding sites (usually at the level of a small adaptation of conformations of the side chains of the active center residues). Another approach to this problem consists in docking the same protein in several different conformations and then selecting the best solutions from each docking run. The third approach is to find a universal structure of the target protein in which docking would produce fairly good results for different classes of ligands. In this case, the number of ≪missed≫ (but correct) solutions decreases, but the number of incorrect options [3] also increases significantly. It should also be noted that most programs for the theoretical docking of proteins work according to the following principle: one protein is fixed in space, and the second is rotated around it in a variety of ways.

At the same time, for each rotation configuration, estimates are made for the evaluation function. The evaluation function is based on surface complementarity (the mutual correspondence of complementary structures (macromolecules, radicals), determined by their chemical properties), electrostatic interactions, van der Waals repulsion, and so on. The problem with this approach is that calculations throughout the configuration space require a lot of time, rarely leading to a single solution [1, 2], which in turn does not allow us to speak of the uniqueness of the target protein and ligand interaction variant. So in the work [2], while modelling by the methods of molecular dynamics, from 200 to 10 000 possible combinations of the formation of a protein complex with a ligand were found. Such a large number of modifications, along with the lack of a criterion for selecting the most probable variants of the bound structures of biological complexes (which would allow a radical reduction in their number) makes it very difficult to interpret the theoretical results obtained for practical use, namely, the finding of catalytic centers and a qualitative assessment of the dissociation constant of interacting substances.

In contrast to the above computer simulation algorithms, mathematical algorithms have been developed in this chapter that allow determining the detection of proteins active regions and detecting the stability of different regions of protein complexes (linear docking) by analyzing the potential energy matrix of pairwise electrostatic interaction between different sites of the biological complex, such as the homodimer of the histone chaperone Nap1–Nap1, the heterodimer of the p53–Mdm2 proteins, and the homodimer Mdm2–Mdm2, which are responsible for the entry of a whole protein molecule into biochemical reactions.

The chapter consists of several parts.

The first part describes the structure and function of proteins Mdm2, P53, Nap1. The second part describes developed algorithms. The third part presents numerical calculations and their analysis The amino acid sequences of the studied proteins P53, Nap1, Mdm2 were taken in [4] with the numbers: P04637, P25293, Q00987, respectively.

5.2 The Structure and Function of the Protein P53

The P53 protein was discovered in 1979 and received its name on the molecular weight (53KDa) [5–7].

Protein P53 is transcription factor regulating the cell cycle, and it suppresses the formation of malignant tumors [8, 9].

The P53 protein in the activated state regulates the transcription of a large number genes, and also interacts with a large number of other proteins, thereby affecting many intracellular processes [10, 11].

One of the functions of protein P53 is the control of the state of cellular DNA [10, 12].

P53 is activated when it receives deviation signals from normal cellular prosesses, and it recognaser damage in the gemetic apparatus. This leads to either an acceleration, or it stop the cell cycle and with strong stress stimulus-to apoptosis [13].

The P53 protein undergoes phosphorylation during cellular stress [14] and its level of concentration in the cell increases [15].

This activates the protein genes, which are involved in cellular apoptosis, such as the protein Mdm2, which is involved in negative regulation of P53 protein [6].

The MDM2 protein binds to the transactivation domain of the P53 protein, which is located on the flexible N-terminus of the P53 protein, which forwards to the regulation of the amount of P53 protein in the cell and leads to its subsequent degradation [16, 17].

As is known, the functions of proteins depend on their three-dimensional structure. The human protein P53 has 393 amino acid residues. Protein domains are independent folding units, which usually have sizes from 40 to 200 amino acid residues [16].

Thus, the P53 protein contains several domains. In the structure of this protein are three main domains: the transactivation domain (1–70); a sequence which specifically binds to $DNA_{(94-293)}$; tetramerization domain (324–355) [16]. Figure 5.1 shows the structure of protein P53. The P53 protein domains are connected by linker regions. Proline-rich domain (71–93) binds to the transactivation domain of the domain, which is responsible for binding to DNA. DNA binding domain is target for a large number of mutations P53 [16].

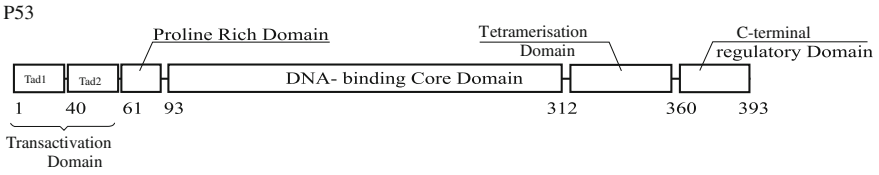

Fig. 5.1 The structure of the protein p53

5.3 The Structure and Functions of the Protein Mdm2

Human Murine double minute 2 (Mdm2) is a 491-amino acid (a.a.) -long phosphoprotein [18, 19]. Mdm2 is an oncogene with both P53-dependent and P53-independent oncogenic activities, and often has increased expression levels in a variety of human cancers [20].

Inhibition functions of protein P53, when it binds with the Mdm2 protein is carried out different ways. These ways help block the transactivation domain P53 and simultaneously promote export P53 from the nucleus to proteasome degradation systems [21].

A detailed study of the structure formed by proteins Mdm2 and P53 showed that the amino terminal domain of Mdm2 forms a deep hydrophobic cleft into which the transactivation domain of P53 binds, thereby concealing itself from interaction with the transcriptional machinery [22, 23].

The direct interaction between the two proteins has been localized to a relatively small hydrophobic pocket domain at the N-terminus of Mdm2 and 15 a.a. amphipathic peptide at the N-terminus of P53. The P53 binding domain of human Mdm2 which can be identified within residues 18–101 and interact with residues 15–29 of P53. Various signals, for example the destruction of cellular DNA leads to an abnormal interaction of Mdm2 and P53, which is the cause of activation P53-dependent cell responses [16, 22]. In the protein Mdm2 several areas were identified see Fig. 5.2 at N-tail of the main region is binding to P53.

In the central part of the protein there are many acidic regions. Moreover, the C-tail contains a zinc-binding domain. This part of the protein interacts with a variety of regulatory factors as well as multiple ribosomal or nucleolar proteins.

The C-terminus also contains a RING domain that has been shown to be responsible for the E3 ubiquitin ligase activity, as well as the binding of the Mdmx and Mdm2 [24].

In this chapter, we have performed simulations of the protein Mdm2 interaction and protein P53 and the interaction between the same proteins of Mdm2 with the formation of a homodimer Mdm2–Mdm2.

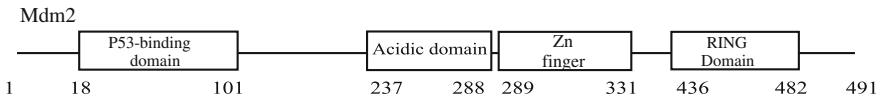

Fig. 5.2 The structure of the protein Mdm2 [16]

5.4 The Structure and Functions of the Protein Nap1

Nucleosome assembly protein 1 (Nap1) is an integral component in the establishment, maintenance, and dynamics of eukaryotic chromatin. It shuttles histones into the nucleus, assembles nucleosomes, and promotes chromatin fluidity [25].

The article [26, 27] presents various functions of the histone chaperone Nap1 protein, mainly its role in nucleosome assembly and disassembly, and the interactions of Nap1 with different chromatin remodelling factors; information is given on various binding sites of Nap1 with other proteins.

Let us consider in more detail the structure of the protein of the histone chaperone Nap1. In [25] was found that of a total of 417 a.a. well structured central sites residues, whereas the N- and C-terminal regions were largely disordered. The central region is defined in [25] is core region (74–365).

The structure of the protein Nap1 can be divided into several sections: unstructured N- and C-tails, Domain I and Domain II. Consider in more detail Domain 1 which is responsible for the dimerization of Nap1 [25].

During the dimerization prosess, an interaction occurs between the long $\alpha 2$-helices of two proteins in opposite directions. The dimer is further stabilized by the $\alpha 2$–$\alpha 3$ loop, the $\alpha 3$-helix, and the $\alpha 3$–$\alpha 4$ loop that wrap around the base of the $\alpha 2$-helix of the dimerization partner. In Fig. 2.2 a schematic representation of the Domain I and Domain II structures is presented. Domain I includes $\alpha 1$-, $\alpha 2$-, $\alpha 3$-helices, which are in most degree responsible for dimerization of the protein Nap1. Domain II spans residues 181–370 of Nap1. Figure 5.4 shows a scheme of the formation of the Nap1–Nap1 homodimer by two proteins of the histone chaperone. In blue color which is denoted by Domain 1 of the first histone chaperone Nap1 with indication of $\alpha 2$ and $\alpha 3$-helices, which take part in homodimerization. Orange color represents Domain 1 of the second protein of the histone chaperone Nap1 amd also shows the $\alpha 2$ and $\alpha 3$-helices. In monochrome, the rest of the proteins that are not actively involved in the formation of the Nap1–Nap1 homodimer are shown.

The dimer interface is characterized mainly by hydrophobic interactions over the entire length of the involved amino acid residues in $\alpha 2$-helices. A wide region of dimerization, covering all dimer diagonally is indicated in color Fig. 5.4.

5.5 Description of the Algorithms

5.5.1 Algorithm 1

This algorithm has been developed to search for protein sites responsible for protein interactions.

During the development of this algorithm we have made the following assumptions:

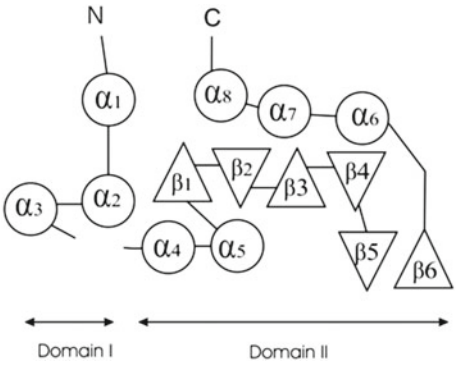

Fig. 5.3 Scheme of domains I and II of protein Nap1 [25]

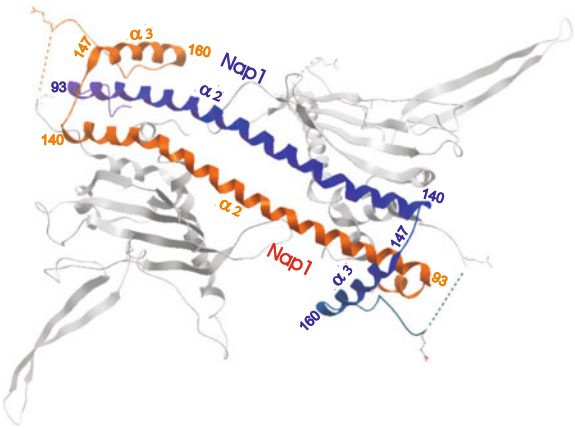

Fig. 5.4 The scheme for the formation of the Nap1–Nap1 homodimer [28]

– we know the short amino acid sequence of one protein, which takes an active part in binding to another protein, with formation large numbers nearly located interacting amino acid residues, for example, the formation of homodimers Mdm2−Mdm2 and Nap1–Nap1,

– we do not know the active site of the whole protein responsible for binding to the short polypeptide sequence.

Thus, using Algorithm 1, we find the active site on the polypeptide sequence of the whole protein. This algorithm (see Fig. 5.5) presents two vectors:

– the one-dimensional array 1 ≪DTEVNKL≫ and one-dimensional array 2 ≪ADHVNRTYOIK≫, which are amino acid sequences of the proteins P_1 and P_2, respectively,

– the one-dimensional array of the P_1 protein has a smaller number of amino acid residues in its polypeptide sequence than the one-dimensional array of the protein P_2. As each step occurs, a shot section of the amino acid sequence of protein P_2 forms, which is equal to the length of the shoter one dimernsional array of protein P_1.

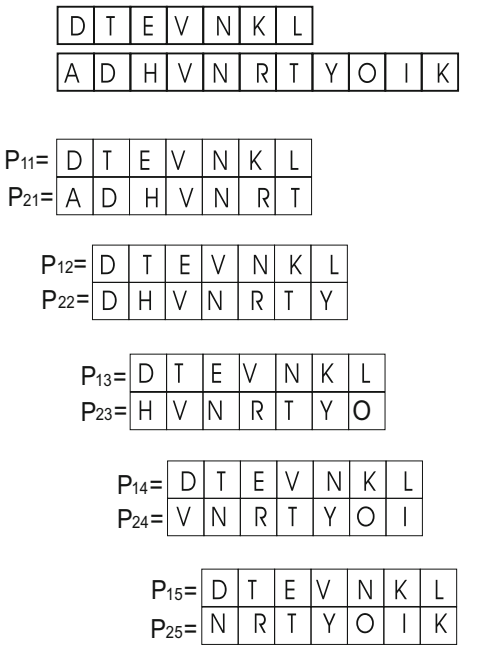

Fig. 5.5 The scheme Algorithm 1

The more short amino acid sequence of one-dimensional array P_1 moves along the more long amino acid sequence one-dimensional array of the protein P_2 with some step, in our example, the step is equal one amino acid.

In each step occurs the formation of a short section of the amino acid sequence of protein P_2, equal to the length of the shorter one-dimensional array of protein P_1.

Each new segment of the one-dimensional array P_2 corresponds to the length of the polypeptide chainone-dimensional array P_1. Five pairs of one-dimansional arrays P_1 and P_2 were successfully formed when the one-dimensional array 1 shifted by one amino acid residue along the one-dimensional array P_2.

$P_{11} = \text{DTEVNKL}\ P_{21} = \text{ADHVNRT}$
$P_{12} = \text{DTEVNKL}\ P_{22} = \text{DHVNRTY}$
$P_{13} = \text{DTEVNKL}\ P_{23} = \text{HVNRTYO}$
$P_{14} = \text{DTEVNKL}\ P_{24} = \text{VNRTYOI}$
$P_{15} = \text{DTEVNKL}\ P_{25} = \text{NRTYOIK}$

Note that the vector 1 remains unchanged in all formed pairs one-dimensional arrays, i.e. $P_{11} = P_{12} = P_{13} = P_{14} = P_{15}$.

After finding all the participating pairs of vectors, we build a matrix of potential energy electrostatic interaction between their amino acid residues. These matrices will have a square form.

Further, from each of these matrices we calculate the value lg(cond(W)) and construct a graph of the dependence of lg(cond(W)) on the order number of the

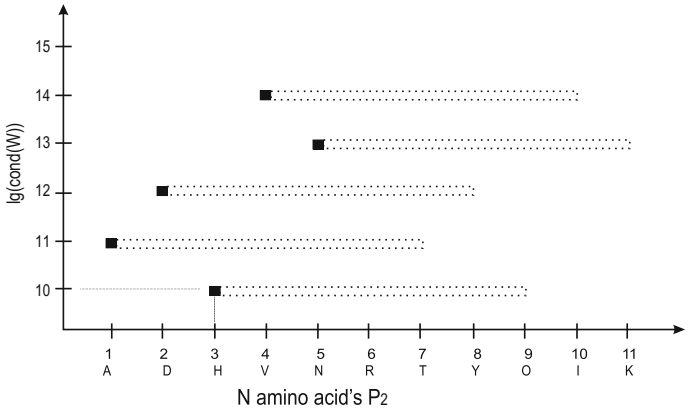

Fig. 5.6 Scheme dependence of lg(cond(W)) from Amino acid sequence

amino acid residue of one-dimensional array P_2, where cond(W_k) is the condition number.

Thus, each resulting value of lg(cond(W)) will correspond to a strictly defined segment of one-dimensional array P_2. Note that on the graph it is postponed opposite the first amino acid residue of a segments P_{21}, P_{22}, P_{23}, P_{24} or P_{25} one-dimensional array P_2.

Figure 5.6 shows graph dependence of values lg(cond(W)) on the sequence number of the polypeptide chains of participating one-dimensional arrays P_1 and P_2. In this example, as we see from graph the smallest value of lg(cond(W)) corresponds to the interaction of the vectors P_{13} is ≪DTEVNKL≫ and P_{23} is ≪HVNRTYO≫. The dotted line indicates the amino acid sequence of one-dimensional array P_2, which participates in the formation of a biological complex with a one-dimensional array P_1. The value of the value lg(cond(W)) is placed opposite the first amino acid of the remainder of the segment of the one-dimensional array P_2. For data processing we will choose several of the smallest values of lg(cond(W)) (see Chap. 2).

We suppose that for the most stable complex of interacting sites has the largest number of nearby points with a minimum value of lg(cond(W)). We call this area a cluster.

5.5.2 Algorithm 2

We developed a second algorithm for detecting interacting regions of protein molecules. The scheme search interacting sections is shown in Fig. 5.7. In this algorithm we take whole amino acid sequences of the two proteins P_1 and P_2. For selecting interacting sites, we shift the frame of a specific size along two one-dimensional arrays of proteins P_1 and P_2.

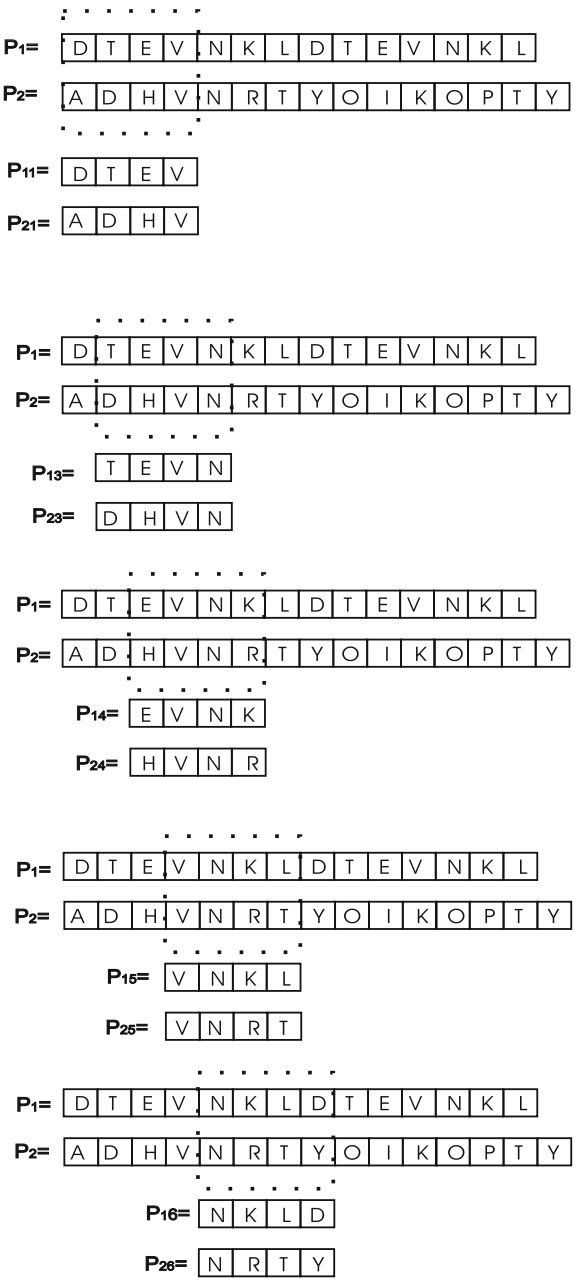

Fig. 5.7 The scheme Algorithm 2

According to the method, we test the interaction sites for the following pairs of proteins: Nap1–Nap1, Mdm2–Mdm2.

Note that Algorithm 2 can be used to analyze the interaction of two proteins, which have identical sites of interaction during the formation of a dimer.

After finding all the participating pairs of one-dimensional arrays, we build a matrix of potential energy electrostatic interactions. These matrices will have a square form. Further, for all matrices we calculate the values lg(cond(W)) and construct a graph of the dependence of lg(cond(W)) on the order number of the amino acid residue of the participating one-dimensional arrays.

The sequence number will be the same for the two considered one-dimensional arrays. In this case, the amino acid residues corresponding to the ordinal number can be different, if the interactions of different proteins are investigated.

5.6 Numerical Simulation of the Formation of Heterodimers and Homodimers According to Algorithm 1

In this section, the interactions of the short amino acid sequences$\mathrm{Mdm2}_{(436-482)}$ and $\mathrm{Nap1}_{(81-150)}$, which take an active part in the formation of Nap1–Nap1 and Mdm2-Mdm2 homodimers, have been modeled. Preliminary information on the activity of these sites of $\mathrm{Mdm2}_{(436-482)}$ and $\mathrm{Nap\,1}_{(81-150)}$ was obtained from previous experimental studies [25, 29].

Numerical simulation was performed according to the developed Algorithm 1. Thus, the purpose of this section is to test the developed Algorithm 1 in determining the most active interaction regions of a full-length protein with a short polypeptide sequence. Numerical calculations were performed with $\varepsilon = 1$ (air) and $\varepsilon = 80$ (water). At the same time, the authors tried to choose a common scale for presenting the obtained graphic data for all the calculations performed in order to facilitate understanding and to allow the reader to visually compare the results of the obtained data. In addition to the graphical representation, we also gave 10 minimum values of lg(cond(W)) with a list of the corresponding interacting amino acid sequences at $\varepsilon = 1$ and $\varepsilon = 80$, and the data were tabulated. We assume that the more precisely the active region of one protein is given when interacting with the whole amino acid sequence of the second protein, the more qualitative the result of the interaction of the two proteins is. It is assumed that a large amount of a.a. (a significant length of polypeptide chain) from each protein corresponds to the formation of the biological complex.

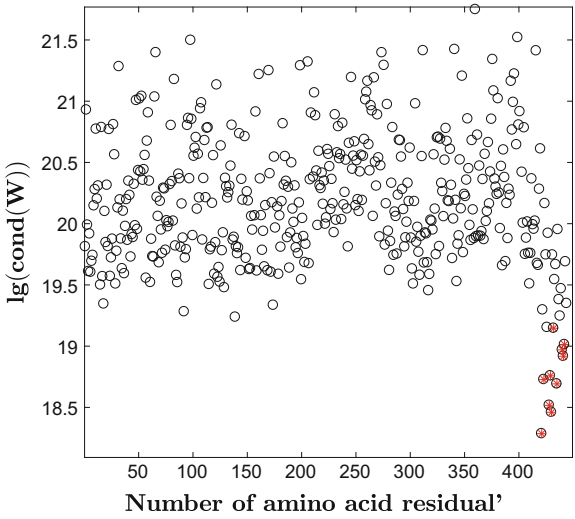

Fig. 5.8 Results of numerical simulation of the interactions of $Mdm2_{(436-482)}$ with Mdm2, $\varepsilon = 1$. The red dots denote the 10 minimum values of lg(cond(W))

5.6.1 *Numerical Calculation of the Interaction of* $\mathbf{Mdm2_{(436-482)}}$ *Mdm2*

A search was carried out for the polypeptide chain Mdm2, which is most inclined to form a complex with the Mdm2 protein Ring domain. To achieve this goal, we took the Mdm2 protein domain polypeptide region (436–482):

$$[EPCVICQGRPKNGCIVHGKTGHLMACFTCAKKLKKRNKPCPVCRQPI]$$

and numerically calculated its interaction with the Mdm2 protein according to Algorithm 1 developed earlier. In this case, the short sequence of the protein $Mdm2_{(436-482)}$ shifted along the long sequence of the protein Mdm2 at intervals of 1 a.a. As a result, for each pair of the obtained one-dimensional arrays, a matrix of potential energy of electrostatic interaction was formed, and the value of lg(cond(W)) was calculated. The value of lg(cond(w)) was plotted opposite the first a.a. section of the Mdm2 protein upon interaction with $Mdm2_{(436-482)}$. The results are shown in Figs. 5.8 and 5.9. In this section, we present one graph that contains all the values of lg(cond(W)) obtained for the interaction of $Mdm2_{(436-482)}$ with Mdm2. We will use scaled graphs of the smallest values of lg(cond (W)), since we will analyze these values.

As can be seen from the Figs. 5.8 and 5.9, the set of minimum values form a cluster from the C-terminus of the Mdm2 protein. The ten minimum values of lg(cond(W)) for the interaction of $Mdm2_{(436-482)}$ with Mdm2, as well as the corresponding amino acid sequences at $\varepsilon = 1$ and $\varepsilon = 80$ are summarized in Tables 5.1 and 5.2.

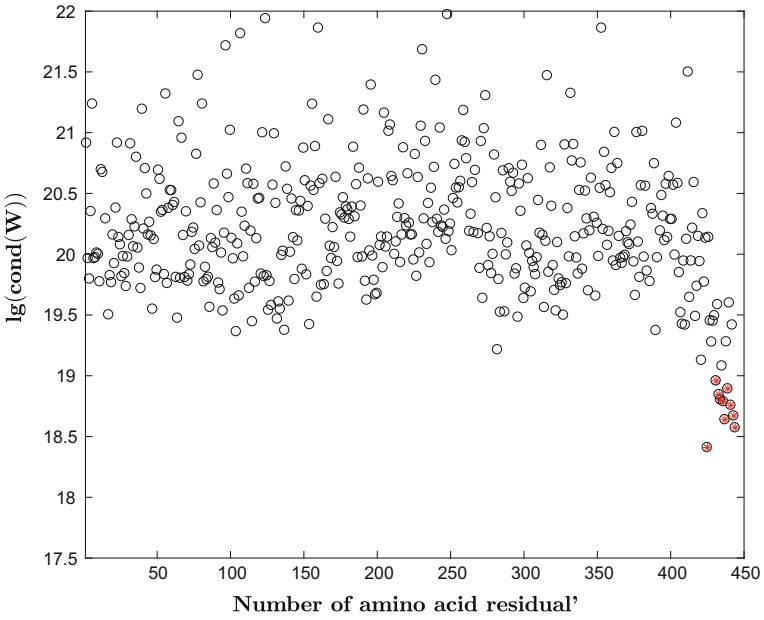

Fig. 5.9 Results of numerical simulation of the interactions of $Mdm2_{(436-482)}$ with Mdm2, $\varepsilon = 80$. The red dots denote the 10 minimum values of lg(cond(W))

It follows from Tables 5.1 and 5.2 that the areas with the minimum values of lg(cond(W)) are almost identical at $\varepsilon = 1$ and $\varepsilon = 80$ and are in the previously identified range of the polypeptide chain of the Mdm2 protein responsible for binding to $Mdm2_{(436-482)}$ from the C-Terminus. Thus, it can be concluded that the sequence $Mdm2_{(436-482)}$ plays an active role in the dimerization of the Mdm2 protein and is most likely to form stable biological complexes in the C-terminus region of the Mdm2 protein. This result is in good agreement with [29–31].

Note that we gave 10 minimum values of lg(cond(W)), characterizing the interactions of $Mdm2_{(436-482)}$ with Mdm2, but we did not exclude the presence of other regions of interaction of $Mdm2_{(436-482)}$ with Mdm2 that did not fall within the given range of the 10 minimum values of lg(cond(W)) from Table 5.1 and 5.2 for $\varepsilon = 1$ and $\varepsilon = 80$. We also did not exclude the existence of other possible sites for binding $Mdm2_{(436-482)}$ to Mdm2.

5.6.2 Numerical Calculations of the Interaction $\mathbf{Nap1_{(81-150)} - Nap1}$

In this section, we consider the results of the numerical modelling of the interaction of the protein region with the whole amino acid sequence of the histone chaperone Nap1 protein.

We selected a region of the protein $Nap1_{(81-150)}$ which takes an active part in the dimerization of the Nap1 protein and made a numerical calculation of the interaction of this region with the polypeptide sequence of the whole protein Nap1.

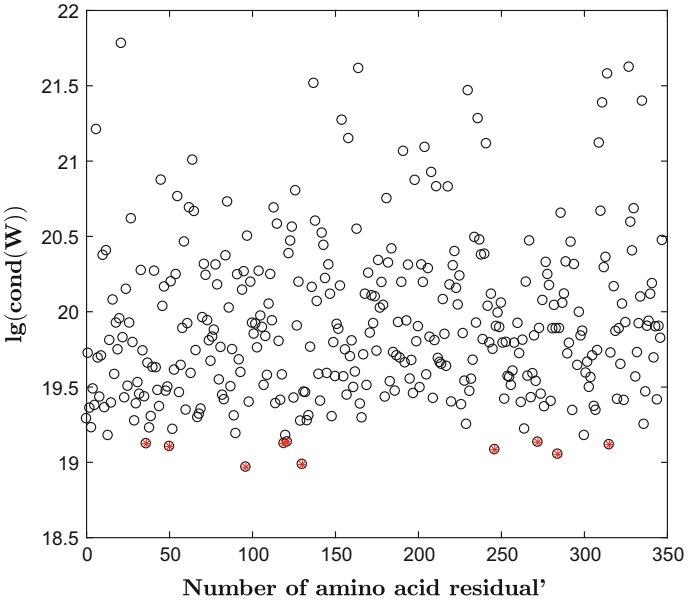

Fig. 5.10 Results of the numerical calculations of $\text{Nap1}_{(81-150)}$ with Nap1 interactions according to Algorithm 1, $\varepsilon = 1$. The red dots denote the 10 minimum values of lg(cond(W))

The amino acid sequence $\text{Nap1}_{(81-150)}$ was moved along the polypeptide sequence of the protein Nap1 at intervals of 1 a.a. according to Algorithm 1. Arrays 70 a.a. long were formed, one of which was represented as the amino acid sequence of the active site of the protein ($\text{Nap1}_{(81-150)}$), and the second array was characterized by serially changing amino acid residues of the protein Nap1. For each pair of the obtained arrays, a matrix of potential energy of pairwise electrostatic interaction was formed and the value of lg(cond(W)) was calculated.

We assume that the more precisely the active site of interaction of one protein is initially plotted, the more accurate the results will be obtained when the active site is located on another protein as they are bound to the biological complex. Numerical calculation of Nap1 interaction with $\text{Nap1}_{(81-150)}$ was carried out according to Algorithm 1 for $\varepsilon = 1$ (air) and $\varepsilon = 80$ (water). The results are shown in Figs. 5.10 and 5.11.

As can be seen from the Fig. 5.11 for $\varepsilon = 80$ a cluster of the smallest values of lg(cond(W)) is observed, with the smallest value obtained at 74 a.a. Note that this 74 a.a. is the first amino acid residue of domain 1 responsible for the formation of the Nap1–Nap1 homodimer. The results obtained during the interaction of $\text{Nap1}_{(81-150)}$ with Nap1, $\varepsilon = 1$, shown in Fig. 5.10 do not demonstrate the existence of cluster

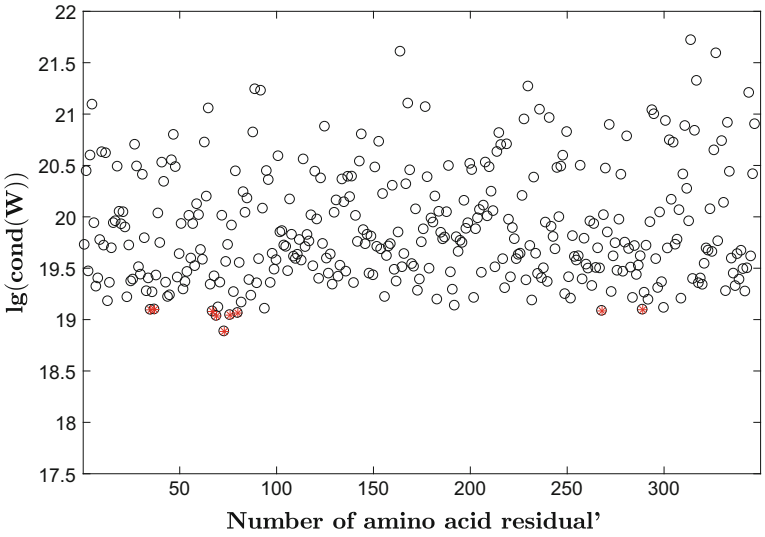

Fig. 5.11 Results of the numerical calculations of $\text{Nap1}_{(81-150)}$ with Nap1 interactions according to Algorithm 1, $\varepsilon = 80$. The red dots denote the 10 minimum values of lg(cond(W))

formation from the minimum values. The minimum value for $\varepsilon = 1$ is obtained at 97 a.a., which is also a satisfactory result because 97 a.a. is located in the region of the beginning of domain 1, while other areas of possible interaction of $\text{Nap1}_{(81-150)}$ with Nap1 in the domain 2 region are observed.

The ten minimum values of lg(cond(W)) for $\text{Nap1}_{(81-150)}$ interaction with Nap1 at $\varepsilon = 1$ and $\varepsilon = 80$ are presented in Tables 5.3 and 5.4.

The results of Table 5.4 show the formation of a cluster from the minimum values of lg(cond(W)) in the region of domain 1 responsible for the formation of the Nap1–Nap1 homodimer at $\varepsilon = 80$. The results of Table 5.3 for $\varepsilon = 1$ do not show the formation of such a cluster from the minimum values of lg(cond (W)). Thus, calculations performed at $\varepsilon = 80$ made it possible to obtain a better result and subsequent analysis than the numerical results obtained at $\varepsilon = 1$.

As can be seen from the Fig. 5.11 and Table 5.3, the polypeptide sequence of the histone chaperone protein Nap1 has its main binding site with the short sequence $\text{Nap1}_{(81-150)}$ in the Domain 1 region. The smallest value of lg(cond(W)) was obtained at 74 a.a. and amounted to 18.884. This amino acid residue (74 a.a.) in domain 1 is the first responsible a.a. for the formation of the Nap1–Nap1 homodimer and the result is in good agreement with previous work [25].

5.7 Numerical Simulation of the Formation of Protein Dimers According to Algorithm 2

In this section, numerical calculations of the interaction of amino acid sequences were performed to determine the active regions of proteins Mdm2 and Nap1 with the formation of the homodimers Nap1–Nap1 and Mdm2−Mdm2.

We used whole amino acid sequences of identical proteins Nap1 and Mdm2 and we shifted a frame of a given size depending on the type of protein along two one-dimensional arrays describing the identical amino acid sequences Nap1 and Nap1, Mdm2 and Mdm2 at intervals of 1 a.a. By the method of successively increasing the size of the frameshift from 20 a.a. up to 70 a.a. we obtained a set of data that, with varying degrees of approximation, allows us to obtain a qualitative result of the interaction of the selected proteins. In this case, we assume that the closer the size of the frameshift to the size of the interacting regions of proteins is given, the more qualitative the result will be of the interaction of the two proteins, provided that amino acid sequences with close order number of the participating amino acid residues of proteins play an important role in the interaction. It is assumed that a large amount of a.a. (a significant length of the polypeptide chain) from each protein corresponds to the formation of the biological complex.

5.7.1 Numerical Calculation of the Interaction of Two Polypeptide Chains of the Mdm2 Protein

In this section, we analyzed the numerical calculation of the homodimer formation Mdm2−Mdm2 according to Algorithm 2. We used the amino acid sequences of the proteins Mdm2 and Mdm2 and formed the corresponding one-dimensional arrays, by shifting the frame along two polypeptide chains at intervals of 1 a.a., in order to identify the most active regions of the interaction of the studied proteins. The ten minimum values of lg(cond(W)) for each calculation obtained are tabulated in the corresponding graph.

We now turn to the analysis of numerical calculations of the interaction of two Mmd2 and Mdm2 proteins at a frameshift length equal to 20 a.a. The results of the numerical interaction are shown in Fig. 5.12 for $\varepsilon = 1$ and in Fig. 5.13 for $\varepsilon = 80$. Ten minimum values of lg(cond(W)) are presented in Tables 5.5 and 5.6.

We now turn to the analysis of numerical calculations of the interaction of two Mdm2 and Mdm2 proteins at a frameshift length equal to 30 a.a. The results of the numerical interaction are are shown in Fig. 5.14 for $\varepsilon = 1$ and in Fig. 5.15 for $\varepsilon = 80$. Ten minimum values of lg(cond(W)) are presented in Tables 5.7 and 5.8.

We now turn to the analysis of numerical calculations of the interaction of two Mdm2 and Mdm2 proteins at a frameshift length equal to 40 a.a. The results of the numerical interaction are are shown in Fig. 5.16 for $\varepsilon = 1$ and in Fig. 5.17 for $\varepsilon = 80$. Ten minimum values of lg(cond(W)) are presented in Tables 5.9 and 5.10.

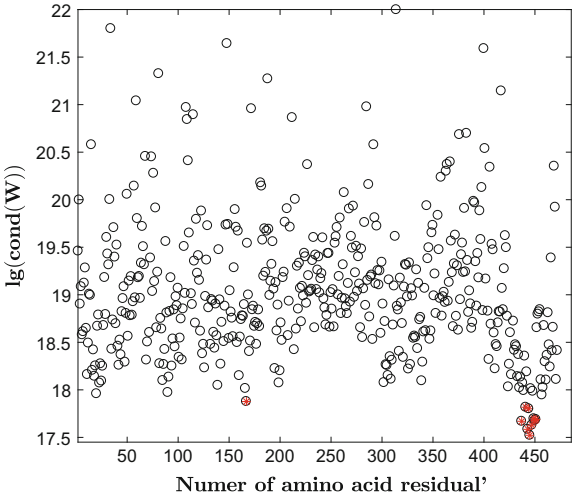

Fig. 5.12 Results of numerical simulation of the interaction of Mdm2 with Mdm2, frame size equal to 20 a.a., $\varepsilon = 1$. The red dots denote the 10 minimum values of lg(cond(W))

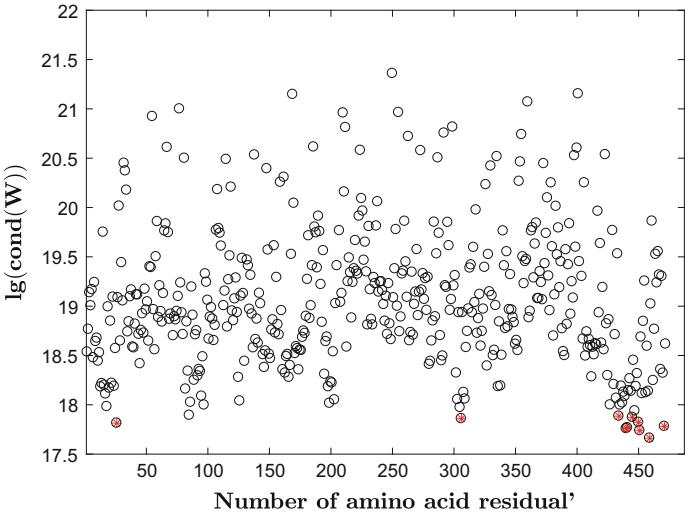

Fig. 5.13 Results of numerical simulation of the interaction of Mdm2 with Mdm2, frame size equal to 20 a.a. for $\varepsilon = 80$. The red dots denote the 10 minimum values of lg(cond(W))

We now turn to the analysis of numerical calculations of the interaction of two Mdm2 and Mdm2 proteins at a frameshift length of 50 a.a. The results of the numerical interaction are are shown in Fig. 5.18 for $\varepsilon = 1$ and in Fig. 5.19 for $\varepsilon = 80$. Ten minimum values of lg(cond(W)) are presented in Tables 5.11 and 5.12.

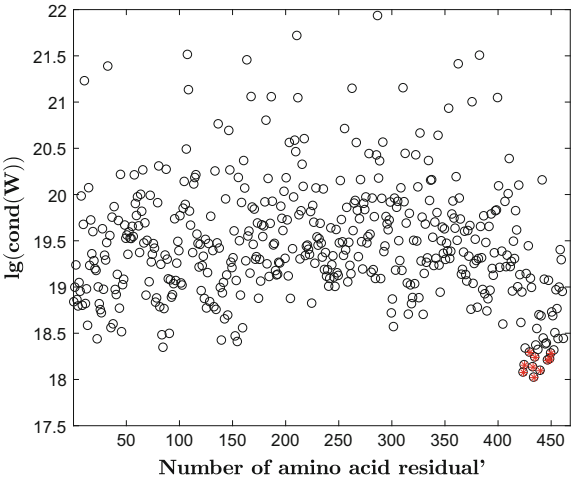

Fig. 5.14 Results of numerical simulation of the interaction of Mdm2 with Mdm2, frame size equal to 30 a.a., $\varepsilon = 1$. The red dots denote the 10 minimum values of lg(cond(W))

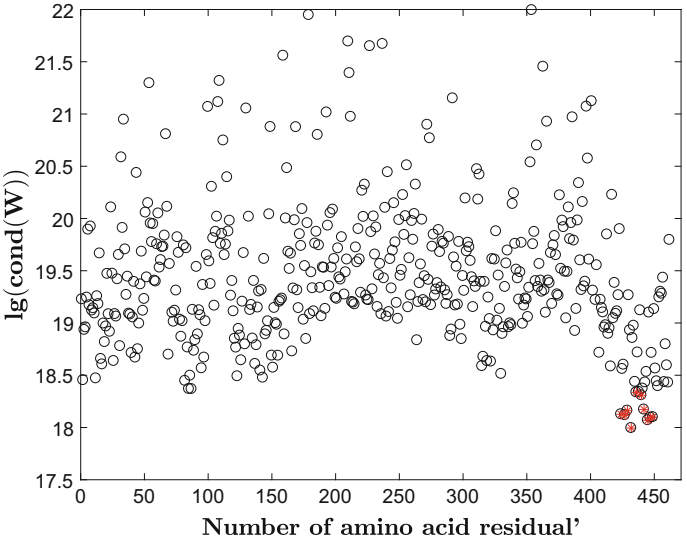

Fig. 5.15 Results of numerical simulation of the interaction of Mdm2 with Mdm2, frame size equal to 30 a.a., $\varepsilon = 80$. The red dots denote the 10 minimum values of lg(cond(W))

As can be seen from Tables 5.1 and 5.8, the greatest number of minimum values lies at the C-terminus of the Mdm2 protein. It also follows from the graphs Figs. 5.12, 5.13, 5.14, 5.15, 5.16, 5.17, 5.18 and 5.19 that, as a result of numerical calculation of the interaction of two polypeptide chains of the Mdm2 protein, according to Algorithm 2, a cluster of the smallest values in the C-terminus regions of two Mdm2

proteins is formed at $\varepsilon = 1$ and $\varepsilon = 80$. This result is in good agreement with earlier experimental work, which indicates the oligomerization of the RING domain of the Mdm2 protein and the important role of the C-terminus of Mdm2 in the formation of the Mdm2−Mdm2 homodimer [29–31].

In this section, we gave 10 minimum values of lg(cond(W)) characterizing the interactions of Mdm2 with Mdm2, but we did not exclude the presence of other regions of interaction of Mdm2 with Mdm2 that did not fall in the above list of 10 minimum values of lg(cond(W)) for $\varepsilon = 1$ and $\varepsilon = 80$. The result of the interaction of two Mdm2 proteins of different frameshift lengths from 20 a.a. up to 50 a.a. identifies in all cases the site of the most stable formed complex in the region of the C-terminus of the Mdm2 protein.

It should also be taken into account that the Algorithm 2 developed by us allows one to analyze the interactions of amino acid residues between two proteins with only approximately symmetrical sequence numbers. We note that if we analyze two identical proteins, we will obtain an analysis of the interaction between identical amino acid sequences. In order to obtain data containing information on the interaction between different regions of the polypeptide chains of proteins, it is better to use Algorithm 1, to extract each protein region of interest from one protein and to determine the stability of each complex formed by it with different regions of the second protein.

To obtain more reliable and qualitative data, it is recommended to take segments of polypeptide sequences of the same size. If we analyze the interactions of sections

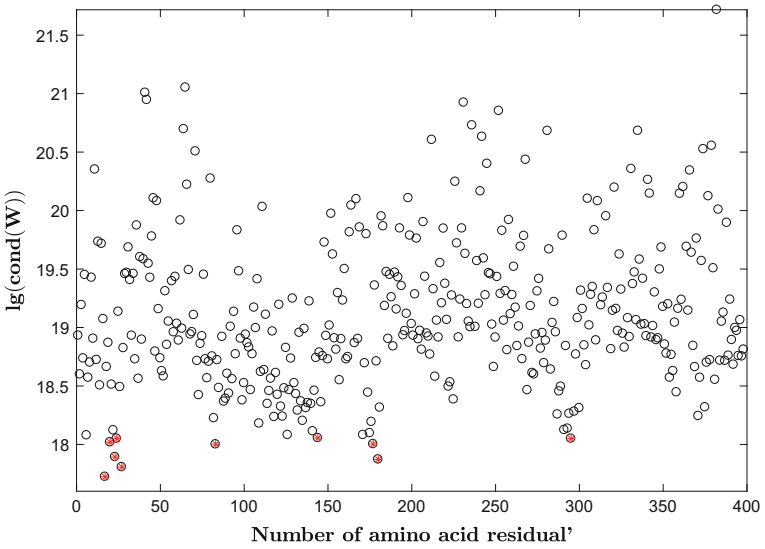

Fig. 5.20 Results of numerical simulation of the interaction of Nap1 with Nap1, frame size equal to 20 a.a., $\varepsilon = 1$. The red dots denote the 10 minimum values of lg(cond(W))

Nap1. We give a step-by-step detailed description of the numerical computations obtained with brief conclusions for each calculation in order to give a clear idea for further modelling of the interaction of other proteins. Note that the formation of the Nap1 homodimer Nap1–Nap1 is due to two identical binding sites in domain 1 of each protein from 74 a.a. to 180 a.a. in opposite directions [25]. The main dimerization site of two proteins belongs to the α2-helix from 90 a.a. to 140 a.a. of each histone chaperone Nap1 protein.

We now turn to the analysis of numerical calculations of the interaction of two Nap1 and Nap1 proteins at a frameshift length of 20 a.a. The results of the numerical interaction are shown in Fig. 5.20 for $\varepsilon = 1$ and in Fig. 5.21 for $\varepsilon = 80$.

As can be seen from the graphs Figs. 5.20 and 5.21, with a frameshift equal to 20 a.a. there are many areas of interaction between proteins Nap1 which are characterized by a small value of lg(cond(W)). In this case, the ten minimum values of lg(cond(W)) obtained by the interaction of Nap1–Nap1 with a frameshift equal to 20 a.a. are given in Table 5.13 for $\varepsilon = 1$ and in Table 5.14 for $\varepsilon = 80$.

As can be seen from the tables above, we were unable to obtain a qualitative interpretation of the numerical calculations of the interaction of the two Nap1 proteins with the formation of the dimer Nap1–Nap1, since according to the available data, the formation of this dimer is carried out with the participation of the amino acid sequence from 74 a.a. to 180 a.a. [25]. Thus, a 20 a.a. frameshift is not suitable for a qualitative calculation of the interaction between the two proteins Nap1.

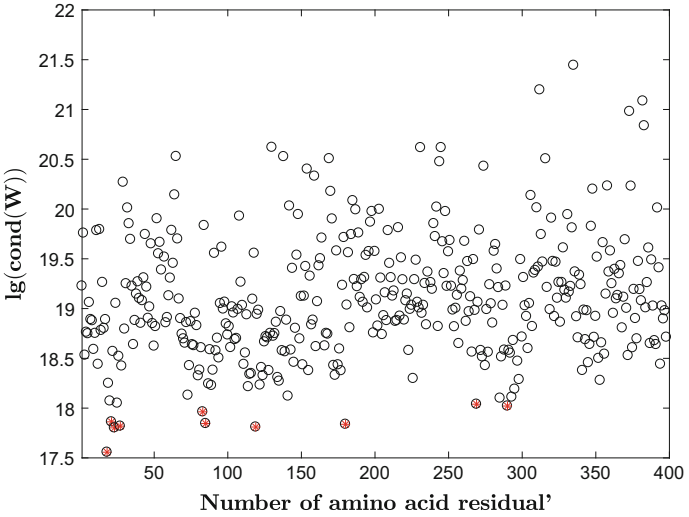

Fig. 5.21 Results of numerical simulation of the interaction of Nap1 with Nap1, frame size equal to 20 a.a., $\varepsilon = 80$. The red dots denote the 10 minimum values of lg(cond(W))

lg(cond(W)) is common logarithm of condition number
$N^{\underline{0}}$ is number of amino acid residual

Let us turn to the numerical calculation results of the interaction of two proteins Nap1 at a frameshift length equal to 30 a.a. The results of the numerical interaction are shown in Fig. 5.22 for $\varepsilon = 1$ and in Fig. 5.23 for $\varepsilon = 80$.

As can be seen from the presented graphs, with a frameshift equal to 30 a.a. there are many areas of interaction between proteins Nap1 that are characterized by a small value of lg(cond(w)). In this case, the ten minimum values of lg(cond(W)) obtained by the interaction of two whole Nap1 proteins with a frameshift equal to 30 a.a. are given in Table 5.15 for $\varepsilon = 1$ and in Table 5.16 for $\varepsilon = 80$.

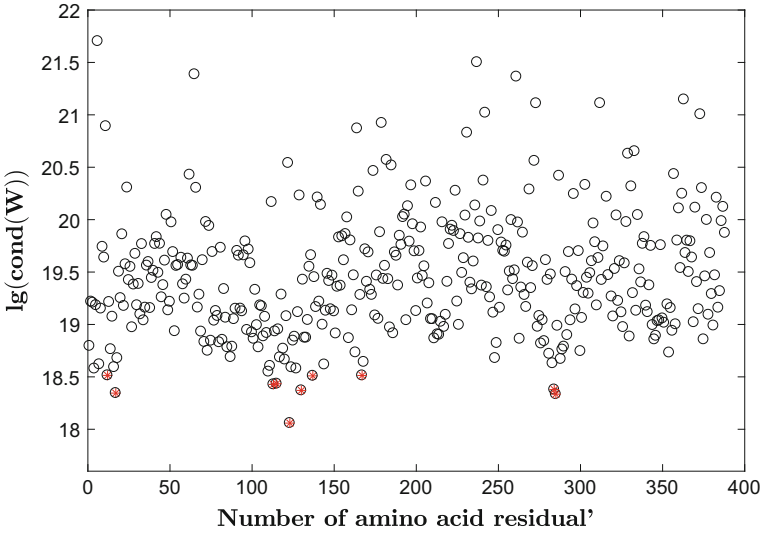

Fig. 5.22 Results of numerical simulation of the interaction of Nap1 with Nap1, frame size equal to 30 a.a., $\varepsilon = 1$. The red dots denote the 10 minimum values of lg(cond(W))

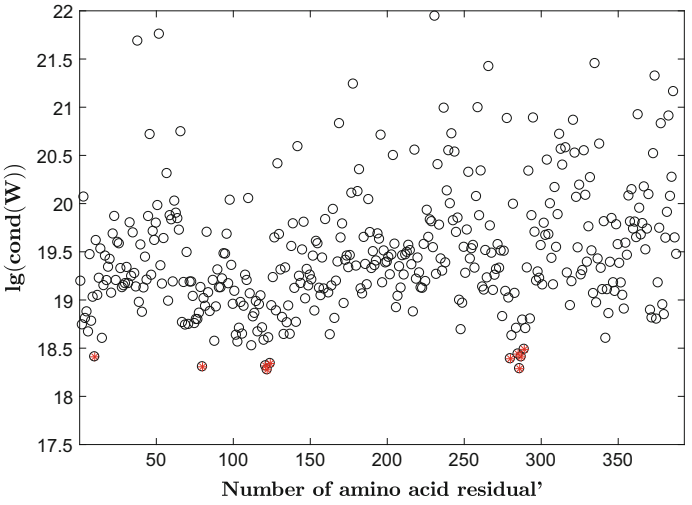

Fig. 5.23 Results of numerical simulation of the interaction of Nap1 with Nap1, frame size equal to 30 a.a., $\varepsilon = 80$. The red dots denote the 10 minimum values of lg(cond(W))

As can be seen from the above results, a larger number of values of lg(cond (W)) fell into the region of domain 1, and an additional cluster was formed from the minimum values in the region 281 a.a. at $\varepsilon = 80$. Despite the fact that half of the values obtained fall within the region of domain 1, the rest of the scattered minimum values of lg(cond(W)) fall on different parts of the polypeptide sequence

Nap1, which significantly complicates the interpretation of the obtained numerical data, namely, the search for protein sites responsible for dimerization. Numerical calculations obtained at $\varepsilon = 1$ are characterized by the formation of a cluster of values in the region of domain 1, with the smallest value of lg(cond(W)) obtained at 124 a.a. and amounting to 18.058. Analysis of the data obtained with a frameshift of 30 a.a. shows a slightly better result than with a 20 a.a. frameshift.

Let us now turn to the numerical results of the calculation of the interaction of two proteins Nap1 at a frameshift length equal to 40 a.a. The results of the numerical interaction are shown in Fig. 5.24 for $\varepsilon = 1$ and in Fig. 5.25 for $\varepsilon = 80$. As can be seen from the graphs, with a frameshift equal to 40 a.a, two clusters are formed from the minimum values at $\varepsilon = 1$ in the 8 a.a. and 111 a.a. regions, ten minimum are

lg(cond(W)) is common logarithm of condition number
$N^{\underline{0}}$ is number of amino acid residual

The results of the numerical calculations presented in Fig. 5.25 and Table 5.18 demonstrate the large number of minimum values of lg(cond(W)) attributable to the domain 1 of the Nap1 protein responsible for the formation of the Nap1–Nap1 dimer at $\varepsilon = 80$.

Let us now turn to the numerical results of the calculation of the interaction of two proteins Nap1 at a frameshift length equal to 50 a.a. The results of the numerical interaction are shown in Fig. 5.26 for $\varepsilon = 1$ and in Fig. 5.27 for $\varepsilon = 80$.

As can be seen from the graphs, with a frameshift equal to 50 a.a. the presence of a cluster of minimum values is observed for $\varepsilon = 1$ in the 75 a.a. and 137 a.a. regions, the minimum of which is obtained at 75 a.a. and amounts to 18.853. Analysis of

lg(cond(W)) is common logarithm of condition number
$N^{\underline{0}}$ is number of amino acid residual

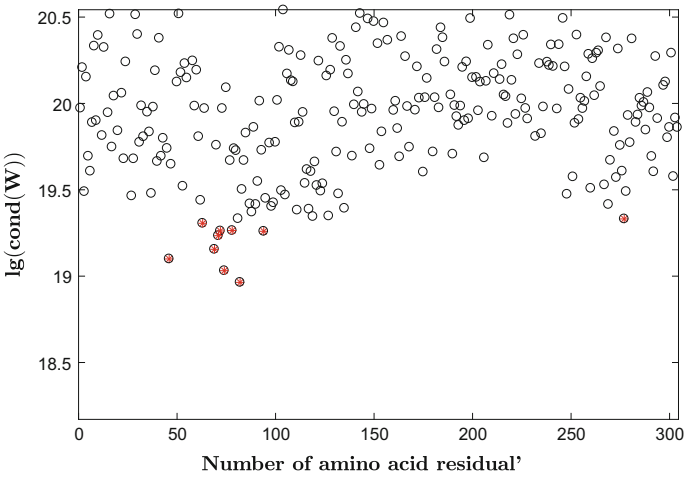

Fig. 5.30 Results of numerical simulation of the interaction of Nap1 with Nap1, frame size equal to 70 a.a., $\varepsilon = 1$. The red dots denote the 10 minimum values of lg(cond(W))

of the graph of the numerical results obtained at $\varepsilon = 80$ demonstrates the formation of a cluster from the minimum values in the region from 74 a.a. to 132 a.a., whose minimum is obtained at 74 a.a. and amounts to 19.012.

Analysis of the numerical results of the numerical experiments carried out with the participation of two identical Nap1 proteins using Algorithm 2, during which frameshifts of different lengths from 20 a.a. up to 70 a.a. determined that when the size of the frame was increased, the results obtained correlated more with the experimental data in which the structure of the Nap1–Nap1 homodimer was analyzed. So with a frameshift length of 20 a.a. there were a large number of possible segments of the polypeptide chain of the protein Nap1 which could form biological complexes with the same amino acid sequences of the second identical protein. However, we cannot say how accurate the data obtained are, because we need to have experimental data on the interaction of different sites between the Nap1 proteins. Also note that the Nap1 protein has a complex three-dimensional native structure, many parts of which are inside the protein and cannot interact with other proteins. With an increase in the length of the frameshift to 30 a.a. we see cluster formation from the minimum values of lg(cond(W)) in several regions of the polypeptide chain of the Nap1 protein, including in the domain 1 region responsible for the homodimerization of the Nap1 protein. With a further increase in the length of the frameshift to 40 a.a., half of the 10 minimum values of lg(cond(W)) fall in domain 1. Analysis of numerical calculations for frameshift dimensions of 50 a.a., 60 a.a., 70 a.a. demonstrated almost identical to the found amino acid sequences of the interacting proteins Nap1 in the domain 1 region. Thus, in finding the interacting regions of proteins Nap1 and Nap1, the best results are those in which a larger-size frameshift was taken: from 50 a.a. to 70 a.a. We explain this by the fact that the interaction between proteins Nap1 is due to an

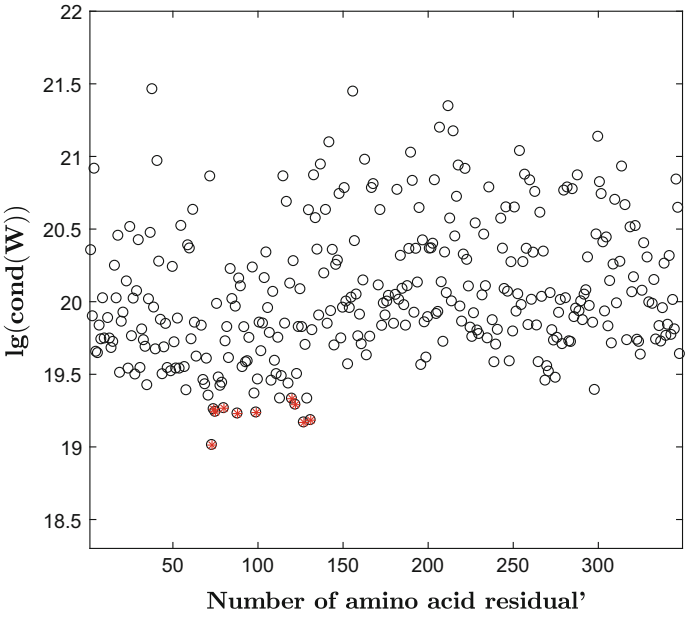

Fig. 5.31 Results of numerical simulation of the interaction of Nap1 with Nap1, frame size equal to 70 a.a., $\varepsilon = 80$. The red dots denote the 10 minimum values of lg(cond(W))

extended site between two proteins, domain 1 is located in the region from 74 a.a. to 180 a.a. [25] .

Thus, the larger size of the frameshift, the closer it allowed us to approach real interactions between proteins. It should be noted that, as an additional criterion determining the binding sites, it is possible to obtain identical binding sites in the form of cluster formation consisting of minimal amino acid residues lg(cond(W)) with a change in the length of the frameshift (Tables 5.21–5.24).

5.7.3 Numerical Calculation of the Interaction of P53 *with Mdm2*

We calculated the interaction between the proteins P53 and Mdm2 according to Algorithm 1 and Algorithm 2.

In this case, we calculated the interaction of the two proteins P53 and Mdm2 separately from the proteins Nap1 and Mdm2, since the nature of the formation of the P53−Mdm2 dimer does not correspond to the characteristics given above, for which the calculation can be applied according to Algorithm 1 or Algorithm 2, since the formation of the biological complex P53−Mdm2 is due to the short amino acid sequence of the P53 protein, which binds to the hydrophobic groove of Mdm2. From

lg(cond(W)) is common logarithm of condition number
$N^{\underline{0}}$ is number of amino acid residual

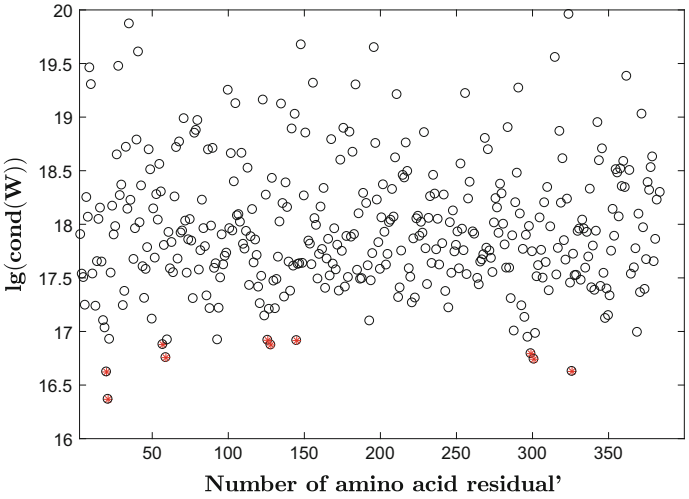

Fig. 5.32 Results of numerical simulation of the interaction of Mdm2 with P53, frame size equal to 10 a.a., $\varepsilon = 1$. The red dots denote the 10 minimum values of lg(cond(W))

the side of the P53 protein, amino acid residues from about 15 a.a. to 30 a.a., arranged consecutively one after the other, and from the side of the protein Mdm2 L54, L57, G58, I61, M62, Y67, Q72, V75, F91, V93, H96, I99, Y100 [23].

In the formation of the dimer P53−Mdm2, the N-termini of the two proteins are involved, but the interacting amino acid residues are not symmetric with respect to the N-terminus of the proteins. However, for example, we calculated the interaction of two given P53 and Mdm2 proteins according to Algorithm 2 and Algorithm 1. Let us now turn to the numerical results of the interaction of the proteins p53 and Mdm2 according to Algorithm 2 with a 10 a.a. frameshift and $\varepsilon = 1$. The results of the numerical calculation are shown in Fig. 5.32. As we can see from the above Fig. 5.32, the four minimum values of lg(cond(W)) fall on the Mdm2 protein domain of the P53-binding domain. The ten minimum values of lg(cond(W)) are given in the Table 5.25. for $\varepsilon = 1$.

As can be seen from the Table 5.25, the first two minimum values of lg(cond(W)) are 21 a.a. and 20 a.a., which are located in the P53-binding domain of the protein Mdm2 [32, 33].

However, it is difficult to accurately identify the binding site of the P53 and Mdm2 protein, and a better experimental or theoretical approach will be required.

Results of numerical calculations of the interaction between proteins P53 and Mdm2 according to Algorithm 2 with a 15 a.a. frameshift at $\varepsilon = 1$ was completed. The numerical results are shown in Fig. 5.33. In Fig. 5.33, we see three clusters, the largest accumulation of minimum values fall in the P53-binding domain of the Mdm2 protein, the second cluster of the 2nd minimum values lies in the regions of 125 a.a. and 126 a.a., the third cluster of third minimum values lies in the region of 300 a.a.

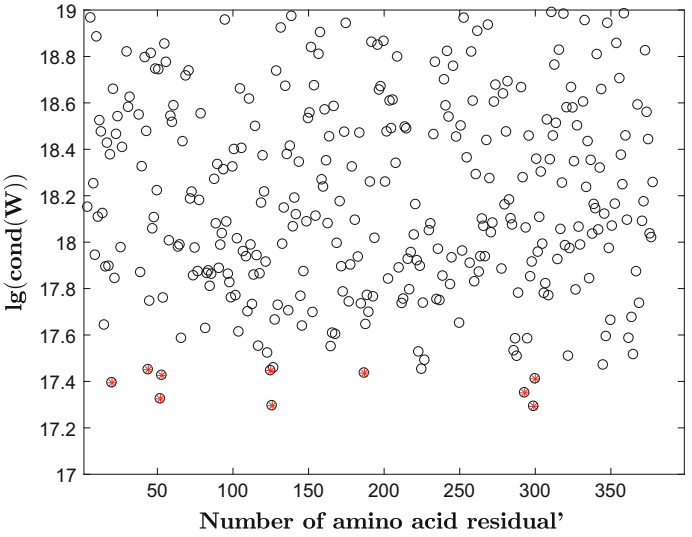

Fig. 5.33 Results of numerical simulation of the interaction of Mdm2 with P53, frame size equal to 15 a.a., $\varepsilon = 1$. The red dots denote the 10 minimum values of lg(cond(W))

As can be seen from Table 5.26, five values of lg(cond(W)) fall on the P53-binding domain of the Mdm2 protein and the N-terminus of the P53 protein, which is in satisfactory agreement with the previously identified binding sites [32, 33].

Analysis of data demonstrates the minimum values of lg(cond(W)) at the site of the P53-binding domain and the N-terminus of the P53 protein, which is in satisfactory agreement with the previously identified binding sites of Mdm2 and P53 proteins.

$N^{\underline{0}}$ is number of amino acid residual

However, the presence of the remaining minimum values, which are not located on the N-terminus of the two proteins, makes it difficult to accurately identify the binding site, nor can we say anything about the structure of the complex formed upon the formation of the dimer Mdm2−P53.

Let us turn to the analysis of the data obtained characterizing the interactions of P53 and Mdm2 proteins according to Algorithm 1. Numerical calculation of the interaction of the $P53_{(11-30)}$ and Mdm2 proteins according to Algorithm 1 for $\varepsilon = 80$.

We selected a short sequence of protein $P53_{(11-30)}$, which is directly involved in the formation of the biological complex with the protein Mdm2. The results of the numerical calculation are shown in Fig. 5.34.

As can be seen from Fig. 5.34, the greatest number of lowest values of lg(cond(W)) fall on the P53-binding domain of the Mdm2 protein, which is in satisfactory agreement with the previously identified binding sites [32, 33].

As can be seen from the Table 5.27 and graph Fig. 5.34 above, the cluster of the smallest values falls on the P53-binding domain of the Mdm2 protein in the interaction of $P53_{(11-30)}$, and the smallest value is obtained at 25 a.a. This result is in satisfactory agreement with earlier experiments, in which a complex part of the interaction of P53 and Mdm2 proteins [32, 33].

In this section, a numerical simulation of the interaction of proteins P53 and Mdm2 was performed without taking into account the phosphorylation of the N-terminus of the P53 protein and the subsequent influence of phosphorylation processes on the stability of the formed complex P53−Mdm2. In the next chapter, we will present a model for the phosphorylation of the amino acid residues of a single protein and the effect of phosphorylation on the stability of the formed biological complex on the example of the dimer Mdm2−P53.

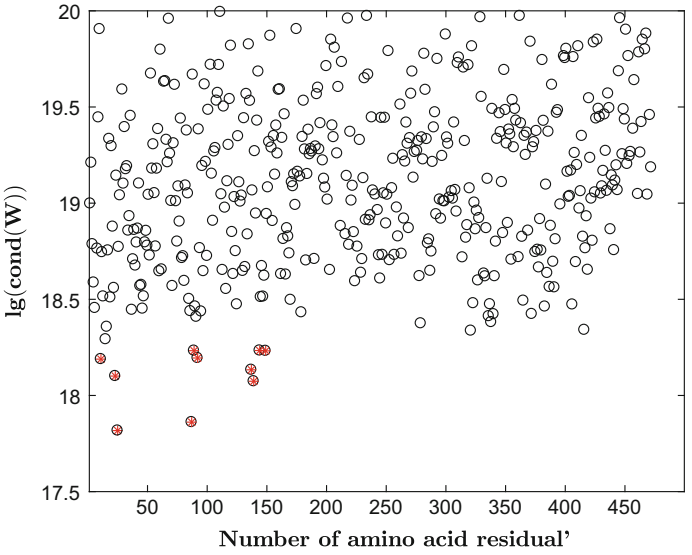

Fig. 5.34 Results of numerical simulation of the interaction of Mdm2 with $P53_{(11-30)}$, $\varepsilon = 80$. The red dots denote the 10 minimum values of lg(cond(W))

Table 5.27 The ten minimum values of lg(cond(W)) and the amino acid sequences of the detected regions regions of the protein $P53_{(11-30)}$ in interaction with Mdm2, $\varepsilon = 80$

$N^{\underline{0}}$	Amino acid sequence MdM2	lg(cond(W))
25	TLVRPKPLLLKLLKSVGAQ	17.817

144	EKPSSSHLVSRPSTSSRRR	18.233

lg(cond(W)) is common logarithm of condition number
$N^{\underline{0}}$ is number

5.8 Matlab Script Algorithm 1 for Mathematical Modeling Identification of Active Sites Interaction of Protein Molecules

Input parameters:

1. S_{100}, S_{20} are amino acid sequences of biological complexes ($S_{100} \geq S_{20}$)
2. sh is step shift
3. epsilon is the dielectric constant of the medium.

Output parameters:

lg(cond(W) is the common logarithm of the condition number of the matrix W, where its elements are composed of the electrostatic potential energy which is created based on the interaction between pair of amino acid residues of biological complexes.

Compute:

lg(cond(W) is the common logarithm of the condition number of the matrix W, which will allow a prediction the reactivity of the studied biological complexes.

5.9 Matlab Script Algorithm 2 for Mathematical Modeling Identification of Active Sites Interaction of Protein Molecules

Input parameters:

1. S_{100}, S_{20} are amino acid sequences of biological complexes ($S_{100} \geq S_{20}$).
2. sh0 is the initial shift
3. sh1 is the length of the frame
4. sh2 is the frame step
5. epsilon is the dielectric constant of the medium

Output parameters:

lg(cond(W) is the common logarithm of the condition number of the matrix W, where its elements are composed of the electrostatic potential energy which is created based on the interaction between pair of amino acid residues of biological complexes.

Compute:

lg(cond(W)) is the common logarithm of the condition number of the matrix W, which will allow a prediction the reactivity of the studied biological complexes.

Chapter 6
Mathematical Modelling of the Effect of Phosphorylation on the Stability of the Formation of Biological Complexes P53–Mdm2 and P53–P300

Abstract This chapter presents a physical model of phosphorylation the amino acid residues of the polypeptide chain of a protein on the formation of biological complexes with other proteins.

6.1 Introduction

In this chapter, we develop a physical model of the effect of phosphorylation of the amino acid residues of the polypeptide chain of a protein on the formation of biological complexes with other proteins, for example, the phosphorylation of the flexible N-terminus of the p53 protein by two amino acid residues 18a.a. and 20a.a., as well as an analysis of the stability of the biological complexes P53–Mdm2 and P53–P300 formed before and after phosphorylation. We took short sites of P53, Mdm2, and P300 proteins in the calculations and analyzed the stability of the heterodimers formed by them.

The authors suggest that a developed model of phosphorylation of the main(key) amino acid residues of the protein will allow us to predict an increase or decrease in the stability of the formed protein complexes before and after phosphorylation with the participation of other non-phosphorylated proteins. The test is supposed to be performed using small sequences of proteins that are directly involved in the formation of the protein complex.

So, in our work, we took sites of the proteins $P53_{(1-22)}$, $P53_{(10-51)}$, $P300_{(1726-1806)}$, $Mdm2_{(25-104)}$, $Mdm2_{(51-104)}$, since according to previous studies [1–4], the N-terminus of the P53 protein is directly involved in complexation with the P300 and Mdm proteins, the Mdm2 protein forms a protein complex with the P53 protein also in the N-terminal region, and the protein region P300 is actively involved in the formation of the dimer with the protein P53 stored in the domain region Taz2 from 1726a.a. to 1806a.a.

T. Koshlan and K. Kulikov, *Mathematical Modeling of Protein Complexes*,
Biological and Medical Physics, Biomedical Engineering,
https://doi.org/10.1007/978-3-319-98304-2_6

Thus, we selected P53, P300 and Mdm2 protein sites in the region responsible for the formation of the heterodimers P53–P300 and P53–Mdm2.

In this chapter, we investigate the interaction of the flexible weakly ordered N-terminus of the P53 protein with the N-terminus of the Mdm2 protein and the Taz2 domain of the P300 protein, taking into account the phosphorylation effect. The presence of the flexible N-terminus of the P53 protein leads to the fact that it can take various conformations when forming a biological complex with proteins such as Mdm2 or P300.

The phosphorylation of some amino acid residues of the N-terminus of the P53 protein leads to a marked change in the affinity of the interaction of the P53 protein with the P300 and Mdm2 proteins.

This affinity change in the phosphorylation of selected amino acid residues at the flexible N-terminus of the P53 protein is of great importance in the fate of the cell, leading to the stabilization of the P53 protein, the arrest of the cell cycle or apoptosis [5].

6.2 Protein Phosphorylation

Protein phosphorylation is the most common form of their regulatory post-translational modification.

Phosphorylation can stimulate or inhibit the catalytic activity of enzymes, the affinity with which the protein binds to other molecules, its intracellular localization and its ability for further covalent modifications. It can also alter its stability.

Most eukaryotic cells are phosphorylated with the participation of protein kinases; their dephosphorylation is catalyzed by phosphoprotein phosphatases.

Protein kinases transfer a phosphate group with ATP to the residues of Ser, Thr, Tyr in protein substrates [6].

Let us consider in more detail some earlier work describing the mechanisms of phosphorylation and the effects of the phosphorylation of the N-terminus of the P53 protein on the interaction with the proteins Mdm2 and P300.

In [5], it was reported that the p53 TAD is phosphorylated by a number of activated kinases and is critical for the many protein-protein interactions that either modulate the stability and subcellular localization of p53 or affect its function as a transcription factor. When unbound, the TAD is unstructured [7], but it adopts a helical conformation upon complex formation. The minimal Mdm2-binding region resides fully within TAD1, which forms a helix encompassing residues 19−25. In cells, complex formation results in ubiquitination of the P53 REG domain by the C-terminal E3 ligase domain of Mdm2, leading to nuclear export and degradation of p53. Since Mdm2 is a transcriptional target of P53, these two proteins form anegative

feedback loop that controls P53 levels in the absence of stress and during the return to homeostasis following stress. The importance of TAD phosphorylation in the regulation of P53 function has led to numerous in vitro studies examining the effects of P53 phosphorylations on interactions with its binding partners. For the interaction with Mdm2, which is primarily stabilized by the hydrophobic effect, phosphorylation prevents complex formation. In contrast, TAD phosphorylation enhances binding to CBP/P300. Thus, phosphorylation couples relief of negative regulation with enhancement of transcriptional activation.

In the absence of cellular stress, most of the serines and threonines of the p53 TAD are unphosphorylated. In particular, the absence of phosphorylation of Thr18 allows tight binding of Mdm2 to suppress P53 activity by enhancing nuclear export and proteasomal degradation. Once a cell experiences a stress, the concentration of p53 rapidly rises to stimulate the appropriate response: e.g. cell cycle arrest or apoptosis.

As in vitro experiments have shown, the binding affinity of the P53 TAD−Mdm2 complex can be reduced 5–25-fold solely by phosphorylation of Thr18 [8–10].

In contrast, the interactions of p53 with its positive cofactors generally start out weak and increase in proportion with increasing phosphorylation. This allows for a nuanced response in which the interactions of p53 with different subgroups of cofactors change over time. The strength of the effect depends on the location of the phosphorylation within the TAD sequence and varies for the different domains of CBP/p300. Single phosphorylation of Ser15, Thr18, Ser20, Ser33, Ser37 or Ser46 generally increases the binding affinities to the Taz1, Taz2 and KIX domains by 2- to 7-fold [11, 12].

The structure of the NMR of the Taz2 complex of the p300 protein and the N-terminal transactivation domain of P53 was reported in [3].

In the complex, p53 forms a short alpha helix and interacts with the Taz2 region through the expanded surface. Mutational analyses demonstrate the importance of hydrophobic residues for complex stabilization. In addition, they suggest that the increased affinity is partly due to electrostatic interactions of phosphate with a neighboring arginine residue in the Taz2 domain of the p53 protein. Thermodynamic experiments have shown the importance of hydrophobic interactions in the complex of Taz2 with p53 in the phosphorylation of Ser (15) and Thr (18).

In [3, 13], Ser20 phosphorylation reduces the binding between p53 and Mdm2, and hence p53 is activated and stabilized. Thus, one mechanism by which p53 is protected against Mdm2 in response to DNA damage involves Ser20 phosphorylation.

The functions and role of checkpoint kinase 2 (Chk2), which is a key mediator of various cellular responses to genotoxic stress protecting the integrity of the eukaryotic genome were reviewed in [14].

In particular, Chk2 takes part in the phosphorylation of the tumor suppressor p53, which results in the stabilization of p53 and transactivation of the p53 target genes. Specific ubiquitin ligase Mdm2 can also be a substrate for the Chk2 kinase.

6.3 Description of the Physical Model

To account for the phosphorylation effect, we made the following assumptions:

- the selected amino acid residues of serine20 and threonine 18 of the P53 protein were replaced by negatively charged phosphoric acid residues OPO_3H_2, which we represented in the form of spheres with a radius equal to 0.3×10^{-9} m;
- residues of phosphoric acid interact with five charged amino acids (aspartic acid, glutamic acid, arginine, histidine, lysine) with a charge of 0.9^{-19} C;
- residues of phosphoric acid interact with selected hydrophobic amino acids (methionine, asparagine, leucine, tyrosine, valine) with a charge of 0.1^{-19} C;
- the distance between the centers of the phosphoric acid residue and the amino acid residue is 1.76^{-9} m.

To analyze the biochemical processes we use the notion of condition number matrix of the potential energy of the pair electrostatic interaction between peptides. In this physical formulation of the problem, it will characterize the degree of stability of the configuration of the biological complex. In order to choose a more stable biochemical compound between proteins, we select the matrix of potential energy of electrostatic interaction with the **smallest** value of the condition number (see Chap. 2).

6.4 Results of a Numerical Calculation of the Formation of Biological Complexes by Different Sites of the P53, Mdm2 and P300 Proteins, Taking into Account the Effect of Phosphorylation of the Flexible N-Terminus of the P53 Protein

We selected next sites of the proteins $P53_{(1-22)}$, $P53_{(10-51)}$, $Mdm2_{(25-104)}$, $Mdm2_{(50-14)}$, $P300_{(1726-1806)}$.

The list of involved amino acid sequences is shown below.

KIYTMIY

We performed a numerical calculation of the potential energy matrix of electrostatic interaction of different pairs of protein sequences: $P53_{(1-22)}-Mdm2_{(25-104)}$, $P53_{(10-51)}-Mdm2_{(51-104)}$, $P53_{(1-22)}-Mdm2_{(50-14)}$, $P53_{(1-22)}-P300_{(1726-1806)}$, $P53_{(10-51)}-P300_{(1726-1806)}$ before and after phosphorylation of 18 aa. and 20 a.a. protein P53.

The results of the numerical calculation are shown in Table 6.1.

As can be seen from the table, upon interaction of the phosphorylated flexible N-terminus of the P53 protein with the Mdm2 protein, an increase in the lg(cond (W)) value is observed for the $P53_{(1-22)}$–$Mdm2_{(25-104)}$ dimers, $P53_{(1-22)}$–$Mdm2_{(51-104)}$, and $P53_{(10-51)}$–$Mdm2_{(51-104)}$, compared with the interaction of the non-phosphorylated region of the P53 protein, which suggests a decrease in the stability of protein complexes formed by different regions of the P53 and Mdm2 proteins and phosphorylation of two amino acid residues from the N-terminus of the P53 protein.

Table 6.2 Results of numerical calculations before and after the phosphorylation of two amino acid residues of the protein P53

$N^{\underline{0}}$	Proteins	Phosphorylation, lg(condW)	Dephosphorylation, lg(condW)
1	$Mdm2_{(54-100)}$–$P53_{(17-30)}$	20.139	17.870

lg(cond(W)) is common logarithm of condition number

Analysis of the data in the table indicates a decrease in the values of lg(cond(W)) during the interaction of the phosphorylated sites of $P53_{(1-22)}$ and $P53_{(10-51)}$ with the protein region $P300_{(1726-1806)}$ as compared to the interaction of $P300_{(1726-1806)}$ with the non-phosphorylated N-termini of the $P53_{(1-22)}$ and $P53_{(10-51)}$ proteins.

Thus, we come to the conclusion that the phosphorylation of the flexible N-region of the protein $P53_{(1-22)}$ and $P53_{(10-51)}$ positively affects the interaction with the Taz2 domain of the protein P300.

If researchers know the exact areas of interaction of two proteins, then numerical calculations should be performed of the effect of phosphorylation of the amino acid residues of one of the proteins, taking into account the precisely defined regions of the two interacting proteins. According to previous experiments [15], active parts of the interaction between proteins P53 and Mdm2 were identified. Active amino acid residues of protein P53 are from 18 a.a. to 27 a.a., arranged consecutively one after another, and active amino acids of Mdm2: L54, L57, G58, I61, M62, Y67, Q72, V75, F91, V93, H96, I99, Y100 [15].

Our next numerical calculation will be performed between the interacting regions of the two proteins before and after phosphorylation of the two amino acid residues of the protein P53.

$P53_{(17-30)}$:17-E**T**F **S**DLWKLLPENN-30

$Mdm2_{(54-100)}$: L54, L57, G58, I61, M62, Y67, Q72, I74, V75, F91, V93, H96, I99, Y100.

Two amino acid residues of the protein P53 are phosphorylated, while in the program complex phosphorylation is performed by changing the letter designations of the amino acid residues to the letter designation ≪X≫, which in this formulation of the problem denotes a negatively charged phosphoric acid residue. Then, taking into account the amino acid substitutions performed for the phosphoric acid residue, the studding amino acid sequence of the P53 protein will look like this:

$P53_{(17-30)}$:17-E**X**F **X**DLWKLLPENN-30

The results of the numerical calculation are shown in Table 6.2.

As we can see from the table above, the phosphorylation processes of two amino acid residues of the protein P53 leads to destabilization of the protein complex $Mdm2_{(54-100)}$–$P53_{(17-30)}$, which may affect the stability of the protein complex formed by whole protein sequences of Mdm2 and P53. Analysis of the numerical calculations is in good agreement with articles [8–10], which pointed to the significant influence of phosphorylation processes on the interaction of proteins Mdm2 and P53.

In this section, we developed a mathematical model of the phosphorylation of the amino acid residues of the polypeptide chain using the protein P53 as an example. We performed a numerical calculation of the potential energy matrixes of the electrostatic interaction of various amino acid sequences of the P53, P300, and Mdm2 proteins, taking into account the phosphorylation of the polypeptide sequence of the P53B protein.

We found that the phosphorylation of two amino acid residues of Thr18 and Ser20 from the N-terminus of the P53 protein leads to an increase in the stability of the biological complexes formed by different regions of the proteins: $P53_{(1-22)}$–$P300_{(1726-1806)}$, $P53_{(10-51)}$–$P300_{(1726-1806)}$, and as well as to a decrease in the stability of biological complexes formed by protein sites:
$P53_{(1-22)}$–$Mdm2_{(25-104)}$, $P53_{(1-22)}$–$Mdm2_{(51-104)}$, $P53_{(10-51)}$–$Mdm2_{(51-104)}$.

The authors suggest that such a model of accounting for phosphorylation of amino a acid residues in the interaction of small regions of proteins will help in future to determine the effect of phosphorylation processes on the stability of whole protein complexes.

6.5 Matlab Script for Mathematical Modelling of the Effect of Phosphorylation on the Stability of the Formation of Biological Complexes P53–Mdm2 and P53–P300

Input parameters:

1. S_1, S_{20} are amino acid sequences of biological complexes ($S_1 \geq S_{20}$)
2. epsilon is the dielectric constant of the medium.

Output parameters:

lg(cond(W) is the common logarithm of the condition number of the matrix W, where its elements are composed of the electrostatic potential energy which is created based on the interaction between pair of amino acid residues of biological complexes.

Compute:

lg(cond(W)) is the common logarithm of the condition number of the matrix W, which will allow a prediction the reactivity of the studied biological complexes.

Chapter 7
Mathematical Modelling of the Interaction of BH3-Peptides with Full-Length Proteins, and Account of the Influence of Point Mutations on the Stability of the Formed Biological Complex on the Example of the Bcl-2 Family Proteins

Abstract This chapter presents a new method that allows one to qualitatively determine the effect of point mutations in peptides on the stability of the formed complex with full-length proteins. On the basis of the developed approach, a qualitative correlation of the obtained results with the dissociation constant was revealed using the example of the formation of the BH3 peptide biological complex of Bmf, Puma, Bad, Hrk, Bax, Bik, Noxa, Bid, Bim, and Bak proteins with the Bcl-xl protein and the BH3 peptides protein Bax with the Bcl-2 protein, taking into account the replacement of amino acid residues.

7.1 Introduction

This chapter is devoted to the investigation of the interaction of BH3-peptides with anti-apoptotic proteins of the Bcl-2 family, which are regulators of mitochondrial apoptosis pathways. Note that disturbances in the process of apoptosis are a sign of a large number of diseases, such as cancer, sarcomas, carcinomas, lymphomas, and leukemias.

Studies results [1–3] indicate that peptides have a pronounced protective effect in various diseases and have a modulating effect on various body systems. Unlike chemotherapy drugs, peptides are selective and effective signaling molecules that bind to certain receptors or ion channels, where they cause intracellular effects. Because peptides are highly selective and effective and at the same time relatively safe and well tolerated, they represent an excellent starting point for the development of new therapeutic agents, and their specificity demonstrates excellent safety, tolerability, and efficacy profiles in people with various pathologies.

We believe that the further development of peptide drugs will be based on the use of computer and mathematical design to find the optimal peptides, taking into account the affinity for their targets, and also to improve their chemical and physical properties.

T. Koshlan and K. Kulikov, *Mathematical Modeling of Protein Complexes*,
Biological and Medical Physics, Biomedical Engineering,
https://doi.org/10.1007/978-3-319-98304-2_7

In this chapter, the effect of point mutations in BH3 peptides on the stability of the biological complexes with Bcl-2 will be determined, as well as the qualitative determination of the dissociation constant for binding different BH3 peptides to Bcl-xl proteins.

Let us examine some of the works devoted to the family of Bcl-2 proteins, as well as the study of the affinity of BH3 peptides for Bcl-2 family proteins. In [4] review recent advances in understanding how BCL2 family proteins control MOMP (mitochondrial outer membrane permeabilization) as well as new nonapoptotic functions for these proteins.

In [5] it was found that the Bcl-2 protein binds to the Bax protein through two interdependent interfaces, which leads to the inhibition of the proapoptotic oligomerization of Bax. Studies of various interfaces with a large number of involved amino acid residues bring additional clarity to the nature of the interaction of proteins of the Bcl-2 family.

In [6] the molecular basis of the binding specificity of proapoptotic BH3 peptides, which contain different motifs, with a pro-apoptotic Bcl-xl protein, was investigated. Various motifs were identified in the BH3 domains of proteins which influenced the binding affinity of the Bcl-xl protein.

In this chapter, in contrast to the above, we propose a mathematical model for determining the affinity of different BH3 peptides for Bcl-2 family proteins, as well as taking into account the effect of point mutations in peptides on the stability of the biological complex formed by them in dependence at amino acid sequence of protein.

The first part of the chapter contains information about the structure and functions of the studied proteins of the Bcl-2 family. The second part is devoted to the numerical calculation of the interaction of peptides of the Bcl-2 family proteins containing the BH3 region with the Bcl-xl protein. In this part, the numerical calculations of the interaction of protein peptides Bmf, Puma, Bad, Hrk, Bax, Bik, Noxa, Bid, Bim, and Bak with the Bcl-xl protein were analyzed and compared with the dissociation constant (K_d). The effect of point mutations in BH3 peptides of the Bax protein on the stability of the biological complexes formed with the Bcl-2 protein was studied. A qualitative comparison of lg(cond(W)) and logarithmic constants of dissociation of K_d is carried out on the example of the interplay of BH3 peptides of Puma, Bad, Hrk, Bax, Bik, Noxa proteins with the Bcl-xl protein.

To analyze the biochemical processes we use the notion of condition number matrix of the potential energy of the pair electrostatic interaction between peptides. In this physical formulation of the problem, it will characterize the degree of stability of the configuration of the biological complex. In order to choose a more stable biochemical compound between proteins, we select the matrix of potential energy of electrostatic interaction with the **smallest** value of the condition number (see Chap. 2).

7.2 Structure and Functions of Bcl-2 Family Proteins

Proteins of the B-cell lymphoma-2 family (Bcl-2) control their own apoptotic path, regulating the process of permeabilization of the outer membrane of the mitochondria through protein-protein interactions.

Structural and biochemical studies have shown the dual role of anti-apoptotic proteins of the Bcl-2 family in inhibiting BH3-only proteins and the activated proteins Bax and Bak. Details of the interactions between the Bcl-2 family proteins are presented in [4].

The proteins of the Bcl-2 family can be divided into 3 groups based on their structure and intracellular functions:

(1) One group includes Bcl-2 antogonist/killer (Bak) and Bcl-2 associated X protein (Bax), which are known as apoptosis effectors. Also called multidomain pro-apoptotic BCL2 family proteins, BAX and BAK contain BCL2 homology (BH) domains 1–3 and can directly permeabilize MOM when activated. Whether Bcl-2-related ovarian killer (Bok) belongs to this same subfamily is not clear. Structurally it is similar to Bak and Bax [7]; however, functionally it does not have the ability to permeabilize the MOM by itself but instead induces apoptosis only in the presence of Bak or Bax [8].

Structural studies have demonstrated that Bak and Bax monomers are globular structures consisting of a central hydrophobic core helix(alfa5) surrounded by eight alpha helices [9–11].

In the Bak monomer, four of these helices(α1, α3, α4, and α6) are long helices that form a circle around the central helix α5 while the others (α2, α7, and α8) are shorter and link either the longer helices or the main structure to the transmembrane (TM) domain which consists of helix α9 [9].

The major structural difference between monomeric Bak and Bax is the orientation of helix α9. In Bax, this helix is buried in a hydrophobic groove formed by helices α3, α4, and α5 [11].

In contrast, the hydrophobic groove of Bak is empty; and the α9 helix of Bak extends away from the remainder of the globular protein.

(2) The second group, called anti-apoptotic or pro-survival Bcl-2 family members, includes Bcl-2, Bcl-x large(Bcl-xl), Bcl-2-like protein 2(Bcl-W), Bcl-2-like protein 10(Bcl-B), myeloid cell leukemia 1(Mcl1), and Bcl-2-related protein A1(Bfl-1) (A1 in mouse). These proteins, which contain four BH domains (BH1-BH4), inhibit apoptosis by binding and sequestering their pro-apoptotic counterparts.

The anti-apoptotic Bcl-2 proteins possess a remarkably similar globular structure containing a so-called ≪Bcl-2 core≫ [12].

This core consists of a bundle of eight alfa-helices that form a hydrophobic groove flanked by the BH1 and BH3 domains. In Bcl-W, the core also includes a short C-terminal helix α-8 attached to the BH2 domain. The hydrophobic groove made by $\alpha 3-\alpha 5$ is termed the ≪BC groove≫ [12] because it binds the BH3 region of binding partners [15] (Scheme of structure Bcl-2, see Fig. 7.1).

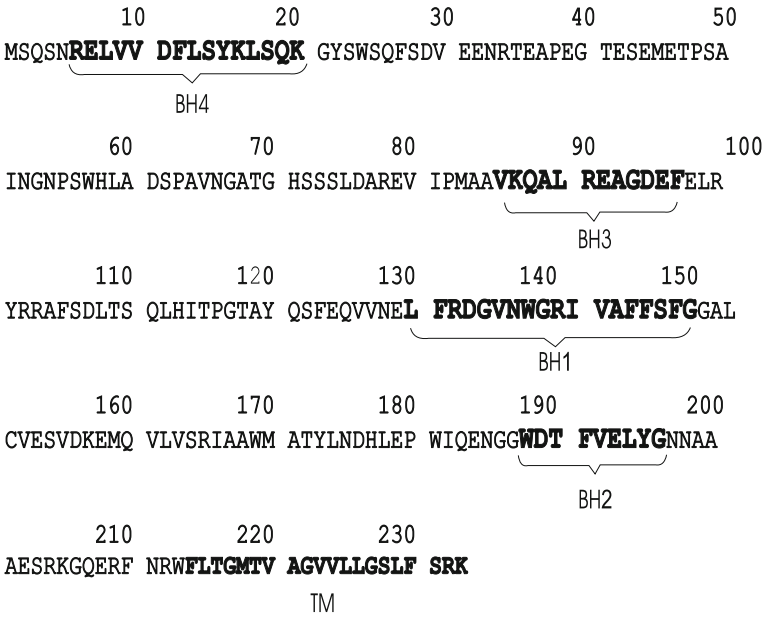

Fig. 7.1 Schema of a Bcl-2 protein. The amino acid sequence Q071817 [13]. Specifying BH domains [14]

The BC groove is crucial for the biology of anti-apoptotic BCL2 family proteins, as it provides an interface for the interaction with the BH3 domain of BH3-only proteins and the apoptotic effectors BAK and BAX. Based on the structure of the BC groove, several BH3 mimics that can occupy this groove and thus inactivate these proteins anti-apoptotic function have been developed and are currently being tested in the clinic [16–18].

(3) The final group, termed BH3-only proteins, includes Bim, Puma, Bid, Bad, Noxa, Bik, Bmf, and Hrk. These polypeptides share only a 15–25 residue BH3 domain in common with other Bcl-2 family proteins. This BH3 domain, however, is critical for the interactions of these proteins with other BCL2 family proteins to regulate MOMP.

The most important role of BH3-only proteins such as Bim, Puma, Bid, and Noxa is to act as integrators of various signals to initiate MOMP. The BH3-only proteins are activated by distinct cytotoxic stimuli in various ways, including enhanced transcription and posttranslational modifications [19].

BH3-only proteins can be divided into direct activators and sensitizers [20, 21].

As pro-apoptotic signals are received, for example, DNA damage or cellular stress, proteins such as Bid or Bad stimulate and compete with effectors for binding to repressors, and not only neutralize the antiapoptical actions of repressors, but also lead to a pro-apoptotic effect of the effectors.

The effectors subsequently initiate apoptotic cell death by their ability to integrate into the outer membrane of the mitochondria, which causes the formation of pores in the membranes. This results in the release of apoptogenic factors, such as cytochrome c and Smac/Diablo from the mitochondria into the cytosol [22].

Thus, the concerted action of different Bcl-2 proteins allows one to keep apoptosis under control in a healthy cell, while a disorder in the regulation leads to serious pathological consequences.

The formation of heterodimers between different proteins of the Bcl-2 family determines whether the cell survives or not [6]. The Bcl-2 family is an important therapeutic target due to over-expression in some cancer cells where these proteins contribute to oncogenesis and resistance to chemotherapy.

In particular, overexpression of the Bcl-xl and Bcl-2 proteins of apoptosis repressors is associated with the development of various oncological diseases. The Bcl-xl and Bcl-2 proteins are the most suitable targets for anticancer therapy.

Thus, in this paper, interactions of various BH3 peptides with the anti-apoptotic proteins Bcl-xl and Bcl-2 will be investigated.

To analyze the biochemical processes we use the notion of condition number matrix of the potential energy of the pair electrostatic interaction between peptides. In this physical formulation of the problem, it will characterize the degree of stability of the configuration of the biological complex. In order to choose a more stable biochemical compound between proteins, we select the matrix of potential energy of electrostatic interaction with the **smallest** value of the condition number (see Chap. 2).

7.3 Numerical Calculation Results. Conclusion

This part of the chapter presents the results of the numerical calculations of the interaction of BH3 peptides with Bcl-xl and Bcl-2 proteins, as well as an analysis of the effect of point mutations in BH3 peptides on their ability to form stable biological complexes with the pro-apoptotic Bcl-xl protein.

7.3.1 Results of Numerical Simulation of the Interaction of BH3-Peptides of Bmf, Puma, Bad, Hrk, Bax, Bik, Noxa, Bid, Bim, and Bak Proteins with the Bcl-xl$_{(1-200)}$ Protein

In this section, the interaction of short BH3-peptide proteins: Bmf, Puma, Bad, Hrk, Bax, Bik, Noxa, Bid, Bim, and Bak with the protein Bcl-xl$_{(1-200)}$ is investigated.

Each of these peptides has its own affinity for the Bcl-xl protein since each peptide has its own unique amino acid sequence.

In this section, we compared the affinity involved in the study of BH3-peptides Bmf, Puma, Bad, Hrk, Bax, Bik, Noxa, Bid, Bim, and Bak during their successive interactions with the protein Bcl-xl$_{(1-200)}$ according to the previously developed algorithm 1.

Note that BH3-peptides take the conformation of a α-helix and are associated with the $\alpha 2$–$\alpha 5$ helixes protein Bcl-xl. This interaction is stabilized through a large number of intramolecular contacts.

According to previous studies [6], the above short peptides related to the full-size Bcl-xl protein can be divided into 2 groups.

The first group (I) includes BH3 peptides (Hrk, Bax, Bik, Noxa) with a higher dissociation constant for Bcl-xl, and the second group (II) (Bmf, Puma, Bad, Bid, Bim, Bak) includes BH3-peptides characterized by a lower Kd value for the Bcl-xl protein. The list of amino acid sequences is given in Table 7.1.

Dissociation constants (K_d) for each peptide group interaction with Bcl-xl$_{(1-200)}$ are given in Table 7.2 according to [6].

As we see from Table 7.2, group I consists of BH3 peptides with a lower affinity for Bcl-xl, the Kd of which varies from 4.69 μmol to 26.01 μmol. Group II comprised BH3 peptides with a higher affinity level; their Kd varied from 0.2 μmol to 0.65 μmol.

Algorithm 1 (see Chap. 5) was used in the implementation of the numerical calculations of the interaction of each BH3 peptide with Bcl-xl$_{(1-200)}$. As the short BH3 peptide moves along the Bcl-xl$_{(1-200)}$ protein, we get the value of lg(cond(W)) for each step of the shift along the long Bcl-xl protein.

Table 7.1 Amino acid sequences of BH3 peptides [6]

$N^{\underline{0}}$	Protein name	Amino acid sequences
1	Bmf	QAEVQIARKLQCIADQFHRL
2	Puma	QWAREIGAQLRRMADDLNAQ
3	Bad	WAAQRYGRELRRMSDEFVDS
4	Hrk	SAAQLTAARLKALGDELHQR
5	Bax	ASTKKLSESLKRIGDELDSN
6	Bik	EGSDALALRLACIGDEMDVS
7	Noxa	ELEVECATQLRRFGDKLNFR
8	Bid	DIIRNIARHLAQVGDSMDRS
9	Bim	RPEIWIAQELRRIGDEFNAY
10	Bak	STMGQVGRQLAIIGDDINRR

Table 7.2 Groups of BH3-peptides according to the degree of affinity for the protein Bcl-xl$_{(1-200)}$

Groups	3-peptides	Kd, μmol
I	Hrk, Bax, Bik, Noxa	4.69−26.01
II	Bmf, Puma, Bad, Bid, Bim, Bak	0.2−0.65

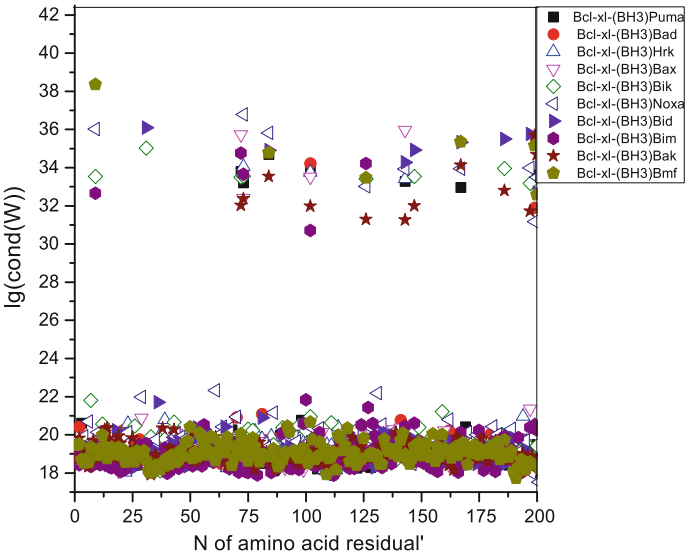

Fig. 7.2 Results of the numerical calculation of the interaction of the BH3-peptides of Bmf, Puma, Bad, Hrk, Bax, Bik, Noxa, Bid, Bim, and Bak proteins with the Bcl-xl$_{(1-200)}$ protein. The colored figures indicate the results obtained during the interaction of BH3 peptides of group II with Bcl-xl$_{(1-200)}$; uncolored figures indicate the results obtained by the interaction of BH3 peptides of group I with Bcl-xl$_{(1-200)}$, $\varepsilon = 1$

In Fig. 7.2 is a graph of the numerical calculations obtained for all ten BH3 peptides upon interaction with the protein Bcl-xl$_{(1-200)}$. We note that the Bcl-xl protein region was involved in the calculation from 1 a.a. to 200 a.a., in a way similar to the experimental article [6].

To analyze the obtained data, we divided the region of the smallest values of lg(cond(W)) in several gradations, starting with the value of 17.65. In this case, we believe that the most stable biological complex is characterized by the smallest value of lg(cond(W)).

In Fig. 7.3 are represented the regions of the smallest values of lg(cond(W)) obtained by the interaction of 10 short peptides with the protein Bcl-xl$_{(1-200)}$. The least-significant part is represented by four areas: I, II, III, and IV, with each successive region including the previous one. Thus, region I is in the range of values of lg(cond(W)) 17.65–17.9; region II−17.65–18.0; region III−17.65–18.1; region IV−17.65–18.2. For 100%, we take the total number of points that fall into each particular area under consideration: I, II, III, IV. The percentage of values for each group of peptides for different regions is summarized in Table 7.3.

As we see from Table 7.3, the regions with the lowest values of lg(cond(W)) (regions I–IV) are represented by the majority of values obtained for peptides of group II, which are characterized by a high affinity for the Bcl-xl$_{(1-200)}$. Thus, region I contains 100% of the values obtained when the BH3 peptides of group II interact

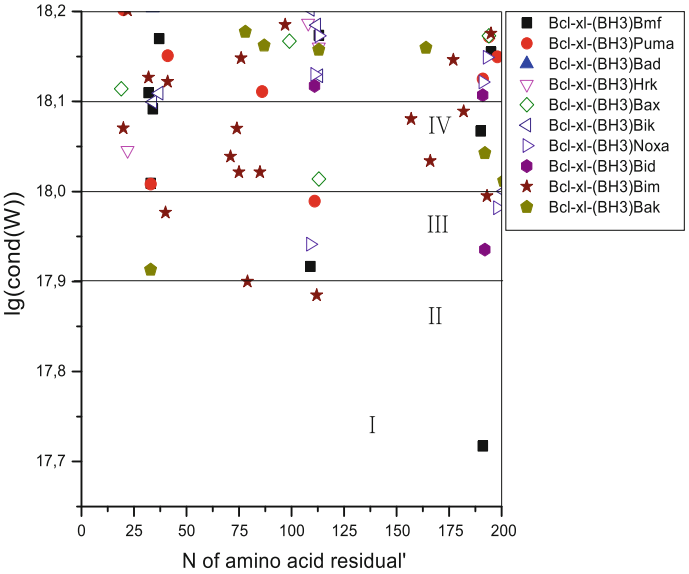

Fig. 7.3 Results of the numerical calculation of the interaction of the BH3-peptides of Bmf, Puma, Bad, Hrk, Bax, Bik, Noxa, Bid, Bim, and Bak proteins with the Bcl-xl$_{(1-200)}$ protein in the region of the smallest values of lg(cond(W)). The colored figures indicate the results obtained during the interaction of BH3 peptides of group II with Bcl-xl$_{(1-200)}$; uncolored figures indicate the results obtained by the interaction of BH3 peptides of group I with Bcl-xl$_{(1-200)}$, $\varepsilon = 1$

Table 7.3 Values of lg(cond(W)) for each group of BH3-peptides

Region	Range of values lg(cond(W))	Hrk, Bax, Bik, Noxa	Bmf, Puma, Bad, Bid, Bim, Bak
I	17.65–17.9	0.0	100.0
II	17.65–18	18.18	81.82
III	17.65–18.1	16	84

V	17.65–18.3	23.1	76.9

with the protein Bcl-xl$_{(1-200)}$. Region II contains 18.18% of the values of lg(cond(W)) obtained from the interaction of BH3 peptides of the group I with the protein Bcl-xl$_{(1-200)}$ and 81.82% of the values of lg(cond(W)), obtained during the interaction of BH3 peptides of group II with the protein Bcl-xl$_{(1-200)}$. The regions containing higher values of lg(cond(W)) (regions III and IV) contain 16 and 28.81% of the values of lg(cond(W)) obtained from the interaction of group I peptides with the Bcl-xl$_{(1-200)}$ and 84 and 71.19% of the values of lg(cond(W)) for the interaction of BH3 peptides of group II with the protein Bcl-xl$_{(1-200)}$, respectively.

As we see from the presented table, as the values of lg(cond(W)) increase, a gradual uneven decrease in the values of lg(cond(W)) in the range of values of

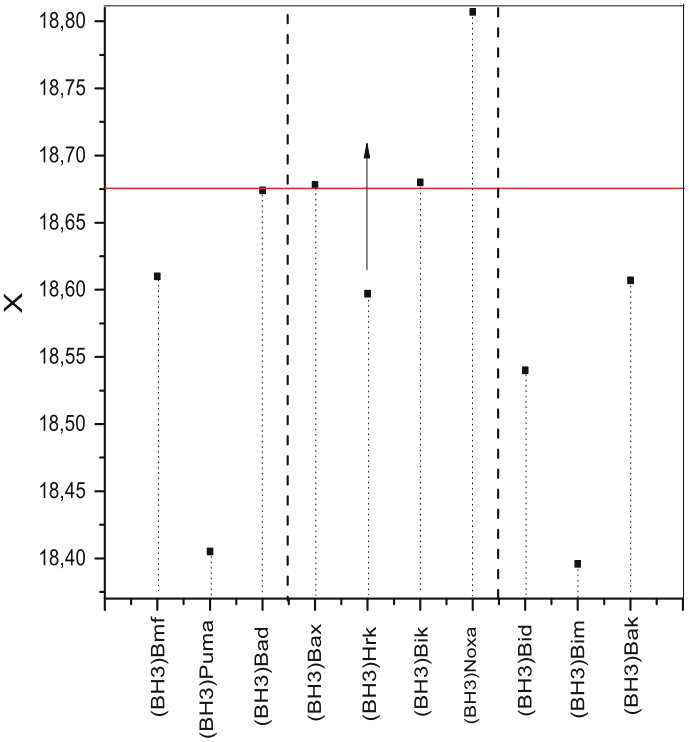

Fig. 7.4 The value of X obtained at interaction of each BH3-peptide protein Bmf, Puma, Bad, Hrk, Bax, Bik, Noxa, Bid, Bim, Bak with the Bcl-xl$_{(1-200)}$, $\varepsilon = 1$

lg(cond(W)) occurs for the second group of proteins and an increase in the values of lg(cond(W)) occurs for the first group of proteins.

Thus, the minimum values of lg(cond(W)) are in higher values for group I BH3-peptides, and in lower values for BH3-peptides of group II, which indicates a higher affinity of BH3 -peptides of group II for the protein Bcl-xl$_{(1-200)}$ than of BH3-peptides of group I for the protein Bcl-xl$_{(1-200)}$.

To verify this assumption, we calculated the mean value of the 100 minimum values, which we will mark as X, for each BH3 peptide in interaction with the Bcl-xl protein. Next, we presented graphically the values obtained for each interacting BH3 peptide with the Bcl-xl$_{(1-200)}$protein (see Fig. 7.4). On this histogram, a red baseline was drawn, which conditionally separates the BH3 peptides of the first and second groups. Above the baseline lie the values of the 100 minimum average values of lg(cond(W)) obtained during the interaction of the BH3 peptides of the group I proteins with the Bcl-xl$_{(1-200)}$ protein. Below the baseline lie the values obtained in the interaction BH3 peptides of group II proteins with the protein Bcl-xl$_{(1-200)}$.

As can be seen from the histogram, six values of X corresponding to the interactions of BH3 peptides of the protein group II with Bcl-xl$_{(1-200)}$ (Bmf, Puma, Bad,

Bid, Bim, Bak) are in the range of values below the baseline. Their values amounted to: 18.61, 18.405, 18.674, 18.54, 18.396, and 18.607. Three values of X corresponding to the interactions of group I BH3 peptides (Hrk, Bik, Noxa) with Bcl-xl$_{(1-200)}$ are in the range of higher values of X and are located above the baseline. However, one value of X corresponding to the interaction of the BH3 peptide of group I of the Bax protein with Bcl-xl$_{(1-200)}$ is below the baseline and its value amounted to 18.597. Thus, an analysis of the given criterion (X) demonstrated that 9 out of 10 BH3 peptides satisfy the given criterion.

Note that in this calculation and subsequent analysis, the 100 minimum values of lg(cond(W)) were chosen for the interaction of each BH3 peptide with the whole amino acid sequence of the Bcl-xl protein.

To achieve more accurate results in the future, it is proposed to take into account the folding of proteins, the structure of the formed dimeric complex, and to analyze the minimum values of lg(cond(W)) with the participation of exclusively interacting regions of whole proteins.

Thus, in the presented section, a qualitative analysis of the determination of the affinity of short BH3 peptides of Bmf, Puma, Bad, Hrk, Bax, Bik, Noxa, Bid, Bim, Bak proteins with the Bcl-xl$_{(1-200)}$ protein was performed and a qualitative agreement with [6] was revealed.

7.3.2 *Interaction of Modified BH3-Peptides of Bax Protein with Bcl-2 Protein Taking into Account the Replacement of Amino Acid Residues*

In this section, the binding of BH3 peptides of the Bax protein was numerically simulated, taking into account various changes in amino acid residues with the Bcl-2 protein. The obtained result will allow us to determine the influence of point mutations in the BH3 peptides of the Bax protein on the stability of the complexes formed with the Bcl-2 protein.

In [23], the binding structure of the Bcl-2 protein to the Bax protein region was determined. The Bax protein peptide forms an amphiphilic α–helix and binds to the BH3-binding hydrophobic groove of the Bcl-2 protein. The intramolecular interaction between the Bcl-2 protein and the Bax protein peptide is mediated by hydrophobic and ionic interactions. Some of the main amino acid residues from the protein Bcl-2 are the amino acid residues in the region from 107a.a. to 146 a.a. as well as the amino acid residue in the 200 a.a. region. The amino acid sequences of the BH3-peptide of the Bax protein with the performed amino acid residue substitutions, as well as the dissociation constants for binding each peptide to the Bcl-2 protein are shown in Table 7.4.

Interaction of the BH3 peptide of the $Bax_{(wt)}$ protein with the Bcl-2 protein was taken as the **main** interaction of the BH3 peptide with the Bcl-2 protein. When point exchanges of amino acid residues in the BH3 peptide of the Bax protein are performed, we assume that the main interactions of these modified BH3 peptides fall on the same sections of the Bcl-2 protein as the $Bax_{(wt)}$ BH3-peptide of the

$mBax_{(E69A)}$	QPPQDASTKKLSECLRRIGD**A**LDSNMELQRMIADVD	476
$mBax_{(R78A)}$	QPPQDASTKKLSECLRRIGDELDSNMELQ**A**MIADVD	57.1

wild type when interacting with the Bcl- 2 and the point replacements of the amino acid residues do not essentially change the binding site with the Bcl-2 protein, but have a significant effect on the affinity of complex formation. When analyzing the interaction of modified BH3 peptides with Bcl-2, the sites identified as the main sites in the interaction of the wild-type BH3 peptide with Bcl-2 will be analyzed.

Figure 7.5 shows the numerical results obtained for the interaction of all $Bax_{(wt)}$ and modified BH3 peptides of the Bax protein with Bcl-2 at low values of lg(cond(w)). The results of numerical simulation of the interaction of the BH3-peptide $Bax_{(wt)}$ with Bcl-2 on the graph are presented by a black square, while the results of the interaction of all other modified BH3 peptides of the Bax protein with Bcl-2 are represented by empty figures.

For further analysis of the data, we identified three significant areas with the lowest values of lg(cond(W)) in the interaction of the BH3 peptide $Bax_{(wt)}$ with the Bcl-2 protein in the range of lg(cond(w)) from 18.75 to 19.15. Recall that each point on the graph represents the first a.a. when binding two amino acid sequences.

The first area lies in the interval from 60 a.a. to 70 a.a., the second region lies in the region from 105 a.a. to 130 a.a., and the third area from 160 a.a. to 180 a.a.

For each of these areas, we calculated the number of hits for each interaction of the BH3 peptide with Bcl-2 and plotted the result in the form of a histogram, see Fig. 7.6.

As can be seen from the histogram, the greatest number of hits-8, is typical for the interaction of the BH3-peptide $Bax_{(wt)}$ with Bcl-2. The number of all other hits for modified BH3 peptides Bax c Bcl-2 corresponds to a smaller number of hits of the minimum values of lg(cond(W)) in these regions. Also, from the given histogram 7.6, the interaction of the BH3-peptide $Bax_{(49-85)}$ with the Bcl-2 protein is characterized by the most frequent hit of the lg(cond(W)) values in the selected regions in comparison with the other modified BH3 peptides of the Bax protein, in which the amino acid residues were substituted.

Thus, six modified BH3-peptides of the protein $Bax_{(49-85)}$ in which the amino acid residue substitutions were performed bind to the Bcl-2 protein worse than the

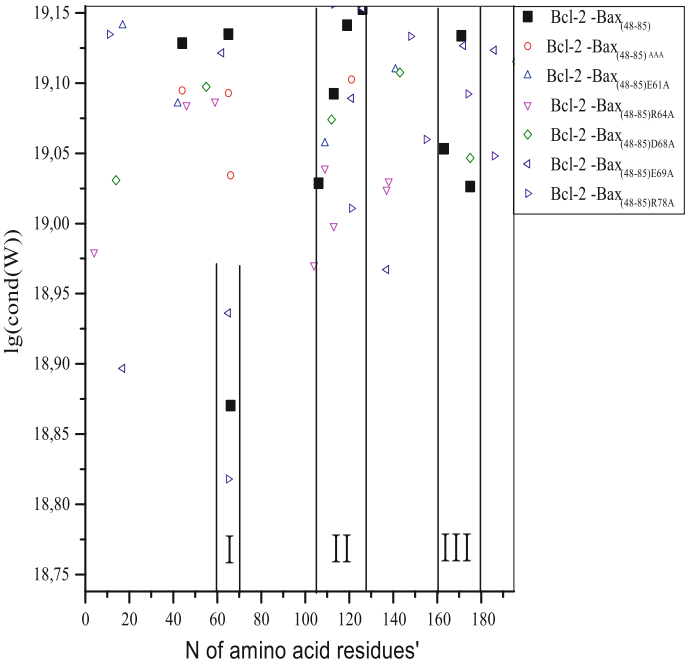

Fig. 7.5 Results of the numerical calculation of the interaction of the Bax3 peptides of the Bax protein with the Bcl-2 protein (fill figures) and the Bax3 peptides of the Bax protein, in which the amino acid residue substitutions (empty figures) were performed, with the Bcl-2 protein in the region of the smallest values of lg(cond(W)), $\varepsilon = 1$

BH3-peptide $Bax_{(wt)}$, while the site $\text{Bax}_{(49-85)}$ is prone to form the most stable biological complexes with the Bcl-2 protein compared to all other $\text{Bax}_{(49-85)}$ peptides in which one or more amino acid residues were replaced by the amino acid residue of alanine (A).

This result is in good agreement with the previously performed experimental article, which indicates that the dissociation constant of mutant peptides upon binding to the Bcl-2 protein is higher than when bounding to the natural site of $\text{Bax}_{(49-85)}$) [23].

7.3.3 Qualitative Definition of the Logarithm of the Dissociation Constant K_d in the Interaction of BH3 Peptides with the Bcl-2 Protein

The task was to find the correspondence and correlation between lg(cond(W)) and the logarithm of the dissociation constant K_d for the interaction of protein molecules. To do this, we compared the available data of the value of lg(K_d) with the calculated value of lg(cond(W)) for binding of the BH3 peptides with Bcl-xl [23] protein.

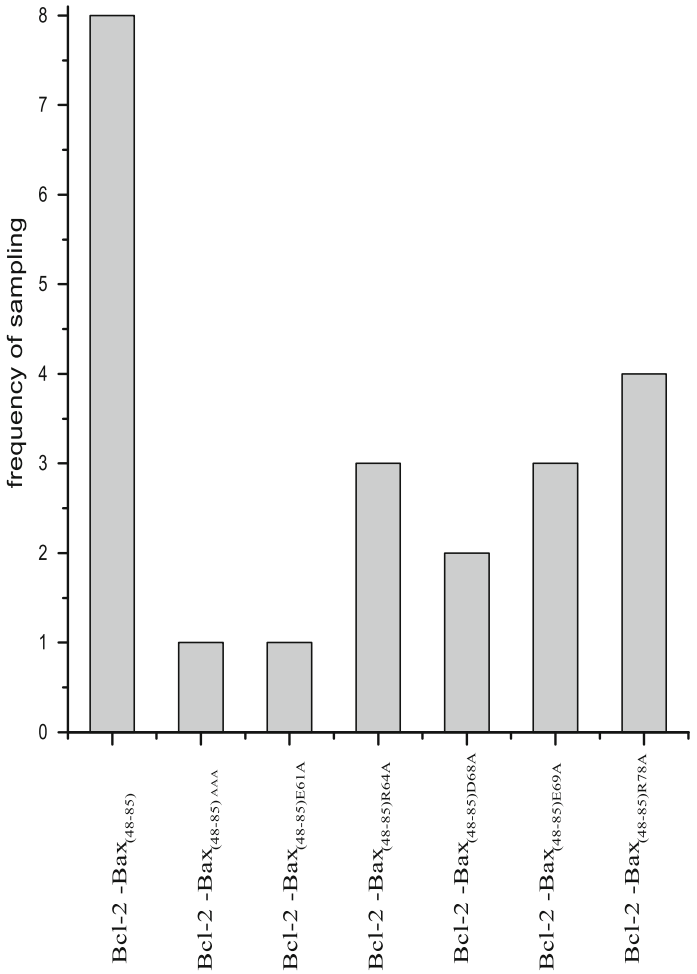

Fig. 7.6 Frequency of BH3 peptides Bax in the three designated regions of the Bcl-2 protein, $\varepsilon = 1$

We performed the calculation of the interaction of the BH3 peptides of proteins $\text{Puma}_{(127-162)}$, $\text{Hrk}_{(23-58)}$, $\text{Bad}_{(137-172)}$, $\text{Bik}_{(41-76)}$, $\text{Bax}_{(48-85)}$, $\text{Noxa}_{(65-100)}$ with the entire amino acid sequence Bcl-xl, as well as with the truncated amino acid sequence of the protein $\text{Bcl-xl}_{(86-233)}$, assuming that not the entire amino acid sequence of the Bcl-xl protein participates in the direct formation of the biological complex with BH3 peptides, in order to determine the correspondence between the theoretical values of lg(cond(W)) and to compare with the experimental values of K_d.

The list of amino acid sequences of BH3-peptides is given in the Table 7.5, as well as their numbers from [13].

Table 7.5 List of amino acid sequences of BH3-peptides [13]

Protein	Amino acid sequence	Number in uniprot
$\text{Puma}_{(127-162)}$	RVEEEEWAREIGAQLRRMADDLNAQYERRRQEEQHR	Q99ML1
$\text{Bad}_{(137-172)}$	APPNLWAAQRYGRELRRMSDEFEGSFKGLPRPKSAG	Q61337
$\text{Hrk}_{(23-58)}$	PGLRWAAAQVTALRLQALGDELHRRAMRRRARPRDP	P62817
$\text{Bik}_{(41-76)}$	LMECVEGRNQVALRLACIGDEMDLCLRSPRLVQLPG	O70337
$\text{Bax}_{(49-84)}$	QPPQDASTKKLSECLRRIGDELDSNMELQRMIADVD	Q07813
$\text{Noxa}_{(65-100)}$	TRVPADLKDECAQLRRIGDKVNLRQKLLNLISKLFN	Q9JM54

The mean values for the 100 minimal values of lg(cond(W)) were calculated for each interacting BH3 peptide of the proteins $\text{Puma}_{(127-162)}$, $\text{Hrk}_{(23-58)}$, $\text{Bad}_{(137-172)}$, $\text{Bik}_{(41-76)}$, $\text{Bax}_{(48-85)}$, $\text{Noxa}_{(65-100)}$ with the Bcl-xl protein. The results obtained are shown in the Fig. 7.7. The graphs Fig. 7.8 show the mean values for 100 minimal values of lg(cond(W)) obtained by the interaction of BH3 peptides with the truncated protein $\text{Bcl-xl}_{(86-233)}$.

The specific values of K_d corresponding to the interactions of each BH3-peptide with the Bcl-xl protein are given below [23].

$$BH3\text{-}peptide\ PUMA\ 4.65$$

$$BH3\text{-}peptide\ BAD\ 18.4$$

$$BH3\text{-}peptide\ HRK\ 17.9$$

$$BH3\text{-}peptide\ BIK\ 23.6$$

$$BH3\text{-}peptide\ Bax > 100$$

$$BH3\text{-}peptide\ Noxa > 1000$$

The values of K_d corresponding to the interaction of $\text{Bax}_{(48-85)}$, $\text{Noxa}_{(65-100)}$ with the Bcl-xl protein are expressed as $\lg(K_d)$.

In the presented graphs Figs. 7.7 and 7.8, BH3 peptides are listed in order with increasing $\lg(K_d)$ when interacting with the Bcl-xl protein. The interaction of BH3 peptides of the proteins $\text{Bax}_{(48-85)}$ and $\text{Noxa}_{(65-100)}$ with Bcl-xl is characterized by the greatest K_d. Thus, the graphs should show an increase in the values of the lg(cond(W)) value, starting from the BH3 peptide of $\text{Puma}_{(127-162)}$ to the BH3 peptide of $\text{Noxa}_{(65-100)}$.

Let us now analyze the results presented in each graphs.

In Fig. 7.7, a baseline was made separating the last two BH3 peptides of $\text{Bax}_{(48-85)}$ and $\text{Noxa}_{(65-100)}$ from the remaining BH3 peptides of $\text{Puma}_{(127-162)}$, $\text{Hrk}_{(23-58)}$,

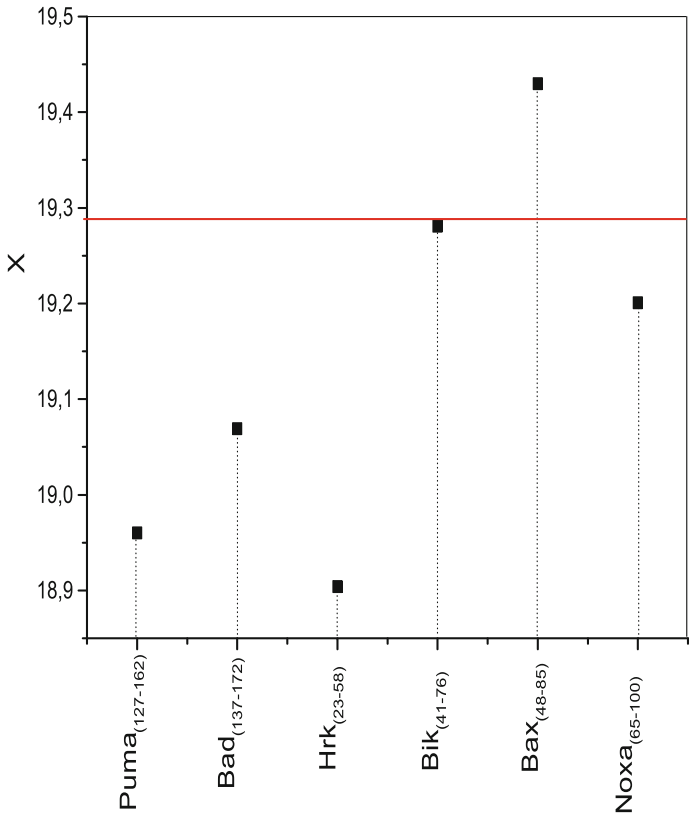

Fig. 7.7 Average value of the one hundred minimum values of lg(cond(W)) for each BH3 peptide upon interaction with the Bcl-xl, $\varepsilon = 1$

$\text{Bad}_{(137-172)}$, $\text{Bik}_{(41-76)}$ with the Bcl-2 protein depending on K_d interacting proteins, since the K_d of the last two BH3 peptides is significantly larger compared to the K_d of previous BH3-peptides.

As seen from the graph, the interaction of the BH3 peptide $\text{Bax}_{(48-85)}$ with Bcl-xl is characterized by a higher K_d and value of lg(cond(W)) compared to the interaction of BH3 peptides $\text{Puma}_{(127-162)}$, $\text{Hrk}_{(23-58)}$, $\text{Bad}_{(137-172)}$, $\text{Bik}_{(41-76)}$ with Bcl-xl. However, the calculated value of lg(cond(W)) in the interaction of the BN3 peptide of $\text{Noxa}_{(65-100)}$ with Bcl-xl lies in a lower range of lg(cond(W)) than the results of the interaction of BH3-peptides, $\text{Bik}_{(41-76)}$ and $\text{Bax}_{(48-85)}$ with Bcl-xl.

One of the reasons that the latter value lies below the baseline is that not all the polypeptide chain of the Bcl-xl protein takes a direct part in the formation of the biological complex with BH3-peptides.

We assume that the main participation in the formation of a biological complex involving Bcl-2 and BH3-peptide proteins occurs in the B1–BH3 domains of the

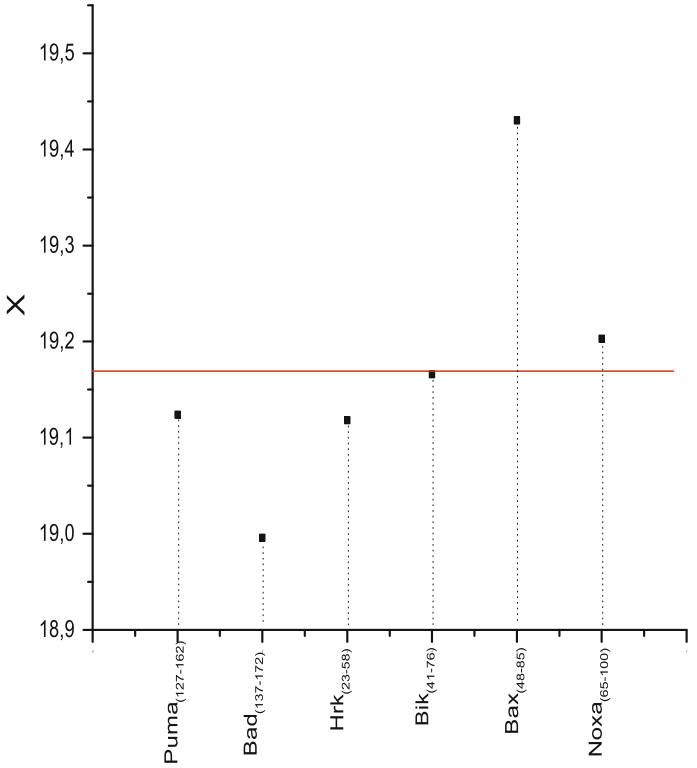

Fig. 7.8 Mean value of the fifty minimum values of lg(cond(W)) for each BH3 peptide when interacting with the truncated Bcl-xl$_{(86-233)}$, $\varepsilon = 80$

Bcl-xl protein. Therefore, an additional calculation of the interaction between BH3-peptides and Bcl-xl$_{(86-233)}$ was carried out.

In Fig. 7.8, a baseline was also made that separates the interactions of BH3 peptides Puma$_{(127-162)}$, Hrk$_{(23-58)}$, Bad$_{(137-172)}$, Bik$_{(41-76)}$ with Bcl-xl$_{(100-233)}$ from the interaction of BH3-peptides Bax, Noxa with Bcl-xl$_{(100-233)}$.

As can be seen from the figure, the values of lg(cond(w)) of the BH3-peptide interaction of Bax$_{(48-85)}$ and Noxa$_{(65-100)}$ with Bcl-xl are above the baseline, as K_d is found for interactions of Bax$_{(48-85)}$–Bcl-xl and Noxa$_{(65-100)}$–Bcl-xl [23] are at higher values than K_d, characterizing the interactions of Puma$_{(127-162)}$, Hrk$_{(23-58)}$, Bad$_{(137-172)}$, and Bik$_{(41-76)}$ with Bcl-xl. We believe that in order to obtain better data, it is necessary to perform a calculation between the contacting regions of the polypeptide chains of the interacting proteins.

Thus in this chapter, a new method has been developed that allows us:

- to qualitatively determine the lg(K_d) of peptides for full-length proteins;
- to determine the effect of point mutations in peptides on the stability of the formed complex with whole proteins.

A qualitative agreement of the results with Kd on the example of the formation of the biological complex of BH3 peptides of Bmf, Puma, Bad, Hrk, Bax, Bik, Noxa, Bid, Bim, and Bak proteins with Bcl-xl$_{(1-200)}$ protein was determined.

The influence of point mutations on the stability of the formed biological complexes was also studied on the example of the interaction of the BH3 peptides of the Bax protein in which point replacements of amino acid residues were made with the whole Bcl-2 protein. The formation of the biological complex of BH3-peptide of the protein Bax$_{(49-85)}$ with Bcl-2 was taken as the main interaction. The numerical results of the interaction of the protein Bax$_{(49-85)}$ with Bcl-2 were compared with the remaining results of the interaction of BH3 peptides Bax with the Bcl-2 protein taking into account the substitution of amino acid residues. As a result, the Bcl-2 protein regions with the largest number of minimum values of lg(cond(W)) were found in the interaction with Bax$_{(49-85)}$. The subsequent analysis of these regions revealed that the other modified BH3 peptides contain much less than the minimum values of lg(cond(W)) in the previously designated regions.

Thus, it is possible to use the obtained result to determine the binding site of the peptide with the whole protein in order to determine the stability of the formation of the biological complex by any modified BH3 peptide of the Bax protein in which the amino acid residues have been replaced with the Bcl-2 protein.

The third stage of the theoretical studies of the interaction of BH3 peptides with proteins of the Bcl-2 family was devoted to finding a qualitative correlation between the values of lg(cond(W)) and lg(K_d). To perform this comparison, we used the results of the values of lg(K_d) [23] obtained by the interaction of BH3 peptides Puma, Hrk, Bad, Bik, Bax, Noxa with the whole Bcl-xl protein. The result was a qualitative determination of the value of lg(K_d) by analyzing lg(cond(W)).

Application of the developed mathematical algorithms will allow us to find the optimal peptides taking into account the affinity for their target proteins and to develop inhibitors or activators of proteins in the future.

Chapter 8
Mathematical Algorithms for Finding the Optimal Composition of the Amino Acid Composition of Peptides Used as a Therapy

Abstract In this chapter, two algorithms have been developed, one of which (Algorithm 3) was developed specifically for the selection of amino acid residues in peptides to improve their affinity in the interaction of peptides with full-length proteins, and Algorithm 4 was developed to search for "scattered" active region of the protein when bound to the peptide.

8.1 Introduction

In this part of the chapter, we will discuss how to improved peptide vaccines by developed algorithms.

Global concern is the rise in the incidence of cancer, recent data released revealed 12.7 million new cases and 7.6 million deaths, just in 2008 [1], in Europe alone, 3.45 million new cases were diagnosed and 1.75 million deaths occurred during 2012 [2].

Nowadays, cancer is the second most common cause of death worldwide [3], caused by an abnormal cellular growth, in a uncontrolled manner, with the ability to invade other tissues, leading to the formation of tumor masses, neo-vascularization (angiogenesis), and metastasis [4] . Lung, colorectal, prostate, and breast cancer are the most diagnosed forms of this disease [5].

Considering the numbers revealed, it is urgent to find new anticancer drugs able to control tumor growth with minimal side effects [6–8].

Potential clinical approaches using ACPs (Anti Cancer peptides).

Although a wide variety of drugs are commercially available, treatments for cancer have one thing in common: the emergence of resistance against multiple drugs [9].

Another associated problem is the lack of selectivity of the available drugs, and their consequent undesirable side effects for the patients [10].

Thus, there is a need for the development of new antineoplastic, with higher selectivity, leading to fewer side effects than current ones. It is desirable that these new compounds present different mechanisms of action, without dependence on activity toward a single specific molecule in the target cells. The main goal is resistance prevention, overcoming the existing mechanisms that cancer cells use, being active and diminishing the side effects [11–13].

Peptide-based cancer vaccines represent the most specific approach to polarize the immune system against malignant cells, since they are preparations made of single epitopes, the minimal immunogenic region of an antigen [14].

In addition, peptides also play an important role in cancer, including early diagnosis, prognostic predictors, and the treatment of cancer patients. Unlike other therapies, peptides show superiority due to their specificity. Recently, peptide-based therapy against cancer, such as peptide vaccines, has attracted increased attention [15, 16].

Here are some results of vaccine trials in Phase II clinical trials.

The complex effect of peptides derived from cancerous tissue of proteins such as LY6K, CDCA1, IMP3, whose peptides were tested in head and neck squamous cell cancer (HNSCC) immunotherapy, was studied [17].

In clinical trials of Phase II, vaccines were used based on the following peptides

$LY6K_{(177-186)}$ RYCNLEGPPI

$CDCA_{(156-164)}$ VYGIRLEHF

$IMP3_{(508-518)}$ KTVNELQNL

HIV is specific peptide ILKEPVHGV

CMV is specific peptide RYLRDQQLL

Phase II clinical trials demonstrate that antigenic vaccination, based on the five above-mentioned peptides, induces an immune response. Positive CTL responses (cytotoxic T-lymphocytes) specific for LY6K peptide after vaccination were observed in 85.7% of patients.

Patients with a positive CTL response showed significantly longer survival periods (overall survival OC) than those who did not have a CTL immune response.

Also, the MST (Median survival time) was 8.1 months for patients with an immune response and 1.4 months for patients who did not have an induced immune response to the vaccination. Also, in some patients, there was a stable remission and an increase in the duration of the period without progression of the disease.

It should also be noted that the result of phase II clinical trials is the complete recovery of the patient from the fourth stage of the disease. After 16 cycles of vaccination, recurrent and metastatic tumors disappeared. Thus, such a combinatorial vaccine with multi-epitope peptides, as monotherapy, can help circumvent the heterogeneity of cancer cells and avoid a peptide-specific immune response due to loss of antigen expression.

This chapter proposes the search for optimal solutions for future improvement and strategies in immunotherapy for various types of tumors.

Vaccines will be developed by improving existing ways of creating peptide vaccines based on the created therapeutic molecular approaches:

1. Increased affinity of existing ligand-receptor interactions

2. Regulation of protein functions by synthesizing new highly selective peptides that will bind to the active site of the target protein

3. Development of highly selective peptides for target proteins, which will activate or inhibit cascade pathways of chemical reactions in cells.

So, based on the method we developed, existing peptide vaccines can be improved by increasing the affinity for the target protein or increasing the affinity of the ligand for the receptor by selecting the amino acid composition of the peptide vaccines. We

Fig. 8.1 Peptide $Bcl2_{(185-200)}$ with the amino acid residues to be replaced

propose an algorithm developed by us that will allow the automatic setting of point replacements of amino acid residues in peptides and obtain numerical results.

To analyze the biochemical processes we use the notion of condition number matrix of the potential energy of the pair electrostatic interaction between peptides. In this physical formulation of the problem, it will characterize the degree of stability of the configuration of the biological complex. In order to choose a more stable biochemical compound between proteins, we select the matrix of potential energy of electrostatic interaction with the **smallest** value of the condition number (see Chap. 2).

8.2 Description of the Algorithm 3

Let the Bcl2 protein peptide be given from 185 a.a. to 200 a.a., in which it is necessary to determine the effects of amino acid substitutions with order numbers 4, 6, 8, 10, 12 on the stability of the formation of the biological complex of each such modified peptide with the Bax protein. In this case, it is necessary to evaluate the binding of each modified peptide to a specific region of the Bax protein, say, from 100 a.a. to 140 a.a. For example, let us analyze the interaction of the peptide $Bcl\text{-}2_{(185-200)}$ with the protein Bax. Red color indicates the variable parameters that the researcher can set independently, depending on the task. In the program, a short array is specified as:

```
S_20=['W'  'I'  'Q' 'D'  'N'  'G'  'G'  'W' ...
 'D'  'A'  'F' 'V'  'E' 'L'  'Y'  'G' ]
```

The amino acid sequence of the whole protein Bax is given by the sequence:

```
S_100=['M'  'D'  'G'  'S'  'G'  'E'  'Q'  'P'  'R' ...
'G'  'G'  'G' 'P'  'T'  'S'  'S'  'E'  'Q'  'I' ...
'M'  'K'  'T'  'G'  'A'  'L'  'L'  'L' 'I'  'F' ...
'V'  'A'  'G'  'V'  'L'  'T'  'A'  'S'  'L'  'T' ...
'I'  'W'  'K' 'K'  'M'  'G']
```

In Fig. 8.1 such a peptide is represented. The red numbers denote the serial numbers of the amino acid residues that will be changed. In the algorithm, it is possible to specify up to 5 replacements of the amino acid residues in one peptide. When one runs the program, one can specify the number of required changes:

```
"Enter the number of replacements"
You enter the required number of replacements: 5
```

After the number of substitutions of a.a. from 1 to 5 is chosen, you should specify the sequence numbers for each a.a. substitution:

```
You must enter the sequence number of a.a. in the peptide: 4
"Enter the sequence number for replacement number 2"
You must enter the sequence number of a.a. in the peptide: 6
"Enter the sequence number for replacement number 3"
You must enter the sequence number of a.a. in the peptide: 8
"Enter the sequence number for replacement number 4"
You must enter the sequence number of a.a. in the peptide: 10
"Enter the sequence number for replacement number 5"
You must enter the sequence number of a.a. in the peptide: 12
```

In the body of the program, one-dimensional arrays consisting of a list of amino acid residues for rotation with point replacements a.a. are preset manually:

```
Sub1=['A' 'T']; %replacement matrix №1
Sub2=['H'];     %replacement matrix №2
Sub3=['K'];     %replacement matrix №3
Sub4=['Y'];     %replacement matrix №4
Sub5=['T'];     %replacement matrix №5
```

The red color denotes a.a., which the researcher sets himself. In this case, such one-dimensional arrays is 5. Next, the program asks you to specify the boundaries of protein 2 (in this case, the full-length protein Bax):

```
"Enter the LEFT boundary of the vector S_100="
Enter the value: 100
"Enter the RIGHT boundary of the vector S_100="
Enter the value: 140
```

The steps and the number of minimum values are set in the program body manually:

```
sh=1;              % step shift
n_el=10;           %amount of minimal elements.
```

All data will be written to the Excel file at the end of the program.

In Fig. 8.2 the average values ($\overline{X}$) of the 10 minimal values of lg(cond(W)) obtained from the interaction of each modified peptide with a region of the whole protein are presented. The minimum average value of the 10 minimal lg(cond(W)) in this case was 17.647. On the graph, this value is seen opposite the sequence number of the fifth amino acid substitution. Such modified peptide, the mean value of 10 minimal lg(cond(W)) of which was the minimum value, is the peptide WIQDNG-GKDAFVELYG. In this methodological example, a modified Bcl-2 protein peptide was identified which, when interacting with the protein region $\text{Bax}_{(100-140)}$, showed the lowest average value of 10 minimal values of lg(cond(W)). Red color indicates the changed amino acid residues. Recall that the researcher can put any number of the smallest values of lg(cond (W)), which correspond to the interaction of the modified peptide with a protein. Thus, to obtain modified peptides with the lowest dissociation constant, it is proposed to analyze peptides that fall within the lower range of the minimum mean values of lg(cond(W)) and not be limited to one modified peptide.

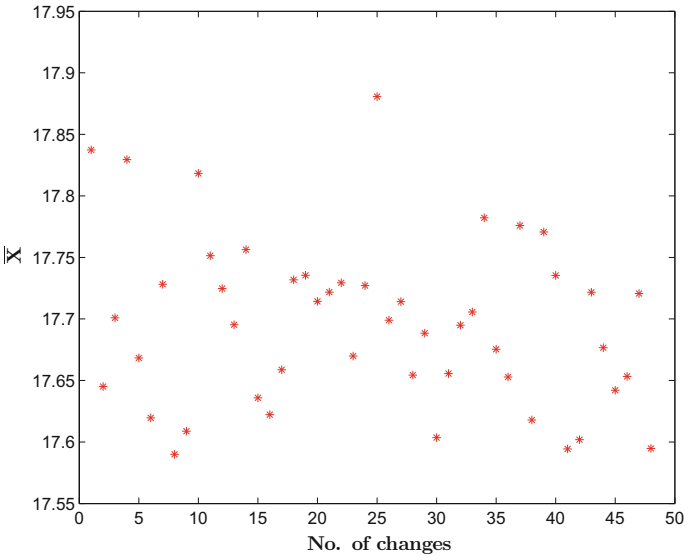

Fig. 8.2 Results of numerical calculation according to Algorithm 3

8.3 Description of the Algorithm 4

Algorithm 4 was developed for cases where the catalytic center of a protein, when bound to a peptide, is formed by different sections of a polypeptide chain located close to three-dimensional space by folding the protein into a native conformation, for example, the Bcl-2 family proteins.

So if BH3-only proteins form complexes due to the participation of the BH3 domain with proteins containing BH1-BH3 domains, such as Bcl-2, Bcl-xl, Bcl-w, then one assumes that the formation of the protein complex is due to the involvement of different sites of a polypeptide chain of a protein containing BH1-BH4 domains. Algorithm 4 allows providing such partial ≪scattered≫ of amino acid residues involved in the formation of a biological complex with another protein. A part of the peptide is supposed to be permanently installed in one of the active regions of the protein polypeptide sequence, the rest of the peptide begins its progress along the amino acid sequence of the protein, and when the second part of the peptide enters the second part of the ≪scattered≫ catalytic center, it is assumed that the value of lg(cond(W)) will decrease. Thus, we assume that it is possible to ≪feel≫ the regions of the ≪scattered≫ catalytic center along the polypeptide chain of the whole protein.

Input data:

The segment protein $\text{Bax}_{(59-74)}$

```
S_20=[ 'L'  'S'  'E'  'C'  'L'  'K'  'R' 'I'  'G'  'D'  'E'...
'L'  'D'  'S'  'N'  'M' ]
```

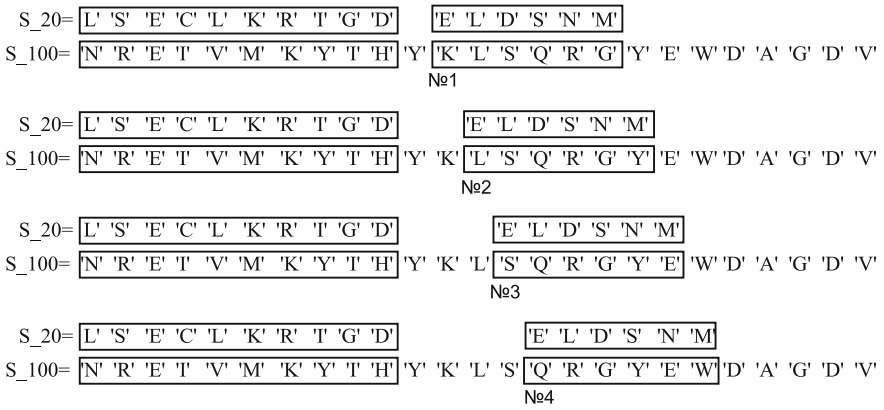

Fig. 8.3 The scheme of Algorithm 4

Table 8.1 The four lowest values of lg(cond(w)) and their corresponding amino acid sequences

$N^{\underline{0}}$	Amino acid sequence of Bcl-2	Amino acid sequence $Bax_{(59-74)}$	lg(cond(W))
7	**NREIVMK**YIHYEWDAG	LSECLKRIGDELDSNM	17.471
3	**NREIVMK**YIHSQRGYE	LSECLKRIGDELDSNM	17.479
1	**NREIVMK**YIHKLSQRG	LSECLKRIGDELDSNM	17.539
8	**NREIVMK**YIHEWDAGD	LSECLKRIGDELDSNM	17.549

The segment protein Bcl-2:

```
S_100=[ 'N'  'R'  'E'  'I' 'V'  'M'   'K'  'Y'  'I'...
'H'  'Y'  'K' 'L'  'S'  'Q'  'R'  'G'  'Y'  'E'  'W' 'D'...
'A'  'G'  'D'  'V'  ]
n_el=4    %amount of minimal elements:
```

Thus, the first matrix will be formed when calculating the interactions between a.a. of the following two one-dimensional arrays Fig. 8.3:

Bold characters denotes an invariable part of the formed one-dimensional array (Table 8.1). The result is shown in Fig. 8.4.

8.4 Schematic Representation of the Increased Affinity of Peptides to Proteins Targets

The above algorithms for analyzing the interaction of short peptides with full-length proteins will allow the selection of higher affinity peptides for receptors or for protein targets. Let us consider several options for the application of mathematical modeling to improve existing peptides and the development of new biologically active peptides.

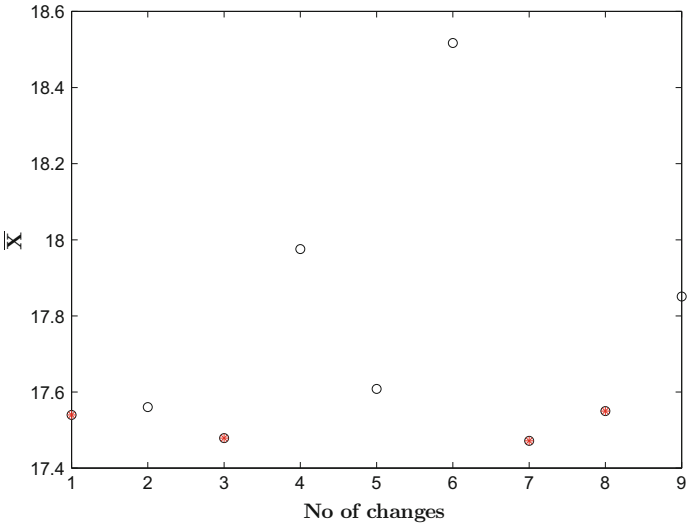

Fig. 8.4 Results of numerical calculation according to Algorithm 4

8.4.1 Increase of the Affinity of the Existing Peptides to the Active Center of the Target Protein

In Figs. 8.5 and 8.6 a model for improving the existing L1 ligand by the method of selecting amino acid residues in the peptide using Algorithm 3 is presented. After the mathematical calculation of the substitution of one amino acid residue for other amino-acid residues, the L1 ligand is converted to the ligand L2, which has an increased affinity for the receptor, compared to the L1 ligand.

The dissociation constants K1 and K2 characterize the affinity of the original ligand L1 to the receptor. The constants K3 and K4 are new constants characterizing the affinity of the new L2 ligand to the same receptor. Ligand L2 as a result of our mathematical algorithm has an increased affinity for the receptor.

Thus, the association constant K1 is smaller than the new K3 association constant. In turn, the dissociation constant K2 is greater than the new dissociation constant K4.

8.4.2 Creation of a New Peptide that Binds to a Given Active Protein Center

One can also synthesize special peptides that will bind to a given site on the receptor (as shown in the Fig. 8.7). Thus, in addition to improving existing ligands, it will be possible to develop new peptides that will selectively bind to a selected region of other proteins.

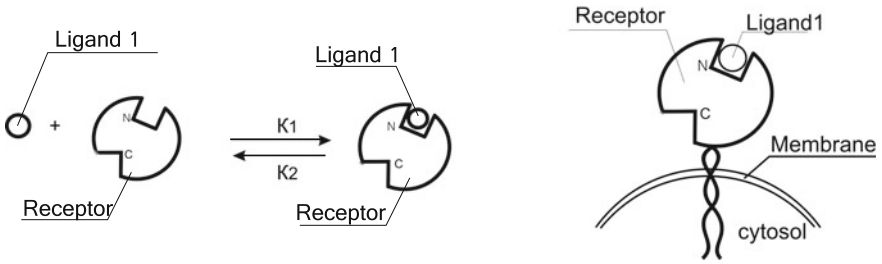

Fig. 8.5 The previously existing peptide ligand L1

Fig. 8.6 Modified peptide ligand L2

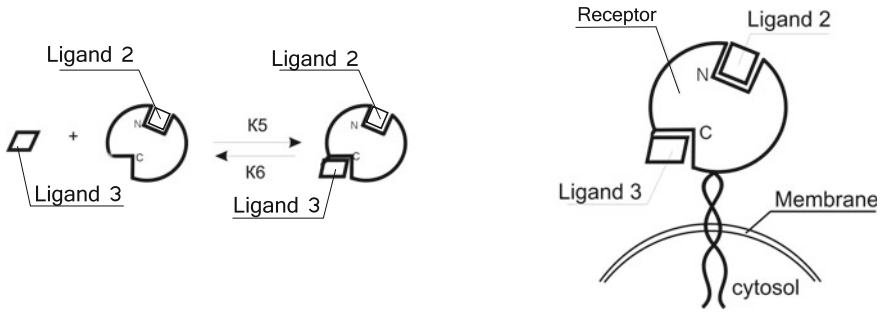

Fig. 8.7 Schema of joining the synthesized peptide (Ligand 3) to a given active site of the target protein (Receptor)

8.4.3 Creation of Peptides That Will Interfere with the Formation of Homo- and Heterodimers

The developed mathematical algorithms will also allow calculating amino acid sequences of peptides that will interfere with the formation of homo and heterodimers, as shown in Fig. 8.8.

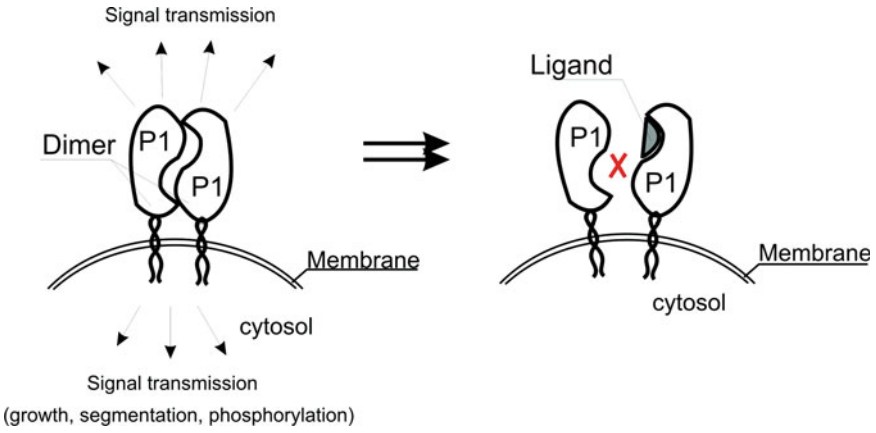

Fig. 8.8 Schema of inhibiting the active site of the protein (P1) by the synthesized peptide (L3)

Thus, the Algorithms 3–4 and methods presented in this chapter will allow to determine of point changes in amino acid residues in peptides. The second proposed algorithm makes it possible to determine the active region of a protein that is ≪scattered≫ along the entire length of the amino acid sequence of the protein when bound to the peptide.

8.5 Matlab Script Algorithm 3 for Finding the Optimal Composition of the Amino Acid Composition of Peptides Used as a Therapy

Input parameters:

1. S_{100}, S_{20} are amino acid sequences of biological complexes ($S_{100} \geq S_{20}$)
2. epsilon is the dielectric constant of the medium
3. sb is the number of replacements
4. a is left boundary of the vector S_{100}
5. b is right boundary of the vector S_{100}
6. sh is step shift

Output parameters:

lg(cond(W) is the common logarithm of the condition number of the matrix W, where its elements are composed of the electrostatic potential energy which is created based on the interaction between pair of amino acid residues of biological complexes.

Compute:

lg(cond(W) is the common logarithm of the condition number of the matrix W, which will allow a prediction the reactivity of the studied biological complexes.

8.6 Matlab Script Algorithm 4 for Finding the Optimal Composition of the Amino Acid Composition of Peptides Used as a Therapy

Input parameters:

1. S_1, S_{20} are amino acid sequences of biological complexes ($S_1 \geq S_{20}$)
2. epsilon is the dielectric constant of the medium
3. sh1 is step shift
4. sh2 is is the length of the frame

Output parameters:

lg(cond(W) is the common logarithm of the condition number of the matrix W, where its elements are composed of the electrostatic potential energy which is created based on the interaction between pair of amino acid residues of biological complexes.

Compute:

lg(cond(W) is the common logarithm of the condition number of the matrix W, which will allow a prediction the reactivity of the studied biological complexes.
