*This volume is dedicated to our colleague
Karl-Heinz Schleifer,
who retired from the Board of Trustees of Bergey's Manual as this volume was in preparation.
We deeply appreciate his efforts as an editor, author and officer of the Trust. He has devoted many
years to helping the Trust meet its objectives.*

Preface to volume 4 of the second edition of *Bergey's Manual*[®] of *Systematic Bacteriology*

Prokaryotic systematics has remained a vibrant and exciting field of study, one of challenges and opportunities, great discoveries and gradual advances. To honor the leaders of our field, the Trust presented the 2010 Bergey's Award in recognition of outstanding contributions to the taxonomy of prokaryotes to Antonio Ventosa.

We expect that this will be the last volume to be edited by Jim Staley and Noel Krieg, both of whom served on the Trust for many years and continued to be active after their retirements. Noel contributed to *Bergey's Manual of Determinative Bacteriology*, in both the 8th edition as an author and the 9th edition as an editor. Moreover, he also edited volume 1 of the 1st edition of *Bergey's Manual of Systematic Bacteriology*. This was a massive achievement for this volume included the "Gram-negatives" and comprised more than one-third of that edition. In the 2nd edition of *Bergey's Manual of Systematic Bacteriology*, Noel and Jim edited volume 2 along with Don Brenner. This three-part volume comprised the *Proteobacteria* and was also a major portion of the current edition. In the current volume, Noel edited the phylum *Bacteroidetes*, which is the largest phylum in this work. In addition to his passion for prokaryotic systematics, Noel is well known by his colleagues and students at Virginia Tech as a dedicated and passionate teacher.

Jim Staley's service to the Trust paralleled that of Noel's. Jim also contributed to *Bergey's Manual of Determinative Bacteriology*, in both the 8th edition as an author and the 9th edition as an editor. He edited volume 3 of the 1st edition of *Bergey's Manual of Systematic Bacteriology* along with Marvin Bryant and Norbert Pfennig and volume 2 of the 2nd edition. In the current volume, he edited the phyla *Acidobacteria*, *Chlamydiae*, *Dictyoglomi*, *Fibrobacteres*, *Fusobacteria*, and *Gemmatimonadetes*. More importantly, he coached and mentored the rest of us throughout the entire editorial process. Most recently, Jim has led the efforts of the Trust to form Bergey's International Society for Microbial Systematics (BISMIS), whose purpose is to

promote excellent research in microbial systematics as well as enhance global communication among taxonomists who study the *Bacteria* and *Archaea*. The society will also serve internationally as an advocate for research efforts on microbial systematics and diversity. We wish Jim the best in this new adventure.

Acknowledgements

The Trust is indebted to all of the contributors and reviewers, without whom this work would not be possible. The Editors are grateful for the time and effort that each has expended on behalf of the entire scientific community. We also thank the authors for their good grace in accepting comments, criticisms, and editing of their manuscripts.

The Trust recognizes its enormous debt to Aidan Parte, whose enthusiasm and professionalism have made this work possible. His expertise and good judgment have been extremely valued.

We also recognize the special efforts of Jean Euzéby in checking and correcting where necessary the nomenclature and etymology of every described taxon in this volume.

The Trust also thanks its Springer colleagues, Editorial Director Andrea Macaluso and Production Manager Susan Westendorf. In addition, we thank Amina Ravi, our manager at our typesetters, SPi, for her work in the proofing and production of the book.

We thank our current copyeditors, proofreaders and other staff, including Susan Andrews, Joanne Auger, Francis Brenner, MaryAnn Brickner, Travis Dean, Robert Gutman, Judy Leventhal and Linda Sanders, without whose hard work and attention to detail the production of this volume would be impossible. Lastly, we thank the Department of Microbiology at the University of Georgia for its assistance and encouragement in thousands of ways.

William B. (Barny) Whitman

On using the *Manual*

NOEL R. KRIEG AND GEORGE M. GARRITY

Citation

The *Systematics* is a peer-reviewed collection of chapters, contributed by authors who were invited by the Trust to share their knowledge and expertise of specific taxa. Citations should refer to the author, the chapter title, and inclusive pages rather than to the editors.

Arrangement of the Manual

As in the previous volumes of this edition, the *Manual* is arranged in phylogenetic groups based upon the analyses of the 16S rRNA presented in the introductory chapter “Road map of the phyla *Bacteroidetes*, *Spirochaetes*, *Tenericutes* (*Mollicutes*), *Acidobacteria*, *Fibrobacteres*, *Fusobacteria*, *Dictyoglomi*, *Gemmatimonadetes*, *Lentisphaerae*, *Verrucomicrobia*, *Chlamydiae* and *Planctomycetes*”. These groups have been substantially modified since the publication of volume 1 in 2001, reflecting both the availability of more experimental data and a different method of analysis. Since volume 4 includes only the phylum *Firmicutes*, taxa are arranged by class, order, family, genus and species. Within each taxon, the nomenclatural type is presented first and indicated by a superscript T. Other taxa are presented in alphabetical order without consideration of degrees of relatedness.

Articles

Each article dealing with a bacterial genus is presented wherever possible in a definite sequence as follows:

a. Name of the genus. Accepted names are in boldface, followed by “defining publication(s)”, i.e. the authority for the name, the year of the original description, and the page on which the taxon was named and described. The superscript AL indicates that the name was included on the Approved Lists of Bacterial Names, published in January 1980. The superscript VP indicates that the name, although not on the Approved Lists of Bacterial Names, was subsequently validly published in the International Journal of Systematic and Evolutionary Microbiology (or the International Journal of Systematic Bacteriology). Names given within quotation marks have no standing in nomenclature; as of the date of preparation of the Manual they had not been validly published in the International Journal of Systematic and Evolutionary Microbiology, although they may have been “effectively published” elsewhere. Names followed by the term “nov.” are newly proposed but will not be validly published until they appear in a Validation List in the International Journal of Systematic and Evolutionary Microbiology. Their proposal in the Manual constitutes only “effective publication”, not valid publication.

b. Name of author(s). The person or persons who prepared the Bergey’s article are indicated. The address of each author can be found in the list of Contributors at the beginning of the *Manual*.

c. Synonyms. In some instances a list of some synonyms used in the past for the same genus is given. Other synonyms can be found in the *Index Bergeyana* or the *Supplement to the Index Bergeyana*.

d. Etymology of the name. Etymologies are provided as in previous editions, and many (but undoubtedly not all) errors have been corrected. It is often difficult, however, to determine why a particular name was chosen, or the nuance intended, if the details were not provided in the original publication. Those authors who propose new names are urged to consult a Greek and Latin authority before publishing in order to ensure grammatical correctness and also to ensure that the meaning of the name is as intended.

e. Salient features. This is a brief resume of the salient features of the taxon. The most important characteristics are given in **boldface**. The DNA G+C content is given.

f. Type species. The name of the type species of the genus is also indicated along with the defining publication(s).

g. Further descriptive information. This portion elaborates on the various features of the genus, particularly those features having significance for systematic bacteriology. The treatment serves to acquaint the reader with the overall biology of the organisms but is not meant to be a comprehensive review. The information is normally presented in the following sequence:

- Colonial morphology and pigmentation
- Growth conditions and nutrition
- Physiology and metabolism
- Genetics, plasmids, and bacteriophages
- Phylogenetic treatment
- Antigenic structure
- Pathogenicity
- Ecology

h. Enrichment and isolation. A few selected methods are presented, together with the pertinent media formulations.

i. Maintenance procedures. Methods used for maintenance of stock cultures and preservation of strains are given.

j. Procedures for testing special characters. This portion provides methodology for testing for unusual characteristics or performing tests of special importance.

k. Differentiation of the genus from other genera. Those characteristics that are especially useful for distinguishing the genus from similar or related organisms are indicated here, usually in a tabular form.

l. Taxonomic comments. This summarizes the available information related to taxonomic placement of the genus and indicates the justification for considering the genus a distinct taxon. Particular emphasis is given to the methods of molecular biology used to estimate the relatedness of the genus to other taxa, where such information is available. Taxonomic information regarding the arrangement and status of the various species within the genus follows. Where taxonomic controversy exists, the problems are delineated and the various alternative viewpoints are discussed.

m. Further reading. A list of selected references, usually of a general nature, is given to enable the reader to gain access to additional sources of information about the genus.

n. Differentiation of the species of the genus. Those characteristics that are important for distinguishing the various species within the genus are presented, usually with reference to a table summarizing the information.

o. List of species of the genus. The citation of each species is given, followed in some instances by a brief list of objective synonyms. The etymology of the specific epithet is indicated. Descriptive information for the species is usually presented in tabular form, but special information may be given in the text. Because of the emphasis on tabular data, the species descriptions are usually brief. The type strain of each species is indicated, together with the collection(s) in which it can be found. (Addresses of the various culture collections are given in the article in volume 1 entitled *Culture Collections: An Essential Resource for Microbiology*.) The 16S rRNA gene sequence used in phylogenetic analysis and placement of the species into the taxonomic framework is given, along with the GenBank (or other database) accession number. Additional comments may be provided to point the reader to other well-characterized strains of the species and any other known DNA sequences that may be relevant.

p. Species *incertae sedis*. The List of Species may be followed in some instances by a listing of additional species under the heading “Species *Incertae sedis*” or “Other organisms”, etc. The taxonomic placement or status of such species is questionable, and the reasons for the uncertainty are presented.

q. References. All references given in the article are listed alphabetically at the end of the family chapter.

Tables

In each article dealing with a genus, there are generally three kinds of table: (a) those that differentiate the genus from similar or related genera, (b) those that differentiate the species within the genus, and (c) those that provide additional information about the species (such information not being particularly useful for differentiation). The meanings of symbols are as follows:

+, 90% or more of the strains are positive

d, 11–89% of the strains are positive

–, 90% or more of the strains are negative

D, different reactions occur in different taxa (e.g., species of a genus or genera of a family)

v, strain instability (NOT equivalent to “d”)

w, weak reaction.

nd, not determined or no data.

nr, not reported.

These symbols, and exceptions to their use, as well as the meaning of additional symbols, are given in footnotes to the tables.

Use of the *Manual* for determinative purposes

Many chapters have keys or tables for differentiation of the various taxa contained therein. For identification of species, it is important to read both the generic and species descriptions because characteristics listed in the generic descriptions are not usually repeated in the species descriptions.

The index is useful for locating the articles on unfamiliar taxa or in discovering the current classification of a particular taxon. Every bacterial name mentioned in the *Manual* is listed in the index. In addition, an up-to-date outline of the taxonomic framework is provided in the introductory chapter “Road map of the phyla *Bacteroidetes*, *Spirochaetes*, *Tenericutes* (*Mollicutes*), *Acidobacteria*, *Fibrobacteres*, *Fusobacteria*, *Dictyoglomi*, *Gemmatimonadetes*, *Lentisphaerae*, *Verrucomicrobia*, *Chlamydiae* and *Planctomycetes*”.

Errors, comments, and suggestions

As in previous volumes, the editors and authors earnestly solicit the assistance of all microbiologists in the correction of possible errors in *Bergey's Manual of Systematic Bacteriology*. Comments on the presentation will also be welcomed as well as suggestions for future editions. Correspondence should be addressed to:

Road map of the phyla *Bacteroidetes*, *Spirochaetes*, *Tenericutes* (*Mollicutes*), *Acidobacteria*, *Fibrobacteres*, *Fusobacteria*, *Dictyoglomi*, *Gemmatimonadetes*, *Lentisphaerae*, *Verrucomicrobia*, *Chlamydiae*, and *Planctomycetes*

WOLFGANG LUDWIG, JEAN EUZÉBY AND WILLIAM B. WHITMAN

This revised road map updates previous outlines of Garrity and Holt (2001) and Garrity et al. (2005) with the description of additional taxa and new phylogenetic analyses. While the outline/road map seeks to be complete for all taxa validated prior to July 1, 2006, some taxa described after that date are included.

The new phylogenetic trees are strict consensus trees based on various maximum-likelihood and maximum-parsimony analyses and corrected according to results obtained when applying alternative treeing methods. Multifurcations indicate that a common branching order was not significantly supported after applying alternative treeing approaches. Detailed branching orders are shown if supported by at least 50% of the “treeings” performed in addition to the maximum-likelihood approach.

Given that the focus is on the higher taxonomic ranks, rather restrictive variability filters were applied. Consequently, resolution power is lost for lower levels. Of special importance, relationships within genera lack the resolution that would be obtained with genus–family level analyses. Furthermore, the type strain tree, which is available online at www.bergeys.org, is an extract of comprehensive trees comprising some thousand sequences. Thus, trees for the specific groups in subsequent chapters, which are based upon smaller datasets and include the variable sequence positions, may differ with respect to detailed topology, especially at levels of closer relationships within and between genera. In the trees shown here, branch lengths – in first instance – indicate significance and only approximate estimated number of substitutions.

Starting with the second edition of *Bergey's Manual of Systematic Bacteriology*, the arrangement of content follows a phylogenetic framework or road map based largely on analyses of the nucleotide sequences of the ribosomal small-subunit RNA rather than on phenotypic data (Garrity et al., 2005). Implicit in the use of the road map are the convictions that prokaryotes have a phylogeny and that phylogeny matters. However, phylogenies, like other experimentally derived hypotheses, are not static but may change whenever new data and/or improved methods of analysis become available (Ludwig and Klenk, 2005). Thus, the large increases in data since the publication of the taxonomic outlines in the preceding volumes have led to a re-evaluation of the road map. Not surprisingly, the taxonomic hierarchy has been modified or newly interpreted for a number of taxonomic units. These changes are described in the following paragraphs.

The taxonomic road map proposed in volume 1 and updated and emended in volume 2 was derived from phylogenetic and principal-component analyses of comprehensive datasets of small-subunit rRNA gene sequences. A similar approach is continued here. Since the introduction of comparative rRNA sequencing (Ludwig and Klenk, 2005; Ludwig and Schleifer, 2005), there has been a continuous debate concerning the justification and power of a single marker molecule for elucidating phylogeny and establishing taxonomy of organisms. Although generally well established in taxonomy, the polyphasic approach cannot currently be applied for sequence-based analyses due to the lack of adequate comprehensive datasets for alternative marker molecules. Even in the age of genomics, the datasets for non-rRNA markers are poor in comparison to more than 400,000 rRNA primary structures available in general and special databases (Cole et al., 2007; Pruesse et al., 2007). Nevertheless, the data provided by the full genome-sequencing projects allow the definition of a small set of genes representing the conserved core of prokaryotic genomes (Cicarelli et al., 2006; Ludwig and Schleifer, 2005). Furthermore, comparative analyses of the core gene sequences globally support the small-subunit rRNA derived view of prokaryotic evolution. Although the tree topologies reconstructed from alternative markers differ in detail, the major groups (and taxa) are verified or at least not disproved (Ludwig and Schleifer, 2005). Consequently, the structuring of this volume is based on updated and curated (<http://www.arb-silva.de>; Pruesse et al., 2007) databases of processed small-subunit rRNA primary structures.

Data analysis

The current release of the integrated small-subunit rRNA database of the SILVA project (Pruesse et al., 2007) provides the basis for these phylogenetic analyses. The tools of the ARB software package (Ludwig et al., 2004) were used for data evaluation, optimization, and phylogenetic inference. A subset of about 33,000 high-quality sequences from *Bacteria* was extracted from the current SILVA SSU Ref database. Among the criteria for restrictive quality analyses and data selection were coverage of at least positions 18–1509 (*Escherichia coli* 16S rRNA numbering), no ambiguities or missing sequence stretches, no chimeric primary structures, low deviation from overall and group-specific consensus and conservation profiles, and good agreement of tree topologies and branch length with processed sequence

data. Unfortunately, only some of the type strain sequences successfully passed this restrictive quality check. The alignment of the sequences of this subset, as well as all type strain sequences initially excluded given incompleteness or lower quality, was manually evaluated and optimized. Phylogenetic treeing was first based on the high-quality dataset and performed applying phylum specific position filters (50% positional identity). The partial or lower quality type strain sequences were subsequently added using a special ARB-tool allowing the optimal positioning of branches to the reference tree without admitting topology changes (Ludwig and Klenk, 2005). The consensus trees used for evaluating or modifying the taxonomic outline were based on maximum-likelihood analyses (RAXML, implemented in the ARB package; Stamatakis et al., 2005) and further evaluated by maximum-parsimony and distance matrix analyses with the respective ARB tools (Ludwig et al., 2004).

Taxonomic interpretation

The phylogenetic conclusions were used for evaluating and modifying the taxonomic outline of the phyla "*Bacteroidetes*", "*Spirochaetes*", *Tenericutes* (*Mollicutes*), "*Acidobacteria*", "*Fibrobacteres*", "*Fusobacteria*", "*Dictyoglomi*", *Gemmatimonadetes*, *Lentisphaerae*, "*Verrucomicrobia*", "*Chlamydiae*", and "*Planctomycetes*". These include all the phyla not described in earlier volumes with the exception of the *Actinobacteria*, which will be included in the fifth and last volume of this edition. There is no particular rationale for inclusion in this volume. Although some of the phyla may be related in a kingdom or superphylum (i.e., "*Chlamydiae*", *Lentisphaerae*, "*Planctomycetes*", and "*Verrucomicrobia*") (Griffiths and Gupta, 2007; Lee et al., 2009; Pilhofer et al., 2008; Wagner and Horn, 2006), most are unrelated to each other (Figure 1). Some are major pathogens of humans, other animals, and plants. Some are exotic and only described in the last decade.

In order to ensure applicability and promote acceptance, the proposed taxonomic modifications were made following a conservative procedure. The overall organization follows the type "taxon" principle as applied in the previous volumes. Taxa defined in the outline of the preceding volumes were only unified, dissected, or transferred in the cases of strong phylogenetic support. This approach is justified by the well-known low significance of local tree topologies (also called "range of unsharpness" around the nodes; Ludwig and Klenk, 2005). Thus, many of the cases of paraphyletic taxa found were maintained in the current road map if the respective (sub)-clusters rooted closely together, even if they were separated by intervening clusters representing other taxa. While reorganization of these taxa may be warranted, it was not performed in the absence of confirmatory evidence. The names of validly published, but phylogenetically misplaced, type strains are also generally maintained. These strains are mentioned in the context of the respective phylogenetic groups. In cases of paraphyly, all concerned species or higher taxa are assigned to the respective (sub)-groups. New higher taxonomic ranks are only proposed if species or genera – previously assigned to different higher taxonomic units – are significantly unified in a monophyletic branch.

Upon the recommendation of the Judicial Commission (De Vos et al., 2005), many of the names and classifications previously proposed by Cavalier-Smith (2002) are not used in this work. The classification used categories not covered by the Rules of the Code and priority and proposed types without standing in nomenclature. For these reasons, the following phylum (or

FIGURE 1. Phyla *Bacteroidetes*, *Spirochaetes*, *Tenericutes*, *Acidobacteria*, *Fibrobacteres*, *Fusobacteria*, *Dictyoglomi*, *Gemmatimonadetes*, *Lentisphaerae*, *Verrucomicrobia*, *Chlamydiae*, and *Planctomycetes*. While the phyla *Lentisphaerae*, *Verrucomicrobia*, *Chlamydiae*, and *Planctomycetes* may be specifically related to each other, the other phyla included in volume 4 are not related.

division) names are not used: *Planctobacteria*, *Sphingobacteria*, and *Spirochaetae*. Likewise, the following class names are not used: *Acidobacteria*, *Chlamydiae*, *Flavobacteria*, *Planctomycea*, and *Spirochaetes*. Lastly, priority for the order name *Acidobacteriales* is no longer attributed to Cavalier-Smith (2002).

Phylum "*Bacteroidetes*"

In previous classifications, the phylum "*Bacteroidetes*" was proposed to comprise three classes, "*Bacteroidia*", "*Flavobacteriia*", and "*Sphingobacteriia*" (Garrity et al., 2005). While the analyses performed here, which were based upon many more sequences and differ-

FIGURE 2. Overview of the phylum "Bacteroidetes". This phylum contains 15 families classified within four classes. Currently, the *incertae sedis* taxa *Balneola* and "*Rhodothermaceae*" are classified within the class "*Cytophagia*".

ent methods, generally support this conclusion, they also justify formation of a fourth class within this phylum, the "*Cytophagia*" (Figure 2). This new class comprises many genera previously classified within the "*Flexibacteraceae*", "*Flammeovirgaceae*", and "*Crenotrichaceae*" (see below). Thus, the phylum "*Bacteroidetes*" comprises at least four phylogenetic groups that are well delineated on the basis of their 16S rRNA gene sequences. In addition, two groups are affiliated with the phylum but could not be readily assigned to one of these classes. While additional evidence may warrant classification with one of the known or novel classes, these organisms were grouped within *Incertae sedis* of the "*Cytophagia*" for the present time (Figure 2).

Class "*Bacteroidia*" and order "*Bacteroidales*"

The class "*Bacteroidia*" contains five families, all classified within the order "*Bacteroidales*". These families include the four families proposed previously (Garrity et al., 2005), *Bacteroidaceae*, "*Rikenellaceae*", "*Porphyromonadaceae*", and "*Prevotellaceae*", as well as a new family proposed here, "*Marinilabiliaceae*" (Figure 3). In addition, on the basis of the dissimilarity of its 16S rRNA gene sequence to other members of the order, *Odoribacter* (*Bacteroides*) *splanchnicus* may represent an additional undescribed family or a member of the "*Marinilabiliaceae*". However, chemotaxonomic characteristics and analyses of the *fimA* gene imply a close relationship to the family "*Porphyromonadaceae*" (Hardham et al., 2008). Therefore, its reclassification is not proposed at this time. Lastly, the recently described marine organism, *Prolixibacter bellariivorans*, appears to represent a deep lineage in this class but whose affiliation with these families is ambiguous (Holmes et al., 2007).

Family *Bacteroidaceae*

In addition to the type genus, *Bacteroides*, this family comprises three monospecific genera, *Acetofilamentum*, *Acetothermus*, and *Anaerorhabdus*, and one genus, *Acetomicrobium*, comprising two species. Because complete 16S rRNA gene sequences are not available for representatives of these four genera, these assignments are tentative. Two genera previously assigned to

this family have also been reassigned. As recommended by Morotomi et al. (2007), *Megamonas* has been transferred to the *Firmicutes*. Based on its rRNA gene sequence, *Anaerophaga* has been transferred to the new family "*Marinilabiliaceae*".

The genus *Bacteroides* comprises at least six lineages or clades. The type species, *Bacteroides fragilis*, together with *Bacteroides acidifaciens*, *caccae*, *finogoldii*, *nordii*, *ovatus*, *salyersiae*, *thetaitotamicon*, and *xylanisolvens*, represent a cluster slightly separated from the other members of the genus. If supported by other evidence, each of the other lineages could be classified as new genera within this family. The other lineages are represented by *Bacteroides cellulolyticus* and *intestinalis*; *Bacteroides coprosus* and *propionifaciens*; *Bacteroides pyogenes*, *suis*, and *tectus*; *Bacteroides barnesiae*, *coprocola*, *coprophilus*, *dorei*, *helicogenes*, *massiliensis*, *plebeius*, *salanitronis*, *uniformis*, and *vulgatus*. The species *Bacteroides eggerthii*, *gallinarum*, and *stercoris* cannot clearly be assigned to one of the lineages.

In addition to these clades within the genus, the following validly published species are probably misclassified. *Bacteroides splanchnicus* was recently reclassified as *Odoribacter splanchnicus* (Hardham et al., 2008); this genus may represent a novel member of family "*Porphyromonadaceae*" (see above). *Bacteroides capillosus* and *cellulosolvens* are probably members of the phylum *Firmicutes*. In addition, rRNA gene sequences are not available for *Bacteroides capillus*, *forsythus*, *furcosus*, *polypragmatus*, and *salivovus*, so their assignment is uncertain.

Lastly, the family *Bacteroidaceae* appears to be paraphyletic, and the family "*Prevotellaceae*" falls within the radiation of *Bacteroides* clades. Because the members of the "*Prevotellaceae*" are generally closely related and the branch length to the *Bacteroidaceae* is fairly long, this conclusion is tentative. While these families were not combined at this time, this classification may warrant further investigation.

Family "*Marinilabiliaceae*"

This family represents a group of sister but not clearly monophyletic branches within the "*Bacteroidales*" and comprises three genera.

FIGURE 3. Genera of the class "Bacteroidia". This class comprises five families and the genus *Prolixibacter*, which has not yet been assigned to a family.

The type genus, *Marinilibilia*, contains two species, *Marinilibilia salmonicolor* and *agarovorans*, and was previously classified within the "Rikenellaceae" (Garrity et al., 2005). The remaining taxa include *Alkaliflexus imshenetskii* and *Anaerophaga thermohalophila*, the latter of which was formerly classified within the *Bacteroidaceae* (Garrity et al., 2005). The current analysis suggests that *Cytophaga fermentans* should be reclassified as a novel genus that is associated with this family. Lastly, rRNA analyses suggest that *Odoribacter* (*Bacteroides*) *splanchnicus*, which was proposed after the deadline for inclusion in this volume, may represent an additional member of the "Marinilabiliaceae". However, chemotaxonomic characteristics and analyses of the *fimA* gene imply a close relationship to the family "Porphyromonadaceae" (Hardham et al., 2008), so this classification is not proposed at this time.

Family "Rikenellaceae"

The family comprises the monospecific genus *Rikenella microfus* and the closely related genus *Alistipes*. The latter genus comprises the type species *Alistipes putredinis* and *Alistipes finegoldii*, *onderdonkii*, and *shahii*. *Marinilibilia*, which was classified within this family by Garrity et al. (2005), is now classified within the family "Marinilabiliaceae".

Family "Porphyromonadaceae"

The genus *Porphyromonas*, which was formed by reclassification of various species of *Bacteroides* (Shah and Collins, 1988), is the type for this family. Originally, this family comprised the genera *Porphyromonas*, *Dysgonomonas*, and *Tannerella* (Garrity et al., 2005).

The genus *Porphyromonas* comprises five subclusters: (1) the type species *Porphyromonas asaccharolytica* and *Porphyromonas circumdentaria*, *endodontalis*, *gingivicanis*, and *uenonis*; (2) *Porphyromonas cangingivalis*, *canoris*, *levii*, and *somerae*; (3) *Porphyromonas crevioricanis*, *gingivalis*, and *gulae*; (4) *Porphyromonas catoniae* and *macacae*; and (5) *Porphyromonas cansulci*.

The genus *Dysgonomonas* comprises the type *Dysgonomonas gadei* and the closely related species *Dysgonomonas capnocytophagoides* and *mossii*.

The last genus is monospecific, *Tannerella forsythia*.

The current analyses add five other genera to this family. These include three monospecific genera represented by *Paludibacter propionisigenes*, *Petrimonas sulfuriphila*, and *Proteiniphilum acetatigenes*. Also included is the recently described genus comprising *Barnesiella viscericola* and *intestinihominis* (Morotomi et al., 2008; Sakamoto et al., 2007). Lastly, the genus *Parabacteroides* comprises the type species *Parabacteroides distasonis* and three closely related species *Parabacteroides goldsteinii*, *johnsonii*, and *merdae* (Sakamoto and Benno, 2006). This last genus was also described after the deadline for inclusion in this volume.

Family "Prevotellaceae"

Although the family "Prevotellaceae" appears within the cluster of species of the family *Bacteroidaceae*, the genera representing the "Prevotellaceae" are well separated from the *Bacteroidaceae*. Therefore, both families are continued in the current classification. The genus *Prevotella*, which was formed by reclassification of various species of *Bacteroides* (Shah and Collins, 1990), is the type for this family. It comprises a number of phylogenetic groups, each of which may warrant reclassification into one or more genera if supported by additional evidence: (1) the type species *Prevotella melaninogenica* and *Prevotella histolytica* and *veroralis*; (2) *Prevotella denticola* and *multiformis*; (3) *Prevotella corporis*, *disiens*, *falsenii*, *intermedia*, *nigrescens*, and *pallens*; (4) *Prevotella maculosa*, *oris*, and *salivae*; (5) *Prevotella bryantii*, and *multisaccharivorax*; (6) *Prevotella baroniae*, *buccae* and *dentalis*; (7) *Prevotella enoeca* and *pleuritidis*; (8) *Prevotella buccalis* and *timonensis*; (9) *Prevotella loescheii* and *shahii*; (10) *Prevotella brevis* and *ruminicola*; and (11) *Prevotella amnii* and *bivia*.

The species *Prevotella albensis*, *bergensis*, *copri*, *marshii*, *oralis*, *olorum*, *paludivivens*, and *stercorea* cannot be clearly assigned to one of the lineages. *Xylanibacter oryzae* is also found within the radiation of the described *Prevotella* clusters. *Prevotella tannerae* represents a more distant branch of the family. In contrast, *Prevotella heparinolytica* and *zooglyphiformans* are clearly separated from the other members of this family and may warrant reclassification. Lastly, *Hallella sergens* is closely related to *Prevotella dentalis*, which has priority (Willems and Collins, 1995). Therefore, *Hallella sergens* is not used.

Class “Flavobacteriia” and order “Flavobacteriales”

This class comprises a single order, “Flavobacteriales”, and is essentially unchanged from the original proposal of Garrity et al. (2005). The order comprises three families, *Flavobacteriaceae*, “*Blattabacteriaceae*”, and *Cryomorphaceae* (Figures 4 and 5) (Bowman et al., 2003). The family “*Myroidaceae*” proposed by

FIGURE 4. Genera of the class “Flavobacteriia”. This class comprises three families. The first part of the family *Flavobacteriaceae* is shown here.

Garrity et al. (2005) was judged to be insufficiently resolved from the *Flavobacteriaceae* and was not used.

Family *Flavobacteriaceae*

This extraordinarily diverse family comprises over 70 genera. The rRNA analyses indicate the presence of many phylogenetic clusters that may warrant separation into novel families if supported by additional evidence. Many of the clusters described here are identical to those found by Bernardet and Nakagawa (2006) or include mostly taxa described after their work. Cluster (1) includes the type genus *Flavobacterium* and *Myroides*. This latter genus includes three closely related species, *Myroides odoratus*, *odoratimimus*, and *pelagicus*. Although the genus *Flavobacterium* is very diverse, the rRNA phylogeny lacks clear indication of clades that might serve as the basis for further subdivision. Species included in this genus include the type species *Flavobacterium aquatile* and, in alphabetical order, *Flavobacterium antarcticum*, *aquidurense*, *branchiophilum*, *columnare*, *croceum*, *cucumis*, *daejeonense*, *defluvii*, *degerlachei*, *denitrificans*, *flevense*, *frigidarium*, *frigidimaris*, *frigoris*, *fryxelicola*, *gelidilacus*, *gillisiae*, *granuli*, *hercynium*, *hibernum*, *hydatis*, *johnsoniae*, *limicola*, *micromati*, *omnivorum*, *pectinovorum*, *psychrolimnae*, *psychrophilum*, *saccharophilum*, *saliperosum*, *segetis*, *solis*, *succinicans*, *suncheonense*, *tegetincola*, *terrae*, *terrigena*, *weaverense*, *xanthum*, and *xinjiangense*. In addition, there are some species for which sequences are not available, including *Flavobacterium acidificum*, *acidurans*, *oceanosedimentum*, and *thermophilum*.

(2) *Capnocytophaga ochracea* (type species), *canimorsus*, *cynodegmi*, *gingivalis*, *granulosa*, *haemolytica*, *ochracea*, and *sputigena*; and *Coenonia anatina*. Although *Galbibacter mesophilus* (Khan et al., 2007c), *Joostella marina* (Quan et al., 2008), and *Zhouia amylobytica* are associated with this cluster, this relationship is not strong.

(3) *Actibacter sediminis* (Kim et al., 2008a); *Aestuariicola saemankumensis* (Yoon et al., 2008d); *Lutibacter litoralis*; *Lutimonas vernicola* (Yang et al., 2007); *Polaribacter filamentus* (type species), *butkevichii*, *franzmannii*, and *glomeratus*; *Polaribacter dokdonensis* (which forms a separate clade from the other species of this genus); *Tenacibaculum maritimum* (type species), *adriaticum*, *aestuarii*, *aiptasiae*, *amylobyticum*, *galleicum*, *litopenaei*, *litoreum*, *lutimaris*, *mesophilum*, *ovolyticum*, *skagerrakense*, and *soleae*.

(4) *Chryseobacterium gleum* (type species), *aquaticum*, *aquifrigidense*, *arothri*, *balustinum*, *bovis*, *caeni*, *daecheongense*, *daeguense*, *defluvii*, *flavum*, *formosense*, *gambrini*, *gregarium*, *haifense*, *hispanicum*, *hominis*, *hungaricum*, *indologenes*, *indoltheticum*, *jejuense*, *joostei*, *luteum*, *marina*, *molle*, *oranimense*, *pallidum*, *pisicum*, *scophthalmum*, *shigense*, *soldanellicola*, *solis*, *taeanense*, *taichungense*, *taiwanense*, *ureilyticum*, *vrystaatense*, and *wanjuense*. In addition to these species, the following taxa appear within the radiation of *Chryseobacterium*, including *Epilithonimonas tenax*, *Kaistella koreensis*, *Sejongia antarctica* (type species) and *jeonii*. Other taxa within this cluster include *Bergeyella zoohelcum*, *Cloacibacterium normanense*, *Elizabethkingia meningoseptica* (type species) and *miricola*, *Empedobacter brevis*, *Ornithobacterium rhinotracheale*, *Riemerella anatipestifer* (type species) and *columbina*, *Wautersiella falsenii*, and *Weeksella virosa*.

(5) *Arenibacter latericius* (type species), *certesii*, *echinorum*, *pal-ladensis*, and *troitsensis*; *Cellulophaga algicola*, *baltica*, and *pacifica* (a clade which does not include the type species); *Costertonia aggregata*, *Flagellimonas eckloniae* (Bae et al., 2007); *Maribacter*

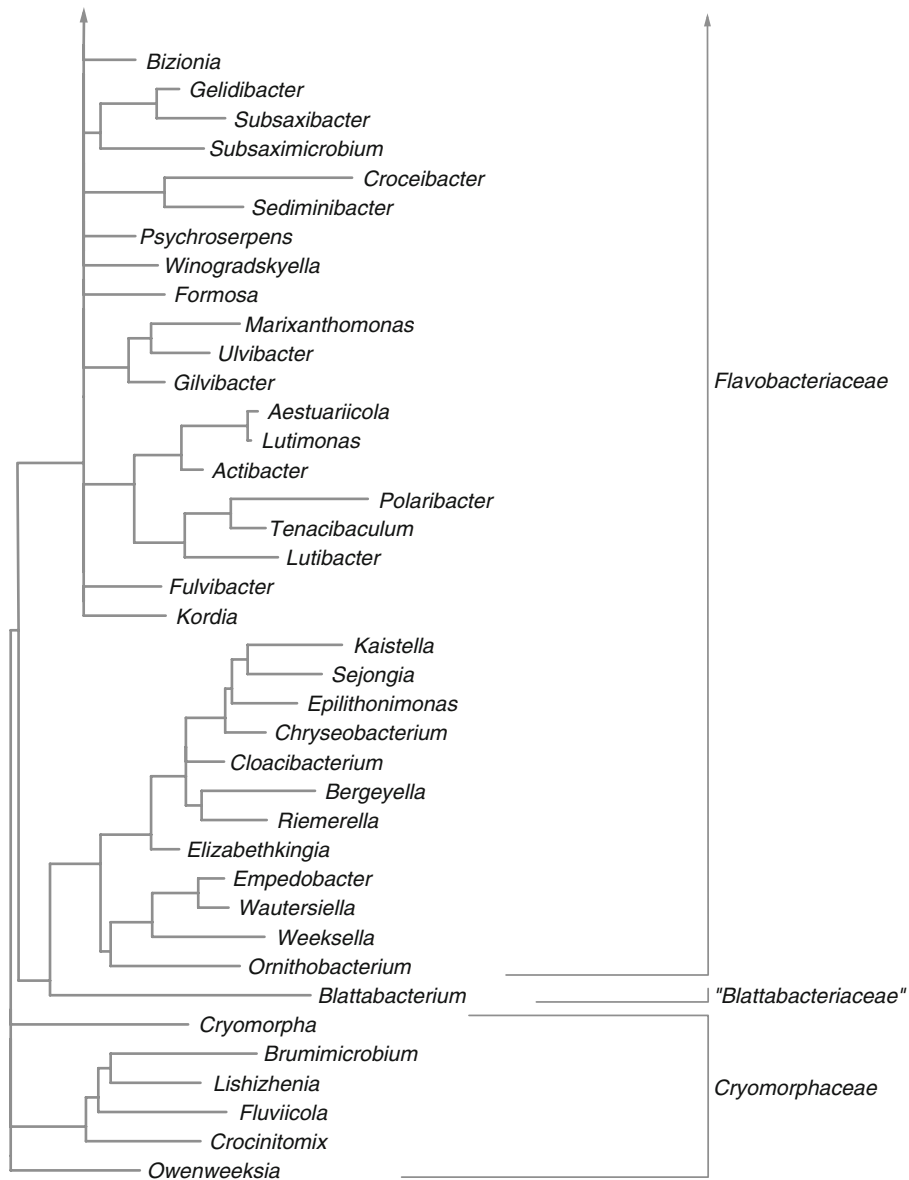

FIGURE 5. Genera of the class "Flavobacteriia". This class comprises three families. The second part of the family *Flavobacteriaceae* and the remaining two families are shown here.

sedimenticola (type species), *aquivivus*, *arcticus*, *dokdonensis*, *forsetii*, *orientalis*, *polysiphoniae*, and *ulvicola*; *Muricauda ruestringensis* (type species), *aquimarina*, *lutimaris*, and *flavescens*; *Pibocella ponti* (which appears within the cluster of *Maribacter* species); *Robiginitalea biformata* and *myxolifaciens*; *Sediminicola luteus*; *Zeaxanthinibacter enoshimensis* (Asker et al., 2007); and *Zobellia galactanivorans* (type species), *amurskyensis*, *laminariae*, *russellii*, and *uliginosa*. In addition, *Cellulophaga lytica* (the type species of this genus) and *fucicola* appear as either a deep branch of this cluster (Bernardet and Nakagawa, 2006) or as an associated but independent group (this analysis). In either case, the reclassification of *Cellulophaga algicola*, *baltica*, and *pacifica* to a new genus would appear to be warranted. Lastly, the type strain of *Pibocella ponti* has been lost.

If available, this strain would be reclassified within *Maribacter*. For that reason, this genus is not included in the outline.

(6) *Algibacter lectus* and *mikhailovii*; *Flaviramulus basaltis*; *Gaetbulibacter saemankumensis* and *marinus*; *Mariniflexile gromovii* and *fucanivorans*; *Tamlana crocina* (Lee, 2007); and *Yeosuana aromativorans*.

(7) *Croceibacter atlanticus* and *Sediminibacter furfurosus* (Khan et al., 2007a).

(8) *Gelidibacter algens* (type species), *gilvus*, *mesophilus*, and *salicanalis*; *Subsaxibacter broadyi*; *Subsaximicrobium wynnwilliamsii* (type species) and *saxinquilinus*.

(9) *Lacinutrix copepodicola*, *algicola*, and *mariniflava*; and *Olleya marilimosa*.

(10) *Gilvibacter sediminis* (Khan et al., 2007a); *Marixanthomonas ophiuræ* (Romanenko et al., 2007). *Ulvibacter litoralis* and *antarcticus*.

(11) *Dokdonia donghaensis*; *Krokinobacter genikus* (type species), *diaphorus*, *eikastus*, and *genicus*.

(12) *Donghaena dokdonensis*; *Nonlabens tegetincola*; *Persicivirga xylanidelens*; *Sandarakinotalea sediminis*; and *Stenothermobacter spongiae*.

(13) *Gillisia limnaea* (type species), *hiemivivida*, *illustrilutea*, *mitskevichiae*, *myxillae*, and *sandarakina*; *Gramella echinicola* (type species) and *portivictoriae*; *Mesonina algae* (type species) and *mobilis*; *Psychroflexus torques* (type species), *gondwanensis*, and *tropicus*; *Salegentibacter salegens* (type species), *agarivorans*, *flavus*, *holothuriorum*, *mishustinae*, *salaries*, and *salinarum*; *Salinimicrobium catena*, *terrae*, and *xinjiangense* (Chen et al., 2008; Lim et al., 2008); and *Zunongwangia profunda* (Qin et al., 2007). Among these taxa, *Salinimicrobium catena* was previously classified as *Salegentibacter catena* (Lim et al., 2008).

(14) *Aequorivita antarctica* (type species), *crocea*, *lipolytica*, and *sublithincola* and *Vitellibacter vladivostokensis*.

In addition to these well delineated clusters, a large number of taxa were not closely associated with any of these clusters or each other. These include: *Aquimarina muelleri* (type species), *brevivita*, *intermedia*, and *latercula*; *Bizionia paragorgiae* (type species), *gelidisalsuginis*, and *saleffrena*; a second clade of *Bizionia* species including *Bizionia algorithergicola* and *myxarmorum*; *Formosa algae* (type species) and *agariphila*; *Fulvibacter tottoriensis*; *Kordia algicida*; *Leeuwenhoekiiella marinoflava* (type species), *aequorea*, and *blandensis*; *Leptobacterium flavescens*; *Mesoflavibacter zeaxanthinifaciens*; *Psychroserpens burtonensis* (type species) and *mesophilus*; and *Winogradskyella thalassocola* (type species), *epiphytica*, *eximia*, and *poriferorum*. The rRNA gene sequences of the following pairs of genera are closely related, which may justify combining them: *Sandarakinotalea*–*Nonlabens*; *Dokdonia*–*Krokinobacter*.

Family “*Blattabacteriaceae*”

This family comprises *Blattabacterium cuenoti*, which is an endosymbiont of insects that has not been grown in pure culture.

Family *Cryomorpaceae*

Proposed by Bowman et al. (2003) to include novel genera of cold-tolerant marine bacteria isolated from sea ice and other polar environments, this family comprises six monospecific genera: *Cryomorpha ignava*, *Brumimicrobium glaciale*, *Crocinitomix catalasitica*, *Fluviicola taffensis*, *Lishizhenia caseimilytica*, and *Owenweeksia hongkongensis*. The phylogenetic analyses conducted here suggest that this family is polyphenetic and contains three lineages that cluster together at the base of the phylogenetic tree for the *Flavobacteriales*. *Cryomorpha* and *Owenweeksia* each comprise one monogeneric lineage, with the remaining four genera comprising the third lineage. However, in the absence of additional evidence, these lineages were not separated at this time.

Class “*Sphingobacteriia*” and order “*Sphingobacteriales*”

This class comprises a single order, the “*Sphingobacteriales*”. It is more circumscribed than the original proposal (2005) and excludes many taxa previously classified within the “*Flexibacteraceae*”. The order comprises three families: *Sphingobacteriaceae*, “*Chitinophagaceae*”, and “*Saprosiraceae*” (Figure 6). The family *Crenotrichaceae* was removed because the type genus *Crenothrix* was transferred to the *Proteobacteria* (Stoecker et al., 2006). The genus *Chitinophaga* then became the type for a new family within the order. Based upon their rRNA gene sequence similarities, the genera *Rhodothermus* and *Salinibacter*, which were also previously classified within the *Crenotrichaceae*, were transferred to the class “*Cytophagia*” as an order *incertae sedis* (see below). Similarly, *Balneola*, which was described after the deadline for

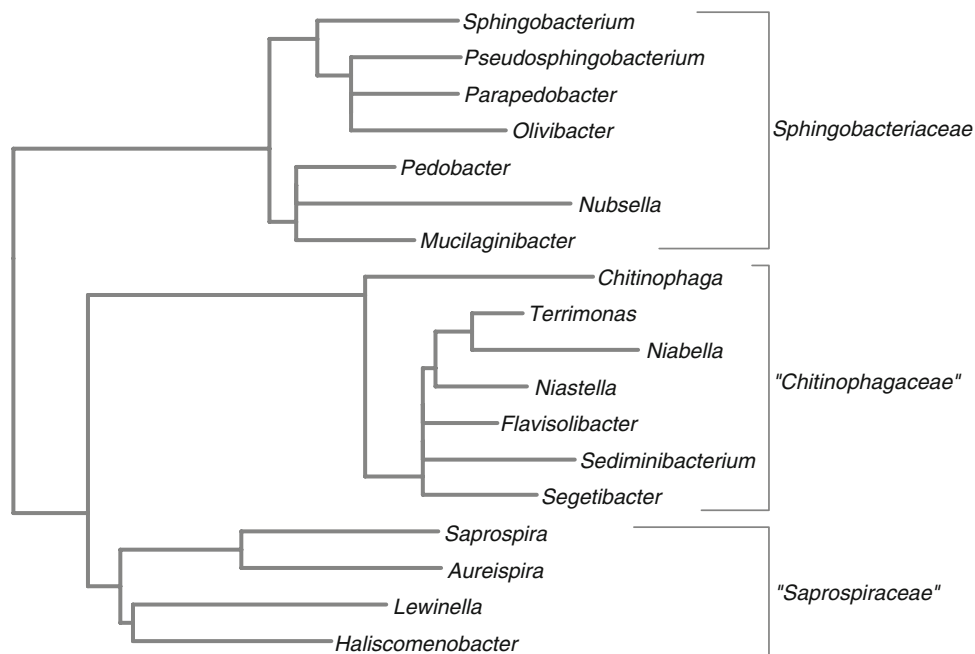

FIGURE 6. Genera of the class “*Sphingobacteriia*”.

inclusion in this volume, was classified within the *Crenotrichaceae* based in part upon its similarity to *Rhodothermus* (Urios et al., 2006). Analyses performed here suggest that it may also be a deep lineage of the “*Cytophagia*”. Lastly, the sequence of the 16S rRNA gene for *Toxothrix trichogenes* is not available, so this genus was transferred to *incertae sedis*. Even with these changes, this class is not clearly monophyletic (Figure 2). The families “*Chitinophagaceae*” and “*Saprospiraceae*” may represent a sister lineage to the family *Sphingobacteriaceae*. However, in the absence of confirmatory evidence, the grouping of the three families into one class was retained in the current outline.

Family *Sphingobacteriaceae*

At the time these analyses were performed, seven genera were identified within this family. The genera *Sphingobacterium*, *Olivibacter*, *Parapedobacter*, and *Pseudosphingobacterium* form one phylogenetic cluster. The genera *Pedobacter*, *Mucilaginibacter*, and *Nubsella* form a second cluster. In addition, the species *Flexibacter canadensis* represents an additional deep phylogenetic group within this family that may warrant classification as a novel genus.

The genus *Sphingobacterium* comprises *Sphingobacterium spirivorum* (type species), *anhuiense*, *canadense*, *composti*, *daejeonense*, *faecium*, *kitahiroshimense*, *mizutaii*, *multivorum*, *siyangense*, and *thalpophilum*. Interestingly, the species epithet *Sphingobacterium composti* was independently proposed for two different organisms by Ten et al. (2006, 2007) and Yoo et al. (2007). Because *Sphingobacterium composti* Ten et al. (2007) has priority, the species of Yoo et al. (2007) warrants renaming. In addition, this genus contains *Sphingobacterium antarcticum*, whose rRNA gene sequence is not available. Related to the genus *Sphingobacterium* are the taxa *Olivibacter sitiensis* (type species), *ginsengisoli*, *solii*, and *terrae* (Ntougiaris et al., 2007; Wang et al., 2008), *Parapedobacter koreensis* (type species) and *solii* (Kim et al., 2007b, 2008b), and *Pseudosphingobacterium domesticum* (Kim et al., 2007b; Vaz-Moreira et al., 2007). These genera were described after the deadline for inclusion in this volume.

The second cluster is composed of *Pedobacter* species, which itself comprises four subclusters. The first subcluster contains *Pedobacter heparinus* (type species), *africanus*, *caeni*, *cryconitis*, *duraquae*, *ginsengisoli*, *himalayensis*, *metabolipauiper*, *panaciterrae*, *pisicum*, *steynii*, and *westerhofensis*. The second subcluster comprises *Pedobacter insulae* and *koreensis*. The third subcluster comprises *Pedobacter daechungensis*, *lentus*, *saltans*, and *terricola*, which may warrant reclassification into a novel genus if supported by additional evidence. A fourth subcluster is represented by *Mucilaginibacter gracilis*, *kameinonesis*, and *paludis* (Pankratov et al., 2007; Urai et al., 2008). A number of species were not closely associated with any of these clusters or each other: *Nubsella zeaxanthinifaciens* (Asker et al., 2008); *Pedobacter agri*, *aquatilis*, *composti*, *roseus*, *sandarokinus*, *suwonensis*, and *terrae*.

Family “*Chitinophagaceae*”

This family contains two phylogenetic clusters. The first cluster includes the genus *Chitinophaga*. This genus comprises *Chitinophaga pinensis* (type species), *arvensicola*, *filiformis*, *ginsengisegetis*, *ginsengisoli*, *japonensis*, *sancti*, *skermani*, and *terraei*. The second cluster includes six related genera with ten species: *Flavisolibacter ginsengisoli* and *ginsengiterrae* (Yoon and Im, 2007); *Niabella aurantiaca* and *solii* (Kim et al., 2007a; Weon et al.,

2008a); *Niastella koreensis* (type species) and *yeongjuensis* (Weon et al., 2006); *Sediminibacterium salmonicum* (Qu and Yuan, 2008); *Segetibacter koreensis* (An et al., 2007); and *Terrimonas ferruginea* (type species) and *lutea*. *Flavisolibacter*, *Niabella*, *Niastella*, *Sediminibacterium*, and *Segetibacter* were described after the deadline for inclusion in this volume (Weon et al., 2006).

Family “*Saprospiraceae*”

As originally proposed by Garrity et al. (2005), the family comprises three related genera and nine species. These include: *Saprospira grandis*; *Haliscomenobacter hydrossis*, and *Lewinella cohaerens* (type species), *agarilytica*, *antarctica*, *lutea*, *marina*, *nigricans*, and *persica*. Recently, the newly discovered genus *Aureispira* (*marina* and *maritime*) has also been classified within this family (Hosoya et al., 2006, 2007).

Class “*Cytophagia*” and order *Cytophagales*

Analyses performed here of the rRNA genes indicate that many of the genera previously classified within the families “*Flexibacteraceae*” and “*Flammeovirgaceae*” are not closely related to the “*Sphingobacteriia*” and should be transferred to a novel class (Figure 7). The order *Cytophagales* is designated the type for the new class. The genus *Cytophaga* is the type for the order and family *Cytophagaceae*. Because the family *Cytophagaceae* includes the type genera of the families “*Flexibacteraceae*” and *Spirosomaceae*, these classifications are not used.

FIGURE 7. Genera of the class “*Cytophagia*”. This class comprises three families and four orders *incertae sedis*.

Family *Cytophagaceae*

This family comprises 19 genera distributed within seven phylogenetic clusters: the first cluster includes *Cytophaga hutchinsonii* (type species) and *aurantiaca*; the second cluster includes *Sporocytophaga myxococcoides* (type and only species); the third cluster includes *Effluviibacter roseus*; *Hymenobacter roseosalivarius* (type species), *actinosclerus*, *aerophilus*, *chitinivorans*, *deserti*, *gelipurpurascens*, *norwichensis*, *ocellatus*, *psychrotolerans*, *rigui*, *solii*, and *xinjiangensis*; and *Pontibacter actiniarum* (type species), *akesuensis*, and *korlensis*. In addition, *Adhaeribacter aquaticus* appears to represent a deep lineage in this cluster.

The fourth cluster includes *Arcicella aquatica* and *rosea*; *Dyadobacter fermentans* (type species), *alkalitolerans*, *beijingensis*, *crusticola*, *ginsengisoli*, *hamtensis*, and *korensis*; *Emticicia ginsengisoli* and *oligotrophica*; *Flectobacillus major* (type species) and *lacus*; *Larkinella insperata*; *Leadbetterella byssophila*; *Persicitalea jodogahamensis* (Yoon et al., 2007b); *Rudanella lutea* (Weon et al., 2008b); *Runella slithyiformis* (type species), *defluvi*, *limosa*, and *zeae*; and *Spirosoma linguale*, *panaciterrae*, and *rigui*. The fifth cluster includes *Flexibacter roseolus*, *elegans*, and *Microscilla marina*. The sixth cluster comprises *Flexibacter flexilis* (type species). The seventh cluster comprises *Flexibacter ruber*.

Cyclobacterium and *Reichenbachiella*, two genera previously classified with this group (Garrity et al., 2005), have been transferred to the “*Cyclobacteriaceae*” and “*Flammeovirgaceae*”, respectively. In addition, *Meniscus glaucopsis* is retained within the *Cytophagaceae* even though the sequence of its rRNA gene is not available.

Family “*Cyclobacteriaceae*”

This family includes the genus *Cyclobacterium*, which was previously classified within the “*Flexibacteraceae*”, and five related genera: *Cyclobacterium marinum* (type species), *amurskyense*, and *lianum*; *Aquiflexum balticum*; *Algoriphagus ratkowskyi* (type species), *alkaliphilus*, *antarcticus*, *aquimarinus*, *boritolerans*, *chordae*, *halophilus*, *localis*, *mannitolivorans*, *marincola*, *ornithinivorans*, *terrigena*, *vanfongensis*, *winogradskyi*, and *yeomjeoni*. This cluster includes *Chimaericella* and *Hongiella* species that were transferred to *Algoriphagus* (Nedashkovskaya et al., 2007b); *Belliella baltica*; *Echinicola pacifica* (type species) and *vietnamensis*; and *Rhodonellum psychrophilum* represent further genera.

Family “*Flammeovirgaceae*”

This family includes the genus *Flammeovirga* and at least seven related genera and one *Candidatus* taxon. This family comprises two phylogenetic groups which are neighbors in all trees but not clearly monophyletic. In addition, *Thermonema*, which was previously classified in this family (Garrity et al., 2005), possesses only low similarity to the other genera and was reclassified to an order *incertae sedis*. Subsequently, it was found that this reassignment was equivocal, and analyses with more representatives of this family are ambiguous (Figure 7). For the purposes of this road map, this genus was retained in an order *incertae sedis*. As a result, this family comprises two phylogenetic groups: *Flammeovirga aprica* (type species), *arenaria*, *kamogawensis*, and *yaeyamensis*; *Flexibacter aggregans*, *litoralis*, and *polymorphus*, which appear to be misclassified; *Flexithrix dorotheae*, *Limibacter armeniacum* (Yoon et al., 2008b); *Perexilbacter aurantiacus* (Yoon et al., 2007a); *Rapidithrix thailandica*

(Srisukchayakul et al., 2007); and *Sediminitomix flava* (Khan et al., 2007b).

The second group comprises *Fabibacter halotolerans*; *Fulvirvirga kasyanovii* (Nedashkovskaya et al., 2007a); *Reichenbachiella agariperforans*; *Roseivirga ehrenbergii* (type species), *echinicomitans*, *sohaensis*, and *spongicola*; and *Persicobacter diffluens*.

In addition, *Flexibacter tractuosus*, which appears to be misclassified, and “*Candidatus Cardinium hertigii*”, a symbiont of parasitoid wasps (Zchori-Fein et al., 2004), are neighboring lineages.

Class “*Cytophagia*” orders *incertae sedis*

In addition to the members of these families whose taxonomic position is relatively well defined, three deep lineages are classified within “*Cytophagia*” as separate orders *incertae sedis*. These lineages include (1) the family “*Rhodothermaceae*”, comprising *Rhodothermus marinus* and *Salinibacter ruber*; (2) the genus *Balneola*, with species *Balneola vulgaris* (type) and *alkaliphila*, which were described after the deadline for inclusion in the volume (Urios et al., 2006, 2008); and (3) *Thermonema lapsum* (type species) and *rossianum* (which may also be assigned to the “*Flammeovirgaceae*”).

The assignment of the first two lineages to this class is ambiguous, and their reclassification may be warranted with additional evidence. *Toxothrix trichogenes*, for which the rRNA gene sequence is not available, is also included as *incertae sedis* within this class.

Phylum “*Spirochaetes*”

As a result of the current analyses of 16S rRNA gene sequences, a single class and order are recognized within the phylum “*Spirochaetes*”. Members of the “*Spirochaetes*” possess a cellular ultrastructure unique to bacteria with internal organelles of motility, namely periplasmic flagella.

Class “*Spirochaetia*” and order *Spirochaetales*

The class comprises a single order. The order *Spirochaetales* comprises four families that are well delineated by 16S rRNA gene sequences (Figure 8). Compared to the previous outline (Garrity et al., 2005), the families *Spirochaetaceae* and *Leptospiraceae* are retained in the current classification. However, the genus *Serpulina* was judged to be a subjective synonym of *Brachyspira* (Ochiai et al., 1997). As a consequence, the family “*Serpulinaceae*” was replaced with “*Brachyspiraceae*”. The genus *Brevinema* was also transferred from the family *Spirochaetaceae* to a novel family “*Brevinemataceae*” in recognition of the differences in 16S rRNA gene sequences. Lastly, four genera of arthropod symbionts for which no sequences are available were transferred from the *Spirochaetaceae* to a fifth family, *incertae sedis*.

Family *Spirochaetaceae*

This family comprises four genera that are well delineated on the basis of their 16S rRNA gene sequences. Compared to previous classifications, the genus *Brevinema* was transferred to a new family on the basis of substantial differences in its 16S rRNA gene sequence. Likewise, the genera *Clevelandina*, *Diplocalyx*, *Hollandina*, and *Pillotina* were transferred to a family *incertae sedis* in the absence of rRNA gene sequences.

The culture for the type species of the genus *Spirochaeta*, *Spirochaeta plicatilis*, is not available, and its rRNA gene has not

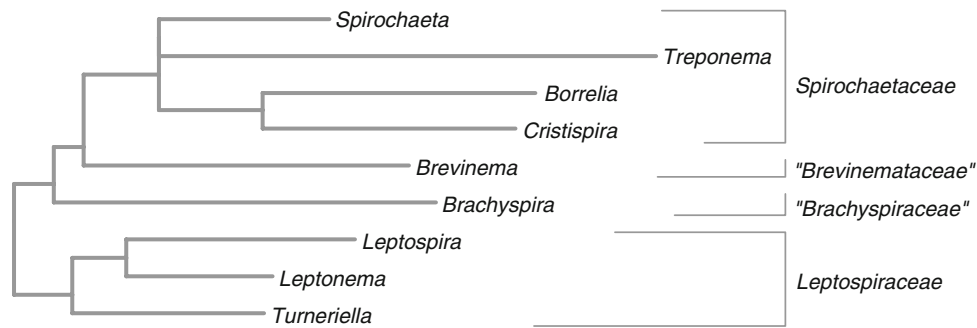

FIGURE 8. Genera of the phylum "Spirochaetes".

been sequenced. Of the remaining species, three are more closely related to *Treponema* and should probably be reclassified within that group (see below). The remaining species of the genus *Spirochaeta* comprise at least seven phylogenetic groups: (1) *Spirochaeta africana* and *asiatica*; (2) *Spirochaeta alkalica*, *americana*, and *halophila*; (3) *Spirochaeta aurantia*; (4) *Spirochaeta bajacaliforniensis* and *smaragdinae*; (5) *Spirochaeta coccooides*; (6) *Spirochaeta isovalerica* and *litoralis*; and (7) *Spirochaeta thermophila*.

The genus *Borrelia* comprises three phylogenetic groups. One group contains the type species, *Borrelia anserina*, and the causative agents of relapsing fever, *Borrelia coriaceae*, *crocidurae*, *duttonii*, *hermsii*, *hispanica*, *miyamotoi*, *parkeri*, *persica*, *recurrentis*, *theileri*, and *turicatae*. Many of these species are transmitted by soft-bodied ticks. The second group includes the causative agent of Lyme disease, *Borrelia burgdorferi*, and species transmitted by hard-bodied ticks, *Borrelia afzelii*, *burgdorferi*, *garinii*, *japonica*, *lusionitanae*, *sinica*, *spielmanii*, *tanukii*, *turdi*, and *valaisiana*. The third group consists solely of *Borrelia turcica*.

In addition, sequences are not available for some named species, including *Borrelia baltazardii*, *brasiliensis*, *caucasica*, *dugesii*, *graingeri*, *harveyi*, *latschewii*, *mazzottii*, *tillae*, and *venezuelensis*.

The genus *Cristispira* is represented by a single species, *Cristispira pectinis*, which is related to *Borrelia*. This microorganism has been identified in the crystalline styles of oysters (Paster et al., 1996).

The genus *Treponema* comprises three phylogenetic groups: *Treponema pallidum* (type species), "*calligyrum*", *denticola*, *medium*, *phagedenis*, *putidum*, "*refringens*", and "*vincentii*"; in addition, *Spirochaeta zuelzeri* is associated with this group. The second group comprises *Treponema amylovorum*, *berlinense*, *bryantii*, *brennaborensis*, *lecithinolyticum*, *maltophilum*, *parvum*, *pectinovorum*, *porcinum*, *saccharophilum*, *socranskii*, and *succinifaciens*. The third group comprises *Treponema azotonutricium* and *primita*; in addition, *Spirochaeta caldaria* and *stenostrepta* are associated with this group. Lastly, no sequence is available for *Treponema minutum*, so its placement is ambiguous.

Family "Brachyspiraceae"

This family comprises a single genus of closely related species: *Brachyspira aalborgi* (type species), *alvinipulli*, *hyodysenteriae*, *innocens*, *intermedia*, *murdochii*, and *pilosicoli*. Many of the species in this genus were previously classified in the genus *Serpulina*, which is not used in the current classification (Ochiai et al., 1997).

Family "Brevinemataceae"

This family is represented by a single genus and species, *Brevinema andersonii*, isolated from rodents.

Family Leptospiraceae

This family comprises the large genus *Leptospira* and two monospecies genera, *Leptonema illini* and *Turneriella parva*. These latter genera were previously classified within the *Leptospira*. However, on the basis of differences in their 16S rRNA gene sequences, they were transferred to novel genera.

The genus *Leptospira* comprises three phylogenetic groups: (1) *Leptospira interrogans* (type species), *alexanderi*, *borgpetersenii*, *kirschneri*, *noguchii*, *santarosai*, and *weilii*; (2) *Leptospira broomii*, *fainei*, *inadai*, *licerasiae*, and *wolffii*; and (3) *Leptospira biflexa*, *meyeri*, and *wolbachii*.

Spirochaetales family incertae sedis

This family includes four genera of symbionts of arthropod invertebrates. Although their morphologies have been described in detail (Bermudes et al., 1988), their 16S rRNA genes have not been sequenced, and their phylogenetic placements are unknown. They are *Clevelandina reticulitermitidis*, *Diplocalyx calotermitidis*, *Hollandina pterotermitidis*, and *Pillotina calotermitidis*.

Phylum Tenericutes

This phylum comprises a single class, *Mollicutes*, which was previously classified within the *Firmicutes* (Garrity et al., 2005). Elevation of these organisms to a separate phylum is justified in part by analyses of a number of conserved phylogenetic markers such as the elongation factor Tu and RNA polymerase (Ludwig and Schleifer, 2005). This classification is further supported by the presence of a wall-less cytoplasmic membrane which is a distinctive cellular structure of this group.

Class Mollicutes

This class comprises four orders, *Mycoplasmatales*, *Entomoplasmatales*, *Acholeplasmatales*, and *Anaeroplasmatales*. While these orders do not agree well with the 16S rRNA gene phylogeny, efforts to reorganize the taxonomy are confounded by the presence of many human and animal pathogens within the group and the priority of some genus names that are seldom used (Brown et al., 2010). A major difficulty is the polyphyletic nature of the genus *Mycoplasma*, species of which are found in 13 distinct clusters distributed over three deep lineages. A fuller

discussion of the complexities of this group along with rRNA gene trees is found in the chapter on *Mycoplasmatales*.

Order *Mycoplasmatales*

This order is the type for the class and comprises two families and four genera. The genera *Mycoplasma* and *Ureaplasma* are classified within the family *Mycoplasmataceae*. The other two genera, *Eperythrozoon* and *Haemobartonella*, contain many blood parasites that have not been cultivated. Although some of the species have been transferred to the genus *Mycoplasma*, the genera are classified within a family *incertae sedis* in recognition of the remaining uncertainties in their classification.

Family *Mycoplasmataceae*

This family contains the genera *Mycoplasma* and *Ureaplasma*. While *Ureaplasma* is well defined on the basis of its rRNA gene sequence phylogeny, *Mycoplasma* is found in at least three deep phylogenetic lineages or groups. The first group contains the type species, *Mycoplasma mycoides*, which is actually more closely related to *Entomoplasma*, the type genus of the order *Entomoplasmatales*, than to most other species of *Mycoplasma* and *Ureaplasma*. A second lineage, called the “*pneumoniae* group”, includes the genus *Ureaplasma* as well as four *Mycoplasma* clusters. The third lineage, called the “*hominis* group”, includes the remaining eight *Mycoplasma* clusters.

The group containing the type species includes: *Mycoplasma mycoides* (type species), *capricolum*, *coltewii*, *putrefaciens*, and *yeatsii*.

The “*hominis* group” includes eight clusters of *Mycoplasma* species. (1) The “*bovis*” cluster comprises *Mycoplasma adleri*, *agalactiae*, *bovigenitalium*, *bovis*, *californicum*, *caviae*, *columbinasale*, *columbinum*, *felifaucium*, *fermentans*, *gallinarum*, *iners*, *leopharyngis*, *lipofaciens*, *maculosum*, *meleagridis*, *opalescens*, *phocirhinis*, *primum*, *simbae*, and *spermatophilum*. (2) The “*equigenitalium*” cluster comprises *Mycoplasma elephantis* and *equigenitalium*. (3) The “*hominis*” cluster comprises *Mycoplasma alkalescens*, *anseris*, *arginini*, *arthritidis*, *auris*, *buccale*, *canadense*, *cloacale*, *equirhinis*, *falconis*, *faucium*, *gateae*, *gypis*, *hominis*, *hyosynoviae*, *indiense*, *orale*, *phocicebrale*, *phocidae*, *salivarium*, *spumans*, and *subdotum*. (4) The “*lipophilum*” cluster comprises *Mycoplasma hyopharyngis* and *lipophilum*. (5) The “*neurolyticum*” cluster comprises *Mycoplasma bovuculi*, *collis*, *cricetuli*, *conjunctivae*, *dispar*, *flocculare*, *hypopneumoniae*, *hyorhinis*, *iguanae*, *lagogenitalium*, *molare*, *neurolyticum*, and *ovipneumoniae*. (6) The “*pulmonis*” cluster comprises *Mycoplasma agassizii*, *pulmonis*, and *testudineum*. (7) The “*sualvi*” cluster comprises *Mycoplasma moatsii*, *mobile*, and *sualvi*. (8) The “*synoviae*” cluster comprises *Mycoplasma alligatoris*, *anatis*, *bovirhinis*, *buteonis*, *canis*, *citelli*, *columborale*, *corogypsi*, *crocydili*, *cynos*, *edwardii*, *felis*, *gallinaceum*, *gallopavonis*, *glycophilum*, *leonicaptivi*, *mustelae*, *oxoniensis*, *pullorum*, *sturni*, *synoviae*, and *verecundum*.

The “*pneumoniae* group” includes four clusters of *Mycoplasma* species and *Ureaplasma*. (1) The “*fastidiosum*” cluster comprises *Mycoplasma cavipharyngis* and *fastidiosum*. (2) The “hemotropic” cluster comprises many species that were formerly classified within the genera *Eperythrozoon* and *Haemobartonella* (see below), including *Mycoplasma coccoides*, *haemocanis*, *haemofelis*, *haemomuris*, *ovis*, *suis*, and *wenyonii*. (3) The “*muris*” cluster comprises *Mycoplasma iowae*, *microti*, *muris*, and *penetrans*. (4) The “*pneumoniae*” cluster comprises *Mycoplasma alvi*, *amphoriforme*, *gallisepticum*, *genitalium*, *imitans*, *pirum*, *pneumoniae*, and *testudinis*. The genus *Ureaplasma* comprises *Ureaplasma urealyticum* (type species), *canigenitalium*, *cati*, *diversum*, *felinum*, *gallorale*, and *parvum*.

Mycoplasmatales family *incertae sedis*

This family includes the genera of blood parasites *Eperythrozoon* and *Haemobartonella*. Species whose 16S rRNA genes have been sequenced are also classified within the *Mycoplasma* hemotropic cluster. On the basis of their 16S rRNA gene sequences, the species of these genera are intermixed in two groups. The first group comprises *Eperythrozoon coccoides* (type species) and *Haemobartonella canis* and *felis*. *Haemobartonella muris*, which is the type species of its genus, is a deep lineage in this group. Upon reclassification to *Mycoplasma*, the *Haemobartonella* species were renamed *haemocanis*, *haemofelis*, and *haemomuris*, respectively, to distinguish them from previously named *Mycoplasma* species. The second group comprises *Eperythrozoon ovis*, *suis*, and *wenyonii*.

Order *Entomoplasmatales*

This order contains two families, *Entomoplasmataceae* and *Spiroplasmataceae*. The order is paraphyletic because it includes the type species of the genus *Mycoplasma*, most species of which are classified in the *Mycoplasmatales*.

Family *Entomoplasmataceae*

This family comprises the genera *Entomoplasma* and *Mesoplasma*. However, on the basis of their 16S rRNA gene sequences, some species of *Acholeplasma* appear to be misclassified within this group. The family comprises four phylogenetic lineages: (1) *Entomoplasma ellychniae* (type species), *Mesoplasma florum* (type species), and *Mesoplasma chauliocola*, *coleopterae*, *corruscae*, *entomophilum*, *grammopterae*, and *tabanidae*; (2) *Mesoplasma photuris*, *seiffertii*, and *syrphidae*, *Entomoplasma lucivorax*, *luminosum*, and *somnilux*; and *Acholeplasma multilocale*; (3) *Mesoplasma lactucae*, and (4) the group containing the type species of *Mycoplasma*, *Mycoplasma mycoides* (see above).

Family *Spiroplasmataceae*

This family comprises the single genus *Spiroplasma*, which itself comprises three relatively deep phylogenetic lineages. In fact, these lineages are no more closely related to each other than to some *Mycoplasma* species. These lineages include (1) *Spiroplasma citri* (type species), *chrysopicola*, *insolitum*, *melliferum*, *penaei*, *phoeniceum*, *poulsonii*, and *syrphidicola*; (2) *Spiroplasma alleghenense*, *cantharicola*, *chinense*, *corruscae*, *culicicola*, *diabroticae*, *diminutum*, *gladiatoris*, *helicoides*, *lampyridicola*, *leptinotarsae*, *lineolae*, *litorale*, *montanense*, *sabaudiense*, *turonicum*, and *velocicrescens*; and (3) *Spiroplasma ixodetis* and *platyhelix*.

Order *Acholeplasmatales* and family *Acholeplasmataceae*

This order comprises the family *Acholeplasmataceae* and a family *incertae sedis* of uncultured plant pathogens classified within “*Candidatus* Phytoplasma”. On the basis of their 16S rRNA gene sequences, both of these groups are well defined phylogenetically. The family *Acholeplasmataceae* comprises four closely related lineages that are all classified with the genus *Acholeplasma*: (1) *Acholeplasma laidlawii* (type species), *equifetale*, *granularum*, *oculi*, and *pleciae*; (2) *Acholeplasma axanthum*, *cavigenitalium*, and *modicum*; *Mycoplasma feliminutum*; (3) *Acholeplasma brassicae*, *morum*, and *vituli*; and (4) *Acholeplasma palmae* and *parvum*.

Order *Anaeroplasmatales* and family *Anaeroplasmataceae*

This order and family comprises two genera which, on the basis of 16S rRNA gene sequence similarity, are not closely related. *Anaeroplasma* is related to members of the order *Acholeplasmatales*. The second genus, *Asteroleplasma*, appears to represent a very deep lineage within the phylum. The genus *Anaeroplasma* comprises three closely related species: *Anaeroplasma abactoclasticum* (type species), *bactoclasticum*, and *varium*. In addition, the species *Anaeroplasma intermedium* has been described for which no sequence is available. *Asteroleplasma anaerobium* is the sole species in the genus *Asteroleplasma*.

Phylum “*Acidobacteria*”

With only seven species, this phylum of mostly oligotrophic heterotrophs comprises two classes of validly published bacteria (Figure 9). However, surveys of environmental DNA indicate that this is one of the most abundant groups of bacteria in soil and many other habitats.

Class “*Acidobacteriia*”, order “*Acidobacteriales*”, and family “*Acidobacteriaceae*”

These taxa comprise two monospecific genera, represented by *Acidobacterium capsulatum* and *Terriglobus roseus*, and *Edaphobacter modestus* (type species) and *aggregans*.

Class *Holophagae*, order *Holophagales*, family *Holophagaceae*, order *Acanthopleuribacterales*, and family *Acanthopleuribacteraceae*

The family *Holophagaceae* comprises two monospecific genera, represented by *Holophaga foetida* and *Geothrix fermentans*. The family *Acanthopleuribacteraceae* comprises one monospecific genus, *Acanthopleuribacter*.

FIGURE 9. Genera of the phylum “*Acidobacteria*”.

Phylum “*Fibrobacteres*”

This phylum comprises the class “*Fibrobacteria*”, the order “*Fibrobacterales*”, the family “*Fibrobacteraceae*”, and the genus *Fibrobacter*. This genus contains two species, *Fibrobacter succinogenes* (type species) and *intestinalis*.

Phylum “*Fusobacteria*”

This phylum comprises a single class, “*Fusobacteriia*”, and order “*Fusobacteriales*”. Two families are currently described (Figure 10). While the family “*Leptotrichiaceae*” is well defined on the basis of 16S rRNA gene sequences, the family “*Fusobacteriaceae*” is more complicated. It comprises five genera. The genus *Fusobacterium* is paraphyletic and includes the lineage containing the genus *Cetobacterium*. The genera *Ilyobacter* and *Propionigenium* are also intermixed. If additional evidence supports these conclusions, reclassification within this family would be warranted.

The phylogenetic groups within the family “*Fusobacteriaceae*” are (1) *Fusobacterium nucleatum* (type species), *canifelinum*, *equinum*, *gonidiaformans*, *mortiferum*, *necrogenes*, *necrophorum*, *perfoetens*, *periodonticum*, *russii*, *simiae*, *ulcerans*, and *varium*; and *Cetobacterium ceti* (type species) and *somerae*, representing a deeper branch; (2) *Ilyobacter polytropus* (type species), *insuetus*, and *tartaricus*; *Propionigenium modestum* (type species) and *maris*; and (3) *Psychrilyobacter atlanticus*, which was described after the deadline for inclusion in this volume, but it appears to be a deep lineage of this family (Zhao et al., 2009).

The phylogenetic groups within the family “*Leptotrichiaceae*” are (1) *Leptotrichia buccalis* (type species), *hofstadii*, *shahii*, *trevisanii*, and *wadei*; (2) *Leptotrichia goodfellowii*; (3) *Sebaldella termitidis*; (4) *Sneathia sanguinegens*; and (5) *Streptobacillus moniliformis*.

Phylum “*Dictyoglomi*”

This phylum comprises the class “*Dictyoglomia*”, the order “*Dictyoglomales*”, the family “*Dictyoglomaceae*”, and the genus

FIGURE 10. Genera of the phylum “*Fusobacteria*”.

Dictyoglopus. This genus contains two species, *Dictyoglopus thermophilum* (type species) and *turgidum*.

Phylum Gemmatimonadetes

This phylum comprises the class *Gemmatimonadetes*, the order *Gemmatimonadales*, the family *Gemmatimonadaceae*, and the genus *Gemmatimonas*. This genus contains one species, *Gemmatimonas aurantiaca*.

Phylum Lentisphaerae

On the basis of their 16S rRNA gene sequences and other molecular markers, this phylum is related to the phyla "*Verrucomicrobia*", "*Chlamydiae*", and "*Planctomycetes*", which form a deep group within the *Bacteria*. The phylum *Lentisphaerae* comprises the class "*Lentisphaeria*" and two orders. The order *Lentisphaerales* comprises the family "*Lentisphaeraceae*" and the monospecific genus *Lentisphaera*, the type of which is *Lentisphaera araneosa*. The order *Victivallales* comprises the family "*Victivallaceae*" and the monospecific genus *Victivallis*, the type of which is *Victivallis vadensis*.

Phylum "Verrucomicrobia"

On the basis of their 16S rRNA gene sequences and other molecular markers, this phylum is related to the phyla "*Chlamydiae*", "*Lentisphaerae*", and "*Planctomycetes*", which form a deep group within the bacteria. "*Verrucomicrobia*" comprises three classes, *Verrucomicrobiae*, *Opiritae*, and "*Spartobacteria*" (Figure 11).

Currently, the class *Verrucomicrobiae* comprises the order *Verrucomicrobiales*, which comprises the families *Verrucomicrobiaceae*, "*Akkermansiaceae*", and "*Rubritaleaceae*". The family *Verrucomicrobiaceae* comprises *Verrucomicrobium spinosum*, *Prostheco bacter fusiformis* (type species), *debonii*, *dejongei*, and *vanneervenii*. In addition, *Prostheco bacter fluviatilis*, which was described after the deadline for inclusion in this volume, is a member of this family (Takeda et al., 2008). The family "*Akkermansiaceae*" comprises the monospecific genus *Akkermansia*, the type of which is *Akkermansia muciniphila*. The family "*Rubritaleaceae*" comprises *Rubritalea marina* (type species), *sabuli*, *spongiae*, *squalenifaciens*, and *tangerina*.

In addition to these genera, four genera were described after the deadline for inclusion in this volume. *Persicirhabdus sediminis*; and *Roseibacillus ishigakijimensis* (type species), *persicus*, and *ponti* (Yoon et al., 2008a), are affiliated with the family "*Rubritaleaceae*". The remaining two genera, *Haloferula rosea* (type species), *harenae*, *helveola*, *phyci*, *rosea*, and *sargassicola* (Yoon et al., 2008c) and *Luteolibacter pohnppeiensis* (type species) and *algae* (Yoon et al., 2008a), appear to be members of the order *Verrucomicrobiales*, but their affiliation with a particular family is more ambiguous. For this reason, they have not been included in the Taxonomic Outline.

The class *Opiritae* comprises the orders *Opiritales* and *Puniceococcales*. The order *Opiritales* comprises a single family, *Opiritaceae*, and two monospecific genera, the type species of which are *Opiritus terrae* and *Alterococcus agarolyticus*. The order *Puniceococcales* comprises a single family, *Puniceococcaceae*, and four genera. The genera form two clusters. The first cluster includes three monospecific genera, the type species of which are *Puniceococcus vermicola*, *Cerasiococcus arenae*, and *Coraliomargarita akajimensis*. The second cluster includes *Pelagicoccus mobilis* (type species),

albus, *croceus*, and *litoralis*. In addition, the genus "*Fucophilus*", which has been described but whose name has never been validly published, is a member of this family.

The class "*Spartobacteria*" comprises the order "*Chthoniobacteriales*", which includes the family "*Chthoniobacteraceae*". This family comprises "*Chthoniobacter flavus*" and the nematode symbionts "*Candidatus Xiphinematobacter brevicolli*" (type species), "*americani*", and "*rivesi*".

Phylum "Chlamydiae"

On the basis of their 16S rRNA gene sequences and other molecular markers, this phylum is related to the phyla *Lentisphaerae*, "*Planctomycetes*", and "*Verrucomicrobia*", which form a deep group within the bacteria. All known members of the phylum "*Chlamydiae*" are obligate intracellular bacteria and multiply in eukaryotic hosts, including humans and other animals and protozoa. They also possess a developmental cycle that is characterized by morphologically and physiologically distinct stages. The intracellular lifestyle of chlamydiae is thus thought to be an ancient trait of this phylum (Everett et al., 1999). As a consequence of the intracellular lifestyle, no species has ever been grown in axenic culture. Because of changes to the Bacteriological Code beginning in 1997, only the species described before that time have been validly published, and many of the newer taxa are limited to *Candidatus* status (Labeleda, 1997; Murray and Stackebrandt, 1995). In addition, even though some species have been cultivated in the free-living amoebae *Acanthamoeba castellanii* and *Acanthamoeba polyphaga*, they have not been deposited in two public culture collections, and thus their names have not been validly published (Heyrman et al., 2005).

The phylum "*Chlamydiae*" comprises a single class, "*Chlamydiai*", and order, *Chlamydiales*. The order comprises eight families of varying relatedness based upon 16S rRNA gene sequence similarities (Figure 12). The family *Chlamydiaceae* contains the type genus for the order. Two taxonomies are in widespread use for this family. One taxonomy assigns all species within this family to the genus *Chlamydia*. The second taxonomy classifies many of these species within a second genus, *Chlamydophila*, in recognition of their differences in a variety of molecular markers including the 16S rRNA gene and some phenotypic markers (Everett et al., 1999). The merits of these approaches have been discussed (Everett and Andersen, 2001; Schachter et al., 2001). While this taxonomic outline uses the taxonomy of Everett et al. (1999), the first taxonomy is used by the authors of the chapter *Chlamydiaceae* (Kuo and Stephens, 2010). On the basis of the taxonomy of Everett et al. (1999), the genus *Chlamydia* comprises *Chlamydia trachomatis* (type species), *muridarum*, and *suis*. The genus *Chlamydophila* comprises *Chlamydophila psittaci* (type species), *abortus*, *caviae*, *felis*, *pecorum*, and *pneumoniae*.

The remaining families in the order are: "*Candidatus Clavichlamydiaceae*" comprising "*Candidatus Clavichlamydia salmonicola*"; "*Criblamydiaceae*" comprising "*Criblamydia sequanensis*"; *Parachlamydiaceae* comprising *Parachlamydia acanthamoebae* (type species and genus), *Neochlamydia hartmannellae*, and "*Protochlamydia amoebophila*"; "*Candidatus Piscichlamydiaceae*" comprising "*Candidatus Piscichlamydia salmonis*"; "*Rhabdochlamydiaceae*" comprising "*Candidatus Rhabdochlamydia porcellionis*" and "*Candidatus Rhabdochlamydia crassificans*"; *Simkaniaceae* comprising *Simkania negevensis* (type species and genus) and "*Candidatus Fritschea*

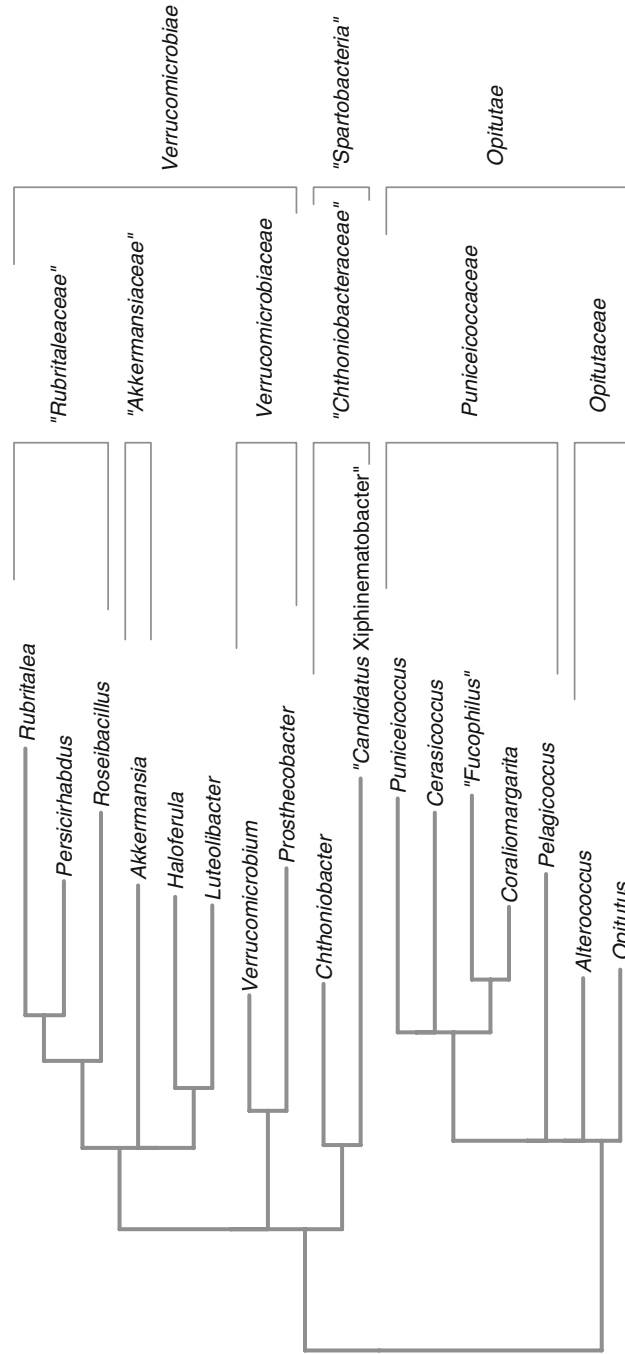

FIGURE 11. Genera of the phylum "Verrucomicrobia".

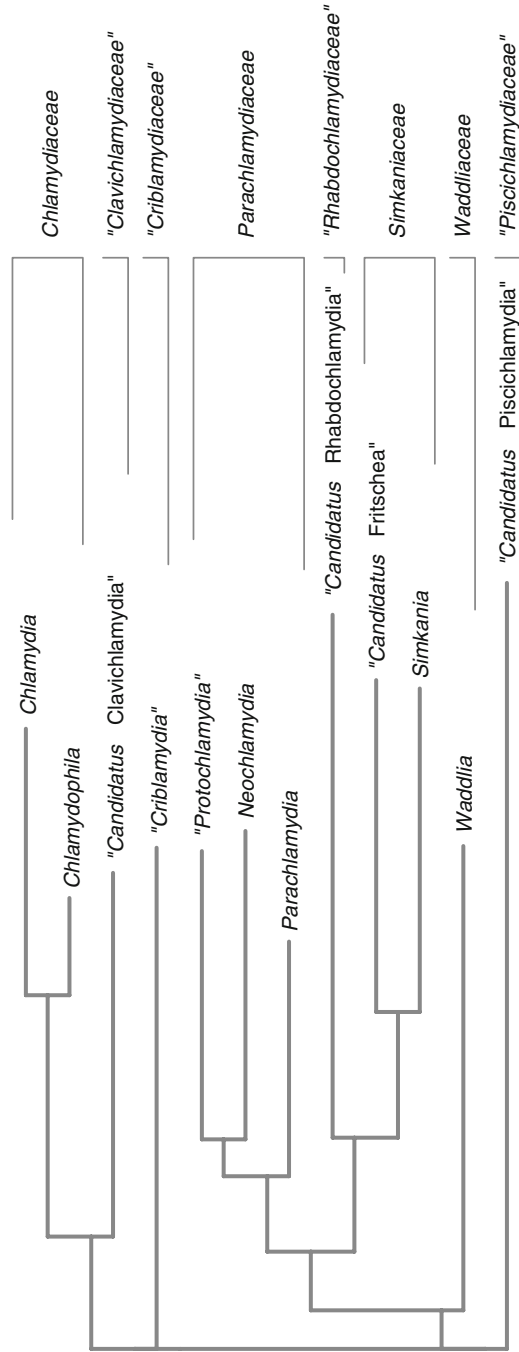

FIGURE 12. Genera of the phylum "Chlamydiae".

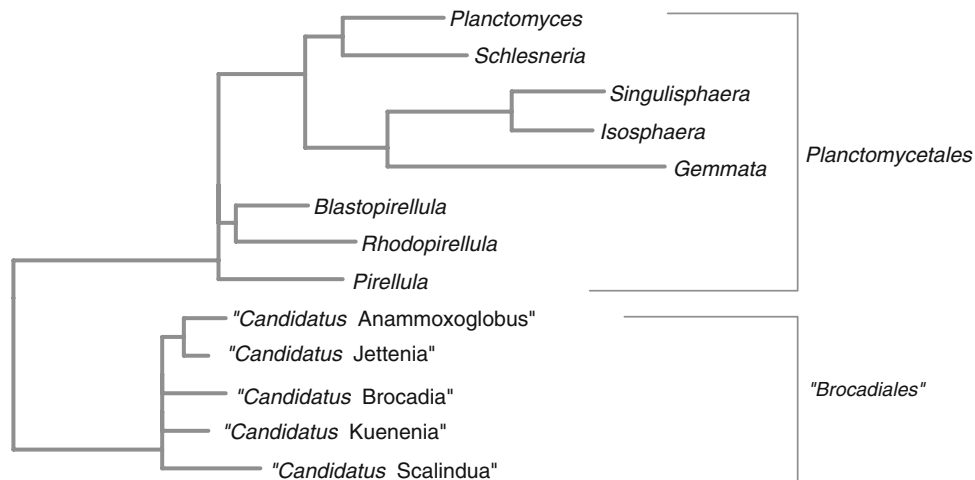

FIGURE 13. Genera of the phylum “Planctomycetes”.

bemisiae” and “*Candidatus Fritschea eriococci*”; and *Waddliaceae* comprising *Waddlia chondrophila* and “*Waddlia malaysiensis*” (Chua et al., 2005).

Phylum “Planctomycetes”

This phylum comprises a single class, “Planctomycetia”, and two orders, Planctomycetales and “Brocadiales” (Figure 13). The order Planctomycetales comprises the family Planctomycetaceae, containing eight diverse genera. The type genus is *Planctomyces*. However, a strain and 16S rRNA gene sequence are not available for the type species, *Planctomyces bekefi*, or for two other validly published species in this genus, *Planctomyces guttaeformis* and *stranskae*. Therefore, the taxonomy of this group is based upon the properties of the species that are available: *Planctomyces brasiliensis*, *limnophilus*, and *maris*. Most of the other genera in this family are monospecific and represented by *Blastopirellula marina*, *Gemmata obscuriglobus*, *Isosphaera pallida*, *Pirellula staleyi* (type species) and *marina*, *Rhodopirellula baltica*, *Schlesneria paludicola*, and *Singulisphaera acidiphila*. In addition to these, *Zavarzinella formosa* was described after the deadline for this volume but could be classified within this family (Kulichvskaya et al., 2009).

The order “Brocadiales” and family “Brocadiaaceae” comprises *Candidatus* species. They include “*Candidatus Brocadia anammoxidans*” and “fulgida”, “*Candidatus Anammoxoglobus propionicus*”, “*Candidatus Jettenia asiatica*”, “*Candidatus Kuenenia stuttgartiensis*”, and “*Candidatus Scalindua brodiae*”, “sorokinii”, and “wagneri”.

- Zhao, J.S., D. Manno and J. Hawari. 2009. *Psychrilyobacter atlanticus* gen. nov., sp. nov., a marine member of the phylum Fusobacteria that produces H₂ and degrades nitramine explosives under low temperature conditions. *Int. J. Syst. Evol. Microbiol.* 59: 491–497.

Taxonomic outlines of the phyla *Bacteroidetes*, *Spirochaetes*, *Tenericutes* (*Mollicutes*), *Acidobacteria*, *Fibrobacteres*, *Fusobacteria*, *Dictyoglomi*, *Gemmatimonadetes*, *Lentisphaerae*, *Verrucomicrobia*, *Chlamydiae*, and *Planctomycetes*

WOLFGANG LUDWIG, JEAN EUZÉBY AND WILLIAM B. WHITMAN

All taxa recognized within this volume of the rank of genus and above are listed below. Within each classification, the nomenclatural type is listed first followed by the remaining taxa in alphabetical order. Taxa appearing on the Approved Lists are denoted by the superscript AL. Taxa that were otherwise validly published are denoted by the superscript VP. Taxa that have not been validly published are presented in quotations. Taxa which were described after the deadline of July 1, 2006, and are therefore not included in this volume are indicated by an asterisk (*).

Phylum XIV. “*Bacteroidetes*”

Class I. “*Bacteroidia*”

Order I. “*Bacteroidales*”

Family I. *Bacteroidaceae*^{AL}

Genus I. *Bacteroides*^{AL(T)}

Genus II. *Acetofilamentum*^{VP}

Genus III. *Acetomicrobium*^{VP}

Genus IV. *Acetothermus*^{VP}

Genus V. *Anaerorhabdus*^{VP}

Family II. “*Marinilabiliaceae*”

Genus I. *Marinilabilia*^{VP(T)}

Genus II. *Alkaliflexus*^{VP}

Genus III. *Anaerophaga*^{VP}

Family III. “*Rikenellaceae*”

Genus I. *Rikenella*^{VP(T)}

Genus II. *Alistipes*^{VP}

Family IV. “*Porphyromonadaceae*”

Genus I. *Porphyromonas*^{VP(T)}

Genus II. *Barnesiella*^{VP}

Genus III. *Dysgonomonas*^{VP}

Genus IV. *Paludibacter*^{VP}

Genus V. *Parabacteroides*^{VP*}

Genus VI. *Petrimonas*^{VP}

Genus VII. *Proteiniphilum*^{VP}

Genus VIII. *Tannerella*^{VP}

Family V. “*Prevotellaceae*”

Genus I. *Prevotella*^{VP(T)}

Genus II. *Xylanibacter*^{VP}

Class II. “*Flavobacteriia*”

Order I. “*Flavobacteriales*”

Family I. *Flavobacteriaceae*^{VP}

Genus I. *Flavobacterium*^{AL(T)}

Genus II. *Actibacter*^{VP*}

Genus III. *Aequorivita*^{VP}

Genus IV. *Aestuariaicola*^{VP*}

Genus V. *Algibacter*^{VP}

Genus VI. *Aquimarina*^{VP}

Genus VII. *Arenibacter*^{VP}

Genus VIII. *Bergeyella*^{VP}

Genus IX. *Bizionia*^{VP}

Genus X. *Capnocytophaga*^{VP}

Genus XI. *Cellulophaga*^{VP}

Genus XII. *Chryseobacterium*^{VP}

Genus XIII. *Cloacibacterium*^{VP}

Genus XIV. *Coenonia*^{VP}

Genus XV. *Costertonia*^{VP}

Genus XVI. *Croceibacter*^{VP}

Genus XVII. *Dokdonia*^{VP}

Genus XVIII. *Donghaeana*^{VP}

Genus XIX. *Elizabethkingia*^{VP}

Genus XX. *Empedobacter*^{VP}

Genus XXI. *Epilithonimonas*^{VP}

Genus XXII. *Flagellimonas*^{VP*}

Genus XXIII. *Flaviramulus*^{VP}

Genus XXIV. *Formosa*^{VP}

Genus XXV. *Fulvibacter*^{VP*}

Genus XXVI. *Gaetbulibacter*^{VP}

Genus XXVII. *Galbibacter*^{VP*}

Genus XXVIII. *Gelidibacter*^{VP}

Genus XXIX. *Gillisia*^{VP}

Genus XXX. *Gilvibacter*^{VP*}

Genus XXXI. *Gramella*^{VP}

Genus XXXII. *Joostella*^{VP*}

Genus XXXIII. *Kaistella*^{VP}

Genus XXXIV. *Kordia*^{VP}

Genus XXXV. *Krokinobacter*^{VP}

Genus XXXVI. *Lacinutrix*^{VP}

Genus XXXVII. *Leeuwenhoekella*^{VP}

Genus XXXVIII. *Leptobacterium*^{VP*}

Genus XXXIX. *Lutibacter*^{VP}

- Genus XL. *Lutimonas*^{VP*}
 Genus XLI. *Maribacter*^{VP}
 Genus XLII. *Mariniflexile*^{VP}
 Genus XLIII. *Marixanthomonas*^{VP*}
 Genus XLIV. *Mesoflavibacter*^{VP*}
 Genus XLV. *Mesonina*^{VP}
 Genus XLVI. *Muricauda*^{VP}
 Genus XLVII. *Myroides*^{VP}
 Genus XLVIII. *Nonlabens*^{VP}
 Genus XLIX. *Olleya*^{VP}
 Genus L. *Ornithobacterium*^{VP}
 Genus LI. *Persicivirga*^{VP}
 Genus LII. *Polaribacter*^{VP}
 Genus LIII. *Psychroflexus*^{VP}
 Genus LIV. *Psychroserpens*^{VP}
 Genus LV. *Riemerella*^{VP}
 Genus LVI. *Robiginitalea*^{VP}
 Genus LVII. *Salegentibacter*^{VP}
 Genus LVIII. *Salinimicrobium*^{VP*}
 Genus LIX. *Sandarakinotalea*^{VP}
 Genus LX. *Sediminibacter*^{VP*}
 Genus LXI. *Sediminicola*^{VP}
 Genus LXII. *Sejongia*^{VP}
 Genus LXIII. *Stenothermobacter*^{VP}
 Genus LXIV. *Subsaxibacter*^{VP}
 Genus LXV. *Subsaxinimicrobium*^{VP}
 Genus LXVI. *Tamiana*^{VP*}
 Genus LXVII. *Tenacibaculum*^{VP}
 Genus LXVIII. *Ulvibacter*^{VP}
 Genus LXIX. *Vitellibacter*^{VP}
 Genus LXX. *Wautersiella*^{VP}
 Genus LXXI. *Weeksella*^{VP}
 Genus LXXII. *Winogradskyella*^{VP}
 Genus LXXIII. *Yeosuana*^{VP}
 Genus LXXIV. *Zeaxanthinibacter*^{VP*}
 Genus LXXV. *Zhouia*^{VP}
 Genus LXXVI. *Zobellia*^{VP}
 Genus LXXVII. *Zunongwangia*^{VP*}
- Family II. “*Blattabacteriaceae*”
 Genus I. *Blattabacterium*^{AL(T)}
- Family III. “*Cryomorphaceae*”
 Genus I. *Cryomorpha*^{VP(T)}
 Genus II. *Brumimicrobium*^{VP}
 Genus III. *Crocinitomix*^{VP}
 Genus IV. *Fluviicola*^{VP}
 Genus V. *Lishizhenia*^{VP}
 Genus VI. *Owenweeksia*^{VP}
- Class III. “*Sphingobacteriia*”
 Order I. “*Sphingobacteriales*”
 Family I. “*Sphingobacteriaceae*”^{VP}
 Genus I. *Sphingobacterium*^{VP(T)}
 Genus II. *Mucilagibacter*^{VP*}
 Genus III. *Nubsella*^{VP*}
 Genus IV. *Olivibacter*^{VP*}
 Genus V. *Parapedobacter*^{VP*}
 Genus VI. *Pedobacter*^{VP}
 Genus VII. *Pseudosphingobacterium*^{VP*}
- Family II. “*Chitinophagaceae*”
 Genus I. *Chitinophaga*^{VP(T)}
- Genus II. *Flavisolibacter*^{VP*}
 Genus III. *Niabella*^{VP*}
 Genus IV. *Niastella*^{VP*}
 Genus V. *Sediminibacterium*^{VP*}
 Genus VI. *Segetibacter*^{VP*}
 Genus VII. *Terrimonas*^{VP}
- Family III. “*Saprospiraceae*”
 Genus I. *Saprospira*^{AL(T)}
 Genus II. *Aureispira*^{VP}
 Genus III. *Haliscomenobacter*^{AL}
 Genus IV. *Lewinella*^{VP}
- Class IV. “*Cytophagia*”
 Order I. “*Cytophagales*”^{AL(T)}
 Family I. “*Cytophagaceae*”^{AL}
 Genus I. *Cytophaga*^{AL(T)}
 Genus II. *Adhaeribacter*^{VP}
 Genus III. *Arcicella*^{VP}
 Genus IV. *Dyadobacter*^{VP}
 Genus V. *Effluviibacter*^{VP}
 Genus VI. *Emticicia*^{VP}
 Genus VII. *Flectobacillus*^{AL}
 Genus VIII. *Flexibacter*^{AL}
 Genus IX. *Hymenobacter*^{VP}
 Genus X. *Larkinella*^{VP}
 Genus XI. *Leadbetterella*^{VP}
 Genus XII. *Meniscus*^{AL}
 Genus XIII. *Microscilla*^{AL}
 Genus XIV. *Persicitalea*^{VP*}
 Genus XV. *Pontibacter*^{VP}
 Genus XVI. *Rudanella*^{VP*}
 Genus XVII. *Runella*^{AL}
 Genus XVIII. *Spirosoma*^{AL}
 Genus XIX. *Sporocytophaga*^{AL}
- Family II. “*Cyclobacteriaceae*”
 Genus I. *Cyclobacterium*^{VP(T)}
 Genus II. *Algoriphagus*^{VP}
 Genus III. *Aquiflexum*^{VP}
 Genus IV. *Belliella*^{VP}
 Genus V. *Echinicola*^{VP}
 Genus VI. *Rhodonellum*^{VP}
- Family III. “*Flammeovirgaceae*”
 Genus I. *Flammeovirga*^{VP(T)}
 Genus II. *Fabibacter*^{VP}
 Genus III. *Flexithrix*^{AL}
 Genus IV. *Fulvivirga*^{VP*}
 Genus V. *Limibacter*^{VP*}
 Genus VI. *Perexilibacter*^{VP*}
 Genus VII. *Persicobacter*^{VP}
 Genus VIII. *Rapidithrix*^{VP*}
 Genus IX. *Reichenbachiella*^{VP}
 Genus X. *Roseivirga*^{VP}
 Genus XI. *Sedimitomix*^{VP*}
- Order II. *Incertae sedis*
 Family I. “*Rhodothermaceae*”
 Genus I. *Rhodothermus*^{VP(T)}
 Genus II. *Salinibacter*^{VP}
- Order III. *Incertae sedis*
 Genus I. *Balneola*^{VP*}
- Order IV. *Incertae sedis*

- Genus I. *Thermonema*^{VP}
 Order V. *Incertae sedis*
 Genus I. *Toxothrix*^{AL}
- Phylum XV. "*Spirochaetes*"
 Class I. "*Spirochaetia*"
 Order I. *Spirochaetales*^{AL(T)}
 Family I. *Spirochaetaceae*^{AL}
 Genus I. *Spirochaeta*^{AL(T)}
 Genus II. *Borrelia*^{AL}
 Genus III. *Cristispira*^{AL}
 Genus IV. *Treponema*^{AL}
 Family II. "*Brachyspiraceae*"
 Genus I. *Brachyspira*^{VP(T)}
 Family III. "*Brevinemataceae*"
 Genus I. *Brevinema*^{VP(T)}
 Family IV. *Leptospiraceae*^{AL}
 Genus I. *Leptospira*^{AL(T)}
 Genus II. *Leptonema*^{VP}
 Genus III. *Turneriella*^{VP}
 Family V. *Incertae sedis*
 Genus I. *Clevelandina*^{VP}
 Genus II. *Diplocalyx*^{VP}
 Genus III. *Hollandina*^{VP}
 Genus IV. *Pillotina*^{VP}
- Phylum XVI. *Tenericutes*^{VP}
 Class I. *Mollicutes*^{AL}
 Order I. *Mycoplasmatales*^{AL(T)}
 Family I. *Mycoplasmataceae*^{AL}
 Genus I. *Mycoplasma*^{AL(T)}
 Genus II. *Ureaplasma*^{VP}
 Family II. *Incertae sedis*
 Genus I. *Eperythrozoon*^{AL}
 Genus II. *Haemobartonella*^{AL}
 Order II. *Entomoplasmatales*^{VP}
 Family I. *Entomoplasmataceae*^{VP}
 Genus I. *Entomoplasma*^{VP(T)}
 Genus II. *Mesoplasma*^{VP}
 Family II. *Spiroplasmataceae*^{VP}
 Genus I. *Spiroplasma*^{AL(T)}
 Order III. *Acholeplasmatales*^{VP}
 Family I. *Acholeplasmataceae*^{AL}
 Genus I. *Acholeplasma*^{AL(T)}
 Family II. *Incertae sedis*
 Genus I. "*Candidatus Phytoplasma*"
 Order IV. *Anaeroplasmatales*^{VP}
 Family I. *Anaeroplasmataceae*^{VP}
 Genus I. *Anaeroplasma*^{AL(T)}
 Genus II. *Asteroleplasma*^{VP}
- Phylum XVII. "*Acidobacteria*"
 Class I. "*Acidobacteriia*"
 Order I. "*Acidobacteriales*"^(T)
 Family I. "*Acidobacteriaceae*"
 Genus I. *Acidobacterium*^{VP(T)}
 Genus II. *Edaphobacter*^{VP}
 Genus III. *Terriglobus*^{VP}
 Class II. *Holophagae*^{VP}
 Order I. *Holophagales*^{VP(T)}
 Family I. *Holophagaceae*^{VP}
 Genus I. *Holophaga*^{VP(T)}
- Genus II. *Geothrix*^{VP}
 Order II. *Acanthopleuribacterales*^{VP}
 Family I. *Acanthopleuribacteraceae*^{VP}
 Genus I. *Acanthopleuribacter*^{VP(T)}
- Phylum XVIII. "*Fibrobacteres*"
 Class I. "*Fibrobacteriia*"
 Order I. "*Fibrobacterales*"^(T)
 Family I. "*Fibrobacteraceae*"
 Genus I. *Fibrobacter*^{VP(T)}
- Phylum XIX. "*Fusobacteria*"
 Class I. "*Fusobacteriia*"
 Order I. "*Fusobacteriales*"^(T)
 Family I. "*Fusobacteriaceae*"
 Genus I. *Fusobacterium*^{AL(T)}
 Genus II. *Cetobacterium*^{VP}
 Genus III. *Ityobacter*^{VP}
 Genus IV. *Propionigenium*^{VP}
 Genus V. *Psychrilyobacter*^{VP*}
 Family II. "*Leptotrichiaceae*"
 Genus I. *Leptotrichia*^{AL(T)}
 Genus II. *Sebaldella*^{VP}
 Genus III. *Sneathia*^{VP}
 Genus IV. *Streptobacillus*^{AL}
- Phylum XX. "*Dictyoglomi*"
 Class I. "*Dictyoglossia*"
 Order I. "*Dictyoglossales*"^(T)
 Family I. "*Dictyoglossaceae*"
 Genus I. *Dictyoglossus*^{VP(T)}
- Phylum XXI. *Gemmatimonadetes*
 Class I. *Gemmatimonadetes*^{VP}
 Order I. *Gemmatimonadales*^{VP(T)}
 Family I. *Gemmatimonadaceae*^{VP}
 Genus I. *Gemmatimonas*^{VP(T)}
- Phylum XXII. *Lentisphaerae*
 Class I. "*Lentisphaeria*"

Phylum XIV. Bacteroidetes phyl. nov.

NOEL R. KRIEG, WOLFGANG LUDWIG, JEAN EUZÉBY AND WILLIAM B. WHITMAN

Bac.te.ro.i.de'tes. N.L. fem. pl. n. *Bacteroidales* type order of the phylum; N.L. fem. pl. n. *Bacteroidetes* the phylum of *Bacteroidales*.

The phylum *Bacteroidetes* is a phenotypically diverse group of Gram-stain-negative rods that do not form endospores. They are circumscribed for this volume on the basis of phylogenetic analysis of 16S rRNA gene sequences. The phylum contains four classes, *Bacteroidia*, *Cytophagia*, *Flavobacteriia*, and *Sphin-*

gobacteria. In addition, the genera *Rhodothermus*, *Salinibacter*, and *Thermonema* appear to represent deep groups of the phylum that can not be readily assigned to any of the four classes.

Type order: Bacteroidales ord. nov.

Class I. Bacteroidia class. nov.

NOEL R. KRIEG

Bac.te.ro.i.di'a. N.L. masc. n. *Bacteroides* type genus of the type order *Bacteroidales*; suff. *-ia* ending proposed by Gibbons and Murray and by Stackebrandt et al. to denote a class; N.L. neut. pl. n. *Bacteroidia* the *Bacteroidales* class.

The class presently contains one order, *Bacteroidales*. The description of the class is the same as that given for the order.

Type order: Bacteroidales ord. nov.

Order I. Bacteroidales ord. nov.

NOEL R. KRIEG

Bac.te.ro.i.da'les. N.L. masc. n. *Bacteroides* type genus of the order; suff. *-ales* ending to denote an order; N.L. fem. pl. n. *Bacteroidales* the *Bacteroides* order.

The order presently includes the families *Bacteroidaceae*, *Marinilabiliaceae*, *Porphyromonadaceae*, *Prevotellaceae*, and *Rikenellaceae*. Straight, fusiform or thin **rods and coccobacilli** that **stain Gram-negative. Nonsporeforming. Mostly anaerobic**, although some are facultatively anaerobic, and saccharolytic, although proteins and other substrates may be utilized. **Nonmotile or motile by gliding.**

Type genus: Bacteroides Castellani and Chalmers 1919, 959^{AL}.

THE EDITORIAL BOARD

Bac.te.ro.i.da.ce'a.e. N.L. masc. n. *Bacteroides* type genus of the family; suff. *-aceae* ending to denote a family; N.L. fem. pl. n. *Bacteroidaceae* the *Bacteroides* family.

The family *Bacteroidaceae* was circumscribed for this volume on the basis of phylogenetic analysis of 16S rRNA gene sequences; the family contains the genera *Acetofilamentum*, *Acetomicrobium*, *Acetothermus*, *Anaerorhabdus*, and *Bacteroides*. The genera *Anaerophaga* and *Megamonas*, which were previously classified with this family,

have been transferred to the family *Marinilabiliaceae* and the *Firmicutes*, respectively (Morotomi et al., 2007). **Straight rods** that **stain Gram-negative. Anaerobic. Nonsporeforming.** Some characteristics that differentiate the genera are given in Table 1.

Type genus: Bacteroides Castellani and Chalmers 1919, 959^{AL}.

TABLE 1. Some characteristics that differentiate the genera of the family Bacteroidaceae^a

Characteristic	<i>Bacteroides</i>	<i>Acetoflamentum</i>	<i>Acetomicrobium</i>	<i>Acetothermus</i>	<i>Anaerorhabdus</i>
Cell size (µm)	0.5–2.0 × 1.6–12	0.18–0.3 × 2–8	0.6–0.8 × 2–7	0.5 × 5–8	0.3–1.5 × 1–3
Motility	-	-	+	-	-
Saccharolytic	+	+	+	+	-
Growth occurs below 50°C	+	+	+	-	+
Major products of glucose fermentation	Succinate and acetate; trace to moderate amounts of isobutyrate and isovalerate	Acetate and H ₂ (in a molar ratio of 1:2) and CO ₂	Acetate and H ₂ or acetate, lactate, ethanol, and H ₂	Acetate and H ₂ in a molar ratio of 1:1:2.	Acetate and lactate
Isolated from	Major constituents of the normal human colonic flora; also found in smaller numbers in the female genital tract; not common in the mouth or upper respiratory tract	Secondary sewage sludge	Sewage sludge	Thermophilically fermenting sewage sludge	Infected appendix, lung abscesses and abdominal abscesses; infrequently from human and pig feces
DNA G+C content (mol%)	39–49	~47	47	~62	34

^aSymbols: +, >85% positive; -, 0–15% positive.

Genus I. **Bacteroides** Castellani and Chalmers 1919, 959^{AL} emend. Shah and Collins 1989, 85

YULI SONG, CHENGXU LIU AND SYDNEY M. FINEGOLD

Bac.te.ro.i'des. N.L. n. *bacter* rod; L. suff. *-oides* (from Gr. suff. *-eides*, from Gr. n. *eidos* that which is seen, form, shape, figure), resembling, similar; N.L. masc. n. *Bacteroides* rodlike.

Rod-shaped cells with rounded ends. Gram-stain-negative. Cells are fairly uniform if smears are prepared from young cultures on blood agar. Nonmotile. **Anaerobic.** Colonies are 1–3 mm in diameter, smooth, white to gray, and nonhemolytic on blood agar. Chemo-organotrophic. **Saccharolytic.** Weakly proteolytic. Most species grow in the presence of 20% bile, but are not always stimulated. Esculin is usually hydrolyzed. Nitrate is not reduced to nitrite. Indole variable. **Major fermentation products are succinate and acetate.** Trace to moderate amounts of isobutyrate and isovalerate may be produced. **Predominant cellular fatty acid is C_{15:0} anteiso.**

DNA G+C content (mol%): 39–49.

Type species: Bacteroides fragilis (Veillon and Zuber 1898) Castellani and Chalmers 1919, 959^{AL}.

Further descriptive information

As defined in *Bergey's Manual of Systematic Bacteriology*, 1st edition, the genus *Bacteroides* comprised more than 60 species (Holdeman et al., 1984). These species exhibited a variety of cellular

morphologies and were biochemically and physiologically extremely heterogeneous. Therefore, Shah and Collins (1989) proposed that this genus should be restricted to *Bacteroides fragilis* and closely related organisms. The application of molecular biology techniques such as DNA–DNA hybridization and 16S rRNA gene sequencing has done much to clarify the inter- and intragenetic structure of *Bacteroides*. 16S rRNA gene sequence analysis indicates that the genus *Bacteroides* is equivalent to the *Bacteroides* cluster within the *Bacteroides* subgroup of the “*Bacteroidetes*” (previously referred as the phylum *Cytophaga–Flavobacteria–Bacteroides*) (Paster et al., 1994; Woese, 1987). The currently described species that conform to the emended description of the genus *Bacteroides* based on biochemical, chemical, and genetic criteria include the members of the “*Bacteroides fragilis* group” [not a formal taxonomic group, but the ten species conforming to the 1989 proposal (Shah and Collins) to restrict the genus] and several other later described species (Figure 14). Other *Bacteroides* species with validly published names that do not conform to the emended generic description require further study (Table 5).

FIGURE 14. Phylogenetic tree based on 16S rRNA gene sequence comparisons (>1300 aligned bases) showing the phylogenetic relationships of *Bacteroides* species. The tree, constructed using the neighbor-joining method, was based on a comparison of approximately 1400 nt. Bootstrap values, expressed as percentages of 1000 replications, are given at branching points. Bar = 1% sequence divergence.

Morphology and general characteristics. Microscopically, members of the genus *Bacteroides* are pale-staining, Gram-stain-negative bacilli with rounded ends, occurring singly or in pairs. Cells are approximately $0.5\text{--}2.0 \times 1.6\text{--}12 \mu\text{m}$. Cells are uniform, pleomorphic, or vacuolized, traits that are medium- and age-dependent. Colonies on blood agar are 1–3 mm in diameter, smooth, circular, entire, convex, white to gray, and nonhemolytic. According to the characteristic special potency antibiotic identification disk profile of *Bacteroides* species, they are resistant to vancomycin (5 μg), kanamycin (1000 μg), and colistin (10 μg). Good growth on bacteroides bile esculin (BBE) medium and other 20% bile (2% oxgall)-containing media is characteristic of species of the genus *Bacteroides*, with the exception of *Bacteroides helcogenes*, *Bacteroides pyogenes*, and some strains of *Bacteroides uniformis*. On BBE agar, *Bacteroides* species hydrolyze esculin, blackening the agar except for most strains of *Bacteroides vulgatus* and some strains of *Bacteroides pyogenes* and *Bacteroides stercoris* that are esculin-negative. β -Galactosidase, alkaline phosphatase, leucyl glycine arylamidase, and alanine arylamidase activities are detected. Both nonhydroxylated and 3-hydroxylated long-chain fatty acids are present. The nonhydroxylated acids are predominantly of the straight-chain saturated, anteiso- and iso-methyl branched-chain types. Characteristics of the *Bacteroides* species are presented in Table 2.

Nutrition and growth conditions. Carbon dioxide is utilized or required and incorporated into succinic acid (Caldwell et al., 1969). Hemin and vitamin K_1 are required or highly stimulatory for growth and are added routinely to media for *Bacteroides*. Growth of described species is most rapid at 37°C and pH near 7.0.

Antibiotics and drug resistance. The *Bacteroides* species are among the most antibiotic resistant of the anaerobes. They are usually resistant to penicillins and not uncommonly resistant to expanded and broad-spectrum cephalosporins (including relatively β -lactamase-resistant drugs such as cefoxitin) and clindamycin (Wexler and Finegold, 1998). Antimicrobial agents that are active against >99% of clinical isolates of *Bacteroides* include metronidazole, chloramphenicol, and carbapenems; however, strains of the *Bacteroides fragilis* group with resistance to imipenem and metronidazole are also encountered. Agents active against 95–99% of *Bacteroides fragilis* isolates include the β -lactam/ β -lactamase inhibitor combinations. *Bacteroides fragilis* group species other than *Bacteroides fragilis* are more likely to be resistant to β -lactam/ β -lactamase inhibitor combinations than *Bacteroides fragilis*. The level of chloramphenicol susceptibility remains quite high, whereas almost uniform resistance to aminoglycosides is observed and resistance to quinolones is common. Several multicenter surveys have documented an alarming gradual increase in resistance rates of *Bacteroides* species worldwide (Snydman et al., 2002). Multiresistant *Bacteroides fragilis* group strains, some of which are capable of transferring resistance genes, have been isolated in several countries. Although the rate of *Bacteroides fragilis* resistance to carbapenems or β -lactam/ β -lactamase inhibitor combination drugs remains low, some investigators have noted a gradual increase in minimum inhibitory concentrations. Agents such as clindamycin and some cephalosporins, which have traditionally been considered good choices against *Bacteroides fragilis* group strains, are losing activity against these clinically important pathogens.

The classical mechanisms of resistance to β -lactams are: (a) production of β -lactamases; (b) alteration of penicillin-binding proteins; and (c) changes in outer membrane permeability to β -lactams. Resistance to clindamycin is mediated by modification of the ribosome. Tetracycline resistance is mediated by both tetracycline efflux and ribosomal protection. 5-Nitroimidazole resistance appears to be caused by a combination of decreased antibiotic uptake and decreased nitroreductase activity (Fang et al., 2002). Two main mechanisms – alteration of target enzymes (gyrase) caused by chromosomal mutations in encoding genes and reduced intracellular accumulation due to increased efflux of the drug – are associated with quinolone resistance in the *Bacteroides fragilis* group (Oh and Edlund, 2003).

Natural habitats and clinical significance. Members of the “*Bacteroides fragilis* group” are major constituents of the normal human colonic flora and are also found in smaller numbers in the female genital tract, but are not common in the mouth or upper respiratory tract. The “*Bacteroides fragilis* group” makes up one-third of all clinical isolates of anaerobes. *Bacteroides fragilis* is the most frequently encountered, with *Bacteroides thetaiotaomicron* second. They are recovered from most intra-abdominal infections and may occur in infections at other sites. *Bacteroides fragilis* strains producing a potent zinc-dependent metalloprotease or enterotoxin with a variety of pathological effects on intestinal mucosal cells have been identified. Enterotoxin-producing *Bacteroides fragilis* strains have been isolated from the intestinal tracts of young farm animals and small children with diarrhea and in cases of extra-abdominal infections including bacteremia, but they have also been isolated from fecal samples from healthy children and adults (Sears et al., 1995). To date, three types of the enterotoxin, each having different virulence and geographical distribution, have been characterized. Other members of the *Bacteroides fragilis* group are present less often in infection.

Enrichment and isolation procedures

A complex medium containing peptone, yeast extract, vitamin K_1 , and hemin is recommended for isolation of most species. The use of selective media along with nonselective media will increase yield and save time in terms of isolation of *Bacteroides*. Fresh or pre-reduced media (commercially available from Anaerobe Systems) are recommended, as both increase the initial isolation efficiency. The recommended minimum medium setup for culture of clinical specimens includes: (a) a nonselective, enriched, Brucella base sheep blood agar plate supplemented with vitamin K_1 and hemin; and (b) a BBE agar plate for specimens from below the diaphragm for the selection and presumptive identification of the “*Bacteroides fragilis* group” (and *Bilophila* spp.). When indicated, a phenylethyl alcohol-sheep blood agar plate to prevent overgrowth by aerobic Gram-stain-negative rods and swarming of some clostridia may also be used. After inoculation, the anaerobic plates should be placed immediately in an anaerobic environment containing at least 5% carbon dioxide. Carbon dioxide is required for optimal growth of most of the saccharolytic species. The plates are examined after incubation for 48 h at 35 or 37°C .

Maintenance procedures

The following procedures are those of Jousimies-Somer et al. (2002). Cultures of *Bacteroides* species can be maintained by regularly subculturing. A young, actively growing culture can be put into stock from liquid or solid media by freezing at -70°C or lyophilizing in a well-buffered medium containing no fermentable carbohydrate. Supplemented (vitamin K_1 and hemin) thioglycolate medium or chopped meat broth incubated for 24–48 h, depending on the growth rate of the isolate, can be used to prepare stock cultures. Broth culture (0.5 ml) is added to an equal volume of sterile 20% skim milk or 15% glycerol prepared in an unbreakable screw-capped vial. For toxin-producing organisms, storage under anaerobic conditions at -70°C after a minimal number of subcultures may be important.

Differentiation of the genus *Bacteroides* from other genera

Bacteroides can be differentiated from other known related genera by 16S rRNA gene sequence analysis because the members form a distinct cluster within the *Bacteroides* subgroup with mean interspecies similarities of approximately 93% (Paster et al., 1994). The stability of this cluster has also been verified by bootstrap analysis with a confidence level of 100%. Species of the genus *Bacteroides* can also be distinguished from species of other closely related genera by bile resistance, cellular fatty acid content, fermentation, and pigmentation (Table 3). Members of the genus can be distinguished from those of the most closely related genera *Prevotella* and *Porphyromonas* by their resistance to 20% bile. In addition, *Bacteroides* species are highly fermentative

and generally produce acetic and succinic acids as the major end products of glucose metabolism, in contrast to asaccharolytic species in the genus *Porphyromonas* and moderately saccharolytic species in *Prevotella*. *Bacteroides* species can also be readily distinguished from *Porphyromonas* species by not being pigmented and containing predominantly 12-methyl-tetradecanoic acid ($\text{C}_{15:0}$ anteiso) as the long-chain fatty acid, in contrast to pigmented *Porphyromonas* species, which contain mainly 13-methyl-tetradecanoic acid ($\text{C}_{15:0}$ iso). All *Bacteroides* species examined so far possess the enzymes glucose-6-phosphate dehydrogenase (G6PDH) and 6-phosphogluconate dehydrogenase (6PGDH), which differs from other genera. Furthermore, the dibasic amino acid of their cell wall peptidoglycan is meso-diaminopimelic acid. The principal respiratory quinones are menaquinones with 10 or 11 isoprene units or both. Sphingolipids are produced (Shah and Collins, 1983). Unfortunately, these features have not been tested in many of the recently described *Bacteroides* species. Characteristics that differentiate *Bacteroides* from related taxa within the phylum “*Bacteroidetes*” are presented in Table 3.

Taxonomic comments

The taxonomy of the genus *Bacteroides* has been in a state of great change in recent years. On the basis of 16S rRNA gene sequence analysis, *Bacteroides* forms the “CFB group” with *Cytophaga* and *Flavobacterium* (Woese, 1987). The “CFB group” is divided into the *Cytophaga*, *Flavobacterium*, and *Bacteroides* subgroups. The *Bacteroides* subgroup is further divided into the *Prevotella* cluster, *Porphyromonas* cluster, *Bacteroides* cluster, and two new unnamed clusters. Accordingly, it is now generally

recognized that the majority of the original *Bacteroides* species fall into three genera: *Prevotella* (bile-sensitive, moderately saccharolytic, pigmented and nonpigmented species), *Porphyromonas* (bile-sensitive, pigmented, asaccharolytic species), and *Bacteroides* (bile-resistant, nonpigmented, saccharolytic species) (Shah and Collins, 1988, 1989, 1990). Several other genera have been described subsequently for those clearly unrelated *Bacteroides* taxa that do not conform to these three major groups (e.g., *Alistipes*, *Anaerorhabdus*, *Dichelobacter*, *Fibrobacter*, *Megamonas*,

Mitsuokella, *Rikenella*, *Sebaldella*, *Tannerella*, and *Tissierella*) (Table 4). However, a large number of taxa still remain unclassified and several, such as *Bacteroides capillosus*, *Bacteroides cellulosolvens*, *Bacteroides ureolyticus*, and *Bacteroides splanchnicus*, are retained in *Bacteroides* until valid new genera are proposed. The genus *Bacteroides* now contains mainly the species that were formerly described as the “*Bacteroides fragilis* group” (including *Bacteroides eggerthii*), as well as several later described species. It is evident from the phylogenetic data (Figure 14) that three

bile-resistant “*Bacteroides fragilis* group” species – *Bacteroides distasonis*, *Bacteroides merdae*, and the recently described *Bacteroides goldsteinii* – cluster close to the bile-sensitive *Tannerella forsythia* (formerly *Bacteroides forsythus*) and display a loose affinity with the first subcluster (the genus *Porphyromonas*), suggesting that a novel genus should be established to accommodate these three species. Sakamoto and Benno (2006) created the genus *Parabacteroides* to encompass three species that were previously classified in *Bacteroides*, viz., *Parabacteroides distasonis* (previously *Bacteroides distasonis*), *Parabacteroides goldsteinii* (previously *Bacteroides goldsteinii*), and *Parabacteroides merdae* (previously *Bacteroides merdae*). A fourth species, *Parabacteroides johnsonii*, was subsequently added (Sakamoto et al., 2007). The description of *Parabacteroides* is as follows (Sakamoto and Benno, 2006). Rods (0.8–1.6 × 1.2–12 μm). Nonmotile. Non-spore-forming. Gram-stain-negative. Obligately anaerobic. Colonies on Eggerth–Gagnon (EG) agar plates are 1–2 mm in diameter, gray to off-white gray, circular, entire, slightly convex, and smooth. Saccharolytic. Major end products are acetic and succinic acids;

lower levels of other acids may be produced. Growth occurs in the presence of 20% bile. Esculin is hydrolyzed. Indole is not produced. G6PDH, 6PGDH, malate dehydrogenase, and glutamate dehydrogenase are present, but not α-fucosidase. The principal respiratory quinones are menaquinones MK-9 and MK-10. Both nonhydroxylated and 3-hydroxylated long-chain fatty acids are present. The nonhydroxylated acids are predominantly of the saturated straight chain and anteiso-methyl branched chain types. The DNA G+C content is 43–46 mol%. The type species is *Parabacteroides distasonis* (Eggerth and Gagnon, 1933) Sakamoto and Benno 2006, 1602^{VP}.

Interestingly, the bile-sensitive oral species *Prevotella heparinolytica* and *Prevotella zoogloeiformans* fall, phylogenetically, within the *Bacteroides* cluster. The Subcommittee on Gram-negative Rods of the International Committee on Systematics of Prokaryotes recommended designating them *Bacteroides heparinolytica* and *Bacteroides zoogloeiformans*, respectively, but studies other than 16S rRNA gene sequence analysis should be performed before the status of these taxa is finalized.

List of species of the genus *Bacteroides*

1. ***Bacteroides fragilis*** (Veillon and Zuber 1898) Castellani and Chalmers 1919, 959^{AL}. [*Bacillus fragilis* Veillon and Zuber 1898, 536; *Fusiformis fragilis* (Veillon and Zuber 1898) Topley and Wilson 1929, 393; *Ristella fragilis* (Veillon and Zuber 1898) Prévot 1938; *Bacteroides fragilis* subsp. *fragilis* (Veillon and Zuber 1898) Castellani and Chalmers 1919, 959]

fra'gi.lis. L. masc. adj. *fragilis* fragile (relating to the brittle colonies that may form under some culture conditions).

Characteristics are as described for the genus and as given in Table 2, with the following additional characteristics. Cells occur singly or in pairs and have rounded ends. Vacuoles are often present, particularly in broth media containing a fermentable carbohydrate. Surface colonies on blood agar are 1–3 mm in diameter, circular, entire, low convex, and translucent to semi-opaque. They often have an internal structure of concentric rings when reviewed by obliquely transmitted light. In general, strains produce no hemolysis on blood agar, although a few strains may be slightly hemolytic, particularly in the area of confluent growth. Growth is often enhanced by 20% bile. Growth may occur at 25 or 45°C. Most strains grow at pH 8.5, but they grow more slowly and less luxuriantly than at pH 7.0. Cells can survive exposure to air for at least 6–8 h. Hemin is either required for growth or markedly stimulates growth. The major fatty acids are C_{15:0} anteiso, C_{15:0} iso, C_{17:0} iso 3-OH, and C_{16:0}. Strains have been isolated from various types of human clinical specimens or conditions including appendicitis, peritonitis, endocarditis, bacteremia, perirectal abscess, infected pilonidal cyst, postsurgical wound infections, and lesions of the urogenital tract; occasionally isolated from the mouth and vagina. It is the major obligately anaerobic, Gram-stain-negative bacterium isolated from various infections.

Although *Bacteroides fragilis* strains show little phenotypic variability, the species comprises genetically heterogeneous strains (Johnson, 1978). A DNA–DNA hybridization study

by Johnson and Ault (1978) led to the distinction of two DNA homology groups, I and II, with about 80% of strains isolated in clinical studies assigned to homology group I. Similarly, two genotypically distinct *Bacteroides fragilis* groups have been identified on the basis of ribotyping, restriction fragment length polymorphism analysis, PCR-generated fingerprinting, insertion sequence content, 16S rRNA gene sequence alignments, multilocus enzyme electrophoresis, and genetic marker sequence analysis (Gutacker et al., 2000, 2002). One group is characterized by the presence of the *cfiA* gene (encoding a metallo-β-lactamase of Ambler's class B) and the absence of the *cepA* gene (encoding a β-lactamase of Ambler's class A). The second group is characterized by the absence of the *cfiA* gene and of the associated insertion sequences, the frequent presence of the *cepA* gene, and a higher genetic heterogeneity (Podglajen et al., 1995; Ruimy et al., 1996). By including strains obtained from Johnson (1978) in their 16S rRNA gene sequence comparison, Ruimy et al. (1996) showed that the two groups described above could be related to DNA homology groups II and I, respectively. However, data obtained so far are still insufficient to clarify definitively whether the two groups may be considered as two distinct genospecies that have diverged recently, or if they represent two *Bacteroides fragilis* groups not yet separated at the species level, but evolving in this direction.

Putative virulence factors of *Bacteroides fragilis* include attachment mechanisms, relative aerotolerance, extracellular enzyme production, and resistance to complement-mediated killing and phagocytosis. A polysaccharide capsule contributes to this resistance and resistance to T-cell activity (Patrick, 2002). An enterotoxin termed *Bacteroides fragilis* toxin, or BFT, is a recognized virulence factor. BFT has been characterized as a 20-kDa zinc-dependent metalloprotease (Moncrief et al., 1995) that mediates the cleavage of E-cadherin, resulting in an altered morphology of certain human intestinal carcinoma cell lines (particularly

HT29/C1cells), fluid accumulation in ligated lamb ileal loops, and intestinal epithelial cell proliferation. It has been reported that the *bft* gene is contained in a 6-kb pathogenicity island termed the *Bacteroides fragilis* pathogenicity island or BfPAI (Franco et al., 1999).

The genomes of the *Bacteroides fragilis* type strain, NCTC 9343^T, and a clinical strain, YCH46, have been sequenced. The genome of *Bacteroides fragilis* NCTC 9343^T contains a single circular chromosome of 5,205,140 bp that is predicted to encode 4274 genes and a plasmid, pBF9343. It shows considerable variation, even within the same strain, and “invertible promoters” appear to regulate much of this variance in many surface-exposed and secreted proteins (Cerdeno-Tarraga et al., 2005). The complete genome sequence has revealed an unusual breadth (in number and in effect) of DNA inversion events that potentially control expression of many different components, including surface and secreted components, regulatory molecules, and restriction-modification proteins. This may be related to its niche as a commensal and opportunistic pathogen, because the resulting diversity in surface structures could increase both immune evasion and the ability to colonize novel sites.

Source: human clinical specimens.

DNA G+C content (mol%): 41–44 (HPLC).

Type strain: ATCC 25285, CCUG 4856, CIP 77.16, DSM 2151, JCM 11019, LMG 10263, NCTC 9343.

Sequence accession no. (16S rRNA gene): AB050106, X83935, M11656; genome sequences of strain NCTC 9343^T, NC_003228, CR626927; genome sequences of strain YCH46, NC_006347, AP006841.

2. ***Bacteroides acidifaciens*** Miyamoto and Itoh 2000, 148^{VP}
a.ci.di'fa.ci.ens. N.L. n. *acidum* (from L. adj. *acidus* sour) acid; L. v. *facio* produce; N.L. part. adj. *acidifaciens* acid-producing.

Characteristics are as described for the genus and as given in Table 2, with the following additional characteristics. After 48 h incubation, surface colonies on EG agar (Mitsuoka et al., 1965) are 1–3 mm in diameter, circular, entire, raised, convex, smooth, and grayish. The specific character of this species is reduction of the pH of pre-reduced anaerobically sterilized peptone-yeast extract (PY) broth with Fildes' digest (PYF) (Fildes et al., 1936) broth without carbohydrate.

Source: mouse cecum.

DNA G+C content (mol%): 39.4–42.4 (HPLC).

Type strain: strain A40, JCM 10556.

Sequence accession no. (16S rRNA gene): AB021164.

3. ***Bacteroides caccae*** Johnson, Moore and Moore 1986, 499^{VP}
cac'cae. Gr. n. *kakkê* feces; N.L. gen. n. *caccae* of feces, referring to the source of isolate.

Characteristics are as described for the genus and as given in Table 2, with the following additional characteristics. Cells of the type strain from peptone-yeast-glucose (PYG) broth cultures occur singly or in pairs; cells may appear vacuolated or beaded in strains from broth cultures in media with a fermentable carbohydrate. Surface colonies on supplemented brain heart infusion (BHI) blood

agar plates (Jousimies-Somer et al., 2002) incubated for 48 h are 0.5–1 mm in diameter, circular, entire, convex, gray, translucent, shiny, and smooth. Rabbit blood may be slightly hemolyzed. Strains grow equally well at 30 and 37°C, but less well at 25 and 45°C. The type strain reduces neutral red and does not produce H₂S. Pyruvate is converted to acetate. Lactate and threonine are not utilized. The major fatty acids are C_{15:0} anteiso, C_{15:0} iso, C_{17:0} iso 3-OH, and C_{16:0}.

Source: human feces and blood.

DNA G+C content (mol%): 40–42 (HPLC).

Type strain: ATCC 43185, CCUG 38735, CIP 104201, JCM 9498, NCTC 13051, VPI 3452A.

Sequence accession no. (16S rRNA gene): X83951.

Additional remarks: Previously referred to as “3542A” DNA homology group (Johnson, 1978; Johnson and Ault, 1978).

4. ***Bacteroides coprocola*** Kitahara, Sakamoto, Ike, Sakata and Benno 2005, 2146^{VP}

co.pro.co'la. Gr. n. *kopros* feces; L. suff. *-cola* (from L. n. *incola*) inhabitant; N.L. n. *coprocola* inhabitant of feces.

Characteristics are as described for the genus and as given in Table 2, with the following additional characteristics. Surface colonies on EG blood agar incubated for 48 h are 1.0 to approximately 3.0 mm in diameter, disc shaped, and grayish white. The major fatty acids are C_{15:0} anteiso, C_{16:0} 3-OH, C_{16:0}, C_{17:0} iso 3-OH, and C_{18:1} ω9c.

Source: feces of healthy humans.

DNA G+C content (mol%): 42.4 (HPLC).

Type strain: strain M16, DSM 17136, JCM 12979.

Sequence accession no. (16S rRNA gene): AB200224.

5. ***Bacteroides coprosuis*** Whitehead, Cotta, Collins, Falsen and Lawson 2005, 2517^{VP}

co.pro.su'is. Gr. n. *kopros* feces; L. gen. n. *suis* of a pig; N.L. gen. n. *coprosuis* of pig feces, from which the organism was isolated.

Characteristics are as described for the genus and as given in Table 2, with the following additional characteristics. Cells usually occur singly, but occasionally in pairs in PYG. Colonies grown on BHI agar plates after 48 h incubation are cream-colored, circular, convex, entire, opaque, and reach a diameter of 1 mm. Strains grow at 25–37°C, but not at 42 or 45°C, with an optimum of 37°C. The major fatty acids are C_{15:0} anteiso and C_{17:0} iso 3-OH. Significant amounts of C_{17:0} iso and C_{15:0} iso are also present.

Source: swine feces.

DNA G+C content (mol%): 36.4 (HPLC).

Type strain: PC139, CCUG 50528, NRRL B-41113.

Sequence accession no. (16S rRNA gene): AJ514258, AF319778.

6. ***Bacteroides distasonis*** Eggerth and Gagnon 1933, 403^{AL} [*Ristella distasonis* (Eggerth and Gagnon 1933) Prévot 1938, 291; *Bacteroides fragilis* subsp. *distasonis* (Eggerth and Gagnon 1933) Holdeman and Moore 1970, 35]

dis.ta.so'nis. N.L. gen. masc. n. *distasonis* of Distaso, named after A. Distaso, a Romanian bacteriologist.

Characteristics are as described for the genus and as given in Table 2, with the following additional characteristics.

In PYG, cells usually occur singly, but occasionally in pairs. Colonies on sheep-blood agar are pinpoint to 0.5 mm in diameter, circular, entire, convex, translucent to opaque, gray-white, soft, smooth, and α -hemolytic (sheep blood). Hemin is required or is highly stimulatory for growth. Resazurin, but not neutral red, is reduced. Propionate is not formed from lactate or threonine. Neither pyruvate nor gluconate is converted to products other than those found after growth in PY. The major fatty acids are C_{15:0} anteiso, C_{15:0} iso, C_{17:0} iso 3-OH, and C_{16:0}. Isolated primarily from human feces, where it is one of the most common species; also isolated from human clinical specimens.

This species has been recently reclassified as *Parabacteroides distasonis* Sakamoto and Benno (2006); see *Taxonomic comments*, above).

Source: human feces, human clinical specimens.

DNA G+C content (mol %): 43–45 (HPLC).

Type strain: ATCC 8503, CCUG 4941, CIP 104284, DSM 20701, JCM 5825, NCTC 11152.

Sequence accession no. (16S rRNA gene): M86695.

7. **Bacteroides dorei** Bakir, Sakamoto, Kitahara, Matsumoto and Benno 2006c, 1642^{VP}

do.re'i. N.L. gen. masc. n. *dorei* of Doré, in honor of the French microbiologist Joel Doré, in recognition of his many contributions to intestinal (gut) microbiology.

Cells are Gram-stain-negative rods, anaerobic, nonmotile, and non-spore-forming. Typical cells are 1.6–4.2 × 0.8–1.2 µm and occur singly. Colonies on EG agar plates after 48 h incubation at 37°C under 100% CO₂ are circular, whitish, raised, and convex, and attain a diameter of 2.0 mm. Optimum temperature for growth is 37°C. Growth occurs in the presence of bile. Esculin is not hydrolyzed. Nitrate is not reduced. No activity is detected for urease and gelatin. Acid is produced from glucose, sucrose, xylose, rhamnose, lactose, maltose, arabinose, mannose, and raffinose. Acid is not produced from cellobiose, salicin, trehalose, mannitol, glycerol, melezitose, or sorbitol. Positive reactions are obtained using API rapid ID 32A for α -fucosidase, α -galactosidase, β -galactosidase, 6-phospho- β -galactosidase, α -glucosidase, β -glucosidase, α -arabinosidase, β -glucuronidase, *N*-acetyl- β -glucosaminidase, glutamic acid, decarboxylase, alkaline phosphatase, arginine arylamidase, leucyl glycine arylamidase, phenylalanine arylamidase, leucine arylamidase, tyrosine arylamidase, alanine arylamidase, glycine arylamidase, histidine arylamidase, glutamyl glutamic acid arylamidase, and serine arylamidase. Negative reactions are obtained for arginine dihydrolase, and proline arylamidase. Major fatty acids are C_{15:0} anteiso (26–32%), C_{17:0} iso 3-OH (17–19%) and C_{18:1} ω 9c (9–12%).

Source: human feces.

DNA G+C content (mol %): 43 (HPLC).

Type strain: 175, JCM 13471, DSM 17855 [strain 219 (JCM 13472) is included in this species].

Sequence accession no. (16S rRNA gene): AB242142.

8. **Bacteroides eggerthii** Holdeman and Moore 1974, 260^{AL}

eg.gerth'i.i. N.L. gen. masc. n. *eggerthii* of Eggerth, named after Arnold H. Eggerth, an American bacteriologist.

Characteristics are as described for the genus and as given in Table 2, with the following additional characteristics. In PYG broth, cells are pleomorphic rods, ranging from coccoid to large rods with vacuoles or swellings, occurring singly or in pairs. Colonies on blood agar are punctiform, circular, entire convex, translucent, gray-white, shiny, smooth, and nonhemolytic. Hemin markedly stimulates growth, but is not required. Without hemin, malate and lactate are produced; with hemin, succinate and acetate are produced. Vitamin B₁₂ is required for production of propionate from succinate. The optimum temperature for growth is 37°C. There is good growth at 30 and 45°C, moderate growth at 25°C. Neutral red is reduced. The major fatty acids are C_{15:0} anteiso, C_{15:0} iso, C_{17:0} iso 3-OH, and C_{16:0}.

Source: human feces and occasionally from clinical specimens.

DNA G+C content (mol %): 44–46 (HPLC).

Type strain: ATCC 27754, CCUG 9559, CIP 104285, DSM 20697, NCTC 11155.

Sequence accession no. (16S rRNA gene): AB050107, L16485.

9. **Bacteroides finegoldii** Bakir, Kitahara, Sakamoto, Matsumoto and Benno 2006b, 934^{VP}

fine.gold'i.i. N.L. gen. masc. n. *finegoldii* of Finegold, in honor of Sydney M. Finegold, a contemporary researcher in anaerobic bacteriology and infectious diseases.

Characteristics are as described for the genus and as given in Table 2, with the following additional characteristics. Cells occur singly. Surface colonies on EG blood agar plates after 48 h are 1–2 mm in diameter, circular, translucent-whitish, raised, and convex. The major fatty acids are C_{15:0} anteiso and C_{17:0} iso 3-OH.

Source: feces of healthy humans.

DNA G+C content (mol %): 42.4–43 (HPLC).

Type strain: strain 199, JCM 13345, DSM 17565.

Sequence accession no. (16S rRNA gene): AB222699.

10. **Bacteroides goldsteinii** Song, Liu, Lee, Bolanos, Vaisanen and Finegold 2006, 499^{VP} (Effective publication: Song, Liu, Lee, Bolanos, Vaisanen and Finegold 2005a, 4526.)

gold.stein'i.i. N.L. gen. masc. n. *goldsteinii* of Goldstein, in honor of an infectious disease clinician who has done much work with anaerobes, Ellie J.C. Goldstein.

Characteristics are as described for the genus and as given in Table 2, with the following additional characteristics. Cells occur singly, occasionally in pairs. Colonies on Brucella blood agar plates at 48 h are gray, circular, convex, entire, opaque, and attain a diameter of 1–2 mm. The major fatty acids are C_{15:0} anteiso and C_{17:0} iso 3-OH. Significant amounts of C_{18:1} ω 9c and C_{17:0} anteiso 3-OH are also present. Habitat is probably the human gut.

This species has been recently reclassified as *Parabacteroides goldsteinii* (Sakamoto and Benno, 2006; see *Taxonomic comments*, above).

Source: human clinical specimens of intestinal origin.

DNA G+C content (mol %): 43 (HPLC).

Type strain: WAL 12034, CCUG 48944, ATCC BAA-1180.

Sequence accession no. (16S rRNA gene): AY974070.

11. **Bacteroides helcogenes** Benno, Watabe and Mitsuoka 1983a, 896^{VP} (Effective publication: Benno, Watabe and Mitsuoka 1983b, 404.)

hel.co.ge'nes. Gr. n. *helkos* abscess; N.L. suff. *-genes* (from Gr. v. *gennaō* to produce), producing; N.L. adj. *helcogenes* abscess-producing.

Characteristics are as described for the genus and as given in Table 2, with the following additional characteristics. Cells are single or in pairs. After 48 h of incubation on EG agar, surface colonies are 1.0–2.0 mm in diameter, circular with entire edges, convex, translucent to opaque, gray to gray-white, shiny, and smooth. Most strains do not grow in peptone-yeast-Fildes-glucose (PYFG) broth containing 20% bile. The major fatty acids are C_{15:0} anteiso and C_{17:0} iso 3-OH.

Source: swine abscesses and feces.

DNA G+C content (mol%): 45.3–46.3 (HPLC).

Type strain: strain P 36-108, ATCC 35417, CCUG 15421, DSM 20613, JCM 6297.

Sequence accession no. (16S rRNA gene): AB200227.

12. **Bacteroides intestinalis** Bakir, Kitahara, Sakamoto, Matsumoto and Benno 2006a, 153^{VP}

in.tes.ti.na'lis. L. n. *intestinum* gut, intestine; L. masc. suff. *-alis* suffix denoting pertaining to; N.L. masc. adj. *intestinalis* pertaining to the intestine.

Characteristics are as described for the genus and as given in Table 2, with the following additional characteristics. Cells occur singly. Surface colonies on EG blood agar plates after 2 d are 1–3 mm in diameter, circular, translucent-whitish, raised, and convex. The major fatty acids are C_{15:0} anteiso and C_{17:0} iso 3-OH.

Source: feces of healthy humans.

DNA G+C content (mol%): 44 (HPLC).

Type strain: strain 341, DSM 17393, JCM 13265.

Sequence accession no. (16S rRNA gene): AB214328.

13. **Bacteroides massiliensis** Fenner, Roux, Mallet and Raoult 2005, 55^{VP}

mas.si'li.en.sis. L. masc. adj. *massiliensis* of Massilia, the ancient Roman name for Marseille, France, where the type strain was isolated.

Characteristics are as described for the genus and as given in Table 2, with the following additional characteristics. Cells usually occur singly. Surface colonies on sheep blood agar plates after 2 d are 1–2 mm in diameter, circular, white-grayish, translucent, raised, and convex. No hemolysis on sheep blood agar. Optimum growth temperature is 37°C, but growth is observed at 25–42°C. The major fatty acid is C_{15:0} anteiso.

Source: human blood culture.

DNA G+C content (mol%): 49 (HPLC).

Type strain: strain B84634, CCUG 48901, CIP 107942, JCM 13223.

Sequence accession no. (16S rRNA gene): AY126616, AB200226.

14. **Bacteroides merdae** Johnson, Moore and Moore 1986, 499^{VP}

mer'dae. L. gen. n. *merdae* of feces, referring to the source of the isolate.

Characteristics are as described for the genus and as given in Table 2, with the following additional characteristics. Cells occur singly or in pairs or short chains. Surface colonies on BHI blood agar plates supplemented with vitamin K and hemin are 0.5–1.0 mm in diameter, circular to slightly irregular, entire, convex, white, shiny, and smooth. Rabbit blood is slightly hemolyzed. The type strain reduces neutral red and resazurin and produces hydrogen sulfide after incubation for 5 d. Pyruvate is converted to acetate and propionate. Lactate, threonine, and gluconate are not utilized. The major fatty acids are C_{15:0} anteiso, C_{15:0} iso, C_{17:0} iso 3-OH, and C_{16:0}.

This species has been recently reclassified as *Parabacteroides merdae* (Sakamoto and Benno, 2006; see *Taxonomic comments*, above).

Source: human feces and occasionally clinical specimens.

DNA G+C content (mol%): 43–46 (HPLC).

Type strain: strain ATCC 43184, CCUG 38734, CIP 104202, JCM 9497, NCTC 13052, VPI T4-1.

Sequence accession no. (16S rRNA gene): AY169416, X83954, U50416.

Additional remarks: Previously referred to as “T4-1” DNA homology group (Johnson, 1978; Johnson and Ault, 1978).

15. **Bacteroides nordii** Song, Liu, McTeague and Finegold 2005b, 983^{VP} (Effective publication: Song, Liu, McTeague and Finegold 2004, 5569.)

nor.di.i. N.L. gen. masc. n. *nordii* of Nord, to honor Carl Erik Nord, who has contributed much to our knowledge of anaerobic bacteriology and intestinal bacteriology.

Characteristics are as described for the genus and as given in Table 2, with the following additional characteristics. Cells occur singly or in pairs. Colonies on Brucella blood agar plates at 48 h are gray, circular, convex, entire, opaque, and attain a diameter of 1–2 mm. The major fatty acids are C_{15:0} anteiso, C_{15:0} iso, C_{16:0} 3-OH, and C_{18:1} ω9c. Probably of intestinal origin.

Source: clinical sources such as peritoneal fluid, appendix tissue, and intra-abdominal abscesses.

DNA G+C content (mol%): 41.4 (HPLC).

Type strain: strain WAL 11050, ATCC BAA-998, CCUG 48943.

Sequence accession no. (16S rRNA gene): AY608697.

16. **Bacteroides ovatus** Eggerth and Gagnon 1933, 405^{AL} [*Pasteurella ovata* Eggerth and Gagnon 1933] Prévot 1938, 292; *Bacteroides fragilis* subsp. *ovatus* (Eggerth and Gagnon 1933) Holdeman and Moore 1970, 35]

o.va'tus. L. masc. adj. *ovatus* ovate, egg-shaped (relating to the cellular shape).

Characteristics are as described for the genus and as given in Table 2, with the following additional characteristics. Cells are oval, occurring singly, but occasionally in pairs. Capsules are detected in some strains. Surface colonies on blood agar are 0.5–1.0 mm, circular, entire, convex, pale buff, semi-opaque, and may have a mottled appearance. There is no hemolysis of sheep blood. Hemin is required or is highly stimulatory for growth. The major fatty acids are C_{15:0} anteiso, C_{17:0} iso 3-OH, C_{18:1} ω9c, and C_{15:0} iso.

Source: human feces and occasionally human clinical specimens.

DNA G+C content (mol%): 39–43 (HPLC).

Type strain: ATCC 8483, BCRC 10623, CCUG 4943, CIP 103756, DSM 1896, JCM 5824, NCTC 11153.

Sequence accession no. (16S rRNA gene): AB050108, L16484, X83952.

17. **Bacteroides plebeius** Kitahara, Sakamoto, Ike, Sakata and Benno 2005, 2146^{VP}

ple.bei'us. L. masc. adj. *plebeius* common, of low class.

Characteristics are as described for the genus and as given in Table 2, with the following additional characteristics. Colonies grown on EG blood agar plates are 1–3 mm in diameter, disc-shaped, grayish-white, and translucent. The major fatty acids are C_{15:0} anteiso, C_{17:0} iso 3-OH, C_{16:0} 3-OH, C_{18:1} ω9c, and C_{16:0}.

Source: feces of healthy humans.

DNA G+C content (mol%): 42.4–43.9 (HPLC).

Type strain: strain M12, DSM 17135, JCM 12973.

Sequence accession no. (16S rRNA gene): AB200217–AB200222.

18. **Bacteroides pyogenes** Benno, Watabe and Mitsuoka 1983a, 896^{VP} (Effective publication: Benno, Watabe and Mitsuoka 1983b, 402.)

py.o'ge.nes. Gr. n. *pyum* pus; N.L. suff. *-genes* (from Gr. v. *genao* to produce) producing; N.L. adj. *pyogenes* pus-producing.

Characteristics are as described for the genus and as given in Table 2, with the following additional characteristics. Cells occur singly or occasionally in pairs with longer rods. After 2 d of incubation on EG agar, surface colonies are 0.5–1.5 mm in diameter, circular with entire edges, low convex, translucent to opaque, cream to light gray, shiny, and smooth. Usually, no hemolysis occurs on blood agar. Strains do not grow well in PYFG–20% bile broth. Some strains hydrolyze esculin.

Source: swine abscess and feces.

DNA G+C content (mol%): 46.1–47.6 (HPLC).

Type strain: strain P 39-88, ATCC 35418, CCUG 15419, DSM 20611, JCM 6294.

Sequence accession no. (16S rRNA gene): AB200229.

19. **Bacteroides salyersiae** corrig. Song, Liu, McTeague and Finegold 2005b, 983^{VP} (Effective publication: Song, Liu, McTeague and Finegold 2004, 5569.) [*Bacteroides salyersae* (sic) Song, Liu, McTeague and Finegold 2004, 5569]

sal'yer.si.ae. N.L. gen. fem. n. *salyersiae* of Salyers, named after Abigail Salyers, an American bacteriologist who has contributed so much to our knowledge of intestinal bacteriology and anaerobic bacteriology in general.

Characteristics are as described for the genus and as given in Table 2, with the following additional characteristics. Cells occur singly, occasionally in pairs. Colonies on Brucella blood agar plates at 24 h are gray, circular, convex, entire, opaque, and attain a diameter of 1–2 mm. The major fatty acids are C_{15:0} anteiso, C_{15:0} iso, C_{16:0} 3-OH, C_{16:0}, and C_{18:1} ω9c. Probably of intestinal origin.

Source: clinical sources such as peritoneal fluid, appendix tissue, and intra-abdominal abscesses.

DNA G+C content (mol%): 42.0 (HPLC).

Type strain: strain WAL 10018, ATCC BAA-997, CCUG 48945.

Sequence accession no. (16S rRNA gene): AY608696.

20. **Bacteroides stercoris** Johnson, Moore and Moore 1986, 501^{VP} ster'co.ris. L. n. *stercus* feces; L. gen. n. *stercoris* of feces, referring to source of isolate.

Characteristics are as described for the genus and as given in Table 2, with the following additional characteristics. Cells occur singly and in pairs. Vacuolated cells are seen sometimes in cultures in broths that contain a fermentable carbohydrate. Surface colonies on supplemented BHI blood agar with rabbit blood are 0.5–1.0 mm in diameter, circular, entire, convex, transparent to translucent, shiny, smooth, and β-hemolytic. Resazurin is reduced, neutral red is not reduced. Pyruvate is converted to acetate. Lactate, threonine, and gluconate are not used. The major fatty acids are C_{15:0} anteiso, C_{15:0} iso, C_{17:0} iso 3-OH, and C_{16:0}.

Source: human feces and occasionally human clinical specimens.

DNA G+C content (mol%): 43–47 (HPLC).

Type strain: ATCC 43183, CCUG 38733, CIP 104203, JCM 9496, NCTC 13053, VPI B5-21.

Sequence accession no. (16S rRNA gene): X83953, U50417.

Additional remarks: previously referred to as the “subsp. a” DNA homology group (Johnson, 1978; Johnson and Ault, 1978).

21. **Bacteroides suis** Benno, Watabe and Mitsuoka 1983a, 896^{VP} (Effective publication: Benno, Watabe and Mitsuoka 1983b, 403.)

su'is. L. n. *sus* swine; L. gen. n. *suis* of the pig.

Characteristics are as described for the genus and as given in Table 2, with the following additional characteristics. Cells are short rods, single or in pairs; longer rods occur only occasionally. After 2 d of incubation on EG agar, surface colonies are 0.5–1.5 mm in diameter, circular with entire edge, low convex, translucent to opaque, gray to gray-white, shiny, and smooth. Slight greening or indefinite hemolysis often apparent on blood agar plates. Either no growth or markedly inhibited and delayed growth occurs in PYFG broth containing 20% bile.

Source: swine abscess and feces.

DNA G+C content (mol%): 42.3–45.7 (HPLC).

Type strain: P 38024, ATCC 35419, DSM 20612, CCUG 15420, JCM 6292.

Sequence accession no. (16S rRNA gene): DQ497991.

22. **Bacteroides tectus** corrig. Love, Johnson, Jones, Bailey and Calverley 1986, 126^{VP} [*Bacteroides tectum* (sic) Love, Johnson, Jones, Bailey and Calverley 1986, 126]

tec'tus. L. masc. adj. *tectus* (from L. v. *tego*) secret, concealed, hidden, referring to difficulty in species identification.

Characteristics are as described for the genus and as given in Table 2, with the following additional characteristics. Cells occur singly, in pairs, and in short chains. On sheep blood agar, surface colonies after 48 h are 2–3 mm in diameter, circular, entire, dome shaped, grayish, and opaque.

Source: subcutaneous fight wound abscesses from cats and dogs, pyothorax of cats, and mouths of normal cats.

DNA G+C content (mol%): 47–48 (HPLC).

Type strain: strain 160, ATCC 43331, CCUG 25929, JCM 10003, NCTC 11853.

Sequence accession no. (16S rRNA gene): AB200228.

23. **Bacteroides thetaiotaomicron** (Distaso 1912) Castellani and Chalmers 1919, 960^{AL} [*Bacillus thetaiotaomicron* Distaso 1912, 444; *Sphaerocillus thetaiotaomicron* (Distaso 1912) Prévot 1938, 300; *Bacteroides fragilis* subsp. *thetaitaomicron* (Distaso 1912) Holdeman and Moore 1970, 35]

the.ta.i.o.ta.o'mi.cron. N.L. n. *thetaitaomicron* a combination of the Greek letters *theta*, *iota* and *omicron* (relating to the morphology of vacuolated forms).

Characteristics are as described for the genus and as given in Table 2, with the following additional characteristics. Cells are pleomorphic and occur singly or in pairs. Cells from blood agar plates or PY broth are smaller and more homogeneous in size and shape than cells from media with a fermentable carbohydrate. Capsules are present in some strains. Surface colonies on blood agar are punctiform, circular, entire, convex, semiopaque, whitish, soft, and shiny. Sheep blood is not hemolyzed. Hemin is either required or is highly stimulatory for growth. The major fatty acids are C_{15:0} anteiso, C_{17:0} iso 3-OH, C_{18:1} ω9c, and C_{16:0} 3-OH.

The genome of *Bacteroides thetaiotaomicron* VPI-5482 has been sequenced. The genome of *Bacteroides fragilis* NCTC 9343^T contains a single circular chromosome of 6,260,361 bp. The genome has large expansions of many paralogous groups of genes that encode products essential to the organism's ability to successfully compete in the human colonic microbiota. Most notable of these is the organism's abundant machinery for utilizing a large variety of complex polysaccharides as a source of carbon and energy. The proteome also reveals the organism's extensive ability to adapt and regulate expression of its genes in response to the changing ecosystem. These factors suggest a highly flexible and adaptable organism that is exquisitely equipped to dominate in its challenging and competitive niche (Xu et al., 2003).

Source: human feces, frequently found in human clinical specimens.

DNA G+C content (mol%): 40–43 (HPLC).

Type strain: ATCC 29148, CCUG 10774, CIP 104206, DSM 2079, JCM 5827, NCTC 10582, VPI 5482.

Sequence accession no. (16S rRNA gene): M58763, AB050109, L16489; genome sequence for strain VPI 5482, NC_004663, AE015928.

24. **Bacteroides uniformis** Eggerth and Gagnon 1933, 400^{AL}. u.ni.form'is. L. masc. adj. *uniformis* having only one form, uniform.

Characteristics are as described for the genus and as given in Table 2, with the following additional characteristics. Cells occur singly or in pairs; an occasional filament may be seen. Vacuoles that do not greatly swell the cell are often present in cells grown in media containing a fermentable carbohydrate. Surface colonies on blood agar are 0.5–2.0 mm in diameter, circular, entire, low convex, gray-to-white, and translucent to slightly opaque. There usually is no hemolysis of blood agar, but some strains may produce a slight greening of the agar. The optimum temperature for growth is 35–37°C. Growth may occur at 25 or 45°C. The major fatty acids are C_{15:0} anteiso, C_{15:0} iso, C_{17:0} iso 3-OH, and C_{16:0}. Strains of *Bacteroides uniformis* and *Bacteroides thetaiotaomicron* are very similar phenotypically, but they differ in their DNA G+C content and are not related by DNA–DNA hybridization analysis. In general, strains of *Bacteroides uniformis* do not grow as well in 20% bile as strains of *Bacteroides thetaiotaomicron*.

Source: part of human and swine fecal flora; also isolated from various human clinical specimens.

DNA G+C content (mol%): 45–48 (HPLC).

Type strain: ATCC 8492, CCUG 4942, CIP 103695, DSM 6597, JCM 5828, NCTC 13054.

Sequence accession no. (16S rRNA gene): L16486, AB050110.

25. **Bacteroides vulgatus** Eggerth and Gagnon 1933, 401^{AL} [*Pasteurella vulgatus* (Eggerth and Gagnon, 1933) Prévot 1938, 292; *Bacteroides fragilis* subsp. *vulgatus* (Eggerth and Gagnon 1933) Holdeman and Moore 1970, 35]

vul.ga'tus. L. masc. adj. *vulgatus* common (referring to the frequent occurrence of the species in fecal flora).

Characteristics are as described for the genus and as given in Table 2, with the following additional characteristics. Cells may be pleomorphic with swellings or vacuoles, but less so than strains of *Bacteroides fragilis*. In broth cultures, cells usually occur singly, occasionally in pairs or short chains. Capsules are detected in some strains. Surface colonies on blood agar are 1–2 mm in diameter, circular, entire, convex, and semi-opaque. Sheep blood is not hemolyzed. Hemin is required or is highly stimulatory for growth. The major fatty acids are C_{15:0} anteiso, C_{15:0} iso, C_{17:0} iso 3-OH, and C_{16:0}.

Source: human feces, occasionally isolated from human infections.

DNA G+C content (mol%): 40–42 (HPLC).

Type strain: ATCC 8482, BCRC (formerly CCRC) 12903, CCUG 4940, CIP 103714, DSM 1447, IFO (now NBRC) 14291, JCM 5826, LMG 7956, LMG 17767, NCTC 11154.

Sequence accession no. (16S rRNA gene): AJ867050, AB050111.

Species incertae sedis

1. **Bacteroides capillosus** (Tissier 1908) Kelly 1957, 433^{AL} [*Bacillus capillosus* Tissier 1908, 193; *Ristella capillosa* (Tissier 1908) Prévot 1938, 292]

ca.pil.lo'sus. L. masc. adj. *capillosus* very hairy.

Comparative 16S rRNA gene sequence analysis demonstrates that *Bacteroides capillosus* is phylogenetically far

removed from the genus *Bacteroides* and, in fact, has a closer affinity to clostridia in the *Firmicutes* and is closely related genealogically to the type strain of *Clostridium orbiscindens* in *Clostridium* cluster IV.

Cells are straight or curved rods, 0.7–1.1 × 1.6–7.0 μm, occurring singly, in pairs, or in short chains after 24 h incubation in

glucose broth. Vacuoles, swellings, and filaments with tapered ends are observed. Surface colonies are minute to 1 mm, circular, entire, convex, translucent, and smooth. Growth of most strains is enhanced by hemin, rumen fluid, or Tween 80. Strains are generally nonfermentative unless Tween 80 is added to the medium, in which case they may be slightly fermentative. Good growth occurs at 37 and 45°C, slight growth at 30°C, and no growth at 25°C. Other characteristics are given in Table 5.

Source: cysts and wounds, human mouth, human infant and adult feces, intestinal tracts of dogs, mice, and termites, and sewage sludge.

DNA G+C content (mol%): 60 (HPLC).

Type strain: ATCC 29799, CCUG 15402.

Sequence accession no. (16S rRNA gene): AY136666.

2. **Bacteroides cellulosolvens** Murray, Sowden and Colvin 1984, 186^{VP}

cell.u.lo.sol'vens. N.L. n. *cellulosum* cellulose; L. v. *solvere* to dissolve; N.L. part. adj. *cellulosolvens* cellulose dissolving, so named because of its ability to ferment cellulosic substrates.

Comparative 16S rRNA gene sequence analysis has demonstrated that *Bacteroides cellulosolvens* is phylogenetically far removed from the genus *Bacteroides* and, in fact, has a closer affinity to the clostridia of the *Firmicutes* and is closely related genealogically to the type strain of *Acetivibrio cellulolyticus* in *Clostridium* cluster III (Lin et al., 1994).

Cells are straight, rod-shaped, approximately 0.8 × 6 µm, and occur singly. They are nonmotile and no flagella are detected by staining or electron microscopy. Non-spore-forming. Bright

^b*Bacteroides ureolyticus* is not included because it was described under the genus *Campylobacter* in *Bergey's Manual of Systematic Bacteriology*, 2nd edition, vol. 2, part C.

^cEnd products from glucose fermentation unless indicated.

^dEnd products from cellobiose fermentation.

^eEnd products from polygalacturonate or pectin.

yellow, circular, convex colonies with rough margins are produced on cellobiose agar. Colonies reach a maximum diameter of 1.0–1.25 mm after 5 d of growth at 35°C. On Solka Floc agar, colonies reach their maximum size after 10 d of growth and show zones of cellulose clearing around the periphery of the colonies and in the agar below. Anaerobic medium is required for growth. Of the substrates tested, only cellulose and cellobiose support growth. The addition of bile (2% oxgall) to cellobiose broth inhibits growth, whereas Tween 80, hemin, and vitamins B₁₂ and K₁ have no effect. Other characteristics are given in Table 5.

Source: sewage sludge (type strain).

DNA G+C content (mol%): 43 (HPLC).

Type strain: WM2, ATCC 35603, DSM 2933, NRCC 2944.

Sequence accession no. (16S rRNA gene): L35517.

3. **Bacteroides coagulans** Eggerth and Gagnon 1933, 409^{AL} [*Pasteurella coagulans* (Eggerth and Gagnon 1933) Prévot 1938, 292]

co.a'gu.lans. L. part. adj. *coagulans* curdling, coagulating (milk).

Cells of the type strain are small ovoid rods, 0.6 × 0.8–2.0 μm, occurring singly, in pairs, or in short chains. Surface colonies on horse blood agar are punctate, circular, entire, slightly raised, translucent, and nonhemolytic. Glucose broth cultures are only slightly turbid; no acid is produced. Growth is inhibited by Tween 80. Grows poorly, if at all, at 25 and 45°C; does not grow at pH 8.5. Other characteristics are given in Table 5.

Source: human feces, urogenital tract, and occasionally from human clinical specimens.

DNA G+C content (mol%): 37 (HPLC).

Type strain: ATCC 29798, DSM 20705, JCM 12528, LMG 8206.

Sequence accession no. (16S rRNA gene): DQ497990.

4. **Bacteroides galacturonicus** Jensen and Canale-Parola 1987, 179^{VP} (Effective publication: Jensen and Canale-Parola 1986, 886.)

ga.lac.tu.ro'ni.cus. N.L. n. *acidum galacturonicum* galacturonic acid; L. masc. suff. *-icus* suffix of various meanings, but signifying in general made of or belonging to; N.L. masc. adj. *galacturonicus* pertaining to galacturonate, with reference to the ability to ferment this compound or polygalacturonate.

Cells grown in broth containing polygalacturonate as the fermentable substrate (PF broth; Jensen and Canale-Parola, 1986) are rod-shaped, 0.6 × 3.5–6 μm, arranged singly or in pairs, and rarely in short chains. Cells up to 12 μm in length are present in cultures. Non-spore-forming, Gram-stain-negative. Six to eight peritrichous flagella per cell are present; however, motility has not been observed under the culture conditions used. Surface colonies on PF agar are white with a tan tinge, irregularly shaped with uneven margins, flat, opaque, rough, and measure 4–5 mm in diameter. Optimal growth is between 35 and 40°C, with no growth at 20 or 45°C. Obligate anaerobe. Pectin, polygalacturonate, D-galacturonate, and D-glucuronate are fermented. Folic acid, pantothenic acid, and biotin are required as growth factors. Neither hemin nor vitamin K is required for growth. Other characteristics are given in Table 5.

Source: human feces.

DNA G+C content (mol%): 36 (*T_m*).

Type strain: strain N6, ATCC 43244, DSM 3978.

Sequence accession no. (16S rRNA gene): DQ497994.

5. **Bacteroides pectinophilus** Jensen and Canale-Parola 1987, 179^{VP} (Effective publication: Jensen and Canale-Parola 1986, 886.)

pec.ti.no'phil.us. N.L. n. *pectinum* pectin; Gr. adj. *philos* loving; N.L. masc. adj. *philus* loving; N.L. masc. adj. *pectinophilus* pectin-loving.

Cells grown in PF broth are rod-shaped, 0.5 × 2.5–5.0 μm, arranged singly or in pairs, and rarely in short chains. Non-spore-forming, Gram-stain-negative, nonmotile. Surface colonies on PF agar are cream, circular, flat, opaque, smooth, and measure 2–3 mm in diameter. Optimal growth is between 35 and 40°C, with no growth at 20 or 45°C. Obligate anaerobe. Pectin, polygalacturonate, D-galacturonate, and D-glucuronate are fermented. Other characteristics are given in Table 5.

Source: human feces.

DNA G+C content (mol%): 45 (*T_m*).

Type strain: strain N3, ATCC 43243.

Sequence accession no. (16S rRNA gene): DQ497993.

6. **Bacteroides polypragmatus** Patel and Breuil 1982, 266^{VP} (Effective publication: Patel and Breuil 1981, 292.)

po.ly.prag'ma.tus. Gr. *polypragmâtos* busy about many things; N.L. masc. adj. *polypragmatus* versatile, reflecting its activity on many carbohydrates.

Cells from Syt broth (Patel and Breuil, 1981) are 0.5–1.0 × 3–5 μm and have pointed ends. Most of the cells are single or in pairs and a few longer chains (50 μm) are also present. Young cells (18 h) exhibit motility and electron microscopic observation indicates the presence of peritrichous flagella. Staining cells with aqueous nigrosin dye demonstrates the presence of capsular material. Surface colonies are glistening, cream, have serrated margins, and are 2–3 mm in diameter after 1 week of incubation. Saccharoclastic. Grows between pH 5.6 and 9.2 and at temperatures ranging from 10 to 43°C. Optimum growth is at pH 7.0–7.8 and 30–35°C. The presence of vitamin K, hemin, or Tween 80 does not affect growth. Tests for acetylmethylcarbinol, ammonia, nitrate reduction, and digestion of gelatin, milk and meat are negative. Major fermentation products are CO₂, H₂, ethanol, and acetic acid. Other characteristics are given in Table 5.

Source: sewage sludge.

DNA G+C content (mol%): 61 (*T_m*).

Type strain: strain GP4, NRC 2288.

Sequence accession no. (16S rRNA gene): none available.

7. **Bacteroides splanchnicus** Werner, Rintelen and Kunstek-Santos 1975, 133^{AL}

splanchn'ni.cus. Gr. pl. n. *splanchna* the “innards”; L. masc. suff. *-icus*, suffix used with the sense of pertaining to; N.L. masc. adj. *splanchnicus* pertaining to the internal organs (referring to the source of isolation).

Phylogenetic analysis of *Bacteroides splanchnicus* based on 16S rRNA gene sequences indicates that *Bacteroides splanchnicus* branches off separately from the three major

clusters mentioned previously, but belongs within the *Bacteroides* subgroup of the CFB phylum (Paster et al., 1994). It most likely represents a novel genus.

Cells from glucose broth are 0.7×1.0 – $5.0 \mu\text{m}$. Colonies on anaerobic blood agar are punctiform to 1 mm in diameter, circular to slightly irregular, entire, convex, translucent, opalescent to yellowish, smooth, and shiny. Hemin is highly stimulatory, but not required. Without hemin, malate, acetate, and hydrogen are produced; with hemin, succinate, acetate, butyrate, and decreased amounts of hydrogen are produced. The presence of vitamin B₁₂ results in propionate production from succinate and decreased butyrate production. Cells contain sphingolipids. Other characteristics are given in Table 5.

Source: human feces and vagina and occasionally from intra-abdominal infections.

DNA G+C content (mol%): not reported.

Type strain: ATCC 29572, CCUG 21054, CIP 104287, DSM 20712, LMG 8202, NCTC 10825.

Sequence accession no. (16S rRNA gene): L16496.

8. ***Bacteroides xylanolyticus*** Scholten-Koerselman, Houwaard, Janssen and Zehnder 1988, 136^{VP} (Effective publication: Scholten-Koerselman, Houwaard, Janssen and Zehnder 1986, 543.) *xylan.o.lyt'i.cus*. N.L. neut. n. *xylanum* xylan; Gr. masc. adj. *lutikos* able to loose, able to dissolve; N.L. masc. adj. *xylanolyticus* xylan-dissolving.

An anaerobic non-spore-forming, Gram-stain-negative rod that is motile with peritrichous flagella. This organism ferments xylan and many soluble sugars (glucose, cellobiose, mannose, xylose, and arabinose). Other hemicelluloses such as gum xanthan, laminaran, locust bean gum, and gum arabic are not utilized. Does not use cellulose. Fermentation products are carbon dioxide, hydrogen, acetate, and ethanol. Produces carboxymethyl cellulase and xylanase, especially when growing on xylan. Growth is optimal between 25 and 40°C and between pH 6.5 and 7.5.

DNA G+C content (mol%): 34.8 ± 0.8 (UV absorbance-temperature profile).

Type strain: strain X5-1, DSM 3808.

Sequence accession no. (16S rRNA gene): none available.

Genus II. *Acetofilamentum* Dietrich, Weiss, Fiedler and Winter 1989, 93^{VP} (Effective publication: Dietrich, Weiss, Fiedler and Winter 1988b, 273.)

THE EDITORIAL BOARD

A.ce'to.fil.a.men'tum. L. n. *acetum* vinegar; L. neut. n. *filamentum* a spun thread; N.L. neut. n. *Acetofilamentum* an acetate-producing, filamentous, threadlike bacterium.

Straight rods. Single cells are 0.18–0.3 μm \times 2–8 μm . Filaments of more than 100 μm in length may be formed. Gram-stain-negative. Nonsporeforming. **Nonmotile.** Temperature range, 25–40°C; optimum, 35–38°C. pH range, 6.5–9.0; optimum, 7.3–8.0. **Yeast extract is required.** Chemo-organotrophic. **Anaerobic, having a strictly fermentative type of metabolism. Hexoses are fermented by glycolysis to acetate and H₂ (in a molar ratio of 1:2) and CO₂.** Isolated from sewage sludge fermenters.

DNA G+C content (mol%): ~47 (*T_m*).

Type species: Acetofilamentum rigidum Dietrich, Weiss, Fiedler and Winter 1989, 93^{VP} (Effective publication: Dietrich, Weiss, Fiedler and Winter 1988b, 273.).

Further descriptive information

The straight, stiff filaments return to the straight form after being bent. In the filaments, a spacerlike septum is formed, reminiscent of the spacers found in the filaments of *Methanobacterium hungatei*.

The cell-wall peptidoglycan contains ornithine as the diamino acid, unlike most other Gram-stain-negative bacteria, which usually contain diaminopimelic acid. A glycine bridge occurs between the ornithine on one peptide chain and the D-alanine on another. The peptidoglycan structure may be a variation of the A β type described by Schleifer and Kandler (1972).

Small, round, whitish to transparent colonies with a smooth surface are formed on agar media.

H₂ and acetate production is directly proportional to the concentration of yeast extract present, up to 0.4%. Increasing H₂ partial pressures inhibit growth, but elevated acetate concentrations do not affect growth.

Carbon sources include glucose, fructose, galactose, ribose, arginine, and alanine. Scant growth occurs on glycine. The following carbon sources are not used: cellulose, starch, glycogen, maltose, sucrose, mannose, xylose, mannitol, glutamate, glycerol, formate, methanol, and phenol.

Enrichment and isolation procedures

For isolation, serially diluted samples of secondary sewage sludge are inoculated onto solidified Medium 1* supplemented with 10% raw sewage sludge supernatant fluid (sterilized by filtration) and incubated under N₂/CO₂ (80:20%, 300 kPa) at 37°C. Colonies of other organisms appear after 2 weeks, but colonies of *Acetofilamentum rigidum* have a diameter <1 mm and develop after 4 weeks of incubation. When subcultured into serum bottles containing liquid Medium 1, the organisms form a cotton-like growth at the bottom after 6 weeks. Pure cultures of these filamentous organisms are obtained by repeated streaking onto solidified Medium 1.

Substrate specificity is tested by omitting glucose from Medium 1 and adding other potential carbon sources from sterile stock solutions.

*Medium 1 (Dietrich et al., 1988b) consists of the following ingredients (g/l): K₂HPO₄, 0.255; KH₂PO₄, 0.255; (NH₄)₂SO₄, 0.255; NaCl, 0.5; MgSO₄·7H₂O, 0.1; CaCl₂·2H₂O, 0.07; yeast extract, 2; peptone, 2; glucose, 2; FeSO₄·7H₂O, 0.002; NaHCO₃, 6; vitamin solution (Wolin et al., 1963), 10 ml; trace mineral solution (Wolin et al., 1963), 10 ml. After boiling under N₂, 0.1 mg resazurin and 50 ml of a reducing agent (containing 2 g NaOH, 0.62 g Na₂S·9H₂O, and 0.62 g cysteine-HCl) are added per liter of medium. The media are dispensed in 10- or 20-ml portions into 25-ml serum tubes or 120-ml serum bottles in an anaerobic chamber, sealed with a butyl rubber stopper and aluminum cap, gassed with 300 kPa N₂/CO₂ (80:20%), H₂/CO₂ (80:20%), or with N₂, and autoclaved. A solidified medium 1 is obtained by addition of agar (20 g/l); the medium is dispensed into Petri dishes in an anaerobic chamber.

Taxonomic comments

The taxonomic placement of *Acetofilamentum* as a member of the family *Bacteroidaceae* is uncertain because of the lack of rRNA gene sequence data.

Differentiation of the genus *Acetofilamentum* from other genera

Characteristics differentiating the genus *Acetofilamentum* from other genera are listed in Table 6.

TABLE 6. Characteristics differentiating the genus *Acetofilamentum* from other genera^a

^bExcept in the absence of Vitamin B₁₂, when filaments up to 50 µm long may be formed.

List of species of the genus *Acetofilamentum*

1. ***Acetofilamentum rigidum*** Dietrich, Weiss, Fiedler and Winter 1989, 93^{VP} (Effective publication: Dietrich, Weiss, Fiedler and Winter 1988b, 273.)

ri'gi.dum. L. neut. adj. *rigidum* stiff.

The characteristics are as described for the genus and as listed in Table 6.

DNA G+C content (mol%): ~47 (*T_m*).

Type strain: MN, DSM 20769.

Genus III. ***Acetomicrobium*** Soutschek, Winter, Schindler and Kandler 1985, 223^{VP}
(Effective publication: Soutschek, Winter, Schindler and Kandler 1984, 388.)

THE EDITORIAL BOARD

A.ce'to.mi.cro'bi.um. L. n. *acetum* vinegar; Gr. adj. *mikros* small; Gr. n. *bios* life; N.L. neut. n. *microbium* a small living being, a microbe; N.L. neut. n. *Acetomicrobium* a microorganism producing acetic acid.

Straight tapered rods, 0.6–0.8 × 2–7 µm, occurring mostly in pairs or short chains. Gram-stain-negative. Nonsporeforming. The murein contains *meso*-diaminopimelic acid. **Motile by means of a single subpolar flagellum or a few lateral flagella.** Optimum temperature, 58–73°C. pH range for growth, 6.2–8.0. Catalase-negative. Cytochromes are not present. Chemoorganotrophic. **Anaerobic, having a strictly fermentative type of metabolism.** One species ferments glucose to

acetate, CO₂, and H₂; the other ferments glucose to acetate, lactate, ethanol, CO₂, and H₂. One species ferments pentoses. Good growth depends on the presence of yeast extract or peptone and carbohydrate. Isolated from sewage sludge.

DNA G+C content (mol%): 45–47.

Type species: ***Acetomicrobium flavidum*** Soutschek, Winter, Schindler and Kandler 1985, 223^{VP} (Effective publication: Soutschek, Winter, Schindler and Kandler 1984, 388.).

Further descriptive information

Colonies on solidified RCM medium* are 3–4 mm in diameter, convex, smooth, yellowish, circular, with an entire margin.

The peptidoglycan contains *meso*-diaminopimelic acid and is of the m-A₂mp direct type, variation Al_γ, as designated by the nomenclature of Schleifer and Kandler (1972).

Acetomicrobium flavidum ferments glucose by glycolysis to acetate, CO₂, and H₂ in a 1:1:2 ratio. No ethanol is formed. *Acetomicrobium faecale* ferments glucose by glycolysis to acetate, lactate, ethanol, CO₂, and H₂.

Small amounts of volatile acids, e.g., propionic acid, are only formed from complex substrates, e.g., yeast extract and peptone.

Enrichment and isolation procedures

Acetomicrobium flavidum was isolated from sludge samples that were diluted anaerobically in growth vials containing 10 ml of RCM. The diluted samples were streaked onto RCA plates in the anaerobic chamber and incubated anaerobically. After repeated plating, single colonies were transferred into Medium 1.[†] Cultures were incubated without shaking at 58°C.

For isolation of *Acetomicrobium faecale*, 400 ml of mesophilically digested sewage sludge and 50 ml of fresh sewage sludge were incubated at 72°C. Then 50 ml portions of digested sludge were replaced daily for 10 d by fresh sewage sludge. The sludge

addition was later replaced by the continuous addition of sterile culture medium[‡] containing 5 g/l glucose. After 4 weeks of continuous operation, samples were plated and, after incubation, single colonies were picked from the agar plates in an anaerobic chamber.

Taxonomic comments

No significant DNA–DNA hybridization occurs between *Acetomicrobium* and *Acetothermus* (Dietrich et al., 1988c). *Acetomicrobium faecale* exhibits a DNA–DNA hybridization value of 64% with *Acetomicrobium flavidum*, indicating that the two species belong in the same genus (Dietrich et al., 1988c).

The taxonomic placement of *Acetomicrobium* as a member of the family *Bacteroidaceae* is not certain because of the lack of rRNA gene sequence data.

Differentiation of the genus *Acetomicrobium* from other genera

Characteristics differentiating *Acetomicrobium* from *Acetofilamentum*, *Acetothermus*, and *Acetivibrio* are listed in Table 6 in the chapter on *Acetofilamentum*.

Differentiation of species of the genus *Acetomicrobium*

Table 7 lists the differential features of the species of *Acetomicrobium*.

List of species of the genus *Acetomicrobium*

1. ***Acetomicrobium flavidum*** Soutschek, Winter, Schindler and Kandler 1985, 223^{VP} (Effective publication: Soutschek, Winter, Schindler and Kandler 1984, 388.)

fla'vi.dum. L. neut. adj. *flavidum* yellowish.

The characteristics are as described for the genus and as listed in Table 7. Glucose, fructose, maltose, cellobiose, glycerol, and starch are fermented. Sucrose, melibiose, mannose, ribose, arabinose, xylose, sorbitol, and mannitol are not fermented.

Source: a thermophilic (60°C) sewage sludge fermentor.

DNA G+C content (mol%): 47 (*T_m*).

Type strain: TN, ATCC 43122, DSM 20664, LMG 6941.

Sequence accession no.: not reported.

2. ***Acetomicrobium faecale*** corrig. Winter, Braun and Zabel 1988, 136^{VP} (Effective publication: Winter, Braun and Zabel 1987, 75.)

fae.ca'le. L. n. *faex faecis* dregs, faeces; L. neut. suff. *-ale* suffix denoting pertaining to; N.L. neut. adj. *faecale* pertaining to

faeces, fecal. (Note: the original specific epithet *faecalis* was corrected to *faecale* by Euzéby (1998).)

The characteristics are as described for the genus and as listed in Table 7. Motile by means of 1 or 2 lateral flagella. Growth occurs best at temperatures 70–73°C and at a pH of 6.5–7.0. Colonies are whitish to translucent, 1–2 mm in diameter, convex, and round with an entire edge. Yeast extract is required for growth. Increasing the NaCl concentration from 0 to 3% causes a decrease in growth; no growth occurs with 4% NaCl. Unlike *Acetomicrobium flavidum*, *Acetomicrobium faecale* ferments pentoses. Carbohydrates used for growth include arabinose, xylose, ribose, fructose, glucose, galactose, mannose, maltose, rhamnose, sucrose, lactose, cellobiose, melibiose, and salicin. Sorbitol, starch, xylan, mannitol, glycogen, glycerol, and cellulose are not used.

Source: a thermophilic (70°C) continuous culture initially inoculated with sewage sludge.

DNA G+C content (mol%): 45 (*T_m*).

Type strain: DSM 20678.

Sequence accession no.: not reported.

*RCM medium contains the following ingredients (g/l of distilled water): yeast extract, 3; meat extract, 10; peptone from casein, 10; sodium acetate, 3; NaCl, 5; glucose, 5; starch, 1; resazurin, 0.001; cysteine–HCl, 0.25; sodium sulfide, 0.25; and NaOH, 0.66. Agar (20 g) was added for a solid medium. For primary isolation, the supernatant solution of centrifuged digested sludge is used instead of distilled water to prepare the medium. The final pH is adjusted to 7 under an N₂ atmosphere.

[†]Medium 1 contains (per liter of distilled water): K₂HPO₄, 0.255 g; KH₂PO₄, 0.255 g; (NH₄)₂SO₄, 0.255 g; NaCl, 0.5 g; MgSO₄·7H₂O, 0.1 g; CaCl₂·2H₂O, 0.07 g; yeast extract, 10 g; FeSO₄·7H₂O, 1 mg; resazurin, 0.5 mg; NaHCO₃, 6 g; cysteine–HCl, 0.625 g; Na₂S·9H₂O, 0.625 g; glucose, 0.15 g; vitamin solution (Wolin et al., 1963), 10 ml; and mineral solution (Wolin et al., 1963), 10 ml.

[‡]Medium for isolation of *Acetomicrobium faecale* contained (per liter): K₂HPO₄, 0.255 g; KH₂PO₄, 0.255 g; (NH₄)₂SO₄, 0.255 g; NaCl, 0.5 g; MgSO₄·7H₂O, 0.1 g; CaCl₂·2H₂O, 0.07 g; yeast extract, 2 g; trypticase, 2 g; sodium acetate, 5 g; FeSO₄·7H₂O, 2 mg; vitamin solution (Wolin et al., 1963), 10 ml; trace mineral solution (Wolin et al., 1963), 10 ml; and NaHCO₃, 6 g. After boiling under nitrogen, 0.1 mg resazurin and 50 ml of reducing agent containing 2 g NaOH, 0.62 g Na₂S·9H₂O, and 0.62 g cysteine–HCl were added. The reduced medium was dispensed and autoclaved under anaerobic conditions.

TABLE 7. Characteristics differentiating species of the genus *Acetomicrobium*^a

Characteristic	<i>A. faecale</i>	<i>A. flavidum</i>

(Effective publication: Dietrich, Weiss and Winter 1988c, 179.)

THE EDITORIAL BOARD

A.ce'to.ther'mus. L.n. *acetum* vinegar; Gr. adj. *thermos* hot; N.L. masc. n. *Acetothermus* a thermophilic microorganism producing acetic acid.

Straight rods 0.5 × 5–8 µm, occurring singly or in pairs. Gram-stain-negative. Nonsporeforming. **Nonmotile.**

Chemoorganotrophic. **Anaerobic, having a strictly fermentative type of metabolism. Optimum temperature, 58°C;** no growth occurs below 50°C or above 60°C. Optimum pH, 7–8. Yeast extract, peptone, and **vitamin B₁₂** are required. **Only glucose and fructose are used as energy sources. Glucose is fermented by glycolysis to acetate, CO₂, and H₂ in a molar ratio of 1:1:2.** Increasing H₂ partial pressures inhibit growth, but elevated acetate concentrations do not affect growth. Isolated from thermophilically fermenting sewage sludge.

DNA G+ C content (mol%): ~62.

Type species: Acetothermus paucivorans Dietrich, Weiss and Winter 1988a, 328^{VP} (Effective publication: Dietrich, Weiss and Winter 1988c, 179.).

Further descriptive information

In the absence of vitamin B₁₂ the organisms form long filaments 0.5 µm in diameter and up to 50 µm long. Optimal growth occurs in a medium containing 0.2% yeast extract and 0.2% peptone. Growth is directly proportional to the concentration of vitamin B₁₂ up to 1 µg/l. NaCl is not required; >1 g/l is inhibitory.

The cell-wall peptidoglycan contains ornithine as the diamino acid, unlike most other Gram-stain-negative bacteria, which usually contain diaminopimelic acid as the diamino acid. The peptidoglycan structure corresponds to the directly cross-linked A1β type described by Schleifer and Kandler (1972).

Glucose and fructose are used as energy sources. The following carbon sources are not used: arabinose, mannose, ribose, xylose, galactose, mannitol, sorbitol, sucrose, maltose, lactose, melibiose, raffinose, starch, cellulose, glycerol, Casamino acids, meat extract, glycogen, pyruvate, glycine, alanine, glutamate, formate, and methanol.

Enrichment and isolation procedures

Enrichment and isolation procedures from sewage sludge digesting at 60°C were done using the medium described for isolation of *Acetomicrobium faecale* (see footnote in the chapter on *Acetomicrobium* for formula) modified by the omission of acetate.

Taxonomic comments

No significant DNA–DNA hybridization occurs between *Acetothermus* and *Acetomicrobium* (Dietrich et al., 1988c). The taxonomic placement of *Acetothermus* as a member of the family *Bacteroidaceae* is not certain because of the lack of rRNA gene sequence data.

Differentiation of the genus *Acetothermus* from other genera

Characteristics differentiating *Acetothermus* from *Acetofilamentum*, *Acetivibrio*, and *Acetomicrobium* are listed in Table 6 in the chapter on *Acetofilamentum*.

List of species of the genus *Acetothermus*

1. ***Acetothermus paucivorans*** Dietrich, Weiss and Winter 1988a, 328^{VP} (Effective publication: Dietrich, Weiss and Winter 1988c, 179.)

pau.ci.vo'rans. L. masc. adj. *paucus* few, little; L. v. *vorare* to eat, swallow; L. part. adj. *vorans* eating, swallowing; N.L. part. adj. *paucivorans* utilizing only a very restricted number of the supplied substrates.

The characteristics are as described for the genus.
Source: thermophilically fermenting sewage sludge.
DNA G+C content (mol%): 62 (*T_m*).
Type strain: TN, DSM 20768. (Note: this strain is no longer listed in the DSMZ catalog.)
Sequence accession no.: not reported.

Genus V. **Anaerorhabdus** Shah and Collins 1986, 573^{VP} (Effective publication: Shah and Collins 1986, 86.)

HAROUN N. SHAH

An.ae.ro.rhab'dus. Gr. pref. *an* not; Gr. n. *aer* air: *anaero* (not living) in air; Gr. fem. n. *rhabdos* rod; N.L. fem. n. *Anaerorhabdus* rod-shaped bacterium not living in air.

Short rods. Nonspore-forming. Nonmotile. Gram-negative. Anaerobic. **Nonsaccharolytic**, although a few carbohydrates may be fermented weakly. Acetic and lactic acids are the major metabolic end products in peptone-yeast extract-glucose broth (PYG). **Glucose-6-phosphate dehydrogenase is produced, but 6-phosphogluconate dehydrogenase, malate dehydrogenase, and glutamate dehydrogenase are absent. Sphingolipids and menaquinones are not produced.** The nonhydroxylated long-chain fatty acids are primarily of the straight-chain saturated and **monounsaturated types. Methyl branched fatty acids are either absent or present in small amounts.** Isolated from infected appendix, lung abscesses, and abdominal abscesses. Infrequently isolated from human and pig feces.

DNA G+C content (mol%): 34.

Type species: Anaerorhabdus furcosa (Veillon and Zuber 1898) Shah and Collins 1986, 573^{VP} [Effective publication: *Anaerorhabdus furcosus* (*sic*) (Veillon and Zuber 1898) Shah and Collins 1986, 86.] [*Bacillus furcosus* Veillon and Zuber 1898, 541; *Fusififormis furcosus* (Veillon and Zuber 1898) Topley and Wilson 1929, 302; *Bacteroides furcosus* (Veillon and Zuber 1898) Hauduroy, Ehringer, Urbain, Guillot and Magrou 1937, 61^{AL}; *Ristella furcosa* (Veillon and Zuber 1898) Prévot 1938, 291].

Enrichment and isolation procedures

Anaerorhabdus isolates grow on blood agar producing small colonies (0.5 mm in diameter) but is improved by culturing on fastidious anaerobic agar. Growth is improved by the addition of rumen fluid.

Differentiation of the genus *Anaerorhabdus* from other genera

Anaerorhabdus differs from *Bacteroides fragilis* and related species in having a significantly lower DNA base composition, in being nonfermentative or weakly fermentative, and in lacking 6-phosphogluconate dehydrogenase, malate dehydrogenase, and glutamate dehydrogenase. *Anaerorhabdus* primarily synthesizes fatty acids of the straight-chain saturated and monounsaturated type, and methyl-branched acids are present in only small amounts. In contrast, the fatty acids of *Bacteroides fragilis* and related species are mainly of the straight-chain saturated, *anteiso*-, and *iso*-methyl branched chain types, with monounsaturated acids either absent or present in only trace amounts. Moreover, *Anaerorhabdus* lacks menaquinones and sphingolipids, whereas *Bacteroides fragilis* and related species synthesize menaquinones and sphingolipids.

List of species of the genus *Anaerorhabdus*

1. ***Anaerorhabdus furcosa*** (Veillon and Zuber 1898) Shah and Collins 1986, 573 [Effective publication: *Anaerorhabdus furcosus* (*sic*) (Veillon and Zuber 1898) Shah and Collins 1986, 86.] [*Bacillus furcosus* Veillon and Zuber 1898, 541; *Fusififormis furcosus* (Veillon and Zuber 1898) Topley and Wilson 1929, 302; *Bacteroides furcosus* (Veillon and Zuber 1898) Hauduroy, Ehringer, Urbain, Guillot and Magrou 1937, 61^{AL}; *Ristella furcosa* (Veillon and Zuber 1898) Prévot 1938, 291].

fur.co'sa. L. fem. adj. *furcosa* forked (pertaining to cell shape). (Note: the original epithet *furcosus* was corrected by Euzéby and Boemare, 2000.)

The description is the one given for the genus, plus the following additional features. Pleomorphic rods, 0.3–1.5 × 1–3 µm, occurring singly, in pairs, or short chains. Some cells appear to be forked or Y-shaped. Colonies on blood agar are 0.5 mm in diameter, circular, entire, low convex, translucent, colorless to gray, smooth, and shiny. Glucose

broth cultures are turbid with smooth sediment; growth is stimulated by rumen fluid. Optimum growth temperature, 30–37°C; slight growth occurs at 25°C but none at 45°C. Acetic and lactic acids are the major metabolic end products in PYG broth; trace amounts of formic and succinic acids may also be produced. Most strains hydrolyze esculin. Phosphate positive. Indole, acetylmethylcarbinol, urease, and H₂S are not produced. Gelatin liquefaction is usually negative although a few strains may be weakly positive. Starch and hippurate are not hydrolyzed. Nitrate is not reduced.

The cell walls do not contain diaminopimelic acid, heptose, or ketodeoxyoctonic acid (KDO). Non-hydroxylated long chain fatty acids are primarily of the straight-chain saturated and mono-unsaturated types with hexadecanoic, octadecanoic, and octadecenoic acids predominating.

DNA G+C content (mol%): 34 (*T_m*).

Type strain: ATCC 25662, VPI 3253.

Sequence accession no. (16S rRNA gene): none available.

Family II. **Marinilabiliaceae** fam. nov.

WOLFGANG LUDWIG, JEAN EUZÉBY AND WILLIAM B. WHITMAN

Ma.ri.ni.la.bi.li.a.ce'ae. N.L. fem. n. *Marinilabilia* type genus of the family; suff. *-aceae* ending to denote family; N.L. fem. pl. n. *Marinilabiliaceae* the *Marinilabilia* family.

The family *Marinilabiliaceae* was circumscribed for this volume on the basis of phylogenetic analysis of 16S rRNA gene sequences and includes the type genus *Marinilabilia*, *Alkaliflexus*, and *Anaerophaga*. All genera are composed of **slender, flexible rods**. Except for *Anaerophaga*, which does not grow on

solid surfaces in culture, cells are **motile by gliding**. Cells **stain Gram-negative**. **Saccharolytic** and **require NaCl** for growth. Some characteristics that differentiate the three genera are given in Table 8.

Type genus: Marinilabilia Nakagawa and Yamasato 1996, 600^{VP}.

TABLE 8. Some characteristics that differentiate the genera of the family *Marinilabiliaceae*^a

Characteristic	<i>Marinilabilia</i>	<i>Alkaliflexus</i>	<i>Anaerophaga</i>
Motile by gliding	+	+	nt
Can grow aerobically	+	-	-
Major products of glucose fermentation	Acetate, succinate, propionate, lactate, formate and H ₂	Propionate, acetate, succinate and formate	Propionate, acetate, and succinate
Growth above 50°C	-	-	+
Isolated from	Marine mud containing decayed algae	Mud from an alkaline soda lake	Oil contaminated sediment in an oil separation tank
DNA G+C content (mol%)	37–41	44	41

^ant, Not tested.

Genus I. **Marinilabilia** Nakagawa and Yamasato 1996, 600^{VP}

MAKOTO SUZUKI

Ma.ri.ni.la.bil'i.a. L. adj. *marinus* marine, pertaining to the sea; L. adj. *labilis* gliding; N.L. fem. n. *Marinilabilia* marine gliding organisms.

Short to very long flexible rods, 0.3–0.5 × 2–50 µm. Resting stage is absent. **Motile by gliding.** **Gram-negative.** Colonies are pink to salmon in color. **Chemo-organotrophic. Facultatively anaerobic**, having both respiratory and fermentative types of metabolism. Catalase-positive. Decompose several kinds of biomacromolecules. **Marine organisms** requiring elevated salt concentrations. Optimum temperature: 28–37°C. Optimum pH: around 7. The major polyamine is spermidine. **The major respiratory quinone is MK-7.**

DNA G+C content (mol%): 41 (HPLC).

Type species: Marinilabilia salmonicolor (Veldkamp 1961) Nakagawa and Yamasato 1996, 600^{VP} emend. Suzuki, Nakagawa, Harayama and Yamamoto 1999, 1555 (*Cytophaga salmonicolor* Veldkamp 1961, 339).

Further descriptive information

Phylogenetic analysis based on 16S rRNA gene sequences indicates that the genus *Marinilabilia* belongs to the family "*Marinilabiliaceae*". The phylogenetic relationships of the genus *Marinilabilia* and related organisms are shown in Figure 15. The nearest neighbor is the genus *Anaerophaga* and the similarities between the species of *Marinilabilia* and *Anaerophaga* are 90.3–92.4%. Two misclassified facultatively anaerobic *Cytophaga* species, *Cytophaga fermentans* and *Cytophaga xylanolytica*, are more distantly related to members of the genus *Marinilabilia*. There is 86.8–89.6% similarity between these two organisms and members of the genus *Marinilabilia*.

Cells of *Marinilabilia salmonicolor* are slender rods with rounded or slightly tapered ends. They are extremely flexible and motile

by gliding. The cells usually vary from 2 to 30 µm in length, but occasionally, very long elements of up to 50 µm long can be seen. These long cells occur even in young cultures and often show flexing and gliding movements. The mean length of cells grown aerobically on agar plates is usually greater than that of cells from stab or anaerobic liquid cultures. In the stationary phase, spherical cells are always found. They vary in diameter from 1.0 to 3.5 µm.

Spermidine is the dominant cellular polyamine when cells are cultivated in marine broth (Hosoya and Hamana, 2004).

Strains of the genus *Marinilabilia* can grow well anaerobically in glucose-mineral medium supplemented with a vitamin mixture (Veldkamp, 1961). Under anaerobic conditions, growth is poor when bicarbonate is omitted from the medium. Under aerobic conditions, *Marinilabilia* strains can grow well when the medium contains 0.1% (w/v) yeast extract, corn steep liquor, or nutrient broth.

Products of fermentation are acetic acid, succinic acid, propionic acid, lactic acid, formic acid, CO₂, H₂, and trace amounts of ethanol (Veldkamp, 1961).

Marinilabilia strains inhabit coastal marine sediments. They have been isolated from marine mud containing decayed algae. One biovar can actively degrade agar.

Enrichment and isolation procedures

Organisms of this group have been recognized as incidentally occurring organisms in enrichment cultures of green sulfur bacteria (Veldkamp, 1961). They were originally enriched by using anaerobic cultures in which agar was the carbon and

energy source. The anaerobic enrichment cultures were incubated in the dark at 30°C for 3–5 d. Anaerobic plate cultures were used for the isolation of these organisms. The medium used for these cultures contained (in g/l): NaCl, 30; KH₂PO₄, 1; NH₄Cl, 1; MgCl₂·6H₂O, 0.5; CaCl₂, 0.04; NaHCO₃, 5; Na₂S·9H₂O, 0.1; ferric citrate, 0.03; agar, 5; yeast extract, 0.3; pH 7. The medium was supplemented with a trace element mixture (Veldkamp, 1961).

Maintenance procedures

Cultures are maintained as paraffin-covered stab cultures at 4°C; transfers are made monthly. Cultures can be kept in broth containing 10% glycerol at –80°C or in the gas phase of liquid nitrogen. They can be preserved by a liquid-drying method using 75% bovine serum in marine broth as a protective reagent.

Differentiation of the genus *Marinilabilia* from other genera

Marinilabilia can be differentiated from related organisms by its relation to oxygen, salt requirement, some physiological characteristics, and cell mass color. Differential features are given in Table 9.

FIGURE 15. 16S rRNA gene sequence-based phylogenetic tree of the genus *Marinilabilia* and related organisms. The tree was constructed by the neighbor-joining method. The numbers at nodes show the percentage bootstrap value of 500 replicates. Bar = evolutionary distance of 0.02 (K_{muc}).

Marinilabilia can be differentiated from *Anaerophaga*, *Alkaliflexus*, *Alistipes*, and *Rikenella* by its relation to oxygen. It can also be differentiated from *Cytophaga fermentans* by its cell mass color and from *Cytophaga xylanolytica* by its salt requirement.

Taxonomic comments

There are two known isolates of the genus *Marinilabilia*. Strain NBRC 15948^T (=ATCC 19041^T), the type strain of *Marinilabilia salmonicolor*, was isolated from marine mud off the coast of California. The second strain, NBRC 14957 (=ATCC 19043), which was isolated from the same environment, has the same characteristics as the type strain and, in addition, is able to degrade agar. These two strains were originally reported as *Cytophaga salmonicolor* and “*Cytophaga salmonicolor* var. *agarovorans*” by Veldkamp (1961). Reichenbach (1989) described *Cytophaga agarovorans* to accommodate “*Cytophaga salmonicolor* var. *agarovorans*”, based on its remarkable agar-degrading ability and higher DNA G+C content. Later, Nakagawa and Yamasato (1996) included these two organisms in the genus *Marinilabilia* as *Marinilabilia salmonicolor* and *Marinilabilia agarovorans*. Phylogenetic analysis of these two organisms using 16S rRNA gene and *gyrB* sequences indicated their close relatedness (Nakagawa and Yamasato, 1996; Suzuki et al., 1999). In particular, the *gyrB* sequences of strains NBRC 15948^T and NBRC 14957 are identical, as determined for a 1.2 kb region. DNA–DNA hybridization also confirmed their close relatedness: over 70% DNA relatedness was found between the two strains (Suzuki et al., 1999). Reichenbach (1989) stated that there was a small percentage difference in the G+C content of the DNA between *Marinilabilia agarovorans* and *Marinilabilia salmonicolor*, namely, 41 vs. 37 mol%, respectively (buoyant density method). A second determination of the G+C content of *Marinilabilia* strains was performed by the HPLC method (Suzuki et al., 1999) and indicated that the G+C content was almost the same for the two strains; by this method,

TABLE 9. Differential characteristics of *Marinilabilia* and related organisms^a

Characteristic	<i>Marinilabilia</i>	<i>Anaerophaga</i>	<i>Alkaliflexus</i>	<i>Cytophaga fermentans</i>	<i>Cytophaga xylanolytica</i>	<i>Alistipes</i>	<i>Rikenella</i>
Cell size, μm	0.3–0.5 × 2–20	0.3 × 4–8	0.3–0.4 × 4–10	0.5–0.7 × 2–10	0.4 × 3–24	0.3–0.5 × 0.9–3.0	0.2–0.3 × 0.3–1.5
Gliding motility	+	–	+	+	+	–	–
Cell mass color	Pink to salmon	Orange to red	Pink	Yellow	Orange to salmon	Gray, brown to black	Gray
<i>Relation to oxygen</i>							
Facultative anaerobe	+	–	–	+	–	–	–
Strict anaerobe	–	+	+	–	–	+	+
Aerotolerant anaerobe	–	–	–	–	+	–	–
Catalase	+	–	+	+	w	trace	nd
Salt requirement	+	+	+	+	–	nd	–
DNA G+C content (mol%)	37–41	42	44	39	46	55–58	60–61

^aSymbols: +, >85% positive; –, 0–15% positive; w, weak reaction; nd, not determined.

the DNA G+C contents of strains NBRC 14957 (*Marinilabilia agarovorans*) and NBRC 15948^T (*Marinilabilia salmonicolor*) were 41.2 and 41.5 mol%, respectively. All of the above information indicates that these two strains belong to a single species. Since *Marinilabilia salmonicolor* was first described as *Cytophaga salmon-*

icolor, *Marinilabilia salmonicolor* is a senior subjective synonym of *Marinilabilia agarovorans*. However, the agar-degrading ability of strain NBRC 14957 is a prominent biochemical characteristic; therefore, this strain is considered as *Marinilabilia salmonicolor* biovar *Agarovorans*.

List of species of the genus *Marinilabilia*

1. ***Marinilabilia salmonicolor*** (Veldkamp 1961) Nakagawa and Yamasato 1996, 600^{VP} emend. Suzuki, Nakagawa, Harayama and Yamamoto 1999, 1555 (*Cytophaga salmonicolor* Veldkamp 1961, 339)

sal.mo.ni'co.lor. L. masc. n. *salmo* -onis salmon; L. masc. n. *color* color; N.L. adj. *salmonicolor* intended to mean salmon-colored.

Slender flexible cylindrical rods with rounded or slightly tapering end, 0.3–0.5 × 2–50 μm, usually around 10–20 μm in length. Resting stages are not observed. Motile by gliding. Gram-negative. The color of the cell mass is salmon to pink. Chemo-organotrophic. Facultative anaerobe. Good growth is obtained in a normal aerobic atmosphere. Marine strains require elevated salt concentrations. Peptones, Casamino

acids, yeast extract, ammonium, and nitrate are suitable nitrogen sources. Arabinose, xylose, glucose, galactose, mannose, fructose, sucrose, lactose, maltose, cellobiose, trehalose, raffinose, inulin, and starch are fermented. Gelatin is liquefied slowly. Catalase is produced. The optimum temperature is 28–37°C. The optimum pH is around 7. The major respiratory quinone is MK-7. The major polyamine is spermidine.

Source: marine mud containing decayed algae.

DNA G+C content (mol%): 41.2–41.5 (HPLC).

Type strain: ATCC 19041, CIP 104809, DSM 6480, LMG 1346, NBRC 15948.

Note: strain NBRC 14957 can degrade agar and is biovar *Agarovorans*.

Genus II. *Anaerophaga* Denger, Warthmann, Ludwig and Schink 2002, 177^{VP}

BERNHARD SCHINK

An.a.e.ro.pha'ga. an Gr. pref. *an* not; Gr. n. *aer* *aeros* air; Gr. v. *phagein* to devour, to eat up; N.L. fem. n. *Anaerophaga* an anaerobic eater.

Slender flexible rods with rounded ends. Strictly anaerobic. Chemo-organotrophic. Nonphotosynthetic. Have a fermentative type of metabolism, using organic compounds as substrates. Inorganic electron acceptors are not used. Media containing a reductant, e.g., cysteine, are necessary for growth. Catalase-negative. Isolated from oil-contaminated sediment in an oil separation tank.

Type species: ***Anaerophaga thermohalophila*** Denger, Warthmann, Ludwig and Schink 2002, 177^{VP}.

DNA G+C content (mol%): 42.

Further descriptive information

The only described species so far is *Anaerophaga thermohalophila*. The strains Fru22^T and Glc12 were isolated as possible agents for tenside (surfactant) production in microbially improved oil recovery (MIOR). Therefore, the organism was enriched and selected under conditions of elevated temperature (50°C) and increased salinity (7.5%, w/v).

The isolated strains ferment hexoses and pentoses to equal molar amounts of acetate, propionate, and succinate (Denger and Schink, 1995; Denger et al., 2002), according to the following equations:

No CO₂ is released in this type of mixed-acid fermentation.

Upon prolonged exposure of fully grown cultures to daylight, an orange-red pigment was produced, which could be extracted from cell pellets by acetone or hexane, indicating

that it was a lipophilic component. Absorption spectra of these extracts showed maxima at 488 and 518 nm and a further shoulder around wavelength 460 nm, as is typical of carotenoids (Reichenbach et al., 1974). Carotenoids are known to be produced by several representatives of aerobic gliding bacteria, including *Flexibacter* sp., *Cytophaga* sp., and several myxobacteria (Reichenbach and Dworkin, 1981). Strain Fru22^T is the first strict anaerobe producing such pigments, although the moderately oxygen-tolerant anaerobe *Cytophaga xylanolytica* also produces carotenoids (Haack and Breznak, 1993). When pigmented cell material after centrifugation was treated with 10% KOH, the color turned dark-red to brownish, similar to the flexirubins of *Cytophaga*, *Sporocytophaga*, and *Flexibacter* spp. (Achenbach et al., 1978; Reichenbach et al., 1974).

Unfortunately, these strains do not grow on agar surfaces, even if the medium is poured and stored in an oxygen-free glove box under a N₂/CO₂ atmosphere (90/10, v/v). Thus, whether gliding motility occurs could not be determined. Spore-like structures or spheres are observed in ageing cultures.

Surface-active compounds were produced by strain Fru22^T optimally at the end of exponential growth (Denger and Schink, 1995). This tenside efficiently stabilized hexadecane/water emulsions. Production was enhanced in the presence of hexadecane, which provides a lipophilic surface in the culture. The surface-active compound(s) was associated partly with the cells and cell surfaces, but was also released into the culture medium.

Enrichment and isolation procedures

Anaerophaga thermohalophila strain Fru22^T and a similar strain, Glc12, were enriched originally from blackish-oily sedimentary residues in an oil separation tank near Hannover, Germany. The mineral salts medium for enrichment and cultivation was bicarbonate-buffered (50 mM), cysteine-reduced (1 mM), and contained, together with other minerals, 75 g of NaCl and 4.0 g of MgCl₂·7H₂O per liter (Denger and Schink, 1995). The pH was 6.7–6.8. During the enrichment, the medium received a few drops (50 µl per 25 ml of medium) of hexadecane to provide a lipophilic boundary layer. Subcultures were inoculated with oily drops from the surface of the preculture. All details concerning cultivation and physiological characterization have been described before (Denger and Schink, 1995). Growth rates and yields were best at 20–70 g of total salt per liter. At 80 g of salt per liter, growth was partly inhibited, and there was no growth at <20 g of salt per liter.

Maintenance procedures

Cultures are maintained either by repeated transfer at intervals of 2–3 months or by freezing in liquid nitrogen using techniques common for strictly anaerobic bacteria. No information exists about survival upon lyophilization.

Differentiation of the genus *Anaerophaga* from other genera

There are substantial differences between *Anaerophaga thermohalophila* strain Fru22^T, *Cytophaga fermentans*, and the described species of the genus *Marinilabilia*. First, strain Fru22 is strictly anaerobic. Moreover, the growth parameters of strain Fru22, especially its growth up to 55°C and its salt tolerance up to 12% (w/v) salt with an optimum around 6% salt, clearly separate this strain from all described *Cytophaga* and *Marinilabilia* species. So far, only few *Cytophaga* species show temperature maxima at 40–45°C (*Cytophaga aprica*, *Cytophaga lytica*) or 45°C (*Cytophaga diffluens*); all three species also tolerate NaCl concentrations up to 6%, but, unlike *Anaerophaga thermohalophila*, all are strict aerobes. *Cytophaga aprica* and *Cytophaga diffluens* have been

reclassified recently as *Flammeovirga aprica* and *Persicobacter diffluens* (Nakagawa et al., 1997).

The genus *Capnocytophaga* has been separated from other *Cytophaga* species as a genus of facultatively anaerobic bacteria that need CO₂ at enhanced concentrations for efficient growth. In addition, *Capnocytophaga* species produce acetate, propionate, and succinate during sugar fermentation; however, all have been described as facultatively aerobic organisms, whereas *Anaerophaga thermohalophila* is strictly anaerobic. Moreover, all species of *Capnocytophaga* described so far are associated with higher animals, especially the oral cavity of man (Leadbetter et al., 1979). No thermophilic or halophilic representatives of *Capnocytophaga* are known.

Taxonomic comments

As indicated by phylogenetic analysis of 16S rDNA sequences, strain Fru22^T is a member of the phylum *Bacteroidetes*, comprising *Cytophaga*, *Flavobacterium*, and *Bacteroides* as representative genera. Based on the similarities of 16S rRNA gene sequences, the closest relatives are representatives of the genus *Marinilabilia* (formerly *Cytophaga*; Suzuki et al., 1999). However, overall sequence similarities of around 91.6% indicate only a moderate relationship and justify the establishment of a new genus, *Anaerophaga*. These genera share a common origin with *Cytophaga fermentans* (Bachmann, 1955); the corresponding overall 16S rRNA gene sequence similarities are 87.9–89.1%. Strain Fru22 shares several properties with *Cytophaga* and *Marinilabilia* species, e.g., its morphology (thin, slender rods), production of a flexirubin-like pigment, and production of sphere-like structures in ageing cultures (Reichenbach, 1992; Staley et al., 1989). Moreover, the facultatively anaerobic species *Cytophaga fermentans*, *Cytophaga xylanolytica*, *Marinilabilia salmonicolor*, and *Marinilabilia agarovorans* all have been described to produce acetate together with propionate and succinate as main products of sugar fermentation (Haack and Breznak, 1993; Staley et al., 1989). The G+C content of the DNA of *Cytophaga fermentans* and *Marinilabilia* sp. is in the range of 30–42 mol%; strain Fru22 (41.8 mol%) would be at the upper limit of this range.

List of species of the genus *Anaerophaga*

1. ***Anaerophaga thermohalophila*** Denger, Warthmann, Ludwig and Schink 2002, 177^{VP}

ther.mo.ha.lo'phi.la. Gr. n. *thermê* heat; Gr. n. *hals*, *halos* salt; N.L. adj. *philus -a -um* (from Gr. adj. *philos -ê -on*) friend, loving; N.L. fem. adj. *thermohalophila* heat and salt loving.

Slender flexible rods (0.3 × 3–8 µm) with rounded ends. Formation of spheres and spore-like structures occur in ageing cultures. Strictly anaerobic. Catalase- and oxidase-negative. Cytochromes of the *b*-type present. Glucose, fructose, arabinose, xylose, cellobiose, mannose, trehalose, raffinose, galactose, starch, and lactose are used for growth. Hexoses and pentoses are fermented to equimolar amounts of acetate, propionate, and succinate. No growth occurs with ribose, sorbose, rhamnose, dulcitol, mannitol, glycerol, glycerate,

tartrate, malate, glycolate, lactate, pyruvate, succinate, fumarate, methanol, ethanol, ethylene glycol, acetoin, alanine, serine, threonine, glutamate, aspartate, proline, cellulose, arabinogalactan, chitin, yeast extract, or peptone. Growth requires media with an enhanced CO₂/bicarbonate content and salt concentrations of at least 2% (w/v). Growth occurs with 2–12% (w/v) salt (optimum, 2–6%). Growth occurs at 37–55°C (optimum, 50°C); no growth occurs at 30 and 60°C. Ageing cultures exposed to daylight form an orange-red carotenoid pigment similar to flexirubin. Habitat: anoxic subsurface sites of enhanced temperature and salt content.

Source: contaminated oil tank sediment.

DNA G+C content (mol%): 41.8 ± 0.7 (HPLC).

Type strain: Fru 22, DSM 12881, OCM 798.

Sequence accession no. (16S rRNA gene): AJ418048.

Genus III. **Alkaliflexus** Zhilina, Appel, Probian, Llobet Brossa, Harder, Widdel and Zavarzin 2005, 1395^{VP} (Effective publication: Zhilina, Appel, Probian, Llobet Brossa, Harder, Widdel and Zavarzin 2004, 251.)

THE EDITORIAL BOARD

Al.ka.li.flex'us. N.L. n. *alkali* (from Ar. *al-qalyi* the ashes of saltwort) soda ash; L. masc. part. adj. *flexus* bent; N.L. masc. n. *Alkaliflexus* referring to life in basic surroundings and to bending/flexible cells.

Thin, flexible rods with slightly tapered ends. A nonrefractile, spherical, cyst-like structure develops at one pole during late growth phase. **Gliding motility is present.** Endospores are not formed. Fruiting bodies are not formed. Gram-negative. **Anaerobic**, with low to modest tolerance to oxygen. Organisms have a strictly **fermentative** type of metabolism; exogenous electron acceptors are not used. Mesophilic. **Alkaliphilic**, grows at pH 7.5–10.2 (optimum, approx. pH 8.5). Sodium ions are required for growth (optimum, 2%; range, 0.08–5.3%). Carbonate/bicarbonate ions (but not chloride) are also required for growth. Cell mass is yellow to pink due to carotenoids. The temperature range for growth is 10–44°C (optimum, 35°C); no growth occurs at 5 or 55°C. Chemorganotrophic. Several carbohydrates are utilized, particularly those that may result from the hydrolysis of cellulose, hemicelluloses, and other natural polysaccharides. Isolated from a cellulose-degrading enrichment culture originating from an alkaline soda lake.

DNA G+C content (mol%): 43–44.

Type species: **Alkaliflexus imshenetskii** Zhilina, Appel, Probian, Llobet Brossa, Harder, Widdel and Zavarzin 2005, 1395^{VP} (Effective publication: Zhilina, Appel, Probian, Llobet Brossa, Harder, Widdel and Zavarzin 2004, 251.).

Enrichment and isolation procedures

Anaerobic cellulose-decomposing alkaliphilic communities were initially enriched in the alkaline (pH 10) soda medium described by Kevbrin et al. (1999). (Note: *Alkaliflexus* does not utilize cellulose and was probably stimulated by cellulose degradation products such as cellobiose that were produced by other bacteria.) After isolation by the methods described by Widdel and Bak (1992), cultures were propagated in the medium of Nedashkovskaya et al. (2006)*.

Differentiation of the genus *Alkaliflexus* from related genera

The adaptation to high pH (optimum, pH 8.5) is a physiological feature that distinguishes the present isolates from all *Marinilabilia*, *Cytophaga*, and *Anaerophaga* species, as well as from any hitherto known member of the phylum *Bacteroidetes*. Moreover, *Marinilabilia* and *Cytophaga* are facultative anaerobes, whereas *Alkaliflexus* is a strict anaerobe. *Anaerophaga* is catalase-negative, whereas *Alkaliflexus* is catalase-positive. Other distinguishing features have been indicated by Nedashkovskaya et al. (2006).

Taxonomic comments

Analysis of 16S rRNA gene sequences indicates that the closest phylogenetic relatives of *Alkaliflexus* are *Marinilabilia salmonicolor*, *Cytophaga fermentans*, and *Anaerophaga thermophila*.

List of species of the genus *Alkaliflexus*

1. **Alkaliflexus imshenetskii** Zhilina, Appel, Probian, Llobet Brossa, Harder, Widdel and Zavarzin 2005, 1395^{VP} (Effective publication: Zhilina, Appel, Probian, Llobet Brossa, Harder, Widdel and Zavarzin 2004, 251.)

im.she.net'ski.i. N.L. gen. masc. n. *imshenetskii* of Imshenetskii, named after Aleksandr A. Imshenetskii (1905–1992), a microbiologist who devoted much of his research to gliding bacteria and the microbial degradation of cellulose.

Characteristics are as described for the genus, with the following additional features. Cell dimensions are 0.25–0.4 × 4–10 µm. Cells usually occur singly or in pairs. Cells survive desiccation. Cells are yellow to salmon-colored or pink due to the presence of a carotenoid or carotenoids. No dependence of color on the presence of light during growth has been observed. The temperature range for growth is 10–44°C, with the optimum being around 35°C; no growth occurs at 5 or 55°C. Catalase-positive. Best growth occurs under strictly anaerobic conditions with a reducing agent such as sulfide. Growth occurs on arabinose, xylose, glucose, galactose, mannose, cellobiose, maltose, sucrose, trehalose, xylan, starch, glycogen, dextran, dextrin, pectin, pullulan, and *N*-acetylglucosamine. Growth is most rapid on cellobiose or starch. No growth occurs on methanol, ethanol, pyruvate, succinate, fumarate, malate, glycerol,

mannitol, inositol, ribose, fructose, lactose, agarose, cellulose, alginate, agar, xanthan, chitin, chitosan, Casamino acids, peptone, gelatin, or yeast extract. The main products of sugar fermentation are propionate, acetate, and succinate; minor products are formate, fumarate, and hydroxyacetate. Vitamins or yeast extract are needed for growth. The predominant cellular fatty acids are C_{15:0} isomers. Habitat: anoxic soda lake sediments rich in organic nutrients. The type strain was isolated as a component of an anaerobic cellulose-degrading enrichment culture originating from Lake Verkhneye Beloye (south-eastern Transbaikal region, Russia).

DNA G+C content (mol%): 43.0–44.4 (*T_m*).

Type strain: Z-7010, DSM 15055, VKM B-2311.

Sequence accession no. (16S rRNA gene): AJ784993.

*The basal medium of Nedashkovskaya et al. (2006) is composed of (g/l): NH₄Cl, 0.2; MgCl₂·6H₂O, 0.05; KH₂PO₄, 0.2; Na₂CO₃, 7.4; NaHCO₃, 18.5; Na₂S·9H₂O, 0.5; and yeast extract, 0.2. The latter three ingredients are added from separately autoclaved stock solutions (sulfide was autoclaved under N₂) to the anoxically cooled medium. Non-chelated trace elements and vitamins are added as described by Widdel and Bak (1992). The medium is dispensed into bottles or tubes with a headspace (30% of total volume) of N₂ and sealed with butyl rubber stoppers. Organic substrates are added before inoculation from separately sterilized stock solutions. Sugars are sterilized by filtration.

Family III. Rikenellaceae fam. nov.

THE EDITORIAL BOARD

Ri.ke.nel.la.ce.ae. N.L. fem. n. *Rikenella* type genus of the family; -aceae ending to denote family; N.L. fem. pl. n. *Rikenellaceae* the *Rikenella* family.

The family *Rikenellaceae* is a phenotypically diverse assemblage of genera that was circumscribed for this volume on the basis of phylogenetic analysis of 16S rRNA gene sequences. The family contains the genera *Rikenella* (type genus) and *Alistipes*. Both are Gram-negative rods that lack swimming motility.

Some characteristics that differentiate the two genera are given in Table 10.

Type genus: **Rikenella** Collins, Shah and Mitsuoka 1985a, 375^{VP} (Effective publication: Collins, Shah and Mitsuoka 1985b, 80.).

TABLE 10. Some characteristics that differentiate the genera of the family *Rikenellaceae*^a

Characteristic	<i>Rikenella</i>	<i>Alistipes</i>
Major products of glucose fermentation	Propionic and succinic acids, with moderate amounts of acetic acid and trace amounts of alcohols	Succinic acid with minor amounts of acetic acid
Major quinone	MK-8	nr
Source	Fecal or cecal specimens from calves, chickens, and Japanese quails	Human and animal specimens of intestinal origin
DNA G+C content (mol%)	59.5–60.7	55–58

^anr, Not reported.

Genus I. *Rikenella* Collins, Shah and Mitsuoka 1985a, 375^{VP}
(Effective publication: Collins, Shah and Mitsuoka 1985b, 80.)

THE EDITORIAL BOARD

Ri.ke.nel'la. L. fem. dim. ending *-ella*; N.L. fem. dim. n. *Rikenella* named after the RIKEN-Institute, Japan, where the organisms were originally isolated.

Rods with pointed ends occurring singly, in pairs, or short chains. Short, filamentous, or swollen forms may occur in media with a high concentration of fermentable carbohydrate. Nonmotile. Nonsporeforming; strains do not survive 70°C for 10 min. Gram negative. **Anaerobic**. Growth enhanced by a fermentable carbohydrate (e.g., glucose). Optimum temperature ~37°C. Poor growth at 45°C and usually no growth below 25°C. **Relatively few sugars are fermented**, but glucose, lactose, mannose, and melibiose are fermented. **Major end products of glucose fermentation are propionic and succinic acids, with moderate amounts of acetic acid**, and trace amounts of alcohols. **Glucose-6-phosphate dehydrogenase, 6-phosphogluconate dehydrogenase, and glutamate dehydrogenase are absent**. Esculin is not hydrolyzed. Nitrate is not reduced. Nonhydroxylated and 3-hydroxylated long-chain fatty acids present. **The fatty acids are primarily of the iso-methyl branched-chain types**; moderate amounts of straight-chain saturated acids are also present. **Menaquinones are produced**. Isolated from fecal or cecal specimens from calves, chickens, and Japanese quails.

DNA G+C content (mol%): 59.5-60.7.

Type species: *Rikenella microfus* (Kaneuchi and Mitsuoka 1978) Collins, Shah and Mitsuoka 1985a, 375^{VP} (Effective publication: Collins, Shah and Mitsuoka 1985b, 80) (*Bacteroides microfus* Kaneuchi and Mitsuoka 1978, 478.).

Further descriptive information

Cells grown on Eggerth–Gagnon agar* for 2 d are 0.15-0.3 × 0.3-1.5 µm (Collins et al., 1985b). Cells from glucose broth are 0.5-0.9 × 1.0-5.0 µm (Holdeman et al., 1984).

Surface colonies on Eggerth–Gagnon agar are 0.5-1 mm in diameter, circular, convex, entire, smooth, translucent, grayish, and β-hemolytic. Some strains form raised, opaque, gray colonies that are 1.0-1.5 mm in diameter.

Growth in peptone-yeast extract-glucose (PYG) broth is enhanced by 20% bile or by 0.0005% hemin plus 0.00005% menadione, but not by 10% rumen fluid or 0.1% Tween 80. Cultures in peptone-yeast extract-Fildes enrichment[†] -glucose (PYFG) broth are turbid with smooth sediment and have a final pH of 5.5-5.8. Only trace amounts of gas are produced.

The major fatty acid is 13-methyltetradecanoic acid. An unsaturated menaquinone of the MK-8 type is present.

*The medium of Eggerth and Gagnon (1933) consists of beef infusion broth containing 1.5% agar, 1% peptone, and 0.4% disodium phosphate. The pH is adjusted to 7.6-7.8. Before dispensing the medium into plates, 5% (v/v) of sterile blood and 0.15% sterile glucose (in the form of a 10% solution) are added.

[†]Fildes enrichment (Willis, 1960) is prepared by adding 50 ml of defibrinated sheep blood, 6 ml of concentrated HCl, and 2 g of pepsin to 150 ml of sterile normal saline. This solution is mixed thoroughly in stoppered bottle and incubated at 55°C overnight. Sufficient 20% NaOH solution is added (usually about 12 ml) to make the digest strongly alkaline to cresol red indicator (about pH 8). The pH is then restored to 7.2 with concentrated HCl. After adding 0.25% chloroform as a preservative, the digest is stored at 4°C. The enrichment digest is usually added to a final concentration of 3-5% (v/v). After addition to a sterile medium, the medium is steamed for 30 min to drive off residual chloroform.

Strains have been isolated from the feces of healthy 2-month-old calves fed an artificial diet, from the feces of adult Japanese quails, and from the cecal contents of chickens. The type strain occurred at a concentration of 10⁹/g (wet wt) in Japanese quail feces. Analysis of partial 16S rRNA gene sequences obtained from guts of various termite species by Ohkuma et al. (2002) indicated that one phylogenetic cluster, composed of the phenotypes from a single termite species, was related to the genus *Rikenella*.

Pathogenicity has not been reported.

Enrichment and isolation procedures

In the method of Kaneuchi and Mitsuoka (1978), samples are emulsified in an anaerobic buffer, plated onto modified Eggerth–Gagnon agar[‡] and glucose-blood-liver agar, and incubated at 37°C anaerobically under 100% CO₂. Grayish to slightly reddish mottled colonies are selected after 2-3 d.

Strains can be maintained on prereduced Eggerth–Gagnon liver slants with H₂CO₃/CO₂ buffer and stored at 4°C, with serial transfer every 3 months.

Differentiation of the genus *Rikenella* from other genera

Unlike *Bacteroides fragilis* and related species, *Rikenella microfus* lacks glucose-6-phosphate dehydrogenase and 6-phosphogluconate dehydrogenase (which are characteristic of the hexose monophosphate shunt-pentose pathway) and glutamate dehydrogenase. Unlike *Mitsuokella multiacida*, *Rikenella microfus* cells are smaller in diameter and attack relatively few carbohydrates. They also contain predominantly long-chain, iso-methyl-branched fatty acids, whereas *Mitsuokella multiacida* contains mainly straight-chain saturated and unsaturated fatty acids and only small amounts of methyl branched-chain fatty acids. In addition, *Rikenella microfus* contains unsaturated menaquinones of the MK-8 type, whereas *Mitsuokella multiacida* does not contain menaquinones.

Taxonomic comments

Comparative analysis of 16S rRNA sequences of *Bacteroides* and related organisms by Paster et al. (1994) indicated that *Rikenella microfus*, together with *Bacteroides putredinis* and two species of *Cytophaga*, belong to a subgroup separate from the bacteroides subgroup (the latter being composed of prevotella, bacteroides, and porphyromonas clusters). However, analysis of base signatures indicated that these species do belong within the bacteroides subgroup.

[‡]Modified Eggerth–Gagnon agar (Mitsuoka et al., 1965) consists of 930 ml of horsemeat infusion broth, 10 g Proteose peptone No. 3 (Difco), 5 g yeast extract, 4 g Na₂HPO₄, 0.5 g soluble starch, 1.5 g glucose, 0.2 g cystine (dissolved in HCl), 10 ml Antifoam B (Dow Corning, in 10% solution), 15 g agar; 50 ml horse blood, and 10 ml cysteine-HCl (in 5% solution). The pH is 7.6-7.8.

List of species of the genus *Rikenella*

1. **Rikenella microfusus** (Kaneuchi and Mitsuoka 1978) Collins, Shah and Mitsuoka 1985a, 375^{VP} (Effective publication: Collins, Shah and Mitsuoka 1985b, 80.) (*Bacteroides microfusus* Kaneuchi and Mitsuoka 1978, 478)

mi.cro.fus'us. Gr.adj. *mikros* small; L. n. *fusus* a spindle; N.L. n. *microfusus* (nominative in apposition) a small spindle (referring to cellular morphology).

The description is as given for the genus, with the following additional information. Acid is produced from glucose, lactose, mannose, and melibiose. Most strains (75%) produce acid from galactose. No acid is produced from amygdalin, arabinose, cellobiose, dextrin, dulcitol, erythritol, fructose, glycerol, glycogen, inositol, inulin, maltose, mannitol, α -methylglucoside, α -methylmannoside, melezitose, raffinose, rhamnose, ribose, salicin, sorbose, sorbitol, starch, sucrose, trehalose, and xylose.

β -Glucuronidase, glutamic acid decarboxylase, and malate dehydrogenase are produced. Gelatin is weakly hydrolyzed.

Casein, starch, and urea are not hydrolyzed. Indole and acetylmethylcarbinol are not produced. No lecithinase activity occurs on egg yolk agar. H₂S production is not evident on sulfide-indole-motility medium.

Growth is inhibited by 0.001% brilliant green, 0.005% crystal violet, neomycin (1600 μ g/ml; slight growth may occur sometimes with a few strains), and rifampin (15 μ g/ml). Strains are resistant to bacitracin (3 U/ml), cephalothin (300 μ g/ml), colistin 10 μ g/ml, polymyxin B (10 μ g/ml), and vancomycin (10 μ g/ml). There is slight to moderate growth in the presence of kanamycin (1000 μ g/ml), penicillin (15 μ g/ml), and erythromycin (60 μ g/ml). Most strains are inhibited by neomycin (1600 μ g/ml) and rifampin (15 μ g/ml).

DNA G+C content (mol%): 59.5-60.7 (T_m).

Type strain: ATCC 29728, CCUG 54772, DSM 15922, JCM 2053, NCTC 11190.

Sequence accession no. (16S rRNA gene): L16498.

Genus II. **Alistipes** Rautio, Eerola, Väisänen-Tunkelrott, Molitoris, Lawson, Collins and Jousimies-Somer 2003b, 1701^{VP} (Effective publication: Rautio, Eerola, Väisänen-Tunkelrott, Molitoris, Lawson, Collins and Jousimies-Somer 2003a, 186.)

EIJA KÖNÖNEN, YULI SONG, MERJA RAUTIO AND SYDNEY M. FINEGOLD

A.li.sti'pes. L. adj. *alius* other; L. masc. n. *stipes* a log, stock, post, trunk of a tree, stick; N.L. masc. n. *alistipes* the other stick.

Straight or slightly curved rods 0.2–0.9 μ m in diameter \times 0.5–4 μ m in length, with rounded ends. Swellings may occur, but spores are not formed. Cells usually occur singly or in pairs, occasionally in longer filaments. Nonmotile. Gram negative. **Obligately anaerobic**. Indole is produced. Gelatin is digested. Nitrate is not reduced to nitrite. Arginine and urea are not hydrolyzed. Produce **succinic acid as the major glucose metabolic end product**, with minor amounts of acetic acid. The major long-chain fatty acid produced is C_{15:0} iso.

Source: human and animal specimens of intestinal origin.

DNA G+C content (mol%): 55–58.

Type species: **Alistipes putredinis** (Weinberg, Nativelle and Prévot 1937) Rautio, Eerola, Väisänen-Tunkelrott, Molitoris, Lawson, Collins and Jousimies-Somer 2003b, 1701 (Effective publication: Rautio, Eerola, Väisänen-Tunkelrott, Molitoris, Lawson, Collins and Jousimies-Somer 2003a, 186.) (*Bacillus putredinis* Weinberg, Nativelle and Prévot 1937, 755; *Ristella putredinis* Prévot 1938, 291; *Bacteroides putredinis* Kelly 1957, 420).

Further descriptive information

Phylogenetic analysis of the 16S rRNA gene sequence indicates that the genus *Alistipes* belongs to the family *Rikenellaceae* within the phylum *Bacteroidetes* (Figure 16).

Colonies are pinpoint to 1 mm in diameter, circular, convex, gray, and opaque or translucent on supplemented (5% sheep blood, 1 μ g/ml vitamin K₁, 5 μ g/ml hemin) Brucella agar after anaerobic incubation for 4 d. In case of pigment-producing *Alistipes* species, strains are (weakly) β -hemolytic. A light brown or brown pigmentation appears on rabbit-laked-blood (RLB) agar within 4–5 d and on kanamycin-vancomycin-laked blood

(KVLB; containing 5% lysed sheep blood) agar plates, but it also appears on Brucella blood agar after extended incubation (10 d).

Strains grow well on solid media under anaerobic conditions. The optimal growth temperature is 37°C. Growth is poor in liquid media even in the presence of supplements. For the demonstration of carbohydrate fermentation, addition of 0.5% Tween 80 may stimulate the growth, but even with this supplementation, the growth can be poor.

According to their characteristic special potency antibiotic identification disk profile, *Alistipes* species are resistant to vancomycin (5 μ g), kanamycin (1000 μ g), and colistin (10 μ g). Bile resistance, which can be tested on bacteroides-bile-esculin (BBE) agar with or without gentamicin, is typical of pigment-producing *Alistipes* species. As with other strict anaerobes, *Alistipes* is susceptible to metronidazole. Susceptibility to penicillin varies due to β -lactamase production by some strains.

Pigment-producing, bile-resistant *Alistipes* species have been isolated from various human clinical specimens, such as inflamed appendix tissue, peritoneal fluid of patients with appendicitis, antibiotic-associated diarrheal feces, and urine (Rautio et al., 2003a; Song et al., 2006). *Alistipes putredinis* has been isolated from inflamed appendix tissue, abdominal and peri-rectal abscesses, pilonidal and Bartholin cysts, human blood, and sheep foot rot (Cato et al., 1979; Holdeman et al., 1984). The clinical significance in these conditions remains unclear, however, since the organisms appear in mixed cultures with other anaerobes and/or aerobes. The isolation of *Alistipes* species from appendix tissue, both inflamed and noninflamed (Rautio et al., 2000), and from the feces of healthy individuals

FIGURE 16. Phylogenetic tree based on 16S rRNA gene sequence comparisons (>1300 aligned bases) showing the phylogenetic relationship of the *Alistipes* species to related taxa. The tree was constructed using the neighbor-joining method, following distance analysis of aligned sequences. Bootstrap analysis was used, with 1000 repetitions.

(Rautio et al., 2003a; Song et al., 2006) as well as from farm soil (Cato et al., 1979) indicates that the habitat is the human and animal gut.

Enrichment and isolation procedures

Alistipes strains can be isolated on solid culture media appropriate for anaerobes, including nonselective Brucella blood agar enriched with vitamin K₁ and hemin, and fastidious anaerobe agar (FAA; Lab M). In addition, pigment-producing, bile-resistant species are also isolated from selective KVLB and BBE agar plates (Rautio et al., 1997).

Growth in liquid media is especially poor. Tween 80 (0.5%) has been used to enhance growth of *Alistipes putredinis* (Holdeman et al., 1984). Of various supplements (bile, formate-fumarate, hemin, horse serum, pyruvate, sodium bicarbonate, and Tween) tested for enhancement of growth of pigment-producing *Alistipes* species in thioglycolate broth

medium, bile and horse serum showed a weak stimulation (Rautio et al., 1997).

Maintenance procedures

For long term storage, young (2–3 d) cultures are transferred into vials containing sterilized 20% skim milk and kept frozen at –70°C. Twenty-year-old strains have been revived successfully from stocks by scraping frozen bacterial suspension onto fresh or prerduced Brucella blood agar and incubating the plates in anaerobic jars or in an anaerobic chamber for 3–5 d before subcultivation for verifying the purity of strains.

Methods for characterization tests

In general, the anaerobic methods described in the Wadsworth-KTL Anaerobic Bacteriology Manual (Jousimies-Somer et al., 2002) are suitable for the study of members of this genus. The spot indole test may give false-negative results, therefore, the

^bUnlike other *Alistipes* spp., *Alistipes putredinis* does not produce pigment, and is susceptible to bile, catalase positive, and asaccharolytic.

^c*Bacteroides sensu stricto*.

^dUnlike other *Porphyromonas* spp., *Porphyromonas catoniae* does not produce pigment, and is moderately saccharolytic.

^eSpecial potency antimicrobial identification disks. Symbols: R, resistant; S, susceptible.

^fSymbols: A, acetic acid; B, butyric acid; IV, isovaleric acid; P, propionic acid; PA, phenylacetic acid; S, succinic acid.

tube indole test is recommended. Commercial API ZYM and API rapid ID 32 A test kits (bioMérieux) and individual Rosco diagnostic tablets (Rosco) can be useful for examining biochemical characteristics. A heavy inoculum from young (2–3 d) cultures should be used for biochemical testing to avoid poor reproducibility of reactions. The enzyme profiles generated by the API ZYM test kit (bioMérieux) proved to be most useful in distinguishing the *Alistipes* species from each other. For demonstration of carbohydrate fermentation, prerduced, anaerobically sterilized (PRAS) peptone-yeast-sugar broth tubes, with or without additional supplements, are used, but results can be affected by poor growth of *Alistipes* strains in liquid media.

Differentiation of the genus *Alistipes* from other genera

Characteristics that differentiate *Alistipes* from related taxa within the phylum *Bacteroidetes* (previously referred to as the

“*Cytophaga–Flavobacteria–Bacteroides*” phylum) are presented in Table 11.

Taxonomic comments

The genus *Alistipes* currently includes four validly published species, *Alistipes putredinis* and *Alistipes finegoldii* (Rautio et al., 2003a, b), and *Alistipes onderdonkii* and *Alistipes shahii* (Song et al., 2006). Phylogenetic analyses of the 16S rRNA gene sequence reveal further heterogeneity within the genus, since occasional strains that are phenotypically similar to but phylogenetically diverse from *Alistipes* species described in the current literature have been reported (Song et al., 2005, 2006). Also, preliminary results on bile-resistant, pigment-producing *Alistipes*-like organisms in ongoing studies by the authors (unpublished) revealed (among approximately 150 strains examined) several groups having a 16S rRNA gene sequence divergence of more than 3% compared to any known *Alistipes* species.

List of species of the genus *Alistipes*

- Alistipes putredinis*** (Weinberg, Nativelle and Prévot 1937) Rautio, Eerola, Väisänen-Tunkelrott, Molitoris, Lawson, Collins and Jousimies-Somer 2003b, 1701 (Effective publication: Rautio, Eerola, Väisänen-Tunkelrott, Molitoris, Lawson, Collins and Jousimies-Somer 2003a, 186.) (*Bacillus putredinis* Weinberg, Nativelle and Prévot 1937, 755; *Ristella putredinis* Prévot 1938, 291; *Bacteroides putredinis* Kelly 1957, 420)
put.re'di.nis. L. n. *putredo* -inis rottenness, putridity; L. gen. n. *putredinis* of putridity.

The description is based on previous literature (Cato et al., 1979; Holdeman et al., 1984; Rautio et al., 2003a; Song et al., 2006). Surface colonies on supplemented Brucella shear blood agar after incubation for 4 d are pinpoint to 0.5 × mm in diameter, circular, entire or slightly irregular, low convex, translucent, gray, dull, and smooth. Colonies

do not produce pigment. No growth occurs in 20% bile. Although only traces of acid products can be detected in a 6-d-old PYG broth (pH > 6), in a 24-h-old meat chopped carbohydrate broth, the main acid detected is succinate. Catalase and indole are produced. The type strain, examined with the API ZYM and API rapid ID 32 A test kits, is positive for alkaline and acid phosphatases, esterase, esterase lipase, naphthol-AS-BI-phosphohydrolase, α-glucosidase, leucyl glycine, alanine, and serine arylamidases, glutamic decarboxylase, and indole. Some characteristics of the species are listed in Table 12.

DNA G+C content (mol%): 55 (HPLC).

Type strain: ATCC 29800, CCUG 45780, CIP 104286, DSM 17216.

Sequence accession no. (16S rRNA gene): L16497.

2. **Alistipes finegoldii** Rautio, Eerola, Väisänen-Tunkelrott, Molitoris, Lawson, Collins and Jousimies-Somer 2003b, 1701^{VP} (Effective publication: Rautio, Eerola, Väisänen-Tunkelrott, Molitoris, Lawson, Collins and Jousimies-Somer 2003a, 186.)

fine.gold'i.i. N.L. gen. masc. n. *finegoldii* of Finegold; named after Sydney M. Finegold, an American contemporary researcher and clinician in recognition of his contribution to anaerobic bacteriology and infectious diseases.

The description is based on previous literature (Rautio et al., 2003a, 1997; Song et al., 2006). Surface colonies on supplemented Brucella sheep blood agar after 4 d of incubation are pinpoint to 1.0 mm in diameter, circular, entire, raised, gray, translucent or opaque, and (weakly) β -hemolytic. Colonies are light brown to brown. No fluorescence is observed under long-wave UV light (365 nm), but the colonies appear black. Esculin hydrolysis differs among strains. Acid is produced from glucose. The strains, examined with the API ZYM and API rapid ID 32 A test kits, are positive for alkaline and acid phosphatases, esterase, esterase lipase, α -chymotrypsin, naphthol-AS-BI-phosphohydrolase, α -galactosidase, β -galactosidase, α -glucosidase, *N*-acetyl- β -glucosaminidase, α -fucosidase, leucyl glycine, alanine, and glutamyl glutamic arylamidases, and indole. Some characteristics of the species are listed in Table 12.

DNA G+C content (mol%): 57 (HPLC).

Type strain: AHN 2437, CCUG 46020, CIP 107999, DSM 17242.

Sequence accession no. (16S rRNA gene): AJ518874.

3. **Alistipes onderdonkii** Song, Könönen, Rautio, Liu, Bryk, Eerola and Finegold 2006, 1988^{VP}

on.der.don'ki.i. N.L. gen. masc. n. *onderdonkii* of Onderdonk; named after Andrew B. Onderdonk, a contemporary American microbiologist, for his contribution to increased knowledge about the intestinal microbiota and anaerobic bacteria.

The description is based on the investigation of 15 strains (Song et al., 2006). Cells are 0.2–0.5 $\mu\text{m} \times$ 0.5–3 μm . Surface colonies on supplemented Brucella sheep blood agar after 4 d are pinpoint to 0.8 mm in diameter, circular, entire, convex, opaque, gray, and (weakly) β -hemolytic. Colonies are light brown to brown. No fluorescence is observed under

long-wave UV light (365 nm), but the colonies appear black. Grows in the presence of 20% bile. Indole positive. Catalase negative. Esculin hydrolysis differs among strains. Acid is produced from glucose. When tested by the API rapid ID 32 A system (bioMérieux), mannose and raffinose are fermented. The strains, examined with the API ZYM and API rapid ID 32A test kits, are positive for alkaline and acid phosphatases, esterase, esterase lipase, naphthol-AS-BI-phosphohydrolase, α -galactosidase, β -galactosidase, α -glucosidase, *N*-acetyl- β -glucosaminidase, leucyl glycine, alanine, and glutamyl glutamic arylamidases, and indole. Some characteristics of the species are listed in Table 12.

DNA G+C content (mol%): 56 (HPLC).

Type strain: WAL 8169, ATCC BAA-1178, CCUG 48946.

Sequence accession no. (16S rRNA gene): AY974071.

4. **Alistipes shahii** Song, Könönen, Rautio, Liu, Bryk, Eerola and Finegold 2006, 1999^{VP}

sha'hi.i. N.L. gen. masc. n. *shahii* of Shah; to honor Haroun N. Shah, a contemporary British microbiologist for his contributions to anaerobic bacteriology.

The description is based on the investigation of six strains (Song et al., 2006). Cells are 0.1–0.2 $\mu\text{m} \times$ 0.6–4 μm . Surface colonies on supplemented Brucella sheep blood agar after 4 d are pinpoint to 1.0 mm in diameter, circular, entire, convex, opaque, gray, and (weakly) β -hemolytic. Colonies are light brown to brown. No fluorescence is observed under long-wave UV light (365 nm), but the colonies appear black. Grows in the presence of 20% bile. Indole positive. Catalase negative. Esculin is hydrolyzed. Acid is produced from glucose. When tested by the API rapid ID 32 A system (bioMérieux), mannose and raffinose are fermented. The strains, examined with the API ZYM and API rapid ID 32 A test kits (bioMérieux), are positive for alkaline and acid phosphatases, esterase, esterase lipase, naphthol-AS-BI-phosphohydrolase, α -galactosidase, β -galactosidase, α -glucosidase, β -glucosidase, *N*-acetyl- β -glucosaminidase, α -fucosidase, leucyl glycine, alanine, and glutamyl glutamic arylamidases, and indole. Some characteristics of the species are listed in Table 12.

DNA G+C content (mol%): 58 (HPLC).

Type strain: WAL 8301, ATCC BAA-1179, CCUG 48947.

Sequence accession no. (16S rRNA gene): AY974072.

Family IV. *Porphyromonadaceae* fam. nov.

NOEL R. KRIEG

Por.phy.ro.mo.na.da.ce'a.e. N.L. fem. n. *Porphyromonas* type genus of the family; suff. -aceae ending to denote a family; N.L. fem. pl. n. *Porphyromonadaceae* the *Porphyromonas* family.

The family *Porphyromonadaceae* is a phenotypically diverse group of genera that was circumscribed for this volume on the basis of phylogenetic analysis of 16S rRNA gene sequences. The family contains the genera *Porphyromonas* (type genus), *Barnesiella*, *Dysgonomonas*, *Paludibacter*, *Petrimonas*, *Proteiniphilum*, and *Tannerella*. In addition, *Parabacteroides*, which was described after the deadline for this volume

should be classified within this family (Sakamoto and Benno, 2006; Sakamoto et al., 2007a). All are **nonmotile rods that stain Gram-negative**. Except as noted below, **strict anaerobes and saccharolytic**. Some characteristics that differentiate the genera are given in Table 13.

Type genus: Porphyromonas Shah and Collins 1988, 129^{VP} emend. Willems and Collins 1995, 580.

TABLE 13. Some characteristics that differentiate the genera of the family *Porphyromonadaceae*^a

Characteristic	<i>Porphyromonas</i>	<i>Barnesiella</i>	<i>Dysgonomonas</i>	<i>Paludibacter</i>	<i>Petrimonas</i>	<i>Proteiniphilum</i>	<i>Tannerella</i>
Cell shape	Short rods or coccobacilli	Rods	Coccobacilli to short rods	Rods with ends usually round to slightly tapered	Rods	Rods	Fusiform cells
Growth in the presence of bile	–	–	+	–	nt	–	–
Can grow aerobically	–	–	+	–	–	–	–
N ² Acetylglucosamine required for growth	–	–	–	–	–	–	+, except bite wound isolates
Saccharolytic	–; Some species are weakly positive	+	+	+	+	–	+
Products of glucose fermentation:	Butyric and acetic acids; propionic, isovaleric, isobutyric, and phenylacetic acids may also be produced	Acetic and succinic acids	Propionic, lactic, and succinic acids	Acetic and propionic acids; succinic acid is a minor product	Acetic acid and H ₂	na	Acetic, butyric, isovaleric, propionic, and phenylacetic acids; smaller amounts of isobutyric and succinic acids may be produced
Predominant menaquinone	MK-9, MK-10	MK-11, MK-12	nt	MK-8	MK-8	nt	MK-10, MK-11
Isolated from:	Oral infections and various other clinical specimens of human and animal origin	Chicken cecum	Human clinical specimens and stools	Rice plant residue (rice straw) collected from irrigated rice-field soil	Oilfield well head	UASB reactor treating brewery wastewater	Human subgingival, gingival, and periodontal pockets, in dental root canals, and around infected dental implants
DNA G+C content (mol%)	44–55	52	38	39	41	47–49	44–48

^aSymbols: +, >85% positive; –, 0–15% positive; w, weak reaction; na, not available; nt, not tested.

Genus I. **Porphyromonas** Shah and Collins 1988, 129^{VP} emend. Willems and Collins 1995, 580.

PAULA SUMMANEN AND SYDNEY M. FINEGOLD

Por.phy.ro.mo'nas. Gr. adj. *porphyreos* purple; Gr. n. *monas* unit; N.L. fem. n. *Porphyromonas* porphyrin cell.

Short rods or coccobacilli, 0.3–1 × 0.8–3.5 µm. Gram-negative, non-sporeforming, and nonmotile. **Obligately anaerobic**. Generally cells form **brown to black colonies on blood agar due to protoheme production**. Most species are asaccharolytic; growth is not significantly affected by carbohydrates but is enhanced by protein hydrolysates such as proteose peptone or yeast extract. **Major fermentation products are usually n-butyric acid and acetic acid**; propionic, isovaleric, isobutyric, and phenylacetic acid may also be produced. The major cellular fatty acid is 13-methyltetradecanoic acid (C_{15:0} iso). Indole is produced by most strains. Nitrate is not reduced to nitrite. Esculin is not hydrolyzed. Most species do not hydrolyze starch. Isolated from oral infections and various other clinical specimens of human and animal origin.

DNA G+C content (mol%): 40–55 (T_m).

Type species: Porphyromonas asaccharolytica (Holdeman and Moore 1970) Shah and Collins 1988, 128^{VP} [*Bacteroides asaccharolyticus* (Holdeman and Moore 1970) Finegold and Barnes 1977, 390; *Bacteroides melaninogenicus* subsp. *asaccharolyticus* Holdeman and Moore 1970, 33].

Further descriptive information

Cell morphology. Most cells in broth cultures are small (0.3–1.0 × 0.8–3.5 µm); however, occasionally longer cells and filaments (≥5 µm) may be formed. Cells from growth on a solid medium are commonly shorter and can appear spherical.

Cell-wall composition. The cell-wall peptidoglycan contains lysine as the diamino acid. 2-Keto-3-deoxyoctulosonic acid is absent. The principal respiratory quinones are unsaturated menaquinones with 9 or 10 isoprene units. Both nonhydroxylated and 3-hydroxylated fatty acids are present. The nonhydroxylated fatty acids are predominantly methyl-branched-chain fatty acids. The predominant fatty acid is C_{15:0} iso; a few species contain comparable amounts of C_{15:0} iso and C_{15:0} anteiso acids. The 3-hydroxylated fatty acids are generally straight-chain saturated fatty acids. Information on the fatty acid content and cell wall composition can be found in Collins et al. (1994) and Bronz and Olsen (1991).

Colony morphology. Colonies on blood agar plates are usually round, entire, smooth (occasionally rough), shiny, convex, and 0.5–3 mm in diameter. The colonies of all but one species (*Porphyromonas catoniae*) are pigmented. The black pigmentation of *Porphyromonas* is caused by the accumulation of hemin used as an iron source for bacterial growth. The species vary in the degree and rapidity of pigment production depending primarily on the type of blood used in the growth medium. Laked rabbit blood agar is considered the most reliable medium for detecting the pigment. The pigmentation ranges from tan to black and may take several days to develop.

Growth conditions. The optimum temperature for growth is 37°C. *Porphyromonas* species favor a slightly alkaline environmental pH and 100% humidity. Hemin and vitamin K₁ are either required or greatly stimulate the growth of most species.

Although some species are weakly saccharolytic, their growth is not significantly affected by carbohydrates. Nitrogenous substances, such as proteose peptone, trypticase, and yeast extract markedly enhance growth.

Metabolism and metabolic pathways. Malate dehydrogenase and glutamate dehydrogenase are present; glucose-6-phosphate dehydrogenase and 6-phosphogluconate dehydrogenase are absent from most species. Proteolytic activity is variable. The strains have a limited ability to ferment amino acids such as aspartate and asparagine.

Genetics. *Porphyromonas* forms a distinct phylogenetic group, and 16S rRNA gene sequencing can be reliably used to differentiate *Porphyromonas* from other genera and from each other, with the exception of *Porphyromonas asaccharolytica* and *Porphyromonas uenonis*, where DNA–DNA reassociation studies are required to distinguish these two species genetically.

The genome of *Porphyromonas gingivalis* has been sequenced and studied by the Forsyth Institute and The Institute for Genomic Research (TIGR) (Nelson et al., 2003). The genome size of this species was determined to be 2176 kb from *Xba*I restriction enzyme digests and 2250 kb from *Spe*I digests. Information and a schematic representation of the *Porphyromonas gingivalis* W83 genome can be found at www.tigr.org. Comparative analysis of the whole-genome sequence with other available complete genome sequences confirmed the close relationship between the phylum *Bacteroidetes* [*Cytophaga–Flavobacteria–Bacteroides* (CFB)] and the green sulfur bacteria. Within the phylum “*Bacteroidetes*” the genomes of *Bacteroides thetaiotaomicron* and *Bacteroides fragilis* were most similar to that of *Porphyromonas gingivalis*. The genome analysis revealed a range of virulence determinants that relate to the novel biology of this bacterium. It also revealed that *Porphyromonas gingivalis* can metabolize a range of amino acids and generate end products that are toxic to the human host.

Antibiotic susceptibility. *Porphyromonas* species are generally very susceptible to most of the antimicrobial agents commonly used for treatment of anaerobic infections, such as amoxicillin-clavulanate, piperacillin-tazobactam, ampicillin-sulbactam, imipenem, cephalosporins, and metronidazole. β-Lactamase production has been described in *Porphyromonas asaccharolytica* (Aldridge et al., 2001), *Porphyromonas catoniae* (Kononen et al., 1996), *Porphyromonas somerae* (Summanen et al., 2005), and *Porphyromonas uenonis* (Finegold et al., 2004). The frequency of β-lactamase production has been reported at approximately 20%. Animal-derived *Porphyromonas* species are more often β-lactamase producers than those derived from humans. Occasional resistance to clindamycin and ciprofloxacin may occur in *Porphyromonas asaccharolytica* and *Porphyromonas somerae*; also, ciprofloxacin resistance of *Porphyromonas gingivalis* has been reported (Lakhssassi et al., 2005).

Pathogenicity. Some species are considered true pathogens and are associated with human or animal infections. In particular, *Porphyromonas gingivalis* is a major causative agent in the

initiation and progression of severe forms of periodontal disease. *Porphyromonas gingivalis* possesses a multitude of cell-surface associated and extracellular activities that contribute to its virulence potential. Several of these factors are adhesins that interact with other bacteria, epithelial cells, and extracellular matrix proteins. Secreted or cell-bound enzymes, toxins, and hemolysins play a significant role in the spread of the organism through tissue, in tissue destruction, and in evasion of host defenses.

Ecology. Several of the members of *Porphyromonas* are indigenous bacterial flora in the oral cavity of humans and animals. Many species are also found in the urogenital and intestinal tracts. *Porphyromonas* species have been isolated from oral infections, and from many infections throughout the body, e.g., blood, amniotic fluid, umbilical cord, pleural empyema, peritoneal and pelvic abscesses, inflamed endometrium, and other infected tissues. *Porphyromonas* species of animal origin have been encountered in humans with animal bite infections.

Enrichment and isolation procedures

A complex medium containing peptone, yeast extract, vitamin K₁, and hemin, and supplemented with 5% blood is recommended for isolation of *Porphyromonas* from body sites. Fresh or prerduced media (commercially available from Anaerobe Systems, Morgan Hill, California) are recommended, as they increase isolation efficacy. For determination of pigmentation, rabbit blood (laked) is preferable to blood from other animals. Kanamycin-vancomycin laked-blood agar with reduced vancomycin concentration (2 µg/ml) may be used as a selective medium when *Porphyromonas* species are sought (Jousimies-Somer et al. 2002). Formulas for basal media are given in Jousimies-Somer et al. (2002).

Inoculated media should immediately be placed in an anaerobic environment, such as an anaerobic pouch, jar, or chamber. If anaerobic systems utilizing palladium catalysts are used, the anaerobic gas mixture must contain hydrogen to enable the palladium to reduce oxygen to water. The plates may be examined after a 48-h incubation. However, a total incubation period of at least 7 d is recommended, because not all *Porphyromonas* species may be detected with shorter incubation times.

Maintenance procedures

Isolates can be put into stock from broth or plate cultures. Freezing at -70°C or lyophilization of young cultures grown in a well-buffered liquid or solid medium is satisfactory for storage of *Porphyromonas* species. Storage of lyophilized cultures at 4°C is recommended. Even with the best storage conditions, only a portion of the original cell population survives. Therefore, a large inoculum in a supportive medium and minimal exposure to oxygen are recommended for the recovery of viable cultures from stored material.

To maintain stock strains in the laboratory, it is advisable to transfer them weekly in chopped meat medium or other suitable medium that does not contain a fermentable carbohydrate.

Differentiation of the genus *Porphyromonas* from other genera

The pigmented *Porphyromonas* species can be differentiated from other anaerobic, Gram-stain-negative genera with relative ease (Table 14). The special-potency antibiotic disks (vancomycin, 5 µg; kanamycin, 1000 µg; and colistin, 10 µg) can be used to separate the Gram-stain-negative genera: *Porphyromonas* species are generally sensitive to vancomycin and resistant to kanamycin and colistin, whereas the other Gram-stain-negative genera are resistant to vancomycin and vary in their resistance to kanamycin and colistin.

A distinctive feature of the porphyromonads is that the predominant fatty acid is 13-methyltetradecanoic acid (C_{15:0} iso); by contrast, *Bacteroides* and *Prevotella* contain 12-methyl tetradecanoic acid (C_{15:0} anteiso) as their major cellular fatty acid. *Bacteroides* and *Prevotella* also produce a simpler metabolic end product profile of mainly acetic and succinic acids (Table 14).

Taxonomic comments

The taxonomy of pigmented Gram-negative bacilli has changed greatly since the first edition of *Bergey's Manual of Systematic Bacteriology*. The genus *Porphyromonas* was created in 1988 (Shah and Collins, 1988), and since then some species

TABLE 14. Differentiation of the genus *Porphyromonas* from other anaerobic Gram-negative rods^a

previously included in the genus *Bacteroides* (*Porphyromonas gingivalis*, *Porphyromonas asaccharolytica*, *Porphyromonas endodontalis*, *Porphyromonas levii*, and *Porphyromonas macacae*) were reclassified as *Porphyromonas* species, and several new species described. *Porphyromonas* now includes 16 validly published species. *Porphyromonas salivosa* is a later heterotypic synonym of *Porphyromonas macacae* (Love, 1995).

The porphyromonads form a natural, but deep, phylogenetic group (Figure 17). The species exhibit levels of 16S rRNA sequence divergence of up to 15%. Phylogenetically, the closest related species to *Porphyromonas* are found in the genera *Bacteroides* and *Prevotella* (approx. 82–89% similarity).

Differentiation of species of the genus *Porphyromonas*

With the exception of *Porphyromonas catoniae*, *Porphyromonas* species form a phenotypically homogeneous group: they are pigmented, sensitive to the special-potency vancomycin disk, and produce butyric acid as the major metabolic end product. *Porphyromonas catoniae* differs in all these aspects. The characteristics useful in differentiating the species are given in Table 15.

Numerous PCR-based identification or detection systems have been described for *Porphyromonas gingivalis* and *Porphyromonas endodontalis* (de Lillo et al., 2004; Fouad et al., 2002; Gomes et al., 2005; Jervoe-Storm et al., 2005; Kuboniwa et al., 2004; Kumar et al., 2003; Noguchi et al., 2005; Seol et al., 2006).

List of species of the genus *Porphyromonas*

- 1. *Porphyromonas asaccharolytica*** (Holdeman and Moore 1970) Shah and Collins 1988, 129^{VP} (*Bacteroides asaccharolyticus* (Holdeman and Moore 1970) Finegold and Barnes 1977, 390^{AL}; *Bacteroides melaninogenicus* subsp. *asaccharolyticus* Holdeman and Moore 1970, 33)

a.sac.cha.ro.ly'ti.cus. Gr. pref. *a* not; Gr. n. *sakchâr* sugar; N.L. fem. adj. *lytica* (from Gr. fem. adj. *lutikê*) able to loosen, able to dissolve; N.L. fem. adj. *asaccharolytica* not digesting sugar.

The description is from Shah and Collins (1988) and Holdeman et al. (1984). Proteolytic activity is weak, but gelatin liquefaction is positive and fibrinolytic activity is present. Starch is not hydrolyzed. Growth is stimulated by 0.5% NaCl. Cellular and colonial morphology and other characteristics are as described for the genus and as given in Table 15. *Porphyromonas asaccharolytica* can be distinguished from *Porphyromonas uenonis* by phenotypic tests (Table 15); however, DNA–DNA reassociation studies are required to distinguish these two species genetically. Susceptible to piperacillin-tazobactam, ampicillin-sulbactam, imipenem, meropenem, trovafloxacin, and metronidazole. Most strains (≥90%) are susceptible to cefoxitin, ciprofloxacin, and clindamycin. β-Lactamase production has been described in *Porphyromonas asaccharolytica* at the rate of 21% (Aldridge et al., 2001).

Source: various human clinical infections.

DNA G+C content (mol%): 52–54 (T_m)

Type strain: ATCC 25260, CCUG 7834, DSM 20707, JCM 6326, LMG 13178, L16490, VPI 4198.

Sequence accession no. (16S rRNA gene): L16490.

- 2. *Porphyromonas cangingivalis*** Collins, Love, Karjalainen, Kanervo, Forsblom, Willems, Stubbs, Sarkiala, Bailey, Wigney and Jousimies-Somer 1994, 676^{VP}

can.gin.gi.val'is. L. n. *canis* dog; L. n. *gingiva* gum; L. fem. suff. *-alis* suffix denoting pertaining to; N.L. fem. adj. *cangingivalis* pertaining to the gums of dogs.

The description is from Collins et al. (1994). In cooked-meat carbohydrate medium and on sheep blood agar plates cells are 0.3–0.6 × 0.8–1.5 μm and occur singly and in clumps; occasionally filaments up to 16 μm long are observed. Some strains indent agar, exhibit peripheral flattening, and have a roughened and dry surface appearance on sheep blood agar. On egg yolk agar, colonies are yellow or orange. After incubation of 5 d, the pH range in media containing

carbohydrates generally is 6.3–6.5. Ammonia is produced in cooked meat medium. Neither lactate nor threonine is converted to propionate, and pyruvate is not utilized. Other characteristics are as described for the genus and as given in Table 15. Some strains are susceptible to penicillin, amoxicillin, carbenicillin, and erythromycin; 35% of the strains produce β-lactamase.

Source: diseased or healthy periodontal pockets of dogs with naturally occurring periodontitis.

DNA G+C content (mol%): 55 (T_m).

Type strain: ATCC 700135, CCUG 47700, NCTC 12856, VPB 4874, X76259.

Sequence accession no. (16S rRNA gene): X76259.

- 3. *Porphyromonas canoris*** Love, Karjalainen, Kanervo, Forsblom, Willems, Stubbs, Sarkiala, Bailey, Wigney and Jousimies-Somer 1994, 207^{VP}

can'or.is. L. n. *canis* dog; L. gen. n. *oris* of the mouth; N.L. gen. n. *canoris* of a dog's mouth.

The description is from Love et al. (1994). In cooked-meat carbohydrate medium and on sheep blood agar plates cells are 0.3–0.6 × 0.8–1.5 μm and occur singly and in clumps; occasionally filaments up to 16 μm long are observed. On sheep blood agar, colonies at 48 h are circular and rough, and have an orange pigmentation. After incubation of 5 d, the pH range in media containing carbohydrates is 6.3–6.5. Ammonia is produced in cooked meat medium. Lactate is converted to propionate, but pyruvate is not utilized and threonine is not converted to propionate. Other characteristics are as described for the genus and as given in Table 15. Strains are susceptible to penicillin, amoxicillin, carbenicillin, and erythromycin.

Source: subgingival pockets of dogs with naturally occurring periodontitis.

^a+, 90% or more of the strains are positive; -, 10% or more of the strains are negative; d, 11–89% of the strains are positive; w, weak positive reaction; na, data not available.

^bReaction by API ZYM System or Rosco Diagnostic tablets. Reactivity in these systems is not always identical (see footnote f).

^cFermentation of most other carbohydrates have been reported negative.

^dUpper-case letters indicate major metabolic products from peptone-yeast-glucose (PYG), lower-case letters indicate minor products, and parentheses indicate a variable reaction for the following acids: A, acetic; P, propionic; IB, isobutyric; B, butyric; IV, isovaleric; V, valeric; L, lactic; S, succinic; PA, phenylacetic.

^e*Porphyromonas salivosa* is a later heterotypic synonym. The cat biovar (*Porphyromonas salivosa*) is lipase-positive, does not ferment sorbitol, and may fluoresce under UV light.

^fNegative by the API ZYM System; positive with the Rosco *o*-nitrophenyl-β-D-galactopyranoside test.

The description is from Collins et al. (1994). On egg yolk agar, colonies may be yellow or orange. After incubation of 5 d, the pH range in media containing carbohydrates is 6.3–6.5. Ammonia is produced in cooked-meat medium. Neither lactate nor threonine is converted to propionate and pyruvate is not utilized. Other characteristics are as described for the genus and as given in Table 15. Strains are susceptible to penicillin, amoxicillin, carbenicillin, and erythromycin. β-Lactamase producing strains have not been detected.

Source: periodontal pockets of dogs with naturally occurring periodontitis.

DNA G+C content (mol%): 49–51 (T_m).

Type strain: CCUG 47702, NCTC 12858, VPB 4875.

Sequence accession no. (16S rRNA gene): X76260.

Taxonomic note: Strain ATCC 55563^f of *Porphyromonas crevioricanis* Hirasawa and Takada 1994, 640^{VP} exhibits 99.9% rRNA gene sequence homology with *Porphyromonas cansulci* 12858^f. The taxonomic standing of these two species remains to be determined.

- 5. *Porphyromonas cationiae*** (Moore and Moore 1994) Willems and Collins 1995, 581^{VP} (*Oribaculum cationiae* Moore and Moore 1994, 189^{VP})

ca.to'ni.ae. N.L. gen. fem. n. *catoniae* of Cato, named in honor of Elizabeth P. Cato, an American microbiologist.

The description is from Willems and Collins (1995) and Moore and Moore (1994). Cells grown in PYG broth are 0.6×0.8 – $1.7 \mu\text{m}$ and occur in pairs and short chains. Cells grown in media containing fermentable carbohydrate may be highly vacuolated. Surface colonies on blood agar plates incubated for 2 d are 0.2–2 mm in diameter, circular, entire, flat to low convex, and transparent. Most strains are not hemolytic on rabbit blood agar; an occasional strain may be beta-hemolytic. No colonies with a dark pigment are produced. Saccharolytic. Abundant growth occurs in peptone-yeast extract or PYG broth. Broth cultures are turbid with a smooth to fine granular sediment. The pH range of PYG broth cultures is 5.0–5.5. Gelatin is hydrolyzed. Starch is hydrolyzed by most strains; some strains hydrolyze milk and meat. H_2S is produced by some strains. The major cellular fatty acids are $\text{C}_{15:0}$ iso and $\text{C}_{15:0}$ anteiso; substantial amounts of $\text{C}_{13:0}$ iso are also present. Sensitive to clindamycin and chloramphenicol. Two of 85 strains were resistant to erythromycin, one strain to tetracycline, and six strains to penicillin. β -Lactamase producing strains have been described (Kononen et al., 1996).

Source: gingival crevices of humans with gingivitis or periodontitis and from humans with healthy gingivae.

DNA G+C content (mol%): 49 (T_m).

Type strain: ATCC 51270, CCUG 41358, NCTC 13056, VPI N3B-3.

Sequence accession no. (16S rRNA gene): X82823.

6. **Porphyromonas circumdentaria** Love, Bailey, Collings and Briscoe 1992, 435^{VP}

cir.cum.den.ta'ri.a. L. adv. and prep. *circum* around, about; L. fem. adj. *dentaria* pertaining to teeth; N.L. fem. adj. *circumdentaria* referring to the isolation of the organism from the vicinity of the teeth.

The description is from Love et al. (1992). In cooked-meat carbohydrate medium and on sheep blood agar plates cells are 0.3 – 0.6×0.8 – $1.5 \mu\text{m}$ and occur singly, in clumps, and occasionally as filaments up to $10 \mu\text{m}$ long. On sheep blood agar, surface colonies at 72 h are 1–2 mm in diameter, and greenish brown. Both colony size and pigment formation are enhanced by growth in the presence of *Staphylococcus epidermidis*. After incubation for 5 d, the pH range in media containing carbohydrates generally is 6.3–6.5. Ammonia is produced in cooked meat medium. Gelatin is hydrolyzed. Neither lactate nor threonine is converted to propionate, and pyruvate is not utilized. Other characteristics are as described for the genus and as given in Table 15.

Source: soft tissue infections (abscesses and empyemas), gingival margins, and subgingival plaque of felines.

DNA G+C content (mol%): 40–42 (T_m).

Type strain: ATCC 51356, CCUG 41934, JCM 13864, NCTC 12469, VPB 3329.

Sequence accession no. (16S rRNA gene): L26102.

7. **Porphyromonas crevioricanis** Hirasawa and Takada 1994, 640^{VP}

cre.vi.o.ri.ca'nis. N.L. gen. n. *crevi* (*sic*) of a crevice; L. gen. n. *oris* of the mouth; L. gen. n. *canis* of a dog; N.L. gen. n. *crevioricanis* of the crevice of a dog's mouth.

The description is from Hirasawa and Takada (1994). Cellular and colonial morphology and other characteristics are as described for the genus and as given in Table 15. Susceptible to penicillin, amoxicillin, sulbenicillin, and erythromycin.

Source: gingival crevicular fluid obtained from beagles.

DNA G+C content (mol%): 44–45 (T_m).

Type strain: NUM 402, ATCC 55563.

Sequence accession no. (16S rRNA gene): DQ677836.

Taxonomic note: Strain NCTC 12858^T of *Porphyromonas cansulci* Collins et al. 1994, 678^{VP} exhibits 99.9% rRNA gene sequence homology with *Porphyromonas crevioricanis* ATCC 55563^T. The taxonomic standing of these two species remains to be determined.

8. **Porphyromonas endodontalis** (van Steenberg, VanWinkelhoff, Mayrand, Grenier and de Graaff 1984) Shah and Collins 1988, 129^{VP} (*Bacteroides endodontalis* van Steenberg, VanWinkelhoff, Mayrand, Grenier and de Graaff 1984, 119^{VP})

en.do.don'ta.lis. Gr. adv. *endon* within; Gr. n. *odous-ontos* tooth; L. fem. suff. *-alis* suffix denoting pertaining to; N.L. fem. adj. *endodontalis* pertaining to the inside of a tooth, within teeth.

The description is from Shah and Collins (1988) van Steenberg et al. (1984), and Holdeman et al. (1984). Protoheme is the major porphyrin produced, but protoporphyrin is also present. Most strains produce colonies that adhere strongly to the agar plates, and growth in liquid media is slow.

Gelatin is hydrolyzed. No proteolytic or collagenolytic activity is detected. Arginine is hydrolyzed; starch is not hydrolyzed. H_2S is produced. Cellular and colonial morphology and other characteristics are as described for the genus and as given in Table 15.

Specific primers based on 16S rRNA sequencing have been described for culture-independent identification of *Porphyromonas endodontalis* (de Lillo et al., 2004). Similarly, the use of PCR amplification of 16S rDNA and the downstream intergenic spacer region (ISR) for culture-independent detection of periodontal pathogens revealed that *Porphyromonas endodontalis* was as strongly associated with periodontitis as *Porphyromonas gingivalis* (Kumar et al., 2003).

Source: infected dental root canals, periodontal pockets, and other oral sites.

DNA G+C content (mol%): 49–51 (T_m).

Type strain: HG370, ATCC 35406, NCTC 13058.

Sequence accession no. (16S rRNA gene): L16491.

9. **Porphyromonas gingivalis** (Coykendall, Kaczmarek and Slots 1980) Shah and Collins 1988, 129^{VP} (*Bacteroides gingivalis* Coykendall, Kaczmarek and Slots 1980, 559^{VP})

gin.gi.val'is. L. n. *gingiva* gum; L. fem. suff. *-alis* suffix denoting pertaining to; N.L. fem. adj. *gingivalis* pertaining to the gums, gingival.

The description is from Shah and Collins (1988) and Holdeman et al. (1984). Protoheme is the major porphyrin produced, but traces of protoporphyrin also occur. Several amino acids, such as aspartate, arginine, cystine, histidine, serine, tryptophan, leucine, methionine, phenylalanine, and isoleucine, are utilized. Proteases are present. Starch is not hydrolyzed. Cellular and colonial morphology and other characteristics are as described for the genus and as given in Table 15.

Porphyromonas gingivalis possesses a multitude of cell-surface-associated and extracellular activities, such as adhesins, secreted or cell-bound enzymes, toxins, and hemolysins that contribute to its virulence potential. Differences in the virulence exist, but the mechanisms underlying these differences are not yet fully understood. Multilocus sequence typing of *Porphyromonas gingivalis* strains from different geographic origins showed high genetic diversity of the species (Enersen et al., 2006).

Porphyromonas gingivalis is generally very susceptible to most of the antimicrobial agents commonly used for treatment of anaerobic infections, such as amoxicillin-clavulanate, piperacillin-tazobactam, ampicillin-sulbactam, imipenem, cephalosporins, and metronidazole. Ciprofloxacin resistance of *Porphyromonas gingivalis* has been reported (Lakhssassi et al., 2005).

Porphyromonas gingivalis is considered a major periodontal pathogen and reported to be a cause of extraoral infections, such as lung abscesses and pulmonary infections. It has also been suggested that *Porphyromonas gingivalis* may contribute to the development of atheromas in cardiovascular disease.

Source: infected dental root canals, periodontal pockets, and other oral sites.

DNA G+C content (mol%): 46–48 (T_m).

Type strain: 2561, ATCC 33277, CCUG 25893, CCUG 25928, CIP 103683, DSM 20709, JCM 12257, NCTC 11834.

Sequence accession no. (16S rRNA gene): L16492.

10. **Porphyromonas gingivicanis** Hirasawa and Takada 1994, 639^{VP}

gin.gi.vi.ca'nis. L. fem. n. *gingiva* gum; L. gen. n. *canis* of a dog; N.L. gen. n. *gingivicanis* of the gums of a dog.

The description is from Hirasawa and Takada (1994). Cellular and colonial morphology and other characteristics are as described for the genus and as given in Table 15. Susceptible to penicillin, amoxicillin, sulbenicillin, and erythromycin.

Source: gingival crevicular fluid obtained from beagles.

DNA G+C content (mol%): 41–42 (T_m).

Type strain: NUM 301, ATCC 55562.

Sequence accession no. (16S rRNA gene): DQ677835.

11. **Porphyromonas gulae** Fournier, Mouton, Lapierre, Kato, Okuda and Menard. 2001, 1187^{VP}

gu'lae. L. n. *gula* [animal] mouth; L. gen. n. *gulae* from the animal mouth, referring to its isolation from subgingival plaque of various animal hosts.

The description is from Fournier et al. (2001). *Porphyromonas gulae* encompasses the "animal *Porphyromonas gingivalis*". Cellular and colonial morphology and other characteristics are as described for the genus and as given in Table 15. Twenty strains were susceptible to amoxicillin and amoxycillin/clavulanate.

Source: subgingival plaque samples of various mammals, including cat, dog, coyote, wolf, bear, and non-human primate, such as squirrel monkey and spider monkey. *Porphyromonas gulae* is the most prominent species of the genus *Porphyromonas* to be found in the oral cavity of mammals.

DNA G+C content (mol%): 51 (T_m).

Type strain: Loup 1, ATCC 51700, CCUG 47701, NCTC 13180.

Sequence accession no. (16S rRNA gene): AF208290.

12. **Porphyromonas levii** (Johnson and Holdeman 1983) Shah, Collins, Olsen, Paster and Dewhirst 1995, 586^{VP} (*Bacteroides levii* Johnson and Holdeman 1983, 15^{VP})

lev'i.i. N.L. gen. masc. n. *levii* of Lev, named after Meir Lev, the American-English microbiologist, who first isolated this organism.

The description is from Shah et al. (1995), Holdeman et al. (1984), and Summanen et al. (2005). Cellular and colonial morphology and other characteristics are as described for the genus and as given in Table 15. Protoheme is the major porphyrin produced, but traces of protoporphyrin also occur. Succinate stimulates growth and can replace the requirement for heme. Few sugars, such as glucose and lactose, are weakly fermented. Glucose broth cultures are turbid with smooth sediment and a final pH of 5.5. Most other commonly occurring sugars, such as arabinose, cellobiose, melezitose, melibiose, raffinose, rhamnose, ribose, salicin, sucrose, trehalose, and xylose, are not fermented. Some amino acids, such as asparagine, tryptophan, phenylalanine, and glutamine, are utilized. Proteases are present. Starch is not hydrolyzed.

Porphyromonas levii is genetically distant from *Porphyromonas somerae*; however, these two species cannot readily be differentiated by phenotypic tests. Although both species contain major C_{15:0} iso, C_{15:0} anteiso acids, the cluster analysis of the cellular fatty acid profiles (Euclidian distance of principal components accounting for the greatest variance of the organisms) differentiates the two species.

Source: bovine rumen, cattle horn abscess, bovine summer mastitis, and bovine necrotizing vulvovaginitis.

DNA G+C content (mol%): 46–48 (T_m).

Type strain: LEV, ATCC 29147, CCUG 21027, CCUG 34320, HAMBI 467, NCTC 11028, VPI 10450, VPI 3300.

Sequence accession no. (16S rRNA gene): L16493.

13. **Porphyromonas macacae** (Slots and Genco 1980) Love 1995, 91^{VP} [*Bacteroides melaninogenicus* subsp. *macacae* Slots and Genco 1980, 84^{VP}; *Bacteroides macacae* (Slots and Genco 1980) Coykendall, Kaczmarek and Slots 1980, 563^{VP}; *Porphyromonas salivosa* Love, Bailey, Collings and Briscoe 1992, 438^{VP}]

ma.ca'cae. N.L. fem. n. *Macaca* genus name of the macaque; N.L. gen. n. *macacae* of the macaque.

The description is from Love et al. (1995) and Holdeman et al. (1984). After 6 d on blood agar plates, colonies are 0.1–0.2 mm, entire, dome shaped, and creamy brown. After 9 d in the presence of *Staphylococcus epidermidis*, however, the colonies are 1.0–1.5 mm in diameter, entire, umbonate with a central depression. As incubation progresses, the surfaces of colonies may become wrinkled with multiple central depressions and peripheral ridging. Gelatin is hydrolyzed. Lipase is not produced. Other characteristics are as described for the genus and as given in Table 15.

Porphyromonas macacae ATCC 33141 can be distinguished by phenotypic criteria from cat strains, suggesting that cat and monkey biovars exist. (See discussion of *Porphyromonas salivosa* under *Taxonomic note*, below.)

Source: oral cavities, subcutaneous abscesses, and pyothoraxes of animals, including cats and monkeys. Important pathogen in animal bite infections in humans.

DNA G+C content (mol%): 43–44 (T_m).

Type strain: 7728-L6C, Slots' strain 7728-L6C, ATCC 33141, CCUG 47703, DSM 20710, NCTC 13100.

Sequence accession no. (16S rRNA gene): L16494.

Taxonomic note: Strain NCTC 11632^T of *Porphyromonas salivosa* (Love et al., 1987) Love et al., 1992, 438^{VP} exhibits 99.3% rRNA gene sequence homology (Paster et al., 1994) and a mean level of DNA–DNA hybridization of 81% (Love, 1995) with *Porphyromonas macacae* ATCC 33141^T; therefore, the species *Porphyromonas salivosa* was included in the species *Porphyromonas macacae* by Love (1995). However, *Porphyromonas macacae* ATCC 33141^T can be distinguished by phenotypic criteria from cat strains (*Porphyromonas salivosa*), suggesting that cat and monkey biovars of *Porphyromonas macacae* exist. The members of the cat biovar have different colonial morphologies on blood agar: the colonies are 0.5–1.5 mm in diameter, circular, entire, dome-shaped, and brown–black at 72 h on blood agar plates. Furthermore, unlike *Porphyromonas macacae* ATCC 33141^T, the cat biovars produce different whole-cell protein and proteinase profiles on SDS-PAGE gels, and are lipase-positive and sorbitol-negative.

14. **Porphyromonas salivosa** (Love, Johnson, Jones, and Calverley 1987) Love, Bailey, Collings and Briscoe 1992, 438^{VP} = *Porphyromonas macacae* (senior heterotypic synonym) (*Bacteroides salivosus* Love, Johnson, Jones and Calverley 1987, 308)

sal.i.vo'sa. L. fem. adj. *salivosa* resembling saliva, slimy.

The description is from Love et al. (1995), Love et al. (1992), and Love et al. (1987). After 72 h on blood agar plates, colonies are 0.5–1.5 mm, entire, dome shaped, and brown–black. Gelatin is hydrolyzed. Lipase is produced.

Porphyromonas salivosa NCTC 11632^T can be distinguished by phenotypic criteria from monkey strains (*Porphyromonas macacae*), suggesting that cat and monkey biovars exist. (See **Taxonomic note**, above, under *Porphyromonas macacae*.)

DNA G+C content (mol%): 42–44 (T_m).

Type strain: ATCC 49407, NCTC 11632, VPB 157, CCUG 33478.

Sequence accession no. (16S rRNA gene): L26103.

15. **Porphyromonas somerae** Summanen, Durmaz, Vaisanen, Liu, Molitoris, Eerola, Helander and Finegold 2006, 925^{VP} (Effective publication: Summanen, Durmaz, Vaisanen, Liu, Molitoris, Eerola, Helander and Finegold 2005, 4458.)

so'mer.ae. N.L. gen. fem. n. *somerae*, of Somer, named in honor of the late Finnish microbiologist Hannele Jousimies-Somer.

The description is from Summanen et al. (2005). Colonies incubated on blood agar for 2 d often exhibit a “patchy” growth pattern, with larger colonies surrounded by smaller colonies; they are circular, entire, and convex. The colonies on laked rabbit blood agar are white–yellow to tan; after 4 d of incubation, the colonies are pigmented (light brown to dark brown) and show no or occasionally weak red fluorescence under long-wave UV light. Weakly saccharolytic, the pH of glucose, lactose, and maltose cultures is 5.3–5.4 after 5 d of incubation. Most other commonly occurring

sugars, such as arabinose, cellobiose, melezitose, melibiose, raffinose, rhamnose, ribose, salicin, sucrose, trehalose, and xylose are not fermented. β -lactamase is produced by 21% of the strains. Some strains are resistant to clindamycin. Other characteristics are as described for the genus and as given in Table 15.

Porphyromonas somerae is genetically distant from *Porphyromonas levii*; however, these two species cannot readily be differentiated by phenotypic tests. Although both species contain major C_{15:0} iso, C_{15:0} anteiso acids, the cluster analysis of the cellular fatty acid profiles (Euclidian distance of principal components accounting for the greatest variance of the organisms) differentiates the two species.

Source: various clinical specimens of non-oral origin, mainly from chronic foot infections of diabetics or other patients with vascular insufficiency.

DNA G+C content (mol%): 47.8 (T_m).

Type strain: WAL 6690, ATCC BAA-1230, CCUG 51464.

Sequence accession no. (16S rRNA gene): AY968205.

16. **Porphyromonas uenonis** Finegold, Vaisanen, Rautio, Eerola, Summanen, Molitoris, Song, Liu and Jousimies-Somer 2005, 547^{VP} (Effective publication: Finegold, Vaisanen, Rautio, Eerola, Summanen, Molitoris, Song, Liu and Jousimies-Somer 2004, 5301.)

ue.no'nis. N.L. gen. masc. n. *uenonis* of Ueno, in honor of the late Japanese microbiologist Kazue Ueno.

The description is from Finegold et al. (2004). Growth is stimulated by 5% horse serum and similar additives. Cellular and colonial morphology and other characteristics are as described for the genus and as given in Table 15. *Porphyromonas uenonis* can be distinguished from *Porphyromonas asaccharolytica* by phenotypic tests (Table 15); however, DNA–DNA reassociation studies are required to distinguish these two species genetically. Susceptible to most antimicrobial agents. Some strains produce β -lactamase.

Source: part of a mixed flora in various infections, which apparently have their origin in the intestinal tract. The habitat is probably the human gut.

DNA G+C content (mol%): 52.5 (T_m).

Type strain: WAL 9902, ATCC BAA-906, CCUG 48615.

Sequence accession no. (16S rRNA gene): AY570514.

Other organisms

Porphyromonas bennonis, a novel species isolated from human clinical specimens, was recently published in IJSEM (Summanen et al., 2009).

DNA G+C content (mol%): 58 (T_m).

Type strain: WAL 1926C, ATCC BAA-1629, CCUG 55979.

Sequence accession no. (16S rRNA gene): EU414673.

The 16S rRNA gene sequence of an organism called “*Porphyromonas canis*” was published in GenBank with accession number AB0034799. “*Porphyromonas canis* sp. nov. isolated from dog”. Unpublished. Strain ATCC 55562^T of *Porphyromonas gingivicanis* Hirasawa and Takada 1994, 640^{VP} exhibits 99.9% rRNA gene sequence homology with “*Porphyromonas canis*”

JCM 10100, suggesting that *Porphyromonas canis* is a later synonym of *Porphyromonas gingivicanis*.

No valid description of the species “*Porphyromonas canis*” can be found in the literature. However, the following information is available.

DNA G+C content (mol%): 52.5 (T_m).

Type strain: JCM 10100.

Sequence accession no. (16S rRNA gene): AB034799.

Taxonomic note: Hardham, Dreier, Wong, Sfintescu and Evans (2005) mentioned an organism named “*Porphyromonas denticanis*”. They indicated that *Porphyromonas salivosa*, “*Porphyromonas denticanis*” (a novel species), and *Porphyromonas gulae* were the most frequently isolated black-pigmented anaerobic bacteria associated with canine periodontitis. However, no valid description of “*Porphyromonas denticanis*” can be found in the literature, and there are no GenBank entries for it.

Genus II. *Barnesiella* Sakamoto, Lan and Benno 2007b, 344^{VP}

THE EDITORIAL BOARD

Bar.ne.si.el'la. N.L. dim. fem. n. *Barnesiella* named after the British microbiologist Ella M. Barnes, who contributed much to knowledge of intestinal bacteriology and to anaerobic bacteriology in general.

Rods (0.8–1.6 × 1.7–11 µm). Nonsporeforming. Nonmotile. Gram-negative. Obligately anaerobic. On Eggerth–Gagnon agar, colonies are 1–2 mm in diameter, gray to off-white–gray, circular, entire, slightly convex, and smooth. Saccharolytic, with a strictly fermentative type of metabolism. Acetic and succinic acids are the main fermentation products. Growth is inhibited on a medium containing 20% bile. Esculin is hydrolyzed. Indole-negative. The predominant menaquinones are MK-11 and MK-12. Isolated from the chicken cecum.

DNA G+C content (mol%): 52.

Type species: *Barnesiella viscericola* Sakamoto, Lan and Benno 2007b, 345^{VP}.

Further descriptive information

Phylogenetic analyses of chicken cecal microbiota, based on 16S rRNA gene clone library analyses, have revealed a large number of novel phylotypes (Lan et al., 2002; Zhu et al., 2002). Using a special anaerobic culture technique, Sakamoto et al. (2007b) obtained unusual strains. Like *Porphyromonas* strains, these obligately anaerobic, nonsporeforming, nonmotile, Gram-negative rods were inhibited by 20% bile. However, their major menaquinones (MK-11 and MK-12) differed from those of most other genera of the family *Porphyromonadaceae*, which

had menaquinones 8, 9, or 10 (except *Tannerella*, which has MK-10 and MK-11). Phylogenetic analysis has shown that these strains represent a new genus in the family.

Enrichment and isolation procedures

Barnesiella strains were isolated from the chicken cecum under strictly anaerobic conditions by the method described by Lan et al. (2002). They were maintained on Eggerth–Gagnon (EG) agar (Merck) supplemented with 5% (v/v) horse blood, with incubation for 2 d at 37°C in an atmosphere of 100% CO₂.

Differentiation of the genus *Barnesiella* from other closely related genera

Some characteristics differentiating the genus *Barnesiella* from other genera are shown in Table 16.

Taxonomic comments

Analyses of the 16S rRNA gene sequences of two cecal isolates that failed to grow in the presence of 20% bile indicated that the strains were related to *Parabacteroides distasonis* (86% sequence similarity). The two strains exhibited 100% 16S rRNA gene sequence similarity with each other.

TABLE 16. Some characteristics differentiating the genus *Barnesiella* from other related genera^{a,b}

Characteristic	<i>Barnesiella</i>	<i>Dysgonomonas</i>	<i>Poludibacter</i>	<i>Parabacteroides</i>	<i>Porphyromonas</i>	<i>Proteiniphilum</i>	<i>Tannerella</i>
Growth in presence of 20% bile	–	+	–	+	–	–	–

^aSymbols: +, >85% positive; –, 0–15% positive; na, not applicable; nr, not reported.

^bData taken from Chen and Dong (2005); Hofstad et al. (2000); Lawson et al. (2002a); Sakamoto and Benno (2006); Sakamoto et al. (2002); Ueki et al. (2006); Sakamoto et al. (2007b).

List of species of the genus *Barnesiella*1. *Barnesiella viscericola* Sakamoto, Lan and Benno 2007b, 345^{VP}

vis.ce.ri'co.la. L. n. *viscus, visceris* intestine; L. suff. n. *-cola* (from L. n. *incola*) inhabitant; N.L. fem. n. *viscericola* inhabitant of the intestine.

The characteristics are as given for the genus, with the following additional features. Urease and catalase-negative. Gelatin is digested. Acid is produced from D-cellobiose, glucose, maltose, D-mannose, and sucrose, but not from L-arabinose, glycerol, lactose, D-mannitol, D-melezitose, D-raffinose, L-rhamnose, salicin, D-sorbitol, D-trehalose, or D-xylose. Using the Rapid ID 32A tests, all strains are positive for α -galactosidase, β -galactosidase, α -glucosidase, β -glucosidase, N-acetyl- β -glucosaminidase, glutamic acid

decarboxylase, α -fucosidase, alkaline phosphatase, leucyl-glycine arylamidase, and alanine arylamidase. Raffinose is fermented. All of the other tests with the Rapid ID 32A system give negative results. The major end products are acetic acid and succinic acid; lower levels of other acids may be produced. Both non-hydroxylated and 3-hydroxylated long-chain fatty acids are present. The major cellular fatty acids are C_{15:0} anteiso and C_{15:0} iso. The predominant respiratory quinones are MK-11 (65–66%) and MK-12 (21–24%). MK-10 is present as a minor menaquinone (10–11%).

Source: the chicken cecum.

DNA G+C content (mol%): 52 (HPLC).

Type strain: C46, DSM 18177, JCM 13660.

Sequence accession no. (16S rRNA gene): AB267809.

Genus III. *Dysgonomonas* Hofstad, Olsen, Eribe, Falsen, Collins and Lawson 2000, 2194^{VP}

INGAR OLSEN

Dys.go.no.mo'nas. Gr. pref. *dys-* with notion of hard, bad, unlucky; Gr. n. *gonos* that which is begotten, reproduction; Gr. fem. n. *monas* a monad, unit; N.L. fem. n. *Dysgonomonas* intended to mean a weakly growing monad.

Coccobacilli to short rods. Nonmotile. Gram-negative. Facultatively anaerobic. Colonies are 1–2 mm in diameter, nonadherent, entire, gray–white, smooth, and nonhemolytic and have a slight aromatic odor. Growth is not observed on MacConkey agar. Requires X factor for growth. May be catalase-positive or -negative. Oxidase-negative. Glucose is fermented, producing acid but no gas. Alkaline phosphatase is generated but not arginine dihydrolase. Nitrate is not reduced. H₂S and acetoin are not produced. Esculin may not be hydrolyzed; gelatin and urea are not hydrolyzed. Indole may be produced. Long-chain cellular fatty acids include straight-chain saturated, anteiso- and iso-methyl branched and 3-hydroxy types. Isolated from human clinical specimens and stools.

DNA G+C content (mol%): 38 (*T_m*).

Type species: *Dysgonomonas gadei* Hofstad, Olsen, Eribe, Falsen and Lawson 2000, 2194^{VP}.

Further descriptive information

Dysgonomonas capnocytophagoides (Hofstad et al., 2000) and *Dysgonomonas mossii* (Lawson et al., 2002a, b) are members of the CDC DF (dysgonic fermenter)-3 group (Daneshvar et al., 1991; Wallace et al., 1989). *Dysgonomonas gadei* (Hofstad et al., 2000) was isolated at the Gade Institute, Bergen, Norway. Comparative 16S rRNA sequence analysis indicates that *Dysgonomonas* is a distinct genus in Family III. “*Porphyromonadaceae*” in the phylum “*Bacteroidetes*”. See *Taxonomic comments* for details.

Cells can be coccobacilli to short rods (Figures 18 and 19). Nitrate is not reduced and the oxidase reaction is negative. The catalase reaction has been reported as negative (Koneman et al., 1997) and as negative or positive (Hofstad et al., 2000). The organisms produce acid by fermentation of glucose (Hofstad et al., 2000; Koneman et al., 1997), xylose and maltose; most strains produce acid from sucrose and lactose,

FIGURE 18. Scanning electron microscopy of cells from colonies of *Dysgonomonas gadei* CCUG 42886^T (a), *Dysgonomonas mossii* CCUG 43457^T (b), and *Dysgonomonas capnocytophagoides* CCUG 17996^T (c). Cells were cultured anaerobically for 48 h at 37°C on human blood agar supplemented with hemin and vitamin K.

FIGURE 19. Transmission electron microscopy of *Dysgonomonas gadei* CCUG 42886^T (a), *Dysgonomonas mossii* CCUG 43457^T (b), and *Dysgonomonas capnocytophagoides* CCUG 17996^T (c). Cells were cultured anaerobically for 48 h at 37°C on human blood agar supplemented with hemin and vitamin K. OM, outer membrane; IM, inner cytoplasmic membrane; G, granule; SLPs, scale-like protrusion.

but not from mannitol (Koneman et al., 1997). Esculin may be hydrolyzed (Hofstad et al., 2000; Koneman et al., 1997). Furthermore, alkaline phosphatase is produced but not arginine dihydrolase. H₂S and acetoin are not produced. Indole may be generated (Hofstad et al., 2000).

Isolates of *Dysgonomonas* species are rare (Koneman et al., 1997; Martínez-Sánchez et al., 1998). They have been recovered from clinical sources such as blood, wounds, urine, peritoneal fluid, umbilicus, stools, and gallbladder. Asymptomatic carriers have been found. The first report on these organisms was made by Wagner et al. (1988), who made multiple isolations in pure culture from the stools of an elderly woman with common variable hypogammaglobulinemia of long standing. DF-3 was also found in stool specimens by Gill et al. (1991) and Grob et al. (1999); several of the patients suffered from prolonged diarrhea. In another study with immunocompromised patients or patients with severe underlying disease, including HIV or inflammatory bowel disease, DF-3 was isolated from stool specimens during a 1-year period (Blum et al., 1992); the clinical spectrum associated with DF-3 ranged from asymptomatic carrier state to symptomatic with chronic diarrhea. Heiner et al. (1992) described an association of enteric DF-3 infection with HIV coinfection and common variable hypogammaglobulinemia. Further, Aronson and Zbick (1988) isolated DF-3 from a 24-year-old man with relapse of acute lymphocytic leukemia, and Grob et al. (1999) detected DF-3 in bacteremia from a patient with acute myelocytic leukemia during aplasia. The former patient became granulocytopenic during intensive chemotherapy and DF-3 was isolated from blood cultures. Recently, a case of *Dysgonomonas capnocytophagoides* in blood culture from a severely neutropenic patient treated for acute myeloid leukemia was reported (Hansen et al., 2005). A soft-tissue abscess in a diabetic patient and a postoperative urinary tract infection in an 81-year-old man yielded DF-3, and in the latter case, DF-3 was recovered together with *Escherichia coli* (Bangsberg et al., 1990; Schonheyder et al., 1991). DF-3 has also been isolated together with *Candida albicans*, *Candida glabrata*, *Staphylococcus aureus*, and enterococci (Lawson et al., 2002a). Melhus (1997) recovered DF-3 from a decubitous ulcer of a subfebrile patient with diarrhea.

Disk diffusion and broth dilution have been used to assess antimicrobial susceptibility of DF-3 isolates (Aronson and Zbick, 1988; Blum et al., 1992; Gill et al., 1991; Heiner et al., 1992; Wagner et al., 1988). The DF-3 strains were resistant to penicillin,

ampicillin, ampicillin-sulbactam, aztreonam, aminoglycosides, cephalosporins (including cephalotin, cefoxitin, ceftriaxone, cefoperazone, and ceftazidime), erythromycin, ciprofloxacin, and vancomycin (Koneman et al., 1997). They are usually susceptible to trimethoprim-sulfamethoxazole and chloramphenicol, and variably susceptible to piperacillin, clindamycin, tetracycline, and imipenem. *Dysgonomonas gadei* was sensitive to metronidazole, clindamycin, doxycycline, imipenem, meropenem, and trimethoprim/sulfamethoxazole (Hofstad et al., 2000). The organism was resistant to cefoxitin and other cephalosporins (cefotaxime, ceftazidime, ceftriaxone, cefuroxime, and cephalotin), aminoglycosides (gentamicin, netilmicin, sulfadiazine), fluoroquinolones (ciprofloxacin, oxafloxacin), vancomycin, and teicoplanin. Similarly, *Dysgonomonas capnocytophagoides* was susceptible to ampicillin, tetracycline, chloramphenicol, clindamycin, and trimethoprim-sulfamethoxazole, while it was resistant to penicillin, cephalosporins, meropenem, aminoglycosides, and ciprofloxacin (Hansen et al., 2005).

Enrichment and isolation procedures

Culture from stool specimens is best performed on cefoperazone-vancomycin-amphotericin blood agar incubated at 35°C in 5–7% CO₂ (Koneman et al., 1997). Growth is relatively slow with pinpoint colonies visible after 24 h. After 48–72 h the colonies turn gray-white, smooth, and are nonhemolytic. A sweet odor may be produced by the organism on agar media (Bernard et al., 1991; Blum et al., 1992; Gill et al., 1991; Wagner et al., 1988).

Taxonomic comments

In 2000, Hofstad et al. isolated an organism from a human gallbladder that resembled CDC Group DF-3 organisms and named it *Dysgonomonas gadei*, thereby creating a new genus *Dysgonomonas*. The authors simultaneously reclassified the organisms previously designated CDC group DF-3 as *Dysgonomonas capnocytophagoides*. Lawson et al. (2002a, b) described another *Dysgonomonas* species, *Dysgonomonas mossii*, from human clinical specimens.

The CDC Group DF-3 has been considered closely related to *Capnocytophaga* species. After whole-cell protein electrophoresis, a separate position was occupied by a DF-3 strain when compared to well-characterized reference strains representing seven *Capnocytophaga* species (Vandamme et al., 1996). The whole-cell protein pattern of *Dysgonomonas gadei* was separate from those of two DF-3 strains and reference strains of *Capnocytophaga*, *Bacteroides*,

and *Prevotella* (Hofstad et al., 2000). The nearest correlation was seen with *Bacteroides uniformis* at approximately 58%.

The cell walls of DF-3 strains had large amounts (24%) of anteiso-branched-chain fatty acid ($C_{15:0}$ anteiso), moderate amounts of saturated iso-branched-chain acids ($C_{14:0}$ iso and $C_{15:0}$ iso), and small to moderate amounts of both branched- and straight-chain hydroxy acids ($C_{15:0}$ 3-OH, $C_{16:0}$ iso 3-OH, $C_{16:0}$ 3-OH, and $C_{17:0}$ iso 3-OH) (Wallace et al., 1989). The dominating cellular fatty acid content of *Dysgonomonas gadei* CCUG 42882^T is $C_{15:0}$ anteiso, $C_{16:0}$, $C_{14:0}$ iso, and $C_{16:0}$ iso 3-OH, which is similar to that of *Dysgonomonas capnocytophagoides* CCUG 17996^T and CCUG 42515 (Hofstad et al., 2000). For comparison, Moore et al. (1994) found that $C_{15:0}$ anteiso, $C_{15:0}$ iso, $C_{17:0}$ iso 3-OH, and $C_{16:0}$ are the major cellular fatty acids in *Bacteroides* and *Prevotella*, and $C_{15:0}$ iso the major cellular fatty acid of *Porphyromonas*. Bernard et al. (1991) detected $C_{15:0}$ iso and $C_{17:0}$ iso 3-OH as the major cellular fatty acids in *Capnocytophaga*. The overall fatty acid composition of DF-3 organisms and *Capnocytophaga* species is clearly different from that of CDC group DF-3-like organisms (Daneshvar et al., 1991). The isoprenoid

quinone content of four group DF-3-like strains was similar with ubiquinone-9 (Q-9) and Q-10 as the major quinone, whereas two other group DF-3-like strains had Q-7 as their major quinones, with smaller amounts of Q-8 and Q-9. Notably, CDC group DF-3 strains F9489 and G4990 did not contain quinones.

Bernard et al. (1991) found that CDC group DF-3 organisms produced significant quantities of propionic acid as metabolic product. Also lactic and succinic acids were detected, but the quantities varied among strains.

Comparative 16S rRNA sequence analysis has indicated that CDC group DF-3 is phylogenetically related to but different from *Bacteroides*, *Porphyromonas*, *Prevotella*, and kindred organisms (Paster et al., 1994; Vandamme et al., 1996). Actually, *Dysgonomonas gadei* and *Dysgonomonas capnocytophagoides* formed a distinct phylogenetic cluster within the *Bacteroides-Prevotella-Porphyromonas* group (Hofstad et al., 2000). Sequence analysis showed that *Dysgonomonas mossii* differed from *Dysgonomonas gadei* (91.7%) and *Dysgonomonas capnocytophagoides* (94.3%) (Lawson et al., 2002a). Other taxa were related to these species (Figure 20) but showed much lower levels of sequence similarity, including

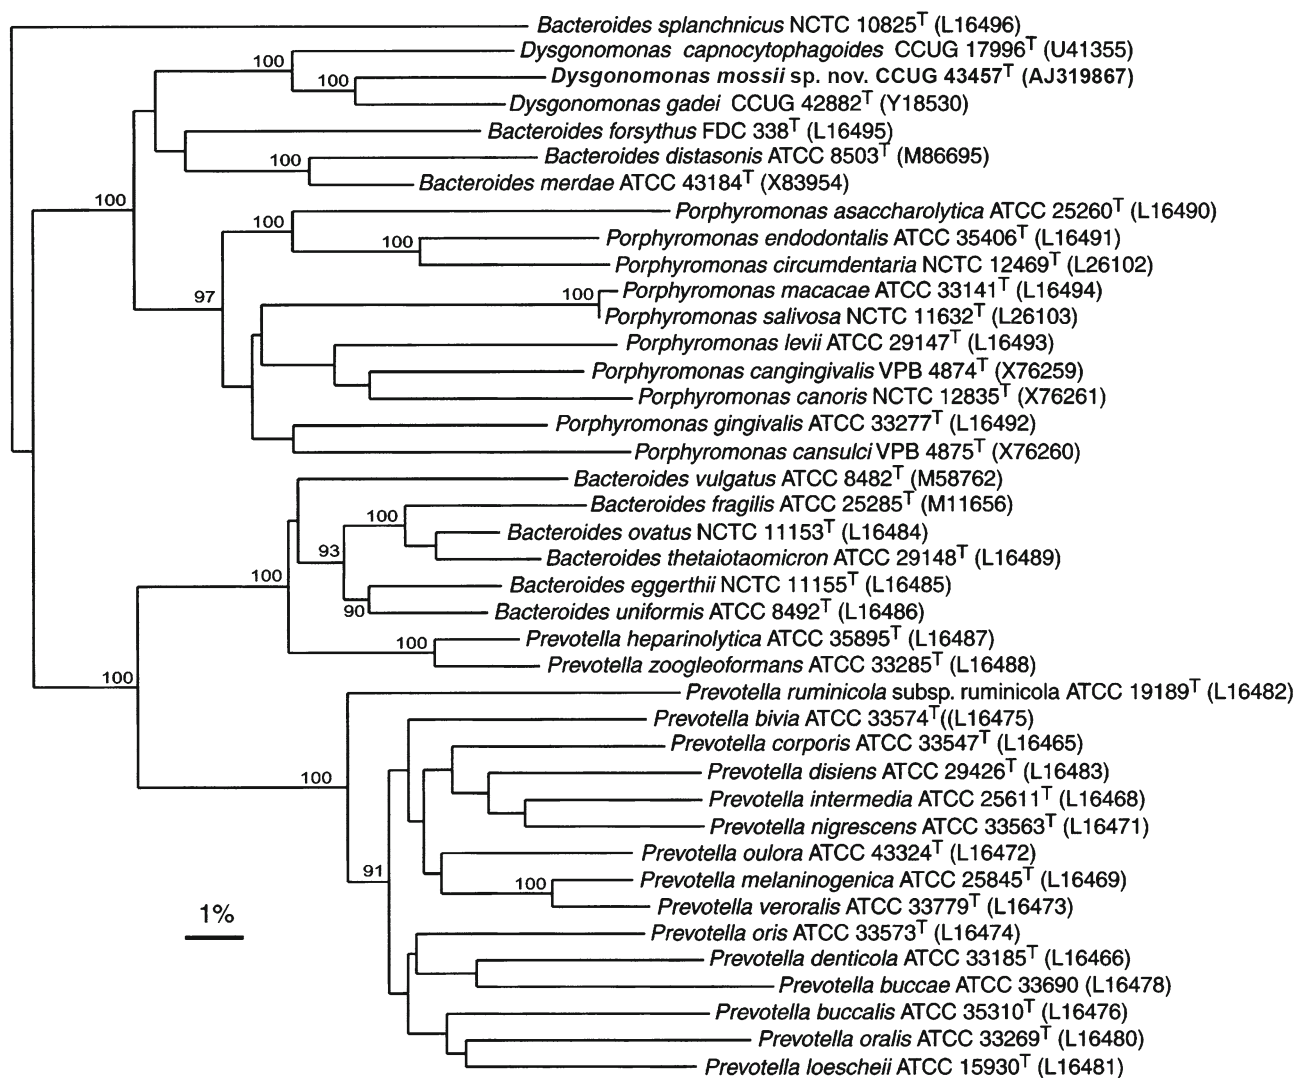

FIGURE 20. Phylogenetic tree of *Dysgonomonas* species and related organisms. (Reproduced with permission from Lawson et al., 2002a. Syst. Appl. Microbiol. 25: 194–197.)

Bacteroides (85–87%), *Porphyromonas* (84–88%), and *Prevotella* (79–85%) and the misclassified strict anaerobic species *Bacteroides distasonis* (87%), *Bacteroides forsythus* (88%), *Bacteroides merdae* (89%), and *Bacteroides splanchnicus* (83%) (Hofstad et al., 2000; Lawson et al., 2002a). Comparative sequence 16S rRNA analysis unequivocally demonstrated three strains in a hitherto unrecognized subline within the *Dysgonomonas* clade (Lawson et al., 2002a). Divergence values of >5% with *Dysgonomonas capnocytophagoides* and *Dysgonomonas gadei* indicated that they may merit classification as a distinct species. Dewhirst et al. (1999) found that strain ASF 519 of *Bacteroides distasonis* fell into an unnamed genus containing *Bacteroides distasonis*, *Bacteroides merdae*, *Bacteroides forsythus*, and CDC group DF-3. *Capnocytophaga*

species were clearly distinct from *Dysgonomonas* (Hofstad et al., 2000).

Differentiation of the species of the genus *Dysgonomonas*

Similarities and differences between the three *Dysgonomonas* spp. are listed in Tables 17–19. Contrary to the other species *Dysgonomonas gadei* produces catalase. *Dysgonomonas gadei* can further be distinguished from *Dysgonomonas capnocytophagoides* and *Dysgonomonas mossii* by the absence of β -glucuronidase production by the latter two. Unlike the other two species, *Dysgonomonas capnocytophagoides* ferments trehalose but does not produce *N*-acetyl- β -glucosaminidase and α -fucosidase. *Dysgonomonas mossii* does not generate glutamyl glutamic acid arylamidase.

List of species of the genus *Dysgonomonas*

1. *Dysgonomonas gadei* Hofstad, Olsen, Eribe, Falsen, Collins and Lawson 2000, 2194^{VP}

ga'de.i. N.L. gen. masc. n. *gadei* of the Gade Institute, Bergen, Norway, where the organism was first isolated.

The following description is according to Hofstad et al. (2000). Nonmotile, Gram-negative coccobacilli that grow relatively slowly on blood agar. After 48 h of aerobic incubation at 35°C in a CO₂-enriched atmosphere, the col-

onies are 1–2 mm in diameter, nonadherent, entire, gray–white, smooth, and nonhemolytic, with a slight aromatic odor. After incubation for a few more d the colonies become coalesced, butyrous, and α -hemolytic. Growth can be seen at 25°C but not at 43°C. Growth occurs under microaerophilic and strictly anaerobic conditions. No growth occurs on MacConkey agar but does occur on nutrient agar around X and XV discs, suggesting a growth dependence for heme. Catalase-positive and oxidase-negative. No nitrate reduction

or production of H₂S or acetoin. Esculin is hydrolyzed, but gelatin and urea are not. Indole-positive. Resistant to ox bile. Glucose is fermented with production of acid but no gas. Acid is also produced from L-arabinose, cellobiose, fructose, lactose, D-mannose, melezitose, melibiose, raffinose, L-rhamnose, D-ribose (weak reaction), salicin, starch, sucrose, trehalose, and xylose. Positive reactions occur for *N*-acetyl- β -glucosaminidase, acid phosphatase, alanine arylamidase, alkaline phosphatase, α -arabinosidase, ester lipase C8 (weak), α -galactosidase, β -galactosidase (weak reaction), α -glucosidase, β -glucosidase, glutamyl glutamic acid arylamidase, α -mannosidase (weak), α -fucosidase, chymotrypsin, alanine arylamidase, leucyl glycine arylamidase, phosphoamidase, and trypsin. Positive and negative reactions are summarized in Tables 17–19.

Source: an infected human gallbladder, but the habitat is unknown.

DNA G+C content (mol%): not determined.

Type strain: ATCC BAA-286, CCUG 42882, CIP 106420.

Sequence accession no. (16S rRNA gene): Y18530.

2. ***Dysgonomonas capnocytophagoideis*** Hofstad, Olsen, Eribe, Falsen, Collins and Lawson 2000, 2194^{VP} (CDC Group DF-3, Wallace, Hollis, Weaver and Moss 1989, 735)

cap.no.cy.to.pha.goi'des. N.L. n. *Capnocytophaga* a genus of CO₂-requiring bacteria; L. suff. *-oides* (from Gr. suff. *-eides*, from Gr. n. *eidos* that which is seen, form, shape, figure) resembling, similar; N.L. adj. *capnocytophagoideis* like *Capnocytophaga*, referring to some properties shared between these organisms.

The following description is based on results obtained by Wallace et al. (1989) and Hofstad et al. (2000). Nonmotile, Gram-negative coccobacilli to short rods. Colonies are 1–2 mm in diameter, nonadherent, entire, gray–white, smooth, and non-hemolytic with a slight aromatic odor

after 48 h of aerobic incubation on blood agar at 35°C in a CO₂-enriched atmosphere (7.5%). No growth on MacConkey agar. Facultatively anaerobic. Catalase- and oxidase-negative. Does not produce H₂S or acetoin. Esculin may be hydrolyzed, but gelatin and urea are not. Indole may be produced. The organism is resistant to ox bile and does not reduce nitrate. Major products from glucose fermentation are propionic, lactic, and succinic acids. Glucose fermentation does not produce gas. Acid is produced from L-arabinose, lactose, maltose, D-mannose, melibiose, raffinose, sucrose, and D-xylose. Positive reactions occur for acid phosphatase, alanine arylamidase, alkaline phosphatase, α -arabinosidase, α -galactosidase, β -galactosidase, β -galactosidase 6-phosphate, α -glucosidase, β -glucosidase, glutamyl glutamic acid arylamidase, leucyl glycine arylamidase, and phosphoamidase. Esterase C-4 production is variable between strains. Positive and negative reactions are listed in Tables 17–19.

Source: human clinical specimens, but the habitat is unknown.

DNA G+C content (mol%): 38 (HPLC).

Type strain: CCUG 17996, CIP 107043, LMG 11519.

Sequence accession no. (16S rRNA gene): U41355.

3. ***Dysgonomonas mossii*** Lawson, Falsen, Inganäs, Weyant and Collins 2002a, 1915^{VP} (Effective publication: Lawson, Falsen, Inganäs, Weyant and Collins 2002a, 194.)

moss'i.i. N.L. gen. masc. n. *mossii* of Moss, to honor Claude Wayne Moss, an American microbiologist who has contributed much to microbial taxonomy.

The following description is according to Lawson et al. (2002a). Nonmotile, Gram-negative coccobacilli to short rods. After anaerobic incubation for 48 h at 37°C on blood agar, colonies are 1–2 mm in diameter, nonadherent, entire, gray–white, smooth, and nonhemolytic, and produce a

slightly aromatic odor. Growth occurs at 25°C but not at 42°C. No growth occurs on MacConkey agar. The organisms grow on nutrient agar around X and XV disks, indicating that they have a requirement for heme. Catalase- and oxidase-negative. Nitrate is not reduced to nitrite. Indole is produced, but not acetoin. The organisms are resistant to ox bile. Esculin and starch are hydrolyzed, but gelatin and urea are not. Glucose is fermented with production of acid but no gas. Acid is produced (conventional methods) from L-arabinose, cellobiose, fructose, inositol (weak reaction), lactose, mannitol (weak reaction), maltose, L-rhamnose (weak reaction), salicin, sucrose, trehalose, and D-xylose. With API rapid ID

32A, acid is produced from mannose, and D-raffinose may be fermented. Positive reactions are obtained for N-acetyl-β-glucosaminidase, alanine arylamidase, alkaline phosphatase, α-galactosidase, β-galactosidase, β-galactosidase 6-phosphate (weak), α-glucosidase, β-glucosidase, leucyl glycine arylamidase, α-mannosidase (weak reaction), and α-fucosidase. Arabinosidase may be produced. Positive and negative reactions are summarized in Tables 17–19.

Source: clinical sources, but the habitat is not known.

DNA G+C content (mol%): 38.5 (HPLC).

Type strain: CDC F9489, CCUG 43457, CIP 107079.

Sequence accession no. (16S rRNA gene): AJ319867.

Genus IV. *Paludibacter* Ueki, Akasaka, Suzuki and Ueki 2006, 43^{VP}

THE EDITORIAL BOARD

Pa.lu.di.bac'ter. L. n. *palus* -udis a swamp, marsh; N.L. masc. n. *bacter* a rod; N.L. masc. n. *Paludibacter* rod living in swamps.

Rods (0.5–0.6 μm × 1.3–1.7 μm), with the ends usually round to slightly tapered. Nonmotile. Nonsporeforming. Gram-negative. Strictly anaerobic. Chemo-organotrophic. Optimum growth temperature, 30°C. No growth occurs at 37°C. Oxidase and catalase-negative. Nitrate is not reduced. Various sugars are fermented, and acetate and propionate are the major fermentation end products with succinate as a minor product. Major cellular fatty acids are C_{15:0} anteiso, C_{15:0}, and C_{17:0} anteiso 3-OH. The major respiratory quinone is MK-8(H₄).

DNA G+C content (mol%): 39.3 (HPLC).

Type species: *Paludibacter propionigenes* Ueki, Akasaka, Suzuki and Ueki 2006, 43^{VP}.

Further descriptive information

Paludibacter propionigenes was isolated from a rice plant residue (rice straw) sample collected from irrigated rice-field soil in the Shonai Branch of the Yamagata Agricultural Experimental Station (Fujishima-machi, Yamagata, Japan) during the flooding period of the field.

Cells can be cultivated at 30°C under an atmosphere of 95% N₂/5% CO₂ in peptone-yeast (PY) broth supplemented with 1% glucose (PYG broth). Colonies on PY4S^{*} agar are grayish white, translucent, circular with a smooth surface, and 1.0–1.5 mm in diameter after 48 h. Propionate and acetate are produced from

fermentation of glucose at a ratio of 2:1. The predominant cellular fatty acids are C_{15:0} anteiso (30.8%), C_{15:0} (19.0%), C_{17:0} anteiso 3-OH (17.9%), and C_{17:0} iso 3-OH (6.2%).

Enrichment, isolation, and maintenance procedures

The type strain was isolated using the anaerobic roll tube method. PY4S agar can be used for maintenance of the strain on agar slants.

Differentiation of the genus *Paludibacter* from related genera

Paludibacter propionigenes is a strict anaerobe isolated from plant residue, whereas *Dysgonomonas capnocytophagoides* and *Dysgonomonas mossii* are facultative anaerobes isolated from human clinical specimens. *Paludibacter propionigenes* cannot grow at 37°C and is inhibited by bile, whereas *Parabacteroides merdae*, *Dysgonomonas capnocytophagoides*, and *Dysgonomonas mossii* can grow at 37°C and are bile tolerant.

Taxonomic comments

By analysis of 16S rRNA gene sequences, the closest neighboring species of *Paludibacter propionigenes* are *Dysgonomonas capnocytophagoides* (90.9% similarity), *Dysgonomonas mossii* (89.8%), and *Parabacteroides merdae* (88.7%).

List of species of the genus *Paludibacter*

1. *Paludibacter propionigenes* Ueki, Akasaka, Suzuki and Ueki 2006, 43^{VP}

pro.pi.on.i.ci'ge.nes. N.L. n. *acidum propionicum* propionic acid; N.L. suff. -genes (from Gr. v. *gennaō* to produce) producing; N.L. part. adj. *propionigenes* producing propionic acid.

The characteristics are as described for the genus, with the following additional features. Elongated cells are occasionally formed both singly and in chains of the short cells. Spherical cells sometimes develop after storage of slant cultures at 4°C. Growth occurs at pH 5.0–7.6 (optimum, 6.6) and at 15–35°C. Growth at 33°C is much slower than at 30°C.

The NaCl concentration range for growth is 0–0.5% in PYG medium. The following compounds are used for growth and acid production: arabinose, cellobiose, fructose, galactose, glucose, mannose, maltose, melibiose, glycogen, soluble starch, and xylose. The following compounds are not used: cellulose, dulcitol, ethanol, fumarate, glycerol, inositol, lactate, lactose, malate, mannitol, melezitose, pyruvate, rhamnose, raffinose, ribose, salicin, sorbitol, sorbose, succinate, sucrose, trehalose, and xylan. Esculin is hydrolyzed, but gelatin and urea are not. H₂S and indole are not produced. No growth occurs in the presence of 0.01% bile salts.

Source: rice plant residue in anoxic rice-field soil in Japan.

DNA G+C content (mol%): 39.3 (HPLC).

Type strain: WB4, DSM 17365, JCM 13257.

Sequence accession no. (16S rRNA gene): AB078842.

*PY4S agar is peptone-yeast extract (PY) broth supplemented with (g/l): glucose, 0.25; cellobiose, 0.25; maltose, 0.25; soluble starch, 0.25; and agar, 15.0.

Genus V. *Petrimonas* Grabowski, Tindall, Bardin, Blanchet and Jeanthon 2005, 1118^{VP}

THE EDITORIAL BOARD

Pe.tri.mo'nas. L. fem. n. *petra* rock, stone; L. fem. n. *monas* a unit, monad; N.L. fem. n. *Petrimonas* stone monad.

Straight rods (0.7–1 × 1.5–2.0 µm) during exponential growth; some longer cells (0.5 × 4.0 µm) may be observed in old cultures. Nonsporeforming. Gram-stain-negative. Chemo-organotrophic. Mesophilic. **Strictly anaerobic, having a fermentative type of metabolism. End products of glucose fermentation are acetate, H₂, and CO₂.** Carbohydrates and some organic acids are fermented. Tryptone is required for growth. **The predominant menaquinone is MK-8**, with smaller amounts of MK-7 and MK-9. The major polar lipids are phosphatidylethanolamine, an unidentified phospholipid, two unidentified aminophospholipids, three unidentified phosphoglycolipids, a glycolipid, an aminolipid, and two additional uncharacterized lipids. The fatty acids include straight chain and branched fatty acids; in addition, 2-OH and 3-OH fatty acids are present. **The major cellular fatty acids are C_{15:0} anteiso, C_{13:0} anteiso, C_{15:0} iso, and C_{15:0}^o.** The major hydroxy fatty acids are C3-OH_{16:0} iso, C3-OH_{17:0} iso, and C_{2-OH} 17:0; about one-third of each of all three appear to be amide-linked. Isolated from a biodegraded oil reservoir.

DNA G+C content (mol%): 40.8 (HPLC).

Type species: *Petrimonas sulfuriphila* Grabowski, Tindall, Bardin, Blanchet and Jeanthon 2005, 1119^{VP}.

Further descriptive information

To date, *Petrimonas sulfuriphila* is the only member of the phylum *Bacteroidetes* to be isolated from a producing well of a biodegraded oil reservoir.

Enrichment and isolation procedures

Enrichment was performed in nitrate broth medium (Difco). Isolation of single colonies was accomplished using the anaerobic roll-tube technique (Hungate, 1969) with nitrate broth solidified with 2% (w/v) purified agar (Difco).

Differentiation of the genus *Petrimonas* from other genera

The predominance of MK-8 as menaquinone is a feature that distinguishes the novel isolate from all its phylogenetic relatives, including *Tannerella* (MK-10, MK-11), *Bacteroides* (MK-10, MK-11), *Parabacteroides distasonis* (MK-10); *Parabacteroides merdae* (MK-9, MK10), and *Porphyromonas* (MK-9, MK-10).

Taxonomic comments

According to 16S rRNA gene sequence analysis by Grabowski et al. (2005), the closest cultivated relatives of the type strain of *Petrimonas sulfuriphila* are *Tannerella forsythia* (88% similarity) and *Parabacteroides merdae* (87% similarity). However, very high rRNA gene sequence similarities (99.6%) were found between *Petrimonas sulfuriphila* and certain environmental clones retrieved from a dechlorinating consortium (GenBank accession no. AJ488088) and the bovine rumen (AB003390).

List of species of the genus *Petrimonas*1. *Petrimonas sulfuriphila* Grabowski, Tindall, Bardin, Blanchet and Jeanthon 2005, 1119^{VP}

sul.fu.ri.phi'la. L. n. *sulfur* sulfur; Gr. adj. *philos* -ê -on loving; N.L. fem. adj. *sulfuriphila* sulfur-loving, indicating that sulfur stimulates growth.

The characteristics are as described for the genus, with the following additional features. Cells occur singly or in pairs. The temperature range for growth at pH 7.2 is 15–40°C; optimum, 37–40°C. Growth occurs in the presence of 0–4% NaCl; optimum, 0%. Yeast extract and elemental sulfur stimulate growth. The following substrates support growth when yeast extract, tryptone, and elemental sulfur are present:

glucose, arabinose, galactose, maltose, mannose, rhamnose, lactose, ribose, fructose, sucrose, lactate, mannitol, glycerol, and cellobiose. Fumarate, pyruvate, and Casamino acids support weak growth. Acetate, formate, butyrate, propionate, methanol, peptone, ethanol, propanol, butanol, toluene, sorbose, and cellulose are not used. Elemental sulfur is reduced to sulfide. Nitrate is reduced to NH₄⁺.

Source: isolated from an oilfield well head in the Western Canadian Sedimentary Basin (Canada).

DNA G+C content (mol%): 40.8 (HPLC).

Type strain: BN3, DSM 16547, JCM 12565.

Sequence accession no. (16S rRNA gene): AY570690.

Genus VI. *Proteiniphilum* Chen and Dong 2005, 2259^{VP}

THE EDITORIAL BOARD

Pro.tei'ni.phi.lum. N.L. neut. n. *proteinum* protein; Gr. adj. *philos* -ê -on loving; N.L. neut. n. *Proteiniphilum* protein-loving.

Rods 0.6–0.9 × 1.9–2.2 µm. **Motile by means of lateral flagella.** Nonsporeforming. Gram-stain-negative. **Obligately anaerobic.** Growth occurs at 20–45°C. Oxidase and catalase-negative. Chemo-organotrophic. Proteolytic. Yeast extract and peptone can be used as energy sources. **Nonsaccharolytic. Carbohydrates, alcohols, and organic acids (except pyruvate) are not used.** Gelatin is not hydrolyzed. **Not resis-**

tant to 20% bile. The major fermentation products from peptone-yeast extract (PY) medium are acetic acid and propionic acid. Nitrate is not reduced. Cellular fatty acids mainly consist of iso-branched fatty acids, predominantly C_{15:0} anteiso.

DNA G+C content (mol %): 46.6–48.9 (T_m).

Type species: *Proteiniphilum acetatigenes* Chen and Dong, 2005, 2261^{VP}.

Further descriptive information

During studies of syntrophic propionate-degrading bacteria from methanogenic environments, Chen and Dong (2005) reported the isolation of mixed cultures consisting of three different organisms that, in combination, were capable of degrading propionate to acetate and methane. The three organisms were: a syntrophic, propionate-degrading bacterium; an organism resembling *Methanobacterium formicicum*; and a rod-shaped bacterium which did not consume propionate or synthesize methane but did accelerate the degradation of propionate by the triculture. Chen and Dong classified the latter organism as the representative of a new genus, *Proteiniphilum*, and a new species, *Proteiniphilum acetatigenes*.

Colonies of *Proteiniphilum acetatigenes* on (PY) agar are circular, slightly convex, white, translucent, and reach 1.5 mm in diameter after 3 d at 37°C. Optimum growth occurs at 37°C. The pH range for growth is 6.0–9.7; optimum is 7.5–8.0.

In addition to yeast extract and peptone, pyruvate, glycine and L-arginine can be used as carbon and energy sources. Tryptone, L-serine, L-threonine, and L-alanine support weak growth. Pyruvate is converted to acetic acid and CO₂.

Enrichment and isolation procedures

Proteiniphilum was isolated from methanogenic propionate-degrading mixtures obtained from the granule sludge of an upflow anaerobic sludge blanket reactor for treatment of brewery wastewater. Isolation was accomplished by initial serial dilution in anaerobic

PY medium followed by selection of colonies on anaerobic roll tubes. Repeated subculturing of colonies in PY broth followed by colony isolation is performed until purity is assured.

Maintenance procedures

Routine cultivation can be accomplished in pre-reduced PY broth in anaerobic tubes under an atmosphere of 100% oxygen-free N₂ with incubation at 37°C.

Differentiation of the genus *Proteiniphilum* from related genera

The rod shape of *Proteiniphilum* differs from the coccobacillary shape of *Dysgonomonas* species; moreover, unlike *Proteiniphilum*, *Dysgonomonas* is nonmotile, facultatively anaerobic, ferments glucose, and has a higher DNA G+C content (47–49 vs 38 mol%). The motility of *Proteiniphilum* and failure to form succinic acid as a major end product from glucose differentiate *Proteiniphilum* from *Parabacteroides distasonis*, *Parabacteroides merdae*, and *Tannerella forsythia*. Unlike *Tannerella forsythia*, *Proteiniphilum* does not produce phenylacetic acid and butyric acid from glucose.

Taxonomic comments

Analysis of 16S rRNA gene sequences indicates that the nearest neighbors of the type strain are *Dysgonomonas* species (89.6–90.6% sequence similarity). The type strain is more distantly related to *Parabacteroides* (85–87% sequence similarity), *Porphyromonas* (84–88%), *Prevotella* (79–85%), and *Tannerella forsythia* (89.3%).

List of species of the genus *Proteiniphilum*

1. ***Proteiniphilum acetatigenes*** Chen and Dong 2005, 2261^{VP}
a.ce'ta.ti.gen.es. N.L. *acetat* -atis acetate; N.L. suff. *-genes* (from Gr. v. *gennaō* to produce) producing; N.L. part. adj. *acetatigenes* acetate-producing.

The characteristics are as described for the genus, with the following additional features. Milk is not curdled. Starch and esculin are hydrolyzed. Indole is not produced. Urease, lecithinase and lipase are not produced. Methyl red and Voges–Proskauer tests are negative. H₂S is not produced from peptone or thiosulfate. NH₃ is produced from yeast extract, peptone and L-arginine. Acetic acid is the main product from fermentation of yeast extract, peptone, pyruvate and L-arginine; propionic acid is also produced. The following substrates are not used: adonitol, amygdalin, L-arabinose, L-aspartate, butanedioic acid, cellobiose, cellulose, citrate, L-cysteine, dulcitol, erythritol, esculin, ethanol, D-fructose, fumarate,

D-galactose, gluconate, D-glucose, L-glutamine, glycogen, hippurate, L-histidine, β-hydroxybutyric acid, inositol, inulin, L-isoleucine, D-lactose, L-leucine, L-lysine, malate, malonate, D-maltose, mannitol, mannose, melibiose, methanol, L-methionine, phenylacetic acid, L-phenylalanine, L-proline, 1-propanol, raffinose, rhamnose, ribitol, ribose, salicin, D-sorbitol, sorbose, succinate, sucrose, starch, trehalose, tryptophan, L-tyrosine, L-valine, xylan, and xylose. The major cellular fatty acids are C_{15:0} anteiso (46.21%), C_{15:0} (8.90%), C_{17:0} iso 3-OH (5.93%), and C_{17:0} anteiso (5.15%).

Source: the type strain was isolated from the granule sludge of an Upflow Anaerobic Sludge Blanket (UASB) reactor treating brewery wastewater.

DNA G+C content (mol%): 46.6–48.9 (*T_m*).

Type strain: TB107, AS 1.5024, JCM 12891.

Sequence accession no. (16S rRNA gene): AY742226.

Genus VII. *Tannerella* Sakamoto, Suzuki, Umeda, Ishikawa and Benno 2002, 848^{VP}

MITSUO SAKAMOTO, ANNE C. R. TANNER AND YOSHIMI BENNO

Tan.ne.rel'la. L. dim. suffix *-ella*; N.L. fem. dim. n. *Tannerella* named after the American microbiologist Anne C. R. Tanner, for her contributions to research on periodontal disease.

Fusiform cells, generally 0.3–0.5 × 1–30 μm. Gram-negative. Nonmotile. **Obligately anaerobic**. **N-acetylmuramic acid (NAM) is required for growth** (some strains do not require NAM). **Growth is inhibited in the presence of 20% bile**. The major end products are acetic acid, butyric acid, isovaleric acid, propionic acid, and phenylacetic acid; smaller amounts of isobutyric

acid and succinic acid may be produced. Esculin is hydrolyzed. Indole variable. **Trypsin activity is positive**. Glucose-6-phosphate dehydrogenase (G6PDH), 6-phosphogluconate dehydrogenase (6PGDH), malate dehydrogenase, and glutamate dehydrogenase are present. The principal respiratory quinones are menaquinones MK-10 and MK-11. Both nonhydroxylated and

3-hydroxylated long-chain fatty acids are present. The nonhydroxylated acids are predominantly of the saturated straight-chain and anteiso methyl-branched-chain types. **The ratio of C_{15:0} anteiso to C_{15:0} iso is high (>20). Isolated originally and principally from human oral cavity. *Tannerella forsythia* has been associated with periodontal disease, root canal infections, and peri-implantitis.**

DNA G+C content (mol%): 44–48.

Type species: *Tannerella forsythia* corrig. (Tanner, Listgarten, Ebersole and Strzempko 1986) Sakamoto, Suzuki, Umeda, Ishikawa and Benno 2002, 848^{VP} (*Bacteroides forsythus* Tanner, Listgarten, Ebersole and Strzempko 1986, 216).

Sequence accession no. (16S rRNA gene): L16495.

Further descriptive information

The genus *Tannerella* is a member of the *Bacteroides* subgroup of the *Cytophaga–Flexibacter–Bacteroides* (CFB) phylum (Paster et al., 1994) that is referred to as the phylum *Bacteroidetes* in this edition of the *Manual*.

In the absence of NAM, cells of *Tannerella forsythia* are often pleomorphic and occur as rods with tapered (fusiform) or rounded ends, long filaments, and spheroids. The spheroids frequently occur in the center of cells and enlarge the diameter of the cell to approximately 5 µm. The spheroids are observed free from the rod forms (Tanner et al., 1979); this cell morphology has been attributed to the presence of a weakened cell wall (Wyss, 1989). In the presence of NAM, cells are regular with rounded or tapered ends (Braham and Moncla, 1992).

In cell cross-sections stained with uranyl acetate and lead citrate and observed by electron microscopy, the outer membrane consists of an outer layer that is approximately 4 nm thick, an inner layer that is 1 nm thick, and a 2 nm electron-lucent space in between. The inner membrane consists of two electron-dense layers, each approximately 2 nm wide, with a 2 nm intervening electron-lucent layer. The inner and outer membranes are separated by a moderately electron-dense zone that is about 16 nm wide and appears to lack a distinct peptidoglycan layer. A regular structured external layer surrounds the outer membrane and consists of subunits, which in some cross-sections resemble adjacent arches that are 10 nm wide and 10 nm high. These subunits are separated from the outer membrane by a 12 nm electron-lucent zone. Electron-dense radial connections appear to extend from the subunits to the outer surface of the outer membrane. Negative staining of tangential sections through the cell periphery indicates that the subunits in the outermost layer are packed in an orthogonal array (Tanner et al., 1986).

The predominant cellular fatty acids are C_{15:0} anteiso and C_{16:0} 3-OH. In contrast, *Bacteroides* and *Parabacteroides* species possess significant levels of C_{15:0} anteiso and C_{17:0} iso 3-OH. Moreover, the ratio of C_{15:0} anteiso to C_{15:0} iso in whole-cell methanolysates of *Tannerella forsythia* is very much higher than those of *Bacteroides* and *Parabacteroides* species (Sakamoto and Benno, 2002, 2006): the ratios range from 22.8 to 95.2% in *Tannerella forsythia* strains but only from 1.9 to 10.3% in *Bacteroides* and *Parabacteroides* species. This is an important feature that differentiates *Tannerella forsythia* from *Bacteroides* and *Parabacteroides* species.

Colonies are pale, speckled pink, circular, entire, and slightly convex on Trypticase soy agar supplemented with 5% (v/v) sheep blood (TSBA) and a NAM disk (Braham and Moncla, 1992). The colonies are generally small with a diameter of

0.5–2 mm after 7–10 d incubation at 37°C. *Tannerella forsythia* is a strict anaerobe and requires CO₂ and H₂ in the atmosphere for growth on agar surfaces. Growth on agar is stimulated by the presence of *Fusobacterium nucleatum* (and strains of *Streptococcus sanguinis*, *Bacteroides fragilis*, *Campylobacter rectus*, *Prevotella intermedia*, and *Veillonella parvula*) in a satellite pattern (Tanner et al., 1986).

The growth of *Tannerella forsythia* strains is inhibited on bacteroides bile esculin agar. In contrast, the growth of *Bacteroides* and *Parabacteroides* species is not inhibited on the media containing 20% bile. In addition, *Tannerella forsythia* requires exogenous NAM as a growth factor (Wyss, 1989). These characteristics are important features that differentiate *Tannerella forsythia* from the *Bacteroides fragilis* group and the genus *Parabacteroides*. Braham and Moncla (1992) reported that *Tannerella forsythia* strains isolated from subgingival plaque samples from monkeys (*Macaca fascicularis*) also require NAM for growth. However, *Tannerella forsythia* strains recovered from cat and dog bite wound infections in humans do not require NAM for growth (Hudspeth et al., 1999). These results suggest that there are host-specific biotypes within the species of *Tannerella forsythia*.

Tannerella forsythia does not react in the API 20A or API 20E test series but does react in other resting cells tests, including API ZYM, API AN-IDENT (Tanner et al., 1985, 1986), and fluorogenic substrate tests (Maiden et al., 1996). *Tannerella forsythia* strains give positive results for α-glucosidase, β-glucosidase, α-fucosidase, and β-glucuronidase. In the absence of NAM there is no detectable pH decrease in media supplemented with carbohydrates (Tanner et al., 1985, 1986). These results suggest that *Tannerella forsythia* may grow too poorly in that medium to ferment the carbohydrate, that cells may have trouble transporting the sugars across their membranes for use in the glycolytic pathway, or may overproduce methyl glyoxyl, thereby leading to toxicity and growth inhibition (Maiden et al., 2004).

The genome-sequencing project of *Tannerella forsythia* ATCC 43037^T has been completed by The Institute for Genomic Research (TIGR). A total of 3034 open reading frames are predicted from the genomic sequence of 3,405,543 bp in length based on the annotation provided by the Oral Pathogen Sequences Databases (ORALGEN, <http://www.oralgen.lanl.gov>). The preliminary genomic annotations as well as a variety of bioinformatics tools useful for studying the *Tannerella forsythia* genome are available at both the ORALGEN and Bioinformatics Resource for Oral Pathogens (BROP, <http://www.brop.org>) (Chen et al., 2005) project web sites.

The minimum inhibitory concentrations (MICs) of antimicrobial agents have been reported by Takemoto et al. (1997). *Tannerella forsythia* strains are most sensitive to clindamycin and metronidazole. *Tannerella forsythia* shows a comparatively lower susceptibility to ciprofloxacin. Most strains are sensitive to penicillin G, ampicillin, amoxicillin, tetracycline, doxycycline, and erythromycin.

Tannerella forsythia has been associated with advanced forms of periodontal disease, including severe and refractory periodontitis. Unlike other periodontopathic bacteria, such as *Porphyromonas gingivalis* and *Prevotella intermedia*, *Tannerella forsythia* is difficult to culture, and its prevalence in periodontal disease may be underestimated. *Tannerella forsythia* is synergistic with *Porphyromonas gingivalis*, and the presence of both accelerates progression of the disease (Yoneda et al., 2001). Pathogenic

factors include a trypsin-like protease (PrTH) (Saito et al., 1997) and a variety of glycosidases, such as α -D-glucosidase, N-acetyl- β -D-glucosaminidase (Hughes et al., 2003), and sialidase (Ishikura et al., 2003). Tan et al. (2001) determined the prevalence and the association of the *prtH* gene of *Tannerella forsythia* in adult periodontitis and periodontally healthy patients. Among the 86 diseased sites examined, 73 (85%) were colonized by *Tannerella forsythia* with the *prtH* genotype. In sites of the periodontally healthy, only 7 of 73 (10%) possessed *Tannerella forsythia* with the *prtH* genotype. These findings suggest a strong association of the *prtH* gene of *Tannerella forsythia* with adult periodontitis.

The outer surface of *Tannerella forsythia* is covered by an S-layer (surface layer) composed of two protein subunits (200 and 210 kDa) that mediate adherence and invasiveness (Sabet et al., 2003). Although mice immunized with purified S-layer and *Tannerella forsythia* whole cells did not develop any abscesses when challenged with viable *Tannerella forsythia* cells, unimmunized mice developed abscesses (Sabet et al., 2003). Other virulence factors include the cell-surface-associated protein (BspA) that mediates adherence to fibronectin (an extracellular matrix component), and fibrinogen (a clotting factor) (Sharma et al., 1998). Honma et al. (2001) constructed a BspA-defective mutant of *Tannerella forsythia* that showed a reduced ability to adhere to fibronectin and fibrinogen compared with the wild-type strain (ATCC 43037^T). Sharma et al. (2005) demonstrated alveolar bone loss in mice infected with the *Tannerella forsythia* wild-type strain, whereas this effect was impaired when the BspA mutant was used.

Huang et al. (2003) investigated the distribution of *Tannerella forsythia* genotypes in a Japanese periodontitis population, and also the relationship between different genotypes and the periodontal status, using the arbitrarily primed polymerase chain reaction (AP-PCR) method. *Tannerella forsythia* ATCC 43037^T and 137 clinical bacterial isolates were separated into 11 distinct AP-PCR genotypes. The majority of *Tannerella forsythia* strains examined belonged to AP-PCR genotypes I (including ATCC 43037^T), II, III, and IV (accounting for 39.7, 20.6, 10.3, and 10.3%, respectively). The strains of Types I and III were mainly isolated from chronic periodontitis subjects, whereas the strains of Types II and IV were mainly isolated from aggressive periodontitis subjects.

A *Tannerella* phylotype (oral clone BU063: GenBank accession no. for 16S rRNA gene is AY008308) was associated with periodontal health, in contrast to *Tannerella forsythia* strains that were associated with periodontal disease (Kumar et al., 2003; Leys et al., 2002).

Tannerella forsythia is found in the subgingival, gingival, and periodontal pockets, in dental root canals (Conrads et al., 1997), and around infected dental implants (Tanner et al., 1997) of humans. *Tannerella forsythia* has been also found in monkey (*Macaca fascicularis*) subgingival plaque samples (Braham and Moncla, 1992). In addition, *Tannerella forsythia* strains have been recovered from cat- and dog-bite wound infections in humans (Hudspeth et al., 1999). *Tannerella forsythia* has also been detected in atheromatous plaques (Haraszthy et al., 2000) and in buccal epithelial cells (Rudney et al., 2005) of humans. From clone libraries of 16S rRNA gene sequences from termite guts, phylotypes related to *Tannerella forsythia* have been found (Hongoh et al., 2005, 2003).

Enrichment and isolation procedures

Isolation and identification of *Tannerella* species has been described (Braham and Moncla, 1992; Tanner et al., 1998; Umeda et al., 1996). Rapid presumptive identification of clinical isolates of *Tannerella forsythia* is based on the following eight criteria (Braham and Moncla, 1992): (1) positive activity for α -glucosidase, (2) positive activity for β -glucosidase, (3) positive activity for sialidase, as it has been reported that sialidase activity is useful for identification of *Tannerella forsythia* (Moncla et al., 1990), (4) positive activity for trypsin-like enzyme, (5) negative indole production, (6) requirement for NAM, (7) colonial morphology, and (8) Gram stain morphology from blood agar medium deficient in NAM. The trypsin-like activity is measured by the benzoyl-DL-arginine-naphthylamide (BANA) test (Loesche et al., 1990). BANA-positive non-black-pigmented bacteria are subcultured with the plates with or without the NAM disk. Subsequently, bacterial colonies that grow only on the plates with NAM are screened as *Tannerella forsythia*. Finally, five filter paper fluorescent spot tests [for indole (Sutter and Carter, 1972), α -glucosidase, β -glucosidase, sialidase, and trypsin-like enzyme] are used for identification of *Tannerella forsythia* (Braham and Moncla, 1992). For the trypsin-like enzyme assay, *N*- α -carbobenzoxy-L-arginine-7-amino-4-methylcoumarin hydrochloride (Camm), fluorogenic substrate, is used.

An agar-free broth medium for *Tannerella forsythia* has been developed by Wyss (1989). This medium consists of BHI broth supplemented with fetal calf serum (FCS) and NAM. Some strains grew without the addition of FCS.

Maintenance procedures

The organism can be maintained by transfer on the same media used for isolation. Recommended procedures for long-term preservation are lyophilization, freezing at -80°C , or storage in liquid nitrogen. Cryoprotective agents such as 10% glycerol or DMSO should be added to cultures before freezing, and heavy cell concentrations should be used.

Differentiation of the genus *Tannerella* from other genera

Differential characteristics of the genus *Tannerella* and some related taxa are shown in Table 20. Although *Tannerella forsythia* is phylogenetically related to *Parabacteroides* species, the ratio of C_{15:0} anteiso to C_{15:0} iso in whole-cell methanolsates of *Tannerella forsythia* is different from those of *Parabacteroides* species. While the ratios of C_{15:0} anteiso to C_{15:0} iso range from 22.8 to 95.2 in *Tannerella forsythia* strains (Sakamoto et al., 2002), those of *Parabacteroides* species range from 3.1 to 10.3. In addition, although the major menaquinones of *Tannerella forsythia* are MK-10 and MK-11, the major menaquinones of *Parabacteroides* species are MK-9 and MK-10 (Sakamoto and Benno, 2006).

Taxonomic comments

As shown in Figure 21, *Tannerella* exhibits a close phylogenetic association with the genus *Parabacteroides* (Sakamoto and Benno, 2006).

The name *Bacteroides forsythus* was published by Tanner et al. (1986) but did not appear on a Validation List in the IJSEM.

Symbols and abbreviations: +, positive; –, negative; D, different reactions in different species; nt, not tested; NF, nonfermentative; F, fermentative; MF, moderately fermentative; A, acetic acid; B, butyric acid; IV, isovaleric acid; L, lactic acid; P, propionic acid; PA, phenylacetic acid; S, succinic acid; G6PDH, glucose-6-phosphate dehydrogenase; 6PGDH, 6-phosphogluconate dehydrogenase; UASB, upflow anaerobic sludge blanket.

^bThe bite wound isolates do not require N-acetylmuramic acid (NAM) for growth.

^c*Porphyromonas asaccharolytica* produces α -fucosidase.

^d*Porphyromonas catoniae* does not produce a black pigment on blood agar

^eSome species are weakly saccharolytic.

^f*Porphyromonas catoniae* contains approximately equal amounts of C_{15:0} anteiso and C_{15:0} iso as the predominant fatty acids.

^g*Prevotella dentalis* lacks menaquinones.

Thus, the name was illegitimate when Sakamoto et al. (2002) created the genus *Tannerella* for the organism in and renamed *Bacteroides forsythus* as *Tannerella forsythensis*. Although this name is legitimate, Maiden et al. (2003) requested an Opinion from the Judicial Commission that the original adjectival form of the specific epithet be conserved, i.e., “*Tannerella forsythia*”. In Opinion 85, the Judicial Commission (2008) agreed with the proposal of Maiden et al. (2003).

List of species of the genus *Tannerella*

- 1. *Tannerella forsythia*** corrig. (Tanner, Listgarten, Ebersole and Strzempko 1986) Sakamoto, Suzuki, Umeda, Ishikawa and Benno 2002, 848^{VP} (*Bacteroides forsythus* Tanner, Listgarten, Ebersole and Strzempko 1986, 216)

for.sy.then'sis. N.L. fem. adj. *for sythia* pertaining to the Forsyth Dental Center, where the species was first isolated.

The characteristics are as given for the genus and as listed in Table 20.

DNA G+C content (mol%): 46 (T_m). It is currently reported at 46.8 mol% based on the genome sequence (<http://www.oralgen.lanl.gov>).

Type strain: JCM 10827, ATCC 43037, CCUG 21028 A, CCUG 33064, CCUG 33226, CIP 105219, FDC 338.

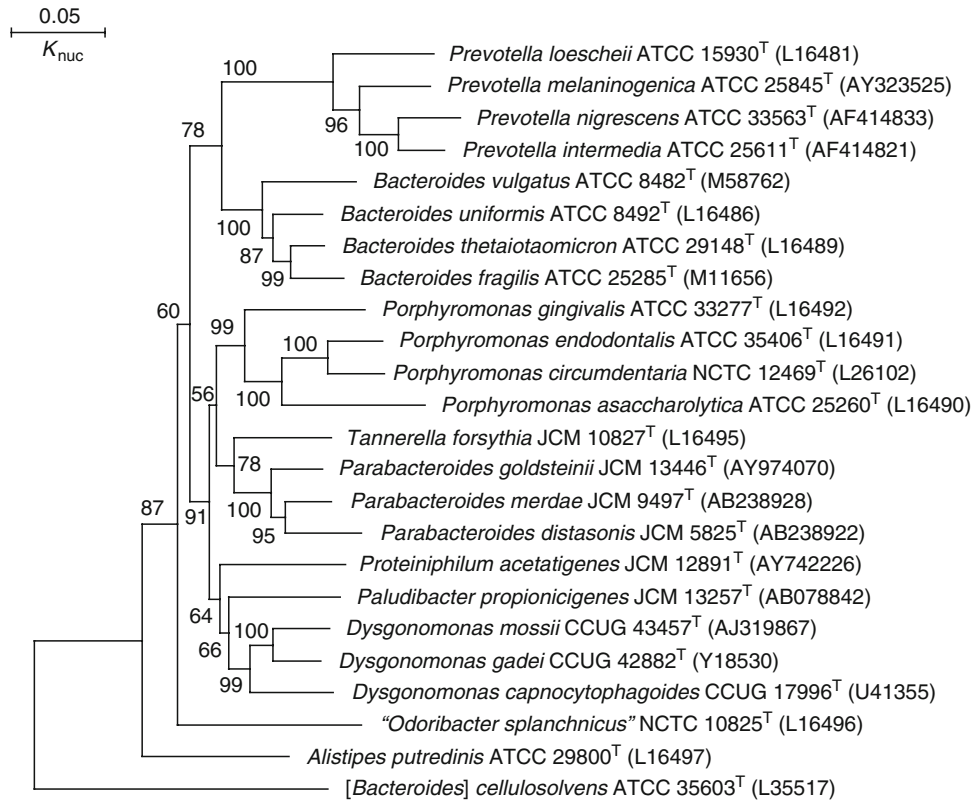

FIGURE 21. Phylogenetic tree showing the relationship between the genus *Tannerella* and some related taxa. The tree was constructed by the neighbor-joining method based on 16S rRNA gene sequences. Numbers at nodes indicate the percentage bootstrap values of 1000 replicates. Bar = 0.05 substitutions per nucleotide position. Accession numbers for 16S rRNA gene sequences are given for each strain.

Sequence accession no. (16S rRNA gene): L16495.

Genome: GenBank accession number withheld until publication of the original paper. Meanwhile, the sequence is available at ORALGEN.

Family V. Prevotellaceae fam. nov.

NOEL R. KRIEG

Pre.vo.tell.a.ce'a.e N.L. fem. n. *Prevotella* type genus of the family; suff. -aceae ending to denote a family; N.L. fem. pl. n. *Prevotellaceae* the *Prevotella* family.

At present, the family is comprised of the type genus *Prevotella* and *Xylanibacter*. The organisms are **anaerobic, nonsporeforming, nonmotile**, rods that **stain Gram-negative. Saccharolytic**. The principal respiratory quinones are unsaturated **menaquinones** with 8–13 isoprene units, depending upon the species.

Some characteristics that differentiate the genera are given in Table 21.

Type genus: Prevotella Shah and Collins 1990, 205^{VP} emend. Willems and Collins 1995, 834^{VP}.

TABLE 21. Some characteristics that differentiate the genera of the family *Prevotellaceae*

Characteristic	<i>Prevotella</i>	<i>Xylanibacter</i>
Cell shape	Short rods	Short to filamentous rods
Major products of glucose fermentation	Succinate and acetate	Acetate, propionate, and succinate
Isolated from	Primarily isolated from oral cavity, but also urogenital and intestinal tracts of animals	Anoxic rice-plant residue
DNA G+C content (mol%)	40–52	44

Genus I. *Prevotella* Shah and Collins 1990, 205^{VP} emend. Willems and Collins 1995, 834^{VP}

HAROUN N. SHAH, MARIE ANNE CHATTAWAY, LAKSHANI RAJAKURANA AND SAHEER E. GHARBIA

Pre.vo.tel'la. N.L. dim. ending *ella*; N.L. fem. n. *Prevotella*, named after the French microbiologist, A. R. Prévot, a pioneer in anaerobic microbiology.

Short rods. Nonsporeforming. Nonmotile. Gram-stain-negative. Anaerobic. **Moderately saccharolytic. Growth is inhibited by 20% bile. Succinic and acetic acids are the major metabolic end products** in peptone-yeast extract-glucose (PYG) broth, but lower levels of other short-chain acids may be produced. **Malate dehydrogenase and glutamate dehydrogenase are present, but glucose-6-phosphate dehydrogenase and 6-phosphogluconate dehydrogenase are absent.** Sphingolipids are produced. The nonhydroxylated long-chain fatty acids are primarily of the **straight-chain saturated and monounsaturated types**; methyl branched fatty acids are either absent or present in small amounts. **Porphyryns** are produced by pigmented species, while **menaquinones are the sole respiratory quinones found in all species so far studied. Diaminopimelic acid is the only dibasic amino acid in the peptidoglycan** (Miyagawa et al., 1981). Neither heptose nor 2-keto-3-deoxyoctulosonic acid has so far been reported (Hofstad, 1974). The primary site of isolation is the oral cavity, but more recently species have been reported from the intestinal tract of man and animals.

DNA G+C content (mol%) of most species: 40–52.

Type species: Prevotella melaninogenica (Oliver and Wherry 1921) Shah and Collins 1990, 206^{VP} emend. Wu, Johnson, Moore and Moore 1992, 536^{VP} [*Fusififormis nigrescens* Schwabacher, Lucas and Rimington 1947, 109; *Bacteroides melaninogenicus* (Oliver and Wherry 1921) Roy and Kelly 1939, 569^{AL}; *Ristella melaninogenica* (Oliver and Wherry 1921) Prévot 1938, 290; *Hemophilus melaninogenicus* (sic) (Oliver and Wherry 1921) Bergey, Harrison, Breed, Hammer and Huntoon 1930, 314; *Bacterium melaninogenicum* Oliver and Wherry 1921, 341].

Further descriptive information

The genus *Prevotella* includes species that produce black, brown, beige or non-pigmented colonies on blood agar plates. However, all appear to have the capacity to produce protoporphyrin and protoheme (Figure 22), which form the prosthetic group of cytochromes. Prior to colonies becoming black (due to over production of protoheme), the brown/beige centers of the colonies show brilliant red fluorescence under long wave ultraviolet radiation (365 nm) due to the production of protoporphyrin (Shah et al., 1979). Once black, (~3–7 d) the UV fluorescence is quenched by virtue of the stabilization of the ring structure of the iron-porphyrin complex (Shah et al., 1979) and colonies appear consistently black. Factors such as the type of blood, hemolysis, temperature, pH, the presence of other isolates, etc., determine the depth and rate of pigmentation. Other characteristic electron carriers present in *Prevotella* species are respiratory quinones. However, only one type, viz. menaquinones, is produced; ubiquinones have not been reported. The former are detectable by scanning cell extracts in iso-octane solution between 240 and 360 nm. Absorption maxima at 244, 248, 260, 269 and 328 nm are characteristic of such compounds (Figure 23). Reduction (e.g., with potassium borohydrate) results in bleaching of absorption at 260–269 nm and a concomitant increase in absorption at 246 nm. These spectral characteristics are consistent with the presence of menaquinones that may

FIGURE 22. Major porphyrins found in pigmented species of *Prevotella* that give the colonies their characteristic appearance on blood agar plates. (Top) The non-UV fluorescent protohemin showing its stabilization by iron in the ring structure. (Bottom) Protoporphyrin; the absence of iron from the porphyrin system enables excitation under long-wavelength UV radiation (365 nm) and the brilliant red fluorescence observed in some species (see text).

be used to confirm members of the genus. However, the number of isoprene units is characteristic for several species and can be ascertained by chromatography or mass spectrometry (Shah and Collins, 1980) (Figure 24). Both the porphyrins and menaquinones form part of an anaerobic electron transport system that is essential to the physiology of this group and therefore they are likely to be stable characters.

Enrichment and isolation procedures

Because energy conservation in *Prevotella* species resolves around porphyrins and menaquinones, their respective precursors, viz. heme and menadione, are required for growth. On blood agar plates, it is unnecessary to add these compounds to the medium, but their inclusion in liquid culture is essential for growth. Hemin is added at 0.5 mg%, while menadione is added at 0.05 mg%. Peptides, rather than free amino acids, are required as sources of nitrogen for growth. This requirement may be met by protein hydrolysates such as trypticase, proteose peptone or yeast extract that have a pronounced effect upon growth. However, these species are also moderately saccharolytic; hence, the inclusion of glucose also helps to stimulate growth. There are many published methods for enrichment and isolation of these species, but all media contain the above components with a thiol reducing agent. A typical enrichment

FIGURE 23. Demonstration of the presence of menaquinones in *Prevotella* species. Dried cells are taken up in isooctane solution and the absorption spectrum between 240 and 350 nm recorded. Characteristic maxima at 244, 248, 260, 269, and 328 nm that are reduced with potassium borohydride (see above, dotted lines) demonstrate the presence of menaquinones. Confirmation of the number of isoprene units is achieved using mass spectrometry (see Figure 24).

medium, often referred to as “BM” (Shah et al., 1976) consists of the following (g/l): trypticase (10), proteose peptone (10), yeast extract (5), glucose (5), sodium chloride (5) and cysteine hydrochloride (0.75), together with hemin and menadione at the above concentrations. The medium is adjusted to pH 7.4 and autoclaved for the standard 121 °C for 15 min. The medium needs to be prepared fresh, especially for isolation. Many of these species are particularly difficult to isolate initially, but once cultured they adapt readily.

Maintenance procedures

Prevotella species possess an electron transport system in which the anaerobic reduction of fumarate takes place. The redox potential of the fumarate/succinate couple at pH 7.0 is about -200 mV greater than the redox couples used by more exacting anaerobes such as methane producing or nitrogen-fixing bacteria (-400 mV). Consequently, the very rigid procedures used for the latter are unnecessary for *Prevotella* species. Once isolated, most standard blood agar media (with 0.5%, v/v, horse blood) may be used to maintain the organisms. Broth cultures are useful for obtaining large quantities of biomass, but are not useful for maintaining cells. On blood agar, cells will grow rapidly (1–2 d) but may be lost if care is not taken to subculture every few days. This is particularly so for species such as *Prevotella intermedia* or *Prevotella nigrescens* that grow rapidly and produce a jet black pigment on blood agar plates (Shah and Gharbia, 1992). If the entire colony becomes black and often “dry”, the organisms rapidly lose their viability. When subculturing from such colonies, a large number of colonies should be taken over to the fresh plate to ensure their survival. It is essential there-

fore, for long-term storage and weekly subculture, that cells are taken from the early exponential phase prior to pigmentation or from central parts of the colony that are non-pigmented/beige during the first few days of growth. Dense cells suspensions ($\sim 10^8$ per ml) may be lyophilized or kept frozen on beads at -80 °C. These should be prepared with minimum exposure to air or, if available, prepared in an anaerobic chamber. Maintenance on standard laboratory slope media or growth and storage in Robertson Cooked Meat broth will result in a loss of viability.

Differentiation of the genus *Prevotella* from other genera

Members of the genera *Prevotella* and *Porphyromonas* previously belonged to the genus *Bacteroides* (Holdeman et al., 1984; Olsen and Shah, 2001; Werner, 1991). However, they differed so markedly in biochemical and chemical properties from the type species, *Bacteroides fragilis*, that they were reclassified into separate genera. *Porphyromonas* encompasses species that are nonfermentative or very weakly fermentative, whereas *Prevotella* species are moderately fermentative. These proposals for reclassification were made well before the acceptance of 16S rRNA gene sequencing, but have now been substantiated by comparative sequence analysis of this gene (see Figure 25), and the number of new species added to both genera continue to increase significantly.

Biochemically, *Prevotella* species appear to occupy an ecological niche where there is a limited range of carbohydrates and free amino acids. Thus, unlike *Bacteroides* species that thrive in the intestinal tract and are able to ferment a vast array of available carbohydrates, the natural habitat of *Prevotella* and *Porphyromonas* species appears to be mainly the oral cavity (especially supra- and sub-gingival dental plaque), where there is a more restricted range of fermentable substrates. *Porphyromonas* species are generally nonfermentative and flourish in more inaccessible, anoxic environments as part of diverse bacterial communities where nitrogenous substrates rather than carbohydrates are available. Some species such as *Porphyromonas gingivalis* produce potent proteinases such as α - and β -gingivain (Shah et al., 1993) that release amino acids and peptides for growth (Shah and Williams, 1987a, b). *Prevotella* species appear to occupy an “intermediate niche” and their biochemical properties are reflected in their function. Some species have limited proteolytic activities, and all species, except the recently proposed “*Prevotella massiliensis*” (Berger et al., 2005), ferment a limited range of carbohydrates such as sucrose or lactose (see Table 22). They differ markedly from the genus *Bacteroides* (*sensu stricto*) in lacking enzymes of the pentose phosphate pathway-hexose monophosphate shunt (*viz.* glucose-6-phosphate dehydrogenase and 6-phosphogluconate dehydrogenase), and because their major habitat is the oral cavity they are unable to grow in the presence of bile. Glutamate and aspartate have been identified among the amino acids metabolized, (Shah and Williams, 1987a, b). Consequently, the enzymes glutamate dehydrogenase and malate dehydrogenase are present and are key markers of the genus. Aspartate catabolism is inextricably linked to the utilization of an electron transport system involving both cytochromes (e.g., cytochrome *b*) and the respiratory quinones (e.g., menaquinones), in which fumarate acts as an electron sink in accept-

FIGURE 24. Mass spectra of the unsaturated menaquinones of three species. Below, *Bacteroides ochraceus* (later *Capnocytophaga*) that previously belonged to this group. It was excluded initially on the basis that it contained six isoprene units (MK-6). Similarly (Top) *Porphyromonas* was separated on the basis of major levels of MK-9. By contrast, most *Prevotella* species analyzed to date possess significant levels of MK-10, MK-11, or MK-12 with lower levels of MK-8, MK-9, and MK-13. The mass spectrum (MK-6, Bottom) shows the characteristic fragmentation pattern of such a compound. The major mass ion at 580 is its molecular weight, 565 ($M^+ - 15$) loss of the ring methyl group (CH_3), while mass ions at 239, 307, 375, 443, and 511 are attributable to the loss of isoprene (68 mass units). Intense peaks at m/e 187 and 225 are derived from the 1-4 naphthoquinone nucleus and are characteristic of menaquinones. This property, which was first introduced for the characterization of the *Bacteroidaceae* (Shah and Collins, (1980, 1983), is now increasingly being reintroduced to support new diversity revealed by 16S rRNA sequence analysis (see e.g., Sakamoto et al., 2005a, b).

ing reducing equivalents from reduced coenzymes generated during catabolism. Components of this system are therefore key features of this genus and have been used as exclusionary criteria in delineating species of this genus. Species are therefore characterized by the presence of unsaturated menaquinones with predominantly 10–13 isoprene units. Both nonhydroxylated and 3-hydroxylated fatty acids are present, with the former being predominantly straight-chain saturated, anteiso- and iso-methyl and branched-chain types. The

DNA base compositions are within the approximate range of 40–52 mol% G+C.

Differentiation of the species of the genus *Prevotella*

The genus *Prevotella* includes 34 validly published species and one that is not validly published. Table 22 gives the physiological characteristics helpful in differentiating the species. The list of species is given below.

List of species of the genus *Prevotella*

1. ***Prevotella melaninogenica*** (Oliver and Wherry 1921) Shah and Collins 1990, 206^{VP} emend. Wu, Johnson, Moore and Moore 1992, 536^{VP} [*Fusiformis nigrescens* Schwabacher, Lucas and Rimington 1947, 109; *Bacteroides melaninogenicus* (Oliver and Wherry 1921) Roy and Kelly 1939, 569^{AL}; *Ristella melaninogenica* (Oliver and Wherry 1921) Prévot 1938, 290; *Hemophilus melaninogenicus* (*sic*) (Oliver and Wherry 1921) Bergey, Harrison, Breed, Hammer and Huntoon 1930, 314; *Bacterium melaninogenicum* Oliver and Wherry 1921, 341].

me.la.ni.no.ge'ni.ca. N.L. n. *melaninum* melanin; N.L. adj. *genicus* -a -um producing, probably derived from Gr. n. *genetes* a begetter; N.L. fem. adj. *melaninogenica* melanin

producing. [Note: the black pigment produced by this organism is due to protoheme (Shah et al., 1979) and not to melanin, as originally thought.]

The description is from Holdeman and Johnson (1982), Holdeman et al. (1984), Miyagawa et al. (1978, 1979, 1981), Miyagawa and Suto (1980), Shah et al. (1979, 1976), Shah and Collins, (1990, 1980, 1983), Shah and Williams (1982), Gregory et al. (1978), Lambe et al. (1974) and van Steenberg et al. (1979). Cells are rods 0.5–0.8 × 0.9–2.5 μm; occasional cells are 10 μm long in glucose broth cultures. Colonies grown on blood agar are 0.5–2 mm in diameter, circular and entire, convex and shiny; cells are usually

FIGURE 25. Neighbor-joining phylogenetic tree of 16S rRNA gene sequences of the type strains of *Prevotella* species deposited in GenBank to show the relationships of strains within the genus. Bootstrap values (expressed as percentages of 1000 replicates) are shown at the nodes. The numbers that precede each strain are the GenBank accession numbers, while those that follow the species names are the Culture Collection numbers. The type species of *Bacteroides* (*Bacteroides fragilis*, NCTC 9343) and *Porphyromonas* (*Porphyromonas asaccharolytica*, ATCC 25260), both former members of the same genus, and *Escherichia coli* (K12) are included for comparison.

darker in the center of the colony; edges are gray to light brown and become darker upon continued incubation (5–14 d). Before the pigmentation develops, the lighter areas of the colony exhibit bright red fluorescence under long wave ultraviolet radiation (365 nm), which is helpful in the presumptive identification of this species. Cells grown on hemolyzed laked blood agar develop pigment more rapidly; some strains do not produce black pigment on horse blood agar, but do on rabbit blood agar; some strains produce beta-hemolysis on rabbit blood agar. Glucose broth cultures are usually turbid with a smooth or stringy sediment and pH of 4.6–5.0 and growth is stimulated with the addition of hemin (1 µg/ml is the requirement for the type strain) or vitamin K₁ (0.1 µg/ml). The majority of strains grow at pH 8.5 and 25°C; some grow at 45°C.

Cells ferment dextrin, fructose, glucose, glycogen, inulin, lactose, maltose, mannose, raffinose, starch, sucrose, but not amygdalin, arabinose, cellobiose, erythritol, inositol, manitol, melibiose, melezitose (variable), rhamnose, ribose, salcin, sorbitol, trehalose or xylan. Esculin (variable) and starch are hydrolyzed and gelatin is digested; nitrate is not reduced; catalase, indole and lecithinase are not produced.

Succinate and acetate are the major fermentation end products from glucose broth culture (1% peptone, 1% yeast extract, vitamin K₁ and hemin); minor products include formate, isobutyrate and isovalerate. H₂ is not produced. Lactate and pyruvate are not utilized; threonine is not converted to propionate. Cells have superoxide dismutase activity. The long-chain fatty acid composition is mainly anteiso- and iso-methyl branched acids with small amounts of straight-

chain acids; the major fatty acid is 12-methyltetradecanoic acid (C₁₅ anteiso). The principal respiratory quinones are unsaturated menaquinones with 10 and 11 isoprene units.

Source: isolated from human gingival crevices and from human clinical specimens.

DNA G+C content (mol%): 36–40 (*T_m*, Bd).

Type strain: ATCC 25845, CCUG 4944 B, CIP 105346, DSM 7089, JCM 6325, NCTC 12963, B282VPI 4196, VPI 15087.

Sequence accession no. (16S rRNA gene): L16469.

2. **Prevotella albensis** Avguštin, Wallace and Flint 1997, 286^{VP} al.ben'sis. N.L. fem. adj. *albensis* referring to Alba, the ancient name for Scotland north of the Forth and Clyde, where the type strain was isolated.

The species was distinguished from *Prevotella ruminicola* and reported to contain several genotypes. The description is based on those given by Bryant et al. (1958), Bryant and Robinson (1962), Pittman and Bryant (1964), Holdeman et al. (1984), Augustin et al. (1997) and on our own observations. Cells are 0.8–1.0 × 1.0–8.0 μm. They have tapered to rounded ends and are encapsulated. Cells contain inclusion bodies after several days growth. It grows well in a carbohydrate medium producing slime and sediment, with a terminal pH of between 4.6 and 5.7. Most strains grow well in a defined medium containing glucose, CO₂, mineral salts, heme, B vitamins, volatile fatty acids (especially, acetate, 2-methylbutyric or isobutyric acid), methionine or cysteine and ammonia or peptides as a nitrogen source. Surface colonies on blood agar plates are 0.5–1 mm in diameter, circular with an entire edge, low convex, translucent to semi-opaque, white, shiny and smooth.

Carbohydrate fermentation reactions are variable among isolates but most ferment glucose, xylose and salicin, but not melibiose, sucrose, mannose, *N*-acetylglucosamine, raffinose or inulin. Much emphasis has been placed on carboxymethylcellulose activities among species isolated from the rumen; however, this species shows only weak activity.

The major metabolic end products from glucose broths are acetic and succinic acids, with low to trace amounts of formic, propionic, isobutyric and isovaleric acids. The long-chain fatty acid composition is mainly anteiso- and iso-methyl branched acids with small amounts of straight-chain acids; the major fatty acid is 12-methyltetradecanoic acid (C_{15:0} anteiso) and pentadecanoic (C_{15:0}). The principal respiratory quinones are menaquinones MK-11 and MK-12 with low levels (~1–5%) of MK-8, MK-9 and MK-13.

Source: the type strain was isolated from sheep rumen.

DNA G+C content (mol%): 39–43 (*T_m*).

Type strain: M384, CIP 105472, DSM 11370, JCM 12258.

Sequence accession no. (16S rRNA gene): AJ011683.

3. **Prevotella baroniae** Downes, Sutcliffe, Tanner and Wade 2005, 1554^{VP}

bar'on.i.ae. N.L. gen. fem. n. *baroniae* of Baron, named in honor of Ellen Jo Baron, the American microbiologist, for her contributions to clinical microbiology.

The description is from Downes et al. (2005). Most cells are coccobacillary, 0.6 × 0.6–2.0 μm. Rod-shaped cells 3–8 μm long may be observed. Colonies on Fastidious Anaerobic Agar after 5 d growth are 1.2–3.8 mm in diameter, circular and high convex; colony morphology can vary from entire

to undulate. They are opaque with a shiny gray periphery and an off-white center, which appears matt in some strains. Growth in peptone-yeast extract (PY) broth is good and is stimulated by the addition of 1% (w/v) fermentable carbohydrates. Optimum growth temperature is 37°C.

Cells are saccharolytic and ferment cellobiose, fructose, glucose, lactose, maltose, mannose, melibiose, raffinose, salicin and sucrose. Acid is not produced from arabinose, mannitol, melezitose, rhamnose, ribose, sorbitol or trehalose. Arginine and urea are not hydrolyzed, gelatin is weakly hydrolyzed and esculin is hydrolyzed. Catalase and indole are not produced and nitrate is not reduced.

Acetic and succinic acids are the major end products of fermentation in PYG broth; minor products include isovaleric acid, and minor amounts of isobutyric acid may be produced in PY broth. The non-hydroxylated fatty acid profile consists predominantly of C_{15:0} iso, C_{15:0} anteiso, C_{16:0} and C_{17:0} anteiso.

Source: isolated from the human oral cavity in patients with endodontic and periodontal infections or dentoalveolar abscesses and from the dental plaque of healthy subjects.

DNA G+C content (mol%): 52 (HPLC).

Type strain: E9.33, CCUG 50418, DSM 16972, JCM 13447.

Sequence accession no. (16S rRNA gene): AY840553.

4. **Prevotella bergensis** Downes, Sutcliffe, Hofstad and Wade 2006, 611^{VP}

berg.en'sis. N.L. fem. adj. *bergensis* referring to Bergen, the Norwegian city where the first strains were isolated.

The description is from Downes et al. (2006). Most cells are bacilli (0.7–0.8 × 0.8–6 μm), but short rod/cocci are often seen. Colonies on Fastidious Anaerobic Agar after 4 d growth are 0.6–0.8 mm in diameter, circular and entire, convex, opaque, and gray to off-white. Growth in broth media produces moderate turbidity and is stimulated by the addition of fermentable carbohydrates. Cells are saccharolytic and ferment arabinose, cellobiose, fructose, glucose, lactose, maltose, mannose, rhamnose, salicin and xylose. Mannitol and trehalose are fermented variably. Melezitose, melibiose, raffinose, ribose, sorbitol and sucrose are not fermented. Arginine, gelatin and urea are not hydrolyzed. Esculin is hydrolyzed. Catalase and indole are not produced and nitrate is not reduced.

Acetic and succinic acids are the major end products of fermentation in PYG broth; trace products include isovaleric acid. The non-hydroxylated fatty acid profile is predominantly C_{14:0} iso, C_{15:0} iso and C_{15:0} anteiso. The menaquinone composition is unknown.

Source: isolated from infections of the skin and soft-tissue abscesses.

DNA G+C content (mol%): 48 (HPLC).

Type strain: 94067913, CCUG 51224, DSM 17361, JCM 13869.

Sequence accession no. (16S rRNA gene): AY350613

5. **Prevotella bivia** (Holdeman and Johnson 1977) Shah and Collins 1990, 206^{VP} (*Bacteroides bivius* Holdeman and Johnson 1977, 341^{VP})

bi'vi.us L. fem. adj. *bivia* having two ways, pertaining to the saccharolytic and proteolytic activities of the species.

The description is taken from Holdeman et al. (1977), Hammann and Werner (1981) and our own observations. Cells are $0.7\text{--}1.0 \times 1.3\text{--}4.6 \mu\text{m}$ and occur in pairs or short chains. On blood agar, colonies are $0.5\text{--}2.0 \text{ mm}$, circular, entire to slightly erose, convex, translucent to semi-opaque, smooth and glistening. Some strains show orange to pink fluorescence under longwave ultraviolet radiation (365 nm). Isolates typically ferment dextrin, glucose, lactose, maltose and mannose, but not amygdalin, cellobiose, inositol, inulin, mannitol, melezitose, melibiose, raffinose, rhamnose, ribose, salicin, sucrose, trehalose or xylose. Starch is hydrolyzed but not esculin.

Prevotella bivia produces acetate and succinate as major metabolic ends from a glucose broth. The cell wall contains meso-diaminopimelic acid. The long-chain fatty acid composition is mainly anteiso- and iso-methyl branched acids with lower levels of straight-chain acids. The major fatty acid is 12-methyltetradecanoic acid ($C_{15:0}$ anteiso). The principal respiratory quinones are unsaturated menaquinones with 10 and 11 isoprene units.

Source: usually isolated from infections in the urogenital or abdominal region, but now generally considered as part of the normal flora of the vagina.

DNA G+C content (mol%): 40 (T_m).

Type strain: ATCC 29303, CCUG 9557, CIP 105105, DSM 20514, JCM 6331, LMG 6452, NCTC 11156.

Sequence accession no. (16S rRNA gene): L16475.

6. **Prevotella brevis** (Bryant, Small, Bouma and Chu 1958) Avguštin, Wallace and Flint 1997, 286^{VP} (*Bacteroides ruminicola* subsp. *brevis* Bryant, Small, Bouma and Chu 1958, 18^{AL}) bre'vis. L. fem. adj. *brevis* short.

The morphological and biochemical characteristics of this species are based on those of Bryant et al. (1958) and Holdeman et al. (1984) and on chemotaxonomic characters reported by Shah and Collins (1980, 1983). The species was originally part of a heterogeneous collection of strains that were assigned to *Bacteroides ruminicola* as *Bacteroides ruminicola* subspecies *brevis* (biovars 1 and 2). Even though DNA–DNA hybridization values (Shah et al., 1982) [see Holdeman et al. (1984)] between the various subspecies of *Bacteroides ruminicola* indicated they were distinct species, their taxonomic status remained unchanged because of the lack of reliable phenotypic characters for delineating each subspecies. They were reassigned to the genus *Prevotella* (Shah and Collins, 1990) and elevated to species rank (along with *Prevotella ruminicola* subsp. *ruminicola* and *Prevotella ruminicola* subsp. *brevis* (biovar 3) now *Prevotella bryantii*) by Avguštin et al. (1997). Clear phenotypic circumscription of these closely related species are still lacking, but it is evident that they represent distinct lineages on the basis of 16S rRNA sequences. However, many of the ill-defined taxa remain *incertae sedis*.

Cells are $0.8\text{--}1.0 \times 1.0\text{--}5.0 \mu\text{m}$ and are often coccoid to oval. Surface colonies on blood agar plates are $0.5\text{--}1 \text{ mm}$ in diameter, circular with an entire edge, low convex, translucent to semi-opaque, white, shiny, and smooth. It grows well in a carbohydrate medium producing slime and sediment with a terminal pH of between 4.6 and 5.7. Most strains grow well in a defined medium containing glucose, CO_2 , mineral

salts, heme, B vitamins, volatile fatty acids (especially, acetate, 2-methylbutyric or isobutyric acid), methionine or cysteine and ammonia or peptides as a nitrogen source.

Carbohydrate fermentation reactions differ among isolates. Most isolates ferment arabinose, cellobiose, dextrin, fructose, glucose, inulin, lactose, maltose, mannose, melibiose, raffinose and sucrose, but not inositol, mannitol, rhamnose, ribose, trehalose or xylose. Strains do not exhibit carboxymethylcellulose activity. The major metabolic end products from glucose broths are acetic and succinic acids, with low to trace amounts of propionic, iso-butyric, formic and isovaleric acids.

The long-chain fatty acid composition is mainly anteiso- and iso-methyl branched acids with small amounts of straight-chain acids; the major fatty acid is 12-methyltetradecanoic acid ($C_{15:0}$ anteiso) and pentadecanoic ($C_{15:0}$). The principal respiratory quinones are menaquinones MK-13 and MK-12 with low levels (~1–5%) of MK-11, MK-10 and MK-9.

Source: the type strain was isolated from bovine rumen.

DNA G+C content (mol%): 45–52 (T_m).

Type strain: GA33, ATCC 19188, CIP 105473).

Sequence accession no. (16S rRNA gene): AJ011682.

7. **Prevotella bryantii** Avguštin, Wallace and Flint 1997, 287^{VP} bry.an'ti.i. N.L. gen. masc. n. *bryantii* of Bryant, named after Marvin Bryant, an American microbiologist.

The morphological and biochemical characteristics of this species are based on that of Bryant et al. (1958) and Holdeman et al. (1984), and on chemotaxonomic characters reported by Shah and Collins (1980, 1983). The species was formerly *Bacteroides ruminicola* subspecies *brevis* (biovar 3) (see above, *Prevotella brevis*) that was reassigned to the genus *Prevotella* (Shah and Collins, 1990) and elevated to species rank as *Prevotella bryantii* by Avguštin et al. (1997).

Cells are $0.8\text{--}1.0 \times 1.0\text{--}5.0 \mu\text{m}$ and are often coccoid to oval. Surface colonies on blood agar plates are $0.5\text{--}1 \text{ mm}$ in diameter, circular with an entire edge, low convex, translucent to semi-opaque, white, shiny, and smooth. It grows well in a carbohydrate medium producing slime and sediment, with a terminal pH of between 4.6 and 5.7. Most strains grow well in a defined medium containing glucose, CO_2 , mineral salts, heme, B vitamins, volatile fatty acids (especially, acetate, 2-methylbutyric or isobutyric acid), methionine or cysteine and ammonia or peptides as a nitrogen source. Carbohydrate fermentation reactions differ among isolates. Most isolates ferment arabinose, dextrin, fructose, glucose, inulin, lactose, maltose, mannose, melibiose, raffinose, sucrose, xylose and xylan, but not N-acetylglucosamine, inositol, mannitol, rhamnose, ribose or trehalose. Strains exhibit carboxymethylcellulose activity.

The major metabolic end products from glucose broths are acetic and succinic acids with low to trace amounts of formic, propionic, isobutyric and isovaleric acids. The long-chain fatty acid composition is mainly anteiso- and iso-methyl branched acids with small amounts of straight-chain acids; the major fatty acid is 12-methyltetradecanoic acid ($C_{15:0}$ anteiso) and pentadecanoic ($C_{15:0}$). The principal respiratory quinones are menaquinones MK-13 and MK-12 with low levels (~1–5%) of MK-11, MK-10 and MK-9.

Source: isolated from the reticulo-rumen of cattle, sheep and elk; it is the predominant species of the rumen of most ruminants. Phenotypically similar strains have been reported from man, but these have been assigned to either *Prevotella oris* or *Prevotella buccae*.

DNA G+C content (mol%): 40–43 (T_m).

Type strain: B14, CIP 105474, DSM 11371.

Sequence accession no. (16S rRNA gene): AJ006457.

8. **Prevotella buccae** (Holdeman, Moore, Churn and Johnson 1982) Shah and Collins 1990, 207^{VP} (*Bacteroides buccae* Holdeman, Moore, Churn and Johnson 1982, 128^{VP}; *Bacteroides capillus* Kornman and Holt, 1982, 266 *Bacteroides pentosaceus* Shah and Collins 1982, 266)

buc'cae. L. gen. n. *buccae* of the mouth, referring to a major natural habitat of the species.

The species was reported by Holdeman et al. (1982) as *Bacteroides buccae* because of its site of isolation. It was named *Bacteroides capillus* by Kornman and Holt (1981) because of its pronounced capsule, and it was also named *Bacteroides pentosaceus* by Shah and Collins (1981) because of its characteristic capacity to ferment pentoses. However, the names *Bacteroides capillus* and *Bacteroides pentosaceus* are regarded as later heterotypic synonyms of *Bacteroides buccae* (Johnson and Holdeman, 1985). The species was later reclassified as *Prevotella buccae* by Shah and Collins (1990). It was delineated from among the *Bacteroides oralis*-*Bacteroides ruminicola* complex using long-chain cellular fatty acid and menaquinone profiles (Shah and Collins, 1980), DNA–DNA hybridization (Shah et al., 1982) and multilocus enzyme electrophoresis (Shah and Williams, 1982). The description is based on these papers and Johnson and Holdeman (1985).

Cells occur in pairs or short chains, are rod-shaped and are 0.5–0.6 × 0.8–6.5 µm in PYG or BM broth cultures. Cells on brain heart infusion agar (BHIA) roll tubes (Holdeman et al., 1980) produce subsurface colonies 1–2 mm in diameter, lenticular and translucent. Colonies grown on blood agar plates are 0.5–3 mm in diameter, circular with an entire edge, low convex, translucent to semi-opaque, white or buff, shiny, smooth and nonhemolytic on rabbit blood. There is no action on rabbit blood or egg yolk agar (Holdeman et al., 1977). Most cells do not grow in PYG containing 10% bile; cells that do grow are markedly inhibited and delayed. Growth is stimulated by heme and for some strains this is an absolute requirement for cytochrome biosynthesis. Pre-reduced broth cultures after incubation at 37°C for 24 h are uniformly turbid with a smooth sediment; the terminal pH after 3–5 d is 4.5–5.0 in broths with carbohydrates or 5.1–5.6 in the absence of sugars.

Cells typically ferment the pentose sugars arabinose and xylose, in addition to cellobiose, dextrin, fructose, glucose, glycogen, lactose, maltose, mannose, melibiose, raffinose, salicin, starch and sucrose. Acid is not produced from melezitose, trehalose, inositol or mannitol. Nitrate is not reduced; indole and catalase are not produced. Gelatin is digested by most strains.

Succinic and acetic acids are the major fermentation end products from glucose broth, with minor amounts of formic, isobutyric and isovaleric acids; no H₂ is produced. The long-chain fatty acid composition is mainly anteiso- and

iso-methyl branched acids, with lower levels of straight-chain acids. The major fatty acid is 12-methyltetradecanoic acid (C_{15:0} anteiso). The principal respiratory quinones are unsaturated menaquinones with 13, 12 and 11 isoprene units.

Source: type strain was isolated from gingival crevice with moderate periodontitis. The normal habitat appears to be the oral cavity.

DNA G+C content (mol%): 52 (T_m , Bd).

Type strain: ATCC 33574, CCUG 15401, CIP 105106, JCM 12245, VPI D3A-6.

Sequence accession no. (16S rRNA gene): L16477.

9. **Prevotella buccalis** (Shah and Collins 1982) Shah and Collins 1990, 207^{VP} (*Bacteroides buccalis* Shah and Collins 1982, 266^{VP})

buc.ca'lis. L. n. *bucca* the mouth; L. fem. suff. *-alis* suffix denoting pertaining to; N.L. fem. adj. *buccalis* buccal, pertaining to the mouth.

The description is from Shah et al. (1981) and was distinguished from the *Bacteroides oralis*-*Bacteroides ruminicola* complex by using long-chain cellular fatty acid and menaquinone profiles (Shah and Collins, 1980, 1983), DNA–DNA hybridization (Shah et al., 1982) and multilocus enzyme electrophoresis (Shah and Williams, 1982).

Cells are short rods on agar; cells grown in broth culture are elongated (0.5–0.8 × 0.9–6.0 µm) and pleomorphic. Colonies grown on agar after 3 d are 0.2–0.5 mm in diameter, circular and entire, convex, shiny, smooth and translucent cream to light gray; they are non-hemolytic on horse blood agar. The organisms ferment cellobiose, fructose, glucose, lactose, maltose, mannose, raffinose, salicin and sucrose, but not arabinose, glycerol, mannitol, melezitose, rhamnose, sorbitol, trehalose or xylose. Starch is not hydrolyzed; indole is not produced; gelatin is not digested; esculin is hydrolyzed.

Acetic and succinic acids are the major metabolic end products in glucose broth, with minor amounts of lactic acid; terminal pH is 5.5. The long-chain fatty acid composition is mainly anteiso- and iso-methyl branched acids with small amounts of straight-chain acids; the major fatty acid is 12-methyltetradecanoic acid (C_{15:0} anteiso). The principal respiratory quinones are unsaturated menaquinones with 11, 12 and 13 isoprene units.

Source: isolated initially from human dental plaque, but has since been reported from other sites.

DNA G+C content (mol%): 45–46 (T_m , Bd).

Type strain: ATCC 35310, CCUG 15557, DSM 20616, JCM 12246, NCDO 2354, NCTC 13064.

Sequence accession no. (16S rRNA gene): L16476.

10. **Prevotella copri** Hayashi, Shibata, Sakamoto, Tomita and Benno 2007, 943^{VP}

cop'ri. N.L. gen. n. *copri* from Gr. gen. n. *kopron* of/from feces.

The description is from Hayashi et al. (2007). Unlike most *Prevotella* species, which are of oral origin, these isolates are from human feces, but unusually, growth is inhibited on *Bacteroides* bile esculin agar.

The cell dimensions have not been reported. Colonies on Eggerth–Gagnon blood agar after 48 h incubation

at 37°C under 100% CO₂ are white, circular and convex. Optimum temperature for growth is 37°C. Esculin is hydrolyzed. Indole is not produced. No activity is detected for urease. Gelatin is not hydrolyzed. Acid is produced from glucose, lactose, sucrose, maltose, raffinose, salicin, xylose, arabinose, cellobiose and rhamnose. Positive reactions are obtained with the API ZYM system for alkaline phosphatase, acid phosphatase, naphthol-AS-BI-phosphohydrolase, α -galactosidase, β -galactosidase, α -glucosidase and β -glucosidase; negative reactions are obtained for lipase (C4), leucine arylamidase, valine arylamidase, cystine arylamidase, trypsin, β -glucuronidase, *N*-acetyl- β -D-glucosaminidase, α -mannosidase and α -fucosidase. Positive reactions are obtained with the An-Ident system for a glucosidase, α -arabinofuranosidase, β -glucuronidase, alkaline phosphatase, α -galactosidase, indoxylacetate hydrolase and arginine and alanine aminopeptidases; negative reactions are obtained for *N*-acetyl- β -D-glucosaminidase, α -L-fucosidase, β -galactosidase and pyroglutamic acid arylamidase, and for leucine, proline, tyrosine, arginine, histidine, phenylalanine and glycine aminopeptidases. Catalase is negative.

The major metabolic end products are succinic and acetic acids. The predominant long-chain fatty acids are C_{16:0}, C_{18:1} ω 9c and C_{15:0} anteiso. The principal respiratory quinones are menaquinones MK-12 and MK-11 with lower levels of MK-8 to -10 and MK-13 (<20%).

Source: The source is human feces. The habitat is the intestinal tract.

DNA G+C content (mol%): 44–45 (HPLC).

Type strain: CB7, JCM 13464, DSM 18205.

Sequence accession no. (16S rRNA gene): AB064923.

11. **Prevotella corporis** (Johnson and Holdeman 1983) Shah and Collins 1990, 207^{VP} (*Bacteroides corporis* Johnson and Holdeman 1983, 19^{VP})

cor'po.ris. L. gen. n. *corporis* of the body; pertaining to the isolation of this organism from human clinical specimens.

The description is from Johnson and Holdeman (1983) and our own observations. Cells occur singly, in pairs and in short chains and are 0.9–1.6 \times 1.6–4.0 μ m long in PYG broth cultures. Growth and fermentation are stimulated by addition of 10% (v/v) serum; hemin and vitamin K are required for growth. Cells mainly appear coccoid, but occasionally cells up to 11 μ m long can be observed. At 48–72 h colonies on anaerobic blood agar are minute to 1 mm in diameter, circular and entire, convex and buff with brown edges; dark brown colonies develop after 4–7 d incubation. Glucose broth cultures are turbid with smooth or ropey sediment that tends to adhere to the bottom of the tube; the terminal pH value is 4.8–5.1.

Cells ferment dextrin and glucose; the majority of strains ferment fructose (except the type strain), glycogen, maltose, mannose and starch. Cells do not ferment amygdalin, arabinose, cellobiose, erythritol, esculin, inositol, lactose, mannitol, melezitose, melibiose, rhamnose, ribose, salicin, sorbitol or xylose. Indole and catalase are not produced. Starch is hydrolyzed. Nitrate is not reduced. Gelatin is digested.

Succinic and acetic acids are the major fermentation end products from PYG broth cultures with vitamin K and

hemin; minor acids produced may include isobutyric and isovaleric acids; no H₂ is produced. Neither lactate nor pyruvate is used; threonine is not converted to propionate. The long-chain fatty acid composition is mainly anteiso- and iso-methyl branched acids with small amounts of straight-chain acids; the major fatty acid is 12-methyltetradecanoic acid (C_{15:0} anteiso). The principal respiratory quinones are unsaturated menaquinones with 11 and 12 isoprene units.

Source: the type strain was isolated from a cervical swab.

DNA G+C content (mol%): 43–46 (T_m).

Type strain: Lambe 532-70A, ATCC 33547, CIP 105107, JCM 8529, NCTC 13065, VPI 9342.

Sequence accession no. (16S rRNA gene): L16465.

12. **Prevotella dentalis** (Haapasalo, Ranta, Shah, Ranta, Lounatmaa and Kroppenstedt 1986a) Willems and Collins 1995, 834^{VP} (*Mitsuokella dentalis* Haapasalo, Ranta, Shah, Ranta, Lounatmaa and Kroppenstedt 1986a, 566^{VP})

den.ta'lis. L. n. *dens dentis* a tooth; L. fem. suff. *-alis* suffix denoting pertaining to; L. fem. adj. *dentalis* pertaining to the teeth.

The species was originally placed in the genus *Mitsuokella* because of its high mol% G+C content (~56–60) (Haapasalo et al., 1986a), which is characteristic of the genus *Mitsuokella*. However, by other criteria, this taxon differed so significantly from *Mitsuokella* that it was reclassified as *Prevotella dentalis* by Willems et al. (Willems and Collins, 1995). This species may be synonymous with *Hallella serogens* (Moore and Moore, 1994).

The description is from Haapasalo et al. (1986a, b) and subsequent observations in our laboratory. Cells occur singly and are blunt-ended oval rods 0.7 \times 1–2 μ m. Peritrichous fimbriae and a thick capsule-like structure are present. Poor growth occurs in liquid media, growth is enhanced on blood agar media supplemented with hemolyzed blood. No growth occurs on kanamycin-vancomycin laked blood agar. Colonies grown on enriched horse blood agar after 3 d are 1–2 mm in diameter, convex, irregular, translucent, wet and mucoid, with a characteristic water drop appearance. Alpha-hemolysis usually occurs on horse and sheep blood agar after 7 d. Using pre-reduced anaerobically sterilized PY broth as a base, cells ferment arabinose, cellobiose, fructose, galactose, glucose, lactose, maltose, mannose and raffinose; melibiose and sucrose are weakly fermented (pH 5.5–5.7). Cells do not ferment erythritol, mannitol, melezitose, rhamnose, salicin or xylose; Starch and gelatin are not hydrolyzed. Esculin is not hydrolyzed except when a chromogenic substrate for the detection of a constitutive enzyme is used with cells grown on agar plates.

The major metabolic end products are succinate and acetate. Hydroxylated and nonhydroxylated long-chain fatty acid methyl esters are present in whole-cell methanol lysates. The major fatty acids are 3-hydroxyhexadecanoic acid (C_{16:0} 3-OH), hexadecanoic acid (C_{16:0}) and 12-methyltridecanoic acid (C_{14:0} iso).

Source: isolated from human dental root canals.

DNA G+C content (mol%): 56–60 (T_m, Bd).

Type strain: ES2772, ATCC 49559, CCUG 48288, DSM 3688, JCM 13448, NCTC 12043.

Sequence accession no. (16S rRNA gene): X81876.

13. **Prevotella denticola** (Shah and Collins 1982) Shah and Collins 1990, 207^{VP} emend. Wu, Johnson and Moore 1992, 536^{VP} (*Bacteroides denticola* Shah and Collins 1982, 266^{VP} emend. Holdeman and Johnson 1982, 404)

den.ti'co.la. L. n. *dens*, *dentis* tooth; L. suff. *-cola* (from L. n. *incola*) inhabitant, dweller; N.L. n. *denticola* tooth dweller.

The description is from Shah and Collins (1981) and Holdeman et al. (1984). The species was distinguished from the *Bacteroides oralis*-*Bacteroides ruminicola* complex by using long-chain cellular fatty acid and menaquinone profiles (Shah and Collins, 1980, 1983), DNA-DNA hybridization (Shah and Collins, 1982) and multilocus enzyme electrophoresis (Shah and Williams, 1982).

Cells are rods and occur in pairs and short chains 0.5–0.7 × 0.7–6.0 µm in glucose broth cultures. Colonies grown on blood agar are 1–2 mm in diameter, circular and entire, low convex, semi-opaque, shiny, smooth and often appear to have white or buff concentric rings. Colonies grown on rabbit blood agar develop pigment more quickly and are darker. Most cells grown on hemolyzed rabbit blood agar after 7 d produce dark brown or black colonies; occasional strains do not develop colonies with a definite pigment. Most colonies show red fluorescence under long wavelength ultraviolet radiation (365 nm). Glucose broth cultures are turbid, have smooth sediment and have a pH of 4.5–4.9. Growth is stimulated by the addition of hemin; vitamin K₁ is not often required. There is no growth in PYG broth with 20% bile.

Cells ferment dextrin, fructose, glucose, glycogen, inulin, lactose, maltose, mannose, raffinose, sucrose and starch. Cells do not ferment amygdalin, arabinose, cellobiose, erythritol, gum arabic, inositol, larch arabinogalactan, mannitol, melibiose, melezitose, rhamnose, salicin, sorbitol, trehalose, xylan or xylose. Esculin and starch are hydrolyzed. Gelatin digestion is variable. Nitrate is not reduced. Catalase, indole and lecithinase are not produced.

Succinate and acetate are the major fermentation end products from glucose broth cultures (1% glucose and peptone, 0.5% yeast extract, vitamin K₁ and hemin); minor production of lactate, isobutyrate and isovalerate may be detected; no H₂ is produced. The long-chain fatty acid composition is mainly anteiso- and iso-methyl branched acids with lower levels of straight-chain acids. The major fatty acid is 12-methyltetradecanoic acid (C_{15:0} anteiso). The principal respiratory quinones are unsaturated menaquinones with 11 and 12 isoprene units.

Source: the normal habitat is the oral cavity but the organisms may be recovered from human clinical specimens.

DNA G+C content (mol %): 49–51 (*T_m*, Bd).

Type strain: Socransky 1210, Shah and Collins 1210, ATCC 35308, CCUG 29542, CIP 104478, DSM 20614, JCM 13449, NCDO 2352, NCTC 13067.

Sequence accession no. (16S rRNA gene): L16467.

14. **Prevotella disiens** (Holdeman and Johnson 1977) Shah and Collins 1990, 207^{VP} (*Bacteroides disiens* Holdeman and Johnson 1977, 337^{VP})

di'si.ens. N.L. part. adj. *disiens* (*sic*) going in two different directions; intended to refer to the fact that the organism is both saccharolytic and proteolytic.

The description is from Holdeman and Johnson (1977) and our own observations. Cells are non-pigmented rods and occur predominantly in pairs or occasionally short chains with longer rods; the longer rods occur both singly and in chains with the short rods. Cells are 0.6–0.9 × 2.0–8.2 µm. Colonies grown on Brucella-laked blood agar plates after 2 d are minute to 2 mm in diameter, circular and entire, convex, translucent to opaque, smooth, shiny and white. There is no hemolysis on blood agar plates; slight greening maybe observed in areas of confluent growth. No brown or black pigmentation is observed on BHI-laked blood agar; some strains show light orange to pink fluorescence on blood agar plates. Cultures in pre-reduced PYG broth are moderately turbid; slight smooth sediment may be observed. Growth is enhanced in broth with fermentable carbohydrate and is turbid and smooth, with a granular or flocculent sediment; growth occurs well in BM broth. Optimal growth occurs at 37°C, but growth can occur at 25 and 45°C. The terminal pH after 1 d is 4.9–5.2 with fermentable carbohydrates and 5.9–6.1 without fermentable carbohydrates. Growth is inhibited in 6.5% NaCl broth.

Strains ferment dextrin, fructose, glucose, glycogen, maltose and starch, but not amygdalin, arabinose, cellobiose, erythritol, esculin, galactose, inositol, lactose, mannitol, mannose, melezitose, melibiose, raffinose, rhamnose, salicin, sorbitol, sucrose, trehalose or xylose. Gelatin and starch are hydrolysed. Nitrate is not reduced. Indole and catalase are not produced. Esculin is not hydrolysed.

Succinic and acetic acids are the major fermentation end products in PYG broth, with minor levels of isovaleric, isobutyric, formic, propionic and lactic acids. The long-chain fatty acid composition is mainly anteiso- and iso-methyl branched acids with lower levels of straight-chain acids. The major fatty acid is 12-methyltetradecanoic acid (C_{15:0} anteiso). The principal respiratory quinones are unsaturated menaquinones with 10 and 11 isoprene units.

Source: recovered from a wide range of human clinical specimens.

DNA G+C content (mol %): 40–42 (*T_m*).

Type strain: ATCC 29426, CCUG 9558, CIP 105108, DSM 20516, JCM 6334, LMG 6453, NCTC 11157, VPI 8057.

Sequence accession no. (16S rRNA gene): L16483.

15. **Prevotella enoecca** Moore, Johnson and Moore 1994, 601^{VP} e.noe'ca. Gr. n. *enoikos* inhabitant, dweller in a place; N.L. fem. adj. *enoeca* inhabiting, because the organism is an inhabitant of the gingival crevice.

The description is from Moore et al. (1994). Cells occur in pairs and short chains and are 0.5 × 2.2–4.5 µm; filaments up to 8 µm long are observed. Colonies grown on rabbit blood agar for 2 d are 1–2 mm in diameter, circular and entire, convex, transparent to translucent and not hemolytic or pigmented. Broth cultures are turbid with a smooth sediment. Terminal pH values of glucose broth cultures incubated for 5 d are 4.8–5.4. Cells ferment fructose, glycogen, lactose, maltose and mannose, but not cellobiose, raffinose, salicin, sucrose, trehalose or xylose. Esculin is not hydrolyzed by the majority of strains. Gelatin may be liquefied.

Succinic and acetic acids are the major end products of fermentation; trace products include formic acid. No H₂ is

produced. The major cellular fatty acids are C_{15:0} anteiso, C_{16:0}, C_{16:0} 3-OH and C_{15:0} iso with low levels of C_{17:0} iso 3-OH and C_{18:2} dimethyl acetyl, C_{14:0}, C_{14:0} iso and C_{17:0} iso.

Source: isolated from the gingival crevices of humans with healthy gingiva or with periodontitis.

DNA G+C content (mol%): 47 (T_m).

Type strain: ATCC 51261, CIP 104472, JCM 12259, NCTC 13068, VPI D194A-25A.

Sequence accession no. (16S rRNA gene): AJ005635.

16. **Prevotella heparinolyticus** (Okuda, Kato, Shiozu, Takazoe and Nakamura 1985) Shah and Collins 1990, 207^{VP} (*Bacteroides heparinolyticus* Okuda, Kato, Shiozu, Takazoe and Nakamura 1985, 439^{VP})

he.pa'ri.no.ly.ti.cus. N.L. n. *heparinum* (from Gr. n. *hēpar* liver) heparin; N.L. adj. *lyticus -a -um* (from Gr. adj. *lutikos -ē -on*) able to loosen, able to dissolve; N.L. fem. adj. *heparinolytica* heparin dissolving.

The description is from Okuda et al. (1985). Colonies grown on blood agar plates are 0.5–0.7 × 0.8–2.0 μm; occasional cells are up to 10 μm long or longer in broth. The cytoplasmic and outer membranes exhibit a trilamellar structure; the outer wall is separated from the outer membrane by an electron-lucent layer; a distinctive capsular structure surrounding the cell is detected by phase-contrast microscopy and India ink negative staining. Colonies on blood agar after 4 d are circular, entire, convex, translucent, smooth and gray. No dark brown or black colonies are produced on hemolyzed rabbit blood agar; sheep blood is not hemolyzed. Broth cultures are turbid and have a dense sediment; harvested cells are markedly viscous. The terminal pH after 5 d in 1% glucose broth is 5.4–5.6. Strains ferment cellobiose, esculin, fructose, glucose, lactose, maltose, mannose, sucrose, salicin, starch and xylose, but not raffinose, mannitol or sorbitol. Nitrate is not reduced. Indole, H₂S, catalase and gelatinase are not produced. Starch and esculin are hydrolyzed. The reliable property that distinguishes this taxon from other non-pigmented *Prevotella* species is its heparin-degrading activity. In addition to heparinase, alkaline phosphatase, esterase, lipase, phosphatase, trypsin, chymotrypsin, glucosidases and galactosidases are produced.

Succinic acid is the major end product of fermentation in PYG broth; low levels of acetic, propionic and isovaleric acids are also produced.

Source: isolated from human periodontal lesions.

DNA G+C content (mol%): 47–49 (Bd).

Type strain: HEP, ATCC 35895, CCUG 27827, LMG 10142.

Sequence accession no. (16S rRNA gene): L16487.

17. **Prevotella intermedia** (Holdeman and Moore 1970) Shah and Collins 1990, 207^{VP} [*Bacteroides intermedius* (Holdeman and Moore 1970) Johnson and Holdeman 1983, 18^{VP}; *Bacteroides melaninogenicus* subspecies *intermedius* Holdeman and Moore 1970, 33]

in.ter.me'di.us. L. fem. adj. *intermedia* intermediate.

The description is from Johnson and Holdeman (1983), Miyagawa et al. (1978, 1979, 1981), Miyagawa and Suto (1980), Shah et al. (1976, 1979), Shah and Collins (1980,

1983, 1990) and Shah and Williams (1982). Cells are 0.4–0.7 × 1.5–2.0 μm; occasional cells are up to 12 μm long. Colonies on rabbit blood agar after 2 d are 0.5–2.0 mm in diameter, circular and entire, low convex, translucent, smooth and beta-hemolytic; older or larger colonies may be opaque; colonies are tan, gray, reddish brown or black. Cells grown on hemolyzed blood agar develop pigment more rapidly (~1–2 d) and are darker. Glucose broth cultures are turbid with a smooth (occasionally ropey or slightly mucoid) sediment with a final pH of 4.9–5.4. Hemin is required for growth, while vitamin K₁ is highly stimulatory or required for fermentation. Growth is inhibited by 6.5% NaCl. Strains grow well between 25 and 45°C. Acid is produced by the majority of strains from fructose, glycogen, inulin, maltose, mannose, raffinose, starch and sucrose, but not from cellobiose, esculin, gum arabic, lactose, ribose, trehalose or xylan. Indole is produced, Starch is hydrolyzed. No H₂ is produced. Neither lactate nor pyruvate is used. Threonine is not converted to propionate.

Succinic and acetic acids are the major end products of fermentation in cultures grown in PYG broth with vitamin K₁ and hemin; minor products include isobutyric and isovaleric acids. No heptose or 2-keto-3-deoxyoctulosonic acid has been detected. The long-chain fatty acid composition is mainly anteiso- and iso-methyl branched acids with small amounts of straight-chain acids; the major fatty acid is 12-methyltetradecanoic acid (C_{15:0} anteiso). The principal respiratory quinones are unsaturated menaquinones with 11 isoprene units with lower levels of MK-10 and MK-12.

Source: isolated initially from human dental plaque but has since been reported from head, neck and pleural infections, from blood, and from abdominal and pelvic sites.

DNA G+C content (mol%): 41–44 (T_m, Bd).

Type strain: ATCC 25611, NCTC 13070, Finegold B422, CCUG 24041, CIP 101222, CIP 103682, DSM 20706, JCM 12248, JCM 11150, VPI 4197.

Sequence accession no. (16S rRNA gene): L16468.

18. **Prevotella loescheii** (Holdeman and Johnson 1982) Shah and Collins 1990, 207^{VP} (*Bacteroides loescheii* Holdeman and Johnson 1982, 406^{VP})

loesche'i.i. N.L. gen. masc. n. *loescheii* of Loesche, named after Walter J. Loesche, an American oral microbiologist.

The description is from Holdeman and Johnson (1982) Miyagawa et al. (1978, 1979, 1981), Miyagawa and Suto (Miyagawa and Suto, 1980), Shah et al. (1979, 1976), Shah and Collins, (1990, 1980, 1983) and Shah and Williams (1982). Cells are rods 0.4–0.6 × 0.8–15.0 μm and occur singly, in pairs and in short chains in glucose broth cultures. Colonies grown on anaerobic blood agar are 1–2 mm in diameter, circular and entire, low convex, translucent, shiny and smooth. Colonies grown on whole blood agar after 48 h are white or buff; up to 14 d, colonies will usually become light brown. Colonies grown on hemolyzed rabbit blood agar up to 21 d develop pigment more rapidly, although definite black or brown colonies will not develop with some strains; most strains will produce a slight beta-hemolysis on rabbit blood agar. Among the pigmented species, colonies of *Prevotella loescheii* strains exhibit the most pronounced fluorescence under ultraviolet radiation (365 nm), due to over-

production of protoporphyrin (Shah et al., 1979). Glucose broth cultures are turbid and have a smooth sediment and a pH of 4.9–5.4. Growth is stimulated by the addition of hemin and 10% serum. Cells ferment cellobiose, dextrin, fructose, glucose, glycogen, inulin (majority), lactose, maltose, mannose, raffinose, sucrose and starch, but not amygdalin, arabinose, erythritol, inositol, mannitol, melezitose, rhamnose, ribose, salicin, sorbitol, trehalose or xylose. Esculin and starch are hydrolyzed and gelatin is digested. Nitrate is not reduced. Catalase, indole and lecithinase are not produced.

Succinate and acetate are the major fermentation end products from glucose broth culture (1% peptone, 1% yeast extract, vitamin K₁ and hemin); trace amounts of lactate and formate may be detected; no H₂ is produced. No heptose or 2-keto-3-deoxyoctulosonic acid has been reported. The long-chain fatty acid composition is mainly anteiso- and iso-methyl branched acids with small amounts of straight-chain acids; the major fatty acid is 12-methyltetradecanoic acid (C_{15:0} anteiso). The principal respiratory quinones are unsaturated menaquinones with 11 isoprene units with lower levels of MK-10 and MK-12.

Source: the normal habitat appears to be the oral cavity, but isolates have been reported from clinical specimens.

DNA G+C content (mol %): 46–48 (T_m).

Type strain: Loesche 8B, ATCC 15930, NCTC 11321, CCUG 5914, JCM 8530, JCM 12249, VPI 9085.

Sequence accession no. (16S rRNA gene): L16481.

19. **Prevotella marshii** Downes, Sutcliffe, Tanner and Wade 2005, 1554^{VP}

mar'shi.i. N.L. gen. masc. n. *marshii* of Marsh, named in honor of British microbiologist Philip Marsh, for his contributions to oral microbiology.

The description is from Downes et al. (2005). Cells are short rods (~0.4 × 0.9–3 µm), but occasionally elongated cells are seen that are up to 6 µm long, occurring singly or in pairs. Colonies on Fastidious Anaerobic Agar after 5 d are 1.8–3.5 mm in diameter, circular and entire, convex, watery, opaque and gray to off-white/gray to greenish gray; heavier growth appears to be cream in color. Under plate microscopy, colonies have a striated appearance with concentric rings of varying opacity and iridescent hues of pink, green and yellow. Broth media cultures are moderately turbid; growth is stimulated by the addition of glucose, fructose or maltose. Cells are moderately saccharolytic and ferment glucose and maltose strongly, fructose and mannose are fermented variably and weakly; arabinose, cellobiose, lactose, mannitol, melezitose, melibiose, raffinose, rhamnose, ribose, salicin, sorbitol, sucrose and trehalose are not fermented. Esculin, arginine and urea are not hydrolyzed; gelatin is hydrolyzed. Catalase and indole are not produced. Nitrate is not reduced.

Acetic and succinic acids are the major end products of metabolism in PYG broth; propionic acid is moderately produced. The long-chain fatty acid profile predominantly comprises C_{15:0} anteiso, C_{15:0} iso, C_{15:0} and C_{14:0} iso.

Source: isolated from the human oral cavity in subjects with endodontic and periodontal infections and from subgingival dental plaque in healthy subjects.

DNA G+C content (mol %): 51 (HPLC).

Type strain: E9.34, CCUG 50419, DSM 16973, JCM 13450.

Sequence accession no. (16S rRNA gene): AF481227.

20. **Prevotella multiformis** Sakamoto, Huang, Umeda, Ishikawa and Benno 2005a, 818^{VP}

mul.ti.for'mis. L. fem. adj. *multiformis* many-shaped, multi-form.

The description is from Sakamoto et al. (2005a). Cells are short rods (~0.5–0.8 × 1.6–6.6 µm) or cocci (coccobacilli) (0.8 × 0.9–1.0 µm) and occur singly. Colonies on Eggerth–Gagnon blood agar after 2 d are 1–2 mm in diameter, circular and entire, slightly convex, gray to light brown and smooth. Cells forming small colonies are cocci and rods, whereas large colonies consist only of cocci. There is no growth in 20% bile. Acid is produced from cellobiose, glucose, glycerol, lactose, maltose, mannose, raffinose and sucrose, but not arabinose, mannitol, melezitose, rhamnose, salicin, sorbitol, trehalose or xylose. Esculin is not hydrolyzed. Gelatin is digested. Catalase, indole and urease are not produced.

Acetic and succinic acids are the major end products of fermentation from glucose broth (composed of peptone, 1%; yeast extract, 1%; and glucose, 1%); minor products include isovaleric acid. Both non-hydroxylated and 3-hydroxylated long-chain fatty acids are present. The major cellular fatty acids are C_{15:0} anteiso, C_{15:0} iso, C_{17:0} iso 3-OH and C_{18:1} ω9c. The principal respiratory quinones are menaquinones MK-11 and MK-12 with lower levels of MK-8, MK-9, MK-10 and MK-13.

Source: isolated from sub gingival plaque from a patient with chronic periodontitis.

DNA G+C content (mol %): 51 (HPLC).

Type strain: PPPA21, DSM 16608, JCM 12541.

Sequence accession no. (16S rRNA gene): AB182483.

21. **Prevotella multisaccharivorax** Sakamoto, Umeda, Ishikawa and Benno 2005b, 1842^{VP}

mul.ti.sac.cha.ri.vo'rax. L. adj. *multus* many/much; L. n. *saccharum* sugar; L. adj. *vorax* devouring, ravenous, voracious; N.L. fem. adj. *multisaccharivorax* liking to eat many sugars.

The description is from Sakamoto et al. (2005b). Cells are 0.8 × 2.5–8.3 µm. Colonies are 0.5–0.7 mm in diameter, gray to off-white–gray, circular, entire, slightly convex and smooth on Eggerth–Gagnon blood agar. Acid is produced from arabinose (variable), cellobiose, glucose, glycerol, lactose, maltose, mannitol, mannose, melezitose, raffinose, rhamnose, salicin (variable), sorbitol, sucrose, trehalose and xylose. Esculin is hydrolyzed. Indole is not produced. Gelatin is digested. Catalase and urease are not produced.

The major end products from glucose broth (composed of peptone, 1%; yeast extract, 1%; and glucose, 1%) are succinic and acetic acids, with lower levels of isovaleric acid. Both nonhydroxylated and 3-hydroxylated long-chain fatty acids are present. The major fatty acids are C_{18:1} ω9c and C_{16:0}. The principal respiratory quinones are menaquinones MK-12 and MK-13 with lower levels of (<10%) MK-10 and MK-11.

Source: isolated from subgingival plaque from patients with chronic periodontitis.

DNA G+C content (mol%): 50 (HPLC).

Type strain: PPPA20, JCM12954, DSM 17128.

Sequence accession no. (16S rRNA gene): AB200414.

22. **Prevotella nigrescens** Shah and Gharbia 1992, 545^{VP}

ni.gres'cens. L. part. adj. *nigrescens* becoming black, referring to the characteristic black colonies formed on blood agar plates.

The description is from Shah and Gharbia (1992), Miyagawa et al. (1978, 1979, 1981), Miyagawa and Suto (Miyagawa and Suto, 1980), Shah et al. (1976, 1979), Shah and Collins, (1980, 1983, 1990) and Shah and Williams (1982). Cells are 0.4–0.7 × 1.5–2.0 µm; occasional cells are up to 12 µm long. Colonies on rabbit blood agar after 2 d are 0.5–2.0 mm in diameter, circular and entire, low convex, translucent, smooth and beta-hemolytic; older or larger colonies may be opaque; colonies are reddish brown or black. Cells grown on hemolyzed blood agar develop pigment more rapidly (~1–2 d) and are darker. Glucose broth cultures are turbid with a smooth (occasionally ropey or slightly mucoid) sediment and a final pH of 4.9–5.4. Hemin and vitamin K₁ are required for growth. Growth is inhibited by 6.5% NaCl and strains grow well between 25 and 45°C. Acid is produced from fructose, glycogen, inulin, maltose, mannose, raffinose, starch and sucrose, but not from cellobiose, esculin, gum arabic, lactose, ribose, trehalose or xylan. Indole is produced. Starch is hydrolyzed. No H₂ is produced.

The major fermentation products from a glucose-containing broth (e.g., BM) are acetic, isobutyric, isovaleric and succinic acids. The long-chain fatty acid composition is mainly anteiso- and iso-methyl branched acids with small amounts of straight-chain acids; the major fatty acid is 12-methyltetradecanoic acid (C_{15:0} anteiso). The principal respiratory quinones are unsaturated menaquinones with 11 isoprene units with lower levels of MK-10 and MK-12.

Sources: isolated initially from human dental plaque but has since been reported from head, neck and pleural infections, from blood, and from abdominal and pelvic sites.

DNA G+C content (mol%): 40–44 (T_m).

Type strain: Lambe 729-74, ATCC 33563, CCUG 9560, CIP 105552, DSM 13386, JCM 6322, JCM 12250, NCTC 9336, VPI 8944.

Sequence accession no. (16S rRNA gene): L16471.

23. **Prevotella oralis** (Loesche, Socransky and Gibbons 1964) Shah and Collins 1990, 207^{VP} (*Ristella oralis* (Loesche, Socransky and Gibbons 1964, 1334) Prévot, Turpin and Kaiser 1967, 264

o.ra'lis. L. n. *os oris* the mouth; L. fem. suff. *-alis* suffix denoting pertaining to; N.L. fem. adj. *oralis* pertaining to the mouth.

The description is from Loesche et al. (1964), Holdeman et al. (1984), Shah et al. (1979, 1976), Shah and Collins (1990, 1980, 1983) and Shah and Williams (1982). Cells from glucose broth are 0.5–0.8 × 1.0–5.0 µm, arranged in pairs and in chains. Surface colonies on hemolyzed rabbit blood agar are 1.0 mm, circular, entire, convex, shiny, smooth, semi-opaque and buff. Strains are nonhemolytic on horse blood infusion agar. In 24 h, glucose broth cultures are moderately turbid with a smooth sediment and pH of

4.5–4.9. Strains grow in up to 3% O₂ and survive exposure to air for up to 80 min. No H₂S is detected in peptone iron agar or in semisolid agar with 0.02% ferrous sulfate and 0.03% sodium hyposulfite, but there is a slight blackening of lead acetate paper suspended over cultures in trypticase broth. The following sugars are fermented: amygdalin, fructose, cellobiose, glucose, glycogen, lactose, maltose, mannose, melibiose, raffinose, salicin, starch and sucrose. Acid is not produced from arabinose, inositol, mannitol, melezitose, trehalose or xylose.

The major fermentation products from a glucose-containing broth (e.g., BM) are acetic, isobutyric, isovaleric and succinic acids. The long-chain fatty acid composition is mainly anteiso- and iso-methyl branched acids with small amounts of straight-chain acids; the major fatty acid is 12-methyltetradecanoic acid (C_{15:0} anteiso). The principal respiratory quinones are unsaturated menaquinones with 11 isoprene units with lower levels of MK-10 and MK-12.

Source: isolated from the gingival crevice area of man and from infections, usually of the oral cavity and upper respiratory and genital tracts.

DNA G+C content (mol%): 43 (T_m).

Type strain: ATCC 33269, CCUG 15408, DSM 20702, JCM 12251, NCTC 11459, VPI D27B-24.

Sequence accession no. (16S rRNA gene): L16480.

24. **Prevotella oris** (Holdeman, Moore, Churn and Johnson 1982) Shah and Collins 1990, 207^{VP} (*Bacteroides oris* Holdeman, Moore, Churn and Johnson 1982, 126^{VP})

or'is. L. gen. n. *oris* of the mouth, referring to a major natural habitat of the species.

The description is from Holdeman et al. (1982) and our own observations. The rod-shaped cells occur in pairs or short chains and are 0.5–0.8 × 0.8–2.6 µm in PYG broth. Cells on BHIA roll tubes (Holdeman et al., 1980) produce subsurface colonies 1–2 mm in diameter and are lenticular and translucent. Colonies grown on blood agar plates are 0.5–1 mm in diameter, circular with an entire edge, low convex, translucent to semi-opaque, white to buff, shiny and smooth. There is no action on rabbit blood or egg yolk agar (Holdeman et al., 1977). Most cells do not grow in PYG containing 10% bile; cells that do grow are markedly inhibited and delayed. Growth is stimulated and required by some strains by the addition of heme. Pre-reduced broth cultures after incubation at 37°C for 24 h are uniformly turbid with a smooth sediment. The terminal pH value after 3–5 d is 4.5–4.9 in media with carbohydrates that are fermented by all strains, and 5.0–5.6 in media with sugars that are not fermented by all strains. All strains ferment dextrin, fructose, glucose, lactose, maltose, mannose, raffinose, starch and sucrose; most strains ferment amygdalin, arabinose, cellobiose, glycogen, melibiose, rhamnose, ribose and salicin. Cells do not ferment erythritol, inositol, mannitol, melezitose, sorbitol or trehalose. Esculin and starch are hydrolyzed. Nitrate is not reduced. Indole and catalase are not produced. Gelatin is digested by most strains.

Succinic and acetic acids are the major fermentation end products from PYG broth culture; minor amounts produced may include isobutyric and isovaleric acids; no H₂ is produced. The long-chain fatty acid composition is mainly

anteiso- and iso-methyl branched acids with small amounts of straight-chain acids; the major fatty acid is 12-methyltetradecanoic acid (C_{15:0} anteiso). The principal respiratory quinones are unsaturated menaquinones with 11 isoprene units (MK-11) with lower levels of MK-10 and MK-12.

Source: isolated from human periodontal flora, systemic human infections, and from large intestines of chickens.

DNA G+C content (mol%): 42–46 (*T_m*).

Type strain: ATCC 33573, CCUG 15405, CIP 104480, JCM 8540, JCM 12252, NCTC 13071, VPI D1A-1A.

Sequence accession no. (16S rRNA gene): L16472.

25. **Prevotella oulorum** corrig. (Shah, Collins, Watabe and Mitsuoka 1985) Shah and Collins 1990, 207^{VP} (*Bacteroides oulorum* Shah, Collins, Watabe and Mitsuoka 1985, 195^{VP})

ou.lo'rum. Gr. n. *oulon* the gums; N.L. gen. pl. n. *oulorum* of the gums.

The description is from Shah et al. (1985) and previous reports: Shah et al. (1976, 1979), Shah and Collins (1980, 1983, 1990) and Shah and Williams (1982). Cells are short rods to cocci, 0.5 × 1.0–1.5 µm, occurring singly, in pairs or in chains of rods. Colonies on Eggerth–Gagnon blood agar after 2 d are 1 mm in diameter, circular and entire, convex, translucent, smooth and shiny, while colonies on blood agar after 2 d show a similar morphology but are low, convex and opaque. Cells grow well in either pre-reduced PYG or BM medium supplemented with hemin and menadione. The terminal pH in glucose-containing broth media is 5.0; the terminal pH in media without glucose is pH 6.2. Cells are saccharolytic, producing acid from glucose, fructose, glycogen, inulin, lactose, maltose, mannose, raffinose, starch and sucrose, but not from arabinose, cellobiose, glycerol, mannitol, melezitose, rhamnose, salicin, sorbitol, trehalose, xylan or xylose. Esculin, but not gelatin, is hydrolyzed. Indole is not produced.

Acetate and succinate are the major end products of fermentation. Both nonhydroxylated long-chain fatty acids (~90%) and 3-hydroxy long-chain fatty acids are present. The major cellular fatty acids are C_{15:0} anteiso, C_{15:0} iso and C_{17:0} iso; minor cellular fatty acids are C_{17:0} iso 3-OH, C_{17:0} anteiso, C_{16:0}, C_{18:0}, C_{16:0} iso and C_{14:0} iso; trace amounts include C_{14:0} iso, C_{15:0}, C_{13:0} anteiso and C_{18:1} ω9*c*. The major respiratory quinones are menaquinones with 10 isoprene units (MK-10, >75%) with lower levels of MK-9 (<5%) and MK-11 (<20%).

Source: isolated from the gingival crevice.

DNA G+C content (mol%): 45–46 (*T_m*, Bd).

Type strain: WPH 179, ATCC 43324, CCUG 20177, CIP 104477, NCTC 11871.

Sequence accession no. (16S rRNA gene): L16472.

26. **Prevotella pallens** Könönen, Eerola, Frandsen, Jalava, Mättö, Salmenlinna and Jousimies-Somer 1998a, 49^{VP}

pal'lens. L. part. adj. *pallens* being or looking or growing pale, referring to the weak pigmentation of colonies on blood agar plates.

This species was first referred to as a *Prevotella intermedia/nigrescens*-like organism by Könönen, Mättö, et al. (1998b). The description is from Könönen, Eerola, et al. (1998a) and our own observations. Cells grown in broth are

short rods or coccobacilli, 0.5–0.8 × 1.2–2 µm. Colonies on supplemented Brucella sheep agar after 3 d are 0.8–1.4 mm diameter, circular and entire, raised convex, smooth and glistening, with a distinct halo of metallic sheen around the colonies and with weak cream pigmentation. Colonies on rabbit laked blood agar after 3–5 d are tan to light brown and exhibit red fluorescence under long-wavelength UV light (365 nm) due to over production of protoporphyrin. Acid is produced from glucose, maltose and sucrose in PYG broth, but not from arabinose, cellobiose, esculin, lactose (except one strain) or xylose. Gelatin is liquefied. Indole is positive. Lipase is negative.

Acetic and succinic acids are the major end products of fermentation; another frequent product is isovaleric acid. The major cellular fatty acids are C_{15:0} anteiso, C_{15:0} iso, C_{17:0} iso 3-OH and an unknown cellular fatty acid with equivalent chain-length at 13.570. The principal respiratory quinones are menaquinones with 11 isoprene units (MK-11) with lower levels of MK-10 and MK-12.

Source: the type strain was isolated from saliva of a young child.

DNA G+C content (mol%): unknown.

Type strain: AHN 10371, ATCC 700821, CCUG 39484, CIP 105551, JCM 11140, NCTC 13042.

Sequence accession no. (16S rRNA gene): Y13105.

27. **Prevotella ruminicola** (Bryant, Small, Bouma and Chu 1958) Shah and Collins 1990, 207^{VP} emend. Avguštin, Wallace and Flint 1997, 286^{VP} (*Bacteroides ruminicola* Bryant, Small, Bouma and Chu 1958, 18^{AL}; *Ruminobacter ruminicola* (Bryant, Small, Bouma and Chu 1958) Prévot 1966, 121).

ru.mi.ni'co.la. L. n. *rumen* -inis first stomach of ruminants, rumen; L. suff. -cola (from L. n. *incola*) inhabitant, dweller; N.L. n. *ruminicola* inhabitant of the rumen.

The morphological and biochemical characteristics of this species are based on the reports of Bryant et al. (1958) and Holdeman et al. (1984) and on the chemotaxonomic characters reported by Shah and Collins (1980, 1983).

Cells are 0.8–1 µm × 0.8–30 µm, with slightly tapered and with rounded ends. Most cells are 1.2–6 µm long. Irregular granules and bipolar staining are seen in some cells. Cells are often encapsulated and are either single or in pairs, with some chains containing long to coccoid cells. Surface colonies are smooth, entire, convex, opaque and light buff in color. Growth occurs at 30 and 37°C. Most strains produce clear zones that are visible after staining with Congo red. The following carbohydrates are fermented: arbutin, salicin, raffinose, mannose, sucrose, melibiose, xylose, arabinose, galactose, fructose, cellobiose, maltose, sucrose, inulin, sucrose, xylan, pectin and esculin. Lactate, trehalose, cellulose, glycerol, mannitol, inositol and gum arabic are not fermented. The species is also proteolytic and plays a key role in ruminal protein degradation. Many strains have activities that suggest that they play important roles in the utilization of polysaccharides of plant origin, including xylans, pectins and starch, and in the metabolism of peptides and proteins. Starch is hydrolyzed and nitrate is not reduced. Acetylmethylcarbinol, H₂S, catalase and indole are not produced.

The major metabolic end products from glucose broth are acetic, formic and succinic acids, with low to trace

amounts of propionic, isobutyric and isovaleric acids. The long-chain fatty acid composition is mainly anteiso- and iso-methyl branched acids, with small amounts of straight-chain acids; the major fatty acid is 12-methyltetradecanoic acid ($C_{15:0}$ anteiso) and pentadecanoic ($C_{15:0}$), but other profiles may exist (see Shah and Collins, 1983). The principal respiratory quinones are menaquinones MK-12 and MK-11 with low levels (~1–5%) of MK-10 and MK-13.

Source: reticulo-rumen of cattle, sheep and elk and presumed to be among the more numerous bacteria in the rumen of most ruminants. Also isolated from the intestinal contents of chickens.

DNA G+C content (mol%): 45–52 (T_m).

Type strain: Bryant 23, ATCC 19189, CIP 105475, JCM 8958.

Sequence accession no. (16S rRNA gene): L16482.

28. **Prevotella salivae** Sakamoto, Suzuki, Huang, Umeda, Ishikawa and Benno 2004, 882^{VP}

sa.li'vae. L. fem. gen. n. *salivae* from/of saliva from which the micro-organism was isolated.

The description is from Sakamoto et al. (2004). Cells are ~0.5–0.8 × 0.8–1.7 μm. Colonies are 1–2 mm in diameter, gray to light brown, circular, entire, slightly convex and smooth on Eggerth–Gagnon agar plates. Acid is produced from arabinose, cellobiose, glucose, lactose, maltose, mannose, raffinose, salicin, sucrose and xylose. Acid is not produced from glycerol, mannitol, melezitose, rhamnose, sorbitol or trehalose. Esculin is hydrolyzed. Indole is not produced. Gelatin is not digested. Catalase and urease are not produced.

Major end products (from a (w/v) peptone (1%), yeast extract (1%) glucose (1%) broth culture) are succinic and acetic acids; small amounts of isovaleric acid are also produced. Malate dehydrogenase and glutamate dehydrogenase (low activity) are present. Both nonhydroxylated and 3-hydroxylated long-chain fatty acids are present. Major fatty acids are $C_{15:0}$ anteiso, $C_{17:0}$ iso 3-OH and $C_{18:1}$ ω9c. The predominant respiratory quinones are menaquinones MK-11 (>67%), MK-12 (20%) and MK-10 (13%).

Source: isolated from the saliva of a patient with chronic periodontitis.

DNA G+C content (mol%): 41–42 (HPLC).

Type strain: EPSA11, DSM 15606, JCM 12084.

Sequence accession no. (16S rRNA gene): AB108826.

29. **Prevotella shahii** Sakamoto, Suzuki, Huang, Umeda, Ishikawa and Benno 2004, 881^{VP}

sha'hi.i. N.L. gen. masc. n. *shahii* of Shah, named after the Trinidadian-born British microbiologist Haroun N. Shah, for his contributions to the taxonomy of the genus *Bacteroides* and related taxa.

The description is from Sakamoto et al. (2004). Most cells are ~0.5–0.8 × 8.3–10.0 μm. Colonies are 1–2 mm in diameter, tan to light brown, circular, entire, slightly convex and smooth on Eggerth–Gagnon blood agar plates. Acid is produced from glucose, lactose, maltose, mannose, raffinose and sucrose, but not from arabinose, cellobiose, glycerol, mannitol, melezitose, rhamnose, salicin, sorbitol, trehalose or xylose. Esculin is not hydrolyzed. Indole is not produced. Gelatin is digested. Catalase and urease are not produced.

Succinic and acetic acids are major end products from glucose broth containing peptone (1%), yeast extract (1%)

and glucose (1%). Both non-hydroxylated long-chain fatty acids (~90%) and 3-hydroxy long-chain fatty acids are present. The major cellular fatty acids are $C_{18:1}$ ω9c, $C_{16:0}$ and $C_{16:0}$ 3-OH. The major respiratory quinones are menaquinones with 11 isoprene units (MK-11, >50%); MK-10 (>15%) and MK-12 (>20%) are also present, with lower levels of MK-8 (<1%) and MK-9 (<1%).

Source: isolated from the normal oral flora.

DNA G+C content (mol%): 44–45 (HPLC).

Type strain: EHS11, DSM 15611, JCM 12083.

Sequence accession no. (16S rRNA gene): AB108825.

30. **Prevotella stercorea** Hayashi, Shibata, Sakamoto, Tomita and Benno 2007, 943^{VP}

ster.co're.a. L. fem. adj. *stercorea* pertaining to feces.

The description is from Hayashi et al. (2007). Colonies on Eggerth–Gagnon blood agar plates after 48 h incubation at 37°C under 100% CO₂ gas are translucent, circular, entire, slightly convex and smooth. Optimum temperature for growth is 37°C.

Acid is produced from glucose, lactose, sucrose, maltose, mannose and raffinose, but not from arabinose, melezitose, rhamnose, salicin or xylose. Growth is inhibited on *Bacteroides* bile esculin agar. Indole is not produced, esculin is not hydrolyzed, nor is gelatinase or urease activity detected. With the API ZYM system, positive reactions are obtained for alkaline phosphatase, acid phosphatase, naphthol-AS-BI-phosphohydrolase, β-galactosidase, α-glucosidase, *N*-acetyl-β-glucosaminidase and α-L-fucosidase; negative reactions are obtained for esterase (C4), esterase lipase (C8), lipase (C4), leucine arylamidase, valine arylamidase, cystine arylamidase, trypsin, chymotrypsin, β-gluconidase and β-glucosidase.

The major metabolic end products are succinic and acetic acids with small amounts of isovaleric acid. Both non-hydroxylated long-chain fatty acids and 3-hydroxy long-chain fatty acids are present. The major fatty acids are $C_{18:1}$ ω9c, $C_{15:0}$ iso and $C_{15:0}$ anteiso. The principal respiratory quinones are menaquinones MK-13 (>50%) and MK-12 (>25%) with lower levels of MK-9 (1%), MK-10 (5%) and MK-11 (<10%).

Source: the type strain was isolated from human feces. The habitat appears to be the human intestinal tract.

DNA G+C content (mol%): 48–49 (HPLC).

Type strain: CB35, DSM 18206, JCM 13469.

Sequence accession no. (16S rRNA gene): AB244774.

31. **Prevotella tanneriae** Moore, Johnson and Moore 1994, 600^{VP}

tan'ne.rae. N.L. gen. fem. n. *tanneriae* of Tanner, in honor of Anne C. R. Tanner, an American microbiologist.

The description is from Moore et al. (1994). Cells occur in short chains grown in PYG broth and are 0.3 × 0.7–8 μm; filaments up to 14 μm long are observed. Colonies on blood agar plates after 2 d are 1–2 mm in diameter, circular, low convex and translucent to transparent. Colonies grown on rabbit blood agar after 5 d may be black, tan to brown to red, or colorless; occasional colonies are surrounded by small clear zones of hemolysis. Broth cultures are cloudy with a smooth sediment. Strains require addition of 10% sterile serum for optimum growth and acid production. Terminal pH values of glucose broth after 5 d are 4.8–5.3. Acid is produced by most strains from dextrin, fructose, glycogen, lactose and maltose, and less reliably (20–50% of isolates) from

raffinose, sucrose and trehalose and mannose. Acid is not produced from amygdalin, cellobiose, melibiose, salicin or xylose. Esculin is not hydrolyzed by the majority of strains. Gelatin is liquefied and starch is hydrolyzed by most strains. Succinic and acetic acids are the major end products of fermentation; minor products include formic and isovaleric acids and trace amounts of isobutyric acid. No H_2 is produced. The major cellular fatty acids are $C_{15:0}$ anteiso, $C_{15:0}$ iso, $C_{17:0}$ iso 3-OH and $C_{18:2}$ dimethyl acetyl; minor cellular fatty acids are $C_{16:0}$, $C_{14:0}$, $C_{16:0}$ 3-OH, $C_{14:0}$ iso and $C_{17:0}$ iso.

Source: the type strain was isolated from gingival crevice of an adult with gingivitis. The normal habitat of this species is the human gingival crevice.

DNA G+C content (mol%): 45 (T_m).

Type strain: ATCC 51259, CCUG 34292, NCTC 13073, VPI N14B-15.

Sequence accession no. (16S rRNA gene): AJ005634.

32. **Prevotella timonensis** Glazunova, Launay, Raoult and Roux 2007, 885^{VP}

ti.mo.n.en'sis. N.L. fem. adj. *timonensis* pertaining to the Hospital de la Timone, the hospital in Marseille, France, from where the type strain was isolated.

The description is from Glazunova et al. (2007). Cells are straight rods. After 48 h growth in Trypticase Soy Broth (TSB) medium, rods are 0.3–0.5 × 0.8–1.4 µm and occur singly. Growth occurs on sheep blood agar and in TSB liquid medium. After 72 h growth on blood sheep agar, surface colonies are circular, white-grayish, smooth, shiny and 1–2 mm in diameter. The temperature range for growth is 25–37°C, with an optimum at 37°C. Acid is produced from glucose, lactose and maltose. With the API 20A system, gelatin hydrolysis is positive; negative results are obtained for indole production, urease, esculin hydrolysis and fermentation of mannitol, sucrose, salicin, xylose, arabinose, glycerol, cellobiose, mannose, melezitose, raffinose, sorption, rhamnose and trehalose. With the API ID 32A system, positive enzyme reactions occur for alkaline phosphatase, β-galactosidase, α-glucosidase, N-acetyl-β-glucosaminidase, α-fucosidase, arginine arylamidase, leucyl glycine arylamidase and alanine arylamidase. No activity is detected for glutamic acid decarboxylase, arginine dihydrolase, β-glucosidase, α-arabinosidase, β-glucuronidase, proline arylamidase, phenylalanine arylamidase, leucine arylamidase, pyroglutamic acid arylamidase, tyrosine arylamidase, glycine arylamidase, histidine arylamidase, glutamyl glutamic acid arylamidase or serine arylamidase. The major cellular fatty acids are $C_{14:0}$, $C_{16:0}$, $C_{14:0}$ iso and a mixture of $C_{18:2}$ ω6,9c and $C_{18:0}$.

Source: the type strain was isolated from a human breast abscess.

DNA G+C content (mol%): unknown.

Type strain: 4401737, CCUG 50105, CIP 108522.

Sequence accession no. (16S rRNA gene): DQ518919.

33. **Prevotella veroralis** (Watabe, Benno and Mitsuoka 1983) Shah and Collins 1990, 207^{VP} emend. Wu, Johnson, Moore and Moore 1992, 536^{VP} (*Bacteroides veroralis* Watabe, Benno and Mitsuoka 1983, 62^{VP}).

ver'o.ral.is. L. adj. *verus* true; N.L. adj. *oralis* pertaining to the mouth and also a specific epithet; N.L. fem. adj. *veroralis* the true (*Prevotella*) *oralis*.

The description is from Watabe et al. (1983), Wu et al. (1992) and our own observations. The rod-shaped cells are 0.5 × 1.0–1.5 µm and occur in pairs of short rods or short chains of long rods. Colonies grown on Eggerth–Gagnon blood agar plates for 2 d are 1.0–2.0 mm in diameter, circular, entire, convex, translucent, smooth and shiny. Growth is not stimulated by bile. Cultures in pre-reduced PY broth are moderately turbid and may have a slight smooth sediment. Growth is enhanced in broth supplemented with fermentable carbohydrate. The optimal temperature is 37°C; the terminal pH in PYG broth is 4.7, and the pH without fermentable carbohydrate is 6.1. Strains ferment cellobiose, esculin, fructose, glycogen, inulin, melibiose, raffinose, starch, sucrose and xylan, but not amygdalin, glycerol, mannitol, rhamnose, ribose, sorbitol or salicin. Starch and esculin are hydrolyzed. Gelatin is liquefied. Nitrate is not reduced. Indole is not produced.

The major fermentation products from a glucose-containing broth (e.g., BM) are acetic, isobutyric, isovaleric and succinic acids. The long-chain fatty acid composition is mainly anteiso- and iso-methyl branched acids, with small amounts of straight-chain acids. The major fatty acids are $C_{18:1}$ ω9c and $C_{15:0}$ anteiso. The principal respiratory quinones are unsaturated menaquinones with approximately equivalent levels (~40–50%) of MK-10 and MK-11 with lower levels of MK-12 (<10%).

Source: isolated from the human oral cavity.

DNA G+C content (mol%): 42 (T_m).

Type strain: ATCC 33779, CCUG 15422, JCM 6290, VPI D22A-7.

Sequence accession no. (16S rRNA gene): L16473.

34. **Prevotella zoogloiformans** (Weinberg, Nativelle and Prévot 1937) Cato, Kelley, Moore and Holdeman 1982, 273^{VP} [*Bacterium zoogloiformans* (*sic*) Weinberg, Nativelle and Prévot 1937, 725; *Capsularis zoogloiformans* (*sic*) Prévot 1938, 293]

zo.o.gle'o.for'mans. Gr. adj. *zōos* alive, living; Gr. masc. noun *gloios* gum, glue; N.L. fem. n. *zoogloea* inhabitant of glue; L. part. adj. *formans* forming; N.L. part. adj. *zoogloiformans* forming zoogloea (pertaining to the glutinous mass produced in broth cultures).

The description is from Cato et al. (1982), Holdeman et al. (1984) and Moore et al. (1994). Cells grown in glucose broth are 0.6–1.0 × 0.8–8.0 µm, have rounded ends, and many stain irregularly. They usually occur singly, occasionally in pairs. No capsules are detected. Cells form a viscous, glutinous mass in broth cultures and produce distinctive towers of “zoogloea” slime on meat particles. Surface colonies on blood agar plates are 0.5–2 mm, circular, entire, pulvinate, opaque, buff colored, shiny, smooth and butyrous. Hemin is required for growth. No growth occurs at 25°C; variable growth occurs at 45°C. In pre-reduced media, the most reliable fermentation reactions are obtained when 10% (v/v) sterile serum is added and cultures are inoculated and incubated in a gaseous atmosphere containing 90% N_2 and only 10% CO_2 . Acid is produced from salicin, raffinose, mannose, sucrose, melibiose, xylose, arabinose, galactose, fructose, cellobiose, maltose, sucrose, inulin, sucrose and xylan, but not from melezitose, rhamnose, ribose, trehalose, mannitol or inositol. Pectin and

esculin are hydrolyzed. The species is proteolytic and plays a key role in ruminal protein degradation. Many strains have activities that suggest that they play important roles in the utilization of polysaccharides of plant origin, including xylans, pectins and starch, and in the metabolism of peptides and proteins. Starch is hydrolyzed and nitrate is not reduced. Acetylmethylcarbinol, H₂S, catalase, and indole are not produced.

The major fermentation products from a glucose-containing broth (e.g., BM) are acetic, isobutyric, isovaleric and succinic acids. The long-chain fatty acid composition is mainly anteiso- and iso-methyl branched acids with small amounts of straight-chain acids; the major fatty acids are C_{18:1} ω9c and C_{15:0} anteiso.

Source: isolated from the oral cavity and intestinal tract of man and animals.

DNA G+C content (mol%): 47 (T_m).

Type strain: ATCC 33285, CCUG 20495, CIP 104479, NCTC 13075, VPI D28K-1.

Sequence accession no. (16S rRNA gene): L16488.

Other organisms

"*Prevotella massiliensis*" has been reported on the basis of comparative 16S rRNA sequence analysis. The species clusters with other *Prevotella* but differs markedly from members of the genus by its inability to ferment any sugars tested while its long-chain fatty acid profile is more compatible with *Clostridium botulinum* or *Bifidobacterium bifidum* (see below). The following description is from Berger et al. (2005):

"***Prevotella massiliensis***" Berger, Adekambi, Mallet and Drancourt 2005, 973

mas.si.li.en'sis. L. fem. adj. *massiliensis* pertaining to Massilia, the ancient Roman name of Marseille, France, where the organism was isolated and characterized.

The description is from Berger et al. (2005). Cells are 1–2 μm which when viewed under electron microscopy exhibit a trilamellar membrane. They are nonmotile and possess no flagella. Colonies are seen on blood agar after 72 h incubation and are non-pigmented, circular, convex, shiny with a smooth surface, approximately 1 mm diameter and non-hemolytic. Growth occurs at 37°C, but not at ambient temperature nor at 44°C; better growth is achieved on 5% sheep blood agar than on trypticase soy or chocolate agar. Using the API 20A identification strip for anaerobes, it is indole-positive. The physiological reaction spectrum of this species is incomplete, but unlike other *Prevotella* species it appears to be nonfermentative. Thus acid is not produced from glucose, mannitol, sucrose, maltose, lactose, salicin, xylose, arabinose, glycerol, cellobiose, mannose, melezitose, raffinose, sorbitol, rhamnose or trehalose. Gelatin and esculin are not hydrolyzed. Other differential tests include its susceptibility to penicillin, imipenem, clarithromycin, clindamycin, metronidazole and kanamycin and its resistance to vancomycin.

The short-chain metabolic end products are unknown, but the long-chain fatty acid profiles are at variance with *Prevotella* species and are more compatible with those of *Clostridium botulinum* or *Bifidobacterium bifidum*. Thus, the major fatty acids are: C_{16:0}^o, C_{16:0} 3-OH, C_{14:0} and C_{18:2}.

Source: isolated from the blood of a patient hospitalized in an intensive care unit. Habitat is not known.

DNA G+C content (mol%): unknown.

Type strain: CIP 107630.

Sequence accession no. (16S rRNA gene): AF487886.

Genus II. *Xylanibacter* Ueki, Akasaka, Suzuki, Hattori and Ueki 2006, 2220^{VP}

THE EDITORIAL BOARD

Xy.la.ni.bac'ter. N.L. n. *xylanum* xylan; N.L. masc. n. *bacter* a rod; N.L. masc. n. *Xylanibacter* rod decomposing xylan.

Short to filamentous rods. Nonmotile. Nonsporeforming. Gram-stain-negative. **Strictly anaerobic.** Chemo-organotrophic. Optimum growth temperature, 30°C. Oxidase and catalase-negative. Nitrate is not reduced. Hemin markedly stimulates growth. **Various sugars are utilized, including xylan. In the presence of cyanocobalamin and hemin, acetate, propionate, and succinate are produced as major fermentation products.** The major cellular fatty acids are C_{15:0} anteiso and C_{17:0} iso 3-OH. The major respiratory quinones are **MK-12(H₂) and MK-13(H₂)**.

DNA G+C content (mol%): 43.6 (HPLC).

Type species: Xylanibacter oryzae Ueki, Akasaka, Suzuki, Hattori and Ueki 2006, 2220^{VP}.

Further descriptive information

Xylanibacter oryzae was isolated from a sample of rice-plant residue (rice stubble and roots) collected from irrigated rice-field soil at the Shonai Branch of the Yamagata Agricultural Experimental Station (Tsuruoka, Yamagata, Japan) during the flooding period of the field.

The addition of hemin to the medium greatly enhances growth, which otherwise occurs very slowly. Cells grown in

peptone-yeast extract-glucose (PYG) broth with hemin are mainly short rods (0.6–0.7 × 2–2.6 μm) but also some longer rods (4–10 μm), whereas cells grown in the absence of hemin are often filamentous rods (20–50 μm long), sometimes in chains. Addition of a B-vitamin mixture or vitamin K does not affect the growth rate.

The end products of glucose fermentation are acetate, succinate, and a small amount of propionate; however, the level of propionate is markedly increased by the addition of either the B-vitamin mixture or cyanocobalamin.

Enrichment, isolation, and maintenance procedures

Rice plant residue samples were homogenized under N₂ gas using a Waring blender. Isolation of the type strain was accomplished using the anaerobic roll-tube method.

For maintenance, PY4S agar* (which has no hemin) is preferred.

*PY4S agar is peptone-yeast extract (PY) broth supplemented with (g/l): glucose, 0.25; cellobiose, 0.25; maltose, 0.25; soluble starch, 0.25; and agar, 15.0.

Differentiation of the genus *Xylanibacter* from other genera

Unlike *Xylanibacter oryzae*, *Prevotella bivia* hydrolyzes gelatin but not esculin, forms no propionate, does not form acid from arabinose, cellobiose, salicin, sucrose, trehalose, and xylose, and has MK-9, MK-10, and MK-11 as its predominant menaquinones. *Prevotella albensis* differs from *Xylanibacter oryzae* by its failure to form acid from carboxymethylcellulose, mannose, sucrose, and trehalose, and by the presence of MK-11 and MK-12 as its predominant menaquinones. *Prevotella oulorum* differs from *Xylanibacter oryzae* by its failure to form propionate, formation

of acid from inulin but not arabinose, cellobiose, salicin, trehalose, and xylose, and by the presence of MK-10 as its predominant menaquinone.

Taxonomic comments

By 16S rRNA gene sequence analysis, the nearest neighbor of *Xylanibacter oryzae* is *Prevotella bivia* with a sequence similarity of 89.5%. Other neighbors are *Prevotella albensis* (sequence similarity of 89.1%) and *Prevotella oulorum* (sequence similarity of 89.1%).

List of species of the genus *Xylanibacter*

1. *Xylanibacter oryzae* Ueki, Akasaka, Suzuki, Hattori and Ueki 2006, 2220^{VP}

o.ryzae. L. fem. n. *oryza* rice and the genus name of rice; L. gen. n. *oryzae* from/of rice or rice plants, referring to rice-plant residue from which the strain was isolated.

The characteristics are as described for the genus, with the following additional features. pH range, 4.7–7.3; optimum, 5.7–6.2. Temperature range, 15–35°C; optimum, 30°C; growth at 37°C is considerably delayed. The NaCl concentration range for growth is 0–0.5% in PYG medium containing hemin and B-vitamin mixture. The following compounds are growth substrates: arabinose, carboxymethylcellulose, cellobiose, fructose, galactose, glucose, lac-

tose, maltose, mannose, pectin, pyruvate, rhamnose, ribose, salicin, soluble starch, sucrose, trehalose, xylose, and xylan. Acids but not gas are produced from these substrates. The following substrates are not used: cellulose powder, filter paper, fumarate, glycerol, inositol, inulin, lactate, malate, mannitol, melezitose, sorbose, and succinate. Esculin is hydrolyzed but gelatin and urea are not. H₂S and indole are not produced. No growth occurs in the presence of bile salts.

Source: stubble and roots of rice-plant residue in anoxic rice-field soil in Japan.

DNA G+C content (mol%): 43.6 (HPLC).

Type strain: KB3, DSM 17970, JCM 13648.

Sequence accession no. (16S rRNA gene): AB078826.

Class II. *Flavobacteriia* class. nov.

JEAN-FRANÇOIS BERNARDET

Fla.vo.bac.te'ri.i.a. N.L. neut. n. *Flavobacterium* type genus of the type order *Flavobacteriales*; suff. *-ia*, ending proposal by Gibbons and Murray and by Stackebrandt et al. to denote class; N.L. neut. pl. n. *Flavobacteriia*, the *Flavobacterium* class.

The class *Flavobacteriia* is circumscribed for this volume on the basis of the phylogenetic analyses of the 16S rRNA sequences in contrast to the proposal by Cavalier-Smith (2002), which was based on a few basic morphological, chemotaxonomic and physiological features. This class includes only the order *Flavobacteriales* (ord. nov., this volume). The description of the class is the same as the order.

Type order: Flavobacteriales ord. nov.

Reference

Cavalier-Smith, T. 2002. The neomuran origin of archaeobacteria, the negibacterial root of the universal tree and bacterial megaclassification. *Int. J. Syst. Evol. Microbiol.* 52: 7–76.

Order I. *Flavobacteriales* ord. nov.

JEAN-FRANÇOIS BERNARDET

Fla.vo.bac.te.ri'a.les. N.L. neut. n. *Flavobacterium* type genus of the order; suff. *-ales* ending to denote an order; N.L. fem. pl. n. *Flavobacteriales* the *Flavobacterium* order.

The order *Flavobacteriales* is circumscribed for this volume on the basis of the phylogenetic analyses of the 16S rRNA sequences. This order contains the families *Flavobacteriaceae*, *Blattabacteriaceae*, and *Cryomorphaceae*. It consists of Gram-stain-negative, nonspore-forming rods or filaments devoid of gas vesicles and intracellular granules of poly- β -hydroxybutyrate, which usually multiply by binary fission; ring-shaped cells are not formed. Members of the family *Blattabacteriaceae* are nonmotile, nonflagellated, nonculturable and poorly characterized intracellular symbionts of insects. The families *Flavobacteriaceae* and *Cryomorphaceae* consist of strictly aerobic or facultatively anaerobic chemo-organotrophs with respiratory metabolism (fermentative metabolism occurs in a few members of the family *Flavobacteriaceae*), nonmotile or motile by gliding, with yellow or orange colonies due to the production of carotenoid and/or flexirubin type pigments.

Many members of these families require NaCl or seawater salts for growth and most of them require organic compounds present in yeast extract, peptone and/or Casamino acids. Members of the family *Flavobacteriaceae* are widespread in soil or fresh, brackish or sea water in temperate, tropical or polar areas, while cultured members of the family *Cryomorphaceae* are so far restricted to low temperature marine habitats. Some members of the family *Flavobacteriaceae* are pathogenic for humans, fish, or amphibians. Menaquinone 6 (MK-6) is the major respiratory quinone in all members of the family *Flavobacteriaceae*.

DNA G+C content (mol%): 27–56.

Type genus: Flavobacterium Bergey, Harrison, Breed, Hammer and Huntoon 1923, 97^{AL} emend. Bernardet, Segers, Vancanneyt, Berthe, Kersters and Vandamme 1996, 139^{VP}.

Further descriptive information

The three families that were grouped into the order *Flavobacteriales* on the basis of phylogenetic analyses represent very different numbers of organisms. While the family *Blattabacteriaceae* is so far limited to a single nonculturable species and the family *Cryomorphaceae* comprises four genera each only represented by a single species, the family *Flavobacteriaceae* currently includes more than 61 genera, some of them comprising more than 40 species. The only *Blattabacterium* species known so far is characterized by its very special habitat. On the other hand, differentiation of the two other families is hindered by the variability of most key characteristics between and within their genera and species. Hence, it is not possible to propose a key to the families of the order *Flavobacteriales* or a table of differentiating characteristics and 16S rRNA sequence analysis remains the best method to allocate a new isolate to a family.

JEAN-FRANÇOIS BERNARDET

Fla.vo.bac.te'ri.a.ce'a.e. N.L. neut. n. *Flavobacterium* type genus of the family; -aceae ending to denote a family; N.L. fem. pl. n. *Flavobacteriaceae* the family *Flavobacterium*.

Gram-stain-negative, nonsporeforming, short or moderately long to filamentous, rigid to flexible rods. Coiled and helical cells are formed by members of some taxa, but ring-shaped cells are not formed. Cells of some species may form coccoid bodies in old cultures. Cells usually divide by binary fission, but a budding process has also been reported in *Formosa agariphila*. Nonmotile or motile by gliding. Flagella are absent; an exception is *Polaribacter irgensii*, although flagellar motility could not be observed in the only strain available. Cells of the three *Muricauda* species produce long and relatively thick appendages. Colonies are round or uneven to rhizoid, convex to flat, and may be sunken into or adherent to the agar. Nondiffusible, light to bright yellow to orange pigments are usually produced, but members of some genera form nonpigmented colonies.

Chemo-organotrophic. Unsaturated menaquinone with six isoprene units (MK-6) is the only or major respiratory isoprenoid quinone. Growth is usually aerobic, but microaerobic to anaerobic growth occurs in members of some genera. The type of metabolism is respiratory or (rarely) fermentative with oxygen as electron acceptor, except for a few species that may use nitrates or nitrites as electron acceptors. Nitrates are usually not reduced. Members of a few genera are able to reduce nitrates, but they cannot reduce nitrites; an exception is *Flavobacterium denitrificans*, a facultative anaerobe that grows by denitrification in mineral medium. Oxidase and catalase activities are usually present. Growth occurs on organic nitrogen compounds (peptones, yeast extract, or Casamino acids) as the sole source of nitrogen and often also of carbon and energy (although carbohydrates are the preferred sources of carbon and energy); inorganic nitrogen is also used by most members of the family. Vitamins and amino acids are not required. Members of most species are able to degrade a range of organic macromolecules such as proteins (e.g., casein, gelatin, etc.), lipids (e.g., lecithin, Tweens, etc.), and simple or complex carbohydrates (e.g., esculin, starch, pectin, agar, chitin, carboxymethylcellulose, etc.); however, crystalline cellulose (i.e., filter paper) is not degraded. Most members of the family are halophilic to varying degrees, requiring NaCl or seawater for growth; some others are merely halotolerant. Most species are mesophilic, but a number of species and genera are psychrophilic. Pigments belong to the carotenoid or flexirubin type or both. Intracellular granules of poly- β -hydroxybutyrate are absent. Sphingophospholipids are absent. Homospermidine is usually the major polyamine. Members of the family typically contain high levels of branched saturated, branched monounsaturated, and branched hydroxy C₁₅-C₁₇ fatty acids.

The organisms are most frequently isolated from soil or from fresh, brackish, or seawater, in temperate, tropical, or polar areas. Some species are frequently isolated from food and dairy products. The organisms also occur in biofilms in various environments. Several species are pathogenic for humans and other warm-blooded animals; other species are pathogenic for freshwater and marine fish, amphibians, and other aquatic

animals, or marine microalgae. Unidentified members of the family have also been found to occur in the guts of insects and intracellularly in amoebae. Analysis of 16S rRNA gene sequences show that the family belongs to the phylum *Bacteroidetes* phyl. nov., class *Flavobacteriia*, order *Flavobacteriales* ord. nov.. The most closely related organisms are members of the families "*Blattabacteriaceae*" and *Cryomorphaceae* (Bowman et al., 2003).

DNA G+C content (mol%): 27–56.

Type genus: **Flavobacterium** Bergey, Harrison, Breed, Hammer and Huntoon 1923, 97^{AL} emend. Bernardet, Segers, Vancanneyt, Berthe, Kersters and Vandamme 1996, 139.

Historical, phylogenetic, and taxonomic overview

The history and evolution of the family *Flavobacteriaceae* and of the genera it comprises have already been extensively presented (Bernardet and Nakagawa, 2006; Bernardet et al., 2002; Bernardet et al., 1996). In the previous edition of *Bergey's Manual of Systematic Bacteriology*, the organisms currently grouped in the family (as well as many organisms now removed from the family) were divided among the chapters "Genus *Flavobacterium*" (Holmes et al., 1984c) and "Order I. *Cytophagales*" (Reichenbach, 1989b). The first mention of the family *Flavobacteriaceae* appeared in Jooste's PhD thesis (Jooste, 1985). The brief description of the family subsequently included in *Bergey's Manual* (Reichenbach, 1989b) was based on the features of the genus *Flavobacterium* as it was defined at that time, i.e., yellow-orange to nonpigmented, nongliding, strictly aerobic organisms retrieved from various environments and from clinical specimens, which may become pathogenic. Extensively revised descriptions of the genus *Flavobacterium* and of the family *Flavobacteriaceae* were published following a thorough polyphasic study; at that time, the family comprised eight genera and the organisms that would later become the genera *Myroides* and *Tenacibaculum* (Bernardet et al., 1996). The publication of minimal standards for the description of new taxa in the family was the opportunity to further emend the description of the family, then comprising 18 genera and two generically misclassified organisms (Bernardet et al., 2002). Following improvement and increased accessibility of molecular sequencing techniques and extensive investigations of various remote, mostly polar and/or marine environments, the number of new genera attributed to the family has been growing at an exponential pace. At the time of writing (February 2006), 54 genera belong to the family (including one with a name that has not been validly published, "*Fucobacter*") and several more are "in press" or accepted for publication in the *International Journal of Systematic and Evolutionary Microbiology*. See *Recently published genera*, below, for more information. The description of *Pibocella ponti* (Nedashkovskaya et al., 2005b) was actually based on an erroneous 16S rRNA gene sequence (O. Nedashkovskaya, personal communication); consequently, this organism is not considered in this chapter.

The 54 genera are listed in Table 23 and their phylogenetic relationships are shown in Figure 26. Phylogenetic analyses

^aSymbols: +, 90% or more of the strains or species are positive; -, 10% or less of the strains or species are positive; (+), 90% or more of the strains or species give a weak or delayed positive response; d, 11–89% of the strains or species are positive; V, varies between references; and *, data in these two boxes were erroneously inverted in Bernardet et al. (2002). Where optimal growth conditions vary between members of the genus, the different conditions are listed, separated by slashes (the number of species that can grow under the corresponding conditions is shown in parentheses for the type genus). Abbreviations: FL, free-living; P, parasitic; S, saprophytic; fe, freshwater environment; me, marine environment; te, terrestrial environment; nd, not determined; F, flexirubin-type pigments; F-, pigments that do not belong to the flexirubin-type but that have not been further characterized; C, carotenoid-type pigments; A, aerobic growth; ME, microaerobic growth or growth in a CO₂-enriched atmosphere; FA, facultatively anaerobic growth; and AN, anaerobic growth.

^bThe number of species is specified in parentheses after the name of the genus.

^cA DNA G+C content of 41 mol% has been reported for *Flavobacterium saliferosum* (Wang et al., 2006).

^dThe transfer of *Stanierella latercula* to the genus *Aquimarina* has been proposed recently (O. Nedashkovskaya, personal communication).

comparing the sequences of the 16S rRNA and DNA gyrase B subunit (*gyrB*) genes (Bernardet and Nakagawa, 2006; Suzuki et al., 2001) have resulted in very similar trees showing a clear delineation of the family within the phylum *Bacteroidetes*. The family comprises two separate, well-defined clades; one clade includes the genera *Weeksella*, *Empedobacter*, *Elizabethkingia*, *Chryseobacterium*, *Riemerella*, and several allied genera, whereas all other genera are grouped in the other clade (Figure 26). This dual structure could be the basis for a future splitting of the family, providing clear differential features are found between members of the two clades. When the distribution of significant traits (e.g., pathogenicity for humans and animals; ability to grow under microaerobic, facultatively anaerobic or anaerobic conditions; halophilic and/or psychrophilic growth conditions; presence of yellow pigment) among the phylogenetic tree is evaluated, it appears that all members of the smaller clade

(i.e., *Weeksella*, *Riemerella*, etc.) are devoid of gliding motility and unable to grow under halophilic (except some *Chryseobacterium* species) or psychrophilic (except members of the genus *Sejongsia*) conditions. This clade also comprises most of the nonpigmented and pathogenic members of the family *Flavobacteriaceae*. Conversely, most members of the other, larger “marine clade” (Bowman, 2006; Bowman and Nichols, 2005) are halotolerant to halophilic, about half of them display gliding motility, and a third are psychrophilic.

Although most members of the family do comply with the theoretical threshold value of 97% 16S rRNA gene sequence similarity below which two bacterial strains belong to different species (i.e., they share less than 70% DNA similarity) (Stackebrandt and Goebel, 1994), there are examples where members of different species actually share up to 98–99% sequence similarity (Bowman, 2000; Li et al., 2003a; Vandamme et al., 1996a).

Habitat

As shown in Table 23, flavobacteria may be free-living (in freshwater, marine, or terrestrial environments), saprophytic, or parasitic. Recent surveys of bacterial communities in various environments [reviewed by Jooste and Hugo (1999) and Bernardet and Nakagawa (2006)] using culture-dependent or -independent methods have revealed many members of the family *Flavobacteriaceae*. They seem to be particularly abundant in marine, mostly polar environments (Abell and Bowman, 2005; Bano and Hollibaugh, 2002; Bowman, 2006; Kirchman et al., 2003; Köpke et al., 2005) where they play an important role in the degradation of organic matter (Barbeyron et al., 2001; Descamps et al., 2006; Elifantz et al., 2005; Humphry et al., 2001; Sakai et al., 2002) and in the nutrient turnover in oceans (Cottrell and Kirchman, 2000; Pinhassi et al., 1999, 2004). Many of them are associated with marine phytoplankton

(Nicolas et al., 2004) and diatoms (Grossart et al., 2005) or their detritus (Abell and Bowman, 2005; Pinhassi et al., 2005); they represent one of the dominant bacterial groups in the sediments of sea-cage salmon farms (Bissett et al., 2006). As a consequence, most of the recently described members of the family have been retrieved from marine plants and animals, seawater, sea ice, or lake water with marine salinity (Barbeyron et al., 2001; Bowman, 2005; Bowman and Nichols, 2002, 2005; Bruns et al., 2001; Cho and Giovannoni, 2003, 2004; Ivanova et al., 2004; Jung et al., 2005; Khan et al., 2006a; Lau et al., 2005b, c, 2006; Mancuso Nichols et al., 2005; McCammon and Bowman, 2000; Nedashkovskaya et al., 2003a, b, c, 2004a, b, c, d, 2005a-i; Sakai et al., 2002; Sohn et al., 2004; Van Trappen et al., 2003, 2004a, b; Yoon et al., 2005a, 2006b, c). Other habitats in which flavobacteria occur abundantly and from which new taxa have been described include: freshwater and river biofilms

(Crump et al., 1999; Manz et al., 1999; Van Trappen et al., 2002) and glaciers (Xiang et al., 2005; Zhu et al., 2003); soil (Bodour et al., 2003; Bowman and Nichols, 2002; Radianingtyas et al., 2003; Rosado and Govind, 2003); and food and dairy products (Bernardet et al., 2006; Hugo et al., 1999, 2004a, b). A few species are also able to infect a variety of plants and animals, as well as humans (Bernardet et al., 2006, 2005; Hugo et al., 2004a, b); others are harbored by insects (Campbell et al., 2004; Dugas et al., 2001; Lysyk et al., 1999) or amoebae (Horn et al., 2001).

Identification

Table 23 lists the main differential features of the 54 genera currently included in the family *Flavobacteriaceae*. Additional information is provided in the chapters dealing with individual genera in this edition. Key characteristics for differentiating members of the family are the presence of gliding motility, the production and type of yellow pigment, the requirement of NaCl or seawater, the temperature range for growth, the ability to grow under microaerobic, facultatively anaerobic or anaerobic conditions, the presence of a number of enzymic activities, and the DNA G+C content (mol%). The emended description of the family (Bernardet et al., 2002) is still relevant since most of the 29 new taxa described since then comply with it, although the proportion of halophilic and/or psychrophilic organisms has increased and a few facultatively anaerobic organisms have been described (i.e., *Algibacter*, *Formosa*, *Gaetbulibacter*, and *Muricauda*). In contrast to members of the family *Flavobacteriaceae*, those of the closely related family "*Blattabacteriaceae*" are unculturable endosymbionts of insects (Clark and Kambhampati, 2003). Although the family *Cryomorphaceae* shares a number of phenotypic traits with the family *Flavobacteriaceae*, the two families are distinctly separate in phylogenetic trees (Bowman et al., 2003). The features that distinguish members of the family *Flavobacteriaceae* from those of related taxa in the phylum *Bacteroidetes* are mostly chemotaxonomic, such as the absence of sphingophospholipids (unlike members of the family *Sphingobacteriaceae*, Steyn et al., 1998) and the presence of MK-6 as the only or major respiratory quinone (unlike all tested members of other families; Hanzawa et al., 1995). The conditions in which some of the above-mentioned differential properties should preferably be determined have been specified previously (Bernardet and Nakagawa, 2006; Bernardet et al., 2002). Various commercial identification galleries, strips, or plates may be used for the identification of members of the family *Flavobacteriaceae*. Many of them, however, cannot grow at incubation temperatures recommended by the manufacturers. Therefore, growth conditions must be adapted to the organisms studied and results must be interpreted carefully.

Candidatus genera

An intraerythrocytic bacterium infecting several frog species and transmitted by a leech feeding on frogs has recently been allocated to the family *Flavobacteriaceae* following analysis of its 16S rRNA and *gyrB* gene sequences (Zhang and Rikihisa, 2004). Initially assumed to be related to *Aegyptianella pullorum* (family *Ehrlichiaeae*, order *Rickettsiales*), which causes similar infections in bird species, the new organism was designated "*Aegyptianella ranarum*". However, BLAST searches showed that its closest relative was *Elizabethkingia meningoseptica* (previously *Chryseobacterium meningosepticum*) and that it made a clade with *Weeksella*

virosa and *Bergeyella zoohelcum* in phylogenetic trees based on 16S rRNA and *gyrB* genes, respectively. Interestingly, *Elizabethkingia meningoseptica* has also been reported to be responsible for outbreaks of hemorrhagic septicemia in frogs (Bernardet et al., 2005 and references therein). Since no cultivation of the organism could be achieved, it was described as "*Candidatus Hemobacterium ranarum*" and brief genus and species descriptions were published, although not in the *International Journal of Systematic and Evolutionary Microbiology* (Zhang and Rikihisa, 2004). Members of the genus "*Hemobacterium*" are nonmotile and nonculturable Gram-stain-negative rods that grow inside red blood cells. Cells of "*Candidatus Hemobacterium ranarum*" grow in membrane-bound inclusions in frog erythrocytes; the type strain is "Toronto" and accession numbers for the 16S rRNA and *gyrB* gene sequences are AY208995 and AY208996, respectively.

Recently published genera

Since the submission and review of the family chapter, the following new genera have been added to the family *Flavobacteriaceae* and their names have been validly published in the *International Journal of Systematic and Evolutionary Microbiology*: *Actibacter* (Kim et al., 2008), *Aestuariicola* (Yoon et al., 2008), *Cloacibacterium* (Allen et al., 2006), *Costertonia* (Kwon et al., 2006b), *Croceitalea* (Lee et al., 2008), *Eudoraea* (Alain et al., 2008), *Flagellimonas* (Bae et al., 2007), *Flaviramulus* (Einen and Øvreås, 2006), *Fulvibacter* (Khan et al., 2008), *Galbibacter* (Khan et al., 2007b), *Gilvibacter* (Khan et al., 2007a), *Jejuia* (Lee et al., 2009), *Joostella* (Quan et al., 2008), *Kriegella* (Nedashkovskaya et al., 2008), *Lep-tobacterium* (Mittra et al., 2009), *Lutaonella* (Arun et al., 2009), *Lutibacter* (Choi and Cho, 2006), *Lutimonas* (Yang et al., 2007), *Mariniflexile* (Nedashkovskaya et al., 2006a), *Marixanthomonas* (Romanenko et al., 2007), *Mesoflavibacter* (Asker et al., 2007b), *Planobacterium* (Peng et al., 2009), *Pseudozobellia* (Nedashkovskaya et al., 2009), *Salinimicrobium* (Lim et al., 2008), *Sandarakinotalea* (Khan et al., 2006c), *Sediminibacter* (Khan et al., 2007a), *Sediminicola* (Khan et al., 2006b), *Tamlana* (Lee, 2007), *Wautersiella* (Kämpfer et al., 2006), *Yeosuana* (Kwon et al., 2006a), *Zeaxanthinibacter* (Asker et al., 2007a), *Zhouia* (Liu et al., 2006), and *Zunongwangia* corrig (Qin et al., 2007).

Descriptions of *Cloacibacterium*, *Costertonia*, *Flaviramulus*, *Lutibacter*, *Mariniflexile*, *Sandarakinotalea*, *Sediminicola*, *Wautersiella*, *Yeosuana*, and *Zhouia* are given below. In addition, the genera *Gaetbulimicrobium* and *Stanielrella* have been transferred to *Aquimarina* (Nedashkovskaya et al., 2006f).

Acknowledgements

The author is indebted to Y. Nakagawa (National Institute of Technology and Evaluation, Biological Resource Center, Kisarazu, Japan) who kindly provided the phylogenetic tree (Figure 26) and to J.P. Bowman (University of Tasmania, Hobart, Australia) and O.I. Nedashkovskaya (Pacific Institute of Bioorganic Chemistry, Vladivostok, Russia) for useful comments on the manuscript.

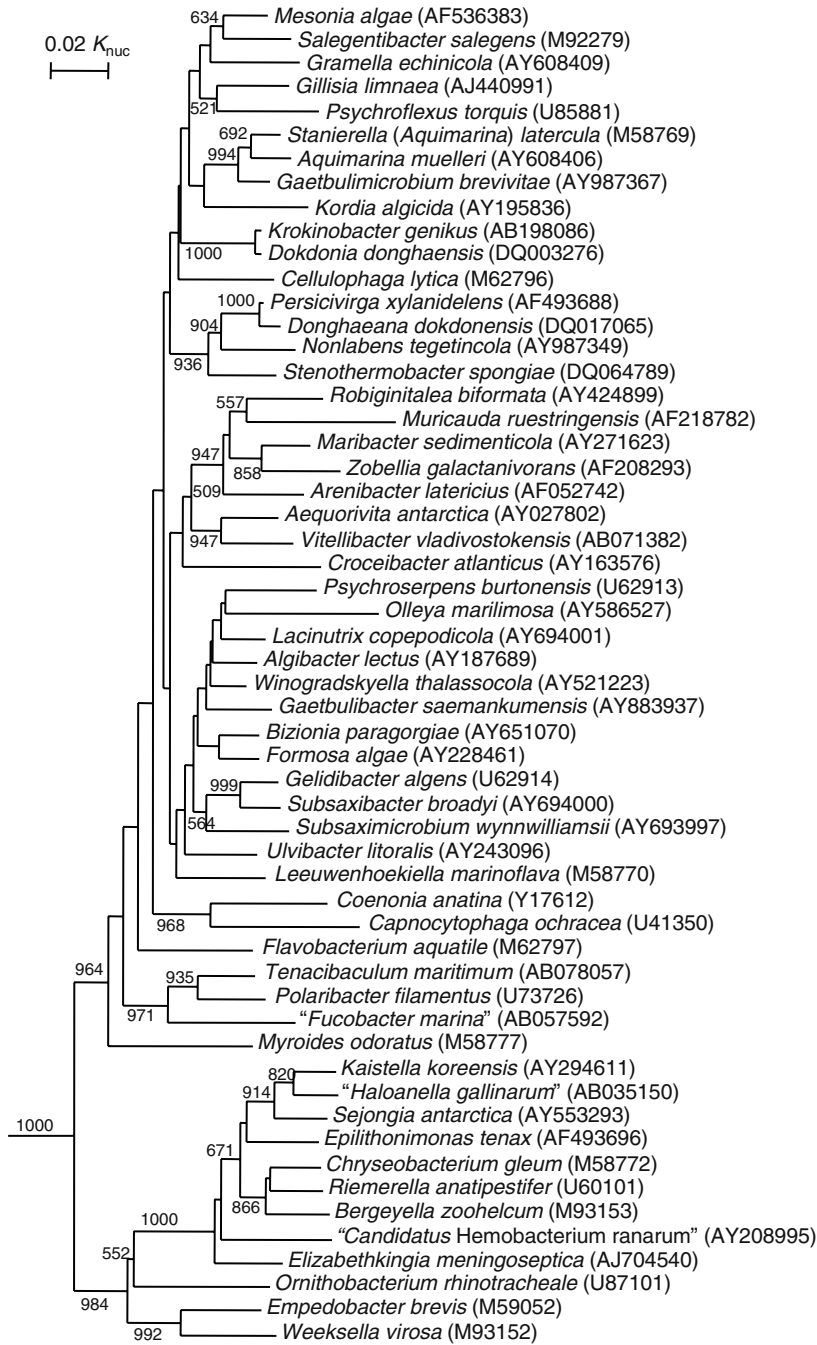

FIGURE 26. Phylogenetic relationships among representatives of the family *Flavobacteriaceae* based on comparisons of 16S rRNA gene sequences using the neighbor-joining method (Saitou and Nei, 1987). All genera in the phylum with validly published names are represented by the sequence of the type strain (except *Empedobacter brevis*) of their type species. Invalid taxa which 16S rRNA gene sequence is available have also been included for information; their names are in quotation marks. Accession numbers for the sequences are given in parentheses. Bar = 0.02 K_{nuc} (Kimura, 1980). Numbers on the branches represent the confidence limits estimated by a bootstrap analysis (Felsenstein, 1985) of 1000 replicates; confidence limits less than 50% are not shown. Sequences were aligned using the CLUSTAL W version 1.8 software package (Thompson et al., 1994). The alignments were modified manually against the 16S rRNA gene secondary structure of *Escherichia coli* (Gutell et al., 1985). Positions at which the secondary structures varied in the strains (positions 66–104, 143–220, 447–487, 841–845, 991–1045, 1134–1140, and 1446–1456; *Escherichia coli* numbering system) and all sites that were not determined in any sequence were excluded from the analysis. *Agrobacterium tumefaciens*, *Bacillus subtilis*, and *Escherichia coli* were used as outgroups.

Genus I. **Flavobacterium** Bergey, Harrison, Breed, Hammer and Huntoon 1923, 97^{AL} emend. Bernardet, Segers, Vancanneyt, Berthe, Kersters and Vandamme 1996, 139

JEAN-FRANÇOIS BERNARDET AND JOHN P. BOWMAN

Fla.vo.bac.te'ri.um. L. adj. *flavus* yellow; L. neut. n. *bacterium* a rod or staff and, in biology, a bacterium (so called because the first ones observed were rod-shaped); N.L. neut. n. *Flavobacterium* a yellow bacterium.

Straight or slightly curved, single rods with rounded or slightly tapered ends typically about 0.3–0.5 µm in diameter and variable in length, often 2–5 µm; shorter (1 µm) or filamentous (10–40 µm) cells and pleomorphism also occur. The longer rods are flexible. Do not form endospores. Several species produce spherical degenerative forms (spheroplasts) in stationary growth phase. **Nonmotile or motile by gliding. Flagella have not been reported. Colonies are pale to bright yellow due to the production of nondiffusible, nonfluorescent carotenoid or flexirubin types of pigments or both.** Gram-stain-negative. Chemoorganotrophic. **Most species are obligately aerobic, having a strictly respiratory type of metabolism** with oxygen as the terminal electron acceptor. A few species may also grow weakly under microaerobic to anaerobic conditions. **About half of the species are able to reduce nitrate to nitrite, but only one species is able to carry out complete denitrification.** The optimum growth temperature range is 20–30°C for most temperate species and 15–20°C for most cold-living species. Most species grow readily on nutrient and tryptic soy agars; no growth factors are required. Most species also grow on media containing up to 2–4% NaCl. **Usually positive for catalase and oxidase.** About half of the species are able to oxidize carbohydrates. Esculin and starch are hydrolyzed by most species, but agar and carboxymethylcellulose are hydrolyzed by only a few species. Strong proteolytic activity occurs. Menaquinone MK-6 is the only or predominant respiratory quinone. Predominant cellular fatty acids are C_{15:0}, C_{15:0} iso, C_{15:0} iso 3-OH, C_{15:0} anteiso, C_{15:1} ω6c, C_{15:1} iso_G, C_{16:0} iso 3-OH, and C_{17:0} iso 3-OH, as well as C_{15:0} iso 2-OH and/or C_{16:1} ω7c and/or C_{16:1} ω7t. Sphingophospholipids are absent in all tested species. Homospermidine is the major polyamine in all tested species. **Occur in soil and in freshwater, marine, or saline environments in warm, temperate, or polar locations. Three species are pathogenic for freshwater fish** and three others have occasionally been isolated from diseased freshwater fish.

DNA G+C content (mol%): 30–41.

Type species: *Flavobacterium aquatile* (Frankland and Frankland 1889) Bergey, Harrison, Breed, Hammer and Huntoon 1923, 100 (*Bacillus aquatilis* Frankland and Frankland 1889, 381) (not *Flavobacterium antarcticum* as erroneously printed in Bernardet and Bowman, 2006).

Further descriptive information

Phylogenetic position. Sequence analysis of 16S rRNA and DNA gyrase large subunit genes has shown that the genus *Flavobacterium* is a member (and the type genus) of the family *Flavobacteriaceae*, order *Flavobacteriales* ord. nov., class *Flavobacteriia*, phylum *Bacteroidetes* [previously the *Cytophaga–Flexibacter–Bacteroides* or *Cytophaga–Flavobacterium–Bacteroides* (CFB) group]. Together with about 50 other genera, it belongs to the larger of the two well-defined clades in the phylogenetic tree of the family, where it occupies a rather separate and deep position (see Figure 27 in the treatment of the family *Flavobacteriaceae*).

This clade contains most of the halophilic/halotolerant members of the family and most of its psychrophilic/psychrotolerant members. Most organisms in the clade are yellow-pigmented and about half of them display gliding motility.

Data on 16S rRNA gene sequencing, DNA–DNA hybridization, and DNA G+C content in the genus *Flavobacterium* have been reviewed recently (Bernardet and Bowman, 2006) and will not be expounded further here. It is, however, necessary to stress the fact that high levels of 16S rRNA gene sequence similarity (i.e., 97.5–98.9%) have been reported between some *Flavobacterium* species (Cousin et al., 2007; Park et al., 2007; Van Trappen et al., 2004b, 2005; Yi and Chun, 2006; Zdanowski et al., 2004). Hence, DNA–DNA hybridization experiments may reveal novel species even when such similarity values are observed. For instance, two novel Antarctic isolates sharing nearly 99% 16S rRNA gene sequence similarity were shown to display only 34% DNA relatedness and the presence of several differentiating phenotypic features allowed the description of two novel species, *Flavobacterium weaverense* and *Flavobacterium segetis* (Yi and Chun, 2006). Similarly, the type (and so far only) strain of *Flavobacterium glaciei* shared 97.2–97.9% 16S rRNA gene sequence similarity with the type strains of *Flavobacterium succinicans*, *Flavobacterium granuli*, and *Flavobacterium hydatis*, but its DNA relatedness values with these three organisms were only 48, 44, and 42%, respectively (Zhang et al., 2006). At the time of writing, the genus *Flavobacterium* comprised 40 species with validly published names (Tables 24). Four additional species have unequivocally been shown not to belong to the genus, although they have not yet been assigned to other or new genera (see the *List of species*, below).

Cell morphology. Cells of *Flavobacterium* strains are usually single, straight, or slightly curved (e.g., *Flavobacterium croceum*; Park et al., 2006a) rods with rounded or slightly tapered ends. Chains of 3–4 cells, sometimes connected by cellular bridges, have been reported in *Flavobacterium denitrificans*. Cells are typically about 0.3–0.5 µm in diameter and 2–5 µm in length, but pleomorphism occurs frequently. Rods of about 1 µm long have been reported in some species and filamentous, flexible cells of 10–40 µm also occur. The size of bacterial cells may decrease during the stationary phase, as reported in *Flavobacterium weaverense* (Yi and Chun, 2006). Rods of *Flavobacterium defluwii* form characteristic knars (Park et al., 2007). Endospores are not formed. The presence of spherical degenerative forms (spheroplasts) in ageing liquid cultures has been reported for *Flavobacterium aquidunense*, *Flavobacterium branchiophilum*, *Flavobacterium columnare*, *Flavobacterium denitrificans*, *Flavobacterium gelidilacus*, *Flavobacterium hercynium*, *Flavobacterium hydatis*, *Flavobacterium indicum*, *Flavobacterium johnsoniae*, *Flavobacterium omnivorum*, *Flavobacterium psychrolimnae*, *Flavobacterium psychrophilum*, *Flavobacterium saliperosum*, and *Flavobacterium succinicans* (Reichenbach, 1989b; Bernardet and Bowman, 2006 and references therein; Cousin et al., 2007; J.F. Bernardet, unpublished data) (Table 24). Although accurate drawings of *Flavobacterium columnare* spheroplasts had

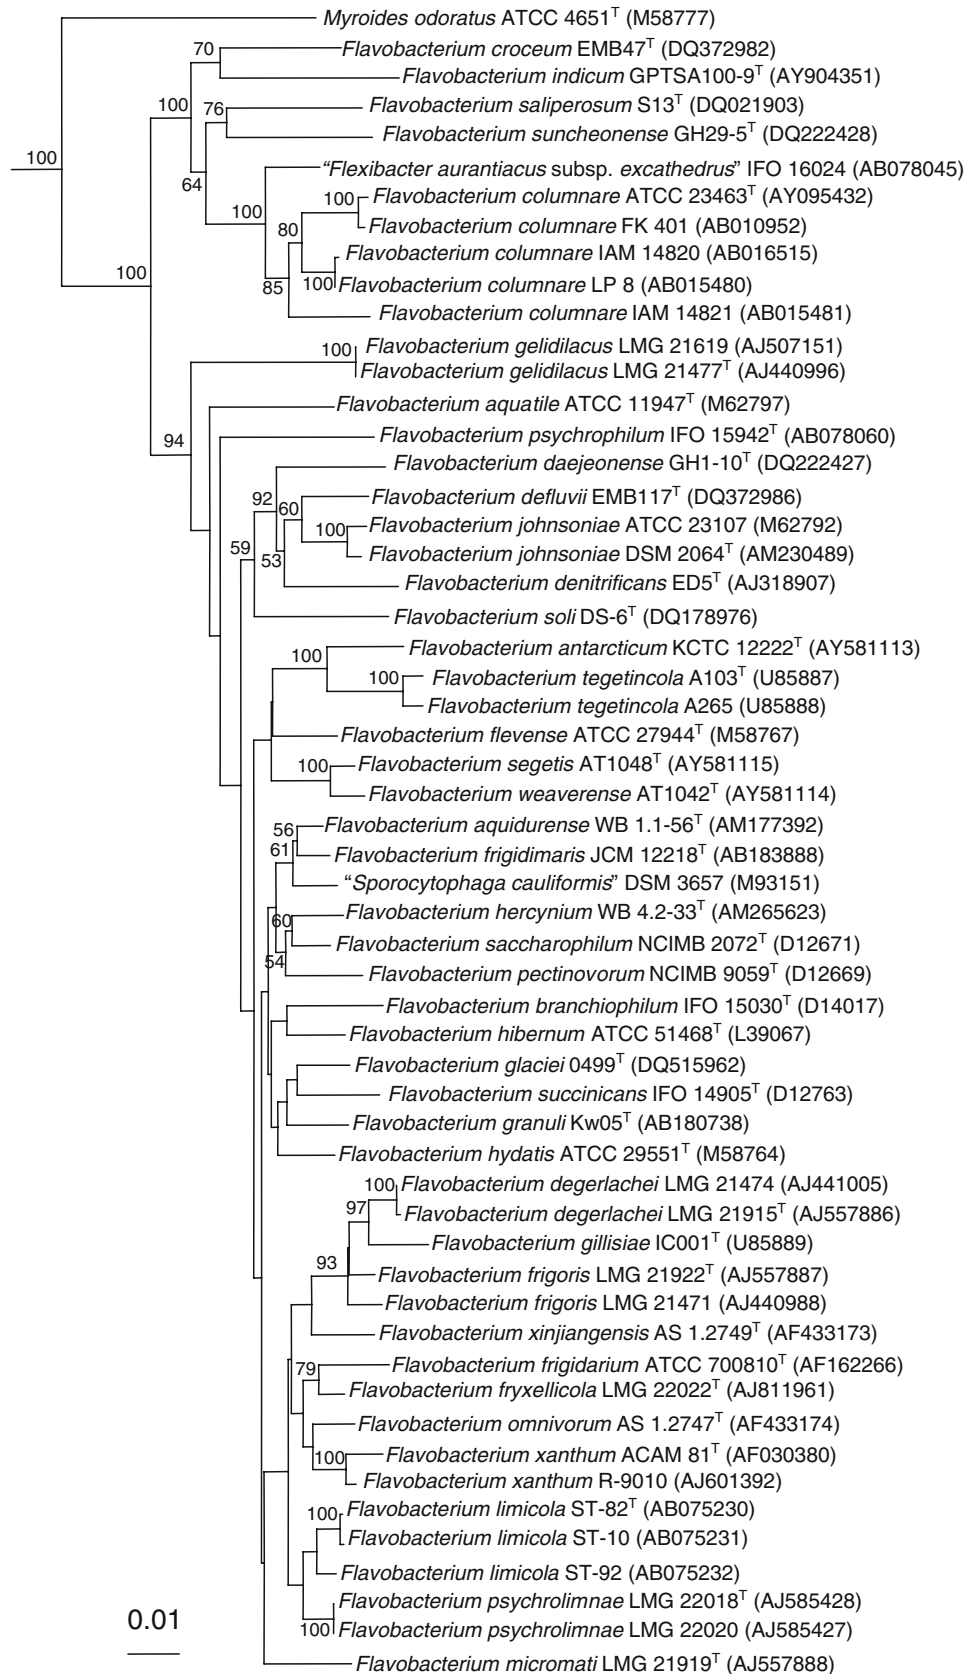

FIGURE 27. Maximum-likelihood distance phylogenetic tree created by the neighbor-joining procedure (Saitou and Nei, 1987) based on nearly complete 16S rRNA gene sequences of members of the genus *Flavobacterium*. *Myroides odoratus* was used as the outgroup. Bootstrap values >50% are indicated at nodes. Bar = maximum-likelihood distance.

TABLE 24. (Continued)

^aSymbols: +, 90% or more of the strains are positive; -, 10% or less of the strains are positive; (+), 90% or more of the strains give a weak or delayed positive response; d, 11–89% of the strains are positive; V, varies between authors; nd, no data available.

^bData from: Anderson and Ordal, 1961; Van der Meulen et al., 1974; Inoue and Komagata, 1976; Christensen, 1977; Strohl and Tait, 1978; Agbo and Moss, 1979; Oyaizu and Komagata, 1981; Holmes et al., 1984; Holt, 1988; Bernardet, 1989; Bernardet and Grimont, 1989; Reichenbach, 1989b; Wakabayashi et al., 1989; Carson et al., 1993; Ostland et al., 1994; Bernardet et al., 1996; Shamsudin and Plumb, 1996; McCammon et al., 1998; Triyanto and Wakabayashi, 1999a; McCammon and Bowman, 2000; Humphry et al., 2001; Tanaki et al., 2003; Van Trappen et al. (2003, 2004b, 2005); Zhu et al., 2003; Aslam et al., 2005; Nogi et al., 2005b; Shocemaker et al., 2005; Yi et al., 2005a; Kim et al., 2006a; Park et al., 2006a; Saha and Chakrabarti, 2006; Wang et al., 2006; Yi and Chun, 2006; Yoon et al., 2006d; Zhang et al., 2006; Cousin et al., 2007; Park et al., 2007; and J.-F. Bernardet (unpublished data). Since some of the characteristics listed were tested by several authors using different methods, the original publications should be consulted for direct comparison.

^cJ.-F. Bernardet, unpublished data.

^dData from the original description.

^eExtreme values of growth temperature and NaCl concentration ranges must be interpreted with care: bacterial growth may still be possible between them and the next lower or higher temperatures or NaCl concentrations tested.

^fDegradation of starch by *Flavobacterium columnae* strains is medium-dependent (see comments on this species in the text).

^gValues in parentheses are those determined by Bernardet et al. (1996) when different from previously published values.

^aValues are given as percentages of total fatty acids. Fatty acids amounting to less than 1% of the total fatty acids in all strains tested are not included; therefore, the percentages do not total 100%. All values are rounded up. When several strains were analyzed, rounded up means are given, but standard deviations are not given.

TABLE 25. (Continued)

^bData from: Bernardet et al. (1996), McCammon et al. (1998), McCammon and Bowman (2000), Humphry et al. (2001), Tamaki et al. (2003), Van Trappen et al. (2003, 2004b, 2005), Zhu et al. (2003), Aslam et al. (2005), Nogi et al. (2005b), Yi et al. (2005a), Kim et al. (2006a), Park et al. (2006a, 2007), Saha and Chakrabarti (2006), Wang et al. (2006), Yi and Chun (2006), Yoon et al. (2006d), Zhang et al. (2006), and Cousin et al. (2007). The fatty acid composition of *Flavobacterium denitrificans* was determined by Cousin et al. (2007).

^cGrowth medium, duration, and temperature are specified when available. Abbreviations and compositions of growth media: NA, not available (growth conditions unspecified); mShieh, modified Shieh agar (per l: 5.0 g peptone, 1.0 g yeast extract, 10 mg sodium acetate, 10 mg BaCl₂·H₂O, 0.1 g K₂HPO₄, 50 mg KH₂PO₄, 0.3 g MgSO₄·7H₂O, 6.7 mg CaCl₂·2H₂O, 1.0 mg FeSO₄·7H₂O, 50 mg NaHCO₃, 15.0 g agar; Song et al., 1988); R2A (per l: 0.5 g yeast extract, 0.5 g proteose peptone, 0.5 g Casamino acids, 0.5 g glucose, 0.5 g soluble starch, 0.3 g sodium pyruvate, 0.3 g K₂HPO₄, 0.05 g MgSO₄·7H₂O, 15.0 g agar; Reasoner and Geldreich, 1985); mR2A, modified R2A agar (i.e., containing 0.75 g/l proteose peptone and 0.25 g/l Casamino acids; Saha and Chakrabarti, 2006); XMM, X minimal medium (per l: 0.02 g FeSO₄, 0.2 g MgSO₄, 0.75 g KNO₃, 0.5 g K₂HPO₄, 0.04 g CaCl₂, 5.0 g soluble xylan, 15.0 g agar; Humphry et al., 2001); CY (per l: 3.0 g casitone, 1.36 g CaCl₂·2H₂O, 1.0 g yeast extract, 15.0 g agar; Nogi et al., 2005b); TSA, tryptic soy agar (per l: 15.0 g pancreatic digest of casein, 5.0 g enzymatic digest of soybean meal, 5.0 g NaCl, 15.0 g agar); PYG, peptone-yeast extract-glucose agar [per l: 5.0 g polypeptone, 5.0 g tryptone, 10.0 g yeast extract, 10.0 g glucose, 40 ml salt solution, 15.0–20.0 g agar. Salt solution (per l): 0.2 g CaCl₂, 0.4 g MgSO₄·7H₂O, 1.0 g K₂HPO₄, 1.0 g KH₂PO₄, 10.0 g NaHCO₃, 2.0 g NaCl; Zhu et al., 2003]; mPYG, modified peptone-yeast extract-glucose agar (per l: 5.0 g peptone, 0.2 g yeast extract, 3.0 g beef extract, 5.0 g glucose, 0.5 g NaCl, and 1.5 g MgSO₄·7H₂O; amount of agar unspecified; Zhang et al., 2006); MM, maintenance medium [per l: 1.0 g yeast extract, 5.0 g lactose (filter-sterilized), 0.5 g K₂HPO₄, 0.5 g (NH₄)₂SO₄, 0.55 g NaCl, 15.0 g agar; McCammon et al., 1998]; and mM1, modified medium M1 [per l: 5.0 g peptone, 0.2 g yeast extract, 2.0 g beef extract, 1.0 g NaCl, 12.0 g agar (modified from Weeks, 1955; S.-J. Liu, personal communication)].

^dFatty acids that are not fully identified, making their significance unclear.

^eFatty acids that could not be separated by GC using the Microbial Identification System (Microbial ID).

^fThe identity of the fatty acid is unknown. The equivalent chain length (ECL) is specified when available.

been published by Garnjobst (1945), these forms have been mistaken for microcysts by several authors. Consequently, *Flavobacterium columnare* has long been considered a myxobacterium (Ordal and Rucker, 1944).

Flagella have not been reported (see *Fine structure*, below), but gliding motility over wet surfaces (such as agar or glass in wet mounts) occurs in 18 of the 40 *Flavobacterium* species (Table 24). A speed of approximately 5 μm/s has been reported for cells of *Flavobacterium johnsoniae* (Nelson et al., 2007). Cells typically also display the movement accurately described by Reichenbach (1989b): “Often a cell oscillates or rotates in a conical orbit with one pole attached and the rest of the cell pointing away from the surface.” Because this type of bacterial motility is only evidenced when special procedures are followed (Bernardet et al., 2002; Reichenbach, 1989b), it may actually have been overlooked in some species. For instance, the presence of gliding motility in *Flavobacterium aquatile* has been a matter of debate, as it seems that it only occurs in rather special culture conditions [see *Taxonomic comments* and the *List of Species*, below, as well as Holmes and Owen (1979) and Holmes et al. (1984c)]. *Flavobacterium denitrificans* was described as a motile organism, but the type of motility was not specified (Horn et al., 2005) and no motility has been reported in *Flavobacterium antarcticum* (Yi et al., 2005a), *Flavobacterium degerlachei* or *Flavobacterium frigidis* (Van Trappen et al., 2004b), or *Flavobacterium indicum* (Saha and Chakrabarti, 2006). However, cells from fresh broth cultures of these five organisms possess distinct gliding motility (J.-F. Bernardet, personal observation).

As repeatedly mentioned, gliding motility seems to be favored by growth on nutrient-poor media, such as Anacker and Ordal’s (Anacker and Ordal, 1955), and by a high amount of moisture on the surface of the agar (Bernardet et al., 2002; McCammon et al., 1998; Nogi et al., 2005b; Reichenbach, 1989b; Van Trappen et al., 2003). In order to explain the mechanisms of gliding motility, a number of non-gliding mutants of *Flavobacterium* strains, obtained through repeated subcultivation on agar plates (Glaser and Pate, 1973; Gorski et al., 1992; Pate, 1988) or treatment of cultures with nitrosoguanidine (Abbanat et al., 1986; Godchaux et al., 1990), has been studied extensively. The latter

procedure produced mutants of the *Flavobacterium johnsoniae* type strain that were deficient in both gliding motility and sulfonolipid synthesis. Restoration of the sulfonolipids (through provision of a specific biosynthetic precursor) also resulted in recovery of the ability to glide, demonstrating that sulfonolipids are specifically required for gliding motility (Abbanat et al., 1986). The existence of non-gliding mutants with normal lipid content indicated, however, that these are not the only molecules involved. Godchaux et al. (1990) showed that two non-gliding mutants of *Flavobacterium johnsoniae* were deficient in the high-molecular-weight (H) fraction of the outer membrane polysaccharide. One of the mutants was also deficient in sulfonolipids, but could be cured by provision of the specific precursor, a process that also resulted in the return of both the H fraction and gliding motility. Hence, the polysaccharide may be the component that is directly involved in gliding and the presence of sulfonolipids in the outer membrane is necessary for the synthesis or accumulation of the polysaccharide (as also suggested by the fact that the second non-gliding, polysaccharide-deficient mutant had normal sulfonolipid content). Recently, a mutant of the fish pathogen *Flavobacterium psychrophilum* that was deficient in gliding motility, growth on iron-depleted media, and extracellular proteolytic activity has been shown to exhibit enhanced biofilm formation and decreased virulence and cytotoxicity; hence, gliding motility and biofilm formation appear to be antagonistic properties (Álvarez et al., 2006). Over the last few years, a number of non-gliding mutants of *Flavobacterium johnsoniae* obtained through transposon mutagenesis have been used to identify several genes involved in gliding motility (see *Genetics*, below). Although some clues have been obtained, the molecular mechanisms of gliding in *Flavobacterium* strains have not yet been fully elucidated.

Cell-wall composition. Although there is clear and unambiguous evidence that lipids (i.e., polar lipids, quinones, and fatty acids) are very useful chemotaxonomic markers in flavobacteria, difficulties in interpreting published data have hindered their exploitation. Table 25 presents the fatty acid composition data of members of the genus *Flavobacterium*. Although some

genera in the family *Flavobacteriaceae* display rather distinct fatty acid compositions (Bernardet et al., 2006; Bernardet and Nakagawa, 2006; Hugo et al., 1999), it is currently impossible to assess whether all *Flavobacterium* species display overall similar fatty acid profiles or species-specific profiles. The main reason is the considerable heterogeneity in the conditions used to grow the different species for fatty acid analysis (Table 25). *Flavobacterium limicola* is a striking example of the influence of growth temperature on fatty acid composition (Tamaki et al., 2003), but growth medium and duration also affect the fatty acid profile considerably, as shown by the significantly different profiles of the *Flavobacterium xanthum* type strain cultivated on tryptic soy agar (McCannon and Bowman, 2000) or modified Shieh agar (Bernardet et al., 1996). Moreover, different analytical procedures have been used to extract and identify fatty acids and the resolution of some of them (e.g., the MIDI system) has changed over the years, affecting the naming of some overlapping peaks and hindering the exact identification of some compounds. Hence, a number of the fatty acids listed in Table 25 (e.g., C_{15:1} iso, C_{16:1} iso, and C_{16:1} cis) are not fully identified and their significance cannot be evaluated. The ten species included in the genus *Flavobacterium* at the time when its description was emended (Bernardet et al., 1996) were grown under the same conditions and their fatty acid compositions were determined using the same procedure. The very similar profile found in all ten species was one of the arguments for delineation of the genus. The various growth conditions used for the subsequently described *Flavobacterium* species now make this kind of interpretation impossible. In order to fully exploit the chemotaxonomic significance of fatty acids in the genus *Flavobacterium* in the future, all strains compared should be cultivated under the same conditions and their fatty acid composition should be determined using the same procedure. The only possible general comment regarding the fatty acid composition of *Flavobacterium* species so far is that all of them contain rather high amounts of C_{15:0} iso and most of them also contain significant amounts of C_{15:0}, C_{15:0} iso 3-OH, C_{15:0} anteiso, C_{15:1} ω6c, C_{15:1} iso G, C_{16:0} iso 3-OH, and C_{17:0} iso 3-OH, as well as C_{15:0} iso 2-OH and/or C_{16:1} ω7c and/or C_{16:1} ω7t (Table 25). This confirms and extends to other *Flavobacterium* species the opinion of Fautz et al. (1981) that the fatty acid profiles of *Flavobacterium johnsoniae*, *Flavobacterium hydatis*, and *Flavobacterium aquatile* are dominated by branched-chain compounds, both non-hydroxylated (mainly C_{15:0} iso) and hydroxylated (C_{15:0} iso 3-OH and C_{17:0} iso 3-OH). *Flavobacteria* are interesting in that they produce both saturated and unsaturated straight-chain fatty acids and iso/anteiso-branched-chain fatty acids (B. Tindall, personal communication).

Divergent opinions have been published regarding the specificity of fatty acid profiles in the genus *Flavobacterium*. Recently, fatty acid analysis has been evaluated as an identification method for the fish pathogen *Flavobacterium columnare*. The fatty acid profile shared by all 31 strains studied differed significantly from those of the type strains of *Flavobacterium aquatile*, *Flavobacterium johnsoniae*, *Flavobacterium hydatis*, and *Flavobacterium psychrophilum* cultivated under the same conditions (Shoemaker et al., 2005). This study also revealed that one of the isolates received as *Flavobacterium columnare* had been misidentified and actually clustered with the *Flavobacterium johnsoniae* type strain. When the fatty acid compositions of

ten *Flavobacterium* strains isolated from creek water and their closest phylogenetic neighbors were determined in parallel and presented as a dendrogram, the novel isolates formed two very coherent clusters that could be readily separated from the reference strains; these clusters were described as the two novel species *Flavobacterium aquidurensis* and *Flavobacterium hercynium* (Cousin et al., 2007). Another study, however, showed that the fatty acid clusters delineated within a collection of polar *Flavobacterium* isolates did not correspond to the species: for instance, fatty acid cluster 5 included all *Flavobacterium micromati* and *Flavobacterium frigidis* strains as well as some *Flavobacterium degerlachei* strains, whereas the latter species also comprised strains belonging to fatty acid cluster 6 (Van Trappen et al., 2004b). This confirmed that members of the genus can differ significantly in their fatty acid composition, even when grown under the same conditions.

Godchaux and Leadbetter (1983) reported on unusual sulfonolipids (capnine and N-acylated versions of capnine, collectively termed capnoids) as significant (ca. 4%) outer membrane lipids in *Flavobacterium johnsoniae*; N-acylated capnines represented >99% of the total capnoids. These compounds are involved in gliding motility (see *Cell morphology*, above), but they cannot be used as chemotaxonomic markers as they also occur in representatives of several other genera of gliding bacteria in the phylum *Bacteroidetes* and in other bacterial groups. The same authors later reported that ornithine amino lipids represent another type of unusual lipids in the outer membrane of *Flavobacterium johnsoniae* (Pitta et al., 1989). The sulfonolipids and ornithine lipids are apparently co-regulated, as their total amount remains constant at 40% of total cellular lipids regardless of mutations or growth conditions.

The type (and so far only) strains of *Flavobacterium croceum* and *Flavobacterium defluvii* are the only new members of the genus in which the polar lipid composition has been studied (Park et al., 2006a, 2007). Although small amounts of phosphatidylglycerol and phosphatidylcholine were present, phosphatidylethanolamine was the predominant polar lipid of the inner membrane, as already reported for *Flavobacterium johnsoniae* (Pitta et al., 1989). Other interesting aspects of the lipids in members of the phylum are the significant proportions of amino-acid-based lipids and the large amounts of hydroxylated fatty acids that are amide-linked rather than ester-linked, confirming the peculiar nature of the polar lipids (B. Tindall, personal communication).

Published data on lipopolysaccharide, capsular polysaccharide, outer-membrane proteins, and glycopeptides of the fish-pathogenic *Flavobacterium* species, as well as on their antigenic properties and role in virulence, have been reviewed by Bernardet and Bowman (2006). Some of these components induce a high titer of protective antibodies and could represent targets for vaccines in the future (Dumetz et al., 2006).

Fine structure. Little information is available on the fine structure of members of the genus *Flavobacterium*. The transmission electron microscopy studies performed on some species (Horn et al., 2005; Møller et al., 2005; Bernardet and Bowman, 2006 and references therein; Park et al., 2006a, 2007; Wang et al., 2006; Yoon et al., 2006d; Liu et al., 2007) revealed that the structure of the cell wall was typical of Gram-stain-negative bacteria. Non-flagellar appendages and fimbriae-like structures

were observed in *Flavobacterium aquatile*, *Flavobacterium branchiophilum*, and *Flavobacterium frigidarium*. Recently, cryoelectron tomography revealed tufts of 5-nm-wide filaments extending from and distributed unevenly on the outer membrane of *Flavobacterium johnsoniae* (Liu et al., 2007). As these filaments were absent in cells of a nonmotile mutant, but restored after the mutant was complemented, they may represent the adhesive surface organelles of the gliding motility machinery. In broth cultures, *Flavobacterium psychrophilum* produces long, tubular blebs that release membrane vesicles into the supernatant. These vesicles display a typical membrane bilayer, contain various proteases, and express several antigenic proteins (Møller et al., 2005). A regular capsule was reported in *Flavobacterium columnare*, *Flavobacterium frigidarium*, and *Flavobacterium hibernum* (Bernardet and Bowman, 2006 and references therein), but the capsule layer observed in *Flavobacterium psychrophilum* was thin and irregular (Møller et al., 2005). A capsule also seems to exist in *Flavobacterium johnsoniae*, since "*Flavobacterium columnare*" strain ATCC 43622 studied by MacLean et al. (2003) was actually later identified as *Flavobacterium johnsoniae* (Darwish et al., 2004; Shoemaker et al., 2005).

Colonial or cultural characteristics. The composition of the agar medium strongly affects colonial morphology of the *Flavobacterium* strains that display gliding motility because low nutrient content promotes this type of motility (see above) (Reichenbach, 1989b). Hence, colonies on nutrient-rich agars are usually circular, low convex to convex, translucent to opaque, smooth and shiny, with entire or uneven to undulate edges, whereas they may be flat and spreading with irregular to rhizoid or filamentous margins on low-nutrient agars (Bernardet and Bowman, 2006). Colonies of *Flavobacterium pectinovorum* merely display a sticky consistency, but the flat, rhizoid colonies of *Flavobacterium columnare* usually strongly adhere to the agar, a trait that may be lost after repeated subcultures. They also frequently display raised, warty to nodular centers that were originally mistaken for the fruiting bodies produced by myxobacteria (Ordal and Rucker, 1944). Different colony types may occur on the same agar plate, as reported for *Flavobacterium columnare* and *Flavobacterium psychrophilum* (Bernardet, 1989; Bernardet and Kerouault, 1989). After prolonged incubation, colonies of *Flavobacterium weaverense* and *Flavobacterium segetis* display a mucoid consistency (Yi and Chun, 2006). The consistency of colonies may also be affected by growth temperature: for instance, colonies of *Flavobacterium hibernum* are mucoid when grown at 25°C and gelatinous at 4°C (McCammon et al., 1998). Colonies of the agar-liquefying species *Flavobacterium flevense*, *Flavobacterium saccharophilum*, and *Flavobacterium tegetincola* are typically sunk into the agar; in *Flavobacterium limicola*, no liquefaction occurs and agar degradation is only visualized using potassium iodide solution (Tamaki et al., 2003).

Colonies of *Flavobacterium* strains are usually pale to bright yellow or orange due to the production of non-diffusible, non-fluorescent carotenoid or flexirubin types of pigments or both (Bernardet and Bowman, 2006; Bernardet et al., 1996, 2002; Reichenbach, 1989b). Ten of the 40 *Flavobacterium* species have been shown to produce predominantly flexirubin type pigments using the simple KOH test (Table 24): the color of the biomass shifts from yellow to dark pink, red or brown when covered with 20% KOH (Bernardet et al., 2002; Reichenbach, 1989b).

Some of these species may in addition produce minor amounts of carotenoids, but the more sophisticated technique necessary to detect these pigments has not been performed. Carotenoid pigments have also not been looked for in a number of *Flavobacterium* species in spite of negative KOH tests (e.g., *Flavobacterium croceum*, *Flavobacterium soli*, *Flavobacterium daejeonense*, *Flavobacterium suncheonense*, *Flavobacterium segetis*, and *Flavobacterium weaverense*). Several *Flavobacterium* species also produce a pink to dark brown, diffusible melanin-like pigment when grown on tyrosine-containing agar (Table 24).

Liquid cultures of *Flavobacterium* strains are usually uniformly turbid. However, cells of *Flavobacterium columnare* frequently adhere to each others (resulting in numerous, tiny aggregates in suspension in the medium) and to the surface of the glass flask (producing a yellow filamentous ring at the upper level of the broth).

Additional information on the colonial and cultural characteristics of *Flavobacterium* strains, as well as the most suitable methods to study them, can be found in Reichenbach (1989b), Bernardet et al. (2002), and Bernardet and Bowman (2006).

Nutrition and growth conditions. Procedures for isolating and cultivating *Flavobacterium* strains have been reviewed extensively (Bernardet and Bowman, 2006; Hugo and Jooste, 2003; Jooste and Hugo, 1999; Reichenbach, 1989b, 1992a). With the exception of some freshwater, NaCl-sensitive species (including the rather fastidious fish-pathogenic species), most *Flavobacterium* species grow readily on commercial media such as nutrient and tryptic soy agars, as well as in the corresponding broths (Table 24). No growth factors are required. The fish pathogens grow well on media containing no NaCl and low nutrient concentrations such as Anacker and Ordal's medium (Anacker and Ordal, 1955), R2A (Reasoner and Geldreich, 1985), and modified Shieh's medium (Song et al., 1988). Many other media, including some selective ones, have been proposed for these economically significant fish pathogens; they have been reviewed extensively by Bernardet and Bowman (2006). All other *Flavobacterium* species tested also grow well on Anacker and Ordal's agar on which gliding strains display their typical spreading colonial morphology optimally (Table 24). Gliding motility is also most active in Anacker and Ordal's broth (Reichenbach, 1989b; Bernardet et al., 2002; J.-F. Bernardet, unpublished data). A glucose-containing medium has been used to grow *Flavobacterium omnivorum* and *Flavobacterium xinjiangense* (Zhu et al., 2003), as well as *Flavobacterium glaciei* (Zhang et al., 2006). Although not essential for growth, glucose has also been included in the growth media for *Flavobacterium columnare* (Song et al., 1988) and *Flavobacterium psychrophilum* (Cepeda et al., 2004; Daskalov et al., 1999). Under optimal conditions, the minimum doubling time is 7.3 h for *Flavobacterium denitrificans* (Horn et al., 2005), 6.8 h for *Flavobacterium segetis*, and 2.9 h for *Flavobacterium weaverense* (Yi and Chun, 2006).

The *Flavobacterium* strains that are able to grow on marine media (e.g., Difco marine 2216E agar) are those that have been retrieved from marine or saline environments, as well as a few strains isolated from temperate (*Flavobacterium soli*) or polar (*Flavobacterium antarcticum*, *Flavobacterium segetis*, *Flavobacterium weaverense*, and *Flavobacterium xanthum*) soil. These species, however, do not require NaCl for growth and are therefore halotolerant, not halophilic. The range of tolerated and optimum

NaCl concentrations for growth are listed in Table 24. Among described species, the highest resistance to NaCl (9%) was found in *Flavobacterium frigidarium* (Humphry et al., 2001), but isolates from saline environments tentatively identified as *Flavobacterium* sp. were recently shown to grow optimally in the presence of 10% NaCl and to tolerate up to 20% (Ghozlan et al., 2006). Although isolated from a freshwater lake, *Flavobacterium flevense* also grows well on marine agar; this fact, together with the ability of *Flavobacterium flevense* to degrade agar, could be a reminiscence of the time when the lake still received an inflow of seawater from the North Sea (Van der Meulen et al., 1974). Other soil and freshwater species, including the above-mentioned fish pathogens, do not grow on marine agar. Growth of *Flavobacterium croceum*, *Flavobacterium limicola*, and *Flavobacterium saliperosum* is severely inhibited by NaCl concentrations of 1–1.5% (Park et al., 2006a; Tamaki et al., 2003; Wang et al., 2006). The fish-pathogenic species are even more NaCl-sensitive: although *Flavobacterium columnare* may tolerate up to 0.5% NaCl (Bernardet and Grimont, 1989), growth is already reduced in the presence of only 0.3% NaCl (Chowdhury and Wakabayashi, 1988). The maximum NaCl concentrations tolerated by *Flavobacterium branchiophilum* and *Flavobacterium psychrophilum* are 0.2% and 0.5–1%, respectively (Bernardet and Kerouault, 1989; Holt et al., 1989; Ostland et al., 1994). Studying the in vitro survival of *Flavobacterium psychrophilum* in water, Madetoja et al. (2003) found that a salinity of $\geq 6\text{‰}$ drastically reduced the number of culturable cells.

Despite the rather chilling specific epithets (e.g., *antarcticum*, *frigidarium*, *frigidimaris*, *frigoris*, *gelidilacus*, *glaciei*, *hibernum*, *psychrolimnae*, *psychrophilum*, etc.) given to the cold-living *Flavobacterium* species, most of them are actually psychrotolerant rather than true psychrophilic organisms. The optimum temperature for growth of the 19 *Flavobacterium* species that have been retrieved from cold or polar environments falls within the 11–21°C range, except for *Flavobacterium hibernum*, which grows optimally at 26°C (Table 24). Intriguingly, the latter species is also the one that is able to grow at the lowest temperature, i.e., –7°C (McCannon et al., 1998). Other psychrotolerant and psychrophilic *Flavobacterium* species are usually able to grow down to 0–5°C. The temperature range for growth of *Flavobacterium* strains that occur in temperate environments is usually 10–25°C, but some of them are able to grow at temperatures as low as 0°C or as high as 37°C (Table 24). *Flavobacterium croceum* is even able to grow up to 45°C (Park et al., 2006a). *Flavobacterium indicum* is the only *Flavobacterium* species that has been retrieved from a warm environment, i.e., spring water at 37–38°C, corresponding to its optimal growth temperature; its growth temperature range is 15–42°C (Saha and Chakrabarti, 2006). The most serious outbreaks of fish disease caused by *Flavobacterium columnare* usually occur in water at 20–30°C (Wakabayashi, 1991), whereas diseases caused by the other major fish pathogen, *Flavobacterium psychrophilum*, typically occur at 3–15°C (Borg, 1960; Holt et al., 1989).

Metabolism and metabolic pathways. Except for the general facts listed at the beginning of this chapter, little is known about these aspects for individual species. Almost all *Flavobacterium* strains are strictly aerobic chemoorganotrophs with a respiratory type of metabolism (Bernardet and Bowman, 2002, 2006; Bernardet et al., 1996). Facultatively anaerobic

growth, however, has been reported in *Flavobacterium hydatis* and *Flavobacterium succinicans* when peptone or yeast extract is provided (Anderson and Ordal, 1961; Bernardet and Bowman, 2006; Chase, 1965; Reichenbach, 1989b; Strohl and Tait, 1978). Recently, weak and delayed anaerobic growth was also reported in *Flavobacterium antarcticum* (Yi et al., 2005a), *Flavobacterium croceum* (Park et al., 2006a), *Flavobacterium weaverense* and *Flavobacterium segetis* (Yi and Chun, 2006), and *Flavobacterium defluvi* (Park et al., 2007). Weak anaerobic growth of the latter organism occurred after 16 d, presumably by fermentation of carbohydrates (Park et al., 2007). The most intriguing *Flavobacterium* species described recently is *Flavobacterium denitrificans*, a facultative anaerobe that grows by carrying out complete denitrification in mineral medium, producing N₂O as a transient intermediate during the reduction of nitrate to nitrite (Horn et al., 2005). This non-fermentative organism uses O₂, NO₃⁻, and NO₂⁻ as electron acceptors, but not sulfate or Fe³⁺. Fifteen of the 40 *Flavobacterium* species are able to supplement their energy metabolism by reducing nitrate to nitrite, but *Flavobacterium denitrificans* is the first truly denitrifying member of the genus described so far. Some *Flavobacterium johnsoniae* strains are able to grow by anaerobic respiration using nitrate as electron acceptor (Reichenbach, 1989b; Stanier, 1947). A “var. *denitrificans*” was proposed by Stanier (1947) for one of these strains as it was an active denitrifier, but its inclusion in the species *Flavobacterium johnsoniae* has been subsequently questioned (Reichenbach, 1989b).

Catalase is produced by all *Flavobacterium* species, cytochrome oxidase by all but a few species, and β -galactosidase by 18 species of the 38 that have been tested. Indole production has not been tested in *Flavobacterium frigidimaris*, *Flavobacterium glaciei*, *Flavobacterium indicum*, *Flavobacterium saliperosum*, or *Flavobacterium soli*; it is negative in all other *Flavobacterium* species. The production of hydrogen sulfide has only been reported in *Flavobacterium columnare*, *Flavobacterium saccharophilum*, *Flavobacterium xanthum*, and *Flavobacterium xinjiangense*.

Most *Flavobacterium* species degrade gelatin and casein and several species also hydrolyze starch and esculin. Other polysaccharides such as chitin, pectin, and carboxymethylcellulose are only hydrolyzed by a few *Flavobacterium* species and the only agarolytic species are *Flavobacterium flevense*, *Flavobacterium limicola*, and *Flavobacterium saccharophilum* (Table 24). Crystalline cellulose (i.e., filter paper) is not decomposed (Bernardet and Bowman, 2006). Saccharolytic capacities vary widely among members of the genus. Some species are able to utilize a wide range of carbohydrates (e.g., *Flavobacterium flevense*, *Flavobacterium frigidimaris*, *Flavobacterium hydatis*, *Flavobacterium johnsoniae*, *Flavobacterium pectinovorum*, and *Flavobacterium saccharophilum*), whereas others utilize few or no carbohydrates and prefer amino acids and proteins (e.g., *Flavobacterium antarcticum*, *Flavobacterium gelidilacus*, *Flavobacterium glaciei*, *Flavobacterium indicum*, *Flavobacterium micromati*, *Flavobacterium saliperosum*, *Flavobacterium suncheonense*, *Flavobacterium tegetincola*, *Flavobacterium weaverense*, and the three fish-pathogenic species). About half of the *Flavobacterium* species produce acid from carbohydrates and degrade Tween compounds and tyrosine, whereas only a few species are able to degrade DNA and urea. The ability of many *Flavobacterium* strains to degrade a variety of biomacromolecules explains their role in mineralizing organic matter in soil and aquatic environments. The combination of polysaccharide-degrading enzymes

and extracellular proteases produced by the fish-pathogenic *Flavobacterium* species is responsible for the extensive skin and muscular necrotic lesions observed in infected fish (Bernardet and Bowman, 2006).

The recently published whole-genome sequence of an *Flavobacterium psychrophilum* strain has yielded some interesting data on its metabolism (Duchaud et al., 2007). Although most genes encoding the enzymes of the glycolytic and pentose phosphate pathways have been identified, the sugar kinase and phosphotransferase systems that allow carbohydrate uptake were found to be missing. This may explain why *Flavobacterium psychrophilum* is unable to use carbohydrates as sources of carbon and energy. Host proteins are first degraded to oligopeptides by secreted proteases; oligopeptides are transported inside the bacterium by extensive uptake systems and degraded to amino acids by numerous peptidases. Amino acids are then processed by various catabolic pathways. Interestingly, *Flavobacterium psychrophilum* also produces cyanophycin synthetase and cyanophycinase, two enzymes also found in cyanobacteria and a few other bacteria. The former synthesizes cyanophycin, a non-ribosomally synthesized polypeptide occurring as storage inclusions in the cytoplasm, whereas the latter degrades cyanophycin to release carbon, nitrogen, and energy in nutrient-poor conditions (Krehenbrink et al., 2002). Hence, this unusual process may also occur in *Flavobacterium psychrophilum*, although cyanophycin inclusions have not been reported so far. Genes encoding the enzymes that degrade lipids to fatty acids have also been identified in the *Flavobacterium psychrophilum* genome. All enzymes of the tricarboxylic acid cycle are present for processing the degradation products of host proteins and lipids. Although *Flavobacterium psychrophilum* is a strict aerobe whose genome contains the genes encoding all components of the aerobic respiratory chain, mechanisms allowing the bacterium to deal with microaerobic conditions have also been identified. They may allow *Flavobacterium psychrophilum* to colonize oxygen-poor environments. The genome has also revealed a number of stress-response mechanisms that probably allow the bacterium to resist iron starvation, oxidative stress, and the reactive oxygen radicals produced in fish macrophages.

The psychrophilic and psychrotolerant *Flavobacterium* species have to overcome the physical constraints resulting from low temperature. For instance, *Flavobacterium frigidimarum* produces a large amount of various NAD(P)⁺-dependent, cold-active dehydrogenases, some of which are thermolabile, whereas others are unexpectedly thermostable (Nogi et al., 2005b). Only the genes orthologous to the *Flavobacterium frigidimarum* genes encoding psychrophilic and thermolabile enzymes have been identified in the genome of *Flavobacterium psychrophilum*. It also contains genes involved in the regulation of membrane fluidity, in the maintenance of protein synthesis, and in the production of proteins with antioxidant properties (Duchaud et al., 2007).

Enzymic activities of *Flavobacterium* strains that may have biotechnological applications in the future have been reviewed recently (Bernardet and Bowman, 2006). In addition, a cold-active, thermolabile xylanase has been described from a creek bed soil isolate sharing 99% full-length 16S rRNA gene sequence similarity with the type strain of *Flavobacterium hibernum* (Lee et al., 2006a), and two *Flavobacterium* strains isolated from lake sediment in Finland have been shown to degrade casein, starch, and carboxymethylcellulose at 5°C (Männistö

and Haggblom, 2006). A soil isolate that was able to rapidly metabolize the organophosphorus pesticide cadusafos has also been definitely allocated to the genus *Flavobacterium* on the basis of the high similarity of its full-length 16S rRNA gene sequence with those of several *Flavobacterium* species (Karpouzias et al., 2005). However, many "*Flavobacterium* sp." strains have actually been tentatively identified on the basis of partial 16S rRNA gene sequence and/or poor phenotypic data. For instance, "*Flavobacterium* sp." ATCC 27551, whose parathion hydrolase activity has been the subject of many publications (e.g., Mulbry and Karns, 1989; Manavathi et al., 2005; Khajamohiddin et al., 2006) dealing with the microbial detoxification of hazardous organophosphate contaminants (such as the insecticides diazinon and parathion), has actually been shown to be a facultatively anaerobic and flagellated strain (Sethunathan and Yoshida, 1973). Degrading activities of the following contaminants with possible applications in bioremediation have been reported in other poorly (probably erroneously) identified "*Flavobacterium* sp.": the solid propellant perchlorate (Okeke and Frankenberger, 2005), gasoline (Lu et al., 2006), various aromatic and chlorinated aromatic hydrocarbons (Plotnikova et al., 2006), the herbicide atrazine (Smith and Crowley, 2006), and the pesticide pentachlorophenol (Pu and Cutright, 2007). The β -galactosidase secreted by a *Flavobacterium* strain isolated from post-processing water in a shrimp and fish processing plant in Greenland met a number of requirements that are necessary for industrial dairy processes (Sørensen et al., 2006).

Genetics. The *Bacteroides thetaiotaomicron* transposable element Tn4351 has been the first tool for mutagenesis in members of the phylum *Bacteroidetes* (Cooper et al., 1997). This transposon has also been shown to function in *Flavobacterium johnsoniae* and cloning vectors based on the cryptic plasmid pCP1 of *Flavobacterium psychrophilum* have been developed to genetically manipulate *Flavobacterium* species and related organisms (McBride and Baker, 1996; McBride and Kempf, 1996). Gliding motility mutants of *Flavobacterium columnare* and *Flavobacterium johnsoniae* had already been obtained through conventional methods (see *Cell-wall composition*, above), but Tn4351 mutagenesis has been used to obtain non-gliding mutants of *Flavobacterium johnsoniae* to elucidate the genetic mechanisms of gliding motility. To date, 15 different genes (*gldA* to *gldN* and *ftsX*) required for gliding motility have been identified. Cells with mutations in any of these genes are completely nonmotile, deficient in chitin utilization, and resistant to infection by bacteriophages (Braun et al., 2005; Kempf and McBride, 2000; McBride, 2001; McBride and Braun, 2004; McBride et al., 2003). Conversely, some gliding activity is retained in *secDF* and *sprA* mutants (Nelson and McBride, 2006; Nelson et al., 2007). Unlike all other proteins involved in gliding motility, *sprA* is at least partially exposed on the cell surface (Nelson et al., 2007). The same group of scientists has sequenced the pCP1 plasmid harbored by most *Flavobacterium psychrophilum* strains (M.J. McBride, sequence no. NC_004811, <http://www.ncbi.nlm.nih.gov>; Chakroun et al., 1998; Madsen and Dalsgaard, 2000; Izumi and Aranishi, 2004). Genetic tools have also been developed for *Flavobacterium psychrophilum*, including selectable markers, plasmid cloning vectors, a reporter system, and a transposon (Álvarez et al., 2004).

The whole-genome sequence of *Flavobacterium psychrophilum* JIP 02/86 (=CIP 103535=ATCC 49511) was recently determined (Duchaud et al., 2007) and consists of a 2,861,988 bp circular chromosome and one copy of the above-mentioned pCP1 cryptic plasmid. The mean G+C content of the whole chromosome is 32.54 mol%. The chromosome contains six rRNA genes, 49 tRNA genes, and 2,432 predicted protein-coding genes. No function could be assigned to 45% of the genes and little conservation was observed when the genome of JIP 02/86 was compared to other published complete genome sequences. The closest to *Flavobacterium psychrophilum* among these was *Bacteroides fragilis* YCH46, but only 50% orthologous genes and very limited synteny were observed between the two genomes. No counterpart was found in other published genomes for 401 putative proteins (16%). The ongoing whole-genome sequence of other members of the genus (*Flavobacterium psychrophilum* CSF-259-93, *Flavobacterium columnare* ATCC 49512, and *Flavobacterium johnsoniae* ATCC 17061^T) and of members of the family *Flavobacteriaceae* (“*Gramella forsetii*” KT0803 and *Leeuwenhoekiella blandensis* MED 217^T) will allow interesting comparisons between the genomes. For instance, the genome size of the pathogen *Flavobacterium psychrophilum* (2.9 Mb) is low compared to that of related environmental organisms such as *Flavobacterium johnsoniae* (6 Mb) and *Leeuwenhoekiella blandensis* (4.2 Mb). The NCBI website (<http://www.ncbi.nlm.nih.gov/genomes/lproks.cgi>) provides information on all these genomes, except that of *Flavobacterium columnare* for which a separate website is available (http://microgen.ouhsc.edu/f_columnare/f_columnare_home.htm).

The genotyping techniques that have been applied to collections of *Flavobacterium* strains have been reviewed recently (Bernardet and Bowman, 2006 and references therein). Random amplified polymorphic DNA, rRNA gene restriction pattern analysis (ribotyping), restriction fragment length polymorphism analysis, repetitive extragenic palindromic DNA-PCR (rep-PCR), and plasmid profiles have resulted either in the differentiation of *Flavobacterium* species or in intra-specific typing with taxonomic or epidemiological applications. The two major fish pathogens *Flavobacterium columnare* and *Flavobacterium psychrophilum*, of which large collections of strains are available and which are economically significant, have been the subjects of most molecular typing studies.

Early reports of phages in *Flavobacterium columnare* and *Flavobacterium johnsoniae* have been mentioned by Reichenbach (1989b). The online directory of phage names (Ackermann and Abedon 2001) lists a number of other phages reportedly isolated from *Flavobacterium* strains. They include: T- ϕ D1B, a member of the family *Myoviridae*, morphotype A1; ϕ CB38, a member of the family *Podoviridae*, morphotype C1; and CMF-1-F, O6N-12P, O6N-24P, and ϕ MT5, four different virus species of the family *Siphoviridae*, morphotype B1. A new flavobacteria-infecting siphonophage, phage 11b, has been isolated recently from strain “*Bacteroidetes bacterium 11B*”, an Arctic sea-ice isolate that shares 97–99% 16S rRNA gene sequence similarity with *Flavobacterium frigroris*, *Flavobacterium degerlachei*, and other polar *Flavobacterium* isolates (Borriss et al., 2003, 2007). Flavobacteriophage 11b has been cultivated and its genome and proteome have been characterized. Its host-specificity is reflected by a low DNA G+C content similar to that of *Flavobacterium* species and by the significant similarity of five of its coding sequences with those of closely related bacteria of the phylum *Bacteroidetes* (Borriss et al., 2007).

Antibiotic sensitivity. Overall, the environmental *Flavobacterium* strains that have been tested for their susceptibility to antimicrobial drugs showed no outstanding resistance (Aslam et al., 2005; Humphry et al., 2001; Park et al., 2006a, 2007; Saha and Chakrabarti, 2006; Strohl and Tait, 1978; Wang et al., 2006; Yoon et al., 2006d). Drug susceptibility of the fish-pathogenic *Flavobacterium* species has been studied extensively to evaluate antibiotics for selective isolation media and for treatment of infected fish. Intrinsic resistance to tobramycin was found in *Flavobacterium columnare* and *Flavobacterium psychrophilum*; the former species was also resistant to neomycin and polymyxin B. Bath or oral antibiotic treatments are still the most effective control method for *Flavobacterium* infections in fish, but resistance to the widely used oxytetracycline, oxolonic acid, and amoxicillin has progressively developed in fish farm isolates; no resistance to florfenicol has been reported yet (Bernardet and Bowman, 2006 and references therein).

Pathogenicity. Strains of *Flavobacterium johnsoniae* have occasionally been isolated from cases of “soft rot” in various plants; it was probably an opportunistic pathogen (Lelliott and Stead, 1987; Liao and Wells, 1986). An organism named “*Cytophaga allerginae*” (later shown to share significant DNA relatedness with *Flavobacterium hydatis* and *Flavobacterium johnsoniae*; Bernardet and Bowman, 2006) was retrieved from the air humidification system of a textile facility and identified as the source of the endotoxin that caused severe cases of hypersensitivity pneumonitis in several workers (Flaherty et al., 1984; Liebert et al., 1984). No other cases have been reported since then.

Freshwater fish are the animals most prone to flavobacterial infections, resulting in considerable economic losses worldwide. Fish diseases caused by *Flavobacterium columnare*, *Flavobacterium psychrophilum*, and *Flavobacterium branchiophilum* have been reviewed extensively (Austin and Austin, 1999; Bernardet and Bowman, 2006; Holt et al., 1993; Nematollahi et al., 2003; Shotts and Starliper, 1999) and basic information is also provided below in the list of species. Although mainly a free-living organism, *Flavobacterium johnsoniae* has been isolated frequently from diseased fish (Christensen, 1977; J.-F. Bernardet, unpublished data) and is considered to be an opportunistic pathogen in a few cases (Carson et al., 1993; Rintamäki-Kinnunen et al., 1997). Originally isolated from diseased fish, *Flavobacterium hydatis* (previously [*Cytophaga*] *aquatilis*; Strohl and Tait, 1978) and *Flavobacterium succinicans* (previously [*Cytophaga*] *succinicans*; Anderson and Ordal, 1961) may also act as opportunistic pathogens. Several other *Flavobacterium*-like organisms have been reported from diseased fish, but they have subsequently been transferred to other or new genera (Bernardet and Bowman, 2006).

Virulence mechanisms of fish-pathogenic *Flavobacterium* species are as yet poorly understood. Adhesive properties, agglutination, and lysis of fish erythrocytes, the ability to escape the bactericidal mechanisms of phagocytes, and production of extracellular proteases and chondroitin AC lyase have been suggested as important virulence factors of *Flavobacterium psychrophilum*, *Flavobacterium columnare*, and *Flavobacterium branchiophilum*, but virulence varies considerably among strains (Bernardet and Bowman, 2006 and references therein). New insights have resulted from the recent

whole-genome sequencing of *Flavobacterium psychrophilum* strain JIP 20/86 (Duchaud et al., 2007; see above). Genome analysis has revealed a number of mechanisms that confer on *Flavobacterium psychrophilum* the ability to colonize and degrade fish tissues: adhesion, biofilm formation, gliding motility, iron acquisition, production of proteases able to hydrolyze the components of skin and muscular tissues, production of cell surface proteins important for bacteria–host interactions, and secretion systems transporting toxins to the bacterial surface. Additional data on virulence will likely result from comparison of this genome to those of other pathogenic (*Flavobacterium branchiophilum*, *Flavobacterium columnare*) and environmental (*Flavobacterium johnsoniae*) *Flavobacterium* species when available (see *Genetics*, above).

Ecology. Members of the genus *Flavobacterium* occur in a variety of soil and freshwater, marine, or saline habitats in warm, temperate, or polar environments (Table 24) (Bernardet and Bowman, 2006). Of the 40 *Flavobacterium* species with validly published names, only one (*Flavobacterium indicum*) has been isolated from a warm habitat (i.e., spring water at 37–38°C), 18 are from cold or polar habitats, and eight are from habitats characterized by moderate salinity such as seawater, sea ice, marine sediment, and saline lake water. *Flavobacterium* strains have not been isolated from hypersaline environments so far. Ghozlan et al. (2006) investigated bacterial communities in water and soil samples from various habitats in Egypt displaying a wide range of salinity. Strains allocated to the genus *Flavobacterium* on the basis of 155 phenotypic tests were only retrieved from salt lakes and solar salterns with non-saturating brines (salinity 13.5–25%) and shown to grow optimally in the presence of 10% NaCl. Several of the recently described *Flavobacterium* species have been isolated following extensive investigation of bacterial communities in Antarctic soil (*Flavobacterium weaverense* and *Flavobacterium segetis*; Yi and Chun (2006) and seawater (*Flavobacterium frigidimaris*; Nogi et al., 2005b). Temperate or frozen soils have also yielded a number of novel *Flavobacterium* species, such as *Flavobacterium omnivorum* and *Flavobacterium xinjiangense* (Zhu et al., 2003), *Flavobacterium soli* (Yoon et al., 2006d), *Flavobacterium daejeonense* and *Flavobacterium suncheonense* (Kim et al., 2006a), and *Flavobacterium glaciei* (Zhang et al., 2006). *Flavobacterium denitrificans* (Horn et al., 2005), isolated from the gut of an earthworm, is also most likely a soil organism (H.L. Drake, personal communication); it participates in the production of large amounts of nitrous oxide, a greenhouse gas, by earthworms. Among the NaCl-sensitive species, *Flavobacterium glaciei* has been isolated from frozen soil (Zhang et al., 2006), *Flavobacterium aquidurensense* and *Flavobacterium hercynium* are from calcium-rich creek water (Cousin et al., 2007), *Flavobacterium saliperosum* is from freshwater lake sediment (Wang et al., 2006), and *Flavobacterium croceum* and *Flavobacterium defluvi* are from activated sludge (Park et al., 2006a, 2007). The fish-pathogenic species (see below) are also very sensitive to NaCl concentration.

Among the few investigations of cultivable bacterial communities using complete or nearly complete 16S rRNA gene sequences are studies from river epilithon (i.e., the biofilm attached to rock surfaces comprising algal and bacterial communities embedded in organic matter) in England (O’Sullivan et al., 2006) and from the calcium-rich water of a German

creek (Brambilla et al., 2007). Both studies revealed the same breadth of diversity among *Flavobacterium* strains, but only a few isolates could be affiliated with described species, with the majority of isolates representing putative novel species. Descriptions of novel *Flavobacterium* species (*Flavobacterium aquidurensense* and *Flavobacterium hercynium*; Cousin et al., 2007) have already resulted from one of these studies. Kisand et al. (2005) studied the distribution and seasonal dynamics of five *Flavobacterium* strains along a Northern Baltic Sea river-marine transect. Two strains were the most abundant bacteria in the river water (mean >10,000 cells/ml), but they decreased in number from the river to the estuary and the open sea. The remaining three strains were only occasionally detectable. Authentic *Flavobacterium* isolates were also recovered from another estuarine environment (Selje et al., 2005) and from water beneath a Canadian glacier (Cheng and Foght, 2007). Interestingly, freeze-tolerant bacteria producing ice-active macromolecules are not restricted to polar areas. A *Flavobacterium* strain exhibiting ice-nucleating activity, but unable to inhibit recrystallization was isolated from soil in a temperate Canadian location (Wilson et al., 2006). New *Flavobacterium* species will most likely emerge from investigations of these and other environments.

Most studies of bacterial communities and phylogenetic diversity in various environments, however, have been based on partial 16S rRNA gene sequences, cloned 16S rRNA genes, or denaturing gradient gel electrophoresis bands. Consequently, the resulting affiliation of the corresponding organisms to the genus *Flavobacterium* is only tentative. For instance, *Flavobacterium* sp. were among the surface and endophytic bacteria that colonize orchid roots (Tsavkelova et al., 2007), and Kim et al. (2006b) reported that 87% of the bacterial community associated with the roots of tomato plants belonged to undescribed members of the genus *Flavobacterium*. Some of the isolates recovered from permafrost in Siberia (Vishnivetskaya et al., 2006) and China (Bai et al., 2006) were identified as *Flavobacterium* sp. *Flavobacterium* strains were also found in three different habitats of a paddy field in Japan: among the epibiotic and intestinal microbial community of several microcrustacean species (Niswati et al., 2005), among the microbial community responsible for the decomposition of buried rice straw compost (Tanahashi et al., 2005), and in the floodwater (Shibagaki-Shimizu et al., 2006). The bacterioplankton communities of water from oligotrophic, eutrophic, and mesotrophic lakes (i.e., lakes with low concentrations of nutrients and low overall productivity, high concentrations of nutrients and high productivity, and intermediate characteristics, respectively) in Germany all contained *Flavobacterium* strains (Gich et al., 2005). A study of the abundance and seasonal dynamics of members of the class *Flavobacteriia* in four eutrophic lakes in Sweden revealed that *Flavobacterium* strains formed one of the two dominant *Flavobacteriia* lineages responsible for the observed *Flavobacteriia* blooms (i.e., episodes where *Flavobacteriia* contributed in excess of 30% of total bacterioplankton). *Flavobacterium* spp. alone or in combination with members of the other lineages also contributed more than 50% of the total 16S rRNA gene pool during some cyanobacterial blooms (Eiler and Bertilsson, 2007). The two *Flavobacterium* strains identified on the basis of their fatty acid profile and partial 16S rRNA sequence from lake and pond sediment in Finland were

able to grow at 0°C (Männistö and Haggblom, 2006). Larvae of some butterflies species (Xiang et al., 2006) have also been shown to harbor *Flavobacterium* strains in the gut. In the search for potential bacterial pathogens to control the hazelnut pest beetle *Oberea linearis*, Bahar and Demirbag (2007) characterized a number of strains isolated from diseased or dead larvae. Conventional phenotypic tests, commercial galleries, and near-full-length 16S rRNA gene sequences have clearly identified one of the isolates as a *Flavobacterium* sp., but bioassays on beetle larvae have failed to reveal any insecticidal effect.

The fish-pathogenic *Flavobacterium* species (e.g., *Flavobacterium branchiophilum*, *Flavobacterium columnare*, and *Flavobacterium psychrophilum*) have mainly been isolated from superficial lesions or internal organs of infected fish, and only rarely from water (Bernardet and Bowman, 2006). Although *Flavobacterium psychrophilum* cells are able to survive in water for several months, they rapidly lose their ability to multiply (Madetoja et al., 2003). Hence, these species seem to be mainly parasitic, as also suggested by their rather fastidious growth on artificial media (especially *Flavobacterium branchiophilum*). The few strains of *Flavobacterium hydatis* and *Flavobacterium succinicans* available and the fish isolates of *Flavobacterium johnsoniae* have been isolated exclusively from external lesions of fish. This suggests that these three species, which grow well on artificial media, are probably saprophytic or commensal organisms that may colonize fish lesions initiated by other bacteria or parasites. Other saprophytic or commensal *Flavobacterium* strains have been reported from the surface of fish eggs and from fish skin, gills, and gut (Huber et al., 2004; Bernardet and Bowman, 2006 and references therein; Hu et al., 2007), but the identification of some of these strains was only based on scant data.

Flavobacterium strains have also been found in air humidification systems (see *Pathogenicity*, above), in amoebae (Horn et al., 2001; Müller et al., 1999), in the water and sediment of intensive fish culture systems (Bernardet and Bowman, 2006 and references therein), and in the wastewater treatment plant of a beer brewery (*Flavobacterium granulii*; Aslam et al., 2005). Many "*Flavobacterium*" strains have reportedly been involved in the spoilage or degradation of various food products, but they have either been subsequently allocated to other genera or shown to play only a minor role (Bernardet and Bowman, 2006 and references therein). Recently, some of the spoilage pectinolytic organisms isolated from various minimally processed frozen vegetables sold in supermarkets in Botswana were tentatively identified as *Flavobacterium* sp. on the basis of commercial identification systems and additional phenotypic tests (Manani et al., 2006).

In the different habitats they colonize, *Flavobacterium* strains participate in the degradation of various organic compounds such as polysaccharides and proteins. For instance, five *Flavobacterium* sp. represented important metabolizers of dissolved organic matter in river estuaries of the Northern Baltic area (Kisand et al., 2002, 2005). The proteases and chondroitin AC lyase secreted by the fish-pathogenic *Flavobacterium* species are responsible for severe necrotic lesions by destroying fish tissues (see *Pathogenicity*, above; Bernardet and Bowman, 2006). Some of the enzymes, especially the cold-active ones, produced by *Flavobacterium* strains may have biotechnological applications in the future (see *Metabolism and metabolic pathways*, above; Bernardet and Bowman, 2006).

Enrichment and isolation procedures

Most *Flavobacterium* strains are easily isolated and cultivated, usually requiring no enrichment or selective isolation procedure and growing in an ambient air atmosphere. Serial dilutions of the source material, such as water, soil, or fish tissue, are spread directly onto agar media and incubated at a temperature corresponding to that of the original habitat. The media used for isolation and cultivation of *Flavobacterium* strains are presented in the section on nutrition and growth conditions. Relevant information on the isolation and cultivation of some species now included in the genus *Flavobacterium* has also been provided by Reichenbach (1989b, 1992a).

The enrichment procedures that have been used occasionally have taken advantage of the special physiological characteristics displayed by some *Flavobacterium* strains. For instance, a pre-enrichment step at 2–4°C has been performed to promote the isolation of psychrophilic/psychrotolerant *Flavobacterium* species from cold environments (e.g., McCammon and Bowman, 2000; Zhu et al., 2003; Yi et al., 2005a; Yi and Chun, 2006; Zhang et al., 2006). Similarly, isolation of chitin-, pectin-, or xylan-degrading *Flavobacterium* strains has been achieved by using an enrichment step on media containing the specific substrate (Agbo and Moss, 1979; Reichenbach (1989b) and references therein; Humphry et al. (2001).

Maintenance procedures

Most cold-living *Flavobacterium* strains can be stored for a few weeks or months at 2–4°C as live cultures on agar plates or slants, whereas agar deeps (e.g., Anacker and Ordal's medium containing 0.4% agar; Anacker and Ordal, 1955) should preferably be used for short-term preservation of other *Flavobacterium* strains (J.-F. Bernardet, unpublished data). For long-term preservation, *Flavobacterium* strains can be lyophilized or maintained at –70°C or –80°C using glycerol (10–30%, v/v) as a cryoprotectant (Bernardet and Bowman, 2006; Reichenbach, 1989b; Yi and Chun, 2006). Commercial media for cryopreservation have also been used successfully (Cepeda et al., 2004).

Procedures for testing special characters

The phenotypic characteristics that allow differentiation of *Flavobacterium* species are listed in Table 24 and those that distinguish *Flavobacterium* species from members of related genera are detailed in the next section. The procedures recommended for testing these characteristics have been specified previously (Bernardet et al., 2002). Additional details have been provided for those features that are unusual or require some experience, such as production of spherical degenerative cells in the stationary phase, colony morphology and consistency, adsorption of Congo red, gliding motility, ability to degrade cellulose or its derivatives, yellow pigment type (flexirubin and/or carotenoid), production of cytochrome oxidase and β-galactosidase, salinity requirement, capnophilic metabolism, and use of commercial identification systems (Bernardet and Bowman, 2006; Bernardet et al., 2002).

Differentiation of the genus *Flavobacterium* from closely related taxa

Nowadays, differentiation of *Flavobacterium* strains from members of other genera in the family *Flavobacteriaceae* is usually

achieved initially through a comparison of 16S rRNA gene sequences with those deposited in databases and the determination of phylogenetic distances.

The features that should be included in the description of novel *Flavobacterium* species have been specified in the minimal standards for describing new taxa in the family *Flavobacteriaceae* (Bernardet et al., 2002). The phenotypic characteristics that differentiate members of genera in the family *Flavobacteriaceae* are listed in Table 23 in the treatment of the family *Flavobacteriaceae* in this volume. However, because the genus *Flavobacterium* contains by far the largest number of species in the family, many of these characteristics also vary within the genus and consequently cannot be used to circumscribe the genus *Flavobacterium* from other genera. The following characteristics vary within the genus: production of spherical degenerative cells in stationary phase; gliding motility; ability to grow at 25°C; acid production from glucose and sucrose; presence of DNase, urease, cytochrome oxidase, H₂S, and β-galactosidase activities; nitrate reduction; carbohydrate utilization; and degradation of agar, starch, esculin, and gelatin. Hence, the only characteristics common to all *Flavobacterium* species so far are: production of yellow pigments; the presence of catalase activity; the absence of a requirement for Na⁺ or seawater; and the inability to grow under anaerobic conditions (except for five of the 40 species), to produce indole, or to grow at 37 and 42°C (except for *Flavobacterium croceum* and *Flavobacterium indicum*).

Information on the relevance of fatty acid composition to identify *Flavobacterium* strains at the genus and species level has been given above (see *Cell-wall composition*). Application of whole-cell protein analysis by SDS-PAGE to members of the genus *Flavobacterium* has been reviewed recently (Bernardet and Bowman, 2006). Another procedure, MALDI-TOF (Matrix-Assisted Laser Desorption/Ionization Time-of-Flight) mass spectrometry analysis, has been used to rapidly group 60 freshwater isolates according to their whole-cell protein pattern; more than half of the isolates grouped around the single *bona fide* *Flavobacterium* strain contained in the database (Brambilla et al., 2007).

The DNA G+C content of *Flavobacterium* strains (i.e., 30–41 mol%) is similar to that of most other members of the family *Flavobacteriaceae* (see Table 23 in the treatment of the family *Flavobacteriaceae*). DNA G+C composition only allows differentiation of *Flavobacterium* strains from *Oleya* (49 mol%) and *Robiginitalea* (55–56 mol%) strains, and from some strains of *Bizionia* (38–45 mol%), *Capnocytophaga* (36–44 mol%), *Muricauda* (41–45 mol%), *Psychroserpens* (27–29 mol%), and *Zobellia* (36–43 mol%).

Taxonomic comments

The early history of the genus *Flavobacterium* and of its type species (*Flavobacterium aquatile*) has been reviewed several times (especially in Holmes and Owen (1979), but also: Weeks, 1955; Holmes and Owen, 1981; Holmes, 1992; Holmes et al., 1984c). Following the description of “*Bacillus aquatilis*” by Frankland and Frankland (1889), the species was designated the type species of the genus *Flavobacterium* when it was created by Bergey et al. (1923). As no type strain had been designated by the Franklands and no original isolate was still available, strain Taylor F36, reputed to be a re-isolate of the original organism from the same source, has become generally accepted (although not

formally proposed) as the type strain of *Flavobacterium aquatile* (Holmes and Owen, 1979; Weeks, 1955). However, this strain displayed serious phenotypic discrepancies compared to the meagre original description of “*Bacillus aquatilis*” and it shared some characteristics with members of the genus *Cytophaga*, such as the structure of the cell wall (Follett and Webley, 1965) and movements that were considered to be gliding by some investigators (Perry, 1973). Moreover, its place and date of isolation were not known with certainty. Since Holmes and Owen (1979) felt that “*Flavobacterium aquatile* was an unfortunate choice as the type species of *Flavobacterium* because the species is currently represented by only one strain which is of uncertain taxonomic affinities”, they proposed to substitute [*Flavobacterium*] *breve* for *Flavobacterium aquatile* as the type species of the genus. They also proposed an emended description of the genus that took into account its successive restrictions. Indeed, because the only original criteria for including an organism in the genus *Flavobacterium* were the production of yellow to orange pigments and the ability to produce acid weakly from carbohydrates (Bergey et al., 1923), the genus had grown to include Gram-stain-positive, Gram-stain-negative, flagellated, gliding, and nonmotile bacteria with high or low DNA G+C content (Holmes and Owen, 1979). In the successive editions of *Bergey's Manual*, flagellated, Gram-stain-positive, and gliding strains were excluded, but species with high and low DNA G+C content were still included (Weeks, 1974).

The genus *Flavobacterium* as emended by Holmes and Owen (1979) was restricted to clinical, environmental, or food bacteria that were aerobic, Gram-stain-negative, chemoorganotrophic, oxidase- and catalase-positive, and nonmotile, usually producing yellow to orange pigments, having a strictly respiratory type of metabolism, actively proteolytic but poorly saccharolytic, with a DNA G+C content of 31–40 mol%. Because the Judicial Commission (Wayne, 1982) had declined to issue the opinion requested by Holmes and Owen (1979) for rejecting the name *Flavobacterium aquatile* as a *nomen dubium* and for changing the type species of the genus *Flavobacterium*, *Flavobacterium aquatile* had to remain the type species of the genus. The description of the genus in the following edition of the *Manual* (Holmes et al., 1984c) was essentially the same as the one these authors had proposed in 1979. However, although all seven species shared the above-mentioned characteristics, the following species or groups of species could already be distinguished on the basis of phenotypic features: (i), *Flavobacterium aquatile*; (ii), [*Flavobacterium*] *breve*, [*Flavobacterium*] *balustinum*, and [*Flavobacterium*] *meningosepticum*; (iii), [*Flavobacterium*] *odoratum*; and (iv), [*Flavobacterium*] *multivorum* and [*Flavobacterium*] *spiritivorum*. The same “natural groups”, some of them expanded by the description of novel species, appeared in the next review on the genus *Flavobacterium* (Holmes, 1992).

In 1996, the results of an extensive polyphasic study of more than 100 bacterial strains representing a variety of flavobacteria (mainly attributed to the genera *Cytophaga*, *Flavobacterium*, *Flexibacter*, *Microscilla*, and *Sphingobacterium*) were published (Bernardet et al., 1996). The main result of the 16S rRNA analysis included in this study was the distinct delineation of a “*Flavobacterium aquatile* rRNA cluster” that comprised *Flavobacterium aquatile*, *Flavobacterium branchiophilum*, [*Cytophaga*] *flevensis*, [*Cytophaga*] *aquatilis*, [*Cytophaga*] *johnsonae* (*sic*), [*Cytophaga*] *pectinovora*, [*Cytophaga*] *saccharophila*, [*Cytophaga*] *succinicans*,

"*Cytophaga allerginæ*", "*Cytophaga xantha*", [*Flexibacter*] *columnaris*, [*Flavobacterium*] *psychrophilus*, [*Flavobacterium*] *aurantiacus*, "*Flavobacterium aurantiacus* subsp. *excathedrus*", "*Promyxobacterium flavum*", and "*Sporocytophaga cauliformis*". Due to the low resolution of the 16S rRNA analysis used at that time, [*Flavobacterium*] *odoratum* was also included in this cluster. Strikingly, all other species included in the genus *Flavobacterium* as delineated by Holmes et al. (1984c) and Holmes (1992) appeared only remotely related to the "*Flavobacterium aquatile* rRNA cluster" and had to be reclassified in other or new genera (i.e., *Chryseobacterium*, *Empedobacter*, and *Bergeyella*; see Vandamme et al. (1994a) and the treatment of these genera and the family *Flavobacteriaceae*). The organisms grouped in the "*Flavobacterium aquatile* rRNA cluster" shared similar fatty acid and whole-cell protein profiles, a number of phenotypic and chemotaxonomic characteristics, and a rather narrow range of DNA G+C content, as well as similar habitats. Hence, both phenotypic and phylogenetic criteria supported inclusion of members of the cluster into an emended genus *Flavobacterium* with *Flavobacterium aquatile* as the type species (Bernardet et al., 1996). An emended description of the genus was proposed that took into account characteristics that were common to all its members. Conversely, as [*Flavobacterium*] *odoratum* differed from the other species by several characteristics and by its clinical origin, it was decided to reclassify this species in a separate genus, *Myroides*, as *Myroides odoratus* (Vancanneyt et al., 1996). The reclassification of [*Cytophaga*] *aquatilis* in the genus *Flavobacterium* made it necessary to propose a new species name for this taxon, *Flavobacterium hydatis*, to avoid the new combination becoming a junior homonym of *Flavobacterium aquatile*. The reclassification of [*Cytophaga*] *johnsonae* was also the opportunity for correcting its specific epithet to *johnsoniae* (Bernardet et al., 1996). As the two [*Flexibacter*] *aurantiacus* strains shared many phenotypic features, similar fatty acid profiles, and high levels of DNA–DNA relatedness with the type strain of *Flavobacterium johnsoniae*, it was proposed to include them in this species (Bernardet et al., 1996). Although clearly attributed to the emended genus *Flavobacterium*, the taxa "*Cytophaga allerginæ*", "*Cytophaga xantha*", "*Flexibacter aurantiacus* subsp. *excathedrus*", "*Promyxobacterium flavum*", and "*Sporocytophaga cauliformis*" were all, except the latter, represented by a single, poorly investigated strain and their names had not been validly published. Hence, pending further research and isolation of additional strains, it was decided not to formally describe novel *Flavobacterium* species for these organisms and to refer to them merely as "*Flavobacterium* sp.". The only strain of "*Cytophaga xantha*" was later included in a study of Antarctic isolates and formally described as *Flavobacterium xanthum* (McCummon and Bowman, 2000); since then, novel strains have been isolated (Van Trappen et al., 2005).

Hence, the genus *Flavobacterium* as it was defined in 1996 comprised soil or freshwater, Gram-stain-negative, aerobic, gliding (except *Flavobacterium branchiophilum*) organisms that contained menaquinone MK-6 as the major respiratory quinone, produced yellow non-diffusible pigments and catalase, and had very similar fatty acid profiles; *Flavobacterium* strains were unable to grow on seawater-containing media (except *Flavobacterium flevense*) or hydrolyze crystalline cellulose; the DNA G+C content was 32–37 mol% and the optimum temperature range was 20–30°C (except *Flavobacterium psychrophilum*). The genus contained *Flavobacterium aquatile* and the following nine other

species: *Flavobacterium branchiophilum*, *Flavobacterium columnare*, *Flavobacterium flevense*, *Flavobacterium hydatis*, *Flavobacterium johnsoniae*, *Flavobacterium pectinovorum*, *Flavobacterium psychrophilum*, *Flavobacterium saccharophilum*, and *Flavobacterium succinicans* (Bernardet et al., 1996). Sixteen additional species had been described at the time of publication of the most recent review on the genus (Bernardet and Bowman, 2006). Description of the following 14 novel species have been published since then: *Flavobacterium denitrificans* (Horn et al., 2005), *Flavobacterium frigidimaris* (Nogi et al., 2005b), *Flavobacterium croceum* (Park et al., 2006a), *Flavobacterium daejeonense* and *Flavobacterium suncheonense* (Kim et al., 2006a), *Flavobacterium glaciei* (Zhang et al., 2006), *Flavobacterium indicum* (Saha and Chakrabarti, 2006), *Flavobacterium saliperosum* (Wang et al., 2006), *Flavobacterium segetis* and *Flavobacterium weaverense* (Yi and Chun, 2006), *Flavobacterium soli* (Yoon et al., 2006d), *Flavobacterium defluvii* (Park et al., 2007), and *Flavobacterium aquidurensense* and *Flavobacterium hercynium* (Cousin et al., 2007). Hence, the genus currently comprises 40 species with validly published names. The description of several other *Flavobacterium* species is pending and it is likely that some of the organisms affiliated to the genus *Flavobacterium* reported from investigations of various environments (e.g., Kisand et al., 2002; Zdanowski et al., 2004; Gich et al., 2005; Green et al., 2006; Kim et al., 2006b; Männistö and Haggblom, 2006; O'Sullivan et al., 2006; Vishnivetskaya et al., 2006; Cheng and Foght, 2007) will ultimately be formally described.

As the genus *Flavobacterium* progressively expanded, some of the recently described species have proved to share only moderate 16S rRNA gene sequence similarity with other members of the genus. For instance, *Flavobacterium croceum*, *Flavobacterium saliperosum*, and *Flavobacterium indicum* share 94, 93.3, and 92.1% 16S rRNA gene sequence similarity, respectively, with the type and only strain of the type species, *Flavobacterium aquatile* (Park et al., 2006a; Saha and Chakrabarti, 2006; Wang et al., 2006). Sequence similarity values as low as 89–92.5% with other *Flavobacterium* species have been reported for *Flavobacterium saliperosum* and *Flavobacterium suncheonense* (Kim et al., 2006a; Wang et al., 2006). As a consequence, *Flavobacterium columnare*, *Flavobacterium croceum*, *Flavobacterium indicum*, *Flavobacterium saliperosum*, *Flavobacterium suncheonense*, and "*Flexibacter aurantiacus* subsp. *excathedrus*" form a distinct, smaller branch in the phylogenetic tree compared to all other *Flavobacterium* species (Figure 27) and this branching is supported by very high bootstrap values. However, 16S rRNA gene sequence similarity values within this smaller branch are moderate to low. For instance, *Flavobacterium columnare*, *Flavobacterium croceum*, *Flavobacterium saliperosum*, and *Flavobacterium suncheonense* share about 93–94% sequence similarity and the sequence similarity between *Flavobacterium indicum* and *Flavobacterium columnare* is as low as 90% (Kim et al., 2006a; Park et al., 2006a; Saha and Chakrabarti, 2006; Wang et al., 2006). Consequently, it would most likely be impossible to include all these species into a single new genus if it was decided to remove them from the genus *Flavobacterium*. Moreover, it has not been possible to identify common features shared by these organisms that would support their differentiation from members of the main branch. Because fatty acid profiles of *Flavobacterium* species have been determined using different procedures and different cultural conditions (see *Cell-wall composition*, above), it has unfortunately been impossible to compare the fatty acid profiles of the different clusters and

branches currently grouped in the genus. Hence, members of the smaller branch should preferably be maintained in the genus *Flavobacterium* pending further studies.

As shown in Figure 27, the branching pattern of the various 16S rRNA gene sequences available for *Flavobacterium columnare* strains clearly shows the three genomic groups (genomovars) repeatedly reported in this species (Arias et al., 2004; Darwish and Ismaiel, 2005; Schneck and Caslake, 2006; Triyanto and Wakabayashi, 1999a, b). Distinct 16S rRNA restriction patterns and particular signatures in the 16S rRNA gene sequence further support delineation of these groups (Triyanto and Wakabayashi, 1999a). The type strain and strain FK 401 belong to genomic group I, strains IAM 14820 and LP 8 to genomic group II, and strain IAM 14821 to genomic group III. 16S rRNA gene sequence similarities and DNA–DNA relatedness among members of genomic group I were 99.4–99.8% and 83–93%, respectively, whereas sequence similarities and DNA–DNA relatedness between representatives of groups I and II were 98.0–98.2% and 44–73%, respectively. The only representative of group III included in the study shared 96.5–97.2% sequence similarity and 45–70% DNA relatedness with members of the other groups (Triyanto and Wakabayashi, 1999a). Slightly lower values were reported by Schneck and Caslake (2006), with 97.9–98.7% 16S rRNA gene sequence similarity among members of genomic group I and 95.8–96.6% sequence similarity between representatives of groups I and III. However, these studies have failed to uncover a correlation between the genomic groups and either the temperature of isolation, the fish host, or the geographic origin. Furthermore, no phenotypic evidence has yet been found to support the splitting of *Flavobacterium columnare* into three different species or subspecies.

Taxonomic and nomenclatural issues in the genus *Flavobacterium* are dealt with by the Subcommittee on the Taxonomy of *Flavobacterium* and *Cytophaga*-like Bacteria of the International Committee on Systematics of Prokaryotes. The subcommittee has issued minimal standards for describing new taxa of the family *Flavobacteriaceae* (Bernardet et al., 2002).

It should be noted that the descriptions of each of 21 *Flavobacterium* species (*Flavobacterium aquatile*, *Flavobacterium antarcticum*, *Flavobacterium croceum*, *Flavobacterium daejeonense*, *Flavobacterium defluvi*, *Flavobacterium denitrificans*, *Flavobacterium flevense*, *Flavobacterium frigidarium*, *Flavobacterium frigidimaris*, *Flavobacterium gillisiae*, *Flavobacterium glaciei*, *Flavobacterium granuli*, *Flavobacterium indicum*, *Flavobacterium omnivorum*, *Flavobacterium saliperosum*, *Flavobacterium segetis*, *Flavobacterium soli*, *Flavobacterium suncheonense*, *Flavobacterium weaverense*, *Flavobacterium xanthum* and *Flavobacterium xinjiangense*) of the 40 species with validly published names was based on a single isolate, even though additional strains of *Flavobacterium xanthum* were subse-

quently isolated (Van Trappen et al., 2005). Descriptions of all these species, apart from *Flavobacterium aquatile* and *Flavobacterium flevense*, were published between 2001 and 2007, although the practice of single-strain description had been discouraged repeatedly (Bernardet et al., 2002; Christensen et al., 2001).

Acknowledgements

The authors wish to acknowledge Jean Euzéby (Ecole Nationale Vétérinaire, Toulouse, France) for correcting the etymology of a number of specific epithets in the List of Species, Brita Bruun (Hillerød Hospital, Denmark) for critically reviewing the manuscript, Richard Holt (Oregon State University) for checking Borg's PhD thesis in search of the first mention of [*Cytophaga*] *psychrophila*, Brian Tindall (DSMZ, Germany) for sharing his expertise on fatty acid analysis and chemotaxonomy, and Gregory D. Wiens (USDA/ARS) for tracing the problematic reference Chester (1897).

Differentiation of species of the genus *Flavobacterium*

Characteristics that differentiate species of the genus are listed in Table 24. Chemotaxonomic and molecular methods have also been evaluated for their ability to differentiate *Flavobacterium* species. Provided identical culture conditions are used, fatty acid profiles may be used to characterize some *Flavobacterium* species, e.g., *Flavobacterium columnare* (see *Cell-wall composition*, above). However, most of the fatty acid clusters delineated in a collection of polar *Flavobacterium* isolates actually contained multiple taxa, as shown by rep-PCR fingerprinting (Van Trappen et al., 2003, 2002). For instance, all strains of *Flavobacterium frigoris*, *Flavobacterium fryxellicola*, *Flavobacterium micromati*, *Flavobacterium psychrolimnae*, and *Flavobacterium xanthum* strains and most *Flavobacterium degerlachei* strains belonged to the same fatty acid cluster, whereas all 22 strains of *Flavobacterium gelidilacus* belonged to a different cluster (Van Trappen et al., 2002, 2003, 2004b, 2005). Strains sharing identical rep-PCR profiles were closely related, although not always at the species level. This technique allowed either differentiation of *Flavobacterium* species from each other or intraspecies typing. For instance, species-specific rep-PCR profiles were found in *Flavobacterium degerlachei*, *Flavobacterium micromati*, *Flavobacterium fryxellicola*, and *Flavobacterium psychrolimnae*, whereas two or three different rep-PCR profiles occurred in *Flavobacterium frigoris* and *Flavobacterium gelidilacus* (Van Trappen et al., 2003, 2004b, 2005).

List of species of the genus *Flavobacterium*

Preliminary note. All species with validly published names included in the genus *Flavobacterium* in the previous edition of the *Manual* (Holmes et al., 1984c) and in Holmes (1992), except *Flavobacterium aquatile*, have been reclassified in other or new genera. They are currently known under the following names: *Chryseobacterium balustinum*, *Chryseobacterium gleum*, *Chryseobacterium indologenes*, *Chryseobacterium indoltheticum*, *Elizabethkingia meningoseptica*, *Empedobacter brevis*, *Myroides odoratus*, *Sphingobacterium multivorum*,

Sphingobacterium spiritivorum, and *Sphingobacterium thalpophilum* (see the corresponding chapters in this volume; Takeuchi and Yokota, 1992; Vandamme et al., 1994a; Vancanneyt et al., 1996; Yabuuchi et al., 1983; Kim et al., 2005b). According to Takeuchi and Yokota (1992), *Flavobacterium yabuuchiae* (Holmes et al., 1988) is a later heterotypic synonym of *Sphingobacterium spiritivorum* (Holmes et al., 1982; Yabuuchi et al., 1983). Described by Yabuuchi et al. (1983), *Sphingobacterium mizutae* was transferred

to the genus *Flavobacterium* by Holmes et al. (1988) under the name *Flavobacterium mizutaii*; however, this organism has been clearly assigned to the genus *Sphingobacterium* in recent publications (see treatment of the genus *Sphingobacterium*; Gherna and Woese, 1992; Kim et al., 2006a).

Most bacterial species included in the *Flavobacterium* chapters of the 7th and 8th editions of the *Manual* (Weeks, 1974; Weeks and Breed, 1957) and considered *species incertae sedis* by Holmes et al. (1984c) have also been reclassified. They are currently known under the following names: *Halomonas halomophila*, *Microbacterium esteraromaticum*, *Microbacterium maritypicum*, *Novosphingobium capsulatum*, *Novosphingobium resinovorum*, *Pedobacter heparinus*, *Planomicrobium okeanokoites*, *Psychroflexus gondwanensis*, *Salegentibacter salegens*, *Terrimonas ferruginea*, and *Zobellia uliginosa* (see the corresponding chapters in this edition of the *Manual*). According to Yabuuchi et al. (1979) and to the catalogs of the major culture collections, the type and only strain of [*Flavobacterium*] *devorans* should be assigned to *Sphingomonas paucimobilis*. Among the *species incertae sedis* listed in the previous edition of the *Manual* (Holmes et al., 1984c) [*Flavobacterium*] *acidificum*, [*Flavobacterium*] *acidurans*, [*Flavobacterium*] *oceanosedimentum*, and [*Flavobacterium*] *thermophilum* have still not been assigned to other genera. Their names have been either included in the Approved Lists of Bacterial Names (Skerman et al., 1980) or validly published. Strains are available in culture collections, but 16S rRNA sequences are not. The reasons for excluding these poorly characterized species from the genus *Flavobacterium* have been given by Holmes et al. (1984c) and Holmes (1993).

The name "*Flavobacterium aureum*" had been proposed, although not validly published, for *Flavobacterium* strains of CDC group IIb by Price and Pickett (1981). These strains have later been transferred to the genus *Chryseobacterium* (see the corresponding chapter in this volume). A bacterium responsible for hemorrhagic septicemia in farmed bullfrog in Taiwan had received the provisional name "*Flavobacterium ranacida*" (Faung et al., 1996 and references therein); this organism and similar isolates from other frog species were later identified as *Elizabethkingia meningoseptica* (previously *Chryseobacterium meningosepticum*; Bernardet et al., 2005). Strain NRRL B-184, tentatively named "*Flavobacterium aurantiacum*", is able to remove aflatoxin from peanut milk (Diarra et al., 2005). According to the online catalog of the Agricultural Research Service Culture Collection (USA), it is actually a strain of *Rhodococcus corynebacteroides* (previously *Nocardia corynebacteroides*). "*Flavobacterium chlorophenolica*" ATCC 39723, isolated from pentachlorophenol-contaminated soil in Minnesota, can mineralize pentachlorophenol at concentrations of 100–200 mg/l. This organism, which has been the subject of many publications since 1985, has recently been reclassified in the genus *Sphingomonas* on the basis of its 16S rRNA gene sequence (Nohynek et al., 1995).

Editorial note: the following novel species have been added to the genus *Flavobacterium* after this chapter was completed and their names have been validly published in the *International Journal of Systematic and Evolutionary Microbiology*: *Flavobacterium terrigena* (Yoon et al., 2007a), *Flavobacterium terrae* and *Flavobacterium cucumis* (Weon et al., 2007), *Flavobacterium filum* (Ryu et al., 2007), *Flavobacterium ceti* (Vela et al., 2007), *Flavobacterium lindanitolerans* (Jit et al., 2008), *Flavobacterium cheniae* (Qu et al., 2008) and *Flavobacterium anhuiense* (Liu et al., 2008).

A complete list of organisms currently belonging to the genus or that were previously attributed to it are available in the List of Prokaryotic Names with Standing in Nomenclature (LPSN) (Euzéby, 1997; <http://www.bacterio.cict.fr/>). This list also provides the current taxonomic status and standing in nomenclature of the taxa that were subsequently excluded from the genus *Flavobacterium*. For instance, according to the LPSN, the name "*Flavobacterium farinofermentans*" Bai (1983) has no standing in nomenclature.

1. ***Flavobacterium aquatile*** (Frankland and Frankland 1889) Bergey, Harrison, Breed, Hammer and Huntoon 1923, 100^{AL} emend. Bernardet, Segers, Vancanneyt, Berthe, Kersters and Vandamme 1996, 140^{VP} [*Bacillus aquatilis* Frankland and Frankland 1889, 381; *Bacterium aquatilis* (Frankland and Frankland 1889) Chester 1897, 96; *Flavobacterium aquatilis* (Frankland and Frankland 1889) Bergey, Harrison, Breed, Hammer and Huntoon 1923, 100; *Chromobacterium aquatilis* (Frankland and Frankland 1889) Topley and Wilson 1929, 404; *Empedobacter aquatile* (Frankland and Frankland 1889) Brisou, Tysset and Jacob 1960, 359]

a.qua'ti.le. L. neut. adj. *aquatile* living in water.

Rods, approximately 0.5–0.7 × 1.0–3.0 µm; longer rods and filaments also occur. Colonies on agar media at 25–30°C are light yellow in color, circular with entire edges, even on Anacker and Ordal's agar on which gliding bacteria usually produce spreading colonies. At 15–20°C, colonies are bright orange with a mucoid consistency. Growth does not occur at 37°C. Catalase-positive. Peptones are used as nitrogen sources, but urea and Casamino acids are not. Tributyrin and lecithin are hydrolyzed. Indole is not produced. Acid but no gas is produced aerobically from glucose, lactose, maltose, and sucrose, but not from arabinose, cellobiose, ethanol, fructose, mannitol, raffinose, rhamnose, salicin, trehalose, or xylose (Holmes et al., 1984c; Wakabayashi et al., 1989). Resistant to the vibriostatic compound O/129 (Bernardet et al., 1996). Other characteristics are as given in the genus description and in Tables 24 and 25.

The long and complex history of this organism, its status as type species of the genus, the unique strain, and its much debated motility and status as neotype strain have been reviewed extensively (see *Taxonomic comments*, above, as well as: Weeks, 1955, 1981; Holmes and Owen, 1979; Holmes et al., 1984c; Holmes, 1992). Perry (1973) observed gliding motility in hanging drop preparations and on agar plates on which he had added small glass beads (although the strain did not produce spreading growth on agar, as most gliding bacteria do), but his view was not shared by other authors (Holmes et al., 1984c and references therein). Consequently, the ability of *Flavobacterium aquatile* to glide still has to be unequivocally established. Using recommended techniques (Bernardet et al., 2002), gliding motility was not observed (J.-F. Bernardet, personal observation). The pseudoflagella and nonfunctional flagella initially reported were later shown by electron microscopy to be non-flagellar appendages similar to those found on several gliding bacteria (Holmes and Owen, 1979; Holmes et al., 1984c and references therein). Although originally reported to contain ubiquinones (Callies and Mannheim, 1978), *Flavobacterium aquatile* was later shown to contain MK-6 as its

major respiratory quinone (Oyaizu and Komagata, 1981), as do all members of the family *Flavobacteriaceae*.

Source: the only available strain has purportedly been isolated from the water of the same deep well in the chalk region of Kent, England, as the original organism.

DNA G+C content (mol%): 32–33 (T_m).

(Neo)type strain: Taylor F36, ATCC 11947, CCUG 29304, CIP 103744, DSM 1132, IAM 12316, IFO (now NBRC) 15052, LMG 4008, NCIMB 8694, NCTC 9758.

Sequence accession no. (16S rRNA gene): M62797.

Note: the erroneous page number in Chester (1897) used in previous publications has been corrected thanks to G.D. Wiens who traced and provided the original paper.

2. **Flavobacterium antarcticum** Yi, Oh, Lee, Kim and Chun 2005a, 640^{VP}

ant.arc'ti.cum. L. neut. adj. *antarcticum* southern and, by extension, pertaining to Antarctica.

Rods, approximately $0.3\text{--}0.4 \times 0.5\text{--}1.3 \mu\text{m}$, frequently forming pairs. Although gliding motility was not reported in the original description, cells distinctly gliding and rotating have been observed in 48-h-old cultures in Anacker and Ordal's broth and tryptic soy broth (J.-F. Bernardet, personal observation). Movements are special, however, being shorter but sharper than those of other gliding *Flavobacterium* strains. Colonies on R2A agar are circular, convex, glistening, and yellow with entire margins. The consistency is butyrous, becoming mucoid after prolonged incubation. In addition to the media listed in Table 24, growth occurs on R2A agar, but not on cetrimide or MacConkey agars. Growth is aerobic (minimum doubling time, 4.9 h), but weak and poor growth was also observed under microaerobic and anaerobic conditions, respectively.

Catalase-positive. Arginine dihydrolase activity is present, but phenylalanine deaminase activity is absent. Indole is not produced and alkalization does not occur on Christensen's citrate agar. Acid is produced from glucose and maltose, but not from arabinose, cellobiose, fructose, lactose, mannitol, raffinose, rhamnose, salicin, sucrose, trehalose, or xylose. The list of enzymic activities detected in the API ZYM gallery is given in the original description. None of the compounds contained in the API 20NE gallery is assimilated. No precipitate is formed on egg-yolk agar, but the colonies are surrounded by clear zones. Elastin is not degraded. The maximum adsorption peak of the pigment is at 452 nm and the next shoulder peak is at 479 nm. Other characteristics are as given in the genus and original species descriptions and in Tables 24 and 25.

Source: the type and, so far, only strain was isolated from a soil sample of a penguin habitat near the King Sejong Station on King George Island, Antarctica.

DNA G+C content (mol%): 38.0 (HPLC).

Type strain: AT1026, CIP 108750, IMSNU 14042, JCM 12383, KCTC 12222.

Sequence accession no. (16S rRNA gene): AY581113.

3. **Flavobacterium aquidurense** Cousin, Päuker and Stackebrandt 2007, 247^{VP}

a.qui.du.ren'se. L. fem. n. *aqua* water; L. adj. *durus* hard; L. suff. *-ensis*, *-e* suffix used with the sense of belonging to

or coming from; N.L. neut. adj. *aquidurense* pertaining to hard water.

Rods, approximately $0.9 \times 2.8 \mu\text{m}$. Colonies on R2A, nutrient, and tryptic soy agars are 1–2.2 mm in diameter, yellow, circular, convex, and spreading with filamentous margins (R2A agar), non-spreading with undulate margins (tryptic soy agar), or umbonate with undulate margins (nutrient agar). Larger (3–8 mm), flat, spreading colonies with filamentous margins are formed on DSMZ medium 67. No growth occurs on MacConkey agar. Growth is aerobic and microaerobic.

Catalase-positive. Indole is not produced. Characteristics included in API ZYM, API 20NE, and GN MicroPlate galleries are given in the original description. The following biochemical characteristics are strain-dependent: nitrate reduction and utilization of *N*-acetyl-D-galactosamine, L-arabinose, D-cellobiose, D-fructose, D-galactose, α -D-lactose, melibiose, sucrose, trehalose, turanose, methyl pyruvate, L-alaninamide, L-alanine, and glycyl-L-aspartic acid. Other characteristics are as given in the genus and original species descriptions and in Tables 24 and 25.

Source: the spring of the Westerhöfer Bach, a hard-water creek from the western slopes of the Harz Mountains, in Westerhof, 40 km north of Göttingen, Germany. Five strains were isolated and characterized, but only the type strain was deposited in culture collections.

DNA G+C content (mol%): 33.5 (T_m).

Type strain: Cousin WB 1.1-56, CIP 109242, DSM 18293.

Sequence accession no. (16S rRNA gene): AM177392.

4. **Flavobacterium branchiophilum** corrig. Wakabayashi, Huh and Kimura 1989, 215^{VP} emend. Bernardet, Segers, Vancanneyt, Berthe, Kersters and Vandamme 1996, 140.

bran.chi.o.phi'lum. Gr. n. *branchion* gill; Gr. adj. *philos* loving; N.L. neut. adj. *branchiophilum* gill loving.

The original spelling of the specific epithet, *branchiophila* (*sic*), was corrected by von Graevenitz (1990).

Rods, approximately $0.5 \times 5.0\text{--}8.0 \mu\text{m}$. Filamentous cells 15–40 μm long also occur. *Flavobacterium branchiophilum* is one of the most fastidious *Flavobacterium* species (J.-F. Bernardet, personal observation). No growth occurs on tryptic soy, nutrient, or Mueller–Hinton agars. Growth is distinctly better on plain Anacker and Ordal's agar than on the enriched version that contains 5 g/l tryptone instead of 0.5 g/l and is commonly used for growing other fish pathogens. Other convenient media are modified Shieh's agar (Song et al., 1988), *Microcycclus–Spirosoma* agar (NCIMB medium 81), and medium for freshwater flexibacteria (NCIMB medium 218; Lewin, 1969). The best growth is achieved on casitone yeast extract agar (NCIMB medium 101) at 20–25°C (J.-F. Bernardet, unpublished data).

Catalase-positive. Acid but no gas is produced aerobically from cellobiose, fructose, glucose, maltose, raffinose, sucrose, and trehalose, but not from arabinose, lactose, mannitol, rhamnose, salicin, or xylose. Tributyrin and lecithin are degraded. Indole is not produced. The list of substrates hydrolyzed in the API ZYM gallery is given in the original description and in Bernardet et al. (1996). Susceptible to the vibriostatic compound O/129 (Bernardet et al., 1996). Other characteristics are as given in the genus

and original species descriptions and in Tables 24 and 25. A DNA G+C content range of 29–31 mol% was originally reported (Wakabayashi et al., 1989), but subsequent investigation of six strains yielded a range of approximately 33–34 mol% (Bernardet et al., 1996; J.-F. Bernardet, unpublished data).

Source: diseased gills of various freshwater fish species (mainly salmonids). This organism is the main causal agent of bacterial gill disease of fish in Japan, Republic of Korea, Hungary, Oregon (USA), and in Ontario (Canada) (Bernardet and Bowman, 2006). The type strain was isolated in 1977 from the gills of a diseased fingerling yamame (*Oncorhynchus masou*) from a hatchery in Gumma Prefecture, Japan.

DNA G+C content (mol%): 32.5–34.2 (T_m).

Type strain: Wakabayashi BGD-7721, ATCC 35035, CCUG 33442, CIP 103527, IFO (now NBRC) 15030, LMG 13707, NCIMB 12904.

Sequence accession no. (16S rRNA gene): D14017.

5. **Flavobacterium columnare** (Bernardet and Grimont 1989) Bernardet, Segers, Vancanneyt, Berthe, Kersters and Vandamme 1996, 140^{VP} [*Bacillus columnaris* Davis 1922, 263; *Chondrococcus columnaris* (Davis 1922) Ordal and Rucker 1944, 18; *Cytophaga columnaris* (Davis 1922) Garnjobst 1945, 127 and Reichenbach 1989b, 2046; *Flexibacter columnaris* (Davis 1922) Leadbetter 1974, 107 and Bernardet and Grimont 1989, 352]

co.lum.na're. L. neut. adj. *columnare* rising as a pillar, referring to the shape of the aggregates formed by the bacteria on external lesions of infected fish.

Rods, approximately $0.3\text{--}0.5 \times 3.0\text{--}10.0 \mu\text{m}$ in 48-h-old broth cultures; filamentous cells up to $25 \mu\text{m}$ occur. Colonies best display their typical flat, spreading, and rhizoid morphology on Anacker and Ordal's agar; they are greenish-yellow and adhere strongly to the agar (see *Colonial or cultural characteristics*, above). Some colonies have a raised, globular, or warty center. Different colony types (i.e., more or less rhizoid) may coexist on the same plate. In agitated Anacker and Ordal's broth cultures, numerous filamentous tufts of bacteria adhere to the glass and/or to the magnet. The particular odor of *Flavobacterium columnare* cultures has been repeatedly reported. Growth does not occur on nutrient agar (J.-F. Bernardet, personal observation), contrary to the report by Reichenbach (1989b). Growth at 37°C is strain-dependent. *Flavobacterium columnare* is the only *Flavobacterium* species whose colonies unequivocally adsorb Congo red; the Congo red-staining material has been shown to be an extracellular galactosamine glycan in the slime (Johnson and Chilton, 1966). Electron microscopy and biochemical studies have revealed the presence of a capsule that is thicker and denser in highly virulent strains than in low virulence ones (Decostere et al., 1999).

Catalase-positive. Arginine dihydrolase and lysine and ornithine decarboxylase activities are absent. Actively proteolytic. Different types of extracellular proteases have been identified; in combination with enzymes degrading the complex acidic polysaccharides of connective tissue (e.g., chondroitin sulfate and hyaluronic acid), they play a major role in the extensive skin and muscular necrotic lesions displayed by diseased fish (see comments below for

Flavobacterium psychrophilum). Peptones and casein hydrolysate serve as nitrogen sources, but NH_4^+ and NO_3^- do not. No acid is produced from carbohydrates. Tributyrin and lecithin are hydrolyzed. Starch degradation is medium-dependent: it is negative on 0.2% starch Anacker and Ordal's agar (Bernardet and Grimont, 1989), but positive on 0.2% starch Hsu-Shotts agar (Shamsudin and Plumb, 1996; Shoemaker et al., 2005). This point has been confirmed recently by testing ten strains in parallel on both media (C. Shoemaker, personal communication). The antibiotics to which *Flavobacterium columnare* are resistant and the substrates it hydrolyzes in the API ZYM gallery are listed in Bernardet and Grimont (1989) and Bernardet et al. (1996). Susceptible to the vibriostatic compound O/129 (Bernardet et al., 1996). Other characteristics are as given in the genus description and in Tables 24 and 25. Additional information can be found in Reichenbach (1989b), Bernardet and Grimont (1989), and Bernardet et al. (1996).

Three different genomic groups (genomovars) have been reported in *Flavobacterium columnare* (see *Taxonomic comments*, above), but the species has not been split due to the lack of phenotypic characteristics to differentiate them. Strain ATCC 43622 was erroneously considered a *Flavobacterium columnare* strain as shown by 16S rRNA and fatty acid data (McCammon et al., 1998; Shoemaker et al., 2005); it may actually belong to *Flavobacterium johnsoniae* (Darwish et al., 2004). Unfortunately, this strain has been used to characterize the glycopeptides of *Flavobacterium columnare* that may provide target molecules for fish vaccines (Vinogradov et al., 2003) and its 16S rRNA gene sequence has been used to infer phylogenetic relationships and to design PCR primers aimed at detecting and identifying *Flavobacterium columnare* strains (Bader and Shotts, 1998; Bader et al., 2003; Toyama et al., 1996).

Flavobacterium columnare is the causal agent of "columnaris disease" and is recognized as an important fish pathogen in temperate to warm freshwater worldwide, causing serious economic losses in a considerable variety of farmed and wild, food and ornamental fish. Virulence for fish has been demonstrated experimentally. For recent reviews on the bacterium and the infection it causes, see Austin and Austin (1999), Shotts and Starliper (1999), and Bernardet and Bowman (2006). No type strain had been designated and only strain NCIMB 1038^T was available in culture collections at the time when Reichenbach was writing the *Flavobacterium* chapter for the first edition of *Bergey's Manual of Systematic Bacteriology*. This strain was isolated in 1955 from the kidney of a diseased chinook salmon (*Oncorhynchus tshawytscha*) from the Snake River, WA, USA. However, because strain NCIMB 1038^T had lost the typical rhizoid and adherent colony morphology through repeated subcultures, Reichenbach (1989b) proposed to use as a neotype a substrain (NCIMB 2248^{NT}) that still displayed these characteristics.

Source: external lesions (and less frequently from internal organs) of diseased fish.

DNA G+C content (mol%): 32–33 (T_m , Bd).

(*Neo*)type strain: 1-S-2cl (Anacker and Ordal, 1955), ATCC 23463, CIP 103531, IAM 14301, LMG 10406, LMG 13035, NBRC 100251, NCIMB 1038, NCIMB 2248. The type strain belongs to genomovar 1.

Sequence accession no. (16S rRNA gene): Genomovar 1: AB078047 (type strain), AB010952 (strain FK 401). Genomovar 2: AB016515 (strain IAM 14820), AB015480 (strain LP 8). Genomovar 3: AB015481 (strain IAM 14821).

Reference strains: Genomovar 1: JIP 39/87 (ATCC 49513, CIP 103532), JIP 44/87 (ATCC 49512, CIP 103533). Genomovar 2: Wakabayashi EK28 (IAM 14820). Genomovar 3: Wakabayashi PH 97028 (IAM 14821, JCM 21327).

6. **Flavobacterium croceum** Park, Lu, Ryu, Chung, Park, Kim and Jeon 2006a, 2445^{VP}

cro'ce.um. L. neut. adj. *croceum* saffron-colored, yellow.

Straight or slightly curved rods, approximately 0.3–0.5 × 1.0–3.2 µm. Colonies on R2A agar are yellow, slightly raised, and circular with entire margins. Growth is severely inhibited by NaCl concentrations above 1%. Weak anaerobic growth occurs only after 16 d on R2A agar.

Catalase-negative. Arginine dihydrolase and lysine and ornithine decarboxylase activities are absent. Xanthine and hypoxanthine are not hydrolyzed. Indole is not produced. Citrate is not utilized. Acid is produced from L-arabinose, D-glucose, *myo*-inositol, lactose, melibiose, and raffinose, but not from D-fructose, D-galactose, D-mannitol, D-mannose, arbutin, or salicin. Enzymic activities detected in the API ZYM gallery and antibiotic resistances are listed in the original description. The major polar lipid is phosphatidylethanolamine; minor amounts of phosphatidylglycerol and phosphatidylcholine are also present. Other characteristics are as given in the genus and original species descriptions and in Tables 24 and 25.

Source: sludge that performed enhanced biological phosphorus removal in a laboratory-scale sequencing batch reactor (Republic of Korea); sodium acetate was supplied as sole carbon source.

DNA G+C content (mol%): 40.8 (HPLC).

Type strain: EMB47, DSM 17960, KCTC 12611.

Sequence accession no. (16S rRNA gene): DQ372982.

7. **Flavobacterium daejeonense** Kim, Weon, Cousin, Yoo, Kwon, Go and Stackebrandt 2006a, 1647^{VP}

da.e.je.o.nen'se. N.L. neut. adj. *daejeonense* of or belonging to Daejeon, a city in the Republic of Korea, from where the type strain was isolated.

Rods, approximately 0.5 × 2.0–3.0 µm. Colonies on R2A agar are yellow, convex, and circular with entire margins. No growth occurs on MacConkey agar.

Catalase-positive. Arginine dihydrolase activity is absent. Indole is not produced. D-Glucose, L-arabinose, D-mannose, and maltose are assimilated, but D-mannitol, *N*-acetylglucosamine, potassium gluconate, capric acid, adipic acid, malic acid, trisodium citrate, and phenylacetic acid are not. Enzymic activities detected in the API ZYM gallery are listed in the original description. In the API 50CH gallery, acid is produced from L-arabinose, D-xylose, D-galactose, D-glucose, D-fructose, D-mannose, esculin, maltose, D-lactose, melibiose, sucrose, inulin, and raffinose. Other characteristics are as given in the genus and species descriptions and in Tables 24 and 25.

Source: greenhouse soil, Daejeon city, Republic of Korea.

DNA G+C content (mol%): 35.0 (HPLC).

Type strain: GH1-10, DSM 17708, KACC 11422.

Sequence accession no. (16S rRNA gene): DQ222427.

8. **Flavobacterium defluvii** Park, Ryu, Vu, Ro, Yun and Jeon 2007, 235^{VP}

de.flu'vi.i. L. gen. n. *defluvii* of sewage.

Rods, approximately 0.4–0.5 × 2.3–6.5 µm. Some cells show a knar. Colonies on R2A agar are pale yellow, glistening, translucent, irregular, slightly raised with curled margins, and slightly sticky. Growth in R2A broth is severely inhibited by the addition of more than 2% NaCl. Good growth occurs on Luria–Bertani agar. Anaerobic growth is not observed after 7 d at 30°C on R2A agar, but weak growth occurs after 16 d. Because the strain is unable to reduce nitrate to nitrite and consequently grow by anaerobic respiration using nitrate or nitrite as an electron acceptor, it probably grows anaerobically by fermenting carbohydrates.

Catalase-positive. Tyrosine is not hydrolyzed, contrary to the statement in Table 1 of the original description (C.O. Jeon, personal communication). Indole and acetoin are not produced. Citrate is not utilized. Acid is produced from L-arabinose, arbutin, D-fructose, D-galactose, D-glucose, lactose, D-mannitol, D-mannose, melibiose, *myo*-inositol, and raffinose, but not from salicin. Enzymic activities detected in the API ZYM gallery and antibiotic resistances are listed in the original description. The major polar lipid is phosphatidylethanolamine. Other characteristics are as given in the genus and original species descriptions and in Tables 24 and 25.

Source: sludge that performed enhanced biological phosphorus removal in a laboratory-scale sequencing batch reactor (Pohang, Republic of Korea).

DNA G+C content (mol%): 33.5 (HPLC).

Type strain: Park EMB117, DSM 17963, KCTC 12612.

Sequence accession no. (16S rRNA gene): DQ372986.

9. **Flavobacterium degerlachei** Van Trappen, Vandecandelaere, Mergaert and Swings 2004b, 89^{VP}

de.ger.lache'i. N.L. masc. gen. n. *degerlachei* of de Gerlache, named after Adrien de Gerlache, the Belgian pioneer who conducted the first scientific expedition in Antarctica in 1897–1899.

Rods, approximately 1 × 3–4 µm, frequently forming pairs or short chains. Although gliding was not reported in the original description, gliding and rotating cells have been observed distinctly in a 48-h-old R2A broth culture (J.-F. Bernardet, personal observation). Colonies on R2A agar are yellow, convex, translucent with entire margins, non-adherent, and 1–3 mm in diameter after 6 d.

Catalase-positive. Arginine dihydrolase, lysine and ornithine decarboxylase, and tryptophan deaminase activities are absent. Enzymic activities detected in the API ZYM gallery are listed in the original description. Glucose, mannose, and maltose are assimilated in the API 20NE gallery. Acid is not produced from carbohydrates in the API 20E gallery. Indole and acetoin are not produced.

Citrate is not utilized. Other characteristics are as given in the genus and original species descriptions and in Tables 24 and 25.

Source: microbial mats from hyposaline to saline lakes in the Vestfold Hills and Larsemann Hills, eastern Antarctica. The 14 original isolates all belong to the same rep-PCR cluster, but are divided into two different fatty acid clusters.

DNA G+C content (mol%): 33.8–34.2 (HPLC).

Type strain: Mergaert R-9106, AC23, CIP 108386, DSM 15718, LMG 21915.

Sequence accession nos (16S rRNA gene): AJ557886 (type strain), AJ441005 (strain LMG 21474).

10. **Flavobacterium denitrificans** Horn, Ihssen, Matthies, Schramm, Acker and Drake 2005, 1263^{VP}

de.ni.tri.fi.cans. N.L. part. adj. *denitrificans* denitrifying.

Rods, approximately $0.3\text{--}0.9 \times 0.8\text{--}5.0 \mu\text{m}$, frequently forming chains of 3–14 cells. Cells may be connected by cellular bridges. Although motility was mentioned in the original description, the type of motility was not specified. Distinct though slow gliding and rotating movements, as well as spheroplasts, were observed in a 48-h-old Anacker and Ordal's broth culture (J.-F. Bernardet, personal observation). Colonies on tryptic soy agar are yellow to dark yellow, flat, circular to irregular, with entire margins. The doubling time under optimal conditions is 7.3 h. Facultatively anaerobic growth occurs in mineral medium by complete denitrification. Membranes contain ϵ -type cytochromes.

Catalase-positive. Arginine dihydrolase activity is present. Lysine decarboxylase and phenylalanine deaminase activities are absent. Indole is not produced. Arabinose, cellobiose, fructose, fumarate, gelatin, glucose, glutamate, inulin, lactose, maltose, mannitol, mannose, *N*-acetylglucosamine, pectin, starch, succinate, and xylose are utilized. 1-Butanol, 1-propanol, acetate, butyrate, chitin, citrate, ethanol, ethanolamine, glycerol, glycolate, isobutyrate, inositol, isovalerate, lactate, oxalate, propionate, raffinose, sucrose, sorbitol, and tartrate are not utilized. Ammonium is used as a nitrogen source. O_2 , NO_3^- , and NO_2^- are used as electron acceptors. N_2O is produced as an intermediate during the reduction of NO_3^- to N_2 . SO_4^{2-} and Fe^{3+} are not used as electron acceptors. Does not grow by fermentation. Other characteristics are as given in the genus and original species descriptions and in Tables 24 and 25. The fatty acid composition has been determined by Cousin et al. (2007).

Source: gut of the earthworm *Aporrectodea caliginosa* collected from garden soil in Bayreuth, Germany. Because denitrifying bacteria retrieved from the gut are usually derived from the soil, the authors considered *Flavobacterium denitrificans* to be a soil organism (H.L. Drake, personal communication).

DNA G+C content (mol%): 34.6 (HPLC).

Type strain: ED5, ATCC BAA-842, CIP 109214, DSM 15936.

Sequence accession no. (16S rRNA gene): AJ318907.

11. **Flavobacterium flevense** (van der Meulen, Harder and Veldkamp 1974) Bernardet, Segers, Vancanneyt, Berthe, Kersters and Vandamme 1996, 141^{VP} (*Cytophaga flevensis* van der

Meulen, Harder and Veldkamp 1974, 340 and Reichenbach 1989c, 2038)

fle.ven'se. L. n. *Flevum* a former inner sea in the central part of The Netherlands which is now a freshwater lake called IJsselmeer; N.L. neut. adj. *flevense* of or belonging to *Flevum*.

Rods, approximately $0.5\text{--}0.7 \times 2.0\text{--}5.0 \mu\text{m}$; almost coccoid in old cultures. Colonies are circular, low convex, sunk in the agar, and yellow-colored due to the production of carotenoid pigments. Spreading is observed occasionally after 1–2 weeks on nutrient agar.

Catalase activity was originally reported as present. Reichenbach (1989b) considered it absent, whereas others have observed a distinctly positive reaction (J.-F. Bernardet, personal observation). Peptones, Casamino acids, NH_4^+ , and NO_3^- are used as N sources. Grows on peptone alone, but the presence of carbohydrates enhances growth. Tributyrin is hydrolyzed, but lecithin is not. Agar, agarose, arabinose, galactose, glucose, inulin, lactose, maltose, mannose, pectin, raffinose, rhamnose, sucrose, and xylose are assimilated. Cellobiose, fucose, ribose, trehalose, and alcohols are not assimilated. van der Meulen et al. (1974) and Reichenbach (1989b) found that starch was not degraded and that nitrate was reduced; opposite results, however, have been obtained by others (J.-F. Bernardet, personal observation). Indole is not produced. Resistant to novobiocin, penicillin G, polymyxin B, and streptomycin; sensitive to chloramphenicol, tetracycline, erythromycin, nalidixic acid, nitrofurantoin, and sulfafurazole. Susceptible to the vibriostatic compound O/129 (Bernardet et al., 1996). Other characteristics are as given in the genus and original species descriptions and in Tables 24 and 25. Additional information can be found in Christensen (1977), Reichenbach (1989b), and Bernardet et al. (1996).

Its ability to grow on media containing full-strength seawater and to degrade agar may suggest that *Flavobacterium flevense* was originally a marine organism that has progressively adapted to freshwater conditions following the separation of its habitat (polders) from the sea (Reichenbach, 1989b; Van der Meulen et al., 1974). A total of 25 Gram-stain-negative, yellow-pigmented, agarolytic strains have been isolated from the IJsselmeer and habitats in contact with this lake, but only strain A-34^T has been studied in detail and deposited in culture collections.

Source: freshwater and wet soil collected in the IJsselmeer (an old bay in the North Sea) area, The Netherlands.

DNA G+C content (mol%): 33–34.9 (Bd, T_m).

Type strain: van der Meulen A-34, ACAM 579, ATCC 27944, CCUG 14832, CIP 104740, DSM 1076, IFO (now NBRC) 14960, LMG 8328, NCIMB 12056.

Sequence accession no. (16S rRNA gene): M58767.

12. **Flavobacterium frigidarium** Humphry, George, Black and Cummings 2001, 1242^{VP}

fri.gi.da'ri.um. L. neut. adj. *frigidarium* of or for cooling, intended to mean belonging to the cold.

Rods, approximately $0.5\text{--}0.7 \times 0.8\text{--}2 \mu\text{m}$, occurring singly or in pairs, with a thick capsule and pili. Colonies on XMM agar (per l: 0.02 g FeSO_4 , 0.2 g MgSO_4 , 0.75 g KNO_3 , 0.5 g K_2HPO_4 , 0.04 g CaCl_2 , 5.0 g soluble xylan, 15.0 g agar) and

on tryptic soy agar are bright yellow, circular, and raised with entire margins. In the original description, the authors carefully stated that “there seemed to be adsorption of Congo red by colonies, indicating the presence of extracellular galactosamine glycan; this may be the capsular substance around the cell”. Adsorption of Congo red could not be confirmed, however (J.-F. Bernardet, personal observation). The bright yellow carotenoid pigment has been tentatively identified as zeaxanthin. Doubling times in XMM broth at 0, 5, 10, 15, and 20°C are 34.8, 28.1, 10.9, 9.6, and 13.1 h ($\pm 10\%$), respectively.

Catalase-positive. Arginine dihydrolase activity is absent. Indole and acetoin are not produced. Neither acid nor gas are produced from glucose, fructose, xylose, mannitol, and maltose. Enzymic activities detected in the API ZYM gallery and antibiotic resistances are listed in the original description. Growth occurs on casein, fructose, gelatin, glucose, glycerol, laminarin, maltose, mannitol, mannose, succinate, tryptone, xylan, and xylose as sole carbon and energy sources. No growth occurs on acetate, adipate, agar, arabinose, caprate, carboxymethylcellulose, chitin, citrate, galactose, gluconate, inositol, lactose, malate, *N*-acetylglucosamine, pectin, phenylacetate, pyruvate, raffinose, ribose, starch, sucrose, trehalose, or tyrosine. Other characteristics are as given in the genus and original species descriptions and in Tables 24 and 25.

Source: shallow-water Southern Ocean sediment recovered near Adelaide Island, Antarctica, during a systematic search for xylanolytic, laminarinolytic, pectinolytic, and cellulolytic bacteria.

DNA G+C content (mol%): 35 (T_m).

Type strain: A2i, ATCC 700810, CIP 107124, LMG 21010, NCIMB 13737.

Sequence accession no. (16S rRNA gene): AF162266.

Note: the strain deposited in the ATCC was originally named “*Flavobacterium xylanivorum*”.

13. ***Flavobacterium frigidimaris*** Nogi, Soda and Oikawa 2005a, 1743^{VP} (Effective publication: Nogi, Soda and Oikawa 2005b, 314.)

fri.gi.di.ma'ris. L. adj. *frigidus* cold; L. gen. n. *maris* of the sea; N.L. gen. n. *frigidimaris* of a cold sea.

Rods, approximately $0.6\text{--}0.8 \times 1.5\text{--}2.0$ μm . Possibly capsulate (J.-F. Bernardet, personal phase-contrast microscopy observation). Colonies on tryptic soy agar are orange-yellow, circular, and low convex with entire to slightly irregular margins. Good growth also occurs on Luria-Bertani agar and on CY agar (per l: 3.0 g casitone, 1.36 g $\text{CaCl}_2 \cdot 2\text{H}_2\text{O}$, 1.0 g yeast extract, 15 g agar; pH 7.2).

Catalase-positive. Large amounts of NAD(P)^+ -dependent alcohol, aldehyde, threonine, valine, and glutamate dehydrogenases are produced. These enzymes are all active at low temperature; the latter three are thermolabile, whereas the two former are unexpectedly thermostable. Acid is produced from arabinose, cellobiose, fructose, galactose, glucose, maltose, mannitol, mannose, raffinose, sucrose, trehalose, and xylose. No acid is produced from glycerol, inositol, lactose, rhamnose, or sorbitol. Other characteristics are as given in the genus and original species descriptions and in Tables 24 and 25.

Source: Antarctic seawater.

DNA G+C content (mol%): 34.5 (HPLC).

Type strain: KUC-1, DSM 15937, JCM 12218.

Sequence accession no. (16S rRNA gene): AB183888.

14. ***Flavobacterium frigoris*** Van Trappen, Vandecandelaere, Mergaert and Swings 2004b, 90^{VP}

fri.go'ris. L. masc. n. *frigor* cold; L. gen. n. *frigoris* of the cold.

Rods, $<1 \times 4\text{--}6$ μm . Gliding motility was not reported in the original description, but gliding and rotating cells have been observed in 48-h-old Anacker and Ordal's and R2A broth cultures (J.-F. Bernardet, personal observation). Colonies on R2A agar are yellow, convex, translucent with entire margins, non-adherent, and 2–5 mm in diameter after 6 d.

Catalase-positive. Arginine dihydrolase, lysine and ornithine decarboxylase, and tryptophan deaminase activities are absent. Enzymic activities detected in the API ZYM gallery are listed in the original description. Glucose, mannose, and maltose are assimilated in the API 20NE gallery. No acid is produced from carbohydrates in the API 20E gallery. Acetoin and indole are not produced. Citrate is not utilized. Nitrate reduction is strain-dependent; the type strain does not reduce nitrate. Other characteristics are as given in the genus and original species descriptions and in Tables 24 and 25.

Source: microbial mats from freshwater, hyposaline, and saline lakes in the Vestfold Hills, Larsemann Hills, and McMurdo Dry Valleys, eastern Antarctica. The 19 original isolates all belong to the same fatty acid cluster but are divided into two different rep-PCR clusters. Four additional strains originating from the same locations were identified during a later study (Van Trappen et al., 2005).

DNA G+C content (mol%): 33.8–34.5 (HPLC).

Type strain: Mergaert R-9014, WA11, CIP 108385, DSM 15719, LMG 21922.

Sequence accession no. (16S rRNA gene): AJ557887 (type strain), AJ440988 (strain LMG 21471).

15. ***Flavobacterium fryxelicola*** Van Trappen, Vandecandelaere, Mergaert and Swings 2005, 771^{VP}

fry.xel.li'co.la. N.L. n. *Fryxellum* Lake Fryxell; L. suff. *-cola* from L. n. *incola* dweller; N.L. n. (nominative in apposition) *fryxelicola* a dweller of Lake Fryxell.

Rods, approximately $1.0\text{--}1.5 \times 3.0\text{--}4.0$ μm . Colonies on R2A agar are yellow-orange, convex, and translucent with entire margins after 6 d.

Catalase-positive. Arginine dihydrolase, lysine and ornithine decarboxylase, and tryptophan deaminase activities are absent (API 20E). Enzymic activities detected in the API ZYM gallery are listed in the original description. Glucose and maltose are assimilated, but arabinose, mannitol, mannose, *N*-acetylglucosamine, gluconate, caprate, adipate, malate, citrate, and phenylacetate are not (API 20NE). Acid is not produced from carbohydrates (API 20E). Acetoin is produced, but indole is not produced. Citrate is not utilized. Other characteristics are as given in the genus and original species descriptions and in Tables 24 and 25.

Flavobacterium fryxelicola belongs to the same fatty acid cluster as all strains of *Flavobacterium frigoris*, *Flavobacterium micromati*, *Flavobacterium psychrolimnae*, and *Flavobacterium*

xanthum, plus some *Flavobacterium degerlachei* strains, but it displays a distinct rep-PCR profile (Van Trappen et al., 2002, 2003, 2004b, 2005).

Source: microbial mats in the fresh/brackish water of Lake Fryxell, McMurdo Dry Valleys, eastern Antarctica.

DNA G+C content (mol%): 35.2–35.9 (HPLC).

Type strain: Mergaert R-7548, FR 64, CIP 108325, DSM 16209, LMG 22022.

Sequence accession no. (16S rRNA gene): AJ811961.

16. **Flavobacterium gelidilacus** Van Trappen, Mergaert and Swings 2003, 1243^{VP}

ge.li.di.la.'cus. L. adj. *gelidus* ice-cold; L. n. *lacus* lake; N.L. gen. n. *gelidilacus* of an ice-cold lake, referring to the isolation source, microbial mats in Antarctic lakes.

Rods, approximately $<1 \times 2\text{--}4 \mu\text{m}$; some longer cells also occur. Gliding was reported as strain-dependent in the original description, the type strain and strain LMG 21619 being negative for this characteristic. However, gliding and rotating cells, as well as spheroplasts, have been observed in 4-d-old Anacker and Ordal's broth culture of the type strain (J.-F. Bernardet, personal observation). Colonies on R2A agar are yellow to orange, circular, convex, and translucent, 1–4 mm in diameter with entire margins after 6 d at 20°C. Colonies do not adhere to the agar.

Catalase-positive. Arginine dihydrolase, lysine and ornithine decarboxylase, and tryptophan deaminase activities are absent (API 20E). Gelatin is degraded, except by strain LMG 21619. Enzymic activities detected in the API ZYM gallery are listed in the original description. Glucose, arabinose, mannose, mannitol, *N*-acetylglucosamine, maltose, gluconate, caprate, adipate, malate, citrate, and phenylacetate are not assimilated (API 20NE). Acid is not produced from glucose, mannitol, inositol, sorbitol, rhamnose, sucrose, melibiose, amygdalin, or arabinose (API 20E). Acetoin and indole are not produced. Citrate is not utilized. Other characteristics are as given in the genus and original species descriptions and in Tables 24 and 25.

The 22 original isolates all belong to the same fatty acid cluster (that also contains all strains of *Flavobacterium frigoris*, *Flavobacterium micromati*, *Flavobacterium psychrolimnae*, and *Flavobacterium xanthum*, and some *Flavobacterium degerlachei* strains), but are divided into three different rep-PCR clusters.

Source: microbial mats from freshwater and saline lakes in the Vestfold Hills and Larsemann Hills, eastern Antarctica.

DNA G+C content (mol%): 30.0–30.4 (HPLC).

Type strain: Mergaert R-8899, AC 35, CIP 108171, DSM 15343, LMG 21477.

Sequence accession no. (16S rRNA gene): AJ440996 (type strain), AJ507151 (strain LMG 21619).

17. **Flavobacterium gillisiae** McCammon and Bowman 2000, 1059^{VP}

gil.lis'i.ae. N.L. gen. fem. n. *gillisiae* of Gillis, named after Monique Gillis, a Belgian microbiologist who pioneered new techniques for bacterial taxonomy.

Rods, approximately $0.4\text{--}0.5 \times 2\text{--}5 \mu\text{m}$. Colonies on R2A agar are orange, convex, circular with entire margins, and have a butyrous consistency. No growth occurs fermentatively

or by anaerobic respiration using ferric iron, nitrate, nitrite, or trimethylamine *N*-oxide as electron acceptors.

Catalase-positive. Arginine dihydrolase activity is present, but lysine and ornithine decarboxylase and tryptophan deaminase activities are absent. Acetoin and indole are not produced. Citrate is not utilized. Sodium nitrate, ammonium chloride, L-glutamate, peptone, and Casamino acids serve as nitrogen sources. Vitamins are not required for growth but are stimulatory. Acid is produced from glucose, mannose, galactose, fructose, sucrose, trehalose, cellobiose, maltose, mannitol, and glycerol, but not from arabinose, rhamnose, xylose, lactose, melibiose, raffinose, adonitol, sorbitol, or inositol. Uric acid and xanthine are not degraded. Other characteristics are as given in the genus and original species descriptions and in Tables 24 and 25.

Source: coastal sea ice from Prydz Bay, Antarctica.

DNA G+C content (mol%): 32 (T_m).

Type strain: ACAM 601, CIP 107449, LMG 21422.

Sequence accession no. (16S rRNA gene): U85889.

18. **Flavobacterium glaciei** Zhang, Wang, Liu, Dong and Zhou 2006, 2924^{VP}

gla.ci'e.i. L. gen. n. *glaciei* of ice, referring to the isolation source, the China No. 1 glacier.

Rods, approximately $0.45\text{--}0.55 \times 2.7\text{--}6.3 \mu\text{m}$. Colonies on PYG agar (per l: 5.0 g peptone, 0.2 g yeast extract, 3.0 g beef extract, 5.0 g glucose, 0.5 g NaCl, and 1.5 g $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$; amount of agar unspecified) are yellow, smooth, convex, and circular with entire margins.

Catalase-positive. Arginine dihydrolase, lysine and ornithine decarboxylase, and tryptophan deaminase activities are absent. Acid is not produced from carbohydrates. The following substrates are assimilated: glucose, maltose, sucrose, trehalose, mannose, dextrin, asparagine, L-glutamic acid, and glucose 1-phosphate. The following substrates are not assimilated: fructose, fucose, galactose, arabinose, cellobiose, rhamnose, lactose, raffinose, melibiose, sorbitol, turanose, xylitol, glycerol, inositol, erythritol, serine, threonine, alanine, histidine, leucine, aspartic acid, malonic acid, lactic acid, acetic acid, citric acid, pyruvate, succinate, and uridine. Acetoin is not produced. Citrate is not utilized. Other characteristics are as given in the genus and original species descriptions and in Tables 24 and 25.

Source: frozen soil collected from the China No. 1 glacier, Xinjiang Uygur Autonomous Region, China.

DNA G+C content (mol%): 36.5 (T_m).

Type strain: 0499, CGMCC 1.5380, CIP 109489, JCM 13953.

Sequence accession no. (16S rRNA gene): DQ515962.

19. **Flavobacterium granuli** Aslam, Im, Kim and Lee 2005, 750^{VP}

gra.nu'li. L. gen. n. *granuli* of a small grain, pertaining to a granule, from which the type strain was isolated.

Rods, approximately $0.3\text{--}0.5 \times 2.0\text{--}5.0 \mu\text{m}$. Colonies on R2A agar are yellow, smooth, non-glossy, convex, circular with entire margins, and 2–4 mm in diameter after 2 d. Colonies on Columbia and brain-heart infusion agars are bright yellow to orange-yellow.

Catalase-positive. Arginine dihydrolase, lysine and ornithine decarboxylase, and tryptophan deaminase activities are absent. Acid is not produced from glucose. Xylan is not degraded. The following substrates are utilized as sole carbon sources: glucose, mannose, *N*-acetylglucosamine, maltose, propionate, and *L*-proline. The following substrates are not utilized as sole carbon sources: *L*-arabinose, mannitol, gluconate, caprate, adipate, malate, citrate, phenylacetate, salicin, *D*-melibiose, *L*-fucose, *D*-sorbitol, valerate, histidine, 2-ketogluconate, 3-hydroxybutyrate, 4-hydroxybutyrate, rhamnose, *D*-ribose, inositol, *D*-sucrose, itaconate, suberate, malonate, acetate, lactate, *L*-alanine, 5-ketogluconate, glycogen, 3-hydroxybenzoate, and *L*-serine. Resistant to ampicillin, tetracycline, and streptomycin; sensitive to kanamycin. Acetoin is produced. Citrate is not utilized. Other characteristics are as given in the genus and original species descriptions and in Tables 24 and 25.

Source: granules used in the wastewater treatment plant of a beer-brewing factory in Kwang-Ju, Republic of Korea. These granules contained aerobic bacteria even though they had been kept under anaerobic conditions for 2 years.

DNA G+C content (mol%): 36.2 (HPLC).

Type strain: Lee Kw05, CIP 108709, KCTC 12201, IAM 15099.

Sequence accession no. (16S rRNA gene): AB180738.

20. **Flavobacterium hercynium** Cousin, Päuker and Stackebrandt 2007, 248^{VP}

her.cy'ni.um. L. neut. adj. *hercynium* of or belonging to *Hercynia*, the Roman name for a mountain range in Germany where the type strain was isolated.

Rods, approximately 0.7–0.8 × 5.8–6.3 μm. Gliding motility is observed on DSMZ medium 67 and on Anacker and Ordal's, nutrient, and R2A agars, but not on DNA or tryptic soy agars. Colonies are brown-beige on medium 67 and Anacker and Ordal's agars, and bright yellow to dark orange on R2A, DNA, nutrient, and tryptic soy agars. They are flat, spreading, with irregular lobate margins or no visible margins on medium 67, Anacker and Ordal's, and R2A agars and circular, non-spreading, umbonate with undulate margins on DNA and tryptic soy agars. No growth occurs on MacConkey agar. Growth is aerobic and microaerobic.

Catalase-positive. Indole is not produced. Gelatin hydrolysis and assimilation of *L*-arabinose and trisodium citrate are strain-dependent. Characteristics included in API ZYM, API 20NE, and GN MicroPlate galleries are given in the original description. Other characteristics are as given in the genus and original species descriptions and in Tables 24 and 25.

Source: isolated from a site located about 320 m downstream of the spring of the Westerhöfer Bach, a hard-water creek from the western slopes of the Harz Mountains, in Westerhof, 40 km north of Göttingen, Germany. Five strains were isolated and characterized, but only the type strain was deposited in culture collections.

DNA G+C content (mol%): 37.5 (T_m).

Type strain: WB 4.2-33, CIP 109241, DSM 18292.

Sequence accession no. (16S rRNA gene): AM265623 (type strain), AM177627 (strain WB 4.2-78).

21. **Flavobacterium hibernum** McCammon, Innes, Bowman, Franzmann, Dobson, Holloway, Skerratt, Nichols and Rankin 1998, 1411^{VP}

hi.ber'num. L. neut. adj. *hibernum* of winter.

Rods, approximately 0.7 × 1.8–13 μm. A thick capsule is produced when cultures are incubated at 4°C. Colonies on "maintenance medium" [per l: 1.0 g yeast extract, 5.0 g lactose (filter-sterilized), 0.5 g K₂HPO₄, 0.5 g (NH₄)₂SO₄, 0.55 g NaCl, 15.0 g agar] are discrete, opaque, shiny, convex, smooth, and yellow. Consistency is mucoid when plates are incubated at 25°C, but gelatinous at 4°C. Colonies on nutrient-poor media are flat, translucent, and spreading. Colonies on tryptic soy agar are orange-yellow. The theoretical minimum temperature for growth is -7°C.

Catalase-positive. Arginine dihydrolase, lysine and ornithine decarboxylase, and tryptophan deaminase activities are absent (API 20E). Oxidase activity was not found in the original study, but retesting of the type strain using dimethyl-*p*-phenylenediamine resulted in a distinctly positive oxidase reaction (J.-F. Bernardet, personal observation). Acid is produced from glucose, rhamnose, sucrose, and arabinose. Citrate is not utilized. Indole and acetoin are not produced (API 20E). Glucose, lactose, galactose, fructose, and sucrose are assimilated, but raffinose is not. The list of substrates utilized in the Biolog system is given in the original description. Utilization of formic acid, glucuronamide, and saccharic acid is strain-dependent. The optimum temperature for β-galactosidase activity is 38.6°C. Other characteristics are as given in the genus and original species descriptions and in Tables 24 and 25.

Source: surface freshwater of Crooked Lake, Vestfold Hills, Antarctica. Recently, a strain sharing 99% full-length 16S rRNA gene sequence similarity with the type strain of *Flavobacterium hibernum* and producing a cold-active xylanase has been isolated from a stream in California (Lee et al., 2006a).

DNA G+C content (mol%): 34 (type strain; HPLC).

Type strain: ACAM 376, ATCC 51468, CIP 105745, DSM 12611, LMG 21424.

Sequence accession no. (16S rRNA gene): L39067.

Note: the strains deposited in the Australian Collection of Antarctic Micro-organisms were originally named "*Flavobacterium ameridies*".

22. **Flavobacterium hydatis** (Strohl and Tait 1978) Bernardet, Segers, Vancanneyt, Berthe, Kersters and Vandamme 1996, 141^{VP} (*Cytophaga aquatilis* Strohl and Tait 1978, 302 and Reichenbach 1989c, 2043)

hy'da.tis. Gr. n. *hûdor* water; N.L. gen. n. *hydatis* from water.

Following reclassification of [*Cytophaga*] *aquatilis* in the genus *Flavobacterium*, the original specific epithet had to be changed because the new combination would have become a junior homonym of *Flavobacterium aquatile*. Hence, the new specific epithet *hydatis*, whose meaning is similar to that of the original epithet, was proposed for this taxon (Bernardet et al., 1996).

Rods, approximately 0.4–0.7 × 1.5–15.0 μm. Flexible. Coccoid forms and long filaments may occur. Colonies on relatively rich media are circular with entire margins,

convex, and yellow-pigmented. Anaerobic growth occurs in the presence of fermentable carbohydrates (see below) and yeast extract (or peptone), or during nitrate reduction. Colonies from anaerobically grown cultures are a light cream color or non-pigmented. Growth may occur up to 35°C, but the cultures degenerate rapidly at 30°C. Colonies do not adsorb Congo red, but the slime layer reportedly stains with ruthenium red.

Catalase-positive. In contrast to the original description, no hydrolysis of carboxymethylcellulose and a positive oxidase reaction have been found (J.-F. Bernardet, personal observation). Oxidase activity was also found by Oyaizu and Komagata (1981), and a weak reaction was reported by Reichenbach (1989b). Acid is produced fermentatively from arabinose, cellobiose, fructose, galactose, glucose, lactose, maltose, mannose, raffinose, sucrose, xylose, glycerol, dulcitol, and mannitol. The same compounds are also metabolized aerobically with acid production. Strong proteolytic activity. Tributyrin is hydrolyzed, but not lecithin. Indole is not produced. Citrate is not utilized. Peptones, Casamino acids, NH_4^+ , and NO_3^- can be used as N sources. Resistant to ampicillin, penicillin G, and polymyxin B; sensitive to chloramphenicol, erythromycin, kanamycin, nalidixic acid, neomycin, novobiocin, and tetracycline. Resistant to the vibriostatic compound O/129 (Bernardet et al., 1996). Other characteristics are as given in the genus and original species descriptions and in Tables 24 and 25. Additional information can be found in Reichenbach (1989b) and in Bernardet et al. (1996).

Source: isolated in 1974 from the gills of a salmon (species unrecorded) suffering from "bacterial gill disease", Platte River Fish Hatchery, Michigan, USA. Four of the five original strains have been lost. Pathogenicity has not been demonstrated experimentally.

DNA G+C content (mol%): 32.0–33.7 (Bd).

Type strain: Strohl strain N, Reichenbach Cyaq1, ATCC 29551, CCUG, 35201, CIP 104741, DSM 2063, IFO (now NBRC) 14958, LMG 8385, NRRL B-14732.

Sequence accession no. (16S rRNA gene): M58764.

23. **Flavobacterium indicum** Saha and Chakrabarti 2006, 2620^{VP}

in'di.cum. L. neut. adj. *indicum* of or belonging to India, from where the type strain was isolated.

Rods, approximately $0.1\text{--}0.2 \times 1\text{--}3 \mu\text{m}$, occurring singly and occasionally in pairs. Filamentous cells appear in ageing cultures (Saha and Chakrabarti, 2006), followed by numerous small spheroplasts (J.-F. Bernardet, personal observation). Colonies on modified R2A agar [containing 0.025% (w/v) Casamino acids instead of 0.05% and 0.075% (w/v) peptone instead of 0.05%] are yellowish orange, circular, and convex to slightly umbonate with irregular margins. Although no gliding motility was originally observed when a broth culture was examined under phase-contrast microscopy, a thin film of translucent growth with finger-like projections appeared at the margins of 5–7-d-old colonies, suggesting that gliding motility did occur on modified R2A agar (Saha and Chakrabarti, 2006). Indeed, moderate gliding and rotating was observed in Anacker and Ordal's and R2A broth cultures (J.-F. Bernardet, personal observation).

Good growth also occurs on 100× diluted tryptic soy agar (colonies on this medium are smaller and more adherent than on modified R2A) and on plain R2A, R3A, Anacker and Ordal's, full- and quarter-strength ZoBell, yeast extract, and NaCl-free nutrient agars. Weak growth occurs on plain nutrient, Luria–Bertani, and LY (Reichenbach, 1989b) agars. No growth occurs on plain tryptic soy, Simmons' citrate, or MacConkey agars.

Catalase activity is very weak. Hypoxanthine and xanthine are not hydrolyzed. No precipitate is formed on egg-yolk agar, but colonies are surrounded by clear zones. D-Fructose and (to a lesser extent) inulin are utilized. L-Arabinose, D-amygdalin, D-galactose, D-glucose, glycerol, glycogen, D-mannose, L-rhamnose, D-sorbitol, and L-xylose are very weakly utilized. Adonitol, D-arabinose, L-arabitol, arbutin, D-cellobiose, dulcitol, *myo*-inositol, D-lactose, D-mannitol, maltose, melibiose, melezitose, raffinose, D-ribose, L-sorbose, sucrose, trehalose, xylitol, and D-xylose are not utilized. Acid is produced from D-fructose and (very weakly) from D-glucose, glycogen, inulin, L-xylose, and D-mannose, but not from the other carbohydrates tested. Antibiotic resistances are listed in the original description. Other characteristics are as given in the genus and original species descriptions and in Tables 24 and 25.

Source: water of a warm (37–38°C) spring in a forest reserve in Assam, India. The spring was undisturbed by human activities but frequented by wild animals.

DNA G+C content (mol%): 31.0 (T_m).

Type strain: Saha and Chakrabarti GPTSA100-9, CIP 109464, DSM 17447, MTCC 6936.

Sequence accession no. (16S rRNA gene): AY904351.

24. **Flavobacterium johnsoniae** (Stanier 1947) Bernardet, Segers, Vancanneyt, Berthe, Kersters and Vandamme 1996, 141^{VP} [*Cytophaga johnsonae* Stanier 1947, 306 and Reichenbach 1989b, 2041; *Cytophaga johnsonii* (*sic*) (Stanier 1947) Stanier 1957, 860]

john.so.ni'ae. N.L. gen. fem. n. *johnsoniae* of Johnson, named after the American microbiologist Delia E. Johnson, who made an early study of chitinolytic gliding soil bacteria.

Following reclassification of [*Cytophaga*] *johnsonae* in the genus *Flavobacterium*, the original specific epithet has been corrected to *johnsoniae*.

Flexible rods, approximately $0.3\text{--}0.4 \times 1.5\text{--}15 \mu\text{m}$. Cells tend to become almost coccoid in ageing cultures, preceding the development of spheroplasts. Colonies on relatively rich media are circular with entire margins, convex, and bright yellow, whereas they are flat, spreading with rhizoid to filamentous margins, and pale yellow on media containing low nutrient concentration (e.g., Anacker and Ordal). Deep orange and pale yellow variants have been reported for the type strain. Zeaxanthin is produced in addition to flexirubin-type pigments (Reichenbach, 1989b).

Catalase activity is present, though moderate. Peptones, Casamino acids, glutamate, proline, urea, and NH_4^+ are good N sources. Growth occurs on mineral salts media containing NH_4^+ and a carbohydrate, such as arabinose, cellobiose, chitin, galactose, glucose, inulin, lactose, maltose, mannose, raffinose, starch, sucrose, and xylose. Acid is produced from sugars and various polysaccharides are

degraded. Strongly proteolytic. Indole is not produced. Tributyrin is degraded, but not lecithin. The organism has a strictly aerobic metabolism. Reichenbach and other authors (Reichenbach, 1989b and references therein) considered the report of Christensen (1977) that the type strain was able to ferment glucose and to produce gas from NO_2^- to be erroneous. This strain is unable to use NO_3^- or fumarate as electron acceptor, but one of Stanier's five original [*Cytophaga johnsonae*] isolates grew anaerobically "to a slight extent", reducing NO_3^- to NO_2^- . It is uncertain, however, whether all five strains belonged to the same species. This is even more the case of Stanier's sixth strain, labeled "var. *denitrificans*", which grew abundantly in anaerobic conditions by denitrification and produced copious amounts of N_2 . Resistant to the vibriostatic compound O/129 (Bernardet et al., 1996). Other characteristics are as given in the genus and species descriptions and in Tables 24 and 25. Additional information can be found in Christensen (1977), Reichenbach (1989b), and Bernardet et al. (1996).

Overall, *Flavobacterium johnsoniae* shows considerable phenotypic and genomic diversity (Reichenbach, 1989b). Many strains isolated from soil and freshwater environments and resembling Stanier's original strains have been labeled [*Cytophaga johnsonae*] or *Flavobacterium johnsoniae*, but it is likely that many of them actually belong to different species. Many *Flavobacterium johnsoniae*-like organisms have also been isolated from superficial lesions of diseased fish and considered opportunistic pathogens. There have been, however, cases of fish disease in which *Flavobacterium johnsoniae* indeed seemed to be the causative agent, but DNA-DNA hybridization between the isolates and the type strain has not been performed to confirm their identification (Bernardet and Bowman, 2006 and references therein). Strains ATCC 29585 and 29586, isolated from diseased fish in Manitoba, Canada, as well as the soil isolate NCIMB 11391 have shown insignificant DNA relatedness with the type strain and consequently cannot be considered *bona fide* *Flavobacterium johnsoniae* strains (Bernardet et al., 1996). Conversely, the two [*Flexibacter aurantiacus*] (Lewin, 1969) strains Lewin DWO and Lewin PSY included in the same study were shown to share significant DNA relatedness with the type strain of *Flavobacterium johnsoniae*, the proposed transfer of these two strains to the species *Flavobacterium johnsoniae* was supported by similarities in phenotypic features and fatty acid composition (Bernardet et al., 1996). The *Flavobacterium johnsoniae* type strain and the two [*Flexibacter aurantiacus*] strains, however, showed rather different whole-cell protein profiles. Strain DSM 425 and the *Flavobacterium johnsoniae* type strain share only 22% DNA relatedness (Reichenbach, 1989b) and occupied rather separate positions in phylogenetic trees (data not shown). Another strain, Hayes S4/1 (=LMG 13161=NCIMB 11391) is available in culture collections, but DNA-DNA hybridization with the type strain has not been performed. Extensive studies are needed to properly delineate this species and to reject misidentified strains; novel *Flavobacterium* species may emerge from this process.

Source: as no type strain had been designated by Stanier (1947), Reichenbach (1989b) designated strain ATCC 17061 the cotype strain because it seemed to be one of the

authentic strains coming from Stanier's original collection and it had been extensively studied. This strain had been isolated from a soil sample from Rothamsted Experimental Station, UK. Of the only two strains that have been shown to share high DNA relatedness with the type strain, viz., NCIMB 1382 (=Lewin DWO=ATCC 23107=LMG 3987) and NCIMB 1455 (=Lewin PSY=ATCC 23108=LMG 10404), only the origin of the former strain is known: garden soil, Minneapolis, Minnesota. Most other strains available in culture collections have been retrieved from soil and freshwater habitats. Recently, three strains sharing very high near full-length (*16S rRNA gene*): rRNA gene sequence similarity with the type strain of *Flavobacterium johnsoniae* have been isolated from river epilithon in England (O'Sullivan et al., 2006).

DNA G+C content (mol%): 33–35.2 (T_m).

(Co)type strain: van Niel MYX 1.1.1, Reichenbach Cy j3, ATCC 17061, CCUG 35202, CFBP 3036, CIP 100931, DSM 2064, IFO (now NBRC) 14942, LMG 1340, LMG 1341, JCM 8514, NCIMB 11054.

Sequence accession no. (16S rRNA gene): AM230489 (type strain), M62792 (strain ATCC 23107).

25. **Flavobacterium limicola** Tamaki, Hanada, Kamagata, Nakamura, Nomura, Nakano and Matsumura 2003, 523^{VP}
li.mi.co'la. L. n. *limus* mud; L. suff. *-cola* from L. gen. n. *incola* dweller; N.L. n. (nominative in apposition) *limicola* a mud-dweller.

Rods, approximately $0.3\text{--}0.6 \times 1.1\text{--}3.2 \mu\text{m}$. Chains of 5–20 cells occur frequently and filamentous cells occasionally appear. Colonies on tryptic soy agar are bright orange-yellow, circular, and convex with entire margins. Adsorption of Congo red by colonies was reported in the original description, but others have not been able to observe it (J.-F. Bernardet, personal observation). Although agar is degraded, no liquefaction occurs and colonies are not sunk in the agar.

Catalase-positive. Arginine dihydrolase activity is present, but lysine and ornithine decarboxylase and tryptophan deaminase activities are absent. Other enzymic activities determined using API 20E, 20NE, ID32E, and ZYM galleries are listed in the original description. The production of extracellular proteases (investigated using hide powder azure as the substrate) by the three isolates is higher at 5°C than at 15 and 23°C. Indole and acetoin are not produced. Citrate is not utilized. Acid is not produced from any of the carbohydrates included in API 50CH strips and GN MicroPlates. In the latter, amino acids such as L-alanine, L-alanylglycine, L-asparagine, L-aspartic acid, L-glutamic acid, glycyl-L-aspartic acid, glycyl-L-glutamic acid, L-ornithine, L-proline, L-serine, and L-threonine allow for better growth than carbohydrates such as D-glucose, mannose, maltose, sucrose, starch, glycogen, and dextrin. Yeast extract stimulates growth. Uric acid is hydrolyzed, but xanthine is not. Agar degradation is revealed by flooding colonies with an I/KI solution. Other characteristics are as given in the genus and original species descriptions and in Tables 24 and 25.

Source: freshwater river sediments in Ibaraki Prefecture, Japan.

DNA G+C content (mol%): 34.0–34.8 (method not specified).

Type strain: Tamaki ST-82, CIP 107957, DSM 15094, JCM 11473, LMG 21930.

Sequence accession no. (16S rRNA gene): AB075230 (type strain), AB075231 (strain ST-10), AB075232 (strain ST-92).

26. **Flavobacterium micromati** Van Trappen, Vandecandelaere, Mergaert and Swings 2004b, 89^{VP}

mi.cro.ma'ti. N.L. gen. n. *micromati* arbitrary name referring to the MICROMAT project ("Biodiversity of microbial mats in Antarctic") in connection with which the strains were isolated.

Rods, $<1 \times 3\text{--}4 \mu\text{m}$. Colonies on R2A agar are orange-red, convex, translucent with entire margins, non-adherent, and 1–3 mm in diameter after 6 d.

Catalase-positive. Arginine dihydrolase, lysine and ornithine decarboxylase, and tryptophan deaminase activities are absent. Enzymic activities detected in the API ZYM gallery are listed in the original description. No growth occurs on carbohydrates in the API 20NE gallery and no acid is produced from carbohydrates in the API 20E gallery. Acetoin is produced. Indole is not produced. Citrate is not utilized. Other characteristics are as given in the genus and original species descriptions and in Tables 24 and 25.

The three original isolates all belong to the same rep-PCR and fatty acid clusters.

Source: microbial mats from freshwater, hyposaline, and saline lakes in the Vestfold Hills and Dry Valleys, eastern Antarctica

DNA G+C content (mol%): 33.1–34.4 (HPLC).

Type strain: Mergaert R-9192, GR 28, CIP 108161, LMG 21919.

Sequence accession no. (16S rRNA gene): AJ557888.

27. **Flavobacterium omnivorum** Zhu, Wang and Zhou 2003, 856^{VP}

om.ni.vo'rum. L. n. *omne* -is everything; L. v. *vorare* to devour; N.L. neut. adj. *omnivorum* eating everything, referring to the ability of the strain to degrade a wide range of macromolecules.

Rods, approximately $0.8 \times 2\text{--}5 \mu\text{m}$; filamentous cells also occur. A limited number of spheroplasts was observed in 4-d-old Anacker and Ordal's broth culture (J.-F. Bernardet, personal observation). Colonies on PYG agar [per l: 5.0 g polypeptone, 5.0 g tryptone, 10.0 g yeast extract, 10.0 g glucose, 40 ml salt solution, 15.0–20.0 g agar. Salt solution (per l): 0.2 g CaCl_2 , 0.4 g $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$, 1.0 g K_2HPO_4 , 1.0 g KH_2PO_4 , 10.0 g NaHCO_3 , 2.0 g NaCl] are orange-yellow, circular, convex, and smooth with entire margins.

Catalase-positive. Arginine dihydrolase, lysine and ornithine decarboxylase, and tryptophan deaminase activities are absent. Indole and acetoin are not produced. Citrate is not utilized. Peptone, Casamino acids, sodium nitrate, and ammonium chloride serve as nitrogen sources, but L-glutamate does not. Acid is not produced from glucose, fructose, xylose, mannitol, or maltose. Uric acid and xanthine are not degraded. Glucose, cellobiose, maltose, fructose, sorbose, sucrose, lactose, rhamnose, mannose, trehalose, melibiose, and arabinose are assimilated, but sorbitol, galactose, D-mannitol, raffinose, glycerol, inositol, and xylose are not. Other characteristics are as given in the genus and original species descriptions and in Tables 24 and 25.

Source: frozen soil enclosed within the China No. 1 glacier, Xinjiang Uygur Autonomous Region, China.

DNA G+C content (mol%): 35.2 (T_m).

Type strain: Zhou ZF-8, AS 1.2747, CIP 108050, JCM 11313, LMG 21986.

Sequence accession no. (16S rRNA gene): AF433174.

28. **Flavobacterium pectinovorum** (Dorey 1959) Bernardet, Segers, Vancanneyt, Berthe, Kersters and Vandamme 1996, 141^{VP} [*Flavobacterium pectinovorum* Dorey 1959, 94; *Empedobacter pectinovorum* (Dorey 1959) Kaiser 1961, 210; *Cytophaga pectinovora* (Dorey 1959) Reichenbach 1989c, 2042]

pec.ti.no.vo'rum. N.L. n. *pectinum* pectin, methylated polygalacturonic acids in plant cell walls; L. v. *vorare* to devour; N.L. neut. adj. *pectinovorum* pectin-devouring.

Rods, approximately $0.4\text{--}0.5 \times 1.0\text{--}5.0 \mu\text{m}$; longer forms (15–25 μm) may appear in rich media and in older cultures. Gliding motility, though not observed by Dorey (1959), has been reported by all other authors. Colonies on all media are bright yellow, circular, and low convex, with entire to lobate margins when incubated at 30°C, whereas pale yellow, flat, spreading swarms are produced at 22°C. The bacterial mass collected on agar is difficult to remove from the loop due to the production of a dry, sticky slime.

Catalase activity is present but moderate. Reichenbach (1989b) reported the presence of oxidase activity, whereas others have found a negative oxidase reaction (J.-F. Bernardet, personal observation). Peptones, Casamino acids, NH_4^+ , and NO_3^- are used as N sources. Grows on mineral media containing arabinose, cellobiose, glucose, inulin, lactose, maltose, pectin, sucrose, or xylose as the sole carbon and energy source, but glycerol, mannitol, and salicin do not allow growth. Acid is produced aerobically from carbohydrates. An inducible, extracellular pectinase (polygalacturonase) is produced; it creates shallow depressions around colonies on pectate gels before liquefying the whole gel. Strongly proteolytic. Indole is not produced. Susceptible to the vibriostatic compound O/129 (Bernardet et al., 1996). Other characteristics are as given in the genus and original species descriptions and in Tables 24 and 25. Additional information can be found in Christensen (1977), Reichenbach (1989b), and Bernardet et al. (1996).

The species was named *Flavobacterium pectinovorum* by Dorey (1959) but was not included in the *Approved Lists of Bacterial Names* (Skerman et al., 1980). Christensen (1977) proposed to reclassify the species as [*Cytophaga*] *johnsonae*, but Reichenbach (1989b) restored it as an independent species under the combination [*Cytophaga*] *pectinovora*, a decision supported by phenotypic differences and very low DNA relatedness between the two type strains.

Source: soil in Southern England. The seven other original strains differed only slightly from the type strain, but they have subsequently been lost. Recently, six strains sharing more than 99% near full-length 16S rRNA gene sequence similarity with the type strain of *Flavobacterium pectinovorum* have been isolated from a hard-water creek in Germany (Brambilla et al., 2007).

DNA G+C content (mol%): 34.0–35.5 (T_m , Bd).

Type strain: Dorey 81, Reichenbach Cy p1, ATCC 19366,

CIP 104742, DSM 6368, IFO (now NBRC) 15945, JCM 8518, LMG 4031, NCIMB 9059, USCC 1365.

Sequence accession no. (16S rRNA gene): D12669, AM230490.

29. **Flavobacterium psychrolimnae** Van Trappen, Vandecandelaere, Mergaert and Swings 2005, 771^{VP}

psy.chro.lim'nae. Gr. adj. *psychros* cold; Gr. fem. N. *limna* lake; N.L. gen. n. *psychrolimnae* of a cold lake.

Rods, approximately $0.5 \times 2.0 \mu\text{m}$. Colonies on R2A agar are yellow, convex, and translucent with entire margins after 6 d.

Catalase-positive. Arginine dihydrolase, lysine and ornithine decarboxylase, and tryptophan deaminase activities are absent (API 20E). Enzymic activities detected in the API ZYM gallery are listed in the original description. β -Galactosidase activity is detected in API 20E and API 20NE galleries, but not in the API ZYM gallery (S. Van Trappen, personal communication). Glucose, maltose, and mannose are assimilated, but arabinose, mannitol, *N*-acetylglucosamine, gluconate, caprate, adipate, malate, citrate, and phenylacetate are not (API 20NE). Acid is not produced from carbohydrates (API 20E). Acetoin and indole are not produced. Citrate is not utilized. Other characteristics are as given in the genus and original species descriptions and in Tables 24 and 25.

Flavobacterium psychrolimnae belongs to the same fatty acid cluster as all strains of *Flavobacterium frigidis*, *Flavobacterium fryxelicola*, *Flavobacterium micromati*, and *Flavobacterium xanthum* and some strains of *Flavobacterium degerlachei*, but it displays a distinct rep-PCR profile (Van Trappen et al., 2002, 2003, 2004b, 2005).

Source: microbial mats in fresh/brackish water lakes in the McMurdo Dry Valleys, eastern Antarctica.

DNA G+C content (mol%): 33.8–34.5 (HPLC).

Type strain: Mergaert R-7582, FR 57, CIP 108326, DSM 16141, LMG 22018.

Sequence accession no. (16S rRNA gene): AJ585428 (type strain), AJ585427 (LMG 22020).

30. **Flavobacterium psychrophilum** (Bernardet and Grimont 1989) Bernardet, Segers, Vancanneyt, Berthe, Kersters and Vandamme 1996, 142^{VP} [*Cytophaga psychrophila* Borg 1948, 120 and Reichenbach 1989c, 2044; *Flexibacter psychrophilus* (Borg 1948) Bernardet and Grimont 1989, 353]

psy.chro.phi'lum. Gr. adj. *psychros* cold; Gr. adj. *philos* loving; N.L. neut. adj. *psychrophilum* cold-loving.

Rods, approximately $0.4\text{--}0.5 \times 1.0\text{--}5.0 \mu\text{m}$; a few cells are longer (8–12 μm). Flexible cells may appear. Gliding motility is slow and readily discernable in some strains only. Narrow and uneven zones of spreading growth may appear at the margins of colonies on Anacker and Ordal's agar. Different colony types may occur on the same plate. The optimum growth temperature is 19–20°C for Japanese isolates (Uddin and Wakabayashi, 1997), but only 15°C for most US isolates (Holt et al., 1989). Growth at 23 and 25°C is strain-dependent and usually weak.

Catalase activity is present, though moderate. Arginine dihydrolase and lysine and ornithine decarboxylase activities are absent. Actively proteolytic. The different types of extracellular proteases have been considered important virulence factors, playing a significant role in the extensive

skin and muscular necrotic lesions displayed by diseased fish. These proteases degrade components of muscle, cartilage, and connective tissue such as elastin, type IV collagen, fibrinogen, gelatin, laminin, fibronectin, actin, and myosin. The two metalloproteases recently purified from *Flavobacterium psychrophilum* exhibit a broad range of hydrolytic activity and are adapted to low temperatures (Secades et al., 2001, 2003). Although unable to hydrolyze any of the commonly tested carbohydrates, *Flavobacterium psychrophilum* strains can degrade the complex acidic polysaccharides of connective tissue such as chondroitin sulfate and hyaluronic acid (Bernardet and Bowman, 2006 and references therein). In combination with the extracellular proteases, these polysaccharide-degrading enzymes most likely participate in tissue necrosis. Peptones and Casamino acids are suitable nitrogen sources. Acid is not formed from carbohydrates. Indole is not produced. Tributyrin and lecithin are hydrolyzed. The antibiotics to which *Flavobacterium psychrophilum* is resistant and the substrates it hydrolyzes in the API ZYM gallery are listed in Bernardet and Grimont (1989) and Bernardet et al. (1996). Susceptible to the vibriostatic compound O/129. Other characteristics are as given in the genus description and in Tables 24 and 25. Additional information and references can be found in Bernardet and Grimont (1989), Bernardet et al. (1996), and Bernardet and Bowman (2006). The whole-genome sequence of strain JIP 02/86 (=TG 02/86=ATCC 49511=CIP 103535) has been published (Duchaud et al., 2007).

Flavobacterium psychrophilum is the causal agent of severe infections ("bacterial cold-water disease" and "rainbow trout fry syndrome") in salmonid fish and has been isolated from external lesions and internal organs of the diseased fish. It is a significant pathogen that causes considerable economic losses in the salmonid aquaculture worldwide. Virulence for fish has been demonstrated experimentally. For reviews on the bacterium and on the diseases it is responsible for, see Holt et al. (1993), Austin and Austin (1999), Shotts and Starliper (1999), Nematollahi et al. (2003), and Bernardet and Bowman (2006). Because no type strain had been designated previously, Reichenbach (1989b) proposed strain NCIMB 1947, deposited by E.J. Ordal, as the cotype strain. This strain was isolated from the kidney of a diseased juvenile coho salmon (*Oncorhynchus kisutch*) in the state of Washington, but the year of isolation is unknown.

Source: external lesions and internal organs of infected salmonid fish.

DNA G+C content (mol%): 32.3–33.8 (T_m , Bd).

(Co)type strain: Ordal 3068, ATCC 49418, CCUG 35200, CIP 103534, DSM 3660, JCM 8519, LMG 13179, IAM 14308, IFO (now NBRC) 15942, NCIMB 1947.

Sequence accession no. (16S rRNA gene): AB078060 (type strain). The other sequence available for this strain, AF090991, is significantly different.

Note: the first mention of the name [*Cytophaga*] *psychrophila* has long been considered to be in a paper by Borg (1960), but an earlier mention was found in his PhD thesis (Borg, 1948) (R.A. Holt, personal communication), thus allowing the correction to the citation in the present description.

31. **Flavobacterium saccharophilum** (Agbo and Moss 1979) Bernardet, Segers, Vancanneyt, Berthe, Kersters and

Vandamme 1996, 142^{VP} (*Cytophaga saccharophila* Agbo and Moss 1979, 363 and Reichenbach 1989c, 2039)

sac.cha.ro.phi'lum. Gr. n. *saccharon* sugar; Gr. adj. *philos* loving; N.L. neut. adj. *saccharophilum* sugar-loving.

Rods, approximately $0.5\text{--}0.7 \times 2.5\text{--}6.0$ μm in length. Pleomorphism is common. Almost coccoid cells occur in ageing agar cultures, whereas slender flexible cells may appear in pure peptone liquid media. Gliding motility is slow, but active. Colonies on nutrient and tryptic soy agars are small, convex, circular, yellow-colored, slimy, and sit in shallow depressions. Large haloes of softened (not liquefied) agar surrounding the colonies are revealed by flooding with Lugol's reagent.

The presence of catalase and oxidase activities originally reported by Agbo and Moss (1979) was not confirmed by Reichenbach (1989b). Catalase activity was observed, but no oxidase activity was found using both a disc and a liquid oxidase reagent [dimethyl-*p*-phenylenediamine and tetramethyl-*p*-phenylenediamine, respectively (bioMérieux); J.-F. Bernardet, personal observation]. Peptones and NH_4^+ serve as sole source of nitrogen. Growth is possible on media containing only peptone, but is considerably improved by the addition of carbohydrates. Arabinose, cellobiose, fructose, galactose, glucose, lactose, maltose, mannose, melibiose, raffinose, rhamnose, sucrose, trehalose, and xylose, as well as agar, agarose, arabinogalactan, carrageenan, pectin, starch, and a few other polysaccharides are used as sole carbon and energy sources. The production of extracellular agarase is induced by the presence of agar or other galactans and polysaccharides associated with plants (e.g., arabinogalactan, starch, and pectin) and repressed by the presence of galactose or glucose. Following repeated subcultivation, two of the original isolates lost their ability to degrade agar. Oxidative metabolism of glucose was reported in the original description. Strongly proteolytic. Indole is not produced. The antibiotics to which *Flavobacterium saccharophilum* is resistant are listed in Agbo and Moss (1979) and Reichenbach (1989b). The substrates hydrolyzed in the API ZYM gallery are listed in Bernardet et al. (1996). Susceptible to the vibriostatic compound O/129. Other characteristics are as given in the genus and original species descriptions and in Tables 24 and 25. Additional information can be found in Reichenbach (1989b) and Bernardet et al. (1996). Although a DNA G+C content of 32 mol% was found using buoyant density (Reichenbach, 1989b), values close to 36 mol% were reported by Agbo and Moss (1979) and by Bernardet et al. (1996) using T_m .

Source: six strains were originally isolated during the summer of 1976 from the River Wey, Guildford, Surrey, UK. Although not formally designated the type strain in the original description, strain 024 is the only currently available strain. Recently, several strains sharing high near full-length 16S rRNA gene sequence similarity with the type strain of *Flavobacterium saccharophilum* have been isolated from river epilithon in England (O'Sullivan et al., 2006) and from a hard-water creek in Germany (Brambilla et al., 2007).

DNA G+C content (mol%): 35.7 (T_m).

Type strain: 024 Agbo and Moss, ACAM 581, ATCC 49530, CIP 104743, DSM 1811, IFO (now NBRC) 15944, JCM 8520, LMG 8384, NCIMB 2072.

Sequence accession no. (16S rRNA gene): D12671, AM230491.

32. **Flavobacterium saliperosum** Wang, Liu, Dai, Wang, Jiang and Liu 2006, 441^{VP}

sa.li.pe.ro'sum. L. n. *sal, salis* salt; L. neut. adj. *perosum* detesting, hating; N.L. neut. adj. *saliperosum* salt-hating.

Rods, approximately $0.35\text{--}0.55 \times 1.5\text{--}2.5$ μm . Small spheroplasts have been observed in 3-d-old Anacker and Ordal's broth culture (J.-F. Bernardet, personal observation). Colonies on modified ATCC medium M1 are yellow, circular, and smooth with entire margins. On tryptic soy agar, colonies are orange-yellow and circular with irregular margins.

Catalase-positive. Acetoin is not produced. Acid is not produced from lactose, arabinose, rhamnose, raffinose, ribose, galactose, melibiose, melezitose, sucrose, xylose, mannose, fucose, fructose, glucose, cellobiose, maltose, salicin, mannitol, or sorbitol. Antibiotic resistances are listed in the original description. Other characteristics are as given in the genus and original species descriptions and in Tables 24 and 25.

Source: sediment of the freshwater Taihu Lake, Jiangsu Province, China. The water quality of the lake has been declining in recent years, with algal blooms occurring regularly.

DNA G+C content (mol%): 41 (T_m).

Type strain: S13, CGMCC 1.3801, CIP 109164, JCM 13331.

Sequence accession no. (16S rRNA gene): DQ021903.

Note: the 16S rRNA sequence was originally deposited in GenBank under the name "*Flavobacterium saliodium*".

33. **Flavobacterium segetis** Yi and Chun 2006, 1243^{VP}

se.ge'tis. L. gen. n. *segetis* of the soil.

Rods, approximately $0.2\text{--}0.3 \times 1.1\text{--}2.3$ μm . Colonies on R2A agar are orange, convex, translucent, glistening, and circular with entire margins. Consistency is butyrous, becoming mucoid after prolonged incubation. Colonies do not adhere to the agar. No growth occurs on cetrimide or MacConkey agars. Grows well under aerobic conditions (minimum doubling time, 6.8 h), weakly under microaerobic conditions (i.e., with 5–15% O_2 and 5–12% CO_2), and poorly under anaerobic conditions (i.e., with 4–10% CO_2).

Catalase-positive. Arginine dihydrolase and L-phenylalanine deaminase activities are absent. The list of enzymic activities detected in API ZYM galleries is given in the original description. In this commercial system, β -galactosidase activity is not detected, whereas a positive result is observed in API 20NE galleries. Indole is not produced and citrate is not utilized. Acid is produced from D-cellobiose, D-glucose, trehalose, maltose, and sucrose, but not from D-fructose, D-mannitol, raffinose, D-salicin, D-xylose, L-arabinose, or L-rhamnose. Acid production from lactose only occurs after 4 weeks. Glucose, mannose, N-acetylglucosamine, and maltose are utilized as sole carbon sources in API 20NE galleries, but arabinose, mannitol, gluconate, caprate, adipate, malate, citrate, and phenylacetate are not. The maximum adsorption peak of pigment is at 472 nm and the next peak is at 452 nm. Other characteristics are as given in the genus and original species descriptions and in Tables 24 and 25.

Source: a soil sample of a penguin habitat near the King Sejong Station on King George Island, Antarctica.

DNA G+C content (mol%): 35 (HPLC).

Type strain: AT1048, CIP 109332, IMSNU 14050, JCM 12385, KCTC 12224.

Sequence accession no. (16S rRNA gene): AY581115.

34. **Flavobacterium soli** Yoon, Kang and Oh 2006d, 999^{VP}

so'li. L. gen. n. *soli* of the soil.

Rods, approximately $0.3\text{--}0.6 \times 1.0\text{--}3.0 \mu\text{m}$; filamentous cells also occur. Colonies on tryptic soy agar are cream-yellow, slightly convex, smooth, glistening, circular with entire margins, with a mucous to viscid consistency, and 2.0–3.0 mm in diameter after 3 d at 25°C. No anaerobic growth occurs on plain tryptic soy agar or on tryptic soy agar supplemented with nitrate.

Catalase-positive. Arginine dihydrolase, lysine and ornithine decarboxylase, and tryptophan deaminase activities are absent. Xanthine and hypoxanthine are not hydrolyzed. Indole is not produced. Antibiotic resistances and the list of enzymic activities detected with the API ZYM gallery are given in the original description. The only substrates utilized as sole carbon sources in the API 50CH gallery are L-arabinose, glucose, mannose, esculin, cellobiose, maltose, starch, gentiobiose, and 5-ketogluconate. Other characteristics are as given in the genus and original species descriptions and in Tables 24 and 25.

Source: soil samples collected on the island of Dokdo, East Sea (disputed between the Republic of Korea and Japan).

DNA G+C content (mol%): 36.9 (HPLC).

Type strain: DS-6, CIP 108840, KCTC 12542.

Sequence accession no. (16S rRNA gene): DQ178976.

35. **Flavobacterium succinicans** (Anderson and Ordal 1961) Bernardet, Segers, Vancanneyt, Berthe, Kersters and Vandamme 1996, 142^{VP} [*Cytophaga succinicans* Anderson and Ordal 1961, 136 and Reichenbach 1989c, 2045; *Flexibacter succinicans* (Anderson and Ordal 1961) Leadbetter 1974, 106] suc.ci'ni.cans. L. n. *succinum* amber; N.L. n. *acidum succinicum* succinic acid (derived from amber); N.L. part. adj. *succinicans* intended to mean forming succinic acid.

Rods, approximately $0.5 \times 4.0\text{--}6.0 \mu\text{m}$; longer (up to 40 μm) cells may occur. In ageing cultures, cell length decreases and diameter increases slightly, preceding the appearance of spheroplasts. Colonies on media with high nutrient concentration are low convex and circular with irregular margins, whereas pale yellow, thin, spreading colonies with rhizoid to filamentous margins appear on low-nutrient media. Non-spreading variants occur and different colony types may coexist on the same agar plate. Growth is usually aerobic, but facultatively anaerobic growth may occur if a fermentable carbohydrate and CO₂ (supplied as 15–25 mM NaHCO₃) are available. When grown anaerobically, the cell mass is unpigmented, whereas yellow-orange carotenoid pigments are produced during aerobic growth.

Catalase activity is absent or weak. Peptones, Casamino acids, glutamate, NH₄⁺, and NO₃⁻ serve as N sources. All strains ferment glucose, galactose, lactose (with a lag period of 6–38 d), maltose, mannose, and starch; some strains also ferment other carbohydrates. Fermentation products are

succinate, acetate, and formate. Only the type strain reduces NO₃⁻ to NO₂⁻. Susceptible to the vibriostatic compound O/129. Slight differences between the three strains in the list of fermentable carbohydrates, the catalase reaction, and the reduction of nitrate have been noticed by Anderson and Ordal (1961) and Reichenbach (1989b). Strain NCIMB 2278 has also been found to differ from the two other strains in its fatty acid composition and strain NCIMB 2279 displays a different whole-cell protein profile (Bernardet et al., 1996). No DNA hybridization experiments have been performed to verify whether the three strains belong to the same species. Other characteristics are as given in the genus and original species descriptions and in Tables 24 and 25. Additional information can be found in Reichenbach (1989b) and Bernardet et al. (1996).

Source: the type strain (strain Anderson and Ordal 8) was isolated in 1954 from the eroded caudal fin of a fingerling chinook salmon (*Oncorhynchus tshawytscha*) at the University of Washington hatchery. This strain was not formally designated the type strain in the original description; it was proposed as the cotype by Reichenbach (1989b). The two other strains were isolated in 1957 from the water of a tank containing salmonid fish in the same hatchery (strain Anderson and Ordal 16) and from a lesion on an adult chinook salmon taken from the Snake River at Brownlee Dam (Idaho) (strain Anderson and Ordal 14). The pathogenicity of the isolates for fish has not been tested experimentally; they were considered nonpathogenic by Anderson and Ordal (1961). No other strain has been isolated since then.

DNA G+C content (mol%): 34.0–36.7 (Bd, T_m).

(Cotype strain: Anderson and Ordal 8, Reichenbach Cysu3, CIP 104744, DSM 4002, IFO (now NBRC) 14905, LMG 10402, NCIMB 2277.

Sequence accession no. (16S rRNA gene): D12673.

36. **Flavobacterium suncheonense** Kim, Weon, Cousin, Yoo, Kwon, Go and Stackebrandt 2006a, 1648^{VP}

sun.che.o.nen'se. N.L. neut. adj. *suncheonense* of or belonging to Suncheon, a city in the Republic of Korea, from where the type strain was isolated.

Rods, approximately $0.3 \times 1.5\text{--}2.5 \mu\text{m}$. Colonies on R2A agar are yellow, convex, and circular with entire margins. No growth occurs on MacConkey agar.

Catalase-positive. Arginine dihydrolase activity is absent. Indole is not produced. None of the carbohydrates in the API 20NE gallery is assimilated. Acid is not produced from any of the substrates in the API 50CH gallery. Enzymic activities detected in the API ZYM gallery are listed in the species description. Other characteristics are as given in the genus and original species descriptions and in Tables 24 and 25.

Source: greenhouse soil, Suncheon city, Republic of Korea.

DNA G+C content (mol%): 39.0 (HPLC).

Type strain: GH29-5, DSM 17707, KACC 11423.

Sequence accession no. (16S rRNA gene): DQ222428.

37. **Flavobacterium tegetincola** McCammon and Bowman 2000, 1060^{VP}

te.ge.tin'co.la. L. n. *teges-etis* a mat or covering; L. n. *incola* dweller; N.L. n. *tegetincola* (nominative in apposition) a mat-dweller, pertaining to the cyanobacterial mat habitat.

Rods, approximately $0.4\text{--}0.5 \times 2\text{--}5 \mu\text{m}$. Colonies on R2A agar are yellow, convex, circular with entire margins, and have a butyrous consistency. No growth occurs fermentatively or by anaerobic respiration using ferric iron, nitrate, nitrite, or trimethylamine *N*-oxide as electron acceptors.

Catalase-positive. Arginine dihydrolase, lysine and ornithine decarboxylase, and tryptophan deaminase activities are absent. Acetoin and indole are not produced. Citrate is not utilized. Casamino acids serve as nitrogen sources, but not sodium nitrate, ammonium chloride, or L-glutamate. Vitamins are not required for growth. Acid is produced from glucose, fructose, and mannitol, but not from arabinose, galactose, rhamnose, xylose, sucrose, trehalose, cellobiose, maltose, melibiose, raffinose, adonitol, sorbitol, inositol, or glycerol. Uric acid and xanthine are not degraded. Other characteristics are as given in the genus and original species descriptions and in Tables 24 and 25.

Source: the type strain was isolated from cyanobacterial mat material collected from Ace Lake, a marine salinity meromictic lake located in the Vestfold Hills area of Antarctica. Only one other strain is known.

DNA G+C content (mol%): 32.0–34.0 (T_m).

Type strain: A103, ACAM 602, CIP 107447, LMG 21423.

Sequence accession no. (16S rRNA gene): U85887 (type strain), U85888 (ACAM 603).

38. **Flavobacterium weaverense** Yi and Chun 2006, 1242^{VP}

wea.ve.ren'se. N.L. neut. adj. *weaverense* of or belonging to the Weaver Peninsula in the Antarctic, the geographical origin of the type strain.

Rods, approximately $0.3\text{--}0.5 \times 1.6\text{--}12.5 \mu\text{m}$ during the exponential growth phase and $0.3\text{--}0.4 \times 0.7\text{--}1.5 \mu\text{m}$ during the stationary phase. Cells occur singly or in chains in R2A and tryptic soy broths; filamentous cells occur in Anacker and Ordal's broth. Colonies on R2A agar are bright yellow, convex, translucent, glistening, and circular with entire margins. The colony consistency is viscous, becoming mucoid after prolonged incubation. Colonies are orange on tryptic soy agar. Colonies do not adhere to the agar. No growth occurs on cetrinide or MacConkey agars. Grows well under aerobic conditions (minimum doubling time, 2.9 h), weakly under microaerobic conditions (i.e., with 5–15% O₂ and 5–12% CO₂), and poorly under anaerobic conditions (i.e., with 4–10% CO₂).

Catalase-positive. L-Phenylalanine deaminase activity is absent. Arginine dihydrolase activity is present using Thornley's semi-solid medium, but absent with the API 20NE gallery. The list of enzymic activities detected in the API ZYM gallery is given in the original description. Indole is not produced and citrate is not utilized. Acid is produced from D-glucose and maltose, but not from D-cellobiose, D-fructose, D-mannitol, raffinose, D-salicin, trehalose, D-xylose, lactose, L-arabinose, L-rhamnose, or sucrose. Glucose, mannose, *N*-acetylglucosamine, and maltose are assimilated (API 20NE), but arabinose, mannitol, gluconate, caprate, adipate, malate, citrate, and phenylacetate are not. The maximum adsorption peak of pigment is at 451 nm and the next peak is at 479 nm. Other characteristics are as given in the genus and original species descriptions and in Tables 24 and 25.

Source: a soil sample collected on the Weaver Peninsula, King George Island, Antarctica.

DNA G+C content (mol%): 37 (HPLC).

Type strain: AT1042, CIP 109334, IMSNU 14048, JCM 12384, KCTC 12223.

Sequence accession no. (16S rRNA gene): AY581114.

39. **Flavobacterium xanthum** (Inoue and Komagata 1976) McCammon and Bowman 2000, 1060^{VP} (*Cytophaga xantha* Inoue and Komagata 1976, 169 and Reichenbach 1989c, 2049) xan'thum. Gr. adj. *xanthos* yellow; N.L. neut. adj. *xanthum* yellow.

The following description of the type strain combines the data of Inoue and Komagata (1976), Reichenbach (1989b), and McCammon and Bowman (2000). Rods, approximately $0.4\text{--}0.5 \times 0.7\text{--}2 \mu\text{m}$. Longer, filamentous cells appear in ageing cultures. Colonies on PYG agar (1% peptone, 0.5% yeast extract, 0.3% glucose, pH 7.2; amount of agar not specified) are bright yellow to orange-yellow, smooth, opaque, and circular with entire margins. No fermentation occurs and there is no growth by anaerobic respiration using ferric iron, nitrate, nitrite, or trimethylamine *N*-oxide as electron acceptors. Casamino acids, peptone, ammonium chloride, and L-glutamate serve as nitrogen sources. Vitamins are not required for growth.

Catalase-positive. Arginine dihydrolase, lysine and ornithine decarboxylase, and tryptophan deaminase activities are absent. Acid is produced from cellobiose, fructose, glucose, maltose, mannitol, mannose, sucrose, trehalose, and xylose, but not from adonitol, arabinose, galactose, glycerol, inositol, lactose, melibiose, rhamnose, raffinose, or sorbitol. Formate, acetate, lactate, and hippurate are assimilated, but succinate, fumarate, citrate, propionate, protocatechuate, and *p*-hydroxybenzoate are not. Uric acid and xanthine are not degraded. Acetoin and indole are not produced. Citrate is not utilized. Other characteristics are as given in the genus and original species description and in Tables 24 and 25. Although a G+C content of 39.3 mol% was originally reported (Inoue and Komagata, 1976), values of approximately 36 mol% were subsequently published (Bernardet et al., 1996; McCammon and Bowman, 2000).

Source: the type strain was isolated from soil (a mud pool according to McCammon and Bowman, 2000) in Showa Station, Antarctica, in February 1967. Eleven additional strains were isolated from microbial mats in Antarctic freshwater lakes by Van Trappen et al. (2005).

DNA G+C content (mol%): 36.0 (T_m).

Type strain: Inoue 5-O-c, ACAM 81, CIP 107448, DSM 3661, IAM 12026, IFO (now NBRC) 14972, LMG 8372, NCIMB 2069.

Sequence accession no. (16S rRNA gene): AF030380 (type strain), AJ601392 (R-9010).

40. **Flavobacterium xinjiangense** Zhu, Wang and Zhou 2003, 856^{VP}

xin.ji.ang.en'se. N.L. neut. adj. *xinjiangense* pertaining to Xinjiang, an autonomous region in north-west China from where the type strain was isolated.

Rods, approximately $0.8 \times 2.5\text{--}5 \mu\text{m}$. Colonies on PYG agar [per l: 5.0 g polypeptone, 5.0 g tryptone, 10.0 g yeast extract, 10.0 g glucose, 40 ml salt solution, 15.0–20.0 g agar. Salt solution (per l): 0.2 g CaCl₂, 0.4 g MgSO₄·7H₂O, 1.0 g K₂HPO₄, 1.0 g KH₂PO₄, 10.0 g NaHCO₃, 2.0 g NaCl] are pale

yellow, circular, convex, and smooth, with entire margins. Good growth also occurs on CIP medium 469 (per l: 10 g peptone, 10 g yeast extract, 5 g sodium chloride, 20 g agar).

Catalase-positive. Arginine dihydrolase, lysine and ornithine decarboxylase, and tryptophan deaminase activities are absent. Indole and acetoin are not produced. Citrate is not utilized. Peptone and Casamino acids serve as N sources, but sodium nitrate, ammonium chloride, and L-glutamate do not. Acid is not produced from glucose, fructose, xylose, mannitol, or maltose. Uric acid and xanthine are not degraded. Glucose, cellobiose, maltose, fructose, sucrose,

arabinose, and xylose are assimilated, but sorbitol, sorbose, galactose, D-mannitol, raffinose, lactose, mannose, trehalose, glycerol, rhamnose, melibiose, and inositol are not. Other characteristics are as given in the genus and original species descriptions and in Tables 24 and 25.

Source: frozen soil enclosed within the China No. 1 glacier, Xinjiang Uygur Autonomous Region, China.

DNA G+C content (mol%): 34.4 (T_m).

Type strain: Zhou ZF-6, AS 1.2749, CIP 108285, JCM 11314, LMG 21985.

Sequence accession no. (16S rRNA gene): AF433173.

Other organisms

These organisms, whose names have not been validly published, have been assigned to the genus *Flavobacterium* by DNA-rRNA hybridization (Bernardet et al., 1996) and, for two of them, by 16S rRNA gene sequencing (Figure 27). Except for "*Sporocytophaga cauliformis*", only one strain is available in culture collections (see *Taxonomic comments*, above).

1. "*Cytophaga allerginae*" Liebert, Hood, Deck, Bishop and Flaherty 1984, 941

al.ler.gi'nae. Gr. pl. n. *alloy* strangers; Gr. n. *ergon* work, act, deed; N.L. gen. n. *allerginae* intended to mean connected with, causing an allergy.

The following description is a combination of data from the original description (Liebert et al., 1984) and unpublished data (J.-F. Bernardet, unpublished observations). Rods, approximately $0.3\text{--}0.5 \times 3.5\text{--}9.0$ μm ; cells up to 30 μm occur occasionally and spheroplasts appear in ageing broth cultures. Cells display gliding motility, pivoting, and flexing movements. Colonies on nutrient agar are bright yellow, and circular with entire margins. Colonies on Anacker and Ordal's agar and on other media with low nutrient concentration are yellow, flat, and irregular with spreading rhizoid margins. Colonies do not adsorb Congo red and do not adhere to the agar. The positive KOH test and the maximum adsorption peak at 450 nm suggest that the yellow pigments belong to the flexirubin type. Grows at $10\text{--}30^\circ\text{C}$, but not at 4 or 37°C . Grows at pH 5.5–9.5 and in nutrient broth containing 1.5% NaCl, but not in the presence of 3.0% NaCl. Good growth occurs under aerobic conditions; weak growth also occurs in half-strength nutrient broth and on plate count agar after 48 h under anaerobic conditions. Contrary to Reichenbach's statement (1989b), anaerobic growth seems to occur even in the absence of nitrate. In addition to the above-mentioned media, growth also occurs on nutrient, plate count, Cook's (per l: 2 g tryptone, 10 g agar), and vy/2 (per l: 5 g bakers' yeast, 1 g $\text{CaCl}_2 \cdot 2\text{H}_2\text{O}$, 1 mg vitamin B_{12} , 15 g agar) agars, but not on MacConkey agar.

Catalase-positive. β -Galactosidase activity is present, but arginine dihydrolase, lysine and ornithine decarboxylase, phenylalanine deaminase, urease, and DNase activities are absent. Casein, gelatin, tyrosine, Tweens 20 and 80, glycerol tributrylate, starch, chitin, and carboxymethylcellulose are degraded, but agar, alginate, and cellulose are not. A dark brown diffusible melanic pigment is produced on tyrosine agar and a precipitate is produced on egg-yolk agar. Acid is produced from glucose, maltose, cellobiose, and arabinose, but not from lactose or sucrose. Glucose is not fermented. Indole and H_2S are not produced. Nitrate is not reduced.

Antibiotic resistances are listed in the original description. A biologically active endotoxin is produced. According to Liebert et al. (1984), the only available strain of "*Cytophaga allerginae*" shares approximately 78% DNA relatedness with the *Flavobacterium hydatis* type strain. However, J.-F. Bernardet (unpublished data) found only 34% DNA relatedness between these two strains, and 16% between "*Cytophaga allerginae*" and the *Flavobacterium johnsoniae* type strain. Fatty acid and whole-cell protein analyses as well as DNA-rRNA hybridization have confirmed that "*Cytophaga allerginae*" belongs to the genus *Flavobacterium* (Bernardet et al., 1996), but 16S rRNA studies and additional DNA-DNA hybridizations are needed to allocate it to a new or a described species. Additional information can be found in Liebert et al. (1984), Reichenbach (1989b), and Bernardet et al. (1996).

Source: an industrial water spray air humidification system; isolated following several cases of lung disease with hypersensitivity pneumonitis-like symptoms that occurred in the late 1970s in a United States textile facility. The strain was identified as the source of the endotoxin responsible for the symptoms (Flaherty et al., 1984; Liebert et al., 1984). This was the first report of a *Flavobacterium* strain implicated in an industrial health-related disease; no other case has been reported since then.

DNA G+C content (mol%): 34–34.8 (T_m).

Type strain: WF-164, ATCC 35408.

2. "*Flexibacter aurantiacus* var. *excathedrus*" Lewin 1969, 200

au.ran.ti'a.cus. N.L. masc. adj. *aurantiacus* orange-colored. ex.cath.e'drus. L. prep. *ex* out of; L. n. *cathedra* a chair, a stool, an arm-chair and, by extension, a cathedral; N.L. masc. adj. *excathedrus* from a cathedral, referring to the origin of the strain, a pool in a cathedral.

Rods, approximately $0.3\text{--}0.5 \times 5.0\text{--}10.0$ μm . Active gliding occurs. Colonies on modified Shieh agar (Song et al., 1988) are yellow, low convex, and circular with regular to lobate margins (J.-F. Bernardet, unpublished data). No growth occurs on media with half-strength sea water. Good growth occurs at 25°C and the highest growth temperature is 40°C .

Catalase-negative. Gelatin, tyrosine, and starch are degraded, but agar, alginate, and carboxymethylcellulose are not. A dark brown diffusible melanic pigment is produced on tyrosine agar. H_2S is not produced and nitrate is not reduced. Tryptone, Casamino acids, and sodium glutamate are used as nitrogen sources. Additional information can be found in Lewin (1969), Lewin and Lounsbury (1969), and Reichenbach (1989b). Fatty acid and whole-cell protein analyses have

shown that "*Flexibacter aurantiacus* var. *excathedrus*" belongs to the genus *Flavobacterium* (Bernardet et al., 1996).

Flexibacter aurantiacus was proposed by Lewin (1969) and Lewin and Lounsbury (1969) to accommodate two strains received as "*Cytophaga aurantiaca*" and "*Cytophaga psychrophila*", but DNA–DNA hybridization later demonstrated that they actually represented two strains of *Flavobacterium johnsoniae* (Bernardet et al., 1996) (see above). Two variants had also been proposed by Lewin (1969) and Lewin and Lounsbury (1969): the marine organism "*Flexibacter aurantiacus* var. *copepodarum*" and the freshwater isolate "*Flexibacter aurantiacus* var. *excathedrus*". DNA–rRNA hybridization experiments have allocated these strains to the marine clade of the family *Flavobacteriaceae* and to the close vicinity of *Flavobacterium columnare*, respectively (Bernardet et al., 1996). The position of "*Flexibacter aurantiacus* var. *excathedrus*" was later defined more accurately by 16S rRNA studies (Figure 27), but DNA–DNA hybridizations are needed to determine whether it can be considered a *Flavobacterium columnare* strain or if the description of a novel species is necessary. Any further study will have to take into consideration the taxonomic status of the three genomovars of *Flavobacterium columnare* (see *Taxonomic comments*, above).

Source: a freshwater pool in (or near?) a cathedral, Cartago, Costa Rica.

DNA G+C content (mol%): 32.5–34.5 (T_m).

Type strain: Lewin CR-134, ATCC 23086, IFO 16024, LMG 3986.

Sequence accession no. (16S rRNA gene): AB078045.

3. "**Promyobacterium flavum**" Imshenetski and Solntseva 1945, 224

fla'vum. L. neut. adj. *flavum* golden yellow.

This organism is remarkably pleomorphic. Rods may be stout, almost coccoid (approx. $0.6\text{--}0.7 \times 1.0\text{--}2.5 \mu\text{m}$) to slender and flexible (approx. $0.4\text{--}0.5 \times 2.5\text{--}6.0 \mu\text{m}$). The stout forms are dominant in ageing broth cultures. Gliding motility is present. Colonies are bright yellow and compact with more or less lobate to spreading margins on rich media, whereas yellow, thin, spreading swarms tend to occupy all the surface of media with low nutrient concentration. The yellow pigments belong to the flexirubin type (positive KOH test). Good growth occurs on nutrient and modified Shieh agars (Song et al., 1988) at 30°C (Bernardet et al., 1996). No growth occurs on media prepared with full-strength seawater.

Metabolism is strictly aerobic. Catalase-negative. Weakly oxidase-positive. Proteins, peptones, and nitrate may serve as sole nitrogen sources. Glucose may serve as the sole source of carbon and energy. Reichenbach (1989b) reported reasonable growth on a mineral agar containing KNO_3 and glucose. Acid is produced from glucose. Gelatin, starch, hemicellulose, and pectin are degraded, but agar, chitin, and cellulose are not. Additional information can be found in Reichenbach (1989b). Fatty acid and whole-cell protein analyzes as well as DNA–rRNA hybridization have shown that "*Promyobacterium flavum*" belongs to the genus *Flavobacterium* (Bernardet et al., 1996), but 16S rRNA studies and DNA–DNA hybridizations are needed to allocate it to a new or a described species.

Source: the original strains isolated from soil in Russia by Imshenetski and Solntseva (1945) have been lost. A strain

was isolated by Vozniakovskaia and Rybakova (1969) from the rhizosphere of a tomato plant in Russia. As its scant description was in accordance with the original species description, this strain has been accepted as the neotype strain by Reichenbach (1989b). The above-mentioned characteristics are those reported by this author for the neotype strain.

DNA G+C content (mol%): 33.0–34.5 (Bd, T_m).

(Neo)type strain: Vozniakovskaya 19, VKM B-1553, DSM 3577, LMG 10389.

4. "**Sporocytophaga cauliformis**" Gräf 1962, 124

cau.li.for'mis. L. n. *caulis* stalk, stem; L. adj. suff. *-formis* shaped like; N.L. fem. adj. *cauliformis* stalk-shaped, stalked.

Rods, approximately $0.4 \times 2.0\text{--}5.0 \mu\text{m}$, flexible, and gliding. Colonies on relatively rich media such as nutrient agar are compact with more or less spreading margins, whereas thin, large, spreading swarms appear on media with low nutrient concentration such as CY agar (per l: 3.0 g casitone, 1.36 g $\text{CaCl}_2 \cdot 2\text{H}_2\text{O}$, 1.0 g yeast extract, 15.0 g agar, pH 7.2). The yellow to orange pigments belong to the flexirubin type (positive KOH test). Grows at 5–30°C and optimally at 22°C.

Catalase- and urease-negative. Oxidase-positive. Peptones may serve as sole N source; NH_3 is released from peptones. Acid is not produced from carbohydrates. Starch is degraded, but cellulose and agar are not. Indole and H_2S are not produced. Nitrate is not reduced. According to Reichenbach (1989b), the classification of this organism in the genus *Sporocytophaga* resulted from the misinterpretation of several degenerative phenomena. Some confusion also occurred with other freshwater isolates and two types were described, each of them represented by a single strain. "*Sporocytophaga cauliformis*" type 2 was considered the type strain of the species; it is catalase-negative and does not produce acid from carbohydrates. Conversely, "*Sporocytophaga cauliformis*" type 1 (Gräf Z2=NCIMB 9487=DSM 3656=LMG 8362) is positive for these two traits. Also, the DSMZ Catalog of Strains states that type 2 degrades chitin and pectin, whereas no such mention is made for type 1.

Fatty acid and whole-cell protein analyses, as well as DNA–rRNA hybridization, have unequivocally shown that the two "*Sporocytophaga cauliformis*" strains belong to the genus *Flavobacterium* (Bernardet et al., 1996). A 16S rRNA gene sequence is available for the type strain (type 2) (Gherna and Woese, 1992). In phylogenetic trees, its closest neighbors are *Flavobacterium saccharophilum*, *Flavobacterium pectinovorum*, and several recently described *Flavobacterium* species (Figure 27), but DNA–DNA hybridization data are needed to elucidate their relationship at the species level. Moreover, phenotypic differences, discrepancies in the respective proportions of some fatty acids, distinct positions in the dendrogram derived from whole-cell protein profiles, and rather different DNA G+C contents suggest that the two "*Sporocytophaga cauliformis*" strains probably belong to different species (Bernardet et al., 1996).

Genus II. *Aequorivita* Bowman and Nichols 2002, 1538^{VP}

JOHN P. BOWMAN

Ae.quo.ri.vi'ta. L. n. *aequor* -oris the even surface of the sea in its quiet state; L. fem. n. *vita* life; N.L. fem. n. *Aequorivita* life (living being) at the sea surface.

Cells are straight or slightly curved **rods or filaments**, 0.5–20 × 0.2–0.5 μm. **Gram-stain-negative**. Cells occur singly or in pairs. Spores and resting cells are not present. Gas vesicles and helical or ring-shaped cells are not formed. **Nonmotile**. **Strictly aerobic, having an oxidative metabolism**. Catalase-positive. Oxidase test is weakly positive. **Chemoheterotrophic**. **Non-agarolytic**. **Colonies are orange or yellow** due to production of carotenoids. **Flexirubin pigments are not produced**. Some species **require Na⁺** for growth. Tolerates up to 6% NaCl; growth with 10% NaCl is either weak or absent. Best growth occurs in organic media containing 1–3% NaCl or seawater salts. All species **produce alkaline phosphatase and esterase and hydrolyze L-tyrosine and gelatin**. Some species are strongly proteolytic and/or lipolytic. **Psychroactive**. Growth occurs between –2 and 25°C. **Optimal growth occurs at 20°C**. **Neutrophilic**, with optimal growth occurring at pH 7.0–7.5. The major fatty acids are C_{15:1} ω10c iso, C_{15:1} ω10c anteiso, C_{15:0} iso, C_{15:0} anteiso, C_{16:1} ω6c iso, C_{17:1} ω5c iso, C_{17:1} ω7c anteiso, and C_{16:0} 3-OH iso. **Known habitats include polar ocean seawater, sea-ice, and quartz stone sublithic communities** located in polar maritime ice-free zones. Also reported to be associated with deep-sea invertebrates.

DNA G+C content (mol%): 33–39.

Type species: Aequorivita antarctica Bowman and Nichols 2002, 1539^{VP}.

Further descriptive information

The genus *Aequorivita* belongs to the family *Flavobacteriaceae* and is most closely related to the seawater species *Vitellibacter vladivostokensis* (Nedashkovskaya et al., 2003c). With *Vitellibacter*, it forms a relatively distinct phylogenetic lineage in the family *Flavobacteriaceae*.

Phenotypic traits differentiating the species of *Aequorivita* are shown in Table 26. All species possess catalase, oxidase (weakly), alkaline phosphatase, and esterase (Tween 80 as substrate) activities. L-Tyrosine is hydrolyzed and, thus, presumably metabolized. Gelatin is also liquefied by all species. The species possesses a range of DNA G+C values (Table 26) that are typical of members of the family *Flavobacteriaceae*. Fatty acid profiles are quite similar between the species and are composed of almost entirely branched chain C₁₅–C₁₇ fatty acids (Table 27).

The species exhibit only a limited capacity to utilize sole carbon and energy sources, showing only poor, equivocal growth on defined media containing a variety of different substrates even when supplemented with yeast extract and a vitamin solution. This suggests other unknown growth factors, present in complex media used for routine growth, are required by strains of this genus.

Aequorivita species have been found to be negative for the following phenotypic characteristics: anaerobic growth (including growth by ferric iron reduction as well as carbohydrate fermentation in the presence and absence of nitrate); oxidative and fermentative acid production from sugars and sugar alcohols; tolerance to NaCl levels of 12% or greater; tolerance to 1% ox

bile salts; hydrolysis of polysaccharides (however, *Aequorivita antarctica* can attack starch); decomposition of uric acid and xanthine; lysine decarboxylase, arginine dihydrolase, ornithine decarboxylase, α-arabinosidase, α-fucosidase, β-glucosidase, β-galactosidase, 6-phospho-β-galactosidase, and β-glucuronidase activities; indole production and Voges–Proskauer tests; and the bathochromic shift assay to detect the presence of flexirubin-type pigments.

Although the presently described species were obtained from Antarctic marine and marine-influenced ecosystems (Bowman and Nichols, 2002; Smith et al., 2000), other studies indicate that members of the genus may be relatively widespread, present in the Arctic and in association with deep-sea invertebrates (Sfanos et al., 2005; unpublished sources). Of the four known species in the genus *Aequorivita*, all except *Aequorivita crocea*, have been isolated from quartz stone sublithic samples. These constitute cyanobacterial-dominated biofilm-like communities existing on the bottom surfaces of semi-translucent quartz stones, protected from surrounding extreme weather conditions, particularly freezing and desiccation. The location of the quartz stones studied so far has been entirely confined to coastal ice-free regions of Antarctica. *Aequorivita* strains were not isolated from soil underlying quartz stone subliths or the immediately adjacent soils, suggesting that quartz stone sublithic communities represented a form of refuge or oasis for these bacteria. *Aequorivita antarctica*, *Aequorivita crocea*, and *Aequorivita lipolytica* have also been found in coastal Antarctic sea-ice and under-ice seawater, suggesting that sublithic environments may be inoculated by windborne marine particulate deposition (Smith et al., 2000).

Enrichment and isolation procedures

Marine agar (Difco, Oxoid) is used for isolation of *Aequorivita* species from sea-ice and seawater samples. Potentially, isolates can be obtained from sea-ice samples, pre-melted at 2–4°C in sterile seawater, and polar seawater samples, diluted in artificial seawater and directly plated onto marine agar. Incubation proceeds at 2–4°C. For isolation of strains from quartz stone subliths, sublithic biomass is scraped off stones using a sterile scalpel and suspended, vortexed, and then diluted in trypticase soy broth containing 1% NaCl. The suspensions are serially diluted and spread onto agar plates and incubated at 4–10°C. *Aequorivita* strains can be grown routinely either on marine agar or trypticase soy agar containing 1% NaCl. No selective media are available for this genus at present and so strains must be identified empirically from amongst the orange- or yellow-pigmented colonies arising from primary isolation plates.

Maintenance procedures

Strains can be maintained for many years cryopreserved in marine broth containing 20–30% glycerol. Strains survive for many months, potentially years, on thick agar plates or on slants, stored at 2–4°C. Strains may also be maintained by lyophilization, although the survival level is presently unknown.

Differentiation of the genus *Aequorivita* from other genera

The most salient traits useful for distinguishing *Aequorivita* from other members of the *Flavobacteriaceae* include a strictly oxidative metabolism, the inability to form acid from carbohydrates, the inability to grow on defined mineral salts media, a lack of flexirubin production, a lack of motility, low growth temperatures (e.g., growth at 4°C, no growth at 30°C or more), a requirement for Na⁺ for growth, and a lack of agarolytic activity. *Aequorivita* differs most significantly from its closest relative, *Vitellibacter vladvostokensis* (Nedashkovskaya et al., 2003c), in terms of flexirubin production (positive for *Vitellibacter vladvostokensis*) and growth temperature (*Vitellibacter vladvostokensis* can grow at 43°C). The DNA G+C content of *Vitellibacter vladvostokensis* is 41 mol%, which is higher than that found for all *Aequorivita* species. The fatty acid profile of *Vitellibacter vladvostokensis* also differs from that of *Aequorivita* spp. by having a very high C_{15:0} iso content.

Taxonomic comments

The genus *Aequorivita* includes four species, *Aequorivita antarctica*, *Aequorivita crocea*, *Aequorivita lipolytica*, and *Aequorivita sublithincola*. Genomic DNA–DNA hybridization levels were highest between *Aequorivita lipolytica* and *Aequorivita crocea*, ranging from 44–57%. Both of these species occur as rod-like cells (0.5–3.0 × 0.4–0.5 µm) and form yellow colonies. This corresponds clearly with 16S rRNA gene sequence data, which indicates that these species are closely related, sharing a gene sequence similarity of 98%. By comparison, *Aequorivita antarctica* and *Aequorivita sublithincola* strains appear as rod-like to filamentous cells (0.5–20 × 0.2–0.5 µm) and form orange colonies. These

species are more genetically distinct, especially *Aequorivita sublithicola*, which occurs as an outlier in the *Aequorivita* 16S rRNA gene cluster. *Aequorivita antarctica* shares 32–39% DNA–DNA

hybridization with *Aequorivita crocea* and *Aequorivita lipolytica*. *Aequorivita sublithicola* genomic DNA hybridization values with the other species are below background hybridization levels.

List of species of the genus *Aequorivita*

1. ***Aequorivita antarctica*** Bowman and Nichols 2002, 1539^{VP}
ant.arc'ti.ca. L. fem. adj. *antarctica* southern; here of or belonging to Antarctica.

Characteristics are as given for the genus and as listed in Table 26.

Source: seawater (ice-covered polar regions), sea-ice, and quartz stone sublithic material.

DNA G+C content (mol%): 38–39 (T_m).

Type strain: SW49, ACAM 640, DSM 14231.

Sequence accession no. (16S rRNA gene): AY027802.

2. ***Aequorivita crocea*** Bowman and Nichols 2002, 1540^{VP}
cro'ce.a. L. fem. adj. *crocea* saffron-colored, yellow.

Characteristics are as given for the genus and as listed in Table 26.

Source: seawater (ice-covered polar regions) and sea-ice.

DNA G+C content (mol%): 33–34 (T_m).

Type strain: Y12-2, ACAM 642, DSM 14293.

Sequence accession no. (16S rRNA gene): AY027806.

3. ***Aequorivita lipolytica*** Bowman and Nichols 2002, 1539^{VP}

li.po.ly'ti.ca. Gr. n. *lipos* fat; Gr. adj. *lytikos* dissolving; N.L. fem. adj. *lipolytica* fat-dissolving.

Characteristics are as given for the genus and as listed in Table 26.

Source: seawater (ice-covered polar regions) and quartz stone sublithic material.

DNA G+C content (mol%): 35–36 (T_m).

Type strain: Y10-2, ACAM 641, DSM 14236.

Sequence accession no. (16S rRNA gene): AY027805.

4. ***Aequorivita sublithicola*** Bowman and Nichols 2002, 1540^{VP}
sub.lith.in'co.la. L. pref. *sub* below; Gr. n. *lithos* stone; L. nom. n. *incola* an inhabitant; N.L. n. *sublithicola* an inhabitant below stone.

Characteristics are as given for the genus and as listed in Table 26. The description is based on a single isolate.

Source: quartz stone sublithic material.

DNA G+C content (mol%): 36–37 (T_m).

Type strain: 9-3, ACAM 643, DSM 14238.

Sequence accession no. (16S rRNA gene): AY170749.

Genus III. **Algibacter** Nedashkovskaya, Kim, Han, Rhee, Lysenko, Rohde, Zhukova, Frolova, Mikhailov and Bae 2004d, 1260^{VP}

OLGA I. NEDASHKOVSKAYA AND SEUNG BUM KIM

Al.gi.bac'ter. L. fem. n. *alga* seaweed; N.L. masc. n. *bacter* from Gr. n. *bacterion* rod; N.L. masc. n. *Algibacter* rod isolated from seaweed.

Thin rods usually measuring $0.4\text{--}0.5 \times 2\text{--}3 \mu\text{m}$. **Motile by gliding**. Produce non-diffusible orange pigments. No flexirubin types of pigments are formed. **Chemoorganotrophs. Can ferment D-glucose**. Positive for oxidase, catalase, alkaline phosphatase, and β -galactosidase. Chitin and cellulose (CM-cellulose and filter paper) are not degraded, but other polysaccharides including agar, alginate, starch, gelatin, and Tweens may be decomposed. Do not grow without seawater or sodium ions. **The major respiratory quinone is MK-6**. Phosphatidylethanolamine is the main polar lipid compound.

DNA G+C content (mol%): 31–33 (T_m).

Type species: ***Algibacter lectus*** Nedashkovskaya, Kim, Han, Rhee, Lysenko, Rohde, Zhukova, Frolova, Mikhailov and Bae 2004d, 1260^{VP}.

Further descriptive information

Phylogenetic analysis of nearly complete 16S rRNA gene sequences of strains of the genus *Algibacter* has revealed that its close relatives are members of the genera *Bizionia* and *Formosa* with a similarity range of 94.2–95.3%.

The main cellular fatty acids are straight-chain unsaturated and branched-chain unsaturated fatty acids ($C_{15:0}$ iso, $C_{15:0}$ anteiso, $C_{15:1}$ iso, $C_{15:0}$, $C_{15:1}$ $\omega 6$, $C_{15:0}$ iso 3-OH, and $C_{17:0}$ iso 3-OH).

On marine agar 2216 (Difco), the algibacters form regular, round, shiny colonies that are sunk in the agar, transparent with entire edges, and bright orange with diameters of 3–4 mm after 48 h at 28°C.

All isolated strains have been grown on media containing 0.5% peptone and 0.1–0.2% yeast extract (Difco), prepared with native or artificial seawater or supplemented with 2–3% NaCl. Growth occurs at 4–35°C, at pH 5.5–10.0, and with 1–6% NaCl. The optimal temperature for growth is 21–23°C and the optimal pH is between 7.5 and 8.3.

Strains of the genus *Algibacter* are susceptible to carbenicillin, lincomycin, and oleandomycin, but resistant to ampicillin, benzylpenicillin, gentamicin, kanamycin, neomycin, polymyxin B, streptomycin, and tetracycline.

The algibacters are dwellers of coastal marine environments and strains have been isolated from seaweeds collected in the temperate latitudes.

Enrichment and isolation procedures

The algibacters were isolated from seaweeds using the direct plating technique on marine agar (Difco). Natural or artificial seawater is sufficient for their cultivation. All isolated strains have been grown on media containing 0.5% peptone and

0.1–0.2% yeast extract (Difco). The algibacters remain viable on marine agar (Difco) or other rich media based on natural or artificial seawater for several weeks. They can survive storage in marine broth or artificial seawater supplemented with 20% glycerol (v/v) at -80°C for at least 5 years.

Differentiation of the genus *Algibacter* from other genera

Algibacters are able to move by means of gliding, to hydrolyze agar, and to produce acid from carbohydrates, in contrast with their nearest neighbors, *Bizionia* species (Bowman and Nichols, 2005; Nedashkovskaya et al., 2005a). DNA G+C content may also be used for differentiation of these two genera (31–33 mol% for *Algibacter* and 37–45 mol% for *Bizionia*). The combination of phylogenetic distances, the distinctiveness of the cellular fatty acid composition, and growth only with seawater or NaCl enable algibacters to be differentiated from their other nearest neighbor, *Formosa* (Nedashkovskaya et al., 2006d). *Algibacter* strains clearly differ from those of the close relative *Lacinutrix* in the ability to move by gliding, to produce acid from carbohydrates, to hydrolyze agar, and by the lower DNA G+C content

(Bowman and Nichols, 2005; Nedashkovskaya et al., 2004d). In comparison with species of the other closest relative, *Gaetbulibacter*, algibacters produce gelatinase, but not nitrate reductase (Jung et al., 2005). In addition, they can be distinguished by their temperature range for growth ($31\text{--}33^{\circ}\text{C}$ for *Algibacter* and $13\text{--}40^{\circ}\text{C}$ for *Gaetbulibacter*). D-Glucose fermentation is a helpful phenotypic feature that enables differentiation between algibacters and their close relatives *Bizionia*, *Lacinutrix*, *Olleya*, *Psychroserpens*, and *Winogradskyella* (Bowman et al., 1997; Bowman and Nichols, 2005; Lau et al., 2005a; Mancuso Nichols et al., 2005; Nedashkovskaya et al., 2005a). Algibacters produce agarase and amylase, in contrast to the genus *Olleya*, and the DNA G+C content is lower than the value determined for *Olleya* (31–33 and 49 mol%, respectively) (Mancuso Nichols et al., 2005). Several phenotypic features, e.g. gliding motility and production of oxidase, agarase, and amylase, that are found in algibacters are not observed among *Psychroserpens* strains (Bowman et al., 1997). Species of the genus *Psychroserpens* hydrolyze casein and Tween 80 and have a lower DNA G+C content (27–29 mol%), in contrast to the algibacters (31–33 mol%).

List of species of the genus *Algibacter*

1. *Algibacter lectus* Nedashkovskaya, Kim, Han, Rhee, Lysenko, Rohde, Zhukova, Frolova, Mikhailov and Bae 2004d, 1260^{VP}

lectus. L. masc. adj. *lectus* chosen, select, referring to a bacterium that forms select, beautiful colonies.

Cells are rod-shaped, $0.4\text{--}0.5\ \mu\text{m}$ in width and $2\text{--}3\ \mu\text{m}$ in length. Colonies are circular, $3\text{--}4\ \text{mm}$ in diameter, convex, shiny, sunk in the agar, bright orange in color, and translucent on solid media containing high nutrient components. Na^+ ions are required for growth. Growth occurs at $4\text{--}35^{\circ}\text{C}$. The optimal temperature for growth is $21\text{--}23^{\circ}\text{C}$. Growth occurs with 1–6% NaCl. The pH range for growth is 5.5–10.0, with optimum growth occurring between pH 7.5 and 8.3. Agar, gelatin, alginate, starch, and Tweens 20 and 40 are hydrolyzed, but casein, Tween 80, and DNA are not. Acid is produced from D-cellobiose, L-fucose, D-galactose, D-glucose,

maltose, sucrose, and DL-xylose, but not from L-arabinose, D-lactose, melibiose, raffinose, glycerol, inositol, or manitol. L-Rhamnose and N-acetylglucosamine are oxidized. D-Lactose and D-mannose are utilized, but not L-arabinose, adonitol, dulcitol, mannitol, inositol, sorbitol, malonate, or citrate. Nitrate is not reduced to nitrite. Indole, H_2S , and acetoin (Voges–Proskauer reaction) are not produced. The organisms are susceptible to carbenicillin, lincomycin, and oleandomycin, but they are resistant to ampicillin, benzylpenicillin, gentamicin, kanamycin, neomycin, polymyxin B, streptomycin, and tetracycline.

Source: three strains were isolated from the green algae *Acrosiphonia sonderi* and *Ulva fenestrata*, Troitsa Bay, Sea of Japan.

DNA G+C content (mol%): 31–33 (T_m).

Type strain: KMM 3902, KCTC 12103, DSM 15365.

Sequence accession no. (16S rRNA gene): AY187689.

Genus IV. *Aquimarina* Nedashkovskaya, Kim, Lysenko, Frolova, Mikhailov, Lee and Bae 2005f, 227^{VP} emend. Nedashkovskaya, Vancanneyt, Christiaens, Kalinovskaya, Mikhailov and Swings 2006f, 2039

OLGA I. NEDASHKOVSKAYA, MARC VANCANNEYT AND SEUNG BUM KIM

Aqui.ma.ri'na. L. fem. n. *aqua* water; L. adj. *marinus* -a -um marine; N.L. fem. n. *Aquimarina* an organism of seawater.

Thin rods usually measuring $0.2\text{--}0.5\ \mu\text{m}$ in width and $1.0\text{--}15.0\ \mu\text{m}$ in length. Cells of some species can move by means of gliding. Produce non-diffusible carotenoid pigments. Flexirubin type of pigments can be produced. **Chemoorganotrophs. Strictly aerobic.** Halophilic. Positive for oxidase, catalase, and alkaline phosphatase. Arginine dihydrolase, lysine decarboxylase, ornithine decarboxylase, and tryptophan deaminase are not produced. **Casein, gelatin, and Tweens 20, 40 and 80 are hydrolyzed.** Urea and cellulose (CM-cellulose and filter paper) are not attacked, but agar, starch, DNA, and chitin may be decomposed. Nitrate reductase is not produced. **Require seawater or sodium ions for growth.** Indole and acetoin production is

negative. **The major respiratory quinone is MK-6. Marine,** from coastal habitats.

DNA G+C content (mol%): 31–38 (T_m).

Type species: *Aquimarina muelleri* Nedashkovskaya, Kim, Lysenko, Frolova, Mikhailov, Lee and Bae 2005f, 227^{VP}.

Further descriptive information

The predominant cellular fatty acids are straight-chain unsaturated and branched-chain unsaturated fatty acids ($\text{C}_{15:1}$ iso, $\text{C}_{15:0}$ iso, $\text{C}_{15:0}$ iso 3-OH, $\text{C}_{17:1}$ iso $\omega 9c$, $\text{C}_{17:0}$ iso 3-OH) and summed feature 3, comprising iso- $\text{C}_{15:0}$ iso 2-OH and/or $\text{C}_{16:1}$ $\omega 7c$ (Table 28).

^aValues refer to the percentage of total fatty acids. Fatty acids amounting to less than 1% in all taxa are not given. Data from Yoon et al. (2006b) and Nedashkovskaya et al. (2006f).

^btr, less than 1%.

^cSummed features consist of one or more fatty acids that could not be separated by the Microbial Identification System. Summed feature 3: C_{15:0} iso 2-OH and/or C_{16:1} ω7c.

On marine agar 2216 (Difco), strains of *Aquimarina* form regular or rhizoid, round, usually shiny colonies that are sunk into the agar or flat, red, dark-red, orange or yellow-brownish colonies with a diameter of 1–4 mm after 48 h at 28°C.

All isolated strains have been grown on media containing 0.5% peptone and 0.1–0.2% yeast extract (Difco), prepared with natural or artificial seawater or supplemented with 2–3% NaCl. All strains grow at 10–33°C and with 1–5% NaCl.

Strains of *Aquimarina* are susceptible to ampicillin, chloramphenicol, doxycycline, erythromycin, lincomycin, and oleandomycin, but resistant to gentamicin, kanamycin, neomycin, and polymyxin B. The susceptibility to benzylpenicillin, carbenicillin, streptomycin, and tetracycline varies depending on the strain.

The aquimarinans inhabit coastal marine environments. Strains have been isolated from seawater and echinoderms in the temperate latitudes.

Enrichment and isolation procedures

The aquimarinans were isolated by direct plating on marine agar (Difco). Natural or artificial seawater is satisfactory for their cultivation. All isolated strains have been grown on media containing 0.5% peptone and 0.1–0.2% yeast extract (Difco). The strains may remain viable on marine agar (Difco) or other rich media based on natural or artificial seawater from 3 d to several weeks. They can survive storage in marine broth or artificial seawater supplemented with 20% (v/v) glycerol at –80°C for at least 5 years.

Differentiation of the genus *Aquimarina* from other genera

Aquimarina species clearly differ from their closest relatives, members of the genus *Kordia*, by production of flexirubin type pigments and the absence of acid formation from carbohydrates (Nedashkovskaya et al., 2005f, 2006f; Sohn et al., 2004). Moreover, aquimarinans produce catalase and grow with Na⁺ ions, in contrast to *Kordia algicida*, which requires not only Na⁺, but also Ca²⁺ and Mg²⁺ ions for growth.

Taxonomic comments

The 16S rRNA gene sequence similarities of *Aquimarina intermedia* with *Aquimarina muelleri* and *Aquimarina latercula* are 96.4 and 96.3%, respectively. The sequence similarity between *Aquimarina muelleri* and *Aquimarina latercula* is 95.4%.

These phylogenetic divergences, taken together with a number of differences in phenotypic characteristics and fatty acid composition, enable separation of the representatives of *Aquimarina muelleri* from their nearest neighbor, [*Cytophaga*] *latercula*. The latter was reclassified as [*Stanieirella*] *latercula* in the same study. Furthermore, 16S rRNA gene sequence similarities between KMM 6258^T, a novel strain, and its nearest neighbors *Aquimarina muelleri* and [*Stanieirella*] *latercula* were 96.3 and 96.4%, respectively. The intermediate phylogenetic position of this isolate supported the placement of KMM 6258^T, *Aquimarina muelleri*, and [*Stanieirella*] *latercula* in the same genus as three distinct species, according to criteria published by Stackebrandt and Goebel (1994). Fatty acid analysis of KMM 6258^T and the type strains of *Aquimarina muelleri* and [*Stanieirella*] *latercula*, carried out according to the standard protocol of the Microbial Identification System (Microbial ID) under the same conditions, showed that the cellular fatty acid profiles of all strains tested were consistent with the description of the genus *Aquimarina* (Table 28). The fatty acid composition and the phylogenetic position of [*Stanieirella*] *latercula* justified its transfer to the genus *Aquimarina* as *Aquimarina latercula* (Nedashkovskaya et al., 2006f). Because gliding motility and catalase production were not observed among cells of [*Stanieirella*] *latercula* in this and previous studies (Nedashkovskaya et al., 2005f; Reichenbach, 1989d), in contrast to other members of the genus *Aquimarina*, an emended description of the genus *Aquimarina* was proposed by Nedashkovskaya et al. (2006f).

Phylogenetic analysis based on 16S rRNA gene sequences indicates that the genus *Aquimarina* forms a cluster with species of the genera [*Gaetbulimicrobium*], *Gelidibacter* and *Algibacter* (Figure 28). The nearest neighbor of *Aquimarina* is the genus [*Gaetbulimicrobium*], consisting of a single species, [*Gaetbulimicrobium*] *brevivitae*, described by Yoon et al. (2006b). A close phylogenetic distance (16S rRNA gene sequence similarity of 96.2%) between the genera *Aquimarina* and [*Gaetbulimicrobium*] justified inclusion of [*Gaetbulimicrobium*] *brevivitae* in the genus *Aquimarina* as *Aquimarina brevivitae*. Similar fatty acid compositions and many common phenotypic traits also supported inclusion of [*Gaetbulimicrobium*] in the genus *Aquimarina* (Table 28).

Differentiation of species of the genus *Aquimarina*

Although species of the genus *Aquimarina* are phylogenetically close to each other and have similar fatty acid compositions (Table 28) and phenotypic characteristics, they can be differentiated by phenotypic traits presented in Table 29.

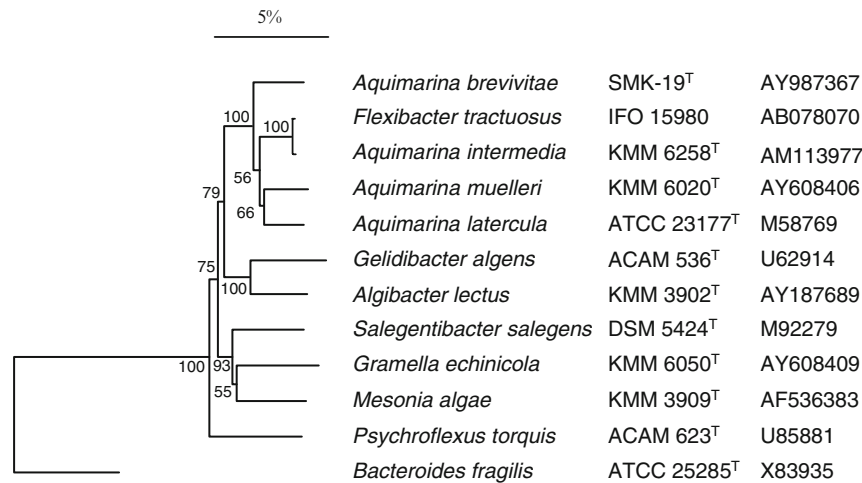

FIGURE 28. Phylogenetic tree of type strains of *Aquimarina* and related species based on 16S rRNA gene sequences.

List of species of the genus *Aquimarina*

1. ***Aquimarina muelleri*** Nedashkovskaya, Kim, Lysenko, Frolova, Mikhailov, Lee and Bae 2005f, 227^{VP}
muelleri N.L. gen. masc. n. *muelleri* of Müller, named after Otto Friedrich Müller (1730–1784), the famous Danish naturalist, for his contributions to the development of marine microbiology.

Cells are 0.3–0.5 \times 5–7 μ m. Colonies are irregular shaped, flat with non-entire edges, 3–5 mm in diameter, and dark-yellow- or brown-colored on marine agar. Alginate is not

degraded. No acid is produced from arabinose, cellobiose, fucose, galactose, glucose, lactose, maltose, melibiose, raffinose, rhamnose, sucrose, xylose, adonitol, dulcitol, glycerol, inositol, mannitol, or N-acetylglucosamine.

Source: seawater collected in Amursky Bay, Gulf of Peter the Great, Sea of Japan.

DNA G+C content (mol%): 31.6–32.5 (T_m).

Type strain: KMM 6020, KCTC 12285, LMG 22569.

Sequence accession no. (16S rRNA gene): AY608406.

2. *Aquimarina brevivitae* (Yoon, Kang, Jung, Oh and Oh 2006b) Nedashkovskaya, Vancanneyt, Christiaens, Kalinovskaya, Mikhailov and Swings 2006f, 2040^{VP} (*Gaetbulimicrobium brevivitae* Yoon, Kang, Jung, Oh and Oh 2006b, 118)

bre.vi.vi'tae. L. adj. *brevis* short; L. gen. n. *vitae* of life; N.L. gen. n. *brevivitae* of a short life, referring to the short-lived cultures of the type strain.

According to Yoon et al. (2006b), cells are 0.2–0.3 × 1.0–15.0 µm. Colonies are circular to irregular, slightly raised, smooth, orange-colored, and 1–2 mm in diameter after cultivation for 48 h at 37°C on marine agar. Carotenoid pigments are produced. Optimal growth is at 37°C, pH 7.0–8.0, and with 2–3% NaCl. Esculin, hypoxanthine, Tween 60, and tyrosine are hydrolyzed, but xanthine is not. Maltose and pyruvate are utilized, but D-cellobiose, D-fructose, D-galactose, trehalose, D-xylose, acetate, citrate, succinate, benzoate, L-malate, salicin, formate, and L-glutamate are not. No acid is produced from L-arabinose, D-fructose, D-galactose, lactose, D-mannose, D-melezitose, melibiose, raffinose, L-rhamnose, D-ribose, sucrose, trehalose, D-xylose, *myo*-inositol, D-mannitol, or D-sorbitol. API ZYM testing indicated the presence of esterase (C4), esterase lipase (C8), leucine arylamidase, valine arylamidase, acid phosphatase, naphthol-AS-BI-phosphohydrolase, and β-glucosidase activities, and the absence of lipase (C14), cystine arylamidase, trypsin, α-chymotrypsin, α-galactosidase, β-glucuronidase, α-glucosidase, N-acetyl-β-glucosaminidase, α-mannosidase, and α-fucosidase activities. Susceptible to cephalothin and novobiocin. The main polar lipids are phosphatidylethanolamine, unidentified phospholipids, and an amino-group-containing lipid that is ninhydrin-positive.

Source: tidal flat sediment at Saemankum, Pyunsan, Yellow Sea, Korea.

DNA G+C content (mol%): 36.0 (HPLC).

Type strain: SMK-19, KCTC 12390, DSM 17196.

Sequence accession no. (16S rRNA gene): AY987367.

3. *Aquimarina intermedia* Nedashkovskaya, Vancanneyt, Christiaens, Kalinovskaya, Mikhailov and Swings 2006f, 2040^{VP}

in.ter.me'di.a. L. fem. adj. *intermedia* intermediate, pertaining to the phylogenetic position of the strain studied.

Cells are 0.4–0.5 × 2.1–3.2 µm. Gliding motility occurs. On marine agar, colonies are 2–3 mm in diameter, circular, shiny with entire edges, and reddish. Optimal growth occurs at 25–28°C and with 2–5% NaCl. No acid is produced from arabinose, cellobiose, fucose, galactose, glucose, lactose, maltose, melibiose, raffinose, rhamnose, sorbose, sucrose, xylose, adonitol, dulcitol, glycerol, inositol, mannitol, citrate or N-acetylglucosamine.

Source: a single strain was isolated from the sea urchin *Strongylocentrotus intermedius* collected in Troitsa Bay, Gulf of Peter the Great, Sea of Japan.

DNA G+C content (mol%): 37.1 (T_m).

Type strain: KMM 6258, DSM 17527, JCM 13506, LMG 23204.

Sequence accession no. (16S rRNA gene): AM113977.

4. *Aquimarina latercula* (Lewin 1969) Nedashkovskaya, Vancanneyt, Christiaens, Kalinovskaya, Mikhailov and Swings 2006f, 2040^{VP} (*Stanielletta latercula* Nedashkovskaya, Kim, Lysenko, Frolova, Mikhailov, Lee and Bae 2005f, 228; *Cytophaga latercula* Lewin 1969, 200)

la.ter'cu.la. L. masc. dim. n. *laterculus* a small brick; N.L. fem. adj. *latercula* brick-like, brick-red color.

Cells are 0.4–0.5 × 2.1–3.2 µm. Gliding movement does not occur. On marine agar, colonies are 1–2 mm in diameter, circular, shiny with entire edges, dark-red-pigmented, and sunk into the agar. Optimal growth is observed at 23–25°C and with about 1.5% NaCl. No acid is produced from arabinose, cellobiose, fucose, galactose, glucose, lactose, maltose, melibiose, raffinose, rhamnose, sorbose, sucrose, xylose, adonitol, dulcitol, glycerol, inositol, mannitol, citrate, or N-acetylglucosamine.

Source: a single strain was isolated from the outflow of a marine aquarium, La Jolla, California, USA.

DNA G+C content (mol%): 34.0 (T_m).

Type strain: ATCC 23177, CIP 104806, DSM 2041, JCM 8515, LMG 1343, NBRC 15938, NCIMB 1399.

Sequence accession no. (16S rRNA gene): M58769.

Genus V. *Arenibacter* Ivanova, Nedashkovskaya, Chun, Lysenko, Frolova, Svetashev, Vysotskii, Mikhailov, Huq and Colwell 2001, 1992^{VP} emend. Nedashkovskaya, Vancanneyt, Cleenwerck, Snauwaert, Kim, Lysenko, Shevchenko, Lee, Park, Frolova, Mikhailov, Bae and Swings 2006g, 159

OLGA I. NEDASHKOVSKAYA AND MARC VANCANNEYT

Are.ni.bac'ter. L. fem. n. *arena* sand; N.L. masc. n. *bacter* from Gr. n. *baktron* rod; N.L. masc. n. *Arenibacter* a sand-dwelling rod.

Rod-shaped cells, 0.4–0.7 × 1.6–5.0 µm, with slightly irregular sides and rounded ends. **Cells of some species have gliding motility.** On marine agar 2216 (Difco), strains of the genus *Arenibacter* form regular, round, shiny, convex colonies with a diameter of 1–4 mm after 48 h at 28°C. Produce non-diffusible, dark-orange carotenoid pigments. **No flexirubin type pigments are produced. Chemoorganotrophs. Strictly aerobic.** Positive for oxidase, catalase, and alkaline phosphatase. The following enzyme activities are present: acid and alkaline phosphatases, α- and β-galactosidases, α- and β-glucosidases, N-acetylglucosaminidase,

esterase lipase (C8), leucine-, valine- and cystine-arylamidases, trypsin, α-chymotrypsin, naphthol-AS-BI-phosphohydrolase, α-mannosidase, and α-fucosidase. Arginine dihydrolase, lysine decarboxylase, ornithine decarboxylase, and tryptophan deaminase are not produced. Agar, casein, starch, alginic acids, cellulose (CM-cellulose and filter paper), chitin, and Tween 80 are not attacked, but gelatin, urea, DNA, and Tweens 20 and 40 can be hydrolyzed by strains of some species. Some species require seawater or Na⁺ for growth. Acetoin is produced; indole and H₂S are not produced. **The major respiratory quinone is MK-6.**

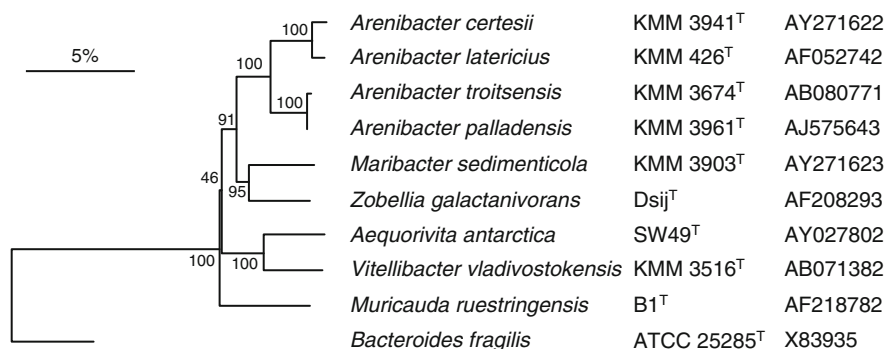

FIGURE 29. Phylogenetic tree of type strains of *Arenibacter* and related species based on 16S rRNA gene sequences.

The main cellular fatty acids are C_{15:1} iso, C_{15:0} iso, C_{15:0}, C_{17:0} iso 3-OH, and summed feature 3 comprising C_{15:0} iso 2-OH and/or C_{16:1} ω7c. The main polar lipid is phosphatidylethanolamine. Marine, isolated from coastal habitats.

DNA G+C content (mol%): 37–41 (T_m).

Type species: *Arenibacter latericius* Ivanova, Nedashkovskaya, Chun, Lysenko, Frolova, Svetashev, Vysotskii, Mikhailov, Huq and Colwell 2001, 1994^{VP} emend. Nedashkovskaya, Vancanneyt, Cleenwerck, Snauwaert, Kim, Lysenko, Shevchenko, Lee, Park, Frolova, Mikhailov, Bae and Swings 2006g, 159.

Further descriptive information

Phylogenetic analysis based on 16S rRNA gene sequences indicated that the genus *Arenibacter* forms a cluster with species of the genera *Maribacter*, *Muricauda*, *Robiginitalea*, and *Zobellia* (Figure 29). The 16S rRNA gene sequence similarities between *Arenibacter* species were 94.8–99.7%. A DNA–DNA hybridization level of 62% was found between *Arenibacter palladensis* KMM 3961^T and *Arenibacter troitsensis* KMM 3674^T. The latter two strains had low DNA–DNA hybridization values (6–20%) with *Arenibacter certesii* KMM 3941^T and *Arenibacter latericius* KMM 426^T.

The lipopolysaccharide of *Arenibacter certesii* KMM 3941^T consists of α-D-rhamnose, α-mannose, and α-galactosyluronic acid phosphate. Lipid A is made up of a bis-phosphorylated disaccharide unit composed of 2,3-diamino-2,3-dideoxy-β-D-glucopyranose and glucosamine (Silipo et al., 2005).

The cellular fatty acid compositions of *Arenibacter* species are given in Table 30.

All isolated strains have been grown on media containing 0.5% peptone and 0.1–0.2% yeast extract (Difco), prepared with natural or artificial seawater or supplemented with 2–3% NaCl. All species grow with 1–6% NaCl and at 10–32°C. Optimal temperature for growth is 23–30°C.

Acid is produced from maltose, D-cellobiose, and sucrose. No acid is produced from adonitol, L-arabinose, dulcitol, inositol, mannitol, or L-sorbose. L-Arabinose, D-glucose, D-lactose, and D-mannose are utilized, but inositol, mannitol, sorbitol, malonate, and citrate are not.

Based on the Biolog GN2 system of testing substrate utilization, the type strains of the four *Arenibacter* species utilize the following substrates: dextrin, D-galactose, gentiobiose, α-D-lactose,

TABLE 30. Cellular fatty acid compositions (%) of *Arenibacter* species^a

Summed feature 3	9.8–11.9 (9.8)	13.5	11.1	9.6

^aOnly fatty acids accounting for more than 1.0% for one of the strains are indicated. Summed feature 3 consists of one or more of the following fatty acids which could not be separated by the Microbial Identification System: C_{15:0} iso 2-OH, C_{16:1} ω7c, and C_{16:1} ω7t.

^bThe range of values for four strains is given. Values for the type strain, *Arenibacter latericius* KMM 426^T, are indicated in parentheses.

maltose, raffinose, sucrose, trehalose, and turanose. Substrates not utilized include α-cyclodextrin, Tween 80, adonitol, D-arabitol, i-erythritol, myo-inositol, psicose, xylitol, monomethyl succinate, acetic acid, cis-aconitic acid, citric acid, formic acid, D-galactonic acid lactone, D-gluconic acid, D-glucosaminic acid, D-glucuronic acid, α-hydroxybutyric acid, β-hydroxybutyric acid, γ-hydroxybutyric acid, p-hydroxyphenylacetic acid, itaconic acid, α-ketoglutaric acid, α-ketovaleric acid, malonic acid, propionic acid, quinic acid, D-saccharic acid, sebacic acid,

succinic acid, bromosuccinic acid, succinamic acid, glucuronamide, alaninamide, D-alanine, L-alanyl-glycine, L-asparagine, glycyl-L-glutamic acid, L-histidine, hydroxy-L-proline, L-leucine, L-ornithine, L-phenylalanine, L-pyroglytamic acid, D-serine, D-serine, DL-carnitine, γ -aminobutyric acid, urocanic acid, inosine, uridine, thymidine, phenylethylamine, putrescine, 2-aminoethanol, 2,3-butanediol, and glucose 6-phosphate.

Strains of the genus *Arenibacter* are susceptible to lincomycin, but are resistant to kanamycin, benzylpenicillin, neomycin, streptomycin, gentamicin, and polymyxin B. Susceptibility to ampicillin, erythromycin, carbenicillin, cephaloridin, oleandomycin, tetracycline, and oxacillin differs among species.

The arenibacters inhabit coastal marine environments. They have been isolated from seaweeds and sediments in the temperate latitudes. The strains are accumulators of iodide (Amachi et al., 2005). An ability to produce α -N-acetylgalactosaminidase occurs among strains of *Arenibacter latericius* (Ivanova et al., 2001). One of the forms of this enzyme, α -N-acetylgalactosaminidase IV, isolated from cells of the type strain KMM 426^T, is able to remove the blood type specificity of human A (II)-erythrocytes, transforming them to O (I)-erythrocytes. The enzyme is active at pH 7–8 and has molecular mass of 84 kDa (Bakunina et al., 2002).

Enrichment and isolation procedures

The arenibacters were isolated by direct plating on marine agar or on medium B containing 0.5% (w/v) Bacto peptone (Difco), 0.2% (w/v) casein hydrolysate (Merck), 0.2% (w/v) Bacto yeast extract (Difco), 0.1% (w/v) glucose, 0.002% (w/v) KH₂PO₄, 0.005% (w/v) MgSO₄·7H₂O and 1.5% (w/v) Bacto agar (Difco) in 50% (v/v) natural seawater and 50% (v/v) distilled water. Natural or artificial seawater is suitable for cultivation. All isolated strains have been grown on media containing 0.5% peptone and 0.1–0.2% yeast extract (Difco). Strains of the genus *Arenibacter* may remain viable on marine agar or other rich media based on natural or artificial seawater for several weeks. They have survived storage at –80°C for at least 5 years.

Differentiation of the genus *Arenibacter* from other genera

Species of the genus *Arenibacter* grow at 37°C and form dark-orange colonies on marine agar, in contrast with the yellow-pigmented *Maribacter* species (Ivanova et al., 2001; Nedashkovskaya et al., 2003b) (Nedashkovskaya et al., 2004a, 2004b, 2006g; Yoon et al., 2005b). *Arenibacter* species can be differentiated from those of *Robiginitalea* by their inability to hydrolyze starch and lower DNA G+C content (37–41 mol% vs 55–56 mol%, respectively) (Cho and Giovannoni, 2004). An inability to produce agarase and lack of flexirubin pigments distinguish *Arenibacter* species from those of *Zobellia* (Barbeyron et al., 2001; Nedashkovskaya et al., 2004f; Reichenbach, 1989d). *Arenibacter*, whose cells are regular rods, differs from its

TABLE 31. Differential characteristics of *Arenibacter* species^a

close relative, *Muricauda*, which can form appendages on the cell walls (Bruns et al., 2001).

Taxonomic comments

Originally the genus *Arenibacter* was described as consisting of non-gliding bacteria that required Na⁺ for growth and were unable to decompose gelatin (Ivanova et al., 2001). However, studies of novel algal isolates and *Arenibacter troitsensis* KMM 3674^T (Nedashkovskaya et al., 2003b, 2006g) indicate that these and other phenotypic traits differ among species and are helpful in differentiating the *Arenibacter* species from one another (Tables 31 and 32).

thine, uridine, glycerol, and glucose 6-phosphate are utilized. D-Fructose, α -D-lactose, lactulose, D-mannitol, succinic acid, glucuronamide, alaninamide, L-alanyl-glycine, L-asparagine, glycyl L-glutamic acid, and D- and L-serine are utilized weakly. Susceptible to erythromycin and cephaloridin. Not susceptible to oxacillin. The acetoin test is positive in API galleries (bioMérieux). Sphingophospholipids are absent.

Source: a sediment sample collected in the South-China Sea and from the holothurian *Apostichopus japonicus* and the brown alga *Chorda filum*, which inhabit Troitsa Bay, Sea of Japan, and the Sea of Okhotsk (The Pacific Ocean), respectively.

DNA G+C content (mol%): 37–38 (T_m).

Type strain: KMM 426, VKM B-2137D, LMG 19693, CIP 106861.

Sequence accession no. (16S rRNA gene): AF052742.

2. ***Arenibacter certesii*** Nedashkovskaya, Kim, Han, Lysenko, Mikhailov and Bae 2004a, 1174^{VP}

cer.te'si.i. N.L. gen. masc. n. *certesii* of Certes, named after A. Certes for his contributions to the development of marine microbiology.

Cells are nonmotile rods, 0.4–0.7 μ m wide and 3–5 μ m long. Colonies are circular, low convex, shiny with entire edges, and 1–3 mm in diameter on marine agar 2216. No growth is observed without Na⁺. Growth occurs with 1–10% NaCl and at 4–38°C. Fumarate is not utilized. Nitrate is reduced.

Source: the single available strain was isolated from the green alga *Ulva fenestrata* collected in Troitsa Bay, Gulf of Peter the Great, Sea of Japan.

DNA G+C content (mol%): 37.7 (T_m).

Type strain: KMM 3941, KCTC 12113, CCUG 48006.

Sequence accession no. (16S rRNA gene): AY271622.

3. ***Arenibacter palladensis*** Nedashkovskaya, Vancanneyt, Cleenwerck, Snauwaert, Kim, Lysenko, Shevchenko, Lee, Park, Frolova, Mikhailov, Bae and Swings 2006g, 159^{VP}

pal.la.den'sis. N.L. masc. adj. *palladensis* pertaining to Pallada Bay, where the strains were isolated.

Cells are 0.4–0.5 \times 1.6–2.3 μ m. On marine agar, colonies are 2–4 mm in diameter and circular with entire edges. Growth is observed at 4–38°C (optimum, 23–25°C). Growth occurs with 0–10% NaCl. According to the results obtained with the Biolog GN2 MicroPlate system, the type strain utilizes D-fructose, lactulose, and D-mannose. Does not utilize α -cyclodextrin, Tweens 40 and 80, adonitol, L-arabinose, D-arabitol, i-erythritol, *myo*-inositol, D-mannitol, psicose, L-rhamnose, xylitol, monomethyl succinate, acetic acid, citric acid, formic acid, D-galactonic acid lactone, D-gluconic acid, D-glucosaminic acid, D-glucuronic acid, α - and β -hydroxybutyric acids, *p*-hydroxyphenylacetic acid, itaconic acid, α -ketoglutaric acid, α -ketovaleric acid, malonic acid, propionic acid, quinic acid, D-saccharic acid, sebacic acid, succinic acid, bromosuccinic acid, succinamic acid, glucuronamide, alaninamide, L-alanyl-glycine, L-asparagine, glycyl-L-glutamic acid, L-histidine, hydroxy-L-proline, L-leucine, L-ornithine, L-phenylalanine, L-pyroglutamic acid, D- and L-serine, DL-carnitine, γ -aminobutyric acid, uronic acid, inosine, uridine, thymidine, phenylethylamine, putrescine, 2-aminoethanol, 2,3-butanediol, glycerol, or glucose 6-phosphate.

Source: the green alga *Ulva fenestrata* in Pallada Bay, Sea of Japan.

DNA G+C content (mol%): 39–41 (T_m).

Type strain: KMM 3961, LMG 21972, CIP 108849.

Sequence accession no. (16S rRNA gene): AJ575643.

4. ***Arenibacter troitsensis*** Nedashkovskaya, Suzuki, Vysotskii and Mikhailov 2003b, 1289^{VP}

tro.it.sen'sis. N.L. masc. adj. *troitsensis* of or belonging to Troitsa Bay, from where the organism was isolated.

Cells are nonmotile rods, 0.4–0.7 μ m wide and 3–5 μ m long. Colonies are circular, low convex, shiny with entire edges, 1–3 mm in diameter on marine agar. No growth is observed without Na⁺. Grows with 1–6% NaCl and at 10–42°C.

Source: a sediment sample from Troitsa Bay, Gulf of Peter the Great, Sea of Japan.

DNA G+C content (mol%): 40.0 (T_m).

Type strain: KMM 3674, JCM 11736.

Sequence accession no. (16S rRNA gene): AB080771.

Genus VI. *Bergeyella* Vandamme, Bernardet, Segers, Kersters and Holmes 1994a, 830^{VP}

THE EDITORIAL BOARD

Ber. gey.el'la. L. dim. suff. -ella; N.L. fem. dim. n. *Bergeyella* named in honor of David H. Bergey.

Rods with parallel sides and rounded ends, typically $0.6 \times 2\text{--}3 \mu\text{m}$. **Intracellular granules of poly- β -hydroxybutyrate are absent.** Endospores are not formed. Gram-stain-negative. **Nonmotile.** Do not glide or spread. **Aerobic**, having a strictly respiratory type of metabolism. Grows at 18–42°C. Growth on solid media is not pigmented. Colonies are circular (0.5–2 mm in diameter), low convex, smooth, and shiny with entire edges. **Catalase- and oxidase-positive.** Agar is not digested. Chemo-organotrophic. Non-saccharolytic. **Indole-positive.** No growth at 42°C, on MacConkey agar, or on β -hydroxybutyrate agar. Grows on blood and chocolate agar but poorly on nutrient agar. Branched-chain fatty acids (C_{15:0} iso, C_{15:0} iso 2-OH, C_{17:1} iso, C_{17:0} iso 3-OH) are predominant. Sphingophospholipids are absent. The major polyamine is homospermidine. *Bergeyella* appears to be part of the oral and/or nasal microbiota of dogs and cats; rare but severe human wound infections can be caused by bites from these animals.

DNA G+C content (mol%): 35–37 (T_m).

Type species: Bergeyella zoohelcum (Holmes et al., 1987) Vandamme, Bernardet, Segers, Kersters and Holmes 1994a, 830^{VP} (*Weeksella zoohelcum* Holmes, Steigerwalt, Weaver and Brenner 1987, 179; CDC Group Ij).

Further descriptive information

Circular, entire, nonhemolytic, nonpigmented colonies having a butyrous consistency develop on 5% horse blood agar (Holmes et al., 1986b). Only scant growth occurs on nutrient agar.

Gelatin is hydrolyzed by the plate method, but not by the stab method. No change occurs in glucose O/F medium. No growth occurs in the presence of 0.0075% (w/v) KCN. No growth occurs at 5°C, on MacConkey agar, or on cetrimide agar. Nitrate, nitrite, and selenite are not reduced. Esculin, Tween 80, and starch are not hydrolyzed.

The following tests give a negative reaction: oxidation of gluconate; phenylalanine deaminase; H₂S production; alkalization of Christensen's citrate medium; arginine deamidase; arginine dihydrolase; lysine decarboxylase; ornithine decarboxylase; 3-ketolactose; ONPG hydrolysis; acid from 10% glucose and lactose; acid or gas from glucose; and acid (in ammonium salts medium under aerobic conditions) from glucose, adonitol, arabinose, cellobiose, dulcitol, ethanol, fructose, glycerol, inositol, lactose, maltose, mannitol, raffinose, rhamnose, salicin, sorbitol, sucrose, trehalose, and xylose.

Bergeyella zoohelcum has been found in 38–90% of nasal and oral fluids and gingival scrapings of dogs (Reina and Borrell, 1992). It can be an opportunistic pathogen of humans, acquired from dog or cat bites, causing rare but serious infections in humans such as leg abscesses (Reina and Borrell, 1992), polymicrobial

tenosynovitis (Isotalo et al., 2000), septicemia (Kivinen et al., 2003), acute cellulitis (Shukla et al., 2004), and pneumonia (Grimault et al., 1996). *Bergeyella zoohelcum* has usually been thought not to be pathogenic for its animal hosts; however, it has been associated with respiratory disease in a cat (Decostere et al., 2002). *Bergeyella*-like strains have also been isolated from a variety of food sources (Botha et al., 1998).

Goldstein et al. (1999) reported that ten *Bergeyella zoohelcum* isolates were sensitive to gatifloxacin, levofloxacin, sparfloxacin, ciprofloxacin, and grepafloxacin. Kivinen et al. (2003) reported that their *Bergeyella zoohelcum* strain was sensitive to all β -lactam antibiotics, including penicillin and cefuroxime, as well as to aminoglycosides and quinolones; however, it was resistant to cotrimoxazole. A strain isolated from a respiratory infection in a cat was susceptible to ampicillin, amoxicillin-clavulanic acid, enrofloxacin, gentamicin, apramycin, ceftiofur, spectinomycin, neomycin, and trimethoprim-sulfamethoxazole, but was resistant to tetracycline, flumequine, and colistin (Decostere et al., 2002).

Enrichment and isolation procedures

There is no specific medium for the selective isolation of *Bergeyella* strains. Growth occurs on blood and chocolate agar, but may be scanty. The organism is best identified by amplifying and sequencing the 16S rRNA gene and comparing it with that of the type strain.

Differentiation of the genus *Bergeyella* from other genera

The following features differentiate the genus *Bergeyella* from the genus *Weeksella*: positive urease activity, failure to grow at 42°C, and failure to grow on MacConkey agar and β -hydroxybutyrate agar.

Taxonomic comments

Bergeyella zoohelcum strains initially belonged Centers for Disease Control and Prevention group Ij. Holmes et al. (1986b) classified the strains of this group as members of a novel species of the genus *Weeksella*, *Weeksella zoohelcum*. The genus *Weeksella* contained two species: *Weeksella zoohelcum* and the type species *Weeksella virosa*. No significant DNA–DNA hybridization occurred between the two species (Holmes et al., 1986b). rRNA gene analysis later showed that *Weeksella* was heterogeneous and *Weeksella zoohelcum* was placed in a new genus, *Bergeyella*, as *Bergeyella zoohelcum* (Vandamme et al., 1994a). *Bergeyella zoohelcum* is currently the only species in the genus. The nearest related genera based rRNA cistron analysis are *Riemerella* and *Chryseobacterium* (Vandamme et al., 1994a).

List of species of the genus *Bergeyella*

1. ***Bergeyella zoohelcum*** (Holmes, Steigerwalt, Weaver and Brenner 1987) Vandamme, Bernardet, Segers, Kersters and Holmes 1994a, 830^{VP} (*Weeksella zoohelcum* Holmes, Steigerwalt, Weaver and Brenner 1987, 179; CDC Group Ij)

zoo.hel'cum. Gr. n *zoon* an animal; Gr. neut. n. *helkos* a wound; N.L. gen. pl. n. *zoohelcum* of animal wounds, because strains are isolated from cat and dog bites and scratches.

Characteristics are as described for the genus.

Source: oral fluids and gingival scrapings of dogs and human wounds caused by cat and dog bites/scratches.

DNA G+C content (mol%): 35–37 (T_m).

Type strain: D658, ATCC 43767, CCUG 12568, CCUG 30535, CIP 103041, NBRC 16014, LMG 8351, LMG 12996, NCTC 11660.

Sequence accession no. (16S rRNA gene): M93153.

Genus VII. *Bizionia* Nedashkovskaya, Kim, Lysenko, Frolova, Mikhailov and Bae 2005d, 377^{VP}

OLGA I. NEDASHKOVSKAYA, SEUNG BUM KIM AND VALERY V. MIKHAILOV

Bi.zi.o'ni.a. N.L. fem. n. *Bizionia* named after the Italian naturalist Bartolomeo Bizio, for his important contribution to the development of microbiology.

Thin rods usually measuring $0.3\text{--}0.5 \times 1.0\text{--}5.0 \mu\text{m}$. No gliding motility. Produce non-diffusible carotenoid pigments. Flexirubin type pigments are not produced. **Chemo-organotrophs**. **Strictly aerobic**. Positive for oxidase, catalase, and alkaline phosphatase. Agar, starch, and chitin are not hydrolyzed, but casein and gelatin are hydrolyzed. Nitrate reductase is not produced. No acid is formed from carbohydrates. **Marine**, isolated from coastal habitats. Require seawater or sodium ions for growth.

The major respiratory quinone is MK-6.

DNA G+C content (mol%): 37–45 (T_m).

Type species: *Bizionia paragorgiae* Nedashkovskaya, Kim, Lysenko, Frolova, Mikhailov and Bae 2005d, 377^{VP}.

Further descriptive information

16S rRNA gene sequence analysis indicates that *Bizionia* forms a cluster with species of the genera *Formosa* (Figure 30).

Major cellular fatty acids are $C_{15:0}$ iso, $C_{15:0}$ anteiso, $C_{15:1}$ iso, $C_{15:1}$ anteiso, $C_{16:1}$ iso, $C_{16:0}$ iso, $C_{16:0}$ iso 3-OH, and summed feature 3, comprising $C_{15:0}$ iso 2-OH and/or $C_{16:1}$ ω7c. It should be noted that cells of strain *Bizionia paragorgiae* KMM 6029^T contain 77.1% branched fatty acids.

On marine agar, colonies are 2–4 mm in diameter, circular, shiny, yellow or golden-yellow, and have a butyrous consistency and entire edges after 48 h at 28°C.

Bizionia strains require peptone or yeast extract for growth and cannot use inorganic nitrogen sources such as sodium nitrate or ammonium chloride (Bowman and Nichols, 2005). All isolated strains have been grown on media containing 0.5% peptone and 0.1–0.2% yeast extract (Difco), prepared with natural or artificial seawater or supplemented with 2–3% NaCl. Growth occurs at –2 to 36°C (optimum at 23–25°C). Growth occurs with 1–17% NaCl (optimum at 1.5–6% NaCl).

Strains of the genus are susceptible to ampicillin, carbenicillin, lincomycin, oleandomycin, streptomycin, and tetracycline. They are resistant to benzylpenicillin, gentamicin, kanamycin, neomycin, and polymyxin B.

Representatives of the genus *Bizionia* inhabit coastal marine environments. Some have been isolated from corals in the temperate latitudes. However, most *bizionias* are cold-adaptive organisms, isolated from Antarctic sea-ice brine and from exoskeletal slime on coastal amphipods.

Enrichment and isolation procedures

Bizionia strains have been isolated by direct plating on marine agar (Difco). Either natural or artificial seawater is suitable for their cultivation. All isolated strains have been grown on media containing 0.5% peptone and 0.1–0.2% yeast extract (Difco). *Bizionia* strains may remain viable on marine agar (Difco) or other rich media based on natural or artificial seawater for several weeks. They have survived storage at –80°C for at least 5 years.

Taxonomic comments

Bizionia species show 96–98% 16S rRNA gene sequence similarity to each other. DNA–DNA hybridization experiments indicate that the species are distinct from one another (Bowman and Nichols, 2005).

Differentiation of the genus *Bizionia* from other genera

Bizionia can be differentiated clearly from its closest relative, *Formosa*, by its absence of gliding motility, its inability to produce acid from carbohydrates, its ability to ferment D-glucose and hydrolyze casein, its requirement for NaCl for growth, and the higher G+C content of its DNA.

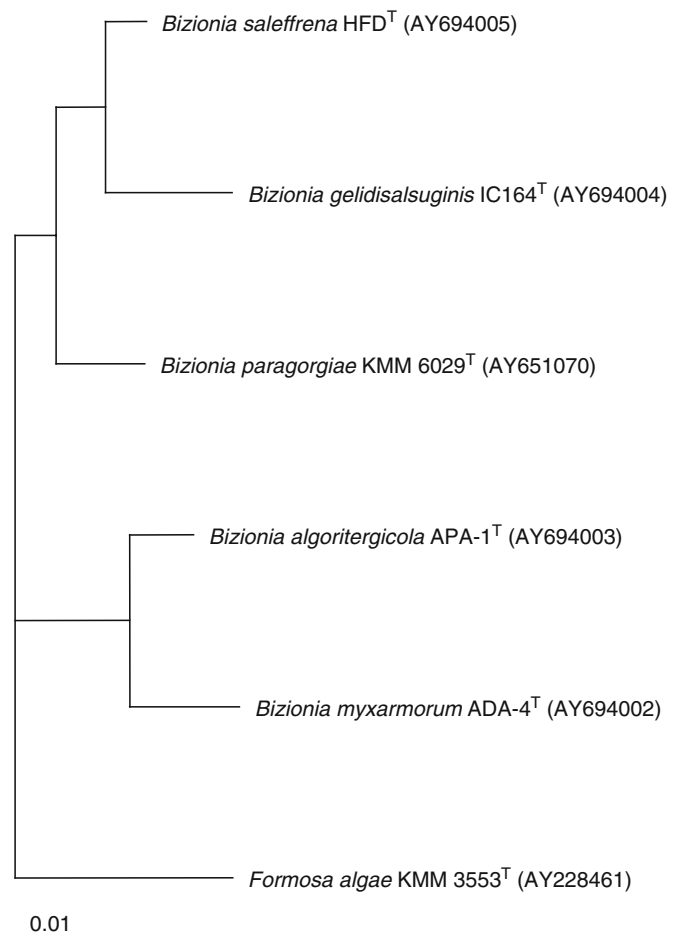

FIGURE 30. Phylogenetic tree based on 16S rRNA gene sequences of the type strains of the genus *Bizionia*. The tree was generated by the neighbor-joining method (Saitou and Nei, 1987). Bar = 0.01 substitutions per nucleotide position.

Differentiation of species of the genus *Bizonia*

Although *Bizonia* species are phylogenetically close to each other and have similar fatty acid compositions and phenotypic

characteristics, they can be distinguished by the set of phenotypic traits shown in Table 33.

List of species of the genus *Bizonia*

- Bizonia paragorgiae*** Nedashkovskaya, Kim, Lysenko, Frolova, Mikhailov and Bae 2005d, 377^{VP}
pa.ra.gor'gi.ae. N.L. gen. n. *paragorgiae* of *Paragorgia*, the generic name of the soft coral *Paragorgia arborea*, from which the type strain was isolated.
Cells are 0.4–0.5 × 1.9–2.3 µm. On marine agar, colonies are 2–4 mm in diameter, circular, shiny, and yellow with entire edges. The optimal growth temperature is 23–25°C. Tween 40 is hydrolyzed, but not Tween 20 or agar. H₂S is produced, but not indole or acetoin (Voges–Proskauer reaction). Acid is not formed from L-arabinose, D-cellobiose, L-fucose, D-galactose, D-glucose, D-lactose, maltose, melibiose, raffinose, L-rhamnose, D-sucrose, DL-xylose, citrate, adonitol, dulcitol, glycerol, inositol, or mannitol. Does not utilize L-arabinose, D-glucose, D-lactose, D-mannose, sucrose, mannitol, inositol, sorbitol, malonate, or citrate.
Source: isolated from the soft coral *Paragorgia arborea* collected in the Makarov Bay, Iturup Island, Sea of Okhotsk.
DNA G+C content (mol%): 37.6 (T_m).
Type strain: KCTC 12304, KMM 6029, LMG 22571.
Sequence accession no. (16S rRNA gene): AY651070.
- Bizonia algorithergicola*** Bowman and Nichols 2005, 1483^{VP}

Cells are 0.3–0.5 × 1–3 µm. On marine agar, colonies are circular, shiny, convex, and golden-yellow with a butyrous consistency and entire edges. Optimal growth is observed with 1.7–2.3% NaCl.
Source: isolated from an unidentified marine amphipod collected in East Antarctica.
DNA G+C content (mol%): 45.0 (T_m).
Type strain: APA-1, ACAM 1056, CIP 108533.
Sequence accession no. (16S rRNA gene): AY694003.
- Bizonia gelidisalsuginis*** Bowman and Nichols 2005, 1482^{VP}
gel.id.i.sal.su'gin.is. L. adj. *gelidus* icy; L. fem. n. *salsugo-inis* the brine; N.L. gen. n. *gelidisalsuginis* of icy brine.
Cells are 0.4–0.5 × 1.5–3.5 µm. On marine agar, colonies are circular, convex, butyrous, and golden-yellow with entire edges. Optimum growth occurs with 5.7% NaCl.

Source: isolated from sea-ice brine in East Antarctica.

DNA G+C content (mol%): 39.0 (T_m).

Type strain: IC164, ACAM 1057, CIP 108536.

Sequence accession no. (16S rRNA gene): AY694004.

4. **Bizionia myxarmorum** Bowman and Nichols 2005, 1483^{VP}
 myx.ar.mor'um. Gr. n. *myxa* slime; L. gen. pl. n. *armorum* of defensive armors; N.L. pl. gen. n. *myxarmorum* of armors slime (of the slime on the carapaces of crustacean hosts).
 Cells are 0.3–0.5 × 1.5–3.5 μm. On marine agar, colonies are circular, convex, butyrous, and golden-yellow with entire edges. Optimal growth occurs with 1.5–2.3% NaCl.
Source: isolated from an unidentified marine amphipod collected in East Antarctica.
DNA G+C content (mol%): 43.0 (T_m).

Type strain: ADA-4, ACAM 1058, CIP 108535.

Sequence accession no. (16S rRNA gene): AY694002.

5. **Bizionia saleffrena** Bowman and Nichols 2005, 1482^{VP}
 sal.ef.fre'na. L. masc. n. *sal salis* salt; L. fem. adj. *effrena* unbridled; N.L. fem. adj. *saleffrena* unbridled by salt (referring to the species' good growth on salt-containing media).
 Cells are 0.4–0.5 × 1.5–5 μm. On marine agar, colonies are circular, convex, butyrous, and golden-yellow with entire edges. Optimum growth occurs with 5.7% NaCl.
Source: isolated from sea-ice brine in East Antarctica.
DNA G+C content (mol%): 40.0 (T_m).
Type strain: HFD, ACAM 1059, CIP 108534.
Sequence accession no. (16S rRNA gene): AY694005.

Genus VIII. **Capnocytophaga** Leadbetter, Holt and Socransky 1982, 266^{VP} (Effective publication: Leadbetter, Holt and Socransky 1979, 13.)

STANLEY C. HOLT

Gr. n. *capnos* smoke; N.L. fem. n. *Cytophaga* a bacterial genus name; N.L. fem. n. *Capnocytophaga* bacteria requiring carbon dioxide and related to the cytophagas.

Short to elongate flexible fusiform to rod-shaped cells, 0.42–0.6 μm in diameter and 2.5–5.7 μm in length. Ends of cells are usually round to tapered. Cells can be pleomorphic. Capsules and sheaths not formed. Gram-stain-negative. Resting stages not known. No flagella. Motility when it occurs is by “gliding” on solid culture media (surface translocation). Facultatively anaerobic. Growth occurs in air with 5% CO₂. Some strains are reported to grow aerobically without CO₂; however, **primary isolation and initial growth require CO₂**. Optimum temperature: 35–37°C. Chemo-organotrophic, with fermentative type of metabolism. **Carbohydrates are used as fermentable substrates and energy sources. Fermentation of glucose yields chiefly acetate and succinate as major acidic end products**; trace amounts of isovalerate are formed. Complex polysaccharides such as dextran, glycogen, inulin, and starch may be fermented. Catalase and oxidase reactions differ among species. Positive for *o*-nitrophenyl-β-D-galactoside (ONPG) and benzidine. Found in association with both animal and human hosts. Originally isolated from the human oral cavity where the cells occupied periodontal pockets. Pathogenicity is uncertain, but members of the genus have been implicated as pathogens in several human and animal infections.

DNA G+C content (mol%): 34–44.

Type species: **Capnocytophaga ochracea** Leadbetter, Holt and Socransky 1982, 266^{VP} (Effective publication: Leadbetter, Holt and Socransky 1979, 14.).

Further descriptive information

The genus consists of five human oral species: *Capnocytophaga gingivalis*, *Capnocytophaga ochracea*, *Capnocytophaga sputigena*, *Capnocytophaga granulosa*, and *Capnocytophaga haemolytica*. Two additional species, *Capnocytophaga canimorsus* and *Capnocytophaga cynodegmi*, form part of the canine and feline oral microbiota. The genus belongs to the family *Flavobacteriaceae*, class *Flavobacteriia*.

Cells can be single, short or elongate flexible rods, or long filaments (Figure 31). Pleomorphic cells have also been observed

when these organisms have been grown in liquid. In liquid culture, cells also grow in characteristic tight masses (Figure 31). When grown on trypticase soy agar (TSA) containing 5% (v/v) sheep's blood (TS-blood agar) prepared by BBL, cells form flat, thin colonies that, when viewed by oblique illumination, have uneven edges (Figures 32–34) that can form fingerlike projections – characteristic of the cells' gliding motility. Gliding motility (surface translocation; Altschul et al., 1997) is consistent with strains of the genus being sensitive to actinomycin D (Dworkin, 1969). Laboratory-prepared TS-blood agar did not support this typical spreading or gliding motility reproducibly; hence, spreading is medium-dependent. Macroscopically, colonies (after incubation for 24 h at 35–37°C) are very small to pinpoint; between 48 and 96 h, colonies are convex and 2–4 mm in diameter. Some colonies appear to pit the agar (Figure 34). Blood is not required for cell growth or gliding motility; the harder the agar surface, the more characteristic the cell spreading or gliding motility [see Leadbetter et al. (1979) for a discussion of the effects of medium and agar concentration on gliding motility]. Cultures have a characteristic sour, bitter almond odor.

The salient staining, growth, genetic and physiological characteristics of the genus *Capnocytophaga* are listed in Table 34. Pigmentation of colonies on an agar surface varies from white-gray to pink and orange-yellow. However, when cells are centrifuged into pellets, all strains are yellow to orange. Pigmentation is not inhibited by the carotenoid inhibitor diphenylamine. The cells are positive for ONPG and benzidine (Collins et al., 1982). Menaquinone-6 and trace amounts of menaquinone-5 constitute the sole respiratory quinones (Collins et al., 1982; Speck et al., 1987).

A detailed study of the fine structure of the genus *Capnocytophaga* was carried out by Holt et al. (1979), Poirier et al. (1979), and Yamamoto et al. (1994). The cell envelope is typical of Gram-stain-negative bacteria (Figure 35). The outer membrane has a tendency to slough material from its surface (Figure 36), which is also typical of Gram-stain-negative

FIGURE 31. Phase-contrast photomicrographs of representative strains of *Capnocytophaga* species. Strains in (a–d) were grown on trypticase soy agar + 5% sheep’s blood and that in (e) was grown in trypticase soy broth. (a) *Capnocytophaga sputigena* strain 4^T (=ATCC 33612^T); (b) *Capnocytophaga ochracea* strain 25^T (=ATCC 33596^T); (c) *Capnocytophaga gingivalis* strain 27^T (=ATCC 33624^T); (d) and (e), *Capnocytophaga* strain 60-38.1 grown in liquid and on a plate, respectively. [Reproduced with permission from Holt et al. (1979). Arch. Microbiol. 122: 17–27, Springer, Berlin.]

micro-organisms. When cells are removed from agar surfaces and prepared for electron microscopy, they are held together by extracellular material (Figure 37), with the outer-most layer of *Capnocytophaga* species staining positively with ruthenium red – presumptive of an acidic mucopolysaccharide layer (Figure 38). Cell division resembles that seen in other Gram-stain-negative bacteria, being characterized by a constriction of the central region of the cell.

There have been several studies reported on the enzymes of *Capnocytophaga* (see Table 35; also Laughon et al., 1982; Nakamura and Slots, 1982; Poirier and Holt, 1983; Lillich and Calmes, 1979; Takeshita et al., 1983). Recently, Ohishi et al. (2005) studied the activity of various inhibitors on the aminopeptidases of *Capnocytophaga granulosa*. *Capnocytophaga* species display significant aminopeptidase activity, exhibiting leucine,

valine, and cystine aminopeptidases by the API ZYM system (Laughon et al., 1982; Slots, 1981), as well as being positive for α -glucosidase. Although the API ZYM pattern is distinct for the aminopeptidases, the *Capnocytophaga* species vary enough in the other enzymic reactions tested to make these chromogenic assays of only limited value for correlating API ZYM reactions with key phenotypic characteristics. *Capnocytophaga ochracea* possesses high levels of phosphoenolpyruvate (PEP) carboxykinase, which is the only CO_2 (or HCO_3^-)-fixing enzyme in the genus (Kapke et al., 1980). Cell-free extracts of *Capnocytophaga ochracea* also contain an NAD-specific glutamate dehydrogenase, as well as high levels of acid and alkaline phosphatase. Detectable levels of the malic enzyme, pyruvic acid carboxylase, PEP carboxylase, or PEP carboxytransphosphorylase have not been observed. Glucose is transported into *Capnocytophaga ochracea*

FIGURE 32. *Capnocytophaga* strain grown on blood agar plate and photographed by oblique illumination. Cells spread from a central streak line in opposite directions (courtesy of M. Newman, University of CA School of Dentistry, Los Angeles).

FIGURE 33. Diluted sample of subgingival plaque after 28 h of growth on TS-blood agar prepared by BBL. Arrows: *Capnocytophaga* species displaying characteristic gliding morphology. Bar = 1 cm. Microbiol.* 10: 557–562 (1977), American Society for Microbiology, Washington, DC.)

by a PEP/phosphotransferase system and then catabolized to pyruvic acid by the Embden–Meyerhof–Parnas pathway (Calmes et al., 1980). Although key enzymes of the Entner–Doudoroff, hexose phosphoketolase, or Warburg–Dickens pathways have not been found, definitive proof of their absence from *Capnocytophaga* will require tracing the distribution of specifically labeled glucose carbons to their specific end products.

Information has been published on the chemical composition of the lipopolysaccharide of *Capnocytophaga* after phenol/water and butanol/water preparative procedures, as well as the biological activity of these molecules (Poirier and Holt, 1983). The lipid chemistry of the genus has also been reported

^bSome strains are positive after initial cultivation; *Capnocytophaga granulosa* can grow aerobically.

^cSome strains are resistant.

(Dees et al., 1982; Holt et al., 1979). Cellular fatty acid analysis of strains of *Capnocytophaga* (Dees et al., 1982; Yamamoto et al., 1994; Vandamme et al., 1996b; Table 36) has revealed the predominant fatty acids to be a saturated, iso-branched-chain,

FIGURE 35. Thin section of *Capnocytophaga ochracea* strain 25^T (=ATCC 33596^T). The outer membrane encloses a periplasmic space, with the cytoplasmic membrane limiting the electron-opaque ribosomes in the cytoplasmic region. The peptidoglycan is closely adherent to the outer aspect of the cytoplasmic membrane. An electron-opaque "fuzz" covers the surface of the outer membrane. Stained with uranyl acetate-lead citrate. Bar = 0.25 μ m.

FIGURE 36. Negatively stained (ammonium molybdate at pH 7.2) *Capnocytophaga ochracea* strain 25^T (=ATCC 33596^T). Numerous outer membrane fragments were in the process of being removed from the cell surface. A large mesosome is apparent. Bar = 0.5 μ m.

15 carbon acid (13-methyltetradecanoate) and a saturated, iso-branched-chain 3-hydroxy acid (13-methyl-3-hydroxy-3-hydroxytetradecanoate). Small amounts of 15-methyl-3-hydroxy-hexadecanoate also occur. The major phospholipids are phosphatidylethanolamine and an ornithine-amino lipid, as well as lesser amounts of lysophosphatidylethanolamine. *Capnocytophaga* species also contain the unique sulfonolipid,

FIGURE 37. Thin section of *Capnocytophaga sputigena* strain 4^T (=ATCC 33612^T). Cells were grown on BBL TS-blood agar at 37°C for 48 h. An agar square was cut from the plate and fixed in glutaraldehyde/osmium tetroxide by standard techniques. Cells were thin-sectioned parallel to the cell-covered agar surface. Bar = 2.5 μ m.

FIGURE 38. Thin section of ruthenium red-fixed *Capnocytophaga ochracea* strain 25^T (=ATCC 33596^T). The ruthenium red has stained the extracellular polysaccharide (arrow). The large periplasmic space (open arrows) encloses the outer membrane, the electron-opaque periplasm, and the inner cytoplasmic membrane. Bar = 0.25 μ m.

1-deoxy-15-methylhexadecaphingamine-1-sulfonic acid, or capnine, which provides a unique characteristic for the genus (Godchaux and Leadbetter, 1980, 1983, 1984).

In vitro agar dilution testing of the sensitivity of *Capnocytophaga* to a variety of antimicrobial agents (Forlenza et al., 1981; Sutter et al., 1981) has been reported (Tables 37 and 38). Essentially all isolates are sensitive at a minimum inhibitory

concentration (MIC₉₀) of at least 1 µg/ml to penicillin, ampicillin, carbenicillin, erythromycin, clindamycin, and tetracycline. Doses of tetracycline, metronidazole, cefoxitin, and chloramphenicol of between 1 and 3.12 µg/ml are effective bactericidal agents, killing 90% of strains examined. For *Capnocytophaga* strains, MIC₉₀ values for cephalothin and cefazolin were only 25 and 50 µg/ml, respectively, whereas for cefamandole, the MIC₉₀ was 3.12 µg/ml. The aminoglycoside antibiotics (i.e., streptomycin, kanamycin, gentamicin, and neomycin) do not inhibit growth of the *Capnocytophaga* species tested, even at concentrations of 50 µg/ml.

Immunological analysis of the antigenic components of *Capnocytophaga* species has revealed the presence of two cell-envelope-associated antigens: a group-specific antigen, which has been found in all species examined so far; and a type-

specific antigen, which has been found only in clinical isolates (Murayama et al., 1982; Stevens et al., 1980). An exopolysaccharide has been recovered from the surface of *Capnocytophaga ochracea* strain 25^T, which exhibits immunoregulatory properties upon DEAE-Sephadex CL-SB column purification (Bolton and Dyer, 1983; Dyer and Bolton, 1985).

Capnocytophaga was originally isolated from the human oral cavity; cells occupied periodontal pockets (Leadbetter et al., 1979; Slots and Genco, 1984). Recently, two additional species have been recovered from dog and cat mouths (Brenner et al., 1989; Butler et al., 1977; Ciantar et al., 2001). Although the pathogenicity of these organisms is not yet clear, capnocytophagas have been implicated as pathogens in several human and animal infections (Fung et al., 1983; Gill, 2000; Kristensen et al., 1995; Lion et al., 1996). Apart from their involvement in human oropharyngeal infections, members of the genus have also been implicated in multiple infections causing keratitis, tonsillitis, and stomatitis. Hematogenous spread from the oropharynx has implicated them in osteomyelitis and endocarditis (Kamma et al., 1995). The organisms are frequently recovered from neutropenic patients as endogenous infections or wound infections as a result of animal bites (Lion et al., 1996; Shurin et al., 1979). *Capnocytophaga* infections due to animal bite are usually a result of transmission of *Capnocytophaga canimorsus*; the bacteria can cause clinical manifestations including septicemia, disseminated intravascular coagulopathy, tissue destruction, meningitis, and even death (Fischer et al., 1995; Greene, 1998; Hawkey et al., 1984; Mossad et al., 1997; Valtonen et al., 1995). Fatal complications because of *Capnocytophaga* infection are found in immunocompromised patients or patients suffering from a chronic disease (Parenti and Snyderman, 1985). In addition to their being frequent isolates from oral sites, members of the genus are also recovered from pulmonary lesions and abscesses, as well as from healthy oral and non-oral sites in their hosts (van Palenstein Helderman, 1981), and from patients with septic arthritis (Winn et al., 1984).

Capnocytophaga species may be found as part of the normal microbiota of humans and primates. They are routinely recovered from periodontal lesions (Newman and Sims, 1979; Newman and Socransky, 1977), as well as from soft-tissue infections and bacteremias. They are frequently recovered from individuals diagnosed with juvenile periodontitis; although previous

^bConcentrations are in $\mu\text{g/ml}$, except for penicillin G and bacitracin, which are in units/ml.

^cMIC₅₀ and MIC₉₀, Minimal concentrations required to inhibit 50 and 90% respectively, of the tested strains. Units are as described in footnote b.

reports have indicated some clinical association between the genus and the clinical outcome of the disease in young adults, this has not been confirmed. Members of the genus are also recovered from a variety of lesions and/or abscesses from compromised hosts. The genus has been isolated from patients with hematological malignancy and profound neutropenia. These patients routinely have oral mucosal ulcerations, which may be the portal of entry of *Capnocytophaga* into the bloodstream.

Capnocytophaga species have also been recovered from sputum and throat samples, spinal fluid, vagina, cervix, amniotic fluid, trachea, and eyes.

Enrichment and isolation procedures

Capnocytophaga species can be isolated selectively by streaking onto Thayer–Martin selective medium or on TS-blood agar containing bacitracin (50 $\mu\text{g/ml}$) and polymyxin B (100 $\mu\text{g/ml}$) (Mashimo et al., 1983). *Capnocytophaga* species have also been isolated by standard laboratory procedures employing TS-blood agar-based media (Forlenza et al., 1980; Gilligan et al., 1981; Leadbetter et al., 1979), blood agar, and chocolate agar. *Capnocytophaga* species do not grow on MacConkey agar. Rummens et al. (1985, 1986) have reported a selective medium (“CAP”) composed of a GC agar supplemented with 1% hemoglobin, 1% Polyvitex, and an antibiotic mixture of polymyxin B (15 U/ml), vancomycin (5 $\mu\text{g/ml}$), trimethoprim (2.5 $\mu\text{g/ml}$), and amphotericin (2.5 $\mu\text{g/ml}$) to be an excellent medium for the recovery of *Capnocytophaga* species from a variety of oral clinical specimens. The plates are incubated for 3–5 d at 35–37°C in an anaerobic chamber (5% CO₂ + 10% H₂ + 85% N₂) or in Brewer jars (under 5% CO₂ + 95% air atmosphere). *Capnocytophaga* species grow as flat, concentrically spreading films from a central colony or point of inoculation (Figures 32–34).

Colonies are removed easily from the agar surface, diluted in sterile phosphate-buffered saline or in a reduced transport fluid (Syed and Loesche, 1972), and restreaked to Thayer–Martin or TS-blood agar. Pure isolates can be obtained by employing this procedure.

Maintenance procedures

Capnocytophaga species can be maintained on TS-blood agar or TS agar. The characteristic spreading morphology is best

observed and maintained on BBL TS-blood agar plates or on TS agar [3% (w/v) agar concentration]. After suitable incubation in an anaerobic environment with at least 5% CO₂ or in Brewer jars (5% CO₂/95% air), stock cultures can be maintained on agar slants or Petri dish agar surfaces in Brewer jars at room temperature or in the refrigerator. Cultures can also be frozen in liquid nitrogen or freeze-dried by standard bacteriological procedures.

Taxonomic comments

Capnocytophaga ochracea ATCC 33596^T [strain 25^T of Leadbetter et al. (1979)] was compared to *Bacteroides ochraceus* (VPI 5567, VPI 5568, VPI 5569), and the Centers for Disease Control (CDC) biogroup DF-1 by DNA–DNA hybridization and phenotypic characteristics (Newman and Sims, 1979; Newman and Socransky, 1977; Williams et al., 1979) and most of these strains were designated *Capnocytophaga ochracea* (Leadbetter et al., 1979); one DF-1 strain was designated *Capnocytophaga gingivalis* by Williams et al. (1979). The original isolate of Loesche, *Bacteroides oralis* var. *elongatus* (strain SS31), is extant as *Bacteroides ochraceus* (originally ATCC 27872^T). DNA–DNA hybridization (Williams et al., 1979), serological cross-reactivity (Stevens et al., 1980; B.F. Hammond, personal communication), and phenotypic characteristics (Socransky et al., 1979) have identified it as *Capnocytophaga ochracea*. Yamamoto et al. (1994) isolated two additional *Capnocytophaga* species from human supragingival dental plaque. *Capnocytophaga haemolytica* [Group A of Yamamoto et al. (1994)] was strongly α-hemolytic and aminopeptidase-negative. *Capnocytophaga granulosa* was capable of aerobic growth, was non-hemolytic, and contained granular inclusions.

Acknowledgements

This presentation of the genus *Capnocytophaga* is dedicated to Professor Edward R. Leadbetter. Ed was one of the original discoverers of this genus along with Dr Sigmund Socransky and me. I first met Ed Leadbetter in 1964, after submitting my PhD thesis to Professor Roger Stanier at the University of California for his comments. After the work had been read and approved by Leadbetter, Stanier, John Ingraham, and Gerry Marr (UC-Davis), I was pronounced fit to go out into the cruel world of academics. Through these past 40 years, it has been my

fortune to have been associated with Ed Leadbetter. Ed taught me the importance of understanding the microbiology of our environment, was instrumental in introducing me to the Delft School of Microbiology, as well as to the genius that was Kees van Niel, and all those other renowned microbe hunters who found their way to Pacific Grove. Ed taught me to look beyond the surface of biology and to attempt to understand the inter-relations of microbes to each other and to us in our complex environment.

Louis Pasteur said: "...chance favors the prepared mind..." – it was Ed Leadbetter who made me realize the true meaning of this phrase.

Differentiation of the species of the genus *Capnocytophaga*

The differential characteristics of *Capnocytophaga* species are listed in Table 39.

List of species of the genus *Capnocytophaga*

1. ***Capnocytophaga ochracea*** Leadbetter, Holt and Socransky 1982, 266^{VP} (Effective publication: Leadbetter, Holt and Socransky 1979, 14.)

*o.chra'*ce.a. L. n. *ochra* yellow ochre; N.L. fem. adj. *ochracea* of the color of ochre, yellow.

Characteristics are as described for the genus. The majority (92%) of strains of *Capnocytophaga ochracea* produce acid from lactose. A variable number (11–89%) are capable of fermenting galactose with acid production. Only 8% of the strains are capable of reducing nitrate. The majority of strains analyzed so far produce acid from amygdalin, esculin, and glycogen, as well as hydrolyze starch and dextran.

Source: human supragingival dental plaque.

DNA G+C content (mol%): 38–39 (*T_m*).

Type strain: 25, ATCC 33596.

Sequence accession no. (16S rRNA gene): X67610, L14635.

Editorial note: in the effective publication of the species by Leadbetter, Holt and Socransky (1979), the type strain is designated ATCC 27872. However, in Validation List no. 8 (IJSB 32: 266–267, 1980), the type strain is designated "strain 25 (=ATCC 33596)". Footnote (c) in Validation List no. 8 states: "Type designated by the author(s) in a personal communication to the editor, IJSB; this announcement establishes the type and satisfies the requirement for valid publication". Footnote (e) states: "Through a clerical error, the wrong strain was cited as the type strain in the original publication; the strain cited here is the actual type (S. Holt, personal communication to the editor, IJSB)".

2. ***Capnocytophaga canimorsus*** Brenner, Hollis, Fanning and Weaver 1990, 105^{VP} (Effective publication: Brenner, Hollis, Fanning and Weaver 1989, 233; CDC group DF-2.)

ca.ni.mor'sus. L. n. *canis* dog; L. n. *morsus* bite, biting; N.L. gen. n. *canimorsus* of a dog bite.

This species was proposed by Brenner et al. (1989) for *Capnocytophaga* strains belonging to CDC Dysgonic Fermenter group 2 (DF-2). The organisms were first described by Bobo and Newton (1976) from a human case of septicemia with meningitis. Butler et al. (1977) extended the original observations by Bobo and Newton and reported a high frequency of association between dog bites in the antecedents and the importance of splenectomy as a predisposing condition. The organism was given the epithet CDC group DF-2 (see above). Brenner et al. (1989) were able to describe similarities between DF-2 and DF-2-like micro-organisms with another closely related bacterium responsible for localized infections due to dog bites and *Capnocytophaga* (originally DF-1) species described by Leadbetter et al. (1979). DF-2 was later found to reside in the oral cavity of dogs and cats. Transmission to humans by bite, scratch, or mere exposure to animals, and their common characteristics with members of the genus *Capnocytophaga* led Brenner et al. (1989) to propose the name *Capnocytophaga canimorsus* for members of group DF-2 and *Capnocytophaga cynodegmi* for the DF-2-like species.

Cells are thin, Gram-stain-negative, nonsporeforming rods, 1–3 μm in length. *Capnocytophaga canimorsus* differs from the other *Capnocytophaga* species by its positive oxidase and catalase reactions, but it does resemble *Capnocytophaga* in other characteristics. For biochemical characteristics of *Capnocytophaga canimorsus* (DF-2 strains), see Brenner et al. (1989).

Source: the type strain was isolated in 1961 from the blood of a male subject. Other strains have been isolated from human cerebrospinal fluid and wounds and the mouths of healthy dogs.

DNA G+C content (mol%): 36–38 (T_m) (type strain).

Type strain: ATCC 35979, CDC 7120, CIP 103936, NCTC 12242.

Sequence accession no. (16S rRNA gene): X97246, L14637.

3. ***Capnocytophaga cynodegmi*** Brenner, Hollis, Fanning and Weaver 1990, 105^{VP} (Effective publication: Brenner, Hollis, Fanning and Weaver 1989, 235.)

cy.no.deg'mi. Gr. *kyon*, *kynos* dog; Gr. n. *degmos* a bite; N.L. gen. n. *cynodegmi* of a dog bite.

This species was proposed for CDC group DF-2-like organisms. Strains are similar to those of *Capnocytophaga canimorsus* in that they are positive for oxidase and catalase, but resemble *Capnocytophaga* species in other characteristics. For biochemical characteristics of DF-2-like strains, see Brenner et al. (1989).

Source: the type strain was isolated from the mouth of a dog. Other strains have been isolated from human dog-bite wounds.

DNA G+C content (mol%): 34–36 (T_m) (type strain).

Type strain: E6447, ATCC 49044, CCUG 24742, CIP 103937, LMG 11513, NCTC 12243.

Sequence accession no. (16S rRNA gene): X97245, L14638.

4. ***Capnocytophaga gingivalis*** Leadbetter, Holt and Socransky 1982, 266^{VP} (Effective publication: Leadbetter, Holt and Socransky 1979, 14.)

gin.gi.va'lis. N.L. fem. adj. *gingivalis* of the gum.

The physiological and morphological characteristics are as described for the genus (Tables 34, 36, and 39). It does not produce acid end products from lactose or galactose. Only 8% of the *Capnocytophaga gingivalis* strains examined reduced nitrate. *Capnocytophaga gingivalis* is physiologically inactive, compared with *Capnocytophaga ochracea*; it does not ferment amygdalin, salicin, cellobiose, esculin, or glycogen and it does not hydrolyze starch.

Source: human supragingival dental plaque.

DNA G+C content (mol%): 40 (T_m) (type strain).

Type strain: 27, ATCC 33624, CCUG 9715, CIP 102945, DSM 3290, JCM 12953, LMG 11514, NCTC 12372.

Sequence accession no. (16S rRNA gene): X67608, L14639.

5. ***Capnocytophaga granulosa*** Yamamoto, Kajiura, Hirai and Watanabe 1994, 327^{VP}

gra.nu.lo'sa. N.L. fem. adj. *granulosa* granular.

Although sharing the major characteristics of the other *Capnocytophaga* species, this species exhibits high aminopeptidase activity (Table 35) and granular inclusions in its cells (Figure 39). The aminopeptidase enzyme was purified and classified as a metallopeptidase and endopeptidase because it released N-terminal amino acid residues exclusively, but did not hydrolyze benzoyl-Arg-*p*-nitroanilide. The enzyme also differs from that found in the other *Capnocytophaga* species in that it was isolated from the envelope fraction and found to hydrolyze a synthetic substrate for chymotrypsin or trypsin. The molecular mass of the *Capnocytophaga gingivalis* aminopeptidase has been reported to be 64 kDa, whereas

FIGURE 39. Thin section of *Capnocytophaga haemolytica* (a) and *Capnocytophaga granulosa* (b) grown anaerobically in GAM broth at 37°C for 18 h. Note the clear areas representative of inclusion bodies at the cell poles. Bar = 0.5 μm . (Reprinted with permission from Yamamoto et al., 1994, Int. J. Syst. Bacteriol. 44: 324–329.)

that isolated and purified from *Capnocytophaga granulosa* was larger (86 kDa). The *Capnocytophaga granulosa* aminopeptidase also shared several characteristics with aminopeptidase B (arginyl aminopeptidase), one of the major aminopeptidases in mammalian organs.

Both *Capnocytophaga granulosa* and *Capnocytophaga haemolytica* contain electron-transparent inclusion bodies when grown in GAM broth (Figure 39). The role of these in the physiology of this species is to be determined.

Source: human dental plaque.

DNA G+C content (mol%): 42–44 (T_m) (type strain).

Type strain: B0611, ATCC 51502, CCUG 32991, CIP 104128, DSM 11449, JCM 8566, LMG 16022, NCTC 12948.

Sequence accession no. (16S rRNA gene): X97248.

6. **Capnocytophaga haemolytica** Yamamoto, Kajiura, Hirai and Watanabe 1994, 327^{VP}

hae.mo.ly'ti.ca. Gr. n. *haema* blood; Gr. adj. *lyticus* -a -um able to loosen, able to dissolve; N.L. fem. adj. *haemolytica* blood dissolving.

The phenotypic characteristics of this species are as described for the genus *Capnocytophaga*. However, the levels of DNA relatedness between *Capnocytophaga haemolytica* and the other *Capnocytophaga* species (excluding *Capnocytophaga granulosa*) are less than 20%. Characteristics of *Capnocytophaga*

haemolytica are its hemolytic activity and the absence of aminopeptidase activity.

Source: human dental plaque.

Type strain: A0404, ATCC 51501, CCUG 32990, CIP 104125, DSM 11385, JCM 8565, LMG 16021, NCTC 12947.

DNA G+C content (mol%): 44 (T_m) (type strain).

Sequence accession no. (16S rRNA gene): X97247.

7. **Capnocytophaga sputigena** Leadbetter, Holt and Socransky 1982, 266^{VP} (Effective publication: Leadbetter, Holt and Socransky 1979, 14.)

spu.ti.ge'na. N.L. fem. adj. *sputigena* sputum-produced.

Physiological and morphological characteristics are as described for the genus (Tables 34 and 39). *Capnocytophaga sputigena* possesses a variable ability to ferment lactose, fructose, and dextran. The strains examined were unable to ferment galactose. Of the *Capnocytophaga sputigena* strains examined, 80% hydrolyzed esculin; none of the examined strains were capable of utilizing cellobiose, glycogen, or starch.

Source: human supragingival dental plaque.

DNA G+C content (mol%): 38–40 (T_m) (type strain).

Type strain: 4, ATCC 33612, CCUG 9714, CIP 104301, DSM 7273, LMG 11518, NCTC 11653.

Sequence accession no. (16S rRNA gene): X67609, L14636.

Genus IX. **Cellulophaga** Johansen, Nielsen and Sjøholm 1999, 1238^{VP}

JOHN P. BOWMAN

Cel.lu.lo.pha'ga. N.L. n. *cellulosum* cellulose; Gr. v. *phagein* to eat; N.L. fem. n. *Cellulophaga* eater of cellulose.

Rod-shaped cells with rounded ends, 1.5–5 × 0.4–0.8 µm. **Gram-stain-negative**. Cells occur singly or in pairs, occasionally in chains. Spores and resting cells are not present. Gas vesicles and helical or ring-shaped cells are not formed. **Motile by gliding**. **Strictly aerobic, with an oxidative type of metabolism**. **Catalase-positive**. **Chemoheterotrophic**. **Colonies are yellow to orange** due to production of carotenoids. **Flexirubin pigments are not produced**. Strains **require Na⁺** for good growth. Good growth occurs between 1 and 5% NaCl; growth does not occur in 10% NaCl. Optimum growth occurs in organic media containing seawater salts. All species: **hydrolyze agar, carrageenan, gelatin, starch, and esculin; produce esterase** (with Tweens as substrates) **and possess β-galactosidase activity; and decompose L-tyrosine and form dark brown pigments on media containing L-tyrosine**. All species **form acid from carbohydrates** including D-glucose, D-galactose, sucrose, trehalose, and cellobiose. Some species are strongly proteolytic, degrading elastin and fibrinogen. Some species **can attack and lyse living and dead eukaryotic cells**, including yeasts and unicellular algal species. All species grow between 10 and 25°C, with temperature optima depending on the species. Neutrophilic, with optimal growth occurring at pH 7.0–7.5. The major fatty acids are C_{15:0}, C_{15:1} ω10c iso, C_{15:0} iso, C_{16:1} ω7c, C_{17:1} ω7c iso, C_{15:0} 3-OH iso, C_{16:0} 3-OH iso, and C_{17:0} 3-OH iso. The major polyamine is **homospermidine**. The major isoprenoid quinone is **menaquinone-6**. The organisms are cosmopolitan inhabitants of marine ecosystems including marine coastal mud and sand, tide pools, seawater (brackish and open ocean), and

surfaces of marine benthic, pelagic and sea-ice-associated macroalgae and microalgae.

DNA G+C content (mol%): 32–38 (HPLC, T_m).

Type species: **Cellulophaga lytica** (Lewin 1969) Johansen, Nielsen and Sjøholm 1999, 1239^{VP} (*Cytophaga lytica* Lewin 1969, 199).

Further descriptive information

The genus *Cellulophaga* is a member of the family *Flavobacteriaceae*, making up a relatively distinct if somewhat broad phylogenetic sublineage (see *Taxonomic comments*). The genus includes five species, *Cellulophaga lytica*, *Cellulophaga algicola*, *Cellulophaga baltica*, *Cellulophaga fucicola*, and *Cellulophaga pacifica*. *Cellulophaga* species form a single 16S rRNA gene cluster that is composed of two distinct subgroups. *Cellulophaga lytica* and *Cellulophaga fucicola* form one subgroup, while *Cellulophaga algicola*, *Cellulophaga baltica*, and *Cellulophaga pacifica* form the second subgroup. These subgroups differ in terms of their 16S rRNA gene sequences by approximately 5–6%. It would seem that there could be grounds to split the genus into two separate sections; however, at present, this is very difficult to justify owing to the many distinct phenotypic and chemotaxonomic features that *Cellulophaga* species share.

The species form characteristically spreading yellow–orange colonies on marine media. These colonies soften and depress the agar immediately around them due to the secretion of agarolytic exoenzymes. Colonial pigmentation can occur with a greenish metallic iridescence or opalescence and appears to

be mainly due to the production of the carotenoid zeaxanthin (Lewin and Lounsbury, 1969). Colonies may appear compact if grown on media with a high nutrient content. Spreading growth and agarolytic activity are more evident on nutrient-poor media, e.g., 0.1% tryptone, 0.1% peptone, and 1.2% agar prepared in seawater. *Cellulophaga* species possess a relatively rapid gliding motility; again, this property is most evident in nutrient-poor situations.

Characteristics that differentiate species of the genus are shown in Table 40. *Cellulophaga* species are generally strongly saccharolytic and are notably active against marine-type polysaccharides, especially agars and alginates, substances commonly produced by various marine macroalgae. The name of the genus is unfortunately not exactly apt because no species in the genus is actually able to degrade cellulose, whether provided in a crystalline powdered form or in the form of paper. However, most species can degrade carboxymethylcellulose, with

the exception of *Cellulophaga pacifica*. Nevertheless, *Cellulophaga* species produce numerous exoenzymes that remain, to date, nearly completely unstudied.

Cellulophaga species, like other members of the family *Flavobacteriaceae*, have menaquinone-6 as the major isoprenoid quinone, accumulate primarily the polyamine homospermidine (Hamana and Nakagawa, 2001), and possess primarily branched chain C₁₅–C₁₇ fatty acids (Table 41). Strains also tend to accumulate the biogenic amine 2-phenylethylamine (Hosoya and Hamana, 2004), presumably due to the decarboxylation of phenylalanine.

Strains of *Cellulophaga lytica* as well as undescribed *Cellulophaga* isolates have been shown to exhibit predatory behavior on pelagic unicellular algae (Skerratt et al., 2002). This activity appears to be due to the release of lytic enzymes in the vicinity of the host cells. *Cellulophaga baltica* and *Cellulophaga fucicola* also exhibit pronounced lytic activity against autoclaved yeast cells and are strongly proteolytic (Johansen et al., 1999).

Cellulophaga lytica-like bacteria are considered, somewhat anecdotally, to be very common in various marine settings including tidal pools and on the surfaces of macroalgae (especially red algae) species (Lewin, 1969). The temperature profile of *Cellulophaga lytica* (growth occurs between >4°C and 35–40°C, optimum 22–30°C) suggests that it favors temperate to tropical marine ecosystems. *Cellulophaga baltica* and *Cellulophaga fucicola* have a preference for brackish seawater (optimal growth occurs with 20 g/l sea salts) and are at least indigenous to the Baltic Sea, occurring on benthic macroalgae (*Fucus serratus* L. in particular) and in surrounding seawater (Johansen et al., 1999). *Cellulophaga algicola* represents a cold-adapted species in the genus, preferring temperatures between 10 and 20°C, and has been isolated mainly from the surfaces of algae associated with coastal Antarctic sea-ice (Bowman, 2000). *Cellulophaga* species forming biofilms on macroalgae may influence the reproductive colonization success of macroalgal populations (Patel et al., 2003). *Cellulophaga algicola* is noted as producing several cold-adapted exoenzymes (Nichols et al., 1999). Molecular studies suggest *Cellulophaga* is widespread in Antarctic sea-ice (Brown and Bowman, 2001). *Cellulophaga pacifica* was isolated from seawater collected from the Sea of Japan in the north-west Pacific Ocean (Nedashkovskaya et al., 2004e). Several other studies have also identified *Cellulophaga* isolates from diverse marine locations, including toxic dinoflagellate blooms, salmonid gill tissue, and deep-sea sediment (Green et al., 2004; various unpublished sources).

Enrichment and isolation procedures

No specific procedure has been established for specific isolation of *Cellulophaga* species. Macroalgal dwelling species can be obtained by homogenizing pieces of seaweed material in sea salts solutions and, after sufficient dilution, spread onto CYT agar (1 g casein, 0.5 g yeast extract, 0.5 g CaCl₂·H₂O, 0.5 g MgSO₄·H₂O, 15 g agar, 1000 ml deionized water, pH 7.3; Johansen et al., 1999) or marine agar (Difco, Oxoid) (Bowman, 2000). Yellow–orange colonies, containing rod-like cells and surrounded by softened agar due to agarolysis, are presumptive for *Cellulophaga* species. Subsequent confirmation using 16S rRNA gene sequencing is generally required because several other members of the family *Flavobacteriaceae* are also capable of agarolytic activity.

^aValues represent percentages of total fatty acids (standard deviations based on results from three experiments are given in parentheses); tr, trace level detected (<1% of total fatty acids); nd, not detected.

^bOnly the major fatty acid constituents were reported in the description of *Cellulophaga pacifica* (Nedashkovskaya et al., 2004e).

Maintenance procedures

Strains can be maintained for many years cryopreserved in marine broth containing 20–30% glycerol. Strains may also be maintained by lyophilization using 20% skim milk as a cryoprotectant.

Differentiation of the genus *Cellulophaga* from other genera

The most salient traits useful for differentiation of *Cellulophaga* spp. from other members of the *Flavobacteriaceae* include a

strictly oxidative metabolism, the ability to form acid from carbohydrates, the ability to grow in defined mineral salts media, the lack of flexirubin pigment production, gliding motility, a requirement for Na⁺ for growth, and agarolytic activity. *Cellulophaga* species have several similarities to other members of the family *Flavobacteriaceae*, in particular members of the genus *Zobellia* (Barbeyron et al., 2001); however, *Cellulophaga* species can be differentiated from these species primarily by lack of budding cells, lack of flexirubin-type pigments, and strictly aerobic growth (Table 42).

TABLE 42. Differentiation of genus *Cellulophaga* from other Na⁺-requiring, agarolytic, yellow-pigmented members of the family *Flavobacteriaceae*^a

Characteristic	<i>Cellulophaga</i>	<i>Alphabacter</i>	<i>Formosa</i>	<i>Marrbacter</i>	<i>Winogradskyella</i>	<i>Zobellia</i>

^aSymbols: +, >85% positive; –, 0–15% positive; D, different results occur in different taxa (species of a genus).

Taxonomic comments

As part of his study of marine bacteria, Lewin (1969) described *Cytophaga lytica*. Reichenbach (1989c) opined that there was considerable heterogeneity in the genus *Cytophaga* and *Cytophaga lytica* was identified, along with many other *Cytophaga* species, as being a part of a distinct group of bacteria, probably constituting a separate genus. Indeed, phylogenetic and chemotaxonomic studies (Nakagawa and Yamasato, 1993) showed that *Cytophaga lytica* was quite distinct from other *Cytophaga* species, in particular the *Cytophaga* species *sensu stricto* such as *Cytophaga hutchinsonii*, which belong to a completely separate section of phylum *Bacteroidetes* and are non-marine in terms of their ecology. There was for a while some confusion that *Cytophaga lytica* was possibly closely related to the marine species *Cytophaga marinoflava*. Different 16S rRNA gene sequences present in the GenBank database were identified as giving conflicting phylogenetic relationships for *Cytophaga lytica* and *Cytophaga marinoflava* (Clayton et al., 1995). This was probably due to a strain mix-up.

Reappraisal of the data indicated that *Cytophaga marinoflava* was distinct from *Cytophaga lytica* (and other *Cellulophaga* species) phylogenetically, as well as in terms of phenotypic characteristics. *Cytophaga marinoflava* was renamed *Leeuwenhoekella marinoflava* (Nedashkovskaya et al., 2005i). Johansen et al. (1999) placed *Cytophaga lytica* in the genus *Cellulophaga* along with novel isolates from Baltic Sea samples, which were described as *Cellulophaga baltica* and *Cellulophaga fucicola*. Subsequently, *Cellulophaga algicola* and *Cellulophaga pacifica* were described from other marine samples. At one point, *Cytophaga uliginosa* (ZoBell and Upham, 1944) Reichenbach (1989c) was also transferred to the genus *Cellulophaga* (Bowman, 2000), mainly on the basis of various phenotypic similarities (e.g., cellular and colony morphology, gliding motility, agarolytic activity, and fatty acid content). However, with the subsequent description of several other genera in the family *Flavobacteriaceae*, it quickly became evident that *Cellulophaga uliginosa* belonged to a separate genus and was thus renamed *Zobellia uliginosa* (Barbeyron et al., 2001).

List of species of the genus *Cellulophaga*

1. ***Cellulophaga lytica*** (Lewin 1969) Johansen, Nielsen and Sjøholm 1999, 1239^{VP} (*Cytophaga lytica* Lewin 1969, 199)

ly'ti.ca. L. fem. adj. *lytica* (from Gr. fem. adj. *lutikê* able to loosen, able to dissolve), loosening, dissolving.

Characteristics are as given for the genus and as listed in Table 40. In addition, *Cellulophaga lytica* strains can use peptones, Casamino acids, and L-glutamate as nitrogen sources and can produce ammonia from peptones. Growth can occur on peptone alone.

Source: isolated from coastal sand and mud, tidal pools, and macroalgal samples.

DNA G+C content (mol%): 32–34 (T_m).

Type strain: ATCC 23178, CIP 103822, DSM 7489, IFO 14961, JCM 8516, LMG 1344, VKM B-1433.

Sequence accession no. (16S rRNA gene): M62796.

Additional remarks: 16S rRNA and GyrB gene sequences for several *Cellulophaga lytica* strains have been published by Suzuki et al. (2001) under GenBank accession numbers AB032509–AB032513 (16S rRNA gene sequences) and AB034213–AB034218 (GyrB gene sequences).

2. ***Cellulophaga algicola*** Bowman 2000, 1866^{VP}

al.gi.co'la. L. n. *alga* alga; L. suff. *-cola* (from L. n. *incola*) inhabitant, dweller; N.L. fem. n. *algicola* algae-dweller.

Characteristics are as given for the genus and as listed in Table 40.

Source: isolated from sea-ice algal material and polar macroalgae.

DNA G+C content (mol%): 36–38 (T_m).

Type strain: IC166, ACAM 630.

Sequence accession no. (16S rRNA gene): AF001366.

3. ***Cellulophaga baltica*** Johansen, Nielsen and Sjøholm 1999, 1238^{VP}

bal'ti.ca. N.L. fem. adj. *baltica* of or belonging to the Baltic Sea.

Characteristics are as given for the genus and as listed in Table 40. In addition, on Biolog GN MicroPlates, most strains

(>80%) are positive for utilization of D-fructose, L-fucose, D-galactose, α -D-glucose, sucrose, trehalose, methyl pyruvate, α -ketobutyrate, and L-glutamate; some strains tested (20–70%) are positive for L-arabinose, gentiobiose, maltose, D-mannose, psicose, L-rhamnose, formate, γ -hydroxybutyrate, 2-oxoglutarate, glucuronamide, L-proline, and L-threonine. Negative results (<10% of strains) were recorded for the following substrates: dextrin, α -cyclodextrin, glycogen, Tween 40, Tween 80, N-acetyl-D-galactosamine, N-acetyl-D-glucosamine, adonitol, D-arabitol, cellobiose, i-erythritol, myo-inositol, α -D-lactose, lactulose, D-mannitol, melibiose, methyl- β -D-glucoside, raffinose, D-sorbitol, turanose, xylitol, acetate, *cis*-aconitate, citrate, D-galactonate lactone, D-glucosamininate, D-galacturonate, D-gluconate, D-glucuronate, α -hydroxybutyrate, β -hydroxybutyrate, *p*-hydroxyphenylacetate, itaconate, α -ketovalerate, DL-lactate, malonate, monomethylsuccinate, propionate, quinate, D-saccharate, sebacate, bromosuccinate, succinate, succinamate, alaninamide, D-alanine, L-alanine, L-alanyl-glycine, L-asparagine, L-aspartate, glycyl-L-aspartate, glycyl-L-glutamate, L-histidine, hydroxy-L-proline, L-leucine, L-ornithine, L-phenylalanine, L-pyroglytamate, D-serine, L-serine, DL-carnitine, γ -aminobutyrate, urocanate, inosine, uridine, thymidine, phenylethylamine, putrescine, 2-aminoethanol, 2,3-butanediol, glycerol, glucose 1-phosphate, glucose 6-phosphate, and DL- α -glycerol phosphate.

Source: isolated from the brown alga *Fucus serratus* L. and surrounding seawater of the Baltic Sea.

DNA G+C content (mol%): 33 (HPLC).

Type strain: NN015840, ATCC 700862, CIP 106307, LMG 18535.

Sequence accession no. (16S rRNA gene): AJ005972.

4. ***Cellulophaga fucicola*** Johansen, Nielsen and Sjøholm 1999, 1238^{VP}

fu.ci.co'la. N.L. n. *Fucus* seaweed genus; L. suff. *-cola* (from L. n. *incola*) inhabitant, dweller; N.L. fem. n. *fucicola* *Fucus*-dweller.

Data are based on a single isolate. Characteristics are as given for the genus and as listed in Table 40. In addition, on

Biolog GN MicroPlates the type strain is positive for utilization of Tween 40, L-arabinose, D-fructose, L-fucose, L-rhamnose, D-sorbitol, methyl pyruvate, and α -ketobutyrate. All other substrates tested were negative (see description of *Cel-lulophaga baltica* for substrate list).

Source: isolated from the brown alga *Fucus serratus* L. from the Baltic Sea.

DNA G+C content (mol%): 32 (HPLC).

Type strain: NN015860, ATCC 700863, CIP 106308, LMG 18536.

Sequence accession no. (16S rRNA gene): AJ005973.

5. ***Cellulophaga pacifica*** Nedashkovskaya, Suzuki, Lysenko, Snauiwaert, Vancanneyt, Swings, Vysotskii and Mikhailov 2004e, 611^{VP}

pa.ci'fi.ca. L. fem. adj. *pacifica* peaceful; referring to the Pacific Ocean, from which the organism was isolated.

Characteristics are as given for the genus and as listed in Table 40.

Source: isolated from seawater collected from the Sea of Japan, north-west Pacific Ocean.

DNA G+C content (mol%): 32 (HPLC), 33 (T_m).

Type strain: JCM 11735, KMM 3664, LMG 21938.

Sequence accession no. (16S rRNA gene): AB100840.

Additional remarks: GenBank accession numbers for the 16S rRNA gene sequence of other *Cellulophaga pacifica* isolates are AB100842 (strain KMM 3915) and AB100841 (strain KMM 3669).

Genus X. ***Chryseobacterium*** Vandamme, Bernardet, Segers, Kersters and Holmes 1994a, 829^{VP}

JEAN-FRANÇOIS BERNARDET, CELIA J. HUGO AND BRITA BRUUN

Chry.se.o.bac.te'ri.um. Gr. adj. *chryseos* golden; L. neut. n. *bacterium* a small rod; N.L. neut. n. *Chryseobac-terium* a yellow rod.

Straight, single rods with rounded ends typically about 0.5 μm in width and variable in length, often 1–3 μm ; filamentous cells and pleomorphism also occur. Do not form endospores. Spherical degenerative forms do not appear in ageing liquid cultures. **Colonies are pale to bright yellow due to the production of non-diffusible, non-fluorescent flexirubin-type pigments.** A strong, aromatic odor is produced. Gram-stain-negative. **Nonmotile. Flagella, gliding movement, or swarming growth have not been reported. Obligately aerobic, having a strictly respiratory type of metabolism** with oxygen as the terminal electron acceptor. **No denitrification occurs and most species do not reduce nitrate or nitrite.** Chemo-organotrophic. Most environmental isolates grow at 5°C, all grow at 15–30°C, and several grow up to 37°C; clinical isolates do not grow at 5°C, but grow at 15–37°C, and some grow at up to 42°C. Grow readily on the usual commercial media; no growth factors are required. Most species also grow in media containing up to 3–5% NaCl. No growth or weak growth on cetrinide agar, but members of a few species are able to grow on MacConkey agar. **Catalase- and oxidase-positive.** Several carbohydrates are oxidized. Esculin is hydrolyzed, but agar is not. Strong proteolytic activity occurs. **Most strains are resistant to a wide range of antimicrobial agents.** Menaquinone-6 (MK-6) is the only or predominant respiratory quinone. Predominant cellular fatty acids are C_{15:0} iso, C_{17:0} iso 3-OH, C_{17:1} iso ω 9c, and summed feature 4 (comprising C_{15:0} iso 2-OH and/or C_{16:1} ω 7c/t). **Members of most species occur in soil and in fresh or seawater habitats. Two species and unclassified strains also occur in human clinical specimens** and hospital environments, but their pathogenicity to man is not well-documented. Two species and unclassified strains have been retrieved from diseased fish. Four species occur in food or dairy products; they may be involved in spoilage.

DNA G+C content (mol%): 29–39.

Type species: ***Chryseobacterium gleum*** (Holmes, Owen, Steigerwalt and Brenner 1984b) Vandamme, Bernardet, Segers, Kersters and Holmes 1994a, 830^{VP} (*Flavobacterium gleum* Holmes, Owen, Steigerwalt and Brenner 1984b, 23).

Further descriptive information

Phylogenetic position. The genus *Chryseobacterium* is a member of the family *Flavobacteriaceae*, phylum *Bacteroidetes*. It belongs to the smaller of the two well-defined clades in the family comprising non-gliding, non-halophilic, and mostly non-psychrophilic organisms, as well as most unpigmented and several pathogenic members of the family (see the Family *Flavobacteriaceae* in this volume of the *Manual*). Besides *Chryseobacterium*, this clade contains the genera *Elizabethkingia*, *Riemerella*, *Bergeyella*, *Kaistella*, *Sejongia*, *Epilithonimonas*, *Ornithobacterium*, *Empedobacter*, and *Weeksella*, as well as some poorly characterized organisms (Figure 40). Except for the three latter genera that are distinctly separate, all genera appear to be highly related phylogenetically and share a number of phenotypic features. Because of this overall very high 16S rRNA gene sequence similarity among members of the clade, some branches (e.g., the *Sejongia* branch) occupy different positions in published phylogenetic trees. *Chryseobacterium hispanicum* is distinctly separate from the other *Chryseobacterium* species. The two *Elizabethkingia* species were only recently separated from the genus *Chryseobacterium* (Kim et al., 2005b). The uncharacterized organisms “*Haloanella gallinarum*” and “*Candidatus Amoebinatus massiliae*” are located on the *Kaistella* branch (Figure 40); given their nearly identical 16S rRNA gene sequences, they may actually belong to the same species.

Several novel species have been described during the short period of time that has elapsed since the writing of the last review on the genus *Chryseobacterium* (Bernardet and Nakagawa, 2006). At the time of writing (July 2006), the genus comprised 18 species with validly published names; the name of one additional species, “*Chryseobacterium proteolyticum*”, has not been validly published. The number of species will likely keep growing since many organisms phylogenetically related to members of the genus *Chryseobacterium* have already been reported from investigations of various environments using both culture-dependent and -independent methods (e.g., Dugas et al., 2001; O’Sullivan et al., 2002; Wery et al., 2003; Drancourt et al., 2004; Greub et al., 2004; Bernardet et al., 2005).

FIGURE 40. Relationships between *Chryseobacterium* species and relatives based on 16S rRNA gene sequences. Only the type strain of each species was included. The sequences of “*Candidatus Chryseobacterium timonae*” (Drancourt et al., 2004) and *Epilithonimonas tenax* (O’Sullivan et al., 2006) were not included in the analysis. GenBank accession numbers are shown. Distances in the tree were calculated using 1164 positions, the ARB neighbor-joining algorithm and a Jukes–Cantor correction. The 16S rRNA gene sequence of *Flavobacterium aquatile* was used as the outgroup. Bar = 0.05 substitutions per nucleotide position. (Courtesy T. Lilburn of the American Type Culture Collection.)

Cell morphology. Members of the genus *Chryseobacterium* commonly appear as small, straight rods, about 0.5 μm wide and 1–3 μm long, with rounded ends and parallel sides. Slightly curved rods have been reported in *Chryseobacterium shigense* (Shimomura et al., 2005) and filamentous forms have been observed in broth cultures of members of several species and in clinical specimens. Interestingly, strains of three *Chryseobacterium* sp. consisting of ultrasmall cells (about 0.2–0.4 μm wide and 0.4–0.7 μm long) have been retrieved recently from the ice core of a Greenland glacier (Miteva and Brenchley, 2005). They may represent intrinsically small organisms or starved, minute forms of normal-sized microbes resulting from extreme environmental conditions (low nutrient concentrations and subzero temperatures). Contrary to the situation in members of some other genera in the family *Flavobacteriaceae* (e.g., *Flavobacterium*, *Gelidibacter*, *Tenacibaculum*, and *Polaribacter*; see the family *Flavobacteriaceae* in this volume), *Chryseobacterium* strains do not produce spherical degenerative forms in ageing liquid cultures. Also, in contrast to many members of the family, cells of *Chryseobacterium* species are devoid of gliding motility.

Cell-wall composition. Table 43 presents the fatty acid composition of members of the genus *Chryseobacterium* and related

genera. “*Chryseobacterium proteolyticum*” was not analyzed in this respect (Yamaguchi and Yokoe, 2000) and only the dominant fatty acids in *Chryseobacterium shigense* were specified (Shimomura et al., 2005). Although all *Chryseobacterium* species contain the same fatty acids in rather similar proportions, they can be differentiated from other members of the clade (e.g., *Elizabethkingia*, *Empedobacter*, *Riemerella*, and *Bergeyella*), which all display rather distinct fatty acid compositions (Bernardet et al., 2006; Hugo et al., 1999). Hence, as for other members of the family *Flavobacteriaceae*, the fatty acid profile is mostly a chemotaxonomic marker at the genus level (Bernardet and Nakagawa, 2006).

Fine structure. Since electron microscopy studies have not been widely performed on members of the genus, little information is available on the fine structure of the cells. Transmission electron microscopy has revealed a thick cell wall (i.e., about 50 nm) in *Chryseobacterium scophthalmum* (Mudarris et al., 1994) and *Chryseobacterium joostei* (Hugo et al., 2003). The scanning electron microscopy studies performed on cells of “*Chryseobacterium proteolyticum*” (Yamaguchi and Yokoe, 2000), *Chryseobacterium daecheongense* (Kim et al., 2005a), *Chryseobacterium shigense* (Shimomura et al., 2005), and the ultrasmall *Chryseobacterium*

^aThe fatty acid composition of "*Chryseobacterium proteolyticum*" has not been determined (Yamaguchi and Yokoe, 2000) and is therefore not included in this table. Fatty acid percentages amounting to less than 1% of the total fatty acids in all species are not included; therefore, the percentages do not total 100%. When several strains were analyzed, rounded up means are given (standard deviations are not given); the number of strains analyzed is given in parentheses after the name of each species. Data are taken from studies using different growth times, media, and temperatures. Abbreviations: tr, trace (less than 1%); na, not available; and nd, not detected. Data from Segers et al. (1993a), Mudarris et al. (1994), Vancanney et al. (1999), Hugo et al. (2003), Kämpfer et al. (2003), Li et al. (2003b), Kim et al. (2004), de Beer et al. (2005a, b), Shen et al. (2005), Shimomura et al. (2005), Yi et al. (2005b), Young et al. (2005), de Beer et al. (2006), Gallego et al. (2006), O'Sullivan et al. (2006), Park et al. (2006b), Tai et al. (2006), and Woon et al. (2006).

^bECL, equivalent chain-length (i.e., the identity of the fatty acids is unknown).

^cAccording to Shimomura et al. (2005), "Considerable proportions of summed feature 4 and C_{17:1} iso ω9c are also present."

^dFatty acids that could not be separated by GC using the Microbial Identification System (Microbial ID) software were considered summed features. Summed feature 3 contained C_{15:0} iso 2-OH and/or C_{16:1} ω7c. Summed feature 4 contained C_{15:0} iso 2-OH and/or C_{16:1} ω7c/l. Summed feature 5 contained C_{17:1} iso 1 and/or C_{17:1} anteiso B.

strains retrieved from a Greenland glacier (Miteva and Brenchley, 2005) have not revealed any special structure.

Colonial or cultural characteristics. Colonies of *Chryseobacterium* strains are circular, convex, translucent to opaque, smooth, and shiny with entire edges. On commonly used agar media (blood, tryptic soy, R2A, and nutrient), colonies are usually bright-yellow-pigmented owing to the production of flexirubin-type pigments (Bernardet et al., 2002). The type of yellow pigments in *Chryseobacterium defluvii*, *Chryseobacterium soldanellicola*, and *Chryseobacterium taeanense* has not been determined, but they most likely belong to the flexirubin type. Colonial pigmentation of most of the recently described species (i.e., *Chryseobacterium defluvii*, *Chryseobacterium daecheongense*, *Chryseobacterium formosense*, *Chryseobacterium taichungense*, *Chryseobacterium taiwanense*, *Chryseobacterium soldanellicola*, and *Chryseobacterium taeanense*) has been described as “yellowish” or “white–yellow”. Indeed, the production of pigment is highly dependent on growth temperature, the presence of daylight, and composition of the culture medium (Bruun, 1982; Holmes et al., 1984a; Hugo et al., 2003). A sentence in the original description of the genus (Vandamme et al., 1994a) stated that non-pigmented strains occurred; this actually referred to the strains of *Elizabethkingia meningoseptica* that have recently been removed from the genus *Chryseobacterium* (Kim et al., 2005b). When grown on tyrosine-containing agar, strains of *Chryseobacterium balustinum*, *Chryseobacterium gleum*, *Chryseobacterium indoltheticum*, and *Chryseobacterium joostei* and some strains of *Chryseobacterium scophthalmum* also produce a pinkish-brown to dark brown, diffusible melanic pigment (Hugo et al., 2003; Mudarris et al., 1994); J.-F. Bernardet, unpublished data); this trait was not investigated for recently described species. After prolonged incubation, colonies of some *Chryseobacterium* species (i.e., *Chryseobacterium balustinum*, *Chryseobacterium daecheongense*, *Chryseobacterium formosense*, *Chryseobacterium joostei*, *Chryseobacterium soldanellicola*, and *Chryseobacterium taeanense*) display a mucoid consistency; this may be related to the production of extracellular slimy substances, as reported for *Chryseobacterium defluvii* and *Chryseobacterium formosense*. Broth cultures are usually uniformly turbid. *Chryseobacterium* strains give off a strong aromatic odor.

Nutrition and growth conditions. *Chryseobacterium* strains are not fastidious. They grow readily on common commercial media such as blood, tryptic soy, and nutrient agars, and the R2A medium of Reasoner and Geldreich (1985). Growth in corresponding broths is also good. The original description of the genus *Chryseobacterium*, containing only six species at the time, stated that all strains grew at 30°C, and that most strains grew at 37°C (Vandamme et al., 1994a). However, several of the novel species described subsequently showed psychrotolerant growth at 5°C: *Chryseobacterium joostei* (Hugo et al., 2003); *Chryseobacterium vrystaatense* (de Beer et al., 2005); *Chryseobacterium daecheongense* (Kim et al., 2005a); *Chryseobacterium soldanellicola* and *Chryseobacterium taeanense* (Park et al., 2005); *Chryseobacterium shigense* (Shimomura et al., 2005); *Chryseobacterium piscium* (de Beer et al., 2006); *Chryseobacterium hispanicum* (Gallego et al., 2006); *Chryseobacterium taiwanense* (Tai et al., 2006); and *Chryseobacterium wanjuense* (Weon et al., 2006). A *Chryseobacterium* strain isolated from forest soil in Northern Finland was able to grow at 0°C and to degrade Tween 80 at 5°C (Männistö and Haggblom, 2006). Possible novel *Chryseobacterium* species have also been isolated from Antarctic soil using a packed-column

bioreactor maintained at 10°C (Wery et al., 2003). When soil samples from Canada were subjected to 48 freeze–thaw cycles in a cryocycler, the surviving fraction of the bacterial community displayed a considerable increase in freeze–thaw tolerance; among these viable bacteria, a *Chryseobacterium* sp. (identified by 16S rRNA gene sequencing) was able to inhibit ice recrystallization (a characteristic of antifreeze proteins) and the supernatant of its culture enhanced the freeze–thaw tolerance of an *Enterococcus* strain (Walker et al., 2006).

Although only three of the 19 *Chryseobacterium* species have been retrieved from marine environments (i.e., *Chryseobacterium indoltheticum*, *Chryseobacterium piscium*, and *Chryseobacterium scophthalmum*), most other species are also halotolerant and able to grow in the presence of 3–5% NaCl (w/v), for instance on marine agar 2216E (Difco). This is even true for many strains of the clinical organisms *Chryseobacterium gleum* and *Chryseobacterium indologenes*, which are also environmental species. Conversely, strains of the three marine species are able to grow on NaCl-free media such as tryptic soy agar (de Beer et al., 2006; Mudarris et al., 1994) J.-F. Bernardet, unpublished data).

Metabolism and metabolic pathways. These aspects have not been investigated extensively in members of the genus *Chryseobacterium* and little is known besides the details listed at the beginning of this chapter and in Table 44. *Chryseobacterium* strains are chemo-organotrophs with a strictly respiratory type of metabolism (Bernardet et al., 2002; Vandamme et al., 1994a). The original description of *Chryseobacterium scophthalmum*, however, stated that members of this species display both respiratory and fermentative metabolisms (Mudarris et al., 1994). Holmes et al. (1984a, b) also reported that some strains of *Chryseobacterium gleum*, *Chryseobacterium indologenes*, and other strains of CDC group IIb (see below) exhibited anaerobic respiration with nitrate as the terminal electron acceptor. Fumarate can also be used as a terminal electron acceptor by *Chryseobacterium indologenes* (Yabuuchi et al., 1983). These organisms are able to grow in the presence of 5–10% CO₂ (B. Bruun, unpublished data). The three above-mentioned *Chryseobacterium* glacier strains were isolated under anaerobic conditions (Miteva and Brenchley, 2005). Strains of *Chryseobacterium daecheongense* (Kim et al., 2005a) and *Chryseobacterium piscium* (de Beer et al., 2006), as well as some strains of *Chryseobacterium gleum* and *Chryseobacterium indologenes* and other unnamed CDC group IIb strains (Bruun, 1982; Holmes et al., 1984b; Weyant et al., 1996; Yabuuchi et al., 1983), reduce nitrate as well as nitrite (Table 44). Members of *Chryseobacterium* species show catalase, oxidase, phosphatase, and strong proteolytic activities. Several carbohydrates are oxidized, but glycerol and trehalose are not oxidized by members of any species (contrary to the statement in the original description of the genus). Esculin is hydrolyzed, but not agar (Vandamme et al., 1994a).

A few studies have been performed on the enzymic activities of some *Chryseobacterium* strains that may have practical or industrial applications in the future. A study on the biodegradation of the insecticide, herbicide, and disinfectant pentachlorophenol (PCP), whose residues represent a health hazard, has shown that a *Chryseobacterium gleum* strain had a higher PCP degradation capacity than that of a *Pseudomonas* strain and an *Agrobacterium radiobacter* strain (Yu and Ward, 1996). Other studies (cited by Yu and Ward, 1996) have reported degradation of chlorinated phenols by *Chryseobacterium gleum* and suggested

^aSymbols and abbreviations: +, 90% or more of the strains are positive; -, 10% or less of the strains are positive; (+) 90% or more of the strains give a weak or delayed positive reaction; d, 11–89% of the strains are positive; V, varies between references; and nd, not determined. Since some of the characteristics listed were tested by several authors using different methods, the original publications should be consulted for direct comparison. Data from Bruun (1982), Yabuuchi et al. (1983, 1990), Holmes et al. (1984b, 1986a), Bruun and Ursing (1987), Ursing and Bruun (1991), Segers et al. (1993a), Mudarris et al. (1994), Vandamme et al. (1994a), Weyant et al. (1996), Vancanneyt et al. (1999), Yamaguchi and Yokoe (2000), Hugo et al. (2003), Kämpfer et al. (2003), Li et al. (2003b), Kim et al. (2004), Bernardet et al. (2005), de Beer et al. (2005), Kim et al. (2005a, b), Shen et al. (2005), Shimomura et al. (2005), Yi et al. (2005b), Young et al. (2005), de Beer et al. (2006), Gallego et al. (2006), O'Sullivan et al. (2006), Park et al. (2006b), Tai et al. (2006), Weon et al. (2006), J.-F. Bernardet (unpublished data), and C.J. Hugo (unpublished data).

^bThe type of yellow pigment in *Chryseobacterium defluvi*, *Chryseobacterium soldanellicola*, *Chryseobacterium taeanense*, and *Kaistella koreensis* has not been determined (Kämpfer et al., 2003; Kim et al., 2004; Park et al., 2006b). The yellow pigment produced by members of the genus *Sejongia* is not of the flexirubin type (Yi et al., 2005b).

^cStrains of *Elizabethkingia meningoseptica* are either not pigmented or produce a weak yellow pigment (e.g., the type strain; Bruun and Ursing, 1987) that seems to belong to the flexirubin type (J.-F. Bernardet, unpublished data).

^aStrains of *Riemerella anatipestifer* and *Riemerella columbina* grown on trypticase soy agar produce a diffusible, light yellow-brown non-flexirubin pigment that gives a beige color to the colonies (J.-F. Bernardet, unpublished data). On Columbia blood agar, colonies of *Riemerella columbina* are grayish-white to beige, whereas those of *Riemerella anatipestifer* are nonpigmented (Vancanney et al., 1999).

^bAlthough its growth on marine agar has not been tested, the type strain of *Elizabethkingia miricola* has been shown to tolerate seawater (Li et al., 2003b).

^cAccording to Holmes et al. (1984b), strains of *Chryseobacterium gleum* varied in acid production from arabinose and xylose, in growth at 42°C, and in urease production, and were negative for acid production from salicin. According to Yabuuchi et al. (1990), strains of *Chryseobacterium gleum* and *Chryseobacterium indologenes* may be distinguished by their positive and negative reaction, respectively, for the following tests: growth at 41°C; production of phenylalanine deaminase; acid production from L-arabinose, ethanol, salicin, and D-xylose; hydrolysis of esculin after 4 h (strains of both species hydrolyze esculin after 24 h); and production of urease on Christensen's urea agar slant after 40 h. According to Ursing and Bruun (1991), members of *Chryseobacterium gleum* and of one allied genomic group could be differentiated from other CDC group IIb strains by their ability to grow at 40°C and to produce acid from arabinose, xylose, and salicin.

^dData from Kim et al. (2005a, b).

that a reductive dechlorination pathway is involved. Organophosphorus tri-esterases, involved in hydrolysis of the tri-ester bonds of pesticides such as diazinon and parathion, have been reported from a *Chryseobacterium balustinum*-like organism (D. Siddavattam, personal communication). Other chemical contaminants, such as aniline (Radianingtyas et al., 2003), and furan and phenolic compounds (López et al., 2004), have been degraded by a mixed culture that included a *Chryseobacterium indologenes* strain. A novel protein-glutaminase purified from "*Chryseobacterium proteolyticum*" deamidates glutamyl residues in proteins and is regarded by the authors as a promising method of improving protein functionality in food systems (Yamaguchi et al., 2001). A *Chryseobacterium* strain has been shown to produce an extracellular keratinase, which may be used for hydrolysis of poultry feathers and depilation of bovine pelts (Brandelli and Riffel, 2005). Screening for strains able to degrade chitosan (a deacetylated derivative of chitin) yielded a *Chryseobacterium* strain whose 16S rRNA gene sequence shared more than 97% similarity with that of *Chryseobacterium taichungense* (Yu and Ward, 1996). Its chitosanase was highly similar to the ChoA chitosanase of the betaproteobacterium *Mitsuaria chitosanitabida*. Oligosaccharides produced by enzymic hydrolysis of chitosan have many industrial applications. Other potentially useful enzymes discovered in *Chryseobacterium* strains include an endopeptidase that cleaves human plasminogen (Lijnen et al., 2000) and various cold-active proteases (Morita et al., 1997). Conversely, enzymes produced by some *Chryseobacterium* strains may have a negative impact; for instance, heat-stable metalloproteases may play a role in the spoilage of milk and milk products (Venter et al., 1999).

Genetics. The use of 16S rRNA gene sequencing and DNA–DNA hybridization in the delineation of the genus *Chryseobacterium* and of *Chryseobacterium* species has been reviewed recently (Bernardet et al., 2006). Importantly, levels of 16S rRNA gene sequence similarity may be very high (i.e., 98–99%) between *Chryseobacterium* species (de Beer et al., 2006; Li et al., 2003b). Consequently, DNA–DNA hybridization studies, or possibly sequencing of a number of household genes (Kuhnert and Korczak, 2006), are necessary even when two strains share high levels of sequence similarity. The DNA G+C contents of members of the genus were considered to be in the range 33–39 mol% (Bernardet et al., 2006) until lower values were reported for the novel species *Chryseobacterium taeannense* (32.1 mol%) and *Chryseobacterium soldanellicola* (28.8 mol%) (Park et al., 2006b). The usefulness of randomly amplified polymorphic DNA (RAPD) typing has been evaluated recently on a collection of *Chryseobacterium* fish isolates. The clusters of strains delineated by this technique matched some of the clusters yielded by SDS-PAGE analysis of whole-cell protein profiles, although RAPD analysis differentiated strains within other SDS-PAGE clusters (Bernardet et al., 2005).

Antibiotic sensitivity. Most studies on the antibiotic sensitivity of *Chryseobacterium* strains have naturally enough focused on [*Chryseobacterium*] *meningosepticum* (now *Elizabethkingia meningoseptica*) strains because of this species' pathogenicity to humans. In some recent studies (Fraser and Jørgensen, 1997; Hsueh et al., 1997), results of *Chryseobacterium* strains have been pooled with those of *Elizabethkingia meningoseptica* strains, whereas, in other studies, results are given separately

for strains of *Chryseobacterium indologenes*, *Chryseobacterium gleum*, and unnamed members of CDC group IIb (see below) (Chang et al., 1997; Kirby et al., 2004; Spangler et al., 1996). Based on these studies, it appears that these taxa, like *Elizabethkingia meningoseptica*, are naturally resistant to polymyxins, aminoglycosides (gentamicin, streptomycin, kanamycin), chloramphenicol, and most β -lactams (penicillins, cephalosporins, carbapenems).

Chryseobacterium indologenes and *Chryseobacterium gleum* have, like *Elizabethkingia meningoseptica*, been found to produce carbapenem-hydrolyzing β -lactamases (Bellais et al., 1999, 2000a, b, 2002b), which means that they are resistant to extended-spectrum cephalosporins and carbapenems, but not necessarily to ureidopenicillins, i.e., piperacillin. An extended-spectrum β -lactamase has also been described in a strain of *Chryseobacterium gleum* (Bellais et al., 2002c). Members of *Chryseobacterium* species have been found, for the most part, to be resistant to tetracyclines, erythromycin, and linezolid, whereas they display intermediate sensitivity or resistance to clindamycin and vancomycin. Sensitivity to trimethoprim-sulfamethoxazole also varies, some strains being sensitive. The most active antibiotics are rifampicin and the newer quinolones (gatifloxacin, levofloxacin, sparfloxacin) (Fraser and Jørgensen, 1997; Kirby et al., 2004; Spangler et al., 1996).

A constitutive resistance to ampicillin, polymyxin B, chloramphenicol, and oxytetracycline was also found in fish-pathogenic *Chryseobacterium* strains; the antibiotic treatment of diseased fish was successful only when oxolonic acid or sulfamethoxazole-trimethoprim were used (Michel et al., 2005). The 50 *Chryseobacterium scophthalmum* isolates tested *in vitro* were all resistant to tetracyclines, amidoglycosides, lincomycin, oleandomycin, penicillin, and sulfadiazine, but susceptible to chloramphenicol, sulfamethoxazole-trimethoprim, furazolidone, fusidic acid, and novobiocin. Infection caused by *Chryseobacterium scophthalmum* in turbot (*Scophthalmus maximus*) was successfully controlled by furazolidone administered by injection or bath (Mudarris and Austin, 1989).

Pathogenicity. Among past and present *Chryseobacterium* species, [*Chryseobacterium*] *meningosepticum* is by far the most important from a clinical point of view. This species, now reclassified as *Elizabethkingia meningoseptica*, has joined [*Chryseobacterium*] *miricola* in the genus *Elizabethkingia* (Kim et al., 2005b) and is described elsewhere in this volume.

The pathogenicity for man is less well-documented for the two *Chryseobacterium* species of clinical interest, *Chryseobacterium indologenes* and *Chryseobacterium gleum*, taxa which were grouped previously, together with allied strains, as CDC group IIb (King, 1959) or *Flavobacterium* species group IIb (Holmes, 1992). However, there are approximately 35 cases of bacteremia caused by *Chryseobacterium indologenes*/group IIb reported in the literature and most of these cases are described in three published series (Hsueh et al., 1996b, c; Stamm et al., 1975). Bacteremias have been associated with indwelling devices, such as arterial and central venous catheters, endotracheal tubes, and drains, in seriously immunocompromised patients, who often have been placed under intensive care. The exact contribution of group IIb strains to the infections has been difficult to determine due to the often polymicrobial nature of the infections and to the severe underlying conditions in the patients. In some of the intubated patients with bacteremia, the same group IIb strain has also been isolated from lower

tract specimens and the clinical diagnosis has been ventilator-associated pneumonia (Hsueh et al., 1996b; Stamm et al., 1975). There are also sporadic case reports of infections in the literature, including bacteremias (Akay et al., 2006; Lin et al., 2003; Nulens et al., 2001; Siegman-Igra et al., 1987), a case of meningitis following surgery and irrigation with tap water of a paranasal sinus (Bagley et al., 1976), urinary tract infections associated with nephrostomy drainage or urinary catheters, pyomyositis in intravenous drug abusers, and infected burn wounds (Hsueh et al., 1996a–c, 1997).

No infections seem definitely to have been ascribed to *Chryseobacterium gleum* during the past 20 years, which may be due to the fact that automatic identification systems dominating the market do not include this species in their databases. Prior to the extensive use of these systems, the bacterium had mainly been isolated from the vagina, but strains have also been found on catheters and in various body fluids (Holmes et al., 1984b).

Although not yet formally described, the two possible novel species “*Chryseobacterium massiliae*” and “*Candidatus Chryseobacterium timonae*” have been isolated from a human nasal swab and from blood, respectively (Drancourt et al., 2004; Greub et al., 2004); however, their pathogenicity to man is doubtful.

Members of some *Chryseobacterium* species have been associated with diseases in various animal species and their significance in veterinary medicine has been reviewed recently (Bernardet et al., 2006). The only *bona fide* *Chryseobacterium balustinum* strain currently available in culture collections was isolated from a diseased freshwater fish (Brisou et al., 1959); since no other cases have been reported since, it most likely acted as an opportunistic pathogen. Extensive investigations of cases of gill hyperplasia and hemorrhagic septicemia in turbot led to the description of *Chryseobacterium scophthalmum* (Bernardet et al., 2006; Mudarris and Austin, 1989; Mudarris et al., 1994). Because strains were also retrieved from healthy turbot and seawater and since no other cases have been reported since the original study, this species is also most likely an opportunistic pathogen. A collection of *Chryseobacterium* strains isolated from a variety of fish species and geographical areas was recently subjected to a polyphasic taxonomic study. Although all isolates originated from external lesions or internal organs of diseased fish, their virulence was not assessed experimentally. None of the isolates belonged to *Chryseobacterium balustinum* or *Chryseobacterium scophthalmum*, but two of them were attributed to *Chryseobacterium joosteii*; other strains, grouped in three clusters, likely constitute the core of novel *Chryseobacterium* species (Bernardet et al., 2005). Finally, diseased leopard frogs (*Rana pipiens*) reared in laboratory facilities have been found to harbor *Chryseobacterium indologenes*-like strains (Olson et al., 1992).

Ecology. *Chryseobacterium* species have been isolated from a variety of environments, as reviewed recently by Bernardet et al. (2006). The presence of members of the family *Flavobacteriaceae* in various complex bacterial communities has been revealed by studies using culture-independent techniques, but only a few of them specifically mention *Chryseobacterium* strains (Gich et al., 2005; Green et al., 2006; Männistö and Haggblom, 2006; O’Sullivan et al., 2002). Even when bacterial strains were actually isolated, they were seldom studied in detail; the vague denomination “*Flavobacterium* sp.” used by many authors may also very likely cover *Chryseobacterium* strains.

Environmental *Chryseobacterium* species have been isolated from: freshwater and lake sediments (Gich et al., 2005; Hayes, 1977; Kim et al., 2005a; Leff et al., 1998; Tatum et al., 1974); the rhizosphere of various plants (Domenech et al., 2006; Park et al., 2006b; Young et al., 2005); soil from temperate (Hayes, 1977; Shen et al., 2005; Tai et al., 2006; Tatum et al., 1974; Weon et al., 2006; Yamaguchi and Yokoe, 2000), tropical (Radianingtyas et al., 2003), and polar (Männistö and Haggblom, 2006; Walker et al., 2006; Wery et al., 2003) regions; glacier ice (Miteva and Brenchley, 2005); and drinking water (Gallego et al., 2006; Pavlov et al., 2004; Ultee et al., 2004).

The significance of *Chryseobacterium* in these habitats has only been investigated in a few instances. *Chryseobacterium* spp. have been reported from composted materials, soil environments, and plant surfaces (Green et al., 2006 and references therein). They were shown to form the largest group after *Pseudomonas* sp. among the culturable bacterial communities of the plant rhizosphere (McSpadden Gardener and Weller, 2001; Park et al., 2005), to colonize seed surfaces, and to be among the most persistent bacteria in root samples (Green et al., 2006). Some *Chryseobacterium* species have been investigated for their ability to adhere to plant roots and to inhibit plant pathogens (Albareda et al., 2006). For instance, *Chryseobacterium soldanellicola*, one of the novel bacterial species described from the rhizosphere of sand-dune plants, inhibited growth of the plant-pathogenic fungus *Fusarium oxysporum* (Park et al., 2006b). A similar result was obtained with a *Chryseobacterium* strain tentatively identified as *Chryseobacterium balustinum* isolated from the rhizosphere of lupins (*Lupinus albus*); this strain, alone or in combination with other bacterial strains, also displayed a growth-promoting effect on pepper and tomato plants (Domenech et al., 2006). Conversely, although the number of *Chryseobacterium* strains in the rhizosphere of wheat increased significantly during the course of a fungal disease, they were unable to inhibit the fungus (McSpadden Gardener and Weller, 2001).

Chryseobacterium species are also present in freshwater and marine environments (Campbell and Williams, 1951; de Beer et al., 2006; Engelbrecht et al., 1996a, b; Gallego et al., 2006; Gennari and Cozzolino, 1989; González et al., 2000; Harrison, 1929; Mudarris and Austin, 1989; Mudarris et al., 1994). Some of these bacteria may be agents of fish diseases (Bernardet et al., 2005; Mudarris and Austin, 1989; Mudarris et al., 1994) (see above). *Chryseobacterium* strains have also been reported from the epibiotic bacterial community of freshwater microcrustaceans (Niswati et al., 2005), from the gut of various insect species, and from the endosymbiotic microflora of amoebae (Bernardet et al., 2006 and references therein).

Industrial environments such as activated sewage sludge (Kämpfer et al., 2003) and paper mill slimes (Oppong et al., 2003) also harbor *Chryseobacterium* strains. Any relationship between *Chryseobacterium taichungense* and the tar that contaminated the soil from which it was isolated was not investigated (Shen et al., 2005).

Chryseobacterium species are frequently isolated from food environments. These sources include the dairy environment, such as fresh cow milk in South Africa (Hugo et al., 2003; Jooste, 1985; Jooste et al., 1985, 1986; Welthagen and Jooste, 1992) and a lactic acid beverage in Japan (Shimomura et al., 2005). They have also been isolated from meat and poultry products (García-López et al., 1998; Hayes, 1977). An extensive

study of *Chryseobacterium* strains retrieved from chicken portions in a poultry abattoir in South Africa (de Beer, 2005) led to the description of *Chryseobacterium vrystaatense* (de Beer et al., 2005). *Chryseobacterium* strains also occur on the surface or in the gut of apparently healthy marine and freshwater fish (de Beer et al., 2006; Gennari and Cozzolino, 1989; González et al., 2000; Lijnen et al., 2000; Morita et al., 1997); J.-F. Bernardet, unpublished data). The role of these bacteria in food is still unclear, but some studies indicate a role in the spoilage of milk and milk products because of the presence of metalloproteases (Venter et al., 1999). *Chryseobacterium shigense*, however, has been considered as a part of the normal bacterial community in the lactic acid beverage from which it was isolated (Shimomura et al., 2005). *Chryseobacterium* strains retrieved from fish may also be involved with spoilage (Engelbrecht et al., 1996a, b; Gennari and Cozzolino, 1989; Harrison, 1929), as suggested by the production of urea and phenylalanine deaminase by *Chryseobacterium piscium* (de Beer et al., 2006).

Members of CDC group IIb, including *Chryseobacterium indologenes* and *Chryseobacterium gleum*, are also found widely in soil and water. Investigations on the microflora of sink drains revealed the presence of several *Chryseobacterium* strains (as well as strains of the closely related species "*Haloanella gallinarum*", see Figure 40) (Bruun et al., 1989; McBain et al., 2003). Because of their natural habitat in water, *Chryseobacterium* strains are also found in the hospital environment and consequently on patients' inner and outer body surfaces, where they can colonize indwelling devices, e.g., endotracheal tubes and intravascular catheters. From here, they can spread and occasionally cause bacteremia, having the potential to colonize other indwelling devices. However, *Chryseobacterium* strains are not part of the normal flora of humans. *Chryseobacterium* and allied unnamed bacteria are the most frequently isolated flavobacteria in the clinical microbiology laboratory (Holmes and Owen, 1981).

Enrichment and isolation procedures

Chryseobacterium species are not difficult to isolate and cultivate; they usually do not require enrichment or selective isolation procedures and they grow in ambient air (Bernardet et al., 1996). The isolation and preservation media used for *Chryseobacterium* species have been discussed in detail by Jooste and Hugo (1999), Hugo and Jooste (2003), and Bernardet et al. (2006).

Cultivation of environmental *Chryseobacterium* strains is usually done on nutrient, tryptic soy, or brain-heart infusion (BHI) agars (Kim et al., 2005a; Shen et al., 2005; Tai et al., 2006; Young et al., 2005), but Luria-Bertani and plate count agars have also been used (Gallego et al., 2006; Tai et al., 2006). Another medium that has also been used for isolation of these bacteria is R2A agar (Gallego et al., 2006; Kämpfer et al., 2003; Miteva and Brenchley, 2005; Park et al., 2005; Weon et al., 2006). A new cultivation approach using a microdispenser and microtiter plates and resulting in highly enriched or pure cultures recently enabled several members of the phylum *Bacteroidetes*, including a *Chryseobacterium* strain, to be isolated from the water of German lakes (Gich et al., 2005).

Strains of some environmental *Chryseobacterium* species have been isolated initially by using enrichment media in screening studies aimed at isolating bacteria exhibiting special metabolic activities. For instance, the two original strains of *Chryseobacterium*

indoltheticum were isolated on a chitin-containing enrichment medium during a search for chitin-decomposing microorganisms in samples of marine mud (Campbell and Williams, 1951). Subsequently, this species was shown to grow well on media devoid of chitin. "*Chryseobacterium proteolyticum*" was isolated from soil samples during a search for protein-deaminating bacteria by using an enrichment medium containing 0.1% carboxybenzoxy-Gln-Gly (Yamaguchi and Yokoe, 2000). *Chryseobacterium defluvi* was isolated using a selective enrichment medium for a phosphorus-removing mixed bacterial culture from activated sludge; it was subsequently cultivated on R2A and nutrient agars (Kämpfer et al., 2003). *Chryseobacterium formosense* was retrieved during a screening of rhizobacteria for proteolytic activity on skimmed milk agar and subcultivated on BHI agar (Young et al., 2005). By successive rounds of filtration (pore size 0.2 µm) and recultivation at 5°C, a number of ultrasmall psychrophiles was isolated from the deep core of a Greenland glacier and three of them were attributed to the genus *Chryseobacterium* by 16S rRNA gene sequence analysis (Miteva and Brenchley, 2005).

Chryseobacterium strains from freshwater fish are best isolated on tryptic soy or nutrient agars (Bernardet et al., 2005; Michel et al., 2005). For the isolation of *Chryseobacterium* species from marine fish, BHI, glucose-yeast extract, marine 2216E, or nutrient agars may be used (de Beer et al., 2006). Other isolation media include proteose (2%) medium and plate count agar containing 0.5% NaCl (*Chryseobacterium balustinum*; Harrison, 1929; Holmes et al., 1984a; Engelbrecht et al., 1996a, b). *Chryseobacterium scophthalmum* was isolated initially from diseased turbot on medium K (0.1% yeast extract, 0.5% beef extract, 0.6% casein, 0.2% tryptone, 0.1% CaCl₂, 1.5% agar, and 750 ml aged seawater per liter, pH 7.2) (Mudarris and Austin, 1989; Mudarris et al., 1994); it also grows well on marine 2216E, nutrient, and tryptic soy agars.

Nutrient agar (Shimomura et al., 2005) and plate count agar (Jooste, 1985; Jooste et al., 1985, 1986; Welthagen and Jooste, 1992) are the preferred isolation media for food-associated *Chryseobacterium* species. Examples are *Chryseobacterium shigense* (Shimomura et al., 2005), *Chryseobacterium joostei* (Hugo et al., 2003), and *Chryseobacterium vrystaatense* (de Beer et al., 2005). Incubation is at 25–30°C for 48–96 h; however, *Chryseobacterium vrystaatense* was first incubated at 4°C for 24 h and then at 25°C for 48 h in order to slow the strong growth of pseudomonads and give the *Chryseobacterium* strains an opportunity to compete (de Beer, 2005).

Isolation of *Chryseobacterium* species from clinical specimens is done on blood, nutrient, or heart infusion agars (Bruun, 1982; Holmes et al., 1984b; Yabuuchi et al., 1983). An amoebal co-culture was used to recover a novel, as yet undescribed *Chryseobacterium* species from polymicrobial human nasal swabs; the novel species, "*Chryseobacterium massiliae*", was among the few amoeba-resistant bacteria in the swabs (Drancourt et al., 2004; Greub et al., 2004).

Maintenance procedures

The preservation media used for *Chryseobacterium* species have been discussed in detail by Jooste and Hugo (1999), Hugo and Jooste (2003), and Bernardet et al. (2006).

For short-term preservation of *Chryseobacterium* species, nutrient agar slants in metal screw-capped bijoux bottles stored at

4°C were used for "*Chryseobacterium proteolyticum*" (Yamaguchi and Yokoe, 2000) and *Chryseobacterium taichungense* (Shen et al., 2005). BHI agar was used in the same way for *Chryseobacterium formosense* (Young et al., 2005). Cultures of *Chryseobacterium scophthalmum* were maintained on slopes of medium K (see above) at 4°C with transfer every 6–8 weeks (Mudarris and Austin, 1989).

For longer-term preservation, *Chryseobacterium* strains may be freeze-dried on filter paper discs (AA discs) and stored in screw-capped Wassermann tubes at –20°C (e.g., *Chryseobacterium joostei*; Hugo et al., 2003). Preservation at –80°C may employ BHI broth with 20% (v/v) glycerol (Brandelli and Riffel, 2005; Park et al., 2006b) or CAS broth (1% casitone, 0.1% MgSO₄·7H₂O, pH 6.8 unadjusted; Reichenbach, 1989b), ox broth, or tryptic soy broth with 10% (v/v) glycerol (Tai et al., 2006; J.-F. Bernardet, unpublished data; B. Bruun, unpublished data).

The preferred long-term preservation method is, however, lyophilization [Mudarris and Austin, 1989; Bernardet et al., 2002, 2006; Tai et al., 2006; BCCM-LMG Bacteria Collection (<http://bccm.belspo.be/lmg.htm>); American Type Culture Collection (<http://www.atcc.org/>)].

Procedures for testing special characters

A number of phenotypic features are of special importance for differentiation between *Chryseobacterium* species (Tables 43 and 44) and related genera in the family *Flavobacteriaceae* (see below). The performance of these phenotypic tests requires some experience and the conditions under which they are performed are critical for reliability and reproducibility; these conditions have been extensively specified previously (Bernardet et al., 2006; Bernardet and Nakagawa, 2002, 2006).

Differentiation of the genus *Chryseobacterium* from closely related taxa

The characteristics differentiating members of the genus *Chryseobacterium* from those of the most closely related taxa (i.e., *Elizabethkingia*, *Epilithonimonas*, *Bergeyella*, *Riemerella*, *Kaistella*, and *Sejongia*) are listed in Tables 43 and 44. They include the production of flexirubin-type pigments, growth on various media and at different temperatures, DNA G+C content, a number of biochemical traits, and fatty acid composition. In addition, members of the genus *Riemerella* have a distinctly capnophilic metabolism (Segers et al., 1993a; Vancanneyt et al., 1999). Some additional features have been proposed by Laffineur et al. (2002); all *Chryseobacterium indologenes*, *Elizabethkingia meningoseptica*, and *Empedobacter brevis* strains studied shared the same characteristics, but *Chryseobacterium indologenes* strains differ from *Bergeyella zoohelcum* and *Weeksella virosa* strains by the production of pyrrolidonyl arylamidase and resistance to desferrioxamine and colistin. The features differentiating *Chryseobacterium* from other, more distant, members of the family *Flavobacteriaceae* are listed in Table 23 of the family *Flavobacteriaceae* in this volume. In addition to the above-mentioned features, they include cell morphology, the absence of gliding motility, halotolerance, and respiratory metabolism. Features that should be included in the description of novel *Chryseobacterium* species have been specified in the minimal standards for describing new taxa in the family *Flavobacteriaceae* (Bernardet et al., 2002). The use of commercial identification galleries and strips as well as the relevance of fatty acid and whole-cell protein profiles, respiratory

quinones, polyamines, and polar lipids for the differentiation between *Chryseobacterium* species and from related taxa have been discussed recently (Bernardet et al., 2006). In an ongoing study of food spoilage caused by *Chryseobacterium* strains, Biolog GN2 MicroPlates yielded differentiating profiles for the type strains of the seven *Chryseobacterium* and two *Elizabethkingia* species tested (C.J. Hugo, personal communication).

Taxonomic comments

The genus *Chryseobacterium* was proposed in 1994 to accommodate six bacterial species previously included in the genus *Flavobacterium*, but which had been clearly separated from the type species of the genus, *Flavobacterium aquatile*, as a result of an extensive polyphasic study (Vandamme et al., 1994a). These six original *Chryseobacterium* species were *Chryseobacterium balustinum*, *Chryseobacterium gleum*, *Chryseobacterium indologenes*, *Chryseobacterium indoltheticum*, *Chryseobacterium meningosepticum*, and *Chryseobacterium scophthalmum*. Although *Chryseobacterium balustinum* and *Chryseobacterium indoltheticum* were the two oldest species (described in 1929 and 1951, respectively), they were not chosen as the type species of the new genus since they were rather poorly characterized and they were each represented by a single strain. The human pathogen *Chryseobacterium meningosepticum* was also not selected, although it had been most extensively studied and many strains were available. This was because 16S rRNA studies had already shown that it occupied a rather separate position compared to the five other *Chryseobacterium* species. *Chryseobacterium gleum* was chosen as the type species since an extensive genomic and phenotypic study had shown that the 12 strains available were rather homogeneous (Holmes et al., 1984b), contrary to the *Chryseobacterium indologenes* strains (Yabuuchi et al., 1983). Novel species progressively joined the genus; conversely, *Chryseobacterium meningosepticum* and *Chryseobacterium miricola* (Li et al., 2003b) were subsequently moved to a new genus, *Elizabethkingia* (Kim et al., 2005b).

A rather confusing issue concerns the group of strains initially named "*Flavobacterium* CDC group IIb" by King (1959). The descriptions of *Chryseobacterium indologenes* and *Chryseobacterium gleum* were based on some of its members, but since many CDC group IIb strains still cannot be assigned to any named species, it was proposed to continue referring to them as "*Chryseobacterium* sp. CDC group IIb" (Bernardet et al., 2006; Ursing and Bruun, 1991).

There are, at the present time, a few other taxonomic or nomenclatural problems in the genus *Chryseobacterium*. "*Chryseobacterium proteolyticum*", although well characterized (Yamaguchi and Yokoe, 2000), was not published in the *International Journal of Systematic and Evolutionary Microbiology* or included in a validation list in this journal; hence, its name is not valid. "*Chryseobacterium massiliae*" has not been described formally and "*Candidatus Chryseobacterium timonae*" is only known through its 16S rRNA gene sequence (Drancourt et al., 2004; Greub et al., 2004).

Taxonomic and nomenclatural issues in the genus *Chryseobacterium* are dealt with by the Subcommittee on the Taxonomy of *Flavobacterium* and *Cytophaga*-like Bacteria of the International Committee on Systematics of Prokaryotes. The subcommittee has issued the above-mentioned minimal standards (Bernardet et al., 2002).

Attention might be drawn to the fact that of the 18 *Chryseobacterium* species with validly published names, 11 (*Chryseobacterium balustinum*, *Chryseobacterium daecheongense*, *Chryseobacterium defluvii*, *Chryseobacterium formosense*, *Chryseobacterium hispanicum*, *Chryseobacterium shigense*, *Chryseobacterium soldanellicola*, *Chryseobacterium taeanense*, *Chryseobacterium taichungense*, *Chryseobacterium taiwanense*, and *Chryseobacterium wanjuense*) have been described on the basis of only one isolated strain and that descriptions of all these species, except *Chryseobacterium balustinum*, were published from 2003 to 2006. In this regard, it should be noted that a proposal was made in 2001 for not publishing species consisting of less than five strains or species for which easily performed phenotypic tests for differentiation from other species in the same genus were not available (Christensen et al., 2001). Tests that differentiate *Chryseobacterium* species are often sparse, as seen in Table 44. Bearing in mind the facts that different studies employ different variations of tests and media bearing the same name and that a certain level of phenotypic variation is to be expected within a species, this underscores the need for a polyphasic study of a large number of *Chryseobacterium* strains including all species using the same defined methods for all strains.

Editorial note: The following novel species have been added to the genus *Chryseobacterium* after this chapter was completed and their names have been validly published in the *International Journal of Systematic and Evolutionary Microbiology*: *Chryseobacterium caeni* (Quan et al., 2007; this paper includes the detailed fatty

acid composition of *Chryseobacterium shigense*); *Chryseobacterium daeguense* (Yoon et al., 2007b); *Chryseobacterium flavum* (Zhou et al., 2007); *Chryseobacterium luteum* (Behrendt et al., 2007); *Chryseobacterium haifense* (Hantsis-Zacharov and Halpern, 2007); *Chryseobacterium hominis* (Vanechoutte et al., 2007); *Chryseobacterium ureilyticum*, *Chryseobacterium gambrini*, *Chryseobacterium pallidum*, and *Chryseobacterium molle* (Herzog et al., 2008); *Chryseobacterium arothri* (Campbell et al., 2008); and *Chryseobacterium soli* and *Chryseobacterium jejuense* (Weon et al., 2008).

Acknowledgements

The authors wish to acknowledge Jean Euzéby (Ecole Nationale Vétérinaire, Toulouse, France) for correcting the etymology of a number of specific epithets in the List of Species and Tim Lilburn (American Type Culture Collection, Manassas, VA) for providing the phylogenetic tree (Figure 40).

Differentiation of species of the genus *Chryseobacterium*

Characteristics that differentiate the various species of the genus are listed in Table 44.

List of species of the genus *Chryseobacterium*

1. ***Chryseobacterium gleum*** (Holmes, Owen, Steigerwalt and Brenner 1984b) Vandamme, Bernardet, Segers, Kersters and Holmes 1994a, 830^{VP} (*Flavobacterium gleum* Holmes, Owen, Steigerwalt and Brenner 1984b, 23)

gle'um. Gr. neut. adj. *gloion* slippery, sticky; N.L. neut. adj. *gleum* (*sic*) sticky.

Rods, approximately 0.5 µm in diameter with varying lengths, 1.0–3.0 µm. Filaments are common. Good growth occurs on tryptic soy and nutrient agars. Colonies on nutrient agar at 35°C are circular, entire and smooth, bright-yellow-pigmented, and up to 2 mm in diameter, becoming mucoid after incubation for 5 d. Cultures have a strong aromatic odor. There is no hemolysis on blood agar. Nitrate reduction and anaerobic growth in the presence of nitrate have been reported for some *Chryseobacterium gleum* strains (Holmes et al., 1984b). A dark brown pigment is produced on tyrosine agar. Tween 20 is hydrolyzed. Growth occurs on β-hydroxybutyrate, but lipid inclusion granules are not formed. Gelatin, casein, and tributyrin are hydrolyzed. Arginine dihydrolase, and lysine and ornithine decarboxylases are not produced. 3-Ketolactose is not produced. In addition to the data listed in Table 44, acid is not produced from adonitol, dulcitol, inositol, raffinose, rhamnose, or sorbitol. H₂S production is negative when tested using the triple-sugar iron test and positive when the lead acetate test is used. The list of substrates hydrolyzed in API ZYM galleries is given in the original species description. Other characteristics are as given in the genus description and

in Tables 43 and 44. The description of *Chryseobacterium gleum* was based on the thorough study of a homogeneous group of 12 CDC group IIb strains (Holmes et al., 1984b); however, phenotypic differentiation of *Chryseobacterium indologenes*, *Chryseobacterium gleum*, and allied members of CDC group IIb is problematic. As acid production from the differentiating carbohydrates (arabinose, xylose, and salicin) is weak and dependent on the type of carbohydrate medium used, the most reliable differentiating test for *Chryseobacterium gleum* is probably its ability to grow at 40°C. This characteristic is only shared with a few allied group IIb strains and not with the type and other strains of *Chryseobacterium indologenes*, according to Ursing and Bruun (1991). This test is, however, not widely used and not applicable in modern automated identification systems. These systems do not contain *Chryseobacterium gleum* in their databases with the result that strains of *Chryseobacterium gleum* and other group IIb strains are identified as *Chryseobacterium indologenes*. Consequently, only publications of infections with *Chryseobacterium indologenes* appear in recent medical literature. Ironically, this means that the original intention of the proposal by Yabuuchi et al. (1983), i.e., for *Chryseobacterium indologenes* to encompass all CDC group IIb strains, is now what is taking place.

Source: ubiquitous in soil and water and, therefore, the hospital environment. Not a member of normal human flora, but occasionally found in clinical specimens due to its occurrence in hospital water. Isolated mainly from vaginal specimens, but also from body fluids.

DNA G+C content (mol%): 36.6–39.0 (type strain: 37.0–38.0) (T_m) (Holmes et al., 1984b; Hugo et al., 1999).

Type strain: Owen F93, Holmes CL 4/79, ATCC 35910, CCUG 14555, NCTC 11432, LMG 8334, LMG 12447, CIP 103039, IFO (now NBRC) 15054, JCM 2410, NCIMB 13462.

Sequence accession nos (16S rRNA gene): M58772, AY468449.

Reference strains: 11 other strains are included in the species description (Holmes et al., 1984b).

2. **Chryseobacterium balustinum** (Harrison 1929) Vandamme, Bernardet, Segers, Kersters and Holmes 1994a, 830^{VP} [*Empedobacter balustinum* (Harrison 1929) Brisou, Tysset and Vacher 1959, 690; *Flavobacterium balustinum* Harrison 1929, 233]

ba.lus.ti'num. Etymology uncertain but possibly derived from L. n. *balux* gold sand or gold dust, probably in reference to the bright yellow color (Holmes et al., 1984a).

Rods, 0.5–0.7 μm in diameter and up to 3.5 μm in length; filaments (10–20 μm) occur. Colonies on tryptic soy and nutrient agars at 25–30°C are circular, convex, entire, smooth, 2 mm in diameter, and bright-yellow-pigmented. The consistency, originally butyrous, becomes mucoid after 2–3 d. There is no hemolysis on blood agar. A brownish pink pigment is produced on tyrosine agar. Other characteristics are as given in the genus description and in Tables 43 and 44. No strain dating back to the original description has been preserved; hence, the only authentic strain available in culture collections is the one isolated from the blood of a diseased freshwater fish (dace, *Leuciscus leuciscus*) in France (Brisou et al., 1959). Harrison (1929) first isolated the bacterium from the scales of halibut (*Hippoglossus hippoglossus*) caught in the Pacific Ocean. Brisou et al. (1959) considered their own isolate as a freshwater variant of [*Flavobacterium*] *balustinum*, renamed it "*Empedobacter balustinum*", and demonstrated that it was able to kill various fish species when injected intraperitoneally, but not rats or mice. It is actually not certain whether Brisou's strain indeed belongs to the same species as the strain described by Harrison. Samples of intestinal content, skin, and muscle from healthy freshwater fish have recently yielded bacterial isolates phenotypically similar to *Chryseobacterium balustinum* (González et al., 2000; Morita et al., 1997), but they have not been definitely identified and their significance has not been elucidated. Polyphasic studies of collections of fish or dairy *Chryseobacterium* isolates have failed to identify novel *Chryseobacterium balustinum* strains (Bernardet et al., 2005; Hugo et al., 1999).

Source: fish.

DNA G+C content (mol%): 33 (Holmes et al., 1984a, b), 34.7 (Yabuuchi et al., 1983), or 35.0 (Hugo et al., 1999) (all by T_m).

(Neo) type strain: CCTM 724, NCTC 11212, ATCC 33487, LMG 8329, LMG 4010, CIP 103103, IFO (now NBRC) 15053, CCUG 13228, NCIMB 2270.

Sequence accession no. (16S rRNA gene): AY468447.

Reference strains: the strain LMG 12856 (=Holmes 42/78=NCTC 11409=CCUG 22401) (16S rRNA gene sequence accession no. AY468481) should not be considered a *Chryseobacterium balustinum* strain; a polyphasic study

has demonstrated it is actually highly related to the *Chryseobacterium indologenes* type strain (Bernardet et al., 2005).

3. **Chryseobacterium daecheongense** Kim, Bae, Schumann and Lee 2005a, 136^{VP}

dae.che.ong.en'se. N.L. neut. adj. *daecheongense* pertaining to Lake Daecheong, Korea, from where the type strain was recovered.

Rods, approximately 0.5 μm in diameter and 0.8–2.0 μm in length. Good growth occurs on R2A, tryptic soy, and nutrient agars at 28–37°C. No growth occurs on β -hydroxybutyrate. Colonies are yellow-pigmented and become mucoid after 3 d of incubation. *sym*-Homospermidine is the major polyamine and phosphatidylethanolamine is the major polar lipid. Nitrate is reduced, but not nitrite. Casein and gelatin are hydrolyzed. Lists of compounds that are utilized as carbon sources and those that show positive reactions in API ZYM galleries are given in the original species description. Other characteristics are as given in the genus description and in Tables 43 and 44. Highest 16S rRNA gene sequence similarity is with the type strain of *Chryseobacterium defluvii* (97.9%), but DNA–DNA relatedness between the two species is only 34%.

Source: the type (and so far only) strain was isolated from the sediment of a freshwater lake in Korea.

DNA G+C content (mol%): 36.6 (HPLC).

Type strain: CPW406, DSM 15235, KCTC 12088.

Sequence accession no. (16S rRNA gene): AJ457206.

4. **Chryseobacterium defluvii** Kämpfer, Dreyer, Neef, Dott and Busse 2003, 95^{VP}

de.flu'vi.i. L. gen. n. *defluvii* of sewage.

Rods, approximately 2.0 μm long; diameter unspecified. Good growth occurs on R2A, tryptic soy, and nutrient agars at 25–30°C. Colonies are yellow-pigmented and circular with entire edges; after prolonged incubation, they merge owing to the production of extracellular slimy substances. In addition to the data listed in Table 44, no acid is produced from adonitol, D-arabitol, dulcitol, erythritol, i-inositol, melibiose, methyl α -D-glucoside, raffinose, L-rhamnose, or D-sorbitol. Lists of compounds that are utilized as carbon sources and chromogenic substrates that are hydrolyzed are given in the original species description. *sym*-Homospermidine is the major polyamine and phosphatidylethanolamine is the major polar lipid. Other characteristics are as given in the genus description and in Tables 43 and 44. Contains the highest proportion of C_{15:0} iso fatty acid (58.5%) of all *Chryseobacterium* species. The highest 16S rRNA gene sequence similarity is with *Chryseobacterium indoltheticum* (96.2%).

Source: the type (and so far only) strain was isolated from activated sewage sludge in Germany.

DNA G+C content (mol%): 38.8 (HPLC) [not determined originally by Kämpfer et al. (2003), but by Kim et al. (2005a, b)].

Type strain: Kämpfer B2, DSM 14219, LMG 22469, CIP 107207.

Sequence accession no. (16S rRNA gene): AJ309324.

Note: *Chryseobacterium defluvium* is the name given for the organism originally deposited in 16S rRNA sequence databases.

5. **Chryseobacterium formosense** Young, Kämpfer, Shen, Lai and Arun 2005, 426^{VP}

for.mo.sen'se. N.L. neut. adj. *formosense* pertaining to Formosa (Taiwan).

Rods, approximately 1.0 µm in diameter and 2.0 µm in length. Good growth occurs on nutrient, tryptic soy, and BHI agars at 20–30°C. Colonies are yellow-pigmented and circular with entire edges; after prolonged incubation, they become mucoid and merge owing to the production of extracellular slimy substances. Negative for arginine dihydrolase, lysine decarboxylase, and tryptophan deaminase. Lists of compounds that are utilized as carbon sources and that show positive reactions in API ZYM galleries are given in the species description. In API ZYM galleries, *Chryseobacterium formosense* showed β-glucosidase activity, but no α-glucosidase activity, in contrast to *Chryseobacterium defluvi* and *Chryseobacterium scophthalmum*. Other characteristics are as given in the genus description and in Tables 43 and 44. The highest 16S rRNA gene sequence similarity is with *Chryseobacterium indoltheticum* (97.5%), but the two type strains share only 27% DNA–DNA relatedness.

Source: the type (and so far only) strain was isolated from the rhizosphere of garden lettuce (*Lactuca sativa* L.) from Kuohsing, Taiwan.

DNA G+C content (mol%): not determined.

Type strain: CC-H3-2, CCUG 49271, CIP 108367.

Sequence accession no. (16S rRNA gene): AY315443.

6. **Chryseobacterium hispanicum** Gallego, García and Ventosa 2006, 1591^{VP}

his.pa'ni.cum. L. neut. adj. *hispanicum* from Spain.

Rods, approximately 0.9–1.5 µm in diameter and 4.0 µm in length. Good growth occurs on R2A, plate count, and tryptic soy agars at 25–28°C. Colonies on tryptic soy agar are white–yellow, opaque, round, convex, and 2–3 mm in diameter after 48 h at 28°C. Growth occurs with 0–2% NaCl (optimal growth without NaCl). The pH range for growth is 5.0–10.0 (optimal growth at pH 7.0). Methyl red test is negative. Acetoin and H₂S are not produced. Casein and gelatin are hydrolyzed. Glucose is not fermented. D-Glucose, L-arabinose, D-mannose, and maltose are used as sole carbon sources. Arginine dihydrolase activity is absent. The list of substrates that show positive reactions in API ZYM galleries is given in the original species description. In addition to the data listed in Table 44, acid is produced from D-arabinose and D-mannose, but not from D-galactose. Other characteristics are as given in the genus description and in Tables 43 and 44. The highest 16S rRNA gene sequence similarity (96.0%) is with *Chryseobacterium indoltheticum* and *Chryseobacterium scophthalmum*; it occupies a separate position in the phylogenetic tree compared to the other *Chryseobacterium* species.

Source: the type (and so far only) strain was isolated from drinking water in Seville, Spain.

DNA G+C content (mol%): 34.3 (*T_m*).

Type strain: VP48, CECT 7129, CCM 7359, JCM 13554.

Sequence accession no. (16S rRNA gene): AM159183.

7. **Chryseobacterium indologenes** (Yabuuchi, Kaneko, Yano, Moss and Miyoshi 1983) Vandamme, Bernardet, Segers,

Kerstens and Holmes 1994a, 830^{VP} (*Flavobacterium indologenes* Yabuuchi, Kaneko, Yano, Moss and Miyoshi 1983, 595)

in.do.lo'ge.nes. N.L. neut. n. *indolum* indole; N.L. suff. *-genes* (from Gr. v. *gennaô* to produce), producing; N.L. neut. adj. *indologenes* (*sic*), indole-producing.

Rods, approximately 0.5 µm in diameter and 1.0–3.0 µm in length. Filaments are common. Good growth occurs on tryptic soy and nutrient agars. Bright-yellow-pigmented. Colonies on nutrient agar at 35°C are circular, convex, entire, smooth, and up to 2 mm in diameter. Cultures have a strong aromatic odor. There is no hemolysis on blood agar. Yabuuchi et al. (1983) reported that this organism can grow under anaerobic conditions in the presence of fumarate and that some strains are able to reduce nitrate to N₂, whereas others reduce neither nitrate nor nitrite. No pigment is produced on tyrosine agar. Gelatin is hydrolyzed. In addition to the data listed in Table 44, acid is produced from glycogen and mannose, but not from rhamnose, ribose, melibiose, raffinose, melezitose, adonitol, dulcitol, or inulin. Lysine and ornithine decarboxylases, and arginine dihydrolase are not produced. H₂S production is negative when tested using the triple-sugar iron test and positive when the lead acetate test is used. Other characteristics are as given in the genus description and in Tables 43 and 44. See above under *Chryseobacterium gleum* for the differentiation from other *Chryseobacterium* species of clinical interest. The highest 16S rRNA gene sequence similarity (99.0%) is with *Chryseobacterium gleum*, but the two type strains share only 22% DNA–DNA relatedness.

Source: ubiquitous in soil and water and therefore in the hospital environment. Not a member of normal human flora, but together with allied members of CDC group IIb the most commonly isolated flavobacteria in the clinical microbiology laboratory. Associated with device-related infections in immunocompromised patients, but its role in these infections is unclear.

DNA G+C content (mol%): 37.6–38.3 (type strain: 37.7) (Yabuuchi et al., 1983) or 38.0–39.0 (type strain: 38.0) (Hugo et al., 1999) (all using *T_m*).

Type strain: RH 542, ATCC 29897, NCTC 10796, LMG 8337, LMG 12453, LMG 12454, CIP 101026, CCUG 14483, CCUG 14556, IFO (now NBRC) 14944, GIFU 1347, CDC 3716.

Sequence accession nos (16S rRNA gene): M58773, AY468450 (type strains).

Reference strains: besides the other strains included in the description of the species, LMG 12452 (=CCUG 12408=CDC B998) shares high DNA–DNA relatedness (Ursing and Bruun, 1991) and similar protein and RAPD profiles (Bernardet et al., 2005) with the type strain.

8. **Chryseobacterium indoltheticum** (Campbell and Williams 1951) Vandamme, Bernardet, Segers, Kersters and Holmes 1994a, 830^{VP} [*Beneckeia indolthetica* (Campbell and Williams 1951) Campbell 1957, 331; *Flavobacterium indoltheticum* Campbell and Williams 1951, 903]

in.dol.the'ti.cum. N.L. n. *indolum* indole; Gr. adj. *thetikos* positive; N.L. neut. adj. *indoltheticum* (*sic*), indole-positive.

Of the two strains isolated by Campbell and Williams (1951) during a screening for chitin-decomposing bacteria

in marine mud samples of unknown origin, only one, the type strain, remains in culture collections. This strain is nonmotile, although it was originally described as motile by means of peritrichous flagella. This discrepancy casts a doubt on the whole original description; it is also possible that the available strain is not one of the original ones. Hence, the features presented in Table 44 were taken from Holmes et al. (1984a), Holmes (1992), Hugo et al. (2003), and Bernardet et al. (2005). Furthermore, another reference strain (LMG 13342) displays a clear positive reaction for the phenylalanine deaminase test, contrary to the type strain. Both strains grow well on tryptic soy agar and produce a dark brown, diffusible pigment on tyrosine agar (J.-F. Bernardet, unpublished data). Other characteristics are as given in the genus description and in Tables 43 and 44. Holmes et al. (1984a) considered this taxon a *species incertae sedis*, but recent polyphasic studies including 16S rRNA gene sequence data have clearly demonstrated that *Chryseobacterium indoltheticum* is a member of the genus *Chryseobacterium* (Bernardet et al., 2005; Hugo et al., 1999, 2003; Vandamme et al., 1994a). These investigators, however, did not succeed in finding new strains.

Source: marine mud samples of unknown origin.

DNA G+C content (mol%): about 34.0 in most studies (T_m); a surprisingly low value (30.0) was found by Hugo et al. (1999) (T_m).

Type strain: Weeks F37, ATCC 27950, CCUG 33445, CIP 103168, LMG 4025, NCIMB 2220.

Sequence accession no. (16S rRNA gene): AY468448 (type strain).

Reference strains: strain LMG 13342 (=PHLS F32=PHLS A 78/68) (16S rRNA gene sequence accession no. AY468444) exhibits very similar phenotypic features, whole-cell protein profiles and 16S rRNA gene sequence (more than 99%) to those of the type strain (Bernardet et al., 2005).

9. ***Chryseobacterium joostei*** Hugo, Segers, Hoste, Vancanneyt and Kersters 2003, 775^{VP}

joos'te.i. N.L. gen. masc. n. *joostei* of Jooste, named after P.J. Jooste, who isolated the first strains of this species from South African raw milk.

Rods, approximately 0.5 μm in diameter and 1.0 μm in length. The cell wall is approximately 50 nm thick. Colonies on nutrient agar are smooth, shiny, bright yellow, circular with entire edges, and butyrous in consistency, becoming mucoid after incubation for 5 d. A brown, diffusible pigment is produced on tyrosine agar. Growth is observed on β -hydroxybutyrate (without production of β -hydroxybutyrate inclusion granules), but not on Simmons' citrate agar. All strains show phosphatase activity, but not gluconate oxidation, or arginine dihydrolase, lysine decarboxylase, or ornithine decarboxylase activities. Produces indole when using Kovac's reagent, but not when using Ehrlich's reagent. 3-Ketolactose is not produced. Hydrolyzes casein, gelatin, and Tween 20. Negative for the methyl red test; does not produce acetoin, does not tolerate 0.0075% (w/v) KCN, and cannot reduce 0.4% (w/v) selenite. In addition to the data listed in Table 44, acid is not produced from 1% (w/v) dulcitol, inositol, raffinose, rhamnose, or sorbitol. Lists of compounds that are utilized/not utilized as

sole carbon sources and substrates that are hydrolyzed/not hydrolyzed in API ZYM galleries are given in the original species description. Other characteristics are as given in the genus description and in Tables 43 and 44.

Source: strains were isolated originally from raw milk samples taken from different farms and from tankers arriving at dairy factories across South Africa; they were distinguished from reference strains of the other *Chryseobacterium* species by their specific whole-cell protein profile (Hugo et al., 1999). More recently, two additional strains were retrieved from ulcerative lesions of Atlantic salmon (*Salmo salar*) in Finland (Bernardet et al., 2005).

DNA G+C content (mol%): 36–37 (type strain: 36.7) (T_m).

Type strain: Hugo Ix5a, LMG 18212, CCUG 46665, CIP 105533.

Sequence accession no. (16S rRNA gene): AJ271010 (type strain); AY468479 (LMG 18208).

Reference strains: LMG 18207 [strain Eh 9 of Jooste (1985)], LMG 18208 [strain Hb 7a of Jooste (1985)], LMG 18209 [strain Hb 7b of Jooste (1985)], LMG 18210 [strain Hbg 12b of Jooste (1985)], LMG 18211 [strain Ip 8b of Jooste (1985)], LMG 18213 [strain Ix 11 of Jooste (1985)], LMG 18214 [strain Sp 6a of Jooste (1985)], LMG 18215 [strain J 68 of Welthagen and Jooste (1992)], LMG 18216 [strain J 75 of Welthagen and Jooste (1992)], LMG 18217 [strain J 79 of Welthagen and Jooste (1992)], LMG 22906 [=CIP 108621; strain UOF CR694 of Bernardet et al. (2005)]; and LMG 22907 [=CIP 108622; strain UOF CR1094 of Bernardet et al. (2005)].

Note: *Chryseobacterium joostei* is the name given for the organism originally deposited in 16S rRNA sequence databases.

10. ***Chryseobacterium piscium*** de Beer, Hugo, Jooste, Vancanneyt, Coenye and Vandamme 2006, 1321^{VP}

pis'ci.um. L. pl. gen. n. *piscium* of fish.

Rods, approximately 0.5 μm in diameter and 1.0 μm in length. Colonies on nutrient agar are shiny, yellow, and translucent with entire edges. Growth occurs in nutrient broth containing 5% NaCl. Strains test positive for gelatin and casein hydrolysis. The reaction on triple-sugar iron agar and 10% lactose is alkaline. All strains show positive reactions with the Biolog GN2 MicroPlate system for only four substrates, namely gentiobiose, D-mannose, succinic acid monomethyl ester, and acetic acid. The highest 16S rRNA gene sequence similarities are with *Chryseobacterium balustinum*, *Chryseobacterium scophthalmum*, and *Chryseobacterium indoltheticum* (99.3, 98.9, and 97.4%, respectively); DNA–DNA relatedness values with these three species are 57, 51, and 52%, respectively. The four *Chryseobacterium piscium* strains were originally distinguished from reference strains of the other *Chryseobacterium* species by their specific whole-cell protein profile, although *Chryseobacterium balustinum* and *Chryseobacterium indoltheticum* display very similar profiles. Other characteristics are as given in the genus description and in Tables 43 and 44.

Source: all four currently known strains have been isolated from fresh fish from the South Atlantic ocean off the South African coast during 1996 (Lingalo, 1997). Production of urea and phenylalanine deaminase suggests that *Chryseobacterium piscium* may be involved in spoilage of the fish.

DNA G+C content (mol%): 33.6 (HPLC; type strain).

Type strain: strain R-23621, LMG 23089, CCUG 51923.

Sequence accession no. (16S rRNA gene): AM040439.

Reference strains: LMG 23086 (=strain R-23611), LMG 23087 (=strain R-23616) and LMG 23088 (=strain R-23620).

11. **Chryseobacterium scophthalmum** (Mudarris, Austin, Segers, Vancanneyt, Hoste and Bernardet 1994) Vandamme, Bernardet, Segers, Kersters and Holmes 1994a, 830^{VP} (*Flavobacterium scophthalmum* Mudarris, Austin, Segers, Vancanneyt, Hoste and Bernardet 1994, 450)
- scoph.thal'mum. N.L. n. *Scophthalmus* scientific name of a genus that encompasses the turbot; N.L. neut. adj. *scophthalmum* (*sic*) pertaining to turbot.

Rods, 0.5 µm in diameter and 1.0–2.0 µm in length; filaments occur. The cell wall is 50 nm thick. The presence of gliding motility initially reported (Mudarris and Austin, 1989) has not been confirmed during further investigations (Mudarris et al., 1994); J.-F. Bernardet, unpublished data). Good growth occurs on marine 2216E, nutrient, and tryptic soy agars at 25–30°C. Colonies are circular, smooth, convex with entire edges, and deep golden-yellow-pigmented. On tyrosine agar, a pink, diffusible pigment is produced by some strains (e.g., the type strain), progressively turning brown. The type strain yields a strong positive reaction in the phenylalanine deaminase test; the six other strains tested are negative. Metabolism is reportedly respiratory and fermentative. Arginine dihydrolase, and lysine and ornithine decarboxylases are not produced. The methyl red test is negative; acetoin is not produced. Blood (β-hemolysis occurs around the areas of growth), casein, gelatin, tributyrin, and Tweens 20, 40, 60, and 85 are degraded, but agar, cellulose, and chitin are not degraded. Lists of compounds that are utilized as carbon sources and substrates that are hydrolyzed in API ZYM galleries are given in the original species description. Sodium nitrate, vitamin-free Casamino acids, and yeast extract are utilized as nitrogen sources. Growth occurs in the presence of 0–4% (w/v) NaCl, but not in the presence of 5% NaCl. Other characteristics are as given in the genus description and in Tables 43 and 44. The highest 16S rRNA gene sequence similarities (98.9 and 97.8%) are with *Chryseobacterium balustinum* and *Chryseobacterium indoltheticum*, respectively (Li et al., 2003b), but the corresponding levels of DNA–DNA relatedness are only 44 and 37% (Mudarris et al., 1994).

Source: the type strain was isolated in 1987 from the gills of a diseased turbot (*Scophthalmus maximus*) in Scotland. Forty-nine other strains were isolated at the same time from healthy and diseased turbot and from seawater. Diseased fish suffered from gill hyperplasia and hemorrhagic septicemia. They displayed hemorrhages in the eyes, skin, and jaw; several internal organs also exhibited necrosis and hemorrhages (Mudarris and Austin, 1989; Mudarris et al., 1994). No other strains of *Chryseobacterium scophthalmum* have been found subsequently, even when collections of *Chryseobacterium* strains isolated from diseased fish have been extensively investigated (Bernardet et al., 2005).

DNA G+C content (mol%): 33.5–34.7 (type strain: 34.1) (T_m).

Type strain: Austin MM1, ATCC 700039, LMG 13028, CIP 104199, CCM 4109, NCIMB 13463, CCUG 33454.

Sequence accession no. (16S rRNA gene): AJ271009 (type strain).

Reference strains: Austin MM1A (=LMG 13029), Austin MM1B (=LMG 13030), Austin MM1D (=LMG 13031), Austin MM2B (=LMG 13032), Austin MM2C (=LMG 13033), and Austin MM4 (=LMG 13034).

Note: the synonym *Cytophaga scophthalmis* is listed in 1989 in the catalog of strains of the Czech Collection of Microorganisms.

12. **Chryseobacterium shigense** Shimomura, Kaji and Hiraishi 2005, 1905^{VP}
- shi.gen'se. N.L. neut. adj. *shigense* pertaining to Shiga prefecture in Japan, the geographical area of isolation of the type strain.

Straight or slightly curved rods, approximately 0.6 µm in diameter; the published scanning electron micrograph shows rods approximately 2.0–4.0 µm in length. Good growth occurs on nutrient agar at 20–30°C. Colonies are deep yellow, circular, and shiny. Casein and gelatin are hydrolyzed. The highest 16S rRNA gene sequence similarity (95.7%) is with *Chryseobacterium joostei*. However, unlike *Chryseobacterium joostei*, *Chryseobacterium shigense* does not grow on MacConkey agar and does not produce acid from maltose or trehalose. The fatty acid composition is not given in detail in the original description, only the amounts of the two major fatty acids (C_{15:0}, 39.7%; and C_{17:0} iso 3-OH, 19.6%) are specified. Other characteristics are as given in the genus description and in Tables 43 and 44.

Source: the type (and so far only) strain was isolated in Japan from a commercial fresh lactic acid beverage; it was considered as a part of the normal bacterial community of the preparation.

DNA G+C content (mol%): 36.6 (HPLC).

Type strain: GUM-Kaji, BAMY 1001, DSM 17126, NCIMB 14047.

Sequence accession no. (16S rRNA gene): AB193101.

13. **Chryseobacterium soldanellicola** Park, Jung, Lee, Lee, Do, Kim and Bae 2006b, 436^{VP}
- sol.da.nel'li.co.la. N.L. n. *soldanella* the species epithet of a plant belonging to the genus *Calystegia*; L. suff. *-cola* (from L. n. *incola*) dweller; N.L. masc. n. *soldanellicola* dweller of *Calystegia soldanella*.

Rods of unspecified size. Good growth occurs on R2A, tryptic soy, and nutrient agars at 25–30°C. Colonies are circular with entire edges, shiny, and yellow, becoming mucoid after prolonged incubation. Growth occurs in the presence of 0–4% (w/v) NaCl within 14 d. The pH range for growth is 5–7 and the optimal pH for growth is 5. Acetoin is not produced. Negative for arginine dihydrolase, lysine decarboxylase, and tryptophan deaminase. Gelatin is hydrolyzed. Glucose, arabinose, mannose, and maltose are weakly assimilated. Compounds that are utilized as carbon sources are given in the original species description. *Chryseobacterium soldanellicola* has the lowest G+C content in the genus. Other characteristics are as given in the genus description and in Tables 43 and 44.

The highest 16S rRNA gene sequence similarity (97.2%) is with *Chryseobacterium indoltheticum*. The type strain displays antifungal activity against the plant pathogen *Fusarium oxysporum*.

Source: the type (and so far only) strain was isolated from the roots of beach morning glory (*Calystegia soldanella*) growing on a sand dune in the coastal area of Tae-an, Chungnam, Korea.

DNA G+C content (mol%): 28.8 (unspecified method).

Type strain: PSD 1-4, KCTC 12382, NBRC 100864.

Sequence accession no. (16S rRNA gene): AY883415.

14. ***Chryseobacterium taeanense*** Park, Jung, Lee, Lee, Do, Kim and Bae 2006b, 436^{VP}

tae.an.en'se. N.L. neut. adj. *taeanense* pertaining to Tae-an, a geographical region in Chungnam, Korea, where the type strain was isolated.

Rods of unspecified size. Good growth on R2A, tryptic soy, and nutrient agars at 25–30°C. Colonies are circular with entire edges, shiny, and yellow, becoming mucoid after prolonged incubation. Growth occurs in the presence of 0–6% (w/v) NaCl within 14 d. The pH range for growth is 5–9 and the optimal pH for growth is 5. Acetoin is not produced. Negative for arginine dihydrolase, lysine decarboxylase, and tryptophan deaminase. Gelatin is hydrolyzed. Weakly assimilates glucose, arabinose, mannose, and maltose. Compounds that are utilized as carbon sources are given in the original species description. Other characteristics are as given in the genus description and in Tables 43 and 44. The highest 16S rRNA gene sequence similarity (97.8%) is with *Chryseobacterium taichungense*.

Source: the type (and so far only) strain was isolated from the roots of *Elymus mollis* (wild rye) growing on a sand dune in the coastal area of Tae-an, Chungnam, Korea.

DNA G+C content (mol%): 32.1 (unspecified method).

Type strain: PHA3-4, KCTC 12381, NBRC 100863.

Sequence accession no. (16S rRNA gene): AY883416.

15. ***Chryseobacterium taichungense*** Shen, Kämpfer, Young, Lai and Arun 2005, 1302^{VP}

tai.chung'en.se. N.L. neut. adj. *taichungense* pertaining to Taichung, a province in Taiwan.

Rods, approximately 2.0 µm in length; diameter unspecified. Good growth occurs on nutrient, BHI, and tryptic soy agars at 25–30°C. Colonies are yellow, shiny, and circular with entire edges, becoming mucoid after prolonged incubation due to the production of extracellular substances. Grows in the pH range 6.0–9.0; optimal pH range for growth is 7.0–8.0. Gelatin is hydrolyzed. In addition to the data listed in Table 44, acid is produced weakly from adonitol, i-inositol, and L-rhamnose; no acid is produced from D-arabitol, dulcitol, erythritol, melibiose, methyl- α -D-glucoside, raffinose, or D-sorbitol. Lists of compounds that are utilized as carbon sources, substrates that show positive reactions in API ZYM galleries, and chromogenic substrates that are hydrolyzed are given in the original species description. Other characteristics are as given in the genus description and in Tables 43 and 44. The highest 16S rRNA gene sequence similarity (96.8%) is with *Chryseobacterium indologenes* and *Chryseobacterium gleum*.

Source: the type (and so far only) strain was isolated from tar-contaminated soil in Taichung, Taiwan.

DNA G+C content (mol%): not determined.

Type strain: Shen CC-TWGS1-8, CCUG 50001, CIP 108519.

Sequence accession no. (16S rRNA gene): AJ843132.

16. ***Chryseobacterium taiwanense*** Tai, Kuo, Lee, Chen, Yokota and Lo 2006, 1774^{VP}

tai.wan.en'se. N.L. neut. adj. *taiwanense* pertaining to Taiwan, from where the type strain was recovered.

Rods, approximately 0.6–0.9 µm in diameter and 1.0–2.2 µm in length. Good growth on nutrient and tryptic soy agars at 30°C. Colonies on tryptic soy agar are yellowish, translucent, and shiny with entire edges. Growth occurs on tryptic soy agar containing 4% NaCl. The pH range for growth is 5.0–10.0 (optimum 6.0–8.0). Casein and gelatin are hydrolyzed. Lists of substrates that show positive reactions in API ZYM galleries and on GN2 MicroPlates are given in the original species description. Other characteristics are as given in the genus description and in Tables 43 and 44. The highest 16S rRNA gene sequence similarities (96.7–97.2%) are with *Chryseobacterium daecheongense*, *Chryseobacterium defluvi*, and *Chryseobacterium taichungense*, but DNA–DNA relatedness between the four type strains is only 8.5–24.2%.

Source: the type (and so far only) strain was isolated from farmland soil in Taiwan.

DNA G+C content (mol%): 36.8 (HPLC).

Type strain: Soil-3-27, BCRC 17412, IAM 15317, LMG 23355.

Sequence accession no. (16S rRNA gene): DQ318789.

17. ***Chryseobacterium vrystaatense*** de Beer, Hugo, Jooste, Willems, Vancannet, Coenye and Vandamme 2005, 2151^{VP}

vry.staa.ten'se. N.L. neut. adj. *vrystaatense* pertaining to Vrystaat (Free State), the South African province where these bacteria were isolated.

Rods, approximately 0.5 µm in diameter and 1.0 µm in length. Colonies on nutrient agar are shiny, deep golden yellow, and translucent as single colonies, with entire edges. It should be noted that, although the table of differentiating characteristics in the original description of the species (de Beer et al., 2005) indicated no growth on MacConkey agar, the formal description stated that the species did grow on this medium; after personal communication with the author, it was confirmed that no growth was observed on MacConkey agar. All strains grow in nutrient broth containing 2% (w/v) NaCl; growth in 3 and 4% NaCl broth is strain-dependent (negative for the type strain). Reactions on triple-sugar iron agar and 10% lactose are alkaline. The ability to produce H₂S varies depending on incubation time on triple-sugar iron agar and sulfide indole motility medium. All strains show positive reactions using the Biolog GN2 MicroPlate system for Tweens 40 and 80, gentiobiose, α -D-glucose, D-mannose, trehalose, succinic acid monomethyl ester, acetic acid, and L-asparagine. Variable reactions are observed for L-aspartic acid, L-glutamic acid, glycyl-L-glutamic acid, L-serine, glycerol, dextrin, α -ketovaleric acid, L-alanyl-glycine, L-threonine, D-mannitol, uridine, thymidine, and inosine.

Other characteristics are as given in the genus description and in Tables 43 and 44. Whole-cell protein analysis delineated three subgroups in the collection of 36 isolates studied, but DNA–DNA relatedness values obtained among representative isolates of these subgroups were above 90%, demonstrating that they actually form a homogeneous genospecies (de Beer et al., 2005). The highest 16S rRNA gene sequence similarities are with *Chryseobacterium joostei*, *Chryseobacterium indologenes*, and *Chryseobacterium gleum* (96.9, 97.1, and 97.1%, respectively); the *Chryseobacterium vrystaatense* type strain shares 46% DNA–DNA relatedness with the *Chryseobacterium joostei* type strain.

Source: all *Chryseobacterium vrystaatense* strains were isolated from raw chicken-portion samples collected at different processing stages from a chicken processing plant in 2003 in the Free State province of South Africa (de Beer et al., 2005).

DNA G+C content (mol%): 37.0–37.6 (type strain: 37.1) (HPLC).

Type strain: de Beer 161, LMG 22846, CCUG 50970.

Sequence accession nos (16S rRNA gene): AJ871397 (type strain), AJ871398 (LMG 22954).

Reference strains: LMG 22847 (=strain R-23600), LMG 22848 (=strain R-23500), and LMG 22954 (=strain R-23533).

18. ***Chryseobacterium wanjuense*** Weon, Kim, Yoo, Kwon, Cho, Go and Stackebrandt 2006, 1502^{VP}

wan.ju.en'se. N.L. neut. adj. *wanjuense* pertaining to Wanju, the Korean province where the type strain was isolated.

Rods, approximately 0.7–0.8 µm in diameter and 2.0–3.5 µm in length. Good growth occurs on R2A, nutrient, and tryptic soy agars at 28°C. Colonies on R2A agar are yellow with entire edges. Growth occurs with 0–2% NaCl (optimum 0–1% NaCl). The pH range for growth is 5.0–9.0 (optimum pH 7.0). Casein and gelatin are hydrolyzed. Chitin and carboxymethylcellulose are not hydrolyzed. Glucose is not fermented. Arginine dihydrolase activity is absent. Lists of substrates that show positive reactions in the API ZYM, 50 CH, 20NE, and ID 32 GN galleries are given in the original species description. Other characteristics are as given in the genus description and in Tables 43 and 44. The highest 16S rRNA gene sequence similarity (97.7%) is with *Chryseobacterium daecheongense*, but the two type strains share only 28% DNA–DNA relatedness.

Source: the type (and so far only) strain was isolated from greenhouse soil cultivated with lettuce in Korea.

DNA G+C content (mol%): 37.8 (HPLC).

Type strain: R2A10-2, KACC 11468, DSM 17724.

Sequence accession no. (16S rRNA gene): DQ256729.

Other organisms

1. ***Chryseobacterium proteolyticum*** Yamaguchi and Yokoe 2000, 3342

pro.te.o.ly'ti.cum. N.L. neut. n. *proteinum* protein; Gr. adj. *lutikos -ê -on* dissolving; N.L. neut. adj. *proteolyticum (sic)* protein-dissolving, proteolytic.

Rods, approximately 0.4–0.5 µm in diameter and 0.8–2.0 µm in length. Good growth occurs on nutrient agar at 30°C. Colonies are circular, and orange or light pinkish cream. The pH range for growth is 5–9; optimal range for growth is pH 6–8. Negative for 3-ketolactose and acetoin production. Lysine and ornithine decarboxylases, and arginine dihydrolase are negative. Casein and gelatin are hydrolyzed. In addition to the data listed in Table 44, acid is produced from soluble starch, but not from adonitol, inositol, or inulin. Other characteristics are as given in the genus description and in Tables 43 and 44. The fatty acid profile was not determined. The highest 16S rRNA gene sequence similarities are with *Chryseobacterium gleum* and *Chryseobacterium indologenes* (96.0 and 95.9%, respectively). The name of this well-described species has not been validly published and the strains have not been deposited in a recognized culture collection or been made available for research. "*Chryseobacterium proteolyticum*" has been shown to produce an enzyme with a great potential for industrial applications, the first protein-deaminating enzyme of microbial origin.

Source: the two strains were isolated from damp soil samples in a rice field (type strain) and on the bank of a brook from Tsukuba, Ibaraki, Japan.

DNA G+C content (mol%): 37.1 for both strains (HPLC).

Type strain: Yamaguchi and Yokoe 9670, FERM P-17664 (Patent Micro-organism Depository, National Institute of Bioscience and Human Technology, Tsukuba, Japan).

Sequence accession no. (16S rRNA gene): AB039830 (type strain).

Other reference strain: Yamaguchi and Yokoe 9671.

2. ***Chryseobacterium massiliae*** Greub, La Scola and Raoult 2004, 474

mas.si'li.ae. L. gen. n. *massiliae* of *Massilia*, the Latin name of Marseille.

A strain provisionally named "*Chryseobacterium massiliae*" was recovered from a nasal swab from a homeless woman suffering from rhinitis in a hospital in Marseille, France, using amoebal co-culture; it was one of the amoeba-resistant bacteria in the sample (Drancourt et al., 2004). The strain was deposited in culture collections, but no detailed study was published. It grows on medium used for growing strains of *Afipia* and *Legionella* (medium 23; CIP catalog of strains) at 30°C in the presence of 5% CO₂.

Source: human nasal swab.

Type strain: Greub 90B, CIP 107752, CCUG 51329.

Sequence accession no. (16S rRNA gene): AF531766.

3. ***Candidatus Chryseobacterium timonae*** Drancourt, Berger and Raoult 2004, 2198

ti'mo.nae. N.L. gen. n. *timonae* of the hospital, La Timone.

Only the 16S rRNA gene sequence of this strain is available.

Source: the strain was isolated from the blood of a 73-year-old man suffering from ulcerative colitis in a hospital in Marseille, France.

Sequence accession no. (16S rRNA gene): AY244770.

Genus XI. *Cloacibacterium* Allen, Lawson, Collins, Falsen and Tanner 2006, 1314^{VP}

THE EDITORIAL BOARD

Clo.a.ci.bac.te'ri.um. L. fem. n. *cloaca* a sewer, canal; L. neut. n. *bacterium* a small rod; N.L. neut. n. *Cloacibacterium* a sewer rod.

Pleomorphic rods. Nonmotile. Gram-stain-negative. A flexirubin-type pigment is not produced. **Yellow to orange carotenoid-type pigments are produced. Facultatively anaerobic.** Catalase- and oxidase-positive. The major end product of glucose fermentation under both aerobic and anaerobic conditions is pyruvate. Cellular fatty acids consist mainly of branched-chain fatty acids, with C_{13:0} iso, C_{15:0} iso, C_{15:1} iso, and C_{17:0} iso 3-OH predominating. **The predominant respiratory quinone is MK-6.**

DNA G+C content (mol%): 31.

Type species: *Cloacibacterium normanense* Allen, Lawson, Collins, Falsen and Tanner 2006, 1314^{VP}.

Further descriptive information

In broth cultures, cells are up to 27 µm long, but cells from agar plate cultures are only 5–9 µm long. Colonies grown on tryptic soy agar for 48 h are 1.0–1.5 mm in diameter, round, entire, and waxy. The temperature range for growth is 18–36°C (optimum, 30°C). No growth occurs at 4°C or at 40°C or above. All strains grow at pH 7 and 8 (optimum, pH 7), and some grow at pH 6 and 9.

Numbers of *Cloacibacterium normanense* in raw sewage from two different treatment plants were 1.4 × 10⁵ and 1.4 × 10⁴ cells/ml, as estimated by a most probable number-PCR method (Allen et al., 2006). The organisms, however, were not detected by this method in treated effluent or in human stool specimens,

indicating that *Cloacibacterium normanense* is unlikely to be a dominant member of the human gastrointestinal tract.

Most isolates tested are resistant to erythromycin (15 µg) and kanamycin (30 µg). All isolates so far tested are sensitive to carbenicillin (100 µg), chloramphenicol (30 µg), ciprofloxacin (5 µg), doxycycline (30 µg), gentamicin (10 µg), oxytetracycline (30 µg), sulfathiazole (0.25 mg), and tetracycline (30 µg).

Taxonomic comments

Analysis of 16S rRNA gene sequences indicates that the bacterial species most closely related to *Cloacibacterium normanense* are *Riemerella anatipestifer* (88.8% sequence similarity), *Riemerella columbina* (94.6% sequence similarity), and *Bergeyella zoohelcum* (94.4% sequence similarity).

Differentiation of the genus *Cloacibacterium* from related genera. Unlike *Cloacibacterium*, *Bergeyella* and *Riemerella* do not produce a yellow pigment. *Bergeyella* and *Riemerella* also have a higher DNA G+C content (35–37 and 33–37 mol%, respectively, vs 31 mol% for *Cloacibacterium*). Unlike *Cloacibacterium*, *Bergeyella* hydrolyzes urea, but not DNA or esculin; also, *Bergeyella* is non-saccharolytic and fails to form acid from glucose. In contrast to *Cloacibacterium*, the genus *Riemerella* is capnophilic and most strains of *Riemerella* grow at 42°C.

List of species of the genus *Cloacibacterium*1. *Cloacibacterium normanense* Allen, Lawson, Collins, Falsen and Tanner 2006, 1314^{VP}

nor.man.en'se. N.L. neut. adj. *normanense* pertaining to the city of Norman, Oklahoma, USA, where the organism was first isolated.

Characteristics are as described for the genus, with the following additional features. No growth occurs on MacConkey agar. Indole-positive. Casein, esculin, gelatin, and starch are hydrolyzed, but alginate, agar, cellulose, chitin, hypoxanthine, pectin, urea, uric acid, and xanthine are not hydrolyzed. DNA is weakly hydrolyzed. Methyl red- and Voges-Proskauer-negative. Nitrate is not reduced. With the API system, acid is produced from α-cyclodextrin and mannose, but not from alanine, ribose, mannitol, sorbitol, lactose, trehalose, raffinose, hippurate, glycogen, melibiose, melezitose, sucrose, L-arabinose, D-arabitol, tagatose, or raffinose. Positive for the following enzyme activities: alkaline phosphatase, acid phosphatase, alanine arylamidase, arginine dihydrolase (weak reaction), arginine arylamidase, chymotrypsin, esterase C4 (weak reaction), ester lipase C8,

α-glucosidase, β-glucosidase, glycine arylamidase, glycyL tryptophan arylamidase, proline arylamidase, leucine arylamidase, leucyl glycine arylamidase, phenylalanine arylamidase, alanine phenylalanine proline arylamidase, leucine arylamidase, naphthol-AS-BI-phosphohydrolase, pyroglutamic acid arylamidase, tyrosine arylamidase, histidine arylamidase, glutamyl glutamic acid arylamidase, serine arylamidase, and valine arylamidase. The following enzyme activities are absent: N-acetyl-β-glucosaminidase, α-arabinosidase, α-fucosidase, α-galactosidase, β-galactosidase, β-glucuronidase, glutamic acid arylamidase, α-mannosidase, β-mannosidase, methyl β-D-glucopyranoside, pyroglutamic acid arylamidase, lipase C14, and trypsin. The major fatty acids are C_{13:0} iso (8–9%), C_{15:0} iso (40–46%), C_{15:1} iso (7–10%), and C_{17:0} iso 3-OH (5–9%).

Source: the type strain was isolated from untreated human wastewater.

DNA G+C content (mol%): 31 (HPLC).

Type strain: NRS1, ATCC BAA-825, CCUG 46293, CIP 108613, DSM 15886.

Sequence accession no. (16S rRNA gene): AJ575430.

Genus XII. *Coenonia* Vandamme, Vancanneyt, Segers, Ryll, Köhler, Ludwig and Hinz 1999, 873^{VP}

THE EDITORIAL BOARD

Coe.no'ni.a. Gr. n. *koinônia* community, association; N.L. fem. n. *Coenonia* refers to the association between these bacteria and a host.

Rods, 0.2–0.4 × 1.25–2.5 µm. Nonsporeforming. Nonmotile. Gram-stain-negative. **Microaerophilic.** Growth is optimal at 37°C in a microaerobic and CO₂-enriched atmosphere; it is weak under anaerobic conditions and absent in aerobic conditions. Catalase- and oxidase-positive. **Hyaluronidase- and chondroitin sulfatase-positive.** The major fatty acid components of all strains examined are branched-chain fatty acids, including C_{13:0} iso, C_{15:0} iso, C_{15:0} anteiso, C_{15:0} iso 3-OH, C_{16:0} 3-OH, and C_{17:0} iso 3-OH.

DNA G+C content (mol%): 35–36.

Type species: Coenonia anatina Vandamme, Vancanneyt, Segers, Ryll, Köhler, Ludwig and Hinz 1999, 873^{VP}.

Further descriptive information

Coenonia anatina causes an exudative septicemic disease in ducks and geese. Strains have been isolated as pure cultures under microaerobic conditions from samples of the respiratory tract (lungs, air sac fibrin, pericard) and brain of ducks and geese, always associated with signs similar to those of *Riemerella anatipestifer*-associated exudative septicemia.

In the northern part of Germany, *Coenonia anatina* strains have been recovered from over 30% of the cases of septicemia-related losses in commercial duck flocks in the period 1994–1995. Vaccination with an inactivated whole culture of *Coenonia anatina* strains has induced protection of ducklings against *Coenonia anatina*-associated disease. These data suggest its pathogenic role (Vandamme et al., 1999).

Differentiation of the genus *Coenonia* from other genera

Coenonia is positive for hyaluronidase and chondroitin sulfatase activities, whereas *Capnocytophaga* species are negative (Vandamme et al., 1999).

Taxonomic comments

Based on 16S rRNA sequence analysis, Vandamme et al. (1999) reported that *Coenonia anatina* exhibited a moderate but distinct relationship to *Capnocytophaga* species, with an overall 16S rRNA sequence similarity of 88.8–90.2%. Similarity values to other representatives of the phylum *Bacteroidetes* were 88.6% and lower.

List of species of the genus *Coenonia*1. *Coenonia anatina* Vandamme, Vancanneyt, Segers, Ryll, Köhler, Ludwig and Hinz 1999, 873^{VP}

a.na.ti'na. L. fem. adj. *anatina* of a duck.

In 16-h-old cultures on blood agar, the mean cell size is 0.2–0.4 × 1.25–2.5 µm. Some cells are spherically swollen, spindle or lemon-shaped, and arranged in short chains. Colonies are flat to convex, circular, nonpigmented to white, with entire edges and a smooth surface on blood agar. Nonhemolytic. Special growth factors are not required. Growth occurs on conventional media. No growth occurs on MacConkey agar or on Simmons citrate agar. Hyaluronidase and chondroitin sulfatase activity is present, but not urease, gelatinase, arginine dihydrolase, phenylalanine deaminase, ornithine decarboxylase, or lysine decarboxylase activities. Nitrate is not reduced. Esculin is hydrolyzed. Acetylmethylcarbinol is produced, but not indole. The methyl red reaction is negative. Citrate is not utilized. No alkali is formed from malonate. Acid is produced in a buffered single-substrate test (BSS medium) from D-glucose, D-fructose, maltose, D-mannose, lactose, D-galactose, N-acetylglucosamine, lactulose, and dextrin, but not from trehalose, adonitol, L-arabinose, dulcitol, myo-inositol, D-mannitol, D-sorbitol, sucrose, salicin, sorbose, or D-xylose. The following activities are present (API ZYM system): alkaline phosphatase, acid phosphatase, esterase C4, ester lipase C8, leucine, valine arylamidase, cystine arylamidase, naphthol-AS-

BI-phosphohydrolase, β-galactosidase, α-glucosidase, N-acetyl-β-glucosaminidase, α-fucosidase, and trypsin. The following are not detected: lipase C14, chymotrypsin, β-glucuronidase, α-galactosidase, β-glucosidase, and α-mannosidase. The following reactions are positive (API ID 32E system): acid from glucose, α-glucosidase, β-glucosidase, α-galactosidase, β-galactosidase, α-maltosidase, lipase, N-acetyl-β-glucosaminidase, and L-aspartic acid arylamidase. The following reactions are negative: arginine dihydrolase, ornithine and lysine decarboxylase, urease, β-glucuronidase, indole production, and acidification of L-arabitol, galacturonate, 5-ketogluconate, mannitol, L-arabinose, D-arabitol, trehalose, rhamnose, inositol, maltose, adonitol, palatinose, sucrose, cellobiose, and sorbitol. The major fatty acid components of all strains examined are C_{13:0} iso (~34%), C_{14:0} (~3%), C_{15:0} iso (~41%), C_{15:0} anteiso (~3%), C_{15:0} iso 3-OH (~6.5%), C_{16:0} 3-OH (~4%) and C_{17:0} iso 3-OH (~6.5%).

Source: the type strain was isolated from a Pekin duck in Germany.

DNA G+C content (mol%): 35–36 (*T_m*).

Type strain: 1502-91, CCUG 46148, CIP 106119, LMG 14382.

Sequence accession no. (16S rRNA gene): Y17612.

Additional remarks: *Coenonia anatina* was previously known as *Riemerella anatipestifer*-like taxon 1502 (Hinz et al., 1998).

Genus XIII. *Costertonia* Kwon, Lee and Lee 2006b, 1352^{VP}

THE EDITORIAL BOARD

Cos.ter.to'ni.a. N.L. fem. n. *Costertonia* named after J.W. Costerton, a famous American biofilm microbiologist.

Rods, 0.35–0.41 × 0.50–0.57 μm, but sometimes they can sometimes be longer than 4 μm. Cells form irregular aggregates during growth in liquid media. **Motile**. Gliding motility is absent. Gram-stain-negative. Aerobic. **Colonies are orange** on marine agar due to non-diffusible carotenoid pigments. Flexirubin-type pigments are absent. Optimal growth occurs at pH 7.5–8.0 and 26–32°C. **NaCl, Ca²⁺, and K⁺ are all required for growth. Nitrate is reduced to N₂**. Oxidase- and catalase-positive. **The major respiratory quinone is MK-6**. The major cellular fatty acids are C_{15:0} iso, C_{15:1} iso, and C_{15:0}*

DNA G+C content (mol%): 35.8 (T_m).

Type species: Costertonia aggregata Kwon, Lee and Lee 2006b, 1352^{VP}.

Enrichment and isolation procedures

Costertonia aggregata was isolated from a mature marine biofilm, including various marine algae, covering a rock-bed of the East Sea (Sea of Japan), Korea. A sample of biofilm was obtained with a razor blade and dispersed in sterile seawater. The dispersed biofilm was serially diluted in sterile seawater and the dilutions were spread onto marine agar 2216 (Difco).

After incubation for 1 week at 25°C, a small orange colony was selected and propagated on marine agar.

Preservation can be accomplished in 20% glycerol solution at –80°C.

Differentiation of the genus *Costertonia* from related genera

Unlike *Maribacter* (91.2–92.4% 16S rRNA gene sequence similarity), *Zobellia* (90.7–91.5%), and *Muricauda* species, *Costertonia* has a requirement not only for Na⁺, but also for other components of seawater, i.e., Ca²⁺ and K⁺. It also contains a larger amount of C_{15:0} iso fatty acid. The DNA G+C content of *Costertonia* is lower than that of *Muricauda* (35.8 mol% vs 41–45.4 mol%), and *Muricauda* species fail to hydrolyze gelatin and reduce nitrate. Unlike *Costertonia* species, *Zobellia* species hydrolyze agar and, in contrast to both *Maribacter* and *Zobellia*, the single *Costertonia* species does not exhibit gliding motility.

Taxonomic comments

16S rRNA gene sequence analysis has shown that *Costertonia aggregata* is related to members of the genera *Maribacter* (91.2–92.4% similarity), *Zobellia* (90.7–91.5%), and *Muricauda* (90.7–91.4%).

List of species of the genus *Costertonia*1. *Costertonia aggregata* Kwon, Lee and Lee 2006b, 1352^{VP}

ag.gre.ga'ta. L. fem. adj. *aggregata* joined together, referring to the formation of aggregates during cultivation in liquid media.

Characteristics are as described for the genus, with the following additional features. Growth occurs at 10–35°C, pH 6.5–9.0, and with 1.5–12.0% sea salts. Nitrate is reduced to N₂ (API 20 E test strip). Positive for β-glucosidase, β-galactosidase, urease, arginine dihydrolase, and protease. The following substrates can be used as carbon sources: acetic acid, N-acetyl-D-galactosamine, N-acetyl-D-glucosamine, *cis*-aconitic acid, adonitol, alaninamide, D-alanine, L-alanine, L-alanyl-glycine, γ-aminobutyric acid, 2-aminoethanol, L-arabinose, D-arabitol, L-asparagine, L-aspartic acid, bromosuccinic acid, cellobiose, citric acid, dextrin, L-erythritol, D-fructose, L-fucose, D-galactonic acid lactone, D-galactose, D-galacturonic acid, gentiobiose, D-gluconic acid, α-D-glucose, glucose 1-phosphate, glucose 6-phosphate, glucuronamide, D-glucuronic acid, L-glutamic acid,

glycerol, DL-α-glycerol phosphate, glycogen, glyceryl L-aspartic acid, glyceryl L-glutamic acid, β-hydroxybutyric acid, L-histidine, γ-hydroxybutyric acid, *p*-hydroxyphenylacetic acid, hydroxy-L-proline, inosine, *myo*-inositol, α-ketoglutaric acid, α-ketovaleric acid, DL-lactic acid, α-D-lactose, lactulose, L-leucine, malonic acid, maltose, D-mannitol, D-mannose, melibiose, methyl β-D-glucoside, methyl pyruvate, L-ornithine, phenylethylamine, L-proline, propionic acid, putrescine, L-pyroglutamic acid, quinic acid, raffinose, L-rhamnose, D-saccharic acid, D-serine, L-serine, D-sorbitol, succinic acid, sucrose, L-threonine, trehalose, turanose, Tweens 40 and 80, uridine, urocanic acid, and xylitol as sole carbon sources. The dominant fatty acids are C_{15:0} iso (39.7%), C_{15:1} iso ω10 (22.4%), C_{15:0} (7.8%), and C_{16:1} ω9 (4.6%).

Source: isolated from a mature marine biofilm covering a rock-bed of the East Sea (Sea of Japan), Korea.

DNA G+C content (mol%): 35.8 (T_m).

Type strain: KOPRI 13342, JCM 13411, KCCM 42265.

Sequence accession no. (16S rRNA gene): DQ167246.

Genus XIV. *Croceibacter* Cho and Giovannoni 2003, 935^{VP} (Effective publication: Cho and Giovannoni 2003, 82.)

JANG-CHEON CHO AND STEPHEN J. GIOVANNONI

Cro.cei.bac'ter. L. adj. *croceus* saffron-colored; N.L. masc. n. *bacter* rod; N.L. masc. n. *Croceibacter* saffron-colored rod shaped bacterium.

Rod-shaped cells with rounded ends. Gram-stain-negative. **Non-motile and no gliding motility**. Aerobic, mesophilic, and chemoheterotrophic. Endospores are not produced. **Carotenoid pigments are produced, but not flexirubin pigments**. NaCl is required for growth. **Gelatin, DNA, starch, casein, and elastin are degraded**.

The major fatty acid types are branched acids and hydroxy acids, including C_{17:0} 3-OH iso, C_{15:0} iso, C_{15:1} iso, and C_{17:1} ω9c iso.

DNA G+C content (mol%): 34.8.

Type species: Croceibacter atlanticus Cho and Giovannoni 2003, 935^{VP} (Effective publication: Cho and Giovannoni 2003, 82.).

Further descriptive information

Phylogenetic analyses based on 16S rRNA gene sequences show that the genus forms a distinct monophyletic clade with several uncultured environmental clones and belongs to the family *Flavobacteriaceae*.

Cells of *Croceibacter* are nonmotile, straight rod-shaped cells, approximately 1.9 µm long and 0.4 µm wide, dividing by binary fission. Transmission electron microscopy has shown that the cells lack flagella, endospores, intracellular granules, and vacuoles.

Colonies of *Croceibacter* can be seen easily on marine agar 2216 after 2 d culture at 25°C. They are 1.8–3.0 mm in diameter, bright orange or saffron-colored, uniformly circular, convex, opaque, and with a smooth surface after 5 d at 25°C. The major fatty acid types in the cell membrane are branched acids (38.9%) and hydroxy acids (41.1%). The predominant fatty acids are C_{17:0} 3-OH iso (28.0%), C_{15:0} iso (13.3%), C_{15:1} iso (9.2%), and C_{17:1} ω9c iso (9.4%).

Organisms are obligately aerobic, mesophilic, NaCl-requiring chemoheterotrophs. The temperature, pH, and NaCl concentration ranges for growth are 10–28°C (optimum, 20–23°C), pH 6.0–10.0 (optimum, pH 7.5–8.0), and 0.5–15% (w/v) NaCl (optimum, 3.0%). The type strain of *Croceibacter atlanticus* is catalase-positive and oxidase-negative. Urease and arginine dehydrolase activities are present. It is negative for indole production and denitrification activity and does not produce acid from glucose. It produces carotenoid pigments with wavelength absorbance spectral peaks at 318 and 483 nm. Photosynthetic gene clusters, bacteriochlorophyll *a*, and photosynthetic activity are not found in the *Croceibacter atlanticus* type strain. The only *Croceibacter* species identified thus far can degrade several high molecular mass compounds, including gelatin, DNA, starch, casein, and elastin after prolonged incubation for 2 weeks, but cannot degrade esculin, dextran, cellulose, alginate, chitin, or carrageenan. According to sole carbon source utilization tests, *Croceibacter* strains utilize a variety of carbohydrates, sugar alcohols, organic acids, and amino acids as sole carbon sources. The type strain of *Croceibacter atlanticus*, the type species of the genus, utilizes DL-glyceraldehyde, D-arabinose, D-galactose, D-fructose, trehalose, maltose, melezitose, D-mannose, D-mannitol, D-sorbitol, pyruvic acid, succinic acid, gluconic acid, L-glutamic acid, L-ornithine, L-proline, L-alanine, L-serine, and L-leucine as sole carbon sources.

The type strain of *Croceibacter atlanticus* is susceptible to chloramphenicol, nalidixic acid, tetracycline, erythromycin, vancomycin, rifampin, and benzylpenicillin, but resistant to kanamycin, carbenicillin, streptomycin, ampicillin, puromycin, gentamicin, and cycloheximide.

Enrichment and isolation procedures

The original liquid culture of *Croceibacter atlanticus* HTCC2559^T was obtained at a depth of 250 m from the Sargasso Sea by high throughput culturing techniques (Connon and Giovannoni, 2002) using a low nutrient heterotrophic medium [LNHM,

consisting of filtered (0.2 µm pore diameter) and autoclaved seawater amended with 1.0 µM NH₄Cl and 0.1 µM KH₂PO₄] supplemented with 0.001% (w/v) of each of D-glucose, D-ribose, succinic acid, pyruvic acid, glycerol, and N-acetyl-D-glucosamine, and 0.002% (v/v) ethanol (Rappé et al., 2002). Single colonies of the strain were obtained easily by spreading the liquid culture on marine agar 2216 after incubation for 5 d at 25°C. Therefore, it is likely that *Croceibacter* can be obtained by spreading seawater on marine agar using a serial dilution plating method.

Maintenance procedures

Frozen stocks as glycerol suspensions (10% glycerol) in liquid nitrogen or at –70°C are routinely used to start a new culture. Either colonies (scraped from the surface of agar media) or broth cultures can be used for preparing glycerol stocks. Lyophilization of liquid cultures is also recommended for long-term storage. Frozen stocks and lyophilization stocks are stable for at least 2 years (confirmed by survival tests). Working stock cultures can be maintained at 4°C only for 3 weeks, so frequent subculturing is required for short-term storage.

Differentiation of the genus *Croceibacter* from other genera

The physiological property of the genus that best differentiates it from related genera is its growth temperature range. The type strain of *Croceibacter atlanticus* does not grow at either 4°C or 30°C, which differentiates it from other genera in the family *Flavobacteriaceae*. Psychrophilic members of the *Flavobacteriaceae* grow at 4°C, but not 30°C, and other members of the family cannot grow at 4°C, but do grow at 30°C or higher. The genus *Croceibacter* can also be differentiated from the genera *Aequorivita* and *Arenibacter* by its different cellular fatty acid profiles and macromolecule degradation patterns.

Taxonomic comments

The genus *Croceibacter* currently contains only one species, *Croceibacter atlanticus*. Phylogenetic analyses based on 16S rRNA gene sequences using different treeing algorithms (distance analyses, maximum-parsimony, and maximum-likelihood) have shown that the genus belongs to the family *Flavobacteriaceae* in the phylum *Bacteroidetes*. 16S rRNA gene sequence similarities to members of the genera *Leeuwenhoekella*, *Aequorivita*, *Psychroserpens*, and *Arenibacter* in the family *Flavobacteriaceae* are only 88–92%. Because of these low sequence similarities, the genus *Croceibacter* forms a very distinct clade within the family. Classification of *Croceibacter* as a genus of the family is based not only on 16S rRNA gene sequence analysis, but also on phenotypic and chemotaxonomic properties.

The type strain of *Croceibacter atlanticus* is most closely related to several as-yet-uncultured environmental clones retrieved from sea-ice, arctic deep-sea water, and coastal mud by high similarity values (98.5–99.5%), indicating that the major habitat of the genus *Croceibacter* is marine environments.

List of species of the genus *Croceibacter*

1. ***Croceibacter atlanticus*** Cho and Giovannoni 2003, 935^{VP} (Effective publication: Cho and Giovannoni 2003, 82.)
at.lan'ti.cus. L. masc. adj. *atlanticus* of the Atlantic Ocean, referring to the isolation of the species from the Atlantic Ocean.

Characteristics of the species are as described for the genus.

Source: marine environments.

DNA G+C content (mol%): 34.8 ± 0.1 (HPLC).

Type strain: HTCC2559, ATCC BAA-628, KCTC 12090.

Sequence accession no. (16S rRNA gene): AY163576.

Genus XV. *Dokdonia* Yoon, Kang, Lee and Oh 2005a, 2326^{VP}

THE EDITORIAL BOARD

Dok.do'ni.a. N.L. fem. n. *Dokdonia* named after Dokdo, an island located on the East Sea in Korea, from where the organisms were isolated.

Rods, 0.3–0.6 × 1.5–5.0 µm. Nonmotile. **Gliding motility does not occur.** Nonsporeforming. Gram-stain-negative. **Strictly aerobic.** Colonies are yellow. Catalase- and oxidase-positive. **Growth does not occur in the absence of NaCl.** Nitrate is not reduced. **Casein is hydrolyzed, but not agar and starch. Acid is not formed from a variety of carbohydrates.** The major fatty acids are C_{15:0} iso, C_{17:0} 3-OH iso, and C_{15:1} iso. The predominant menaquinone is MK-6. Isolated from seawater.

DNA G+C content (mol%): 38 (HPLC).

Type species: ***Dokdonia donghaensis*** Yoon, Kang, Lee and Oh 2005a, 2326^{VP}.

Enrichment and isolation procedures

Dokdonia donghaensis was isolated from seawater by standard dilution plating techniques on marine agar 2216 (MA; Difco) with incubation at 25°C.

Differentiation of the genus *Dokdonia* from related genera

Dokdonia differs from *Cellulophaga* by its lack of gliding motility, its failure to hydrolyze agar and starch, and its inability to form acid from any of a large variety of carbohydrates.

Taxonomic comments

As indicated by 16S rRNA gene sequence analysis by Yoon et al. (2005a), the nearest neighbors of *Dokdonia* are species of the genus *Cellulophaga* (90.4–92.2% sequence similarity). *Dokdonia* showed less than 91.7% similarity to the other species of the *Flavobacteriaceae*.

Yoon et al. (2005a) reported that the two available strains of *Dokdonia donghaensis* exhibited a mean DNA–DNA relatedness level of 78%.

List of species of the genus *Dokdonia*1. *Dokdonia donghaensis* Yoon, Kang, Lee and Oh 2005a, 2326^{VP}

dong.ha.en'sis. N.L. fem. adj. *donghaensis* of or belonging to Donghae, the Korean name of the East Sea of Korea, where Dokdo is located and from where the organism was isolated.

The description is as given for the genus, with the following additional features. Colonies on MA are circular, slightly convex, glistening, smooth, yellow, and 1.0–2.0 mm in diameter after 3 d at 30°C. Growth occurs at 4 and 35°C and optimum growth is at 30°C; no growth occurs at 36°C. Optimum pH is 7.0–8.0; growth occurs at pH 5.5, but not at 5.0. Optimal growth occurs in the presence of 2% (w/v) NaCl; no growth occurs in the presence of 7% NaCl. Anaerobic growth does not occur on MA or on MA supplemented with nitrate. Esculin and Tween 60 are hydrolyzed, but not hypoxanthine or xanthine. Indole and H₂S are not produced. Arginine dihydrolase, lysine decarboxylase, ornithine decarboxylase, and tryptophan deaminase are absent. The following enzyme activities are present (API ZYM system): alkaline phosphatase, esterase (C4), esterase lipase (C8), leucine arylamidase, and valine arylamidase. Negative for *N*-acetyl-β-glucosaminidase, acid phosphatase, α-chymotrypsin, cystine arylamidase, α-fucosidase, α-galactosidase, β-galactosidase,

α-glucosidase, β-glucosidase, β-glucuronidase, lipase (C14), α-mannosidase, naphthol-AS-BI-phosphohydrolase, and trypsin activities. Growth occurs on peptone and tryptone as sole carbon and nitrogen sources, but not on DL-aspartate, Casamino acids, D-cellobiose, D-fructose, D-galactose, D-glucose, L-glutamate, L-leucine, L-proline, D-ribose, sucrose, or trehalose. No acid is produced from L-arabinose, D-cellobiose, D-fructose, D-galactose, D-glucose, *myo*-inositol, lactose, maltose, D-mannitol, D-mannose, melibiose, raffinose, L-rhamnose, D-ribose, sucrose, trehalose, D-sorbitol, or D-xylose. Susceptible to carbenicillin, cephalothin, chloramphenicol, lincomycin, oleandomycin, penicillin G, and tetracycline, but not to ampicillin, polymyxin B, gentamicin, novobiocin, kanamycin, neomycin, and streptomycin. The major fatty acids (>10% of total fatty acids) are C_{15:0} iso, C_{17:0} 3-OH iso, and C_{15:1} iso. The major polar lipids are phosphatidylethanolamine, unidentified phospholipids, an unidentified glycolipid, and an amino-group-containing lipid that is ninhydrin-positive.

Source: the type strain was isolated from seawater collected near Dokdo Island, Korea.

DNA G+C content (mol%): 38 (HPLC).

Type strain: DSW-1, DSM 17200, KCTC 12391.

Sequence accession no. (16S rRNA gene): DQ003276.

Genus XVI. *Donghaeana* Yoon, Kang, Lee and Oh 2006c, 190^{VP}

THE EDITORIAL BOARD

Dong.hae.a'na. N.L. n. *Donghae* the Korean name of the East Sea in Korea; L. fem. suff. -ana suffix used with the sense of belonging to; N.L. fem. adj. used as a substantive *Donghaeana* pertaining to the East Sea of Korea, where the island of Dokdo is located.

Rods or elongated rods, 0.4–0.6 × 1.0–30.0 µm. Nonmotile. **Gliding motility is not present.** Nonsporeforming. Gram-stain-negative. Strictly aerobic. **Growth does not occur in the absence of NaCl.** Nitrate is not reduced. Anaerobic growth does not occur with nitrate. **Casein, starch, and Tweens 20 and**

40 are hydrolyzed, but not agar, gelatin, or urea. β-Galactosidase and α-glucosidase are not produced. Acid is not produced from glucose or maltose. **Glucose and sucrose are not utilized.** The predominant menaquinone is MK-6. The major polar lipids are phosphatidylethanolamine, unidentified

phospholipids, and amino-group-containing lipids that are ninhydrin-positive.

DNA G+C content (mol%): 36.9.

Type species: *Donghaeana dokdonensis* Yoon, Kang, Lee and Oh 2006c, 190^{VP}.

Enrichment and isolation procedures

Donghaeana dokdonensis was isolated from seawater by a standard dilution plating technique on marine agar 2216 (MA; Difco) with incubation at 20°C.

Differentiation of the genus *Donghaeana* from related genera

Donghaeana is similar to *Nonlabens* in many characteristics, but differs in its inability to grow at 37°C, its hydrolysis of casein,

but not gelatin, its inability to utilize glucose and sucrose, and a higher DNA G+C content (36.9 mol% vs 33.6 mol%). *Donghaeana* differs from *Stenothermobacter* by its lack of gliding motility, the absence of β-galactosidase and α-glucosidase activities, its hydrolysis of casein, but not gelatin, its inability to utilize glucose and sucrose, and a slightly lower DNA G+C content (36.9 mol% vs 41.0 mol%).

Taxonomic comments

Using 16S rRNA gene sequence analysis, the nearest neighbors of *Donghaeana dokdonensis* are *Nonlabens tegetincola* and *Stenothermobacter spongiae*, with sequence similarity values of 93.3–98.2% (Yoon et al., 2006c).

List of species of the genus *Donghaeana*

1. *Donghaeana dokdonensis* Yoon, Kang, Lee and Oh 2006c, 190^{VP}

dok.do.nen'sis. N.L. fem. adj. *dokdonensis* of or belonging to Dokdo, a Korean island, where the type strain was isolated.

Characteristics are as described for the genus, with the following additional features. After 3 d at 25°C, colonies on MA are 0.8–1.4 mm in diameter, circular, convex, glistening, smooth, and orange. Temperature range for growth is 4–32°C; optimum is 25°C. Optimum pH is 7.0–8.0; growth occurs at pH 5.5, but not pH 5.0. Optimal NaCl concentration is 2%; no growth occurs at >8% NaCl. Esculin and Tween 60 are hydrolyzed, but hypoxanthine, xanthine, and L-tyrosine are not. Indole is not produced. Arginine dihydrolase, lysine decarboxylase, ornithine decarboxylase, and tryptophan deaminase are absent. The following enzymes are present (API ZYM system): esterase (C4), esterase lipase (C8), leucine arylamidase, valine arylamidase, acid phosphatase, and naphthol-AS-BI-phosphohydrolase. The following are not present: N-acetyl-β-glucosaminidase, α-chymotrypsin, cystine

arylamidase, α-fucosidase, α-galactosidase, β-glucuronidase, α-glucosidase, β-glucosidase, lipase (C14), α-mannosidase, and trypsin. Growth occurs on peptone and tryptone as sole carbon and nitrogen sources, but no growth occurs on DL-aspartate, Casamino acids, cellobiose, D-fructose, D-galactose, L-glutamate, L-leucine, L-proline, D-ribose, or trehalose. No acid is produced from L-arabinose, D-fructose, D-galactose, myo-inositol, lactose, D-mannitol, D-mannose, melezitose, melibiose, raffinose, L-rhamnose, D-ribose, D-sorbitol, sucrose, trehalose, or D-xylose. Susceptible to chloramphenicol, cephalothin, novobiocin, and lincomycin, but not to polymyxin B, ampicillin, gentamicin, kanamycin, or neomycin. The major fatty acids (>10% of total fatty acids) are C_{15:0} iso (19.2%), C_{15:0} anteiso (11.1%), C_{17:0} 3-OH iso (10.5%), and C_{15:0} (10.2%).

Source: the type strain was isolated from seawater.

DNA G+C content (mol%): 36.9 (HPLC).

Type strain: DSW-6, DSM 17205, KCTC 12402.

Sequence accession no. (16S rRNA gene): DQ017065.

Genus XVII. *Elizabethkingia* Kim, Kim, Lim, Park and Lee 2005b, 1291^{VP}

BRITA BRUUN AND JEAN-FRANÇOIS BERNARDET

E.liz.a.beth.kin'gi.a. N.L. fem. n. *Elizabethkingia* named in honor of Elizabeth O. King, who first described bacteria associated with infant meningitis, notably [*Flavobacterium*] *meningosepticum* in 1959.

Straight, single rods with rounded ends, typically 0.5 μm wide and variable in length, often forming filaments. Do not form endospores. Spherical degenerative forms do not appear in ageing liquid cultures. **Nonmotile.** Flagellar motility, gliding movement, and swarming growth have not been reported. **Colonies are typically nonpigmented or weakly yellow pigmented,** circular, convex, smooth and shiny, with entire edges, and up to 2 mm in diameter. A strong aromatic odor is produced. Gram-stain-negative. **Obligately aerobic, having a strictly respiratory type of metabolism** with oxygen as the terminal electron acceptor. **Nitrate is not reduced.** Chemo-organotrophic. Growth occurs at 22–37°C, but not at 5 or 42°C. Growth occurs readily on the usual commercial media. No growth factors are required. Growth on seawater media is possible. Growth on cetrimide and MacConkey agars is slow

and weak, but is also strain-dependent. **Catalase, oxidase, phosphatase, and β-galactosidase activities are present.** Acid, but no gas, is produced from a number of carbohydrates in media with low peptone concentrations. Strong proteolytic activity occurs. Esculin, gelatin, and casein are hydrolyzed, but agar is not. Malonate is not utilized. **Resistant to a wide range of antimicrobial agents.** Menaquinone MK-6 is the predominant respiratory quinone. Predominant cellular fatty acids are C_{15:0} iso, C_{17:0} iso 3-OH, C_{17:1} iso ω9c, and summed feature 4 (comprising C_{15:0} iso 2-OH and/or C_{16:1} ω7c/t). As they are ubiquitous in soil and freshwater, **strains of *Elizabethkingia meningoseptica* occasionally occur in the hospital environment and clinical specimens; they are opportunistic pathogens of humans and various animals.**

DNA G+C content (mol%): 35.0–38.2.

Type species: Elizabethkingia meningoseptica (King 1959) Kim, Kim, Lim, Park and Lee 2005b, 1291^{VP} (*Flavobacterium meningosepticum* King 1959, 247; *Chryseobacterium meningosepticum* Vandamme, Bernardet, Segers, Kersters and Holmes 1994a, 830).

Further descriptive information

The genus *Elizabethkingia*, which contains *Elizabethkingia meningoseptica*, the most important clinical species of the family *Flavobacteriaceae*, and *Elizabethkingia miricola* (Li et al., 2003a), was recently separated from the genus *Chryseobacterium* (Kim et al., 2005b). However, members of the two genera still share a very considerable number of phenotypic features, as well as most of their taxonomic history (Bernardet et al., 2006). Hence, this chapter will focus on the few differential characteristics between *Elizabethkingia* and *Chryseobacterium* and readers are invited to refer to the *Chryseobacterium* chapter in this volume of the *Manual*. In particular, the phylogenetic tree (Figure 40) and the tables showing fatty acid composition (Table 43) and phenotypic characteristics (Table 44) that appear in the *Chryseobacterium* chapter all include the two *Elizabethkingia* species as well as the closest phylogenetic relatives of the two genera; they will consequently not be repeated here.

Phylogenetic position. Analysis of 16S rRNA gene sequences shows that the genus *Elizabethkingia* belongs to the family *Flavobacteriaceae*, phylum *Bacteroidetes*. Interspecific 16S rRNA gene sequence similarity values may be higher than 98%. Together with the genera *Chryseobacterium*, *Riemerella*, *Bergeyella*, *Kaistella*, *Sejongia*, *Ornithobacterium*, *Empedobacter*, and *Weeksella*, *Elizabethkingia* belongs to the smaller of the two well-defined clades in the family (see Figure 40 in the treatment of *Chryseobacterium* in this volume). In contrast to most members of the larger clade, it shares with these genera a number of significant traits, such as halophilic and psychrophilic characteristics and the absence of gliding motility. Most nonpigmented and pathogenic members of the family belong to the smaller clade.

The separate position of [*Chryseobacterium*] *meningosepticum* compared to the other *Chryseobacterium* species was established in 1994 when the genus *Chryseobacterium* was described (Vandamme et al., 1994a) following extensive phylogenetic investigations (Bauwens and De Ley, 1981; Mudarris et al., 1994; Segers et al., 1993a) of members of the phylogenetic branch that would eventually become the family *Flavobacteriaceae* (Bernardet et al., 1996). However, because of the low resolution of the technique used at that time (i.e., DNA–rRNA hybridization) and because the number of shared characteristics far exceeded that of differential ones, it was decided to include the organism known as [*Flavobacterium*] *meningosepticum* (which grouped strains previously known as CDC group IIa) in the new genus *Chryseobacterium*, while acknowledging that it was the most aberrant member of the genus and consequently not a good candidate for the type species (Vandamme et al., 1994a). In 2003, a novel species [*Chryseobacterium*] *miricola* (Li et al., 2003a) was shown to share the separate position of [*Chryseobacterium*] *meningosepticum* that had been confirmed and determined more precisely in the meantime using 16S rRNA gene sequence analysis. As shown in Figure 40 in the *Chryseobacterium* chapter and in other published phylogenetic trees (Bernardet et al., 2006; de Beer et al., 2005; Kim et al., 2005b; Li et al., 2003a), [*Chryseobacterium*] *meningosepticum* and [*Chryseobacterium*] *miricola* are not the closest relatives of the genus *Chryseobacterium* according to 16S

rRNA gene sequence analysis as the three branches comprising (i) the genera *Riemerella* and *Bergeyella*, (ii) the two *Sejongia* species, and (iii) *Kaistella koreensis* fall in between.

Polyphasic investigation of six strains received as [*Chryseobacterium*] *meningosepticum* and of the [*Chryseobacterium*] *miricola* type strain by Kim et al. (2005b) showed that members of the two species share 97.8–98.4% 16S rRNA gene sequence similarity with each other and only approximately 91–94% sequence similarity with the other *Chryseobacterium* species; these values are similar to those reported in the description of [*Chryseobacterium*] *miricola* (Li et al., 2003a). The proposal of the new genus *Elizabethkingia* to accommodate [*Chryseobacterium*] *meningosepticum* and [*Chryseobacterium*] *miricola* was based on their phylogenetic distance to other *Chryseobacterium* species, as well as on differences in fatty acid profiles and a few phenotypic features (Kim et al., 2005b). The results of DNA–DNA hybridization experiments between and among members of the genera *Elizabethkingia* and *Chryseobacterium* have been reviewed recently (Bernardet et al., 2006).

Cell morphology. Cells of *Elizabethkingia* occur as straight rods of variable length, often 1.0–3.0 μm long and about 0.5 μm wide, with rounded ends and parallel sides. Filament formation is environmentally influenced and occurs in broth cultures, old cultures, and clinical specimens, such as cerebrospinal fluid. The presence of a capsule has been reported in some *Elizabethkingia meningoseptica* strains following their passage on mice (Holmes et al., 1984a). In contrast to members of some other genera in the family *Flavobacteriaceae* (e.g., *Flavobacterium*, *Gelidibacter*, *Tenacibaculum*, and *Polaribacter*; see the chapter Family *Flavobacteriaceae* in this volume), *Elizabethkingia* strains do not produce spherical degenerative forms in ageing liquid cultures. Also, in contrast to many members of the family, cells of *Elizabethkingia* species are devoid of gliding motility.

Cell-wall composition. Table 43 of the *Chryseobacterium* chapter in this volume presents the fatty acid composition of members of the genus *Elizabethkingia* and of related genera. The fatty acid compositions of the two *Elizabethkingia* species as determined by Kim et al. (2005b) are similar. It is important to note that the fatty acid profiles of the two *Elizabethkingia miricola* strains reported in this study differ significantly from the composition given previously for the type strain (Li et al., 2003a). Whether these discrepancies result from different growth conditions cannot be demonstrated since conditions are not specified or incompletely specified in the corresponding publications. Although *Elizabethkingia* strains contain mainly the same fatty acids as other members of the clade, differences in the proportions of some components allow strains to be differentiated from *Chryseobacterium*, *Empedobacter*, *Riemerella*, *Sejongia*, *Kaistella*, and *Bergeyella* strains, which all display rather distinct fatty acid compositions (Bernardet et al., 2006; Hugo et al., 1999). Compared with these organisms, strains of *Elizabethkingia* contain rather low amounts of C_{17:1} iso ω 9c and a high proportion of summed feature 4 (comprising C_{15:0} iso 2-OH and/or C_{16:1} ω 7c/t). Branched-chain fatty acids account for 80% and 88% of all fatty acids in *Elizabethkingia meningoseptica* and *Elizabethkingia miricola*, respectively (Li et al., 2003a; Yabuuchi et al., 1983). As for other members of the family *Flavobacteriaceae*, the fatty acid profile is mainly a chemotaxonomic marker at the genus level (Bernardet and Nakagawa, 2006).

Fine structure. No study specifically investigating the fine structure of *Elizabethkingia meningoseptica* cells has been published. Electron micrographs of the bacterium in samples of infected mice lungs were obtained recently in the course of a study evaluating the virulence mechanisms of *Elizabethkingia meningoseptica* on a murine pulmonary infection model (Lin et al., 2006) (see below, section Pathogenicity). Micrographs revealed the usual structure common to all Gram-stain-negative bacteria, but it was not possible to assess whether cells of *Elizabethkingia meningoseptica* displayed the thick cell wall reported in some *Chryseobacterium* species (see the corresponding chapter in this volume).

Colonial or cultural characteristics. Colonies of *Elizabethkingia* strains are circular, convex, translucent to opaque, smooth, and shiny, with entire edges. Similar to the colonies of many *Chryseobacterium* strains, their butyrous consistency turns mucoid after a few days of incubation (Kim et al., 2005b). Colonies of *Elizabethkingia miricola* are very sticky on solid media (Kim et al., 2005b). Broth cultures are usually uniformly turbid.

On commonly used media such as tryptic soy, blood, and nutrient agars, colonies are usually nonpigmented (i.e., white to creamy-white) or very pale yellow. Colonies of *Elizabethkingia miricola* are “white–yellow” according to Li et al. (2003a) and Kim et al. (2005b). The latter authors also described as white–yellow the colonies of the five *Elizabethkingia meningoseptica* strains they studied. Production of pigment by *Elizabethkingia meningoseptica* is strain-dependent; however, a weak yellow pigment occurs in the DNA groups containing the neonatal meningitis and bacteremia strains, whereas the other DNA groups are nonpigmented (see below; Bruun and Ursing, 1987). The type of pigment produced weakly by some *Elizabethkingia* strains is discussed below. The production of a diffusible, pinkish-brown melanic pigment on tyrosine agar by *Elizabethkingia meningoseptica* is strain-dependent (Bernardet et al., 2005). No hemolysis occurs on blood agar, but the medium may show a green discoloration (Holmes et al., 1984a).

Although no particular odor was reported for strains of *Elizabethkingia meningoseptica* (Bruun and Ursing, 1987; Holmes et al., 1984a; Kim et al., 2005b; Li et al., 2003a) and *Elizabethkingia miricola* (Kim et al., 2005b; Li et al., 2003a), all *Elizabethkingia meningoseptica* strains studied were found to give off a rather strong aromatic odor similar to that of *Chryseobacterium* strains (J.-F. Bernardet, unpublished data; B. Bruun, unpublished data).

Nutrition and growth conditions. *Elizabethkingia* strains grow readily on various commercially available media such as blood, tryptic soy, brain-heart infusion (BHI), and nutrient agars. Visible colonies (1.0–1.5 mm in diameter) appear within 24 h on nutrient agar. Growth of *Elizabethkingia meningoseptica* on MacConkey agar varies among strains (Holmes et al., 1984b; Weyant et al., 1996). Growth of the *Elizabethkingia miricola* type strain on MacConkey agar was described as slow by Li et al. (2003a); however, Kim et al. (2005b) reported that the two strains of this species grow well on this medium. Very slow growth of *Elizabethkingia miricola* occurs on cetrinide agar (Li et al., 2003a). Growth on β -hydroxybutyrate has been reported for *Elizabethkingia meningoseptica* (Holmes et al., 1984a).

Both species grow in ambient air and at temperatures of 22–37°C. Growth is more limited at room temperature (18–20°C)

and no growth is observed at 5 or 42°C. The growth rate of the *Elizabethkingia miricola* type strain on BHI agar plates was similar at 30 and 37°C (Li et al., 2003a). The growth curve of several *Elizabethkingia meningoseptica* isolates in Luria broth at 37°C was determined by Lin et al. (2006); all strains reached exponential phase within 6 h. Strains of the *Elizabethkingia meningoseptica* DNA groups comprising the neonatal meningitis and bacteremia isolates could grow at 40°C, in contrast to the other DNA groups (Bruun and Ursing, 1987); interestingly, these strains were the same as those that were weakly pigmented (see above), the other strains being unable to grow at 40°C and devoid of pigment. Some of the *Elizabethkingia meningoseptica* isolates studied by Olsen (1966) grew at up to 41°C, whereas others ceased growing at 38°C; the author suggested that this difference could be related to the climate in the country of isolation.

Both *Elizabethkingia* species are halotolerant – a feature observed in members of most *Chryseobacterium* species. Strains of *Elizabethkingia meningoseptica* are able to grow on marine agar 2216E (Difco) (Bernardet et al., 2005). The ability to grow in the presence of 3% NaCl in broth culture varies among strains. The type strain of *Elizabethkingia miricola* can tolerate seawater (Li et al., 2003a).

Metabolism and metabolic pathways. Available data on the metabolism of *Elizabethkingia meningoseptica* mainly result from three sources that have included rather extensive collections of strains (B. Holmes and R.J. Owen, unpublished data cited by Holmes et al., 1984a, b; Bruun and Ursing, 1987; Weyant et al., 1996). Recent studies have focused on a few *Elizabethkingia meningoseptica* strains and on the only two available strains of *Elizabethkingia miricola* (Bernardet et al., 2005; Kim et al., 2005b; Li et al., 2003a). *Elizabethkingia* strains are chemo-organotrophs with a strictly respiratory type of metabolism (Bernardet et al., 2002, 2006; Vandamme et al., 1994a). The type strain of *Elizabethkingia miricola* and all *Elizabethkingia meningoseptica* strains grow well in the presence of 5–10% (v/v) CO₂ (B. Bruun, unpublished data; Li et al., 2003a). Members of *Elizabethkingia* species show catalase, oxidase, and phosphatase activities. They also produce β -galactosidase, but discrepancies have been reported between the different techniques used to test this characteristic in *Elizabethkingia meningoseptica* strains (Bernardet et al., 2005; Bruun and Ursing, 1987).

Table 44 of the *Chryseobacterium* chapter in this volume presents the differential characteristics of members of *Elizabethkingia* and related genera. *Elizabethkingia* strains demonstrate strong proteolytic activity, hydrolyzing casein and gelatin, and produce indole from tryptophan (Bernardet et al., 2005; Bruun and Ursing, 1987; Weyant et al., 1996). All 149 *Elizabethkingia meningoseptica* strains studied by the CDC (Weyant et al., 1996) and all 52 strains studied by Bruun and Ursing (1987) produced indole. In the latter study, no strains produced urease, in contrast to the study of 49 *Elizabethkingia meningoseptica* strains by Holmes et al. (1984b) and to the CDC's study (Weyant et al., 1996), where the trait varied among strains. The authors attributed the variable results reported for urease production to methodological differences (direct enzymic method versus Christensen's urea). Disagreement exists between Li et al. (2003a) and Kim et al. (2005b) as to whether the type strain of *Elizabethkingia miricola* produces indole or not, but they agree on the production of urease by the two strains (Kim et al., 2005b; Li et al., 2003a). In contrast to the *Elizabethkingia miricola* type strain (Li et al.,

2003a), the only three strains of *Elizabethkingia meningoseptica* tested also degrade tyrosine (Bernardet et al., 2005).

The production of a precipitate on egg yolk agar is strain-dependent in *Elizabethkingia meningoseptica* (Bernardet et al., 2005); it occurs in the two *Elizabethkingia miricola* strains (Li et al., 2003a).

Several carbohydrates including D-glucose, D-fructose, D-mannitol, mannose, lactose, and maltose are oxidized, but cellobiose, rhamnose, raffinose, galactose, sucrose, melezitose, salicin, adonitol, dulcitol, sorbitol, and inositol are not oxidized (Bruun and Ursing, 1987; Holmes et al., 1984b; Kim et al., 2005b; Li et al., 2003a; Weyant et al., 1996). Acid production from trehalose (number of positive strains/number of strains tested is 51/52), melibiose (25/52), D-xylose (9/52), and L-arabinose (3/52) is strain-dependent in *Elizabethkingia meningoseptica* (Bruun and Ursing, 1987). The two *Elizabethkingia miricola* strains produce acid from trehalose, but not from arabinose or xylose (Kim et al., 2005b; Li et al., 2003a). Esculin is hydrolyzed by *Elizabethkingia* strains, but chitin and agar are not. The description of the genus *Elizabethkingia* states that starch is not hydrolyzed (Kim et al., 2005b). Starch hydrolysis was indeed listed as negative in the table of phenotypic characteristics of *Elizabethkingia miricola*; yet, it was described as positive in the species description (Li et al., 2003a).

Production of H₂S was considered negative for all members of the genus *Elizabethkingia* by Kim et al. (2005b), although a positive result was reported for the type strain of *Elizabethkingia miricola* by Li et al. (2003a). None of the *Elizabethkingia meningoseptica* strains studied (Bruun and Ursing, 1987; Holmes et al., 1984a; Weyant et al., 1996) reduce nitrate; this trait is also negative in the two *Elizabethkingia miricola* strains (Kim et al., 2005b; Li et al., 2003a).

In accordance with other members of the family *Flavobacteriaceae*, *Elizabethkingia* strains contain no sphingophospholipids and menaquinone MK-6 is their only or major respiratory quinone (Bernardet et al., 2002; Kim et al., 2005b). Homospermidine is the major polyamine in *Elizabethkingia meningoseptica* (Hamana and Matsuzaki, 1990), as it is in several *Chryseobacterium* species and in members of the genera *Bergeyella*, *Ornithobacterium*, *Riemerella*, and *Weeksella* (Hamana and Nakagawa, 2001).

Very few enzymic activities of *Elizabethkingia* strains that may have practical or industrial applications have been reported to date. An endoglycosidase activity has been detected in an *Elizabethkingia meningoseptica* strain; the availability of the cleavage site of this enzyme, named endo F, was extremely variable in the different N-linked glycoproteins tested, making endo F a possible tool for studying glycans and protein backbones and for defining the nature of the glycan/protein interface (Elder and Alexander, 1982). This bacterial strain was later shown to actually represent a second strain of *Elizabethkingia miricola* (Kim et al., 2005b). The proline-specific endopeptidase produced by an *Elizabethkingia meningoseptica* strain was heterologously expressed in *Escherichia coli* cells and efficient methods were devised to purify the enzyme that accumulated in the periplasmic space (Diefenthal and Dargatz, 1995).

Genetics. After early DNA–DNA hybridization studies of [*Flavobacterium*] *meningosepticum* strains had shown that the type strain shared only 29–65% DNA relatedness with the other strains (Owen and Snell, 1976), further studies have confirmed

the considerable intraspecific heterogeneity. In an investigation of 52 [*Flavobacterium*] *meningosepticum* strains (Ursing and Bruun, 1987), two main DNA groups were found that were about 40–55% interrelated and comprising 4 and 48 strains, respectively. The type strain of the species was found in the smaller group. Biochemical or physiological characteristics that could differentiate the two DNA groups were not found (Bruun and Ursing, 1987); therefore, a subdivision of the species was not proposed. The larger DNA group was further divided into four subgroups when ΔT_m values were taken into consideration; 25 of the 28 strains in the largest subgroup were invasive neonatal isolates, indicating that the DNA groups defined within the species might differ with regard to pathogenic significance (Ursing and Bruun, 1987).

The recent study by Kim et al. (2005b) further confirmed the isolated position of the type strain compared to other [*Chryseobacterium*] *meningosepticum* strains: although four strains shared nearly identical 16S rRNA gene sequences and 90–100% DNA–DNA relatedness, the type strain shared about 98% 16S rRNA gene sequence similarity with them and a DNA–DNA relatedness value of only 31–35%. Again, no phenotypic clue was found to support a division of the species. The sixth “[*Chryseobacterium*] *meningosepticum*” strain studied proved to share very high 16S rRNA gene sequence similarity and DNA–DNA relatedness values with the [*Chryseobacterium*] *miricola* type strain, indicating that it actually represents a second strain of this species.

The fact that strains of *Elizabethkingia meningoseptica* and *Elizabethkingia miricola* show only 23–54% DNA relatedness, while sharing 97.8–98.4% 16S rRNA gene sequence similarity (see above; Kim et al., 2005b) should be emphasized. The same situation occurs between members of the genus *Chryseobacterium* (see the corresponding chapter in this volume). Consequently, DNA–DNA hybridization experiments or possibly sequencing of a number of household genes (Kuhnert and Korczak, 2006) are necessary even when 16S rRNA gene sequence similarities between different strains are above the theoretical threshold value of 97%.

The DNA G+C contents of members of the genus are in the range 35.0–38.2 mol% (Kim et al., 2005b). In this study, five *Elizabethkingia meningoseptica* strains showed DNA G+C contents of 37.2 ± 0.6 mol%, in accordance with previous data (Holmes et al., 1984a; Ursing and Bruun, 1987). Thanks to the identification of a second strain of *Elizabethkingia miricola*, the G+C content for the species was re-evaluated as 35.3 ± 0.3 mol%, compared to 34.6 mol% as reported previously for the type strain (Li et al., 2003a).

Plasmids have not been detected in *Elizabethkingia meningoseptica* and allied taxa using the single colony lysis technique (Owen and Holmes, 1981).

An invasive neonatal strain and an environmental strain of *Elizabethkingia meningoseptica* selected among the DNA groups delineated by Ursing and Bruun (1987) were recently compared using suppressive subtraction hybridization (Lin et al., 2006). The genes present specifically in the invasive strain were identified, but their function remains unknown as their identity to known references and their deduced amino acid sequences were low.

McBride and Baker (1996) and McBride and Kempf (1996) demonstrated that genetic manipulation of *Elizabethkingia*

meningoseptica strains is possible by using the genetic tools (selectable marker, suicide vector, and transposon) they developed to manipulate *Flavobacterium johnsoniae*.

Three different molecular typing methods have been used so far to type *Elizabethkingia meningoseptica* clinical isolates for epidemiological and taxonomic studies. Ribotyping was applied to the collection of 52 strains previously characterized using extensive phenotypic analysis (Bruun and Ursing, 1987) and DNA–DNA hybridization experiments (Ursing and Bruun, 1987) (see above). Ribotyping proved to be a useful epidemiological tool because it allowed the differentiation of strains within genomic groups and because the similar profiles found in isolates originating from the same outbreak (Bruun et al., 1989) pointed to a common source of infection (Colding et al., 1994). The technique was also found to have taxonomic relevance because it was able to identify the DNA groups of Ursing and Bruun. In particular, the only three isolates sharing high DNA relatedness with the type strain also shared with it a unique *Hind*III ribotype. Ribotyping was also applied to another collection of 92 isolates of *Elizabethkingia meningoseptica* whose serotypes had been determined previously (Quilici and Bizet, 1996). Again, ribotyping clustered the isolates belonging to some serotypes (e.g., C, G, and N) and differentiated strains within other serotypes; however, the different banding patterns found in isolates originating from the same outbreak suggested different sources of infection. Hence, as reported for many other bacterial species, the type of information yielded by ribotyping depends on the restriction enzyme (or combination of enzymes) used.

Pulsed-field gel electrophoresis of bacterial DNAs previously subjected to enzymic macrorestriction demonstrated the identity of environmental and clinical isolates (Hoque et al., 2001), the relapse of a catheter-related bacteremia (Sader et al., 1995), and the identity of isolates involved in different outbreaks (Green et al., 1999).

Randomly amplified polymorphic DNA (RAPD) analysis was recently evaluated on a collection of *Chryseobacterium* and *Elizabethkingia* fish isolates and reference strains. In contrast to the results of 111 phenotypic characteristics and of whole-cell protein profiles (SDS-PAGE) that clustered the three included *Elizabethkingia meningoseptica* strains, RAPD yielded three different profiles, demonstrating that it could probably be used to differentiate and type larger collections of strains (Bernardet et al., 2005). On the other hand, multilocus enzyme electrophoresis was not able to differentiate between all *Chryseobacterium*, *Elizabethkingia*, and *Empedobacter* species (Hugo and Jooste, 1997).

Antigenic structure. Six serovars of *Elizabethkingia meningoseptica*, A–F, were initially reported from human infections, mainly invasive neonatal infections (King, 1959). The most commonly found type is serovar C, seen in about two-thirds of typed isolates from neonatal infections (Bloch et al., 1997). Richard et al. (1979a, b) have described additional serovars, G–N, derived from clinical specimens, but not invasive neonatal infections. Some of these new serovars (i.e., I, J, and L) actually appear to be strains of *Empedobacter brevis* (Holmes et al., 1984a). Other investigators have found cross-reactions between strains of *Elizabethkingia meningoseptica* and strains of CDC group IIb (containing *Chryseobacterium gleum*, *Chryseobacterium indologenes*, and allied strains) and CDC group IIc (King, 1959; Owen and Lapage, 1974; Price and Pickett, 1981).

Antibiotic sensitivity. As observed in *Chryseobacterium gleum*, *Chryseobacterium indologenes* and other, unnamed members of CDC group IIb (see above), *Elizabethkingia meningoseptica* strains are naturally resistant to polymyxins, aminoglycosides (e.g., gentamicin, streptomycin), chloramphenicol, and most β -lactam antibiotics, including penicillin and ampicillin (Aber et al., 1978; Bruun, 1987; Chang et al., 1997; Fraser and Jorgensen, 1997; Kirby et al., 2004; Olsen, 1967). *Elizabethkingia meningoseptica* strains produce at least three β -lactamases, two unrelated carbapenem-hydrolyzing class B metallo- β -lactamases [BlaB (Rossolini et al., 1998) and GOB (Bellais et al., 2000a)], plus a non-inducible extended-spectrum β -lactamase, Ambler class A, CME-2 (Bellais et al., 2000b). Consequently, *Elizabethkingia meningoseptica* is resistant to carbapenems (imipenem, meropenem) and extended spectrum cephalosporins (cefotaxime, ceftazidime, cefepime). Some strains are, however, susceptible to ureidopenicillins and piperacillin-tazobactam susceptibility ranged from 39 to 70% in two studies (Fraser and Jorgensen, 1997; Kirby et al., 2004). Recently, the high levels and rates of imipenem resistance in *Elizabethkingia meningoseptica* isolates from Hangzhou, China, were shown to result from the presence of heterogeneous BlaB and/or GOB metallo- β -lactamases, as well as from other, undefined mechanisms of carbapenem resistance (Chen et al., 2006).

Elizabethkingia meningoseptica strains are mainly resistant to tetracyclines, erythromycin, and linezolid, and resistant or intermediately susceptible to clindamycin and vancomycin (Bruun, 1987; Fraser and Jorgensen, 1997; Kirby et al., 2004). Sensitivity to trimethoprim-sulfamethoxazole varies, ranging from 33 to 80% of strains (Fraser and Jorgensen, 1997; Kirby et al., 2004). The antibiotics that are most active against *Elizabethkingia meningoseptica* are minocycline, rifampicin, and the newer quinolones (levofloxacin, gatifloxacin, sparfloxacin, moxifloxacin), whereas susceptibility to ciprofloxacin varies (Fraser and Jorgensen, 1997; Kirby et al., 2004; Spangler et al., 1996).

No data exist on the antibiotic sensitivity of the two strains of *Elizabethkingia miricola*, but it is presumed that susceptibilities are about the same as described above for *Elizabethkingia meningoseptica*.

Pathogenicity. The pathogenicity of *Elizabethkingia meningoseptica* has been reviewed recently by Bernardet et al. (2006). Among past and present *Chryseobacterium* species, *Elizabethkingia meningoseptica* is by far the most important species found in human infections. Invasive neonatal and infant disease, notably meningitis, has been reported from all over the world since the disease was first reported in 1944 (although bacterial etiology was first established retrospectively by King, 1959). The infection is not common. Von Graevenitz (1985) estimated that about 120 cases of invasive neonatal disease had been reported in the literature by 1985, while Bloch et al. (1997) found 308 patient reports in the English language literature up to 1994 of cultures positive for *Elizabethkingia meningoseptica*, of which about 60% were judged to represent true infections (Bloch et al., 1997 and references therein). About half of these occurred in infants <3 months of age, of which 85% represented cases of meningitis, sometimes with concomitant bacteremia and pneumonia. The mortality was 57%, with post-meningitis sequelae, mainly hydrocephalus, occurring in the majority of the survivors. Prematurity occurred in more than half of the cases and accounted for 66% of the mortality. In the non-English language literature,

15 cases, mainly of neonatal meningitis, have been published (see Bernardet et al. (2006) for references). Since 1994, 13 cases of neonatal infection have been reported (Chiu et al., 2000; Güngör et al., 2003; Hoque et al., 2001; Tekerekoglu et al., 2003; Tizer et al., 1995).

Elizabethkingia meningoseptica infections in infants typically occur as small epidemics in neonatal wards, including neonatal intensive care units. Surveillance cultures from uninfected infants hospitalized with the cases and from the hospital environment often reveal extensive colonization with *Elizabethkingia meningoseptica* (see Bernardet et al. (2006)).

Disease after the age of 1 year is rare, with less than 100 cases reported in the English language literature up to 1994 (Bloch et al., 1997 and references therein). Since then, few cases have been published (Chiu et al., 2000; Gunnarsson et al., 2002; Lin et al., 2004; Manfredi et al., 1999; Ozkalay et al., 2006; Sader et al., 1995). Adult cases occur as outbreaks in hospitals or as sporadic infections after trauma/surgery or in patients severely immunocompromised because of malignancy, end-stage hepatic and renal disease, and extensive burns. Outbreaks have taken place after administration of contaminated medicine, such as parenteral anesthetics and aerosolized polymyxin B, or ingestion of contaminated water or ice cubes. Clinically, the most common manifestations have been bacteremia and pneumonia, but colonization without signs of infection also occurs, with *Elizabethkingia meningoseptica* being found in wounds, urine, and mucous membranes.

Strains of *Elizabethkingia meningoseptica* have been isolated from a variety of diseased animals, such as cats, dogs, turtles, snakes, and several bird species, as well as various frogs and fish species (for a recent review, see Bernardet et al. (2006), and references therein). Infected birds displayed various pathological signs: pericarditis or joint infection in chicken, inflamed hemorrhagic traumatic lesion in pigeon, and liver infection in zebra finch (Vancanneyt et al., 1994). Frogs infected by *Elizabethkingia meningoseptica* exhibited signs of hemorrhagic septicemia, leg and abdominal swelling, extreme lethargy, and severe enlargement of liver, spleen, and kidney (Chung, 1990; Green et al., 1999; Mauel et al., 2002). Severe outbreaks caused mass mortality in all developmental stages of frogs in intensive frog aquaculture systems; recurrence of outbreaks was observed frequently (Chung, 1990). The uncultured organism successively named “*Aegyptianella ranarum*” and “*Candidatus Hemobacterium ranarum*” that replicates in the red blood cells of several frog species and that is phylogenetically related to *Elizabethkingia meningoseptica* (Zhang and Rikihisa, 2004) is discussed in the Family *Flavobacteriaceae* in this volume.

Infections in fish imported to France from Africa and Asia have been reported recently. Samples of internal organs of diseased Koi carp (*Cyprinus carpio*), snake fish (*Erpetoichthys calabaricus*), and gourami (*Colisia lalia*) yielded pure cultures of *Elizabethkingia meningoseptica*; all fish suffered from hemorrhagic septicemia and carps also displayed skin lesions (Bernardet et al., 2005; N. Keck and J.-F. Bernardet, unpublished data). An *Elizabethkingia meningoseptica* strain retrieved from *Sinperca chuatsi* was one of the bacterial fish pathogens used by Yin et al. (2006) to test the bactericidal activity of an antimicrobial peptide from cDNA previously isolated from a fish leukocyte cDNA library. The minimal bactericidal concentration of the synthetic mature peptide, epinecidin-1, on *Elizabethkingia*

meningoseptica was the lowest of all Gram-stain-negative bacteria tested.

Although various animal species have been reported to harbor *Elizabethkingia meningoseptica*, its transfer from infected animals to humans is unlikely as no transfer from human to human has ever been reported.

Only scant information is currently available on the virulence mechanisms of *Elizabethkingia meningoseptica*. A possible clue was found in a strain isolated from a diseased bullfrog (see above), tentatively named “[*Flavobacterium*] *ranacida*” (Chung, 1990; Faung et al., 1996) but later shown to actually represent an *Elizabethkingia meningoseptica* strain (Bernardet et al., 2005). As the concentration of its major fatty acid, 13-methyl myristate, was increased it was able to induce changes in morphology and ultimately lysis of human platelets. At non-lytic concentrations, the fatty acid inhibited platelet response to various agents (Faung et al., 1996). The strong lytic activity of 13-methyl myristate on platelets and its ability to perturb membrane function could explain, at least partly, the hemorrhagic septicemia caused by *Elizabethkingia meningoseptica* in infected frogs.

In an attempt to evaluate the virulence mechanisms of *Elizabethkingia meningoseptica*, environmental strains and isolates from cases of invasive infection were selected from those studied by Ursing and Bruun (1987) and tested in penetration and cytotoxicity assays on cell cultures, in serum susceptibility tests, and in a murine pulmonary infection model (Lin et al., 2006). All strains were resistant to the bactericidal activity of normal human sera, but were unable to penetrate cultured cells and devoid of cytotoxic activity. Electron microscopic studies of samples of infected lung following intratracheal challenge of mice revealed that a strain originating from an invasive infection was able to invade the epithelial cells of the respiratory tract in contrast to the environmental isolate. Both strains, however, were cleared from the lung within 7 d; they did not spread to the liver or spleen and the mice survived the infection (Lin et al., 2006).

Ecology. Although the majority of *Elizabethkingia meningoseptica* strains have been isolated from clinical specimens, strains have also been found in soil, river water, and water reservoirs, as well as in various humid environments in hospitals, such as apparatus (bronchoscopes, respirators), medicine, catheters, sinks, and tap water (Bruun, 1982; Bruun et al., 1989; du Moulin, 1979; Heeg et al., 1994; Holmes, 1987; Hoque et al., 2001; Olsen, 1969; Owen and Holmes, 1981; Ursing and Bruun, 1987). An *Elizabethkingia meningoseptica* strain was part of the bacterial community in the water of a spent nuclear fuel pool in a nuclear power plant (Chicote et al., 2005). The environmental distribution of *Elizabethkingia meningoseptica* is also reflected by the strains identified from diseased birds, mammals, and freshwater animals (see above) and from lake amoebae (Hadas et al., 2004). Although *Elizabethkingia meningoseptica* appears to be rather resistant to chlorine and other disinfectants (Green et al., 1999 and references therein), the implementation of strict hygienic procedures such as isolation, plus disinfection and autoclaving of equipment, usually succeeds in stopping outbreaks (Bruun et al., 1989; Chung, 1990; Green et al., 1999; Heeg et al., 1994). However, in one neonatal intensive care unit, screening cultures of water tanks and taps remained positive even after sink taps were repaired and chlorinated and after the water temperature was raised to 43°C; only when taps were

replaced did cultures become negative (Hoque et al., 2001). Strains of *Elizabethkingia meningoseptica* usually belong to biofilm bacterial communities, as was shown during an outbreak in a frog-housing facility (Green et al., 1999).

So far, no clinical isolate of *Elizabethkingia miricola* is known. The type strain was retrieved from the condensation water of the space station Mir (Li et al., 2003a) and, although previously considered to be a strain of *Elizabethkingia meningoseptica*, the second strain was isolated from a contaminated commercial preparation of carboxypeptidase A (Elder and Alexander, 1982; Kim et al., 2005b).

Contrary to some *Chryseobacterium* species (see the corresponding chapter in this volume and Bernardet et al. (2006), strains of *Elizabethkingia* have not been reported from food products so far. Two dairy isolates grouped with the *Elizabethkingia meningoseptica* type strain as a result of multilocus enzyme electrophoresis (Hugo and Jooste, 1997), but a later comparison of fatty acid and whole-cell protein profiles did not confirm this identification (Hugo et al., 1999).

Enrichment and isolation procedures

The two species of *Elizabethkingia* are not fastidious and do not require enrichment or special procedures for isolation and cultivation. They grow well at 37°C (also at room temperature) on ordinary media, such as blood, tryptic soy, BHI, and nutrient agars, and are often recognized in the clinical microbiology laboratory by their resistance to antibiotics to which most other Gram-stain-negative rods are susceptible.

Maintenance procedures

Preservation methods used for *Elizabethkingia* strains do not differ from those used for strains of *Chryseobacterium* and related organisms (see the corresponding chapter in this volume and Bernardet et al. (2006). Commercial agar deeps of bacterial strain storage medium (e.g., Bio-Rad) are convenient for short-term preservation. For long-term preservation, *Elizabethkingia* strains may be frozen at -80°C in casitone broth with 10% (v/v) glycerol, BHI broth with 20% (v/v) glycerol, or ox broth with 10% (v/v) glycerol (Reichenbach, 1989b; Park et al., 2006b; B. Bruun, unpublished data). The last method has successfully preserved strains of *Elizabethkingia meningoseptica* for at least 25 years. The preferred method is, however, lyophilization (Bernardet et al., 2002, 2006).

Procedures for testing special characters

Phenotypic differentiation between the two *Elizabethkingia* species and from related *Chryseobacterium* species and *Empedobacter brevis* is difficult and requires strict adherence to the described methods and the conditions under which they are performed. These methods and conditions have been thoroughly reviewed previously (Bernardet et al., 2002, 2006; Bernardet and Nakagawa, 2006).

One of the most significant differential characteristics between members of the family *Flavobacteriaceae* is the production of yellow pigments. The pigments belong either to the carotenoid- or flexirubin-types, but members of some *Flavobacterium* species may produce both types of pigments (see the family *Flavobacteriaceae* and genus *Flavobacterium* chapters in this volume). An easy test based on the color shift induced by a 20% KOH solution is available to differentiate between the

two types (Reichenbach, 1989b), but drops of the solution must be deposited on a rather thick mass of bacterial cells collected with a loop (as recommended in the minimal standards for describing new taxa in the family *Flavobacteriaceae*, Bernardet et al., 2002) rather than directly on colonies. This requirement is especially important for weakly pigmented colonies such as those of *Elizabethkingia miricola* and some *Elizabethkingia meningoseptica* strains, as shown by the negative result obtained by Kim et al. (2005b) when they directly flooded *Elizabethkingia* colonies with KOH. When the KOH solution was deposited on bacterial masses, however, those *Elizabethkingia meningoseptica* strains that produced pale yellow colonies turned light brown, whereas no color shift occurred for nonpigmented strains (Bernardet et al., 2006). Hence, small amounts of flexirubin-type pigments seem to be produced by pigmented *Elizabethkingia meningoseptica* strains. It is important to note that pigment production is highly dependent on growth temperature, the presence of daylight, and the composition of the culture medium (Bruun, 1982; Holmes et al., 1984a; Hugo and Jooste, 2003).

Differentiation of the genus *Elizabethkingia* from other genera

The characteristics that differentiate members of the genus *Elizabethkingia* from those of the most closely related taxa (especially *Chryseobacterium*, but also *Bergeyella*, *Riemerella*, *Kaistella*, and *Sejonia*) are listed in Tables 43 and 44 of the *Chryseobacterium* chapter in this volume. They include various biochemical traits, production of yellow pigments, growth at different temperatures, G+C contents, and fatty acid composition. For characteristics that differentiate *Elizabethkingia* from more distantly related members of the family *Flavobacteriaceae*, see the corresponding chapter in this volume.

Although restricted to well-equipped research laboratories, the determination of fatty acid and whole-cell protein profiles allows a clear differentiation between strains of *Elizabethkingia*, *Chryseobacterium*, and related genera (Bernardet et al., 2005, 2006; de Beer et al., 2005, 2006; Hugo et al., 1999; Kim et al., 2005b). The fatty acid profile of members of the genus *Elizabethkingia* mainly differs from that of *Chryseobacterium* strains in the proportions of C_{17:1} iso ω9c and summed feature 4 (see Table 43 of the *Chryseobacterium* chapter). Although only one strain of each reference species was analyzed, the table of fatty acid compositions published by Kim et al. (2005b) is interesting because all strains were grown under the same conditions, thus allowing direct comparison.

Differentiation of *Elizabethkingia meningoseptica* strains from isolates of *Chryseobacterium gleum*, *Chryseobacterium indologenes*, and *Empedobacter brevis* in the clinical microbiology laboratory is based on a limited number of phenotypic tests, including the absence of or slow production of yellow pigment, acid from trehalose, and β-galactosidase (ONPG test) (Bernardet et al., 2006; Ursing and Bruun, 1991). Differentiation between strains of the two *Elizabethkingia* species rests only on the sticky colony consistency and the ability of *Elizabethkingia miricola* to hydrolyze 2-naphthyl butyrate (API ZYM galleries) in contrast to *Elizabethkingia meningoseptica* (Kim et al., 2005b).

Commercial identification galleries and kits are mostly adapted to clinical organisms that grow well at 37°C. They have been used to study collections of *Elizabethkingia meningoseptica* isolates, although discrepancies between the different

commercial galleries and conventional tests have been reported (Bernardet et al., 2006, 2005; Bruun and Ursing, 1987; Kim et al., 2005b). Most commercial identification systems include *Elizabethkingia meningoseptica* in their analytical profile index. This species can be differentiated from *Chryseobacterium* species using the API 20E, 20NE, ID 32E, ID 32GN, and Biotype 100 galleries, the Vitek GNI+ and Vitek2 ID-GNB systems (Bernardet et al., 2006 and references therein), and the Biolog GN2 MicroPlate (C.J. Hugo, personal communication). Although not a clinical organism and not included in databases, *Elizabethkingia miricola* was also tested successfully on various commercial galleries (Kim et al., 2005b; Li et al., 2003a). Fourteen of the 95 tests in the Biolog GN2 MicroPlate system differentiated the type strain of *Elizabethkingia miricola* from the type strain of *Elizabethkingia meningoseptica* (C.J. Hugo and A. Mielmann, personal communication) but, because *Elizabethkingia meningoseptica* is a phenotypically heterogeneous species, the importance of this finding is unclear.

When the minimal standards for describing new taxa in the family *Flavobacteriaceae* were published (Bernardet et al., 2002), the genus *Elizabethkingia* had not yet been separated from *Chryseobacterium* and [*Chryseobacterium*] *miricola* had not been described. However, the general principles for the family and the minimal standards for describing new *Chryseobacterium* species should be followed when novel *Elizabethkingia* species are described.

Taxonomic comments

The genus *Elizabethkingia* has only recently been proposed to accommodate two former *Chryseobacterium* species, [*Chryseobacterium*] *meningosepticum* and [*Chryseobacterium*] *miricola*, that shared a separate position compared to all other *Chryseobacterium* species in phylogenetic trees (Kim et al., 2005b). Physiological and biochemical tests differentiating the two species are sparse (see above; also see Table 44 of the *Chryseobacterium* chapter in this volume). The two *Elizabethkingia miricola* strains show DNA–DNA hybridization values of 23–54% to the five *Elizabethkingia meningoseptica* strains included in the study of Kim et al. (2005b). The

argument for creating the novel species *Elizabethkingia miricola* is, however, confounded by the fact that *Elizabethkingia meningoseptica* is known to be a heterogeneous species divided into two main DNA groups about 40–55% related to each other (Ursing and Bruun, 1987). The type strain of the species is in the small DNA group consisting of only four strains versus a total of 48 strains in the larger DNA group. This heterogeneity was confirmed by Kim et al. (2005b) (see above). In spite of its genomic heterogeneity, *Elizabethkingia meningoseptica* was chosen as the type species of the new genus because of its long standing description, its clinical significance, and because the numerous strains available had been subjected to extensive phenotypic and genomic studies (B. Holmes and R.J. Owen, unpublished data cited in Holmes et al., 1984b; Bruun and Ursing, 1987; Ursing and Bruun, 1987; Kim et al., 2005b). Hopefully, the new status of *Elizabethkingia meningoseptica* as the type species of a genus should prevent further changes in its nomenclature. For the time being, however, we are left with the genomic heterogeneity of this species. Hence, it is possible that the species will be split in the future, provided sound and convenient differential characteristics between the resulting species are found.

Taxonomic and nomenclatural issues in the genus *Elizabethkingia* are dealt with by the Subcommittee on the Taxonomy of *Flavobacterium* and *Cytophaga*-like Bacteria of the International Committee on Systematics of Prokaryotes. The subcommittee has issued the above-mentioned minimal standards (Bernardet et al., 2002).

Acknowledgements

The authors wish to acknowledge Tim Lilburn (American Type Culture Collection) for supplying the phylogenetic tree (Figure 40 in this volume of the *Manual*).

List of species of the genus *Elizabethkingia*

1. ***Elizabethkingia meningoseptica*** (King 1959) Kim, Kim, Lim, Park and Lee 2005b, 1291^{VP} (*Flavobacterium meningosepticum* King 1959, 247; *Chryseobacterium meningosepticum* Vandamme, Bernardet, Segers, Kersters and Holmes 1994a, 830)

me.nin.go.sep'ti.ca. Gr. n. *meninx*, *meningos* meninges, membranes covering the brain; Gr. adj. *septikos* putrefactive; N.L. fem. adj. *meningoseptica* presumably referring to the association of the bacterium with both meningitis and septicemia.

Rods, approximately 0.5 µm in diameter and various lengths (1–3 µm). Filaments are common. Good growth occurs on tryptic soy, blood, and nutrient agars, while growth on MacConkey agar is strain-dependent. Growth occurs at 22–37°C; strains from invasive neonatal disease grow at 40°C. Colonies on nutrient agar at 35°C are circular, entire, and smooth, 1–2 mm in diameter. Cultures have a characteristic aromatic odor. Strains deriving from invasive neonatal disease (e.g., the type strain) are weakly yellow-pigmented, while others are nonpigmented. Oxidase- and catalase-positive. Urease

is sometimes produced using Christensen's urea. Indole and β-galactosidase are produced. Gelatin is hydrolyzed. 2-Naphthyl butyrate is not hydrolyzed in the API ZYM gallery. Production of a precipitate on egg yolk agar is strain-dependent. Tyrosine is degraded by some strains. Other biochemical and physiological characteristics are given in Tables 43 and 44 of the *Chryseobacterium* chapter in this volume. Several serovars have been described. DNA–DNA hybridization studies have delineated two main DNA groups that cannot be differentiated phenotypically.

Source: the type strain was isolated from cerebrospinal fluid in Massachusetts in 1949. The species is not a member of normal human flora, but it causes invasive disease in neonates and occasionally in immunocompromised patients.

DNA G+C content (mol%): 36.4–37.9 (type strain: 37.9 ± 0.3) (T_m ; Holmes et al., 1984a; Ursing and Bruun, 1987); 36.6–37.8 (type strain: 37.1) (HPLC; Kim et al., 2005b).

Type strain: strain 14 of King (1959), ATCC 13253, NCTC 10016, LMG 12279, CCUG 214 (serovar A).

Sequence accession nos (16S rRNA gene): AY468445, AJ704540.

Reference strains: the three strains that shared high DNA relatedness with the type strain in the study of Ursing and Bruun (1987) are: Richard's strain 3.83 (no longer available), GTC 10941 (Gifu 1606) and NCTC 13393 (Holmes' strain E 847, Greaves' strain F2, NCIB 7-61). Other reference strains are: NCTC 10585 (strain 422 of King, 1959; serovar B); NCTC 10586 (strain 3375 of King, 1959; serovar C); NCTC 10587 (strain 6925 of King, 1959; serovar D); NCTC 10588 (strain 8388 of King, 1959; serovar E); NCTC 10589 (strain 8707 of King, 1959; serovar F); NCTC 11305 (CIP 78.30; Richard et al., 1979b; serovar G); NCTC 11306 (CIP 79.5; Richard et al., 1979a; serovar H); and NCTC 11309 (CIP 79.29; Richard et al., 1979a; serovar K).

2. **Elizabethkingia miricola** (Li, Kawamura, Fujiwara, Naka, Liu, Huang, Kobayashi and Ezaki 2003a) Kim, Kim, Lim, Park and Lee 2005b, 1292^{VP} (*Chryseobacterium miricola* Li, Kawamura, Fujiwara, Naka, Liu, Huang, Kobayashi and Ezaki 2003a, 527)

mi.ri'co.la. N.L. neut. n. *mirum* derived from *mir* (peace in Russian, name of the Russian space station); L. suff. *-cola* from L. masc. or fem. n. *incola* inhabitant; N.L. masc. or fem. n. *miricola* inhabitant of the Mir space station.

Rods, approximately 0.5 µm in diameter and 1.0–2.5 µm in length. Good growth occurs on tryptic soy, blood, BHI, nutrient, and MacConkey agars. Very slow growth occurs on cetrimide agar. Growth occurs at 22–37°C, but not at 5 or 42°C. Colonies are white–yellow, circular, entire, smooth, and very sticky on solid media. Oxidase- and catalase-positive. Indole and β-galactosidase are produced. Gelatin and urea are hydrolyzed. 2-Naphthyl butyrate is hydrolyzed in the API ZYM gallery. The type strain forms a precipitate when grown on egg yolk agar. D-Mannitol, sodium citrate, and N-acetyl-D-glucosamine are assimilated, but tyrosine is not degraded. Other biochemical and physiological characteristics are given in Tables 43 and 44 of the *Chryseobacterium* chapter in this volume.

Source: the type strain was isolated from condensation water in the space station Mir; a second strain was recently identified from the contaminated commercial preparation of an enzyme.

DNA G+C content (mol%): 35.3 ± 0.3 (type strain: 35.0) (HPLC; Kim et al., 2005b).

Type strain: strain W3-B1 of Li et al. (2003a), DSM 14571, JCM 11413, GTC 862.

Sequence accession no. (16S rRNA gene): AB071953.

Reference strain: ATCC 33958.

Genus XVIII. **Empedobacter** (ex Prévot 1961) Vandamme, Bernardet, Segers, Kersters and Holmes 1994a, 830^{VP}

THE EDITORIAL BOARD

Em.pe.do.bac'ter. Gr. adj. *empedos* fixed, immovable; N.L. masc. n. *bacter* a small rod; N.L. masc. n. *Empedobacter* nonmotile rod

Rods, typically 0.5 µm wide and 1–2 µm long, but some longer rods may be present. Gram-stain-negative. **Nonmotile**. Nonsporeforming. Intracellular poly-β-hydroxybutyrate granules are absent. **Aerobic**, having a strictly respiratory type of metabolism. Chemo-organotrophic. All strains grow at 30°C; some strains grow at 37°C. **Growth on solid media is light yellow**. Growth occurs on MacConkey agar and β-hydroxybutyrate agar. **Positive for catalase, oxidase, and phosphatase. Indole-positive**. Several carbohydrates are oxidized, but glycerol and trehalose are not. **Casein, gelatin, tributyrin, DNA, and Tween 20 are hydrolyzed, but not esculin, urea, or agar**. Fatty acids C_{15:0} iso, C_{16:1} ω7c, C_{16:1} ω5c, C_{16:0}, C_{16:0} 3-OH, and C_{17:0} iso 3-OH are predominant. Sphingophospholipids are absent. The only respiratory quinone is menaquinone-6. Resistant to a wide range of antimicrobial agents.

DNA G+C content (mol%): 31–33 (T_m).

Type species: Empedobacter brevis (Holmes and Owen 1982) Vandamme, Bernardet, Segers, Kersters and Holmes 1994a, 830^{VP} [*Flavobacterium breve* (ex Lustig 1890) Holmes and Owen 1982, 233; *Bacillus brevis* Lustig 1890, 521; *Bacillus canalicolis brevis* Cornil and Babes 1890, 292; *Bacillus canalis parvus* Eisenberg 1891, 362; *Bacterium canalis parvus* (*sic*) (Eisenberg 1891) Chester 1897, 130; *Bacterium canale* Mez 1898, 55; *Bacterium breve* (Lustig 1890) Chester 1901, 69; *Flavobacterium brevis* (*sic*) (Lustig 1890) Bergey, Harrison, Breed, Hammer and Huntoon 1923, 116; *Pseudobacterium brevis* (*sic*) (Lustig 1890) Krasil'nikov 1949, 239; *Empedobacter breve* (*sic*) (Lustig 1890) Prévot 1961, 181].

Further descriptive information

Good growth occurs on nutrient agar. Colonies are circular, low convex, smooth, and shiny, with entire edges. The colony size is pinpoint to 2.0 mm in diameter on nutrient agar; colonies on blood agar are pinpoint to 2.5 mm in diameter and non-hemolytic. The light yellow pigmentation does not change with variation of medium and temperature. Growth occurs at room temperature (18–22°C); some strains grow at 37°C; no strains grow at 5 or 42°C. Although some strains grow at 37°C, the majority will only produce acid from carbohydrates when incubated at 30°C and prolonged incubation may be necessary.

The cellular polyamine homospermidine, characteristic of members of the *Flavobacterium–Cytophaga–Sphingobacterium* complex, is present (Hamana and Nakagawa, 2001).

The pathogenicity of *Empedobacter brevis* for humans and other animals is not clear, but at least in some instances it seems to be an opportunistic pathogen. Mori (1888) inoculated laboratory animals with canal water and, when the animals died, he isolated *Empedobacter brevis* from their blood and internal organs. Whether the organism caused death of the animals is uncertain, but the cultures were pathogenic for guinea pigs, mice, and rabbits. Holmes et al. (1978) reviewed the history of isolation of *Empedobacter brevis* strains from various clinical specimens and indicated that there was no definite evidence that these strains were the causative agents of the infections, since some were obtained from mixed cultures, others were possible contaminants, and still others were isolated from cases where the clinical details were not well described. *Empedobacter brevis*

has been isolated from the anterior chamber and the vitreous in a series of patients who had developed endophthalmitis after cataract extraction by the same surgeon on the same day; the source of infection was unknown (Janknecht et al., 2002). *Empedobacter brevis* has been isolated from the cerebrospinal fluid of a dog, where it occurred at high levels (Haburjak and Schubert, 1997). Various species of flavobacteria, including *Empedobacter brevis*, were isolated from damaged gills, pins, and skin ulcers of the Atlantic salmon (*Salmo salar*), rainbow trout (*Oncorhynchus mykiss*), and cod (*Gadus morhua*) and from exoskeleton lesions of king crab (*Paralithodes camtschaticus*) (Serdyuk, 1998). *Empedobacter brevis* was one of the species isolated from moribund Koi carp and goldfish, which often had severe ulceration; however, the primary causative agent was “atypical” *Aeromonas salmonicida*, with aggravation by the secondary invaders *Aeromonas hydrophila* and *Pseudomonas fluorescens* (Robertson and Austin, 1994).

Empedobacter brevis is also a parasite of certain protists. Córdova et al. (2002) found *Empedobacter brevis* and several other bacterial species to be present in the cytoplasm of *Alexandrium catenella* – a chain-forming dinoflagellate that is toxic and causes paralytic shellfish poisoning; however, *Empedobacter brevis* was not associated with production of the algal saxitoxin. In several instances, the *Alexandrium catenella* clones were simultaneously infected by different species of bacteria. The intracellular bacteria were alive and appeared to be dividing. Antibiotic treatment of *Alexandrium catenella* did not generate bacteria-free cells and led to the killing of the host cells. Bottone et al. (1992) showed that when the amoebae *Acanthamoeba castellanii* and *Acanthamoeba polyphaga* were cocultivated with *Empedobacter brevis*, *Xanthomonas maltophilia*, and *Pseudomonas paucimobilis*, enhancement of amoebal growth was better than that obtained in the presence of *Staphylococcus aureus*, *Staphylococcus epidermidis*, and *Escherichia coli*, the standard cocultivation species used for isolation of amoebae from clinical specimens. The authors concluded that contamination of contact lens care systems with *Acanthamoeba* spp. and a bacterium capable of supporting amoebic growth might be involved in amoeba-induced keratitis by providing large inocula of amoebae. Wadowsky and Yee (1983) found that satellite growth of *Legionella pneumophila* occurred with an environmental isolate of *Flavobacterium breve* on a medium deficient in cysteine – an amino acid required by *Legionella pneumophila* for growth; presumably, *Empedobacter brevis* secreted cysteine or a related compound into the medium.

Empedobacter brevis is resistant to a wide range of antimicrobial agents (Vandamme et al., 1994a). Janknecht et al. (2002) found an isolate of *Empedobacter brevis* to be resistant to aminoglycosides, cephalosporins (cefotiam, ceftriaxone, ceftazidim), and fosfomicin, but sensitive to ampicillin, piperacillin, imipenem, quinolones, tetracycline, and chloramphenicol. The occurrence of intrinsic metallo- β -lactamases in *Empedobacter brevis* may partially explain the resistance of the organism to penicillin. Bellais et al. (2002a) reported that the Ambler class B β -lactamase gene *bla*_{EBR-1} occurred in a strain of *Empedobacter brevis* isolated from a

rectal swab. When cloned and expressed in *Escherichia coli*, the enzyme hydrolyzed penicillins, cephalosporins, and carbapenems efficiently, but not aztreonam.

Empedobacter brevis can be found free living in water and in food (Hugo and Jooste, 1997). Turtura et al. (2000) reported that *Empedobacter brevis* was one of several species isolated from black crusts taken from open-air stone monuments in Bologna, Italy, that dated back to between the twelfth and nineteenth centuries. The presence of these species in the black crusts was not occasional, but instead the result of an ecologically significant process of colonization.

Enrichment and isolation procedures

Special procedures are not normally required for the isolation of *Empedobacter brevis*. However, the ability of this species to grow on MacConkey agar and β -hydroxybutyrate agar may provide some selectivity.

Differentiation of the genus *Empedobacter* from other genera

The genus *Empedobacter* contains a single species, *Empedobacter brevis*. The nearest relative of *Empedobacter* is *Weeksella*, which also includes a single species, *Weeksella virosa* (Vandamme et al., 1994a). *Empedobacter brevis* differs from *Weeksella virosa* in that it forms yellow colonies, has a saccharolytic metabolism, exhibits DNase activity, is resistant to penicillin, fails to grow at 42°C, and has a lower DNA G+C content (31–33 mol% vs 35–38 mol%).

Features differentiating *Empedobacter* from other genera of rRNA superfamily V are listed by Vandamme et al. (1994a). In a study of 130 food isolates of *Chryseobacterium* and *Empedobacter*, Hugo and Jooste (1997) reported that use of the multilocus enzyme electrophoresis technique was able to correctly identify the *Empedobacter* group.

Taxonomic comments

The taxonomic history of *Empedobacter brevis* prior to 1984 has been reviewed by Holmes et al. (1984a), who included *Empedobacter brevis* in the genus *Flavobacterium* as *Flavobacterium breve*. In a later review by Holmes (1992), members of *Flavobacterium* were divided into four groups, of which the first group contained *Flavobacterium breve* and several other *Flavobacterium* species. Vandamme et al. (1994a) indicated that, based on chemotaxonomic and phenotypic features and on DNA-rRNA hybridization experiments, *Flavobacterium breve* and *Weeksella virosa* belonged to a separate position in rRNA superfamily V. However, the level of genotypic divergence between the two species was about 6°C [$T_{m(e)}$] and the two species differed in many biochemical features, including fatty acid composition. Consequently, Vandamme et al. (1994a) concluded that the two taxa should be considered as members of different genera and, accordingly, they revived the genus name *Empedobacter* for *Flavobacterium breve*, a name that had been applied previously to the same species by Prévot (1961).

List of species of the genus *Empedobacter*

1. ***Empedobacter brevis*** (Holmes and Owen 1982) Vandamme, Bernardet, Segers, Kersters and Holmes 1994a, 830^{VP} [*Flavobacterium breve* (ex Lustig 1890) Holmes and Owen 1982, 233; *Bacillus brevis* Lustig 1890, 521; *Bacillus canalicolis brevis* Cornil and Babes 1890, 292; *Bacillus canalis parvus* Eisenberg 1891, 362; *Bacterium canalis parvis* (sic) (Eisenberg 1891) Chester 1897, 130; *Bacterium canale* Mez 1898, 55; *Bacterium breve* (Lustig 1890) Chester 1901, 69; *Flavobacterium brevis*

(*sic*) (Lustig 1890) Bergey, Harrison, Breed, Hammer and Huntoon 1923, 116; *Pseudobacterium brevis* (*sic*) (Lustig 1890) Krasil'nikov 1949, 239; *Empedobacter breve* (*sic*) (Lustig 1890) Prévot 1961, 181]

bre'vis. L. masc. adj. *brevis* short.

The following characteristics are taken from Holmes et al. (1984a). No acid is produced from adonitol, arabinose, cellobiose, dulcitol, ethanol, fructose, glycerol, inositol, lactose, mannitol, raffinose, rhamnose, salicin, sorbitol, sucrose, trehalose, or xylose. Some strains hydrolyze Tween 80. The following tests are all negative: acid and/or gas production from glucose in a peptone/water medium, oxidation of gluconate, 3-ketolactose production, malonate utilization, arginine deamidase, arginine dihydrolase, lysine decarboxylase, ornithine decarboxylase, phenylalanine

deaminase, β -galactosidase (ONPG), alkali production on Christensen's citrate, fluorescent pigment production on King's medium B, pigment production on tyrosine agar, growth on cetrinide agar and Simmons' citrate agar, reduction of 0.4% (w/v) selenite, H₂S production, KCN tolerance, nitrate reduction, and production of opalescence on lecithovitellin agar.

Source: various sources including canal water, clinical specimens, food, fish and marine animals, dogs, and protists.

DNA G+C content (mol%): 31–33 (T_m).

Type strain: CL88/76 (Holmes et al., 1978), NCTC 11099, ATCC 43319, CCUG 7320, CIP 103104, IFO (NBRC) 14943, LMG 4011.

Sequence accession nos: M33888 (5S rRNA), D14022 (16S rRNA).

Genus XIX. *Epilithonimonas* O'Sullivan, Rinna, Humphreys, Weightman and Fry 2006, 177^{VP}

THE EDITORIAL BOARD

Ep.i.lith.on.i.mo'nas. N.L. n. *epilithon -is* (or *epilithonum -i*) epilithon; L. fem. n. *monas* a unit, monad; N.L. fem. n. *Epilithonimonas* a monad isolated from epilithon.

Rounded rods, 0.6–0.7 × 1.0–2.5 μ m, that do not form chains or filaments. No gliding motility. Gram-stain-negative. Strictly aerobic. Colonies are orange. **Flexirubin pigments are present.** Growth occurs between 4 and 30°C. **No growth occurs on marine agar.** Oxidase- and catalase-positive. **Nitrate is reduced.** A few carbohydrates, including glucose, are utilized for growth. **Acid is not produced from glucose. Indole-negative.** Fatty acids contain a large proportion of saturated branched-chain, monosaturated and hydroxy fatty acids. The most abundant individual fatty acids are C_{15:0} iso and summed feature 3 (C_{16:1} ω 7c/C_{15:0} iso 2-OH). Na⁺ is not required. Isolated from freshwater environments.

DNA G+C content (mol%): 37.5 (HPLC).

Type species: ***Epilithonimonas tenax*** O'Sullivan, Rinna, Humphreys, Weightman and Fry 2006, 177^{VP}.

Enrichment and isolation procedures

Epilithonimonas tenax was isolated from the surface film on river stones. Samples of the epilithon were serially diluted in sterile deionized water containing 1 μ l/l Tween 20. The spread-plate technique was used with various common media such as plate count agar (PCA) containing 20 μ g/ml cycloheximide to inhibit eukaryotic micro-organisms. Plates were incubated at 20°C for 10 d and orange, spreading colonies were selected, subcultured twice on their original isolation medium, and purified on PCA.

Differentiation of the genus *Epilithonimonas* from related genera

Epilithonimonas differs from members of the genera *Bergeyella*, *Elizabethkingia*, *Riemerella*, and *Sejongia* by possessing flexirubin-type pigments. An ability to reduce nitrate distinguishes it from *Bergeyella*, *Elizabethkingia*, *Kaistella*, *Riemerella*, *Sejongia*, and most species of *Chryseobacterium*, except *Chryseobacterium balustinum* and *Chryseobacterium daecheongense*. Lack of indole production distinguishes it from *Bergeyella*, *Elizabethkingia*, *Kaistella*, *Sejongia*, and most species of *Chryseobacterium*, except *Chryseobacterium daecheongense* and *Chryseobacterium scophthalmum*. The inability of *Epilithonimonas* to form acid from glucose differentiates it from *Elizabethkingia*, *Riemerella*, *Sejongia*, and most species of *Chryseobacterium*, except *Chryseobacterium daecheongense* and *Chryseobacterium scophthalmum*.

Taxonomic comments

16S rRNA gene sequence analysis has shown that *Epilithonimonas tenax* belongs to a monophyletic cluster containing the genera *Bergeyella*, *Chryseobacterium*, *Elizabethkingia*, *Kaistella*, *Riemerella*, and *Sejongia*. It forms a discrete lineage positioned between the genus *Elizabethkingia* and the other genera (O'Sullivan et al., 2006).

List of species of the genus *Epilithonimonas*

1. *Epilithonimonas tenax* O'Sullivan, Rinna, Humphreys, Weightman and Fry 2006, 177^{VP}

ten'ax. L. fem. adj. *tenax* sticky, holding firm, referring to the organism's viscous colonies.

Characteristics are as described for the genus, with the following additional features. Colonies on PCA after 1 week at 20°C are 3–6 mm in diameter, bright orange, opaque, and smooth, with an entire edge and a viscous consistency.

Growth occurs on trypticase soy agar, nutrient agar, MacConkey agar, and DNase agar, but not on marine agar 2216 or cetrinide agar. Esculin and starch are hydrolyzed, but not agar, arginine, DNA, Tween 80, or gelatin. No β -galactosidase, urease, or xylanase activities. Growth occurs on the following substrates: acetic acid, L-alanyl-glycine, α -cyclodextrin, dextrin, gentiobiose, α -D-glucose, L-glutamic acid, glycogen, glycy-L-aspartic acid, glycy-L-glutamic acid, inosine,

α -ketovaleric acid, mannose, maltose, L-ornithine, L-proline, L-serine, Tween 40, sucrose, L-threonine, thymidine, trehalose, and uridine. No growth occurs on the following substrates: *N*-acetyl-D-galactosamine, *N*-acetylglucosamine, *cis*-aconitic acid, adipate, adonitol, alaninamide, D-alanine, L-alanine, γ -aminobutyric acid, 2-aminoethanol, arabinose, D-arabitol, L-asparagine, L-aspartic acid, bromosuccinic acid, 2,3-butanediol, caprate, DL-carnitine, cellobiose, citric acid, i-erythritol, formic acid, D-fructose, L-fucose, D-galactonic acid, D-galactose, D-galacturonic acid, D-gluconic acid, D-glucosaminic acid, glucuronamide, D-glucuronic acid, glucose 1-phosphate, glucose 6-phosphate, glycerol, DL- α -glycerol phosphate, L-histidine, α -hydroxybutyric acid, β -hydroxybutyric acid, γ -hydroxybutyric acid, *p*-hydroxyphenylacetic acid, hydroxy-L-proline, *myo*-inositol, itaconic acid, α -ketobutyric

acid, α -ketoglutaric acid, DL-lactic acid, α -D-lactose, lactulose, L-leucine, malate, malonic acid, mannitol, melibiose, methyl- β -D-glucoside, methylpyruvate, monomethyl succinate, phenylacetate, L-phenylalanine, phenylethylamine, propionic acid, D-psicose, putrescine, L-pyroglutamic acid, quinic acid, raffinose, L-rhamnose, D-saccharic acid, sebacic acid, D-serine, D-sorbitol, succinamic acid, succinic acid, turanose, Tween 80, urocanic acid, or xylitol. Susceptible to penicillin G, ampicillin, and rifampin, but not to chloramphenicol, streptomycin, kanamycin, or tetracycline.

Source: the type strain was isolated from epilithon-covered stones from the River Taff in Cardiff, UK.

DNA G+C content (mol%): 37.5 (HPLC).

Type strain: EP105, DSM 16811, NCIMB 14026.

Sequence accession no. (16S rRNA gene): AF493696.

Genus XX. *Flaviramulus* Einen and Øvreås 2006, 2460^{VP}

THE EDITORIAL BOARD

Fla.vi.ra'mu.lus. L. adj. *flavus* yellow; L. masc. dim. n. *ramulus* small branch; N.L. masc. n. *Flaviramulus* small yellow branch.

Cells in stationary phase are rods, 0.2–0.3 × 1–3 μ m. Exponential phase cells are rods, but stationary phase cells are pleomorphic, 0.2–0.3 μ m in diameter and 1–30 μ m long. Branched and curled cells are also seen in stationary phase cultures. As cultures age, cells degenerate into spheroplasts ranging from 0.15 to 1 μ m in diameter. **Cells are motile by polar adhesion to a glass surface, with a rotational movement;** cells grip the surface at the opposite pole and then are released at the first pole. Gram-stain-negative. **Aerobic. Oxidase-negative. Cells contain yellow and orange carotenoids.** Flexirubin-type pigments are not found. **Seawater, yeast extract or thiamine, and amino acids are required for growth.** Menaquinone-6 is the major respiratory quinone.

DNA G+C content (mol%): 31.4 (T_m).

Type species: ***Flaviramulus basaltis*** Einen and Øvreås 2006, 2460^{VP}.

Further descriptive information

Einen and Øvreås (2006) reported the isolation of four yellow-pigmented, Gram-stain-negative, motile strains of bacteria from the glassy rind of basaltic pillow lavas collected from the seafloor in the Norwegian/Greenland Sea at a depth of 1,300 m below sea level. The seafloor temperature at the sampling site was -0.7°C .

Motility is best observed in fresh cultures grown in FM broth* containing <0.05% yeast extract. Cells adherent to a glass surface have a rotational movement of about three rotations per second. Polar appendages occur on many of the cells that are motile, but not on nonmotile cells. No spreading growth occurs on marine agar (MA) or FM agar.

The *Flaviramulus* strains were able to produce acid from the following compounds: *N*-acetyl-D-glucosamine, D-arabinose,

D-cellobiose, D-fructose, D-glucose, lactose, maltose, D-mannitol, L-rhamnose, D-ribose, sucrose, and xylan. Alcohols did not support growth. The following compounds were used in the Biolog system: L-aspartic acid, cellobiose, cyclodextrin, dextrin, D-fructose, D-galactose, D-galacturonic acid, gentiobiose, D-glucose, D-glucose 1-phosphate, D-glucose 6-phosphate, D-glucuronic acid, L-glutamic acid, glycogen, glycy-L-aspartic acid, glycy-L-glutamic acid, ketobutyric acid, ketoglutaric acid, DL-lactic acid, D-lactose, lactulose, maltose, D-mannose, methyl-D-glucoside, L-ornithine, L-proline, pyruvic acid methyl ester, raffinose, L-rhamnose, succinamic acid, succinic acid, succinic acid monomethyl ester, sucrose, trehalose, turanose, and Tweens 40 and 80. The following Biolog substrates were not utilized: acetic acid, *N*-acetyl-D-galactosamine, *cis*-aconitic acid, adonitol, L-alaninamide, D-alanine, L-alanine, L-alanyl-glycine, L-arabinose, D-arabitol, L-asparagine, bromosuccinic acid, citric acid, i-erythritol, formic acid, L-fucose, D-galactonic acid lactone, D-gluconic acid, D-glucosaminic acid, glucuronamide, L-histidine, α -, β -, and γ -hydroxybutyric acid, *p*-hydroxyphenylacetic acid, hydroxy-L-proline, *myo*-inositol, itaconic acid, ketovaleric acid, L-leucine, malonic acid, D-mannitol, melibiose, L-phenylalanine, propionic acid, D-psicose, L-pyroglutamic acid, quinic acid, D-saccharic acid, sebacic acid, D-sorbitol, and xylitol.

Enrichment and isolation procedures

The outer glassy rim of the basalt was chipped off and the glass was placed in sterile seawater and stored in closed flasks in the dark for 3 years at 10°C . Portions of the seawater were plated onto MA [marine broth 2216 (Difco) solidified with 1.5% agar] and incubated at 10°C . After incubation for 14 d, small yellow colonies were selected and purified.

Cultures can be grown in FM broth at 22°C . Preservation can be accomplished at -80°C in marine broth supplemented with 15% glycerol.

*The Flavobacteriaceae Medium (FM) of Einen and Øvreås (2006) contains (g/l distilled water): sea salts (Sigma), 30; D-glucose, 5; and yeast extract, 0.5; pH adjusted to 8.0.

Differentiation of the genus *Flaviramulus* from related genera

Several of the phenotypic characteristics of *Flaviramulus* differ from those of members of the genera *Gaetbulibacter* and *Algibacter*. The most important difference between *Flaviramulus* and the genera *Gaetbulibacter* and *Algibacter* is that *Flaviramulus* is obligately aerobic, whereas *Gaetbulibacter* and *Algibacter* are capable of fermentation/anaerobic respiration. In addition, *Flaviramulus* is oxidase-negative, grows at 0°C, grows in media with

0.5% NaCl, and hydrolyzes Tween 80. Phenotypic differences between *Flaviramulus* and other genera of *Flavobacteriaceae* have been described by Einen and Øvreås (2006).

Taxonomic comments

16S rRNA gene sequence analysis showed that the type strain of *Flaviramulus basaltis* is closely related to the type strains of *Gaetbulibacter saemankumensis* and *Algibacter lectus* (94.3 and 94.8% similarities, respectively).

List of species of the genus *Flaviramulus*

1. *Flaviramulus basaltis* Einen and Øvreås 2006, 2460^{VP}

ba.sal'tis. L. masc. gen. n. *basaltis* of basalt, pertaining to the source of isolation.

The following properties are in addition to those given for the genus. Colonies grown on MA are shiny, dark yellow, circular, and convex, with entire margins. Cells are catalase-positive and alkaline phosphatase-positive. Growth occurs from -2.0 to 34.0°C, with optimum growth at 17.5–22.8°C. The salinity range for growth is 3–60 g/l sea salts, with an optimum of 24–60 g/l. Growth is supported at pH 6.5–8.6, with optimum growth at pH 6.5–8.2. Utilizes and produces

acids from several sugars. Utilizes organic acids and amino acids. Does not utilize alcohols. Hydrolyzes L-tyrosine, esculin, carrageenan, gelatin, starch, DNA, urea, and Tweens 20, 40 and 80, but not agar, cellulose, or chitin. Produces H₂S from cysteine. Branched fatty acids are predominant.

Source: the type strain was isolated from seafloor basalt offshore of Jan Mayen in the Norwegian/Greenland Sea at a depth of 1300 m.

DNA G+C content (mol%): 31.4 ± 0.6 (*T_m*).

Type strain: H35, CIP 109091, DSM 18180.

Sequence accession no. (16S rRNA gene): DQ361033.

Genus XXI. **Formosa** Ivanova, Alexeeva, Flavier, Wright, Zhukova, Gorshkova, Mikhailov, Nicolau and Christen 2004, 707^{VP} emend. Nedashkovskaya, Kim, Vancanneyt, Snauwaert, Lysenko, Rohde, Frolova, Zhukova, Mikhailov, Bae, Oh and Swings 2006d, 166

ELENA P. IVANOVA

For.mo'sa. L. fem. adj. (used as a substantive) *Formosa* beautiful, finely formed.

Rod-shaped cells with slightly irregular sides and pointed ends, approx. 0.8–1.8 × 0.4–0.9 μm. **Cells have gliding motility. Buds may be produced. Do not form endospores or resting stages. Gram-stain-negative.** Poly-β-hydroxybutyrate is not accumulated as an intracellular reserve product. An arginine dihydrolyase system is not present. Aerobic; however, anaerobic growth can occur on D-glucose by anaerobic respiration with nitrate. Chemo-organotrophic. Positive for oxidase, catalase, and alkaline phosphatase. May require Na⁺ for growth. Agar hydrolysis differs among species. Produce non-diffusible carotenoid pigments. Flexirubin pigments are not detected. Isolated from marine habitats of the North Pacific.

DNA G+C content (mol%): 34–36.

Type species: Formosa algae Ivanova, Alexeeva, Flavier, Wright, Zhukova, Gorshkova, Mikhailov, Nicolau and Christen 2004, 707^{VP} emend. Nedashkovskaya, Kim, Vancanneyt, Snauwaert, Lysenko, Rohde, Frolova, Zhukova, Mikhailov, Bae, Oh and Swings 2006d, 161.

Further descriptive information

Phylogenetically, *Formosa* is a member of the family *Flavobacteriaceae*. Species of the genus form a distinct lineage within the family. Similar topologies of phylogenetic trees are retrieved by neighbor-joining, maximum-likelihood, and maximum-parsimony algorithms and supported by high bootstrap values. The level of 16S rRNA gene sequence similarity with the two phylogenetically most closely related genera, *Psychroserpens* and *Gelidibacter*, is almost equidistant, reaching 94.2% sequence similarity and 82 sequence differences with, for example,

Psychroserpens burtonensis. The closest uncultured sequence, from bacteria from the toxic dinoflagellate *Alexandrium tamarense* (Groben et al., 2000), had 97.2% sequence similarity and 27 differences.

Phosphatidylethanolamine is the only phospholipid identified in bacteria of this genus. Amino-containing lipids that were detected on TLC plates are ninhydrin-positive (Ivanova et al., 2004).

MK-6 was the major lipoquinone among isoprenoid quinones, as detected using HPLC (Nedashkovskaya et al., 2006d).

The predominant cellular fatty acids are branched-chain saturated and unsaturated, namely, C_{15:0}, C_{15:0} iso, C_{15:1} ω6c, C_{15:0} iso, C_{15:0} iso 3-OH, C_{17:0} iso 3-OH, and summed feature 3 (comprising any combination of C_{16:1} ω7c, C_{16:1} ω7t, and C_{15:0} iso 2-OH) (Table 45). In spite of the intraspecific heterogeneity of the fatty acids content of micro-organisms belonging to the family *Flavobacteriaceae* (Bernardet et al., 1996, 2002; Holmes, 1984a, 1993), bacteria of the genus *Formosa* retain a high proportion of branched-chain saturated and unsaturated cellular fatty acids, a characteristic feature of the family *Flavobacteriaceae*.

The cell morphology of *Formosa algae* KMM 3553^T has been observed by atomic force microscopy (Ivanova et al., 2004) and that of strain KMM 3901^T has been observed by scanning and transmission electron microscopy as described by Bruns et al. (2001). Cells of strain KMM 3901^T showed budding fission (Figure 41). The buds are usually formed on mature cells of strain KMM 3901^T. In addition to producing buds, cells of KMM 3901^T formed a fibrillar network that connected them to one another. The formation of a fibrillar network by flavobacteria

Summed feature 3	5.9	15.8	12.1

^aValues of less than 1% for all strains are not shown. Summed feature 3, which could not be separated by the Microbial Identification System, consists of one or more of the following fatty acids: C_{15:0} iso 2-OH, C_{16:1} ω7c, and C_{16:1} ω7t. tr, Trace amount (<1% of total); –, not detected.

was first reported by Reichenbach (1989b). Similar features have also been found in strains of *Winogradskyella* (Nedashkovskaya et al., 2005a). The extracellular fibrils may facilitate attachment of cells to suitable substrates and to other cells, followed by biofilm formation on the surface of algae in natural habitats (Nedashkovskaya et al., 2005a).

On solid media containing high nutrient concentrations (e.g., marine agar), colonies formed by *Formosa algae* KMM 3553^T are circular, 1–3 mm in diameter, and low-convex. Colonies formed by *Formosa agariphila* KMM 3901^T are round, flat, 3–4 mm in diameter, translucent, and sunk into the agar, whereas colonies of *Formosa agariphila* KMM 3962 are 2–3 mm in diameter and slightly sunk into the agar after 24–48 h. Colonies are pale to light yellow depending on the strain. The yellow color of the colonies is due to production of carotenoid pigments (with absorbance peaks at 455 and 480 nm). Flexirubin pigments are not detected.

Under laboratory conditions, growth of *Formosa agariphila* KMM 3901^T in broth results in the formation of small aggregates. Cells of strains KMM 3553^T and KMM 3901^T produce a dense slime on solid media.

There are no specific growth requirements for strains of *Formosa*. Some strains may require Na⁺ ions for growth. Natural seawater [50% (v/v)] may need to be added to the base medium when testing for acid production from carbohydrates. The temperature range for growth is 4–34°C, with optimum growth at 21–23°C.

All strains of *Formosa algae* and *Formosa agariphila* KMM 3962 show remarkable resistance to benzylpenicillin, gentamicin, kanamycin, neomycin, polymyxin B, streptomycin ampicillin, carbenicillin, lincomycin, and oleandomycin. *Formosa agariphila*

KMM 3901^T is susceptible to ampicillin, carbenicillin, lincomycin, and oleandomycin.

Formosa strains have been isolated from marine habitats of the North Pacific. These organisms may be free-living or colonizers of the surfaces of marine algae. *Formosa algae* represents one of the numerically dominant groups of the brown alga (*Fucus evanescens*)-degrading enrichment community. *Formosa agariphila* KMM 3901^T was isolated from the green alga *Acrosiphonia sonderi* in Troitsa Bay, Gulf of Peter the Great, East Sea (also known as the Sea of Japan). *Formosa agariphila* KMM 3962 was isolated from seawater in Amursky Bay (Gulf of Peter the Great), East Sea.

Enrichment and isolation procedures

Species of *Formosa* can usually be isolated by direct inoculation of 0.1 ml algal homogenate or 0.1 ml seawater onto marine agar 2216 (Difco) or medium B.* Strains of *Formosa algae* were isolated from enrichment experiments during the degradation of the thallus of brown algae (*Fucus evanescens*) (Ivanova et al., 2002a, b), with addition of a protein inhibitor for the endo-(1 → 3)-β-D-glucanases (Yermakova et al., 2002) to the enrichment culture.

Short-term survival of *Formosa* can be achieved for approximately 2 weeks on marine agar 2216 plates stored at 4°C. Long-term preservation of cultures can be accomplished in marine broth supplemented with 30% glycerol at –80°C.

Differentiation of the genus *Formosa* from other genera

Differential phenotypic features for the genus *Formosa* and its close relatives within the family *Flavobacteriaceae* are presented in Table 46. For most flavobacteria, determining generic affiliation based on phenotypic traits is difficult because of the great variation among species. A polyphasic taxonomic approach is recommended to differentiate different members of *Flavobacteriaceae*. Species of *Formosa* share many similar phenotypic features with species of *Algibacter* and *Gaetbulibacter*. In contrast to *Formosa*, *Psychroserpens burtonensis* (Bowman et al., 1997) has a characteristic cell morphology, a non-saccharolytic metabolism, and a low DNA G+C content. Strains of *Gelidibacter algens* have different cell morphology and also contain significant levels of characteristic C_{15:1} anteiso ω10c and C_{17:1} anteiso ω7c fatty acids.

Taxonomic comments

The level of rRNA gene sequence similarity between *Formosa algae* KMM 3553^T and *Formosa agariphila* KMM 3901^T is 98.9–99.1%.

Differentiation of species of the genus *Formosa*

The identification of novel isolates as existing species of *Formosa* may be problematic due to high interspecies variation in phenotypic characteristics, as occurs, for example, in *Formosa agariphila*. The correct allocation of newly discovered taxa will require partial and/or full sequencing of 16S rRNA genes and DNA–DNA hybridization. The differential characteristics of species of *Formosa* are given in Table 47.

*Medium B contains: Bacto peptone (Difco), 0.02 g; casein hydrolysate (Merck), 0.02 g; Bacto yeast extract (Difco), 0.02 g; 0.1% glucose, 0.01 g; KH₂PO₄, 0.002 g; MgSO₄·7H₂O, 0.0005 g; Bacto agar (Difco), 15 g; 500 ml natural seawater and 500 ml distilled water; pH 7.5–7.8.

All strains are negative for the following characteristics: flexirubin pigments; urease activity; nitrate reduction; H₂S, indole, and acetoin production; hydrolysis of casein, cellulose (CM-cellulose and filter paper), chitin, Tween 80, and DNA; acid formation from L-arabinose, cellobiose, D-lactose, melibiose, raffinose, L-rhamnose, L-sorbose, sucrose, acetate, citrate, fumarate, malate, adonitol, inositol, and sorbitol; utilization of sucrose, inositol, sorbitol, citrate, and malonate; and susceptibility to benzylpenicillin, gentamicin, kanamycin, neomycin, polymyxin B, and streptomycin.

List of species of the genus *Formosa*

- 1. *Formosa algae*** Ivanova, Alexeeva, Flavier, Wright, Zhukova, Gorshkova, Mikhailov, Nicolau and Christen 2004, 707^{VP} emend. Nedashkovskaya, Kim, Vancanneyt, Snauwaert, Lysenko, Rohde, Frolova, Zhukova, Mikhailov, Bae, Oh and Swings 2006d, 166

al'gae. L. fem. gen. n. *algae* of an alga, pertaining to the source of isolation, brown algae.

Characteristics are as described for the genus plus the following features. Exhibits gliding motility. Colonies are light yellow, circular, 1–3 mm in diameter, and low-convex on solid media containing high nutrient concentrations. Produces carotenoid pigments with absorbance peaks at 455 and 480 nm. Flexirubin pigments are absent. No growth is detected at 2 or 37°C; optimum growth is at 23°C. Grows at pH 5.0–10.0; optimum pH is 8.0–8.5. Alkalitolerant. Grows in 0–6% NaCl. Does not hydrolyze agar or chitin. Starch, gelatin, and urea are weakly hydrolyzed. Hydrolyzes esculin and Tween 40. Acid is produced from L-fucose, D-glucose, maltose, DL-xylose, and mannitol, but not from L-arabinose, cellobiose, D-lactose, melibiose, raffinose, L-rhamnose, L-sorbose, sucrose, acetate, citrate, fumarate, malate, adonitol, inositol, or sorbitol. Utilizes D-mannose, but not sucrose, inositol, sorbitol, citrate, or malonate (API identification system; bioMérieux). H₂S, indole, and acetoin (Voges–Proskauer reaction) are not produced. Nitrate can be reduced to nitrite. According to the Biolog system, utilizes Tween 40, D-galactose, gentiobiose, α-D-glucose, monosuccinate, citric acid, D-glucuronic acid, succinamic acid, succinic acid, alaninamide, glycyl-L-aspartic acid, hydroxy-L-proline, L-ornithine, L-pyroglutamic acid, urocanic acid, thymidine, 2-aminoethanol, and glycerol. Does not utilize α-cyclodextrin, dextrin, glycogen, Tween 80, N-acetyl D-glucosamine, adonitol, cellobiose, L-arabinose, D-arabitol, i-erythritol,

D-fructose, L-fucose, *myo*-inositol, α-D-lactose, lactulose, maltose, D-mannitol, D-mannose, melibiose, methyl α-D-glucoside, D-psicose, raffinose, L-rhamnose, D-sorbitol, sucrose, trehalose, turanose, xylitol, acetic acid, *cis*-aconitic acid, formic acid, D-galactonic acid lactone, D-galacturonic acid, D-glucosaminic acid, D-glucuronic acid, α-hydroxybutyric acid, β-hydroxybutyric acid, γ-hydroxybutyric acid, *p*-hydroxyphenylacetic acid, itaconic acid, α-ketoglutaric acid, α-ketobutyric acid, α-ketovaleric acid, DL-lactic acid, malonic acid, propionic acid, quinic acid, D-saccharic acid, sebacic acid, bromosuccinic acid, glucuronamide, D-alanine, L-alanine, L-alanyl-glycine, L-asparagine, L-aspartic acid, L-glutamic acid, L-histidine, L-leucine, L-ornithine, L-phenylalanine, L-proline, D-serine, L-serine, L-threonine, DL-carnitine, γ-aminobutyric acid, inosine, uridine, phenylethylamine, 2,3-butanediol, DL-α-glycerol phosphate, α-D-glucose 1-phosphate, or D-glucose 6-phosphate. Not susceptible to ampicillin, lincomycin, benzylpenicillin, kanamycin, oleandomycin, tetracycline, neomycin, streptomycin, gentamicin, or polymyxin B. Phosphatidylethanolamine is the only phospholipid identified. Sphingophospholipids are absent.

- 2. *Formosa agariphila*** Nedashkovskaya, Kim, Vancanneyt, Snauwaert, Lysenko, Rohde, Frolova, Zhukova, Mikhailov, Bae, Oh and Swings 2006d, 166^{VP}
a.ga.ri.phi'la. N.L. neut. n. *agarum* agar; Gr. adj. *philos* loving; N.L. fem. adj. *agariphila* agar-loving.

Cells are 0.4–0.6 μm in width, 0.8–1.2 μm in length, and can be connected by thread-like structures. Budding morphology may be observed. On marine agar, colonies are 2–4 mm in

diameter, yellow, circular, flat or convex, opaque or translucent, shiny with entire edges, and sunk into the agar. Growth occurs at 4–33°C; optimal temperature for growth is 21–23°C. Growth occurs in 1–8% NaCl. Agar, gelatin, and esculin are hydrolyzed, but not casein, DNA, Tween 80, cellulose (CM-cellulose and filter paper), or chitin. Acid is formed from L-fucose, D-galactose, D-glucose, maltose, DL-xylose, and mannitol, but not from L-arabinose, cellobiose, D-lactose, melibiose, L-rhamnose, raffinose, L-sorbose, sucrose, adonitol, glycerol, dulcitol, inositol, or sorbitol. Utilizes L-arabinose, D-lactose, D-mannose, and sucrose, but not inositol, sorbitol, malonate,

or citrate. Produces β -galactosidase. Nitrate is not reduced to nitrite. H₂S, indole, and acetoin (Voges–Proskauer reaction) production are not produced. Some strains are susceptible to ampicillin, carbenicillin, lincomycin, and oleandomycin. Resistant to benzylpenicillin, gentamicin, kanamycin, neomycin, polymyxin B, tetracycline, and streptomycin.

Source: algae and seawater.

DNA G+C content (mol%): 35–36 (T_m).

Type strain: KMM 3901, KCTC 12365, LMG 23005, DSM 15362.

Sequence accession no. (16S rRNA gene): AY187688.

Genus XXII. *Gaetbulibacter* Jung, Kang, Lee, Lee, Oh and Yoon 2005, 1848^{VP}

THE EDITORIAL BOARD

Gaet.bu.li.bac'ter. N.L. n. *gaetbulum -i* gaetbul, the Korean name for a tidal flat; N.L. masc. n. *bacter* from Gr. neut. n. *baktron* rod; N.L. masc. n. *Gaetbulibacter* rod isolated from a tidal flat.

Rods, 0.4–0.5 × 3.0–4.5 μ m. Non-flagellated. **Gliding motility is present.** Nonsporeforming. Gram-stain-negative. Aerobic. Growth also occurs under anaerobic conditions on marine agar and on marine agar with nitrate. Colonies are yellow. Flexirubin pigments are absent. Optimal pH is 7.0–8.0; weak growth at pH 5.5; no growth at pH 5.0. **NaCl range for growth is 0–7%;** optimum is 2–5%, but no growth is seen at >8%. Catalase- and oxidase-positive. Urease-negative. Nitrate is reduced. Starch is hydrolyzed, but not casein or gelatin. Acid is produced from a variety of carbohydrates. The predominant menaquinone is MK-6. Isolated from tidal flat sediments.

DNA G+C content (mol%): 34.7–34.9 (HPLC).

Type species: *Gaetbulibacter saemankumensis* Jung, Kang, Lee, Lee, Oh and Yoon 2005, 1848^{VP}.

Further descriptive information

Jung et al. (2005) reported that growth occurred under anaerobic conditions after incubation in an anaerobic chamber on both marine agar (Difco) and on marine agar supplemented with nitrate, both of which had been prepared anaerobically using nitrogen.

Gaetbulibacter strains are sensitive to the following antibiotics (concentration per disc is given in parentheses): lincomycin (15 μ g), benzylpenicillin (10 U), and carbenicillin (25 μ g). They are resistant to ampicillin (10 μ g), gentamicin (10 μ g), polymyxin B (300 U), streptomycin (30 μ g), tetracycline (30 μ g), and neomycin (15 μ g).

Enrichment and isolation procedures

The three available strains of *Gaetbulibacter saemankumensis* were isolated by the dilution plating technique on marine agar 2216 (Difco), with incubation at 30°C.

Differentiation of the genus *Gaetbulibacter* from related genera

The ability of *Gaetbulibacter* strains to reduce nitrate distinguishes them from members of the genera *Algibacter*, *Bizionia*, and *Formosa*. Unlike members of the genus *Bizionia*, *Gaetbulibacter* strains have gliding motility, form acid from carbohydrates, hydrolyze starch, do not hydrolyze casein or gelatin, and fail to produce H₂S. *Gaetbulibacter* strains differ from those of *Algibacter* by growing in the presence of 7% NaCl and by their failure to hydrolyze gelatin. They differ from *Formosa* strains by growing in the presence of 7% NaCl and by lacking urease activity.

Taxonomic comments

By 16S rRNA gene sequence analysis, the closest neighbors of *Gaetbulibacter saemankumensis* are *Algibacter lectus* (94.9% sequence similarity), *Bizionia paragorgiae* (94.5%), and *Formosa algae* (93.8%).

DNA–DNA relatedness values among the three available strains of *Gaetbulibacter saemankumensis* ranged from 83 to 106%, indicating that the strains are members of the same species (Jung et al., 2005).

List of species of the genus *Gaetbulibacter*

1. *Gaetbulibacter saemankumensis* Jung, Kang, Lee, Lee, Oh and Yoon 2005, 1848^{VP}

sae.man.kum.en'sis. N.L. masc. adj. *saemankumensis* of or belonging to Saemankum, from where the organism was originally isolated.

Characteristics are as given for the genus, with the following additional features. Esculin, tyrosine, and Tween 20 are hydrolyzed, but not hypoxanthine, xanthine, or Tweens 40, 60, and 80. The following enzyme activities are present (API ZYM system): *N*-acetyl- β -glucosaminidase, acid phosphatase, alkaline phosphatase, cystine arylamidase, esterase (C4),

esterase lipase (C8), α -glucosidase, lipase (C14), leucine arylamidase, and valine arylamidase. Activities of the following enzymes are not found: α -galactosidase, β -galactosidase, β -glucuronidase, α -mannosidase, α -fucosidase, naphthol-AS-BI-phosphohydrolase, and trypsin. α -Chymotrypsin and β -glucosidase activities differ among strains (absent in the type strain). The following compounds are utilized as sole carbon and energy sources: cellobiose, D-fructose, D-galactose, D-glucose, L-rhamnose, and D-xylose. The following compounds are not utilized: L-alanine, L-asparagine, D-gluconic acid, glycerol, L-malic acid, melibiose, propionic

acid, pyruvic acid, raffinose, L-serine, D-sorbitol, succinic acid, and trehalose. Utilization of maltose, L-proline, and sucrose differs among strains (positive for the type strain). Acid is produced from cellobiose, D-galactose, lactose, and maltose, but not from L-arabinose, D-fructose, D-mannitol, melezitose, melibiose, *myo*-inositol, raffinose, D-ribose, D-sorbitol, trehalose, or D-xylose. Acid production differs among strains for D-glucose and sucrose (positive for the type strain) and for D-mannose and L-rhamnose (negative

for the type strain). The major cellular fatty acids are C_{15:0} iso, C_{17:0} iso 3-OH, C_{15:1} iso, C_{15:0} anteiso, C_{15:0} iso 3-OH, and C_{16:1} ω7c and/or C_{15:0} iso 2-OH.

Source: the type strain was isolated from tidal flat sediment at Saemankum, Pyunsan, Korea.

DNA G+C content (mol%): 34.7–34.9 (HPLC).

Type strain: SMK-12, DSM 17032, KCTC 12379.

Sequence accession no. (16S rRNA gene): AY883937 (type strain).

Genus XXIII. *Gelidibacter* Bowman, McCammon, Brown, Nichols and McMeekin 1997, 675^{VP}

JOHN P. BOWMAN

Ge.li.di.bac'ter. L. adj. *gelidus* ice-cold or icy; N.L. masc. n. *bacter* rod; N.L. masc. n. *Gelidibacter* ice-cold or icy rod.

Cells are **rod-shaped or filamentous with rounded ends**, 0.4–0.6 × 1–15 μm. **Gram-stain-negative**. Cells occur singly, in pairs, and occasionally in chains. Spores and resting cells are not present. Gas vesicles and helical or ring-shaped cells are not formed. **Motile by gliding. Strictly aerobic, with an oxidative type of metabolism. Catalase-positive. Oxidase-negative. Chemoheterotrophic. Colonies are yellow** due to production of carotenoids. **Flexirubin pigments are not produced**. Strains **require Na⁺** for good growth. Best growth occurs in organic media containing seawater salts. Hydrolyze esculin, produce glutamate decarboxylase, and utilize D-glucose, glycogen and L-proline. Growth occurs between <4 and 25°C (optimum, 20–25°C). Neutrophilic, with optimal growth occurring at pH 7.0–7.5. The major fatty acids include C_{15:1} ω10c iso, C_{15:1} ω10c anteiso, C_{15:0} iso, C_{15:0} anteiso, C_{16:1} ω7c, and C_{16:0} 3-OH iso. The major polyamine is **homospermidine** and the major isoprenoid quinone is **menaquinone-6**. The organisms inhabit seawater, polar sea-ice, polar saline lakes, and quartz stone sublithic communities from maritime, ice-free areas of Antarctica.

DNA G+C content (mol%): 37–42.

Type species: ***Gelidibacter algens*** Bowman, McCammon, Brown, Nichols and McMeekin 1997, 675^{VP}.

Further descriptive information

The genus *Gelidibacter* is a member of the family *Flavobacteriaceae*. The first strains of the genus to be isolated were from several Antarctic marine samples and the genus is most closely related to other Antarctic genera, including *Subsaxibacter* and *Subsaximicrobium* (Bowman and Nichols, 2005). The genus contains four species: *Gelidibacter algens*, *Gelidibacter gilvus*, *Gelidibacter mesophilus*, and *Gelidibacter salicanalis*.

Gelidibacter species typically form pale to bright yellow colonies with a mucoid consistency and with a spreading margin. The species are all active gliders. Gliding motility is best seen on nutrient-poor media or media containing utilizable carbohydrates. Cells appear usually as rods of highly variant lengths from coccobacilli to filamentous cells up to 15–20 μm long. In older cultures, cells may degenerate into spheroplast-like bodies approximately 1–2 μm in diameter. This feature is particularly obvious in some strains of *Gelidibacter algens*.

Species in the genus *Gelidibacter* are strictly aerobic, saccharolytic chemoheterotrophs, but are also able to utilize a range of amino acids and organic acids. Amino acids are required for growth of some species; however, the specific amino acids

required are currently unknown. Thus, for growth on single carbon source media, yeast extract (approx. 0.1%) must be added. The ability to degrade macromolecules is present, although it varies considerably between species and even between strains. Acid is formed oxidatively from carbohydrates, although this can sometimes be weak. Acid production is best observed on a phenol red-containing oxidation/fermentation medium developed for marine bacteria (Leifson, 1963). Phenotypic tests that differentiate the species are shown in Table 48. All species synthesize several peptide arylamidases (Bowman and Nichols, 2005). *Gelidibacter* species do not denitrify, produce lipase (with olive oil as the substrate), or tolerate ox bile salts (1% concentration added to marine agar). Strains are also unable to degrade agar, alginate, carboxymethylcellulose, cellulose (crystalline power, filter paper), chitin, xylan, xanthine, or uric acid. *Gelidibacter* strains are usually negative for dextranase activity; however, equivocal results have been obtained on marine agar that contains dextran blue (Bowman et al., 1997). The following enzymic activities are not present among known *Gelidibacter* species: α-arabinosidase, β-glucuronidase, pyroglutamate arylamidase, lysine decarboxylase, and ornithine decarboxylase. H₂S is not formed from L-cysteine or thiosulfate, and indole is not produced. *Gelidibacter* species are unable to utilize the following carbon sources: L-fucose, salicin, valerate, citrate, itaconate, phenylacetate, caprate, adipate, suberate, DL-3-hydroxybutyrate, DL-lactate (some strains of *Gelidibacter algens* may exhibit weak growth on this substrate), or L-histidine. Due to weak growth on substrates and the need to add yeast extract to the medium for many strains, carbon source data should be considered with caution.

Gelidibacter species, like other members of the family *Flavobacteriaceae*, have menaquinone-6 as the major isoprenoid quinone, accumulate primarily the polyamine homospermidine (Hamana and Nakagawa, 2001), and possess primarily branched chain C₁₅–C₁₇ fatty acids (Table 49).

Gelidibacter species inhabit various polar marine and marine-derived ecosystems, including seawater, sea-ice (especially in samples rich in algae) (Bowman et al., 1997), saline polar lakes, and quartz stone sublithic communities (Bowman and Nichols, 2005; Smith et al., 2000). 16S rRNA gene clones of this genus are frequently recovered from these ecosystems, which suggests that the genus comprises numerically significant populations in various permanently cold, aerobic, marine niches (Brinkmeyer et al., 2003; Brown and Bowman, 2001; Groudieva

et al., 2004; Junge et al., 2002). Molecular analysis and cultural studies, however, indicate that this genus has a widespread distribution in the world's oceans. Members of the genus have been either isolated or detected in seawater, benthic and salt marsh sediment, and on the surfaces of microalgae, macroalgae and salmonid fish, in several (mainly temperate) locations (Madrid et al., 2001; Kelly and Chistoserdov, 2001; Bowman and Nowak, 2004; Macián et al., 2002; Pinhassi et al., 2003; various unpublished sources).

Enrichment and isolation procedures

No selective methods are available for direct isolation of *Gelidibacter* species. Empirical approaches for isolation can be achieved most simply by suspension and dilution of marine samples (as indicated above) followed by serial dilution onto marine agar (Difco Laboratories, Oxoid). Plates are incubated aerobically in the dark between 4 and 20°C. The appearance

of golden-yellow and orange colonies can be indicative of *Gelidibacter* strains, but identification requires further confirmation with phenotypic characterization and 16S rRNA gene sequence analysis.

Maintenance procedures

Strains can be maintained for many years cryopreserved in marine broth containing 20–30% glycerol. Strains can survive for many months, potentially years, on thick agar plates or on slants when stored at 2–4°C. Strains may also be maintained by lyophilization, although the survival level is somewhat variable if 20% skim milk is used as a cryoprotectant.

Differentiation of the genus *Gelidibacter* from other genera

The most useful traits for differentiating *Gelidibacter* from other members of the *Flavobacteriaceae* include yellow pigmentation, lack of flexirubin pigments, gliding motility, strictly oxidative metabolism, ability to form acid from carbohydrates, ability to grow at low temperatures (e.g., 4°C), requirement for Na⁺ for growth (or good growth on media containing sea salts), and lack of agarolytic activity. Several genera of the family *Flavobacteriaceae* possess at least some proportion of the above traits; thus, any phenotypic-based identifications are at best tentative and 16S rRNA gene sequencing is required for any definitive identification.

List of species of the genus *Gelidibacter*

1. ***Gelidibacter algens*** Bowman, McCammon, Brown, Nichols and McMeekin 1997, 675^{VP}
al'gens. L. part. adj. *algens* feeling cold, referring to the low temperature of the typical habitats of this species.
Characteristics are as given for the genus, as listed in Table 48, and as indicated in the text. In addition, peptones alone can support growth (1% peptone in seawater). Acid is formed oxidatively from D-mannose, starch, and (weakly) from dextran.
Source: sea-ice core, Ellis Fjord, Vestfold Hills, Antarctica (type strain).
DNA G+C content (mol%): 36–38 (T_m).
Type strain: ACAM 536, ATCC 700364.
Sequence accession no. (16S rRNA gene): U62914.
Additional remarks: sequence accession numbers (16S rRNA gene sequences) for *Gelidibacter algens* strains ACAM 550 and ACAM 551 are U62916 and U62915, respectively.
2. ***Gelidibacter gilvus*** Bowman and Nichols 2005, 1483^{VP}
gil'vus. L. masc. adj. *gilvus* pale yellow.
Characteristics are as given for the genus, as listed in Table 48, and as indicated in the text. In addition, *Gelidibacter gilvus* strains form pale yellow colonies, unlike other *Gelidibacter* species, which produce colonies with more intense pigmentation. Also, unlike other *Gelidibacter* species, colonies of *Gelidibacter gilvus* are very sticky, viscid, and gummy in consistency due to the copious production of a so-far uncharacterized, cell-attached exopolysaccharide. Acid is produced oxidatively from L-arabinose, D-mannose, D-galactose, D-fructose, L-rhamnose, D-xylose, D-mannitol, N-acetyl-D-glucosamine, cellobiose, lactose, maltose, sucrose, trehalose, melibiose, inositol, and glycerol, but not from melezitose, raffinose, dextran, adonitol, or D-sorbitol.
Source: sea-ice algae from fast sea-ice cores obtained from the coastal areas of the Vestfold Hills, an ice-free region of East Antarctica (type strain).
DNA G+C content (mol%): 39 (T_m).
Type strain: IC158, ACAM 1054, CIP 108531.
Sequence accession no. (16S rRNA gene): AF001369.
3. ***Gelidibacter mesophilus*** Macián, Pujalte, Márquez, Ludwig, Ventosa, Garay and Schleifer 2002, 1328^{VP}
me.so.phi'lus. Gr. n. *mesos* middle; Gr. adj. *philus* loving; N.L. masc. adj. *mesophilus* middle (temperature)-loving, mesophilic.
Characteristics are as given for the genus, as listed in Table 48, and as indicated in the text. Gliding motility is best observed on seawater mineral salts media containing carbohydrates, including L-rhamnose, raffinose, sucrose, cellobiose, or melibiose. In addition to those mentioned in Table 48, the following carbon sources are utilized: D-galactose, trehalose, L-rhamnose, sucrose, melibiose, cellobiose, lactose, and amygdalin.
Source: seawater from the Mediterranean coast of Valencia, Spain (type strain).
DNA G+C content (mol%): 39–40 (T_m).
Type strain: 2SM29, CECT 5103, DSM 14095.
Sequence accession no. (16S rRNA gene): AJ344133.
Additional remarks: the GenBank accession number for the 16S rRNA gene sequence of *Gelidibacter mesophilus* CECT 5104 (=2SM28) is AJ344134.
4. ***Gelidibacter salicanalis*** Bowman and Nichols 2005, 1484^{VP}
sal.i.can.a'lis. L. n. *sal salis* salt; L. n. *canalis -is* channel; N.L. gen. n. *salicanalis* of the salt channel, referring to the sea-ice brine channel habitat of this species.
Characteristics are as given for the genus, as listed in Table 48, and as indicated in the text. Colonies are golden with a smooth edge on nutrient-rich media. On nutrient-poor media (such as 0.1× marine agar), colonies have a more pronounced spreading margin indicative of gliding cells. Acid is produced from L-arabinose, D-mannose, D-galactose, N-acetyl-D-glucosamine, cellobiose, lactose, maltose, sucrose, and trehalose.
Source: sea-ice algae collected from pack-ice brine, Southern Ocean (type strain).
DNA G+C content (mol%): 42 (T_m).
Type strain: IC162, ACAM 1053, CIP 108532.
Sequence accession no. (16S rRNA gene): AY694009.

Genus XXIV. *Gillisia* Van Trappen, Vandecandelaere, Mergaert and Swings 2004a, 446^{VP}

STEFANIE VAN TRAPPEN

Gil.lis'i.a. N.L. fem. n. *Gillisia* named after Monique Gillis, a Belgian bacteriologist, who has made major contributions to bacterial taxonomy.

Rod-shaped cells, generally 0.5–0.7 × 3.0–4.0 μm (*Gillisia limnaea*, *Gillisia mitskevichiae*, and *Gillisia myxillae*) or 0.3–0.6 × 1.0–10.0 μm (*Gillisia illustrilutea*, *Gillisia sandarakina*, and *Gillisia hiemivivida*). **Gram-stain-negative**. Endospores are not produced. **Non-motile** by gliding. Strictly **aerobic** with respiratory metabolism. Chemo-organotrophic. Catalase-positive. Produce **yellow** or **orange pigments**. Flexirubin type pigments are not formed. **Halotolerant** to **halophilic**. Optimal growth occurs at 20–25°C, with the species *Gillisia illustrilutea* and *Gillisia sandarakina* being true **psychrophiles**. Strains are characterized by a **unique fatty acid composition**, with large amounts of branched fatty acids

(C_{15:0} anteiso, C_{15:1} iso, C_{16:0} iso, and C_{16:0} iso 3-OH are the main constituents).

DNA G+C content (mol%): 32–39.

Type species: ***Gillisia limnaea*** Van Trappen, Vandecandelaere, Mergaert and Swings 2004a, 447^{VP}.

Further descriptive information

16S rRNA gene sequence analysis demonstrates that the genus belongs to the family *Flavobacteriaceae*, with the genera *Algibacter*, *Aquimarina*, *Bizionia*, *Formosa*, *Mesonina*, *Psychroflexus*, *Salegentibacter*, *Stanierella*, and *Ulvibacter* as nearest neighbors.

Fatty acids. In the genus *Gillisia*, the most dominant fatty acids are branched fatty acids with C_{15:0} anteiso, C_{15:1} iso, C_{16:0} iso, and C_{16:0} iso 3-OH as the main constituents. However, the clear differences observed between *Gillisia limnaea* and *Gillisia mitskevichiae* on the one hand and *Gillisia illustrilutea*, *Gillisia sandarakina*, and *Gillisia hiemivivida* on the other (see Table 50) could be due to differences in growth conditions of the cultures that were used for fatty acid analysis. Strains of *Gillisia limnaea* and *Gillisia mitskevichiae* were grown on marine agar for 48 h at 20 or 25°C, whereas strains of *Gillisia illustrilutea*, *Gillisia sandarakina*, and *Gillisia hiemivivida* were cultivated on marine agar at 15 or 20°C for 3–5 d to yield sufficient cells. For *Gillisia myxillae*, the exact growth conditions of the culture that was used to determine the fatty acid composition are not known.

Colonial and cultural characters. On marine agar, species have yellow (light orange for *Gillisia sandarakina* and *Gillisia hiemivivida*) colonies that are circular and convex with diameters of 1–4 mm and entire margins. The pigments are non-diffusible. *Gillisia illustrilutea*, *Gillisia sandarakina*, and *Gillisia hiemivivida* form colonies with a butyrous consistency. For *Gillisia limnaea*, colonies on the AOA medium of Anacker and Ordal (1955) are flat, round with entire margins, and 0.7–0.9 mm in diameter after 14 d incubation.

Nutrition and growth conditions. *Gillisia* species are cold-adapted. For *Gillisia limnaea*, growth occurs at 5–25°C with

optimal growth at 20°C. The type strain of *Gillisia mitskevichiae* grows at 4–31°C with optimal growth at 25°C. The type strain of *Gillisia myxillae* grows at 4–28°C with optimal growth at 12–20°C; no growth occurs at 36°C or higher. Strains of *Gillisia illustrilutea* and *Gillisia sandarakina* grow at 1–20°C, but not at 25°C or higher, indicating that these species are true psychrophiles. For *Gillisia hiemivivida*, growth occurs at 1–25°C with no growth at 30°C or higher. *Gillisia illustrilutea*, *Gillisia sandarakina*, and *Gillisia hiemivivida* can also grow at –2°C in marine broth.

All species of the genus *Gillisia* can tolerate high salt concentrations with *Gillisia limnaea* and *Gillisia illustrilutea* being moderately halotolerant (growth occurs in up to 1.5 M NaCl), whereas the other species are halophilic (for *Gillisia mitskevichiae*, growth is dependent on 0.2–2.5 M NaCl; for *Gillisia myxillae*, growth occurs in 2.0–10.0% NaCl with an optimum of 4.0–6.0% NaCl; for *Gillisia sandarakina* and *Gillisia hiemivivida*, growth is dependent on 0.2–1.5 M NaCl).

Enrichment and isolation procedures

Species of the genus *Gillisia* have been isolated from several aquatic habitats and the surface of a marine sponge. The type species, *Gillisia limnaea*, was isolated from a microbial mat from Lake Fryxell in the McMurdo Dry Valleys in Antarctica. *Gillisia mitskevichiae* was derived from a seawater sample that was collected in Amursky Bay, Gulf of Peter the Great, Sea of Japan. The type strain of *Gillisia myxillae* was isolated from the surface of the marine sponge *Myxilla incrustans*. *Gillisia illustrilutea*, *Gillisia sandarakina*, and *Gillisia hiemivivida* were isolated from an Antarctic sea-ice algal assemblage. All strains were isolated on marine agar at relatively low temperatures (4–25°C) and with incubation for up to 14 d. For *Gillisia limnaea* and *Gillisia illustrilutea*, growth can also be obtained on trypticase soy agar (TSA), nutrient agar (NA), and the R2A medium of Reasoner and Geldreich (1985).

Maintenance procedures

Cultures can be maintained in the laboratory by transfer on the same media used for isolation. The recommended conditions for long-term storage are cryopreservation at –80°C or lyophilization.

Differentiation from closely related taxa

Table 51 indicates characteristics that are useful for distinguishing members of the genus *Gillisia* from related genera within the family *Flavobacteriaceae*.

Taxonomic comments

Based on 16S rRNA gene sequences of the type strains, the genus *Gillisia* forms a distinct lineage within the family *Flavobacteriaceae*, which is supported by a very high bootstrap value (100%; see Figure 42). The highest sequence similarities (89.5–91.3%) are found with members of the genera *Algibacter*, *Aquimarina*, *Bizionia*, *Formosa*, *Mesonina*, *Psychroflexus*, *Salegentibacter*, [*Stanierella*], and *Ulvibacter*. Sequence similarities within the genus *Gillisia* are clearly higher (around 93.0–98.0%).

Differentiation of species of the genus *Gillisia*

The differential characteristics of species of the genus *Gillisia* are presented in Table 52.

TABLE 50. Whole-cell fatty acid profiles of species of the genus *Gillisia*^a

Fatty acid	<i>G. limnaea</i>	<i>G. mitskevichiae</i>	<i>G. illustrilutea</i>	<i>G. sandarakina</i>	<i>G. hiemivivida</i>	<i>G. myxillae</i>

List of species of the genus *Gillisia*

1. *Gillisia limnaea* Van Trappen, Vandecandelaere, Mergaert and Swings 2004a, 447^{VP}

lim.nae'a. Gr. adj. *limnaios* of or from the marsh; N.L. fem. adj. *limnaea* living in the water, referring to the isolation source, microbial mats in Lake Fryxell.

The morphological characteristics are as described for the genus. Cells are 0.7 μm wide and 3.0 μm long. Grows at 5–25°C; optimal growth at 20°C. Weak growth is observed at 30°C and no growth occurs at 37°C. Convex, translucent colonies with diameters of 1–3 mm and entire margins are formed on marine agar plates after 6 d. Colonies on AOA are flat, round with entire margins, and 0.7–0.9 mm in diameter after 14 d. Growth also occurs on nutrient agar and R2A and colonies do not adhere to the agar. No growth on TSA. Growth occurs in up to 5% NaCl, but not in 10% NaCl. The physiological and nutritional characteristics of *Gillisia limnaea* are presented in Table 52. Positive for cytochrome oxidase, catalase, and β -galactosidase. Esculin and gelatin are hydrolyzed. Acids are not produced from carbohydrates.

Source: the type strain was isolated from microbial mats, Lake Fryxell, Antarctica.

DNA G+C content (mol%): 37.8–38.9 (HPLC; Mesbah et al., 1989).

Type strain: LMG 21470, DSM 15749.

Sequence accession no. (16S rRNA gene): AJ440991.

2. *Gillisia hiemivivida* Bowman and Nichols 2005, 1485^{VP}

hi.em.i.vi.vi'da. L. fem. n. *hiems -emis* the cold (of winter); L. fem. adj. *vivida* lively; N.L. fem. adj. *hiemivivida* lively in the cold.

The morphological characteristics are as described for the genus. Cells are 0.4–0.6 μm wide and 1.0–7.0 μm long. Growth occurs at 22°C in marine broth. Good growth occurs on marine agar at 1–25°C. No growth occurs at 30°C or higher. Colonies are circular and convex, with entire edges and butyrous consistency on marine agar. Requires sea salts for growth. Media supplemented only with Na⁺ ions do not support growth. Grows in media containing 0.2–1.5 M NaCl, with optimal growth occurring in approximately

0.3–0.5 M NaCl. Grows in media prepared with 2× strength sea salts, but no growth occurs in 4× strength sea salts. Does not grow on TSA containing 1% (w/v) NaCl, TSA, or NA. Does not require yeast extract for growth. Can use inorganic nitrogen sources such as sodium nitrate and ammonium chloride. The physiological and nutritional characteristics of *Gillisia hiemivivida* are presented in Table 52. In mineral salts growth media, can utilize D-glucose, glycogen, N-acetylglucosamine, DL-arabinose, D-mannose, maltose, sucrose, sodium propionate, L-alanine (weak growth), and L-proline as sole carbon and energy sources. Hydrolyzes gelatin, starch, Tween 80, L-tyrosine, and urea. Produces α -glucosidase, β -glucosidase, and alkaline phosphatase.

Source: the type strain was isolated from sea-ice algae collected from fast sea cores obtained from the coastal areas of the Vestfold Hills, an ice-free region of East Antarctica.

DNA G+C content (mol%): 34.0 (T_m ; Sly et al., 1986).

Type strain: IC154, ACAM 1061, CIP 108528.

Sequence accession no. (16S rRNA gene): AY694006.

3. ***Gillisia illustrilutea*** Bowman and Nichols 2005, 1484^{VP}

il.lus.tri.lu.te'a. L. adj. *illustris* bright; L. fem. adj. *lutea* yellow; N.L. fem. adj. *illustrilutea* bright yellow.

The morphological characteristics are as described for the genus. Cells are 0.3–0.5 μm wide and 1.0–10.0 μm long. Growth occurs at 22°C in marine broth. Good growth occurs on marine agar at 1–20°C. No growth occurs at 25°C or higher. Colonies are circular and convex, with entire edges and a butyrous consistency on marine agar. Not halophilic. Grows in 0–1.25 M NaCl, with optimal growth occurring in approximately 0.2–0.3 M NaCl. Grows in media prepared with 2× strength sea salts, whereas no growth occurs in 4× strength sea salts. Grows on TSA containing 1% (w/v) NaCl, TSA, and NA. Does not require yeast extract for growth and can use inorganic nitrogen sources such as sodium nitrate and ammonium chloride. The physiological and nutritional characteristics of *Gillisia illustrilutea* are presented in Table 52. In mineral salts growth media, can utilize D-glucose, D-mannose, maltose, sucrose, sodium propionate, and L-proline as sole carbon and energy sources. Hydrolyzes DNA and produces α -galactosidase, α -glucosidase, and β -glucosidase.

Source: the type strain was isolated from sea-ice algae collected from fast sea cores obtained from the coastal areas of the Vestfold Hills, an ice-free region of East Antarctica.

DNA G+C content (mol%): 32.0 (T_m ; Sly et al., 1986).

Type strain: IC157, ACAM 1062, CIP 108530.

Sequence accession no. (16S rRNA gene): AY694008.

4. ***Gillisia mitskevichiae*** Nedashkovskaya, Kim, Lee, Mikhailov and Bae 2005c, 322^{VP}

mit.ske.vi'chi.ae. N.L. gen. fem. n. *mitskevichae* of Mitskevich, named in honor of Irina N. Mitskevich, Russian marine microbiologist, for her contributions to the development of marine microbiology.

The morphological characteristics are as described for the genus. Cells are 0.5–0.7 μm wide and 3.0–4.0 μm long. Growth occurs at 4–31°C. Colonies are circular, convex, and shiny with entire edges, 1–3 mm in diameter on marine agar 2216. No growth is observed without Na⁺; grows in 1–12% NaCl. The pH range for growth is 5.5–10.0, with optimum

growth occurring between pH 7.6 and 8.3. The physiological and nutritional characteristics of *Gillisia mitskevichiae* are presented in Table 52. Positive for oxidase, catalase, urease, and alkaline phosphatase. Casein, gelatin, DNA, urea, and Tweens 40 and 80 are degraded. Forms acid from glucose, sucrose, and N-acetylglucosamine. Susceptible to ampicillin, carbenicillin, oleandomycin, lincomycin, streptomycin, and tetracycline; resistant to kanamycin, benzylpenicillin, neomycin, gentamicin, and polymyxin B.

Source: the type strain was isolated from seawater collected in Amursky Bay, Gulf of Peter the Great, Sea of Japan.

DNA G+C content (mol%): 36.4 (T_m ; Marmur and Doty, 1962).

Type strain: KMM 6034, KCTC 12261, NBRC 100590, LMG 22575.

Sequence accession no. (16S rRNA gene): AY576655.

5. ***Gillisia myxillae*** Lee, Lau, Tsoi, Li, Plakhotnikova, Dobretsov, Wu, Wong and Qian 2006b, 1797^{VP}

my.xil'lae. N.L. fem. n. *Myxilla* systematic name of a genus of sponges; N.L. gen. fem. n. *myxillae* of/from *Myxilla*, referring to the isolation of the type strain from the sponge *Myxilla incrustans*.

The morphological characteristics are as described for the genus. Cells are 0.5 μm wide and 1.3–2.0 μm long. Growth occurs at 4–28°C, with optimum growth occurring between 12.0 and 20.0°C. Colonies are circular, convex with a smooth surface and entire edges, and 2–4 mm in diameter on marine agar. No growth is observed without Na⁺; grows in 2–10% NaCl. The pH range for growth is 5.0–10.0, with optimum growth occurring between pH 7.0 and 9.0. The physiological and nutritional characteristics of *Gillisia myxillae* are presented in Table 52. Positive for oxidase, catalase, lipase (C14), and tryptophan deaminase. Casein, starch, DNA, and Tweens 20 and 40 are degraded. Susceptible to benzylpenicillin, chloramphenicol, ampicillin, and tetracycline; resistant to streptomycin and kanamycin.

Source: the type strain was isolated from the surface of the marine sponge, *Myxilla incrustans*, Friday Harbor, San Juan Island, WA.

DNA G+C content (mol%): 34.6 (HPLC; Mesbah et al., 1989).

Type strain: JCM 13564, NRRL B-41416.

Sequence accession no. (16S rRNA gene): DQ202393.

6. ***Gillisia sandarakina*** Bowman and Nichols 2005, 1484^{VP}

san.da.ra.kin'a. N.L. fem. adj. *sandarakina* (from Gr. fem. adj. *sandarakinē*) of orange color.

The morphological characteristics are as described for the genus. Cells are 0.4–0.5 μm wide and 1.0–10.0 μm long. Growth occurs at 22°C in marine broth. Good growth occurs on marine agar at 1–20°C. No growth occurs at 25°C or higher. Colonies are small (1 mm diameter), circular, and convex, with entire edges and butyrous consistency on marine agar. Requires sea salts for growth. Media supplemented only with Na⁺ ions do not support growth. Grows in 0.2–1.5 M NaCl, with optimal growth occurring in approximately 0.3–0.5 M NaCl. Grows in media prepared with 2× strength sea salts, but no growth occurs with 4× strength sea salts. Does not grow on TSA, TSA containing 1% (w/v)

NaCl, or NA. Does not require yeast extract for growth and can use inorganic nitrogen sources such as sodium nitrate and ammonium chloride. The physiological and nutritional characteristics of *Gillisia sandarakina* are presented in Table 52. In mineral salts growth media, can utilize D-glucose, DL-arabinose, D-mannose, sodium propionate (weak growth), and L-proline as sole carbon and energy sources. Hydrolyzes gelatin, starch, Tween 80, and L-tyrosine. Produces

α -glucosidase, β -glucosidase, and alkaline phosphatase. Reduces nitrate to nitrite.

Source: the type strain was isolated from sea-ice algae collected from fast sea cores obtained from the coastal areas of the Vestfold Hills, an ice-free region of East Antarctica
DNA G+C content (mol%): 36.0 (T_m ; Sly et al., 1986).
Type strain: IC148, ACAM 1060, CIP 108529.
Sequence accession no. (16S rRNA gene): AY694007.

Genus XXV. *Gramella* Nedashkovskaya, Kim, Lysenko, Frolova, Mikhailov, Bae, Lee and Kim 2005e, 393^{VP}

OLGA I. NEDASHKOVSKAYA, SEUNG BUM KIM AND VALERY V. MIKHAILOV

Gra.me'l'a. N.L. dim. fem. n. *Gramella* named after of the Danish pharmacologist and pathologist Hans Christian Gram (1853–1938), who proposed the differential staining of bacteria.

Thin rods usually measuring 0.5–0.7 × 2.1–3.6 μ m. **Motile by means of gliding.** Produce non-diffusible yellow–orange pigments. No flexirubin type of pigments are produced. **Chemo-organotrophs. Strictly aerobic.** Halophilic. Positive for oxidase, catalase, and alkaline phosphatase. Arginine dihydro-lase, and lysine and ornithine decarboxylases are not produced. Agar, urea, and chitin are not hydrolyzed. **The major respiratory quinone is MK-6.** **Marine,** from coastal habitats. Require seawater or sodium ions for growth.

DNA G+C content (mol%): 39–40.

Type species: *Gramella echinicola* Nedashkovskaya, Kim, Lysenko, Frolova, Mikhailov, Bae, Lee and Kim 2005e, 393^{VP}.

Further descriptive information

Phylogenetic analysis based on 16S rRNA gene sequences indicated that the genus *Gramella* forms a cluster with species of the genera *Salegentibacter* and *Mesonina* (Lau et al., 2005c; Nedashkovskaya et al., 2005e). The 16S rRNA gene sequence similarity between *Gramella echinicola* KMM 6050^T and *Gramella portivictoriae* UST040801-001^T is 98%. The level of DNA–DNA reassociation between strains KMM 6050^T and UST040801-001^T is 13% (Lau et al., 2005c).

The main cellular fatty acids are straight-chain unsaturated and branched-chain unsaturated fatty acids (C_{15:0} anteiso, C_{15:0} iso, C_{15:0}, C_{16:0} iso, C_{16:0} iso 3-OH, C_{17:0} iso 3-OH, and summed feature 3 comprising C_{15:0} iso 2-OH and/or C_{16:1} ω 7c).

On marine agar 2216 (Difco), colonies are regular, round, convex, smooth, nontransparent, and bright orange or yellow, with entire edges and diameters of 2–4 mm after 48 h at 28–30°C.

All isolated strains have been grown on media containing 0.5% peptone and 0.1–0.2% yeast extract (Difco), prepared with native or artificial seawater or supplemented with 2–3% NaCl. Good growth is observed on marine agar 2216 (Difco). Growth is observed at 4–37°C. The optimum temperature for growth is 23–30°C. Growth occurs in 1–15% NaCl and at pH 6.0–10.0 (optimum pH 7.0–8.0).

Gramella strains are susceptible to tetracycline, but resistant to kanamycin and streptomycin. Some strains may be susceptible to ampicillin, chloramphenicol, doxycycline, erythromycin, neomycin, and penicillin, but resistant to gentamicin, carbenicillin, lincomycin, oleandomycin, and polymyxin B.

The gramellas inhabit coastal marine environments and have been isolated from the sea urchin (*Strongylocentrotus intermedius*) and sediments collected in the temperate latitudes.

Enrichment and isolation procedures

Gramella strains were isolated from echinoderms and sediment samples by direct plating on marine agar (Difco). Either natural or artificial seawater is suitable for their cultivation. All isolated strains have been grown on media containing 0.5% peptone and 0.1–0.2% yeast extract (Difco). Cultures may stay alive on marine agar or other rich medium based on natural or artificial seawater for several weeks. They have survived storage at –80°C for at least 5 years.

Differentiation of the genus *Gramella* from other genera

There are many common traits between the genus *Gramella* and its closest relatives, *Mesonina algae* and *Salegentibacter* species. However, *Gramella* strains differ from *Mesonina* strains by their ability to hydrolyze starch and by a higher DNA G+C content (Nedashkovskaya et al., 2003a). Members of the genus *Gramella* may be distinguished from those of the genus *Salegentibacter* by production of H₂S and by a higher DNA G+C content (Dobson et al., 1993; McCammon and Bowman, 2000; Nedashkovskaya et al., 2004g, 2005e, h, 2006c).

Acknowledgements

We thank Dr Pei-Yuan Qian from Coastal Marine Laboratory/ Department of Biology, The Hong Kong University of Science and Technology for kind providing us with the micrograph of strain *Gramella portivictoriae* UST040801-001^T.

List of species of the genus *Gramella*

1. *Gramella echinicola* Nedashkovskaya, Kim, Lysenko, Frolova, Mikhailov, Bae, Lee and Kim 2005e, 393^{VP}
e.chi.ni.co'la. L. n. *echinus* a hedgehog, a sea urchin; L. suff. -cola (from L. n. incola) dweller; N.L. n. *echinicola* a sea-urchin-dweller.

Cells are 0.5–0.7 × 2.1–2.7 μ m. On marine agar, colonies are 2–4 mm in diameter, circular, shiny with entire edges, and yellow–orange in color. Growth occurs at 4–37°C. Hydrolyzes gelatin, starch, and Tweens 40 and 80, but not agar, urea, or chitin. No acid is formed from L-arabinose, cellobiose,

L-fucose, D-lactose, melibiose, L-rhamnose, DL-xylose, citrate, adonitol, dulcitol, glycerol, inositol, or mannitol. Does not utilize D-lactose, D-mannose, inositol, malonate, or citrate. Nitrate is not reduced. H₂S and indole are not produced.

Source: the only available strain was isolated from the sea urchin *Strongylocentrotus intermedius* in Troitsa Bay, Sea of Japan.

DNA G+C content (mol%): 39.6 (T_m).

Type strain: KMM 6050, KCTC 12278, NBRC 100593, LMG 22585.

Sequence accession no. (16S rRNA gene): AY608409.

2. ***Gramella portivictoriae*** Lau, Tsoi, Li, Plakhotnikova, Dobretsov, Wong and Qian 2005c, 2499^{VP}

por.ti.vic.to'ri.ae. L. n. *portus* harbor; L. gen. fem. n. *victoriae* of victory; N.L. gen. fem. n. *portivictoriae* of Victoria Harbor, Hong Kong, the source of isolation of the type strain.

According to Lau et al. (2005c), cells of the type strain are 0.6 µm wide and 3.6 µm long Figure 43. On marine agar, colonies are 2–4 mm in diameter, circular, convex with smooth surfaces, and yellow. Growth is observed at 4–36°C. Growth occurs at pH 6.0–10.0 (optimum, 7.0–8.0). Esculin, gelatin, starch, and Tweens 40 and 80 are hydrolyzed, but not agar, urea, or chitin. D-Galactose, D-glucose, sucrose, and glycerol, but not citrate, are used as sole carbon sources on agar media supplemented with 4% (w/v) carbon source. Utilization of γ-hydroxybutyric acid is observed with the MicroLog 3 system. No growth or acid production occurs with carbon sources in the API 50CH, API 20E, and API 20NE test systems. Positive for the following enzyme activities: acid phosphatase; α-chymotrypsin; cystine, leucine, and valine arylamidases; esterase (C4); esterase lipase (C8); lipase (C14); α-galactosidase; α- and β-glucosidases; trypsin; and naphthol-AS-BI-phosphohydrolase. Negative for N-acetyl-β-glucosaminidase,

FIGURE 43. Micrograph of strain *Gramella portivictoriae* UST040801-001^T showing the rod-shaped morphology; bar = 1 µm. (Printed with permission of P.-Y. Qian.)

α-fucosidase, β-glucuronidase, α-mannosidase, and tryptophan deaminase activities. Nitrate is not reduced. H₂S and indole are not produced. Susceptible to chloramphenicol and tetracycline. Resistant to kanamycin and streptomycin.

Source: the only available strain was isolated from sediment in Victoria Harbor, Hong Kong, South-China Sea.

DNA G+C content (mol%): 39.9 (T_m).

Type strain: UST040801-001, JCM 13192, NRRL B-41137.

Sequence accession no. (16S rRNA gene): DQ002871.

Genus XXVI. ***Kaistella*** Kim, Im, Shin, Lim, Kim, Lee, Park, Lee and Lee 2004, 2323^{VP}

THE EDITORIAL BOARD

Ka.is.tel'la. L. dim. suff. *-ella*; N.L. fem. dim. n. *Kaistella* arbitrary name after KAIST, Korea Advanced Institute of Science and Technology.

Rod-shaped cells. Nonsporeforming. Gram-stain-negative. Flagella not present. Aerobic. Colonies are yellow. Catalase- and oxidase-positive. **No growth occurs on MacConkey agar.** Nitrate is not reduced to N₂. **Indole-positive.** **β-Glucosidase-positive.** Negative for arginine dihydrolase and β-galactosidase. **No acid is produced from glucose.** Esculin and gelatin are hydrolyzed, but not starch. Glucose, arabinose, and β-hydroxybutyrate are not assimilated. The major isoprenoid quinone is MK-6. Isolated from freshwater.

DNA G+C content (mol%): 41–42.

Type species: ***Kaistella koreensis*** Kim, Im, Shin, Lim, Kim, Lee, Park, Lee and Lee 2004, 2323^{VP}.

Further descriptive information

The genus description is based on data for three strains. Analysis based on 16S rRNA gene sequences indicated that the genus *Kaistella* belongs to the *Chryseobacterium*–*Bergeyella*–*Riemerella* branch of the family *Flavobacteriaceae*.

Regarding the long-chain fatty acid content of *Kaistella*, C_{15:0} iso was dominant, with significant levels of C_{15:0} anteiso, C_{17:0} iso 3-OH, and C_{17:1} iso ω9c. *Kaistella* strains possessed the distinctive fatty acids C_{13:0} iso and C_{15:0} anteiso, similar to those found in members of the genera *Bergeyella* and *Riemerella*.

The following compounds are assimilated: acetate, adipate, L-alanine, caprate, citrate, glycogen, 4-hydroxybenzoate, inositol, itaconate, DL-lactate, malate, malonate, maltose, mannitol, phenylacetate, L-proline, propionate, rhamnose, and suberate. No assimilation of the following occurs: N-acetylglucosamine, arabinose, fucose, glucose, histidine, 3-hydroxybenzoate, β-hydroxybutyrate, 2-ketogluconate, 5-ketogluconate, mannose, melibiose, D-ribose, salicin, L-serine, sorbitol, D-sucrose, and valerate.

Differentiation of the genus *Kaistella* from other genera

Kaistella strains differ from those of *Chryseobacterium* in that they do not produce acid from glucose, lack β-galactosidase activity,

cannot hydrolyze starch or assimilate glucose, arabinose or 3-hydroxybutyrate, and cannot grow on MacConkey agar. *Kaistella* strains differ from those of *Bergeyella* and *Riemerella* in that they are indole-positive, have β -glucosidase activity, and grow aerobically on nutrient agar. Also, the DNA G+C contents of *Kaistella* strains are higher than those of *Chryseobacterium*, *Bergeyella*, and *Riemerella* species.

Taxonomic comments

Kaistella koreensis Chj707^T was most closely related to *Chryseobacterium balustinum* ATCC 33487^T and *Chryseobacterium scophthalmum* LMG 13028^T (94.3 and 94.1% 16S rRNA gene sequence similarities, respectively). Additional information can be found in Kim et al. (2004).

List of species of the genus *Kaistella*

1. ***Kaistella koreensis*** Kim, Im, Shin, Lim, Kim, Lee, Park, Lee and Lee 2004, 2323^{VP}

ko.re.en'sis. N.L. fem. adj. *koreensis* pertaining to Korea, where the organisms were first isolated.

The description is the same as that of the genus.

Source: the available strains were isolated from natural mineral water from Daejeon City, Korea.

DNA G+C content (mol%): 41.2–41.6 (HPLC).

Type strain: Chj707, IAM 15050, KCTC 12107.

Sequence accession no. (16S rRNA gene): AF344179 (type strain, partial sequence).

Additional remarks: the GenBank accession numbers for the 16S rRNA gene sequences of *Kaistella koreensis* strains Ko2 (=KCTC 12108=IAM 15051) and Ko10 (=KCTC 12109=IAM 15052) are AY294611 (complete sequence) and AY299974 (partial sequence), respectively.

Genus XXVII. *Kordia* Sohn, Lee, Yi, Chun, Bae, Ahn and Kim 2004, 678^{VP}

SANG-JIN KIM

Kor'di.a. N.L. fem. n. *Kordia* arbitrary name derived from the acronym KORDI, which stands for Korea Ocean Research and Development Institute.

Straight rods. Nonmotile and nongliding. Gram-stain-negative. Strictly aerobic. Oxidase-positive, but catalase-negative. Produce **extracellular polysaccharides and carotenoid-type pigments**, but not flexirubin-type pigments. Several carbohydrates are used as sole carbon sources. **Unable to grow in the absence of any of the ions Na⁺, Ca²⁺, and Mg²⁺.** Require 1–5% (w/v) NaCl for growth, with optimal growth in 3% NaCl. Degrade gelatin, skimmed milk, and starch. Major cellular fatty acids are saturated iso-branched and 3-hydroxy iso-branched fatty acids. The respiratory quinone is menaquinone-6.

DNA G+C content (mol%): 34.

Type species: ***Kordia algicida*** Sohn, Lee, Yi, Chun, Bae, Ahn and Kim 2004, 678^{VP}.

Further descriptive information

Cells are 0.3–0.5 × 2–5 μ m when grown in ZoBell 2216e medium at 25°C for 24 h. Resting stages are absent.

The colony color is yellow on ZoBell 2216e and tryptic soy agar (TSA) containing seawater, but white on peptone-seawater agar medium. After 3 d, colonies are about 1.2 mm in diameter, slightly convex (elevation), entire (margin), and round (configuration). Growth occurs at 5–40°C, pH 6–10, and 1–5% NaCl. Grows optimally at 30°C, pH 7–8 and 3% NaCl. Sea salts (Na⁺, Ca²⁺, and Mg²⁺) are required for growth. H₂S and indole are not produced. Nitrate is reduced to nitrite. Acid is not produced from glucose. The O/F test is negative with glucose. No growth occurs on urea, NH₄, or NO₃ as inorganic nitrogen sources; growth does occur when Casamino acids, sodium glutamate, peptone, tryptone, and yeast extract are supplied instead of an inorganic nitrogen source. Gelatin, skimmed milk, and starch are degraded, but not cellulose, carboxymethylcellulose, agar, chitin, alginate, pectin, or inulin.

The following substrates are oxidized: α -cyclodextrin, dextrin, glycogen, *N*-acetyl-D-glucosamine, adonitol, i-erythritol,

gentiobiose, α -D-glucose, maltose, D-mannitol, D-mannose, raffinose, sucrose, citric acid, D-glucuronic acid, α -ketoglutaric acid, DL-lactic acid, quinic acid, succinic acid, alaninamide, L-aspartic acid, L-glutamic acid, glycyl-L-aspartic acid, glycyl-L-glutamic acid, L-ornithine, L-proline, L-threonine, DL-carnitine, uridine, glucose 1-phosphate, and glucose 6-phosphate.

The following substrates are not oxidized: Tween 40, Tween 80, *N*-acetyl-D-galactosamine, L-arabinose, D-arabitol, cellobiose, D-fructose, L-fucose, D-galactose, *myo*-inositol, α -D-lactose, lactulose, melibiose, methyl β -D-glucoside, D-psicose, L-rhamnose, D-sorbitol, trehalose, turanose, xylitol, methyl pyruvate, monomethyl succinate, acetic acid, *cis*-aconitic acid, formic acid, D-galactonic acid lactone, D-galacturonic acid, D-gluconic acid, D-glucosaminic acid, α -hydroxybutyric acid, β -hydroxybutyric acid, γ -hydroxybutyric acid, *p*-hydroxyphenylacetic acid, itaconic acid, α -ketobutyric acid, α -ketovaleric acid, malonic acid, propionic acid, D-saccharic acid, sebacic acid, bromosuccinic acid, succinamic acid, glucuronamide, D-alanine, L-alanine, L-alanyl-glycine, L-asparagine, L-histidine, hydroxyl-L-proline, L-leucine, L-phenylalanine, L-pyroglutamic acid, D-serine, L-serine, γ -aminobutyric acid, urocanic acid, inosine, thymidine, phenylethylamine, putrescine, 2-aminoethanol, 2,3-butanediol, glycerol, and DL- α -glycerol phosphate.

Distinctive features of the fatty acid profile are the presence of a high level of C_{15:0} iso (41.2%) and the presence of C_{15:0} iso 3-OH, C_{16:0} iso 3-OH, and C_{17:0} iso 3-OH.

The type strain was isolated from a seawater sample associated with a red tide in Masan Bay, Republic of Korea.

Enrichment and isolation procedures

Kordia algicida was isolated by enrichment culture of seawater samples collected during an outbreak of red tides caused by a microalga. A seawater sample was collected at a depth of 1 m from Masan Bay, Republic of Korea, during an algal bloom caused

by a marine microalga, *Skeletonema costatum*. The sample was filtered through a 1.2- μ m pore-size membrane filter, co-cultured with *Skeletonema costatum*, and incubated at 20°C under a cycle of light (approx. 5,000 lux for 14 h) and dark (10 h) periods. The cells of *Skeletonema costatum* in a co-culture tube were completely killed after 3 d. The bacterium responsible for killing *Skeletonema costatum* was isolated from the co-culture tube using ZoBell 2216e agar medium (Sohn et al., 2004). *Kordia algicida* also showed algal activity against other algal species, namely, *Thalassiosira* sp., *Heterosigma akashiwo*, and *Cochlodinium polykrikoides*.

Maintenance procedures

Kordia algicida can be maintained as a glycerol suspension (20%, w/v) at -80°C.

Differentiation of the genus *Kordia* from other genera

Characteristics that differentiate the genus from other phylogenetically related genera in the family *Flavobacteriaceae* are given in Table 53.

Taxonomic comments

Kordia algicida is the only member of the genus *Kordia* and, based on 16S rRNA gene sequence analysis, is not closely related to any known genera. The highest similarities were to the type strains of *Cytophaga latercula* (92.5%), *Flexibacter tractuosus* (92.1%), *Salegentibacter salegens* (91.0%), *Cellulophaga lytica* (90.9%), *Cellulophaga fucicola* (90.7%), *Tenacibaculum maritimum* (90.5%), and *Polaribacter franzmannii* (90.1%). The position of *Kordia algicida* is not stable within the *Cytophaga-Flavobacterium-Bacteroides* complex, because branching positions in the trees varied depending on phylogenetic methods employed (Sohn et al., 2004). The estimated genome size of *Kordia algicida* is about 5.0 Mbp (<https://moore.jcvi.org/moore/SingleOrganism.do?speciesTag=KAOT1&pageAttr=pageMain>). The partial genome sequencing is now finished and the further annotation work is in progress (http://www.moore.org/program_areas/science/initiatives/marine_microbiology/initiative_marine_microbiology.asp).

List of species of the genus *Kordia*

1. ***Kordia algicida*** Sohn, Lee, Yi, Chun, Bae, Ahn and Kim 2004, 678^{VP}

al.gi'ci.da. L. fem. n. *alga -ae* alga; L. suff. *-cida* (from L. v. *caedere* to cut or to kill), killer; N.L. n. *algicida* alga-killer.

The description of this species is the same as that of the genus.

Source: the type strain was isolated from a seawater sample associated with a red tide in Masan Bay, Republic of Korea.

DNA G+C content (mol%): 34 (HPLC).

Type strain: OT-1, KCTC 8814P, NBRC 1000336.

Sequence accession no. (16S rRNA gene): AY195836.

Genus XXVIII. ***Krokinobacter*** Khan, Nakagawa and Harayama 2006a, 326^{VP}

THE EDITORIAL BOARD

Kro.ki'no.bac.ter. Gr. adj. *krokinos* yellow; N.L. masc. n. *bacter* from Gr. n. *bakterion* rod; N.L. masc. n. *Krokinobacter* a yellow, rod-like bacterium.

Rods, 0.5–0.7 × 2.5–4.0 μm. Gram-stain-negative. **Aerobic.** **Lemon-yellow** carotenoid-type pigments are present. **Flexirubin-negative.** Catalase- and oxidase-positive. **Gelatin, casein, and DNA are hydrolyzed, but not agar, carrageenan, cellulose, chitin, starch, or urea.** Very weak growth, or no growth, occurs at temperatures below 10°C and above 30°C. **No growth occurs in the presence of 0 or 10% NaCl.** No acid is produced from glucose. **Nitrate is not reduced.** Denitrification does not occur. The following substrates are utilized: aspartic acid, dextrin, cellobiose, D-fructose, gentiobiose, α-D-glucose, glutamic acid, glycine, glycyL-aspartic acid, lactose, lactulose, maltose, methyl-β-D-glucoside, ornithine, raffinose, sucrose, trehalose, turanose, proline, threonine, and uridine. Do not utilize the following substrates: aconitic acid, adonitol, alaninamide, alanine, aminobutyric acid, aminoethanol, arabitol, asparagine, bromosuccinic acid, butanediol, carnitine, citric acid, erythritol, formic acid, fucose, galactonic acid lactone, galactose, galacturonic acid, gluconic acid, glucosaminic acid, glucose phosphate, glucuronamide, glucuronic acid, glycerol, glycerol phosphate, glycyL-L-glutamic acid, histidine, α-, β- and γ-hydroxybutyric acids, *p*-hydroxyphenylacetic acid, inosine, inositol, itaconic acid, α-ketobutyric acid, α-ketoglutaric acid, α-ketovaleric acid, leucine, malonic acid, mannose, melibiose, phenylalanine, phenylethylamine, propionic acid, psicose, putrescine, pyroglutamic acid, pyruvate, quinic acid, rhamnose, saccharic acid, sebacic acid, serine, sorbitol, succinamic acid, succinic acid, succinate, thymidine, urocanic acid, and xylitol. The major cellular fatty acids are C_{15:0} iso, C_{15:1} iso, C_{17:0} iso 3-OH, and summed feature A (C_{16:1} ω7c and/or C_{15:0} iso 12-OH; fatty acids that could not be separated by GC). Isolated from marine sediment samples.

DNA G+C content (mol%): 33–39.

Type species: ***Krokinobacter genikus*** Khan, Nakagawa and Harayama 2006a, 326^{VP}.

Enrichment and isolation procedures

Five *Krokinobacter* strains were isolated from marine sediment samples collected from the Pacific coastline of Japan. Three-day-old colonies on marine agar were lemon-yellow, slightly convex, and 1–2 mm in diameter. The organisms were

Gram-stain-negative rods, 0.5–0.7 × 2.5–4.0 μm, and were negative for the presence of flexirubin-type pigments. Their optimum growth temperature was 15–25°C.

Differentiation of the genus *Krokinobacter* from related genera

Unlike members of the genus *Cellulophaga*, *Krokinobacter* strains are unable to hydrolyze agar and starch. Their ability to hydrolyze casein and DNA, but not agar or starch distinguishes them from strains of *Algibacter*. Unlike *Psychroserpens* strains, *Krokinobacter* strains hydrolyze DNA and have a higher DNA G+C content (33–39 mol% vs 27–29 mol%). *Krokinobacter* strains differ from members of the genera *Psychroflexus* and *Salegentibacter* by their ability to hydrolyze casein, but not starch, and also differ from *Salegentibacter* strains by reducing nitrate.

Taxonomic comments

Based on 16S rRNA gene sequence analysis, the five strains formed a distinct monophyletic cluster within the family *Flavobacteriaceae*. The most closely related species with a validly published name was *Cellulophaga lytica*, with sequence similarities of 91.2–91.7%.

DNA–DNA hybridization experiments with the five strains indicated that the strains should be classified as representatives of three species: *Krokinobacter genikus* (three strains), *Krokinobacter diaphorus* (one strain), and *Krokinobacter eikastus* (one strain).

Differentiation of species of the genus *Krokinobacter*

Krokinobacter genikus can be differentiated from *Krokinobacter diaphorus* and *Krokinobacter eikastus* by its ability to utilize acetic acid, but not mannitol, and by the absence of arachidonic acid (C_{20:4} ω6c) in its fatty acid profile. *Krokinobacter diaphorus* differs from the other two species in being unable to use both acetic acid and mannitol and in having a lower DNA G+C content (33 mol% vs 37–38 mol%). *Krokinobacter eikastus* can be differentiated from the other two species by its ability to use mannitol, but not acetic acid.

List of species of the genus *Krokinobacter*

1. ***Krokinobacter genikus*** Khan, Nakagawa and Harayama 2006a, 326^{VP}

ge'ni.kus. N.L. masc. adj. *genikus* from Gr. masc. adj. *genikos* principal, typical.

The characteristics are as given for the genus, with the following additional features. Colonies on marine agar 2216 are yellow and slightly convex. Grows optimally at 20°C and with 3% NaCl. Acetic acid is utilized, but not mannitol. Unlike

other *Krokinobacter* species, does not contain arachidonic acid as part of the cellular fatty acid composition.

Source: the type strain was isolated from marine sediment at Odawara, Japan.

DNA G+C content (mol%): 37–39 (HPLC).

Type strain: Cos-13, CIP 108744, NBRC 100811.

Sequence accession no. (16S rRNA gene): AB198086.

2. ***Krokinobacter diaphorus*** Khan, Nakagawa and Harayama 2006a, 327^{VP}

di.aph'or.us. N.L. masc. adj. *diaphorus* from Gr. masc. adj. *diaphoros* different, unlike.

The characteristics are as given for the genus, with the following additional features. Colonies on marine agar 2216 are slightly convex and yellowish. Grows optimally at 20°C and with 3% NaCl. Neither acetic acid nor mannitol is utilized. The cellular fatty acids include arachidonic acid.

Source: the type strain was isolated from marine sediment at Kisarazu, Japan.

DNA G+C content (mol%): 33 (HPLC).

Type strain: MSKK-32, CIP 108745, NBRC 100817.

Sequence accession no. (16S rRNA gene): AB198089.

3. ***Krokinobacter eikastus*** Khan, Nakagawa and Harayama 2006a, 327^{VP}

ei.kas'tus. N.L. masc. adj. *eikastus* from Gr. masc. adj. *eikastos* similar, comparable.

The characteristics are as given for the genus, with the following additional features. The optimal growth temperature is 20°C and the optimal salt concentration is 3%. Colonies are slightly convex and yellowish on marine agar 2216. Mannitol is utilized, but acetate is not utilized. The cellular fatty acids include arachidonic acid.

Source: the type strain was isolated from marine sediment collected at Kisarazu, Japan.

DNA G+C content (mol%): 38 (HPLC).

Type strain: PMA-26, CIP 108743, NBRC 100814.

Sequence accession no. (16S rRNA gene): AB198088.

Genus XXIX. ***Lacinutrix*** Bowman and Nichols 2005, 1482^{VP}

JOHN P. BOWMAN

La.ci.nu'trix. L. n. *lacus* lake; L. fem. n. *nutrix* feeder; N.L. fem. n. *Lacinutrix* lake feeder (in the sense of contributing to lake food chains).

Straight or slightly curved **rod-shaped cells**, 0.4–0.5 × 1–2 µm. Cells occur singly or in pairs. Spores and resting cells are not present. Gas vesicles and helical or ring-shaped cells are not formed. **Nonmotile. Gram-stain-negative. Strictly aerobic, with an oxidative type of metabolism. Catalase- and oxidase-positive. Chemoheterotrophic. Colonies are golden-yellow** due to production of carotenoids. **Flexirubin pigments are not produced. Sodium ions are required** for growth. Best growth occurs in organic media containing seawater salts. Grows between –2 and 25°C, with temperature optima of 15–20°C in seawater-containing media. Neutrophilic, with optimal growth occurring at about pH 7.5. The major fatty acids include C_{15:1} ω10*c* iso, C_{15:1} ω10*c* anteiso, C_{15:0} iso, C_{15:0} anteiso, and C_{16:0} iso. The major isoprenoid quinone is **menaquinone-6**. Habitat: Antarctic saline lakes in association with the calanoid copepod species *Paralabidocera antarctica*.

DNA G+C content (mol%): 37.

Type species: ***Lacinutrix copepodicola*** Bowman and Nichols 2005, 1482^{VP}.

Further descriptive information

The genus *Lacinutrix* is a member of the family *Flavobacteriaceae*, represented at the time of writing by a single species, *Lacinutrix copepodicola*, which was isolated directly from copepod samples collected from an Antarctic lake with marine salinity (Bowman and Nichols, 2005). Physiologically, the species has features that are consistent with the majority of members of the family *Flavobacteriaceae*, including Gram-stain-negative cell walls, an aerobic chemoheterotrophic metabolism, the ability to synthesize carotenoids, the formation of mainly branched chain fatty acids, and the possession of menaquinones as the primary respiratory isoprenoid quinones. Based on available cultivation and

molecular data (unpublished data from the National Center of Biotechnology Information; <http://www.ncbi.nlm.nih.gov>), members of the genus *Lacinutrix* appear to be widely distributed in marine habitats, including polar sea-ice, and in association with marine algae and animals collected from high latitude oceanic regions. Members of the marine genus *Psychroserpens*, which are the closest relatives of *Lacinutrix*, also have a similar distribution pattern in the marine environment.

Isolation and maintenance procedures

Strains can be isolated directly from source material, typically cold water marine samples (<10°C), as described above by serial dilution plating directly onto marine agar 2216 (Difco) and incubation at 2–15°C. Routine cultivation should be performed aerobically on marine agar 2216 at 15–20°C. Strains can be maintained as frozen suspensions in marine broth 2216 containing 20–30% (v/v) glycerol at –70°C. Strains may survive for several months, potentially years, on thick-agar (marine agar 2216) plates or on slants, stored at 2–4°C.

Differentiation of the genus *Lacinutrix* from other genera

The most useful traits for differentiating *Lacinutrix* from other members of the *Flavobacteriaceae* include yellow pigmentation, lack of flexirubin pigments, lack of motility, a strictly oxidative metabolism, formation of acid from carbohydrates, growth at low temperatures (e.g., 4°C), requirement for sodium ions for growth (or good growth on sea-salts-containing media), and lack of agarolytic activity. Several genera of the family *Flavobacteriaceae* possess at least some proportion of the above traits; thus, any phenotypic-based identifications are at best tentative and 16S rRNA gene sequencing is required for any definitive identification.

List of species of the genus *Lacinutrix*1. *Lacinutrix copepodicola* Bowman and Nichols 2005, 1482^{VP}

co.pe.pod.i'col.a. N.L. neut. pl. n. *copepoda* copepods (small type of crustacean); L. fem. or masc. suff. *-cola* (from L. n. *incola*) the dweller, inhabitant; N.L. masc. or fem. n. *copepodicola* the inhabitant of copepods.

Characteristics are as described for the genus, with the following additional features. Colonies are golden-yellow, circular, convex, with an entire edge and a butyrous consistency on marine agar 2216. Growth occurs in 0.1–2.0 M NaCl, with optimal growth at seawater salinities (0.3–0.4 M NaCl). Grows well in media containing 2× strength sea salts; no growth occurs with 4× strength sea salts. Does not require divalent cations found in seawater for growth; all salinity requirements can be met with NaCl. Grows poorly on trypticase soy agar (Oxoid) containing 1% (w/v) NaCl. Does not grow on trypticase soy agar or nutrient agar (Oxoid). Can grow on a mineral salts medium prepared with sea salts and containing ammonium chloride or sodium nitrate as the sole nitrogen source and D-glucose as the sole carbon and energy source. Other sole carbon and energy sources include glycogen, D-mannose, maltose, sucrose, and L-proline, but not N-acetyl-D-glucosamine, L-rhamnose, DL-arabinose, L-fucose, D-melibiose, salicin, acetate, propionate, valerate, caprate, adipate, suberate, citrate, DL-3-hydroxybutyrate, DL-lactate, itaconate, phenylacetate, L-alanine, L-histidine, or L-serine. Acid production from carbohydrates is undetectable in Leifson's oxidation/fermentation medium (Leifson, 1963).

Gelatin, Tween 80, and L-tyrosine are hydrolyzed, but not agar, chitin, carboxymethylcellulose, dextran, xylan, xanthine, uric acid, casein, elastin, starch, esculin, DNA, or urea. Produces alkaline phosphatase; produces N-acetyl-β-glucosaminidase weakly. Negative for arginine dihydrolase, lysine decarboxylase, ornithine decarboxylase, and glutamate decarboxylase. H₂S is not produced from L-cysteine. Indole is not produced. No growth occurs in the Simmons' citrate test. Lipase (olive oil substrate) and lecithinase (egg yolk reaction) activities are not observed. Nitrate is not reduced. Negative for α-arabinosidase, α-galactosidase, β-galactosidase, 6-phospho-β-galactosidase, α-glucosidase, β-glucosidase, β-glucuronidase, and α-fucosidase. Positive for arginine arylamidase, leucyl glycine arylamidase, phenylalanine arylamidase, leucine arylamidase, tyrosine arylamidase, glycine arylamidase, histidine arylamidase, serine arylamidase, alanine arylamidase, and glutamyl glutamate arylamidase. Negative for proline arylamidase and pyroglutamate arylamidase. Does not tolerate 1% (w/v) ox bile salts.

Source: isolated directly from the calanoid copepod species *Paralabidocera antarctica* dwelling in Ace Lake in the Vestfold Hills, an ice-free region of East Antarctica.

DNA G+C content (mol%): 37 (*T_m*).

Type strain: DJ3, ACAM 1055, CIP 108538.

Sequence accession no. (16S rRNA gene): AY649001.

Additional remarks: the GenBank accession number (16S rRNA gene sequence) for *Lacinutrix copepodicola* KMM 3838 is AB261015.

Genus XXX. *Leeuwenhoekiella* Nedashkovskaya, Vancanneyt, Dawyndt, Engelbeen, Vandemeulebroecke, Cleenwerck, Hoste, Mergaert, Tan, Frolova, Mikhailov and Swings 2005i, 1035^{VP}

OLGA I. NEDASHKOVSKAYA, MARC VANCANNEYT AND VALERY V. MIKHAILOV

Leeu.wen.hoe.ki.el'la. N.L. fem. dim. n. *Leeuwenhoekiella* named in honor of the famous Dutchman Antonie van Leeuwenhoek (1632–1723), discoverer of micro-organisms.

Thin rods usually measuring 0.4–0.7 × 1.5–4.0 μm. **Motile by gliding**. Produce non-diffusible yellow pigments. No flexirubin-type pigments are formed. **Chemo-organotrophs. Strictly aerobic**. Positive for oxidase, catalase, alkaline phosphatase, and β-galactosidase. **Halotolerant**. Agar, DNA, urea, cellulose (CM-cellulose and filter paper), and chitin are not attacked. Casein, gelatin, starch, and Tweens 20, 40, and 80 are hydrolyzed. Nitrate is not reduced. H₂S, indole, and acetoin are not produced. **Marine**, from coastal habitats. Can grow without seawater or Na⁺. **The major respiratory quinone is MK-6**.

DNA G+C content (mol%): 35–43 (*T_m*).

Type species: *Leeuwenhoekiella marinoflava* (Reichenbach 1989c) Nedashkovskaya, Vancanneyt, Dawyndt, Engelbeen, Vandemeulebroecke, Cleenwerck, Hoste, Mergaert, Tan, Frolova, Mikhailov and Swings 2005i, 1035^{VP}.

Further descriptive information

Phylogenetic analysis based on 16S rRNA gene sequences revealed that the genus *Leeuwenhoekiella* forms a distinct lineage within the family *Flavobacteriaceae* with sequence similarity levels below 92.2% with members of the following genera: *Vitellibacter*,

Aequorivita, *Arenibacter*, *Muricauda*, *Zobellia*, and *Maribacter* (Figure 44).

Dominant cellular fatty acids are straight-chain unsaturated and branched-chain unsaturated fatty acids C_{15:1} iso, C_{15:0} iso, C_{17:1} iso ω9c, C_{17:0} iso 3-OH, and summed feature 3 (C_{15:0} iso 2-OH and/or C_{16:1} ω7c).

Phenotypic properties of the type strains are given in Table 54. On marine agar 2216 (Difco), colonies are regular, round, usually shiny, and yellow, with a diameter of 2–4 mm after 48 h at 28°C.

All isolated strains have been grown on media containing 0.5% peptone and 0.1–0.2% yeast extract (Difco), prepared with natural or artificial seawater or supplemented with 2–3% NaCl. Growth is observed at 4–41°C (optimum, 23–30°C). Growth occurs in 0–17% NaCl; optimum growth varies from 0 to 5% NaCl. Utilizes L-arabinose, D-glucose, D-lactose, D-mannose, and sucrose. Inositol, sorbitol, malonate, and citrate are not utilized.

Strains are susceptible to carbenicillin, lincomycin, doxycycline, erythromycin, and chloramphenicol. They are resistant to ampicillin, gentamicin, kanamycin, neomycin, oleandomycin, polymyxin B, and streptomycin.

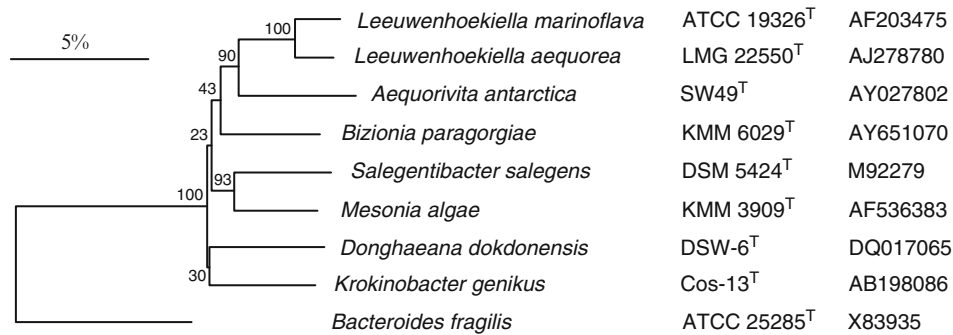

FIGURE 44. Phylogenetic tree based on the 16S rRNA gene sequences of *Leeuwenhoekiella marinoflava* ATCC 19326^T and *Leeuwenhoekiella aequorea* LMG 22550^T and representative members of related genera in the family *Flavobacteriaceae*. The tree was generated by the neighbor-joining method (Saitou and Nei, 1987). The numbers at nodes indicate bootstrap values (%). Bar = 0.05 substitutions per nucleotide position.

^bData are from Nedashkovskaya et al. (2005i) and Pinhassi et al. (2006).

Leeuwenhoekiella species inhabit the coastal marine environment. They have been isolated from seawater and echinoderms in the temperate and Antarctic latitudes.

Enrichment and isolation procedures

Leeuwenhoekiella species were isolated from seawater and the sea urchin *Strongylocentrotus intermedius* by direct plating on marine agar. *Leeuwenhoekiella blandensis* MED 217^T was isolated from a surface seawater sample enriched with Na₂HPO₄. For strain isolation, 0.1 ml of a 100× dilution of a water sample was spread onto Zobell agar plates prepared with natural seawater. Either natural or artificial seawater is suitable for cultivation. All isolated strains can grow on media containing 0.5% peptone and 0.1–0.2% yeast extract (Difco). The strains remain viable on marine agar or other rich media based on natural or artificial seawater from 3 d to several weeks. They can survive storage at –80°C for at least 5 years.

Differentiation of the genus *Leeuwenhoekiella* from other genera

An ability to grow in 15% NaCl differentiates *Leeuwenhoekiella* species from all their closest relatives. *Leeuwenhoekiella* species may be distinguished from members of the genus *Arenibacter* by their caseinase and amylase activities. A lack of flexirubin-type pigments, failure to hydrolyze agar, lack of a requirement for Na⁺ ions or seawater for growth, and failure to reduce nitrates to nitrites clearly separate *Leeuwenhoekiella* strains from representatives of the genus *Zobellia*. Phenotypic features such as production of caseinase, gelatinase, and amylase, and the ability to grow without Na⁺ ions or seawater may be helpful in differentiating *Leeuwenhoekiella* from *Muricauda* species. *Leeuwenhoekiella* species move by gliding and form acid from carbohydrates and decompose starch, in contrast to members of the genera *Vitellibacter* and *Aequorivita*. *Leeuwenhoekiella* strains can be separated

from those of the genus *Maribacter* by growth without Na⁺ ions or seawater, growth at 37°C, and by hydrolysis of casein.

Taxonomic comments

16S rRNA gene sequence similarity between *Leeuwenhoekiella aequorea* LMG 22550^T and *Leeuwenhoekiella marinoflava* ATCC 19326^T was 97.1%. DNA–DNA binding values between *Leeuwenhoekiella aequorea* LMG 22550^T and *Leeuwenhoekiella marinoflava* LMG 1345^T ranged from 9 to 14%. Sequence similarities between the two copies of the 16S rRNA gene of strain *Leeuwenhoekiella blandensis* MED 217^T and sequences of *Leeuwenhoekiella aequorea* LMG 22550^T and *Leeuwenhoekiella marinoflava* ATCC

19326^T were 96.1–96.7 and 95.7–96.7%, respectively. DNA–DNA hybridization experiments carried out between strains MED 217^T and ATCC 19326^T show a level of DNA–DNA reassociation of 21%. These data indicate that strains LMG 22550^T and ATCC 19326^T represent two separate species within the genus *Leeuwenhoekiella* (Wayne et al., 1987). The genome of strain *Leeuwenhoekiella blandensis* MED 217^T was sequenced and its size was equal to 4.24 Mbp. This value is consistent with that reported for *Leeuwenhoekiella marinoflava* (Callies and Mannheim, 1980). The size of the genome of *Leeuwenhoekiella marinoflava* ATCC 19326^T was determined to be 2.26×10^9 Da or 4.20 Mbp.

List of species of the genus *Leeuwenhoekiella*

1. ***Leeuwenhoekiella marinoflava*** (Reichenbach 1989c) Nedashkovskaya, Vancanneyt, Dawyndt, Engelbeen, Vandemeulebroecke, Cleenwerck, Hoste, Mergaert, Tan, Frolova, Mikhailov and Swings 2005i, 1035^{VP} [*Cytophaga marinoflava* (ex Colwell, Citarella and Chen 1966) Reichenbach 1989c, 2036; *Cytophaga marinoflava* Colwell, Citarella and Chen 1966, 1102]

ma.ri.no fla'va. L. adj. *marinus* marine; L. adj. *flavus* golden yellow; N.L. fem. adj. *marinoflava* (*sic*) marine and yellow-pigmented.

Rod-shaped cells, 0.5–0.6 × 1.6–2.3 µm. On marine agar 2216, colonies are 2–4 mm in diameter, circular with entire edges, and bright yellow. No acid is formed from trehalose, citrate, acetate, fumarate, or malate. Susceptible to carbenicillin, doxycycline, erythromycin, and chloramphenicol. Resistant to ampicillin and streptomycin.

Source: the single available strain was isolated from seawater collected in the North Sea off Aberdeen, Scotland.

DNA G+C content (mol%): 38 (T_m).

Type strain: ATCC 19326, DSM 3653, JCM 8517, LMG 1345, NBRC 14170, NCIMB 397.

Sequence accession no. (16S rRNA gene): M58770.

2. ***Leeuwenhoekiella aequorea*** Nedashkovskaya, Vancanneyt, Dawyndt, Engelbeen, Vandemeulebroecke, Cleenwerck, Hoste, Mergaert, Tan, Frolova, Mikhailov and Swings 2005i, 1036^{VP} ae.quo.re'a. L. fem. adj. *aequorea* of the sea, marine.

Rod-shaped cells, 0.5–0.6 × 1.6–2.3 µm. On marine agar 2216, colonies are 2–4 mm in diameter, circular with entire edges, and bright yellow. No acid is formed from acetate, citrate, fumarate, or malate.

Source: the type strain and several other strains were isolated from Antarctic seawater. Strain LMG 22555 was isolated from the sea urchin *Strongylocentrotus intermedius* in the Troitsa Bay, Sea of Japan.

DNA G+C content (mol%): 35–36 (T_m).

Type strain: LMG 22550, CCUG 50091.

Sequence accession no. (16S rRNA gene): AJ278780.

3. ***Leeuwenhoekiella blandensis*** Pinhassi, Bowman, Nedashkovskaya, Lekunberri, Gomez-Consarnau and Pedrós-Alió 2006, 1492^{VP}

bla.den'sis. L. fem. adj. *blandensis* pertaining to *Blande* or *Blanda*, the name the Romans used for the city of Blanes, which has given its name to the Bay of Blanes, where the type strain was isolated.

Rod-shaped cells 0.4–0.7 × 1.5–4.0 µm; short chains were also observed. On marine agar 2216, colonies are 2–3 mm in diameter, round with entire edges, shiny, and bright yellow. Forms acid from D-glucose and DL-xylose. No acid is produced from D-galactose, sucrose, or mannitol.

Source: the type strain was isolated from a surface sea water sample enriched with inorganic phosphate, from the Bay of Blanes in the northwestern Mediterranean Sea on the coast of Spain.

DNA G+C content (mol%): 42.5 (T_m).

Type strain: MED 217, CECT 7118, CCUG 51940.

Sequence accession nos (16S rRNA gene): DQ294290 and DQ294291 (two copies).

GenBank accession number (genome sequence): AANC00000000.

Genus XXXI. **Lutibacter** Choi and Cho 2006, 773^{VP}

THE EDITORIAL BOARD

Lu.ti.bac'ter. L. n. *lutum* mud; N.L. masc. n. *bacter* rod; N.L. masc. n. *Lutibacter* rod from mud.

Rod-shaped cells. Nonmotile. Gram-stain-negative. Heterotrophic. Aerobic. **Catalase-positive. Oxidase-negative.** The predominant menaquinone is MK-6. Dominant fatty acids are C_{15:0} iso 3-OH, C_{15:0} iso, C_{15:0} anteiso, and C_{16:0} iso 3-OH. Cells contain carotenoids, but **no flexirubin-type pigments**. The genus is a member of the family *Flavobacteriaceae*.

DNA G+C content (mol%): 33.9 (HPLC).

Type species: Lutibacter litoralis Choi and Cho 2006, 775^{VP}.

Enrichment and isolation procedures

A slurry of tidal flat sediment was spread on a plate of marine agar 2216 (Difco) and incubated at 30°C for 1 week. A colony was selected and subsequently purified four times on marine agar.

Maintenance procedures

The organism can be maintained on marine agar at 4°C. It can be preserved in marine broth containing 30% (v/v) glycerol at -80°C.

Differentiation of the genus *Lutibacter* from other genera

For characteristics that differentiate the genus *Lutibacter* from related genera, see Table 70 in the treatment on *Tenacibaculum* in this volume. In particular, *Lutibacter* can be differentiated from *Polaribacter* (Gosink et al., 1998) by its colony color (yellow vs salmon pink to orange), ability to grow at 25°C, and utilization of citrate, L-leucine, tartrate, pyruvate, and succinate. *Lutibacter* can be distinguished from *Tenacibaculum* (Suzuki et al., 2001)

by its hydrolysis of esculin, negative oxidase reaction, failure to grow at pH 6, and growth on pyruvate and succinate. *Lutibacter* can also be differentiated from *Polaribacter* and *Tenacibaculum* by its large proportion of C_{15:0} anteiso and by the proportions of several fatty acids, including C_{16:0} iso 3-OH, C_{15:1} iso C, and summed feature 3 (C_{16:1} ω7c and/or C_{15:0} iso 2-OH).

Taxonomic comments

Phylogenetic analyses based on 16S rRNA gene sequences revealed that the type strain formed a very robust clade with *Tenacibaculum* and *Polaribacter* species. The closest relatives of the type strain were members of the genera *Tenacibaculum* (90.6–91.8%) and *Polaribacter* (91.0–91.5%) (Choi and Cho, 2006).

List of species of the genus *Lutibacter*

1. *Lutibacter litoralis* Choi and Cho 2006, 775^{VP}

li.to.ra'lis. L. masc. adj. *litoralis* of the shore.

Characteristics are as described for the genus, with the following additional features. Cells are 0.3–0.8 × 1.0–5.7 μm. Spherical cells occur in old cultures. On marine agar 2216 (Difco), colonies are circular, entire, convex, shining, opaque, and yellow. Absorption maxima of the pigments are 450 and 475 nm. Growth occurs at 5–30°C (optimum, 25–30°C) and pH 7–8. Grows in sea salt concentrations of 1–5% (w/v). Positive for catalase, amylase, gelatinase, and DNase. Negative for oxidase, nitrate reductase, and Tween 80 hydrolysis. With the API 20NE system, esculin hydrolysis and gelatinase activities are positive, but nitrate reductase, indole production, and acid production from glucose, arginine dihydrolase and urease are negative. Grows on acetone,

citrate, D-fructose, raffinose, D-salicin, D-sorbitol, glycine, glycogen, myo-inositol, L-arginine, L-lysine, L-ornithine, pyruvic acid, succinate, tartrate, urea, Casamino acids, L-leucine, peptone, tryptone, and yeast extract. No growth occurs on acetate, acetamide, α-ketobutyric acid, benzoate, DL-cysteine, cellobiose, D-galactose, D-glucose, D-mannitol, D-mannose, D-ribose, trehalose, D-xylose, ethanol, formic acid, glycerol, inulin, 2-propanol, lactose, L-arabinose, L-ascorbate, L-asparagine, L-rhamnose, maleic acid, N-acetylglucosamine, polyethylene glycol, salicylate, sucrose, thiamine, DL-aspartate, L-proline, or L-glutamate.

Source: the type strain was isolated from tidal flat sediment in Ganghwa, Korea.

DNA G+C content (mol%): 33.9 (HPLC).

Type strain: CL-TF09, JCM 13034, KCCM 42118.

Sequence accession no. (16S rRNA gene): AY962293.

Genus XXXII. *Maribacter* Nedashkovskaya, Kim, Han, Lysenko, Rohde, Rhee, Frolova, Falsen, Mikhailov and Bae 2004b, 1021^{VP}

OLGA I. NEDASHKOVSKAYA AND SEUNG BUM KIM

Ma.ri.bac'ter. L. neut. n. *mare* the sea; N.L. masc. n. *bacter* from Gr. n. *baktron* rod; N.L. masc. n. *Maribacter* rod inhabiting marine environments.

Rod-shaped cells, 0.2–0.7 × 1.2–10 μm, with rounded ends. Motile by gliding. Produce non-diffusible yellow carotenoid pigments. No flexirubin pigments are produced. **Chemo-organotrophs. Strictly aerobic.** Positive for oxidase, catalase, and alkaline phosphatase. Arginine dihydrolase, and lysine and ornithine decarboxylases are not produced. Casein, urea, and chitin are not attacked. Tween 40 is hydrolyzed. Hydrolysis of agar, gelatin, starch, Tweens 20 and 80, and DNA varies among species. Indole, H₂S, and acetoin are not produced. **Marine,** from coastal habitats. May require seawater or sodium ions for growth. **The major respiratory quinone is MK-6. The main polar lipid is phosphatidylethanolamine.**

DNA G+C content (mol%): 35–39 (*T_m*).

Type species: *Maribacter sedimenticola* Nedashkovskaya, Kim, Han, Lysenko, Rohde, Rhee, Frolova, Falsen, Mikhailov and Bae 2004b, 1021^{VP}.

Further descriptive information

Phylogenetic analysis based on 16S rRNA gene sequences indicated that the genus *Maribacter* created a cluster with *Zobellia*

species (Figure 45). The 16S rRNA gene sequence similarities of *Maribacter* and its nearest neighbor *Zobellia uliginosa* were 92.9–94.3%, but their relationship did not have significant bootstrap support. Species of the genus *Maribacter* possess 16S rRNA gene sequence similarities to one another that range from 95.1 to 97.4%. Only the 16S rRNA gene sequence similarity value between strains *Maribacter aquivivus* KMM 3949^T and *Maribacter ulvicola* KMM 3951^T is higher than 97%. The DNA–DNA hybridization value between strains KMM 3949^T and KMM 3951^T was 51%.

The main cellular fatty acids are C_{15:1} iso, C_{15:0} iso, C_{15:0}, C_{17:0} iso 3-OH, and summed feature 3 comprising C_{15:0} iso 2-OH and/or C_{16:1} ω7c. Further fatty acid data can be found in Table 55.

On marine agar 2216 (Difco), maribacters form regular, round, shiny, yellow–orange colonies with entire or rhizoid edges, and are 1–4 mm in diameter after 48 h at 28°C. Some are sunken into the agar.

All isolated strains have been grown on media containing 0.5% peptone and 0.1–0.2% yeast extract (Difco), prepared with natural or artificial seawater or supplemented with 2–3%

FIGURE 45. Phylogenetic tree based on the 16S rRNA gene sequences of the type strains of species of the genus *Maribacter* and the related species *Zobellia galactanivorans*. Bar = 0.01 substitutions per nucleotide position.

NaCl. Growth occurs at 4–35°C (optimum, 21–24°C) and in 1–7% NaCl (optimum, 1–3% NaCl). Growth does not occur in the absence of NaCl or in the presence of greater than 10% (w/v) NaCl. The optimal pH for growth is 7.0–8.0; growth occurs at pH 5.5, but not at pH 5.0.

No acid is produced from citrate, adonitol, *N*-acetylglucosamine, glycerol, inositol, sorbitol, or sorbose. Mannitol, inositol, sorbitol, malonate, and citrate are not utilized.

Maribacter strains are susceptible to carbenicillin, lincomycin, and oleandomycin, but are resistant to benzylpenicillin, gentamicin, kanamycin, neomycin, polymyxin B, and streptomycin. Some species may be susceptible to novobiocin and tetracycline and resistant to cephalothin.

Species of the genus *Maribacter* inhabit coastal marine environments. They have been isolated from seawater, sediments, and seaweeds collected in temperate latitudes.

^aData from Nedashkovskaya et al. (2004b) and Yoon et al. (2005b).

Enrichment and isolation procedures

The maribacters inhabit coastal marine environments and were isolated from seawater, sediments, and seaweeds by direct plating on marine agar (Difco). Natural or artificial seawater is sufficient for their cultivation. All isolated strains have been grown on media containing 0.5% peptone and 0.1–0.2% yeast extract (Difco). Strains of *Maribacter* may remain viable on marine agar (Difco) or other rich media based on natural or artificial seawater for several weeks. They have survived storage at –80°C for at least 5 years.

Differentiation of the genus *Maribacter* from other genera

Maribacter strains differ from those of its closest relative, the genus *Zobellia*, by their inability to produce flexirubin-type pigments and lack of caseinase activity (Barbeyron et al., 2001; Nedashkovskaya et al., 2004b, f; Yoon et al., 2005b).

Differentiation of species of the genus *Maribacter*

Species of the genus *Maribacter* have many common phenotypic traits; however, there are enough variable phenotypic properties to differentiate them clearly (Table 56).

Cells are 0.5–0.7 × 2–10 μm (Figure 46). On marine agar, colonies are 2–4 mm in diameter, circular, shiny with entire edges, yellow, and slightly sunken into the agar. Growth occurs at 4–33°C (optimum, 22–24°C) and in 1–6% NaCl.

Source: isolated from sediment in Troitsa Bay, Gulf of Peter the Great, Sea of Japan.

DNA G+C content (mol%): 35.0 (T_m).

Type strain: KMM 3949, KCTC 12968, CCUG 48009.

Sequence accession no. (16S rRNA gene): AY271625.

3. ***Maribacter dokdonensis*** Yoon, Kang, Lee, Lee and Oh 2005b, 2054^{VP}

dok.do.nen'sis. N.L. masc. adj. *dokdonensis* pertaining to Dokdo, the Korean island from where the strains were isolated.

Cells are rods, 0.3–0.4 × 0.8–4.0 μm. Colonies are circular or rhizoid, glistening, slightly convex, yellow, and 1.0–2.0 mm in diameter after incubation for 3 d on marine agar at 30°C. Growth occurs at 4–35°C. Optimal pH for growth is 7.0–8.0; growth occurs at pH 5.5, but not at pH 5.0. Optimal growth occurs in the presence of 2–3% (w/v) NaCl; growth does not occur in the absence of NaCl or in the presence of greater than 10% (w/v) NaCl. Esculin, tyrosine, and Tween 60 are hydrolyzed, but hypoxanthine and xanthine are not. Anaerobic growth does not occur on marine agar or on marine agar supplemented with nitrate. Tests for arginine dihydrolyase, lysine and ornithine decarboxylases, and tryptophan deaminase are negative. In assays with the API ZYM system, esterase (C4), esterase lipase (C8), leucine arylamidase, acid phosphatase, naphthol-AS-BI-phosphohydrolase, β-glucosidase, N-acetyl-β-glucosaminidase, cystine arylamidase, trypsin, α-chymotrypsin, α- and β-galactosidases, β-glucuronidase, α-glucosidase, α-mannosidase, and α-fucosidase are absent. D-Fructose and salicin are utilized, but acetate, succinate, benzoate, L-malate, pyruvate, formate, and L-glutamate are not utilized. Acid is produced from D-mannose, melezitose, and trehalose, but not from D-ribose. Acid production from D-fructose differs among strains (positive for the type strain). Susceptible to novobiocin (5 μg), but not to cephalothin (30 μg). The major polar lipids are phosphatidylethanolamine, two unidentified phospholipids, an unidentified glycolipid and an amino group-containing lipid that is ninhydrin-positive.

Source: isolated from seawater off Dokdo, an island located at the edge of East Sea, Korea.

DNA G+C content (mol%): 35.9–36.1 (HPLC).

Type strain: DSW-8, KCTC 12393, DSM 17201.

Sequence accession no. (16S rRNA gene): AY960749.

4. ***Maribacter orientalis*** Nedashkovskaya, Kim, Han, Lysenko, Rohde, Rhee, Frolova, Falsen, Mikhailov and Bae 2004b, 1022^{VP}

o.ri.en.ta'lis. L. masc. adj. *orientalis* eastern, bacterium inhabiting the East.

Cells are $0.5\text{--}0.7 \times 2\text{--}10 \mu\text{m}$. On marine agar, colonies are 2–4 mm in diameter, circular, shiny with entire edges, and yellow–orange. Growth occurs at $4\text{--}32^\circ\text{C}$ (optimum, $21\text{--}23^\circ\text{C}$) and in 1–5% NaCl.

Source: isolated from seawater in Amursky Bay, Gulf of Peter the Great, Sea of Japan.

DNA G+C content (mol%): 39.0 (T_m).

Type strain: KMM 3947, KCTC 12967, CCUG 48008.

Sequence accession no. (16S rRNA gene): AY271624.

5. **Maribacter ulvicola** Nedashkovskaya, Kim, Han, Lysenko, Rohde, Rhee, Frolova, Falsen, Mikhailov and Bae 2004b, 1022^{VP} ul.vi.co'la. N.L. fem. n. *Ulva* generic name of the green alga *Ulva fenestrata*; L. suff. *-cola* (from L. n. *incola*) dweller; N.L. n. *ulvicola* *Ulva fenestrata* dweller.

Cells are flexible rods, $0.25\text{--}0.30 \times 4\text{--}6 \mu\text{m}$ (Figure 47). On marine agar, colonies are 2–4 mm in diameter, circular, shiny with entire edges, yellow, and slightly sunken into the agar. Growth occurs at $4\text{--}32^\circ\text{C}$ (optimum, $21\text{--}23^\circ\text{C}$) and in 1–4% NaCl. Agar is weakly hydrolyzed.

Source: isolated from the green alga *Ulva fenestrata*, collected in Troitsa Bay, Gulf of Peter the Great, Sea of Japan.

DNA G+C content (mol%): 35–37 (T_m).

Type strain: KMM 3951, KCTC 12969, DSM 15366.

Sequence accession no. (16S rRNA gene): AY271626.

Genus XXXIII. *Mariniflexile* Nedashkovskaya, Kim, Kwak, Mikhailov and Bae 2006a, 1636^{VP}

THE EDITORIAL BOARD

Ma.ri.ni.fle'xi.le. L. adj. *marinus* *-a -um* marine; L. part. adj. *flexilis* *-e* pliant, pliable, flexible; N.L. neut. n. *Mariniflexile* a flexible marine bacterium.

Rods, $0.4\text{--}0.5 \times 2\text{--}3 \mu\text{m}$. **Motile by gliding**. Nonsporeforming. Gram-stain-negative. **Colonies are orange**. Chemo-organotrophic. **Do not require Na⁺ ions for growth**, but grow best with 1–2% NaCl. **Oxidase- and catalase-positive**. Alkaline phosphatase-positive. **D-Glucose is fermented in the O-F test. Agar and starch are not hydrolyzed**. The predominant cellular fatty acids are straight-chain saturated, branched-chain saturated and unsaturated fatty acids, C_{15:0} iso, C_{15:0} anteiso, C_{15:1} iso, C_{15:0}^o, C_{17:0} iso 3-OH, and summed feature 3 (comprising C_{16:1} ω 7 and/or C_{15:0} iso 2-OH). The main menaquinone is MK-6. Isolated from the sea urchin *Strongylocentrotus intermedius*.

DNA G+C content (mol%): 35.7 (T_m).

Type species: ***Mariniflexile gromovii*** Nedashkovskaya, Kim, Kwak, Mikhailov and Bae 2006a, 1636^{VP}.

Further descriptive information

Mariniflexile gromovii was isolated from the sea urchin *Strongylocentrotus intermedius* in Troitsa Bay, Gulf of Peter the Great, East Sea (Sea of Japan).

Colonies of *Mariniflexile gromovii* are circular, 2–3 mm in diameter, convex, shiny, orange, and translucent on marine agar 2216 (Difco). Growth occurs at $4\text{--}37^\circ\text{C}$; optimum, $23\text{--}25^\circ\text{C}$. The salinity range for growth is 0–6% NaCl.

Mariniflexile gromovii is susceptible to ampicillin, carbenicillin, lincomycin, and tetracycline. It is resistant to benzylpenicillin, gentamicin, kanamycin, neomycin, oleandomycin, polymyxin B, and streptomycin.

Enrichment and isolation procedures

Portions (0.1 ml) of homogenates of sea urchin tissues were inoculated onto plates of marine agar. After primary isolation and purification, strains were cultivated at 28°C on marine agar. The organism can be preserved at -80°C in marine broth containing 20% (v/v) glycerol.

Differentiation of the genus *Mariniflexile* from related genera

Mariniflexile gromovii differs from *Yeosuana aromativorans* by: its ability to form acid from L-fucose and DL-xylose; its ability to ferment glucose in the O-F test; positive oxidase reaction; gliding motility; a lower G+C content (35–36 mol% vs 51–52 mol%); its ability to grow in the absence of Ca²⁺, Mg²⁺, and NaCl; and its broader temperature range for growth ($4\text{--}37^\circ\text{C}$ vs $23\text{--}39^\circ\text{C}$). *Mariniflexile gromovii* can be differentiated from *Algibacter lectus* by: its ability to grow in the absence of NaCl; its inability to hydrolyze agar and starch; and a higher G+C content (35–36 mol% vs 31–33 mol%).

Taxonomic comments

On the basis of 16S rRNA gene sequence analysis, the nearest neighbors of *Mariniflexile gromovii* are the species *Algibacter lectus* and *Yeosuana aromativorans*, with sequence similarities of 93.8 and 93.6%, respectively. The rRNA gene sequence of *Mariniflexile gromovii* has less than 93.1% similarity to those of other members of the *Flavobacteriaceae*.

List of species of the genus *Mariniflexile*1. *Mariniflexile gromovii* Nedashkovskaya, Kim, Kwak, Mikhailov and Bae 2006a, 1636^{VP}

gro.mo'vi.i. N.L. gen. masc. n. *gromovii* of Gromov, named in honor of B.V. Gromov, the Russian aquatic and marine microbiologist.

Characteristics are as described for the genus, with the following additional features. Decomposes gelatin. The following compounds are not hydrolyzed: casein, Tweens 20, 40 and 80, urea, cellulose (carboxymethylcellulose and filter paper), chitin, and DNA. Acid is produced from L-fucose and DL-xylose, but not from L-arabinose, cellobiose, D-galactose, D-glucose, glycerol, inositol, D-lactose, maltose, mannitol, melibiose, raffinose, or sucrose. L-Rhamnose and N-acetylglucosamine are oxidized. D-Lactose, D-mannose, and sucrose are utilized, but not L-arabinose, adonitol, citrate, dulcitol,

inositol, malonate, mannitol, or sorbitol. Nitrate is not reduced. Indole, H₂S, and acetoin (Voges–Proskauer reaction) production are negative. Cellular fatty acids accounting for more than 1.0% of the total are C_{15:1} iso (16.9%), C_{15:1} anteiso (1.6%), C_{15:0} iso (15.0%), C_{15:0} anteiso (5.4%), C_{15:0} (13.8%), C_{15:1} ω6c (3.1%), C_{15:0} iso 3-OH (4.3%), C_{15:0} iso 2-OH (1.4%), C_{15:0} 3-OH (1.6%), C_{16:1} iso (1.5%), C_{16:0} iso (1.0%), C_{16:0} (1.4%), C_{16:0} iso 3-OH (2.5%), C_{16:0} 3-OH (1.1%), C_{17:1} ω6c (1.1%), C_{17:0} 3-OH (8.9%), and summed feature 3 (8.4%; comprising C_{16:1} ω7 and/or C_{15:0} iso 2-OH).

Source: isolated from the sea urchin *Strongylocentrotus intermedius* in Troitsa Bay, Gulf of Peter the Great, East Sea (Sea of Japan).

DNA G+C content (mol%): 35.7 (T_m).

Type strain: KMM 6038, KCTC 12570, LMG 22578.

Sequence accession no. (16S rRNA gene): DQ312294.

Genus XXXIV. *Mesonia* Nedashkovskaya, Kim, Han, Lysenko, Rohde, Zhukova, Falsen, Frolova, Mikhailov and Bae 2003a, 1970^{VP} emend. Nedashkovskaya, Kim, Zhukova, Kwak, Mikhailov and Bae 2006e, 2435

OLGA I. NEDASHKOVSKAYA AND SEUNG BUM KIM

Me.so'ni.a. N.L. fem. n. *Mesonia* arbitrary name, derived from the abbreviation MES (Marine Experimental Station of Pacific Institute of Bioorganic Chemistry, FEB RAS) near the site where the bacteria were isolated.

Thin rods usually measuring 0.4–0.5 × 1.0–2.3 μm. **Cells may be motile by means of gliding**. Produce non-diffusible yellow pigments. No flexirubin pigments are formed. **Chemo-organotrophs. Strictly aerobic**. Positive for oxidase, catalase, and alkaline phosphatase and negative for β-galactosidase. Agar, alginate, starch, chitin, and cellulose (carboxymethylcellulose and filter paper) are not hydrolyzed, but gelatin and Tween 20 are hydrolyzed. Do not grow without seawater or Na⁺. **The major respiratory quinone is MK-6**. Phosphatidylethanolamine is the main polar lipid. **Marine**, isolated from coastal seaweeds.

DNA G+C content (mol%): 32–37.

Type species: *Mesonia algae* Nedashkovskaya, Kim, Han, Lysenko, Rohde, Zhukova, Falsen, Frolova, Mikhailov and Bae 2003a, 1970^{VP}.

Further descriptive information

Phylogenetic analysis of nearly complete 16S rRNA gene sequences indicate that *Mesonia* forms a cluster group with the genera *Salegentibacter* and *Gramella*, with similarities of 92.0–92.5% and 92.1–92.2%, respectively (see the phylogenetic tree in the treatment of the family *Flavobacteriaceae* in this volume).

Dominant fatty acids of the genus *Mesonia* are straight-chain unsaturated and branched-chain unsaturated fatty acids. The fatty acid profile includes C_{15:0} iso, C_{15:1} iso, C_{15:0'}, C_{16:0} iso, C_{15:0} iso 3-OH, C_{17:1} iso ω9c, C_{17:0} iso 3-OH, and summed feature 3 (C_{16:1} ω7 and/or C_{15:0} iso 2-OH).

On marine agar 2216 (Difco), *Mesonia* strains form regular, round, convex, smooth, and opaque colonies with entire edges and diameters of 1–4 mm after 48 h at 28°C. Usually, the colonies are yellow, but strains that form white colored colonies also occur.

All isolated strains have been grown on media containing 0.5% peptone and 0.1–0.2% yeast extract (Difco), prepared

with natural or artificial seawater or supplemented with 2–3% NaCl. Good growth is observed on marine agar 2216. Growth occurs at 4–39°C (optimum, 21–30°C) and with 1–15% NaCl.

Mesonia strains are susceptible to lincomycin and resistant to gentamicin, kanamycin, neomycin, polymyxin B, and streptomycin. Susceptibility to ampicillin, benzylpenicillin, carbenicillin, oleandomycin, and tetracycline differs among strains.

Strains of the genus *Mesonia* have been isolated from the green alga *Acrosiphonia sonderi*, a common dweller of coastal marine environment, and from seawater samples in the temperate latitudes.

Enrichment and isolation procedures

Mesonia strains were isolated from seaweed and seawater samples by direct plating on marine agar. Natural or artificial seawater is suitable for their cultivation. All isolated strains have been grown on media containing 0.5% peptone and 0.1–0.2% yeast extract (Difco). Strains of the genus may remain viable for several weeks on marine agar or other rich medium based on natural or artificial seawater. They have survived storage at –80°C for at least 5 years.

Differentiation of the genus *Mesonia* from other genera

The results of phenotypic examination indicate that strains of the genus *Mesonia* can be differentiated from those of its closest relative, *Gramella*, by their inability to hydrolyze starch and their lower DNA G+C content. The absence of nitrate reductase allows *Mesonia* strains to be differentiated from those of *Salegentibacter*.

Differentiation of species of the genus *Mesonia*

Table 57 lists characteristics that differentiate the two species of *Mesonia*.

List of species of the genus *Mesonía*

- 1. *Mesonía algae*** Nedashkovskaya, Kim, Han, Lysenko, Rohde, Zhukova, Falsen, Frolova, Mikhailov and Bae 2003a, 1970^{VP}
algae. L. n. *alga* alga, seaweed; L. gen. n. *algae* of alga.
 Cells are 0.4–0.5 × 1.6–2.3 µm. On marine agar, colonies are 2–4 mm in diameter, circular, shiny with entire edges, and yellow, although white strains occur. Growth occurs at 4–34°C (optimum, 21–23°C) and with 1–15% NaCl. Gelatin, casein, and Tweens 20, 40 and 80 are hydrolyzed, but not agar, alginate, starch, cellulose (carboxymethylcellulose and filter paper), or chitin. No acid is formed from L-arabinose, cellobiose, L-fucose, D-galactose, D-glucose, D-lactose, maltose, D-mannose, melibiose, raffinose, L-rhamnose, sucrose, DL-xylose, citrate, adonitol, dulcitol, glycerol, inositol, or mannitol. Does not utilize L-arabinose, D-glucose, D-lactose, D-mannose, sucrose, mannitol, inositol, sorbitol, N-acetylglucosamine, gluconate, caprate, adipate, malate, malonate, phenylacetate, or citrate. Nitrate is not reduced. H₂S is produced, but indole and acetoin (Voges–Proskauer reaction) production are negative.
Source: isolated from the green alga *Acrosiphonia sonderi* collected in Troitsa Bay, Gulf of Peter the Great, Sea of Japan.
DNA G+C content (mol%): 32.7–34.0 (*T_m*).
Type strain: KMM 3909, KCTC 12089, CCUG 47092.
Sequence accession no. (16S rRNA gene): AF536383.
- 2. *Mesonía mobilis*** Nedashkovskaya, Kim, Zhukova, Kwak, Mikhailov and Bae 2006e, 2435^{VP}
mo'bi.lis. L. fem. adj. *mobilis* movable, mobile, referring to the ability to move by gliding.
 Cells are 0.4–0.5 × 1.0–2.1 µm. On marine agar, colonies are 1–3 mm in diameter, circular, convex, and shiny with entire edges. Produces non-diffusible yellow pigments. Flexirubin-type pigments are absent. Growth occurs at 4–39°C (optimum, 28–30°C), with 1–12% NaCl (optimum, 3–4% NaCl) and at pH 6.0–9.5 (optimum, pH 7.5). Gelatin and Tween 20 are hydrolyzed, but not agar, alginate, casein, starch, Tweens 40 and 80, DNA, urea, cellulose (carboxymethylcellulose and filter paper), or chitin. Forms acid from D-glucose and maltose, but not from L-arabinose, cellobiose, L-fucose, D-galactose, D-lactose, melibiose, raffinose, L-rhamnose, sucrose, DL-xylose, citrate, adonitol, dulcitol, glycerol, inositol, mannitol, malate, or fumarate. L-Arabinose and D-mannose are utilized, but D-lactose, sucrose, mannitol, inositol, and sorbitol are not. Nitrate is not reduced. H₂S, indole, and acetoin (Voges–Proskauer reaction) production are negative. Susceptible to ampicillin and benzylpenicillin; resistant to carbenicillin, oleandomycin, and tetracycline.
Source: isolated from seawater collected in Troitsa Bay, Gulf of Peter the Great, Sea of Japan.
DNA G+C content (mol%): 36.1 (*T_m*).
Type strain: KMM 6059, KCTC 12708, LMG 23670.
Sequence accession no. (16S rRNA gene): DQ367409.

Genus XXXV. **Muricauda** Bruns, Rohde and Berthe-Corti 2001, 2005^{VP} emend. Yoon, Lee, Oh and Park 2005d, 1018

ALKE BRUNS AND LUISE BERTHE-CORTI

Mu'ri.cau.da. L. masc. n. *mus* mouse (gen. *muris* of the mouse); N.L. fem. n. *cauda* tail; N.L. fem. n. *Muricauda* tail of the mouse, referring to electron micrographs in which the bacterial appendages appeared like mouse tails.

Rod-shaped cells. Size varies between 0.2–0.6 × 1.1–6.0 µm depending on the species. Cells of older cultures (3–4 d) of *Muricauda ruestringensis* and *Muricauda aquimarina* are characterized by long (up to 3 µm) and relatively thick **appendages** (*Muricauda ruestringensis*: 20–30 nm). Gram-stain-negative.

Nonmotile in hanging drop preparations. **Facultatively anaerobic or strictly aerobic**. Chemo-organotrophic, with both an oxidative and a fermentative type of metabolism. Endospores are not formed. Colonies are circular, slightly convex, 0.5–1.2 mm in diameter and **yellow in color** (*Muricauda ruestringensis*) or

golden yellow (*Muricauda aquimarina* and *Muricauda flavescens*) after 3 d. No flexirubin-type pigment is produced. Catalase-positive. Oxidase-positive. Nitrate is not reduced. H₂S is not produced. Optimal growth occurs at 20–37°C, at pH 6.5–7.5, and in the presence of 2% NaCl (*Muricauda ruestringensis*) to 3% NaCl (*Muricauda aquimarina* and *Muricauda flavescens*). No hydrolysis of high-molecular-mass carbohydrates such as starch, agar, or crystalline cellulose occurs. The fatty acid profile is characterized by high amounts of branched fatty acids. The genus is closely related to other *Flavobacteriaceae*, which have been isolated from marine and marine-derived habitats.

DNA G+C content (mol%): 41–45.

Type species: ***Muricauda ruestringensis*** Bruns, Rohde and Berthe-Corti 2001, 2005^{VP}.

Further descriptive information

Phylogeny. Several members of the *Flavobacteriaceae* have been isolated from marine or marine-derived habitats. A comparison of 16S rRNA gene sequence data of all genera that have been isolated mainly from these habitats clearly indicates that the genus *Muricauda* is closely related to the genera *Arenibacter*, *Maribacter*, *Pibocella*, *Robiginitalea*, and *Zobellia* (Figure 48). The genus *Muricauda* comprises three species with validly published names: *Muricauda ruestringensis*, which is represented by only one type strain, strain B1^T (Bruns et al., 2001); *Muricauda aquimarina*, represented by two strains (SW-63^T and SW-72); and *Muricauda flavescens*, represented by strains SW-62^T and SW-74 (Yoon et al., 2005d).

Morphology. When grown on marine agar, all species produce yellow to golden yellow colonies of 0.5–1.5 mm in diameter after 3 d. Colonies are circular, convex in shape with a glistening surface. Young cells from suspension cultures are rod-shaped with rounded edges. However, with increasing age of the cultures the populations differentiate into larger coccus-shaped cells and into rod-shaped cells. *Muricauda ruestringensis* and *Muricauda aquimarina* have been described as exhibiting appendages when grown in liquid cultures. *Muricauda flavescens* has not yet been described as exhibiting appendages; however, the formation of vesicles has been observed clearly by electron microscopy. The production of appendages and vesicles is a distinctive characteristic of the genus *Muricauda*, although some other species within the *Cytophaga–Flavobacteria–Bacteroides* group are known to have cell structures that look very much like appendages, i.e., *Flavobacterium aquatile* strain ATCC 11947^T (Thomson et al., 1981), *Flexibacter* strain BH3, *Cytophaga johnsonae*, *Polaribacter irgensii*, and *Winogradskyella thalassocola*. The appendages of *Flexibacter* consist of extruded material derived from the lipopolysaccharide membrane and are probably related to the gliding motility of this species (Humphrey et al., 1979). The nature of the appendages of *Flavobacterium aquatile* has not yet been characterized. Gosink et al. (1998) showed that the appendages of *Polaribacter irgensii* strain 23-P^T are true flagella, although motility in this genus has never been observed. The recently isolated *Winogradskyella thalassocola* has been described to form network-like structures whose composition and function is also not known (Nedashkovskaya et al., 2005a).

Fine structure. Ultrathin sections of *Muricauda ruestringensis* show the typical ultrastructure of a Gram-stain-negative bacterium, with the exception that there are holes in the outer

membrane of older cultures (Figure 49). In addition, older cultures (3–4 d) are characterized by long and relatively thick appendages, which can be observed by light microscopy at 1,000× when stained with Nile Red. This staining indicates that they are lipid-containing structures (Müller et al., 2001). Bruns et al. (2001) have characterized the appendages of the type strain *Muricauda ruestringensis* strain B1^T. They are 20–30 µm long and often located in a polar position. The appendages exhibit a maturation process that begins with the formation of a vesicle at the cell surface (Figure 49), after which a stalk develops between vesicle and cell surface (Figure 49). The vesicle-like structures at the end of the stalks exhibit fibrillar-like structures on their surface (Figure 49). Ultrathin sections have revealed that the appendages are formed as a continuum of the outer membrane and are covered by a membrane (Figure 49). Because older cultures of *Muricauda ruestringensis* often form flocks, Bruns et al. (2001) suggested that the appendages might enable the cells to connect to each other.

Life cycle. Müller et al. (2001) suggest that *Muricauda ruestringensis* exhibits a complex life cycle in which the appendages of the cells are involved as a DNA-containing structure. By dual staining with DAPI and Nile Red, the authors showed that DNA was transferred from cells into the vesicles during the process of vesicle formation (Müller et al., 2001). They also demonstrated that fully developed vesicles of *Muricauda ruestringensis* B1^T are liberated from the progenitor cell and contain a double set of chromosomal DNA. The authors suggested an asymmetric life cycle for *Muricauda ruestringensis* strain B1^T (Müller et al., 2001). This type of multiplication seems to be unique among the *Flavobacteriaceae*. *Muricauda aquimarina* also shows relative long and thick appendages (Yoon et al., 2005d). The character of these appendages, however, has not been analyzed.

Chemotaxonomically significant components. All described strains of the genus are yellow- to golden yellow-pigmented when grown on the complex medium marine agar 2216 (Difco). The strains produce no flexirubin-type pigment (Bruns et al., 2001; unpublished data from the authors). All members of the genus exhibit an unsaturated menaquinone with six isoprene units (MK-6) as the respiratory pigment.

The genus *Muricauda* is characterized by cellular fatty acid profiles containing high amounts of straight-chain, branched and hydroxy fatty acids. The major cellular fatty acids of all three species are C_{15:1} iso, C_{15:0} iso, and C_{17:0} 3-OH iso. The growth medium strongly affects the proportion of the straight-chain fatty acid C_{15:0}. The proportion of C_{15:0} in *Muricauda ruestringensis* is about 1% when cells are cultivated with mineral PAC* medium containing sodium pyruvate (0.1%, w/v), sodium acetate (0.4%, w/v), and Casamino acids (0.1%, w/v) as the carbon source. In contrast, when cells are cultivated on the complex medium marine agar 2216 (Difco), this fatty acid amounts to 13%.

Growth conditions. All described *Muricauda* species grow well in liquid cultures or on solid media composed of artificial

*PAC medium contains (per liter of artificial seawater of 2.25% salinity): sodium pyruvate, 1.0 g; sodium acetate, 4.0 g; Casamino acids, 1.0 g; vitamin solution, 3.0 ml; mineral salt solution (DSMZ medium no. 124; DSMZ Catalogue of Strains, 1983), 1.0 ml; NaNO₃, 1.46 g; and Na₂HPO₄, 1.4 g; pH 7.2.

FAMILY I. FLAVOBACTERIACEAE

0.02

FIGURE 48. Neighbor-joining tree based on 16S rRNA gene sequences of marine members of the family *Flavobacteriaceae*. The tree shows the position of the *Muricauda* species *Muricauda aquimarina*, *Muricauda flavescens*, and *Muricauda ruestringensis*. Bootstrap values (expressed as percentages of 1,000 replications) are shown at the branching points. *Bacteroides fragilis* was used as the outgroup. Bar = 0.02 substitutions per nucleotide position.

FIGURE 49. Electron micrographs of the cell morphology and ultrastructure of *Muricauda ruestringensis*. Scanning electron micrographs: (a) formation of cell appendages starts with a vesicle-like structure on the bacterial surface (bar = 0.5 μm); (b, c) formation and growth of a stalk up to a length of approximately 5 μm (bars = 0.5 μm); (d) single cell with an appendage that has a vesicle-like structure which exhibits fibrillar-like structures (bar = 0.5 μm). Ultrathin sections of ultrastructural features: (e) older cells show holes (arrows) in the cell membrane which otherwise show a typical Gram-negative arrangement (bar = 0.1 μm); (f) appendages are formed as a continuum of the outer membrane (bar = 50 nm). OM, Outer membrane; CM, cytoplasmic membrane.

seawater supplemented with amino acids and trace elements or in marine broth. *Muricauda* species show good growth in media containing 0.5–9.0% NaCl, but not in media with an NaCl concentration of more than 10%. The optimal NaCl concentration varies between *Muricauda* species: 3% NaCl is optimal for *Muricauda ruestringensis*, whereas 2% is optimal for *Muricauda aquimarina* and *Muricauda flavescens*. The pH tolerance for growth varies between 6.0 and 8.0, with optimal growth at pH 6.5–7.5. All species have a wide temperature range showing good growth between 8 and 40°C. Bruns et al. (2001) report 30°C as optimal for *Muricauda ruestringensis* and Yoon et al. (2005d) report 37°C to be optimal for *Muricauda aquimarina* and *Muricauda flavescens*. All species grow under oxic conditions. *Muricauda ruestringensis* also shows good growth at dissolved oxygen concentrations as low as 0.8 $\mu\text{mol/l}$ and weak growth under anoxic conditions. Anoxic growth has not been observed for *Muricauda aquimarina* and *Muricauda flavescens*.

Metabolism and metabolic pathways. All members of the genus *Muricauda* are chemo-organotrophic. *Muricauda aquimarina* and *Muricauda flavescens* are described as having an exclusively respiratory-type metabolism. *Muricauda ruestringensis* is described as being facultatively anaerobic, exhibiting an anaerobic metabolism when peptone and yeast extract are supplied as the carbon source. All *Muricauda* species are able to hydrolyze esculin, tyrosine, and Tweens 20, 40, and 60. They grow with the sugars cellobiose, fructose, lactose, mannose, raffinose, and sucrose, or with succinate. Acid is produced from cellobiose, D-fructose, D-glucose, lactose, maltose, D-mannose, melibiose, sucrose, trehalose, and raffinose. All species are unable to reduce nitrate or nitrite and do not produce H_2S . They are also unable to degrade high-molecular-mass carbohydrates such as

starch or agar. Birchwood xylan is not degraded when tested on solid marine salts basal medium using the method of Baumann and Baumann (1981). *Muricauda* species do not hydrolyze casein, gelatin, hypoxanthine, urea, or xanthine. No growth occurs with acetate, pyruvate, glutamate, butyrate, citrate, lactate, formate, benzoate, methanol, ethanol, gelatin, starch, urea, xanthine, serine, mannitol, or hexadecane when these are supplied as the sole carbon source. No acids are produced from D-sorbitol, *myo*-inositol, D-ribose, D-mannitol, adonitol, or L-rhamnose.

Ecology. All known *Muricauda* species have been isolated from salt water habitats. *Muricauda ruestringensis* strain B1^T was isolated from a continuous culture with a suspension composed of artificial seawater and intertidal sediment taken from the German North Sea coast and which contained an autochthonous community. The culture was run at a dissolved oxygen concentration of 0.8 $\mu\text{mol/l}$ (Berthe-Corti and Bruns, 1999). The intertidal Wadden sediment from the German North Sea coast is a nutrient-rich habitat characterized by strong shifts in temperature, salinity, and oxygen concentration. It is rich in species belonging to the *Cytophaga-Flavobacteria-Bacteroides* group (Llobet-Brossa et al., 1998). *Muricauda aquimarina* and *Muricauda flavescens* have been taken from the water column of a salt lake near Hwajinpo Beach of the East Sea in Korea. This lake is fed by a river and has a direct connection to the East Sea in Korea.

Enrichment and isolation procedures

All *Muricauda* species were isolated using the standard dilution plating technique. Before isolation, *Muricauda ruestringensis* was enriched in a sediment-suspension culture (as described

above). Isolation was performed at 25°C on solid modified nutrient agar* *Muricauda aquimarina* and *Muricauda flavescens* have been isolated from the water column of a salt lake using marine agar 2216 (Difco). Cultures were incubated at 30°C.

Maintenance procedures

Muricauda can be maintained in the laboratory by transfer onto the isolation medium described above. Long-term storage of *Muricauda ruestringensis* has only been tested in the liquid PAC medium containing 20–25% glycerol. J.-H. Yoon recommends using nutrient broth from Difco with the addition of 20% glycerol for long-term storage of *Muricauda aquimarina* and *Muricauda flavescens* (personal communication).

Differentiation of the genus *Muricauda* from other closely related taxa

Phylogenetically, the genus *Muricauda* is clearly affiliated to the family of *Flavobacteriaceae*. It shares the inability to degrade crystalline cellulose (filter paper) with the other members of the *Flavobacteriaceae*. Among the complex organic substrates that some members of the phylum *Bacteroidetes* are able to degrade, cellulose has a particular taxonomic significance. The inability to degrade crystalline cellulose is one major characteristic used

to distinguish members of the *Flavobacteriaceae* from those of the genus *Cytophaga*. Moreover, the genus *Muricauda* produces yellow to golden yellow pigments, which is a typical characteristic of most *Flavobacteriaceae*. Production of flexirubin-type pigment is a further distinguishing characteristic within the *Flavobacteriaceae*. *Muricauda* was negative for the flexirubin reaction, whereas other members of the *Flavobacteriaceae* such as *Zobellia* produce this pigment (Table 58). While all closely related members of the *Flavobacteriaceae* have a strictly aerobic respiratory metabolism, *Muricauda ruestringensis* is a facultatively anaerobic organism. All other differential characteristics of closely related *Flavobacteriaceae* isolated from marine or marine-derived habitats are summarized in Table 58.

Finally, the most striking differential characteristic making *Muricauda* an extraordinary member of the *Flavobacteriaceae* is its phenotypic appearance. The appendages formed as a continuum of the outer membrane have never been described for other marine *Flavobacteriaceae* (Table 58).

Acknowledgements

The authors wish to express their appreciation to J.-H. Yoon for providing the strains *Muricauda aquimarina* SW-63^T and *Muricauda flavescens* SW-62^T.

List of species of the genus *Muricauda*

1. *Muricauda ruestringensis* Bruns, Rohde and Berthe-Corti 2001, 2005^{VP}

rue.strin'gen.sis. N.L. fem. adj. *ruestringensis* of or belonging to the former village of Rüstringen, which was destroyed by a tidal wave in 1362.

Cells are 0.3–0.6 × 1.1–2.7 µm. Cells from older cultures (3–4 d) exhibit long and relatively thick (20–30 nm) appendages. On mineral agar, colonies are yellow, circular, slightly convex, and 0.5–1.0 mm in diameter after 3 d at 30°C. The temperature range for growth is 8–40°C, with optimal growth at 20–30°C. The pH tolerance ranges between pH 6.0 and 8.0. Optimal pH for growth is 6.5–7.5. Slightly halophilic, showing good growth in media containing 0.5–9.0% (w/v) NaCl, with optimal growth at 3% (w/v) NaCl. Facultatively anaerobic. Growth on marine agar occurs under oxic and under anoxic conditions. The predominant respiratory lipoprotein is MK-6. The major fatty acids are C_{15:0} iso, C_{15:1} iso, and C_{17:0} 3-OH iso.

Source: strain B1^T was isolated from an enrichment culture containing intertidal sediment of the North Sea coast near the former village of Ruestringen.

DNA G+C content (mol%): 41.4 (HPLC).

Type strain: B1, DSM 13258, LMG 19739.

Sequence accession no. (16S rRNA gene): AF218782.

2. *Muricauda aquimarina* Yoon, Lee, Oh and Park 2005d, 1019^{VP}

a.qui.ma.ri'na. L. n. *aqua* water; L. adj. *marinus* of the sea; N.L. fem. adj. *aquimarina* pertaining to seawater.

Cells are 0.2–0.5 × 2.5–6.0 µm. On marine agar, colonies are golden yellow, circular, slightly convex, and 0.8–1.2 mm in diameter. Growth occurs at 10°C, but not at 4°C; maximum growth temperature is 44°C. Optimal pH for growth is around 7.0. Growth occurs in media containing up to 9% (w/v) NaCl, but does not occur in the absence of NaCl. No growth under anoxic conditions. The major fatty acids are C_{15:0} iso, C_{15:1} iso, and C_{17:0} 3-OH iso.

Source: the type strain was isolated from a salt lake near Hwajinpo Beach of the East Sea in Korea.

DNA G+C content (mol%): 44.1–44.2 (HPLC).

Type strain: SW-63, JCM 11811, KCCM 41646.

Sequence accession no. (16S rRNA gene): AY445075.

3. *Muricauda flavescens* Yoon, Lee, Oh and Park 2005d, 1018^{VP}

fla.ves'cens. L. v. *flavesco* to become golden yellow; L. part. adj. *flavescens* becoming golden yellow.

Most characteristics of relevance are identical to those of the species *Muricauda aquimarina*. Cells are 0.2–0.5 × 2.5–6.0 µm. On marine agar, colonies are golden yellow, circular, slightly convex, and 0.8–1.2 mm in diameter. Growth occurs at 10°C, but not at 4°C; the maximum growth temperature is 44°C. The optimal pH for growth is around 7.0. Growth occurs up to 9% (w/v) NaCl (Yoon et al., 2005d), but also occurs in a medium without the addition of NaCl and containing (per liter) 17.0 g casein peptone, 3.0 g soya peptone, 2.5 g D-glucose, and 2.5 g K₂HPO₄ (unpublished data from the authors). No growth occurs under anoxic conditions. The major fatty acids are C_{15:0} iso, C_{15:1} iso, and C_{17:0} 3-OH iso.

Source: the type strain was isolated from a salt lake near Hwajinpo Beach of the East Sea in Korea.

DNA G+C content (mol%): 45.2–45.4 (HPLC).

Type strain: SW-62, JCM 11812, KCCM 41645.

Sequence accession no. (16S rRNA gene): AY445073.

*Solid modified nutrient agar contains (g/l of artificial seawater): Bacto Peptone (Difco), 2.5; yeast extract, 1.5; and agar, 15.0. The artificial seawater contains (g/l of distilled water): NaCl, 23.6; KCl, 0.64; MgCl₂·6H₂O, 4.53; MgSO₄·7H₂O, 5.94; CaCl₂·2H₂O, 1.3. To avoid precipitation, the CaCl₂·2H₂O should be sterilized separately. The pH of the medium must be adjusted to 7.2.

Genus XXXVI. *Myroides* Vancanneyt, Segers, Torck, Hoste, Bernardet, Vandamme and Kersters 1996, 930^{VP}

THE EDITORIAL BOARD

My.roi'des. Gr. n. *myron* perfume; L. suff. *-oides* (from Gr. suff. *-eides*, from Gr. n. *eidos* that which is seen, form, shape, figure), resembling, similar; N.L. masc. n. *Myroides* resembling perfume.

Rods, 0.5 × 1–2 µm. Longer rods and long chains (containing 4–10 cells) may occur in broth medium. Nonmotile. **No gliding motility** or swarming occurs. Gram-stain-negative. **Yellow or yellow to orange colonies are usually produced**. A characteristic fruity odor is produced by most strains. **Aerobic**, having a strictly respiratory type of metabolism with oxygen as the terminal electron acceptor. Good growth occurs on nutrient agar and MacConkey agar. No hemolysis occurs on blood agar. Growth occurs at 18–22 and 37°C, but not at 5 or 42°C. NaCl is not required, but growth occurs in the presence of at least 5% NaCl. Positive for oxidase and gelatinase; catalase-positive or (in one species) weakly positive. Indole-negative. Nitrate is

not reduced. Negative for arginine dihydrolase and β-galactosidase. Esculin is not hydrolyzed. **Nonsaccharolytic**. The major isoprenoid quinone is menaquinone-6. The dominant polyamine component is homospermidine. The dominant fatty acids are C_{15:0} iso, C_{15:0} iso 3-OH, C_{16:0} 3-OH, C_{17:0} iso 3-OH, and C_{17:1} iso ω9c. Two species are sources of nosocomial infections in humans; a third has been isolated from seawater.

DNA G+C content (mol%): 30–38.

Type species: ***Myroides odoratus*** (Stutzer and Kwaschnina 1929) Vancanneyt, Segers, Torck, Hoste, Bernardet, Vandamme and Kersters 1996, 931^{VP} (*Flavobacterium odoratum* Stutzer in Stutzer and Kwaschnina 1929, 221).

Further descriptive information

Vancanneyt et al. (1996) reported that *Myroides odoratus* and *Myroides odoratimimus* hydrolyzed the following substrates, as determined by API ZYM galleries: 2-naphthyl-phosphate, 2-naphthyl-butyrate, 2-naphthyl-caprylate, L-leucyl-2-naphthylamide, and naphthol-AS-BI-phosphate. N-Benzoyl-DL-arginine-2-naphthylamide, 6-Br-2-naphthyl-β-D-galactopyranoside, 2-naphthyl-β-D-galactopyranoside, naphthol-AS-BI-β-D-glucuronide, 2-naphthyl-α-D-glucopyranoside, 6-Br-2-naphthyl-α-D-glucopyranoside, 1-naphthyl-N-acetyl-β-D-glucosaminide, 6-Br-2-naphthyl-α-D-mannopyranoside, and 2-naphthyl-α-L-fucopyranoside are not hydrolyzed. Very weak or no hydrolysis occurs with the substrates 2-naphthylmyristate, L-valyl-2-naphthylamide, L-cystyl-2-naphthylamide, and N-glutaryl-phenylalanine-2-naphthylamide.

Myroides odoratus is most commonly recovered from human urine specimens, sometimes in significant numbers, and from colonization of amputation sites (Davis et al., 1979; Holmes et al., 1979; Vancanneyt et al., 1996). Strains of *Myroides odoratimimus* have been isolated from human wounds, urine, human leg slough, pus, and a water sample (Vancanneyt et al., 1996). The role of *Myroides odoratus* and *Myroides odoratimimus* as causative agents of infection is ill-defined and data are still emerging. Yağci et al. (2000) reported an outbreak of *Myroides odoratimimus* that occurred in a urology ward of a hospital over a 3-year period and described the use of DNA fingerprinting for characterization of the isolates. Green et al. (2001) reported a case of bacteremia and recurrent cellulitis caused by *Myroides odoratus* in an evidently immunocompetent male; this appears to be the first documented life-threatening infection in an immunocompetent host. Motwani et al. (2004) reported a case of cellulitis caused by *Myroides odoratus* that progressed to septic shock.

Some strains of *Myroides odoratus* have been found in insect guts (Spiteller et al., 2000) and freshwater fishes (the bacterial niche being unidentified; González et al., 2000).

The type strain of *Myroides pelagicus* was obtained during the isolation of crude oil-utilizing and -emulsifying bacteria from seawater by Maneerat et al. (2005). *Myroides pelagicus* (and also *Myroides odoratus* and *Myroides odoratimimus*) produced surface-active compounds in marine broth 2216 (Difco), which were identified as cholic acid, deoxycholic acid, and their glycine conjugates. These findings were the first indication that bile acids could be produced by prokaryotic cells. Maneerat et al. (2006) reported that the type strain of *Myroides pelagicus* could grow on weathered crude oil and was capable of emulsifying it. Bile acids cannot emulsify crude oil and Maneerat et al. (2006) showed that the biosurfactant able to emulsify crude oil was excreted in the culture supernatant and was identified as being a mixture of L-ornithine lipids.

Enrichment and isolation procedures

Special procedures are not normally required for the isolation of *Myroides odoratus* and *Myroides odoratimimus*. *Myroides pelagicus* was isolated from seawater and can be cultured in marine broth 2216 (Difco).

Differentiation of the genus *Myroides* from other genera

The genus differs from *Flavobacterium* species by its lack of gliding motility, its ability to grow well at 37 °C, its salt tolerance, and differences in its fatty acid composition. Whereas *Flavobacterium* species are mainly soil and freshwater organisms, *Myroides odoratus* and *Myroides odoratimimus* are associated with nosocomial infections in humans. The characteristics of being non-saccharolytic and indole-negative differentiate *Myroides odoratus* from *Elizabethkingia meningoseptica* and other similar medically important organisms.

Taxonomic comments

Bernardet et al. (1996) emended the description of the genus *Flavobacterium* and restricted members of this genus to aerobic, chemoheterotrophic, Gram-stain-negative rods that occur in soil and freshwater, have gliding motility, form cream to yellow colonies, and decompose several polysaccharides but not cellulose. *Flavobacterium odoratum* (now *Myroides odoratum*) did not have gliding motility and occurred in clinical specimens, so it was removed from the genus *Flavobacterium*. Analysis of 16S rRNA gene sequences had also indicated that *Flavobacterium odoratum* was phylogenetically distinct from the other members of the *Flavobacterium* (Gherna and Woese, 1992; Nakagawa and Yamasato, 1993, 1996) (Vandamme et al., 1994a). In a polyphasic taxonomic study that included DNA-rRNA hybridizations and an analysis of whole-cell protein patterns, fatty acid compositions, and phenotypic characteristics, Vancanneyt et al. (1996) concluded that *Flavobacterium odoratum* should be placed in a new genus, *Myroides*. Moreover, they also gave species status, *Myroides odoratimimus*, to a genetically homogeneous subgroup within *Flavobacterium odoratum* based on the lack of significant DNA-DNA hybridization with *Myroides odoratum* strains.

Yoon et al. (2006a) reported that the type strain of *Myroides pelagicus* shared 93–95% 16S rRNA gene sequence similarity with the type strains of *Myroides odoratus* and *Myroides odoratimimus*. Moreover, the DNA-DNA relatedness values of the strain with the type strains of *Myroides odoratus* and *Myroides odoratimimus* were less than 70%, indicating that the strain belonged to a novel species.

Differentiation of species of the genus *Myroides*

Table 59 lists some features that differentiate the three species of the genus.

List of species of the genus *Myroides*

1. ***Myroides odoratus*** (Stutzer and Kwaschnina 1929) Vancanneyt, Segers, Torck, Hoste, Bernardet, Vandamme and Kersters 1996, 931^{VP} (*Flavobacterium odoratum* Stutzer in Stutzer and Kwaschnina 1929, 221)

o.do.ra'tus. L. part. masc. adj. *odoratus* perfumed.

Characteristics are as given for the genus and as listed in Table 59, with the following additional features given by Vancanneyt et al. (1996). No positive reaction is observed

in Biotype 100 galleries. In the Biolog GN MicroPlate assay, all strains, even the negative control, oxidize all wells after a few hours of incubation. DNA-DNA hybridization values among the strains range from 55 to 100%. The major fatty acids are C_{15:0} iso, C_{15:0} iso 3-OH, C_{15:0} anteiso, C_{16:0} 3-OH, C_{17:0} iso 3-OH, and C_{17:1} iso ω9c.

Source: commonly recovered from human urine specimens, sometimes in significant numbers, and from colonization of

amputation sites. Some strains have been found in insect guts and freshwater fishes.

DNA G+C content (mol%): 35–38 (T_m).

Type strain: ATCC 4651, CCUG 7321, CIP 103105, DSM 2801, IFO (now NBRC) 14945, JCM 7458, LMG 1233, NCTC 11036.

Sequence accession no. (16S rRNA gene): M58777.

2. *Myroides odoratimimus* Vancanneyt, Segers, Torck, Hoste, Bernardet, Vandamme and Kersters 1996, 931^{VP}

o.do.ra.ti'mi.mus. L. part. masc. adj. *odoratus* a specific epithet; L. n. *mimus* a mimic, an imitator; N.L. n. *odoratimimus* imitator of (*Myroides*) *odoratus*.

Characteristics are as given for the genus and as listed in Table 59, with the following additional features given by Vancanneyt et al. (1996). As determined by Biotype 100 galleries, growth occurs on L-aspartate, L-glutamate, and L-proline. Growth on L-malate, succinate, and fumarate differs depending on the strain studied. When the Biolog GN MicroPlate assay is used, all strains oxidize Tween 40, Tween 80, methylpyruvate, monomethylsuccinate, acetic acid, α-hydroxybutyric acid, α-ketoglutaric acid, DL-lactic acid, propionic acid, succinic acid, bromosuccinic acid, succinamic acid, alaninamide, L-alanine, L-alanyl-glycine, L-asparagine, L-aspartic acid, L-glutamic acid, glycyl-L-aspartic acid, glycyl-L-glutamic acid, L-leucine, L-ornithine, L-proline, L-serine, L-threonine, inosine, uridine, and thymidine. Reactions differ among strains for oxidation of L-fucose, formic acid, β-hydroxybutyric acid, γ-hydroxybutyric acid, α-ketobutyric acid, α-ketoglutaric acid, L-histidine, L-phenylalanine, D-serine, urocanic acid, phenylethylamine, 2,3-butanediol, and glycerol.

The following substrates are not oxidized: α-cyclodextrin, dextrin, glycogen, N-acetyl-D-galactosamine, N-acetyl-D-

glucosamine, adonitol, L-arabinose, D-arabitol, cellobiose, meso-erythritol, D-fructose, D-galactose, gentiobiose, α-D-glucose, myo-inositol, α-D-lactose, lactulose, maltose, D-mannitol, D-mannose, melibiose, methyl β-D-glucoside, D-psicose, raffinose, L-rhamnose, D-sorbitol, sucrose, trehalose, turanose, xylitol, *cis*-aconitic acid, citric acid, D-galactonic acid lactone, D-galacturonic acid, D-gluconic acid, D-glucosaminic acid, D-glucuronic acid, *p*-hydroxyphenylacetic acid, itaconic acid, malonic acid, quinic acid, D-saccharic acid, sebacic acid, glucuronamide, D-alanine, hydroxy-L-proline, L-pyroglytamic acid, DL-carnitine, γ-aminobutyric acid, putrescine, 2-aminoethanol, DL-α-glycerolphosphate, glucose 1-phosphate, and glucose 6-phosphate.

DNA–DNA hybridization values among the strains range from 80 to 100%. The major fatty acids are C_{13:0} iso, C_{15:0}², C_{15:0} iso, C_{15:0} iso 3-OH, C_{16:0} 3-OH, C_{17:0} iso 3-OH, C_{17:1} iso ω9c, and summed feature 4 (C_{15:0} iso 2-OH and/or C_{16:1} ω7c/t).

Source: human wounds, urine, human leg slough, pus, and a water sample.

DNA G+C content (mol%): 30–35 (T_m).

Type strain: CCUG 39352, CIP 105170, JCM 7460, LMG 4029, NCTC 11180.

Sequence accession no. (16S rRNA gene): AJ854059.

3. *Myroides pelagicus* Yoon, Maneerat, Kawai and Yokota 2006a, 1919^{VP}

pe.la'gi.cus. L. masc. adj. *pelagicus* belonging to the sea.

Characteristics are as given for the genus and as listed in Table 59, with the following additional features given by Yoon et al. (2006a). Colonies on LB agar are circular, convex, and yellow to orange. Temperature range for growth is 10–37°C; no growth occurs at 4 or 45°C. The pH range for growth is 5–9. NaCl is not required for growth, but the organism can tolerate up to 9% NaCl (w/v). Oxidase-positive. Catalase is weakly positive.

The following reactions are positive: gelatin hydrolysis, Voges–Proskauer test, citrate utilization, alkaline phosphatase, leucine arylamidase, acid phosphatase, and naphthol-AS-BI-phosphohydrolase. The following substrates are utilized (Biolog MicroPlate system): glycogen, methyl pyruvate, monomethyl succinate, acetic acid, α-ketoglutaric acid, α-ketoglutaric acid, DL-lactic acid, succinic acid, bromosuccinic acid, succinamic acid, L-alanine, L-alanyl glycine, L-asparagine, L-aspartic acid, L-glutamic acid, glycyl-L-aspartic acid, glycyl-L-glutamic acid, L-leucine, L-ornithine, L-proline, L-serine, L-threonine, inosine, uridine, and thymidine.

The following reactions are negative: ONPG, arginine dihydrolase, lysine decarboxylase, ornithine decarboxylase, urease, production of H₂S and indole, nitrate and nitrite reduction, esterase (C4), esterase lipase (C8), lipase (C4), valine arylamidase, cystine arylamidase, trypsin, chymotrypsin, α-galactosidase, β-galactosidase, α-glucosidase, β-glucosidase, and tryptophan deaminase. The following substrates are not utilized (Biolog MicroPlate system): cyclodextrin, dextrin, Tween 40, Tween 80, N-acetyl-D-glucosamine, N-acetyl-D-galactosamine, adonitol, L-arabinose, D-arabitol, cellobiose, i-erythritol, D-fructose, L-fucose, D-galactose, gentiobiose, α-D-glucose, myo-inositol, α-D-lactose, lactulose, maltose, D-mannitol, D-mannose, melibiose, methyl β-D-glucoside, D-psicose, raffinose, L-rhamnose,

D-sorbitol, sucrose, trehalose, furanose, xylitol, *cis*-aconitic acid, citric acid, formic acid, D-galactonic acid lactone, D-galacturonic acid, D-gluconic acid, D-glucosaminic acid, D-glucuronic acid, α -hydroxybutyric acid, γ -hydroxybutyric acid, *p*-hydroxyphenylacetic acid, itaconic acid, α -ketobutyric acid, malonic acid, propionic acid, quinic acid, D-saccharic acid, sebacic acid, glucuronamide, alaninamide, D-alanine, L-histidine, hydroxyl-L-proline, L-phenylalanine, L-pyrroglutamic acid, D-serine, DL-carnitine, γ -aminobutyric acid, urocanic acid, phenylethylamine, putrescine, 2-aminoethanol,

2,3-butanediol, glycerol, DL- α -glycerol phosphate, glucose 1-phosphate, and D-glucose 6-phosphate.

The major quinone system is menaquinone-6. The major cellular fatty acids are C_{15:0} iso, C_{17:1} iso ω 9c, and C_{17:0} iso 3-OH.

Source: the type strain was isolated from seawater, off the coast of Thailand.

DNA G+C content (mol%): 33.6 (HPLC).

Type strain: SMI, IAM 15337, KCTC 12661.

Sequence accession no. (16S rRNA gene): AB176662.

Genus XXXVII. *Nonlabens* Lau, Tsoi, Li, Plakhotnikova, Dobretsov, Wong, Pawlik and Qian 2005b, 2281^{VP}

THE EDITORIAL BOARD

Non.la'bens. L. adv. *non* not; L. part. adj. *labens* gliding; N.L. fem. n. (N.L. part. adj. used as a substantive)
Nonlabens non-gliding.

Short rods. Nonmotile. Nonsporeforming. Gram-stain-negative. Strictly aerobic. MK-6 is the only respiratory quinone. **Colonies are orange. NaCl (2.0–4.0%) is required for growth.** Flexirubin-type pigments are not produced. Catalase- and oxidase-positive. **Acetoin is produced. Gelatin is hydrolyzed. No α - and β -glucosidase and β -galactosidase activities are present.** Isolated from a microbial mat in a subtropical estuary.

DNA G+C content (mol%): 33.6 (HPLC).

Type species: *Nonlabens tegetincola* Lau, Tsoi, Li, Plakhotnikova, Dobretsov, Wong, Pawlik and Qian 2005b, 2281^{VP} emend. Lau, Tsoi, Li, Plakhotnikova, Dobretsov, Wu, Wong, Pawlik and Qian 2006, 184.

Enrichment and isolation procedures

Nonlabens tegetincola was isolated from a microbial mat covering a polystyrene surface retrieved from an estuarine mangrove habitat in the Bahamas. The isolation medium was a special marine agar (SMA) consisting of 5.0 g peptone and 3.0 g yeast extract dissolved in seawater. The medium was sterilized by filtration

(0.22 μ m pore diameter) and solidified with agar. Orange colonies, 2–4 mm in diameter, were selected after 48 h at 30°C.

Differentiation of the genus *Nonlabens* from related genera

Members of the genus *Nonlabens* differ from those of *Psychroflexus* in that they require NaCl, are able to hydrolyze gelatin, lack α - and β -glucosidase activities, and are unable to grow at temperatures below 12°C. They differ from members of the genus *Salegentibacter* in their requirement for NaCl, orange pigmentation (rather than yellow), production of acetoin, lack of β -galactosidase activity, and inability to grow at temperatures below 12°C.

Taxonomic comments

Phylogenetic analysis based on 16S rRNA gene sequences indicates that the nearest neighbors of *Nonlabens* are members of the genera *Psychroflexus* and *Salegentibacter*, with sequence similarity values of 88.5–90.7% (Lau et al., 2005b).

List of species of the genus *Nonlabens*

1. *Nonlabens tegetincola* Lau, Tsoi, Li, Plakhotnikova, Dobretsov, Wong, Pawlik and Qian 2005b, 2281^{VP} emend. Lau, Tsoi, Li, Plakhotnikova, Dobretsov, Wu, Wong, Pawlik and Qian 2006, 184

te.get.in'col.a. L. n. *teges-etis* mat; L. n. *incola* an inhabitant; N.L. n. *tegetincola* mat-inhabitant, pertaining to its microbial mat habitat.

Characteristics are as described for the genus, with the following additional features. Colonies on SMA agar are orange, circular, 2.0–4.0 mm in diameter, and convex, with smooth surfaces and entire translucent margins. No diffusible pigment is produced. Grows at 12.0–44.0°C (optimum 28.0–36.0°C) and pH 5.0–10.0. Acetoin is produced, but not indole or H₂S. Nitrate is not reduced. DNA, gelatin, starch, and Tweens 20, 40 and 80 are hydrolyzed, but not agar, casein, cellulose, or chitin. The following enzymes are present: acid phosphatase, alkaline phosphatase, α -chymotrypsin, cystine arylamidase, leucine arylamidase, valine arylamidase, esterase (C4), esterase lipase (C8), lipase (C14), trypsin, and naphthol-AS-BI-phosphohydrolase. The

following enzymes are not present: *N*-acetyl- β -glucosaminidase, arginine dihydrolase, α -fucosidase, α -galactosidase, β -galactosidase, α -glucosidase, β -glucosidase, β -glucuronidase, α -mannosidase, lysine decarboxylase, ornithine decarboxylase, tryptophan deaminase, and urease. Except for acid production from sucrose, no growth or acid production is observed from carbon sources included in the API 50CH, API 20E, and API 20NE test systems. Utilization of 57 carbon sources occurs when tested by the MicroLog 3 system; the compounds used include acetic acid, adonitol, L-alaninamide, L-alanine, L-alanyl-glycine, D-arabitol, L-aspartic acid, citric acid, α -cyclodextrin, dextrin, L-erythritol, D-fructose, L-fucose, D-galactonic acid lactone, D-galactose, D-galacturonic acid, D-gluconic acid, D-glucosaminic acid, α -D-glucose, glucuronamide, D-glucuronic acid, L-glutamic acid, glycogen, glycyl-L-aspartic acid, glycyl-L-glutamic acid, α -hydroxybutyric acid, *myo*-inositol, α -ketobutyric acid, α -ketoglutaric acid, α -ketovaleric acid, DL-lactic acid, α -D-lactose, lactulose, malonic acid, maltose, D-mannitol, D-mannose, melibiose, methyl β -D-glucoside,

methylpyruvate, monomethyl succinate, L-ornithine, L-proline, propionic acid, quinic acid, D-psicose, raffinose, L-rhamnose, D-saccharic acid, L-serine, D-sorbitol, succinamic acid, sucrose, L-threonine, trehalose, turanose, and uridine. The predominant fatty acids are C_{15:0} iso, C_{15:0} iso 3-OH, C_{16:0} iso, C_{16:0} iso 3-OH, C_{17:0} iso 3-OH, summed feature 3 (comprising C_{15:0} iso 2-OH and/or C_{16:1} ω7c), and an unknown fatty acid with a carbon chain length equivalent

of 13.6 (altogether representing 78.3% of the total). Susceptible to ampicillin, chloramphenicol, penicillin, streptomycin, and tetracycline, but not to kanamycin.

Genus XXXVIII. *Olleya* Mancuso Nichols, Bowman and Guezennec 2005, 1560^{VP}

THE EDITORIAL BOARD

Olleya. N.L. fem. n. *Olleya* named in honor of June Olley, who has made significant contributions to the area of predictive microbiology.

Rods, approximately 0.3–0.5 × 2.0–2.5 μm. Motile by gliding. Endospores are not formed. Gram-stain-negative. Cell mass is orange/yellow. Flexirubin pigments are absent. Growth occurs at 4–30°C, but not at 37°C. Strictly aerobic. Chemo-heterotrophic. Catalase-positive. **Oxidase-positive. NaCl or sea salts are required for growth. Acid is produced from carbohydrates.** β-Galactosidase activity is not present. **Agar and starch are not hydrolyzed.** The major fatty acids include C_{15:1} iso ω10c, C_{15:0} iso, C_{15:0} iso β-OH, C_{15:1} anteiso ω10c, C_{15:0}, and C_{15:0} iso α-OH.

DNA G+C content (mol%): 49 (*T_m*).

Type species: *Olleya marilimosa* Mancuso Nichols, Bowman and Guezennec 2005, 1560^{VP}.

Enrichment and isolation procedures

Olleya marilimosa was isolated from material sampled from the cod end of a plankton net (20 μm pore size) trawled through the Southern Ocean; the sea temperature was 4°C and the salinity was 3.5%. Aliquots of 20 μl from the net were spread onto SNA (nutrient broth made with seawater plus 12 g/l agar) and SNA + 2% glucose and incubated at 2°C. After initial isolation, colonies were subcultured onto marine agar (MA)* and MA-glucose.

List of species of the genus *Olleya*

- Olleya marilimosa*** Mancuso Nichols, Bowman and Guezennec 2005, 1560^{VP}

mar.i.lim.o'sa. L. gen. neut. n. *maris* of the sea; L. adj. *limosus* -a -um full of slime, slimy; N.L. fem. adj. *marilimosa* of the sea and slimy.

Characteristics are as described for the genus, with the following additional features. After 1 week at 20°C on MA, colonies are orange/yellow, translucent, 1–2 mm in diameter, circular, and convex, with an entire edge and a butyrous consistency. Colonies exhibit a spreading margin on dilute agar and an enhanced mucoid morphology when grown on MA-glucose. The pH range for growth is 5–9. Growth

Differentiation of the genus *Olleya* from related genera

Members of the genus *Olleya* can be differentiated from those of the genus *Lacinutrix* by their gliding motility, oxidase activity, growth at 30°C, acid formation from carbohydrates, and higher DNA G+C content (49 mol% vs 37 mol%). They differ from members of the genus *Bizionia* by their gliding motility, acid production from carbohydrates, utilization of carbohydrates, inability to produce H₂S and hydrolyze casein, and higher DNA G+C content (49 mol% vs 38–45 mol%). They differ from members of the genus *Algibacter* by their aerobic instead of fermentative metabolism, lack of β-galactosidase, inability to hydrolyze agar and starch, and higher DNA G+C content (49 mol% vs 31–33 mol%).

Taxonomic comments

By 16S rRNA gene sequence analysis, the taxa most closely related to *Olleya marilimosa* are *Lacinutrix copepodicola*, *Bizionia saleffrena*, *Bizionia paragorgiae*, and *Algibacter lectus*, having sequence similarities of 94.0, 94.1, 94.2, and 94.5%, respectively (Mancuso Nichols et al., 2005).

occurs between 1.2 and 5.2% NaCl, with optimal growth occurring in approximately 1.2–2.9% NaCl. Yeast extract or peptone is required for growth. Nitrate is not reduced to nitrite. Indole, DNase, β-galactosidase, lipase, urease, and acetoin (Voges–Proskauer reaction) are not produced. Degrades Tween 80, elastin, gelatin, and tyrosine, but not agar, starch, esculin, casein, cellulose, or xanthine. Citrate is utilized as a sole carbon source, but uric acid is not. Acid is produced from glucose. Glucose, maltose, and mannose are assimilated, but arabinose, mannitol, D-gluconate, capric acid, adipic acid, malate, and trisodium citrate are not. The following enzyme activities are present: N-acetyl-β-glucosaminidase, alanine arylamidase, alkaline phosphatase, arginine arylamidase, glutamyl glutamic acid arylamidase, glycine arylamidase, histidine arylamidase, leucine arylamidase, leucyl glycine arylamidase, phenylalanine arylamidase, serine arylamidase, and tyrosine arylamidase. The following enzyme activities are not present: α-arabinosidase, arginine

*MA contains: yeast extract (Oxoid L21), 1 g; bacteriological peptone (Oxoid L375), 5 g; artificial sea salts (Sigma S9883), 32 g; agar, 15 g; and distilled water, 1,000 ml. For MA-glucose, a glucose stock solution is autoclaved separately before being combined with MA to give a final concentration of 3% glucose.

dihydrolase, α -fucosidase, α -galactosidase, β -galactosidase, β -galactosidase-6-phosphate, α -glucosidase, β -glucosidase, β -glucuronidase, glutamic acid decarboxylase, lysine decarboxylase, ornithine decarboxylase, proline arylamidase, pyroglutamic acid arylamidase, and tryptophan deaminase. The exopolysaccharide produced by the type strain is composed of the following monosaccharides (percentage of total sugars): arabinose, 5; mannose, 74; galactose, 3;

glucose, 8; glucuronic acid, 8; and *N*-acetylglucosamine, 1 (Nichols et al., 2005).

Source: the type strain was isolated from particulate material from the Southern Ocean at approximately 65° 32' 06 S 143° 10' 16 E.

DNA G+C content (mol%): 49 (T_m).

Type strain: CAM030, ACAM 1065, CIP 108537.

Sequence accession no. (16S rRNA gene): AY586527.

Genus XXXIX. **Ornithobacterium** Vandamme, Segers, Vancanneyt, Van Hove, Mutters, Hommez, Dewhirst, Paster, Kersters, Falsen, Devriese, Bisgaard, Hinz and Mannheim 1994b, 35^{VP}

HAFEZ M. HAFEZ AND PETER VANDAMME

Or.ni.tho.bac.te'ri.um. Gr. n. *ornis* -ithos bird; L. neut. n. *bacterium* rod; N.L. neut. n. *Ornithobacterium* bird bacterium, because it was first isolated from birds.

Cells are pleomorphic rods, 0.2–0.4 × 1.3 μ m. Gram-stain-negative. **Nonsporeforming. Nonmotile.** Metabolism is **chemo-organotrophic** and **mesophilic**. Growth occurs at 30–42°C. *Ornithobacterium* strains grow in various atmospheric conditions, but preferentially **microaerobically**. *Ornithobacterium* strains exhibit various levels of capnophilic metabolism. Colonies are not pigmented on common growth media. **Oxidase-positive. Catalase-negative. β -Galactosidase (ONPG)-positive.** Most strains are urease-positive. **Indole-negative. Nitrate is not reduced to nitrite.** This genus has been referred to as *Pasteurella*-like, *Kingella*-like, or pleomorphic Gram-stain-negative rod (PGNR); the name TAXON 28 has also been used. *Ornithobacterium* strains cause respiratory disease in avian species worldwide.

DNA G+C content (mol%): 37–39.

Type species: ***Ornithobacterium rhinotracheale*** Vandamme, Segers, Vancanneyt, Van Hove, Mutters, Hommez, Dewhirst, Paster, Kersters, Falsen, Devriese, Bisgaard, Hinz and Mannheim 1994b, 35^{VP}.

Further descriptive information

The genus *Ornithobacterium* is a member of the family *Flavobacteriaceae* and represents a distinct line of descent within this family. Related bacteria are the bird pathogens *Riemerella anatispestifer* and *Coenonia anatina* (Vandamme et al., 1994a). The family includes *Flavobacterium*, the type genus, and the genera *Bergeyella*, *Capnocytophaga*, *Chryseobacterium*, *Ornithobacterium*, *Riemerella*, and *Weeksella* (Bernardet et al., 2002).

Morphology and physiology. Growth in broth media reveals more cellular pleomorphism than growth on agar surfaces. In addition, cells have a more variable length (0.6–5 μ m).

Most strains grow aerobically, microaerobically, anaerobically, and in a CO₂-enriched atmosphere. Growth occurs at 30, 35, and 42°C; weak or no growth occurs at 24°C. Strains produce convex, circular, and grayish white to yellowish colonies, with an entire edge and smooth surface on blood agar. Colonial adherence, spreading, or corrosion is not observed. No hemolysis occurs on blood agar. Smooth, nonpigmented colonies develop within 2 d of incubation on rich peptone, peptone-blood, or chocolate agar at 36°C. No growth occurs on MacConkey agar, Endo agar, Drigalski agar, or Simmons' citrate medium. No growth factors are required.

Ornithobacterium is oxidase-positive; however, Ryll et al. (2002) were able to isolate and identify an oxidase-negative strain of *Ornithobacterium rhinotracheale* from turkey flocks in Germany. Alkaline phosphatase activity is present. Urease production may test positive either on Lautrop's non-proliferative test or after a prolonged incubation time (up to 7 d) and may yield variable results in both Christensen urea agar slants and urea broth. Nitrates are not reduced; some strains reduce nitrites, but no denitrification occurs. Arginine dihydrolase is usually present if strains are grown in Möller's medium (Difco) within 3 d of incubation at 36°C. Lysine and ornithine decarboxylases, phenylalanine deaminase, lecithinase, DNase, and gelatinase activities are absent. Hydrogen sulfide is not detected in Kligler's agar, triple-sugar iron agar, or SIM agar. Esculin is not hydrolyzed. Acetylmethylcarbinol is produced in the Voges–Proskauer test. The methyl red test is negative. Hyaluronidase and chondroitin sulfatase activities are present.

Ethanol is not oxidized. D-Glucose in OF medium is either weak and slowly oxidized or not detected. Most strains use D-galactose, D-glucose, D-mannose, lactose, and sucrose as carbon sources. D-Xylose, D-mannitol, D-sorbitol, and malonate are usually not used as carbon sources. In general, carbohydrates are better catabolized in media supplemented with 2% chicken serum. Wheat starch is acidified by most strains within 1–5 d of incubation at 36°C.

Due to the variable ability of *Ornithobacterium rhinotracheale* strains to grow in the liquid media that are normally used for identification purposes, the biochemical reactions of *Ornithobacterium rhinotracheale* may appear inconsistent. However, under optimal conditions, the biochemical properties of the organism are fairly constant.

Ecology and pathogenicity. Infection with *Ornithobacterium rhinotracheale* has been recognized in many countries worldwide and incriminated as a possible additional causative agent in respiratory disease complexes in poultry (Allymehr, 2006; Arns et al., 1998; Back et al., 1998a; Canal et al., 2005; Charlton et al., 1993; Dudouyt et al., 1995; El-Gohary, 1998; El-Sukhon et al., 2002; Hafez et al., 1993; Hafez and Friedrich, 1998; Hinz et al., 1994; Koga and Zavaleta, 2005; Naeem et al., 2003; Sakai et al., 2000; Soriano et al., 2002; Tanyi et al., 1995; Travers et al., 1996; Turan and Ak, 2002; van Beek et al., 1994; J. DuPreez, personal communication). Retrospective examination of

culture collections has revealed that *Ornithobacterium rhinotracheale* had already been isolated from turkeys in 1981 and from rooks in 1983 in Germany. Also, examination of bacterial isolates collected before 1990 from chickens, partridge, and turkeys in the United Kingdom, Israel, Belgium, and France confirmed that they were strains of *Ornithobacterium rhinotracheale* (Hinze and Hafez, 1997; Vandamme et al., 1994b).

Typing. Although several investigators have described microbiological isolation and identification of *Ornithobacterium rhinotracheale*, there are few reports using molecular typing techniques. Amonsin et al. (1997) characterized 55 *Ornithobacterium rhinotracheale* isolates from eight countries of four continents by multilocus enzyme electrophoresis (MLEE), repetitive sequence based-PCR (rep-PCR), and 16S rRNA gene sequencing. Using MLEE, the *Ornithobacterium rhinotracheale* isolates could be discriminated into six electrophoretic types (ETs), of which only three were recovered from domesticated poultry. A total of 50 of the 55 isolates (90.9%) examined were assigned to one of two closely related clones (ET 1 and ET 2) that comprise the ET 1 complex. Furthermore, the data suggested a geographic component to the variation typical of a clonal population structure. In addition, the results suggested host specificity among clones of *Ornithobacterium rhinotracheale*. Virtually all the *Ornithobacterium rhinotracheale* isolates recovered from domesticated poultry were assigned to the ET 1 complex, whereas only a single non-ET 1 complex isolate was recovered from domesticated poultry populations. In contrast, none of the four isolates from rooks or guinea fowl were assigned to the common ET 1 complex. Moreover, the clustering obtained by analysis of rep-PCR banding patterns predicted that *Ornithobacterium rhinotracheale* clones infecting passeriform birds (rooks) are genetically distinct from clones infecting galliform birds (chickens, turkeys, and guinea fowl).

In another study, Leroy-Setrin et al. (1998) compared 23 strains of *Ornithobacterium rhinotracheale* which were isolated in France between 1994 and 1995 from 17 geographical regions using plasmid profiles, ribotyping, and random amplified polymorphic DNA (RAPD) analysis. All isolates were poorly discriminated by ribotyping although different enzymes were used. The RAPD method gave a good level of discrimination and demonstrated the genetic diversity of the *Ornithobacterium rhinotracheale* strains isolated among several species in France.

An endogenous plasmid has been reported in one strain of *Ornithobacterium rhinotracheale* (Back et al., 1997, cited by Jansen et al., 2004). Jansen et al. (2004) too were able to detect the plasmid pOR1 in only two isolates of the numerous *Ornithobacterium rhinotracheale* strains that were analyzed. These two isolates might have represented the same strain, since both isolates originated from the same geographical region and were the rare serotype K. The apparent rare occurrence of pOR1 suggests that the plasmid was introduced into *Ornithobacterium rhinotracheale* on a single recent occasion and has not spread in the population.

Within the species *Ornithobacterium rhinotracheale*, several serotypes seem to exist. Serological typing can be carried out using serological examination with known positive antisera in agar gel precipitation (AGP), or ELISA. In AGP, monospecific reactions can be obtained using heat-extracted antigen. However, some cross-reactions have been observed (Hafez and Sting, 1999; van Empel et al., 1997). Currently 18 serotypes, designated A to R,

seem to exist. Most of the chicken isolates belong to serotype A. The turkey isolates are more heterogeneous and belong to serotypes A, B, and D. Serotype C could only be isolated from chickens and turkeys in South Africa and USA (van Empel and Hafez, 1999).

van Empel et al. (1998) (from van Empel, 1998) characterized 56 isolates belonging to different serotypes, independently isolated from bird species from various countries, by amplified fragment length polymorphism (AFLP) analysis. They were able to group *Ornithobacterium rhinotracheale* strains into five minor or three major clusters that showed some association with serotyping.

Popp and Hafez (2003) investigated several *Ornithobacterium rhinotracheale* isolates from turkeys and chickens originating from Germany, Hungary, and Spain by pulsed-field gel electrophoresis (PFGE) of genomic macro-restriction fragments using the enzyme *Sa*I. In general, most isolates showed differences in DNA fingerprints, although the overall profiles were very similar and a correlation between geographic origin, serotype, and DNA fingerprint pattern was observed. In contrast, Koga and Zavaleta (2005) recently investigated 25 *Ornithobacterium rhinotracheale* isolates from broilers, breeders, and layers from several geographic zones of Peru using PCR and rep-PCR techniques. All 25 isolates tested had a genetic profile similar to that of the *Ornithobacterium rhinotracheale* type strain, which was isolated from a turkey in the UK.

Finally, typing of *Ornithobacterium rhinotracheale* isolates has also been performed using the primers M13 (5'-TATG-TAAAACGACGGCCAGT-3') and ERIC 1R (5'-ATGTAAGCTC-CTGGGGATTAC-3'); variations were found between all tested serotypes (Hafez and Beyer, 1997; Hung and Alvarado, 2001).

Hemagglutination. Fitzgerald et al. (1998) tested 25 *Ornithobacterium rhinotracheale* isolates for their ability to hemagglutinate chicken red blood cells. Ten of the 25 isolates, which were sensitive to fosfomicin (MIC values below 128 µg/ml), were able to agglutinate red blood cells. The remaining 15 isolates were resistant to fosfomicin (MIC values above 128 µg/ml). Only five of these isolates had the ability to agglutinate red blood cells. The ability of certain isolates of *Ornithobacterium rhinotracheale* to agglutinate red blood cells raises the issue of differences in virulence. The ability to agglutinate red blood cells could be used as an alternative method for serotyping *Ornithobacterium rhinotracheale*. Similar results were obtained by testing some isolates from Mexico by Soriano et al. (2002). They found that all isolates tested showed hemagglutination activity with glutaraldehyde-fixed erythrocytes.

Antimicrobial susceptibility. Most published reports on antimicrobial susceptibility are based on disc diffusion tests and are difficult to compare. Using this method, all tested *Ornithobacterium rhinotracheale* isolates from Germany showed high susceptibility to amoxicillin, chloramphenicol, and chlortetracycline. Of these isolates, 90 and 36% were susceptible to erythromycin and furazolidone, respectively. In addition, only 6% of tested isolates were susceptible to enrofloxacin. None of isolates were susceptible to apramycin, neomycin, gentamicin, or sulfonamide/trimethoprim (Hafez et al., 1993), or to lincospectin/spectinomycin, cortimoxazol (sulfonamide) or lincospectin. The susceptibility to enrofloxacin seems to be location-related, since most turkey isolates from Germany and the Netherlands

are resistant, whereas 98% of isolates from France (Dudouyt et al., 1995) and 71% of isolates from Belgium (Devriese et al., 1995) are susceptible to enrofloxacin.

Nagaraja et al. (1998) reported on the antimicrobial susceptibility of *Ornithobacterium rhinotracheale* isolates from the USA. All tested isolates were susceptible to tylosin, ampicillin, penicillin, erythromycin, and spectinomycin. Of 68 samples, 54 were susceptible to tetracycline, neomycin, and sarafloxacin and a small number of isolates were susceptible to streptomycin, sulfamethoprim, and gentamicin. These isolates differed significantly from German isolates in their pattern of susceptibility for at least two antibiotics, erythromycin and sarafloxacin. In Canada, *Ornithobacterium rhinotracheale* could be isolated from enrofloxacin-treated birds in mono-cultures (Joubert et al., 1999). van Veen et al. (2001) tested *Ornithobacterium rhinotracheale* isolates collected in the Netherlands between 1996 and 1999 in the agar gel diffusion test for their sensitivity to amoxicillin, tetracycline, enrofloxacin, and trimethoprim/sulfonamide. The percentages of strains susceptible to amoxicillin and tetracycline decreased in successive years from approximately 62 to 14% and four strains were resistant to enrofloxacin or sulfonamide/trimethoprim. Twelve multiresistant strains were tested against seven alternative antibiotics; they were resistant to all antibiotics tested except clavulanic acid-potentiated amoxicillin. Varga et al. (2001) examined *Ornithobacterium rhinotracheale* isolates from Hungary using MIC determinations. Among the 16 drugs examined, penicillin G, ampicillin, ceftazidim (MICs from ≤ 0.06 to $0.12 \mu\text{g/ml}$), erythromycin, tylosin, tilmicosin (with some exceptions, MICs were from ≤ 0.06 to $1 \mu\text{g/ml}$) and tiamulin (MICs from ≤ 0.06 to $2 \mu\text{g/ml}$) were the most effective. Lincomycin, oxytetracycline, and enrofloxacin also gave good inhibition, but at a higher concentration with most strains (MICs ranged in most cases from 2 to $8 \mu\text{g/ml}$). The other antibiotics inhibited the growth of *Ornithobacterium rhinotracheale* only in very high concentrations (colistin) or not at all (apramycin, spectinomycin, polymyxin B). Popp and Hafez (2002) investigated the susceptibility profiles of *Ornithobacterium rhinotracheale* isolates from several countries using the MIC method. The obtained results showed that 84–88% of the isolates were susceptible to amoxicillin, cefotaxime, and tiamulin. Of the isolates, 45% were susceptible to chlortetracycline and 30% to tetracycline and penicillin, whereas 25% were susceptible to tiamulin. In addition, only 6–12% of tested isolates were susceptible to enrofloxacin.

Malik et al. (2003) examined in vitro antibiotic resistance profiles of 125 isolates of *Ornithobacterium rhinotracheale* strains isolated from turkeys in Minnesota in 1996–2002. The majority of isolates were sensitive to clindamycin, erythromycin, spectinomycin, and ampicillin. Resistance against sulfachloropyridazine decreased from 1996 to 2002, but an increase in resistance was seen against gentamicin, ampicillin, sulfa-trimethoprim, and tetracycline. The resistance against penicillin remained constant from year to year. Soriano et al. (2003) determined the MIC of ten antimicrobial drugs for Mexican isolates and found a marked resistance trend. The susceptibility of *Ornithobacterium rhinotracheale* to amoxicillin, enrofloxacin, and oxytetracycline was variable. However, consistently higher MIC values were obtained for gentamicin, fosfomicin, trimethoprim, sulfamethazine, sulfamerazine, sulfaquinoxaline, and sulfachloropyridazine.

Host range. Strains have been isolated from respiratory tracts of turkey, chicken, chukar partridge, duck, goose, guinea fowl, gull, ostrich, partridge, pheasant, pigeon, quail, and rook, mostly associated with infections such as tracheitis, pericarditis, sinusitis, airsacculitis, and pneumonia (Charlton et al., 1993; Hafez et al., 1993; Leroy-Setrin et al., 1998; van Empel et al., 1997; Vandamme et al., 1994b).

Transmission. *Ornithobacterium rhinotracheale* is transmitted horizontally by direct and indirect contact. *Ornithobacterium rhinotracheale* infection appears to have become endemic and can affect every new restocking even in previously cleaned and disinfected poultry houses, especially in areas with intensive poultry production, as well as in multiple age farms. Such infection can occur despite the fact that *Ornithobacterium rhinotracheale* is highly sensitive to different chemical disinfectants and preparations based on different organic acids (formic and glyoxylic acids) and that preparations containing different aldehydes can inactivate *Ornithobacterium rhinotracheale* in vitro at concentrations of 0.5% within 15 min (Hafez and Schulze, 2003). Studies of the ability of *Ornithobacterium rhinotracheale* to remain viable in poultry litter indicate that *Ornithobacterium rhinotracheale* can survive for 1 d at 37°C , 6 d at 22°C , 40 d at 4°C , and at least 150 d at -12°C ; however, it does not survive for 24 h at 42°C . Survival at the lower temperatures may be associated with the higher incidence of *Ornithobacterium rhinotracheale* infection in poultry during winter months (Lopes et al., 2002b). Surveillance of exposure to *Ornithobacterium rhinotracheale* infection in the field has shown that the prevalence of infection is higher during winter months. In addition, Amonsin et al. (1997) suggested that *Ornithobacterium rhinotracheale* might be introduced to domesticated poultry flocks from wild bird populations.

Vertical transmission is suspected based on some reports of the isolation of *Ornithobacterium rhinotracheale* at a very low incidence from reproductive organs and hatching eggs, infertile eggs, and dead embryos (Back et al., 1998b; El-Gohary, 1998; Tanyi et al., 1995). This might be the reason for the worldwide prevalence of the disease (Tanyi et al., 1995). On the other hand, Varga et al. (2001) found that *Ornithobacterium rhinotracheale* did not survive on eggshell at 37°C for more than 24 h, whereas upon inoculation into embryonated chicken eggs, it killed embryos by the 9th day and, from the 14th day post-inoculation, no *Ornithobacterium rhinotracheale* could be cultured from the eggs at all. This suggested that *Ornithobacterium rhinotracheale* was not transmitted via eggs during hatching. van Veen et al. (2004) observed that specific pathogen-free broiler chickens that were placed in hatching incubators at a commercial turkey hatchery during hatch showed respiratory tract lesions at post-mortem examination that were positive for *Ornithobacterium rhinotracheale* by bacteriological and immunohistological examination.

Pathogenicity. The severity of clinical signs, duration of the disease, and mortality are extremely variable and are influenced by many environmental factors such as poor management, inadequate ventilation, high stocking density, poor litter conditions, poor hygiene, high ammonia level, concurrent diseases, and the type of secondary infection. Further information concerning the clinical aspects of *Ornithobacterium* infections can be found in the following references: DeRosa et al., 1997; Droual and Chin, 1997; Hafez, 1998, 2002; Heeder et al., 2001; Hafez

et al., 1993; Jirjis et al., 2004; Marien et al., 2005; Odor et al., 1997; Ryll et al., 1996; Sprenger et al., 1998; Szalay et al., 2002; Travers, 1996; van Beek et al., 1994; Vandekerchove et al., 2004; van Empel et al., 1996; van Empel and Hafez, 1999; Van Looock et al., 2005; van Veen et al., 2000b; Zorman-Rojs et al., 2000.

Determination of pathogenicity by the embryo lethality test has been done by Hafez and Popp (2003) using specific pathogen-free hatching eggs as described for *Escherichia coli* by Wooley et al. (2000).

Several attempts to combat infection by using vaccines have been carried out with various results (Bisschop et al., 2004; Bock et al., 1997; Cauwerts et al., 2002; Hafez and Sting, 1999; Lopes et al., 2002a; Schuijffel et al., 2005, 2006; van Empel and van den Bosch, 1998).

Isolation and detection procedures

Isolation. Samples for bacterial culture should be collected in the early stages of the disease. *Ornithobacterium rhinotracheale* can usually be isolated from trachea, tracheal swabs, lungs, and air sacs. Culture of heart, blood, and liver tissue under field conditions has yielded negative results. However, the bacteria could be isolated from these organs, as well as from joints, brains, ovary, and oviduct, after experimental infections. Primary isolation and initial in vitro growth should be performed on 5–10% sheep blood agar plates incubated under microaerobic conditions at 37°C for 24–48 h. These conditions provide the highest isolation rates and optimal growth. After several subcultivations, some strains may be adapted to grow under aerobic conditions, although growth is always significantly better under microaerobic conditions (van Empel and Hafez, 1999).

Serological detection of *Ornithobacterium*. Serological examination can be carried out using ELISA tests or other methods. The following references should be consulted for details: Bock et al. (1997), Back et al. (1998b), Erganis et al. (2002), Hafez and Sting (1996), Hafez et al. (2000), Lopes et al. (2000), and van Empel et al. (1996, 1997). The advantage of serological tests over bacteriological examination is that antibodies persist for several weeks after infection, whereas bacterial shedding is briefer. However, *Ornithobacterium rhinotracheale* excretion and antibody response may also be affected by a number of factors such as antibiotic therapy and vaccination. The influence of antibiotic therapy on the serological response to *Ornithobacterium rhinotracheale* remains unclear. Popp and Hafez (2002) investigated the effect of drug therapy using amoxicillin on antibody kinetics after experimental infection. The results

showed that the immediate treatment did not influence the antibody response, whereas the treatment that started at the seventh day post-infection resulted in lower antibody response compared to infected controls.

Other detection methods. In field trials using a sensitive immunohistochemical staining method, *Ornithobacterium rhinotracheale* was the cause of 70% of the cases of respiratory symptoms in broiler chickens, whereas through bacteriology and/or serology only 30% of the cases could be connected to *Ornithobacterium rhinotracheale* (van Empel et al., 1999; van Veen et al., 2000a).

Finally, molecular detection of *Ornithobacterium rhinotracheale* infection can be performed through a specific PCR using the primer combination OR16S-F1 (5'-GAGAATTAATTTACG-GATTAAG) and OR16S-R1 (5'-TTCCGCTTGGTCTCCGAA-GAT). This combination amplifies a 784 bp fragment on the 16S rRNA gene of *Ornithobacterium rhinotracheale*, but not that of other closely related bacteria with which *Ornithobacterium rhinotracheale* can be confused (Hung and Alvarado, 2001; van Empel et al., 1998).

Maintenance procedures

Cultures may be stored for many years by lyophilization, freezing at -80°C, or in liquid nitrogen. Cryoprotective agents such as 10% glycerol or dimethylsulfoxide should be added to cultures before freezing. After a storage period of 6 weeks at 6–8°C, blood agar cultures are subcultivable on blood agar.

Differentiation of the genus *Ornithobacterium* and other bird pathogens of the family *Flavobacteriaceae*

Ornithobacterium rhinotracheale, like its phylogenetic neighbors *Riemerella columbina* and *Coenonia anatina*, was initially recognized during the course of long-term studies on the etiology of respiratory tract infections in birds as phenotypically unusual isolates. Table 60 lists the differential diagnostic characteristics that can be used to distinguish *Ornithobacterium rhinotracheale* from other bird pathogens of the family *Flavobacteriaceae*, namely, *Riemerella anatipestifer*, *Riemerella columbina*, *Coenonia anatina*, and *Chryseobacterium meningosepticum*. Species differentiation can also be achieved through whole-cell protein electrophoresis and whole-cell fatty acid analyses (Segers et al., 1993a; Vancanneyt et al., 1999; Vandamme et al., 1994b, 1999). Analysis of the outer-membrane-proteins of 56 *Ornithobacterium rhinotracheale* strains from various countries and belonging to different serotypes confirmed the high protein electrophoretic homogeneity within this species (van Empel et al., 1998).

List of species of the genus *Ornithobacterium*

1. ***Ornithobacterium rhinotracheale*** Vandamme, Segers, Vancanneyt, Van Hove, Mutters, Hommez, Dewhirst, Paster, Kersters, Falsen, Devriese, Bisgaard, Hinz and Mannheim 1994b, 35^{VP} rhi.no.tra.che.a'le. Gr. n. *rhis rhinos* nose, nostril; L. n. *trachia* windpipe; L. neut. adj. suff. *-ale* pertaining to; N.L. neut. adj. *rhinotracheale* relating to the nostrils and windpipe, because the organism was first isolated there.

The description is as given for the genus, with the following additional information. The following enzyme activities

are always present: alkaline and acid phosphatase, ester lipase C8, leucine arylamidase, phosphoamidase, α -glucosidase, β -glucosaminidase, phosphodiesterase, alanine arylamidase, glycine arylamidase, lysine arylamidase, proline arylamidase, α -glutamyl- α -glutamic acid arylamidase, glycyl-phenylalanine arylamidase, phenylalanyl-arginine arylamidase, prolyl-arginine arylamidase, seryl-methionine arylamidase, 2-glycyl-glycyl-arginine arylamidase, and alanyl-phenylalanyl-prolyl-alanine arylamidase. All strains exhibit strong or weak α - and β -galactosidase, esterase C4, valine and cysteine arylamidase, and

trypsin activities. The following activities are always absent: β -glucuronidase, β -glucosidase, α -mannosidase, α -fucosidase, lipase C14, phenylalanine deaminase, hippurate hydrolysis, γ -glutamyl arylamidase, and phospholipase. No acid is produced from D-glucosaminic acid, D-saccharic acid, L-fucose, D-mannitol, D-sorbitol, trehalose, or D-xylose. Lyxose, ribose, glucose, galactose, and mannose are the principal carbohydrate components in whole-cell extracts; altrose, sorbose, and heptose do not occur. The branched fatty acids C_{15:0} iso, C_{15:0} iso 3-OH, and C_{17:0} iso 3-OH are the major fatty acid components. Additional fatty acids present in small quantities in all strains are two unidentified fatty acids with equiva-

lent chain-length values of 13.566 and 16.580, C_{16:0}, C_{17:0} iso, and C_{16:0} iso 3-OH.

Source: the type strain was isolated from a turkey in the UK.

DNA G+C content (mol%): 37–39 (*T_m*).

Type strain: ATCC 51463, CCUG 23171, CIP 104009, LMG 9086, MCCM 01774.

Sequence accession nos (16S rRNA gene): L19156 and U87101 (type strain). The accession numbers of additional reference strains included in a polyphasic taxonomic study (Vandamme et al., 1994b) are U87102 (LMG 11553), U87103 (LMG 15870), U87104 (LMG 11554), and U87105 (LMG 14578).

Genus XL. *Persicivirga* O'Sullivan, Rinna, Humphreys, Weightman and Fry 2006, 177^{VP}

THE EDITORIAL BOARD

Per.si.ci.vir'ga. L. neut. n. *persicum* peach; L. fem. n. *virga* rod; N.L. fem. n. *Persicivirga* peach-colored rod.

Irregularly straight to curved rods, 0.5–0.6 × 2.2–7.5 μ m. No visible flagella. **No gliding motility.** Gram-stain-negative. **Growth occurs at 4–20°C;** no growth occurs at 30°C. Colonies are peach-orange colored. **Flexirubin pigments are present.** Strictly aerobic. **Oxidase- and catalase-negative.** **Growth requires Na⁺ ions or natural seawater.** **Nitrate is not reduced.** **Do not utilize carbohydrates for growth.** The most abundant fatty acids are saturated branched-chain, unsaturated branched-chain and hydroxy fatty acids; C_{15:0} iso and C_{15:0} anteiso are the most abundant individual fatty acids. Isolated from coastal seawater.

DNA G+C content (mol%): 34.7.

Type species: *Persicivirga xylanidelens* O'Sullivan, Rinna, Humphreys, Weightman and Fry 2006, 178^{VP}.

Enrichment and isolation procedures

Coastal seawater samples were serially diluted in aged seawater from a circulating marine aquarium that had been filter-sterilized (0.2 μ m pore diameter) after dilution to 36‰ salinity with distilled water (O'Sullivan et al., 2006). Plating of dilutions was done on three different agar media that were made with this sterilized seawater: plate count agar (PCA; Oxoid) plus 50 μ g/ml kanamycin; casein-yeast-tryptone (Holmes, 1992); and R2A (Difco). Plates were incubated for 10 d at 20°C. Suspected colonies were subcultured twice and then purified on PCA containing aged seawater.

Viability can be maintained at 4°C on a low-nutrient medium (SAP2 agar; Holmes, 1992). Strains can also be preserved at -80°C in SP5 liquid medium (Holmes, 1992) containing 30% glycerol.

Differentiation of the genus *Persicivirga* from related genera

Unlike *Cellulophaga* strains, *Persicivirga xylanidelens* lacks gliding motility, is catalase-negative, does not hydrolyze agar or starch, does not grow at 30°C, and does not produce acid from glucose. In contrast to *Salegentibacter* strains, *Persicivirga xylanidelens* requires NaCl, but does not grow with 15% NaCl, does not produce acid from glucose, does not reduce nitrate, does not grow at 30°C, does not hydrolyze esculin or starch, and is catalase- and oxidase-negative. Unlike *Psychroflexus* strains, it is catalase- and oxidase-negative, grows at 20°C, does not hydrolyze starch, and does not produce acid from glucose. Unlike *Gillisia* strains, *Persicivirga xylanidelens* is catalase- and oxidase-negative, grows at 4°C, and hydrolyzes Tween 80 but not esculin. *Persicivirga xylanidelens* differs from *Mesonina* strains by failing to grow at

30°C, being catalase- and oxidase-negative, and failing to grow in the presence of 15% NaCl.

Taxonomic comments

O'Sullivan et al. (2006) indicated that, based on 16S rRNA gene sequence analyses, the type strain of *Persicivirga xylanidelens* was related to members of the large marine *Flavobacteriaceae* branch and formed a low bootstrap grouping with members of the genus *Cellulophaga*. Its position varied according to other sequences used in the analysis and, in some trees, it was more closely associated with the genera *Psychroflexus*, *Gillisia*, *Mesonina*, and *Salegentibacter*, or formed a separate branch on its own. However, the strain exhibited <90% 16S rRNA gene sequence similarity to any recognized species within the *Flavobacteriaceae*.

List of species of the genus *Persicivirga*

1. *Persicivirga xylanidelens* O'Sullivan, Rinna, Humphreys, Weightman and Fry 2006, 178^{VP}

xy.lan.i.del'ens. N.L. n. *xylanum* xylan; L. part. adj. *delens* destroying; N.L. part. adj. *xylanidelens* xylan-destroying.

Characteristics are as described for the genus, with the following additional features. Colonies on PCA plus artificial seawater for 1 week at 20°C are 1–2 mm in diameter, peach-orange, opaque, smooth with an entire edge, and have a creamy consistency. Cell mass is orange-pigmented and flexirubin pigments are synthesized. Growth occurs at 4 and 20°C, but not at 30 or 37°C. Growth occurs in the presence of 5% NaCl, but not in 10% NaCl. Growth occurs on marine agar 2216, but not on tryptone soy agar, nutrient agar, MacConkey agar, cetrimide agar, or DNase agar (all containing

2.5% NaCl). Xylanase activity is present, but urease activity is absent. Tween 80 and gelatin are hydrolyzed, but agar, arginine, esculin, and starch are not hydrolyzed. Nitrate and nitrite are not reduced. Indole is not produced. Acid is not produced from glucose. Resistant to chloramphenicol, penicillin G, streptomycin, kanamycin, ampicillin, and tetracycline, but sensitive to rifampin. Growth is not detected for any substrates included in the API 20NE and Biolog GN2 commercial arrays.

Source: the type strain was isolated from coastal sea water, Hope Cove, near Plymouth, UK.

DNA G+C content (mol%): 34.7 (HPLC).

Type strain: SW256, DSM 16809, NCIMB 14027.

Sequence accession no. (16S rRNA gene): AF493688.

Genus XLI. *Polaribacter* Gosink, Woese and Staley 1998, 231^{VP}

JAMES T. STALEY

Po.lar.i.bac'ter. N.L. adj. *polaris* pertaining to the geographic poles; N.L. masc. n. *bacter* from Gr. n. *baktron* rod or staff; N.L. masc. n. *Polaribacter* rod-shaped bacteria from polar habitats.

Rods, curved rods, or filaments. Cell size varies between 0.8 and 48 µm in length and 0.25 and 1.6 µm in diameter depending on species, growth medium, temperature, and physiological state of the culture. Nonmotile; some cells may have flagella, but motility has not been observed. Coccoid bodies often seen in ageing cultures. **Gas vesicles are produced by some species.** Gram-stain-negative. Heterotrophic. **Aerobic. Psychrophilic or mesophilic.** Organisms grow well in marine media or media that have been supplemented with NaCl. Organisms produce acid from a variety of carbohydrates. Starch is hydrolyzed. Cells can grow on yeast extract. Colonies produce yellow, orange, salmon, or pink non-diffusible pigments that are not flexirubins. **Some strains produce rhodopsin pigments** that stimulate growth in presence of light. Some strains have been isolated from polar marine and sea ice environments and grow at temperatures of 10°C or lower. **All strains have been isolated from marine habitats.**

DNA G+C content (mol%): 30–33.

Type species: ***Polaribacter filamentus*** Gosink, Woese and Staley 1998, 232^{VP}.

Further descriptive information

The genus *Polaribacter* was named because the initial strains of this genus that were isolated from polar sea ice communities formed a novel clade in the phylum *Bacteroidetes* based on 16S rRNA gene sequence analyses. Similarities were noted between the three novel polar species and a previously described species, *Flectobacillus glomeratus*. Therefore, the phylogenetic, phenotypic, and genotypic properties of this latter species were compared to those of members of the new genus *Polaribacter* (Gosink et al., 1998). In particular, DNA–DNA hybridization values between *Flectobacillus glomeratus* and the three polar species of *Polaribacter* were from 14 to 31%, which is within the expected range of values for members of a genus. Based on this information, *Flectobacillus glomeratus* was reclassified as an additional member of the genus *Polaribacter* and renamed *Polaribacter glomeratus*. Two novel species have been reported recently from marine habitats in temperate zone waters.

Recent reports indicate that at least some *Polaribacter* species produce bacterial rhodopsins. These have been shown to

stimulate growth in the presence of light (Gómez-Consarnau et al., 2007).

Enrichment, isolation and maintenance

These bacteria were first isolated from the sea ice microbial community using Ordal's seawater cytophaga (SWCm) agar (Irgens et al., 1989) with succinate as a carbon source. However, strains also grow well on marine agar 2216 (Difco). The organisms are maintained best by freezing cultures in growth medium with 15% glycerol at -80°C or in liquid nitrogen. Many strains do not survive well using lyophilization.

Differentiation of the genus *Polaribacter* from related genera

The closest relatives of members of the genus *Polaribacter* are found in the genus *Tenacibaculum*. However, *Polaribacter* species differ from *Tenacibaculum* species by 16S rRNA gene sequence

similarities which range, for example, from 92.4–93.1% for *Tenacibaculum lutimaris* (Yoon et al., 2005c). *Tenacibaculum* species move by gliding motility and in this regard also differ from *Polaribacter* species in which motility has not yet been demonstrated. *Tenacibaculum maritimum* is a fish pathogen that lives in association with black and red sea bream. Other members of the genus *Tenacibaculum* have been isolated from various other marine environments including pelagic marine habitats, tidal flats, macroalgae, sponges, and halibut eggs.

Differentiation of the species of the genus *Polaribacter*

The species can be differentiated on the basis of nutritional characteristics including carbon source utilization, growth on various media, biochemical properties, and temperature range for growth (Table 61). Fatty acid composition differs among those strains that have been tested (Table 62).

List of species of the genus *Polaribacter*

- 1. *Polaribacter filamentus*** Gosink, Woese and Staley 1998, 232^{VP}
fil.a.men'tus. L. n. *filum* thread; N.L. masc. adj. *filamentus* threadlike, filamentous.
 Characteristics are as described for the genus and as listed in Tables 61 and 62, with the following additional features. Colonies are orange- to salmon-colored, circular, flat to convex, entire, smooth, opaque, and butyrous. Organisms grow from 4 to 19°C, but not at 21°C. L-Glutamate and glycerol are used as carbon sources. Gelatin is hydrolyzed. Acid is produced from DL-arabinose, rhamnose, D-galactose, D-glucose, mannose, and glycerol. Principal fatty acids include C_{15:0} iso 3-OH (22%), C_{15:0} iso (22%), and C_{15:1} iso G (12%) when grown on SWCm agar (Irgens et al., 1989) at 10°C.
Source: isolated from surface seawater in pack ice, 350 km north of Deadhorse, Alaska.
DNA G+C content (mol%): 32 ± 1 (*T_m*).
Type strain: 215, ATCC 700397, CIP 106479.
Sequence accession no. (16S rRNA gene): U73726.
- 2. *Polaribacter butkevichii*** Nedashkovskaya, Kim, Lysenko, Kalinovskaya, Mikhailov, Kim and Bae 2006b, 1459^{VP} (Effective publication: Nedashkovskaya, Kim, Lysenko, Kalinovskaya, Mikhailov, Kim and Bae 2005g, 411.)
but.ke.vi'chi.i. N.L. gen. masc. n. *butkevichii* of Butkevich, named in honor of V.S. Butkevich, a Russian marine microbiologist.
 Characteristics are as described for the genus and as listed in Tables 61 and 62, with the following additional features. Colonies are orange, circular, convex, viscous entire, smooth, translucent, and butyrous. Sodium ions are required for growth. Casein, gelatin, starch, DNA, Tween 40, and Tween 80 are hydrolyzed. Acid is produced from D-glucose, D-galactose, D-maltose, DL-xylose, and glycerol. A yellow non-diffusible pigment is produced. Growth occurs at 4–32°C.
Source: the type strain was isolated from seawater from Amursky Bay, Gulf of Peter the Great, Sea of Japan, Russia.
DNA G+C content (mol%): 32.4 (*T_m*).
Type strain: KMM 3938, CCUG 48005, KCTC 12100.
Sequence accession no. (16S rRNA gene): AY189722.
- 3. *Polaribacter dokdonensis*** Yoon, Kang and Oh 2006e, 1252^{VP}
dok.do.nen'sis. N.L. masc. adj. *dokdonensis* of or belonging to Dokdo, an island of Korea where the type strain was isolated.
 Characteristics are as described for the genus and as listed in Tables 61 and 62, with the following additional features. Colonies are orange, circular, convex, and smooth. Optimal growth occurs at 25–28°C. NaCl is required for growth. Tweens 20, 40, 60, and 80 are hydrolyzed, but casein, xanthine, and L-tyrosine are not. Rhodopsin pigments are produced.
Source: the type strain was isolated from seawater off Dokdo in the East Sea of Korea (also known as the Sea of Japan).
DNA G+C content (mol%): 30 (HPLC).
Type strain: DSW-5, DSM 17204, KCTC 12392.
Sequence accession no. (16S rRNA gene): DQ004686.
- 4. *Polaribacter franzmannii*** Gosink, Woese and Staley 1998, 233^{VP}
franz.man'ni.i. N.L. gen. masc. n. *franzmannii* of Franzmann, named in honor of Peter D. Franzmann, an Australian microbiologist and polar researcher.
 Characteristics are as described for the genus and as listed in Tables 61 and 62, with the following additional features. Colonies are orange, circular, flat to convex, entire, smooth, opaque, and viscous. Cells can grow on glycerol and N-acetylglucosamine. Acid is produced from D-fructose, D-galactose, D-glucose, mannose, lactose, maltose, sucrose, and trehalose. Esculin and gelatin are hydrolyzed. Cells can grow at temperatures of <4 to 10°C, but not at 15°C. Principal fatty acids include C_{15:0} iso 3-OH (17%), C_{15:1} iso G (11%), and 9% each of C_{15:0} iso, C_{15:1} ω6c, and C_{16:1} ω7c when grown on SWCm agar (Irgens et al., 1989) at 10°C.

6. *Polaribacter igensii* Gosink, Woese and Staley 1998, 233^{VP}

ir.gen'si.i. L. gen. masc. n. *igensii* of Irgens, named in honor of Roar L. Irgens, the first microbiologist to observe polar marine gas vacuolate bacteria.

Characteristics are as described for the genus and as listed in Tables 61 and 62, with the following additional features. Colonies are orange, circular, convex, entire, smooth, translucent, and butyrous. Rhodopsin has been reported in this species. The type strain can grow on DL-malate. Acid is produced from a number of carbohydrates including D-galactose, D-glucose, mannose, and glycerol. Growth occurs from at least as low as –1.5 to 12°C (Irgens et al., 1989). Principal fatty acids include C_{15:0} iso 3-OH (38%), C_{15:0} iso (12%), and C_{15:0} 3-OH (10%) when grown on SWCm agar (Irgens et al., 1989) at 10°C.

Sequence accession no. (16S rRNA gene): M61002.

Genus XLII. *Psychroflexus* Bowman, McCammon, Lewis, Skerratt, Brown, Nichols and McMeekin 1999, 2^{VP} (Effective publication: Bowman, McCammon, Lewis, Skerratt, Brown, Nichols and McMeekin 1998, 1606.)

JOHN P. BOWMAN

Psy.chro.flex'us. Gr. adj. *psychros* cold; L. masc. n. *flexus* bend, curve; N.L. masc. n. *Psychroflexus* cold bend.

Cells are straight or slightly curved **rods**, 0.4–1.5 × 0.5–3 μ m. One species forms partially coiled filaments up to 50 μ m in length in liquid media, whereas on solid surfaces the filaments formed are of indeterminate length. Coccoid-like cells are formed in old cultures. Cells occur singly or in pairs. Spores and resting cells are not present. Gas vesicles and helical or ring-shaped cells are not formed. Nonmotile or motile by gliding. **Gram-stain-negative. Strictly aerobic, having an oxidative type of metabolism.** Catalase-positive. Oxidase-positive. **Chemoheterotrophic. Non-agarolytic. Colonies are bright orange** due to production of carotenoids, including β -carotene. **Flexirubin pigments are not produced.** Produce alkaline phosphatase, α -glucosidase, β -glucosidase, and α -amylase. Strains **usually require Na⁺** for growth. Strains are **stenohaline or halotolerant.** Stenohaline species grow over a narrow range of seawater salinity. **Moderate halophiles** grow best with elevated NaCl concentrations (optimal levels 5–10%). Yeast extract may be required for growth by some strains. Species range from psychrophilic to mesophilic in terms of the response of their growth rates to temperature. **Neutrophilic**, with optimal growth occurring at pH 7.0–7.5. The major fatty acids are C_{15:1} ω 10*c* anteiso, C_{15:0} anteiso, C_{16:0} iso, C_{16:0} 3-OH iso, and C_{17:0} 3-OH iso/anteiso. One species produces **polyunsaturated fatty acids**. The major respiratory quinone is menaquinone-6. The major polyamine is

homospermidine. **Habitats, depending on the species, include polar sea-ice algal assemblages or hypersaline lakes.**

DNA G+C content (mol%): 33–36.

Type species: Psychroflexus torquis Bowman, McCammon, Lewis, Skerratt, Brown, Nichols and McMeekin 1999, 1^{VP} (Effective publication: Bowman, McCammon, Lewis, Skerratt, Brown, Nichols and McMeekin 1998, 1607.).

Further descriptive information

The genus *Psychroflexus* is a member of the family *Flavobacteriaceae* and comprises three species, *Psychroflexus torquis*, *Psychroflexus gondwanensis*, and *Psychroflexus tropicus*, which exhibit evidence of considerable ecomiche specialization.

Psychroflexus torquis includes rod-like to filamentous cells that are capable of gliding motility and have an absolute requirement for seawater and an associated stenohaline growth pattern. The species is slow-growing (doubling time 20–24 h at 10°C) and highly psychrophilic. In liquid media, partly coiled filaments are observed frequently (Bowman et al., 1998). On agar media, *Psychroflexus torquis* tends to form thin, filamentous cells that are often hundreds of micrometers long.

All *Psychroflexus* species produce catalase, cytochrome *c* oxidase, alkaline phosphatase, α -glucosidase, β -glucosidase, and acid from mannose. All produce α -amylases. Properties known

to be absent from *Psychroflexus* species include: hydrolysis of casein, agar, chitin, uric acid, and xanthine; nitrate reduction; production of H₂S (from L-cysteine and thiosulfate); and lysine decarboxylase, ornithine decarboxylase, arginine dihydrolase, tryptophan deaminase, phenylalanine deaminase, α -arabinosidase, α -fucosidase, α -galactosidase, β -galactosidase, 6-phospho- β -galactosidase, β -glucuronidase, and α -mannosidase activities.

Other traits differentiating the species are shown in Table 63.

Psychroflexus species form homospermidine and menaquinone-6 as the major polyamine and quinone, respectively (Hamana and Nakagawa, 2001). In addition, *Psychroflexus torquis* accumulates high levels of 2-phenylethylamine (Hosoya and Hamana, 2004). The major fatty acids amongst *Psychroflexus* species are branched-chain fatty acids with chain lengths of 15 or 16 carbon atoms (Table 64).

A draft genome sequence is available for the type strain of *Psychroflexus torquis* ATCC 700755^T. This strain contains a single genome of 4.29 Mbp, contains no extrachromosomal DNA, and has an overall G+C content of 35 mol%. A total of 3862 predicted open reading frames is present. The genome includes three *rna* operons (coding rRNA subunit genes) and 38 tRNA genes. The genome has a relatively low gene coding level, only 82%. This is explained by the unusually heavy infiltration of lateral gene transferred (LGT) genetic elements into the genome, forming a series of "islands" ranging in size from 9 to 142 kb in length. These genomic islands are demarcated by lower than average coding density and the presence of phage-type integrases, retron-type reverse transcriptases, and various transposase-like insertional elements. Indeed, more than 200 of these gene types are present in the genome. Based on annotation data and database comparisons, as much as 25% of

the *Psychroflexus torquis* genome comprises these LGT islands. Genes coding polyunsaturated fatty acid synthesis genes (*pfa* operon) (Allen and Bartlett, 2002) and a large exopolysaccharide genetic locus are located on genomic islands, suggesting that LGT elements may have been critical for the acquisition of some of the more unusual traits of this species. The remainder of the genome contains, at higher coding density, genes conserved amongst the phylum *Bacteroidetes* that code for central and intermediary metabolism and housekeeping cellular activities. The *Psychroflexus torquis* genome has a metabolome comparable to that of other members of the *Flavobacteriaceae* that have genome sequence data (e.g., *Croceibacter atlanticus*, *Robiginitalea bififormata*, *Polaribacter irgensii* and several others), with a preference for the oxidative catabolism of carbohydrates. Numerous response regulatory genes and transporters are present suggesting that the micro-organism is particularly sensitive to the surrounding environment. Many genes are present for the import and export of high molecular mass substances, inorganic ions, solutes, and carbohydrates. Two *BetT* high affinity choline/glycine betaine/carnitine transporters and eight putative proline:sodium ion symporters are present with possible protective roles, conferring osmotolerance and/or cryotolerance. Overall, peptide sequences have the greatest similarities with those of the genome of *Croceibacter atlanticus*, a pelagic member of the *Flavobacteriaceae*. The lack of various genes or pathways for synthesis of pantothenic acid and cobalamin, as well as specific receptor proteins for these compounds, indicates that these vitamins are essential nutrients for growth. This is borne out by the need to supplement defined mineral salts media with yeast extract before any growth of *Psychroflexus torquis* can be achieved. Highly similar orthologs to genes found necessary for gliding (*gld* genes) in *Flavobacterium johnsoniae* (Braun and

McBride, 2005) are present in the *Psychroflexus torquis* genome. The bright orange pigment of *Psychroflexus torquis* colonies is indicative of carotenoid biosynthesis and genes encoding the synthesis of β-carotene and zeaxanthin are present. The species also appears to be able to synthesize proteorhodopsin (Friedrich et al., 2002) and possesses a blue light receptor gene ortholog, although at this stage it is unknown if light provides an enhancement to the growth of this species.

Psychroflexus torquis has the unusual ability to produce the polyunsaturated fatty acids eicosapentaenoic acid (EPA) and arachidonic acid (Nichols et al., 1997). As the incubation temperature is reduced from 15 to 2°C, the production of EPA

increases more than fourfold, indicating the importance of this lipid to *Psychroflexus torquis* for low temperature growth. No other member of the family *Flavobacteriaceae* has been shown to be able to form polyunsaturated fatty acids, including the two other known *Psychroflexus* species. Extreme psychrophily is also relatively uncommon in the family, although psychroactive growth is very prevalent. So far only isolated from dense algal assemblages within sea-ice, *Psychroflexus torquis* has a pronounced epiphytic lifestyle.

In comparison, both *Psychroflexus gondwanensis* and *Psychroflexus tropicus* are inhabitants of hypersaline lakes, including those of Antarctica and the Hawaiian Archipelago, respectively. Neither form filaments nor are they capable of gliding; they appear to be mainly planktonic bacteria. The growth rates of these two species are much faster than that of *Psychroflexus torquis*. These species are halotolerant and have relatively high salinity optima for growth, suggesting a preference for moderate but not extremely hypersaline ecosystems. Both *Psychroflexus gondwanensis* and *Psychroflexus tropicus* exhibit growth at low temperatures, but have growth rate temperature optima of 25–35°C, as compared to 10–15°C found for *Psychroflexus torquis*, when grown in liquid media.

Enrichment and isolation procedures

Currently, no specific method of enrichment is available for isolation of *Psychroflexus* species. Plating melted sea-ice material or hypersaline lake water onto marine agar media or organic media containing high levels of salt (10–12%) can be used to directly isolate *Psychroflexus* species, with bright orange colonies being indicative of the genus. *Psychroflexus torquis* colonies are typically very viscous and elastic due to production of an exopolysaccharide and are best isolated from sea-ice samples rich in algae. Incubation temperatures depend on the species (see above).

Maintenance procedures

Strains can be maintained for many years cryopreserved in marine broth containing 20–30% glycerol. Strains survive for many months, potentially years, on thick agar plates or on slants stored at 2–4°C. Strains may also be maintained by lyophilization, although the procedure is generally not useful for *Psychroflexus torquis*.

Differentiation of the genus *Psychroflexus* from other genera

The most salient traits useful for distinguishing *Psychroflexus* spp. from other members of the *Flavobacteriaceae* include orange pigmentation, lack of flexirubin pigments, strictly aerobic oxidative metabolism, the ability to use carbohydrates such as starch, and the ability to grow at low temperatures.

Taxonomic comments

Psychroflexus gondwanensis was originally described as *Flavobacterium gondwanense* (Dobson et al., 1993).

List of species of the genus *Psychroflexus*

- 1. *Psychroflexus torquis*** Bowman, McCammon, Lewis, Skerratt, Brown, Nichols and McMeekin 1999, 2^{VP} (Effective publication: Bowman, McCammon, Lewis, Skerratt, Brown, Nichols and McMeekin 1998, 1607.)

tor'quis. L. masc. n. *torquis* a twisted neck-chain, referring to coiling of cellular filaments.

Characteristics are as given for the genus, as listed in Table 63, and as given in the text. In addition, *Psychroflexus torquis*

forms orange, circular, mucoid, viscid to elastic, convex or dome-like, opaque, entire, smooth, glistening colonies up to 10 mm in diameter.

Source: inhabits sea-ice algal assemblages.

DNA G+C content (mol%): 33 (T_m), 35 (genome sequence).

Type strain: 651, ACAM 623, ATCC 700755, CIP 106069.

Sequence accession no. (16S rRNA gene): U85881.

Sequence accession no. (genome): NZ_AAPR00000000.

2. ***Psychroflexus gondwanensis*** corrig. (Dobson, Colwell, Franzmann and McMeekin 1993) Bowman, McCammon, Lewis, Skerratt, Brown and Nichols and McMeekin 1999, 2^{VP} (Effective publication: Bowman, McCammon, Lewis, Skerratt, Brown, Nichols and McMeekin 1998, 1608.) (*Flavobacterium gondwanense* Dobson, Colwell, Franzmann and McMeekin 1993, 81)

gond.wa.nen'sis. N.L. masc. adj. *gondwanensis* of or belonging to Gondwanaland or Gondwana, one of the two ancient supercontinents, which originally included Antarctica and other, separate continental landmasses.

Characteristics are as given for the genus, as listed in Table 63, and as given in the text. In addition, *Psychroflexus gondwanensis* forms orange, circular, butyrous or viscid, convex, opaque, entire, smooth, glistening colonies up to 5 mm in diameter.

Source: inhabits various hypersaline lakes of Antarctica (James et al., 1994).

DNA G+C content (mol%): 36 (T_m).

Type strain: ACAM 44, ATCC 51278, CCUG 33444, CIP 104040, DSM 5423, LMG 13192.

Sequence accession no. (16S rRNA gene): M92278.

Additional note: the original spelling, *gondwanense*, did not agree in gender with the generic name *Psychroflexus* and thus was corrected on Validation List no. 68, Int. J. Syst. Bacteriol. 49: 1–3, 1999).

3. ***Psychroflexus tropicus*** Donachie, Bowman and Alam 2004, 937^{VP}

trop'i.cus. L. masc. adj. *tropicus* tropical, relating to the species tropical lake habitat.

Characteristics are as given for the genus, as listed in Table 63, and as given in the text. In addition, *Psychroflexus tropicus* forms orange, circular, butyrous, convex, opaque, entire, smooth, glistening colonies up to 4 mm in diameter. Esterases (C_4 , C_8 , and C_{14}), and leucine, valine, and cystine arylamidases are produced. Trypsin, chymotrypsin, acid phosphatase, and phosphohydrolase activities are present. In Biolog GN trays, the following carbon sources test positively in the presence of 7.5% NaCl, but not with 2 or 4% NaCl: L-alanine, L-alanyl-glycine, L-asparagine, L-aspartate, L-glutamate, L-leucine, L-ornithine, L-proline, L-serine, L-threonine, monomethyl succinate, and L-alaninamide. Glycerol, D-glucose, D-fructose, D-mannose, D-sorbitol, trehalose, starch, and D-arabitol are utilized. Acid is produced oxidatively from sucrose and 5-ketogluconate.

Source: inhabits hypersaline lakes of the Hawaiian Archipelago.

DNA G+C content (mol%): 35 (T_m).

Type strain: LA1, ATCC BAA-734, DSM 15496.

Sequence accession no. (16S rRNA gene): AF513434.

Genus XLIII. ***Psychroserpens*** Bowman, McCammon, Brown, Nichols and McMeekin 1997, 674^{VP}

JOHN P. BOWMAN

Psy.chro.ser'pens. Gr. adj. *psychros* cold; L. masc. or fem. n. *serpens* serpent; N.L. masc. n. *Psychroserpens* cold serpent.

Cells are **flexible rods with rounded ends**, 0.5–0.6 × 2–6 μm, occurring singly or in pairs. Cultures also frequently include **coiled or roughly helical filamentous cells** up to 20 μm in length. Spores, resting cells, and gas vesicles are not present. **Nonmotile. Gram-stain-negative. Colonies are yellow due to accumulation of carotenoids. Flexirubin pigments are not produced. Strictly aerobic, having an oxidative type of metabolism.** Catalase-positive. Oxidase-negative. **Chemoheterotrophic. Non-agarolytic. Carbohydrates are not utilized, except for glycogen.** Acid is not formed from carbohydrates. **Seawater salts and yeast extract are required** for growth. **Psychrophilic.** Grows between –2 and 18°C, with optimal growth at 10–12°C and pH 6–8. The major fatty acids are $C_{15:0}$, $C_{15:0}$ iso, $C_{15:0}$ anteiso, $C_{15:1}$ ω10c iso, $C_{15:1}$ ω10c anteiso, $C_{16:1}$ ω11c iso, $C_{15:1}$ ω11c, $C_{15:1}$ ω4c, and $C_{16:1}$ ω5c. **Isolated from saline lakes of Antarctica.**

DNA G+C content (mol%): 27–29.

Type species: ***Psychroserpens burtonensis*** Bowman, McCammon, Brown, Nichols and McMeekin 1997, 674^{VP}.

Further descriptive information

Psychroserpens is a genus of the family *Flavobacteriaceae* and currently includes one species, *Psychroserpens burtonensis*.

Psychroserpens burtonensis was isolated from the waters of Burton Lake, a saline lake located in the Vestfold Hills ice-free region of Eastern Antarctica (68° S 78° E). Burton Lake has salinity levels and composition that are nearly the same as seawater and receives an inflow of seawater from a closely adjacent fjord in the summer when surface ice melts sufficiently. The species is characterized by psychrophilic growth and a preference for organic acids as carbon sources.

Psychroserpens burtonensis occasionally forms ring-shaped cells and more frequently helical or coiled cells. This is most obvious in stationary growth phase cultures. In young, exponentially growing cultures, cells tend to appear as flexible rods. The organism requires vitamins and other unknown substances in yeast extract for growth. Growth is also markedly stimulated by the addition of Tween 20 or Tween 40. The species can hydrolyze casein, Tween 20, and Tween 40. Some strains can also attack gelatin and Tween 80. The species forms alkaline phosphatase. The species cannot degrade most polysaccharides (starch, chitin, dextran, agar), esculin, DNA, L-tyrosine, uric acid, or xanthine. Other standard tests (indole production, Voges–Proskauer test, H₂S production, nitrate reduction, etc.) are negative (Bowman et al., 1997).

Psychroserpens burtonensis does not in general utilize carbohydrates, alcohols, aromatics, or amino acids. Organic acids and some other compounds are preferred for growth and include: glycogen, α -glycerol phosphate, butyrate, malonate, glutarate, pimelate, azelate, citrate, oxaloacetate, citrate, and 2-aminobutyrate. Some strains can also utilize isobutyrate, *trans*-aconitate, and L-serine. A detailed phenotypic description of the species has been published (Bowman et al., 1997).

The major fatty acids are C_{15:0}^{*}, C_{15:0} iso, C_{15:0} anteiso, C_{15:1} ω 10c iso, C_{15:1} ω 10c anteiso, C_{16:1} ω 11c iso, C_{15:1} ω 11c, C_{15:1} ω 4c, and C_{16:1} ω 5c (Bowman et al., 1997). The major isoprenoid quinone is menaquinone-6 and the major polyamine is homospermidine (Hamana and Nakagawa, 2001).

Undescribed strains and environmental clones closely related to *Psychroserpens burtonensis* but probably representing cold- and non-cold-adapted novel *Psychroserpens* species have been obtained or detected from a variety of marine habitats, suggesting the genus is widely distributed. Habitats include Antarctic and Arctic sea-ice and seawater, gills of salmon cultured in marine waters, sea surface microlayer, marine biofilms, and the surfaces of macroalgae including kelp (Abell and Bowman, 2005; Agogu e et al., 2005; Bowman and Nowak, 2004; Brinkmeyer et al., 2003; Brown and Bowman, 2001).

Enrichment and isolation procedures

Psychroserpens burtonensis can be isolated by direct plating of sample material onto marine agar followed by incubation at 4–10°C. The species grows slowly, with colonies taking at least 5–10 d to appear and grow to full size.

Maintenance procedures

For long-term storage, *Psychroserpens burtonensis* can be cryopreserved at –80°C in marine broth 2216 supplemented with 30% glycerol. Strains survive well on marine agar 2216 plates or slants stored at 2–4°C. The species shows generally poor survival following lyophilization.

Differentiation of the genus *Psychroserpens* from other genera

The most salient traits useful for distinguishing *Psychroserpens* from other members of the *Flavobacteriaceae* include coiled/helical cellular morphology, yellow pigmentation, lack of motility, strictly aerobic oxidative metabolism, inability to use carbohydrates, lack of reactivity in most standard phenotypic tests, and a requirement for low temperatures. The species also has a distinctive fatty acid profile, although various components can only be accurately identified by GC-MS analysis.

List of species of the genus *Psychroserpens*

1. ***Psychroserpens burtonensis*** Bowman, McCammon, Brown, Nichols and McMeekin 1997, 675^{VP}

bur.ton.en'sis. N.L. masc. adj. *burtonensis* pertaining to Burton Lake, Antarctica, the body of water from where the organism was first isolated.

Characteristics are as given for the genus and as given in the text.

Source: saline lakes of Antarctica.

DNA G+C content (mol %): 27–29 (*T_m*).

Type strain: ACAM 188, ATCC 700359, CIP 105822.

Sequence accession no. (16S rRNA gene): U62913.

Genus XLIV. ***Riemerella*** Segers, Mannheim, Vancanneyt, De Brandt, Hinz, Kersters and Vandamme 1993a, 774^{VP} emend. Vancanneyt, Vandamme, Segers, Torck, Coopman, Kersters and Hinz 1999, 293

THE EDITORIAL BOARD

Rie.me.rel'la. N.L. fem. n. *Riemerella* named in honor of O.V. Riemer, who first described *Riemerella anatipestifer* infections in geese in 1904 and referred to the disease as *septicemia anserum exsudativa* (Riemer, 1904).

The following description is based on those given by Segers et al. (1993a) and Vancanneyt et al. (1999). **Rods, 0.2–0.5 × 1.0–2.5 μ m**. Nonmotile. No gliding motility. Nonspore-forming. Gram-stain-negative. **All strains grow microaerobically and most of them grow aerobically on blood agar**. Some strains grow anaerobically at 37°C. Colonies are smooth and nonpigmented or grayish-white to beige. Growth on litmus lactose agar is strain-dependent. No growth occurs on MacConkey agar. Most strains show a positive Voges–Proskauer reaction. Nitrates are not reduced. **Acid production from glucose is frequently negative in peptone-containing media**. The following enzymes are present: **oxidase**, **catalase**, gelatinase, α -glucosidase, α -maltosidase, alkaline phosphatase, acid phosphatase, esterase lipase C8, esterase C4, naphthol-AS-BI-phosphohydrolase, leucine arylamidase, valine arylamidase, cystine arylamidase, and L-aspartic acid arylamidase. The following reactions are strain-dependent: urease, chymotrypsin, trypsin, arginine dihydrolase, indole production, hemolysis on blood, and

esculin hydrolysis. Depending on the micro-test kit used, the following enzyme reactions give variable results: β -glucosidase, α -galactosidase, and lipase (these three reactions are positive in the API ID32E and negative in the API ZYM system); and *N*-acetyl- β -glucosaminidase [negative in API ZYM and API ID32E, positive in LRA-ZYM-Oxidase (Hinz et al., 1998); only some representative *Riemerella anatipestifer* strains have been tested using the latter system]. The following enzyme activities are absent: chondroitin sulfatase, hyaluronidase, β -galactosidase, β -glucuronidase, α -mannosidase, α -fucosidase, trypsin, ornithine decarboxylase, and lysine decarboxylase. None of the strains use malonate as a carbon source or assimilate the following compounds (API 20NE system): D-glucose, L-arabinose, D-mannose, D-mannitol, *N*-acetylglucosamine, maltose, D-gluconate, caprate, adipate, L-malate, citrate, or phenylacetate. No acid production occurs with the following (API ID32E system): D- and L-arabitol, galacturonate, 5-ketogluconate, phenol red, D-mannitol, maltose, adonitol, palatinose,

sucrose, L-arabinose, trehalose, rhamnose, inositol, sorbitol, and cellobiose. Using the buffered single substrate (BSS) test, however, acidification of the following carbohydrates may be detected: D-glucose, maltose, D-mannose, and dextrin and, to a lesser extent, D-fructose, L-sorbose, and trehalose, but no acid is produced from lactose, D-galactose, N-acetyl-D-glucosamine, lactulose, trehalose, sucrose, D-mannitol, L-arabinose, myo-inositol, D-sorbitol, D-xylose, dulcitol, salicin, or adonitol. Menaquinone-6 is the major respiratory quinone detected in the type species. The dominant fatty acids are the branched-chain fatty acids C_{13:0} iso, C_{15:0} iso, C_{15:0} anteiso, C_{15:0} iso 3-OH, and C_{17:0} iso 3-OH. Isolated mainly from diseased birds and, in a few cases, from pigs.

DNA G+C content (mol%): 29–37.

Type species: *Riemerella anatipestifer* (Hendrickson and Hilbert 1932) Segers, Mannheim, Vancanneyt, De Brandt, Hinz, Kersters and Vandamme 1993a, 775^{VP} [*Moraxella anatipestifer* (Hendrickson and Hilbert 1932) Bruner and Fabricant 1954, 461; *Hemophilus anatipestifer* Hauduroy, Ehringer, Urbain, Guillot and Magrou 1937, 247; *Pasteurella anatipestifer* (sic) Hauduroy, Ehringer, Guillot, Magrou, Prévot, Rosset and Urbain 1953, 367; *Pasteurella anatipestifer* (Hendrickson and Hilbert 1932) Breed, Murray and Smith 1957, 397; *Pfeifferella anatipestifer* Hendrickson and Hilbert 1932, 249].

Further descriptive information

The illness caused by *Riemerella anatipestifer* is an exudative septicemia in ducks, pigeons, and other domestic and wild birds. *Riemerella anatipestifer* has been isolated from ducks, geese, turkeys, chickens, pheasants, quails, and wild free-living waterfowl (Asplin, 1955; Bangun et al., 1987; Bruner et al., 1970; Graham et al., 1938; Hendrickson and Hilbert, 1932; Loh et al., 1992; Pierce and Vorhies, 1973; Sandhu and Rimlet, 1997; Singh et al., 1983; Smith et al., 1987; Zehr and Ostendorf, 1970). The infection can be peracute, acute, or chronic. The organism is thought to be transmitted vertically by transovarian passage. Lateral transmission occurs through injuries, such as toenail scratches of the webbed foot in ducklings, or by entrance through the respiratory epithelium. The disease is of major economic importance in the duck industry, since the mortality in ducklings is usually 2–30% and can be as high as 95%. *Anatipestifer* disease can be treated with a range of antibiotics.

The CAMP cohemolysin has been implicated as a potential virulence factor of *Riemerella anatipestifer* and the CAMP cohemolysin gene, *cam*, of reference strain 30/90 of serotype 19 has been cloned and expressed in *Escherichia coli* (Crasta et al., 2002). The amino acid sequence of the Cam protein has high homology with sequences of O-sialoglycoprotein endopeptidases and the Cam protein has been shown to be a sialoglycoprotease by its ability to hydrolyze radioiodinated glycophorin A (Crasta et al., 2002).

There are at least 21 serotypes of *Riemerella anatipestifer* that have been identified by slide and tube agglutination tests

with antisera (Loh et al., 1992; Pathanasophon et al., 1994). Inactivated bacterins and live vaccines are available that can offer protection against homologous strains or serotypes of *Riemerella anatipestifer*, but are unable to protect against heterologous serotypes (Pathanasophon et al., 1996; Sandhu, 1991).

An ELISA based on a recombinant fragment of an *Riemerella anatipestifer* surface protein has been developed to aid early detection of the infection in ducks (Huang et al., 2002); also, a direct and indirect antibody ELISA has been developed for detection of duck yolk IgY and duck serum IgY. Kardos et al. (2007) have described a PCR assay that can rapidly identify *Riemerella anatipestifer* from bacterial cultures.

Riemerella columbina seems to be uniquely associated with disease in pigeons (Vancanneyt et al., 1999).

Enrichment and isolation procedures

A definitive diagnosis of *anatipestifer* disease can best be done by isolating and identifying the organism. *Riemerella* strains can be isolated from the organs of infected birds (liver, lung, spleen, heart, blood, kidney, brain) at necropsy by plating onto chocolate agar or 5% sheep blood agar, with incubation for 24 h at 37°C in a microaerobic CO₂-containing atmosphere, e.g., composed of 5% O₂/10% CO₂/85% N₂ or of 5% O₂/3.5% CO₂/7.5% H₂/84% N₂.

Differentiation of the genus *Riemerella* from related genera

Table 44 in the chapter on the genus *Chryseobacterium* lists phenotypic characteristics that are helpful in differentiating *Riemerella* from *Chryseobacterium* and *Bergeyella*.

Taxonomic comments

DNA–rRNA hybridization studies by Segers et al. (1993a) showed that *Riemerella anatipestifer* belongs to the family *Flavobacteriaceae* and that it is related particularly to the genera *Chryseobacterium* and *Bergeyella*. 16S rRNA gene sequence analysis by Subramaniam et al. (1997) supported the conclusion that the closest phylogenetic neighbors of *Riemerella anatipestifer* were members of the genera *Chryseobacterium* and *Bergeyella*.

Vancanneyt et al. (1999) found that *Riemerella columbina* strains were highly related to those of *Riemerella anatipestifer* based on DNA–rRNA hybridization experiments; however, there was no significant DNA–DNA hybridization with the type strain of that species, thereby, establishing the separate species status of *Riemerella columbina*.

Differentiation of the species of the genus *Riemerella*

Riemerella columbina can be differentiated from *Riemerella anatipestifer* by its grayish-white to beige pigmentation on Columbia blood agar and by its hydrolysis of esculin. Also, see the species description of *Riemerella columbina* for additional features that may help to differentiate the two species.

List of species of the genus *Riemerella*

1. *Riemerella anatipestifer* (Hendrickson and Hilbert 1932) Segers, Mannheim, Vancanneyt, De Brandt, Hinz, Kersters and Vandamme 1993a, 775^{VP} [*Moraxella anatipestifer* (Hendrickson and Hilbert 1932) Bruner and Fabricant 1954, 461; *Hemophilus anatipestifer* Hauduroy, Ehringer, Urbain, Guillot and Magrou 1937, 247; *Pasteurella anatipestifer* (sic) Hauduroy, Ehringer, Guillot, Magrou, Prévot, Rosset and Urbain 1953, 367; *Pasteurella anatipestifer* (Hendrickson and Hilbert 1932) Breed, Murray and Smith 1957, 397; *Pfeifferella anatipestifer* Hendrickson and Hilbert 1932, 249]

a.na.ti.pes'ti.fer. L. n. *anas -atis* duck; L. adj. *pestifer* that brings destruction, noxious, pernicious; N.L. n. *anatipestifer* one who brings destruction of ducks.

The description is as given for the genus, with the following additional features (Segers et al., 1993a). Cells occur singly, in pairs, or in short chains. Smooth, nonpigmented colonies develop within 2 d during microaerobic incubation on rich peptone, peptone-blood, or chocolate agar at 36°C. Optimum temperature, 37°C; most strains grow at 45°C, but not at 4°C. Thiamine is required, but low concentrations of pyrithiamine and amprolium are inhibitory. The litmus milk reaction is strain-dependent. Most strains liquefy gelatin, Löffler's blood serum, and coagulated egg medium. Growth occurs in Huddleson's thionine medium, in Huddleson's basic fuchsin medium, and on agar containing 10% bile in serum. No growth occurs on agar containing 40% bile in serum, citrate agar, in KCN broth or in glycerol phosphate medium. H₂S is not produced. The following enzyme activities are present: cystine arylamidase, phosphoamidase, α-glucosidase, and esterase C4. The following enzyme activities are absent: α-galactosidase, β-glucosidase, β-glucosaminidase, lipase C14, and phenylalanine deaminase. Highly susceptible to penicillin, but highly resistant to polymyxin B and kanamycin. The fatty acids include branched fatty acids C_{13:0} iso, C_{15:0} iso, C_{15:0} anteiso, C_{15:0} iso 3-OH, C_{17:0} iso 3-OH, and an unidentified fatty acid with an equivalent chain-length of 13.566. Segers et al. (1993a) reported that menaquinone-7 is the sole respiratory quinone in the type strain of *Riemerella anatipestifer*; however, Vancanneyt et al. (1999) reported that menaquinone-6 is the major respiratory quinone detected in the type species.

Source: the type strain was isolated from a duck in the United States.

DNA G+C content (mol%): 35 (*T_m*).

Type strain: LMG 11054, ATCC 11845, CCUG 14215, CCUG 21370, CIP 82.28, JCM 9532, LMG 11606, MCCC 00568, NCTC 11014.

Sequence accession no. (16S rRNA gene): U10877, U60101.

Additional note: the illness caused by this organism is not restricted to ducks.

2. **Riemerella columbina** Vancanneyt, Vandamme, Segers, Torck, Coopman, Kersters and Hinz 1999, 294^{VP}
co.lum.bi'na. L. fem. adj. *columbina* pertaining to pigeons.

The following description is based on that given by Vancanneyt et al. (1999). The description of *Riemerella columbina* is as for the genus. On Columbia blood agar, all strains show good growth when incubated aerobically at 37°C and microaerobically at 24, 37, and 42°C and produce a gray-white or beige pigment (*Riemerella anatipestifer* strains are nonpigmented). No growth occurs anaerobically at 37°C. No growth occurs on litmus lactose agar (variable for *Riemerella anatipestifer* strains). All strains tested hydrolyze esculin (negative for *Riemerella anatipestifer* strains). When using the API ID32E system, all strains are positive for β-glucosidase activity (negative for *Riemerella anatipestifer* strains; this reaction is, however, negative for *Riemerella columbina* strains in the API ZYM system). Indole is not produced. All strains exhibit chymotrypsin activity (variable reactions for *Riemerella anatipestifer* strains). Using the BSS test, all strains produce acid from D-glucose, maltose, D-mannose, and dextrin (variable reactions for *Riemerella anatipestifer*). A negative or weakly positive reaction occurs for acid production from D-fructose and L-sorbose. The dominant fatty acids are the branched-chain fatty acids C_{13:0} iso, C_{13:0} anteiso, C_{15:0} iso, C_{15:0} anteiso, C_{15:0} iso 3-OH, C_{17:0} iso 3-OH, and "summed feature 4".

Source: isolated from pigeons with respiratory disease. The type strain was isolated from a pigeon palatine cleft in Germany.

DNA G+C content (mol%): 36 (*T_m*).

Type strain: Hinz x183-89, CCUG 47689, CIP 106288, LMG 11607.

Sequence accession no. (16S rRNA gene): AF181448.

Genus XLV. **Robiginitalea** Cho and Giovannoni 2004, 1104^{VP}

JANG-CHEON CHO AND STEPHEN J. GIOVANNONI

Ro.bi.gi.ni.tal'e.a. L. gen. n. *robiginis* rust; L. fem. n. *talea* a rod; N.L. fem. n. *Robiginitalea* a rust-colored rod.

Cell shape varies from straight rods in exponential phase to coccoid cells in stationary phase. Gram-stain-negative. **Non-motile and no gliding motility.** Nonsporeforming. Poly-β-hydroxybutyrate granules are not formed. Obligately aerobic and chemoheterotrophic. **Produce carotenoid pigments, but not flexirubin pigments.** Require NaCl for growth. Oxidase- and catalase-positive. **Degrade starch and esculin.** Utilize a variety of carbon compounds as sole carbon sources. The major fatty acid types are branched acids and hydroxy acids.

DNA G+C content (mol%): 55–56.

Type species: **Robiginitalea biformata** Cho and Giovannoni 2004, 1105^{VP}.

Further descriptive information

Phylogenetic analysis based on 16S rRNA gene sequences has shown that the genus forms a distant lineage within the family

Flavobacteriaceae. The genus *Robiginitalea* currently contains only one species, *Robiginitalea biformata*, with HTCC 2501^T as the type strain.

Cell morphology varies with the growth stage of the cells. Cells in early exponential phase are straight rods, approximately 3.6 μm long and 0.5 μm wide, whereas cells in stationary phase become coccoid, 0.6–1.2 μm in diameter. Transmission electron microscopy has shown that the cells lack flagella, endospores, intracellular granules, and vacuoles. Gliding motility and flagella are not observed.

Colonies on marine agar 2216 grown at 30°C for 4 d are 1.0–2.0 mm in diameter, rusty orange-colored, uniformly circular, opaque, and pulvinate.

The predominant fatty acids are C_{15:0} iso (24–28%), C_{15:1} iso (14–21%), and C_{17:0} 3-OH iso (25–27%). The major fatty acid

types are branched acids and hydroxy acids, comprising 75.7–77.9% total fatty acids.

The organisms are obligately aerobic, mesophilic, NaCl-requiring, and chemoheterotrophic. The temperature, pH, and NaCl concentration ranges for growth are 10–44°C (optimum 30°C), pH 6.0–9.0 (optimum pH 8.0–8.5), and 0.25–10% (w/v) NaCl (optimum 2.5%). Tests for esculin hydrolysis and β -galactosidase activity are positive. Tests for denitrification, indole production, glucose acidification, arginine dihydrolase, urease, and gelatin hydrolysis are negative. Carotenoid pigments are produced with wavelength absorbance peaks at 339 and 457 nm, with a major peak at 457 nm. Photosynthetic gene clusters, bacteriochlorophyll *a*, and photosynthetic activity are not found. Starch is degraded after 3 weeks of incubation, but not gelatin, DNA, casein, elastin, dextran, cellulose, alginate, chitin, or carrageenan. Sole carbon sources include D-ribose, D-xylose, D-glucose, D-fructose, L-sorbose, D-mannose, sucrose, β -lactose, trehalose, cellobiose, maltose, melibiose, raffinose, N-acetyl-D-glucosamine, succinic acid, propionic acid, lactic acid, L-glutamate, L-ornithine, L-proline, and L-serine. The organisms are susceptible to nalidixic acid, tetracycline, erythromycin, rifampin, and benzylpenicillin, but resistant to chloramphenicol, kanamycin, carbenicillin, streptomycin, ampicillin, puromycin, vancomycin, gentamicin, and cycloheximide.

The type strain of the single species of the genus was isolated from the oceanic surface, indicating that its major habitat is the marine environment.

Enrichment and isolation procedures

The original liquid cultures of *Robiginitalea biformata* were obtained from the surface of the Sargasso Sea by a dilution-to-extinction method using low nutrient heterotrophic medium consisting of filtered (0.2 μ m pore size) and autoclaved seawater supplemented with 1.0 μ M NH₄Cl and 0.1 μ M KH₂PO₄ amended with 0.001% (w/v) each of D-glucose, D-ribose, succinic acid, pyruvic acid, glycerol, and N-acetyl D-glucosamine, and 0.002% (v/v) ethanol (Connon and Giovannoni, 2002). Single colonies were obtained easily by spreading the liquid culture on marine agar 2216 (Difco) after incubation for 5 d at 25°C. Therefore, it is likely that *Robiginitalea* can be obtained by spreading seawater on marine agar using a serial dilution plating method. Currently, there is no special method to enrich *Robiginitalea* from the mixed marine microbial community.

Maintenance procedures

Frozen stocks as a glycerol suspension (10–30%) stored in liquid nitrogen or at –70°C are routinely used to start a new culture. Lyophilization of liquid cultures is also recommended for long-term storage. Frozen stocks and lyophilization stocks are stable for at least 1 year (confirmed by survival tests). Working stock cultures can be maintained on slants at 4°C for 2 months.

Differentiation of the genus *Robiginitalea* from related genera

16S rRNA gene sequence analysis is the most convincing evidence for the uniqueness of the genus *Robiginitalea*. All the currently classified genera in the family *Flavobacteriaceae* show less than 90% of 16S rRNA gene sequence similarity to strains of the genus *Robiginitalea*. One of major differentiating characteristics of the genus compared to other members of the family *Flavobacteriaceae* is its DNA G+C content, 54.7–56.4 mol%, which is more than 10 mol% higher than that of the other genera within the family. Other differential properties of the genus include pleomorphic properties and the upper limit of the growth temperature (44°C). Although the fatty acid profile of *Robiginitalea biformata* is similar to that of *Muricauda ruestringensis*, it differs significantly from those of members of the genera *Zobellia*, *Arenibacter*, *Aequorivita*, *Vitellibacter*, and *Croceibacter*.

Taxonomic comments

The only species currently included in the genus is *Robiginitalea biformata*. Classification of *Robiginitalea* as a distinct genus of the family *Flavobacteriaceae* is based on 16S rRNA gene sequence analyses as well as phenotypic and chemotaxonomic properties. The 16S rRNA gene sequence similarities of *Robiginitalea biformata* to members of other genera in the family *Flavobacteriaceae* are only 88–89%. None of the other taxa with validly published names shows more than 90% 16S rRNA gene sequence similarity to *Robiginitalea biformata*. Strains that are most closely related to *Robiginitalea biformata* belong to the genera *Zobellia* (88.6–89.7%), *Arenibacter* (88.3–88.4%), *Aequorivita* (88.3–89.2%), and *Vitellibacter* (87.8–88.0%). Phylogenetic analysis has shown that the genus forms a distinct lineage within the *Flavobacteriaceae*, and its sister polyphyletic clade contains the genera *Muricauda*, *Zobellia*, *Arenibacter*, *Aequorivita*, and *Vitellibacter*.

List of species of the genus *Robiginitalea*

1. ***Robiginitalea biformata*** Cho and Giovannoni 2004, 1105^{VP} bi.for.ma'ta. L. fem. adj. *biformata* double-formed, two-shaped, pertaining to different cell morphology in different growth phases.

Characteristics of the species are as described for the genus.

Source: seawater from the surface of the western Sargasso Sea, Atlantic Ocean.

DNA G+C content (mol%): 55–56 (HPLC).

Type strain: HTCC2501, ATCC BAA-864, KCTC 12146.

Sequence accession no. (16S rRNA gene): AY424899.

Genus XLVI. **Salegentibacter** McCammon and Bowman 2000, 1062^{VP} emend. Ying, Liu, Wang, Dai, Yang and Liu 2007, 221

JOHN P. BOWMAN

Sal.e.gent'i.bac.ter. L. n. *salis* salt; L. part. adj. *egentis* needy; Gr. n. *bakterion* rod; L. masc. n. *Salegentibacter* salt-needy rod.

Cells are **rod-shaped**, 0.5–0.8 × 1.2–11.5 µm. Cells may occur singly, in pairs, or in short chains. Spores and resting cells are not present. Gas vesicles and helical or ring-shaped cells are not formed. **Nonmotile or motile by gliding**. Gram-stain-negative. **Strictly aerobic, having an oxidative type of metabolism**. Catalase-positive. Most species are oxidase-positive. **Chemoheterotrophic. Colonies are bright-yellow-pigmented** due to production of carotenoids. **Flexirubin pigments are not produced**. Most strains form alkaline phosphatase, amylase, Tween esterases (Tweens 20, 40, and 80), gelatinase, elastinase, and alginase, and produce H₂S from L-cysteine. Strains do not form cellulases, chitinases, produce indole from L-tryptophan, or form acetoin (Voges–Proskauer test). **Some species require Na⁺ ions for growth. Halotolerant**. Tolerates 8% or more NaCl. The major fatty acids are C_{15:0}, C_{15:1} iso, C_{15:0} iso, C_{15:0} anteiso, summed feature 3 (C_{16:1} ω7c/C_{15:0} 2-OH iso), C_{16:0} 3-OH iso, C_{17:0} 3-OH iso, and C_{17:0} 2-OH. The major respiratory quinone is **menaquinone-6**. The major polyamine is homospermidine. Habitats include the surfaces of marine fauna including holothurians, sea urchins and sponges, hypersaline lake surface waters, and marine sediment.

DNA G+C content (mol%): 37–44 (T_m, HPLC).

Type species: Salegentibacter salegens (Dobson, Colwell, McMeekin and Franzmann 1993) McCammon and Bowman 2000, 1062^{VP} (*Flavobacterium salegens* Dobson, Colwell, McMeekin and Franzmann 1993, 81).

Further descriptive information

The genus *Salegentibacter* is a member of the family *Flavobacteriaceae* and is composed of six known species: *Salegentibacter salegens*, *Salegentibacter holothuriorum*, *Salegentibacter mishustinae*, *Salegentibacter flavus*, *Salegentibacter agarivorans*, and *Salegentibacter catena*. All species produce distinctive yellow-pigmented colonies on complex marine media such as marine agar 2216 (Difco). Pigmentation of *Salegentibacter salegens* is suppressed when grown on Tween 20-containing growth media (Dobson et al., 1993). *Salegentibacter* species are strictly aerobic chemoheterotrophs with a saprophytic or epiphytic lifestyle consuming naturally occurring proteins, polysaccharides, and carbohydrates. *Salegentibacter salegens*, detected by indirect immunofluorescence, has been observed to colonize diatoms and chlorophytes of various saline, meromictic Antarctic lakes (James et al., 1994). *Salegentibacter* species have been recovered from various moderately hypersaline ecosystems (Ghozlan et al., 2006).

Phenotypic characteristics that enable differentiation of *Salegentibacter* species are shown in Table 65. All species of the genus are considerably halotolerant, with *Salegentibacter salegens*, *Salegentibacter mishustinae*, and *Salegentibacter agarivorans* able

to grow in the presence of up to 20% (w/v) NaCl. Regarding temperature responses, *Salegentibacter* species are mesophilic, with some species able to grow at 0–4°C or up to 42°C. Optimal growth for most species occurs at the salinity and pH of seawater (1–4% salinity and around pH 8.0). Although most species are nonmotile, *Salegentibacter agarivorans* has observable gliding motility and, also unlike the other species of the genus, is agarolytic (Nedashkovskaya et al., 2006c). Although *Salegentibacter* species appear as relatively featureless rod-shaped cells, cells of *Salegentibacter catena* have been shown to form appendage-like structures in the stationary growth phase (Ying et al., 2007). The appendages may be large bleb-like structures (Zhou et al., 1998). Fatty acid compositions of some *Salegentibacter* species are given in Table 66.

Enrichment and isolation procedures

For isolation of *Salegentibacter* strains from water or sediment, samples are serially diluted on an organic, salt-containing medium. Isolation from marine fauna usually involves homogenization of tissue samples in seawater. For the isolation of most *Salegentibacter* species, marine agar 2216 (Difco) can be used for primary isolation and subsequent purification. For *Salegentibacter catena*, a low-nutrient agar medium can be used (0.05% peptone, 0.01% yeast, and 1.5% agar, dissolved in seawater) for primary isolation. Marine agar 2216 can be used for subsequent purification.

Maintenance procedures

The most convenient form of storage of *Salegentibacter* species is cryopreservation in marine broth 2216 containing 20% (v/v) glycerol at –80°C. *Salegentibacter* species can also be readily lyophilized.

Differentiation of the genus *Salegentibacter* from other genera

The most salient traits useful for distinguishing *Salegentibacter* species from other members of the *Flavobacteriaceae* include yellow pigmentation, lack of flexirubin pigments, lack of motility of most species, strictly aerobic oxidative metabolism, ability to use carbohydrates such as starch, proteolytic activity, and, in particular, the ability to grow at NaCl concentrations of 8% or more.

Taxonomic comments

Salegentibacter salegens was originally described as *Flavobacterium salegens* (Dobson et al., 1993), but later phylogenetic and fatty acid analyses indicated that the species was misclassified at the genus level (McCammon and Bowman, 2000).

sal'e.gens. L. n. *sal* salt; L. adj. *egens* needy; *salegens* needing salt.

The characteristics are the same as given for the genus, as listed in Tables 65 and 66, and as described in the text. In addition, nitrate and ammonia are utilized as inorganic nitrogen sources. Esculin is hydrolyzed. Negative for ornithine and lysine decarboxylases. L-Arginine, D-gluconate, and L-ornithine are either utilized or are stimulatory. D-Fructose, cellobiose, maltose, raffinose, pyruvate, fumarate, succinate, L-alanine, L-proline, and L-tryptophan are either utilized or are stimulatory for some strains. The following compounds are neither utilized nor are stimulatory: L-rhamnose, DL-xylose, trehalose, salicin, adonitol, D-mannitol, D-sorbitol, citrate, malonate, L-asparagine, L-cysteine, L-glycine, L-histidine, L-isooleucine, L-leucine, L-lysine, L-serine, L-threonine, L-tyrosine, L-valine, and hydroxy-L-proline. Acid is produced from mannitol by some strains. No acid is produced from L-rhamnose, L-sorbose, melibiose, adonitol, dulcitol, D-sorbitol, inositol, or glycerol. The optimal salinity for growth is ~5%. Growth occurs between pH 5 and 10 (optimum pH

8.0–8.5). Colonies are bright yellow, circular, convex, have an entire edge, and are 1–3 mm in diameter after 3–5 d on marine agar 2216 at 25°C.

Source: isolated from saline, meromictic lakes of Antarctica (James et al., 1994).

DNA G+C content (mol%): 37–38 (T_m , HPLC). The DNA G+C content was reported originally as 39–41 mol% (T_m) by Dobson et al. (1993); however, subsequent reanalysis by spectrophotometry and by HPLC indicated that the type strain has mean G+C values of 37 mol% (McCammon and Bowman, 2000; Nedashkovskaya et al., 2004, 2005).

Type strain: ACAM 48, ATCC 51522, CCUG 33447, CIP 104041, DSM 5424, LMG 13193.

Sequence accession no. (16S rRNA gene): M92279.

^a–, Not detected or at a level below 1% total fatty acid content.

The characteristics are as given for the genus, as listed in Tables 65 and 66, and as described in the text, with the following additional features. Gliding motility is present. Inositol, D-mannitol, D-sorbitol, citrate, and malonate are not utilized. No acid is produced from L-rhamnose, L-sorbose, adonitol, dulcitol, inositol, D-mannitol, or D-sorbitol. From the Microlog GN2 plate system, the following substrates produce positive results: α-D-glucose, α-lactose, sucrose, methylpyruvate, monomethylsuccinate, D-galactonate, D-gluconate, β-hydroxybutyrate, *p*-hydroxyphenylacetate, itaconate, 2-oxoglutarate, DL-lactate, propionate, succinate, succinamate, alaninamide, L-alanyl-glycine, L-asparagine, L-aspartate, L-glutamate, glycyl-L-aspartate, L-phenylalanine, L-proline, L-pyroglutamate, L-threonine, and urocanate. Based on the API ZYM system, positive for the following enzyme activities: α-galactosidase, β-galactosidase, α-glucosidase, β-glucosidase, N-acetyl-β-glucosaminidase, alkaline phosphatase, acid phosphatase, naphthol-AS-BI-phosphohydrolase, C8 esterase/lipase, leucine arylamidase, valine arylamidase, trypsin, and α-chymotrypsin. Colonies are bright yellow, shiny, slimy, circular, convex, sunken into the agar surface, and are 1–3 mm

in diameter after 3–5 d incubation on marine agar 2216 at 25°C. The optimal salinity for growth is 2–4%. Growth occurs between pH 5.7 and 10.0; optimum pH is 7.5–8.3.

Source: isolated from the tissues of a sponge (*Artemisia* sp.) collected near Onecotan Island, Kuril Islands, Sea of Okhotsk.

DNA G+C content (mol%): 39 (HPLC).

Type strain: KCTC 12560, KMM 7019, LMG 23205.

Sequence accession no. (16S rRNA gene): DQ191176.

3. *Salegentibacter catena* Ying, Liu, Wang, Dai, Yang and Liu 2007, 221^{VP}

ca.te'na. L. n. *catena* chain, referring to the fact that cells frequently occur in chains.

Cells frequently occur in chains. Cells produce appendage-like structures when in stationary growth phase. The characteristics are otherwise the same as given for the genus, as listed in Tables 65 and 66, and as described in the text, with the following additional features. Esculin is hydrolyzed, but not carboxymethylcellulose. The following compounds are not utilized: L-arabinose, L-fucose, L-rhamnose, D-galactose, DL-xylose, maltose, melibiose, raffinose, adonitol, D-mannitol, inositol, D-sorbitol, D-gluconate, acetate, propionate, pyruvate, DL-lactate, citrate, L-malate, succinate, malonate, L-alanine, and L-proline. No acid is produced from D-mannose, L-rhamnose, melibiose, adonitol, dulcitol, inositol, D-mannitol, or D-sorbitol. Based on the API ZYM system, strong activity is exhibited for the following enzymes: α-glucosidase, alkaline phosphatase, acid phosphatase, naphthol-AS-BI-phosphohydrolase, C8 esterase/lipase, leucine arylamidase, and valine arylamidase. Weak activity occurs for C4 esterase, C14 lipase, cystine arylamidase, and trypsin. Colonies are saffron yellow, shiny, circular, convex, have an entire edge, and are 3–5 mm in diameter after 5 d on marine agar 2216 at 25°C. The optimal salinity for growth is 1–4%. Grows between pH 6.5 and 9.0, with optimum growth at pH 7.5–8.2.

Source: isolated from marine sediment collected from the Xijiang oilfield located in the South China Sea.

DNA G+C content (mol%): 44 (*T_m*).

Type strain: HY1, CGMCC 1.6101, JCM 14015.

Sequence accession no. (16S rRNA gene): DQ640642.

fla'vus. L. masc. adj. *flavus* golden yellow.

The characteristics are the same as given for the genus, as listed in Table 65, and as described in the text. In addition, DL-xylose, raffinose, salicin, adonitol, inositol, D-mannitol, D-sorbitol, and citrate are not utilized. No acid is produced from L-rhamnose, inositol, D-mannitol, or D-sorbitol. Colonies are bright yellow, shiny, circular, convex, and are 1–3 mm in diameter after 3–5 d on marine agar 2216 at 25°C. The optimal salinity for growth is ~3%. Growth occurs between pH 5 and 10. Optimum growth occurs at pH 8.0–8.5.

Source: isolated from marine sediment collected from the Chazhma Sea, Sea of Japan.

DNA G+C content (mol%): 40 (HPLC).

Type strain: Fg 69, CIP 107843, KMM 6000.

Sequence accession no. (16S rRNA gene): AY6822200.

5. ***Salegentibacter holothuriorum*** Nedashkovskaya, Suzuki, Vancanneyt, Cleenwerck, Zhukova, Vysotskii, Mikhailov and Swings 2004g, 1109^{VP}

ho.lo.thu.ri.o'rum. N.L. gen. pl. n. *holothuriorum* of holothurians (sea cucumbers).

The characteristics are the same as given for the genus, as listed in Table 65, and as described in the text. In addition, D-mannitol, inositol, D-sorbitol, citrate, succinate, and malonate are not utilized. Acid is not produced from L-rhamnose, L-sorbose, melibiose, adonitol, dulcitol, inositol, D-mannitol, D-sorbitol, or glycerol. The optimal salinity for growth is ~3%. Colonies are bright yellow, shiny, circular, convex, have an entire edge, and are 1–3 mm in diameter after 3–5 d on marine agar 2216 at 25°C. The major phospholipid present in cells is phosphatidylethanolamine.

Source: isolated from the tissues of a holothurian (*Apostichopus japonicus*) collected from the Sea of Japan.

DNA G+C content (mol%): 37 (HPLC).

Type strain: KMM 3524, LMG 21968, NBRC 100249.

Sequence accession no. (16S rRNA gene): AB116148.

6. ***Salegentibacter mishustinae*** Nedashkovskaya, Kim, Lysenko, Mikhailov, Bae and Kim 2005h, 237^{VP}

mi.shu'sti.nae. N.L. gen. n. *mishustinae* of Mishustina, in honor of Irina E. Mishustina, a Russian marine microbiologist.

The characteristics are the same as given for the genus, as listed in Tables 65 and 66, and as described in the text. In addition, D-mannitol, inositol, D-sorbitol, citrate, succinate, and malonate are not utilized. Acid is not produced from L-rhamnose, L-sorbose, melibiose, adonitol, dulcitol, inositol, D-mannitol, D-sorbitol, or glycerol. Colonies are bright yellow, shiny, circular, convex, have an entire edge, and are 13 mm in diameter after 3–5 d on marine agar 2216 at 25°C.

Source: isolated from the tissues of a sea urchin (*Strongylocentrotus intermedius*) collected from Troitsa Bay, Gulf of Peter the Great, Sea of Japan.

DNA G+C content (mol%): 37–38 (HPLC).

Sequence accession no. (16S rRNA gene): AY576653.

Genus XLVII. *Sandarakinotalea* Khan, Nakagawa and Harayama 2006c, 960^{VP}

THE EDITORIAL BOARD

San.da.ra.ki.no.ta'le.a. Gr. adj. *sandarakinos* -e -on of orange color; L. fem. n. *talea* a slender staff, a rod; N.L. fem. n. *Sandarakinotalea* an orange-colored rod.

Rods, 0.5–0.7 × 3–5 µm. Nonmotile. Gliding motility is not present. Gram-stain-negative. **Aerobic. Colonies are light orange** due to a carotenoid pigment. Flexirubin-type pigments are not formed. Catalase- and oxidase-positive. Growth occurs at 10–40°C; optimum, 15–20°C; no growth occurs at 4°C. **Growth requires NaCl and either a potassium or magnesium salt. Sea salts are required for growth. Starch, DNA, and gelatin are hydrolyzed. Nitrate is not reduced.** The predominant fatty acids are C_{15:0} iso, C_{15:0} anteiso, C_{16:0} iso, and C_{17:0} iso 3-OH. **Pentadecenoic acid (C_{15:1}) is absent.** The only respiratory quinone present is MK-6. Isolated from marine sediment.

DNA G+C content (mol%): 35–37.

Type species: ***Sandarakinotalea sediminis*** Khan, Nakagawa and Harayama 2006c, 962^{VP}.

Further descriptive information

Khan et al. (2006c) reported that the mean percentage values for cellular fatty acids assayed in four isolates of *Sandarakinotalea sediminis* were as follows: C_{15:0} iso (27%), C_{17:0} iso 3-OH (13%), C_{15:0} anteiso (10%), C_{16:0} iso (10%), C_{17:1} iso ω9c (7%), C_{16:0} iso 3-OH (6%), summed feature 4 (C_{16:1} ω7c/C_{15:0} iso 2-OH) (6%), C_{16:0} iso (3%), C_{15:0} iso 3-OH (3%), C_{17:1} ω6c (3%), C_{17:1} anteiso ω9c (2%), C_{14:0} iso (2%), and C_{17:0} 2-OH (2%). Fatty acids amounting to less than 1% of the total fatty acid content in all strains are not listed.

Enrichment and isolation procedures

Sandarakinotalea sediminis has been isolated from marine sediments. Strains are cultured at 20°C on 1.2% agar plates or slants

prepared with 0.5× marine agar 2216 (Difco) diluted in artificial seawater (Naigai Chemicals).

For long-term preservation, cells can be stored at –80°C in artificial seawater supplemented with 20% (v/v) glycerol.

Differentiation of the genus *Sandarakinotalea* from related genera

Sandarakinotalea strains differ from those of the genera *Algibacter*, *Aquimarina*, *Kordia*, *Mesonina*, *Psychroflexus*, and *Salegentibacter* by being unable to grow at 4°C. Unlike *Kordia* strains, *Sandarakinotalea* strains are catalase-positive and unable to reduce nitrate. In contrast to *Algibacter* and *Aquimarina* strains, they do not exhibit gliding motility and have higher G+C content (35–37 mol% vs 31–33 mol%). Unlike *Psychroflexus* strains, they can hydrolyze gelatin. *Sandarakinotalea* strains differ from those of *Mesonina* by their ability to hydrolyze DNA and starch. They can be distinguished from both *Mesonina* and *Aquimarina* strains by their ability to grow at 37°C and by their inability to grow in the presence of 8–10% NaCl.

Taxonomic comments

Based on 16S rRNA gene sequence analysis, the species most closely related to *Sandarakinotalea sediminis* are *Psychroflexus torquis* and *Algibacter lectus* (90.7 and 90.9% similarities, respectively). *Sandarakinotalea sediminis* has 88–90.1% similarity to members of related genera in the family *Flavobacteriaceae* such as *Aquimarina*, *Kordia*, *Mesonina*, and *Salegentibacter*.

The four strains of *Sandarakinotalea sediminis* isolated so far share DNA–DNA reassociation values of 67–99% with each other.

List of species of the genus *Sandarakinotalea*1. *Sandarakinotalea sediminis* Khan, Nakagawa and Harayama 2006c, 962^{VP}

se.di.mi'nis. L. gen. n. *sediminis* of sediment.

The characteristics are as given for the genus, with the following additional features. Cells may form filaments 5–10 µm in length after incubation for 6 or 7 d. Colonies are circular or irregular. Growth is supported by 10, 30, 50, and 70% (v/v) artificial seawater. Growth in 0.2× LB medium [2 g tryptone (Difco) and 1 g yeast extract (Difco) dissolved in 1,000 ml water] requires addition of NaCl and either a potassium or magnesium salt. Agar, cellulose, carboxymethylcellulose, chitin, esculin, and urea are not hydrolyzed. Indole is not produced from tryptophan. Acid is not produced from glucose. The following substrates are oxidized (Biolog GN2 MicroPlate system): L-alanyl glycine, L-aspartic acid, α-cyclodextrin, dextrin, L-glutamic acid, glycogen, glycyl L-aspartic acid, glycyl L-glutamic acid, α-ketobutyric acid, α-ketovaleric acid, maltose, mannitol, monomethyl succinate, L-ornithine, L-proline, L-serine, and L-threonine. The following compounds are not oxidized: acetic acid, N-acetyl-D-galactosamine, N-acetyl-D-glucosamine, *cis*-aconitic acid, adonitol, alaninamide, D-alanine, L-alanine, γ-aminobutyric acid, 2-aminoethanol, L-arabinose, D-arabitol, L-asparagine,

bromosuccinic acid, 2,3-butanediol, DL-carnitine, cellobiose, citric acid, i-erythritol, D-fructose, formic acid, L-fucose, D-galactose, D-galactonic acid lactone, D-galacturonic acid, gentiobiose, D-gluconic acid, D-glucosaminic acid, α-D-glucose, glucose 1-phosphate, glucose 6-phosphate, glucuronamide, D-glucuronic acid, glycerol, DL-α-glycerol phosphate, glycyl L-aspartic acid, glycyl L-glutamic acid, L-histidine, α-, β- and γ-hydroxybutyric acids, *p*-hydroxyphenylacetic acid, hydroxy-L-proline, *myo*-inositol, itaconic acid, α-ketoglutaric acid, DL-lactic acid, α-D-lactose, lactulose, L-leucine, malonic acid, melibiose, methyl β-D-glucoside, methylpyruvic acid, phenylethylamine, L-phenylalanine, propionic acid, D-psicose, putrescine, L-pyroglutamic acid, quinic acid, raffinose, L-rhamnose, D-saccharic acid, sebacic acid, D-serine, D-sorbitol, succinamic acid, succinic acid, sucrose, trehalose, turanose, Tweens 40 and 80, urocanic acid, uridine, thymidine, and xylitol. Mannose is oxidized only by the type strain CKA-5^T and inosine is oxidized only by reference strain CKA-36.

Source: the type strain was isolated from marine sediment collected on the Pacific Ocean coast at Katsuurra, Japan.

DNA G+C content (mol%): 35–37 (HPLC).

Type strain: CKA-5, LMG 23247, NBRC 100970.

Sequence accession no. (16S rRNA gene): AB206954.

Genus XLVIII. *Sedimicola* Khan, Nakagawa and Harayama 2006b, 843^{VP}

THE EDITORIAL BOARD

Se.di.mi.ni.co'la. L. n. *sedimen -inis* sediment; L. masc. suff. *-cola* (from L. n. *incola*) an inhabitant; N.L. masc. n. *Sedimicola* an inhabitant of sediment, referring to the source of the strains.

Rods, 0.5–0.7 × 3–5 µm. Nonmotile. Gram-stain-negative. Colonies are golden-yellow. Flexirubin-type pigments are not produced. **Aerobic.** Catalase-positive. Weakly positive for oxidase. Growth occurs at 10–30°C; optimum, 20°C. **Growth occurs in 10–100% strength artificial seawater; NaCl alone is not sufficient to support growth. Nitrate is reduced. Gelatin, casein, and starch are hydrolyzed.** Predominant cellular fatty acids are C_{15:0} iso, C_{15:0} anteiso, C_{15:1} iso, C_{17:1} iso ω9c, C_{17:0} iso 3-OH, and summed feature 3 (C_{16:1} iso ω7c/i-C_{15:0} 2-OH). **Pentadecanoic acid (C_{15:0}) is absent.** Isolated from sediments collected on the shores of the Pacific Ocean and the Sea of Japan.

DNA G+C content (mol%): 38–40.

Type species: *Sedimicola luteus* Khan, Nakagawa and Harayama 2006b, 843^{VP}.

Enrichment and isolation procedures

Isolation can be accomplished on marine agar 2216 (Difco). Cultures are grown at 20°C. Long-term preservation can be

achieved by storing the organisms at –80°C in artificial seawater containing 20% (v/v) glycerol.

Differentiation of the genus *Sedimicola* from other genera

Sedimicola strains can be differentiated phenotypically from those of other genera by the following combination of features: the ability to reduce nitrate; the ability to degrade gelatin, casein, and starch; and a lack of pentadecanoic acid (C_{15:0}).

Taxonomic comments

Analysis of 16S rRNA gene sequences indicates that members of the genus *Sedimicola* have 87.9–90.5% sequence similarity to those of the following genera: *Arenibacter*, *Maribacter*, *Muricauda*, *Robiginitalea*, *Ulvibacter*, *Vitellibacter*, and *Zobellia*.

The four *Sedimicola luteus* strains isolated so far exhibit 99.3–99.7% rRNA gene sequence similarity to one another. They also show DNA–DNA reassociation values of 93–104% with each other.

List of species of the genus *Sedimicola*1. *Sedimicola luteus* Khan, Nakagawa and Harayama 2006b, 843^{VP}

lu'te.us. L. masc. adj. *luteus* golden yellow, because the colony color is golden yellow.

The characteristics are as described for the genus, with the following additional features. Seven-day-old cells form

filaments of 5–10 µm. Gelatin, casein, and starch are hydrolyzed, but not urea, chitin, cellulose, carboxymethylcellulose, or DNA. Nitrate is reduced. Indole is not produced from tryptophan. Acid is not produced from glucose. The following compounds are oxidized (Biolog GN2 MicroPlate system): N-acetyl-D-galactosamine, L-aspartic acid, cellobiose,

α -cyclodextrin, dextrin, D-fructose, D-galactose, gentiobiose, α -D-glucose, glucose 1-phosphate, L-glutamic acid, glycogen, glycyl L-aspartic acid, glycyl L-glutamic acid, DL-lactic acid, α -D-lactose, lactulose, maltose, D-mannitol, D-mannose, melibiose, methyl β -D-glucoside, L-ornithine, L-proline, raffinose, sucrose, L-threonine, trehalose, and turanose. Does not oxidize the following compounds: acetic acid, N-acetyl D-glucosamine, *cis*-aconitic acid, adonitol, alaninamide, D-alanine, L-alanine, L-alanyl glycine, γ -aminobutyric acid, 2-aminoethanol, L-asparagine, bromosuccinic acid, 2,3-butanediol, D-arabitol, DL-carnitine, citric acid, D-galactonic acid lactone, D-galacturonic acid, D-gluconic acid, D-glucosaminic acid, D-glucuronic acid, glycerol, DL- α -glycerol phosphate, α -, β - and γ -hydroxybutyric

acid, *p*-hydroxyphenylacetic acid, i-erythritol, formic acid, L-fucose, glucose 6-phosphate, glucuronamide, inosine, *myo*-inositol, itaconic acid, L-histidine, hydroxy-L-leucine, α -ketoglutaric acid, α -ketovaleric acid, malonic acid, methyl pyruvic acid, monomethyl succinic acid, phenylethylamine, L-phenylalanine, propionic acid, putrescine, L-pyroglutamic acid, quinic acid, L-rhamnose, D-serine, L-serine, D-sorbitol, xylitol, D-saccharic acid, sebamic acid, succinamic acid, succinic acid, thymidine, Tween 40, and Tween 80.

Source: the type strain was isolated from marine sediment on the shore of the Sea of Japan.

DNA G+C content (mol%): 38–40 (HPLC).

Type strain: CNI-3, LMG 23246, NBRC 100966.

Sequence accession no. (16S rRNA gene): AB206957.

Genus XLIX. *Sejongia* Yi, Yoon and Chun 2005b, 414^{VP}

HANA YI AND JONGSIK CHUN

Se.jong'i.a. N.L. fem. n. *Sejongia* named after the King Sejong Station, where the type species was isolated.

Rods with parallel sides and rounded ends, generally 0.4–0.5 \times 1.0–3.1 μ m. Gram-stain-negative. Spores are not formed. Nonmotile. **Do not glide** or spread. **Aerobic**, exhibiting only weak growth under microaerobic and anaerobic conditions. **Psychrotolerant**, with optimum growth temperatures of 19–22°C. Optimum growth is observed at pH 7–8 and in 0% NaCl. Growth occurs on R2A, Anacker and Ordal's agar (AOA), nutrient agar (NA) and tryptic soy agar (TSA), but not on cetrimide or MacConkey agars. Colonies are convex, translucent, circular, glistening, butyrous, and **yellow** with entire margins, becoming mucoid after prolonged incubation on R2A. Do not adhere to agar plates. Catalase- and oxidase-positive. Congo red is not adsorbed. The maximum absorption peak of the yellow pigment in ethanolic extracts is at 452 nm and the next shoulder peak is at 480 nm. **No flexirubin-type pigments are produced.** Acid is produced aerobically or fermentatively from some carbohydrates. The major isoprenoid quinone is MK-6. The predominant cellular fatty acids are C_{15:0} iso (12.2–13.6%), C_{15:0} anteiso (15.2–24.2%), and C_{17:1} iso ω 9c (8.6–21.3%).

DNA G+C content (mol%): 34–36.

Type species: *Sejongia antarctica* Yi, Yoon and Chun 2005b, 414^{VP}.

Further descriptive information

Based on 16S rRNA gene sequence analysis, the genus is phylogenetically related to the genera *Bergeyella*, *Chryseobacterium*, *Kaistella*, and *Riemerella* in the family *Flavobacteriaceae*. See *Taxonomic comments* section for detailed information. Differential characteristics for the species are given in Table 67 and other characteristics are given in Table 68.

Fatty acids. The dominant fatty acids in *Sejongia antarctica* are C_{15:0} iso, C_{15:0} anteiso, and C_{17:1} iso ω 9c; those in *Sejongia jeonii* are C_{15:0} iso and C_{15:0} anteiso. Fairly large differences in the amount of C_{15:0} anteiso (15.2% vs 24.2%) and C_{17:1} iso ω 9c (21.3% vs 8.6%) are found between *Sejongia antarctica* and *Sejongia jeonii*. Overall, the fatty acid compositions of *Sejongia* species are similar to those of phylogenetically related species, but they differ from them somewhat in quantities. This may result

from different growth media and the low growth temperature of *Sejongia* spp. compared with other mesophilic species. The full fatty acid composition of *Sejongia antarctica* is C_{17:1} iso ω 9c (21.3%), C_{15:0} anteiso (15.2%), C_{15:0} iso (13.6%), C_{15:1} anteiso A (6.6%), C_{17:0} iso 3-OH (5.6%), C_{16:0} iso 3-OH (5.1%), C_{16:1} iso H (3.6%), C_{17:0} 2-OH (3.3%), C_{13:0} anteiso (3.2%), C_{16:0} iso (2.8%), summed feature 3 (C_{15:0} iso 2-OH and/or C_{16:1} ω 7c/t) (2.7%), C_{15:0} (2.6%), C_{13:0} iso (2.5%), C_{17:1} anteiso ω 9c (2.5%), C_{15:0} 2-OH (1.9%), C_{14:0} iso (1.5%), and C_{18:1} ω 5c (1.5%); trace amounts (less than 1% of total fatty acids) of C_{15:0} iso 3-OH, C_{12:0} 3-OH, ECL (equivalent chain-length, i.e., the identity of the fatty acids is unknown) 13.566, C_{15:1} iso F, C_{12:0} iso, C_{14:0} iso 3-OH, ECL 16.580, and C_{17:1} ω 8c are also present. The full fatty acid composition of *Sejongia jeonii* is C_{15:0} anteiso (24.2%), C_{15:0} iso (12.2%), C_{16:1} iso H (9.1%), C_{16:0} iso 3-OH (9.0%), C_{17:1} iso ω 9c (8.6%), C_{16:0} iso (5.7%), C_{14:0} iso (5.0%), C_{17:0} iso 3-OH (4.4%), C_{13:0} anteiso (3.6%), C_{13:0} iso (2.9%), summed feature 3 (2.6%), C_{17:0} 2-OH (2.3%), C_{17:1} anteiso ω 9c (1.9%), C_{15:0} 2-OH (1.9%), C_{15:0} (1.5%), C_{15:0} iso 3-OH (1.3%), and C_{12:0} iso (1.0%); trace amounts of C_{18:1} ω 5c, C_{14:0} iso 3-OH, ECL 16.580, C_{17:1} ω 6c, ECL 13.566, and C_{14:0} are also present.

Isoprenoid quinone		

^aSymbols: +, positive; -, negative.

Colonial characteristics. Freshly grown cells are catalase- and oxidase-positive. Colonies of *Sejongia* appear convex, translucent, circular, glistening, and butyrous with entire margins; they then become mucoid after prolonged incubation and do not adhere to the agar. The colonial color is bright to pale yellow depending on growth media. The maximum absorption peak of the yellow pigment in ethanolic extracts is at 452 nm and the next shoulder peak is at 480 nm. Flexirubins are not detected from a bathochromic shift test of the absorption peak or from a color change test of cell mass by addition of KOH solution.

Motility. Gliding motility is not observed by direct microscopic examination of the edge of colonies in exponential phase on AOA agar (Anacker and Ordal, 1955), R2A medium (Reasoner and Geldreich, 1985), and CY agar (casitone, 3 g; yeast extract, 1 g; CaCl₂·2H₂O, 1 g; sea salts, 40 g; agar, 15 g; distilled water, 1 l) plates. Cellular motility is not observed by the hanging drop technique for cells in exponential phase in R2A and CY broth. Congo red is not adsorbed by directly flooding colonies on agar plates with 0.01% aqueous Congo red solution.

Nutrition and growth conditions. Maximum growth is observed on R2A and abundant growth is observed on AOA, NA, and TSA. No growth is observed on cetrinide or

MacConkey agars. The organisms are aerobic and grow poorly under microaerobic conditions [with 5–15% O₂ and 5–12% CO₂ created by the Campy Pak Plus system (BBL)] and anaerobic conditions [with 4–10% CO₂ created by the GasPak Plus system (BBL)]. Microaerobic growth is better than anaerobic growth. Growth is observed at pH 6–11 (optimum pH 7–8) and 0–3% NaCl (optimum 0%). The temperature range for growth determined by a temperature-gradient incubator (TVS 126MA; Advantec) in R2A broth is 5–30°C. Cardinal temperature plots based on the Ratkowsky temperature growth model (Ratkowsky et al., 1983) are given in Figure 50. The notional minimum, optimum, and maximum growth temperatures for *Sejongia antarctica* are -16.6, 18.9, and 28.2°C and those for *Sejongia jeonii* are -10.9, 21.5, 30.9°C, respectively. According to Isaksen and Jorgensen (1996) who defined psychrotolerant bacteria as those that are able to grow at ≤0°C, but not at >35°C and have temperature optima at ≤25°C, the two *Sejongia* species are psychrotolerant.

Metabolism and metabolic pathways. Neither nitrate nor nitrite is reduced. Indole is produced, but H₂S is not. There is no alkaline reaction on Christensen's citrate agar (Christensen, 1949). L-Phenylalanine deaminase activity is present, but arginine dihydrolase, β-galactosidase, and urease activities

FIGURE 50. Fitted Ratkowsky model of growth versus temperature data for *Sejongia antarctica* (filled circles) and *Sejongia jeonii* (open circles). \sqrt{r} is the square root of the growth rate.

are absent. Casein, esculin, DNA, gelatin, egg yolk, starch, and Tween 80 are decomposed, but agar, alginate, carboxymethyl-cellulose, chitin, and pectin are not. Positive reactions for both lecithinase and Tween esterase are delayed in *Sejongia antarctica*. L-Tyrosine is hydrolyzed weakly by *Sejongia antarctica*, but not by *Sejongia jeonii*. Elastin is decomposed by *Sejongia jeonii*, but not by *Sejongia antarctica*. None of the compounds contained in API 20NE kits (glucose, arabinose, mannose, mannitol, N-acetylglucosamine, maltose, gluconate, caprate, adipate, malate, citrate, and phenylacetate) are assimilated as a sole carbon source. Alkaline phosphatase, esterase lipase (C8), leucine arylamidase, valine arylamidase, acid phosphatase, naphthol-AS-BI-phosphohydrolase, and α -glucosidase are positive. Esterase (C4), lipase (C14), cystine arylamidase, trypsin, α -chymotrypsin, α -galactosidase, β -galactosidase, β -glucuronidase, β -glucosidase, N-acetyl- β -glucosaminidase, α -mannosidase, and α -fucosidase are negative with the API ZYM kit. Acid is produced aerobically from D-glucose and maltose, but not from L-arabinose, cellobiose, D-fructose, lactose, D-mannitol, raffinose, L-rhamnose, D-salicin, sucrose, trehalose, or D-xylose on the modified O/F agar of Leifson (1963) (casitone, 1.0 g; yeast extract, 0.1 g; ammonium sulfate, 0.5 g; Tris buffer, 0.5 g; phenol red, 0.01 g; Bacto agar, 15 g; distilled water, 1 l; adjusted to pH 7.0). Acid is produced fermentatively from D-glucose, maltose, starch, and glycogen, but not from glycerol, erythritol, D-arabinose, L-arabinose, D-ribose, D-xylose, L-xylose, D-adonitol, methyl β -D-xylopyranoside, D-galactose, D-fructose, D-mannose, L-sorbose, L-rhamnose, dulcitol, inositol, D-mannitol, D-sorbitol, methyl α -D-mannopyranoside, methyl α -D-glucopyranoside, N-acetylglucosamine, amygdalin, arbutin, esculin ferric citrate, salicin, cellobiose, D-lactose (bovine origin), melibiose, sucrose, trehalose, inulin, melezitose, raffinose, xylitol, gentiobiose, turanose, D-lyxose, tagatose, D-fucose, L-fucose, D-arabitol, L-arabitol, potassium gluconate, potassium 2-ketogluconate, or potassium 5-ketogluconate with the API 50 CH kit using API 50 CHB/E

medium. *Sejongia jeonii* produces acid fermentatively from D-mannose, but *Sejongia antarctica* does not.

Ecology. The two *Sejongia* species with validly published names were cold-adapted psychrotolerant bacteria isolated from Antarctica (Yi et al., 2005b). *Sejongia antarctica* and *Sejongia jeonii* were isolated from an eutrophic terrestrial environment, i.e., a soil and a moss sample from a penguin habitat, near the King Sejong Station on King George Island, Antarctica.

Enrichment and isolation procedures

Terrestrial samples for isolation of psychrotolerant *Sejongia* strains should be kept at a low temperature. Initial enrichment of samples in refrigerated liquid media at 4°C for 1–2 d may enhance the isolation. The enriched samples can be applied directly to isolation media and incubated at low temperatures (4–10°C) for up to 1 month.

Maintenance procedures

Freshly grown cultures may be maintained on agar plates at 4°C by monthly transfer. For long-term storage, a dense suspension of cells in 20% glycerol may be maintained at –80°C or may also be freeze-dried.

Differentiation from closely related taxa

Members of the genus *Sejongia* can be differentiated from those of the genus *Chryseobacterium* by their lack of flexirubin-type pigments, and from those of the genera *Bergeyella* and *Riemerella* by their yellow pigmentation.

Taxonomic comments

The two *Sejongia* species, i.e., *Sejongia antarctica* and *Sejongia jeonii*, show 97.7% 16S rRNA gene sequence similarity, corresponding to 31 nucleotide differences. They belong to separate genomic species, sharing a low DNA–DNA relatedness value of 27% based on slot-blot DNA–DNA hybridization (Yi et al., 2005b). Based on 16S rRNA gene sequence similarities, the closest bacterial relatives of the genus *Sejongia* are *Chryseobacterium* (91.9–95.7% for *Sejongia antarctica*; 93.4–96.3% for *Sejongia jeonii*), *Elizabethkingia* (92.5–93.3%; 93.3–93.9%), *Riemerella* (92.6–93.0%; 92.3–93.5%), *Bergeyella* (92.6%; 92.5%), and *Kaistella* (92.5%; 93.3%). This relationship between *Sejongia* spp. and other members of the above-mentioned genera is also highlighted in the phylogenetic tree (Figure 51), a neighbor-joining tree of *Sejongia* and related taxa based on 16S rRNA gene sequences. The genera *Sejongia*, *Bergeyella*, *Chryseobacterium*, *Elizabethkingia*, *Kaistella*, and *Riemerella* form a monophyletic suprageneric clade in the family *Flavobacteriaceae*. The branching order within this suprageneric group and the position of *Sejongia* vary depending on the tree-making algorithm used. The two *Sejongia* species were consistently recovered as a robust monophyletic clade that could be differentiated from *Chryseobacterium* spp. at the time of its description (Yi et al., 2005b). Young et al. (2005) simultaneously described a novel *Chryseobacterium* species named *Chryseobacterium formosense*. Based on comprehensive phylogenetic analysis, *Chryseobacterium formosense* is phylogenetically placed between *Sejongia* and *Chryseobacterium* spp., although its position is not stable (Figure 51). *Chryseobacterium formosense* shows high 16S rRNA gene sequence similarities to both *Chryseobacterium* (95.3–97.4%) and *Sejongia* (95.7–96.3%) strains. The generic status of *Chryseobacterium*

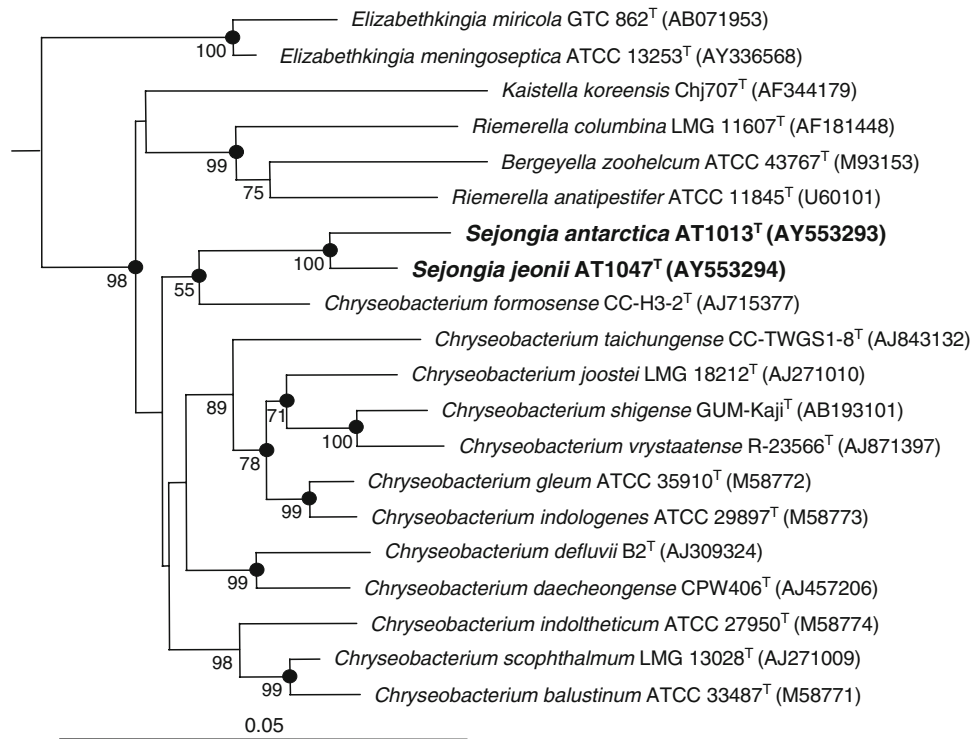

FIGURE 51. Neighbor-joining tree of the genus *Sejongia* and related taxa based on 16S rRNA gene sequences. Numbers at nodes are percentages of bootstrap support (>50%) from 1000 resampled datasets. Filled circles indicate that the corresponding nodes (groupings) were also recovered in maximum-likelihood and maximum-parsimony trees. *Flavobacterium aquatile* (M62797), *Ornithobacterium rhinotracheale* (U87101), *Empedobacter brevis* (D14022), and *Weeksella virosa* (M93152) were used as outgroups (not shown). The manual sequence alignment based on bacterial 16S rRNA secondary structure and phylogenetic analysis was performed using the program JPHYDIT (Jeon et al., 2005). Bar = 0.05 nt substitution per position.

formosense should be re-evaluated using additional physiological and chemotaxonomic properties.

Although the genus *Sejongia* forms a distinct monophyletic clade within the suprageneric group containing the genera *Bergeyella*, *Chryseobacterium*, *Elizabethkingia*, *Kaistella*, and *Riemerella*, the distinctness of the generic status of *Sejongia* has become less clear by the addition of *Chryseobacterium formosense*. Because *Sejongia* and *Chryseobacterium formosense* were validly published

simultaneously (Yi et al., 2005b; Young et al., 2005), the relationship between these two taxa was not reported at the time of their description. However, *Sejongia* spp. and *Chryseobacterium formosense* can be easily differentiated at the genus level by the presence of flexirubin. *Chryseobacterium formosense*, like all chryseobacteria, has flexirubin, but *Sejongia* species do not. The taxonomic status of *Chryseobacterium formosense* should be re-evaluated with additional phenotypic and genotypic methods in future.

List of species of the genus *Sejongia*

1. *Sejongia antarctica* Yi, Yoon and Chun 2005b, 414^{VP}

ant.arc'ti.ca. L. fem. adj. *antarctica* southern, and by extension of or belonging to Antarctic, the geographical origin of the type strain.

Cells are approximately $1.0\text{--}3.1 \times 0.4\text{--}0.5 \mu\text{m}$. Grows at 4–28°C with notional optimum of 18.9°C. Does not decompose elastin. Hydrolyzes L-tyrosine weakly. Does not produce acid fermentatively from D-mannose.

Source: the type strain was isolated from a soil sample of penguin habitats near the King Sejong Station on King George Island, Antarctica.

DNA G+C content (mol%): 34 (HPLC).

Type strain: AT1013, IMSNU 14040, KCTC 12225, JCM 12381.

Sequence accession no. (16S rRNA gene): AY553293.

2. *Sejongia jeonii* Yi, Yoon and Chun 2005b, 414^{VP}

je.on'i.i. N.L. gen. masc. n. *jeonii* of Jeon, named in honor of the late Jae Gyu Jeon, who devoted his life to polar research.

Cells are approximately $1.0\text{--}3.1 \times 0.4\text{--}0.5 \mu\text{m}$. Grows at 4–31°C with notional optimum of 21.5°C. Decomposes elastin. Does not hydrolyze L-tyrosine. Produces acid fermentatively from D-mannose.

Source: the type strain was isolated from a moss sample of penguin habitats near the King Sejong Station on King George Island, Antarctica.

DNA G+C content (mol%): 36 (HPLC).

Type strain: AT1047, IMSNU 14049, KCTC 12226, JCM 12382.

Sequence accession no. (16S rRNA gene): AY553294.

Genus L. **Stenothermobacter** Lau, Tsoi, Li, Plakhotnikova, Dobretsov, Wu, Wong, Pawlik and Qian 2006, 183^{VP}

THE EDITORIAL BOARD

Ste.no.ther.mo.bac'ter. Gr. adj. *stenos* narrow; Gr. adj. *thermos* hot; N.L. masc. n. *bacter* rod; N.L. masc. n. *Stenothermobacter* a rod with narrow temperature range, pertaining to the narrow temperature range that supports growth of the type strain.

Rods, >2.5 µm in length with tapered ends, forming chains of up to four cells. Gram-stain-negative. **Slow gliding motility is present**. Colonies are orange. Flexirubin-type pigments are not produced. Temperature range for growth, 20.0–36.0°C; optimum, 28.0–30.0°C. **Require 2.0–6.0% NaCl for growth. Strictly aerobic**. Chemo-organotrophic. Oxidase-positive. Catalase activity is very weak. Acetoin is produced, but not H₂S. **DNA and casein are not hydrolyzed. β-Galactosidase and α-glucosidase are produced, but not β-glucosidase**. MK-6 is the only respiratory quinone. Isolated from the marine sponge *Lissodendoryx isodictyalis*.

DNA G+C content (mol%): 41.0

Type species: **Stenothermobacter spongiae** Lau, Tsoi, Li, Plakhotnikova, Dobretsov, Wu, Wong, Pawlik and Qian 2006, 184^{VP}.

Enrichment and isolation procedures

Stenothermobacter spongiae was isolated from tissue of the marine sponge *Lissodendoryx isodictyalis* on a special marine agar (SMA) consisting of 5.0 g peptone and 3.0 g yeast extract dissolved in seawater. The medium was sterilized by filtration (0.22 µm pore

diameter) and solidified with agar. Orange colonies 2–4 mm in diameter were selected after 48 h at 30°C.

Differentiation of the genus *Stenothermobacter* from related genera

Stenothermobacter spongiae can be differentiated from *Nonlabens tegetincola* by its gliding motility, higher DNA G+C content (41.0 mol% vs 33.6 mol%), inability to hydrolyze DNA, narrower temperature range for growth (20–36°C vs 12–44°C), and by its α-glucosidase and β-galactosidase activities. It can be differentiated from *Donghaena dokdonensis* by its gliding motility, β-galactosidase activity, inability to hydrolyze casein, and higher DNA G+C content (41.0 mol% vs 36.9 mol%).

Taxonomic comments

Analysis of 16S rRNA gene sequences by Lau et al. (2006) indicated that the nearest neighbors of *Stenothermobacter spongiae* were the type strains of *Nonlabens tegetincola* (93.3% sequence similarity) and *Donghaena dokdonensis* (93.6%). The sequence similarity to strains of other species of the *Flavobacteriaceae* was 90.9% or less.

List of species of the genus *Stenothermobacter*

1. **Stenothermobacter spongiae** Lau, Tsoi, Li, Plakhotnikova, Dobretsov, Wu, Wong, Pawlik and Qian 2006, 184^{VP}

spon'gi.ae. L. gen. n. *spongiae* of a sponge, pertaining to the isolation source of the type strain.

The description is as given for the genus, with the following additional features. Colonies on SMA are orange, circular, 2.0–4.0 mm in diameter, and convex with smooth surfaces and entire margins. No diffusible pigment is produced. pH range for growth is 6.0–10.0. Acetoin is produced, but not indole or H₂S. Nitrate is not reduced. Gelatin, starch, and Tweens 20, 40 and 80 are hydrolyzed, but not agar, casein, carboxymethylcellulose, chitin, or DNA. The following enzyme activities are present: acid phosphatase, alkaline phosphatase, β-galactosidase, α-glucosidase, α-chymotrypsin, cystine arylamidase, leucine arylamidase, valine arylamidase, esterase (C4), esterase lipase (C8), lipase (C14), trypsin, and naphthol-AS-BI-phosphohydrolase. No activity is found for N-acetyl-β-glucosaminidase, arginine dihydrolase, α-fucosidase, α-galactosidase, β-glucosidase, β-glucuronidase, α-mannosidase, lysine decarboxylase, ornithine decarboxylase, tryptophan deaminase, or urease. Growth, but not acid

production, occurs with the following sole carbon sources (API 20E, API 20NE, and API 50CH systems): D-arabinose, D-galactose, D-glucose, glycerol, D-mannitol, melibiose, D-sorbitol, starch, and sucrose. The following carbon sources are utilized (MicroLog 3 system): acetic acid, L-alaninamide, L-alanine, L-alanyl-glycine, L-aspartic acid, L-glutamic acid, glycyl-L-aspartic acid, glycyl-L-glutamic acid, α-ketoglutaric acid, α-ketovaleric acid, maltose, melibiose, monomethyl succinate, L-ornithine, propionic acid, L-proline, raffinose, and sucrose. Susceptibility is exhibited toward ampicillin, chloramphenicol, penicillin, streptomycin, and tetracycline, but not to kanamycin. The predominant fatty acids (>5%) are C_{15:0} anteiso, C_{15:0} iso, C_{15:0} iso 3-OH, C_{17:0} iso 3-OH, C_{17:1} iso ω9c, and summed feature 3 (comprising C_{15:0} iso 2-OH and/or C_{16:1} ω7c) (altogether representing 76.2% of the total fatty acids).

DNA G+C content (mol%): 41 (HPLC).

Type strain: UST030701-156, JCM 13191, NRRL B-41138.

Sequence accession no. (16S rRNA gene): DQ064789.

Genus LI. **Subsaxibacter** Bowman and Nichols 2005, 1481^{VP}

JOHN P. BOWMAN

Sub.sa.xi.bac'ter. L. pref. *sub* below; L. neut. n. *saxum* stone; N.L. masc. n. *bacter* rod; N.L. masc. n. *Subsaxibacter* bacterial rod living below stone.

Small coccibacilli, 0.4–1.0 × 0.3–0.5 µm. **Gram-stain-negative**. Cells occur singly or in pairs. Spores and resting cells are not present. Gas vesicles and helical or ring-shaped cells are not

formed. **Gliding motility is present. Strictly aerobic. Oxidative metabolism. Catalase-positive. Oxidase weakly positive. Chemoheterotrophic. Colonies are orange** due to production

of carotenoids. **Flexirubin pigments are not produced.** **Sodium ions** are required for growth. Best growth occurs in organic media containing seawater salts. **Psychrophilic.** Grows between -2 and 20°C , with temperature optima at 10 – 15°C in seawater or NaCl-containing media. Neutrophilic, with optimal growth occurring at about pH 7.5–8.0. The major fatty acids include $\text{C}_{15:1}$ iso $\omega 10$, $\text{C}_{15:1}$ anteiso $\omega 10$, $\text{C}_{15:0}$ iso, $\text{C}_{15:0}$ anteiso, $\text{C}_{16:1}$ $\omega 7$, $\text{C}_{17:1}$, and $\text{C}_{16:0}$ 3-OH iso. The major isoprenoid quinone is **menaquinone-6**. Habitat: Antarctic quartz stone sublithic cyanobacterial biofilms.

DNA G+C content (mol%): 35.

Type species: ***Subsaxibacter broadyi*** Bowman and Nichols 2005, 1481^{VP}.

Further descriptive information

The genus *Subsaxibacter* is a member of the family *Flavobacteriaceae* and is represented currently by a single species, *Subsaxibacter broadyi* (Bowman and Nichols, 2005). This species was isolated from cyanobacteria-dominated biofilm material obtained from the undersides of quartz stones, partially buried in field soils of an ice-free coastal area of Antarctica (see the treatment of the genera *Gelidibacter* and *Subsaximicrobium* for more details) (Smith et al., 2000). Physiologically, the genus has many features that are typical of the family *Flavobacteriaceae* (Bernardet et al., 2002). Based on currently available cultivation and molecular data (published and unpublished data from the National Center of Biotechnology Information; <http://www.ncbi.nlm.nih.gov>), the genus *Subsaxibacter* has yet to be isolated from other saline habitats; however, a cultivation-independent survey of corroding concrete samples from a sewer system (Okabe et al., 2007) detected 16S rRNA gene sequences that grouped with those of *Subsaxibacter*.

Isolation and maintenance procedures

Strains of *Subsaxibacter* can be potentially isolated directly from quartz stone biofilm scrapings thoroughly suspended in a 1:10

dilution of trypticase soy broth (Oxoid) supplemented with 1% (w/v) NaCl. The suspension is then serially diluted onto the same medium containing 1.5% agar and incubated aerobically in the dark at 2 – 10°C for several weeks. Bright orange viscid colonies that form slowly may be indicative of *Subsaxibacter* strains. Routine cultivation should be performed aerobically on marine agar 2216 at 10 – 15°C . The species is slow-growing compared to related species of the genus *Subsaximicrobium* and colonies may take up to 2 weeks to form. Strains can be maintained as frozen suspensions in marine broth 2216 containing 20–30% (v/v) glycerol at -70°C . Strains may survive for several months, potentially years, on thick agar marine agar 2216 plates or on slants, stored at 2 – 4°C .

Differentiation of the genus *Subsaxibacter* from other genera

The most useful traits for differentiating *Subsaxibacter* from other members of the *Flavobacteriaceae* include: orange pigmentation; lack of flexirubin pigments; ability to glide; strictly oxidative metabolism; inability to form acid from carbohydrates; requirement for low temperatures for growth (e.g., <15 – 20°C) and no growth at 25°C ; requirement for sodium ions for growth (good growth on sea salts-containing media); and lack of agarolytic activity. These basic traits can be used to readily differentiate *Subsaxibacter* from most of its relatives in the family *Flavobacteriaceae*. *Subsaxibacter* strains differ from those of *Subsaximicrobium*, which share the same quartz stone habitat, in being much more slow-growing, forming comparatively viscid colonies, possessing a relatively narrow salinity tolerance, requiring yeast extract for growth, being unable to hydrolyze most macromolecules, and having an overall general lack of bioactivity in standard biochemical tests. Several other genera of the family *Flavobacteriaceae* possess at least some proportion of the traits possessed by *Subsaxibacter* and, thus, any phenotypic-based identification may require 16S rRNA gene sequencing to achieve a completely definitive identification.

List of species of the genus *Subsaxibacter*

1. *Subsaxibacter broadyi* Bowman and Nichols 2005, 1481^{VP}

broa.dy'i. N.L. gen. masc. n. *broadyi* of Broady, named in honor of P.A. Broady, an Antarctic microbiologist from New Zealand who pioneered the study of many Antarctic terrestrial biomes.

Characteristics are as described for the genus, with the following additional features. Colonies are bright orange, circular, convex, with an entire edge and a viscid consistency on marine agar 2216. No growth occurs at 25°C ; optimal temperature for growth, 10 – 15°C . Growth occurs in 0.1–1.25 M NaCl, with optimal growth at seawater salinities (0.3–0.4 M NaCl). Grows well in media containing double-strength sea salts (70 g/l dehydrated sea salts), but no growth occurs with quadruple-strength sea salts. Does not require divalent cations found in seawater for growth; all salinity requirements can be met with NaCl. Grows well on trypticase soy agar (Oxoid) containing 1% (w/v) NaCl, but poor or no growth occurs on trypticase soy agar and nutrient agar (Oxoid). Requires yeast extract for growth. The following compounds are not

utilized in a basal mineral salts medium containing yeast extract, a vitamin solution, and ammonium chloride: D-glucose, glycogen, maltose, sucrose, N-acetyl-D-glucosamine, L-rhamnose, DL-arabinose, L-fucose, D-mannose, melibiose, salicin, acetate, propionate, valerate, caprate, adipate, suberate, citrate, DL-3-hydroxybutyrate, DL-lactate, itaconate, phenylacetate, L-alanine, L-proline, L-histidine, and L-serine. Acid production from carbohydrates is undetectable in Leifson's oxidation/fermentation medium (Leifson, 1963). Gelatin and Tween 80 are hydrolyzed. Strains may also hydrolyze esculin. L-Tyrosine may be hydrolyzed weakly. Casein, elastin, starch, agar, chitin, carboxymethylcellulose, dextran, xylan, xanthine, uric acid, DNA, and urea are not hydrolyzed. Alkaline phosphatase is produced. Some strains are positive for glutamate decarboxylase activity. Activity not observed for arginine dihydrolase, lysine decarboxylase, or ornithine decarboxylase. H_2S is not produced from L-cysteine. Indole is not produced. No growth occurs in the Simmons' citrate test. Lipase (olive oil as the substrate) and lecithinase (egg yolk

reaction) activity is not observed. Nitrate is not reduced. Negative for α -arabinosidase, α -galactosidase, α -glucosidase, β -glucosidase, β -galactosidase, 6-phospho- β -galactosidase, β -glucuronidase, *N*-acetyl- β -D-glucosaminidase, and α -fucosidase activity. Positive for arginine arylamidase, leucyl glycine arylamidase, phenylalanine arylamidase, leucine arylamidase, tyrosine arylamidase, glycine arylamidase, histidine arylamidase, serine arylamidase, alanine arylamidase, and glutamyl glutamate arylamidase. Negative for pyroglutamate

arylamidase and proline arylamidase. Does not tolerate 1% (w/v) ox bile salts.

Source: the type strain was isolated from cyanobacterial biofilms attached to the undersides of partially buried quartz stones found in the Vestfold Hills, an ice-free region of East Antarctica.

DNA G+C content (mol%): 35 (T_m).

Type strain: P7, ACAM 1064, CIP 108527.

Sequence accession no. (16S rRNA gene): AY693999.

Genus LII. *Subsaximicrobium* Bowman and Nichols 2005, 1480^{VP}

JOHN P. BOWMAN

Straight **rod-shaped cells**, 0.3–0.5 \times 1–6 μ m. In stationary growth phase cultures, cells may transform into spheroplasts, 1–3 μ m in diameter. **Gram-stain-negative**. Cells occur singly or in pairs. Spores and resting cells are not present. Gas vesicles and helical or ring-shaped cells are not formed. **Gliding motility** is present. **Strictly aerobic**. **Oxidative metabolism**. **Catalase-positive**. **Oxidase-positive**. **Chemoheterotrophic**. **Colonies are orange** due to production of carotenoids. **Flexirubin pigments are not produced**. **Sodium ions are required** for growth. Best growth occurs in organic media containing seawater salts. **Psychrophilic**. Grows between –2 and 20°C, with temperature optima at 15–20°C in seawater or NaCl-containing media. Neutrophilic, with optimal growth occurring at about pH 7.5–8.0. The major fatty acids include $C_{15:1}$ iso ω 10c, $C_{15:1}$ anteiso ω 10c, $C_{15:0}$ iso, $C_{15:0}$ anteiso, $C_{16:1}$ ω 7c, $C_{15:0}$ anteiso 3-OH, and $C_{16:0}$ iso 3-OH. The major isoprenoid quinone is **menaquinone-6**. Inhabits Antarctic quartz stone sublithic cyanobacterial biofilms.

DNA G+C content (mol%): 39–40.

Type species: *Subsaximicrobium wynnwilliamsii* Bowman and Nichols 2005, 1481^{VP}.

Further descriptive information

The genus *Subsaximicrobium* is a member of the family *Flavobacteriaceae*, represented currently by two closely related species, *Subsaximicrobium wynnwilliamsii* and *Subsaximicrobium saxinquilinus* (Bowman and Nichols, 2005). Both species were isolated from cyanobacteria-dominated biofilm material obtained from the undersides of quartz stones, partially buried in feldfield soils of an ice-free coastal area of Antarctica called the Vestfold Hills (latitude 78°S, longitude 68°E). The quartz stone sublithic habitat is an unusual oasis-like zone in which marine-type bacteria are found. Within the sublithic biofilms, these bacteria may be partially protected from the surrounding harsh soil conditions, i.e., regular diurnal freezing, continuous desiccation, and, during summer, relatively intense ultraviolet light radiation. The microbial community of quartz stone subliths, which includes *Subsaximicrobium* and species of its immediate relatives, *Subsaxibacter* and *Gelidibacter*, has been described using cultivation-dependent and -independent methods (Smith et al., 2000). Physiologically, the genus has features that are typical of the family *Flavobacteriaceae* (Bernardet et al., 2002). The two species of *Subsaximicrobium* are quite closely related sharing up to 60% DNA–DNA similarity (mean 50–55%). Phenotypic tests

differentiating the species are shown in Table 69 and are based on available data only. Most strains that were isolated from Vestfold Hills quartz stone material belonged to *Subsaximicrobium wynnwilliamsii* (Bowman and Nichols, 2005). Based on currently available cultivation and molecular data (published and unpublished data from the National Center of Biotechnology Information; <http://www.ncbi.nlm.nih.gov>), members of the genus *Subsaximicrobium* have yet to be isolated from other saline habitats. The species require sodium ions for growth and the sublithic habitats in which they are found are located in a maritime locale, which suggests that they may also occur in cold marine waters or sea-ice.

Isolation and maintenance procedures

Strains can be isolated directly from quartz stone biofilm scrapings thoroughly suspended in 1:10 dilution of trypticase soy broth (Oxoid) supplemented with 1% NaCl. The suspension is then serially diluted onto the same medium containing 1.5% agar and incubated aerobically in the dark at 2–15°C for 1–4 weeks. Bright orange colonies that form within 1–2 weeks are usually indicative of *Subsaximicrobium*. Routine cultivation and storage should be performed aerobically on marine agar 2216 at 15–20°C. Strains can be maintained as frozen suspensions in

marine broth 2216 containing 20–30% (v/v) glycerol at -70°C . Strains may survive for several months, potentially years, on thick agar marine agar 2216 plates or on slants, stored at $2\text{--}4^{\circ}\text{C}$.

Differentiation of the genus *Subsaximicrobium* from other genera

The most useful traits for differentiating *Subsaximicrobium* from other members of the *Flavobacteriaceae* include orange pigmentation, lack of flexirubin pigments, ability to glide, strictly oxidative metabolism, ability to form acid from carbohydrates, relatively rapid growth at low temperatures (e.g., 4°C) and at 25°C , requirement for sodium ions for growth (or good growth on sea salts-containing media), and lack of agarolytic activity.

These basic traits can be used to differentiate *Subsaximicrobium* from its closest relatives *Subsaxibacter* and *Gelidibacter*. *Subsaxibacter* differs in being much more slow-growing, forming crumbling and/or viscid colonies, having a lower salinity tolerance, possessing a requirement for yeast extract, and being unable to hydrolyze casein or starch. *Gelidibacter* differs in that its species have a yellow pigment, mainly possess a lower salt tolerance (an exception is *Gelidibacter salicanalis*), and are able to form detectable acid production from D-glucose. Several other genera of the family *Flavobacteriaceae* possess at least some proportion of the traits possessed by *Subsaximicrobium*; thus, any phenotypic-based identification is at best tentative and 16S rRNA gene sequencing is required for any definitive identification.

List of species of the genus *Subsaximicrobium*

1. *Subsaximicrobium wynnwilliamsii* Bowman and Nichols 2005, 1481^{VP}

wynn.wil.li.ams'i.i. N.L. gen. masc. n. *wynnwilliams* of Wynn-Williams, named in honor of the late David Donaldson Wynn-Williams, British Antarctic microbiologist.

Characteristics are as described for the genus, with the following additional features. Colonies are usually bright orange, circular, and convex, with an entire edge and a butyrous consistency on marine agar 2216. A minority of strains may possess a golden-yellow pigmentation. Most strains grow poorly at 25°C ; the optimal temperature for growth is $15\text{--}20^{\circ}\text{C}$. Growth occurs in 0.25–2.0 M NaCl, with optimal growth at seawater salinities (0.3–0.4 M NaCl). Poor growth occurs in media containing double-strength sea salts (70 g/l dehydrated sea salts), and no growth occurs with quadruple-strength sea salts. Does not require divalent cations found in seawater for growth; all salinity requirements can be met with NaCl. Grows well on trypticase soy agar (Oxoid) containing 1% (w/v) NaCl, but poor or no growth occurs on trypticase soy agar and nutrient agar (Oxoid). Growth can occur on a mineral salts medium prepared with sea salts and containing ammonium chloride or sodium nitrate as the sole nitrogen source and D-glucose as the sole carbon and energy source. Other sole carbon and energy sources include glycogen, maltose, sucrose, and L-proline, but not N-acetyl-D-glucosamine, L-rhamnose, DL-arabinose, L-fucose, D-mannose, melibiose, salicin, propionate, valerate, caprate, adipate, suberate, citrate, DL-3-hydroxybutyrate, DL-lactate, itaconate, phenylacetate, L-histidine, or L-serine. Some strains (but not the type strain) can grow on acetate and/or L-alanine. Acid production from carbohydrates is undetectable in Leifson's oxidation/fermentation medium (Leifson, 1963). Gelatin, Tween 80, esculin, starch, and L-tyrosine are hydrolyzed, but not agar, chitin, carboxymethylcellulose, dextran, xylan, xanthine, uric acid, DNA, or urea. Most strains can decompose starch and weakly decompose casein. Some strains can also degrade elastin. Produces alkaline phosphatase and α -glucosidase. Most strains possess glutamate decarboxylase activity; some strains are positive for β -glucosidase and weakly positive for N-acetyl- β -D-glucosaminidase. No activity is observed for arginine dihydrolase, lysine decarboxylase, or ornithine decarboxylase. H_2S is not produced from

L-cysteine. Indole is not produced. No growth occurs in the Simmons' citrate test. Lipase (olive oil as the substrate) or lecithinase (egg yolk reaction) activity is not observed. Nitrate is not reduced. Negative for α -arabinosidase, α -galactosidase, β -galactosidase, 6-phospho- β -galactosidase, β -glucuronidase, and α -fucosidase activity. Positive for arginine arylamidase, leucyl glycine arylamidase, phenylalanine arylamidase, leucine arylamidase, tyrosine arylamidase, glycine arylamidase, histidine arylamidase, serine arylamidase, alanine arylamidase, and glutamyl glutamate arylamidase. Negative for pyroglutamate arylamidase. Some strains may produce proline arylamidase. Does not tolerate 1% (w/v) ox bile salts.

Genus LIII. *Tenacibaculum* Suzuki, Nakagawa, Harayama and Yamamoto 2001, 1650^{VP}

MAKOTO SUZUKI

Te.na.ci.ba'cu.lum. L. adj. n. *tenax -acis* holding fast; L. neut. n. *baculum* stick; N.L. neut. n. *Tenacibaculum* rod-shaped bacterium that adheres to the surface of marine organisms.

Rods, 1.5–30 \times 0.4–0.5 μ m. Ring-shaped cells and gas vesicles are not formed. Spores are not formed. Cells are **nonflagellated**. **Cells are motile by gliding**. Gram-stain-negative. Cells produce a yellow pigment that is mainly zeaxanthin. **Flexirubin-type pigments are absent**. **Chemo-organotrophic**. **Aerobic**. **Catalase- and oxidase-positive**. Grow well on media containing seawater. **The major respiratory quinone is menaquinone-6**. All strains have been isolated from marine environments.

DNA G+C content (mol%): 31–33.

Type species: Tenacibaculum maritimum (Wakabayashi, Hikida and Masumura 1986) Suzuki, Nakagawa, Harayama and Yamamoto 2001, 1650^{VP} [*Flexibacter maritimus* Wakabayashi, Hikida and Masumura 1986, 398 emend. Bernardet and Grimont 1989, 353; *Cytophaga marina* (ex Hikida, Wakabayashi, Egusa and Masumura 1979) Reichenbach 1989a, 2044; *Flexibacter marinus* Hikida, Wakabayashi, Egusa and Masumura 1979, 427].

Further descriptive information

The genus *Tenacibaculum* belongs to the family *Flavobacteriaceae* and is closely related to the genus *Polaribacter* with 16S rRNA gene sequence similarities between strains of these species of 91.0–93.3% (Figure 52). 16S rRNA gene sequence similarities between strains of *Tenacibaculum* species are 93.3–98.5%.

The cells are rod-shaped and often elongate to 10–30 μ m and sometimes up to 100 μ m. Pleomorphism is not usually observed, but spherical cells are observed in aged cultures.

The dominant cellular fatty acids are the branched-chain unsaturated fatty acid $C_{15:0}$ iso and hydroxylated fatty acids $C_{16:0}$ iso 3-OH, $C_{17:0}$ iso 3-OH, and summed feature 3 (comprising $C_{15:0}$ iso 2-OH and/or $C_{16:1}$ ω 7c).

All species grow on media containing peptone and yeast extract prepared with natural or artificial seawater, such as marine agar 2216 (Difco). Some species are able to grow on media supplemented with 1–3% NaCl only. Growth is observed at 4–34°C. Some species can grow at 40°C, but *Tenacibaculum ovolyticum* cannot grow at 28°C or higher.

Members of the genus *Tenacibaculum* are commonly found in marine environments. They usually attach to or associate with the surface of marine organisms such as fishes, macroalgae or microalgae, and invertebrates.

Enrichment and isolation procedures

Strains of the genus *Tenacibaculum* have been isolated from marine samples, particularly from the surfaces of marine organisms. Two fish-pathogenic species, *Tenacibaculum maritimum* and *Tenacibaculum ovolyticum*, have been isolated from the surface of diseased fish or fish eggs (Hansen et al., 1992; Wakabayashi et al., 1986). These species were isolated by direct streaking of external lesions, kidney tissues, or adherent epiflora of eggs onto agar plates. *Tenacibaculum mesophilum* and *Tenacibaculum amylolyticum* were isolated from homogenates of marine macroalgae or sponges (Suzuki et al., 2001). *Tenacibaculum skagerakense* was isolated from filtered (0.8 μ m pore diameter) seawater (Frette et al., 2004). *Tenacibaculum lutimaris*, *Tenacibaculum litoreum*, and *Tenacibaculum aestuarii* were isolated from tidal flat sediment by the dilution plating technique or by direct streaking onto agar plates (Choi et al., 2006; Jung et al., 2006; Yoon et al., 2005c). The media for isolation of these bacteria were standard or diluted marine agar or cytophaga agar made with 70–100% seawater.

Maintenance procedures

For temporary preservation, cultures may be stored at 4°C for several weeks. For long-term preservation, cultures can be kept in broth containing 10% glycerol at –80°C or in the gas phase of liquid nitrogen. Lyophilization may give satisfactory results.

Differentiation of the genus *Tenacibaculum* from other genera

The differentiating features of *Tenacibaculum* and closely related genera are listed in Table 70. *Tenacibaculum* strains can be differentiated from those of *Polaribacter* by cell morphology, cell mass

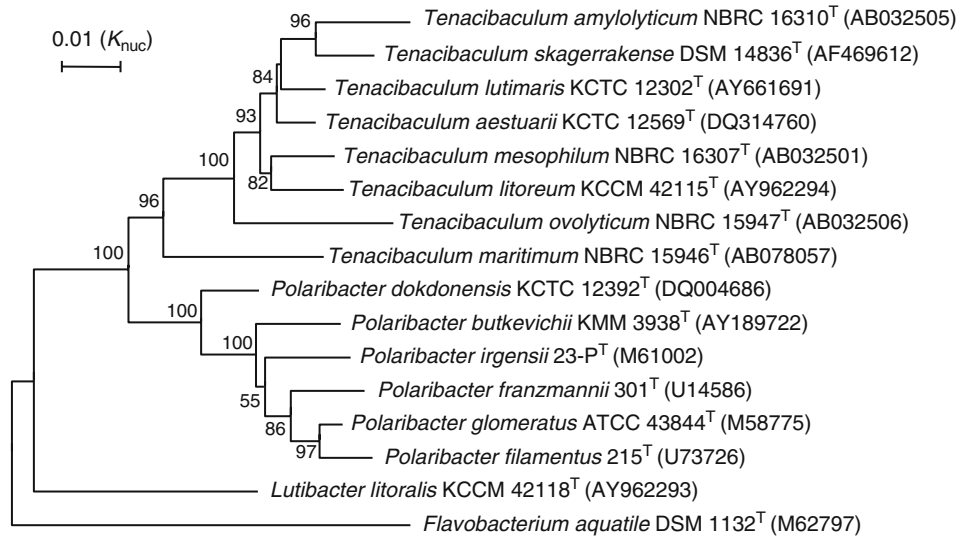

FIGURE 52. Neighbor-joining tree obtained with the 16S rRNA gene sequences of strains of *Tenacibaculum*, *Polaribacter*, and *Lutibacter* species. Bootstrap values (500 resamplings) greater than 50% are indicated at the nodes. Bar = genetic distance of 0.01 (K_{nuc}).

color, and growth temperature. They can also be differentiated from those of *Lutibacter* by oxidase activity and growth pH range.

Taxonomic comments

Tenacibaculum maritimum is a fish-pathogenic bacterium and some intraspecific varieties have been studied. Two major O-serotypes (O1 and O2) have been described in *Tenacibaculum maritimum* strains isolated from marine fish in Spain (Avenidaño-Herrera et al., 2004a). These serotypes were associated mainly with the host fish species (sole or turbot). Serotype O1 contained the majority of the sole isolates, whereas serotype O2 consisted of turbot isolates. There was an intermediate minor serotype, O1/O2, for Japanese strains, which were isolated from sea bream. In 2005, a novel O-serotype, O3, was reported from strains isolated from cultured sole from Portugal and south of Spain (Avenidaño-Herrera et al., 2005).

Intraspecific diversity of *Tenacibaculum maritimum* was also studied by the randomly amplified polymorphic DNA (RAPD) method (Avenidaño-Herrera et al., 2004c). The results of RAPD analysis indicated there were two major groups that correlated strongly with the O-serotype grouping.

Species-specific PCR primers using 16S rRNA gene sequences for *Tenacibaculum maritimum* were reported by Toyama et al. (1996). A nested PCR method for the specific diagnosis of *Tenacibaculum maritimum* in fish samples was reported by Avenidaño-Herrera et al. (2004b).

Differentiation of species of the genus *Tenacibaculum*

The differential characteristics of species of the genus *Tenacibaculum* are listed in Table 71.

List of species of the genus *Tenacibaculum*

1. ***Tenacibaculum maritimum*** (Wakabayashi, Hikida and Masumura 1986) Suzuki, Nakagawa, Harayama and Yamamoto 2001, 1650^{VP} [*Flexibacter maritimus* Wakabayashi, Hikida and Masumura 1986, 398 emend. Bernardet and Grimont 1989, 353; *Cytophaga marina* (ex Hikida, Wakabayashi, Egusa and Masumura 1979) Reichenbach 1989a, 2044; *Flexibacter marinus* Hikida, Wakabayashi, Egusa and Masumura 1979, 427]

mar.i.ti'mum. L. neut. adj. *maritimum* of the sea, maritime.

The characteristics are as described for the species and as listed in Tables 70 and 71, with the following additional features. Rods, 0.5 × 2–30 µm. Spherical cells are often present. Cell mass color is pale yellow. Colonies have an uneven edge and diameters of less than 5 mm at 5 d. Microcysts are not formed. Growth occurs at 15–34°C, with optimum growth at 30°C. The pH range for growth is 5.9–8.6; no growth occurs at pH 5. Seawater, at least 1/3 strength, is required for growth. Growth occurs on Casamino acids. Nitrate is reduced. Gelatin, Tween 80, and DNA are hydrolyzed, but not starch. Esterase lipase (C8) is present (API ZYM system); lipase (C14), trypsin, and naphthol-AS-BI-phosphohydrolase activities are weakly positive. Lysis of dead cells of *Escherichia coli* is negative. L-Glutamate is utilized weakly as a carbon source, but citrate, L-leucine, sucrose, L-proline, and DL-aspartate are not utilized.

Source: isolated from diseased red sea bream (*Pagrus major*), black sea bream (*Acanthopagrus schlegeli*), rock bream (*Oplegnathus fasciatus*), sole (*Solea* spp.), turbot (*Scophthalmus maximus*), and gilthead (*Sparus aurata*). The type strain was isolated from a diseased red sea bream fingerling (*Pagrus major*) reared in a floating net cage offshore Ondo, Hiroshima Prefecture, Japan.

DNA G+C content (mol%): 31.3–32.5 (T_m).

Type strain: R2, ATCC 43398, CIP 103528, CCUG 35198, LMG 11612, NBRC 15946, NCIMB 2154.

Sequence accession no. (16S rRNA gene): AB078057.

2. ***Tenacibaculum aestuarii*** Jung, Oh and Yoon 2006, 1580^{VP}

aes.tu'a.ri.i. L. gen. n. *aestuarii* of the tidal flat, from where the organism was isolated.

The characteristics are as described for the species and as listed in Tables 70 and 71, with the following additional features. Cells are 0.3 × 2.0–3.5 µm. Cell mass color is pale yellow. Colonies are smooth, irregular with spreading edges, greenish, and glistening. No growth occurs under anaerobic conditions on marine agar 2216 (Difco) or on marine agar with nitrate. Optimum pH is 7.5–8.5; weak growth occurs at pH 5.5; no growth at pH 5.0. No growth occurs in the presence of more than 7% (w/v) NaCl. Growth does not occur in the absence of NaCl. Tyrosine and Tweens 20, 40, 60 and 80 are hydrolyzed, but esculin, urea, hypoxanthine, and xanthine are not. With the API ZYM system (bioMérieux), alkaline phosphatase, esterase (C4), leucine arylamidase, valine arylamidase, α-chymotrypsin, acid phosphatase, phosphohydrolase, and β-glucosidase are present, but cystine arylamidase, α-galactosidase, β-galactosidase, β-glucuronidase, α-glucosidase, N-acetyl-β-glucosaminidase, α-mannosidase, and α-fucosidase are absent. Peptone and tryptone are utilized as sole carbon and energy sources. D-Glucose, D-galactose, D-fructose, cellobiose, trehalose, and L-leucine are not utilized. Acid is not produced from D-sorbitol, myo-inositol, D-xylose, D-ribose, D-fructose, D-mannitol, melibiose, L-arabinose, melezitose, D-glucose, D-galactose, L-rhamnose, D-mannose, cellobiose, lactose, sucrose, maltose, trehalose,

or raffinose. Susceptible to cephalothin, lincomycin, oleandomycin, and carbenicillin, but not to polymyxin B, streptomycin, penicillin G, ampicillin, gentamicin, novobiocin, tetracycline, kanamycin, or neomycin. The major cellular fatty acids are C_{15:0} iso, C_{16:0} iso 3-OH, and summed feature 3 (comprising C_{15:0} iso 2-OH and/or C_{16:1} ω7c).

Source: the type strain was isolated from tidal flat sediment at Saemankum, Pyunsan, Korea.

DNA G+C content (mol%): 33.6 (HPLC).

Type strain: SMK-4, JCM 13491, KCTC 12569.

Sequence accession no. (16S rRNA gene): DQ314760.

3. **Tenacibaculum amylolyticum** Suzuki, Nakagawa, Harayama and Yamamoto 2001, 1650^{VP}

am.y.lo.ly'ti.cum. Gr. n. *amulon* starch; N.L. adj. *lyticus -a -um* (from Gr. adj. *lutikos -ê -on*) able to loosen, able to dissolve; N.L. neut. adj. *amylolyticum* starch-dissolving.

The characteristics are as described for the species and as listed in Tables 70 and 71, with the following additional features. Rods, 0.4 × 2–5 μm. Cell mass color is bright yellow. Colonies on 1/5 × LBM agar (tryptone, 2.0 g; yeast extract, 1.0 g; agar, 15 g, 1000 ml Jamarin S synthetic seawater at pH 7.2; Suzuki et al., 2001) are circular with a spreading and undulating margin, a flat elevation, and 20–30 mm diameter after 5 d incubation. At least half-strength seawater is required for sufficient growth. Growth occurs at 19–35°C, with optimum growth at 30°C in liquid media. No growth occurs at temperatures at or below 15°C and at or above 40°C. pH range for growth is 5.3–8.3 in liquid media. Nitrate is reduced weakly. Casein, starch, tyrosine, gelatin, Tween 80, and DNA are hydrolyzed. Growth occurs on peptone, tryptone, Casamino acids, L-proline, and L-glutamate as the sole carbon and nitrogen sources.

Source: the type strain was isolated from the green alga *Avrainvillea riukiuiensis*, which was collected in Palau.

DNA G+C content (mol%): 31 (HPLC).

Type strain: CIP 107214, DSM 13766, MBIC4355, NBRC 16310.

Sequence accession no. (16S rRNA gene): AB032505.

4. **Tenacibaculum litoreum** Choi, Kim, Hwang, Yi, Chun and Cho 2006, 639^{VP}

li.to.re'um. L. neut. adj. *litoreum* of the shore.

The characteristics are as described for the species and as listed in Tables 70 and 71, with the following additional features. Straight rods, 0.3–0.5 × 2–35 μm. Spherical cells are rare. Cell mass is pale yellow. On marine agar 2216, colonies are irregular with spreading edges, greenish, glistening, and 5–10 mm in diameter after 5 d incubation at 30°C. Growth occurs at 5–40°C, with optimum growth at 35–40°C. pH range for growth is 6–10; no growth occurs at pH 5. Growth occurs in NaCl concentrations of 3–5% (w/v) and in sea salt concentrations of 1–10% (w/v). Starch, gelatin, DNA, and Tween 80 are hydrolyzed. Positive for nitrate reductase and gelatinase, but negative for indole production, acid production from glucose, arginine dihydrolase, urease, hydrolysis of esculin, and β-galactosidase (API 20NE system). Alkaline phosphatase, esterase (C4 and C8), leucine arylamidase, valine arylamidase, cystine arylamidase, trypsin, α-chymotrypsin, acid phosphatase, and naphthol-AS-BI-phosphohydrolase are

present, but lipase (C14), α-galactosidase, β-galactosidase, β-glucuronidase, α-glucosidase, β-glucosidase, N-acetyl-β-glucosaminidase, α-mannosidase and α-fucosidase are absent (API ZYM system). Growth occurs on Casamino acids, tryptone, yeast extract, peptone, L-arginine, L-ornithine, L-proline, and L-lysine. No growth occurs on acetate, benzoate, citrate, maleic acid, ethanol, glycerol, L-leucine, tartrate, pyruvic acid, succinate, sucrose, L-glutamate, D-ribose, DL-aspartate, N-acetylglucosamine, L-arabinose, D-xylose, D-fructose, D-glucose, D-mannose, trehalose, inulin, D-mannitol, D-sorbitol, D-salicin, raffinose, D-galactose, urea, or lactose. Major fatty acids are summed feature 3 (comprising C_{15:0} iso 2-OH and/or C_{16:1} ω7c; 19.6%), C_{15:0} iso (18.8%), and C_{17:0} iso 3-OH (13.6%). Also contains minor amounts of C_{18:3} ω6c(6,9,12) (1.5%) and summed feature 4 (C_{17:1} iso₁ and/or C_{17:1} anteiso B; 1.3%).

Source: the type strain was isolated from tidal flat sediment in Ganghwa, Korea.

DNA G+C content (mol%): 30 (T_m).

Type strain: CL-TF13, KCCM 42115, JCM 13039.

Sequence accession no. (16S rRNA gene): AY962294.

5. **Tenacibaculum lutimaris** Yoon, Kang and Oh 2005c, 797^{VP}

lu.ti.ma'ris. L. neut. n. *lutum* mud; L. neut. n. *mare-is* the sea, marine; N.L. gen. n. *lutimaris* of a mud of the sea.

The characteristics are as described for the species and as listed in Tables 70 and 71, with the following additional features. Rods, 0.5 × 2–10 μm. Cell mass color is pale yellow. Colonies are irregular, smooth, and glistening on marine agar 2216 at 30°C. Colonies are adherent to the agar surface. Growth occurs at 10–39°C, with optimum growth at 30–37°C. No growth occurs at 4°C or above 41°C. Optimum pH is 7–8; no growth occurs at pH 4.5. Optimal growth occurs in the presence of 2–3% (w/v) NaCl; no growth occurs in the absence of NaCl. Tyrosine is hydrolyzed, but esculin, hypoxanthine, Tweens 20, 40 and 60, xanthine, and urea are not hydrolyzed. H₂S is not produced. Growth under anaerobic conditions does not occur on marine agar. The ability to grow under anaerobic conditions on marine agar supplemented with nitrate differs among strains (negative for type strain). Growth occurs on peptone, tryptone, and Casamino acids as sole carbon and nitrogen sources. No growth occurs on D-glucose, sucrose, D-ribose, DL-aspartate, L-proline, L-glutamate, or L-leucine. No acid is produced from L-arabinose, cellobiose, D-fructose, D-galactose, D-glucose, lactose, maltose, D-mannose, melibiose, melezitose, raffinose, L-rhamnose, D-ribose, sucrose, trehalose, D-xylose, adonitol, D-sorbitol, *myo*-inositol, or D-mannitol. Major fatty acids are summed feature 3 (comprising C_{15:0} iso 2-OH and/or C_{16:1} ω7c), C_{15:0} iso, C_{16:0} iso 3-OH, C_{15:0}, and C_{17:0} iso -OH.

Source: the type strain was isolated from a tidal flat on Daepo Beach in the Yellow Sea, 3Korea.

DNA G+C content (mol%): 32.3–32.8 (HPLC).

Type strain: TF-26, KCTC 12302, DSM 16505.

Sequence accession no. (16S rRNA gene): AY661691.

6. **Tenacibaculum mesophilum** Suzuki, Nakagawa, Harayama and Yamamoto 2001, 1650^{VP}

me.so.phi'lum. Gr. n. *mesos* middle; Gr. adj. *philos* loving; N.L. neut. adj. *mesophilum* middle (temperature)-loving, i.e., mesophilic.

The characteristics are as described for the species and as listed in Tables 70 and 71, with the following additional features. Rods, $0.5 \times 1.5\text{--}10 \mu\text{m}$. Spherical cells are rare. Cell mass color is yellow. Colonies on $1/5 \times$ LBM medium are circular with a spreading, undulating margin and a flat elevation, and have diameters of 40–50 mm after 5 d. Growth requires $1/10$ strength seawater or 1% (w/v) NaCl. Growth occurs at 15–40°C, with optimum growth at 28–35°C in liquid media. No growth occurs at temperatures at or below 10°C and at or above 45°C. Growth occurs at pH 5.3–9.0 in liquid media; no growth occurs at pH 5.0. Nitrate is not reduced. Casein, tyrosine, gelatin, Tween 80, and DNA are hydrolyzed. Growth occurs on peptone, tryptone, Casamino acids, DL-aspartate, L-proline, and L-glutamate as sole carbon and nitrogen sources. Citrate, L-leucine, and sucrose are not used as carbon sources.

Source: the type strain was isolated from the sponge *Halichondria okadai*, which was collected in Numazu, Japan.

DNA G+C content (mol%): 31–32 (HPLC).

Type strain: CIP 107215, DSM 13764, MBIC1140, NBRC 16307.

Sequence accession no. (16S rRNA gene): AB032501.

7. **Tenacibaculum ovolyticum** (Hansen, Bergh, Michaelsen and Knappskog 1992) Suzuki, Nakagawa, Harayama and Yamamoto 2001, 1650^{VP} (*Flexibacter ovolyticus* Hansen, Bergh, Michaelsen and Knappskog 1992, 457)

o.volyt'ic.um. L. n. *ovum* egg; N.L. adj. *lyticus -a -um* (from Gr. adj. *lutikos -ê -on*) able to loosen, able to dissolve; N.L. neut. adj. *ovolyticum* egg-damaging.

The characteristics are as described for the species and as listed in Tables 70 and 71, with the following additional features. Rods, $0.4 \times 2\text{--}20 \mu\text{m}$ that occasionally grow to filaments 70–100 μm long. Cell mass color is pale yellow. Microcysts are not formed. The cells exhibit gliding motility. Oxidase-positive. Congo red is not adsorbed. Acid is not produced from carbohydrates. Gelatin, tyrosine, DNA, and Tween 80 are hydrolyzed, but not agar, starch, carboxymethylcellulose, cellulose, chitin, or urea. Nitrate reductase is present. H₂S is not produced. Pigment is produced on tyrosine. Tryptone, Casamino acids, yeast extract, and sodium glutamate can serve as nitrogen sources in a medium based on artificial seawater; KNO₃ cannot be used. Ammonia is not produced. Arginine dihydrolase, lysine decarboxylase, and ornithine decarboxylase activities are negative. Citrate is not used as

a sole carbon source. Indole is not produced. Requires 50% seawater for growth; alternatively, media based on artificial seawater containing 1–3% NaCl may be used. No high-viscosity extracellular polysaccharide is produced in liquid cultures. Growth is not stimulated by halibut egg homogenate. Growth occurs at 4°C, but not at 30°C. The following enzymic activities are present (API ZYM system): acid phosphatase, alkaline phosphatase, esterase (C4), esterase lipase (C8), leucine arylamidase, valine arylamidase, and naphthol-AS-BI-phosphohydrolase. The following activities are absent: lipase (C4), cystine arylamidase, trypsin, chymotrypsin, α -galactosidase, β -galactosidase, β -glucuronidase, α -glucosidase, β -glucosidase, *N*-acetyl- β -glucosaminidase, α -mannosidase, and α -fucosidase.

Source: the type strain was isolated from the adherent epiflora of halibut eggs in Western Norway.

DNA G+C content (mol%): 30–32 (*T_m*).

Type strain: EKD002, ATCC 51887, CCUG 35199, CIP 106403, IAM 14318, LMG 13026, NBRC 15947, NCIMB 13127.

Sequence accession no. (16S rRNA gene): AB032506.

8. **Tenacibaculum skagerrakense** Frette, Jørgensen, Irming and Kroer 2004, 523^{VP}

ska.ger.rak.en'se. N.L. neut. adj. *skagerrakense* of or belonging to Skagerrak, Denmark, referring to the place of isolation.

The characteristics are as described for the species and as listed in Tables 70 and 71, with the following additional features. Rods, $0.5 \times 2\text{--}15 \mu\text{m}$, during exponential growth. Spherical cells occur often in the stationary phase. Gliding motility is not observed. Cell mass color is yellow. Colonies are circular and have a spreading edge. At least $1/4$ -strength seawater is required for growth. Growth occurs in up to 150% strength seawater. Growth occurs at 10–40°C, with optimum growth at 25–37°C. Resistant to temperatures up to 50°C. pH range, 6–9. Casein, collagen, hydroxyethylcellulose, starch, barley β -glucan, and pullulan are hydrolyzed. Growth occurs on sucrose, aspartate, and (weakly) L-leucine. Nitrate is reduced.

Source: the type strain was isolated from the <0.8 μm fraction of a seawater sample taken from Skagerrak, Denmark, at a depth of 30 m

DNA G+C content (mol%): 35.2 (HPLC).

Type strain: D30, ATCC BAA-458, DSM 14836.

Sequence accession no. (16S rRNA gene): AF469612.

Genus LIV. **Ulvibacter** Nedashkovskaya, Kim, Han, Rhee, Lysenko, Falsen, Frolova, Mikhailov and Bae 2004c, 121^{VP}

OLGA I. NEDASHKOVSKAYA AND SEUNG BUM KIM

Ul.vi.bac'ter. N.L. fem. n. *Ulva* generic name of the green alga *Ulva fenestrata*; N.L. masc. n. *bacter* from Gr. n. *bakterion* rod; N.L. masc. n. *Ulvibacter* rod isolated from *Ulva fenestrata*.

Thin rods, usually measuring $0.4\text{--}0.5 \times 2.5\text{--}7.3 \mu\text{m}$. **No gliding motility occurs.** Produce non-diffusible yellow–orange pigments. **Flexirubin pigments are produced.** **Chemo-organotrophs.** **Strictly aerobic.** Positive for oxidase, catalase, and alkaline phosphatase. Gelatin, Tweens 20 and 40, and DNA are hydrolyzed, but agar, alginate, casein, starch, chitin, and cellulose (carboxymethylcellulose and filter paper) are not

hydrolyzed. Carbohydrates are not oxidized or utilized. Growth does not occur without seawater or Na⁺. **The major respiratory quinone is MK-6.** **Marine**, isolated from coastal seaweeds.

DNA G+C content (mol%): 36–38.

Type species: **Ulvibacter litoralis** Nedashkovskaya, Kim, Han, Rhee, Lysenko, Falsen, Frolova, Mikhailov and Bae 2004c, 121^{VP}.

Further descriptive information

Phylogenetic analysis of almost-complete 16S rRNA gene sequences indicate that the genus *Ulvibacter* forms a cluster that includes members of the family *Flavobacteriaceae* such as *Cellulophaga*, *Arenibacter*, *Zobellia*, *Muricauda*, *Aequorivita*, *Vitellibacter*, and *Leeuwenhoekiella marinoflava* (Nedashkovskaya et al., 2004c). The closest relatives of *Ulvibacter* are *Cellulophaga* and *Leeuwenhoekiella*.

The predominant cellular fatty acids are the straight-chain unsaturated and branched-chain unsaturated fatty acids C_{15:0} iso, C_{15:1} iso, C_{16:0} iso, C_{16:0} iso 3-OH, and C_{17:0} iso 3-OH.

On marine agar 2216 (Difco), ulvibacters form regular, round, convex, smooth, shiny, yellow–orange colonies with entire edges and diameters of 2–4 mm after 48 h at 28°C.

Ulvibacter strains grow on media containing 0.5% peptone and 0.1–0.2% yeast extract (Difco), prepared with natural or artificial seawater or supplemented with 2–3% NaCl. Good growth is observed on marine agar 2216. Growth occurs at 4–36°C (optimum, 21–23°C) and with 1–6% NaCl.

Strains of *Ulvibacter* are susceptible to carbenicillin, lincomycin, oleandomycin, and tetracycline, and resistant to ampicillins, gentamicin, kanamycin, neomycin, polymyxin B, and streptomycin.

The ulvibacters are inhabitants of coastal marine environments. Strains have been isolated from seaweeds collected in the temperate latitudes.

Enrichment and isolation procedures

Strains of *Ulvibacter* have been isolated from seaweeds by direct plating on marine agar. Natural or artificial seawater is suitable for their cultivation. All isolated strains have been grown on media containing 0.5% peptone and 0.1–0.2% yeast extract (Difco). Growth occurs at 4–36°C (optimum, 21–23°C) and with 1–6% NaCl. The organisms may remain viable for several weeks on marine agar or other rich medium based on natural or artificial seawater. They have survived storage at –80°C for at least 5 years.

Differentiation of the genus *Ulvibacter* from other genera

Phenotypic analysis indicates that *Ulvibacter* strains can be clearly differentiated from those of its closest relatives, *Cellulophaga* and *Leeuwenhoekiella*, by production of flexirubin-type pigments and by an inability to oxidize carbohydrates and hydrolyze starch (Johansen et al., 1999; Nedashkovskaya et al., 2004c, e, 2005i). Moreover, the absence of agarase helps to separate *Ulvibacter* from *Cellulophaga*, and the NaCl requirement differentiates the ulvibacters from *Leeuwenhoekiella*.

List of species of the genus *Ulvibacter*

1. *Ulvibacter litoralis* Nedashkovskaya, Kim, Han, Rhee, Lysenko, Falsen, Frolova, Mikhailov and Bae 2004c, 121^{VP}

li.to.ra'lis. L. masc. adj. *litoralis* of or belonging to the sea-shore.

Rod-shaped cells 0.4–0.5 × 2.5–7.3 μm. On marine agar, colonies are 2–4 mm in diameter, circular, convex, shiny with entire edges, viscous, and yellow–orange in color. Growth is observed at 4–36°C (optimum, 21–23°C). Growth occurs at 1–6% NaCl. Gelatin, Tweens 20 and 40, and DNA are hydrolyzed. Does not hydrolyze agar, casein, alginate, starch, Tween 80, cellulose (carboxymethylcellulose and filter paper), or chitin. No acid is produced from cellobiose, L-fucose,

D-galactose, melibiose, raffinose, L-rhamnose, DL-xylose, adonitol, dulcitol, or glycerol. Does not utilize L-arabinose, D-glucose, D-lactose, D-mannose, maltose, sucrose, mannitol, inositol, sorbitol, malonate, citrate, N-acetylglucosamine, gluconate, caprate, adipate, malate, or phenylacetate. Nitrate is reduced. Indole, H₂S, and acetoin (Voges–Proskauer reaction) are not produced.

Source: two strains were isolated from the green alga *Ulva fenestrata* collected in Troitsa Bay, Sea of Japan.

DNA G+C content (mol %): 36–38 (T_m).

Type strain: KMM 3912, KCTC 12104, CCUG 47093.

Sequence accession no. (16S rRNA gene): AY243096.

Genus LV. *Vitellibacter* Nedashkovskaya, Suzuki, Vysotskii and Mikhailov 2003c, 1285^{VP}

OLGA I. NEDASHKOVSKAYA, MAKOTO SUZUKI AND VALERY V. MIKHAILOV

Vi.tel.li.bac'ter. L. n. *vitellus* egg yolk; N.L. masc. n. *bacter* rod; N.L. masc. n. *Vitellibacter* egg-yolk-colored rod.

Thin rods, usually measuring 0.3–0.5 × 3–10 μm. **No gliding motility**. Produce nondiffusible, bright orange pigments. Flexirubin-type pigments are formed. **Chemo-organotrophs. Strictly aerobic**. Positive for oxidase, catalase, and alkaline phosphatase. Gelatin, casein, DNA, and Tweens 20 and 40 are hydrolyzed, but agar, alginate, starch, urea, chitin, and cellulose (carboxymethylcellulose and filter paper) are not attacked. **Marine**, from coastal habitats. Growth does not occur without seawater or Na⁺. **The major respiratory quinone is MK-6. The main cellular fatty acids** are branched-chain saturated fatty acids C_{15:0} iso and C_{15:0} anteiso.

DNA G+C content (mol %): 41–42.

Type species: Vitellibacter vladivostokensis Nedashkovskaya, Suzuki, Vysotskii and Mikhailov 2003c, 1285^{VP}.

Further descriptive information

According to phylogenetic analysis based on 16S rRNA gene sequences, members of the genus *Vitellibacter* form a coherent cluster with those of the genus *Aequorivita* with sequence similarities of 92.9–93.6%. 16S rRNA gene sequence similarities of *Vitellibacter vladivostokensis* KMM 3516^T with other closely related members of the family *Flavobacteriaceae*, including members of the genera *Ulvibacter*, *Leeuwenhoekiella*, *Robiginitalea*, *Arenibacter*, *Zobellia*, *Muricauda*, and *Maribacter*, are less than 90.5%.

Dominant fatty acids of the genus *Vitellibacter* are branched-chain saturated fatty acids C_{15:0} iso and C_{15:0} anteiso. The use of fatty acid composition to differentiate the genus *Vitellibacter* from other members of the family *Flavobacteriaceae* has been discussed by Nedashkovskaya et al. (2003c).

On marine agar 2216 (Difco), vitellibacters form regular, round, convex, smooth, nontransparent, bright orange colonies with entire edges and diameters of 2–4 mm after 48 h at 28°C.

Strains have been grown on media containing 0.5% peptone and 0.1–0.2% yeast extract (Difco), prepared with natural or artificial seawater or supplemented by 2–3% NaCl. Good growth is observed on marine agar 2216 (Difco). Growth occurs at 4–43°C (optimum, 28°C) and with 1–6% NaCl.

The single available strain of the genus *Vitellibacter* is susceptible to carbenicillin, lincomycin, and oleandomycin and resistant to ampicillins, gentamicin, kanamycin, neomycin, polymyxin B, streptomycin, and tetracycline.

Vitellibacter vladivostokensis inhabits coastal marine environments. It was isolated from the edible holothurian *Apostichopus japonicus* collected in the temperate latitudes.

Enrichment and isolation procedures

Vitellibacter vladivostokensis was isolated from *Apostichopus japonicus* by direct plating on marine agar. Natural or artificial seawater is suitable for its cultivation. Vitellibacters may remain viable on marine agar or other rich media based on natural or artificial seawater for several weeks. They have survived storage at –80°C for at least 5 years.

Differentiation of the genus *Vitellibacter* from other genera

Vitellibacter can be differentiated from its closest relative, *Aequorivita*, by its ability to produce flexirubin-type pigments, grow at 43°C, and hydrolyze DNA (Bowman and Nichols, 2002; Nedashkovskaya et al., 2003c).

List of species of the genus *Vitellibacter*

1. *Vitellibacter vladivostokensis* Nedashkovskaya, Suzuki, Vysotskii and Mikhailov 2003c, 1285^{VP}

vla.di.vo.sto.ken'sis. N.L. adj. *vladivostokensis* pertaining to Vladivostok, a city in Asian Russia, where the organism was first isolated.

Cells are 0.3–0.5 × 3–10 µm. Flexirubin-type pigments are produced. Gelatin, casein, DNA, and Tweens 20 and 40 are hydrolyzed, but not agar, starch, alginate, urea, or Tweens 60 and 80. No acid is formed from L-arabinose, cellobiose, L-fucose, D-galactose, D-glucose, D-lactose, maltose, melibiose, raffinose, L-rhamnose, L-sorbose, sucrose, DL-xylose, adonitol, dulcitol, glycerol, inositol, mannitol, sorbitol, N-acetylglu-

cosamine, or citrate. Glycerol, N-acetylglucosamine, acetate, citrate, malonate, tartrate, and alanine are utilized, but L-arabinose, D-glucose, D-lactose, D-mannose, sucrose, inositol, mannitol, and sorbitol are not utilized. Nitrate is not reduced to nitrite. H₂S and indole are not produced. The predominant fatty acids are C_{15:0} iso (68.8%) and C_{15:0} anteiso (8.4%).

Source: the single available strain was isolated from the holothurian *Apostichopus japonicus* collected in Troitsa Bay, Gulf of Peter the Great, Sea of Japan.

DNA G+C content (mol%): 41.3 (T_m).

Type strain: KMM 3516, IFO 16718.

Sequence accession no. (16S rRNA gene): AB071382.

Genus LVI. *Wautersiella* Kämpfer, Avesani, Janssens, Charlier, De Baere and Vaneechoutte 2006, 2328^{VP}

PETER KÄMPFER

Wau.ter.si.el'la. N.L. fem. dim. n. *Wautersiella* named after Georges Wauters, a Belgian microbiologist, who first recognized this group of organisms as a separate entity.

Rods, 0.5–1.0 × 2.0–3.0 µm, with rounded ends. **Nonmotile**. Gram-stain-negative. **Aerobic**, having a strictly respiratory type of metabolism with oxygen as the terminal electron acceptor. **Oxidase- and catalase-positive**. Colonies on blood agar at 37°C are circular, entire, slightly convex, smooth, glistening, and pale beige. Some strains display yellow-pigmented colonies. The major cellular fatty acids are C_{15:0} iso and summed feature 4 (C_{15:0} iso 2-OH and/or C_{16:1} ω7*t*). The hydroxy acids include the hydroxylated fatty acids C_{15:0} iso 3-OH and C_{17:0} iso 3-OH. Isolated from clinical specimens.

DNA G+C content (mol%): 33.8–34.4.

Type species: *Wautersiella falsenii* Kämpfer, Avesani, Janssens, Charlier, De Baere and Vaneechoutte 2006, 2328^{VP}.

Further descriptive information

Wautersiella falsenii is described as a Gram-stain-negative nonfermenting species with phenotypic characters resembling those

of members of the genera *Empedobacter* and *Weeksella*. A total of 26 isolates were collected between 1980 and 2004 by at least ten different Belgian clinical laboratories, originating from various human clinical samples including blood, wounds, pus, respiratory tract, ear discharge, vaginal swab, and pleural fluid.

Growth occurs on blood agar, nutrient agar (Oxoid), tryptone soy agar (Oxoid), trypticase soy broth (BBL) supplemented with 1.5% agar (BBL), and R2A agar (Oxoid) at 20–37°C.

Differentiation of the genus *Wautersiella* from related genera

Tables 72 and 73 list the main differential characteristics of the genera belonging to this rRNA group.

Taxonomic comments

16S rRNA gene sequence analyses of the type strain of *Wautersiella falsenii* clearly place the genus in the family *Flavobacteri-*

TABLE 72. Differential biochemical characteristics of *Wautersiella falsenii* genomovars 1 and 2, *Empedobacter brevis*, and *Weeksella virosa*^{a,b}

List of species of the genus *Wautersiella*

1. *Wautersiella falsenii* Kämpfer, Avesani, Janssens, Charlier, De Baere and Vanechoutte 2006, 2328^{VP}

fal.sen'i.i. N.L. gen. n. *falsenii* of Falsen, in honor of the contemporary Norwegian microbiologist Enevold Falsen.

The characteristics are as described for the genus and as listed in Tables 72 and 73, with the following additional features. The main cellular fatty acids are C_{15:0} iso, C_{17:0} iso 3-OH, summed feature 4 (C_{15:0} iso 2-OH and/or C_{16:1} ω7*t*), and C_{15:0} iso 3-OH. Acid is produced from glucose and maltose oxidatively. Tests for the following are positive: urease, indole production, alkaline phosphatase, trypsin (benzyl-arginine arylamidase), and pyrrolidonylaminopeptidase. The following are negative: citrate utilization, nitrate reduction (nitrite reduction is variable), lysine decarboxylase, ornithine decarboxylase, and arginine dihydrolase. Gelatin hydrolysis is positive or weakly and delayed positive. Casein hydrolysis is negative or weakly and delayed positive.

The species contains two genomovars that differ in their 16S rRNA gene sequences and tDNA-PCR patterns. All

aceae. In phylogenetic trees, the highest similarities occur with strains of *Empedobacter* (94–95%) and *Weeksella virosa*. The 16S rRNA gene sequences of the *Wautersiella falsenii* isolates were similar to one another, but two clusters (genomovars) could be distinguished. The sequence similarities for the 14 isolates of genomovar 1 were 99.5–100% and the similarities for the 12 isolates of genomovar 2 were 99.4–100%. The similarity between both clusters was 98.3–99.5%. The presence of two clearly different groups was also shown by tRNA-intergenic length polymorphism (tDNA-PCR) analysis, which enabled differentiation of the species from all other species that have been studied thus far with this technique (Kämpfer et al., 2006).

genomovar 1 isolates ($n = 14$) display rapid hydrolysis of gelatin and esculin, are β-galactosidase (ONPG)-negative, and all except one alkalize galacturonate. All genomovar 2 isolates ($n = 12$) except one are negative for esculin hydrolysis and galacturonate alkanization and most isolates are β-galactosidase-positive and weakly positive for gelatin hydrolysis. The fatty acid profile is as described for the genus, with only minor differences between both genomovars (Table 73).

Source: the type strain of the species and of genomovar 1, NF 993^T, was isolated from a surgical wound. The reference strain of genomovar 2, NF 770 (=CCUG 51537=CIP 108860), was isolated from blood.

DNA G+C content (mol%): 33.8–34.4 (HPLC); values for the type strain of genomovar 1 and the reference strain of genomovar 2 were 33.8 ± 0.4 and 34.4 ± 0.2 mol%, respectively.

Type strain: NF 993, CCUG 51537, CIP 108861.

Sequence accession no. (16S rRNA gene): AM084341.

Genus LVII. *Weeksella* Holmes, Steigerwalt, Weaver and Brenner 1987, 179^{VP} (Effective publication: Holmes, Steigerwalt, Weaver and Brenner 1986b, 185.)

THE EDITORIAL BOARD

Weeksella. N.L. dim. ending *-ella*; N.L. fem. n. *Weeksella* named after Owen B. Weeks for his contributions to the taxonomy of the genus *Flavobacterium*.

Rods with parallel sides and rounded ends, typically 0.6 μm wide and 2–3 μm long. Intracellular granules of poly-β-hydroxybutyrate are absent. Endospores are not formed. Gram-stain-negative. **Nonmotile**. Do not glide or spread. **Aerobic**, having a strictly respiratory type of metabolism. **Grow at temperatures from 18 to 42°C. Growth on solid media is not pigmented. Catalase- and oxidase-positive. Urease-negative. Growth occurs on MacConkey agar and β-hydroxybutyrate agar.** Casein is digested. Agar is not digested. Chemo-organotrophic. **Nonsaccharolytic. Indole is produced.** Not found in the general environment, but

seem to be parasites, saprophytes, or commensals of the internal surfaces of man and other warm-blooded animals.

DNA G+C content (mol%): 35–38 (T_m).

Type species: *Weeksella virosa* Holmes, Steigerwalt, Weaver and Brenner 1987, 179^{VP} (Effective publication: Holmes, Steigerwalt, Weaver and Brenner 1986b, 185.).

Further descriptive information

Colonies are circular (diameter of 0.5–2 mm), low convex, smooth and shiny, with entire edges. On nutrient agar, colonies

are circular, entire, mucoid, and nonpigmented after incubation for 24 h. Nonhemolytic on 5% horse blood agar.

Susceptible to penicillin and to most antimicrobial agents (Pedersen et al., 1970; Von Graevenitz, 1981). Tween 20 is hydrolyzed. Gelatin is hydrolyzed (by both stab and plate methods).

The following tests all give a negative reaction: acidity in glucose O-F medium (alkaline reaction); growth in the presence of 0.0075% KCN; growth at 5°C; growth on cetrinide agar; reduction of nitrate, nitrite, and selenite; hydrolysis of esculin and

starch; citrate utilization (Simmons' medium); malonate utilization; gluconate oxidation; phenylalanine deaminase; urease (Christensen's medium); opalescence on lecithovitellin agar; extracellular DNase; indole production (as detected by Kovacs' reagent); H₂S production (lead acetate paper and triple-sugar iron agar methods); lipid inclusion granules (following growth on β-hydroxybutyrate); alkaline reaction on Christensen's citrate; arginine desamidase; arginine dihydrolase; lysine decarboxylase; ornithine decarboxylase; 3-ketolactose formation; ONPG hydrolysis; acid or gas from glucose in peptone-water medium; acid from 10% (w/v) glucose and lactose; and acid production (in ammonium salt medium under aerobic conditions) from glucose, adonitol, arabinose, cellobiose, dulcitol, ethanol, fructose, glycerol, inositol, lactose, maltose, mannitol, raffinose, rhamnose, salicin, sorbitol, sucrose, trehalose, and xylose.

Hydrolysis of the following substrates occurs (using API ZYM galleries): 2-naphthyl phosphate at pH 8.5 and at pH 5.4; naphthol-AS-BI-phosphodiamide; bis-(*p*-nitrophenyl)-phosphate; L-lysyl-β-naphthylamide; L-aspartyl-β-naphthylamide; L-alanyl-β-naphthylamide; DL-methionyl-β-naphthylamide; glycyl-glycyl-β-naphthylamide hydrobromide; glycyl-L-phenylalanyl-β-naphthylamide; glycyl-L-prolyl-β-naphthylamide; L-leucyl-glycyl-β-naphthylamide; α-L-glutamyl-β-naphthylamide; and *N*-carbobenzoxy-glycyl-glycyl-L-arginine-β-naphthylamide.

No hydrolysis of the following substrates occurs (using API ZYM galleries): 2-naphthyl butyrate; 2-naphthyl myristate; L-cystyl-2-naphthylamide; *N*-glutaryl-phenylalanine-2-naphthylamide; 6-bromo-2-naphthyl-α-D-galactopyranoside; 2-naphthyl-β-D-galactopyranoside; naphthol-AS-BI-β-D-glucuronic acid; 2-naphthyl-α-D-glucopyranoside; 6-bromo-2-naphthyl-β-D-glucopyranoside; 1-naphthyl-*N*-acetyl-β-D-glucosaminide; 6-bromo-2-naphthyl-α-D-mannopyranoside; 2-naphthyl-α-L-fucopyranoside; 6-bromo-2-naphthyl-β-D-xylopyranoside; *p*-nitrophenyl-α-D-xylopyranoside; *p*-nitrophenyl-β-D-fucopyranoside; *p*-nitrophenyl-β-L-fucopyranoside; *o*-nitrophenyl-*N*-acetyl-α-D-glucosaminide; *p*-nitrophenyl lactoside; *p*-nitrocatechol-sulfate; 4-methylumbelliferyl-arabinopyranoside; 4-methylumbelliferyl-cellobiopyranoside; L-hydroxyprolyl-β-naphthylamide; γ-L-glutamyl-β-naphthylamide; *N*-benzoyl-L-leucyl-naphthylamide; *N*-carbobenzoxy-L-arginine-4-methoxy-β-naphthylamide hydrochloride; and L-prolyl-β-naphthylamide hydrochloride.

The pathogenicity of *Weeksellia virosa* is not known. Most strains have been isolated from women (urine, cervix, vagina, Bartholin's gland cyst, blood, umbilical stump, and ear), but some have been isolated from the urethra, spinal fluid, and blood of men (Mardy and Holmes, 1988; Tatum et al., 1974).

Enrichment and isolation procedures

There is no specific medium for the selective isolation of *Weeksellia* strains. Growth occurs on nutrient agar and blood agar. The organism is best identified by amplifying and sequencing the 16S rRNA gene and comparing it with that of the type strain.

Differentiation of the genus *Weeksellia* from other genera

The following features differentiate members of the genus *Weeksellia* from those of the genus *Bergeyella*: ability to grow at 42°C, ability to grow on MacConkey agar and β-hydroxybutyrate agar, and negative urease activity.

Taxonomic comments

Phenotypic characterization by Holmes et al. (1986b) of 29 strains of aerobic Gram-stain-negative rods previously assigned to CDC group IIf (Tatum et al., 1974) indicated that the strains form a homogeneous species; it had been suggested previously by Holmes and Owen (1981) that they belong to a prospective new genus. In addition, ten of the strains chosen for DNA–DNA hybridization experiments yielded reassociation values of 96–100% (and, under stringent conditions, 77–100%) to strain NCTC 11634^T of group IIf, indicating that the strains belonged to a single genospecies. There was no significant DNA–DNA hybridization to any other species tested (including CDC group

IIf; see below). Holmes et al. (1986b) compared the phenotypic characteristics of group IIf to those of other genera of Gram-stain-negative nonfermenters that had similar DNA G+C contents to those of group IIf and they concluded that, based on both scientific grounds and practical considerations, the species should be placed in a new genus, *Weeksella*, as *Weeksella virosa*.

Holmes et al. (1986a) also placed the strains of another CDC group, group IIj, as a second species in the genus *Weeksella*, viz., *Weeksella zoohelcum*. However, rRNA gene sequence analysis later showed that the genus *Weeksella* was heterogeneous (Vandamme et al., 1994a) and *Weeksella zoohelcum* was placed in a new genus, *Bergeyella*, as *Bergeyella zoohelcum*. Thus, *Weeksella virosa* currently remains the only species in the genus *Weeksella*.

List of species of the genus *Weeksella*

1. ***Weeksella virosa*** Holmes, Steigerwalt, Weaver and Brenner 1987, 179^{VP} (Effective publication: Holmes, Steigerwalt, Weaver and Brenner 1986b, 185.)

vi.ro'sa. L. fem. adj. *virosa* slimy.

Characteristics are as described for the genus.

Source: most strains have been isolated from clinical specimens.

DNA G+C content (mol%): 35–38 (T_m).

Type strain: NCTC 11634, ATCC 43766, CCUG 30538, CIP 103040, IFO (now NBRC) 16016, LMG 12995.

Sequence accession no. (16S rRNA gene): M93152.

Genus LVIII. ***Winogradskyella*** Nedashkovskaya, Kim, Han, Snauwaert, Vancanneyt, Swings, Kim, Lysenko, Rohde, Frolova, Mikhailov and Bae 2005a, 51^{VP}

OLGA I. NEDASHKOVSKAYA, SEUNG BUM KIM AND VALERY V. MIKHAILOV

Wi.no.grad.sky.el'la. N.L. fem. n. *Winogradskyella* named after Sergey Winogradskyi, Russian soil microbiologist who made great contributions to the taxonomy of bacteria of the *Cytophaga–Flavobacterium–Bacteroides* phylum.

Rod-shaped cells, 0.4–0.6 × 1.0–1.3 μm, with rounded ends. **Motile by gliding**. Produce non-diffusible yellow carotenoid pigments. No flexirubin pigments are produced. Cells can form network-like structures. **Chemo-organotrophs. Strictly aerobic**. Oxidase-, catalase-, and alkaline phosphatase-positive. Arginine dihydrolase, lysine decarboxylase, ornithine decarboxylase, and β-galactosidase are not produced. Gelatin and Tween 40 are hydrolyzed, but casein, chitin, and urea are not attacked. Hydrolysis of agar, gelatin, starch, DNA, and Tweens 20 and 80 varies among species. Indole and H₂S are not produced. Nitrate is not reduced. **Marine**, from coastal habitats. Require seawater or Na⁺ for growth. **The major respiratory quinone is MK-6. The main polar lipid is phosphatidylethanolamine.**

DNA G+C content (mol%): 32–37.

Type species: ***Winogradskyella thalassocola*** Nedashkovskaya, Kim, Han, Snauwaert, Vancanneyt, Swings, Kim, Lysenko, Rohde, Frolova, Mikhailov and Bae 2005a, 52^{VP}.

Further descriptive information

Phylogenetic analysis based on 16S rRNA gene sequences indicates that the genus *Winogradskyella* forms a cluster with members of the family *Flavobacteriaceae* such as *Psychroserpens*, *Olleya*, *Lacimutrix*, *Algibacter*, and *Gaetbulibacter*. *Psychroserpens burtonensis* was found to be the nearest neighbor (Figure 53). These relationships with *Winogradskyella* are supported by a high bootstrap value and also by different tree-making algorithms. The

low sequence similarity values between strains of *Winogradskyella* and other *Cytophaga*-like bacteria described to date are 85.6–92.1%. *Winogradskyella* species possess 16S rRNA gene sequence similarities to one another that range from 94.7 to 97.1%. The DNA–DNA relatedness values between the type strains of *Winogradskyella* species are 34–45%.

The predominant cellular fatty acids are C_{15:1} iso, C_{15:0} iso, C_{16:0} iso 3-OH, C_{17:0} iso 3-OH, and summed feature 3 (C_{15:0} iso 2-OH and/or C_{16:1} ω7c).

Cells of *Winogradskyella* can form network-like structures or aggregates (Figure 54). On marine agar 2216 (Difco), *Winogradskyella* species form regular, round, shiny, yellow colonies with diameters of 2–4 mm after 48 h at 28°C. The colonies are usually slightly sunk in the agar.

All isolated strains have been grown on media containing 0.5% peptone and 0.1–0.2% yeast extract (Difco), prepared with natural or artificial seawater or supplemented with 2–3% NaCl. Growth occurs in 1–8% NaCl, at pH 6.0–10.0, and at 4–44°C. The optimal growth temperature is 21–25°C.

No acid is formed from L-arabinose, D-galactose, D-lactose, melibiose, L-rhamnose, DL-xylose, adonitol, dulcitol, inositol, sorbitol, or citrate. Does not utilize L-arabinose, D-lactose, D-sucrose, inositol, mannitol, sorbitol, malonate, or citrate.

Strains of the genus *Winogradskyella* are susceptible to chloramphenicol and resistant to kanamycin.

Winogradskyella species inhabit coastal marine environments. They have been isolated from seaweeds and sponges.

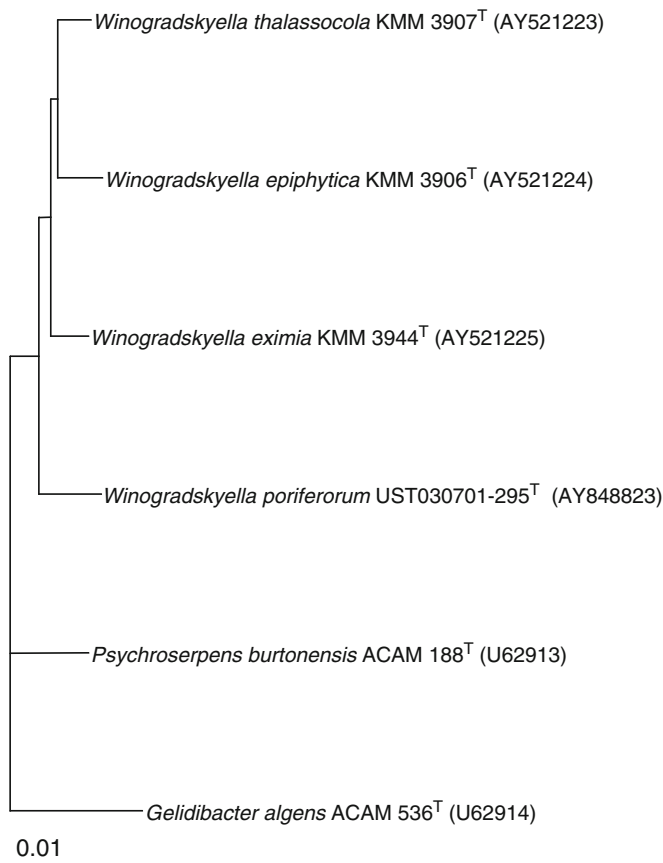

FIGURE 53. Phylogenetic tree based on the 16S rRNA gene sequences of the type strains of the genus *Winogradskyella* and representative members of the family *Flavobacteriaceae*. Bar = 0.01 substitutions per nucleotide position.

List of species of the genus *Winogradskyella*

1. ***Winogradskyella thalassocola*** Nedashkovskaya, Kim, Han, Snauwaert, Vancanneyt, Swings, Kim, Lysenko, Rohde, Frol-ova, Mikhailov and Bae 2005a, 52^{VP}

tha.las.so.co'la. Gr. n. *thalassa* the sea; L. suffix *-cola* dweller; N.L. n. *thalassocola* a sea dweller

Cells are 0.4–0.6 × 1.0–1.3 μm and can form network-like structures or aggregates. On marine agar, colonies are 2–4 mm in diameter, circular, shiny with entire edges, yellow, and viscous. Growth occurs at 4–33°C. Optimal temperature for growth is 21–23°C. Growth is observed in 1–8% NaCl. No acid is produced from L-arabinose, D-galactose, D-lactose, melibiose, L-rhamnose, DL-xylose, citrate, adonitol, dulcitol, or inositol. L-Arabinose, D-lactose, sucrose, mannitol, inositol, sorbitol, malonate, and citrate are not utilized. β-Galactosidase activity is negative. Susceptible to carbenicillin and lincomycin; resistant to gentamicin, neomycin, polymyxin B, and streptomycin.

Source: isolated from brown alga *Chorda filum*, collected in Troitsa Bay in the Gulf of Peter the Great, Sea of Japan.

DNA G+C content (mol%): 34.6 (T_m).

Type strain: KMM 3907, KCTC 12221, LMG 22492, DSM 15363.

Sequence accession no. (16S rRNA gene): AY521223.

Enrichment and isolation procedures

Winogradskyella species were isolated from samples of seaweeds and sponges by direct plating on marine agar (Difco) and modified marine agar prepared with filtered natural seawater (Lau et al., 2005a; Nedashkovskaya et al., 2005a). Either natural or artificial seawater is suitable for their cultivation. All isolated strains have been grown on media containing 0.5% peptone and 0.1–0.2% yeast extract (Difco). *Winogradskyella* strains may remain viable on marine agar or other rich media based on natural or artificial seawater for several weeks. They have survived storage at –80°C for at least 5 years.

Differentiation of the genus *Winogradskyella* from other genera

Members of the genus *Winogradskyella* can be differentiated from those of its closest relative, *Psychroserpens*, by the presence of gliding motility, oxidase activity, and higher DNA G+C content (32–37 mol% vs 27–29 mol%) (Bowman et al., 1997; Lau et al., 2005a; Nedashkovskaya et al., 2005a). The latter feature clearly distinguishes *Winogradskyella* from another relative, *Olleya*, which has a DNA G+C content of 49 mol% (Mancuso Nichols et al., 2005). *Winogradskyella* species are able to move by means of gliding and cannot grow with 12% NaCl, in contrast to members of the genus *Lacinutrix* (Bowman and Nichols, 2005). An inability to ferment D-glucose differentiates *Winogradskyella* strains from those of the genera *Algibacter* and *Gaetbulibacter* (Jung et al., 2005; Nedashkovskaya et al., 2004d). Moreover, *Winogradskyella* strains may be separated from those of *Gaetbulibacter* by the presence of gliding motility and by the absence of nitrate reduction.

Differentiation of the species of the genus *Winogradskyella*

Differential features of *Winogradskyella* species are given in Table 74.

2. ***Winogradskyella epiphytica*** Nedashkovskaya, Kim, Han, Snauwaert, Vancanneyt, Swings, Kim, Lysenko, Rohde, Frol-ova, Mikhailov and Bae 2005a, 53^{VP}

e.pi.phy'ti.ca. N.L. fem. adj. *epiphytica* (derived from Gr. *epi* on and *phyt*-relating to plants) onto plant, pertaining to the original isolation from the surface of the algal fronds.

Cells are 0.4–0.6 × 1.0–1.3 μm and can form network-like structures or aggregates. On marine agar, colonies are 2–4 mm in diameter, circular, shiny with entire edges, yellow, and viscous. Growth occurs at 4–37°C (optimum, 23–25°C). Growth occurs in 1–8% NaCl. No acid is formed from L-arabinose, D-galactose, D-lactose, melibiose, L-rhamnose, DL-xylose, citrate, adonitol, dulcitol, or inositol. Does not utilize L-arabinose, D-lactose, sucrose, mannitol, inositol, sorbitol, malonate, or citrate. β-Galactosidase activity is negative. Nitrate is not reduced. Susceptible to carbenicillin and lincomycin. Resistant to gentamicin, neomycin, and polymyxin B.

Source: isolated from the green alga *Acrosiphonia sonderi*, collected in Troitsa Bay in the Gulf of Peter the Great, Sea of Japan.

DNA G+C content (mol%): 35.2 (T_m).

Type strain: KMM 3906, KCTC 12220, LMG 22491, CCUG 47091.

Sequence accession no. (16S rRNA gene): AY521224.

Sequence accession no. (16S rRNA gene): AY521225.

4. *Winogradskyella poriferorum* Lau, Tsoi, Li, Plakhotnikova, Dobretsov, Lau, Wu, Wong, Pawlik and Qian 2005a, 1591^{VP}
por.if.er.or'um. N.L. gen. pl. n. *poriferorum* of the phylum *Porifera*, referring to the isolation source sponge, of the phylum *Porifera*.

On marine agar, colonies are 2–4 mm in diameter, convex, smooth, and circular with entire edges. Growth is observed at 12–44°C, at pH 6.0–10.0, and in 1–4% NaCl. Esculin is utilized as a sole carbon source, but none of the other substrates tested in the API 50CH system are utilized. In the API galleries (bioMérieux), the following enzyme activities are exhibited: α-chymotrypsin, cystine arylamidase, leucine arylamidase, valine arylamidase, esterase (C4), esterase

lipase (C8), lipase (C14), acid phosphatase, naphthol-AS-BI-phosphohydrolase, and trypsin. Tryptophan deaminase, *N*-acetyl- β -glucosaminidase, lysine decarboxylase, ornithine decarboxylase, arginine dihydrolase, α - and β -galactosidases, α - and β -glucosidases, β -glucuronidase, α -fucosidase, α -mannosidase, and urease activities are not observed.

Sequence accession no. (16S rRNA gene): AY848823.

Genus LIX. *Yeosuana* Kwon, Lee, Jung, Kang and Kim 2006a, 731^{VP}

THE EDITORIAL BOARD

Yeo.su.a'na. N.L. fem. n. *Yeosuana* named after Yeosu City, where the type strain of the type species was isolated.

Rods, 0.2–0.3 × 0.7–1.7 μ m. Nonmotile. **No gliding motility.** Gram-stain-negative. Colonies are yellowish-brown due to carotenoid pigments. Flexirubin type pigments are not produced. Temperature range for growth, 23–39°C; optimum, 33–46°C. **Requires 0.5–4.0% NaCl; optimum, 2.0%. Growth does not occur without supplementation with either CaCl₂ or MgCl₂, even in the presence of NaCl.** Yeast extract is not required for growth. **Aerobic. Oxidase-negative.** Catalase is weakly positive. **Nitrate is not reduced. Indole and H₂S are not produced. Gelatin is hydrolyzed, but not urea, agar, casein, or starch. Acid is not produced from carbohydrates.** Major cellular fatty acids are straight-chain and branched-chain unsaturated fatty acids. Major respiratory quinones are MK-5 and MK-6.

DNA G+C content (mol%): 51.4 (HPLC).

Type species: *Yeosuana aromatorans* Kwon, Lee, Jung, Kang and Kim 2006a, 731^{VP}.

Enrichment and isolation procedures

One gram of estuarine sediment (from Gwangyang Bay, Yeosu City, Republic of Korea) was enriched for 2 years at 10–30°C in MM2 medium* supplemented with 1 mg/l each of pyrene and benzo(a)pyrene (BaP). After serial dilution, a sample of the slurry was plated onto marine agar 2216 (MA). The type strain of *Yeosuana aromatorans* was one of isolates able to grow on MA.

Differentiation of the genus *Yeosuana* from related genera

The DNA G+C content of *Yeosuana* (51.4 mol%) is much higher than that of members of the genera *Algibacter*, *Bizionia*, *Formosa*, *Gaetbulibacter*, *Gelidibacter*, *Subsaxibacter*, and *Subsaximicrobium*, whose values range from 31 to 45 mol%; moreover, unlike these genera, *Yeosuana* requires sea salts (not merely NaCl) for growth. *Yeosuana* differs from members of the genera *Gelidibacter*, *Algibacter*, *Formosa*, and *Gaetbulibacter* by its failure to form acid from carbohydrates. Gliding motility is present in *Algibacter*, *Formosa*, *Gaetbulibacter*, *Gelidibacter*, *Subsaxibacter*, and *Subsaximicrobium*, but does not occur in *Yeosuana*. *Yeosuana* does not hydrolyze agar (unlike *Algibacter* species), casein (unlike *Bizionia* and *Subsaximicrobium* species), or starch (unlike *Bizionia*, *Formosa*, *Gaetbulibacter*, and *Subsaximicrobium* species). It differs from *Formosa* and *Gaetbulibacter* species by its failure to reduce nitrate.

Taxonomic comments

Kwon et al. (2006a) reported that, by 16S rRNA gene sequence analysis, the closest neighbors of *Yeosuana aromatorans* are *Gelidibacter algens* (94.7% gene sequence similarity), *Gaetbulibacter saemankumensis* (94.5%), and *Gelidibacter gilvus* (94.4%). *Yeosuana* also has high sequence similarities to members of the genera *Subsaximicrobium* (93.3%), *Subsaxibacter* (93.9%), *Gaetbulibacter* (94.5%), *Algibacter* (94.2%), *Bizionia* (93.6–94.3%), and *Formosa* (93.2%).

List of species of the genus *Yeosuana*

1. *Yeosuana aromatorans* Kwon, Lee, Jung, Kang and Kim 2006a, 731^{VP}

a.ro.ma.ti.vo'rans. L. n. *aroma -atis* spice; L. part. adj. *vorans* devouring; N.L. part. adj. *aromatorans* degrading aromatic compounds.

Characteristics are as described for the genus, with the following additional features. Forms yellowish-brown colonies, 1.0–1.5 mm in diameter on MA. β -Glucosidase, β -galactosidase, and protease activities are present. The following compounds are utilized: α -cyclodextrin, dextrin, cellobiose,

D-fructose, gentiobiose, α -D-glucose, α -D-lactose, maltose, D-mannose, sucrose, methyl pyruvate, α -ketobutyric acid, L-proline, glucose 1-phosphate, and glucose 6-phosphate. The following are utilized weakly: D-galactose, α -ketoglutaric acid, L-alanine, L-alanyl glycine, L-asparagine, L-glutamic acid, glycyl L-aspartic acid, glycyl L-glutamic acid, hydroxy-L-proline, uridine, and L-threonine. Polycyclic aromatic hydrocarbons are degraded, including pyrene and BaP. The predominant fatty acids are C_{15:0} iso (21.7%), C_{15:0} anteiso (14.9%), C_{15:1} ω 10c iso (14.8%), and C_{16:1} (10.9%).

Source: the type strain was isolated from estuarine sediment of Gwangyang Bay, Yeosu City, Korea.

DNA G+C content (mol%): 51.4 (HPLC).

Type strain: GW1-1, JCM 12862, KCCM 42019.

Sequence accession no. (16S rRNA gene): AY682382.

*MM2 contains 18 mM (NH₄)₂SO₄, 1 μ M FeSO₄·7H₂O, and 100 μ l of 1 M KH₂PO₄/Na₂HPO₄ buffer solution in 1 l aged seawater, pH 7.2.

Genus LX. *Zhouia* Liu, Wang, Dai, Liu and Liu 2006, 2826^{VP}

THE EDITORIAL BOARD

Zhou'i.a. N.L. fem. n. *Zhouia* named after Pei-Jin Zhou, a pioneer of environmental microbiology in China.

Rods, 0.25–0.3 × 1.3–3.0 µm. Nonmotile. **No gliding motility.** Nonsporeforming. Gram-stain-negative. **Strictly aerobic. NaCl is required for growth. Growth occurs at 42°C.** Colonies are yellow to pale yellow. Catalase-positive. Oxidase-negative. Urease-negative. Flexirubin pigments are not produced. Nitrate is not reduced. Starch and gelatin are hydrolyzed, but not agar, casein, or Tweens 40 and 80. **Acid is produced from cellobiose, but not glucose.** Glucose and sucrose are utilized. The menaquinone is MK-6. The major fatty acids are C_{15:1G} iso, C_{15:0} iso, summed feature 4 (C_{15:0} iso 2-OH and/or C_{16:1} ω7c/t), and C_{15:0}.

DNA G+C content (mol%): 34.5.

Type species: *Zhouia amylolytica* Liu, Wang, Dai, Liu and Liu 2006, 2827^{VP}.

Enrichment and isolation procedures

Strains were isolated by spreading dilutions of marine sediment samples onto marine agar 2216 (MA; Difco), with subsequent incubation at 30°C. Colonies on MA are circular, slightly raised,

smooth, yellow to pale yellow, and 2.0–3.0 mm in diameter after incubation for 2 d.

Differentiation of the genus *Zhouia* from related genera

Zhouia amylolytica, the only species currently recognized, can be differentiated from members of the genus *Coenonia* by its requirement for NaCl, hydrolysis of gelatin, inability to hydrolyze Tween 40, production of acid from cellobiose, and its lack of C_{13:0} as a major cellular fatty acid. It differs from other members of the *Flavobacteriaceae* such as *Aquimarina*, *Cellulophaga*, *Gaetbulimicrobium*, *Psychroflexus*, and *Winogradskyella* by the presence of summed feature 4 (C_{15:0} iso 2-OH and/or C_{16:1} ω7c/t) as a characteristic fatty acid.

Taxonomic comments

Based on 16S rRNA gene sequence analysis, the nearest neighbor of the type strain of *Zhouia amylolytica* is *Coenonia anatina* LMG 14382^T, with 90.2% similarity.

List of species of the genus *Zhouia*1. *Zhouia amylolytica* Liu, Wang, Dai, Liu and Liu 2006, 2827^{VP}

a.my.lo.ly'ti.ca. Gr. n. *amylos* starch; N.L. adj. *lyticus* from Gr. adj. *lutikos* dissolving; N.L. fem. adj. *amylolytica* dissolving starch, pertaining to the ability of the bacterium to hydrolyze starch.

The description is as given for genus, with the following additional features. Growth occurs at 7–42°C, with optimum growth at 30°C; growth does not occur at 4 or 45°C. Temperature range for growth, 6.0–8.0; optimum, 7.2–7.4; no growth at pH 5.8 or 8.2. NaCl is required for growth; optimum concentration, 4.5–5%; no growth occurs in >9% NaCl. The following compounds are utilized: acetic acid, *N*-acetyl-D-galactosamine, *N*-acetyl-D-glucosamine, L-alanine, L-alanyl glycine, L-asparagine, L-aspartic acid, cellobiose, α-cyclodextrin, dextrin, D-fructose, L-fucose, D-galactonolactone, D-galactose, gentiobiose, D-glucose 1-phosphate, D-glucose 6-phosphate, L-glutamic acid, glycogen, glycyl-L-aspartic acid, glycyl-L-glutamic acid, inosine, α-ketobutyric acid, α-ketoglutaric acid, α-ketovaleric acid, DL-lactic acid, α-D-lactose, L-leucine, maltose, melibiose, methyl-β-D-glucoside, L-ornithine, L-proline, propionic acid, D-psicose, raffinose, L-rhamnose, D-sorbitol,

succinic acid monomethyl ester, L-threonine, trehalose, turanose, urocanic acid, and uridine. The following compounds are not utilized: *cis*-aconitic acid, adonitol, L-alaninamide, D-alanine, γ-aminobutyric acid, 2-aminoethanol, L-arabinose, D-arabitol, bromosuccinic acid, 2,3-butanediol, DL-carnitine, citric acid, i-erythritol, formic acid, D-galactonic acid, D-gluconic acid, D-glucosaminic acid, glucuronamide, D-glucuronic acid, glycerol, DL-α-glycerol phosphate, L-histidine, α-hydroxybutyric acid, β-hydroxybutyric acid, γ-hydroxybutyric acid, *myo*-inositol, itaconic acid, malonic acid, D-mannitol, methyl pyruvate, L-phenylalanine, phenylethylamine, putrescine, L-pyroglutamic acid, quinic acid, D-saccharic acid, sebacic acid, D-serine, L-serine, succinamic acid, succinic acid, thymidine, Tweens 40 and 80, and xylitol. The major fatty acids are C_{15:1G} iso (24.2%), C_{15:0} iso (14.9%), summed feature 4 (C_{15:0} iso 2-OH and/or C_{16:1} ω7c/t; 10.7%), and C_{15:0} (9.4%).

Source: the type strain was isolated from sediment from the South China Sea, China.

DNA G+C content (mol%): 34.5 (T_m).

Type strain: HN-171, CGMCC 1.6114, JCM 14016.

Sequence accession no. (16S rRNA gene): DQ423479.

Genus LXI. *Zobellia* Barbeyron, L'Haridon, Corre, Kloareg and Potin 2001, 993^{VP}

OLGA I. NEDASHKOVSKAYA AND MAKOTO SUZUKI

Zo.bel'li.a. N.L. fem. n. *Zobellia* named after C.E. ZoBell, who isolated and characterized numerous marine bacteria, notably [*Cytophaga*] *uliginosa* in 1944, and for his general contribution to the taxonomy of marine bacteria.

Rod-shaped cells with rounded ends, 0.3–0.5 × 1.2–8.0 µm. **Motile by gliding.** Produce non-diffusible yellow–orange carotenoid pigments. Flexirubin-type pigments are produced. **Chemorganotrophs. Strictly aerobic. The major respiratory quinone**

is MK-6. The main polar lipid is phosphatidylethanolamine. Positive for oxidase, catalase, β-galactosidase, and alkaline phosphatase. Arginine dihydrolase, lysine decarboxylase, ornithine decarboxylase, and urease are not produced. H₂S, indole, and

acetoin are not produced. Agar and gelatin are hydrolyzed; hydrolysis of casein, gelatin, starch, alginate, chitin, DNA, and Tweens varies among species. **Marine**, isolated from coastal habitats. Require seawater or Na⁺ for growth.

DNA G+C content (mol%): 36–44 (T_m).

Type species: Zobellia galactanivorans (Barbeyron, Gerard, Potin, Henrissat and Kloareg 1998) corrig. Barbeyron, L'Haridon, Corre, Kloareg and Potin 2001, 994^{VP} (*Cytophaga drobachiensis* Barbeyron, Gerard, Potin, Henrissat and Kloareg 1998, 528).

Further descriptive information

Phylogenetic analysis based on 16S rRNA gene sequences indicates that the genus *Zobellia* forms a cluster with *Arenibacter*, *Maribacter*, *Muricauda*, and *Robiginitalea* (Figure 55). The closest relatives of *Zobellia* strains are members of the genus *Maribacter*, with similarities of 92.1–94.1%. 16S rRNA gene similarities between members of the genus *Zobellia* and other close neighbors range from 88.9 to 91%. 16S rRNA gene sequence similarities between the various *Zobellia* species are 96.7–99.3%.

Dominant cellular fatty acids are straight-chain unsaturated and branched-chain unsaturated fatty acids C_{15:1} iso, C_{15:0} iso, C_{17:0} iso 3-OH, and summed feature 3, comprising C_{15:0} iso 2-OH and/or C_{16:1} ω7c/t (see Table 75).

Differential phenotypic characteristics are given in Table 76. On marine agar 2216 (Difco), strains of *Zobellia* form regular, round, shiny colonies, usually with entire edges, which are sunk in the agar. Colonies are yellow–orange to dark red or dark orange with a diameter of 2–4 mm after 48 h at 28°C. The colonies usually spread rapidly on the surface of the agar.

All isolated strains have been grown on media containing 0.5% peptone and 0.1–0.2% yeast extract (Difco), either prepared with natural or artificial seawater, or supplemented with 2–3% NaCl. Growth is observed at 4–45°C (optimum, 21–35°C). Growth occurs in 1–10% NaCl (optimum, 2–3% NaCl). *Zobellia* grow between pH 5.8 and 9.4 (optimum of about 7.0).

Acid is produced from L-fucose, D-galactose, D-lactose, melibiose, and L-sorbose, but not from N-acetylglucosamine,

FIGURE 55. Phylogenetic tree showing relationship among the species of the genus *Zobellia*. The tree was generated by the neighbor-joining method (1987). Numbers at the nodes indicate bootstrap values (%) of 1000 replicates (only values $\geq 50\%$ are cited). Bar = genetic distance of 0.01 (K_{nuc}).

List of species of the genus *Zobellia*

- Zobellia galactanivorans*** (Barbeyron, Gerard, Potin, Henrissat and Kloareg 1998) corrig. Barbeyron, L'Haridon, Corre, Kloareg and Potin 2001, 994^{VP} (*Cytophaga drobachiensis* Barbeyron, Gerard, Potin, Henrissat and Kloareg 1998, 528)

ga.lac.ta.ni.vo'rans. N.L. n. *galactan* polygalactose; L. v. *vorare* to devour; N.L. fem. adj. *galactanivorans* galactan-devouring.

Cells are 0.3–0.4 × 3.0–8.0 μm. On marine agar, colonies are 2–4 mm in diameter, circular, shiny with entire or irregular edges, yellow–orange, and sunk into the agar;

citrate, adonitol, dulcitol, glycerol, or inositol. All species utilize L-arabinose, D-glucose, D-lactose, D-mannose, sucrose, and mannitol, but not inositol, sorbitol, malonate, or citrate.

Zobellia species are susceptible to carbenicillin, lincomycin, and oleandomycin. They are resistant to gentamicin, kanamycin, neomycin, and polymyxin B.

Zobellia species are common inhabitants of the marine environment. They have been isolated from seawater, sediments, and seaweeds in the temperate latitudes.

Enrichment and isolation procedures

Zobellia species were isolated by direct plating on marine agar or ZoBell agar (Nedashkovskaya et al., 2004f; ZoBell and Upham, 1944), except *Zobellia galactanivorans*, formerly [*Cytophaga*] *drobachiensis* (Barbeyron et al., 1998), which was isolated on a basal salts medium (Quatrano and Caldwell, 1978) supplemented with 2% (w/v) ι-carrageenan. Either natural or artificial seawater is suitable for their cultivation. All isolated strains have been grown on media containing 0.5% peptone and 0.1–0.2% yeast extract (Difco). Strains may remain viable on marine agar or other rich medium based on natural or artificial seawater for several weeks. They have survived storage at –80°C for at least 5 years.

Differentiation of the genus *Zobellia* from other genera

Zobellia strains differ from those of all their close relatives, i.e., members of the genera *Arenibacter*, *Maribacter*, *Muricauda* and *Robiginitalea*, by their production of flexirubin-type pigments (Bruns et al., 2001; Cho and Giovannoni, 2004; Nedashkovskaya et al., 2003b, 2004a, b, f, 2006g; Yoon et al., 2005b). Also, *Zobellia* strains can be differentiated from those of *Arenibacter*, *Muricauda*, and *Robiginitalea* by their ability to hydrolyze agar. Moreover, *Zobellia* strains liquefy gelatin, move by gliding, and reduce nitrate to nitrite, in contrast to strains of *Muricauda* and *Robiginitalea*.

Taxonomic comments

The genus *Zobellia* was created by Barbeyron et al. (2001) and contains Gram-stain-negative, aerobic, gliding, agarolytic, flexirubin-producing bacteria of marine origin. One of the species, *Zobellia uliginosa*, was isolated from beach sand in California and was originally classified as *Flavobacterium uliginosum* (ZoBell and Upham, 1944). Later, it was transferred to the genus *Cytophaga* as *Cytophaga uliginosa* (Reichenbach, 1989a), reclassified in the genus *Cellulophaga* as *Cellulophaga uliginosa* (Bowman, 2000) and finally assigned to the new genus *Zobellia* based on its higher DNA G+C content, its maximum growth temperature, the presence of flexirubin pigments, and its unique phylogenetic position (Barbeyron et al., 2001).

they spread very fast on agar plates. Growth occurs between 10 and 45°C (optimum, about 35°C) and in a salt concentration of 1.0–8% NaCl (optimum, 2%). The following substrates are utilized: N-acetylglucosamine, DL-glycerol phosphate, mannitol, L-rhamnose, sucrose, phosphate, and L-serine, but not adipate, caprate, gluconate, α-ketobutyric acid, 2-ketogluconate, D-lyxose, malate, phenylacetate, D-tagatose, L-threonine, or urocanic acid. Carrageenans (κ and ι) are decomposed.

Summed feature 3 ^b	14.5	15.5	14.9	14.3	9.9

^aData are taken from Nedashkovskaya et al. (2004f). Those fatty acids for which the mean amount for all taxa was less than 1% are not given; nd, not detected; tr, trace.

^bSummed feature 3 consists of one or more of the following fatty acids which could not be separated by the Microbial Identification system: C_{16:1} ω7c, C_{16:1} ω7t, and C_{15:0} iso 2-OH.

Source: the single strain was isolated from the red alga *Delesseria sanguinea*, collected in the English Channel, France.

DNA G+C content (mol%): 43.4 (*T_m*), 43.0 (HPLC).

Type strain: Dsjj, CIP 106680, DSM 12802.

Sequence accession no. (16S rRNA gene): AF208293.

Note: the original spelling *galactanovorans* (*sic*) has been corrected (Int. J. Syst. Evol. Microbiol. Notification that new names and new combinations have appeared in volume 51, part 3, of the IJSEM, 2001, 51: 1231–1233).

2. ***Zobellia amurskyensis*** Nedashkovskaya, Suzuki, Vancanneyt, Cleenwerck, Lysenko, Mikhailov and Swings 2004f, 1647^{VP} a.mur.sky.en'sis. N.L. fem. adj. *amurskyensis* of Amursky Bay, where the bacterium was isolated.

Cells are 0.4–0.5 × 1.2–1.4 μm. On marine agar, colonies are 2–4 mm in diameter, circular, shiny with entire edges, dark orange, and sunk into the agar. Growth occurs at 4–32°C (optimum, 23–25°C) and in 1–6% NaCl (optimum, 2% NaCl).

Source: isolated from seawater, collected in Amursky Bay, Gulf of Peter the Great, Sea of Japan.

DNA G+C content (mol%): 37.1 (*T_m*).

Type strain: KMM 3526, LMG 22069, CCUG 47080.

Sequence accession no. (16S rRNA gene): AB121974.

3. ***Zobellia laminariae*** Nedashkovskaya, Suzuki, Vancanneyt, Cleenwerck, Lysenko, Mikhailov and Swings 2004f, 1647^{VP} la.mi.na'ri.ae. N.L. gen. n. *laminariae* of *Laminaria*, the generic name of the brown alga *Laminaria japonica*, from which the bacterium was isolated.

^aSymbols: +, >85% positive; -, 0–15% positive.

^bData are taken from: Barbeyron et al. (2001), Bowman (2000), Bruns et al. (2001), Cho and Giovannoni (2004), Nedashkovskaya et al. (2004f), Reichenbach (1989a), Yoon et al. (2005b), and ZoBell and Upham (1944).

Cells are 0.4–0.5 × 1.2–1.4 μm. On marine agar, colonies are 2–4 mm in diameter, circular, shiny with entire edges, dark red, and sunk into the agar. Growth occurs at 4–30°C (optimum, 21–23°C), and in salt concentrations from 1.5 to 6% NaCl (optimum, 2%).

Source: isolated from the brown alga *Laminaria japonica*, collected in Troitsa Bay, Gulf of Peter the Great, Sea of Japan.

DNA G+C content (mol%): 36–37 (*T_m*).

Type strain: KMM 3676, LMG 22070, CCUG 47083.

Sequence accession no. (16S rRNA gene): AB121975.

4. ***Zobellia russellii*** Nedashkovskaya, Suzuki, Vancanneyt, Cleenwerck, Lysenko, Mikhailov and Swings 2004f, 1647^{VP} rus.sel'li. N.L. gen. n. *russellii* of H.L. Russell, an American scientist, for his contribution to the development of marine microbiology.

Cells are 0.4–0.5 × 1.2–1.4 μm. On marine agar, colonies are 2–4 mm in diameter, circular, shiny with entire edges, dark orange, and sunk into the agar. Growth occurs at 4–38°C (optimum, 25–28°C) and with NaCl concentrations between 1 and 10% NaCl (optimum, 2–3%).

Source: isolated from the green alga *Acrosiphonia sonderi*, collected in Troitsa Bay, Gulf of Peter the Great, Sea of Japan.

DNA G+C content (mol%): 38.6 (T_m).

Type strain: KMM 3677, LMG 22071, CCUG 47084.

Sequence accession no. (16S rRNA gene): AB121976.

5. **Zobellia uliginosa** Barbeyron, L'Haridon, Corre, Kloareg and Potin 2001, 995^{VP} [*Cellulophaga uliginosa* Bowman 2000, 1867; *Cytophaga uliginosa* (ZoBell and Upham 1944) Reichenbach 1989a, 2037; *Agarobacterium uliginosum* (ZoBell and Upham 1944) Breed 1957, 326; *Flavobacterium uliginosum* ZoBell and Upham, 1944, 263]

u.li.gi.no'sa. L. fem. adj. *uliginosa* moist, marshy.

Cells are 0.4–0.5 × 1.2–1.4 µm. On marine agar, colonies are 2–4 mm in diameter, circular, shiny with entire edges, dark

orange, sunk into the agar, and have very tenacious slime. Growth occurs at 4–37°C (optimum, 25–28°C), and at NaCl concentrations from 1 to 6% (optimum, 2%). β-Glucosidase (esculin test) is positive. No brown pigment is formed with tyrosine. The following substrates are utilized: N-acetylglucosamine, gluconate, 2-ketogluconate, α-ketobutyric acid, mannitol, L-threonine, and urocanic acid. DL-Glycerol phosphate, L-rhamnose, and L-serine are not utilized.

Source: isolated from a marine mud, Lemon, Costa Rica.

DNA G+C content (mol%): 42.9 (HPLC, T_m).

Type strain: ZoBell 553, ACAM 538, ATCC 14397, CCUG 33448, CECT 4277, CIP 104808, DSM 2061, IFO (now NBRC) 14962, LMG 3809, NCIMB 1863.

Sequence accession no. (16S rRNA gene): M62799.

Family II. **Blattabacteriaceae** fam. nov.

SRINIVAS KAMBHAMPATI

Blat.ta.bac.te.ri.a.ce'a.e. N.L. n. *Blattabacterium* type genus of the family; *-aceae* ending to denote a family; N.L. fem. pl. n. *Blattabacteriaceae* the *Blattabacterium* family.

Gram-stain-negative, slightly curved and straight rods that are intracellular symbionts of cockroaches and of one termite species. These endosymbiotic bacteria are found predominantly in specialized cells of insect fat bodies. Nonmotile and nonflagellated. They play a role in the conversion of uric acid metabolites into usable nitrogenous compounds under anaerobic conditions. The endosymbionts are transmitted vertically from mother to offspring. They possess highly reduced genomes, with an estimated genome size of approximately 638 kbp.

Type genus: **Blattabacterium** Hollande and Favre 1931, 754^{AL}.

Further comments

Although this family is represented by a single genus and species, the clades of *Blattabacterium cuenoti* from various cockroach families should likely be elevated to the species level. Clark and Kambhampati (2003) showed that the sequence divergence (up to 2.2%) in the 16S rRNA gene of the endosymbiont from six different species of the wood-feeding cockroach, *Cryptocercus*, is comparable to that reported for congeneric free-living and endosymbiotic bacterial species (see the genus description for details). It has long been assumed that all extant cockroach species harbor endosymbiotic bacteria, however, Lo et al. (2007) could not detect *Blattabacterium* in members of the cockroach genus *Nocticola*.

Genus I. **Blattabacterium** Hollande and Favre 1931, 754^{AL}

SRINIVAS KAMBHAMPATI

Blat.ta.bac.te'ri.um. L. fem. n. *blatta* an insect that shuns the light, the cockroach, chafer, moth, etc.; L. neut. n. *bacterium* rod; N.L. neut. n. *Blattabacterium*, an endosymbiotic bacterium harbored by cockroaches and one termite species.

Blattabacterium are present only as **intracellular symbionts (endosymbionts)** in almost all species of cockroaches (Blattaria: Dictyoptera) studied so far and one species of termite, *Mastotermes darwiniensis* (Mastotermitidae: Isoptera). Lo et al. (2007) reported that they could not detect the presence of *Blattabacterium* in members of the cockroach genus *Nocticola*. **Plump, slightly curved and straight rods**, about 1 µm in diameter and 1.6–9.0 µm in length, usually with rounded ends. Length slightly variable among cockroach species. Within a cockroach species, longer forms occur inside specialized cells of abdominal fat body called **mycetocytes**; shorter forms occur in gonads and embryos. Binary fission pairs are common in mycetocytes. **Enveloped by host cell membranes**. Gram-stain-variable to Gram-stain-positive staining but has a **Gram-negative type cell-wall** structure composed of peptidoglycan surrounded by an outer membrane. **Nonmotile. Nonflagellated. Possesses enzymes of the tricarboxylic acid cycle and respiratory cytochromes**.

DNA G+C content (mol%): 26–28 (Bd).

Type species: **Blattabacterium cuenoti** (Mercier 1906) Hollande and Favre 1931, 754^{AL} (*Bacillus cuenoti* Mercier 1906, 684).

Further descriptive information

The description of *Blattabacterium* presented in this chapter is taken from Dasch et al. (1984) with updates and modifications.

Phylogenetic treatment. In the 8th edition of *Bergey's Determinative Manual*, *Blattabacterium* was placed in the tribe *Wolbachieae*, family *Rickettsiaceae*, order *Rickettsiales* (Dasch et al., 1984). Since then, molecular phylogenetic studies have been undertaken on *Blattabacterium* and their relationship to free-living bacteria. Bandi et al. (1994) sequenced the 16S rRNA gene of *Blattabacterium* from one representative each of five families of cockroaches and undertook a phylogenetic analysis

that included homologous sequences from several free-living bacteria. They concluded that *Blattabacterium* belongs to the *Flavobacterium-Bacteroides* group, which, in this second edition of the *Systematics Manual*, is denoted as the phylum "*Bacteroidetes*".

Cell morphology. The light microscopic and ultrastructural appearance of *Blattabacterium* varies somewhat among different cockroach species, in different tissues of a single species, and in response to the recurrent hormonal changes of the host's incomplete metamorphosis. The endosymbionts harbored by various species of cockroaches differ primarily in length and DNA sequence (see *Taxonomic comments*, below). In *Blatta orientalis* they are 2.5–5.3 µm long; in *Cryptocercus punctulatus*, 2.5–8.1 µm; in *Heterogamia*, 5.3–9.0 µm; in *Blatta aethiopica*, 1.6 µm; and in *Blatta germanica*, 3.0 µm (Buchner, 1965). The slightly curved, longer forms occur in the mycetocytes. The shorter forms occur in the ovaries and during embryonic development (Sacchi et al., 1996, 2000). Very small dense forms 0.3 × 1.0 µm are occasionally found mixed with the larger endosymbionts in the fat body mycetocytes of *Blaberus*, *Blattella*, *Byrsotria*, *Nauphoeta*, and *Periplaneta* (Meyer and Frank, 1960; Milburn, 1966; Sacchi et al., 1996). However, there is no indication that cockroaches and *Mastotermes darwiniensis* harbor more than one species of endosymbiont in their fat body cells (Bandi et al., 1994, 1995; Clark et al., 2001; Clark and Kambhampati, 2003; Sacchi et al., 1996, 2000; Sabree et al., 2009; Sanchez-Lopez et al., 2009). The large endosymbionts may stain Gram-positive or Gram-stain-variable; the differences are possibly due to their physiologic state. Unlike most Gram-stain-positive bacteria, dilute sodium dodecyl sulfate abolishes the Gram-positive staining property of the endosymbionts (Malke and Bartsch, 1966). Cytoplasmic vacuoles and cross-walls are evident in freshly isolated endosymbionts. The Feulgen reaction of the endosymbionts is positive but diffuse (Rizki, 1954). The endosymbionts are not acid-fast, are not encapsulated, have no flagella, and stain well with Giemsa

and Delafield or Heidenhain's hematoxylin. They do not stain with Sudan dyes, the Baker acid hematin test for phospholipids, or periodic acid Schiff reagent for polysaccharides. *Blattabacterium* are not fluorescent or birefringent (Richards and Brooks, 1958). Poorly fixed specimens and endosymbionts isolated in hypotonic solutions may appear swollen and yeastlike. Nucleoid areas with associated metachromatic granules that divide simultaneously with transverse fission have been observed (Buchner, 1965). Ultrastructurally, these appear to correspond to the electron-dense bodies and complex mesosome-like structures that are often associated with division septa (Anderson, 1964; Brooks, 1970; Bush and Chapman, 1961; Daniel and Brooks, 1972; Gromov and Mamkaeva, 1980).

Cell-wall composition. Muramic acid and glucosamine have been identified in the cell wall of the endosymbionts of *Periplaneta americana*, indicating the occurrence of peptidoglycan (Daniel and Brooks, 1967; Sacchi et al., 1998). This is consistent with the finding of naturally occurring endosymbiont sphaeroplasts (Milburn, 1966) and the formation of sphaeroplasts by injection of lysozyme into the host (Daniel and Brooks, 1972). However, the precise mechanism of lysozyme sphaeroplast-forming ability is not clear, since denatured lysozyme is equally effective.

Fine structure. Other than size, ultrastructural differences are negligible in *Blattabacterium* found in the nymphal fat body mycetocytes of cockroach genera representative of five divergent families of Blattaria: *Blaberus*, *Blatta*, *Byrsotria*, *Cryptocercus*, *Nauphoeta*, and *Periplaneta* (Brooks, 1970). This is in contrast to the location of the mycetocytes themselves, which may be isolated (*Cryptocercus*, and in the termite, *Mastotermes*), loosely scattered in the fat body (*Pycnoscelus*, *Blatta aethiopica*), banded in a single (*Blatta orientalis*, *Rhicnoda*), double (*Nauphoeta*), or triple row (*Blattella*), or cluster (*Ectobia*), each surrounded by a monolayer of fat body cells (Buchner, 1965; Koch, 1967; Sacchi et al., 2000). The endosymbionts are housed singly or as binary fission pairs in mycetocytes enveloped by a host-derived vacuolar membrane (Bigliardi et al., 1989). Relative to the host cytoplasm, the endosymbiont cytoplasm is electron-dense, although it is otherwise unremarkable in its content of ribosomes, loose DNA fibrils, and mesosome-like membrane invaginations. The endosymbiont cell wall is usually thin (5–10 nm) for a Gram-stain-positive bacterium and, indeed, it has an ultrastructure characteristic of Gram-stain-negative bacteria (Anderson, 1964; Brooks, 1970; Daniel and Brooks, 1972). The additional host cell membrane might be responsible for the Gram-positive staining properties reported by Gromov and Mamkaeva (1980). The encapsulating host membranes are lost from the endosymbionts only during the extracellular phases of their transfer from the fat body mycetocytes to the oocyte cytoplasm to ensure their hereditary transmission (Anderson, 1964; Daniel, 1973). At this time the endosymbionts are completely enveloped by the highly microvillous surface of the oocyte oolemma until egg maturation is complete (Sacchi et al., 1996). A similar endosymbiont transfer occurs in the rudimentary ovaries of males, but some tissue tropism is involved since the testes are not infected (Brooks and Kurtti, 1972). During embryonic development, complex extracellular and transmembrane movements of the endosymbionts occur between the time of their initial penetration of the oolemma and ultimate seques-

tration in the larval mycetocytes (Buchner, 1965; Sacchi et al., 1996, 2000).

By the freeze-fracture technique, alterations occur in the disposition of membrane particles on the convex surface of the plasma membrane of the endosymbionts present at the oocyte-follicle interface, following changes in the levels of host juvenile hormone (Liu, 1973, 1974). An apparent hormone-related transformation of the usual rod-shaped endosymbionts into large rounded forms filled with concentric lamellar membranes during the later instar ecdyses and oocyte development of false ovoviviparous cockroaches has been described (Milburn, 1966).

Cultural characteristics and life cycle. Cultivation of *Blattabacterium* *in vitro* or in tissue culture cells has not been accomplished. The endosymbionts contribute nutritional factors to the host (Sabree et al., 2009). Maintenance of endosymbionts in host insect is inhibited by treatment with the antibiotics penicillin, streptomycin, chloramphenicol, chlortetracycline, and oxytetracycline, sulfathiazole, egg white lysozyme, incubation at 37°C, and the insecticide lindane, but not aerosporin. Numerous reports of successful cultivation of the cockroach endosymbionts have appeared along with studies on the biochemistry of these cultures (Brooks, 1970). Gier (1947) and Brooks and Richards (1966) have carefully reviewed the problems inherent in preventing contamination with the diverse normal cockroach flora and in fulfilling Koch's postulates for the cultivation of endosymbionts. For none of the microorganisms so far cultivated is there a convincing relationship to the endosymbionts, as measured by definitive criteria such as common antigens, DNA base composition, common distinctive metabolic properties, and enzymes. Limited extracellular culture of endosymbionts in the presence of embryo cell cultures has been reported (Landureau, 1966) but not intracellular growth of endosymbionts in either vertebrate or invertebrate tissue culture systems.

Blattabacterium are transmitted in eggs vertically from the mother to offspring of both sexes. Using electron microscopy, Sacchi et al. (1996, 1988, 1998, 2000) and Sacchi and Grigolo (1989) studied the transovarial transmission of *Blattabacterium* in cockroaches and in the termite *Mastotermes darwiniensis*. They observed *Blattabacterium* in young follicular cells and intracellular spaces of both cockroaches and *Mastotermes darwiniensis*. In neotenic reproductives of *Mastotermes darwiniensis*, however, bacteriocytes were firmly attached to the germ layer of adjacent ovarioles. The bacterial infection occurred in the oocytes. Sacchi et al. (2000) suggested that *Blattabacterium* are discharged from the bacteriocytes by exocytosis and then cross the ovariole sheath and follicular epithelium. Giorgi and Nordin (1994), in a study of endosymbionts during embryogenesis of *Blattella germanica*, suggested that *Blattabacterium* are involved in digestion of yolk granules and migration of vitelophages to the center of the yolk. However, no experimental evidence for the production of lytic enzymes by *Blattabacterium* exists. Endosymbionts in the embryos of *Blattella germanica*, *Periplaneta americana*, and *Mastotermes darwiniensis* are located in the periplasm just beneath the vitelline membrane, and the turnover of *Blattabacterium* in the successive stages of embryo development is similar in the previously mentioned host species (Sacchi et al., 2000). The studies by Sacchi and colleagues cited above cumulatively demonstrate that the complex

pattern of transovarial transmission is similar in cockroaches and *Mastotermes darwiniensis*, further confirming the close phylogenetic relationship of the endosymbionts from cockroaches and *Mastotermes darwiniensis* (Bandi et al., 1995).

Metabolism and metabolic pathways. The precise role of *Blattabacterium* in cockroach nutrition and excretion remains unknown because of the inability to culture them outside the host. However, the endosymbionts are necessary for host survival because aposymbiotic cockroaches do not survive unless fed on specialized diets containing yeast or liver (Brooks, 1963; Dasch et al., 1984). *Blattabacterium* are likely play a role in the conversion of uric acid into usable nitrogenous compounds under anaerobic conditions (Chapman, 1998; Cochran, 1985; Wren and Cochran, 1987). Whereas most terrestrial insects are uricotelic and void uric acid, cockroaches store urates internally rather than excreting them (Cochran, 1985). Under conditions of high dietary nitrogen, urates, in the form of uric acid, accumulate in cockroach fat bodies. When such individuals are fed nitrogen-poor diets, internally stored urates are mobilized. Only trace amounts of urates are present in the excreta (Nation and Patton, 1961; Srivastava and Gupta, 1961). Thus, if urates are mobilized in periods of dietary nitrogen stress and not excreted, they must be utilized for metabolic purposes (Cochran, 1985). However, insects have a limited capacity for degradation of purine molecules, and pathways for conversion of uric acid to allantoin and allantoin to allantoic acid are not known from cockroach tissues (Cochran, 1975). This suggests that another component is involved, and fat bodies are a likely site because of their involvement in uric acid synthesis and storage. Since the discovery that mycetocytes are surrounded by urocytes with contact between cell membranes, it has been suggested *Blattabacterium* might be involved in uric acid metabolism. When cockroaches are rendered aposymbiotic, there is a 20-fold increase in uric acid content of fat bodies (Malke, 1964; Malke and Schwartz, 1966). Although this suggests endosymbionts are utilizing stored uric acid for synthesis of essential amino acids (Clarebrough et al., 2000) the full genome sequence of *Blattabacterium* (see below) indicated that no uricolytic enzymes are encoded by the *Blattabacterium* genome.

Because claims for the culture of *Blattabacterium* have not been substantiated, reports of the presence of guanase, uricase, urease, xanthine oxidase, malic and lactic dehydrogenases, and synthesis of ascorbic acid based on such cultures are questionable. However, direct histochemical studies on endosymbionts present in the mycetocytes and respirometric studies on isolated endosymbionts indicate that the endosymbionts do reduce tetrazolium dyes, succinate, and cytochrome *c* while they consume oxygen. These results suggest that they have a complete set of respiratory cytochromes and an aerobic metabolism. The endosymbionts also transaminate alanine to pyruvate and glutamate to aspartate (Brooks, 1970). In many other studies, fractions enriched in endosymbionts have been compared with similarly prepared fractions from cockroaches that had been freed of their endosymbionts. Although the greater glycolytic and tricarboxylic acid cycle activities of such enriched endosymbiont fractions have been attributed to the endosymbionts (Laudani et al., 1974), the endosymbionts might merely eliminate an inhibitor that depresses such host activities. Since only the tissues containing endosymbionts exhibit significant respiration in the presence of added uric acid, it was assumed that the endosymbionts might play an important role in the uric

acid catabolism of the cockroach. Recent evidence (Sabree et al., 2009; Sanchez-Lopez et al., 2009) suggested that whereas *Blattabacterium* utilize breakdown products of uric acid, they are not directly involved in uric acid catabolism.

Symbiotic insects, even when deprived of intestinal bacteria, but not aposymbiotic cockroaches (derived from chlortetracycline-treated adults), are able to synthesize labeled cysteine, glutathione, methionine, and taurine from ³⁵S-sulfate and to transfer labeled sulfur from cysteine to methionine (Block and Henry, 1961). Furthermore, only symbiotic insects can label the essential amino acids tyrosine, phenylalanine, isoleucine, valine, threonine, and arginine to a significant level from [U-¹⁴C]glucose; the nonessential amino acids are labeled as well (Henry, 1962). The lighter melanization of aposymbiotic cockroaches may in part be due to their inability to synthesize tyrosine. Similarly, significant aromatic ring cleavage of phenylalanine occurs in symbiotic but not in aposymbiotic cockroaches, although this is not a major metabolic pathway even in the symbiotic cockroaches (Murdock et al., 1970).

Recently, Sabree et al. (2009) obtained the full genome sequence of *Blattabacterium* from the American cockroach, *Periplaneta americana* and Sanchez-Lopez et al. (2009) reported the full genome sequence of *Blattabacterium* from the German cockroach, *Blattella germanica*. The genome sizes of *Blattabacterium* from both host species were similar to each other at approximately 638 kbp; these small genomes are consistent with the finding that all insect endosymbionts studied to date also exhibit highly reduced genome sizes relative to free-living bacteria (Wernegreen, 2002). A major difference between *Blattabacterium* from the two host species is that whereas the one from the American cockroach contained a 3.5 kbp plasmid, no plasmid was detected in *Blattabacterium* from the German cockroach. The genome sequence confirmed that *Blattabacterium* is a member of *Flavobacteriales* (*Bacteroidetes*) and its closest living relative is *Sulcia muelleri*, an endosymbiont commonly found in sap-feeding insects (McCutcheon et al., 2009).

Sabree et al. (2009) and Sanchez-Lopez et al. (2009) reconstructed the metabolic pathways from the genomic sequence and found that although *Blattabacterium* lacks uricolytic enzymes it can recycle nitrogen from urea and ammonia, which are uric acid degradation products, into glutamate, using urease and glutamate dehydrogenase. They also suggested that *Blattabacterium* can subsequently produce all of the essential amino acids, various vitamins, and other compounds from a limited set of metabolic substrates. The metabolic pathways inferred for *Blattabacterium* from the German cockroach were highly similar to those inferred for *Blattabacterium* from the American cockroach (Sanchez-Lopez et al., 2009). Thus, the full genome sequence of *Blattabacterium* confirms its suspected role in nitrogen metabolism, including nitrogen recycling from ammonia and urea and extensive capabilities for amino acid biosynthesis.

Genetics. The *Blattabacterium* 16S rRNA gene has been sequenced from a number of cockroach species and from *Mastotermes darwiniensis* (Bandi et al., 1994, 1995; Clark et al., 2001; Clark and Kambhampati, 2003; Lo et al., 2007, 2005a; Maekawa et al., 2005b). Clark et al. (2001) and Clark and Kambhampati (2003) also sequenced the 23S rRNA gene from various *Cryptocercus* species (see *Taxonomic comments*, below).

Many insect endosymbionts, representing diverse bacterial lineages, have been shown to have a highly reduced genome

size (Wernegreen, 2002). In general, insect endosymbiont genomes exhibit about 80% reduction relative to that of *Escherichia coli*. *Blattabacterium* also has a highly reduced genome that has been estimated to be about 638 kbp (Sabree et al., 2009; Sanchez-Lopez et al., 2009). The American cockroach *Blattabacterium* genome encodes 581 open reading frames (ORFs), of which 520 have a known function. More than half of these ORFs are involved in amino acid metabolism, translation and biogenesis, cell-wall and cell-membrane biogenesis or coenzyme metabolism and energy production. Thirty-three tRNA genes, corresponding to all amino acids, as well as the complete transcriptional machinery, are encoded in the genome. Relative to free-living bacteria, genes involved in transcriptional regulation, signal transduction, secondary metabolites, and defensive activities are disproportionately deleted. Those involved in translation, amino acid metabolism, and coenzyme metabolism are generally retained (Sabree et al., 2009). This pattern of gene loss and retention is similar to that noted for other insect endosymbionts (Moran and Wernegreen, 2000; Ochman and Moran, 2001). The *Blattabacterium* genome contains genes for the complete biosynthetic pathways for all amino acids with the exception of asparagine, glutamate, methionine, and serine (Sabree et al., 2009). Thus, *Blattabacterium* manufactures most amino acids from a few nitrogen-rich substrates such as glutamate, urea, and ammonia. Finally, since the *Blattabacterium* genome does not encode enzymes essential for uric acid degradation, it is not clear where the initial steps of uric acid degradation occur.

Antibiotic and drug sensitivity. No significant differences have been reported in the antibiotic sensitivity of endosymbionts of different cockroach species subjected to either prolonged feeding or repeated injections. Penicillin, oxytetracycline, chlortetracycline, streptomycin, sigmamicin, penetracin, chloramphenicol, and sulfathiazole, but not aerosporin, are effective (Brooks, 1970). Although significantly reduced, the endosymbiont populations are rarely completely eliminated. Aposymbiosis is most readily obtained by interruption of the hereditary transmission of the endosymbionts to the ovary. Resistant endosymbiont strains have arisen with continued antibiotic treatment.

Pathogenicity. The endosymbionts are not known to be infectious or pathogenic to insects, other invertebrates, or vertebrates. Reinfection of aposymbiotic cockroaches with isolated endosymbionts, to fulfill Koch's postulates, has not been accomplished (Brooks and Richards, 1966).

Enrichment and isolation procedures

To isolate the blattbacteria, fat bodies from frozen or fresh, surface-sterilized insects must be dissected in a buffer containing 25 mM KCl, 10 mM MgCl₂, 250 mM sucrose, 250 mM EDTA, 35 mM Tris/HCl, pH 7.5 (Buffer A; Charles and Ishikawa (1999)). The tissue is homogenized in 10 ml of Buffer A and filtered successively through nylon mesh filters having pore

sizes of 100 µm, 20 µm, and 11 µm. The filtrate is centrifuged at 1500 × g for 25 min at 4°C and the pellet is resuspended in 10 ml of Buffer A containing 100 mM EDTA rather than 250 mM EDTA (Buffer B). Percoll gradients (27% and 70% in 5% PEG-6000; 1% Ficoll, 1% BSA fraction V, 250 mM sucrose) are prepared. Five milliliters of 70% Percoll is placed in a 50-ml centrifuge tube followed by 5 ml of 27% Percoll and 5 ml of cell suspension. The mixture is centrifuged at 12,000 × g for 15 min at 4°C. The suspension is recovered from the interface of the Percoll gradients. Ten milliliters of Buffer B is added and the suspension centrifuged at 3000 × g for 12 min at 4°C. The pellet is redissolved in 1 ml of Buffer B and centrifuged in a microcentrifuge for 12 min at 3000 × g. The final pellet is redissolved in 100 µl of Buffer B for use in restriction digests and pulsed-field gel electrophoresis. Since *Blattabacterium* are intracellular symbionts, it is difficult to obtain a preparation that is not contaminated by host DNA. However, a preparation that contains 50–55% endosymbiont DNA is adequate for gel electrophoresis (S. Kambhampati, unpublished data) and shotgun cloning for subsequent use in DNA sequencing (van Ham et al., 2003). A much simpler protocol for the isolation of fractions highly enriched for *Blattabacterium* DNA was described by Sabree et al. (2009).

Procedures for testing special characteristics

Molecular diagnosis. The presence of *Blattabacterium* can be confirmed by PCR amplification using 16S rRNA and 23S rRNA gene primers shown in Table 77 (Bandi et al., 1994; Clark and Kambhampati, 2003). The primers were designed based on consensus bacterial sequences of the respective genes and will therefore likely result in the amplification of the target fragment from a variety of bacterial species. DNA sequencing is therefore required to confirm that the amplified fragment is indeed from *Blattabacterium*.

Taxonomic comments

Bandi et al. (1994) concluded that there is parallel cladogenesis between the hosts and endosymbionts (Figure 56). Clark et al. (2001) and Clark and Kambhampati (2003) concluded that, based on 16S rRNA and 23S rRNA gene sequences, there is co-cladogenesis between the wood-feeding cockroach, *Cryptocercus*, and the *Blattabacterium* harbored by them. The parallel cladogenesis between cockroaches and their endosymbionts was supported by Lo et al. (2003). Hurst et al. (1999) showed that male-killing bacteria harbored by some members of Coccinellidae are a sister group of *Blattabacterium*. Moran et al. (2003) showed that the endosymbionts in the "yellow bacteriome" of the glassy winged sharpshooter, *Homolodisca coagulata*, are closely related to *Blattabacterium* and to the bacterial species endosymbiotic in ladybeetles.

The 16S rRNA gene sequence of *Blattabacterium* has been used to infer divergence times among their hosts. The 16S

The numbers above the branches are bootstrap values in per cent. The sequences for cockroach endosymbionts are from Bandi et al. (1994), Clark and Kambhampati (2003), and S. Kambhampati (unpublished). The outgroup (*Flavobacterium* sp.) sequence is from GenBank (accession no. AJ009687).

rRNA gene of free-living bacteria (Ochman and Wilson, 1987) and insect endosymbionts (Clark et al., 2001; Clark and Kambhampati, 2003; Lo et al., 2003; Maekawa et al., 2005a, 2005b; Moran et al., 1993) evolves in a clocklike manner. Therefore, it is possible to estimate divergence times among the host species harboring *Blattabacterium* by analyzing the DNA sequence of the endosymbiont 16S rRNA gene. Moran et al. (1993) estimated a rate of 0.0076–0.0232 nucleotide substitutions per site per 50 million years (MY) for the 16S rRNA gene of the aphid endosymbiont, *Buchnera aphidicola*. Lo et al. (2003) proposed a nucleotide substitution rate of 0.0087 per site per 50 MY for the 16S rRNA gene of *Blattabacterium* from various cockroach species. Maekawa et al. (2005b) and Maekawa et al. (2005a) estimated nucleotide substitution rates of 0.0084–0.0111 per site per 50 MY for the 16S rRNA gene of *Blattabacterium* harbored by *Cryptocercus* species, and 0.0087–0.0137 per site per 50 MY for the 16S rRNA gene of *Blattabacterium* harbored by two genera (*Salganea* and *Panesthia*) of Blaberidae, respectively. It must be noted, however, that all of these rates of evolution are based on a number of assumptions related to the age of termite-cockroach split, monophyly of cockroaches, endosymbiont

lineage extinction, uniform rates of evolution within and among lineages, the extent to which taxon sampling is representative of all lineages, and fossil record. Unfortunately, the evidence for many of these assumptions is equivocal. Thus, the estimates of divergence times among hosts based on the *Blattabacterium* 16S rRNA gene must be interpreted with caution.

Bandi et al. (1995) sequenced the 16S rRNA gene from *Blattabacterium* of *Mastotermes darwiniensis* and compared it to that from cockroach endosymbionts. They concluded endosymbionts from the termite are monophyletic with those from cockroaches, implying monophyly of cockroaches and termites. Since *Mastotermes darwiniensis* is the only termite that is known to harbor *Blattabacterium*, all subsequent lineages of termites have evidently lost the endosymbiont (*Mastotermes darwiniensis* is the basal lineage among extant termites; Kambhampati and Eggleton, 2000).

Dasch et al. (1984) stated that the basic similarity in the DNA base composition, ultrastructure, mechanism of transmission to subsequent insect generations, and antibiotic sensitivities of the endosymbionts from different cockroaches, suggest that there is no strong basis for further speciation. However, recent evidence suggests that the endosymbiont clades in various cockroach families should probably be elevated to species status. For example, Clark and Kambhampati (2003) found that the sequence divergence (up to 2.2%) in the 16S rRNA gene of the endosymbiont from six different species of the wood-feeding cockroach, *Cryptocercus*, is comparable to that reported for congeneric free-living (Brenner et al., 1998; Fanrong et al., 1999; Wen et al., 1999; Yoon et al., 1998) and endosymbiotic (Sauer et al., 2000) bacterial species. Overall, the sequence divergence in the 16S rRNA gene of *Blattabacterium* harbored by various cockroach species shown in Figure 56 ranges from 0.6% (congeneric species) to 5.2% (taxa from different families). Thus, a thorough investigation is warranted to clarify the taxonomic status of *Blattabacterium* harbored by diverse cockroach species.

The mol% G+C of the DNA (Bd) has been determined for endosymbionts and their hosts from nine species of cockroaches in six different subfamilies. Endosymbiont DNA base compositions vary from 25.8 to 28.3 mol% G+C, except for 21.8 mol% obtained in a single determination on the endosymbionts of *Supella longipalpa*. Based on the full genome sequence, Sabree et al. (2009) reported a G+C content of 28.2 mol% for *Blattabacterium* from the American cockroach. Similarly, Sanchez-Lopez et al. (2009) estimated a G+C content of 27.1 mol% based on the full genome sequence of *Blattabacterium* from the German cockroach. Although no phylogenetic trends are obvious among the various species, the DNA G+C compositions of the endosymbionts of two *Parcoblatta* species and two *Blaberus* species are identical (27.3 and 26.5 mol%, respectively). In contrast, the cockroach DNAs differ greatly in the number (1–3), amount, and G+C compositions of the satellite DNA peaks, whereas the main band of DNA only varies from 33.5 to 36.3 mol% (Dasch, 1975).

Acknowledgements

The author's studies on cockroaches were supported by NSF grant DEB 98-06710. This is article number 06-196-B of the Kansas Agricultural Experiment Station.

List of species of the genus *Blattabacterium*1. *Blattabacterium cuenoti* (Mercier 1906) Hollande and Favre 1931, 754^{AL} (*Bacillus cuenoti* Mercier 1906, 684)

cu.en.ot'i. N.L. gen. masc. n. *cuenoti* of Cuenot; named after L. Cuenot, who studied intracellular inclusions in orthopteran insects.

The characteristics are as described for the genus. Originally studied in *Blatta orientalis*, the oriental cockroach.

DNA G+C content (mol%): 28.2 (Bd).

Type strain: none designated.

Sequence accession numbers: As of August 2009, 171 nucleotide sequences of *Blattabacterium* have been deposited in GenBank. None of these was designated a type strain. A vast majority of these are 16S rRNA gene sequences; several are 23S rRNA gene sequences from *Cryptocercus* species (Clark

et al., 2001; Clark and Kambhampati, 2003). Accession numbers for *Blattabacterium* harbored by selected host species are as follows: 16S rRNA gene from *Cryptocercus* species: AF310161–310163; AF322458–AF322473 (Clark and Kambhampati, 2003); AY631413, AY631415, AY631417, AY631419, AY631421, AY631423 (S. Kambhampati, unpublished). 16S rRNA gene from various cockroach species: X75622–X75626 (Bandi et al., 1994). 16S rRNA gene from *Mastotermes darwiniensis*: Z35665 (Bandi et al., 1995). 23S rRNA gene from *Cryptocercus* species: AF322491–AF322523; AF363691–363721 (Clark and Kambhampati, 2003); AY631416, AY631418, AY631420, AY631422, AY631424, AY631414 (S. Kambhampati, unpublished). The full genome sequence of *Blattabacterium* from the American cockroach is available from GenBank under accession numbers CP00421 and CP001430.

Family III. **Cryomorphaceae** Bowman, Nichols and Gibson 2003, 1353^{VP}

JOHN P. BOWMAN

Cry.o.mor.pha.ce'a.e. N.L. fem. n. *Cryomorpha* the type genus of the family; - *aceae* ending to denote a family; N.L. fem. pl. n. *Cromorphaceae* the *Cryomorpha* family.

Cells are rodlike and sometimes filaments. Multiply by **binary fission**. Usually **do not contain spores or other resting cells** or gas vesicles. **Motile by gliding motility or are nonmotile.** **Gram-stain-negative.** **Strictly aerobic or facultatively anaerobic.** **Chemoorganotrophic** metabolism. Anaerobic growth, if it occurs, is supported by fermentation of carbohydrates. Do not fix nitrogen. **Colonies are yellow or orange due to carotenoid biosynthesis.** Most species do not form detectable flexirubin type pigments. **Most genera require seawater salts for growth. Most genera require organic compounds** present in yeast extract, peptone, and/or Casamino acids for growth. **Have a limited versatility** in regard to nutritional and catabolic activities and are **generally unreactive in most standard phenotypic tests. Most species do not utilize carbohydrates.** For fatty acid profiles, see Table 78. Cultured members of the *Cryomorphaceae* occur in a range of marine habitats including marine sediments, coastal sands, sand-filtered sea water, sea water particulates, and sea-ice algal assemblages. Also found in marine-derived refugia, i.e., quartz stone sublithic communities located in coastal ice-free regions of Antarctica. Most cultured species are able to grow at low temperatures and are isolated from low temperature ecosystems. Molecular studies, however, suggest the family is present in a wide range of non-extreme ecosystems both marine and terrestrial, across tropical to polar regions.

DNA G+C content (mol%): 35–40.

Type genus: **Cryomorpha** Bowman, Nichols and Gibson 2003, 1352^{VP}.

Further descriptive information

Described in 2003, the family *Cryomorphaceae* represents a broad cluster of mostly marine species of the phylum *Bacteroidetes* (Figure 57). Phylogenetically, the family is weakly monophyletic, occurring in an adjacent position to the family *Flavobacteriaceae* (Yarza et al., 2008). The family so far includes six genera, each only represented by a single species (Bowman et al., 2003, Lau et al., 2005, 2006; O'Sullivan et al., 2005). Phenotypic characteristics useful for differentiating the member genera are shown in the determinative key given below. A notable feature is the lack of activity in most standard phenotypic tests, indicative of a restricted nutritional range. Comparatively fastidious growth factor requirements possessed by these species also suggests that members of this family may be largely dependent on decaying organic biomass, and thus could have significant roles in organic remineralization processes.

The family *Cryomorphaceae* is widespread in the environment, present in a wide range of marine and terrestrial habitats as indicated by several culture-independent studies (Abell and Bowman, 2005; Acinas et al., 2004; Aguilo-Ferretjans et al., 2008; Alain et al., 2002; Bissett et al., 2006; Bowman and McCuaig, 2003; Brinkmeyer et al., 2003; Brown et al., 2005; Collins et al., 2003; Crump and Hobbie, 2005; DeLong et al., 2006; Fuchs et al., 2005; Goffredi et al., 2004; Green et al., 2004; Humayoun et al., 2003; Kirchman et al., 2003; López-García et al., 2003; Nielsen et al., 2004; Pinhassi et al., 2004; Reysenbach et al., 2000; Schaefer et al., 2002; Skidmore et al., 2005; Sorensen et al., 2005; Webster et al., 2004; Zwart et al., 2002). A clade within the family

Cryomorphaceae has been designated the AGG58 cluster, named for clones detected in marine aggregates (DeLong et al., 1993). This group has been found to be widespread in aquatic environments (O'Sullivan et al., 2004). A general consensus of phylogenetic surveys of marine-type ecosystems, suggests *Cryomorphaceae* is much less numerous than that of the marine members of the family *Flavobacteriaceae*. Whether this suggests a pattern of niche specialization for *Cryomorphaceae* or a natural consequence of evolutionary processes among bacteria is unknown at this time.

Key to the genera of the family *Cryomorphaceae*

1. DNA G+C content is 36–37 mol%. Cells are rod shaped. Colonies are orange. Nonmotile. No growth occurs at 37°C. Oxidase-negative. Strictly aerobic. Does not utilize D-glucose. Does not reduce nitrate. Does not hydrolyze gelatin. Isolated from quartz stone sublithic communities of ice-free coastal areas of Antarctica and seawater particulates collected off Antarctic coastlines.
→ Genus I. *Cryomorpha*
2. DNA G+C content is 38–40 mol%. Cells are rod shaped. Colonies are orange. Motile by gliding. No growth occurs at 37°C. Oxidase-negative. Facultatively anaerobic. Utilizes D-glucose. Reduces nitrate to nitrate. Does not hydrolyze gelatin. Isolated from marine sediment and sea-ice algal assemblages collected off Antarctic coastlines.
→ Genus II. *Brumimicrobium*
3. DNA G+C content is 35 mol%. Cells are rod shaped or filamentous. Colonies are yellow. Motile by gliding. No growth occurs at 37°C. Oxidase-negative. Strictly aerobic. Utilizes D-glucose. Reduces nitrate to nitrate. Does not hydrolyze gelatin. Isolated from beneath frozen sand in a coastal bay of Alaska, USA.
→ Genus III. *Crocinitomix*
4. DNA G+C content is 39–40 mol%. Cells are rod shaped or filamentous. Colonies are orange. Motile by gliding. Growth occurs at 37°C. Oxidase-positive. Strictly aerobic. Utilizes D-glucose. Reduces nitrate to nitrate. Hydrolyzes gelatin. Isolated from a tank used for sand-filtering of sea water, Hong Kong, China.
→ Genus IV. *Fluviicola*
5. DNA G+C content is 37.2 mol%. Cells are rod shaped with rarer longer filaments. Colonies are yellow-orange. May form flexirubin pigments. Motile by gliding. Growth occurs at 4–25°C. Oxidase-negative. Strictly aerobic. Does not utilize glucose. Negative for nitrate and nitrite reduction. Weakly hydrolyzes gelatin. No growth occurs on seawater-containing media. Isolated from water of the River Taff, Cardiff, UK.
→ Genus V. *Lishizhenia*
6. DNA G+C content is 35.8 mol%. Cells are rod shaped. Colonies are light orange. Cells are motile by gliding. Growth occurs at 4–37°C. Oxidase-positive. Strictly aerobic. Does not utilize D-glucose. Gelatin and casein are hydrolyzed. Isolated from sand-filtered sea water collected at Port Shelter, adjacent to the Coastal Marine Laboratory, Hong Kong University of Science and Technology.
→ Genus VI. *Owenweeksia*

Genus I. *Cryomorpha* Bowman, Nichols and Gibson 2003, 1352^{VP}

JOHN P. BOWMAN

Cry.o.mor'pha. Gr. neut. n. *kryos* icy cold, frost; Gr. fem. n. *morphe* shape or form; N.L. fem. n. *Cryomorpha* cold shape.

Cells are slender, flexible **rods with rounded ends**, 0.3–0.5 $\mu\text{m} \times 0.5\text{--}3\ \mu\text{m}$. Occur singly or in pairs. **Gram-stain-negative**. Spores, resting cells, and gas vesicles not present. **Nonmotile**. **Colonies are orange**. **Flexirubin pigments are not produced**. **Strictly aerobic with an oxidative type of metabolism**. Catalase positive. Oxidase negative. **Chemoheterotrophic**. **Non-agarolytic**. The organisms have an inert metabolism in that they **do not utilize carbohydrates**, do not form acid from carbohydrates, and are unreactive in most standard biochemical tests. Strains **require sea water salts and yeast extract** for growth. Growth occurs between -2 and 22°C , with optimal growth at $15\text{--}20^\circ\text{C}$ and pH 6–8. Major fatty acids are $\text{C}_{14:0}$ iso, $\text{C}_{15:0}$ iso, $\text{C}_{15:0}$ anteiso, $\text{C}_{16:0}$ iso, $\text{C}_{14:1}$ iso $\omega 9c$, $\text{C}_{15:1}$ iso $\omega 10c$, $\text{C}_{15:1}$ anteiso $\omega 10c$, $\text{C}_{14:0}$ iso 2-OH, and $\text{C}_{15:0}$ anteiso 2-OH. **Isolated from quartz stone sublithic communities and Southern Ocean sea water particulates**.

DNA G+C content (mol%): 36–37.

Type species: *Cryomorpha ignava* Bowman, Nichols and Gibson 2003, 1352^{VP}.

Further descriptive information

Cryomorpha is the type genus of the family *Cryomorphaceae* within which it forms a distinct line of descent (Figure 57).

Colonies are pinpoint to small (0.5–1 mm), orange, circular, entire edged, viscid to butyrous, and convex.

Like other members of the *Cryomorphaceae*, *Cryomorpha ignava* requires sea water and organic compounds occurring in peptone or yeast extract for growth, and it has a restricted versatility in regard to its catabolic activity. It slowly hydrolyzes Tween 80 and urea, but otherwise is unreactive in standard phenotypic tests including various commercial test strips and trays. The species

has an absolute requirement for sea water and is quite stenohaline. It requires yeast extract for growth; no growth occurs in sea-water media supplemented only with peptone, and growth occurs with peptone only if a vitamin solution is supplied suggesting the species requires specific vitamin growth factors that are present in yeast extract. Catalase activity in strains is very pronounced. The fatty acid profile (Table 78) is decidedly unusual, containing large amounts of branched-chain fatty acids such as $\text{C}_{14:0}$ iso 2-OH, $\text{C}_{15:0}$ anteiso 2-OH, $\text{C}_{16:1}$ iso $\omega 11c$, $\text{C}_{14:1}$ iso $\omega 9c$ and $\text{C}_{14:0}$ iso that are rarely found in other Gram-stain-negative bacteria.

Enrichment and isolation procedures

Cryomorpha ignava can be isolated by direct plating of sample material onto Marine agar followed by incubation at $4\text{--}20^\circ\text{C}$. The species grows relatively slowly, with colonies taking at least 4–7 d to appear and grow to full size.

Maintenance procedures

For long-term storage *Cryomorpha ignava* can be cryopreserved at -80°C in Marine 2216 broth supplemented with 30% glycerol. Strains survive well on Marine agar plates or slants stored at $2\text{--}4^\circ\text{C}$.

Differentiation of the genus *Cryomorpha* from other genera

The most salient traits useful for distinguishing *Cryomorpha* from other members of the *Cryomorphaceae* include orange pigmentation, lack of motility, strictly aerobic oxidative metabolism, inability to use carbohydrates, lack of reactivity in most phenotypic tests, and ability to grow at low temperatures. The species also has a distinctive fatty acid profile.

List of species of the genus *Cryomorpha*

1. *Cryomorpha ignava* Bowman, Nichols and Gibson 2003, 1352^{VP} ig.na'va L. fem. adj. *ignava* lazy, pertaining to the biochemical and nutritionally inert nature of the species.

The characteristics are as given for the genus, as listed in Table 78, and as given in the text.

Source: quartz stone sublithic communities and sea water particulates.

DNA G+C content (mol%): 36–37 (T_m).

Type strain: 1-22, ACAM 647, CIP 107453, LMG 21436.

Sequence accession no. (16S rRNA gene): AF170738.

Genus II. *Brumimicrobium* Bowman, Nichols and Gibson 2003, 1352^{VP}

JOHN P. BOWMAN

Bru'mi.mi.cro'bi.um. L. fem. n. *bruma* winter; N.L. neut. n. *microbium* microbe; N.L. neut. n. *Brumimicrobium* winter microbe.

Cells are slender, flexible **rods with rounded ends**, $1\text{--}3\ \mu\text{m} \times 0.3\text{--}0.5\ \mu\text{m}$, occurring singly or in pairs. **Gram-stain-negative**. Spores, resting cells, and gas vesicles are not present. **Gliding motility is present**. **Colonies are orange**. **Flexirubin pigments are not produced**. **Facultatively anaerobic**. **Possesses an oxidative metabolism under aerobic conditions**. **Under anaerobic growth conditions the metabolism shifts to the fermentation of sugars**. Catalase-positive. Oxidase-negative. **Chemoheterotrophic**. **Non-agarolytic**. **Utilizes D-glucose**. Reduces nitrate to nitrite. Strains **require Na⁺ and yeast extract** for growth. Peptone can serve as a nitrogen source. Psychroactive. Slightly halophilic.

Major fatty acids are $\text{C}_{13:0}$ iso, $\text{C}_{15:0}$ iso, and $\text{C}_{15:1}$ anteiso $\omega 10c$. **Isolated from polar marine sediment and sea-ice algal assemblages**.

DNA G+C content (mol%): 38–40.

Type species: *Brumimicrobium glaciale* Bowman, Nichols and Gibson 2003, 1352^{VP}.

Further descriptive information

The genus *Brumimicrobium* is a member of the family *Cryomorphaceae* (Bowman et al., 2003) within which it forms a distinct line of descent (Figure 57).

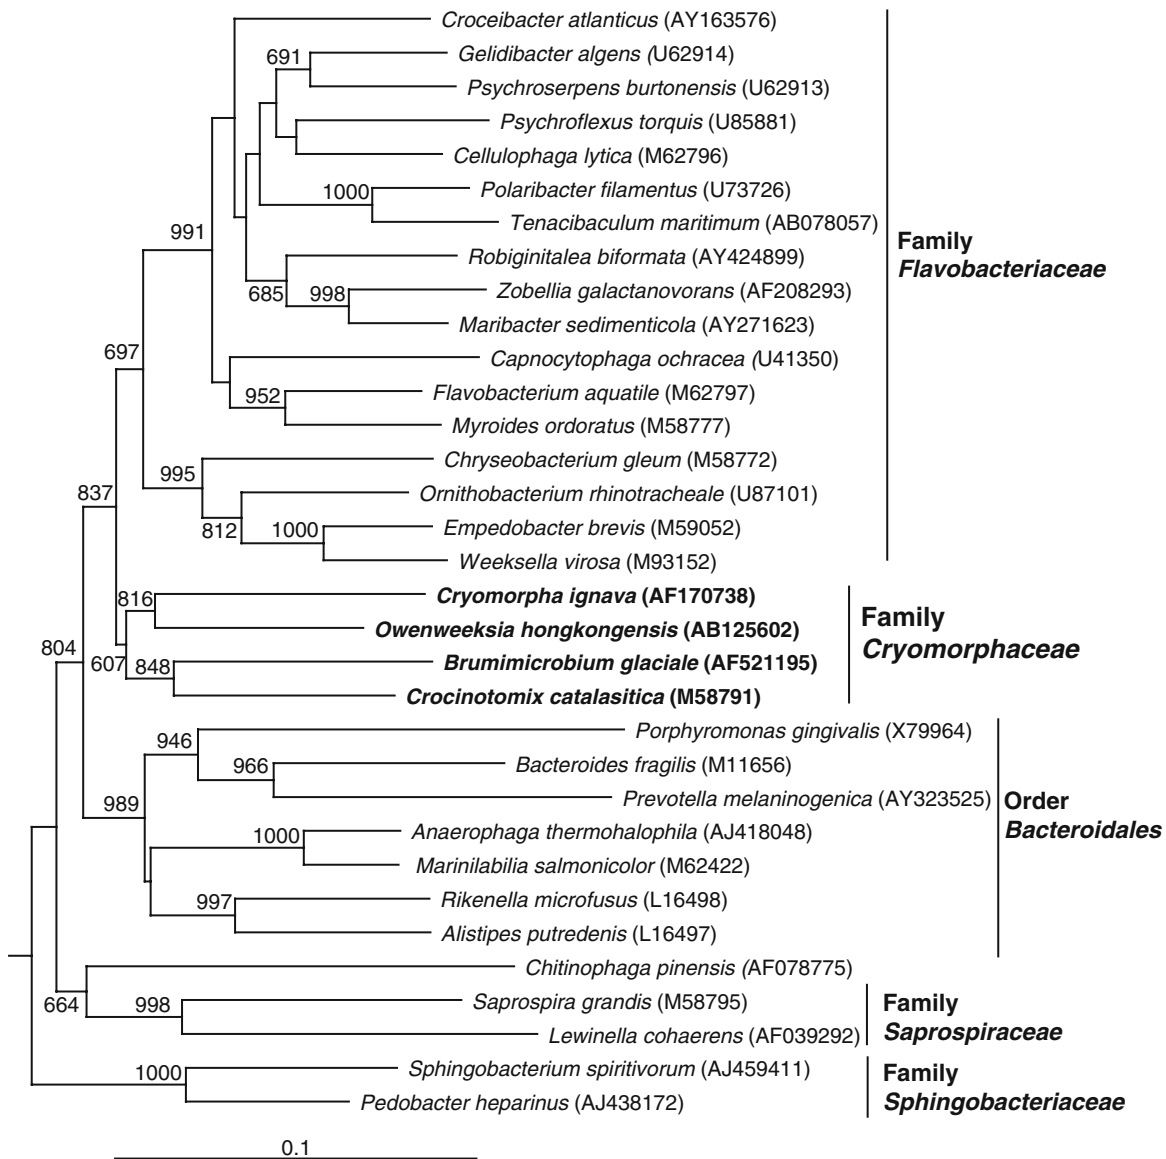

FIGURE 57. Phylogenetic tree based on 16S rRNA gene sequences showing the positions of the genera of the family *Cryomorphaceae* in relation to other related taxa of the phylum *Bacteroidetes*, including family *Flavobacteriaceae*, order *Bacteroidales*, family *Saprospiraceae* and family *Sphingobacteriaceae*. The tree is based on nearly complete 16S rRNA gene sequences clustered by maximum-likelihood and neighbor-joining methods (PHYLIP; J. Felsenstein, University of Washington, Seattle, WA, USA). Numbers at branch lengths are bootstrap values indicating the number of times the branch node was recovered following 1000 replications of the cluster analysis.

Colonies are 1–2 mm in diameter, orange, convex, circular, entire edged, and possess a gelid consistency. Gliding motility is best observed from growth on dilute media rather than Marine 2216 agar. Like other members of the *Cryomorphaceae*, the species requires factors occurring in peptone or yeast extract for growth and has a restricted catabolic versatility. It hydrolyzes Tween 80, and some strains degrade DNA. Alkaline phosphatase is produced. Some strains form β -galactosidase. Otherwise, the organisms are unreactive in standard phenotypic tests, including various commercial test strips and trays. The only known carbon and energy substrate is D-glucose, which the organism can use oxidatively under aerobic conditions, and fermentatively when under anaerobic conditions. Under aerobic conditions, no acid is formed from D-glucose. Other common

substrates tested do not support growth. *Brumimicrobium glaciale* requires Na^+ for growth and is quite stenohaline. The species grows well with yeast extract; however, growth occurs in seawater media containing peptone or Casamino acids if vitamins are provided. This suggests the species has specific vitamin growth factors that are present in yeast extract.

The species is psychroactive and neutrophilic, growing between -2 and 27°C , with optimal growth at 16 – 19°C and pH 6–8. The fatty acid profile (Table 78) is made up mainly of C_{15} branched-chain fatty acids, a profile that differs from other members of the family *Cryomorphaceae*.

Strains of *Brumimicrobium glaciale* have been isolated from both the sea-ice and marine sediments of Antarctica (Bowman et al., 2003).

Enrichment and isolation procedures

Brumimicrobium glaciale can be isolated by direct plating of sample material (sediment, sea-ice samples melted in sterile sea water at 4°C) onto Marine agar followed by incubation at 4–20°C. The species grows relatively slowly, with colonies taking several days to appear and grow to full size.

Maintenance

For long-term storage, *Brumimicrobium glaciale* can be cryopreserved at –80°C in Marine 2216 broth supplemented with 30%

glycerol. Strains survive well on Marine 2216 agar plates or slants stored at 2–4°C.

Differentiation of the genus *Brumimicrobium* from other genera

The most salient traits useful for distinguishing *Brumimicrobium* from other members of the *Cryomorphaceae* include orange pigmentation, gliding motility, facultatively anaerobic metabolism, ability to use D-glucose, lack of reactivity in most phenotypic tests, and ability to grow at low temperatures. The species also has a distinctive fatty acid profile containing only a few major fatty acids.

List of species of the genus *Brumimicrobium*1. *Brumimicrobium glaciale* Bowman, Nichols and Gibson 2003, 1352^{VP}

gla'ci.a.l.e. L. neut. adj. *glaciale* icy, frozen.

The characteristics are as given for the genus, as listed in Table 78, and as given in the text. Inhabits sea-ice algal assemblages and polar marine sediment.

DNA G+C content (mol%): 38–40 (T_m).

Type strain: IC156, ACAM 645, CIP 107451, LMG 21434.

Sequence accession no. (16S rRNA gene): AF521195.

Genus III. *Crocinitomix* Bowman, Nichols and Gibson 2003, 1353^{VP}

JOHN P. BOWMAN

Crocinitomix L. adj. *crocinitomix* of or pertaining to saffron; L. fem. n. *tomix* a string or thread; N.L. fem. n. *Crocinitomix* saffron-colored thread (filament).

Cells are short **rods with rounded ends or filaments**, 0.3–0.5×0.5→20 μm. Occur singly or in pairs. **Gram-stain-negative**. Spores, resting cells, and gas vesicles not present. **Gliding motility is present**. Colonies are **yellow**. **Flexirubin pigments are not produced**. **Strictly aerobic, having an oxidative type of metabolism**. Catalase-positive. Oxidase-negative. **Chemoheterotrophic**. **Non-agarolytic**. **Carbohydrates are not utilized**. Acid is not formed from carbohydrates. Strains **require Na⁺ and yeast extract** for growth. Growth occurs between 0 and 30°C, with optimal growth yield at 20–22°C and pH 6–8. Major fatty acids are C_{15:0}, C_{15:0} iso, C_{15:1} iso ω10c, C_{15:1} ω11c, and C_{16:1} ω12c. **Isolated from beneath frozen sand of the marine upper littoral zone (Subarctic Alaska)**.

DNA G+C content (mol%): 35.

Type species: *Crocinitomix catalasitica* (Lewin 1969) Bowman, Nichols and Gibson 2003, 1353^{VP} (*Microscilla aggregans* subsp. *catalasitica* Lewin 1969, 197).

Further descriptive information

Crocinitomix is a member of the family *Cryomorphaceae* within which it forms a distinct line of descent (Figure 57 in the family *Cryomorphaceae* section). Colonies are saffron-colored, smooth, circular, convex, with slightly irregular edges and a butyrous consistency when grown on Marine 2216 agar. Like other members of the *Cryomorphaceae*, the species requires seawater salts and organic compounds occurring in peptone or yeast extract for growth and has a restricted versatility in regards to its catabolic activity. Growth with peptone occurs if a vitamin solution is supplied, suggesting the species has specific vitamin growth factors which are present in yeast extract.

The type strain attacks L-tyrosine and L-3,4-dihydroxyphenyl-L-alanine and produces alkaline phosphatase and arginine arylamidase activity. The type strain may also be able to form H₂S from L-cysteine (Lewin and Lounsbury, 1969), however,

this activity could not be reproduced (Bowman et al., 2003). Acidification, clotting, or redigestion of curd does not occur in litmus milk. The type strain is otherwise unreactive in standard phenotypic tests including various commercial test strips and trays. The fatty acid profile (Table 78) includes monounsaturated fatty acids with unusual double bond positions including C_{15:1} ω11c, C_{16:1} ω12c, and C_{17:1} ω13c. These fatty acids are apparently unique to this organism which suggests that the organism contains a novel fatty acid desaturase.

Only one isolate (ATCC 23190) of this species has been obtained to date. ATCC 23190 originated from beneath a layer of frozen coastal sand collected in the shallows of subarctic Auke Bay, Alaska.

Enrichment and isolation procedures

Crocinitomix catalasitica was isolated by direct plating of diluted sample material onto Marine agar followed by incubation at 20°C.

Maintenance procedures

For long term storage, *Crocinitomix catalasitica* can be cryopreserved at –80°C in Marine 2216 broth supplemented with 30% glycerol. Strains survive well on Marine 2216 agar plates or slants stored at 2–4°C. The organisms can also be stored by lyophilization.

Differentiation of the genus *Cryomorpha* from other genera

The most salient traits useful for distinguishing *Crocinitomix* from other members of the *Cryomorphaceae* include yellow pigmentation, gliding motility, strictly aerobic oxidative metabolism, inability to use carbohydrates, lack of reactivity in most phenotypic tests, and ability to grow at low temperatures. The species also has a distinctive fatty acid profile (Table 78).

List of species of the genus *Crocinitomix*1. *Crocinitomix catalasitica* (Lewin 1969) Bowman, Nichols and Gibson 2003, 1353^{VP} (*Microscilla aggregans* subsp. *catalasitica* Lewin 1969, 197)

cat.a.la.si'ti.ca. N.L. neut. n. *catalasum* catalase; L. suff. *-icus -a -um*, suffix used in adjectives with the sense of relating to; N.L. fem. adj. *catalasitica* relating to catalase, pertaining to the ability of this species to produce catalase.

The characteristics are as given for the genus, as listed in Table 78, and as given in the text. The only known habitat is frozen sand collected from the marine upper littoral zone of Auke Bay, Alaska, USA.

DNA G+C content (mol%): 35 (T_m).

Type strain: ATCC 23190, NCIMB 1418.

Sequence accession no. (16S rRNA gene): AB078042, M58791.

Genus IV. *Fluviicola* O'Sullivan, Rinna, Humphreys, Weightman and Fry 2005, 2193^{VP}

THE EDITORIAL BOARD

Flu.vi.i.co'la L. masc. n. *fluvius* -ii river; L. suff. -cola (from L. masc. or fem. n. *incola*) inhabitant, dweller; N.L. masc. n. *Fluviicola* river dweller.

Rods 0.4–0.5×1.5–5.7 μm, with rarer longer filaments of up to 51 μm in length. Nonflagellated. **Motile by gliding.** Gram-stain-negative. Strictly aerobic. Cell mass is pigmented yellow-orange. **Flexirubins are synthesized.** **Temperature range for growth, 4–25°C;** optimum, ~20°C. Catalase-positive. **Oxidase-negative.** **Growth does not occur in the presence of Na⁺ ions.** **Negative for nitrate and nitrite reduction.** **Glucose is not utilized for growth.** Fatty acids contain a high proportion of branched-chain fatty acids (mainly C_{15:0} iso and C_{15:1} iso ω10*c*), as well as significant amounts of hydroxy fatty acids (mainly C_{17:0} iso 3-OH). Isolated from freshwater environments.

DNA G+C content (mol%): 37.2.

Type species: *Fluviicola taffensis* O'Sullivan, Rinna, Humphreys, Weightman and Fry 2005, 2193^{VP}.

Enrichment and isolation

Fluviicola taffensis was isolated after incubation for 6 d on casein-yeast-tryptone (CYT) agar* at 20°C, from a 10⁻² dilution of water from the River Taff, a river in Wales.

List of species of the genus *Fluviicola*1. *Fluviicola taffensis* O'Sullivan, Rinna, Humphreys, Weightman and Fry 2005, 2193^{VP}

taf.fen'sis. N.L. masc. adj. *taffensis* pertaining to the River Taff, a river in Wales.

The characteristics are as described for the genus, with the following additional features. Colonies are 1–5 mm in diameter, circular, flat, transparent, shiny, yellow-orange, and creamy on high nutrient solid media. Growth occurs on nutrient agar, plate count agar, tryptic soy agar, and DNase agar, but not on Marine agar 2216, MacConkey agar, or Cetrinide agar. Indole is not produced. Negative for β-galactosidase, urease, and xylanase activity. Capable of

Differentiation of the genus *Fluviicola* from related genera

The main feature distinguishing *Fluviicola* from *Crocinitomix*, *Owenweeksia*, *Brumimicrobium*, and *Cryomorpha* is that *Fluviicola* originated from a freshwater habitat and cannot grow in the presence of Na⁺ ions, whereas the other genera occur in marine habitats and require Na⁺ ions or natural seawater. The aerobic metabolism of *Fluviicola* differentiates it from the fermentative metabolism of *Brumimicrobium*, and gliding motility differentiates it from *Cryomorpha*. Failure to grow at 30°C distinguishes *Fluviicola* from *Crocinitomix* and *Owenweeksia*. Unlike *Owenweeksia*, *Fluviicola* lacks oxidase activity. Unlike *Brumimicrobium*, it does not reduce nitrate and does not utilize glucose.

Taxonomic comments

O'Sullivan et al. (2005) reported that, based on 16S rRNA gene sequence analysis and on construction of a neighbor-joining phylogenetic tree, *Fluviicola* was a member of the family *Cryomorphaceae* within the phylum *Bacteroidetes*. The 16S rRNA gene sequence of *Fluviicola taffensis* showed 88% sequence similarity to that of *Crocinitomix catalasitica*.

DNA hydrolysis and weak gelatin hydrolysis, but not hydrolysis of agar, arginine, esculin, or starch. Acid is not produced from glucose. Does not utilize glucose, arabinose, mannose, mannitol, *N*-acetylglucosamine, maltose, gluconate, caprate, adipate, malate, citrate, or phenylacetate. Resistant to chloramphenicol, streptomycin, and kanamycin, but susceptible to penicillin G, ampicillin, rifampin, and tetracycline. The type strain was isolated from water of the River Taff, Cardiff, UK.

DNA G+C content (mol%): 37.2 (HPLC).

Type strain: RW262, DSM 16823, NCIMB 13979.

Sequence accession no. (16S rRNA gene): AF493694.

Genus V. *Lishizhenia* Lau, Ren, Wai, Qian, Wong and Wu 2006, 2321^{VP}

THE EDITORIAL BOARD

Li.shi.zhe'ni.a N.L. fem. n. *Lishizhenia* named after Li Shizhen (1518–1593), the famous Chinese naturalist.

Rods 0.3–0.5 × 0.5–3.8 μm. Nonflagellated. **Cells are motile by gliding.** Nonsporeforming. Gram-stain-negative. **Halophilic**, growing between 1.0 and 7.5% (w/v) NaCl with optimum growth at 1–3%. **Organic growth factors such as yeast extract or peptone are required for growth.** Colonies are light orange. **Strict aerobes.** **Oxidase-positive.** Catalase- and alkaline phosphatase-positive. **Casein and gelatin are hydrolyzed.** **Carbohydrates are not utilized.** Major respiratory quinone is MK-6. Predominant fatty acids are C_{15:0} iso, C_{15:1} iso, C_{17:0} iso 3-OH, and C_{15:0} iso 2-OH / C_{16:1} ω7*c*.

DNA G+C content (mol%): 35.8.

Type species: *Lishizhenia caseinilytica* Lau, Ren, Wai, Qian, Wong and Wu 2006, 2321^{VP}.

Enrichment and isolation procedures

Lishizhenia caseinilytica was isolated from the outlet of a tank storing sand-filtered sea water by direct plating of samples onto YPS-SW agar*, with incubation for 3 d at 30°C. Orange

*CYT agar contains (g/l of distilled water): pancreatic digest of casein, 1.0; CaCl₂·2H₂O, 0.5; MgSO₄·7H₂O, 0.5; yeast extract, 0.5; and purified agar, 15.0; pH 7.2.

*YPS-SW medium contains: yeast extract, 4 g; peptone, 2 g; starch, 10 g; agar, 15 g; seawater filtered through a membrane filter (0.45 μm pore diameter), 750 ml; and distilled water, 250 ml.

colonies were selected and then purified by repeated restreaking on YPS-SW agar. Cultures can be preserved at -80°C in Marine broth 2216 supplemented with 50% (w/v) glycerol.

Differentiation of the genus *Lishizhenia* from related genera

Unlike *Owenweeksia hongkongensis*, *Lishizhenia caseinilytica* has caseinase activity and a lower mol% G+C of its DNA (35.8 vs 39–40). In contrast to *Fluviicola taffensis*, it requires Na^+ ions, is oxidase positive, lacks DNase, and is susceptible to chloramphenicol. It differs from *Brumimicrobium glaciale*, *Crocinitomix*

catalasitica, and *Cryomorpha ignava* by its ability to grow at 35°C , tolerance to 7.5% NaCl, and positive oxidase reaction.

Taxonomic comments

Lau et al. (2006) reported that, based on 16S rRNA gene sequence analyses, *Lishizhenia caseinilytica* formed a distinct lineage within the family *Cryomorphaceae* and was linked to *Brumimicrobium glaciale* with bootstrap support of 91% by the neighbor-joining algorithm and 80% by maximum-parsimony analysis. Sequence similarities to other members of the family *Cryomorphaceae* were less than 91%.

List of species of the genus *Lishizhenia*

1. *Lishizhenia caseinilytica* Lau, Ren, Wai, Qian, Wong and Wu 2006, 2321^{VP}

ca.sei.ni.ly'ti.ca. N.L. n. *caseinum* casein; N.L. adj. *lyticus* -a -um (from Gr. adj. *lutikos* -ê -on), able to loosen, able to dissolve; N.L. fem. adj. *caseinilytica* casein-dissolving.

The characteristics are as described for the genus, with the following additional features. Enlarged cells and filamentous cells are seen occasionally in stationary phase in broth culture. Colonies are light orange, circular, convex, smooth, glistening, and translucent with an entire margin. Carotenoid pigments are present. Cells are motile by gliding but do not swarm on Marine agar. Mesophilic, growing between 4 and 37°C ; optimum, $27\text{--}30^{\circ}\text{C}$. Growth occurs between pH 5.0 and 9.0; optimum, $\sim\text{pH}$ 7.0. No acid is formed from the following carbohydrates, nor are they utilized: *N*-acetylglucosamine, *D*-adonitol, amygdalin, *D*- and *L*-arabinose, *D*- and *L*-arabitol, arbutin, *D*-cellobiose, dextran, dulcitol, erythritol, esculin, ferric citrate, *D*-fructose, *D*- and *L*-fucose, *D*-galactose, gentiobiose, *D*-glucose, glycerol, glycogen, inositol, *D*-lactose, *D*-lyxose, *D*-maltose, *D*-mannose, *D*-melezitose, *D*-melibiose, methyl α -*D*-glucopyranoside, methyl α -*D*-mannopyranoside, methyl- β -*D*-xylopyranoside,

D-mannitol, potassium gluconate, potassium 2-ketogluconate, potassium 5-ketogluconate, *D*-raffinose, *L*-rhamnose, *D*-ribose, salicin, *D*-sorbitol, *L*-sorbitol, sucrose, *D*-tagatose, *D*-trehalose, *D*-turanose, xylitol, *D*- and *L*-xylose. Glucose, sucrose, and mannitol are not fermented. The cellular fatty acids (and their percentages) are as follows: $\text{C}_{13:0}$ (0.1); $\text{C}_{14:0}$ (1.6); $\text{C}_{16:0}$ (0.5); $\text{C}_{11:0}$ iso (trace); $\text{C}_{13:0}$ iso (0.3); $\text{C}_{13:1}$ at 12–13 (0.1); $\text{C}_{15:0}$ iso (44); $\text{C}_{15:1}$ iso (34.8); $\text{C}_{16:0}$ iso (trace); $\text{C}_{17:1}$ iso ω 5c (0.5); $\text{C}_{14:0}$ iso 3-OH (trace); $\text{C}_{15:0}$ iso 3-OH (2.5); $\text{C}_{16:0}$ 3-OH (0.5); $\text{C}_{16:0}$ iso 3-OH (0.4); $\text{C}_{17:0}$ iso 3-OH (9.3); sum ($\text{C}_{15:0}$ iso 2-OH/ $\text{C}_{16:1}$ ω 7c) (2.0); and sum ($\text{C}_{16:1}$ iso/ $\text{C}_{14:0}$ 3-OH) (trace). Sensitivity is exhibited toward ampicillin (10 μg), chloramphenicol (30 μg), penicillin G (2 U), rifampin (10 μg), tetracycline (30 μg), and polymyxin B (300 U). Resistance is exhibited toward kanamycin (10 μg), gentamicin sulfate (10 μg), and spectinomycin (10 μg).

Source: sand-filtered sea water collected at Port Shelter, adjacent to the Coastal Marine Laboratory, Hong Kong University of Science and Technology.

DNA G+C content (mol%): 35.8 ± 0.5 (HPLC).

Sequence accession no. (16S rRNA gene): AB176674.

Genus VI. *Owenweeksia* Lau, Ng, Ren, Lau, Qian, Wong, Lau and Wu 2005, 1055^{VP}

JOHN P. BOWMAN

O.wen.week'si.a N.L. fem. n. *Owenweeksia* named after Owen B. Weeks, who did a lot of work in the 1950s, 1960s and 1970s on *Flavobacterium*, *Cytophaga* and related species.

Cells are flexible short **rods**, $0.3\text{--}0.5 \times 0.5\text{--}4$ μm . **Filaments may be formed in media supplemented with 0.1% Tween 20**. Cells of old cultures and cells grown at low temperature are enlarged or distorted in shape. **Gram-stain-negative**. Spores and resting cells not present. **Motile by gliding**. **Strictly aerobic, having an oxidative type of metabolism**. Catalase-positive. Oxidase-positive. **Chemoheterotrophic**. **Non-agarolytic**. **Carbohydrates are not utilized**. Acid is not formed from carbohydrates. **Colonies are orange due to carotenoid pigments**. **Flexirubin pigments are not produced**. Strains **require seawater salts and either peptone or yeast extract** for growth. Growth occurs between $4\text{--}37^{\circ}\text{C}$ and pH 5–9, with optimal growth at $25\text{--}33^{\circ}\text{C}$ and pH 6–8. The major fatty acids are $\text{C}_{15:1}$ iso, $\text{C}_{15:0}$ iso, $\text{C}_{17:0}$ iso 3-OH, summed feature

($\text{C}_{15:0}$ iso 2-OH/ $\text{C}_{16:1}$ ω 7c) and $\text{C}_{15:0}$ iso 3-OH. The major respiratory quinone is menaquinone-6. **Isolated from a tank containing sand-filtered sea water**.

DNA G+C content (mol%): 39–40.

Type species: *Owenweeksia hongkongensis* Lau, Ng, Ren, Lau, Qian, Wong, Lau and Wu 2005, 1055^{VP}.

Further descriptive information

Owenweeksia hongkongensis is a member of the family *Cryomorphaceae*, forming a distinct line of descent, only distantly related to *Cryomorpha ignava* (85% 16S rRNA similarity).

Like other members of the *Cryomorphaceae*, *Owenweeksia hongkongensis* requires sea water and organic compounds occurring

in peptone or yeast extract for growth and has a restricted versatility in regard to its catabolic activity. The species grows at salinities between 1–7.5‰. The species produces alkaline phosphatase and esterase (substrate Tween 20), and hydrolyzes gelatin. *Owenweeksia hongkongensis* cannot degrade polysaccharides, casein, or DNA, and cannot lyse autoclaved yeast cells or hemolyze rabbit blood. H₂S and indole production are negative. The species does not utilize or produce acid from a wide range of carbohydrates which suggests that it may utilize mainly amino acids or lipids for growth. Three unidentified fatty acids have been detected in *Owenweeksia hongkongensis*, with equivalent chain lengths of 11.543, 13.565 and 16.582.

Enrichment and isolation procedures

Owenweeksia hongkongensis was isolated from a tank storing sand-filtered sea water by direct plating of samples onto YPS-SW medium and incubating at 30°C. The isolate was subsequently

obtained in pure culture on YPS-SW lacking starch. *Owenweeksia hongkongensis* can be routinely cultured and stored on YP-SW (YPS-SW medium lacking starch), Marine 2216 (Difco), or in a medium containing 0.4% yeast extract in artificial sea water*.

Maintenance procedures

For long term storage, *Owenweeksia hongkongensis* can be cryopreserved at –80°C in YP-SW supplemented with 20% glycerol.

Differentiation of the genus *Owenweeksia* from other genera

The most salient traits useful for distinguishing *Owenweeksia* from other members of the *Cryomorphaceae* include orange pigmentation, gliding motility, strictly aerobic oxidative metabolism, gelatinase production, inability to use carbohydrates, and ability to grow at 30°C or more. The genus also has a substantially different fatty acid profile.

List of species of the genus *Owenweeksia*

Class III. *Sphingobacteriia* class. nov.

PETER KÄMPFER

Sphin.go.bac.te.ri.i'a. N.L. neut. n. *Sphingobacterium* type genus of the type order; suff. *-ia* ending proposed by Gibbons and Murray and by Stackebrandt et al. to denote a class; N.L. neut. pl. n. *Sphingobacteriia* the *Sphingobacterium* class.

The class is defined on the basis of sequence similarities of 16S rRNA gene sequences and comprises morphologically diverse nonsporeforming bacteria that stain Gram-negative. Growth is aerobic or facultatively anaerobic, and a yellow pigmentation is often formed. The class contains one order, *Sphingobacteriales*.

All genera studied for this feature (mainly *Sphingobacterium*) contain high concentrations of sphingophospholipids as cellular lipid components.

DNA G+C content (mol%): 36–49.8.

Type order: **Sphingobacteriales** ord. nov.

Order I. *Sphingobacteriales* ord. nov.

PETER KÄMPFER

Sphin.go.bac.te.ri'a.les. N.L. neut. n. *Sphingobacterium* type genus of the order; suff. *-ales* ending to denote an order; N.L. fem. pl. n. *Sphingobacteriales* the *Sphingobacterium* order.

Cells are rod-shaped and usually nonmotile. Aerobic or facultatively anaerobic. Limited fermentative capabilities are observed in some members. Menaquinones are of the MK-7 (rarely MK-6) type, and a fatty acid pattern containing C_{15:0} iso, C_{15:0} iso 2-OH, C_{15:0} iso 3-OH, C_{16:0}, C_{16:1} ω7c, C_{16:0} 3-OH and C_{17:0} iso 3-OH as the most important components are characteristic. The order contains two families, *Sphingobacteriaceae* Steyn, Segers, Vancanneyt, Sandra, Kersters and Joubert 1998 and *Chitinophagaceae* fam. nov.

Type genus: **Sphingobacterium** Yabuuchi, Kaneko, Yano, Moss and Miyoshi 1983, 592^{VP}.

THE EDITORIAL BOARD

Sphin.go.bac.te.ri.a.ce'a.e. N.L. neut. n. *Sphingobacterium* type genus of the family; *-aceae* ending to denote a family; N.L. fem. pl. n. *Sphingobacteriaceae* family of *Sphingobacterium*

Rods, 0.3–0.6×0.5–0.6 µm. **Aerobic**, having a strictly respiratory type of metabolism. **Flagella are absent**. **Colonies are usually yellowish after several days**. **Catalase-, oxidase-, and phosphatase-positive**. **Indole not produced**. Homospermidine is the major polyamine. Features that differentiate the family from *Flavobacteriaceae* are the possession of **sphingophospholipids and ceramides**, the presence of **menaquinone 7**, a higher mean mol% G+C content of the DNA, and a unique fatty acid content (with C_{15:0} iso, C_{15:0} iso 2-OH, C_{15:0} iso 3-OH, C_{16:0}, C_{16:1} ω7c, C_{16:0} 3-OH, and C_{17:0} iso 3-OH being the most important components). Isolated from soil, activated sludge, and clinical specimens. Free-living and saprophytic, but some species can be opportunistic pathogens.

DNA G+C content (mol%): 36–45.

Type genus: **Sphingobacterium** Yabuuchi, Kaneko, Yano, Moss and Miyoshi 1983, 592^{VP}.

The family includes two genera, *Sphingobacterium* and *Pedobacter*, which are part of rRNA superfamily V and are closely related by rRNA cistron similarity (Steyn et al., 1998).

Most bacteria do not contain sphingophospholipids (SPLs), but members of *Sphingobacteriaceae* contain high concentrations of SPLs as cellular lipid components. The lipid portion of a

sphingophospholipid is a sphingosine molecule in which the amino group is acylated by a fatty acid chain, forming a ceramide. The major molecular species of sphingobacterial ceramides were identified by Yano et al. (1983, 1982) as 2-*N*-2'-hydroxy-13'-methyltetradecanoyl-15-methylhexadecasphinganine, 2-*N*-13'-methyltetradecanoyl-15-methylhexadecasphinganine, and 2-*N*-13'-methyltetradecanoyl-hexadecasphinganine. Naka et al. (2003) reported that the SPLs of the type strains of *Sphingobacterium spiritivorum*, *Sphingobacterium antarcticum*, *Sphingobacterium faecium*, *Sphingobacterium mizutaii*, *Sphingobacterium multivorum*, and *Sphingobacterium thalpophilum* contained ceramide phosphorylethanolamines (CerPE-1 and CerPE-2), ceramide phosphoryl-myoinositols (CerPI-1 and CerPI-2), and ceramide phosphorylmannose (CerPM-1). The ceramide of CerPE-1, CerPI-1, and CerPM-1 was composed of 15-methylhexadecasphinganine (isoheptadeca sphinganine, C_{17:0} iso) and 13-methyltetradecanoic acid (isopentadecanoic acid, C_{15:0} iso), whereas that of CerPE-2 and CerPI-2 was composed of isoheptadeca sphinganine and 2-hydroxy-13-methyltetradecanoic acid (2-hydroxy isopentadecanoic acid, C_{15:0} iso 2-OH). *Sphingobacterium* and *Pedobacter* species contain homospermidine as the major polyamine (Hamana and Nakagawa, 2001a).

Genus I. **Sphingobacterium** Yabuuchi, Kaneko, Yano, Moss and Miyoshi 1983, 592^{VP}

THE EDITORIAL BOARD

Sphin.go.bac.te'ri.um. N.L. n. *sphingosinum* (from Gr. gen. n. *sphingos* of sphinx, and suff. *-ine*) sphingosine; N.L. pref. *sphingo-* pertaining to sphingosine; L. neut. n. *bacterium* a rod, and in biology a bacterium; N.L. neut. n. *Sphingobacterium* a sphingosine-containing bacterium.

Straight rods. Gram-stain-negative. Nonsporeforming. **Lack flagella** but may exhibit a flagellum-independent spreading mechanism known as “sliding motility”. **Catalase-positive**. Chemorganotrophic, without specialized growth factor requirements. **Colonies usually become yellowish after several days at room temperature**. **Indole and acetylmethylcarbinol are not produced**. **Nonproteolytic**. Gelatin is not hydrolyzed. **Heparinase negative**. **Acid is produced from carbohydrates oxidatively**, not fermentatively. Cellular lipids contain **sphingophospholipids** whose ceramide moieties are chiefly branched-chain dihydrosaturated C_{17:0} sphingosin, and the major acid is C_{15:0} iso 2-OH.

DNA G+C content (mol%): 39–42.

Type species: **Sphingobacterium spiritivorum** (Holmes et al., 1982) Yabuuchi, Kaneko, Yano, Moss and Miyoshi 1983, 594^{VP} (*Flavobacterium spiritivorum* Holmes, Owen and Hollis 1982, 161; *Flavobacterium yabuuchiae* Holmes, Weaver, Steigerwalt and Brenner 1988, 351).

Further descriptive information

Some strains of *Sphingobacterium spiritivorum* exhibit sliding motility which, as defined by Henriksen (1972) is “a kind of surface translocation produced by the expansive forces in a

growing culture in combination with special surface properties of the cells resulting in reduced friction between cell and substrate. The micromorphological pattern is that of a uniform sheet of closely packed cells in a single layer. The sheet moves slowly as a unit.”

Sphingobacterium spiritivorum, *Sphingobacterium multivorum*, *Sphingobacterium mizutaii*, and *Sphingobacterium thalpophilum* are free-living and saprophytic organisms (Bernardet et al., 1996) found in environmental habitats such as soil (Fenton and Jarvis, 1994) and composted manure (Kuo et al., 2000). They have also been isolated from human clinical specimens and hospital environments and may be opportunistic pathogens (Yabuuchi et al., 1983). Blood and urine have been the most common sources for the isolation of *Sphingobacterium spiritivorum*. The species has caused cellulitis in the leg of an elderly man (Marinella, 2002); the organism was probably acquired by walking barefoot on soil. Another bacterium isolated from cellulitis of a leg of another elderly man was initially identified as *Sphingobacterium spiritivorum* but later shown by 16S rRNA gene analysis to belong to an undescribed species closely related to *Sphingobacterium mizutaii* (Tronel et al., 2003). *Sphingobacterium multivorum* has been isolated from activated sludge (Liu et al., 2004) and from various clinical specimens; it has occasionally

been associated with serious infections such as septicemia in persons immunocompromised by conditions such as cystic fibrosis, kidney damage, or diabetes (Areekul et al., 1996; Freney et al., 1987; Potvliege et al., 1984; Reina et al., 1992). *Sphingobacterium mizutaii* has been isolated from clinical specimens such as ventricular fluid, synovial fluid, and urine, but its pathogenicity is unknown (Yabuuchi et al., 1983). *Sphingobacterium thalophilum* has been isolated from blood and from leg and foot wounds (Holmes et al., 1983). Strains of *Sphingobacterium thalophilum* have also been isolated from composted manure and are capable of converting oleic acid to 10-ketostearic acid and 10-hydroxystearic acid; these strains may be suited for developing a large-scale production of these products (Kuo et al., 2000).

Sphingobacterium antarcticum has been isolated only from Antarctic soil (Shivaji et al., 1992) and, since it cannot grow above 30°C (at least under laboratory conditions,) it seems unlikely to have clinical significance.

The type strain of *Sphingobacterium faecium* was isolated from the feces of *Bos sprunigenius Taurus*, and reference strain IFO 15337 was isolated from the feces of *Hippopotamus amphibius*. The pathogenicity, if any, of *Sphingobacterium faecium* is unknown.

An aerobic, mesophilic, Gram-stain-negative, nonmotile, rod-shaped bacterium named "*Candidatus comitans*", which is phylogenetically related to the genus *Sphingobacterium*, was reported to live in a mutualistic association with the myxobacterium *Chondromyces crocatus* (Jacobi et al., 1997, 1996). Although rod-shaped when observed in association with the myxobacteria, the cells became highly pleomorphic when grown without the myxobacteria and stopped multiplying after a few transfers. Moreover, some strains of the myxobacteria failed to grow in the absence of the companion sphingobacterium. The nature of the association between the two bacterial species is not understood, but "*Candidatus comitans*" grew well when the two bacteria were physically separated by a membrane that allowed small molecules produced by either strain to pass through.

Some sphingobacteria can utilize or degrade unusual compounds. *Sphingobacterium multivorum* isolated from aerobic sludge was reported to use the herbicide mefenacet as a carbon and energy source (Ye et al., 2004). A strain of *Sphingobacterium multivorum* that was resistant to the antimicrobial compound ϵ -poly-L-lysine (ϵ -PL), a compound that is industrially produced by *Streptomyces albulus* and used as a food additive due to its antimicrobial activities, was reported to produce an aminopeptidase that degraded the ϵ -PL and released L-lysine (Kito et al., 2002). A soil isolate of *Sphingobacterium multivorum* that had been grown on KDN (2-keto-3-deoxy-D-glycero-D-galacto-nononic acid)-oligosaccharide alditols as the sole carbon source synthesized an inducible, periplasmic sialidase that selectively catalyzed the hydrolysis of different types of ketosidic linkages of KDN, but not N-acetylneuraminyllinkages (Nishino et al., 1996). Some strains of *Sphingobacterium thalophilum* have been reported to be capable of cometabolic degradation of pentachlorophenol (PCP) when grown on glucose; the PCP-degrading enzyme was induced by the PCP itself (Liu et al., 2004).

Sphingobacterium multivorum has been used as the recipient via conjugation of a Tn5-marked symbiotic plasmid from *Rhizobium leguminosarum* biovar *trifolii*; root nodules were formed in white clover by the transconjugant but did not fix N₂ (Fenton and Jarvis, 1994).

Differentiation of the genus *Sphingobacterium* from other genera

The genus *Sphingobacterium* differs from the genus *Flavobacterium* by the presence of high concentrations of sphingophospholipids as cellular lipid components, by having menaquinone 7 instead of menaquinone 6, by lacking gliding motility (most strains of *Flavobacterium* are positive), and by having a higher G+C content of its DNA (39–45 vs 32–37 mol%).

Sphingobacterium differs from the genus *Pedobacter* by lacking heparinase (*Pedobacter piscium* is an exception, and *Sphingobacterium antarcticum* has not been tested), production of acid from melibiose (*Sphingobacterium antarcticum* has not been tested, and most strains of *Pedobacter* are negative), an ability to assimilate melezitose (data not reported for *Sphingobacterium antarcticum*), the presence of urease activity (however, most strains of *Sphingobacterium mizutaii* do not hydrolyze urea), and the presence of α -fucosidase activity (except *Sphingobacterium mizutaii*).

Taxonomic comments

Sphingobacterium spiritivorum and *Sphingobacterium multivorum* were formerly included in the genus *Flavobacterium* in the first edition of *Bergey's Manual of Systematic Bacteriology* (Holmes et al., 1984). Later, these species were placed in a newly created genus, *Sphingobacterium*, by Yabuuchi et al. (1983) based on DNA–DNA hybridization data and chemotaxonomic considerations, especially the presence of sphingophospholipids. These authors also included a third species, *Sphingobacterium mizutaii* (name corrected to *mizutaii* by Holmes et al., 1988). *Sphingobacterium mizutaii* was renamed *Flavobacterium mizutaii* as an objective synonym by Holmes et al. (1988), however, rRNA cistron analysis (summarized by Bernardet et al., 1996) indicates that *Sphingobacterium mizutaii*, *Sphingobacterium spiritivorum*, and *Sphingobacterium multivorum*, although closely related to the genus *Flavobacterium*, are sufficiently distinct from it to deserve placement in a separate genus.

Holmes et al. (1988) created the species *Sphingobacterium yabuuchiae*, which differed from *Sphingobacterium spiritivorum*, despite a DNA–DNA hybridization value of 63% between them, by not hydrolyzing 2-naphthyl phosphate (acid phosphatase) strongly at pH 5.4. However, Takeuchi and Yokota (1992) reported that the type strains of both species did hydrolyze 2-naphthyl phosphate at pH 5.4, and that the two species show high similarity in whole-cell protein patterns in SDS–PAGE and in their physiological characteristics. Consequently, Takeuchi and Yokota concluded that the two species were synonymous, i.e., *Sphingobacterium spiritivorum*.

The species *Sphingobacterium faecium* was added to the genus by Takeuchi and Yokota (1992), based on DNA–DNA hybridization, SDS–PAGE, and chemotaxonomic features.

The heparinase-positive species *Sphingobacterium heparinum* (Payza and Korn 1956) Takeuchi and Yokota 1993 was reclassified by Steyn et al. (1998) in a new genus, *Pedobacter*, based on studies using SDS–PAGE and DNA–rRNA hybridization. Although most species of *Pedobacter* are heparinase-positive, the heparinase-negative species *Sphingobacterium piscium* Takeuchi and Yokota 1993 was also reclassified into the genus *Pedobacter* by Steyn et al. 1998 based on rRNA cistron analysis.

Sphingobacterium antarcticum was included in the genus by Shivaji et al. (1992) based on chemotaxonomic data. It differed from the other species by its low-temperature range for growth (2–30°C).

Differentiation of the species of the genus *Sphingobacterium*

Table 79 lists characteristics that differentiate the species of *Sphingobacterium*.

List of species of the genus *Sphingobacterium*

- Sphingobacterium spiritivorum*** (Holmes, Owen and Hollis 1982) Yabuuchi, Kaneko, Yano, Moss and Miyoshi 1983, 594^{VP} (*Flavobacterium spiritivorum* Holmes, Owen and Hollis 1982, 161; *Flavobacterium yabuuchiae* Holmes, Weaver, Steigerwalt and Brenner 1988, 351)

spi.ri.ti'vo.rum. L. n. *spiritus* spirit; L. adj. suff. *vorus* devouring, eating; N.L. neut. adj. *spiritivorum* spirit-devouring, intended to refer to the ability of the organism to attack spirits (i.e., alcohol), producing acid in the process

The following data are taken from Holmes et al. (1982), Yabuuchi et al. (1983), and Takeuchi and Yokota (1992). Some strains show distinctive spreading growth on media containing 0.3% agar, but little or no spreading on media containing 0.5% agar. At the edge of the spreading growth, the cells are arranged in a monolayer, which is typical of

sliding (but not gliding) translocation. Other strains show moderate spreading on semisolid agar medium. Growth occurs at 18–22°C and 37°C but not at 5°C and 42°C.

The following tests are positive: hydrolysis of DNA, esculin, tributyrin, Tween 20, Tween 80, and urea; catalase; oxidase; phosphatase; α-galactosidase; β-D-galactosidase; β-D-cellobiosidase; growth on MacConkey agar, on β-hydroxybutyrate agar, in a standard mineral base medium containing 0.2% glucose and 0.1% (NH₄)₂SO₄, and in the presence of 40% bile. In an ammonium salt medium, acid is produced oxidatively from D-arabinose, cellobiose, ethanol (3%), fructose, galactose, glucose, glycerol, lactose, maltose, mannitol, mannose, melezitose, raffinose, rhamnose, salicin, sucrose, trehalose, and xylose. Gelatin is hydrolyzed by the plate method but not liquefied.

The following tests are negative: acid production from adonitol, dulcitol, glycogen, inositol, D-ribose, and sorbitol; alkali production on Christensen's citrate; growth on Simmons citrate; arginine desmidase; arginine dihydrolase; casein hydrolysis; fluorescence on King medium B; gas from glucose in peptone water sugar medium; gluconate oxidation; growth on cetrinide agar; H₂S production; lysine decarboxylase; malonate utilization; nitrate and nitrite reduction; opalescence on lecithovitellin agar; ornithine decarboxylase; phenylalanine deaminase; pigment production on tyrosine agar; reduction of 0.4% selenite; and 3-ketolactose production. Starch hydrolysis was reported as negative by Holmes et al. (1982) but positive by Yabuuchi (1983).

When tested by API ZYM galleries, no activity was found for the following enzymes: esterase (C-4), lipase (C-14); L-valyl-2-naphthylamide hydrolase, L-cystyl-2-naphthylamide hydrolase, N-glutaryl-L-phenylalanyl-2-naphthylamide hydrolase, α-D-galactosidase, β-D-glucuronidase, α-D-mannosidase, α-D-xylosidase, β-D-fucosidase, β-L-fucosidase, N-acetyl-α-D-glucosaminidase, lactosidase, L-tyrosyl-2-naphthylamide hydrolase, L-phenylalanyl-2-naphthylamide hydrolase, L-hydroxyproyl-2-naphthylamide hydrolase, N-benzoyl-L-leucyl-2-naphthylamide hydrolase, L-isoleucyl-2-naphthylamide hydrolase, and L-prolyl-2-naphthylamide hydrolase.

The type strain is susceptible to sulfadiazine and sulfamethoxazole-trimethoprim but resistant to nalidixic acid and 14 other drugs.

DNA G+C content (mol%): 40 (*T_m*).

Type strain: CDC E7288, ATCC 33861, CCUG 13224, CDC 13224, CIP 100542, DSM 11722, GIFU 3101, JCM 1277, JCM 6897, LMG 8347, NBRC 14948, NCTC 11386.

Sequence accession no. (16S rRNA gene): D14026, EF090267, M58778.

2. *Sphingobacterium anhuiense* Wei, Zhou, Wang, Huang and Lai 2008, 2100^{VP}

an.hu.i.en'se. N.L. neut. adj. *anhuiense* pertaining to Anhui, the province where the type strain was isolated.

Cells are 0.4–0.8×1.8–2.5 μm. Colonies are circular, convex, and bright yellow after 24 h cultivation at 30°C on TYB agar. Growth occurs at 4–35°C; optimum, 25–30°C. The pH range for growth is 6.0–8.0; optimum, 6.5–7.5. Growth occurs with 0–3% NaCl but not with 4% NaCl in modified TYB broth. Starch and DNA are hydrolyzed but Tween 80, casein, and urea are not. Positive for oxidase, methyl-α-D-glucosidase, β-galactosidase, and the Voges-Proskauer test, but negative for arginine dihydrolase, ornithine decarboxylase, lysine decarboxylase, tryptophan decarboxylase, urease, and H₂S production. Citrate is not utilized and indole is not produced (API 20NE system). The following substrates are utilized: N-acetylglucosamine, esculin, D-arabinose, L-arabinose, arbutin, cellobiose, fructose, D-fucose, L-fucose, D-galactose, glucose, inulin, D-lactose, laetrole, maltose, D-mannose, melibiose, methyl-α-D-glucoside, methyl-α-D-mannoside, raffinose, salicoside, starch, and sucrose. The following are not utilized (API 50 CHB system): D-adonitol, D-arabitol, L-arabitol, dulcitol, erythritol, D-fucose,

D-gentiobiose, glycerol, glycogen, gluconate, inositol, 2-ketogluconate, 5-ketogluconate, D-lyxose, mannitol, melezitose, methyl-β-D-xyloside, L-rhamnose, D-ribose, sorbitol, L-sorbitose, D-tagatose, turanose, xylitol, D-xylose, and L-xylose. The predominant isoprenoid quinone is MK-7. Major cellular fatty acids are C_{15:0} iso (32.2%), C_{17:0} iso 3-OH (9.8%), and summed feature 3 (C_{15:0} iso 2-OH and/or C_{16:1} ω7c; 33.7%).

Source: forest soil in Anhui province, China.

DNA G+C content (mol%): 36.3 (HPLC).

Type strain: CW 186, CCTCC AB 207197, KCTC 22209.

Sequence accession no. (16S rRNA gene): EU364817.

3. *Sphingobacterium antarcticum* corrig. Shivaji, Ray, Rao, Saisree, Jagannadham, Kumar, Reddy and Bhargava 1992, 105^{VP}

ant.arc'ti.cum. L. neut. adj. *antarcticum* southern, pertaining to the Antarctic. (*Note:* The original name, *Sphingobacterium antarcticus*, was corrected by Euzéby, 1998)

The following characteristics are taken from Shivaji et al. (1992) and Takeuchi and Yokota (1992). Rods 0.5–1.0 μm×2–3 μm. Colonies on peptone-yeast extract agar are round, pale or bright yellow, smooth, slightly convex, 1–2 mm in diameter. No growth factors are required. Optimal temperature, 25°C; range, 2–30°C, with no growth above 30°C. Optimum pH, 6.9; range for growth, 6–8. NaCl is not required but can be tolerated up to 0.5M.

The following tests are positive: catalase, oxidase, phosphatase, gelatinase, urease, and β-galactosidase; hydrolysis of Tween 20, Tween 80, esculin, and gelatin; H₂S production; growth on β-hydroxybutyrate agar and MacConkey agar; acid production from cellobiose, glucose (1% and 10%), lactose (1% and 10%), mannose, and raffinose; growth on L-arabinose, formate, D-fructose, D-galactose, glucose, glutamate, glycerol, β-hydroxybutyrate, meso-inositol, lactate, lactose, malate, maltose, mannitol, D-mannose, pyruvate, raffinose, L-rhamnose, D-ribose, sorbitol, sucrose, succinate, and D-xylose.

The following tests are negative: fluorescent pigment formation on King's A and B medium; gas production from carbohydrates; intracellular poly-β-hydroxybutyrate granules; starch and casein hydrolysis; reduction of nitrate and nitrite; indole production; growth on cetrinide agar; utilization of acetate, cellulose, citrate, dextrin, glycogen, inulin, malonate, melibiose, and starch as carbon sources; arginine dihydrolase; lysine decarboxylase; acid production from arabinose, ethanol, fructose, galactose, glycerol, meso-inositol, maltose, mannitol, melezitose, rhamnose, salicin, sorbitol, sucrose, and xylose.

The major carotenoid pigments were identified as zeaxanthin, β-cryptoxanthin, and β-carotene (Jagannadham et al., 2000). The major fatty acid is C_{16:1}; the long-chain bases of the sphingophospholipids are C_{16:1}, C_{17:0}, and C_{16:0}.

Source: soil from Schirmacher Oasis, Antarctica.

DNA G+C content: 39–40 (*T_m*).

Type strain: 4BY, ATCC 51969, MTCC 675.

GenBank accession numbers (16S rRNA gene): not reported.

4. *Sphingobacterium canadense* Mehnaz, Weselowski and Lazarovits 2008, 1^{VP} (Effective publication: Mehnaz, Weselowski and Lazarovits 2007, 522.)

ca.na.den'se. N.L. neut. adj. *canadense* of or belonging to Canada, pertaining to its isolation from Canada.

Cells are 0.8–1.0×1.0–1.9 μm. Growth occurs on LB medium at 20–37°C but not at 41°C. Growth occurs at pH 5–10. NaCl concentrations of 0.5–3% are tolerated. After 24–48 h growth on LB, colonies are circular, entire, low convex, and smooth; they initially are off-white in color and turn yellow after a few days; the pigment is not fluorescent. Bacterial cultures are positive for indoleacetic acid production and negative for phosphate solubilization. The following substrates are oxidized: dextrin, α-cyclodextrin, *N*-acetyl-D-galactosamine, *N*-acetyl-D-glucosamine, D-cellobiose, D-fructose, D-galactose, gentiobiose, D-glucose, D-lactose, lactulose, maltose, D-mannose, D-melibiose, D-raffinose, sucrose, D-trehalose, succinic acid monomethyl ester, acetic acid, formic acid, α-ketovaleric acid, propionic acid, L-asparagine, L-proline, and glycerol. The following are not oxidized: D-mannitol, L-arabinose, L-fucose, myo-inositol, maltose, L-rhamnose, D-sorbitol, xylitol, citric acid, D,L-lactic acid, malonic acid, succinic acid, D-alanine, L-alanine, potassium gluconate, trisodium citrate, capric acid, adipic acid, phenylacetic acid, L-aspartic acid, L-glutamic acid, L-histidine, L-leucine, L-ornithine, L-phenylalanine, D-serine, L-serine, and L-threonine. Acid is produced from D- and L-arabinose, D-xylose, D-glucose, D-fructose, D-mannose, methyl-α-D-glucopyranoside, esculin ferric citrate, salicin, D-cellobiose, D-maltose, D-lactose, D-melibiose, D-sucrose, inulin, D-melezitose, D-raffinose, starch, D-turanose, and L-fucose. No acid production occurs with glycerol, erythritol, D-ribose, L-xylose, D-adonitol, methyl-β-D-xylopyranoside, D-galactose, L-sorbose, L-rhamnose, dulcitol, inositol, D-mannitol, D-sorbitol, methyl-α-D-mannopyranoside, arbutin, D-trehalose, *N*-acetylglucosamine, amygdalin, glycogen, xylitol, gentiobiose, D-lyxose, D-tagatose, D-fucose, D-arabitol, L-arabitol, potassium gluconate, potassium 2-ketogluconate, and potassium 5-ketogluconate. Positive for oxidase, urease, nitrate reduction, β-glucosidase, β-galactosidase, and gelatin hydrolysis. Negative for indole production, glucose fermentation, and arginine dihydrolase. The major cellular fatty acids are C_{16:0}, C_{15:0} iso, C_{17:0} iso 3-OH and summed feature 3 (C_{16:1} ω7c/C_{16:1} ω6c).

Source: corn roots in London Ontario, Canada.

DNA G+C content (mol%): 40.5 (HPLC).

Type strain: CR11, LMG 23727, NCCB 100125.

Sequence accession no. (16S rRNA gene): AY787820.

5. ***Sphingobacterium composti*** Ten, Liu, Im, Aslam and Lee 2007, 1372^{VP} (Effective publication: Ten, Liu, Im, Aslam and Lee 2007, 1732.)

com.pos'ti. N.L. gen. n. *composti* of compost.

Cells are 0.4–0.8×2.0–2.5 μm. Colonies are 1.0–1.5 mm in diameter, smooth, convex, round, glossy, and slightly yellow after 6d at 30°C on R2A medium. Growth occurs between 15 and 42°C; optimum, 30°C. Growth occurs at pH 5.5–8.5; optimum, pH 6.5–7.0. The organism grows in the presence of 4% NaCl but not 5%. Growth occurs on trypticase soy agar but not on MacConkey agar. Oxidase positive. Lipase negative. DNA is hydrolyzed but chitin, starch, cellulose, xylan, casein, collagen, and esculin are not. The following substrates are utilized for growth: D-glucose, D-galactose,

D-mannose, D-lyxose, L-xylose, *N*-acetyl-D-glucosamine, salicin, D-cellobiose, D-lactose, D-maltose, D-sucrose, D-trehalose, D-mannitol, and D-sorbitol. The following substrates are not utilized: D-arabinose, L-arabinose, D-fructose, D-fucose, D-xylose, D-melibiose, D-raffinose, L-rhamnose, L-sorbose, D-ribose, pyruvate, formate, acetate, propionate, D,L-3-hydroxybutyrate, valerate, caprate, maleate, fumarate, phenylacetate, benzoate, 3-hydroxybenzoate, 4-hydroxybenzoate, citrate, lactate, malate, malonate, succinate, glutarate, tartrate, itaconate, adipate, suberate, oxalate, gluconate, ethanol, D-adonitol, dulcitol, inositol, xylitol, glycerol, amygdalin, methanol, glycogen, inulin, dextran, L-alanine, L-arginine, L-asparagine, L-aspartic acid, L-cysteine, L-glutamic acid, L-glutamine, L-histidine, glycine, L-isoleucine, L-leucine, L-lysine, L-methionine, L-phenylalanine, L-proline, L-serine, L-threonine, L-tryptophan, L-tyrosine, and L-valine. With the API 20E system, β-galactosidase activity and the Voges-Proskauer test are positive, but arginine dihydrolase, lysine decarboxylase, ornithine decarboxylase, tryptophan deaminase, urease, and gelatinase activities are not present. H₂S and indole are not produced. Acid is produced from D-glucose, D-melibiose, D-sucrose, and amygdalin but not from L-arabinose, D-mannitol, inositol, D-sorbitol, and L-rhamnose. The major fatty acids are C_{15:0} iso, C_{17:0} iso 3-OH, C_{15:0} iso 2-OH, and/or C_{16:1} ω7c.

Source: compost that was collected near Daejeon city in South Korea.

DNA G+C content (mol%): 36.0 (HPLC).

Type strain: T5-12, CCUG 52467, KCTC 12578, LMG 23401.

Sequence accession no. (16S rRNA gene): AB244764.

6. ***Sphingobacterium composti*** Yoo, Weon, Jang, Kim, Kwon, Go and Stackebrandt 2007, 1592^{VP}

com.pos'ti. N.L. gen. n. *composti* of compost.

Cells are 0.5–0.6×1.0–2.0 μm. Colonies on trypticase soy agar are yellow, circular, and convex with entire margins. The temperature, pH, and NaCl ranges for growth are 10–45°C, pH 6–9, and 0–5% NaCl, respectively. Nitrate is not reduced. Indole is not produced. Glucose is not fermented. The following enzyme activities occur: oxidase, arginine dihydrolase, β-galactosidase, alkaline phosphatase, esterase lipase (C8), leucine arylamidase, valine arylamidase, acid phosphatase, naphthol-AS-BI-phosphohydrolase, α-glucosidase, β-glucosidase, and *N*-acetyl-β-glucosaminidase. No activity occurs for esterase (C4), lipase (C14), cystine arylamidase, trypsin, α-chymotrypsin, α-galactosidase, β-glucuronidase, α-mannosidase, and α-fucosidase activities. Tweens 20 and 80 are hydrolyzed but Tween 40, esculin, casein, chitin, carboxymethylcellulose, DNA, gelatin, starch, tyrosine, and urea are not. The following substrates are assimilated: D-glucose, L-arabinose, D-mannose, *N*-acetylglucosamine, D-maltose, D-sucrose, salicin, and D-melibiose. No assimilation occurs of D-mannitol, potassium gluconate, capric acid, adipic acid, malic acid, trisodium citrate, phenylacetic acid, L-rhamnose, D-ribose, inositol, itaconic acid, suberic acid, sodium malonate, sodium acetate, lactic acid, L-alanine, potassium 5-ketogluconate, glycogen, 3-hydroxybenzoic acid, L-serine, L-fucose, D-sorbitol, propionic acid, valeric acid, L-histidine, potassium 2-ketogluconate,

3-hydroxybutyric acid, 4-hydroxybenzoic acid, and L-proline. Acid is produced from D-arabinose, L-arabinose, D-galactose, D-glucose, D-fructose, D-mannose, methyl- α -D-mannopyranoside, methyl- α -D-glucopyranoside, amygdalin, arbutin, salicin, D-cellobiose, D-maltose, D-lactose, D-sucrose, D-raffinose, and L-fucose. Weak acid production occurs with D-xylose, D-melibiose, D-trehalose, and gentiobiose. No acid production occurs with glycerol, erythritol, D-ribose, L-xylose, D-adonitol, methyl- β -D-xylopyranoside, L-sorbose, L-rhamnose, dulcitol, inositol, D-mannitol, D-sorbitol, N-acetylglucosamine, inulin, D-melezitose, starch, glycogen, xylitol, D-turanose, D-lyxose, D-tagatose, D-fucose, D-arabitol, L-arabitol, potassium gluconate, potassium 2-ketogluconate, and potassium 5-ketogluconate. The major fatty acids are summed feature 3 (C_{15:0} iso 2-OH and/or C_{16:1} ω 7c), C_{15:0} iso, and C_{17:0} iso 3-OH

Source: cotton-waste composts in South Korea.

DNA G+C content (mol%): 42.3 (HPLC).

Type strain: 4M24, DSM 18850, KACC 11313.

Sequence accession no. (16S rRNA gene): EF122436.

Taxonomic note: *Sphingobacterium composti* Yoo et al. 2007 is a later homonym of *Sphingobacterium composti* Ten et al. 2007.

7. ***Sphingobacterium daejeonense*** Kim, Ten, Liu, Im and Lee 2006, 2035^{VP}

dae.jeon.en'se. N.L. neut. adj. *daejeonense* pertaining to Daejeon, a city in Korea, where the type strain was isolated.

Cells are 0.5–1.0 \times 1.2–1.8 μ m. Colonies are 1–2 mm in diameter, smooth, convex, round, and slightly yellow after 3 d at 30°C on R2A medium. Growth occurs between 15 and 42°C; optimum, 30°C. The pH range for growth is pH 5.0–9.0; optimum, pH 6.5–7.0. Tolerates 5% (w/v) NaCl, but not 7%. Growth occurs on Trypticase soy agar but not on MacConkey agar. Oxidase-positive. No hydrolysis of chitin, starch, cellulose, DNA, xylan, casein, and esculin. The following substrates are utilized for growth: D-glucose, D-galactose, D-mannose, D-fructose, D-arabinose, D-lyxose, D-xylose, L-xylose, N-acetyl-D-glucosamine, salicin, D-cellobiose, D-lactose, D-maltose, D-melibiose, sucrose, D-trehalose, D-raffinose, D-adonitol, and amygdalin. The following substrates are not utilized for growth: D-fucose, ethanol, L-rhamnose, L-sorbose, L-arabinose, D-ribose, pyruvate, formate, acetate, propionate, D,L-3-hydroxybutyrate, valerate, caprate, maleate, fumarate, phenylacetate, benzoate, 3-hydroxybenzoate, 4-hydroxybenzoate, citrate, lactate, malate, malonate, succinate, glutarate, tartrate, itaconate, adipate, suberate, oxalate, gluconate, dulcitol, inositol, D-mannitol, D-sorbitol, xylitol, glycerol, methanol, glycogen, inulin, dextran, L-alanine, L-arginine, L-asparagine, L-aspartic acid, L-cysteine, L-glutamic acid, L-glutamine, L-histidine, glycine, L-isoleucine, L-leucine, L-lysine, L-methionine, L-phenylalanine, L-proline, L-serine, L-threonine, L-tryptophan, L-tyrosine, and L-valine. With the API 20E system, β -galactosidase and the Voges–Proskauer test are positive, but arginine dihydrolase, lysine decarboxylase, ornithine decarboxylase, tryptophan deaminase, urease, gelatinase, H₂S, and indole production are negative. Acid is produced from D-glucose, D-melibiose, and amygdalin but not from L-arabinose, D-mannitol, inositol, D-sorbitol,

L-rhamnose, or sucrose. MK-7 is the predominant menaquinone. The major fatty acids are C_{15:0} iso, summed feature 4 (C_{15:0} iso 2-OH and/or C_{16:1} ω 7c) and C_{17:0} iso 3-OH.

Source: compost collected near Daejeon city in South Korea

DNA G+C content (mol%): 38.7 (HPLC).

Type strain: TR6-04, CCUG 52468, KCTC 12579, LMG 23402.

Sequence accession no. (16S rRNA gene): AB249372.

8. ***Sphingobacterium faecium*** Takeuchi and Yokota 1993, 864^{VP} (Effective publication: Takeuchi and Yokota 1992, 478.)

fae'ci.um. L. n. *faex faecis* dregs; L. gen. pl. n. *faecium* of feces.

The following data are taken from Takeuchi and Yokota (1993). Rods 0.4–0.5 \times 0.5–1.0 μ m. No sliding translocation occurs. Circular, entire, low convex, smooth, and opaque colonies develop on nutrient agar after 2d; on nutrient agar, a yellow or creamy white, nonfluorescent pigment is produced. Growth occurs at 5°C and 37°C but not at 42°C.

The following tests are positive: catalase, oxidase, urease, DNase, and phosphatase (alkaline and acid); esculin hydrolysis; utilization of L-arabinose, cellobiose, D-fructose, D-glucose, inulin, maltose, raffinose, starch, sucrose, and D-xylose; acid production from D- and L-arabinose, L-fucose, inulin, melibiose, melezitose, raffinose, salicin, and trehalose; production of α -galactosidase, β -glucosidase, and valine arylamidase.

The following tests are negative: trypsin; β -glucuronidase; gelatinase; indole; reduction of nitrate and nitrite; utilization of agar, arginate, cellulose, chitin, heparin, pectin, polypectate, and succinoglucon; acid production from ethanol (3%), mannitol, rhamnose, D-ribose, sorbose, xylitol, and L-xylose.

The major isoprenoid quinone is MK-7. The major non-polar fatty acids from whole cells are C_{15:0}, C_{16:1}, C_{15:0} iso 2-OH, C_{15:0} iso 3-OH, and C_{17:0} iso 3-OH.

Source: The type strain was isolated from the feces of *Bos sprunigenius taurus*. Reference strain NBRC 15299 was isolated from the feces of *Hippopotamus amphibios*.

DNA G+C content (mol%): 39–40 (HPLC).

Type strain: KS 0470, CIP 104193, JCM 21820, LMG 14022, NBRC 15299.

Sequence accession no. (16S rRNA gene): AJ438176.

9. ***Sphingobacterium kitahiroshimense*** Matsuyama, Katoh, Ohkushi, Satoh, Kawahara and Yumoto 2008, 1579^{VP}

kitahi.ro.shim.en'se. N.L. neut. adj. *kitahiroshimense* pertaining to Kitahiroshima city, where the type strain was isolated).

Cells are 0.5–0.6 \times 0.6–0.8 μ m. Oxidase positive. Circular, entire, low convex, smooth colonies develop on nutrient agar after 2d, and a yellow or creamy white, nonfluorescent pigment is produced. The temperature range for growth is 4–37°C; no growth occurs at 42°C. Esculin is hydrolyzed but gelatin is not. Indole is not produced. Nitrate is not reduced. Urease, alkaline phosphatase, acid phosphatase, α -glucosidase, β -glucosidase, α -galactosidase and α -mannosidase activities are present. The following substrates are utilized (GN2 Biolog system): dextrin, Tween 40, Tween 80, cellobiose, N-acetylglucosamine, D-fructose,

D-galactose, gentiobiose, α -D-glucose, α -D-lactose, maltose, D-mannose, melibiose, raffinose, L-rhamnose, sucrose, trehalose, turanose, α -ketovaleric acid, L-alanine, L-glutamic acid, L-threonine, L-proline, and L-serine. Acid is produced from trehalose, raffinose, L-arabinose, and L-xylose. The following enzyme activities do not occur: arginine dihydrolase, DNase, esterase (C4), lipase (C4), cystine arylamidase, trypsin, chymotrypsin, β -galactosidase, and fucosidase. No utilization occurs of citrate, L-arabinose, L-histidine, adonitol, erythritol, L-fucose, D-sorbitol, xylitol, formic acid, D-gluconic acid, DL-lactic acid, malonic acid, inosine, or glycerol. Acid is not produced from rhamnose. Contains branched-17:0 dihydrosphingosine as the main sphingosine. Predominant fatty acids are C_{15:0} iso 2-OH and/or C_{16:1} ω 7c (summed feature 3), 40.28%; C_{15:0} iso, 28.89% and C_{17:0} iso 3-OH, 12.83%.

Source: soil from Kitahiroshima city, Japan.

DNA G+C content (mol%): 36.9 (HPLC).

Type strain: 10C, JCM 14970, NCIMB 14398.

Sequence accession no. (16S rRNA gene): AB361248.

10. **Sphingobacterium mizutaii** Yabuuchi, Kaneko, Yano, Moss and Miyoshi 1983, 595^{VP}

mi.zu'tai.i. N.L. gen. masc. n. *mizutaii* of Mizuta, named after Shunsuke Mizuta, Japanese pediatrician, who first reported a case of meningitis in a premature baby from whose spinal fluid the type strain of the species was isolated. (Note: The original spelling *mitzai* was corrected by Holmes et al. (1988). Objective synonym: *Flavobacterium mizutaii* Holmes, Weaver, Steigerwalt and Brenner 1988, 353)

The following data are taken from Yabuuchi et al. (1983). The characteristics are as described for the genus, with the following additional information. No sliding or gliding translocation occurs. Bile (40%) is tolerated. Acid is produced from D-arabinose, cellobiose, fructose, glucose, lactose, maltose, mannose, melezitose, rhamnose, salicin, and sucrose in oxidation-fermentation medium. Esculin is hydrolyzed.

The following tests are negative: α -galactosidase; acid production from ethanol (3%), glycogen, inulin, and mannitol; utilization of malonate; growth at pH 5.0; fumarate respiration; hydrolysis of starch and DNA; and reaction on egg yolk agar.

Most strains do not oxidize glycogen or hydrolyze urea. Nitrate is not reduced to nitrite, but the type strain and some other strains reduce nitrite to N₂.

The major fatty acids are C_{16:1}, C_{15:0} iso, C_{15:0} iso 2-OH, and C_{17:0} iso 3-OH, with small percentages of C_{16:0}, C_{17:1} iso, and C_{15:0} iso 3-OH.

The type strain is susceptible to carbenicillin, chloramphenicol, tetracycline, erythromycin, sulfadiazine, and sulfamethoxazole-trimethoprim but is resistant to penicillin, ampicillin, cephalothin, streptomycin, amikacin, kanamycin, gentamicin, clindamycin, colistin, and polymyxin B.

Pathogenicity has not been defined. The natural habitat of this organism is not known, but the organism has been isolated from clinical specimens.

DNA G+C content (mol%): 39.0–41.5 (T_m).

Type strain: ATCC 33299, CCGU 15907, CIP 101122, GIFU 1203, KC1794, LMG 8340, NBRC 14946, NCTC 12149.

Sequence accession no. (16S rRNA gene): AJ438175, D14024, M58796.

11. **Sphingobacterium multivorum** (Holmes, Owen and Weaver 1981) Yabuuchi, Kaneko, Yano, Moss and Miyoshi 1983, 594^{VP} (*Flavobacterium multivorum* Holmes, Owen and Weaver 1981, 25; CDC group IIk biotype 2 of Tatum, Ewing and Weaver 1974)

mul.ti.vo'rum. L. adj. *multus* many; L. v. *vorare* to swallow; N.L. neut. adj. *multivorum* intended to mean produces acid from many carbohydrates.

The following data are taken from Holmes et al. (1981) and Yabuuchi et al. (1983). No sliding motility occurs on semisolid agar medium. A weak acid reaction is observed on Kligler iron agar slants. Growth occurs at 18–20°C and 37°C but not at 5°C and 42°C. Growth occurs in a standard mineral base medium containing 0.2% glucose and 0.1% (NH₄)₂SO₄.

The following tests are positive: growth on MacConkey agar; growth in heart infusion broth adjusted to pH 5.0; hydrolysis of urea, esculin, tributyrin, and Tween 20; oxidase, phosphatase, α -galactosidase, and β -galactosidase; acid production (in an ammonium salt medium) from D-arabinose, L-arabinose, cellobiose, fructose, galactose, glucose, glycerol, glycogen, inulin, lactose, maltose, mannose, melezitose, raffinose, salicin, sucrose, trehalose, and xylose.

The following tests are negative: fluorescence on King medium B; acid production from adonitol, dulcitol, ethanol (3%), inositol, mannitol, rhamnose, D-ribose, and sorbitol; alkaline reaction on Christensen citrate agar; growth on cetrimide; growth on Simmons citrate; arginine desamidase; arginine deaminase; casein hydrolysis; fluorescence on King medium B; gas from peptone–water–glucose medium; gluconate oxidation; H₂S production (by both lead acetate paper and triple sugar iron agar methods); indole production; 3-ketolactose production; lysine decarboxylase; malonate utilization; ornithine decarboxylase, phenylalanine deaminase; reduction of selenite and nitrate; reduction of nitrite to N₂; and starch hydrolysis.

Tests for the following enzyme activities are positive (using various API ZYM galleries): alkaline phosphatase, L-leucyl-2-naphthylamide hydrolase, acid phosphatase, phosphoamidase, N-acetyl- β -D-glucosaminidase, β -D-cellobiosidase, L-phenylalanyl-2-naphthylamide hydrolase, L-lysyl-2-naphthylamide hydrolase, L-histidyl-2-naphthylamide hydrolase, glycyl-2-naphthylamide hydrolase, α -L-aspartyl-2-naphthylamide hydrolase, L-arginyl-2-naphthylamide hydrolase, L-alanyl-2-naphthylamide hydrolase, S-benzyl-L-cysteyl-2-naphthylamide hydrolase, L-methionyl-2-naphthylamide hydrolase, L-glycyl-glycyl-2-naphthylamide hydrolase, glycyl-L-phenylalanyl-2-naphthylamide hydrolase, glycyl-L-prolyl-2-naphthylamide hydrolase, L-leucyl-glycyl-2-naphthylamide hydrolase, L-seryl-tyrosyl-2-naphthylamide hydrolase, L-glutaminy-2-naphthylamide hydrolase, α -L-glutamyl-2-naphthylamide hydrolase, L-ornithyl-2-naphthylamide hydrolase, L-seryl-2-naphthylamide hydrolase, L-tryptophyl-2-naphthylamide hydrolase, and N-carbobenzoxy-glycyl-glycyl-L-arginyl-2-naphthylamide hydrolase.

Tests for the following enzyme activities are negative (using various API ZYM galleries): esterase (C-4), lipase (C-14),

L-cystyl-2-naphthylamide hydrolase, *N*-benzoyl-DL-arginyl-2-naphthylamide hydrolase, *N*-glutaryl-L-phenylalanyl-2-naphthylamide hydrolase, β -D-glucuronidase, α -D-mannosidase, β -D-fucosidase, β -L-fucosidase, *N*-acetyl- α -D-glucosaminidase, arylsulfatase, L-hydroxypropyl-2-naphthylamide hydrolase, *N*-benzoyl-L-leucyl-2-naphthylamide hydrolase, *N*-carbobenzoxy-L-arginyl-4-methoxyl-2-naphthylamide hydrolase, and L-prolyl-2-naphthylamide hydrolase.

The major carotenoid pigments were identified as zeaxanthin, β -cryptoxanthin, and β -carotene (Jagannadham et al., 2000). The major fatty acids extracted from saponified whole cells of the type strain are C_{15:0} iso 2-OH, C_{15:0} iso, C_{16:1}, and C_{17:0} iso 3-OH. Zeaxanthin and menaquinone-7 biosynthesis occurs via the methylerythritol phosphate pathway (Rosa-Putra et al., 2001).

The type strain is susceptible to sulfadiazine, sulfamethoxazole-trimethoprim, carbenicillin and gentamicin but resistant to penicillin, ampicillin, cephalothin, amikacin, kanamycin, colistin, and polymyxin B. Intermediate levels of susceptibility are observed with streptomycin, tetracycline, chloramphenicol, erythromycin, and nalidixic acid.

DNA G+C content (mol%): 42 (T_m).

Type strain: CDC B5533, ATCC 33613, CCUG 11736, CIP 100541, DSM 11691, GIFU 2812, JCM 21156, LMG 8342, NBRC 14947, NCTC 11343, NRRL B-14861.

Sequence accession no. (16S rRNA gene): AB100738, AY787820, D14025.

12. **Sphingobacterium siyangense** Liu, Shen, Wang and Chen 2008, 1461^{VP}

si.yang.en'se. N.L. neut. adj. *siyangense* pertaining to Siyang in Jiangsu Province, China, the city where the strain was isolated).

Cells are 0.7–0.9×0.8–1.7 μ m. Colonies are 1.0–2.0 mm in diameter, slightly yellowish, convex, circular and smooth with entire margins after 2 d on LB agar. Growth occurs at 4–42°C; optimum, 30–37°C. Growth occurs at pH 3.0–10.0; optimum, 6.0–8.0. Tolerant to 0–4% NaCl; optimum, 0–2%. Growth occurs on nutrient agar and cetrimide agar, but not on Simmons' citrate agar or MacConkey agar. Oxidase positive. The following tests are positive (API 20E system): β -galactosidase, arginine dihydrolase, arginine decarboxylase, urease, and nitrate reduction. Negative for ornithine decarboxylase, lysine decarboxylase, tryptophan deaminase, indole and H₂S production, and the Voges-Proskauer reaction. Starch, DNA, esculin, and Tween 20 are hydrolyzed but casein, gelatin, carboxymethylcellulose, Tween 80, and chitin are not. Acid is produced from trehalose and L-rhamnose, but not from D-glucose, cellobiose, D-galactose, sucrose, D-lactose, melezitose, melibiose, raffinose, D-mannitol, D-sorbitol, and inositol. The following substrates are utilized: D-xylose, melibiose, turanose, maltose, D-fructose, D-glucose, D-lactose, sucrose, L-sorbose, trehalose, D-galactose, raffinose, L-rhamnose, L-arabinose, cellobiose, D-ribose, D-mannose, melezitose, i-erythritol, adonitol, L-arabitol, xylitol, D-sorbitol, D-mannitol, salicin, inulin, dextrin, *N*-acetyl-D-glucosamine, gluconate, lysine, amygdalin and glycerol; inositol, acetate, malonate, and tyrosine are not utilized. The predominant fatty acids are C_{15:0} iso (32.9%), C_{16:0} (10.9%) and summed feature 3 (C_{15:0} iso 2-OH and/or C_{16:1} ω 7 ϵ ; 24.1%).

Source: soil sample from Jiangsu Province, PR China.

DNA G+C content (mol%): 38.5 (T_m).

Type strain: SY1, CGMCC 1.6855, KCTC 22131.

Sequence accession no. (16S rRNA gene): EU046272.

13. **Sphingobacterium thalpophilum** (Holmes, Hollis, Steigerwalt, Pickett and Brenner 1983) Takeuchi and Yokota 1993, 864^{VP} (Effective publication: Takeuchi and Yokota 1992, 479) (*Flavobacterium thalpophilum* Holmes, Hollis, Steigerwalt, Pickett and Brenner 1983, 679)

thal.po'phi.lum. Gr. n. *thalpos* warmth; Gr. neut. adj. *philon* loving; N.L. neut. adj. *thalpophilum* warmth-loving.

The following data are taken from Holmes et al. (1983), Dees et al. (1985), and Takeuchi and Yokota (1993). No sliding motility occurs. Colonies on nutrient agar are circular, low convex, smooth, and opaque after 2 d. Eventually a yellow pigment is produced that is not fluorescent. Nonhemolytic on 5% (v/v) horse blood agar. No brown pigment is produced on tyrosine agar. Growth occurs at room temperature (18–22°C) and at 37°C and at 42°C but not at 5°C.

Does not tolerate 0.0075% KCN. Growth occurs on β -hydroxybutyrate agar (without production of lipid inclusion granules) and on MacConkey agar, but not on cetrimide agar.

The following tests are positive: acid slant and weak acid on Triple iron agar (TSI) slants; utilization of L-arabinose, cellobiose, D-fructose, D-glucose, inulin, maltose, raffinose, sucrose, and D-xylose; reduction of nitrate to nitrite; catalase, phosphatase, urease, phosphatase, and β -D-galactosidase; acid production in ammonium salt medium under aerobic conditions from glucose, adonitol, D- and L-arabinose, cellobiose, fructose, L-fucose, glycerol, inulin, lactose, maltose, D-raffinose, rhamnose, salicin, sucrose, trehalose, and xylose; acid production from 10% (w/v) glucose and lactose; hydrolysis of Tween 20, Tween 80, esculin, DNA, and tributyrin; production of α -galactosidase, β -glucosidase, esterase (C4), cystine arylamidase, valine arylamidase, α -mannosidase, and α -fucosidase.

The following tests are negative: acid production from ethanol (3%), L-xylose, mannitol, D-ribose, sorbose, and xylitol; hydrolysis of casein; nitrite reduction; opalescence on lecithovitellin agar; citrate utilization; malonate utilization; gluconate oxidation; arginine deiminase; arginine deaminase; lysine decarboxylase; ornithine decarboxylase; phenylalanine deaminase; production of 3-ketolactose; indole production; H₂S production; selenite production; production of acid in ammonium salt medium under aerobic conditions from dulcitol, ethanol, inositol, mannitol, and sorbitol; gas from glucose in peptone water medium.

Starch hydrolysis was reported as negative by Holmes et al. (1983) but positive by Dees et al. (1985). DNase was reported negative by Takeuchi and Yokota (1992) but positive by Dees et al. (1985) and positive for six of seven strains by Holmes et al. (1983).

The following substrates are hydrolyzed (using API ZYM galleries): 2-naphthyl phosphate at pH 8.5; L-leucyl-2-naphthylamide; 2-naphthyl phosphate at pH 5.4; naphthol-AS-B-phosphodiamide; 2-naphthyl- α -D-glucopyranoside; 1-naphthyl-*N*-acetyl- β -D-glucosaminide; 4-methylumbelliferyl-cellobiopyranoside; L-pyrrolidonyl- β -

naphthylamide; L-lysyl- β -naphthylamide; L-histidyl- β -naphthylamide; glycyl- β -naphthylamide; L-aspartyl- β -naphthylamide; L-arginyl- β -naphthylamide; L-alanyl- β -naphthylamide; γ -L-glutamyl- β -naphthylamide; S-benzyl-L-cysteyl- β -naphthylamide; DL-methionyl- β -naphthylamide; glycyl-glycyl- β -naphthylamide hydrobromide; glycyl-L-phenylalanyl- β -naphthylamide; glycyl-L-prolyl- β -naphthylamide; L-leucyl-glycyl- β -naphthylamide; L-seryl-L-tyrosyl- β -naphthylamide; L-glutamine- β -naphthylamide hydrochloride; α -L-glutamyl- β -naphthylamide; L-ornithyl- β -naphthylamide; L-seryl- β -naphthylamide; L-threonyl- β -naphthylamide; L-tryptophyl- β -naphthylamide; and N-carbobenzoxy-glycyl-glycyl-L-arginine- β -naphthylamide.

No hydrolysis of the following substrates occurs (using API ZYM galleries): 2-naphthyl butyrate; 2-naphthyl myristate; L-cystyl-2-naphthylamide; N-benzoyl-DL-arginine-2-naphthylamide; N-glutaryl-phenylalanine-2-naphthylamide; naphthol-AS-B1- β -D-glucuronic

acid; 6-bromo-2-naphthyl- α -D-mannopyranoside; 6-bromo-2-naphthyl- β -D-xylopyranoside; *p*-nitrophenyl- α -D-xylopyranoside; *p*-nitrophenyl- β -D-fucopyranoside; *p*-nitrophenyl- β -L-fucopyranoside; *o*-nitrophenyl-N-acetyl- α -D-glucosaminide; L-hydroxyprolyl- β -naphthylamide; N-benzoyl-L-leucyl- β -naphthylamide; L-isoleucyl- β -naphthylamide; and L-prolyl- β -naphthylamide hydrochloride.

The major nonpolar fatty acids from whole cells are C_{15:0} iso, C_{16:1}, C_{15:0} 2-OH, C_{15:0} 3-OH, and C_{17:0} iso 3-OH.

Resistant to ampicillin, carbenicillin, cephalothin, amikacin, gentamicin, kanamycin, tobramycin, chloramphenicol, and tetracycline (strain K-1232 is susceptible). Susceptible to rifampin.

DNA G+C content (mol %): is 42–45 (T_m).

Type strain: K-1173, ATCC 43320, CCUG 22397, CIP 100935, NBRC 14963, NCTC 11429, NRRL B-14902.

Sequence accession no. (16S rRNA gene): AJ438177, D14020, M58779.

Genus II. *Pedobacter* Steyn, Segers, Vancanneyt, Sandra, Kersters and Joubert 1998, 171^{VP}

ROSA MARGESIN AND SISINTHY SHIVAJI

Pe.do.bac'ter. Gr. neut. n. *pedon* soil; N.L. masc. n. *bacter* rod; N.L. masc. n. *Pedobacter* rod from soil.

Rod-shaped cells, 0.5–0.9 \times 0.8–3.2 μ m. **Gram-stain-negative**. Endospores are not formed. Nonmotile (*Pedobacter africanus*, *Pedobacter caeni*, *Pedobacter roseus*, *Pedobacter suwonensis*, *Pedobacter piscium*, *Pedobacter himalayensis*) or motile by gliding (*Pedobacter heparinus*, *Pedobacter cryoconitis*, *Pedobacter saltans*). **Aerobic**. Isolates grow at 5°C; maximum temperature for growth is 25°C (*Pedobacter cryoconitis*, *Pedobacter himalayensis*) or 30°C; *Pedobacter saltans* and *Pedobacter suwonensis* grow at 37°C. Colonies on solid media are round (diameter, 0.5–4 mm), convex with entire margins, pale white or pigmented (yellow to pink), sometimes mucoid/slimy (*Pedobacter caeni*, *Pedobacter cryoconitis*, *Pedobacter himalayensis*, *Pedobacter suwonensis*). **Catalase-, oxidase-, and phosphatase-positive; esculin hydrolysis positive. Nitrate reductase- and urease-negative**. H₂S is not produced from thiosulfate; indole is not produced from tryptophan. Chemoorganotrophic with oxidative type of metabolism. Glucose is not fermented. D-Glucose, D-lactose, D-maltose, D-mannose, L-melibiose, N-acetylglucosamine, salicin, sucrose, and trehalose are used as sole carbon sources. Adipate, caprate, citrate, citric acid, D-arabitol, L-arabitol, D-fucose, lysine, D-lyxose, malate, D-tagatose, dulcitol, inositol, 5-ketogluconate, phenylacetate, and L-sorbose are not utilized as sole carbon sources. Acid is not produced from D-adonitol and L-rhamnose. Major fatty acids are C_{15:0} iso 2-OH/C_{16:1} ω 7c, C_{15:0} iso, and C_{17:0} iso 3-OH. All the species are phylogenetically closely related to one another at the 16S rRNA gene level (>95%) except *Pedobacter saltans*, which shows >10% difference.

DNA G+C content (mol %): 36–45.

Type species: ***Pedobacter heparinus*** (Payza and Korn 1956) Steyn, Segers, Vancanneyt, Sandra, Kersters and Joubert 1998, 175^{VP}; (*Flavobacterium heparinum* Payza and Korn 1956, 854; *Cytophaga heparina* Christensen 1980, 474; *Sphingobacterium heparinum* Takeuchi and Yokota 1992, 465–482).

Further descriptive information

At the time of writing, nine species of *Pedobacter* had been described; five of them since 2003. See the *Editorial note*, below,

for a listing of the 22 species since published. However, only the type species *Pedobacter heparinus* has been studied in detail. Systematic investigations do not exist. In this edition of the *Manual*, the genus *Pedobacter* is included in the phylum *Bacteroidetes*, class *Sphingobacteriia*, order *Sphingobacteriales*, and family *Sphingobacteriaceae*.

Cell morphology. Cells of *Pedobacter* are rod shaped (0.5–0.9 μ m wide) with rounded or slightly tapering ends. The length of the rods varies from short (0.5–1.0 μ m) to long (up to 6–10 μ m) Figure 58. Filament formation has been observed with *Pedobacter caeni*, and occasionally with *Pedobacter heparinus*. No flagella or pili have been observed.

Cell-wall composition. The cell wall of *Pedobacter* species is Gram-stain-negative and there is a need to study its

FIGURE 58. Phase-contrast photomicrograph of *Pedobacter heparinus* DSM 2366, grown in nutrient broth for 24 h at 30 °C. Bar = 10 μ m.

ultrastructural characteristics. It possesses sphingolipids, but little is known with respect to other lipids that may be present. *Pedobacter cryoconitis* produces an extracellular mucous polysaccharide capsule (Margesin et al., 2003). This could be an adaptative feature, as it is generally observed in psychrophilic microorganisms (Gounot, 1999). Psychrophilic species of *Pedobacter*, namely *Pedobacter cryoconitis* and *Pedobacter himalayensis*, also produce mucus (Margesin et al., 2003; Shivaji et al., 2005), and colonies of mesophilic *Pedobacter caeni* (Vanparys et al., 2005) are slimy. In these species, the chemical nature of the mucus and the slime is yet to be determined. All species of *Pedobacter* contain MK-7 as the major menaquinone (68–90%) (Kwon et al., 2007; Shivaji et al., 2005; Steyn et al., 1998), however, the composition of the menaquinones varies from species to species. In *Pedobacter himalayensis* (Shivaji et al., 2005), the menaquinones present are MK-7 (68%), MK-7 (H₂) (5%), MK-8 (6%), MK-8 (H₂) (13%), and MK-9 (H₂) (8%). In *Pedobacter suwonensis* (Kwon et al., 2007), MK-7 constitutes 90.5% of the total, with MK-9 (5.6%), and MK-8 (3.9%) constituting less than 10% together. The predominance of MK-7 in the genus *Pedobacter* is a characteristic feature of the family *Sphingobacteriaceae* and is a discriminating chemotaxonomic feature that differentiates *Pedobacter* from *Cytophaga* (Reichenbach, 1989).

The cellular fatty acid composition of the various species of *Pedobacter* has been studied as a chemotaxonomic marker, and the predominant fatty acids are C_{15:0} iso, C_{15:0} iso 2-OH, C_{15:0} iso 3-OH, C_{16:0}, C_{16:1} ω7c, C_{17:1} iso ω9c, and C_{17:0} iso 3-OH (Dees et al., 1985; Hwang et al., 2006; Kwon et al., 2007; Shivaji et al., 2005; Steyn et al., 1998; Takeuchi and Yokota, 1992; Vanparys et al., 2005, 1983; Yabuuchi and Moss, 1982). In eight of the species, namely *Pedobacter suwonensis*, *Pedobacter himalayensis*, *Pedobacter cryoconitis*, *Pedobacter heparinus*, *Pedobacter africanus*, *Pedobacter piscium*, *Pedobacter saltans*, and *Pedobacter caeni*, all of the above seven fatty acids are present, but in *Pedobacter roseus*, C_{15:0} iso 3-OH, C_{16:0}, and C_{17:1} iso ω9c are absent and C_{16:0} iso 3-OH is unique to the species (Hwang et al., 2006). Quantitatively, the predominant fatty acid is C_{15:0} iso (15–35%), followed by C_{16:1} ω7c (20–31%) (Kwon et al., 2007; Margesin et al., 2003; Shivaji et al., 2005). As a group, the branched-chain fatty acids, (C_{15:0} iso, C_{15:0} iso 2-OH, C_{15:0} iso 3-OH, C_{17:1} iso ω9c, and C_{17:0} iso 3-OH), constitute 70–80% of the total fatty acids. The unsaturated fatty acid C_{16:1} ω7c is also present in substantial quantities (20–30%) and the saturated fatty acid C_{16:0} constitutes 3–9% of the total cellular fatty acid content (Shivaji et al., 2005; Steyn et al., 1998). The other fatty acids that are observed in a few of the species of *Pedobacter* in trace amounts or <5% of the total fatty acid composition include C_{14:0}, C_{15:0}, C_{15:1} ω6c, C_{15:0} anteiso, C_{16:1} ω5c, C_{16:0} 10 methyl, C_{16:0} 2-OH, C_{16:0} 3-OH, C_{17:1} anteiso ω9c, and C_{17:0} iso 3-OH (Shivaji et al., 2005; Steyn et al., 1998; Vanparys et al., 2005). The preponderance of branched and unsaturated fatty acids in species of *Pedobacter* would imply that the membranes of these bacteria prefer increased membrane fluidity, since branched and unsaturated fatty acids are known to increase membrane fluidity and unbranched and saturated acids decrease it (Chintalapati et al., 2005; Shivaji, 2005). It is also interesting to note that a characteristic feature of all the representatives of *Sphingobacteriaceae*, including the species belonging to the genera *Sphingobacterium* and *Pedobacter*, is the presence of significant amounts of C_{15:0} iso, C_{15:0} iso 2-OH, C_{16:1} ω7c, and C_{17:0} iso 3-OH (Shivaji et al., 2005; Steyn et al., 1998).

This feature also differentiates *Pedobacter* from other genera of the family *Flavobacteriaceae* (Bernardet et al., 1996).

Cellular polyamine analysis of *Sphingobacterium antarcticus* (Shivaji et al., 1992), *Sphingobacterium multivorum*, *Sphingobacterium spiritivorum*, *Pedobacter heparinus*, *Pedobacter piscium*, and *Flexibacter canadensis* indicated that homospermidine is the major polyamine. These three genera are phylogenetically related based on 16S rRNA gene sequence and also with respect to the presence of homospermidine. Therefore, homospermidine could serve as a chemotaxonomic marker (Hamana and Nakagawa, 2001b) of these closely related genera. *Pedobacter heparinum* and *Pedobacter piscium* contain homospermidine in amounts of 2.5 μmol/g wet weight. *Pedobacter heparinum* also contains low amounts of putrescin and spermidin (0.04 and 0.07 μmol/g wet weight, respectively). Cadaverine, spermine, and agmatine were not detected (Hamana and Nakagawa, 2001b).

Colonial characteristics. Colonies on solid media are round, convex, with entire margins. They become visible on nutrient agar after 48 h at 20–25°C, and are typically 1–4 mm in diameter. *Pedobacter caeni* colonies range from 0.5 to 8 mm in diameter (Vanparys et al., 2005). The size of the colonies varies with the temperature, age, and growth medium. Colonies are smaller when growth conditions are suboptimal and unfavorable (personal observations).

Most species of *Pedobacter* are pigmented. On nutrient agar, the pigment color is yellow in *Pedobacter cryoconitis*, *Pedobacter heparinus*, *Pedobacter africanus*, *Pedobacter piscium*, *Pedobacter saltans*, and *Pedobacter caeni*; pinkish yellow in *Pedobacter suwonensis*; and pink in *Pedobacter roseus* (Hwang et al., 2006; Kwon et al., 2007; Margesin et al., 2003; Shivaji et al., 2005; Steyn et al., 1998; Vanparys et al., 2005). Colonies of *Pedobacter himalayensis* and *Pedobacter saltans* are pale white (Shivaji et al., 2005). The intensity of pigmentation varies considerably and may be affected by the growth medium, the incubation temperature, and the incubation period. The degree of pigmentation is more pronounced with aging: colonies may be initially creamy white and then turn to yellow. The pigments are cell bound and do not diffuse into the medium, and the color may vary from translucent yellow to dirty yellow or bright yellow depending on the media composition, as observed in *Pedobacter heparinus* (Christensen, 1980; Payza and Korn, 1956; Steyn et al., 1998). The pigments are nonfluorescent in ultraviolet light. The pink pigment in *Pedobacter roseus* shows an absorption maximum at 481–482 nm and a shoulder at 499–500 nm and differs from the yellow pigment of *Pedobacter heparinus* which shows two distinct absorption peaks at 452 and 477 nm (Hwang et al., 2006). These pigments of the various pigmented species of *Pedobacter* are not of the flexirubin type and do not give a flexirubin reaction with 20% KOH (Hwang et al., 2006; Kwon et al., 2007; Steyn et al., 1998; Vanparys et al., 2005). Flexirubin pigments reversibly change color from yellow, orange, or pink to violet-red or purple-brown when exposed to KOH (Reichenbach, 1989) and are a characteristic feature of *Flexibacter*, *Sporocytophyga*, and many species of *Flavobacterium* (Hirsch, 1980; Humphrey and Marshall, 1980; Jooste, 1985; Oyaizu et al., 1982; Reichenbach et al., 1981).

Macroscopically visible formation of slime/mucus on solid media is a typical feature of *Pedobacter caeni*, *Pedobacter cryoconitis*, *Pedobacter himalayensis*, and *Pedobacter suwonensis* (Margesin et al., 2003; Shivaji et al., 2005; Vanparys et al., 2005).

Slime formation is more pronounced with aged cultures and induced by low temperature and on media with low nutrient contents (personal observations).

Cells are nonmotile (*Pedobacter africanus*, *Pedobacter caeni*, *Pedobacter roseus*, *Pedobacter suwonensis*, *Pedobacter piscium*, *Pedobacter himalayensis*) or motile by gliding (*Pedobacter heparinus*, *Pedobacter cryoconitis*, *Pedobacter saltans*) (Hwang et al., 2006; Kwon et al., 2007; Margesin et al., 2003; Shivaji et al., 2005; Steyn et al., 1998; Vanparys et al., 2005). Gliding usually results in spreading growth on solid media (Christensen and Cook, 1972). No flagella or pili have been observed (Hwang et al., 2006; Steyn et al., 1998).

Nutrition and growth conditions. All nine *Pedobacter* species are able to grow at 5°C in nutrient broth and on nutrient agar. The optimum temperature for growth (in terms of growth rate) is 20°C for species isolated from cold habitats (*Pedobacter cryoconitis*, *Pedobacter himalayensis*, *Pedobacter piscium*), whereas isolates from temperate regions grow best at 25–30°C (*Pedobacter heparinus*, *Pedobacter africanus*, *Pedobacter caeni*, *Pedobacter roseus*) or 34°C (*Pedobacter suwonensis*). The maximum growth temperature is 25°C for *Pedobacter himalayensis* and *Pedobacter cryoconitis*, and 30°C for *Pedobacter africanus* and *Pedobacter piscium*. Growth at 37°C has only been reported for *Pedobacter saltans* and *Pedobacter suwonensis* and for some strains of *Pedobacter heparinus* (Steyn et al., 1998; Takeuchi and Yokota, 1992); slow growth at 37°C has been reported for *Pedobacter caeni* (Vanparys et al., 2005).

The pH range for growth in liquid complex media is 5–8 (*Pedobacter cryoconitis*, *Pedobacter suwonensis*), 6–8 (*Pedobacter roseus*), or 6–10 (*Pedobacter himalayensis*); the optimum pH for growth is 7 (Hwang et al., 2006; Kwon et al., 2007; Margesin et al., 2003; Payza and Korn, 1956; Shivaji et al., 2005). Most *Pedobacter* species grow in the presence of 2% (w/v) NaCl, and *Pedobacter himalayensis* grows in the presence of 5% (w/v) NaCl (Shivaji et al., 2005).

Metabolism and metabolic pathways. *Pedobacter* species are chemoorganotrophic with an oxidative type of metabolism. Glucose is not fermented. The carbohydrates most frequently attacked (and utilized as sole carbon source) are D-glucose, D-lactose, D-maltose, D-mannose, melibiose, N-acetylglucosamine, salicin, sucrose, trehalose, and often arbutin. Adipate, caprate, citrate, citric acid, D-arabitol, L-arabitol, D-fucose, lysine, D-lyxose, malate, D-tagatose, dulcitol, inositol, 5-ketogluconate, phenylacetate, and L-sorbose are not utilized as sole carbon sources; D-xylitol and erythritol are utilized rarely. Acid is produced from a range of carbohydrates but not from D-adonitol and L-rhamnose, and rarely from D-sorbitol. Most species are not able to grow on MacConkey's agar; exceptions are *Pedobacter himalayensis* and *Pedobacter roseus* (Hwang et al., 2006; Shivaji et al., 2005).

Pedobacter strains degrade a wide range of organic compounds such as the volatile organic compounds ethyl benzene, *m*-xylene, styrene, and *o*-xylene (Khomenkov et al., 2005); synthetic polypeptides such as high-molecular mass (5000–150,000) polymers of polyaspartic acid (Tabata et al., 2000); and diesel oil (Margesin et al., 2003).

The major respiratory isoprenoid quinone is MK-7 (91% in *Pedobacter suwonensis*, 68% in *Pedobacter himalayensis*). MK-8 (4–6%) and MK-9 (6–8%) have been found in small amounts

in *Pedobacter himalayensis* (Kwon et al., 2007; Shivaji et al., 2005) (see above).

All strains show activities of β -galactosidase and phosphatase (alkaline and acidic). Most strains are proteolytic and hydrolyze gelatin. *Pedobacter cryoconitis* produces a cold-active metalloprotease (Margesin et al., 2005). Nitrate reductase, thiosulfate reductase (H₂S production from thiosulfate), urease, and tryptophan deaminase (indole production) are generally not produced. Arginine dihydrolase is only produced by *Pedobacter himalayensis*. Leucine arylamidase and naphthol phosphohydrolase is frequently produced, whereas cystine arylamidase, β -glucuronidase, and lipase (C₁₄) are rarely produced (Hwang et al., 2006; Kwon et al., 2007; Margesin et al., 2003; Shivaji et al., 2005; Steyn et al., 1998; Takeuchi and Yokota, 1992; Vanparys et al., 2005).

A characteristic property of *Pedobacter heparinus* is the production of heparinases and chondroitinases. These enzymes are polysaccharide lyases that employ an elimination mechanism to cleave glycosaminoglycans. Heparinases (EC 4.2.2.7) cleave heparin-like glycosaminoglycans, such as (sulfated) heparin and heparan sulfate. *Pedobacter heparinus* utilizes heparin as its sole source of carbon, nitrogen, and sulfur. Heparin catabolism occurs both aerobically (higher activity at pH 6.5 than at pH 8.5) and anaerobically (higher activity at pH 8.5 than at pH 6.5) (Payza and Korn, 1956). The bacterium produces three different heparinases that differ in size, charge properties, and substrate specificities. Heparinase I primarily cleaves heparin and contains two unique calcium-binding sites, one of which is directly involved in enzymic activity (Shriver et al., 1999). Heparinase II degrades both heparin and heparan sulfate; it exhibits a stronger affinity toward heparin but its turnover rate of heparan sulfate is higher. The enzyme has been crystallized (see Shaya et al., (2004) and references therein) and differs from heparinase III in substrate specificity (Wei et al., 2005). In addition to *Pedobacter heparinus*, other *Pedobacter* species (*Pedobacter africanus*, *Pedobacter caeni*, *Pedobacter suwonensis*, *Pedobacter himalayensis*, *Pedobacter saltans*) also show heparinase activity.

Pedobacter heparinus produces two chondroitinases (Gu et al., 1995). Chondroitin is a sulfated mucopolysaccharide that consists of glucuronic acid and N-acetylgalactosamine units. Chondroitinase B from *Pedobacter heparinus* is the only known lyase that is strictly specific for the glycosaminoglycan dermatan sulfate. Michel et al. (2004) combined crystallographic structural data, enzyme kinetic analysis, and modeling to develop a more complete understanding of how chondroitinase B degrades dermatan sulfate and demonstrated the essential role of calcium for enzyme activity. The enzyme is an important enzymic tool for the identification and structural characterization of glycosaminoglycans, which are modified in many human diseases (Aguilar et al., 2003).

Genetics. *Flavobacterium heparinum* which is now known as *Pedobacter heparinus* is the most extensively studied species of the genus *Pedobacter* because of its ability to produce three heparinases (Lohse and Linhardt, 1992; Yang et al., 1985) and two chondroitinases (Gu et al., 1995). The genetics of this genus developed because of the commercial importance of these enzymes. Su et al. (2001) were the first to report a genetic system, pIBXF1, a mobile conjugative plasmid, for the introduction of heterologous DNA into this bacterium. pIBXF1 was constructed by assembling (a) an *Escherichia coli* mobile plasmid,

a derivative of pLB21, for conjugative DNA transfer; (b) a DNA fragment from *Flavobacterium heparinum* to facilitate homologous recombination; and (c) the trimethoprim resistance gene (*Tpr*) of *Flavobacterium heparinum* under the control of the *hepA* regulatory region. Blain et al. (2002) used pIBXF1 and showed that the transconjugants of *Flavobacterium heparinum* expressed high levels of the three heparinase genes (*hepA*, *hepB*, and *hepC*) encoding HepI, HepII, and HepIII, respectively, and the two chondroitinase genes (*csIA* and *csIB*) encoding ChnA and ChnB. The heparinases HepI, HepII, and HepIII and the chondroitinases ChnA and ChnB from the recombinant *Flavobacterium heparinum* strains were purified and shown to be identical to their native counterparts (Blain et al., 2002; Gu et al., 1995; Lohse and Linhardt, 1992; Yang et al., 1985). Earlier, for the want of an expression system in *Flavobacterium heparinum*, heparinases and chondroitinases were expressed in *Escherichia coli* (Sasisekharan et al., 1993; Su et al., 1996; Tkalec et al., 2000), but degradation of protein and formation of inclusion bodies made the process inefficient.

Molecular analysis of the heparinase genes, *hepA* (Sasisekharan et al., 1993), *hepB*, and *hepC* (Su et al., 1996), revealed no significant homology either at the DNA or protein levels, nor were they closely linked on the *Flavobacterium heparinum* chromosome (Su et al., 1996). Structural and functional studies employing chemical modifications and site-directed mutagenesis indicated that in HepI and HepII a histidine residue was critical for the catalytic function (Godavarti and Sasisekharan, 1998; Shriver et al., 1998), and two putative calcium-binding sites in HepI were essential for the catalytic function (Liu et al., 1999; Shriver et al., 1999). Further, crystallization of HepII revealed that it is a unit of two molecules, which is consistent with the finding that recombinant HepII functions as a dimer in solution (Shaya et al., 2004).

The two chondroitinase genes (*csIA* and *csIB*) also share no significant homology either at the DNA or peptide level. They are separated by approximately 5 kbp on the *Flavobacterium heparinum* chromosome, are translated in the same orientation (Tkalec et al., 2000), and are not linked to the *hep* genes. Crystal structures of both the enzymes (Fethiere et al., 1999, 1998; Huang et al., 1999; Li et al., 1998) suggest that the chondroitinases are very different with respect to their structures and catalytic mechanisms. Michel et al. (2004) studied the structure of chondroitinase B complexed with several dermatan sulfate and chondroitin sulfate oligosaccharides and demonstrated that chondroitinase B absolutely requires calcium for its activity, indicating that the protein-Ca²⁺-oligosaccharide complex is functionally relevant. A feature common to the heparinases and chondroitinases from *Flavobacterium heparinum* is that these enzymes are posttranslationally modified by glycosylation (Huang et al., 1995) and that the glycosylation site(s) contains the consensus sequence Asp-Ser or Asp-Thr, similar to the sequence described for *Flavobacterium meningosepticum* (Plummer et al., 1995).

Heparinases and chondroitinase from *Flavobacterium heparinum* are presently being developed for therapeutic applications. HepI has been used to neutralize the anticoagulant properties of heparin (Baug and Zimmermann, 1993). HepI and HepIII regulate cell adhesion, differentiation, migration, and proliferation (Jackson et al., 1991; Kjellen and Lindahl, 1991; Silver,

1998). ChnA and ChnB inhibit fibroblast proliferation and tumor cell invasion, proliferation, and angiogenesis (Denholm et al., 2000).

Antibiotic or drug sensitivity. Sensitivity to sulfamethoxazole and resistance to amikacin (conferring β -lactamase activity), ampicillin, gentamicin, and kanamycin are characteristic features of most *Pedobacter* species. Resistance of the type strain, *Pedobacter heparinus*, to gentamicin (60 μ g/ml) and kanamycin (100 μ g/ml), and its sensitivity to chloroamphenicol (100 μ g/ml), erythromycin (300 μ g/ml), and tetracycline (50 μ g/ml), are useful selective markers for the genetic manipulation of the strain (Su et al., 2001). Information on minimal inhibitory concentrations (MIC) of antimicrobial agents is not available.

Pedobacter species isolated from fruit bodies of *Clitocybe* species (Agaricales) is capable of detoxifying tolaasin, an extracellular toxin that induces brown blotch disease of cultivated mushrooms (Tsukamoto et al., 2002). Cells are released into water from the fungal fruit bodies without disrupting the fungal cells, which indicates that the bacteria are attached to the surface of fungal mycelia rather than residing in the fungal protoplasm.

Pathogenicity. *Pedobacter* strains are classified in Biohazard group 1, which consists of organisms that are unlikely to cause human disease. Strains should be handled under containment level 1 and can be distributed unrestrictedly to any bona fide teaching, research, or industrial institution.

Ecology. All representatives of the genus *Pedobacter* have been isolated from environmental terrestrial and aquatic habitats, such as soil (*Pedobacter heparinus*, *Pedobacter africanus*, *Pedobacter suwonensis*, *Pedobacter saltans*), activated sludge (*Pedobacter africanus*), glacier cryoconite (*Pedobacter cryoconitis*), glacial water (*Pedobacter himalayensis*), and freshwater. Other *Pedobacter* strains have been associated with fish (*Pedobacter piscium*) or fruit bodies of Agaricales (*Clitocybe* sp.), are members of the microflora in a commercial nitrifying inoculum (*Pedobacter caeni*), are found in liquid swine manure, or found in maple sap at the taphole of maple trees (Hwang et al., 2006; Kwon et al., 2007; Lagace et al., 2004; Leung and Topp, 2001; Margesin et al., 2003; Shivaji et al., 2005; Steyn et al., 1992; Tabata et al., 2000; Takeuchi and Yokota, 1992; Vanparys et al., 2005). *Pedobacter* strains have been found worldwide and under various climate conditions ranging from cold regions (Himalayan Mountains, India; Tyrolean Alps, Austria; Iceland) to temperate regions (Belgium, Russia, Canada, USA, Japan, Korea, and South Africa).

Enrichment and isolation procedures

No special procedure is required for the isolation of *Pedobacter* strains. They have been isolated either by direct isolation technique or after enrichment appropriate for aerobic bacteria. For isolation, a suitable buffered diluent is used to release microbial cells from the matrix of a representative amount of sample, and the suspension is diluted to a cell density suitable for enumeration on agar plates. Dilutions are spread onto the surface of solid media for cultivation. An enrichment procedure has been described for *Pedobacter caeni* (Vanparys et al., 2005). The time and temperature required for growth of *Pedobacter* colonies depend on the species and on the environmental conditions prevailing in the natural habitat of the isolates. Colonies appear after 2–3 d at 20–30°C, or after 4–7 d at 10°C. Recommended

media for isolation of *Pedobacter* strains include commercially available trypticase soy agar (TSA; Difco), nutrient agar (NA; Difco), and R₂A agar (Difco).

Maintenance procedures

The bacteria can be maintained in the laboratory by regular transfer (subculturing) on the medium used for isolation (most commonly used media are TSA, NA, R₂A) and storage of the plates at 1–4°C. For long-term preservation, storage in liquid nitrogen (–196°C) or at –80°C in 10% skimmed milk or in R2A broth supplemented with 30% (v/v) glycerol is recommended. Culture collections distribute *Pedobacter* strains as (vacuum) dried cultures.

Procedures for testing special characters

Heparinase. The presence of heparinase can be detected by following the disappearance of heparin in inoculated growth media (Gesner and Jenkin, 1961) or by the production of acid formed as a result of the fermentation of the heparin (Salysers et al., 1977). Two plate assays for detecting heparinase activity in growing cells on heparin agar plates have been developed. The test medium described by Joubert et al. (1984) contains phytone (soybean meal digest; 10 g/l), yeast extract (1 g/l), heparin (Grade II, from porcine intestinal mucosa; Sigma; 1 mg/ml), sodium chloride (1 g/l), barium chloride (1 mg/ml), and purified agar (15 g/l). A loopful of a broth culture of the organism to be tested is spread onto the surface of the agar plate, and the inoculated plate is incubated for 4–5 d at 25°C. Sulfate is released by the breakdown of heparin and reacts with barium chloride to form an insoluble white precipitate of barium sulfate on the agar plates. The required incubation time (2–5 d) for the precipitate to form depends on the strain.

Zimmermann et al. (1990) recommends growing the bacteria (*Pedobacter heparinus*) on Luria–Bertani (LB) agar plates containing heparin (1 mg/ml) for 48 h at 30°C. The cells are washed from the plates with distilled water, and 5 ml of a protamine sulfate solution (from salmon; Sigma; 2%) is poured onto the plates. After 1–2 h at room temperature, a clear zone surrounding heparinase-producing cells is observed. Activity of concentrated/purified enzyme solutions can be detected after 1 h at 37°C. The method is based on the differential precipitation of heparin and heparinase-generated heparin fragments by protamine sulfate.

It is important to note that growth conditions must be appropriate for the strains to be tested. Purified agar or agarose must be used, because ordinary laboratory grade agar is contaminated with sulfate, which can give false-positive results. Contamination with sulfated mucopolysaccharides of animal origin must also be avoided (Joubert et al., 1984).

Chondroitinase. An agar plate assay can be used to demonstrate chondroitinase activity in growing cells. The medium and the procedure are similar to those described previously for the detection of heparinase activity, but the medium contains chondroitin sulfate (Sigma Chemical Co., grade II, from whale or shark cartilage; 5 g/l) (Joubert et al., 1984). Aguilar et al. (2003) developed an improved spectrophotometric method to measure chondroitinase activity in cell suspensions. Cells are incubated with chondroitin sulfate or dermatan sulfate, and

substrate degradation is followed with the Dimethylmethylene Blue assay.

Utilization of organic compounds as sole carbon sources. This can be tested on the basis of colony formation on mineral medium agar supplemented with 0.1–0.5% of carbon source, or on the basis of growth (optical density) in liquid cultures (Hwang et al., 2006; Margesin et al., 2003; Shivaji et al., 2005).

Enzyme activities. Special care has to be given to incubation temperature when testing enzyme activity. With cold-tolerant strains, the optimum temperature for enzyme production is often considerably lower (5–10°C) than the optimum temperature for growth (Margesin et al., 2005, 2003).

Gliding motility. Gliding is the translocation of nonflagellated bacteria in contact with a solid surface and has been defined by Henrichsen (1972) as “movement which is continuous and regularly follows the long axis of the cells which are predominantly aggregated in bundles during the movement.” It is his definition that is recommended here (Holmes et al., 1984). Gliding usually results in spreading growth on solid media (Christensen, 1980). Two preconditions are essential: (1) The agar plates must be humid (preferably freshly poured), because the gliding motility is dependent on humidity (amount of surface moisture) and (2) The cells must be cultured on agar with low nutrient concentration because peptone concentrations higher than 0.25–0.5% are inhibitory to gliding. Spreading may be absent when cells are grown on nutrient agar.

Gliding may be studied by microscopy of the colony edge on thinly poured agar plates after overnight incubation using a high power dry lens (Henrichsen, 1972; Holmes et al., 1984). Steyn et al. (1992) described somersaulting motility of three of four *Pedobacter saltans* strains; on a microscope slide the cells seem to somersault and then glide for one or two cell lengths. Christensen (1980) reclassified *Flavobacterium heparinum* as *Cytophaga heparina* because of its gliding motility.

Differentiation of the genus *Pedobacter* from other genera

The genera *Sphingobacterium* and *Pedobacter* constitute the family *Sphingobacteriaceae* and, although they share a number of common biochemical and chemotaxonomical features, they can be differentiated. The main differential characteristic is the concentration of fatty acids in the membrane lipids. *Sphingobacterium* species, except *Sphingobacterium mizutae*, possess greater amounts of C_{15:0} iso 2-OH (16–26% in *Sphingobacterium* compared with 2–15% in *Pedobacter*). *Pedobacter* taxa, except *Pedobacter saltans*, possess significantly higher amounts of C_{16:1} ω5c (1–5%). Significant amounts of C_{15:0} iso 2-OH and/or C_{16:1} ω7c are characteristic of all members of the family *Sphingobacteriaceae* (Steyn et al., 1998).

Other useful characteristics to differentiate the two genera pertain to the source of isolation and to selected enzyme activities and carbohydrate metabolism. *Pedobacter* strains have been isolated from various terrestrial and aquatic environmental habitats but not from clinical sources, while most representatives of *Sphingobacterium* are of clinical origin (Steyn et al., 1998) except *Sphingobacterium antarcticus*, which was isolated from soil (Shivaji et al., 1992). Both genera include facultative psychrophilic isolates. Most *Pedobacter* strains are not able to assimilate D-melezitose and to produce acid from melibiose. Activities of urease

and α -fucosidase are absent in *Pedobacter* strains but are present in *Sphingobacterium*, except *Sphingobacterium mizutae*. Steyn et al. (1998) used heparinase activity to differentiate *Pedobacter* (which exhibits activity in several species) from *Sphingobacterium* (activity absent). However, Chao et al. (2003, 2004) reported heparinase production by *Sphingobacterium* species. The sphingobacterial heparinase differs from the enzyme produced by *Pedobacter heparinus* in several characteristics such as molecular mass, composition, charge properties, active site, and substrate specificities. Trypsinase activity is absent in heparinase-producing strains of *Pedobacter* (except *Pedobacter piscium*).

Taxonomic comments

The genus *Pedobacter*, represented by the type strain *Pedobacter heparinus*, was carved out from the genus *Sphingobacterium* (Steyn et al., 1998) in the family *Sphingobacteriaceae*. *Pedobacter heparinus* was first described as *Flavobacterium heparinum* (Payza and Korn, 1956) and was later reclassified as *Cytophaga heparina* (Christensen, 1980), although its position in the genus *Cytophaga* was debatable (Reichenbach, 1989). Takeuchi and Yokota (1992) proposed the transfer of *Cytophaga heparina* to the genus *Sphingobacterium* (Yabuuchi et al., 1983) as *Sphingobacterium heparinum* based on the observed homogeneity in morphological, physiological, and chemotaxonomic characteristics with *Sphingobacterium*. Subsequent studies on DNA-rRNA hybridization results using 16 heparinase-producing bacteria related to *Sphingobacterium heparinum* indicate that the genus is phylogenetically heterogeneous since $T_{m(e)}$ differences for the DNA-rRNA hybrids was 8–12°C $T_{m(e)}$ (Steyn et al., 1998). In well-characterized genera, differences in $T_{m(e)}$ values are normally in the range of 4–7°C (De Ley, 1992). Furthermore, based on the rRNA cistron similarity studies, it is clear that the 16 heparinase-producing bacteria with $T_{m(e)}$ ranging between 70 and 80°C are distinct from the *Sphingobacterium* branch, which contains strains of *Sphingobacterium spiritivorum*, *Sphingobacterium multivorum*, *Sphingobacterium mizutae*, *Sphingobacterium faecium*, and *Sphingobacterium thalpophilum* with a mean $T_{m(e)}$ of about 68°C. Prompted by these genotypic studies, the genus *Pedobacter* was created to include the heparinase-producing isolates (Steyn et al., 1998) along with the reclassified *Sphingobacterium heparinum* and *Sphingobacterium piscium* as *Pedobacter heparinus* and *Pedobacter piscium*. It is apparent that *Pedobacter* splits into two sub-branches at $T_{m(e)}$ values of 70.9°C, with *Pedobacter saltans* forming one sub-branch and all the other species including *Pedobacter heparinus* forming the second sub-branch with $T_{m(e)}$ values in the range of 74–80°C (Steyn et al., 1998). Phylogenetic studies also demonstrate that *Pedobacter heparinus* is distantly related to *Flexibacter canadensis* located at the borderline of the *Sphingobacterium* and *Pedobacter* branches (Dobson et al., 1993; Gherna and Woese, 1992; Manz et al., 1996; Nakagawa and Yamasato, 1993, 1996; Steyn et al., 1998).

The genus *Pedobacter* was described by Steyn et al. (1998) to include heparinase-producing, obligately aerobic, Gram-stain-negative rods. Even at that juncture, it was clear that the genus consisted of two distinct sub-branches, with *Pedobacter heparinus* representing one branch and *Pedobacter saltans* the other branch, based on DNA-rRNA hybrids (Steyn et al., 1998). Furthermore, DNA-DNA hybridization studies indicate that the *Pedobacter heparinus* sub-branch is further segregated into six genotypic subgroups represented by *Pedobacter heparinus* (Ia1),

Pedobacter africanus (Ia3), three unnamed *Pedobacter* species (Ia2, Ib1 and Ib2), *Pedobacter* strain LMG 1035, and *Pedobacter piscium* (II). *Pedobacter saltans* constitutes a homogeneous group (III) by itself (Steyn et al., 1998). Between the genotypic subgroups and between the two sub-branches, the similarity at the whole genome level is <20%. It is also surprising that even within the subgroup the similarity is not always high. For instance, though the two strains of *Pedobacter heparinus* (subgroup Ia1) and the three strains of *Pedobacter saltans* (subgroup III) exhibit >90% similarity, strains of Ia2, Ia3, Ib1, and Ib2 show <60% similarity (Steyn et al., 1998). These results imply genomic heterogeneity within the genotypic groups, and there is a need to investigate the genus more thoroughly. The low DNA-DNA hybridization values indicate that the various species of the genus are not closely related. A similar low similarity has been reported earlier for species of *Cytophaga* (Behrens (1978), from Reichenbach). Between 1998 and 2006, five more new species, namely *Pedobacter cryoconitis*, *Pedobacter caeni*, *Pedobacter himalayensis*, *Pedobacter roseus*, and *Pedobacter suwonensis* have been added to the already existing four species, namely *Pedobacter heparinus*, *Pedobacter piscium*, *Pedobacter africanus*, and *Pedobacter saltans*. These new species also show very little similarity at the DNA-DNA level, with the nearest phylogenetic neighbor ranging from 19.7% between *Pedobacter cryoconitis* and *Pedobacter piscium* (Margesin et al., 2003), 14% between *Pedobacter caeni* and *Pedobacter africanus* (Vanparrys et al., 2005), and 42% between *Pedobacter himalayensis* and *Pedobacter cryoconitis* (Shivaji et al., 2005). DNA-DNA hybridization values are not available for *Pedobacter roseus* vs. *Pedobacter heparinus*, and for *Pedobacter suwonensis* vs. *Pedobacter heparinus*, since the phylogenetic neighbors vary by more than 4% at the 16S rRNA gene level (Hwang et al., 2006; Kwon et al., 2007). Thus the entire genus appears to be genotypically heterogeneous, and this is further corroborated by a wide variation in the G+C content of DNA, which ranges from 36 to 45 mol% (Hwang et al., 2006; Kwon et al., 2007; Margesin et al., 2003; Shivaji et al., 2005; Steyn et al., 1998; Vanparrys et al., 2005). *Pedobacter saltans* appears to be different from all the remaining eight species and this is clearly evident based on phylogenetic analysis of the 16S rRNA gene sequence. All the species of *Pedobacter* except *Pedobacter saltans* form a robust monophyletic cluster with high bootstrap values (Figure 59). *Pedobacter saltans* differs phylogenetically from all the remaining *Pedobacter* species and exhibits a difference of 9–11% at the 16S rRNA gene level with those species. The remaining species are phylogenetically closely related with one another and the similarity at the rRNA gene level ranges from 2 to 5% (Hwang et al., 2006; Kwon et al., 2007; Margesin et al., 2003; Shivaji et al., 2005; Steyn et al., 1998; Vanparrys et al., 2005).

According to the criteria set by Stackebrandt and Goebel (1994) for discriminating species, it would appear that all the existing nine *Pedobacter* species at the 16S rRNA gene level differ by >2.5% and/or exhibit <70% similarity at the DNA-DNA level, and are thus different species, but a few of them, such as *Pedobacter suwonensis* (Kwon et al., 2007) and especially *Pedobacter Saltans*, differ from the nearest phylogenetic neighbor by >5% at the 16S rRNA gene level and have low DNA-DNA hybridization values; thus their species status could be reconsidered by investigating more strains and arriving at distinguishing phenotypic characteristics.

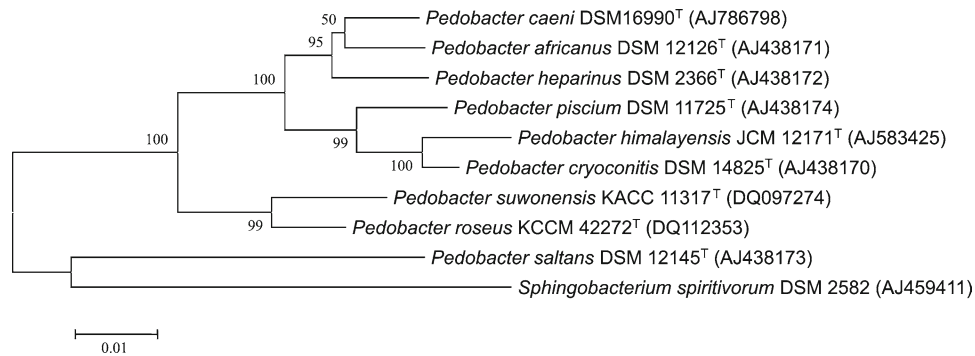

FIGURE 59. Neighbor-joining tree based on 16S rRNA gene sequences (1455 bases) showing the phylogenetic relationship between species of the genus *Pedobacter* and *Sphingobacterium spiritivorum*. Bootstrap values (expressed as percentage of 1000 replications) greater than 50% are given at the nodes.

Editorial note: An additional 22 species have been published since this chapter was written: *Pedobacter agri* (Roh et al., 2008), *Pedobacter alluvionis* (Gordon et al., 2009), *Pedobacter aquatilis* (Gallego et al., 2006), *Pedobacter borealis* (Gordon et al., 2009), *Pedobacter composti* (Lee et al., 2009), *Pedobacter daechungensis* (An et al., 2009), *Pedobacter duraquae* (Muurholm et al., 2007), *Pedobacter ginsengisoli* (Ten et al., 2006a), *Pedobacter glucosidilyticus* (Luo et al., 2010), *Pedobacter hartoni* (Muurholm et al., 2007), *Pedobacter insulae* (Yoon et al., 2007a), *Pedobacter korensis* (Baik et al., 2007), *Pedobacter lentus* (Yoon et al., 2007c), *Pedobacter metabolipaupe*

(Muurholm et al., 2007), *Pedobacter nyackensis* (Gordon et al., 2009), *Pedobacter oryzae* (Jeon et al., 2009), *Pedobacter panaciterrae* (Yoon et al., 2007d), *Pedobacter sandarakinus* (Yoon et al., 2006), *Pedobacter steynii* (Muurholm et al., 2007), *Pedobacter terrae* (Yoon et al., 2007b), *Pedobacter terricola* (Yoon et al., 2007c), and *Pedobacter westerhofensis* (Muurholm et al., 2007).

Differentiation of the species of the genus *Pedobacter*

Differential characteristics of the species of *Pedobacter* are presented in Table 80.

List of species of the genus *Pedobacter*

1. ***Pedobacter heparinus*** (Payza and Korn 1956) Steyn, Segers, Vancanneyt, Sandra, Kersters and Joubert 1998, 175^{VP} (*Flavobacterium heparinum* Payza and Korn 1956, 854; *Cytophaga heparina* Christensen 1980, 474; *Sphingobacterium heparinum* Takeuchi and Yokota 1992)

he.pa.ri'nus. Gr. neutr. n. *hepar* liver; N.L. masc. adj. *heparinus* referring to the liver and to the degradation of heparin, a sulfated mucopolysaccharide occurring in liver.

Characteristics are as described for the genus and as listed in Table 80. Cell length varies from short rods to long rods (0.5–6 μm). Motile by gliding. Colony color varies from creamy white on R2A to translucent yellow to dark orange-yellow on TSA and NA. Colonies reach a diameter of 1–3 mm after 48–72 h of cultivation, and are round, convex, with entire margins. Grows at pH 6–8 and at 5 to 30°C. Some strains grow at 37°C (Takeuchi and Yokota, 1992), others do not grow at this temperature (Payza and Korn, 1956). No growth at 42°C. No growth on MacConkey's agar. Positive for heparinase, chondroitinase, assimilation of D-mannitol, D-sorbitol, and L-fucose; acid is not produced from mannose.

DNA G+C content (mol%): 42–43 (T_m).

Type strain: ATCC 13125, CCUG 12810, CIP 104194, CIP 105498, DSM 2366, NBRC 12017, JCM 7457, LMG 4024, LMG 10339, NCIMB 9290, NRRL B-14731.

Sequence accession no. (16S rRNA gene): AJ43817, M11657.

2. ***Pedobacter africanus*** Steyn, Segers, Vancanneyt, Sandra, Kersters and Joubert 1998, 175^{VP}

a.fri.ca'nus. L. masc. adj. *africanus* of or belonging to Africa, the source of isolation.

Characteristics are as described for the genus and as listed in Table 80. Differs from its closest phylogenetic neighbor, *Pedobacter caeni*, by its ability to assimilate L-rhamnose and D-turanose and its inability to assimilate L-xylose and to produce acid from D-lactose, D-melibiose and sucrose. Activities of α-glucosidase, N-acetyl-β-glucosaminidase, naphthol phosphohydrolase, and heparinase are present. Produces slimy colonies on agar plates; the colonies are translucent yellow. Grows at pH 6–8.

DNA G+C content (mol%): 43–45 (T_m).

Type strain: CCUG 39353, CIP 105499, DSM 12126, LMG 10353, NBRC 100065, NCIMB 13641.

Sequence accession no. (16S rRNA gene): AJ438171.

3. ***Pedobacter caeni*** Vanparys, Heylen, Lebbe and De Vos 2005, 1316^{VP}

ca.e'ni. L. neut. n. *caenum* sludge; L. gen. neut. n. *caeni* of/from sludge.

Characteristics are as described for the genus and as listed in Table 80. Cell length varies from short to long (3–10 μm). Filament formation occurs. Differs from the other species of the genus by its ability to assimilate L-xylose, its inability to assimilate D-fructose, D-galactose, D-turanose, and D-xylose, its

ability to produce acid from inositol, and the absence of the enzymes α -glucosidase, *N*-acetyl- β -glucosaminidase, and naphthol-phosphohydrolase. Produces slimy colonies on TSA, R2A and NA; colonies are initially creamy white and yellow when aging. The colony diameter ranges from 0.5 to 8 mm. Grows at 1–30°C and at pH 6–9. Streptomycin-sensitive.

DNA G+C content (mol%): 42.7 (T_m).

Type strain: DSM 16990, LMG 22862.

Sequence accession no. (16S rRNA gene): AJ786798.

4. ***Pedobacter cryoconitis*** Margesin, Sproer, Schumann and Schinner 2003, 1295^{VP}

cry.o.co.ni'tis. N.L. gen. n. *cryoconitis* from cryoconite, referring to glacier cryoconite, where the strain was first found.

Characteristics are as described for the genus and as listed in Table 80. Differs from the other species of the genus by presence of DNase activity and assimilation of 2-ketogluconate. Differentiated from its closest phylogenetic neighbor, *Pedobacter himalayensis*, by its gliding motility, its ability to assimilate glycogen and to produce acid from mannitol, and its inability to assimilate D-adonitol, D-arabinose, L-fucose, glycerol, and D-mannitol. Heparinase and lysine decarboxylase are absent. Degrades diesel oil cometabolically. Temperature range for growth, 1–25°C. Produces light yellow, slimy colonies on NA and R₂A agar plates.

DNA G+C content (mol%): 43.4 (T_m).

Type strain: A37, DSM 14825, LMG 21415.

Sequence accession no. (16S rRNA gene): AJ438170.

5. ***Pedobacter himalayensis*** Shivaji, Chaturvedi, Reddy and Suresh 2005, 1084^{VP}

him.a.lay.en'sis. N.L. masc. adj. *himalayensis* of or belonging to the Himalaya.

Characteristics are as described for the genus and as listed in Table 80. Differentiated from the other species of the genus by the presence of arginine dihydrolase activity, the ability to assimilate gluconate, and the production of acid from D-mannitol but not from D-arabinose and D-glucose. Differs from its closest phylogenetic neighbor, *Pedobacter cryoconitis*, by its ability to grow on MacConkey's agar, to grow in presence of 5% (w/v) NaCl, to produce heparinase, and to assimilate D-adonitol, D-arabinose, L-fucose, glycerol, D-mannitol, methyl- α -D-mannoside, and L-xylose. Pale-white slimy colonies are formed on R2A and NA, with absence of a yellow or pink pigment. Grows from 4 to 25°C and at pH 6–10.

DNA G+C content (mol%): 41.0 (T_m).

Type strain: HHS 22, JCM 12171, MTCC 6384.

Sequence accession no. (16S rRNA gene): AJ583425.

6. ***Pedobacter piscium*** (Takeuchi and Yokota 1992) Steyn, Segers, Vancanneyt, Sandra, Kersters and Joubert 1998, 175^{VP} (*Sphingobacterium piscium* Takeuchi and Yokota 1992, 481)

pis'ci.um. L. masc. n. *piscis* fish; L. gen. pl. n. *piscium* of/from fishes.

Characteristics are as described for the genus and as listed in Table 80. Differs from the other species of the genus by its ability to assimilate α -mannoside. Positive for valine arylamidase; negative for heparinase activity and assimilation of methyl- α -D-mannoside. Differs from its closest phylogenetic neighbors *Pedobacter cryoconitis* and *Pedobacter himalayensis* by its ability to grow at 30°C. Colonies are creamy white (PY) to yellow (NA, TSA).

DNA G+C content (mol%): 40–43 (T_m).

Type strain: CIP 104195, ATCC 13125, JCM 7454, LMG 14024, NBRC 14985.

Sequence accession no. (16S rRNA gene): AJ438174.

7. ***Pedobacter roseus*** Hwang, Choi and Cho 2006, 1834^{VP}

ro.se'us. L. masc. adj. *roseus* rose-colored, pink, referring to the color of the colonies on agar plates.

Characteristics are as described for the genus and as listed in Table 80. Differs from the other species of the genus by the presence of significant amounts of the fatty acid C_{16:0} iso 3-OH (7.2%) and the formation of pink colonies on R₂A agar, NA and R2A. Rods are short (length, 0.8–1.1 μ m). Grows on MacConkey's agar. Glycerol, inulin, and L-xylose are assimilated. α -Fucosidase activity occurs but not β -glucosidase or heparinase activity. Grows at 5–33°C and pH 5–8.

DNA G+C content (mol%): 41.3 (T_m).

Type strain: CL-GP80, JCM 13399, KCCM 42272.

Sequence accession no. (16S rRNA gene): DQ112353.

8. ***Pedobacter saltans*** Steyn, Segers, Vancanneyt, Sandra, Kersters and Joubert 1998, 175^{VP}

sal'tans. L. v. *saltare* to dance; L. part. adj. *saltans* dancing, referring to the gliding motility of the strain.

Characteristics are as described for the genus and as listed in Table 80. Differs from the other species of the genus by its ability to assimilate L-cellobiose. Strains of the species assimilate D-adonitol and glycerol but are unable to assimilate methyl- α -D-mannoside. Heparinase activity is present. Esterase-lipase (C8) activity is absent. Sensitive to chloroamphenicol (30 μ g/ml) and tetracycline (30 μ g/ml). Motile by gliding. Grows at 15–37°C and at pH 6–8. Colonies are small and creamy white on R2A, NA and TSA.

DNA G+C content (mol%): 36–38 (T_m).

Type strain: CCUG 39354, ATCC 51119, CIP 105500, DSM 12145, JCM 21818, LMG 9526, LMG 10337, NBRC 100064, NCIMB 13643.

Sequence accession no. (16S rRNA gene): AJ438173.

9. ***Pedobacter suwonensis*** Kwon, Kim, Lee, Jang, Seok, Kwon, Kim and Weon 2007, 481^{VP}

su.won.en'sis. N.L. masc. adj. *suwonensis* of or belonging to Suwon City (Korea), where the strain was first found.

Characteristics are as described for the genus and as listed in Table 80. The cell length is 1.4–3.2 μ m. Differs from the other species of the genus by its ability to assimilate D-melezitose, its wide growth temperature range (2–37°C), and its relatively high optimum temperature for growth (34°C). Activities of heparinase, α -fucosidase, and valine arylamidase are present. Pinkish-yellow colonies are formed on R2A, NA and TSA. Produces slime on R2A agar.

DNA G+C content (mol%): 44.2 (T_m).

Type strain: 15-52, DSM 18130, KACC 11317.

Sequence accession no. (16S rRNA gene): DQ097274.

Acknowledgements

R. Margesin thanks Dr F. Schinner for providing the photomicrograph (Figure 58) and Dr H.Y. Weon for providing supplementary data about *Pedobacter suwonensis*. S. Shivaji thanks Ms Preeti Chaturvedi for sequence analysis and construction of the phylogenetic tree.
