Serum chemistries, including blood urea nitrogen (BUN), creatinine, aspartate transaminase (AST), and alanine transaminase (ALT) and a complete blood count with platelets should be performed at baseline and periodically thereafter depending on the presence of other factors that may increase the likelihood of toxicity (e.g., advanced age, alcohol abuse, pregnancy).^{2,34} Hepatotoxicity should be suspected in patients whose transaminases exceed five times the upper limit of normal (ULN) or whose total bilirubin exceeds 3 mg/dL (51 μmol/L) and in patients with symptoms such as nausea, vomiting, and jaundice with liver enzyme elevations of more than three times ULN. At this point, the offending agent(s) should be discontinued. Typically, all TB drugs are stopped, followed by the sequential reintroduction of the drugs, along with frequent testing of liver enzymes. This usually is successful in identifying the offending agent; other agents may be continued³⁴ (Table 75-4).

Patient Care and Monitoring

1. Rapidly identify a new TB case.
2. Assess the patient's risk factors and signs and symptoms to determine whether the patient might be infected with TB.
3. Isolate the patient with active disease to prevent the spread of the disease.
4. Collect appropriate samples for smears and cultures.
5. Obtain a thorough medication history.
6. Select and recommend appropriate antituberculosis treatment. Consider HIV status, pregnancy, type of TB infection, renal function, liver function, etc.
7. Ensure adherence to the treatment regimen by the patient.
8. Obtain AFB stains to evaluate the effectiveness of treatment.
9. Consider TDM if no clinical improvement.
10. Secondary goals are identification of the index case that infected the patient, identification of all persons infected by both the index case and the new case of TB, and the completion of appropriate treatments for those individuals.

Patient Encounter, Part 4

Based on the information provided, which clinical and laboratory parameters should be monitored in this patient to determine efficacy and avoid toxicity?

Is this patient a candidate for therapeutic drug monitoring? Why or why not?

Therapeutic Drug Monitoring

TDM or applied pharmacokinetics is the use of serum drug concentrations to optimize therapy.^{34,41,42} Non-AIDS patients with drug-susceptible TB generally do well. TDM may be used if patients are failing appropriate DOT (no clinical improvement after 2 to 4 weeks or smear-positive after 4 to 6 weeks). On the other hand, patients with AIDS, diabetes, and various GI disorders often fail to absorb these drugs properly and are candidates for TDM. Also, patients with hepatic or renal disease should be monitored, given their potential for overdoses. In the treatment of MDR-TB, TDM may be particularly useful.^{44,48} Finally, TDM of the TB and HIV drugs is perhaps the most logical way to untangle the complex drug interactions that take place. For a complete list of drug interactions, visit the CDC website at www.cdc.gov/nchstp/tb/tb_hiv_drugs/toc.htm.^{54,55} In particular, interactions between the rifamycins (e.g., rifampin, rifapentine, rifabutin) and the HIV protease

inhibitors and non-nucleoside reverse transcriptase inhibitors are common and require dose and frequency modifications in many cases. Because these are constantly being updated, the preceding link is an excellent way to keep current.

Abbreviations Introduced in This Chapter

AIDS	Acquired immunodeficiency syndrome
ALT	Alanine transaminase
AST	Aspartate transaminase
BCG	Bacille Calmette-Guérin
CDC	Centers for Disease Control and Prevention
CNS	Central nervous system
DOT	Directly observed therapy
HIV	Human immunodeficiency virus
HTN	Hypertension
IGRA	Interferon gamma release assay
INF	Interferon
LTBI	Latent tuberculosis infection
MDR-TB	Multidrug-resistant tuberculosis
MGIT	Mycobacterial growth indicator tube
NIDDM	Non-insulin-dependent diabetes mellitus
PCR	Polymerase chain reaction
PPD	Purified protein derivative
RFLP	Restriction fragment length polymorphism
TB	Tuberculosis
TDM	Therapeutic drug monitoring
ULN	Upper limit of normal
WBC	White blood cell

Self-assessment questions and answers are available at <http://mhpharmacotherapy.com/pp.html>.

Gastrointestinal Infections

Bradley W. Shinn, Elizabeth D. Hermsen,
and Ziba Jalali

LEARNING OBJECTIVES

● Upon completion of the chapter, the reader will be able to:

1. Describe the epidemiology and clinical presentation of commonly encountered GI infections.
2. Summarize common risk factors associated with the development of a GI infection.
3. Given a patient with a GI infection, develop an individualized treatment plan.
4. Outline the impact of widespread antimicrobial resistance on current treatment recommendations for GI infections.
5. Discuss the effect of host immunosuppression on the risk of disease complications and treatment strategies associated with GI infections.
6. Educate patients on appropriate prevention measures of GI infections.
7. Describe the role of antimicrobial prophylaxis and/or vaccination for GI infections.

KEY CONCEPTS

- 1 Rehydration is the foundation of therapy for GI infections.
- 2 The indiscriminate use of proton-pump inhibitor (PPI) therapy leads to GI-tract bacterial colonization and increased susceptibility to enteric bacterial infections.
- 3 Blood in the stool indicates the possibility of inflammatory mucosal disease of the colon such as enterohemorrhagic *Escherichia coli* (EHEC), which is an important cause of bloody diarrhea in the United States.
- 4 Traveler's diarrhea is most commonly caused by bacteria such as *Shigella*, *Salmonella*, *Campylobacter*, and enterotoxigenic *E. coli* (ETEC), although viruses are increasingly recognized as a significant cause of traveler's diarrhea as well.
- 5 The education of travelers about high-risk food and beverages is an important component in the prevention of traveler's diarrhea.
- 6 Nosocomial *Clostridium difficile*-associated diarrhea (CDAD) is almost always associated with antimicrobial use; therefore, unnecessary and inappropriate antibiotic therapy should be avoided. Almost all antibiotics except aminoglycosides have been associated with CDAD.
- 7 Viruses are the most common cause of diarrheal illness in the world. A live, oral vaccine is licensed and recommended for use in infants for the prevention of rotavirus infection.

INTRODUCTION

One of the primary concerns related to GI infection, regardless of the cause, is dehydration, which is the second leading cause of worldwide morbidity and mortality.¹ Worldwide, dehydration is especially problematic for children younger than age 5. However, the highest rate of death in the United States occurs among the elderly.¹ 1 *Rehydration is the foundation of therapy for GI infections, and oral rehydration therapy (ORT) is usually preferred (Table 76-1).*

- In the United States, each year 31 major pathogens cause about 9 million episodes of foodborne illness, almost 56,000 hospitalizations, and 1,350 deaths. Most illnesses are caused by norovirus, nontyphoidal *Salmonella* (NTS), *C. perfringens*, and *Campylobacter*.² 2 *The indiscriminate use of proton-pump inhibitor (PPI) therapy leads to GI-tract bacterial colonization and increased susceptibility to enteric bacterial infections.*³

BACTERIAL INFECTIONS

SHIGELLOSIS

Epidemiology

- *Shigella* causes bacillary dysentery, which refers to diarrheal stool containing pus and blood. Worldwide, there are an estimated 165 million annual cases of shigellosis, with 1 million associated deaths,⁴ and approximately 450,000 infections each year in the United States, which results in more than

Table 76-1

Clinical Assessment of Degree of Dehydration in Children Based on Percentage of Body Weight Loss

Variable	Mild (3–5%)	Moderate (6–9%)	Severe (10% or More)
Blood pressure	Normal	Normal	Normal to reduced
Quality of pulses	Normal	Normal to slightly decreased	Moderately decreased
Heart rate	Normal	Increased	Increased (bradycardia in severe cases)
Skin turgor	Normal	Decreased	Decreased
Fontanelle	Normal	Sunken	Sunken
Mucous membranes	Slightly dry	Dry	Dry
Eyes	Normal	Sunken orbits/decreased tears	Deeply sunken orbits/decreased tears
Extremities	Warm, normal capillary refill	Delayed capillary refill	Cool, mottled
Mental status	Normal	Normal to listless	Normal to lethargic to comatose
Urine output	Slightly decreased	Less than 1 mL/kg/hr	Less than 1 mL/kg/h
Thirst	Slightly increased	Moderately increased	Very thirsty
Fluid replacement	ORT 50 mL/kg over 2–4 hours	ORT 100 mL/kg over 2–4 hours	Lactated Ringer's 40 mL/kg in 15–30 minutes, then 20–40 mL/kg if skin turgor, alertness, and pulse have not returned to normal or Lactated Ringer's or normal saline 20 mL/kg, repeat if necessary, and then replace water and electrolyte deficits over 1–2 days, followed by ORT 100 mL/kg over 4 hours

From Martin S, Jung R. Gastrointestinal infections and enterotoxigenic poisonings. In: DiPiro JT, Talbert RL, Yee GC, et al, eds. *Pharmacotherapy: A Pathophysiologic Approach*. 8th ed. New York: McGraw-Hill; 2011:1951–1967.

6,000 hospitalizations.^{4,5} Shigellosis usually affects children 6 months to 10 years of age. In the United States, shigellosis is a serious problem in daycare centers and in areas with crowded living conditions or poor sanitation. Most cases of shigellosis are transmitted through the fecal–oral route. Activities that may lead to shigellosis include handling toddlers' diapers, ingesting pool water, or consuming vegetables from a sewage-contaminated field. *Shigella* transmission from contaminated food (e.g., salads, raw vegetables, dairy products, and meat) and water, although less common, is associated with large outbreaks. Several large *Shigella* outbreaks have been reported on cruise ships associated with poor sanitation.

Pathogenesis

Shigella organisms are nonmotile, nonlactose-fermenting, gram-negative rods and are members of the Enterobacteriaceae family. There are four species of *Shigella*: *S. dysenteriae* (serogroup A), *S. flexneri* (serogroup B), *S. boydii* (serogroup C), and *S. sonnei* (serogroup D), which is responsible for most shigellosis cases in the United States. Infection with *Shigella* occurs after ingestion of as few as 10 to 100 organisms, which may explain the ease of person-to-person spread and the high secondary attack rate when an index case is introduced into a family. On average, symptoms develop about 3 days (range, 1 to 7) after contracting the bacteria.⁶

Shigella strains invade intestinal epithelial cells, with subsequent multiplication, inflammation, and destruction. The organism infects the superficial layer of the gut, rarely penetrates beyond the mucosa, and seldom invades the bloodstream. However, bacteremia can occur in malnourished

children and immunocompromised patients and is associated with a mortality rate as high as 20%.⁷

Treatment and Monitoring

- Although infection with *Shigella* is generally self-limited and responds to supportive care, antibiotic therapy is indicated because it shortens the duration of illness and shedding and consequently reduces the risk of transmission. Antibiotic resistance is a growing worldwide problem for enteric bacterial pathogens. Antibiotic susceptibility testing is recommended for the management of patients with suspected *Shigella* infection. When antimicrobial susceptibility of the organism is unknown, the recommended treatment of choice is a fluoroquinolone such as levofloxacin or ciprofloxacin. Alternative agents include azithromycin and ceftriaxone.⁸ These antibiotics should be administered for 3 days at the following doses: levofloxacin 500 mg orally once daily, ciprofloxacin 500 mg twice daily, or azithromycin 500 mg once daily. Azithromycin may also be given to children at a dose of 10 mg/kg daily for 3 days. Antimotility agents are not recommended because they can worsen dysentery and may be related to the development of toxic megacolon. No vaccines are licensed currently for the prevention of shigellosis.

SALMONELLOSIS

Epidemiology

Salmonella typhi and *Salmonella paratyphi*, which cause typhoid fever, have high host specificity for humans. In the

Clinical Presentation and Diagnosis of Shigellosis

- Biphasic illness
 - Early—high fever, watery **diarrhea** without blood
 - Later—after approximately 48 hours, colitis develops with urgency, **tenesmus**, and dysentery.
- Low-grade fever
- More frequent small-volume stools (“fractional stools”)
- Abdominal cramping
- Vomiting (35%)
- Complications of shigellosis
 - Proctitis or rectal prolapse—more common in infants and young children
 - Toxic megacolon—more commonly associated with *S. dysenteriae* 1 infection
 - Intestinal obstruction
 - Colonic perforation
 - Bacteremia—more common in children
 - Metabolic disturbances
 - Leukemoid reaction—WBC count more than 50,000/mm³ (more than 50 × 10⁹/L)
 - Neurologic disease—most commonly seizures (approximately 10% of patients)
 - Reactive arthritis or Reiter’s syndrome—most common in men aged 20 to 40 years
 - Hemolytic-uremic syndrome (HUS)—mortality rate greater than 50%
- Microscopic examination of stool is extremely useful and reveals multiple polymorphonuclear leukocytes and red blood cells (RBCs). Diagnosis is usually confirmed by stool culture

Patient Encounter 1

A 55-year-old man presents with headache, fever, abdominal pain, and bloody diarrhea for 48 hours. He states that his wife had similar symptoms several days ago. His stool Gram stain reveals the presence of leukocytes, and his WBC is 52 × 10³/mm³ (52 × 10⁹/L).

What test should you send?

Stool culture showed many *Shigella sonnei*.

What treatment do you recommend?

- United States, typhoid fever is now a rare disease with approximately 300 clinical cases reported per year. However, infections secondary to these organisms cause an estimated 20 million cases and 200,000 deaths annually worldwide.⁹

Nontyphoidal *Salmonella* (NTS) are important causes of reportable food-borne infection. There are an estimated 1.4 million cases of NTS illness annually in the United States, and almost 94 million worldwide.¹⁰ The highest incidence is in those younger than 1 year of age and older than 65 years of age or in those with HIV/AIDS. Outbreaks of intestinal salmonellosis have been associated with undercooked poultry and eggs, unpasteurized orange juice, tomatoes, cantaloupe, alfalfa sprouts, and cilantro. Exotic pets, especially reptiles (e.g., snakes, turtles, and iguanas), are an increasing source of human salmonellosis, accounting for 3% to 5% of all cases. NTS strains may also result in bacteremia and focal disease, such as endovascular infections, osteomyelitis, meningitis, and septic arthritis. Antimicrobial-resistant strains are associated with excess bloodstream infections and hospitalizations.¹¹ Recurrent *Salmonella* bacteremia is an AIDS-defining illness.

- Risk factors for salmonellosis include extremes of age; alteration of endogenous GI flora due to antimicrobial therapy, surgery, or acid-suppressive therapy³; diabetes; malignancy; rheumatologic disorders; HIV infection; and therapeutic immunosuppression. Proper food handling and storage can help prevent *Salmonella* gastroenteritis. Effective handwashing is important, especially when handling eggs and poultry.

Pathogenesis

Salmonella are motile, nonlactose-fermenting, gram-negative rods. In salmonellosis, the organisms penetrate the epithelial lining to the lamina propria with production of diffuse inflammation. The distal ileum and colon are sites of infection.

Treatment and Monitoring

► Gastroenteritis

- *Salmonella* gastroenteritis is usually self-limited, and antibiotics have no proven value. Patients respond well to ORT. Symptoms typically diminish in 3 to 7 days without sequelae. Antibiotic use may result in a higher rate of chronic carriage and relapse. Antimicrobial use should be limited to preemptive therapy among patients at higher risk for extraintestinal spread or invasive disease (Table 76–2). Antimotility agents should not be used. Avoiding milk products and following a BRAT diet (bananas, rice, applesauce, toast) may help reduce diarrhea associated with gastroenteritis.

► Enteric Fever

- The current drug of choice for typhoid fever is a fluoroquinolone, such as ciprofloxacin. The recommended adult dose of ciprofloxacin for uncomplicated typhoid fever is 500 mg orally twice daily for 5 to 7 days; however, decreased susceptibility to ciprofloxacin is a significant problem in the Indian subcontinent, Southeast Asia, Mexico, the Arabian Gulf, and Africa. All *S. typhi* isolates should be tested for fluoroquinolone resistance. In the United States, *S. typhi* with decreased ciprofloxacin susceptibility is associated with

Clinical Presentation and Diagnosis of Salmonellosis

Gastroenteritis

- Onset 8 to 48 hours after ingestion of contaminated food.
- Fever, diarrhea, and cramping.
- Stools are loose, of moderate volume, and without blood.
- Headache, myalgias, and other systemic symptoms can occur.
- Diagnosis relies on isolation of the organism from stool or ingested food.
- Certain underlying conditions (e.g., AIDS, inflammatory bowel disease, and prior gastric surgery) predispose the patient to more severe disease.

Enteric Fever

- Febrile illness 5 to 21 days after ingestion of contaminated food or water. The fever may progress in stepwise manner to become persistent and high grade. Relative bradycardia may be noted at the fever peak.
- Chills, diaphoresis, headache, anorexia, cough, weakness, sore throat, dizziness, and muscle pains may be present before onset of fever.
- Diarrhea is an early symptom and occurs in approximately 50% of cases.
- Intestinal hemorrhage or perforation, leukopenia, anemia, and subclinical disseminated intravascular coagulopathy may be seen.
- Rose spots, a coated tongue, and/or hepatosplenomegaly may be noted.
- Culture of stool, blood, or bone marrow for *Salmonella* species is helpful.

Table 76–2

Antimicrobial Indications for Nontyphoidal Salmonellosis (NTS)

Age 3 months or less or 65 years or more
 Fever and systemic toxicity
 HIV/AIDS
 Other immunodeficiency (e.g., steroid use, organ transplantation)
 Uremia or hemodialysis or renal transplant
 Malignancy
 Sickle cell anemia or hemoglobinopathy
 Inflammatory bowel disease
 Aortic aneurysm, prosthetic heart valve, vascular or orthopedic prosthesis

travel to the Indian subcontinent.⁹ If ciprofloxacin resistance is present, ceftriaxone may be used; however, this agent may be less suitable in some low- and middle-income countries due to cost and route of administration. Azithromycin

(500 mg once daily for 7 days for adults or 20 mg/kg/day up to a maximum of 1000 mg/day for 7 days for children) is an effective alternative for uncomplicated typhoid fever.¹²

- Two typhoid vaccines are available currently for use in the United States: an oral live-attenuated vaccine (Vivotif Berna-TM vaccine, Swiss Serum and Vaccine Institute) and a parenteral capsular polysaccharide vaccine (Typhim Vi, Pasteur Merieux). Immunization is recommended only for travelers going to endemic areas such as Latin America, Asia, and Africa; household contacts of a chronic carrier; and laboratory personnel who frequently work with *S. typhi*.

► Bacteremia and Focal Infections

- Treatment of *Salmonella* bacteremia should be initiated with either a fluoroquinolone (e.g., levofloxacin, ciprofloxacin) or a third-generation cephalosporin (e.g., ceftriaxone).⁸ Given increasing antimicrobial resistance, life-threatening infections should be treated with both agents until susceptibilities are available.¹⁰ If there is no evidence of an endovascular infection, therapy for bacteremia should continue for 10 to 14 days. For patients with suspected meningitis, high-dose ceftriaxone is preferred because of its optimal penetration of the blood–brain barrier. Osteomyelitis and joint infections, often associated with sickle-cell anemia, are difficult to eradicate and require longer durations of antimicrobial therapy (at least 4 to 6 weeks).¹⁰ In persons with HIV infection and an initial episode of *Salmonella* bacteremia, a longer-duration of antibiotic therapy (1 to 2 weeks of parenteral therapy followed by 4 weeks with an oral fluoroquinolone) is recommended to prevent relapse of bacteremia.

► Chronic Carrier State

A chronic carrier state, defined as positive stool or urine cultures for more than 12 months, develops in 1% to 4% of adults with typhoid fever. Persistence of the organism is often due to biliary tract carriage, which is higher in persons with biliary tract abnormalities. In patients with normal gallbladder function, effective agents for eradication of chronic carriage include amoxicillin (3 g orally divided three times a day in adults for 3 months), trimethoprim-sulfamethoxazole (one double-strength tablet orally twice a day for 3 months), or ciprofloxacin (750 mg orally twice daily for 4 weeks). Surgery in combination with antibiotic therapy is indicated in patients with biliary tract abnormalities.

CAMPYLOBACTERIOSIS

Epidemiology

- *Campylobacter jejuni* is the most commonly identified cause of bacterial diarrhea worldwide. In the United States, this organism accounts for an estimated 1.4 million infections, 13,000 hospitalizations, and 100 deaths annually.¹³ Risk factors for *Campylobacter* infection include consumption of contaminated foods of animal origin, especially undercooked poultry or other foods that are cross-contaminated by raw poultry meat during food preparation; unpasteurized milk;

Patient Encounter 2

A 45-year-old Hispanic man with AIDS presents to the emergency department (ED) with fever, nausea, two episodes of vomiting, abdominal pain, and nonbloody diarrhea for 2 days. He reports that his diarrhea is improving, but he developed fever and chills a few hours before he came to the ED. Other history is noncontributory. His physical examination is positive for fever and diffuse abdominal pain. An abdominal ultrasound did not show any abnormal findings. Two sets of blood cultures were sent to the laboratory, and he is admitted to the hospital.

What primary risk factor does this patient have for a disseminated Salmonella infection?

Do any further tests need to be performed before you can decide on a treatment recommendation?

What treatment do you recommend? Are there any special considerations due to this patient's HIV infection?

contaminated water; foreign travel; contact with farm animals and pets; and the use of antimicrobial therapy.¹⁴ Between 25% and 50% of *C. jejuni* infections in the United States appear to be related to chicken exposure or consumption. People should be instructed to wash their hands after contact with raw meats and animals.

The age and sex distributions of *Campylobacter* infections are unique among bacterial enteric pathogens. In developed countries, there are two age peaks: younger than 1 year of age and 15 to 44 years of age. There is a mild male predominance among infected persons. The reason for this distinct age and sex distribution remains unknown. The epidemiology of *Campylobacter* infections is quite different in developing countries; *Campylobacter* diarrhea is primarily a pediatric disease in developing countries.

Pathogenesis

Campylobacter spp. are gram-negative bacilli that have a curved or spiral shape. *Campylobacter* are sensitive to stomach acidity; as a result, diseases or medications that buffer gastric acidity may increase the risk of infection. The infectious dose for *C. jejuni* is low, similar to that for *Salmonella* spp. After an incubation period, infection is established in the jejunum, ileum, colon, and rectum.

Treatment and Monitoring

Effective fluid and electrolyte replacement is the cornerstone of therapy for patients with *Campylobacter* infection. In most cases, this can be accomplished with the use of oral glucose–electrolyte solutions; however, severe cases may require IV fluids. Antibiotic therapy should be considered in patients with high fevers, bloody stools, symptoms lasting longer than 1 week, pregnancy, infection with HIV, and other immunocompromising conditions.

Clinical Presentation and Diagnosis of Campylobacteriosis

- Incubation period of 1 to 7 days.
- A brief prodrome of fever, headache, and myalgias is followed by crampy abdominal pain, a high fever, and several bowel movements per day, which may be watery or bloody.
- The abdominal pain and tenderness may be localized, and pain in the right lower quadrant may mimic acute appendicitis. Abdominal pain is more prevalent in *Campylobacter* infection than in either *Shigella* or *Salmonella* infections.
- Tenesmus occurs in approximately 25% of patients.
- Fecal leukocytes and red blood cells (RBCs) are detected in the stools of 75% of infected individuals. Diagnosis of *Campylobacter* is established by stool culture.

Macrolides are the recommended first-line drug class for the treatment of *Campylobacter* infections.⁸ The recommended dosage of azithromycin for adults is 500 mg orally daily for 3 days and it is 500 mg orally four times daily for 5 days for erythromycin. The recommended regimen for children is azithromycin 20 mg/kg (up to 1 g) orally daily. A fluoroquinolone or a tetracycline are alternatives; however, the widespread use of these agents in food animals has resulted in fluoroquinolone-resistant *Campylobacter* strains worldwide.^{13,14} In 1999, 18% of human *Campylobacter* isolates in the United States were fluoroquinolone resistant, and this rate is much higher in many developing countries.¹⁵

Campylobacter fetus is the most commonly identified species in patients with bacteremia, which primarily occurs in patients who are elderly or immunocompromised. In addition, focal infections such as cellulitis, vascular infections, meningitis, and abscesses may be present. *C. fetus* has a predilection for the vascular endothelium and implanted medical devices.¹⁶ For these serious infections, treatment with a third-generation cephalosporin, gentamicin, ampicillin, or a carbapenem is recommended.⁸ Antimotility agents should be avoided because they may prolong the duration of symptoms and have been associated with worse outcomes. Postinfectious complications associated with *Campylobacter* infection include reactive arthritis (1%) and Guillain-Barré syndrome (0.1%).¹⁷

ENTEROHEMORRHAGIC ESCHERICHIA COLI

Epidemiology

3 Blood in the stool indicates the possibility of inflammatory mucosal disease of the colon such as enterohemorrhagic *Escherichia coli* (EHEC), a pathogenic subgroup of shiga toxin-producing organisms and an important cause of bloody diarrhea in the United States. Acute hemorrhagic colitis has been primarily

Patient Encounter 3

A 55-year-old woman presents with a 3-day history of high fevers, headaches, and diarrhea. She reports having 7 to 10 loose watery stools per day. She had chicken for lunch in a local restaurant last week, which she really liked. Otherwise, she denies any unusual foods, any recent travel, or any sick contacts. She doesn't have any pets at home. She is able to keep food down. The only positive physical findings are diffuse abdominal tenderness, fever, and high blood pressure. Fecal leukocytes were negative. A stool culture was sent, which showed moderate *Campylobacter jejuni*.

How would you treat this patient?

- associated with the O157:H7 serotype. This serotype has been responsible for large outbreaks of infection, has higher rates of complications, and appears to be more pathogenic than non-EHEC STEC strains. The spectrum of disease associated with *E. coli* O157:H7 includes bloody diarrhea, which is seen in as many as 95% of patients; nonbloody diarrhea; hemolytic-uremic syndrome (HUS); and thrombotic thrombocytopenic purpura (TTP). HUS is the most common cause of acute kidney injury in children in the United States and frequently leads to prolonged hospitalization, dialysis, and extended follow-up medical care.¹⁸

- Approximately 70,000 cases of EHEC illness occur every year in the United States and lead to more than 2,000 hospitalizations. The highest incidence is in patients aged 5 to 9 years and 50 to 59 years. This organism is also associated with significant morbidity and mortality in elderly, institutionalized patients. Both young and old patients are at particular risk to develop postinfectious complications, TTP, and HUS.¹⁹ Outbreaks of diarrhea due to *E. coli* O157:H7 and other STECs have occurred following ingestion of contaminated beef, hamburgers from fast-food chains, unpasteurized milk and other dairy products, vegetables (e.g., alfalfa sprouts, coleslaw, and lettuce), and apple juice. The most important reservoir for *E. coli* O157:H7 is the GI tract of cattle. Person-to-person transmission also occurs, and swimming in infant pools or contaminated lakes or drinking municipal water are additional risk factors. The incidence of diagnosed *E. coli* O157:H7 infections in the United States are greater among rural than urban populations; *E. coli* O157:H7 infections occur in summer and autumn.

Pathogenesis

The infectious dose of EHEC is very low, between 1 and 100 colony-forming units (CFUs). The two major virulence factors for EHEC are the production of two Shiga-like cytotoxins (Shiga toxin [Stx] I and II) and adhesion-causing attachment-effacement lesions. These cytotoxins are responsible for vascular damage and systemic effects such as HUS. Adhesion mediates initial attachment of EHEC to intestinal epithelial cells. Following attachment, these organisms produce lesions

Clinical Presentation and Diagnosis of EHEC

- Incubation period of 3 to 5 days
- Bloody stools
- Fever usually absent
- Leukocytosis
- Abdominal tenderness
- HUS in 2% to 10% of patients (especially children 1 to 5 years of age and the elderly in nursing homes); develops on average 1 week after the onset of diarrhea.
- EHEC belonging to serotype O157:H7 characteristically do not ferment sorbitol, whereas more than 70% of intestinal floral *E. coli* do. To properly screen EHEC strains in cases of diarrhea, stool should be placed on special sorbitol-MacConkey agar. Colonies of *E. coli* O157:H7, which do not ferment the sorbitol, can be identified readily and confirmed by serotyping with specific antisera. In addition, stool should be tested directly for the presence of Stx I and II by enzyme immunoassay (EIA).

on individual intestinal epithelial cells in the small or large intestine and cause diarrhea.

Treatment and Monitoring

- The only recommended treatment of EHEC infection is supportive, including fluid and electrolyte replacement, often in the form of ORT. Most illnesses resolve in 5 to 7 days. Patients should be monitored for the development of HUS. Antibiotics are currently contraindicated because they can induce the expression and release of toxin. Antimotility agents should be avoided because they delay clearance of the pathogen and toxin, which increases the risk of systemic complications. The use of narcotics and nonsteroidal anti-inflammatory drugs (NSAIDs) should also be avoided in acutely infected patients.²⁰

- Prevention of EHEC infection is especially important because once an infection is established, no therapeutic interventions are available to lessen the risk of the development of HUS.¹⁸ Hamburgers should be cooked thoroughly until the temperature of the thickest part of the patty is 72°C. All surfaces and utensils that contact raw meat should be washed thoroughly before reuse. Fruits and vegetables should be washed thoroughly, especially those that will not be cooked. Handwashing is also very important and should include the supervision of handwashing by children in daycare centers.

CHOLERA

Epidemiology

Cholera is an intestinal infection that is caused by the bacterium *Vibrio cholerae* that leads to a massive loss of fluid through the GI tract and often results in life-threatening

Patient Encounter 4

A very pleasant 73-year-old white woman with a 48-hour history of hematochezia and hemoptysis presents to the ED. She denies any recent travel, exotic foods, raw foods, or sick contacts. She does note that she ate cold-cut sandwiches at a fundraiser approximately 3 days before her symptoms started. She also noticed that she has three friends who developed bloody diarrhea who also ate at this same fundraiser. She denies any fevers, shakes, chills, cough, sore throat, shortness of breath, chest pain, nausea or vomiting, dysuria, hematuria, edema, or night sweats. On her initial presentation, she had a CT that showed pancolitis and terminal ileitis. She was started on antibiotic therapy including ciprofloxacin and metronidazole. Fecal leukocytes were negative. A stool culture was sent and was positive for Stx. The final culture result was positive for *Escherichia coli* O157:H7.

What would be your recommendation for this patient?

Two days later, she develops acute kidney injury and thrombocytopenia.

What is the most likely diagnosis?

Clinical Presentation and Diagnosis of Cholera

- Incubation period of 18 hours to 5 days.
- Abrupt, painless onset of watery diarrhea and vomiting. The diarrheal fluid is usually clear and may be as much as 10 to 20 liters per day.
- Large volumes of rice-water stools, which may have fishy odor.
- Dehydration, which may be severe. Patients suffering from severe dehydration owing to rapid fluid loss are at risk for death within several hours of disease onset. Typical symptoms of severe dehydration include low blood pressure, poor skin turgor, sunken eyes, and rapid pulse.
- Severe muscle cramps in extremities owing to the electrolyte imbalances are caused by fluid loss. These cramps should resolve with treatment.
- Metabolic acidosis.

dehydration and shock.²¹ The biotypes of *V. cholerae* responsible for pandemics are serogroup O1 (El Tor) and serogroup O139.²² Worldwide this infection affects 3 to 5 million people and causes more than 100,000 deaths per year. Although not associated with pandemics, serogroups O75 and O141 have caused small outbreaks of severe diarrhea in the United States. Cholera can be transmitted by water or by food tainted with contaminated water, particularly undercooked seafood. Research on cholera has led to the refinement of general rehydration therapy, including the proper use of IV and oral rehydration solutions.²¹

Pathogenesis

V. cholerae is a gram-negative bacillus. Vibrios pass through the stomach to colonize the upper small intestine. They possess filamentous protein extensions that attach to receptors on the intestinal mucosa, and their motility assists with penetration of the mucus layer.²¹ The cholera enterotoxin consists of two subunits, one of which (subunit A) is transported into the cells and causes an increase in cyclic adenosine monophosphate (cAMP), which leads to the secretion of fluid into the small intestine. This large volume of GI fluid results in the watery diarrhea that is characteristic of cholera. The stools consist of an electrolyte-rich isotonic fluid that is highly infectious.²¹

Treatment and Monitoring

The cornerstone of cholera treatment is fluid replacement. Without treatment, the case-fatality rate for severe cholera is approximately 50%. For cholera, rice-based ORT is better

than glucose-based ORT because it reduces the number of stools.²³ Antibiotic prophylaxis is not warranted. A short course of antibiotic therapy shortens the course of the disease and decreases the severity of symptoms. The current WHO treatment protocol recommends antibiotics for only “severe” symptoms; however, the International Center for Diarrheal Disease Research, Bangladesh (ICDDR,B) recommends antibiotics for both severe and moderate cases.²⁴ The WHO recommendation is usually interpreted to provide antibiotics only to patients with severe dehydration (i.e. greater than 10% body weight loss). With effective antibiotic therapy, the illness is shortened by about 50%, and the duration of excretion of *V. cholerae* in the stool is shortened to 1 or 2 days.²⁴ Several experts argue that antibiotics should be used more liberally in significant outbreaks.^{24,25} A tetracycline (e.g., doxycycline) is recommended as first-line therapy; however, some strains are resistant. Other therapeutic options include a fluoroquinolone, trimethoprim-sulfamethoxazole, and azithromycin.⁸ Fluoroquinolones are not recommended for children. Single-dose azithromycin demonstrated a dramatic resolution of diarrhea at 24 hours in one study.²⁶ This agent is increasingly utilized in areas where multidrug-resistant strains are prevalent.²⁵

Primary preventive strategies include ensuring a safe water supply and safe food preparation, improving sanitation, and patient education. A number of safe and effective oral vaccines for cholera are available, which can prevent 50% to 60% of cholera episodes during the first 2 years after vaccination.²⁷ However, cholera vaccination is not recommended by the Centers for Disease Control and Prevention (CDC) for most people traveling from the United States to endemic areas. The WHO recommends immunization of high-risk groups, such as children and patients infected with HIV, in countries where the disease is endemic.²⁵

TRAVELER'S DIARRHEA

Epidemiology

Traveler's diarrhea (TD) commonly occurs when visitors from developed countries travel to developing countries. More than 50 million people are at risk for TD each year.²⁸

These infections arise following the consumption of food or water contaminated with bacteria, viruses, or parasites.

4 *Bacteria such as Shigella, Salmonella, Campylobacter, and enterotoxigenic E. coli (ETEC) are responsible for 60% to 85% of TD cases.*²⁸ *Noroviruses are increasingly recognized as a significant cause of TD as well.*²⁹ Most of these illnesses occur during the first 2 weeks of travel and last about 4 days without therapy.³⁰ Protozoans are an uncommon cause but should be suspected if diarrhea lasts for more than 2 weeks.

Food and water contaminated with fecal matter are the main sources of pathogens that lead to TD. Particularly problematic foods and beverages include salads, unpeeled fruits, raw or poorly cooked meats and seafood, unpasteurized dairy products, and tap water (including ice).³⁰ Bottled water is generally safe if the cap and seal are intact. Food from street vendors and buffet-style meals are particularly risky.³¹ The consumption of more than five alcoholic drinks per day has been demonstrated to be a risk factor for TD, especially in males.³² Providing effective education about the types of foods and activities to avoid during travel may decrease the number of cases of TD.

Pathogenesis

Enterotoxigenic *E. coli*, one of the most common causes of TD and responsible for up to 70% of cases in Mexico, produces both heat-labile enterotoxins (LT) and heat-stable enterotoxins (ST). Both toxins demonstrate cellular mechanisms similar to those of cholera toxins and lead to a great increase in both fluid and electrolyte secretion. These *E. coli* strains are not invasive, as are the Shiga-toxin-producing EHEC strains. These organisms do not cause inflammation and lead to a profuse, watery diarrhea without blood, leukocytes, or abdominal cramping.

Clinical Presentation and Diagnosis of Traveler's Diarrhea

- Frequent, loose stools
- Associated with nausea and vomiting
- Abdominal pain
- Fecal urgency
- Dysentery
- Signs and symptoms related to specific causative pathogen

Treatment and Monitoring

- The goal of treatment is to maintain hydration and functional status and to prevent disruption of travel plans. For travelers with mild cases of diarrhea, oral rehydration salts can prevent and treat dehydration and may be particularly important for children and the elderly.³³ Loperamide (4-mg loading dose, then 2 mg orally after each loose stool to a maximum of 16 mg/day) may be used for milder diarrhea; however, this agent is not recommended if bloody diarrhea or fever is present. Antibiotics are effective at reducing the duration of illness to 1 or 2 days. Providing the traveler with a means for empiric self-treatment is an effective method of treating this illness without promoting the inappropriate use of antibiotics. Therapy should be initiated after the first episode of diarrhea that is uncomfortable or interferes with activities.³⁴
- Trimethoprim-sulfamethoxazole and doxycycline are no longer recommended because of widespread resistance. In general, levofloxacin (500 mg orally once daily for 1 to 3 days) or ciprofloxacin (500 mg orally twice daily for 1 to 3 days) are recommended as first-line agents for travel to most parts of the world.^{30,33} Azithromycin (1,000 mg as a single oral dose or 500 mg daily for 1 to 3 days) is an alternative and is preferred in areas where quinolone-resistant *Campylobacter* is prevalent (e.g., Thailand, India).³⁰ Azithromycin can also be used in pregnant women and children (10 mg/kg/day orally for 3 days).³³ Rifaximin (200 mg orally three times daily for 3 days), a nonabsorbed oral antibiotic, is approved for treatment of TD caused by ETEC in persons at least 12 years old. This agent may be a good choice for persons traveling to destinations where ETEC is the predominant pathogen, such as Mexico.³⁰ One meta-analysis found that use of an antimicrobial agent plus loperamide was more effective than use of an antimicrobial alone in decreasing the duration of illness.³⁵ Thus many clinicians will recommend the use of loperamide in dysentery if it is combined with an antibiotic.³⁰
- 5 *The education of travelers about high-risk food and beverages is an important component in the prevention of TD.* Slogans such as “peel it, boil it, cook it, or forget it” can help to remind travelers of the foods that may be contaminated. However, many travelers find it difficult to follow dietary recommendations. In a study of American travelers, almost 50% developed diarrhea despite receiving advice on preventive dietary measures.³⁶ Antibiotic prophylaxis is not recommended by the CDC because it can lead to drug-resistant organisms and may give travelers a false sense of security.³⁰ However, some healthcare professionals do prescribe prophylactic antibiotics for those who are at high risk of developing TD (e.g., immunocompromised persons, patients with impaired gastric acid production) or for those who cannot risk temporary incapacitation (e.g., athletes, diplomats, business people). A fluoroquinolone antibiotic, such as levofloxacin or ciprofloxacin, is usually used first line for this purpose at a dose of one tablet daily during travel and for 2 days following return.³³ Although not approved for prophylaxis, rifaximin may be an excellent option for travelers to Mexico because it is not absorbed and should

be less likely to select out resistant organisms than are the fluoroquinolones.³⁷ Bismuth subsalicylate (Pepto-Bismol; 525 mg orally four times daily for up to 3 weeks) provides a rate of protection of about 60% against TD.³⁰ However, this agent should not be used in persons taking anticoagulants or other salicylates. Probiotics colonize the GI tract and may prevent pathogenic organisms from causing infections. These agents may provide protection rates as high as 50%,³⁸ but additional studies are needed, and these products suffer from lack of standardization. No effective vaccines are available for TD.

CLOSTRIDIUM DIFFICILE INFECTION

Epidemiology

C. difficile is the primary cause of nosocomial infectious diarrhea in hospitalized patients. Both the incidence and severity of *C. difficile* infection (CDI) have been increasing in the United States.³⁹ The number of *C. difficile* cases that were reported in 2005 (84 per 100,000) was nearly three times higher than the 1996 rate.⁴⁰ There has also been a significant increase in severe cases, colectomies, and death related to CDI.⁴¹ A more virulent, epidemic strain (NAP1/B1/027) was initially identified in the 1980s and is now commonly associated with outbreaks. These strains are associated with an increased production of toxins A and B, which are the primary virulence determinants for *C. difficile*.⁴⁰ In addition, an increasing proportion of CDI patients have a community-acquired infection. These patients are often younger, lack traditional risk factors, and generally have less severe disease compared with those with hospital-acquired infections.³⁹ A primary risk factor for these community-acquired infections appears to be therapeutic gastric acid suppression.⁴² Common risk factors for hospital-acquired CDI include increasing age, severe underlying illness, intensive care unit admission, gastric acid suppression,⁴³ and exposure to antimicrobials, especially broad-spectrum, multiple-drug regimens.⁴⁴ **6** *Nosocomial Clostridium difficile-associated diarrhea (CDAD) is almost always associated with antimicrobial use; therefore, unnecessary and inappropriate antibiotic therapy should be avoided. Clindamycin, cephalosporins, and penicillins are the antibiotics most commonly associated with CDAD, but almost all antibiotics except aminoglycosides have been implicated.*⁴⁵ Fluoroquinolones are also strongly associated with CDAD.⁴⁶

Pathogenesis

C. difficile, a gram-positive, spore-forming anaerobe, is spread by the fecal-oral route, and patient-to-patient spread is an important mode of transmission within the hospital. The organism is ingested either as the vegetative form or spores, which can survive for long periods in the environment and can traverse the acidic stomach. In the small intestine, spores germinate into the vegetative form. Once the GI tract is colonized with spores, disruption of the gut flora, which occurs with antibiotic therapy, allows *C. difficile* to proliferate.

Toxin production is essential for the disease to occur and is responsible for the inflammation, fluid and mucus secretion, and mucosal damage that lead to diarrhea or colitis.

Treatment and Monitoring

Patients who develop CDI while receiving an antibiotic should have the antibiotic discontinued, if possible. If antimicrobial therapy must continue, an attempt should be made to switch the patient to an agent with a lower risk of CDI.⁴⁷ The use of concurrent antibiotics during CDI therapy, or soon thereafter, lowers the chances of both a clinical and global cure (i.e., clinical cure with no recurrence after 4 weeks).⁴⁸ Although a systematic review has concluded that no antimicrobial agent is clearly superior for the initial cure of CDI,⁴⁹ clinical practice guidelines recommend that initial antimicrobial therapy should be based on the degree of illness.⁵⁰ If severe or complicated disease is present, empiric antimicrobial therapy should begin as soon as the diagnosis is suspected. If relatively mild symptoms are present, antimicrobial therapy may be delayed until stool toxin assay results are available.⁵⁰

Metronidazole (500 mg orally three times daily for 10 to 14 days) is the recommended first-line drug for initial treatment of mild-to-moderate CDI. Oral vancomycin (125 mg four times daily for 10 to 14 days) is the recommended first-line drug therapy for initial treatment of severe CDI,⁵⁰ which is usually defined as a serum creatinine increase to more than 1.5 times baseline or a white blood cell count greater than 15,000 cells/mm³ ($15 \times 10^9/L$). Other risk factors for severe disease include age greater than 65 years, hypoalbuminemia, immunosuppression, and severe underlying disease.⁴⁴ For the treatment of severe, complicated CDI (refractory hypotension, ileus, and/or toxic megacolon), a higher dose of vancomycin (500 mg orally four times daily) may be combined with IV metronidazole (500 mg every 8 hours). Vancomycin may be given as a retention enema (500 mg in 100 mL of normal saline every 6 hours) if a complete ileus is present.⁵⁰ The use of antimotility agents should be avoided because they may precipitate toxic megacolon. Surgical intervention may be lifesaving, particularly in cases complicated by toxic megacolon or colonic perforation.

A study from a single, tertiary care hospital suggests that Infectious Diseases Society of America guidelines regarding the initial use of oral vancomycin may not be consistently followed in practice. Although not statistically significant, these data support the guidelines by noting a trend toward lower mortality and hospital length of stay in patients with severe CDI who were given oral vancomycin. These authors conclude that antimicrobial stewardship teams could play an important role in better assuring that initial CDI therapy is based on severity.⁵¹ The cost of oral vancomycin capsules (approximately \$1,000 for a 10-day course) is much higher than metronidazole; however, vancomycin for IV use can be prepared for oral use at a much lower cost.⁴⁴ The FDA has also approved fidaxomicin, an oral macrolide antibiotic, for the treatment of CDI in patients who are at least 18 years old. This drug is minimally absorbed and has no activity against organisms other than

Clinical Presentation and Diagnosis of CDAD

- Symptoms can start as early as the first day of antimicrobial therapy or several weeks after antibiotic therapy is completed.
- Asymptomatic carriage.
- Diarrhea:
 - Acute watery diarrhea with lower abdominal pain, low-grade fever, and mild or absent leukocytosis.
 - Mild, with only three or four loose watery stools per day.
 - *C. difficile* toxins are present in stool, but sigmoidoscopic examination is normal.
- Colitis:
 - Profuse, watery diarrhea with 5 to 15 bowel movements per day, abdominal pain, abdominal distention, nausea, and anorexia
 - Left or right lower quadrant abdominal pain and cramps that are relieved by passage of diarrhea
 - Dehydration and low-grade fever
 - Sigmoidoscopic examination may reveal a nonspecific diffuse or patchy erythematous colitis without pseudomembranes
- Pseudomembranous colitis: Same symptoms as colitis, but sigmoidoscopic examination reveals a characteristic membrane with adherent yellow or off-white plaques, usually in distal colon.
- Toxic megacolon: Suggested by acute dilation of the colon to a diameter greater than 6 cm, associated systemic toxicity, and the absence of mechanical obstruction. It carries a high mortality rate.
- Fulminant colitis: Acute abdomen and systemic symptoms such as fever, tachycardia, dehydration, and hypotension. Some patients have marked leukocytosis (up to 40×10^3 white blood cells/mm³ [40×10^9 /L]). Diarrhea is usually prominent but may not occur in patients with paralytic ileus and toxic megacolon.
- Recurrent disease:
 - Risk factors include increased age, recent abdominal surgery, increased number of *C. difficile* diarrheal episodes, and leukocytosis.
 - 20% to 25% of patients develop a second episode of CDAD within 2 months of the initial diagnosis.
- In most cases, *C. difficile* toxin testing of a single unformed stool specimen effectively establishes the diagnosis. Stool culture is the most sensitive test, but it is not clinically practical due to slow turnaround time. Enzyme immunoassay (EIA) testing for toxin A and B is used in most labs. This test is rapid, but less sensitive, and repeat testing may be necessary if the initial test is negative. Newer tests, such as EIA detection of glutamate dehydrogenase (GDH) or use of polymerase chain reaction (PCR) technology, may ultimately improve diagnostic testing for CDI.
- Leukocytosis, hypoalbuminemia, and fecal leukocytes are nonspecific but suggestive of *C. difficile* infection.
- In selected patients, sigmoidoscopy, colonoscopy, or abdominal CT scan can provide useful diagnostic information.

clostridia, which allows for preservation of normal gut flora.⁵² The recommended dose of fidaxomicin is 200 mg orally twice daily for 10 days. In clinical trials, fidaxomicin resulted in clinical cure rates that were similar to those achieved with oral vancomycin, but there were significantly fewer recurrences in those treated with fidaxomicin.⁵³ However, recurrence rates were similar among patients infected with the more virulent NAP1/B1/027 strain. One study did suggest that fidaxomicin might provide improved cure rates versus vancomycin if a patient must continue antibiotics while receiving therapy for CDI.⁴⁸ However, fidaxomicin is very costly (approximately \$3,000 for a 10-day course).

The recurrence rate after an initial episode of CDI is approximately 20% to 25%, with the highest risk within the first 2 weeks.⁴⁴ This rate is independent of which first-line agent is used. Treatment of the first recurrence of CDI is usually treated with the same regimen used for the initial episode; however, this choice should also depend on the clinical condition of the patient, as recommended for the initial therapy choice.⁵⁰ Metronidazole should not be used beyond the first recurrence or for long-term

chronic treatment due to the risk of neurotoxicity. The treatment of second or later recurrences of CDI should be undertaken with vancomycin using a tapered and/or pulse regimen.^{40,50} Fidaxomicin may be superior to vancomycin at preventing CDAD recurrences secondary to non-NAP1/B1/027 strains. Rifaximin, approved for the treatment of TD, and nitazoxanide, approved for the treatment of *Giardia* or *Cryptosporidium*, may be useful for the prevention of recurrent CDI episodes.⁴⁴ Rifaximin, administered directly following a course of metronidazole or vancomycin, may be an option for the prevention of recurrent episodes of CDI in some patients. Fecal microbiota transplantation has a reported efficacy of about 90% in preventing recurrent CDI, and one report suggests that this therapy might emerge as a first-line therapy for severe infection.⁵⁴

Strict infection control measures, including contact precautions, should be instituted for all patients with CDAD. Environmental cleaning with chlorine-containing agents should be used to eliminate *C. difficile* spores. Because alcohol is ineffective in killing spores, it is essential that healthcare workers wash their hands with soap and water rather than

Patient Encounter 5

A 70-year-old man presents to the ED because of diffuse abdominal pain and nonbloody diarrhea. One day earlier he had been discharged from the hospital, where he had received ceftriaxone and levofloxacin for 7 days for an upper respiratory infection. Soon after going home, he passed numerous liquid brown stools. A few hours later, the patient became disoriented, and an ambulance was called. His medical history is unremarkable. Laboratory values: WBC count $50 \times 10^3/\text{mm}^3$ ($50 \times 10^9/\text{L}$), hematocrit 43% (0.43), sodium 125 mEq/L (125 mmol/L), potassium 5.6 mEq/L (5.6 mmol/L), CO_2 14 mEq/L (14 mmol/L), and metabolic acidosis. An abdominal radiograph series show no evidence of obstruction. The patient was admitted to the hospital.

What GI disease do you suspect based on this information?

From your suspicion, what diagnostic tests and treatment would you recommend for this patient?

In the hospital, he receives fluids and vancomycin 125 mg orally four times daily. Stool was sent for *C. difficile* toxin assay, which came back positive. The patient continues to have abdominal pain but no bowel movement. On day 3 of hospitalization, his abdomen is distended with diffuse pain. His WBC count remains elevated. A CT scan of the abdomen showed colonic dilation to greater than 6 cm. The patient became febrile and hypotensive, requiring multiple pharmacologic support for hypotension.

What are this patient's risk factors for Clostridium difficile-associated diarrhea (CDAD)?

What do these new findings suggest?

How does this progression change your treatment recommendations?

- using alcohol-based hand sanitizers. Meticulous handwashing is the single most important strategy to decrease the patient-to-patient transmission of *C. difficile*. The administration of currently available probiotic agents is not recommended to prevent primary CDI or to treat recurrences.^{44,50}

CRYPTOSPORIDIOSIS

Epidemiology

Cryptosporidiosis has been recognized as a human disease since the 1970s, with increasing importance in the 1980s and 1990s because of its relationship with HIV/AIDS.

- *Cryptosporidium* accounts for 2.2% and 6.1% of diarrhea cases in immunocompetent people in developed and developing countries, respectively.⁵⁵ In the United States, the number of reported cases of cryptosporidiosis increased from 6,479 in 2006 to 10,500 in 2008. This increase was partially attributed to multiple large recreational water outbreaks and likely reflects increased use of communal swimming venues (e.g., lakes, swimming pools, and water parks) by young children.⁵⁶

Cryptosporidiosis is spread person-to-person, usually via the fecal-oral route; by animals, particularly cattle and sheep; and through the environment, especially water.

- People at increased risk of contracting cryptosporidiosis include household and family contacts and sexual partners of someone with the disease, healthcare workers, daycare workers, users of public swimming areas, and people traveling to regions of high endemicity.⁵⁵

Pathogenesis

Cryptosporidium is an intracellular protozoan parasite that is capable of completing its entire life cycle within one host. Humans become infected on ingestion of the oocysts, and

Clinical Presentation and Diagnosis of Cryptosporidiosis

General

- 7- to 10-day incubation period.
- Profuse, watery diarrhea with mucus but not blood or leukocytes that lasts for approximately 2 weeks.
- Nausea, vomiting, and abdominal cramps often accompany the diarrhea.
- Fever may be present.
- Simplest method of diagnosis is detection of oocysts by modified acid-fast staining of a stool specimen. Standard ova and parasite test does not include *Cryptosporidium*.

Immunocompetent

- May manifest as asymptomatic disease, acute diarrhea, or persistent diarrhea lasting for several weeks
- Usually self-limiting

Immunocompromised

- May manifest as asymptomatic disease; transient infection for less than 2 months; chronic diarrhea lasting at least 2 months, or fulminant infection, with at least 2 L of watery stool per day
- Asymptomatic disease more common in those with a CD4^+ cell count greater than 200 cells/ mm^3 ($200 \times 10^6/\text{L}$), and fulminant infection more common in those with a CD4^+ cell count of less than 50 cells/ mm^3 ($50 \times 10^6/\text{L}$)

autoinfection and persistent infections are possible owing to repeated life cycles within the GI tract. As few as 10 to 100 oocysts can cause infection.⁵⁵

Treatment and Monitoring

- In general, immunocompetent persons and those with asymptomatic infection do not require antimicrobial therapy. In patients with HIV/AIDS, the optimal therapy is restoration of immune function through the use of antiretroviral therapy (ART). In persons in whom antimicrobial therapy is deemed necessary or in HIV/AIDS patients in whom ART is ineffective, a combination of an antimicrobial and an antidiarrheal agent is recommended.⁵⁵

Nitazoxanide is the only FDA-approved agent for the treatment of cryptosporidiosis in adults and children. This agent has demonstrated efficacy in cryptosporidiosis in immunocompetent persons, malnourished children, and HIV/AIDS patients.⁵⁷ Patients who are infected with both HIV and *Cryptosporidium* usually require longer therapy durations and higher doses than immunocompetent patients.⁵⁷ Alternative agents include paromomycin, azithromycin, and clarithromycin.⁵⁸

Patient Encounter 6

A 35-year-old man with a past medical history significant for recent kidney transplant presents with diarrhea for 1 month. He reports four to five watery stools per day. He also complains of abdominal pain and weight loss. He denies any fever, nausea, and vomiting. Stool studies including fecal leukocytes, culture, and ova and parasites were all negative.

What additional diagnostic test should you order and why?

*An acid-fast staining of stool was positive for *Cryptosporidium parvum*. What treatment would you recommend for this patient?*

Prevention of cryptosporidiosis can prove difficult because the oocysts are resilient to many disinfectants and antiseptics, including ammonia, alcohol, and chlorine.⁵⁵ Most traditional water-treatment methods, including filtration, do not eradicate all oocysts, which is problematic in the face of the small dose of *Cryptosporidium* that is necessary for infection.

- Routine screening of drinking water should be considered for water-treatment plants, and severely immunocompromised individuals should be advised to avoid water in lakes and streams and contact with young animals.⁵⁵

VIRAL GASTROENTERITIS

- Viruses are the most common cause of diarrheal illness in the world and, in the United States, account for 450,000 illnesses and 160,000 hospitalizations for adults and children, respectively, and more than 4,000 deaths.⁵⁹ Many viruses may cause gastroenteritis, including rotaviruses, noroviruses, astroviruses, enteric adenoviruses, and coronaviruses (Table 76-3). This chapter focuses on rotaviruses.

ROTAVIRUS

- Rotavirus causes between 600,000 and 875,000 deaths each year, with the highest rates in the very young and in developing countries. Rotavirus is the leading cause of childhood gastroenteritis and death worldwide. Most infections occur in children between 6 months and 2 years of age, typically during the winter season, but adults may be infected as well. Rotavirus causes more than 2 million hospitalizations and 600,000 deaths per year in children younger than 5 years of age.⁶⁰ Person-to-person transmission occurs through the fecal-oral route.

The mechanism of diarrhea has not been clearly elucidated, but theories include a reduction in the absorptive surface along with impaired absorption owing to cellular damage, enterotoxigenic effects of a rotavirus protein, and stimulation of the enteric nervous system.

Table 76-3

Agents Responsible for Acute Viral Gastroenteritis and Diarrhea

Virus	Peak Age	Peak Time	Duration	Transmission	Symptoms
Rotavirus	6 months–2 years	Winter	3–8 days	Fecal–oral, water, food	Diarrhea, vomiting, fever, abdominal pain
Enteric adenovirus	Less than 2 years	Year-round	7–9 days	Fecal–oral	Diarrhea, respiratory symptoms, vomiting, fever
Astrovirus	Less than 7 years	Winter	1–4 days	Fecal–oral, water, shellfish	Vomiting, diarrhea, fever, abdominal pain
Noroviruses	More than 5 years	Variable	12–24 hours	Fecal–oral, food, aerosol	Nausea, vomiting, diarrhea, abdominal cramps, headache, fever, chills, myalgia

Modified from Martin S, Jung R. Gastrointestinal infections and enterotoxigenic poisonings. In: DiPiro JT, Talbert RL, Yee GC, et al, eds. Pharmacotherapy: A Pathophysiologic Approach. 8th ed. New York: McGraw-Hill; 2011:1951–1967.

Clinical Presentation and Diagnosis of Rotavirus Infection

- Incubation period of 2 days
- 2- to 3-day **prodrome** of fever and vomiting
- Profuse diarrhea without blood or leukocytes (up to 10 to 20 stools per day)
- Severe dehydration
- Anorexia
- Fever may be present
- Presentation in adults may vary from asymptomatic to nonspecific symptoms of headache, malaise, and chills to severe diarrhea, nausea, and vomiting
- Diagnosis can be made by polymerase chain reaction (PCR) of the stool

Patient Encounter 7

A 12-month-old infant was brought to the ED for 10 watery stools in the last 36 hours. She attends a home daycare center. Her mom reports that three other kids at the same daycare center developed the same symptoms. She also vomited four times today. Positive physical findings include low-grade fever plus hyperactive bowel sounds.

What diagnostic test would you recommend?

What treatment would you recommend for this patient?

How can you prevent this infection?

- The cornerstone of rotavirus treatment is supportive care and rehydration with ORT or IV fluids if necessary. Antimotility and antisecretory agents should not be used owing to their potential side effects in children and the self-limited nature of the disease. **7** *A live, oral rotavirus vaccine is approved by the FDA for use in infants aged 6 weeks to 32 weeks and provides protection against rotavirus infection for at least 24 months.* The CDC Advisory Committee on Immunization Practices recommends vaccination at 2, 4, and 6 months.

FOOD POISONING

- Each year in the United States, approximately 76 million food-borne illnesses occur, leading to 325,000 hospitalizations and more than 5,000 deaths. Many bacterial and viral pathogens that have been discussed previously in this chapter (e.g., *Salmonella*, *Shigella*, *Campylobacter*, *E. coli*, and noroviruses) can cause food poisoning. Other bacteria that can cause food-borne illness include *Staphylococcus aureus*, *C. perfringens*, *C. botulinum*, and *Bacillus cereus* (**Table 76-4**). Food poisoning should be suspected if at least two individuals present with similar symptoms after the ingestion of a common food in the prior 72 hours.

OUTCOME EVALUATION

Patients with GI infections should be evaluated for resolution of GI symptoms, as well as any related systemic signs and symptoms. If antimicrobial therapy was used, completion of the course of therapy should be assessed. Documented clearance of the offending microorganism is not necessary.

Table 76-4

Food Poisonings

Organism	Onset (Hours)	Associated Foods	Duration	Symptoms	Treatment
<i>Staphylococcus aureus</i>	1–6	Salad, pastries, ham, poultry	12 hours	Nausea, vomiting	Supportive
<i>Bacillus cereus</i> —emetic	0.5–6	Rice, noodles, pasta, pastries	24 hours	Vomiting	Supportive
<i>Bacillus cereus</i> —diarrheal	8–16	Meats, vegetables, soups, sauces, milk products	24 hours	Diarrhea, abdominal pain	Supportive
<i>Clostridium perfringens</i> (type A)	8–12	Meats, poultry	24 hours	Nausea; abdominal cramps; profuse, watery diarrhea	Supportive
<i>Clostridium botulinum</i>	18–24	Canned fruits, vegetables, meats, honey, salsa, relish	Weeks	Acute GI symptoms followed by symmetric, descending, flaccid paralysis; death is possible	Supportive (including mechanical ventilation); trivalent antitoxin

Patient Care and Monitoring

1. Observe the patient for signs and symptoms of dehydration, and rehydrate as necessary (see Tables 76–1 and 76–2).
2. Monitor for increase in stool consistency and decrease in stool frequency.
3. If pharmacologic agents are used, monitor for any adverse effects.
4. Evaluate the patient for any complications or effects specific to the afflicting pathogen.

Abbreviations Introduced in This Chapter

AAD	Antibiotic-associated diarrhea
ART	Antiretroviral therapy
cAMP	Cyclic adenosine monophosphate
BRAT	Bananas, rice, applesauce, toast
CDAD	<i>Clostridium difficile</i> -associated diarrhea
CDC	Centers for Disease Control and Prevention
CDI	<i>Clostridium difficile</i> infection
CFUs	Colony-forming units
EHEC	Enterohemorrhagic <i>Escherichia coli</i>
ETEC	Enterotoxigenic <i>Escherichia coli</i>
EIA	Enzyme immunoassay
ELISA	Enzyme-linked immunosorbent assay
GBS	Guillain-Barré syndrome
HUS	Hemolytic-uremic syndrome
ICDDR, B	International Center for Diarrheal Disease Research, Bangladesh
ORT	Oral rehydration therapy
LT	Heat-labile enterotoxin
NSAID	Nonsteroidal anti-inflammatory drug
MIC	Minimum inhibitory concentration
NTS	Nontyphoidal <i>Salmonella</i>
PCR	Polymerase chain reaction
STEC	Shiga toxin-producing <i>E. coli</i>
ST	Heat-stable enterotoxin
Stx	Shiga toxin
TD	Traveler's diarrhea
TTP	Thrombotic thrombocytopenic purpura
VRE	Vancomycin-resistant <i>Enterococcus</i>
WHO	World Health Organization

Intra-Abdominal Infections

Joseph E. Mazur and Joseph T. DiPiro

LEARNING OBJECTIVES

● Upon completion of the chapter, the reader will be able to:

1. Define and differentiate between primary and secondary intra-abdominal infections (IAIs).
2. Describe the microbiology typically seen with primary and secondary IAIs.
3. Describe the clinical presentation typically seen with primary and secondary IAIs.
4. Describe the role of culture and susceptibility information for diagnosis and treatment of IAIs.
5. Recommend the most appropriate drug and nondrug measures to treat IAIs.
6. Recommend an appropriate antimicrobial regimen for treatment of a primary and a secondary IAIs.
7. Describe the patient-assessment process during the treatment of IAIs.

KEY CONCEPTS

- 1 Most intra-abdominal infections (IAIs) are “secondary” infections that are caused by a defect in the GI tract that must be treated by surgical drainage, resection, and/or repair.
- 2 Primary peritonitis generally is caused by a single organism (*Staphylococcus aureus* in patients undergoing continuous ambulatory peritoneal dialysis [CAPD] and *Escherichia coli* in patients with cirrhosis).
- 3 Secondary IAIs usually are caused by a mixture of enteric gram-negative bacilli and anaerobes. This mix of organisms enhances the pathogenic potential of the bacteria.
- 4 For peritonitis, early and aggressive IV fluid resuscitation and electrolyte replacement therapy are essential. A common cause of early death is hypovolemic shock caused by inadequate intravascular volume expansion and tissue perfusion.
- 5 Cultures of secondary (IAI) sites generally are not useful for directing antimicrobial therapy. Treatment generally is initiated on a “presumptive” or empirical basis.
- 6 Antimicrobial regimens for secondary IAIs should include coverage for enteric gram-negative bacilli and anaerobes. Antimicrobial agents that may be used for treatment of secondary IAIs include the following: (a) a carbapenem, (b) piperacillin-tazobactam, or (c) ceftazidime or cefepime plus metronidazole. An aminoglycoside or colistin may be another treatment option.

- 7 Treatment of primary peritonitis for CAPD patients should include an antistaphylococcal antimicrobial such as a first-generation cephalosporin (cefazolin) or vancomycin, usually given by the intraperitoneal (IP) route.
- 8 The duration of antimicrobial treatment should be for a total of 4 to 7 days for most secondary IAIs.
- 9 Healthcare-associated infections are becoming more common for IAIs secondary to acute care hospital admissions or admissions from chronic care settings. The major pathogens include more resistant gram-negative flora, *Candida* infections causing peritonitis, and Enterococcal species.

Intra-abdominal infections (IAIs) are those contained within the peritoneal cavity or retroperitoneal space. The peritoneal cavity extends from the undersurface of the diaphragm to the floor of the pelvis and contains the stomach, small bowel, large bowel, liver, gallbladder, and spleen. The duodenum, pancreas, kidneys, adrenal glands, great vessels (aorta and vena cava), and most mesenteric vascular structures reside in the retroperitoneum. IAIs may be generalized or localized. They may be contained within visceral structures, such as the liver, gallbladder, spleen, pancreas, kidney, or female reproductive organs. Two general types of IAI are discussed throughout this chapter: peritonitis and abscess.

Peritonitis is defined as the acute inflammatory response of the peritoneal lining to microorganisms, chemicals, irradiation,

Patient Encounter 1, Part 1

A 46-year-old man with chronic kidney disease and sickle cell disease is admitted to the inpatient unit with a veno-occlusive crisis. He is also on peritoneal dialysis and is anuric. He presents with severe lower back pain and is in sickle cell crisis, is neurologically drowsy, and is a poor historian.

HPI: Left lower back pain is his chief complaint

PMH: ESRD secondary to sickle cell disease for the last 5 years

Meds: Chronic pain medications (oxycodone 10 mg orally every 12 hours) plus a phosphate binder (sevelamer carbonate 800 mg orally with meals)

SOC: Married with four children, drinks alcohol three times per week

PE: Soft, nontender, nondistended abdomen, positive bowel sounds. Rest of the physical exam is noncontributory

VS: T 99°F (37.2°C), BP 82/47 mm Hg, P 132 beats/min, RR 18 breaths/min, Wt 172 lb (78.2 kg), Ht 6 ft (183 cm)

Labs: Hct 16.9% (0.169), Hgb 5.9 g/dL (59 g/L; 3.66 mmol/L), WBC $15.2 \times 10^3/\text{mm}^3$ ($15.2 \times 10^9/\text{L}$), serum creatinine 9 mg/dL (796 $\mu\text{mol}/\text{L}$), BUN 63 mg/dL (22.5 mmol/L), Na 129 mEq/L (129 mmol/L), K 4.6 mEq/L (4.6 mmol/L), Cl 92 mEq/L (92 mmol/L), CO_2 23 mEq/L (23 mmol/L), total bilirubin 2 mg/dL (34 $\mu\text{mol}/\text{L}$), aPTT 32.3 seconds

What is in the differential diagnosis for this patient?

What is the pharmacotherapeutic-centered problem list that the pharmacy clinician should focus on?

Comment on other laboratory tests that should be done in this patient and their significance to treatment.

Patient Encounter 2, Part 1

A 60-year-old woman who has been in the intensive care unit for 2 days previously with an upper GI bleed has suddenly decompensated and a Mayday (code blue) is called, necessitating an emergency response from the medical team. She has a significant past medical history, most notably for alcohol-induced cirrhosis requiring previous hospital admissions and new-onset acute renal failure. She was being treated with a single-agent antibiotic for a diagnosis of spontaneous bacterial peritonitis (SBP). A diagnostic paracentesis on this admission revealed ascetic fluid comprising $450 \text{ cells}/\text{mm}^3$ ($450 \times 10^6/\text{L}$) and a positive fluid culture for gram-negative rods and gram-positive cocci.

PE: The patient is in acute respiratory distress with neurologic function near comatose. She is not mechanically ventilated yet.

VS: T 102°F (38.9°C), BP 80/40 mm Hg, P 140 beats/min, RR 30 breaths/min, Wt 220 lb (dry weight on admission [100 kg]), Ht 5 ft 4 in (163 cm)

Labs: Na 135 mEq/L (135 mmol/L), K 6 mEq/L (6 mmol/L), Cl 101 mEq/L (101 mmol/L), CO_2 16 mEq/L (16 mmol/L), glucose 352 mg/dL (19.5 mmol/L), BUN 75 mg/dL (26.8 mmol/L), serum creatinine 5.1 mg/dL (451 $\mu\text{mol}/\text{L}$), total bilirubin 9.2 mg/dL (157 $\mu\text{mol}/\text{L}$), lactate 4.2 mg/dL (0.47 $\mu\text{mol}/\text{L}$), Hct 27% (0.27), Hgb 9.0 g/dL (90 g/L; 5.59 mmol/L), WBC $33 \times 10^3/\text{mm}^3$ ($33 \times 10^9/\text{L}$) with differential of 22% (0.22) bands.

The patient's blood pressure is dropping, and the patient is still hypotensive and is emergently intubated in the medical intensive care unit.

Comment on the current treatment plan that requires immediate attention by the pharmacy clinician and the one for treatment/monitoring over the next 24 to 48 hours.

What nonpharmacologic and pharmacologic options are available to address the patients' deteriorating clinical status?

or foreign-body injury. This chapter deals only with peritonitis of infectious origin.

An *abscess* is a purulent collection of fluid separated from surrounding tissue by a wall consisting of inflammatory cells and adjacent organs. It usually contains necrotic debris, bacteria, and inflammatory cells. Peritonitis and abscess differ considerably in presentation and approach to treatment.

EPIDEMIOLOGY AND ETIOLOGY

Peritonitis may be classified as primary, secondary, or tertiary. Primary peritonitis, also called *spontaneous bacterial peritonitis*, is an infection of the peritoneal cavity without an evident source of bacteria from the abdomen.^{1,2} In secondary peritonitis, a focal disease process is evident within the abdomen. Secondary peritonitis may involve perforation of the GI tract (possibly because of ulceration, ischemia, or obstruction), postoperative peritonitis, or posttraumatic peritonitis (e.g., blunt or penetrating trauma). Tertiary peritonitis occurs in critically ill patients, and it is an infection that persists or

recurs at least 48 hours after apparently adequate management of primary or secondary peritonitis.

① *Primary peritonitis develops in 10% to 30% of hospitalized patients with alcoholic cirrhosis.*³ Patients undergoing continuous ambulatory peritoneal dialysis (CAPD) average one episode of peritonitis every 2 years.⁴ Secondary peritonitis may be caused by perforation of a peptic ulcer; traumatic perforation of the stomach, small or large bowel, uterus, or urinary bladder; appendicitis; pancreatitis; diverticulitis; bowel infarction; inflammatory bowel disease; cholecystitis; operative contamination of the peritoneum; or diseases of the female genital tract such as septic abortion, postoperative uterine infection, endometritis, or salpingitis. Appendicitis is one of the most common causes of IAI. In 2007, 326,000 appendectomies were performed in the United States for suspected appendicitis.⁵

Primary peritonitis in adults occurs most commonly in association with alcoholic cirrhosis, especially in its end stage, or with ascites caused by postnecrotic cirrhosis, chronic active hepatitis, acute viral hepatitis, congestive heart failure, malignancy, systemic lupus erythematosus, and nephrotic syndrome. It also may result from the use of a peritoneal catheter for dialysis with renal failure or CNS ventriculoperitoneal shunting for hydrocephalus. Abscesses are the result of chronic inflammation and may occur without preceding generalized peritonitis. They may be located within the peritoneal cavity or in a visceral organ and may vary in size, taking a few weeks to years to form. The causes of intra-abdominal abscess overlap those of peritonitis and, in fact, may occur sequentially or simultaneously. Appendicitis is the most frequent cause of abscess.

PATHOPHYSIOLOGY

IAI results from bacterial entry into the peritoneal or retroperitoneal spaces or from bacterial collections within intra-abdominal organs. In primary peritonitis, bacteria may enter the abdomen via the bloodstream or the lymphatic system by transmigration through the bowel wall, through an indwelling peritoneal dialysis (PD) catheter, or via the fallopian tubes in females. Hematogenous bacterial spread (through the bloodstream) occurs more frequently with tuberculosis peritonitis or peritonitis associated with cirrhotic ascites. When peritonitis results from PD, skin-surface flora are introduced via the peritoneal catheter. In secondary peritonitis, bacteria most often enter the peritoneum or retroperitoneum as a result of perforation of the GI or female genital tracts caused by diseases or traumatic injuries.

If bacteria that enter the abdomen are not contained by cellular and humoral defense mechanisms, bacterial dissemination occurs throughout the peritoneal cavity, resulting in peritonitis. This is more likely to occur in the presence of a foreign body, hematoma, necrotic tissue, large bacterial inoculum, continuing bacterial contamination, and contamination involving a mixture of synergistic organisms.

The fluid and protein shift into the abdomen (called *third spacing*) may be so dramatic that circulating blood volume is decreased, which causes decreased cardiac output and hypovolemic shock. Accompanying fever, vomiting, or diarrhea may worsen the fluid imbalance. A reflex sympathetic response, manifested by sweating, tachycardia, and vasoconstriction, may be evident. With an inflamed peritoneum, bacteria and endotoxins are absorbed easily into the bloodstream (translocation), and this may result in septic shock.¹ Other foreign substances present in the peritoneal cavity potentiate peritonitis, notably feces, dead tissues, barium, mucus, bile, and blood.

Many of the manifestations of IAIs, particularly peritonitis, result from cytokine activity. Inflammatory cytokines are produced by macrophages and neutrophils in response to bacteria and bacterial products or to tissue injury, resulting from the surgical incision.¹ The outer membrane components of gram-negative and gram-positive organisms contribute

to the cascade of proinflammatory cytokines, ultimately leading to end-organ dysfunction (lungs, heart, kidneys) and septic shock.⁶ Peritonitis may result in death because of the effects on major organ systems.

An abscess occurs if peritoneal contamination is localized but bacterial elimination is incomplete. The location of the abscess often is related to the site of primary disease. For example, abscesses resulting from appendicitis tend to appear in the right lower quadrant or the pelvis; those resulting from diverticulitis tend to appear in the left lower quadrant or pelvis. A mature abscess may have a fibrinous capsule that isolates bacteria and the liquid core from antimicrobials and immunologic defenses.

Microbiology of Intra-Abdominal Infection

2 Primary bacterial peritonitis is often caused by a single organism. In children, the pathogen is usually *Streptococcus pneumoniae* or a group A *Streptococcus*, *E. coli*, *S. pneumoniae*, or *Bacteroides* species.^{4,7} When peritonitis occurs in association with cirrhotic ascites, *E. coli* and *Klebsiella* are isolated most frequently.⁸ Other potential pathogens are *Haemophilus pneumoniae*, *Klebsiella*, *Pseudomonas*, anaerobes, and *S. pneumoniae*.⁹ Occasionally, primary peritonitis may be caused by *Mycobacterium tuberculosis*. Peritonitis in patients undergoing PD is caused most often by common skin organisms ranging from *S. aureus* to *S. epidermidis*, to *Pseudomonas aeruginosa*.¹⁰ Occasionally, aerobic gram-negative bacilli may cause infections, particularly in patients undergoing dialysis during hospitalization.

3 Because of the diverse bacteria present in the GI tract, secondary intra-abdominal infections are often polymicrobial.^{2,11} The mean number of different bacterial species isolated from infected intra-abdominal sites ranged from three when infection involves the small intestine to 26 with the colon.¹¹

Bacterial Synergism and Other Factors

A combination of aerobic and anaerobic organisms appears to increase the severity of infection. Facultative bacteria (e.g., *E. coli*) may provide an environment conducive to the growth of anaerobic bacteria.² Although many bacteria isolated in mixed infections are nonpathogenic by themselves, their presence may be essential for the pathogenicity of the bacterial mixture.³ Facultative bacteria in mixed infections have the ability to:

- Promote an appropriate environment for anaerobic growth through oxygen consumption
- Produce nutrients necessary for anaerobes
- Produce extracellular enzymes that promote tissue invasion by anaerobes

Complicating the clinical picture for treatment are polymicrobial IAIs with certain bacterial species being isolated such as Enterococci or *P. aeruginosa*. Depending on the patients' immune system (immunocompromised host), targeting these organisms may be necessary to avoid treatment failure or mortality.¹²

Clinical Presentation of Primary Peritonitis

General

Patients may not be in acute distress, particularly with peritoneal dialysis.

Symptoms

Patient may complain of nausea, vomiting (sometimes with diarrhea), and abdominal tenderness.

Signs

- Temperature may be only mildly elevated or not elevated in patients undergoing peritoneal dialysis.
- Bowel sounds are hypoactive.
- Cirrhotic patients may have worsening encephalopathy.
- There may be cloudy dialysate fluid with peritoneal dialysis.

Laboratory Tests

- The WBC may be only mildly elevated.
- Ascitic fluid usually contains more than $0.3 \times 10^3/\text{mm}^3$ ($0.3 \times 10^9/\text{L}$) leukocytes, and bacteria may be evident on Gram stain of a centrifuged specimen.

Other Diagnostic Tests

Culture of peritoneal dialysate or ascitic fluid should be positive.

Clinical Presentation of Secondary Peritonitis

General

Patients may be in acute distress.

Symptoms

- Patients may complain of nausea, vomiting, and generalized abdominal pain.
- Patients may demonstrate abdominal guarding and a “boardlike abdomen.”

Signs

- Tachypnea and tachycardia are present.
- Temperature is normal initially, then may increase to 100°F to 102°F (37.8–38.9°C) within the first few hours, and may continue to rise for the next several hours.
- Hypotension and shock may develop if intravascular volume is not restored.
- Decreased urine output may develop owing to dehydration.
- Bowel sounds are faint initially and eventually cease.

Laboratory Tests

- The WBC is high (WBCs $15\text{--}20 \times 10^3/\text{mm}^3$ [$15\text{--}20 \times 10^9/\text{L}$]), with neutrophils predominating and an elevated percentage of immature neutrophils (bands).
- The hematocrit and blood urea nitrogen increase because of dehydration.
- Hyperventilation and vomiting result in early alkalosis, which changes to acidosis and lactic acidemia to reduced intravascular volume and diminished tissue perfusion.

Other Diagnostic Tests

Abdominal radiographs may be useful because free air in the abdomen (indicating intestinal perforation) or distension of the small or large bowel is often evident.

CLINICAL PRESENTATION AND DIAGNOSIS

IAIs have a wide spectrum of clinical features. Peritonitis usually is easily recognized, but intra-abdominal abscess often may continue unrecognized for long periods of time. Patients with primary and secondary peritonitis present quite differently.

TREATMENT

Desired Outcomes

The primary goals of treatment are correction of the intra-abdominal disease processes or injuries that have caused infection and drainage of collections of purulent material (abscess). A secondary objective is to resolve the infection without major organ system complications (e.g., pulmonary, hepatic, cardiovascular, or renal failure) or adverse drug effects. Ideally, the patient should be discharged from the hospital with full function for self-care and routine daily activities.

General Approach to Treatment

The treatment of IAI most often requires the coordinated use of three major modalities: (a) prompt drainage; (b) support of vital functions; and (c) appropriate antimicrobial therapy

to treat infection not eradicated by surgery.¹³ Antimicrobials are an important adjunct to drainage procedures in the treatment of secondary IAIs; however, the use of antimicrobial agents without surgical intervention usually is inadequate. For most cases of primary peritonitis, drainage procedures may not be required, and antimicrobial agents become the mainstay of therapy.

4 In the early phase of serious IAIs, attention should be given to preserving major organ system function. With generalized peritonitis, large volumes of IV fluids are required to maintain intravascular volume, to improve cardiovascular function, and to ensure adequate tissue perfusion and oxygenation. Adequate urine output should be maintained to ensure appropriate fluid resuscitation and to preserve renal function. A common cause of early death is hypovolemic

Patient Encounter 1, Part 2: Physical Examination and Diagnostic Tests

PE: The patient is still encephalopathic and somnolent.

The patient is placed on ECG monitoring revealing atrial fibrillation. Ascitic fluid analysis is reported as following: hazy yellow color with 2,446 cu/mm³ ($2.446 \times 10^9/L$) WBC, (31% [0.31] neutrophils, 3% [0.03] lymphocytes, 66% [0.66] macrophages). Urinalysis is not significant because the patient is anuric. Other physical exam findings are nonsignificant.

VS: As noted previously

Labs: As noted previously

Serum: As noted previously

KUB: Negative findings

DPL (diagnostic peritoneal lavage): 2,446 cu/mm³ ($2.446 \times 10^9/L$)

Microbiological cultures: 4/4 bottles from the blood positive for gram-negative rods resembling *Pseudomonas aeruginosa*, and *E. coli*. cultured in the dialysate fluid.

Discuss the most appropriate pharmacologic course of treatment, outlining medications, dosing, and monitoring parameters.

List the goals of treatment and follow-up plan that should be developed by the clinician to ensure positive patient outcomes.

shock caused by inadequate intravascular volume expansion and tissue perfusion.

An additional important component of therapy is nutrition. IAIs often involve the GI tract directly or disrupt its function (paralytic ileus). The return of GI motility may take days, weeks, and occasionally, months. In the interim, enteral or parenteral nutrition as indicated facilitates improved immune function and wound healing to ensure recovery.

Nonpharmacologic Therapy

► Drainage Procedures

Primary peritonitis is treated with antimicrobials and rarely requires drainage. Secondary peritonitis requires surgical removal of the inflamed or gangrenous tissue to prevent further bacterial contamination. If the surgical procedure is suboptimal, attempts are made to provide drainage of the infected or gangrenous structures.

The drainage of purulent material is the critical component of management of an intra-abdominal abscess. This may be performed surgically or with percutaneous image-guided techniques.¹⁴ Without adequate drainage of the abscess, antimicrobial therapy and fluid resuscitation can be expected to fail. The most valuable microbiologic information may be obtained at the time of percutaneous or operative abscess drainage.

Patient Encounter 2, Part 2

The patient's clinical status grows worse over the next couple of hours despite the efforts of the team. She is now placed on vasopressor therapy combined with fluid, antibiotics are begun emergently, and steroids are also begun. Urine output is less than 10 mL/h and the patient is still mechanically ventilated.

What are your next steps in terms of a care plan as well as monitoring parameters for this patient?

Detail the limitations to certain pharmacologic versus surgical treatments for this patient, and comment on the overall prognosis based on the clinical findings.

► Fluid Therapy

In patients with peritonitis, hypovolemia is often accompanied by acidosis, and large volumes of a solution such as lactated Ringer's may be required initially to restore intravascular volume. Maintenance fluids should be instituted (after intravascular volume is restored) with 0.9% sodium chloride and potassium chloride (20 mEq/L [20 mmol/L]) or 5% dextrose and 0.45% sodium chloride with potassium chloride (20 mEq/L [20 mmol/L]). The administration rate should be based on estimated daily fluid loss through urine and nasogastric suction, including 0.5 to 1.0 L for insensible fluid loss. Potassium would not be included routinely if the patient is hyperkalemic or has renal insufficiency. Aggressive fluid therapy often must be continued in the postoperative period because fluid will continue to sequester in the peritoneal cavity, bowel wall, and lumen.

Pharmacologic Therapy

► Antimicrobial Therapy

The goals of antimicrobial therapy are as follows:

- To control bacteremia and prevent the establishment of metastatic foci of infection
- To reduce suppurative complications after bacterial contamination
- To prevent local spread of existing infection

After suppuration has occurred (e.g., an abscess has formed), a cure by antibiotic therapy alone is difficult to achieve; antimicrobials may serve to improve the results with surgery.

- **5** *An empirical antimicrobial regimen should be started as soon as the presence of IAI is suspected and before identification of the infecting organisms is complete.* Therapy must be initiated based on the likely pathogens, which vary depending on the site of IAI and the underlying disease process. Cultures of secondary IAI sites generally are not useful for directing antimicrobial therapy. **Table 77-1** lists the likely pathogens against which antimicrobial agents should be directed.

Table 77-1

Likely Intra-Abdominal Pathogens

Type of Infection	Aerobes	Anaerobes
Primary Bacterial Peritonitis		
Children (spontaneous)	Group A <i>Streptococcus</i> , <i>Escherichia coli</i> , pneumococci	—
Cirrhosis	<i>E. coli</i> , <i>Klebsiella</i> , pneumococci (many others)	—
Peritoneal dialysis	<i>Staphylococcus</i> , <i>Streptococcus</i>	—
Secondary Bacterial Peritonitis		
Gastroduodenal	<i>Streptococcus</i> , <i>E. coli</i>	—
Biliary tract	<i>E. coli</i> , <i>Klebsiella</i> , enterococci	<i>Clostridium</i> or <i>Bacteroides</i> (infrequent)
Small or large bowel	<i>E. coli</i> , <i>Klebsiella</i> spp., <i>Proteus</i> spp.	<i>Bacteroides fragilis</i> and other <i>Bacteroides</i> ; <i>Clostridium</i>
Appendicitis	<i>E. coli</i> , <i>Pseudomonas</i>	<i>Bacteroides</i> spp.
Abscesses	<i>E. coli</i> , <i>Klebsiella</i> , enterococci	<i>B. fragilis</i> and other <i>Bacteroides</i> , <i>Clostridium</i> , anaerobic cocci
Liver	<i>E. coli</i> , <i>Klebsiella</i> , enterococci, staphylococci, amoeba	<i>Bacteroides</i> (infrequent)
Spleen	<i>Staphylococcus</i> , <i>Streptococcus</i>

► Antimicrobial Experience

Many studies have been conducted evaluating or comparing the effectiveness of antimicrobials for treatment of IAIs. Substantial differences in patient outcomes from treatment with a variety of agents generally have not been demonstrated.¹⁵

Important findings from the last 20 years of clinical trials regarding selection of antimicrobials for IAIs are as follows:

- Antimicrobial regimens for secondary IAIs should cover a broad spectrum of aerobic and anaerobic bacteria from the GI tract. Worrisome is the development of hospital-acquired IAIs such as *P. aeruginosa*, *Acinetobacter* spp., *Proteus* spp., B-lactamase producing bacteria, methicillin-resistant *S. aureus* (MRSA), *Enterobacteriaceae*, *Candida* spp., and Enterococci that make the clinical management of these patients challenging.
- Single-agent regimens (such as antianaerobic cephalosporins, extended-spectrum penicillins with β -lactamase inhibitors, or carbapenems) are as effective as combinations of aminoglycosides or fluoroquinolones with antianaerobic agents. This is also true for antimicrobial treatment of acute bacterial contamination from penetrating abdominal trauma.
- Newer agents such as tigecycline and ertapenem may offer some theoretical advantages in the treatment of IAIs, but have some limitations. Tigecycline has a broad spectrum of activity against both aerobic and anaerobic gram negative rods, but lacks sufficient anti-*Pseudomonas* activity. Ertapenem is an example of a carbapenem that has a favorable pharmacokinetic profile (once daily dosing) and, like the other agents, lacks MRSA activity.
- Clindamycin and metronidazole appear to be equivalent in efficacy when combined with agents effective against aerobic gram-negative bacilli (e.g., gentamicin or aztreonam).
- For most patients, antimicrobial treatment can be completed orally with moxifloxacin, ciprofloxacin

and metronidazole, levofloxacin plus metronidazole, or amoxicillin-clavulanate or the combination of ciprofloxacin and metronidazole.

- Four to 7 days of antimicrobial treatment are sufficient for most IAIs of mild to moderate severity.

IAI presents in many different ways and with a wide spectrum of severity. The antibiotic regimen employed and duration of treatment depend on the specific clinical circumstances (i.e., the nature of the underlying disease process and the condition of the patient).

Recommendations

6 For most IAIs, the antimicrobial regimen should be effective against both aerobic and anaerobic bacteria.¹⁶ Although it is impossible to provide antimicrobial activity against every possible pathogen, agents with activity against enteric gram-negative bacilli, such as *E. coli* and *Klebsiella*, and anaerobes, such as *B. fragilis* and *Clostridia* spp., should be administered.

Table 77-2 presents the recommended agents for treatment of community-acquired and complicated IAIs from the Infectious Diseases Society of America and the Surgical Infection Society.¹⁶ These recommendations were formulated using an evidence-based approach. Most community-acquired infections are “mild to moderate,” whereas healthcare-associated infections tend to be more severe and difficult to treat. Table 77-3 presents guidelines for treatment and alternative regimens for specific situations. These are general guidelines; there are many factors that cannot be incorporated into such a table.

When used for IAI, aminoglycosides should be combined with agents that are effective against the majority of *B. fragilis*; however, their side-effect profile may prohibit use secondary to nephrotoxicity. Clindamycin or metronidazole is the agent of first choice, but others, such as antianaerobic cephalosporins (e.g., cefoxitin, cefotetan, or ceftizoxime), piperacillin, mezlocillin, and combinations of extended-spectrum penicillins

Table 77-2

Recommended Agents for the Treatment of Community-Acquired Complicated Intra-Abdominal Infections in Adults

Agents Recommended for Mild to Moderate Infections	Agents Recommended for High-Severity Infections
β-Lactam/β-Lactamase Inhibitor Combinations	
Ticarcillin-clavulanate	Piperacillin-tazobactam
Carbapenems	
Ertapenem	Imipenem/cilastatin
Others	
Tigecycline	Meropenem, Doripenem
Combination Regimens	
Cefazolin, cefuroxime, cefotaxime, or ceftriaxone plus metronidazole	Third- or fourth-generation cephalosporins (ceftazidime, cefepime) plus metronidazole
Ciprofloxacin or levofloxacin in combination with metronidazole	Ciprofloxacin or levofloxacin, in combination with metronidazole
	Aztreonam plus metronidazole
	Tigecycline plus ciprofloxacin
	Piperacillin-tazobactam + aminoglycoside
	Imipenem or meropenem + aminoglycoside ^a

Table 77-3

Guidelines for Initial Antimicrobial Agents for Intra-Abdominal Infections

Primary Agents	Alternatives
Primary Bacterial Peritonitis	
Cirrhosis	Cefotaxime
	1. Add clindamycin or metronidazole if anaerobes are suspected. 2. Other third-generation cephalosporins, extended-spectrum penicillins, aztreonam, and imipenem as alternatives. 3. Piperacillin-tazobactam.
Peritoneal dialysis	Initial empiric regimens: Cefazolin or cephalothin plus ceftazidime or cefepime
	1. An aminoglycoside may be used in place of ceftazidime or cefepime. 2. Imipenem/cilastatin or cefepime may be used alone. 3. Quinolones may be used in place of ceftazidime or cefepime if local susceptibilities allow.
	<i>Staphylococcus</i> : penicillinase-resistant penicillin or first-generation cephalosporin
	1. Alternative for methicillin-resistant staphylococci is vancomycin. 2. For vancomycin-resistant <i>Staphylococcus aureus</i> , linezolid, daptomycin, or quinupristin-dalfopristin must be used.
	<i>Streptococcus</i> or <i>Enterococcus</i> : ampicillin
	1. An aminoglycoside may be added for enterococcal peritonitis. 2. Linezolid or quinupristin-dalfopristin should be used to treat vancomycin-resistant enterococcus not susceptible to ampicillin.
	Aerobic gram-negative bacillic ceftazidime or cefepime
	1. The regimen should be based on in vitro sensitivity tests.
	<i>Pseudomonas aeruginosa</i> : two agents with differing mechanisms of actions, such as an oral quinolone plus ceftazidime, cefepime, tobramycin, or piperacillin

(Continued)

Table 77-3

Guidelines for Initial Antimicrobial Agents for Intra-Abdominal Infections (Continued)

Primary Agents		Alternatives
Secondary Bacterial Peritonitis		
Perforated peptic ulcer	First-generation cephalosporins	1. Antianaerobic cephalosporins ^a 2. Possibly add aminoglycoside if patient condition is poor 3. Aminoglycoside with clindamycin or metronidazole; add ampicillin if patient is immunocompromised or if biliary tract origin of infection
Other	Imipenem-cilastatin, meropenem, ertapenem, or extended-spectrum penicillins with β -lactamase inhibitor	1. Ciprofloxacin with metronidazole 2. Aztreonam with clindamycin or metronidazole 3. Antianaerobic cephalosporins ^a
Abscess		
General	Imipenem-cilastatin, meropenem, ertapenem, or extended-spectrum penicillins with β -lactamase inhibitor	1. Aztreonam with clindamycin or metronidazole 2. Ciprofloxacin with metronidazole 3. Aminoglycoside with clindamycin or metronidazole
Liver	As above but add a first-generation cephalosporin	1. Use metronidazole if amoebic liver abscess is suspected
Spleen	Aminoglycoside plus penicillinase-resistant penicillin	1. Alternatives for penicillinase-resistant penicillin are first-generation cephalosporins or vancomycin
Appendicitis		
Normal or inflamed	Antianaerobic cephalosporins ^a (discontinued immediately postoperation)	1. Ampicillin-sulbactam
Gangrenous or perforated	Imipenem-cilastatin, meropenem, ertapenem, antianaerobic cephalosporins or extended-spectrum penicillins with β -lactamase inhibitor	1. Aztreonam with clindamycin or metronidazole 2. Ciprofloxacin with metronidazole 3. Aminoglycoside with clindamycin or metronidazole
Acute cholecystitis	First-generation cephalosporin	1. Aminoglycoside plus ampicillin if severe infection
Cholangitis	Aminoglycoside with ampicillin with or without clindamycin or metronidazole	1. Use vancomycin instead of ampicillin if patient is allergic to penicillin
Acute contamination from abdominal trauma	Antianaerobic cephalosporins ^a or ampicillin-sulbactam	1. A carbapenem 2. Ciprofloxacin plus metronidazole
Pelvic inflammatory disease	Cefotetan or ceftioxin with doxycycline	1. Clindamycin with gentamicin 2. Ampicillin-sulbactam with doxycycline 3. Ciprofloxacin with doxycycline and metronidazole

^aCeftioxin, cefotetan, and ceftiozime.

From DiPiro JT, Talbert RL, Yee GC, et al, eds. *Pharmacotherapy: A Pathophysiologic Approach*. 8th ed. New York: McGraw-Hill; 2011.

with β -lactamase inhibitors would be suitable alternative. Pre-emptive antifungal therapy should maybe be indicated with either an azole antifungal (fluconazole) or an echinocandin (casposungin) in patients who are immunocompromised or postsurgical with recurrent infection.

In immunocompromised patients or patients with valvular heart disease or a prosthetic heart valve, there is justification to provide specific antimicrobial activity against enterococci. Ampicillin or other penicillins that are active against enterococci (e.g., penicillin, piperacillin, and mezlocillin) should be used in patients at high-risk, patients with persistent or recurrent intra-abdominal infection, or patients who are immunosuppressed, such as after organ transplantation. Ampicillin remains the drug of choice for this indication because it is most active in vitro against enterococci and is relatively inexpensive. Vancomycin is active against most enterococci; however, resistance is increasing, and this agent should be reserved for established infections when first-line therapies cannot be used.

Intraperitoneal (IP) administration of antibiotics is preferred over IV therapy in the treatment of peritonitis that

occurs in patients undergoing CAPD.¹⁷ The International Society of Peritoneal Dialysis revised its guidelines for the diagnosis and pharmacotherapy of PD-associated infections.¹⁰ The guidelines provide dosing recommendations for intermittent and continuous therapy based on the modality of dialysis (CAPD or automated peritoneal dialysis [APD]) and the extent of the patient's residual renal function.

7 *Antimicrobial agents effective against both gram-positive and gram-negative organisms should be used for initial IP empirical therapy for peritonitis in PD patients.* The most important factors to take into consideration for initial antimicrobial selection are the dialysis center's and the patient's history of infecting organisms and their sensitivities. The use of cefazolin (loading dose [LD] 500 mg/L, maintenance dose [MD] 125 mg/L) plus ceftazidime (LD 500 mg/L, MD 125 mg/L) or cefepime (LD 500 mg/L, MD 125 mg/L) or an aminoglycoside (gentamicin-tobramycin LD 8 mg/L, MD 4 mg/L) is suitable for initial empirical therapy; if patients are allergic to cephalosporin antibiotics, vancomycin (LD 1,000 mg/L, MD 25 mg/L) or an aminoglycoside should

be substituted. Aztreonam is an alternative to ceftazidime or cefepime in this patient population. Another option is monotherapy with imipenem-cilastin (LD 750 mg/L, MD 50 mg/L) or cefepime. Antimicrobial doses should be increased empirically by 25% in patients with residual renal function (more than 100 mL/day urine output).¹⁰ Antimicrobial therapy should be continued for at least 1 week after the dialysate fluid is clear and for a total of at least 14 days. The reader is referred to these guidelines for additional information.¹⁰

After acute bacterial contamination, such as with abdominal trauma where GI contents spill into the peritoneum, combination antimicrobial regimens are not required. If the patient is seen soon after injury (within 2 hours) and surgical measures are instituted promptly, antianaerobic cephalosporins (e.g., cefoxitin or cefotetan) or extended-spectrum penicillins are effective in preventing most infectious complications. Antimicrobials should be administered as soon as possible after injury.¹⁸

For appendicitis, the antimicrobial regimen used should depend on the appearance of the appendix at the time of operation, which may be normal, inflamed, gangrenous, or perforated. Because the condition of the appendix is unknown preoperatively, it is advisable to begin antimicrobial agents before the appendectomy is performed. Reasonable regimens would be antianaerobic cephalosporins or, if the patient is seriously ill, a carbapenem or β -lactam- β -lactamase-inhibitor combination. If, at operation, the appendix were normal or inflamed, postoperative antimicrobials would not be required. If the appendix is gangrenous or perforated, a treatment course of 5 to 7 days with the agents listed in Table 77-2 is appropriate.

8 *Acute intra-abdominal contamination, such as after a traumatic injury, may be treated with a short course (24 hours) of antimicrobials.¹⁸ For established infections (i.e., peritonitis or intra-abdominal abscess), an antimicrobial course limited to 4 to 7 days is justified.* Under certain conditions, therapy for longer than 7 days would be justified, for example, if the patient remains febrile or is in poor general condition, when relatively resistant bacteria are isolated, or when a focus of infection in the abdomen still may be present. For some abscesses, such as pyogenic liver abscess, antimicrobials may be required for a month or longer.

OUTCOME EVALUATION

Whether diagnosed with primary or secondary peritonitis, monitor the patient for relief of symptoms. Once antimicrobials are initiated and the other important therapies described earlier are used, most patients should show improvement within 2 to 3 days. Successful antimicrobial therapy with resolution of infection will result in decreased pain, manifested as resolution of abdominal guarding and decreased use of pain medications over time. The patient should not appear in distress, with the exception of recognized discomfort and pain from incisions, drains, and a nasogastric tube.

Monitor vital signs and WBC count with differential; each should normalize as the infection resolves. At 24 to 48 hours, aerobic bacterial culture results should be available.

If a suspected pathogen is not sensitive to the antimicrobial agents being given, the regimen should be changed if the patient has not shown sufficient improvement. If the isolated pathogen is extremely sensitive to one antimicrobial and the patient is progressing well, concurrent antimicrobial therapy often may be discontinued.

With anaerobic culturing techniques and the slow growth of these organisms, anaerobes often are not identified until 4 to 7 days after culture, and sensitivity information is difficult to obtain. For this reason, anaerobic culture information generally is not helpful for selection of the antianaerobic component of the antimicrobial regimen. A report indicating that anaerobes were not isolated should not be the sole justification for discontinuing antianaerobic drugs because anaerobic bacteria that were present in the infectious process may not have been transported properly to the microbiology laboratory, or other problems may have led to bacterial death in vitro.

Once the patient's temperature is normal for 48 to 72 hours and the patient is eating, consider changing the IV antibiotic to an oral regimen for the duration of antibiotic treatment. Monitor the serum creatinine level to evaluate for renal complications as well as potential drug toxicity, especially if an aminoglycoside is a component of the antibiotic regimen. Bowel sounds should return to normal. Evaluate the patient daily for development of rash or other drug-related adverse effects.

For patients with primary peritonitis, if peritoneal dialysate cultures were positive initially, repeat cultures should be negative. For patients with secondary peritonitis, monitor the amount of fluid draining if a drain was placed. The volume of drainage should lessen as the infection resolves. Repeat abdominal radiographs should return to normal.

If symptoms do not improve, the patient should be evaluated for persistent infection. There are many reasons for poor patient outcome with IAI; improper antimicrobial selection is only one. The patient may be immunocompromised, which decreases the likelihood of successful outcome with any regimen. It is impossible for antimicrobials to compensate for a nonfunctioning immune system. There may be surgical reasons for poor patient outcome. Failure to identify all intra-abdominal foci of infection or leaks from a GI anastomosis may cause continued IAI. Even when IAI is controlled, accompanying organ system failure, most often renal or respiratory, may lead to patient demise. **9** *Healthcare-associated infections are becoming more common for IAIs secondary to acute care hospital admissions or admissions from chronic care settings. The major pathogens include more resistant gram-negative flora, Candida infections causing peritonitis, and Enterococcal species.*

The outcome from IAI is not determined solely by what transpires in the abdomen. Unsatisfactory outcomes in patients with IAIs may result from complications that arise in other organ systems. Infectious complications commonly associated with mortality after IAI are urinary tract infections and pneumonia.¹⁹ Reasons for antimicrobial failure may not always be apparent. Even when antimicrobial susceptibility tests indicate that an organism is susceptible

Patient Care and Monitoring

1. A thorough patient medication history should be taken at the time of admission to document all recent medication use, including nonprescription medications and use of complementary or alternative medicines. Any drug allergies or intolerances also should be documented.
2. The initial antimicrobial regimen should conform to standard guidelines unless an appropriate justification for an alternative regimen is evident. With the first few doses of antimicrobial, assess the patient for hypersensitivity reactions or other acute intolerances.
3. Review the dosages of all medications to be sure that they are appropriate for age, weight, and major organ function. Verify that the drugs selected are not contraindicated in the patient with allergies or other intolerances.
4. Confirm that all necessary acute and chronic medications are continued postoperatively.
5. Monitor vital signs (i.e., temperature and heart rate) and laboratory assessments (i.e., WBC count) daily to assess resolution of infection and efficacy of pain medications. When possible, interview the patient to obtain additional information about pain control.
6. Evaluate fluid status to ensure that the patient is not hypovolemic. In a seriously ill patient, assess intravascular volume by monitoring blood pressure and heart rate, but do so more accurately by measuring central venous pressure or urinary output via a urinary bladder catheter. Urine output should equal or exceed 0.5 mL/kg of body weight per hour.
7. Review results of cultures obtained preoperatively or during the surgical procedure. Evaluate the appropriateness of antibiotic therapy based on susceptibility information. Although some investigators suggest that routine culturing of patients with community-acquired intra-abdominal infections contributes little to their management, other investigators suggest that antimicrobial therapy should be based on susceptibility of the bacteria collected from the operative site because this has been shown to correlate with clinical outcome.²⁰
8. Assess serum creatinine and aminoglycoside serum concentrations if the patient is being treated with an aminoglycoside. Adjust aminoglycoside dose based on serum concentrations; target peak concentration with multiple doses per day = 6 mcg/mL (6 mg/L; 12.5 μmol/L gentamicin or 12.8 μmol/L tobramycin).
9. On the fifth day of antimicrobial treatment or when GI function returns, determine whether parenteral antimicrobial agents can be switched to oral agents to complete therapy.
10. Assess nutritional needs and recommend appropriate supplementation. When the patient is tolerating an oral diet, determine whether any parenteral medications can be switched to the oral route.
11. Monitor the patient for the development of potential complications of treatment such as delayed hypersensitivity reactions, antibiotic-induced diarrhea, pseudomembranous colitis, or fungal superinfections (manifested as oral thrush).
12. Provide information to the patient concerning the medications administered in the hospital as well as any new medications prescribed for use at home. Advise the patient to contact his or her doctor or pharmacist if he or she experience any adverse effects from medications.

in vitro to the antimicrobial agent, therapeutic failures may occur. Possibly there is poor penetration of the antimicrobial agent into the focus of infection, or bacterial resistance may develop after initiation of antimicrobial therapy. Also, it is possible that an antimicrobial regimen may encourage the development of infection by organisms not susceptible to the regimen being used. Superinfection in patients being treated for IAI can be caused by *Candida*; however, Enterococci or opportunistic gram-negative bacilli such as *Pseudomonas* and *Serratia* may be involved.

Treatment regimens for IAI can be judged as successful if the patient recovers from the infection without recurrent peritonitis or intra-abdominal abscess and without the need for additional antimicrobials. A regimen can be considered unsuccessful if a significant adverse drug reaction occurs, reoperation or percutaneous drainage is necessary, or patient improvement is delayed beyond 1 or 2 weeks.

Abbreviations Introduced in This Chapter

APD	Automated peritoneal dialysis
CAPD	Continuous ambulatory peritoneal dialysis
DPL	Diagnostic peritoneal lavage
IAIs	Intra-abdominal infections
IP	Intraperitoneal
LD	Loading dose
MD	Maintenance dose
MRSA	Methicillin-resistant <i>S. aureus</i>
PD	Peritoneal dialysis

Self-assessment questions and answers are available at <http://mhpharmacotherapy.com/pp.html>.

Parasitic Diseases

J. V. Anandan

LEARNING OBJECTIVES

● Upon completion of the chapter, the reader will be able to:

1. Identify the primary reasons why some parasitic diseases may be more prevalent in the U.S. population.
2. Describe the treatment algorithm for giardiasis and amebiasis.
3. List one effective therapy for nematodes and select the drugs of choice for strongyloidiasis and tapeworms.
4. List three major reasons why travelers are infected with malaria.
5. Describe the presenting signs and symptoms of malaria.
6. List some specific toxicities of mefloquine.
7. Identify the monitoring parameters for quinidine gluconate in severe malaria.
8. Define the major complications of falciparum malaria.
9. Discuss the cardiovascular complications of chronic South American trypanosomiasis.
10. Describe the steps to take to eradicate lice infestation and scabies.

KEY CONCEPTS

- 1 For treatment of giardiasis (or as empirical treatment), metronidazole 250 mg three times daily for 7 days or tinidazole 2 g as a single dose is recommended.
- 2 Diagnostic tests for amebiasis include stool for ova, antigen detection, or polymerase chain reaction (PCR) testing.
- 3 The drug of choice for nematode infestations (hookworm, enterobiasis, and ascariasis) is mebendazole, whereas ivermectin is indicated for strongyloidiasis and praziquantel is indicated for tapeworms.
- 4 The primary reasons why travelers are infected with malaria are failure to take chemotherapy, inappropriate chemotherapy, and delay in seeking medical care.
- 5 Falciparum malaria must be considered a life-threatening medical emergency.
- 6 Treatment of serious malarial infection requires admission to an acute care service, IV administration of quinidine gluconate, and symptomatic support.
- 7 Complications of falciparum malaria include hypoglycemia, acute renal failure, pulmonary edema, seizure, and coma.
- 8 The chronic presentation of American trypanosomiasis includes cardiovascular, GI, and CNS manifestations.
- 9 Lice infestation should be treated with 1% permethrin followed by treatment of immediate family members and sexual partners. Bedding and clothes should be sterilized by washing in the hot cycle of the washing machine.
- 10 The diagnosis of scabies is made by obtaining skin scrapings and detecting the mite in a wet mount. Topical therapy is 5% permethrin.

Parasitic medicine is an ever-changing field. The increased desire of large segments of the U.S. population to travel to Asia, Africa, and other parts of the world can expose them to parasitic infections that are endemic in those areas. The influx of refugees and new immigrant populations from Asia and other parts of the world have brought new parasitic infections to our shores. Migrant farm workers who work and live in substandard hygienic conditions, the large and growing Central and South American immigrant population, and the presence of immunosuppressed populations (e.g., those with the AIDS and transplant patients) represent other significant sources of parasitic infections in the United States.¹⁻¹⁰ Clearly, there is a

need for health professionals in the United States to be familiar with the pathophysiology and treatment of parasitic diseases.

Defined next are some terms that are frequently used when discussing parasitic diseases.⁹ *Symbiosis* is defined as “living together,” when two species are dependent on each other for food and protection. The term *commensalism*, from the Latin translation of “eating at the same table,” implies a mutual association in which both organisms may benefit, or at least one benefits but does no harm to the other. In contrast, *parasitism*, although resembling symbiosis in one aspect (i.e., it is also an intimate relationship between two species), does not represent a mutually beneficial association. One species (the host) does not benefit from the relationship, and in fact the relationship may be detrimental to its very survival. Parasites have made morphologic, biochemical, reproductive, and defensive adaptations over time. These adaptations have increased the ability of parasites to survive host defenses and have allowed them to utilize the host’s biochemical systems to synthesize necessary cellular components. Beef and pork tapeworms (cestodes) possess highly developed reproductive systems that allow them to transfer easily to new hosts. Because of the lack of digestive systems, cestodes are completely host-dependent for all nutrients. Cestodes (tapeworms) (*Taenia saginata* and *Taenia solium*) use specialized suckers that enable them to obtain blood and vital nutrients from their host. *Entamoeba histolytica*, the causative agent for amebiasis, once it has gained access to the human colon or large intestine is able to invade and utilize its specialized proteolytic enzyme to penetrate and erode the GI mucosa. *E. histolytica* is also able to survive in adverse conditions when it leaves the host by walling itself off and forming **cysts**; this protects the parasite from environmental conditions until it is ready to infect the next host.

Although acquired immunity to some parasitic diseases may lower the level of infection, absolute immunity as seen in bacterial and viral infections is seldom seen in parasitic diseases. Since parasitic infections produce a wide variety of antigens because of the many life cycle phases, it is more difficult to identify a constant antigenic protein against which specific antibodies are protective. However, malaria remains a likely candidate for a vaccine and there are ongoing studies to develop one.

Space constraints do not allow detailed discussions of the world of parasites, and clinicians and students are directed to some excellent resources for further details on parasites and parasitic diseases.^{9,11} Discussion in this chapter includes those parasitic diseases that are more likely to be seen in the United States and includes GI parasites (primarily giardiasis and amebiasis), protozoan infections (malaria and South American trypanosomiasis), some common helminthic diseases (specifically those caused by nematodes and cestodes), and ectoparasites (lice and scabies).

GIARDIASIS

Epidemiology and Etiology

Giardia lamblia (also known as *G. intestinalis* or *G. duodenalis*), an enteric protozoan, is the most common intestinal parasite responsible for diarrheal syndromes throughout the world.

Giardia is the most frequently identified intestinal parasites in the United States, with a prevalence rate of 5% to 15% in some areas. *G. lamblia* has been identified as the first enteric pathogen seen in children in developing countries, with prevalence rates between 15% and 30%.¹¹

There are two stages in the life cycle of *G. lamblia*: the trophozoite and the cyst. *G. lamblia* is found in the small intestine, the gallbladder, and in biliary drainage.⁹ The distribution of giardiasis is worldwide, with children being more susceptible than adults.

Pathophysiology

Giardiasis is caused by ingestion of *G. lamblia* cysts in fecally contaminated water or food.^{9–15} The protozoan excysts in the low gastric pH to release the trophozoite. Colonization and multiplication of the trophozoite lead to mucosal invasion, localized edema, and flattening of the villi, resulting in malabsorption states in the host. Achlorhydria, hypogammaglobulinemia, or deficiency in secretory immunoglobulin A (IgA) predispose to giardiasis.¹¹ Individuals with HIV infection and AIDS may have higher carriage rates than the general population. Some patients may develop lactose intolerance after chronic giardiasis.

Clinical Presentation and Diagnosis of Giardiasis

Acute Onset

- Diarrhea, cramp-like abdominal pain, bloating, and flatulence
- Malaise, anorexia, nausea, and belching

Chronic Symptoms

- Diarrhea: Foul-smelling, copious, light-colored, and greasy stools
- Weight loss, steatorrhea, and vitamin B₁₂ and fat-soluble vitamin deficiencies
- Constipation alternating with diarrhea

Diagnosis

- Diagnosis is made by examination of fresh stool or a preserved specimen during acute diarrheal phase
- Fresh stool may show trophozoites, whereas preserved specimens yield cysts. (*Note:* stool for ova may show the presence of other parasites [e.g., *Cryptosporidium parvum*, *E. histolytica*, or *E. hartmanni*]; multiple stool samples may be needed.)
- Even though stool examination for ova and parasites has remained the major means of diagnosis, other diagnostic tests include enzyme-linked immunosorbent assay (ELISA), which is considered to be between 85% and 98% sensitive and almost 100% specific (ProSpec T, Giardia Microplate Assay, Remel, Lenexa, KS).

Patient Encounter 1: Giardiasis

AD is a 33-year-old artist from San Francisco who had traveled to Playa Melague in Mexico to complete a painting assignment for a permanent Canadian resident. While there he rented a small house out of town and occasionally ate at local restaurants. Three weeks after his return from Mexico he developed diarrhea, alternating with constipation. When he is seen at the travel clinic at University of California, he reports nausea and crampy diarrhea with foul-smelling stools in the last 2 weeks.

Are his symptoms characteristic of giardiasis?

How would you differentiate giardiasis from possible Escherichia coli–induced diarrhea?

Clinical Presentation and Diagnosis

► Pharmacologic Therapy

1 All symptomatic adults and children over the age of 8 years with giardiasis should be treated with metronidazole 250 mg three times daily for 7 days, or tinidazole 2 g as a single dose, or nitazoxanide (Alina) 500 mg twice daily for 3 days.^{12,13,16} The pediatric dose of metronidazole is 15 mg/kg/day three times daily for 7 days. Alternative drugs include furazolidone 100 mg four times daily or paromomycin 25 to 35 mg/kg/day in divided doses daily for 7 days. Paromomycin may be used in pregnancy instead of metronidazole. Pediatric patients can also be treated with suspensions of furazolidone 6 mg/kg/day in four divided doses for 7 days.

Quinacrine 100 mg three times in adults or 5 mg/kg/day in pediatric patients for 5 to 7 days, is available from a specialized pharmacy (e.g., Panorama Compounding Pharmacy).¹²

Outcome Evaluation

Patients with symptomatic giardiasis and positive stool samples or positive enzyme-linked immunosorbent assay

Patient Care and Monitoring: Giardiasis

1. Metronidazole produces cure rates between 85% and 95%.
2. Diarrhea will cease within a few days, although in some patients it may take 1 to 2 weeks.
3. Cyst excretion will cease within days.
4. Intestinal dysfunction (manifested as increased transit time) and radiologic changes primarily due to chronic infection may take months to resolve.
5. Patients who fail therapy with metronidazole should receive a second course with either metronidazole or an alternative agent; nitazoxanide has been shown to be effective in resistant giardiasis.

(ELISA) tests should be treated with metronidazole for 7 days. Patients who fail initial therapy with metronidazole should receive a second course of therapy. Pregnant patients can receive paromomycin 25 to 35 mg/kg/day in divided doses for 7 days. Giardiasis can be prevented by good hygiene and by using caution in food and drink consumption.

AMEBIASIS

Epidemiology and Etiology

Amebiasis remains one of the most important parasitic diseases because of its worldwide distribution and serious GI manifestations. The major causative agent in amebiasis is *E. histolytica*, which invades the colon and must be differentiated from *Entamoeba dispar*, which is associated with an asymptomatic carrier state and is considered nonpathogenic.^{17–20} Invasive amebiasis is almost exclusively the result of ingesting *E. histolytica* cysts found in fecally contaminated food or water. Approximately 50 million cases of invasive disease result each year worldwide, leading to an excess of 100,000 deaths. In the general population, the highest incidence is found in institutionalized mentally retarded patients, sexually active homosexuals, AIDS patients, the Native American population, and new immigrants from endemic areas (e.g., Mexico, South and Southeast Asia, West and South Africa, and portions of Central and South America).^{18,20}

Pathophysiology

E. histolytica invades mucosal cells of colonic epithelium, producing the classic flask-shaped ulcer in the submucosa. The trophozoite toxin has a cytotoxic effect on cells. If the trophozoite gets into the portal circulation, it will be carried to the liver, where it produces abscess and periportal fibrosis. Liver abscesses are more common in men than women and are rarely seen in children.^{18,20} Amebic ulcerations can affect the perineum and genitalia, and abscesses may occur in the lung and brain.

Erosion of liver abscesses can result in peritonitis. Liver abscesses that are located in the right lobe can spread to the lungs and pleura. Pericardial infection, although rare, may be associated with extension of the amebic abscesses from the liver.^{21–23}

Pharmacologic Therapy

Metronidazole (Flagyl), dehydroemetine, and chloroquine (Aralen) are tissue-acting agents, and iodoquinol (Yodoxin), diloxanide furoate (Furamide), and paromomycin (Humatin) are luminal amebicides. A systemic or tissue-acting agent may be so well absorbed that the amounts of the drug remaining in the bowel may be insufficient to have luminal or local effects. A lumenally active agent, on the other hand, may not attain effective enough levels in the tissue to be efficacious. Asymptomatic cyst passers (identified by stool examinations, and who may develop invasive disease)

Clinical Presentation and Diagnosis of Amebiasis

Review of the patient's history should include the following: recent travel, type of foods ingested (e.g., salads or unpeeled fruit), the nature of water and fluid consumed, and description of any symptoms of friends or relatives who ate the same food.

Intestinal Disease

- Vague abdominal discomfort
- Symptoms may range from malaise to severe abdominal cramps, flatulence, and nonbloody or bloody diarrhea (heme-positive in 100% of cases) with mucus
- May have low-grade fever, but this may be absent in many patients
- Eosinophilia is usually absent, although mild leukocytosis is not unusual

Note: Fecal screening may show other intestinal parasites, including *Cryptosporidium* spp., *Balantidium coli*, *Dientamoeba fragilis*, *Isopora belli*, *G. lamblia*, or *Blastocystis hominis*.

Amebic Liver Abscess

- May present with high fever with significant leukocytosis with left shift, anemia, elevated alanine aminotransferase, and dull abdominal pain on palpation

- *Physical findings:* Right upper quadrant pain, hepatomegaly, and liver tenderness, with referred pain to the left or right shoulder (*Note:* Erosion of liver abscesses may present as peritonitis.)

2 Diagnosis

- *Intestinal amebiasis is diagnosed by demonstrating E. histolytica cysts or trophozoites (may contain ingested erythrocytes) in fresh stool or from a specimen obtained by sigmoidoscopy.*
- *Microscopy may not differentiate between the pathogenic E. histolytica and the nonpathogenic (commensal) E. dispar or E. moshkovskii in stools.*
- *Sensitive techniques are available to detect E. histolytica in stool: antigen detection, antibody test (ELISA) and PCR.*
- **Endoscopy** with scrapings or biopsy and stained slides (iron hematoxylin or trichrome) may provide more definitive diagnosis of amebiasis.
- *Diagnosis for liver abscess includes serology and liver scans (using isotopes by ultrasound or CT) or MRI; however, none of these are specific for liver abscess. In rare instances, needle aspiration of hepatic abscess may be attempted using ultrasound guidance.*

and patients with mild intestinal amebiasis should receive a luminal agent: paromomycin 25 to 35 mg/kg/day three times daily for 7 days, or iodoquinol 650 mg three times daily for 20 days. These regimens have cure rates of between 84% and 96%. The pediatric dose of paromomycin is the same as

that used in adults, whereas the pediatric dose of iodoquinol is 30 to 40 mg/kg (maximum: 2 g) per day in three doses for 20 days, and the pediatric dose of diloxanide furoate is 20 mg/kg/day in three doses for 10 days. Paromomycin is the preferred agent in pregnant patients.¹²

Patients with severe intestinal disease or liver abscess should receive metronidazole 750 mg three times daily for 10 days, followed by the luminal agents indicated previously. The pediatric dose of metronidazole is 50 mg/kg/day in divided doses, which should be followed by a luminal agent. An alternative regimen of metronidazole is 2.4 g/day for 2 days in combination with the luminal agent.^{20,21} Tinidazole administered in a dose of 2 g daily for 3 days (pediatric dose: 50 mg/kg for 3 days; can be crushed and added to cherry syrup) is an alternative to metronidazole.¹² If there is no prompt response to metronidazole or aspiration of the abscess, an antibiotic regimen should be added. Patients who cannot tolerate oral doses of metronidazole should receive an IV dose of metronidazole.¹⁹

Patient Encounter 2: Amebiasis

PL is a 23-year-old college student who has recently returned from a holiday trip to Malaysia and Thailand. While there he had consumed the local food and traveled extensively in Thailand. PL now presents in the emergency department with complaints of a 3-week history of sharp, crampy, and postprandial abdominal pain. The pain is more intense over the right lower quadrant and associated with watery nonbloody diarrhea and **tenesmus**. PL indicates that he had some diarrhea while he was in Thailand and received some medications from a local physician.

What specific findings in this patient suggest that he may have giardiasis or amebiasis?

What other information do you need to confirm a diagnosis of amebiasis?

What is the major complication of amebiasis?

Outcome Evaluation

Follow-up in patients with amebiasis should include repeat stool examinations, serology, colonoscopy (in colitis), or computed tomography (CT) a month after the end of therapy. Serial liver scans have demonstrated healing of liver abscesses over 4 to 8 months after adequate therapy.¹⁸

Patient Care and Monitoring: Amebiasis

1. Follow-up in patients with amebiasis should include repeat stools (1 to 3), colonoscopy (in colitis) or CT (in liver abscess) between days 5 and 7, at the end of the course of therapy, and a month after the end of therapy.
2. Most patients with either intestinal amebiasis or colitis will respond in 3 to 5 days with amelioration of symptoms.
3. Those with liver abscess may take up to 7 days before there will be decreases in pain and fever. In liver abscess, patients not responding by the fifth day may require aspiration of the abscesses or exploratory laparotomy.
4. Serial liver scans have demonstrated that healing of liver abscesses take from 4 to 8 months following adequate therapy.

Preventive Measures

- Travelers and tourists visiting endemic areas should avoid local tap water, ice, salads, and unpeeled fruits. Boiled water is safe.
- Water can be disinfected by the use of iodine 2% (5 drops/L) or chlorine 6% (laundry bleach: 4 drops/L) or use of a commercial water purifier, such as Portable Aqua tablets (Wisconsin Pharmaceutical).

HELMINTHIC DISEASES

Helminthic infections include three groups of organisms: roundworms or nematodes, flukes (trematodes), and tapeworms (cestodes). Because of space constraints, only brief descriptions of some of the helminthic infections most commonly seen in North America and their treatments are provided here. Although helminthic infections may not produce clinical manifestations, they can cause significant pathology. One factor that determines the pathogenicity of helminthic infections is their population density; a high-density population (“worm burden”) results in predictable disease presentation. In the United States, these infections are reported most frequently in recent immigrants from Southeast Asia, the Caribbean, Mexico, and Central America.^{1,24–28} Populations at risk include institutionalized patients (both young and elderly), preschool children in daycare centers, residents of Native American reservations, and homosexuals.^{24,25} Certain conditions and drugs (anesthesia and corticosteroids) can cause atypical localization of worms. Immunocompromised hosts can be overwhelmed by some helminthic infections, such as *Strongyloides stercoralis*.

Nematodes

► Hookworm Disease

Hookworm infection is caused by *Ancylostoma duodenale* or *Necator americanus*. *N. americanus* is found in the

southeastern United States.^{24–25} Infective larvae enter the host in contaminated food or water or penetrate the skin and migrate to the small intestine. The adult worm attaches to GI mucosa and causes injury by lytic destruction of the tissue. Over a period of time, the adult worm can cause anemia and hypoproteinemia in the host.^{26–28}

► Treatment

3 The drug of choice is mebendazole (Vermox), which is also active against ascariasis, enterobiasis, trichuriasis, and hookworm.¹² The adult and pediatric (age more than 2 years) oral dose of mebendazole for hookworm is 100 mg twice daily for 3 days. An alternative agent that can be used in both pediatric and adult patients is albendazole (Zentel), 400 mg as a single oral dose. Diagnosis is by detection of eggs or larvae in stool. Stool examination for eggs and the larvae should be repeated in 2 weeks and the patient retreated if necessary.

Ascariasis

The causative agent in ascariasis is the giant roundworm *Ascaris lumbricoides*, which is found worldwide and is responsible for about 4 million infections in the United States (it primarily affects residents of the Appalachian mountain range and the Gulf Coast states).^{29–31} Migration of the worm into the lungs usually produces pneumonitis, fever, cough, eosinophilia, and pulmonary infiltrates. *Ascaris* infection can also cause abdominal discomfort, intestinal obstruction, and appendicitis. Diagnosis is made by detection of the characteristic eggs in the stool or passed worms.

► Treatment

In both adults and pediatric patients older than 2 years of age, mebendazole 100 mg orally twice daily for 3 days is the treatment to use. An alternative agent is pyrantel pamoate (Antiminth).¹² The stool should be checked within 2 weeks and the patient retreated when warranted.

Enterobiasis

Enterobiasis, or pinworm infection, is caused by *Enterobius vermicularis*. It is the most widely distributed helminthic infection in the world.^{24,32} There are approximately 42 million cases in the United States, primarily affecting children. The most common manifestation of the infection is cutaneous irritation in the perianal region, resulting from the migrating female or the presence of eggs. The intense pruritus may lead to dermatitis and secondary bacterial infections. Diagnosis is made by the use of a perianal swab and cellophane tape sampling, which will aid in egg identification.

► Treatment

The three agents that are administered for enterobiasis include pyrantel pamoate, mebendazole, and albendazole.¹² The oral dose of pyrantel pamoate is 11 mg/kg (maximum: 1 g)

as a single dose that can be repeated in 2 weeks. The oral dose of mebendazole for both adults and children older than 2 years of age is 100 mg as a single dose. This may be repeated in 2 weeks.¹² Following treatment, to eradicate the eggs, all bedding and underclothing should be sterilized by steaming or washing in the hot cycle of the washing machine.

Strongyloidiasis

Strongyloidiasis is caused by *Strongyloides stercoralis*, which has a worldwide distribution and is predominantly prevalent in South America (Brazil and Columbia) and in Southeast Asia.^{33–38} Strongyloidiasis is primarily seen among institutionalized populations (those in mental hospitals and children's hospitals) and immunocompromised individuals (those with HIV infection, AIDS, and patients with hematologic malignancies).^{33,36,37} The worm is usually found in the upper intestine, where the eggs are deposited and hatch to form the rhabditiform larvae. The rhabditiform larva (male and female) migrate to the bowel where they may be excreted in the feces. If excreted in the feces, the larva can evolve into either one of two forms after copulation: a free-living non-infectious rhabditiform larvae, or an infectious filariform larvae. The filariform larva can penetrate host skin and migrate to the lungs and produce progeny, a process called autoinfection. This can result in hyperinfection (i.e., an increased number of larva in the intestine, lungs, and other internal organs), especially in an immunocompromised host.

Patients with acute infection may develop a localized pruritic rash, but heavy infestations can produce eosinophilia (10% to 15% [0.10 to 0.15]), diarrhea, abdominal pain, and intestinal obstruction. Administration of corticosteroids or other immunosuppressive drugs to an infected individual can result in hyperinfections and disseminated strongyloidiasis.^{33–35} Diagnosis of strongyloidiasis is made by identification of the rhabditiform larva in stool, sputum, or duodenal fluid, or from small bowel biopsy specimens. Even though antigen testing (ELISA essay) remains the most sensitive method, stool examinations and other body fluids should also be utilized in the diagnosis.^{36,38}

► Treatment

3 The drug of choice for strongyloidiasis is oral ivermectin 200 mcg/kg/day for 2 days, whereas albendazole 400 mg twice daily is given for 7 days as an alternative.^{12,38} With hyperinfection or disseminated strongyloidiasis, immunosuppressive drugs should be discontinued and treatment should be initiated with ivermectin 200 mcg/kg/day until all symptoms are resolved. Failure with ivermectin therapy has been reported.³⁹ Patients should be tested periodically to ensure the elimination of the larva. Individuals from an endemic area who are candidates for organ transplantation must be screened for *S. stercoralis*.³⁸

Cestodiasis

Cestodiasis (tapeworm infection) is caused by species of the phylum Platyhelminthes (flatworms) and include, among

others, the pork tapeworm (*Taenia solium*) and the beef tapeworm (*T. saginata*).^{9,40} The tapeworm attaches itself to the mucosal wall of the upper jejunum by the scolex (mouth parts) and by two to four cup-shaped suckers and a structure called a rostellum, which may have hooks in some species. Since the parasite lacks a digestive system, it obtains all nutrients directly from the host. The scolex, proglottids (segments), and eggs are specific for each species and used for identification of tapeworms. Tapeworm infections are caused by ingestion of poorly cooked meat that contains the larva or cysticerci. Cysticerci, when released from the contaminated meat by host digestive juices, mature in the host jejunum. Cystercercosis is a systemic disease caused by the larva of *T. solium* (oncosphere or hexacanth) and is usually acquired by ingestion of eggs in contaminated food or by autoinfection.^{41–45} The larvae can penetrate the bowel and migrate through the bloodstream to infect different organs, including the CNS (neurocystercosis). Diagnosis of both *T. saginata* and *T. solium* is accomplished by recovery of the gravid proglottids and the scolex in the stool. Newer diagnostic tools for neurocystercosis include serum and cerebrospinal antigen and antibody testing.⁴⁵

► Treatment

3 Tapeworm infections (*T. saginata* and *T. solium*) are treated with praziquantel 5 to 10 mg/kg as a single dose (use the same dose for adults and pediatric patients).¹² The treatment for cystercercosis and neurocystercosis may include surgery, anticonvulsants (neurocystercosis can cause seizures), and anthelmintic therapy. The anthelmintic therapy of choice is albendazole 400 mg twice daily for 8 to 30 days.^{45,46} The pediatric dose of albendazole is 15 mg/kg (maximum: 800 mg) in two divided doses for 8 to 30 days. The doses for both adults and pediatric subjects can be repeated if necessary. Praziquantel is an alternative therapy.¹²

Outcome Evaluation

Morbidity and disease due to helminthic infections is related to the intensity of infection. The major adverse effects of helminthic infections are malnutrition, fatigue, and diminished work capacity. Unlike other helminthic infections, strongyloidiasis can cause autoinfection, and in the presence of immunosuppression, it can cause CNS and disseminated infections, which have high mortality.⁴²

The most serious complication of cystercercosis is neurocystercosis that can cause strokes and seizures.^{44,45} Treatment of neurocystercosis with anthelmintic treatment remains controversial.

MALARIA

Malaria is one of the most devastating parasitic diseases, affecting a population in excess of 500 million and causing between 700,000 and 2.7 million deaths a year worldwide.^{3,5,7} In the year 2000, approximately 27 million U.S. travelers visited countries where malaria is endemic.

Patient Encounter 3, Part 1: Malaria

CP is a 43-year-old Vietnamese man who had returned recently from a visit to Vietnam and Cambodia. He indicates that he had also visited a refugee camp on the border between Thailand and Cambodia. He was well since returning from Asia until 2 days ago, when he developed a temperature as high as 39°C (102.2°F), with anorexia, headache, chills, sweats, myalgias, and abdominal pain. He took a few doses of acetaminophen, which relieved his headache, but his fever only subsided transiently and came back after a few hours. CP is brought in by his daughter to the emergency department with high fever (greater than 39.8°C [greater than 103.6°F]), headache, abdominal pain, nausea, stiffness of the neck, and back pain. The patient's daughter indicates that CP did not take any antimalarial drugs on his trip.

Are the symptoms in this patient consistent with malaria?

What places this patient at risk for malaria?

What additional information do you need to develop a therapeutic plan for this patient?

In 2009, the Centers for Disease Control and Prevention indicated that there were 1,484 cases of malaria, of which 661 were in U.S. civilians, 18 cases in U.S. military personnel, 201 cases among foreign residents, and 604 among patients of unknown status.⁵ There were four fatalities, three due to *Plasmodium falciparum* (the malaria species in the fourth case was not reported).⁴ *The primary reasons for morbidity and death in malaria are failure to take recommended chemoprophylaxis, inappropriate chemoprophylaxis, delay in seeking medical care or in initiating therapy promptly, and misdiagnosis.* Evaluation of a patient should include specific travel history, details of chemoprophylaxis, and physical findings (e.g., splenomegaly).

Malaria is transmitted by the bites of the *Anopheles* mosquitoes, which introduce into the bloodstream one of four species of sporozoites of the plasmodia (*Plasmodium falciparum*, *P. ovale*, *P. vivax*, or *P. malariae*).^{47–56} Initial symptoms of malaria are nonspecific and may resemble influenza and include chills, headache, fatigue, muscle pain, rigors, and nausea. The onset of the symptoms is between 1 and 3 weeks following exposure. Fever may appear 2 to 3 days after initial symptoms and may follow a pattern and occur every 2 or 3 days (*P. vivax*, *P. ovale*, and *P. malariae*). Fever with *P. falciparum* can be erratic and may not follow specific patterns. It is not unusual for patients to have concomitant infections with *P. vivax* and *P. falciparum*. Falciparum malaria must always be regarded as a life-threatening medical emergency.

Epidemiology and Etiology

The distribution of the various species of malaria is not well defined, but *P. vivax* is reported to be prevalent in the

Indian subcontinent, Central America, North Africa, and the Middle East, whereas *P. falciparum* is predominantly in Africa (including sub-Saharan Africa), both East and West Africa, Haiti, the Dominican Republic, the Amazon region of South America, Southeast Asia, and New Guinea.^{5,48,51} Most *P. ovale* infections occur in Africa, whereas the distribution of *P. malariae* is worldwide.⁷ Most infections in the United States are reported in American travelers, recent immigrants, or immigrants who have visited friends and family in an endemic area.^{4,7} Placental transmission and blood transfusions are also sources of malaria.

Within minutes after the bite of the *Anopheles* mosquito, the sporozoites invade hepatocytes in the liver and begin an asexual phase called schizonts (exoerythrocytic stage or schizogony). The patient may be asymptomatic during this period. After a lapse of between 5 and 15 days (depending on the species), schizonts rupture to release daughter cells (merozoites) into the blood, which then invade erythrocytes. In erythrocytes, the merozoites undergo a number of sequential forms: a ring form, trophozoite, schizont, and merozoite, which then invade new erythrocytes. This asexual phase is about 48 hours for *P. falciparum*, *P. vivax*, and *P. ovale*, and 72 hours for *P. malariae*. Subsequently, the merozoites develop into gametocytes and undergo a sexual phase (sporogony) in the *Anopheles* mosquito. In the mosquito, the gametocytes undergo a number of stages: zygote, ookinete, and oocyst, and finally transform into sporozoites in the salivary glands, where it is again able to infect the next host. Unlike *P. falciparum* and *P. malariae*, which only remain in the liver for about 3 weeks before invading erythrocytes, *P. ovale* and *P. vivax* can remain in the liver for extended periods in a latent stage (as hypnozoites); this can result in the recurrence of the infection after weeks or months. Primaquine therapy is necessary to eradicate this stage of the infection.

Pathophysiology

The clinical presentation of malaria can be quite variable. Normally, the appearance of a prodrome with headache, abdominal pain, fatigue, fever, and chills, which coincides with the erythrocytic phase of malaria, occurs frequently between 10 and 21 days after being exposed.^{48,51} This phase causes extensive hemolysis, which results in anemia and splenomegaly. The most serious complications are caused by *P. falciparum* infections. Infants and children under the age of 5 years and nonimmune pregnant women are at high risk for severe complications with falciparum infections.^{52–58} The complications associated with falciparum malaria are related to two unique features of *P. falciparum*: (a) its ability to produce high parasitism (up to 80%) of red cells of all ages; and (b) the propensity to be sequestered in postcapillary venules of critical organs such as brain, liver, heart, lungs, and kidneys.^{51,53,54} It has been postulated that tissue hypoxia from anemia, together with *P. falciparum*-parasitized red blood cell adherence to endothelial cells in capillaries, contributes to severe ischemia and metabolic derangements. *P. malariae* is implicated in immune-mediated **glomerulonephritis** and nephrotic syndrome.⁵¹

Patient Encounter 3, Part 2: Falciparum Malaria

CP presents with fever, nausea, headache, myalgias, chills, and body aches including back pain.

PMH: Otherwise healthy 43-year-old male

FH: Father died of stroke at age 87 years; mother, who is 82-year-old, has rheumatoid arthritis and lives with an unmarried daughter

SH: Owns a dry-cleaning business; infrequently drinks a beer

Meds: Acetaminophen 325 mg

ROS: In addition to the complaints noted previously, he complains of severe nausea and fatigue

PE

Gen: Patient is slightly agitated and febrile

VS: BP 125/70 mm Hg; P 120 beats/min, RR 36 breaths/min, T 40.1°C (104.2°F)

Skin: Warm and dry to touch

HEENT: Slightly dry oral mucosa

ABD: Splenomegaly

Rest of the systems were WNL

Labs: Sodium 131 mEq/L (131 mmol/L); hemoglobin 10.2 g/dL (102 g/L or 6.33 mmol/L); potassium 4.9 mEq/L (4.9 mmol/L); hematocrit 31% (0.31); chloride 96 mEq/L (96 mmol/L); WBC $14.8 \times 10^3/\text{mm}^3$ ($14.8 \times 10^9/\text{L}$); BUN 28 mg/dL (10 mmol/L); total bilirubin 1.8 mg/dL (30.8 $\mu\text{mol/L}$); Scr 1.4 mg/dL (124 $\mu\text{mol/L}$); platelets $110 \times 10^3/\text{mm}^3$ ($110 \times 10^9/\text{L}$); glucose 77 mg/dL (4.3 mmol/L); aspartate aminotransferase 87 U/L (1.45 $\mu\text{kat/L}$); albumin 3.2 g/dL (32 g/L); alanine aminotransferase 94 U/L (1.57 $\mu\text{kat/L}$); blood smear (Giemsa stain): *P. falciparum*

In view of the above information, what is your assessment of this patient?

Identify your treatment goals and monitoring parameters.

Clinical Presentation and Diagnosis

Innovations for detecting malaria include DNA or RNA probes by polymerase chain reaction (PCR) and monoclonal antibody testing.⁵⁹ These, however, are not widely available for clinical use. A *P. falciparum*-specific monoclonal antibody test, histidine-rich protein 2 (HRP-2), has been evaluated and considered to be fairly sensitive for *P. falciparum* and is recommended by the World Health Organization as an alternative for microscopic test (the “gold standard”). However, the rapid malaria diagnostic tests (MRDTs) are restricted from wide use by cost, regulatory standards, operative expertise, and availability.⁵⁹

Clinical Presentation and Diagnosis of Malaria

Initial Presentation

Include a careful travel history of patient and physical findings (e.g., splenomegaly) and details of antimalarial chemoprophylaxis, when obtainable.

Erythrocytic Phase

1. Prodrome: Headache, anorexia, malaise, fatigue, and myalgia
2. Nonspecific complaints include abdominal pain, diarrhea, chest pain, and arthralgia
3. Paroxysm: High fever, chills, and rigor
4. Cold phase: Severe pallor, cyanosis of the lips and nail beds
5. Hot phase: Fever between 40.5°C (104.9°F) and 41°C (105.8°F) (seen more frequently with *P. falciparum*)
6. Sweating phase: Follows the hot phase by 2 to 6 hours
7. When fever resolves, it is followed by marked fatigue and drowsiness, warm dry skin, tachycardia, cough, headache, nausea, vomiting, abdominal pain, diarrhea and delirium, anemia, and splenomegaly

5 *P. falciparum* malaria is a life-threatening emergency. Complications include hypoglycemia, acute renal failure, pulmonary edema, severe anemia (high parasitism), thrombocytopenia, heart failure, cerebral congestion, seizures, coma, and adult respiratory distress syndrome.

Diagnostic Procedures for Malaria

1. To ensure a positive diagnosis, blood smears (both thick and thin films) should be obtained every 12 to 24 hours for 3 consecutive days.
2. The presence of parasites in the blood 3 to 5 days after initiation of therapy suggests resistance to the drug regimen.

Treatment

The primary goal in the management of malaria is the rapid identification of the *Plasmodium* species by blood smears (both thick and thin smears repeated every 12 hours for 3 days). Antimalarial therapy should be initiated promptly to eradicate the infection within 48 to 72 hours and avoid complications such as hypoglycemia, pulmonary edema, and renal failure.^{48,54}

Pharmacologic Therapy

The chemoprophylaxis regimen for malaria is outlined in [Table 78-1](#).¹²

► Chemotherapy for Malarial Infection

In an uncomplicated attack of malaria (for all plasmodia except chloroquine-resistant *P. falciparum* and *P. vivax*),

Table 78-1

Chemoprophylaxis for Malaria

Plasmodia-Sensitive	Drug	Dose	Pediatric Dose	Comments
Chloroquine-sensitive	Chloroquine phosphate (oral) ^a	300 mg (base) once weekly beginning 1 week prior to departure and continued for 4 weeks after leaving endemic area	5 mg (base) per kg of body weight once weekly (maximum 300 mg)	Hydroxychloroquine sulfate 310 (base) or 400 mg salt once a week may be used instead of chloroquine; regimen will be similar to chloroquine
When leaving an area endemic for <i>P. vivax</i> or <i>P. ovale</i>	Primaquine (oral)	30 mg base (52.6 mg salt) daily for 14 days after departure, in addition to the above	0.6 mg/kg base (1 mg/kg salt) daily for 14 days after departure	<i>Contraindicated</i> in those with G6PD deficiency and in pregnancy and lactation
Chloroquine-resistant <i>P. falciparum</i>	Atovaquone-proguanil (oral)	250 mg atovaquone and 100 mg proguanil (1 tablet) once daily	62.5 mg atovaquone and 25 mg proguanil once daily 11–20 kg: 1 tablet 21–30 kg: 2 tablets 31–40 kg: 3 tablets Greater than or equal to 40 kg: 1 adult tablet daily	Begin 1–2 days before departure and continue for 1 week after leaving high-risk area Recommended also for primary prophylaxis in mefloquine-resistant <i>P. falciparum</i>
	Alternatives			
	Doxycycline (oral)	100 mg daily	Greater than or equal to 8 years of age 2 mg/kg (maximum 100 mg)	Effective for mefloquine-resistant <i>P. falciparum</i> . Start 1–2 days before departure, continue through stay in endemic area, and continue regimen for 4 weeks after returning
	Mefloquine (oral)	228 mg (base) (250 mg salt) weekly	Less than or equal to 5–10 kg: 4.6 mg/kg base (5 mg/kg salt) once weekly 11–20 kg: 1/4 tablet 21–30 kg: 1/2 tablet 31–45 kg: 3/4 tablet Greater than or equal to 45 kg: 1 tablet	Start 1–2 week before departure and continue for 4 week after leaving endemic area; may start 3–4 week earlier to assess tolerance <i>Contraindications:</i> History of seizure, psychiatric disorders (including depression and anxiety), or arrhythmias
	Primaquine (oral)	30 mg base (1 mg/kg salt for adult) daily	0.6 mg/kg base (1 mg/kg salt up to adult dose)	Alternative or second-line regimen; see above for contraindications

G6PD, glucose-6-phosphate dehydrogenase deficiency.

^aPediatric dose can be calculated and tablet pulverized and placed in gelatin capsules. Parents can be instructed to suspend dose in food, simple syrup, or drink.

For further information, see Ref 21: Rao S, Solaymani-Mohammadi S, Petri WA Jr, Parker SK. Hepatic amebiasis: A reminder of the complications. *Curr Opin Pediat* 2009;21:145–149 (Table 73.19 on p. 1276).

the recommended oral regimen is chloroquine 600 mg (base) initially, followed by 300 mg (base) 6 hours later, and then 300 mg (base) daily for 2 days.¹² 6 In severe illness or *falciparum* malaria, patients should be admitted to an acute care unit, and quinidine gluconate 10 mg salt/kg as a loading dose (maximum 600 mg) in 250 mL normal saline should be administered IV slowly over 1 to 2 hours. This should be followed by continuous infusion of 0.02 mg/kg/min of quinidine for at least 24 hours until oral therapy can be started. In patients who have received either quinine or mefloquine, the loading dose of quinidine should be omitted. Oral quinine salt (650 mg every 8 hours) plus doxycycline 100 mg twice daily should follow the IV dose of quinidine to complete 7 days of therapy.^{12,52,54} The pediatric dose of IV quinidine

gluconate is the same as the dose for adults. The pediatric dose of oral quinine is 25 mg/kg/day in three divided doses, whereas the dose of doxycycline (children older than 8 years) is 4 mg/kg in two divided doses for 7 days. An alternative to doxycycline is clindamycin 900 mg (20 mg/kg/day) three times daily for 3 days. The pediatric dose of clindamycin is the same as in adults. (In patients who cannot tolerate quinidine or if quinidine is not readily available, IV artesunate 2.4 mg/kg/dose × 3 days, at 0, 12, 24, 48, and 72 hours may be used, followed by oral therapy. Artesunate is available from the Centers for Disease Control and Prevention (CDC) under an investigational new drug application. The pediatric dose of artesunate is same as in adults. Oral therapy may include atovaquone/proguanil, doxycycline, mefloquine or clindamycin.)¹²

Patient Encounter 3, Part 3: Malaria

Following treatment of falciparum malaria, CP has remained well for 3 weeks. However, 2 days ago, he started developing fever and chills, nausea, and abdominal pain. When seen in the emergency department he has a fever of 38.4°C (101.1°F) and complains of severe headache. Examinations of a thick and thin blood smear of the patient's blood identified *P. falciparum* infection. When CP is questioned about his compliance with his medication, he is not very cooperative. He is admitted to the hospital and received a course of IV quinidine and oral quinine for 7 days. In a follow-up exam 4 weeks later, a repeat blood smear was negative for parasites and the patient was asymptomatic.

In *P. falciparum*, *P. vivax*, *P. ovale*, or *P. malariae* (chloroquine-resistant) infections, a dose of 750 mg of mefloquine followed by 500 mg 12 hours later is recommended.¹² The pediatric dose of mefloquine is 15 mg/kg (less than 45 kg) followed by 10 mg/kg 8 to 12 hours later. Mefloquine is associated with sinus bradycardia, confusion, hallucinations, and psychosis and should be avoided in patients with a history of cardiovascular problems or depression. IV quinidine gluconate followed by quinine plus doxycycline or clindamycin should be administered for severe illness as indicated previously. The IV quinidine regimen requires close monitoring of the ECG (QT-segment) and other vital signs (hypotension and hypoglycemia). An alternative oral treatment for *P. falciparum* infections in adults, especially those with history of seizures, psychiatric disorders, or cardiovascular problems, is the combination of atovaquone 250 mg and proguanil 100 mg (Malarone) (two tablets twice daily for 3 days).¹² The pediatric dose of Malarone is as follows: it is not indicated for children less than 5 kg; 9 to 10 kg: 3 pediatric tablets/day × 3 days; 11 to 20 kg: one adult tablet/day × 3 days; 21 to 30 kg: 2 adult tablets/day 3 days; 31 to 40 kg: 3 adult tablets/day 3 days; greater than 40 kg: 2 adults tablets twice daily × 3 days. **7** Since falciparum malaria is associated with serious complications, including pulmonary edema, hypoglycemia, jaundice, renal failure, confusion, delirium, seizures, coma, and death, careful monitoring of fluid status and hemodynamic parameters is mandatory. Exchange transfusion that may be required in patients with *P. falciparum* malaria in whom parasitemia may be between 5% and 15% remains a controversial modality.^{12,57} Either peritoneal or hemodialysis may be indicated in renal failure.^{48,51}

Outcome Evaluation

When advising potential travelers on prophylaxis for malaria, be aware of the incidence of chloroquine-resistant *P. falciparum* malaria and the countries where it is prevalent.⁶⁰⁻⁷⁴ In patients who have *P. vivax* or *P. ovale* malaria (note that some patients can have *P. falciparum* and one of these species), following the treatment of the acute phase of malaria and screening for glucose-6-phosphate dehydrogenase

Patient Care and Monitoring: Malaria

1. Acute *P. falciparum* malaria resistant to chloroquine should be treated with IV quinidine via central venous catheter and fluid status and the electrocardiogram (ECG) should be monitored closely.
2. The loading dose of quinidine should be omitted in those patients who have received quinine or mefloquine.
3. Hypoglycemia that is associated with both *P. falciparum* and quinidine administration should be checked every 4 to 6 hours and corrected with dextrose infusions (5% to 10%).
4. Quinidine infusions should be slowed temporarily or stopped if the QT interval is greater than 0.6 second, the increase in the QRS complex is greater than 25%, or hypotension unresponsive to fluid challenge results.
5. The suggested quinidine levels should be maintained at 3 to 7 mg/dL (9.2 to 21.6 μmol/L). If quinidine is not readily available, artesunate obtained from the Centers for Disease Control and Prevention on an investigational protocol should be utilized (contact: www.cdc.gov/malaria/features/artesunate_now_available.htm).¹²
6. Blood smears should be checked every 12 hours until parasitemia is less than 1%.
7. Resolution of fever should take place between 36 and 48 hours after initiation of the IV quinidine therapy, and the blood should be clear of parasites in 5 days.
8. When parenteral therapy is required for more than 48 hours or the patient's renal function deteriorates, the dose of quinidine should be lowered by half.

Advice to Travelers

All travelers to endemic areas should be advised to remain in well-screened areas, to wear clothes that cover most of the body, and sleep in mosquito nets. Travelers should adhere to malaria chemoprophylaxis regimens and carry the insect repellent DEET (*N, N-diethylmetatoluamide*) or other insect sprays containing DEET for use in mosquito-infested areas. Relapse of *P. falciparum* between 2 and 4 weeks may take place if the initial therapeutic regimen is not completed.

deficiency, patients should receive a regimen of primaquine for 14 days to ensure eradication of the hypnozoite stage of *P. vivax* or *P. ovale*.^{61,62} For detailed recommendations for prevention of malaria, go to www.cdc.gov/travel/.

AMERICAN TRYPANOSOMIASIS**Etiology**

Two distinct forms of the genus *Trypanosoma* occur in humans. One is associated with African trypanosomiasis

(sleeping sickness) and the other with American trypanosomiasis (Chagas' disease). *Trypanosoma brucei gambiense* and *Trypanosoma brucei rhodesiense* are the causative organisms for the East African and West African trypanosomiasis, respectively. *T. brucei rhodesiense* causes the acute disease and is the more virulent of the two species. Both East and West African trypanosomiasis are transmitted by various species of tsetse fly belonging to the genus *Glossina*. Further discussion of this subject will focus on American trypanosomiasis.

Trypanosoma cruzi is the agent that causes American trypanosomiasis. American trypanosomiasis is transmitted by a number of species of reduviid bugs (*Triatoma infestans* and *Rhodnius prolixus*) that live in wall cracks of houses in rural areas of North, Central, and South America.⁷⁵⁻⁷⁹ The reduviid bug is infected by sucking blood from animals (e.g., opossums, dogs, and cats) or humans infected with circulating trypomastigotes. American trypanosomiasis is endemic in all Latin American countries and can be transmitted congenitally, by blood transfusion, and by organ transplantation.

Clinical Presentation and Diagnosis

► Pharmacologic Therapy

The drugs used for *T. cruzi* include nifurtimox (Lampit) and benznidazole (Rochagan). Oral nifurtimox is available from the CDC, whereas benznidazole is only available in Brazil.^{12,80-83} The adult dose of nifurtimox is 8 to 10 mg/kg/day in divided doses for 120 days. Since children seem to tolerate

Patient Care and Monitoring of Trypanosomiasis

1. It is essential to identify *T. cruzi*-infected patients by serology and to monitor the cardiovascular status of these patients by ECG periodically.
2. Some patients will benefit from implantation of pacemakers.
3. All transplant candidates from areas endemic for Chagas' disease need to be screened for *T. cruzi*. Immunosuppression in these patients can lead to overwhelming infections.

the dose better than adults, the pediatric dose of nifurtimox for 1- to 10-year-old children is 15 to 20 mg/kg/day, and for 11- to 16-year-old children is 12.5 to 15 mg/kg/day in divided doses.¹² Symptomatic treatment for heart failure associated with Chagas' disease should be initiated. The GI complications may require surgical revisions and reconstruction.

Outcome Evaluation

Treatment of the acute phase of the disease (i.e., fever, malaise, edema of the face, and hepatosplenomegaly) is nifurtimox. The congestive heart failure associated with cardiomyopathy of Chagas' disease is treated the same way as cardiomyopathy from other causes.^{76,79}

Clinical Presentation and Diagnosis of Trypanosomiasis

Acute

- Unilateral orbital edema (Romana's sign)
- Granuloma (chagoma)
- Fever, hepatosplenomegaly, and lymphadenopathy

Chronic 8

- *Cardiac*: cardiomyopathy and heart failure
- *ECG*: first-degree heart block, right bundle-branch block, and arrhythmias
- *GI*: enlargement of the esophagus and colon ("mega" syndrome)
- *CNS*: meningoencephalitis, strokes, seizures, and focal paralysis

Diagnosis

Positive history of exposure and use of serology: indirect hemagglutination test, ELISA (Chagas EIA, Abbott Labs, Abbott Park, IL), and complement fixation (CF) test. (Note: CF may produce false-positive reactions in those exposed to leishmaniasis, syphilis, and malaria. PCR may be more definitive for diagnosis.)

ECTOPARASITES

A parasite that lives outside the body of the host is called an ectoparasite. Approximately 6 to 12 million subjects become infested with pediculosis (lice infestation) yearly in the United States. Pediculosis is usually associated with poor hygiene, and infections are passed from person to person through social and sexual contact.

Lice

The two species that belong to this group include *Pediculus humanus capitis* (head louse) and *Pediculus humanus corporis* (body louse).⁸⁴⁻⁸⁸ The eggs (or nits) remain firmly attached to the hair, and in about 10 days the lice hatch to form nymphs, which mature in 2 weeks. The lice become attached to the base of the hair follicle and feed on the blood of the host.¹⁰ Pubic or crab lice is found on the hairs around the genitals but may occur in other parts of the body (e.g., eyelashes or axillae). Hypersensitivity to the secretions from lice can produce macular swellings and lead to secondary bacterial infections.

► Treatment

- 9 The agent of choice for all three infections (body, head, and crab lice) is 1% permethrin (Nix).¹² Permethrin has

both pediculicidal and ovicidal activity against *P. humanus capitis*. The cure rate is reported to be between 90% and 97%. A cream rinse of permethrin 1% (Nix-Crème Rinse) is also available. Individuals with a history of hypersensitivity to ragweed or chrysanthemum may react to permethrin and should avoid this preparation. An alternative agent is oral ivermectin 100 mcg/kg for 3 days (days 1, 2, and 10). Permethrin can cause itching, burning, stinging, and tingling with application. Permethrin 1% should be applied to the dry scalp after shampooing and be left on the scalp for 10 minutes. The application may need to be repeated. Because of the reports of resistance to permethrin, an alternative agent is 0.5% malathion (Ovide), which has to be left on the scalp for 90 minutes and has also been found to be effective. Two applications of malathion, 7 days apart, may be necessary to eradicate the infection.¹² An alternative for head lice is Spinosad 0.9% Creme which became available for patients who may not tolerate permethrin.⁹¹ For the relief of pruritus, calamine lotion with 0.1% menthol or an equivalent agent may be used. *All individuals, including immediate family members and sexual partners of the primary host, should be treated. All bedding and clothes should be sterilized as previously indicated for enterobiasis.*

SCABIES

10 Scabies is caused by the itch mite *Sarcoptes scabiei hominis*, which affects both humans and animals. Infection usually affects the interdigital and popliteal folds, axillary folds, the umbilicus, and the scrotum. The infection causes severe itching and excoriations in the interdigital web spaces, buttocks, groin, and scalp.^{89,90} *Diagnosis is made by identifying the mite from skin scrapings on a wet mount.*

Treatment

10 The agent of choice for scabies is permethrin 5% (Elimite) cream.¹² Alternative agents in subjects who cannot use permethrin are crotamiton 10% (Eurax) and oral ivermectin (Stromectol) 200 mcg/kg as a single dose. To initiate the treatment with permethrin, the skin should be scrubbed in a warm soapy bath to remove the scabs. The permethrin lotion should then be applied to the whole body, avoiding the face, mucous membranes, and eyes, and left on for 8 to 14 hours. A single application eradicates 97% of scabies. However, in subjects with poor response, permethrin application can be combined with oral ivermectin therapy.⁹⁰ All close contacts should be treated appropriately. The pruritus associated with scabies may persist for 2 to 4 weeks because of the remnants of mite parts in the skin.

Outcome Evaluation

Infections due to arthropods can be controlled by preventing their access to the host. Improving living conditions and avoiding sharing common personal items like hats and hair brushes may minimize these infections due to arthropods. Permethrin (1% to 5%) is an effective agent for all these infections.

Abbreviations Introduced in This Chapter

CDC	Centers for Disease Control and Prevention
CF	Complement fixation
DEET	<i>N,N</i> -Diethylmetatoluamide
ELISA	Enzyme-linked immunosorbent assay
IgA	Immunoglobulin A
PCR	Polymerase chain reaction

Urinary Tract Infections

Warren E. Rose and Kathryn R. Matthias

LEARNING OBJECTIVES

● Upon completion of the chapter, the reader will be able to:

1. Determine the diagnostic criteria for significant bacteriuria.
2. Interpret the signs and symptoms of urinary tract infections (UTIs) and differentiate those of upper versus lower urinary tract disease.
3. Identify the organism responsible for the majority of uncomplicated UTIs.
4. Assess the laboratory tests that help in diagnosing patients with UTI.
5. Recommend appropriate drug, dose, and duration for uncomplicated and complicated UTI prophylaxis and empiric treatment.
6. Evaluate and select therapy for uncomplicated and complicated UTIs based on specific urine culture results and patient characteristics.
7. Formulate appropriate monitoring and education information for patients with UTIs.

KEY CONCEPTS

- 1 Urinary tract infections (UTIs) are thought of as either uncomplicated or complicated. Generally this refers to absence or presence, respectively, of functional or structural abnormalities within the urinary tract.
- 2 The majority of uncomplicated UTIs are the result of a single causative organism, which is primarily *Escherichia coli* in up to 85% of cases. The remaining 15% are caused by *Staphylococcus saprophyticus* along with *Klebsiella* species (spp.), *Proteus* spp., *Pseudomonas* spp., *Enterobacter* spp., and *Enterococcus* spp.
- 3 Symptoms of lower UTIs include **dysuria**, gross hematuria, suprapubic heaviness, **nocturia**, increased urinary frequency, and urgency.
- 4 Symptoms of upper UTIs include fever, nausea, vomiting, malaise, and often severe flank pain.
- 5 The goals of treatment are to eradicate the causative pathogen, to prevent or treat consequences of infection, and to prevent, if possible, recurrence of infection.
- 6 Uncomplicated UTIs may be managed with a short course antimicrobial therapy with one-dose, 3-day, or 5-day regimens, depending on the clinical factors.
- 7 Complicated UTIs including acute pyelonephritis should be treated for at least 7 days and sometimes 2 weeks or longer.
- 8 Treatment of catheterized patients with bacteriuria should follow one of two treatment algorithms: (a) for

asymptomatic patients, hold antibiotics and remove the catheter if possible; or (b) for symptomatic patients, initiate antibiotic therapy and remove the catheter if possible.

- 9 Any urinary tract infection in a male is considered complicated and should be treated with at least 2 weeks of targeted antimicrobial therapy. Male patients with prostatic sources or prior treatment failure should be treated for up to 6 weeks.

Urinary tract infections (UTIs) are comprised of a diverse array of syndromes depending on the location of the infection within the urinary tract.¹⁻³ UTIs occur frequently and are responsible for approximately 5.3 million annual visits to primary care and surgical specialty offices along with approximately 2.6 million annual visits to hospital outpatient and emergency departments.^{4,5} In simplest of terms, a UTI is defined by microorganism(s) in the urinary tract, which does not represent contamination.

- **Bacteriuria**, or bacteria in the urine, does not always represent infection. For this reason a number of quantitative diagnostic criteria have been created (**Table 79-1**) to identify the amount of bacteria in the urine that most likely represents true infection (hence the term “significant bacteriuria”).⁶ Furthermore, UTIs are classified as lower tract or upper tract disease. Patients can present differently with upper versus lower tract disease, and upper tract disease is thought of as a

Table 79-1

Diagnostic Criteria for Significant Bacteriuria

- Greater than or equal to 10^2 CFU coliforms/mL (10^5 CFU/L) or greater than or equal to 10^5 CFU noncoliforms/mL (10^8 CFU/L) in a symptomatic female
- Greater than or equal to 10^3 CFU organisms/mL (10^6 CFU/L) in a symptomatic male
- Greater than or equal to 10^5 CFU same organisms/mL (10^8 CFU/L) in asymptomatic individuals on two consecutive specimens
- Any growth of bacteria on suprapubic catheterization in a symptomatic patient
- Greater than or equal to 10^2 CFU organisms/mL in a catheterized patient

much more severe infection since patients are more likely to be admitted to the hospital. An example of lower tract syndrome is **cystitis**, which involves inflammation of the bladder and commonly causes symptoms such as dysuria, nocturia, gross **hematuria**, and occasional suprapubic tenderness. An example of upper urinary tract disease is **pyelonephritis**. Pyelonephritis is an inflammation of the kidney that is usually due to infection. Patients with uncomplicated UTI are more frequently treated as outpatients as compared with those patients with complicated UTIs.

EPIDEMIOLOGY AND ETIOLOGY

The prevalence and type of UTIs generally vary by age and gender.⁷⁻⁹ UTIs may occur at any age, even in infants. Premature infants, for example, have a higher rate than full-term infants, and neonatal boys are five to eight times more likely to have UTIs than neonatal girls. In young children 1 to 5 years of age, significant bacteriuria occurs more in girls than boys, 4.5% compared with 0.5%, respectively.¹⁰ Once adulthood is reached, bacteriuria increases in young, nonpregnant women (range, 1% to 3%), yet remains low in men (up to 0.1%).¹¹ Symptomatic UTI affects 30% of women between 20 and 40 years of age, which represents a prevalence that is 30 times greater than that of men in the same age group. Upwards of 40% to 50% of the female population will experience a symptomatic UTI at some time during their life.⁴

The etiology of UTIs has remained relatively unchanged over the past several decades. **1** *UTIs are either uncomplicated or complicated.* There is a lack of consensus regarding the definition of what makes a UTI complicated (specifically in postmenopausal women or patients with diabetes mellitus), but in general, a complicated UTI refers to a structural or functional abnormality of the urinary tract.¹ Patients with complicated UTIs are typically given longer treatment durations than those patients with uncomplicated infections. Those with complicated UTIs by definition are also prone to more frequent infections. It is important to note that an upper UTI does not necessarily imply complicated UTI, nor does lower UTI imply uncomplicated UTI.

Patient Encounter, Part 1

BM is a 25-year-old female who presents to a local primary care physician with complaints of painful urination, blood in her urine with last menstrual cycle 3 weeks ago, and frequent need to urinate especially at night, which began 5 days ago. She denies vomiting, fever, nausea, or flank pain. Upon questioning she does admit that she is sexually active with only one partner and uses oral contraceptives. She also uses spermicidal jellies occasionally when she is noncompliant with the daily oral contraceptive regimen. She states that she had a similar episode approximately 3 months earlier.

What symptoms are suggestive of a lower urinary tract infection (UTI)?

What risk factors does she have for a UTI?

What additional patient information is required before creating an appropriate treatment plan for this patient?

The frequency of causative organisms changes depending on the location of infection and patient characteristics. **2** Almost all uncomplicated UTIs are the result of a single causative organism, which is primarily *Escherichia coli* in up to 85% of cases.¹² A variety of other organisms may cause uncomplicated UTIs, but represent the minority of pathogens. Other organisms include gram-positives such as *Staphylococcus saprophyticus* and *Enterococcus* spp. and gram-negative bacteria such as *Pseudomonas aeruginosa*, *Klebsiella pneumoniae*, *Proteus* spp., and *Enterobacter* spp.¹³⁻¹⁵ The chances of isolating an organism other than *E. coli* are higher in patients who have recurrent UTIs, particularly those patients whose UTIs are considered complicated. It is also more common for organisms other than *E. coli* to cause UTIs in the hospitalized population than in the general population.^{16,17}

PATHOPHYSIOLOGY

There are three potential ways for bacteria to enter into the urinary tract and cause infection: the ascending, hematogenous, and lymphatic pathways.

Ascending Pathway

The ascending pathway occurs when bacteria colonizing the urethra subsequently travel upwards, or ascend, the urethra to the bladder and cause cystitis (**Fig. 79-1**). The ascending route may help to explain why UTIs occur more commonly in women than in men. Women have a shorter urethra than men, and colonization of the female urethra is likely due to its proximity to the perirectal area. The use of spermicidal agents increases the colonization of the vagina with uropathogens.¹⁸ Additionally, massage of the urethra in women as well as sexual intercourse may

FIGURE 79-1. Anatomy and associated infections of the urinary tract. (From Sprandel KA, Lesch CA, Rodvold KA. Lower urinary tract infection. In: Schwinghammer TL (ed). *Pharmacotherapy Casebook: A Patient-Focused Approach*. 6th ed. New York City: McGraw-Hill; 2005:315; With permission).

lead to bacteria gaining entrance into the bladder.^{19,20} Once in the bladder, bacteria are not limited to causing cystitis. These bacteria may continue to ascend the urinary tract via the ureters and cause more complicated infections, such as pyelonephritis.

Hematogenous Pathway

The hematogenous route occurs through the seeding of the urinary tract with pathogens carried by the blood supply. These pathogens represent an infection at some other primary site in the body. *Staphylococcus aureus* bacteremia, for example, can cause renal abscesses via the hematogenous route, and pyelonephritis can be experimentally produced in rabbits by IV injection of *Salmonella* spp., *Mycobacterium tuberculosis*, or even yeast (*Candida* spp.).²¹ However, experimentally creating this pathway has not been successful with all organisms. Experimental hematogenous seeding of the kidneys could not be created with the IV injection of large inocula of *E. coli* or *P. aeruginosa* in a mouse model.²²

Lymphatic Pathway

The lymphatic system, also known as the secondary circulatory system, connects the bladder to the kidney and may represent a way for bacteria to be transported and subsequently cause infection. Although this pathway is classically included as a route of infection, there is a lack of data showing the lymphatic pathway as a significant mechanism for development of infection. As a result this pathway is not believed to be a significant host mechanism.

Host Defense Mechanisms

Urine possesses characteristics that are less than ideal for bacterial metabolism and growth. Some of these characteristics include low pH, significant urea concentration, and high osmolality. Also, bacteria in the bladder can stimulate an urge to urinate. Additionally, prostatic fluid secretions in men can inhibit bacterial growth, whereas normal vaginal flora in women such as *Lactobacillus* spp. can secrete lactic acid, which can decrease the pH of the environment.²³⁻²⁵

There are several other host factors that inhibit bacterial virulence factors. These virulence factors are mechanisms that bacteria utilize to cause infection and/or ensure their survival. The first is glycosaminoglycan, a compound produced by the body that coats the epithelial cells of the bladder. This compound essentially separates the bladder from the urine by forming a protective layer against bacterial adhesion.²⁶ A second compound known as Tamm-Horsfall protein is secreted into the urine and prevents *E. coli* from binding to receptors present on the surface of the bladder. Other factors implicated in contributing to host defense mechanisms against UTIs include immunoglobulins, specifically IgA.

Risk Factors

There are several risk factors for development of UTIs.¹¹ Common risk factors for UTIs in women include sexual intercourse, use of a cervical diaphragm, use of spermicidal jellies, diabetes, and pregnancy.²⁷⁻²⁹ In men, the risks are increased in uncircumcised males and older age men with **prostatic hyperplasia**. Common risk factors for both men and women include urologic instrumentation, urethral catheterization, renal transplantation, neurogenic bladder, and urinary tract obstruction.^{30,31}

TREATMENT

Desired Outcomes

5 The goals of treatment are to eradicate the causative pathogen, prevent or treat consequences of infection, administer targeted antimicrobial therapy for the identified or most likely pathogen, and prevent, if possible, recurrence of infection. Therapy is directed at microbiologic eradication of the offending organism through antibiotics with a defined duration of treatment based on the UTI classification.

Clinical Presentation and Diagnosis of UTIs

General

- Most women present with hematuria; however, this is not a presentation restricted only to UTIs.
- Elderly patients frequently will not present with common signs and symptoms of UTI, but may present with altered mental status.
- More than 95% of uncomplicated UTIs are caused by a single organism.
- Patients may present with urosepsis.

3 Signs and Symptoms of Lower UTI

- Dysuria, gross hematuria, suprapubic heaviness, nocturia, increased urinary frequency and urgency

4 Signs and Symptoms of Upper UTI

- Fever, nausea, vomiting, malaise, and often severe flank pain

Laboratory Tests

Urinalysis should show:

- **Pyuria** typically greater than 10 white blood cells/mm³ urine (10⁶/L)
- Bacteriuria, usually greater than 10⁵ CFU organisms/mL (10⁸ CFU/L)
- Nitrites present
- Leukocyte esterase present

Other Diagnostic Tests

- Bacterial urine culture
- Presence of costovertebral tenderness (upper UTI only)

Patient Encounter, Part 2 of Patient BM: Medical History, Physical Exam, and Diagnostic Tests

PMH: Type 1 diabetes mellitus diagnosed at age 8 years (well controlled)

Uncomplicated cystitis diagnosed 3 months ago (prescribed a 3-day course of sulfamethoxazole-trimethoprim)

FH: Mother living with asthma (well controlled); father living with chronic obstructive pulmonary disease

SH: Unmarried, sexually active with one partner, works as a veterinary technician

Allergies: None

Medications:

- Insulin glargine 38 units subcutaneously daily
- Regular insulin before meals (number of units based on calorie count and pre-meal fingerstick blood glucose)
- Ethinyl estradiol 20 mcg/norethindrone 1 mg daily

ROS: (+) dysuria, urinary frequency; (–) fever, nausea, vomiting, flank pain

PE:

VS: BP 118/68 mm Hg, P 60 beats/min, RR 14 breaths/min, T 36.2°C

CV: RRR, normal S1, S2; normal findings

Abd: Soft, nontender, nondistended; (+) bowel sounds, no hepatosplenomegaly, heme (–) stool

Lab: Within normal limits including blood glucose; (–) pregnancy test

Urinalysis: Greater than 200 white blood cells/mm³; urine nitrates negative

Urine Gram stain: Gram-negative rods, more than 10⁵ CFU/mL

Given this additional information, what is your assessment of the patient's condition?

Identify your treatment goals for the patient.

What nonpharmacologic and pharmacologic alternatives are available for the patient?

General Approach to Treatment

- Antimicrobial therapy is the cornerstone of treatment in UTIs. The selected antimicrobial should ideally be well tolerated, lend itself to patient compliance (low total number of doses), have adequate concentrations at the site of the infection in the urinary tract, have good oral bioavailability, and be narrow in antimicrobial spectrum to limit **collateral damage** and resistance development in human flora not affiliated with the infection.¹ **Table 79-2** reviews oral and IV antibiotics frequently used to treat UTIs with comments on their use, and **Table 79-3** reviews frequency, duration, and doses of oral antibiotics used commonly for outpatient treatment of UTIs.

Nonpharmacologic Therapy

Although there are limited data in the literature and sometimes conflicting results, several nonpharmacologic therapies have been proposed for prevention of UTIs. The intake of large volumes of cranberry juice has been associated with a

decrease in the number of UTIs over a year period in patients with recurrent UTIs in small randomized controlled trials. The efficacy is uncertain in the general population and with smaller intake volumes.³²⁻³⁴ Probiotics such as *Lactobacillus* spp. have been used to decrease vaginal pH in women and potentially reduce the growth of pathogenic bacteria.^{24,25} Topical estrogen replacement therapy significantly decreases the incidence of UTIs in postmenopausal women as compared with placebo.³⁵ Methenamine hippurate and methenamine mandelate have no antimicrobial properties but decrease the incidence of UTIs when used for prophylaxis. Patient education of common risk factors is important.

Table 79-2

Commonly Used Antimicrobial Agents for the Treatment of UTIs

Agent	Comments
Oral Therapy	
<i>Penicillins</i>	
Amoxicillin	Increasing <i>E. coli</i> resistance has limited amoxicillin use in acute cystitis despite broad-spectrum activity.
Amoxicillin-clavulanic acid	Amoxicillin-clavulanic acid is empirically preferred due to resistance. Ampicillin is the drug of choice for enterococci-sensitive to penicillin, but oral bioavailability is approximately 50%.
Pivmecillinam	Pivmecillinam is a prodrug of mecillinam and is recommended for treatment of acute cystitis. It should be avoided in patients with suspected pyelonephritis. Neither pivmecillinam nor mecillinam are currently approved for use by the U.S. FDA.
<i>Cephalosporins</i>	
Cefaclor	There are no major advantages of these agents over other oral agents in the treatment of UTIs, and they may have inferior efficacy as compared with other oral agents such as fluoroquinolones. They may be useful in cases of resistance to amoxicillin and trimethoprim-sulfamethoxazole, but concern exists for use as a first-line agent for uncomplicated cystitis therapy due to potential selection of cephalosporin resistant organisms (collateral damage). These agents are not active against enterococci. Susceptibility of cephalexin cannot be accurately predicted based on cefazolin susceptibility testing.
Cefadroxil	
Cefixime	
Cefpodoxime	
Cefuroxime	
Cephalexin	
Cephadrine	
<i>Tetracyclines</i>	
Doxycycline	These agents have been effective for initial episodes of UTI; however, resistance can develop rapidly. Avoid during pregnancy.
Minocycline	
Tetracycline	
<i>Fluoroquinolones</i>	
Ciprofloxacin	The newer quinolones have a greater spectrum of activity; rates of resistance are increasing. Concern for use as a first-line agent for uncomplicated UTI therapy exists due to potential selection of multidrug resistant organisms (collateral damage). These agents are often effective for pyelonephritis. Avoid in pregnancy and children. Moxifloxacin is not listed due to limited urinary excretion.
Levofloxacin	
Norfloxacin	
Ofloxacin	
<i>Miscellaneous</i>	
Trimethoprim-sulfamethoxazole	This combination is highly effective against most aerobic enteric bacteria except <i>P. aeruginosa</i> . High urinary tract tissue levels and urine levels are achieved, which may be important in complicated UTI treatment. Also effective as prophylaxis for recurrent infections. Generally well tolerated and low cost but increasing resistance rates above 20% in certain regions has limited empiric use. Its use may be precluded in patients with sulfa allergies.
Nitrofurantoin	This agent is effective in treatment and prophylaxis in patients with uncomplicated or recurrent lower tract UTIs. Should not be used in patients with low estimated CrCl (less than 40 to 60 mL/min [0.67 to 1.00 mL/s]) due to limited urine concentrations and potential increased risk of neuropathy.
Azithromycin	Commonly used for sexually transmitted diseases (i.e., chlamydia infections) rather than for UTIs. Single-dose therapy for uncomplicated cystitis. Has been recommended for empiric therapy since resistance rates are low but may have inferior efficacy when compared with short courses of other oral antibiotic agents.
Fosfomicin	
Parenteral Therapy	
<i>Aminoglycosides</i>	
Amikacin	Gentamicin and tobramycin are generally equally effective, whereas tobramycin has slightly better coverage of certain <i>Pseudomonas</i> spp. Amikacin generally is reserved for multidrug-resistant bacteria. Typically used as a short course of therapy followed by a switch to an oral agent. Concern for neurotoxicity and ototoxicity generally limit use, especially in patients with impaired renal function.
Gentamicin	
Tobramycin	
<i>Penicillins</i>	
Ampicillin	These agents are generally effective for susceptible bacteria. The extended-spectrum penicillins are active against certain strains of <i>Pseudomonas</i> spp. They are very useful in renally impaired patients since urine concentration can remain adequate or when an aminoglycoside is avoided. Empiric use of ampicillin with an aminoglycoside is recommended only in patients with suspected infection due to <i>Enterococcus</i> spp.
Ampicillin-sulbactam	
Ticarcillin-clavulanate	
Piperacillin	
Piperacillin-tazobactam	
<i>Cephalosporins</i>	
First-, second-, third-, and fourth-generation	Second- and third-generation cephalosporins have a broad spectrum of activity against gram-negative bacteria, but are not active against enterococci. Only ceftazidime and cefepime have activity against certain strains of <i>Pseudomonas</i> spp. They are useful for nosocomial infections and urosepsis due to susceptible pathogens. A single ceftriaxone dose could be used in lieu of an IV fluoroquinolone for acute uncomplicated pyelonephritis.
<i>Carbapenems</i>	
Doripenem	These agents have broad-spectrum activity, including gram-positive, gram-negative, and anaerobic bacteria. Ertapenem is not active against <i>Pseudomonas</i> spp. All may be associated with <i>Candida</i> spp. superinfections. Rarely used for UTIs.
Ertapenem	
Imipenem-cilastatin	
Meropenem	

(Continued)

Table 79-2

Commonly Used Antimicrobial Agents for the Treatment of UTIs (Continued)

Agent	Comments
<i>Fluoroquinolones</i> Ciprofloxacin Levofloxacin	These agents have broad-spectrum activity against both gram-negative and gram-positive bacteria. They provide high urine and tissue concentrations and are actively secreted in reduced renal function. Switch to oral therapy when possible due to excellent bioavailability.
<i>Monobactam</i> Aztreonam	Only active against gram-negative bacteria, including some strains of <i>P. aeruginosa</i> . Generally useful for nosocomial infections when aminoglycosides are to be avoided and in patients with type 1/immediate hypersensitivity to penicillins.
<i>Glycopeptide</i> Vancomycin	May be considered in combination for empiric therapy based on patient risk factors for multidrug-resistant organisms and gram-positive cocci shown in urinalysis.

Table 79-3

Overview of Outpatient, Oral Antimicrobial Therapy for Lower and Upper Tract UTIs

Indications	Antibiotic	Adult Dose ^a	Frequency	Duration	
Lower Tract UTIs					
Uncomplicated	Nitrofurantoin macrocrystals	100 mg	Every 12 hours	5–7 days	
	Nitrofurantoin monohydrate	100 mg	Every 12 hours	5–7 days	
	Trimethoprim-sulfamethoxazole	1 DS ^b tablet	Every 12 hours	3 days	
	Trimethoprim	100 mg	Every 12 hours	3 days	
	Fosfomycin	3,000 mg	Single dose	1 day	
	Pivmecillinam ^c	400 mg	Every 12 hours	3–7 days	
	Alternative options:	Ciprofloxacin	250 mg	Every 12 hours	3 days
		Levofloxacin	250 mg	Every 24 hours	3 days
		Ofloxacin	200 mg	Every 12 hours	3 days
		Amoxicillin-clavulanic acid	500 mg	Every 8 hours	3 days
		Cefdinir	100 mg	Every 12 hours	7 days
		Cefaclor	250–500 mg	Every 8 hours	7 days
	Complicated	Cefpodoxime-proxetil	100 mg	Every 12 hours	7 days
Trimethoprim-sulfamethoxazole		1 DS ^b tablet	Every 12 hours	7–10 days	
Trimethoprim		100 mg	Every 12 hours	7–10 days	
Ciprofloxacin		500 mg	Every 12 hours	7–10 days	
Norfloxacin		400 mg	Every 12 hours	7–10 days	
Levofloxacin		250 mg	Every 24 hours	7–10 days	
Amoxicillin-clavulanic acid		500 mg	Every 8 hours	7–10 days	
Recurrent infections—continuous prophylaxis		Trimethoprim-sulfamethoxazole	½ SS ^d tablet	Every 24 hours	6 months
	Trimethoprim	100 mg	Every 24 hours	6 months	
	Ciprofloxacin	125 mg	Every 24 hours	6 months	
	Nitrofurantoin	50 or 100 mg	Every 24 hours	6 months	
	Cefaclor	250 mg	Every 24 hours	6 months	
	Cephalexin	125 mg	Every 24 hours	6 months	
Upper Tract UTIs					
Uncomplicated Acute pyelonephritis ^e	Ciprofloxacin	500 mg	Every 12 hours	7 days	
	Ciprofloxacin (extended release)	1,000 mg	Every 24 hours	7 days	
	Levofloxacin (extended release)	750 mg	Every 24 hours	5 days	
	Trimethoprim-sulfamethoxazole	1 DS ^b tablet	Every 12 hours	14 days	

^aMajority of listed antimicrobial agents require dosage adjustment in patients with significant renal dysfunction.

^bDS, double strength (160 mg trimethoprim/800 mg sulfamethoxazole).

^cNot approved for use by the U.S. FDA as of November 2011.

^dSS, single strength (80 mg trimethoprim/400 mg sulfamethoxazole).

^eDoses listed for acute pyelonephritis are for oral regimens.

Pharmacologic Therapy

► Uncomplicated UTIs

Cystitis Uncomplicated cystitis in patients with absence of fever or flank pain represents the most common type of UTIs. It is frequently managed in the outpatient setting and occurs mostly in women of childbearing age.¹ *E. coli* represent the vast majority of causal organisms in this setting, but a minority of cases may be caused by *S. saprophyticus*, *K. pneumoniae*, *Proteus mirabilis*, *Enterococcus* spp., and a small percentage of other organisms.^{12–15} As such, treatment in the outpatient setting is frequently relegated to a urinalysis and empiric therapy without a urine culture.^{1,36,37} Patients are subsequently monitored for resolution of signs and symptoms. **6** *Uncomplicated UTIs may be managed with a short course antimicrobial therapy with one-dose, 3-day, or 5-day regimens depending on the clinical factors involved.*

For acute uncomplicated UTIs, it is reasonable to pursue oral empiric therapy with one dose (3,000 mg) of fosfomycin, a 3-day course of trimethoprim-sulfamethoxazole (one double-strength tablet twice daily), or a 5-day course of nitrofurantoin (100 mg twice daily) depending on the patient's characteristics and risk factors.¹ The antibiotic selection for empiric therapy partly depends on known resistance rates in the geographic region, particularly *E. coli* resistance to trimethoprim-sulfamethoxazole.^{12,38,39} Empiric therapy with trimethoprim-sulfamethoxazole should be considered only if the local resistance rates in *E. coli* is less than 20%, due to poor UTI treatment responses with trimethoprim-sulfamethoxazole when resistance rates are above this threshold.^{1,40} Although fluoroquinolone antibiotics and certain β -lactam agents can be highly active and efficacious against *E. coli*, these agents should be considered alternative agents in uncomplicated UTIs due to their broad-spectrum activity and risk of resistance development in bacteria unaffiliated with the infection.¹

► Complicated UTIs

7 Complicated UTIs including acute pyelonephritis should be treated for at least 7 days and sometimes 2 weeks or longer.

► Acute Pyelonephritis

In contrast to patients who present with lower UTIs, those who present with pyelonephritis usually have high-grade fever (greater than 38.3°C [100.9°F]) and severe flank pain. Select patients with pyelonephritis may be treated in the outpatient setting; however, patients whose infection is severe enough to cause vomiting, decreased food intake, and dehydration may need to be treated in an inpatient hospitalized setting. These patients will often receive IV antibiotics initially before being switched to oral therapy depending on susceptibility testing.

Patients with pyelonephritis are traditionally given 14 days of therapy; however, there are limited data showing success in treating acute uncomplicated pyelonephritis for

7 to 10 days. More studies need to be conducted to determine the efficacy for shorter duration regimens.¹ Gram stain and culture are important in ensuring that appropriate antimicrobial coverage is selected. Stratification is used to manage patients with acute pyelonephritis. Women who present with mild cases of pyelonephritis (defined as low-grade fever and a normal to slightly elevated peripheral white blood count, without nausea or vomiting) may be treated as outpatients.¹ Those patients who exhibit more severe signs and symptoms will need to be admitted to an acute care setting for appropriate treatment. The same holds true for antibiotic selection in these patients. Those who are treated in an outpatient setting can be treated with trimethoprim-sulfamethoxazole, fluoroquinolones, or even β -lactam/ β -lactamase inhibitors, such as amoxicillin-clavulanic acid. In cases where an initial, one-time IV antibiotic is used as supplemental therapy, a single ceftriaxone dose or single high-dose aminoglycoside therapy could be used in lieu of an IV fluoroquinolone. This practice is a recommended addition to therapy if local prevalence of fluoroquinolone resistance exceeds 10%.¹ In those patients who are admitted to the hospital, antibiotic therapy is usually broader in nature, especially in patients suspected of having bacteremia or **urosepsis**. These patients will typically receive IV therapy such as a fluoroquinolone or a β -lactam plus an aminoglycoside.^{1,41,42} When selecting fluoroquinolone antibiotics for treatment of gram-negative pyelonephritis, ciprofloxacin may be ideal due to its relatively narrow spectrum of activity against these organisms.¹

• Special Populations

► Pregnant Women

Changes to the urinary tract in pregnant women predispose them to an increased incidence of bacteriuria and subsequent UTIs that may follow. These changes include alterations in amino acid and other nutrient concentrations in the urine along with physiologic changes such as reduced bladder tone and dilation of the renal pelvis and ureters.^{43,44}

An association exists between maternal UTI during pregnancy and fetal death, mental retardation, and developmental delay.⁴⁵ Due to this known association and because up to 7% of pregnant women will develop an asymptomatic bacteriuria that may progress to pyelonephritis, screening for UTI is necessary.^{2,27} In pregnant patients with significant bacteriuria, whether symptomatic or asymptomatic, treatment is recommended to avoid these complications. In the majority of patients, a sulfonamide (with the exception of use during the third trimester due to concerns for hyperbilirubinemia), amoxicillin-clavulanic acid, cephalexin, or nitrofurantoin are effective treatment options. Tetracyclines and fluoroquinolones should be avoided due to risk of teratogenicity and ability to inhibit cartilage and bone development, respectively. Follow-up usually consists of a urine culture 1 to 2 weeks after completion of therapy and then subsequent monthly urine cultures until birth.

► Catheterized Patients

An indwelling catheter is commonly used in various healthcare settings and is associated with UTIs.^{30,46} Bacteria may be introduced into the bladder via the catheter in several ways, including direct infection introduction during catheterization (via colonization and subsequently traveling the length of the catheter through bacterial motility or capillary action). UTIs as a result of an indwelling catheter are common and occur at a rate of 5% per day of catheter presence.⁴⁷

The approach to management of a patient with bacteriuria and an indwelling urinary catheter follows two paths.⁴⁶

8 *The first, in asymptomatic patients with catheterization, is to hold antibiotics and remove the catheter if possible. The second, in symptomatic patients with catheterization, is to initiate antibiotic therapy and remove the catheter if possible.* In both of the above situations, if discontinuation of the catheter is not possible, the patient should be recatheterized with a new urinary catheter if the previous catheter is greater than 2 weeks old.⁴⁶

► UTIs in Men

9 *Although UTIs in men are not always complicated by definition, due to the relative infrequency of UTIs in men compared with women, an abnormality (structural or functional) should be suspected and therefore treated as a probable complicated infection until proven otherwise.*⁴⁸ For this reason, men should not be treated with a single dose or short course of therapy if diagnosed with a UTI. Typically these patients will receive 2 weeks of therapy and in situations of failure may be treated up to 6 weeks, particularly if a prostatic source of infection is suspected. Prostatic enlargement, as previously mentioned, is a risk

Patient Encounter, Part 3: Creating a Care Plan

Based on the information presented, create a care plan for this patient's UTI. Your plan should include:

- A statement of the drug-related needs and/or problems*
- A patient-specific detailed therapeutic plan*
- Monitoring parameters to assess efficacy and safety*

factor in men, and the prevalence of benign prostatic hyperplasia in the elderly population may predispose this population to UTIs.

OUTCOME EVALUATION

- Monitor the patient for resolution of symptoms, with a goal of 48 to 72 hours to resolution after start of antimicrobial therapy.
- If possible, follow up on susceptibilities of the infecting organism (urine culture).
- Repeat culture is necessary only if symptoms do not acutely abate or reinfection or recurrence occurs. Resistance rates to *E. coli* are increasing to several of the agents commonly prescribed for UTI, and certain isolates are multidrug resistant.⁴⁹
- Depending on chosen antibiotic therapy, evaluate the patient based on drug therapy monitoring parameters including those presented in [Table 79–4](#) to optimize therapy and decrease incidence of adverse drug events.

Table 79–4

Monitoring Parameters for Select Antibiotics Used in the Treatment of UTIs

Drug Class or Drug	What to Monitor	Frequency	Endpoint
Aminoglycosides	SCr, urine output	Every 24 hours	Prevention of nephrotoxicity manifested by a rise in SCr
	Aminoglycoside serum concentrations	Depends on duration of therapy. At least once weekly; more frequently if evidence of changing renal function	Trough serum concentrations less than 2 mg/L (less than 4.2 μmol/L for gentamicin and less than 4.3 μmol/L for tobramycin) or less than 8 mg/L (13.7 μmol/L) for amikacin, ^a to decrease risk of nephrotoxicity and ototoxicity
Nitrofurantoin	SCr	Only if renal function changing or unstable	Nitrofurantoin metabolites may accumulate in renal insufficiency and lead to neuropathy; avoid if CrCl less than 40 mL/min (0.67 mL/s)
Aminoglycosides Nitrofurantoin Tetracyclines Sulfonamides	Liver profile SCr	Periodic monitoring Only if renal function changing or unstable	Prevention of cholestasis Decreases in glomerular filtrate rate can significantly decrease the urine concentration of these agents

^aStreptomycin concentrations are different than those listed here; because streptomycin is not used to treat UTIs, monitoring for this agent is not included.

Patient Care and Monitoring

1. Assess the patient's symptoms to determine response to the antimicrobial regimen you have chosen.
2. Review any microbiologic data:
 - Based on urinalysis and Gram stain (if available), is your empiric selection reasonable?
 - Based on culture and susceptibility data (if available), are there any changes that need to be made from your initial empiric antimicrobial selection (i.e., resistance to the regimen initially selected)?
3. Determine whether the patient may benefit from prophylactic therapy (i.e., recurrent UTIs secondary to chronic urinary catheterization due to paraplegia).
4. Evaluate the patient for the presence of adverse drug reactions, drug allergies, and potential drug interactions.
5. Stress the importance of complying with the prescribed antimicrobial regimen and to follow up with the healthcare provider if signs and symptoms recur.

Abbreviations Introduced in This Chapter

CFU	Colony-forming units
CrCl	Creatinine clearance
SCr	Serum creatinine
UTI	Urinary tract infection

Sexually Transmitted Infections

Marlon S. Honeywell and Evans Branch III

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

1. Analyze the behavioral considerations and assess the importance of contraception with regard to the contributing factors of sexually transmitted infections (STIs).
2. Apply the “expedited partner treatment” method when recommending treatment for STIs.
3. Identify the patient populations that are typically affected by specific STIs.
4. Identify causative organisms for STIs.
5. Devise a list of the clinical signs and symptoms corresponding to each type of STI and classify patients based on recommended criteria.
6. Select appropriate diagnostic procedures for STIs.
7. Identify STI treatment regimens and recommend therapy when appropriate.
8. Design a patient care plan based on the monitoring parameters.

KEY CONCEPTS

- 1 Optimal detection and treatment of sexually transmitted infections (STIs) depends on counseling by a patient-friendly and knowledgeable clinician who can establish open communication with the patient. Patients, especially adolescents, should be counseled on the importance of using condoms, spermicides, and diaphragms properly.
- 2 Generally, when treating an STI, the patient being treated should be provided with a sufficient quantity of medication for his/her partner, increasing the probability that the initial infection will be cured in both individuals. Counseling regarding the appropriate use of condoms, cervical diaphragms, spermicides, and emergency contraception is also important to mitigate the occurrence of reinfection.
- 3 Patients treated for gonorrhea should be assumed to be coinfecting with *Chlamydia trachomatis*; treatment recommendations should cover both organisms. Treatment of *Neisseria gonorrhoeae* with fluoroquinolones is inadvisable in those with a history of recent foreign travel, infections acquired in California or Hawaii, infections in other areas with increased gonococcal resistance, or in men who have sex with men (MSM). Additionally, treatment on gonorrhea over time has resulted in drug resistance to some cephalosporins.
- 4 Parenterally administered penicillin G is recommended for all stages of syphilis.
- 5 Metronidazole and tinidazole are the standard agents for trichomoniasis; advise patients to avoid the consumption of alcohol during treatment.
- 6 Due to the variable appearance of genital warts, treatment may be based on the size, site, and morphology of the lesions. Treatment options include podofilox, imiquimod, sinecatechins, podophyllin resin, and bichloro- and trichloroacetic acid. The Gardasil® vaccine was FDA approved for the prevention of vulvar, vaginal, and cervical cancer and genital warts.
- 7 Acyclovir, valacyclovir, and famciclovir may be prescribed to treat first and intermittent episodes of genital herpes and to suppress active herpetic infections.
- 8 Bacterial vaginosis (BV) is a clinical syndrome categorized by an overgrowth of polymicrobial anaerobic organisms, such as *Gardnerella vaginalis*, *Prevotella* species, *Mycoplasma hominis*, and *Mobiluncus* species. BV infection leads to the replacement of the normal hydrogen peroxide-producing lactobacillus and an increase in vaginal pH from 4.5 to 7.
- 9 In patients with pelvic inflammatory disease (PID), resolution of infection (i.e., *N. gonorrhoeae*, *C. trachomatis*, *Streptococcus* spp., and gram-negative facultative bacteria) and mitigation of sequelae should be the main goal of pharmacologic therapy.

Though we have made progress in medicine, age-old problems of infectious disease continue to plague us.¹ Even with the discovery of newly improved antibiotics, sexually transmitted infections (STIs) have not been eradicated. Many have reemerged secondary to modern social trends of sexual activity, and some as a result of the HIV epidemic, socioeconomic concerns, and the global lack of preventive education. Educating the public decreases the probability of infection in some individuals; however, this tactic alone may not be sufficient. **1** *Optimal detection and treatment of STIs depends on counseling by a patient-friendly and knowledgeable clinician who can establish open communication with the patient.*

BEHAVIORAL CONSIDERATIONS

The correlation between risky sexual behavior and STIs is well documented.² Inconsistent and incorrect condom use increases the incidence of new STIs. **1** *Assuming that patients, especially adolescents, consistently use and understand how to use condoms, spermicides, or diaphragms can be detrimental and may contribute to nonpharmacologic mismanagement.*³ Healthcare providers who manage persons at risk for STIs should counsel women concerning the option for emergency contraception, if indicated, and provide it in a timely fashion if desired by the woman or the couple. Plan B (two 750 mcg of levonorgestrol) is approved in the United States for the prevention of unintended pregnancy.⁴

In addition to the increasing number of adolescents engaging in unsafe sexual practices is a high incidence of men who have sex with men (MSM) and women who have sex with women (WSW). Many MSM do not disclose their HIV status. This “don’t ask, don’t tell” practice has been linked to an upsurge in newly diagnosed HIV infections and STIs among previously noninfected people.⁵ Although limited data are available with regard to STIs in WSW, risk of transmission probably varies by the specific STI and sexual techniques. Sharing penetrative items or employing practices involving digital vaginal or digital anal contact most likely represent common modes of transmission. This possibility is supported by reports of metronidazole-resistant trichomoniasis and genotype-specific HIV transmitted sexually between women who reported such behaviors and an increased prevalence of bacterial vaginosis (BV) among monogamous WSW.⁶

Sexual abuse in adolescents and children is being reported more often in the United States. Any child or adolescent with an STI should be evaluated for sexual abuse.⁷ In cases of abusive contact, commonly found infections include *Neisseria gonorrhoeae* or *Chlamydia trachomatis*. Abusive cases should be reported to the police.

The emergence of “swingers” (a person who engages in the exchanging of spouses for sexual activities) as a new category of at-risk patients has been seen in STI clinics throughout the world. In fact, one clinic in South Limburg reports that swingers comprise approximately 12% of total consultations since 2007, most of which involved a predominantly older group of people (median age 43 years).⁸ To this end, swingers

now represent a group with risky behaviors that must be identified and treated when necessary.

2 *Optimally, both sex partners should be treated simultaneously for an STI; however, this is difficult to accomplish. Clinics and health departments often proactively attempt dual treatment by providing a prescription for the partner to the **index patient** (the patient who is evaluated by a clinician), a practice commonly known as expedited partner treatment. Counseling regarding the appropriate use of condoms, cervical diaphragms, spermicides, and emergency contraception is also important to mitigate the occurrence of reinfection.*

Accurate reporting of STIs is imperative to the evaluation of trends in sexual behaviors; reporting may be provider- or laboratory-based. State and local health departments may assist with the mechanism by which STIs are reported, and cases must be conveyed in accordance with statutory requirements. Confidentiality should always be exercised in such cases.^{9,10}

GONORRHEA

Gonorrhea is a curable STI caused by the gram-negative diplococcus *Neisseria gonorrhoeae*. Proper therapeutic management with antimicrobial agents is essential to eradicate this infection and prevent the development of associated sequelae such as a urethritis, cervicitis, or dysuria.

In the United States, the highest rate of gonococcal infection is seen within the 15- to 24-year-old age groups for both sexes; although more cases are reported in men. Approximately 700,000 new cases occur annually in the United States.^{9,10} Factors associated with an increased risk of infection include ethnicity, low socioeconomic status, and illicit drug use. The risk of a cervical infection after a single episode of vaginal intercourse is approximately 50% and increases with multiple exposures. Furthermore, rates of reinfection are significantly higher among ethnic minorities.

Patient Encounter 1, Part 1

KL is a 27-year-old African American female who visits a clinic complaining of profuse urethral discharge for the past several days. She also informs the nurse that she did not have a menstrual cycle last month and that a home pregnancy test taken this morning revealed that she was indeed pregnant. The patient admits to having sexual intercourse without barrier contraception (condoms) with her boyfriend within the past week or two and is not sure of other sexual encounter(s) in which he may have been involved.

What information is suggestive of gonorrhea?

What potential risk factors for STIs are present?

What impact will pregnancy have on diagnostic and treatment plans for STI management?

PATHOPHYSIOLOGY

Attachment to mucosal epithelium, mediated in part by pili and opa (outer membrane opacity proteins), is followed by penetration of *N. gonorrhoeae* through epithelial cells to the submucosal tissue within 24 to 48 hours. A vigorous response by neutrophils begins with sloughing of the epithelium, development of submucosal microabscesses, and exudation of pus. Stained smears usually reveal large numbers of gonococci within a few neutrophils, whereas most cells contain no organisms.¹¹

DIAGNOSIS

Several laboratory tests are available to aid in the diagnosis of gonorrhea and include Gram-stained smears, endocervical or vaginal specimens, culture, or the DNA hybridization probe. A Gram stain of a male urethral specimen that demonstrates polymorphonuclear leukocytes with intracellular gram-negative diplococci may be considered diagnostic in symptomatic men. A negative Gram stain should not be considered sufficient for ruling out infection in asymptomatic men.⁹ Additionally, Gram stain of endocervical, pharyngeal, or rectal specimens are also insufficient to detect infections. All patients who test positive for gonorrhea should be tested for other STIs, including chlamydia, syphilis, and HIV.

Clinical Presentation of Gonorrhea^{9,10}

General

- Purulent discharge

Signs

- Painful or swollen testicles
- Tubal scarring

Symptoms

Men:

- May be asymptomatic, although acute urethritis is the predominant manifestation
- Urethral discharge and dysuria, usually without urinary frequency or urgency
- When compared with nongonococcal urethritis, the discharge in gonococcal urethritis is generally more profuse and purulent
- Dysuria

Women:

- Cervicitis, urethritis, increased vaginal discharge, dysuria and intermenstrual bleeding
- Abdominal pain

Patient Encounter 1, Part 2

PMH: Currently receiving no medications; no prior history of STIs; no drug allergies noted

FH: Noncontributory

SH: Admits to having unprotected sex with boyfriend. Does not smoke or drink alcohol

ROS: C/o vaginal discharge, recent nonpruritic rash development across abdominal area noted over past 3 to 5 days

PE:

VS: BP 130/80 mm Hg, P 70 beats/min, T 37°C (98.6°F)

Lab: Urethral discharge swab revealed *N. gonorrhoeae*; rapid plasma reagin (RPR) test was positive.

Given this additional information, what is your assessment of the patient's condition?

What consideration should be given to other STIs?

Identify your treatment goals for this patient.

What pharmacologic alternatives are available for this patient?

TREATMENT

Desired Outcome

The desired outcome is complete eradication of *N. gonorrhoeae* and avoidance of sequelae.

Pharmacologic Therapy^{4,9,12,13}

3 Patients infected with gonorrhea often are coinfecting with *Chlamydia trachomatis* and should receive therapy to eradicate both organisms concurrently. Although fluoroquinolones and broad-spectrum cephalosporins have been effective in the treatment of gonorrhea, resistant strains of *N. gonorrhoeae* have emerged. In Far-Eastern countries, as many as 50% of gonococcal strains exhibit decreased susceptibility to fluoroquinolones. Although ciprofloxacin is still an option for treatment, gonococcal resistance to ciprofloxacin is usually indicative of its resistance to other fluoroquinolones. As a result, monitoring for fluoroquinolone resistance is now essential to ensure proper treatment and to ascertain the maximum time that this class may be employed as a treatment option.

Fluoroquinolones should not be prescribed for infections in MSM, in those with a history of recent foreign travel or partners' travel, or for infections acquired in California or Hawaii or infections in other areas with increased gonococcal resistance.¹⁴

Gonococcal resistance to some cephalosporins has emerged.¹⁵ Presently, the recommended first-line treatment for gonorrhea in most countries is third-generation cephalosporins, and in some cases, spectinomycin and azithromycin.¹⁶ However, resistance to oral third-generation

Patient Encounter 1, Part 3

Unprotected sex is a major risk factor for contracting STIs. Although the purulent discharge is consistent with gonorrhea infection, a positive urethral swab coupled with an incubation period consistent with gonorrhea confirms the diagnosis. A serologic test for syphilis should be performed on all pregnant women at the first prenatal visit, and a RPR should be performed at the time pregnancy is confirmed and treatment provided. Although the patient has confirmed gonorrhea, infection with *Chlamydia trachomatis* occurs commonly in this setting. Additionally, pregnant patients should be tested for this infection during the first prenatal visit and treated appropriately. Further, the presence of a rash could possibly suggest that the patient may have contracted syphilis previously, potentially indicative of secondary syphilis.

If this patient had an allergy to penicillin, how would the therapeutic management of the identified problems change?

cephalosporins has developed in Asia and Australia and in other parts of the world. The mechanism of resistance appears to be associated with a mosaic penicillin-binding protein in addition to other chromosomal mutations previously found to confer resistance to β -lactam antimicrobials. To mitigate the prevalence of cephalosporin resistance, strong antimicrobial management programs, expanding surveillance networks and procedures, and STI control and prevention are warranted.

Combined hormonal contraception has been evaluated to determine whether it deters the acquisition of gonococcal infections in women. Although the transmission of *N. gonorrhoea* is poorly understood, data from an original study suggested that combined hormonal therapy may lessen the probability of infection.¹⁷ More studies are required to support this theory as a viable option for prevention.

Treatment of gonorrhea may vary according to clinical presentation and are indicated as follows⁹:

Uncomplicated Gonococcal Infection of the Cervix, Urethra, and Rectum* Ceftriaxone 250 mg intramuscularly *or* cefixime 400 mg orally *or* single-dose injectable cephalosporin regimens *plus* azithromycin 1 g orally *or* doxycycline 100 mg orally twice daily for 7 days. Several alternative agents possess notable activity; however, they should not be used if pharyngeal infection is suspected. Alternatives include cefpodoxime 400 mg orally *or* cefuroxime axetil 1 g orally *or* azithromycin 2 g. Although unavailable in the United States, spectinomycin has also been prescribed.

● **MSM or Heterosexuals with a History of Recent Travel***

Ceftriaxone 250 mg intramuscularly *or* cefixime 400 mg

orally *plus* treatment for chlamydial infection if it has not been ruled out.

Uncomplicated Gonococcal Infection of the Pharynx* Ceftriaxone 250 mg intramuscularly *plus* azithromycin 1 g orally *or* doxycycline 100 mg orally twice daily for 7 days.

Coverage for Coinfection with *Chlamydia Trachomatis* Azithromycin 1 g orally as a single dose *or* doxycycline 100 mg orally twice daily for 7 days.

► **Treatment of Gonorrhea in Special Situations**

Uncomplicated infections of the cervix, urethra, and rectum can be treated with one of the following regimens in adults:

Recommendations During Pregnancy

- Pregnant women should be treated with a recommended *or* alternative cephalosporin. For women who cannot tolerate a cephalosporin, azithromycin 2 g orally may be prescribed. For treatment of presumptive *or* diagnosed *C. trachomatis*, azithromycin *or* amoxicillin is recommended.
- Doxycycline and fluoroquinolones are contraindicated.

Recommendations for Disseminated Gonococcal Infection (Regimens Should Be Continued for 24 to 48 Hours) Ceftriaxone 1 g intramuscularly *or* IV every 24 hours *or* cefotaxime 1 g IV every 8 hours *or* ceftizoxime 1 g IV every 8 hours. Continue regimens for 24 to 48 hours after improvement is noted. Once improvement begins, therapy should be converted to Cefixime 400 mg orally twice daily for at least 1 week.

Uncomplicated Infections of the Cervix, Urethra, and Rectum in Children Weighing Less Than 45 kg Ceftriaxone 250 mg intramuscularly as a single dose *or* spectinomycin 40 mg/kg intramuscularly as a single dose (not to exceed 2 g).

Gonococcal Conjunctivitis Ceftriaxone 1 g intramuscularly once for adults has demonstrated excellent response rates. Lavage of the infected eye(s) once with saline solution should also be considered. Patients treated for gonococcal conjunctivitis should also be treated empirically for *C. trachomatis* infection.

Ophthalmic Neonatorum or Prophylactic Treatment for Infants Whose Mothers Have Gonococcal Infection Ceftriaxone 25 to 50 mg/kg IV *or* intramuscularly in a single dose, not to exceed 125 mg.

Ophthalmic Neonatorum Prophylaxis Erythromycin (0.5%) ophthalmic ointment in a single application to the eyes *or* tetracycline (1%) ophthalmic ointment in a single application to the eyes.

PATIENT CARE AND MONITORING

Monitoring is generally not required.

*Regimens are given for one dose only.

CHLAMYDIA

EPIDEMIOLOGY

Infection with *C. trachomatis* has increased dramatically in recent years. This bacterium is the most common cause of nongonococcal urethritis, accounting for as many as 50% of cases. Worldwide, this intracellular, gram-negative bacterium produces approximately 92 million new genital infections. The prevalence is highest in individuals less than 25 years of age. Associated sequelae include pelvic inflammatory disease (PID), ectopic pregnancy, and infertility.

PATHOPHYSIOLOGY

C. trachomatis possesses characteristics resembling both bacteria and viruses. Its major membrane is comparable to that of gram-negative bacteria, although it lacks a peptidoglycan cell wall and requires cellular components from the host for replication. Chlamydia transmission risk is thought to be less than that of gonorrhea.

DIAGNOSIS

Common tests used to diagnose *C. trachomatis* include culture, the enzyme immunoassay, the DNA hybridization probe, or the direct fluorescent monoclonal antibody test. Diagnosis has been confirmed in women through urine or swab specimen collected from the endocervix and in men using a urethral swab or urine specimen. Most women are asymptomatic; therefore, an annual screening or physical is necessary, as early detection may reduce rates of transmission.

Clinical Presentation of Chlamydia^{9,10,13}

General

- Asymptomatic

Signs

- Beefy red cervix that bleeds easily (women)

Symptoms

- When present, the urethral discharge is watery and less purulent than that seen with acute gonococcal urethritis. Complications resulting from lack of treatment or inadequate treatment include epididymitis (in males) and PID including associated complications in women.

Other Diagnostic Tests

- Culture is usually positive for both chlamydia and gonorrhea.

TREATMENT^{9,18}

Uncomplicated Urethral, Endocervical, or Rectal Infection in Adults

The recommended adult regimen is azithromycin 1 g orally in a single dose *or* doxycycline 100 mg orally twice daily for 7 days. An alternate regimen is erythromycin ethylsuccinate 800 mg orally four times daily for 7 days *or* erythromycin base 500 mg orally four times daily for 7 days *or* levofloxacin 500 mg orally once daily for 7 days.

The recommended regimen for pregnancy is azithromycin 1 g orally in a single dose *or* amoxicillin 1 g orally in a single dose *or* amoxicillin 500 mg orally three times daily for 7 days.

Alternate regimens include erythromycin base 500 mg orally four times daily for 7 days *or* 250 mg orally four times daily for 14 days *or* erythromycin ethylsuccinate 800 mg orally four times daily for 7 days *or* 400 mg orally four times daily for 14 days.

C. trachomatis Infection in Infants

Treatment of ophthalmia neonatorum or infant pneumonia should be with erythromycin base or ethylsuccinate 50 mg/kg/day orally divided into four doses daily for 14 days.

PATIENT CARE AND MONITORING

Monitoring is generally not required.

SYPHILIS

Syphilis, attributed to the spirochete *Treponema pallidum*, can have numerous and complex manifestations. Clinician familiarity, stage-specific diagnosis, and effective treatment are vital. Missed or inappropriately treated syphilis may result in cardiovascular complications, neurologic disease, or congenital syphilis.

EPIDEMIOLOGY

After the 1940s, the incidence of syphilis declined drastically following the introduction of penicillin, but rose when HIV arrived from obscurity in the 1980s. In 2009, rates of primary and secondary syphilis increased for the tenth consecutive year, reaching the highest rate reported since 1995. Although increases have occurred mostly among men, in 2009, 62% of cases from 44 states and the District of Columbia occurred in MSM. Increases also were observed among women during 2004 through 2008; cases were mostly noted in the south. The primary and secondary syphilis rate among blacks was nine times the rate among whites, emphasizing the need for enhanced preventive measures among blacks and MSM. The disparity among men and women has been observed across racial and ethnic groups and is highest in the South and among non-Hispanic blacks.¹⁹

PATHOPHYSIOLOGY

T. pallidum rapidly penetrates intact mucous membranes or microscopic dermal abrasions, and within a few hours, enters the lymphatics and blood to produce systemic illness. During the secondary stage, examinations commonly demonstrate abnormal findings in the cerebrospinal fluid (CSF). As the infection progresses, the parenchyma of the brain and spinal cord may subsequently be damaged.

Stages of Syphilis

► Primary Syphilis

Usually manifests as a solitary, painless chancre. Primary syphilis develops at the site of infection approximately 3 weeks after exposure to *T. pallidum*; the chancre is highly infectious.^{9,20}

► Secondary Syphilis

Without appropriate treatment, primary syphilis will advance to secondary syphilis, a stage usually apparent from its clinical symptomatology. Symptoms include fatigue, diffuse rash, fever, lymphadenopathy, and genital or perineal condyloma latum. Additionally, the skin is most often affected and a rash may present as macular, macropapular, or pustular lesions or may involve skin surfaces including the palms of the hands and soles of the feet.

► Latent Syphilis

Early Latent Usually occurs during the first year after infection and may be established in patients who have seroconverted, who have had symptoms of primary or secondary syphilis, or who have had sex with a partner with primary, secondary, or latent syphilis.

Late Latent Patients should be considered to have late latent syphilis if the aforementioned criteria (early latent) are not met. In both stages, patients are usually asymptomatic and the lesions noted in the primary and secondary phase usually resolve; however, individuals are still seropositive for *T. pallidum*.

Tertiary Syphilis Develops years after the initial infection and may involve any organ in the body.

Congenital Syphilis

Congenital syphilis is a condition in which the fetus is infected with *T. pallidum* as a result of the hematogenous spread from an infected mother, although transmission may also occur from direct contact with the infectious genitalia of the mother. Since the primary stage of syphilis is characterized by spirochetemia, infectious rates of the fetus are nearly 100% if the mother has primary syphilis.^{20,21}

DIAGNOSIS

Diagnostic procedures include dark-field microscopy, nontreponemal exams^{9,20} (i.e., the Venereal Disease Research Laboratory [VDRL] and the rapid plasma reagin [RPR]

Patient Encounter 2

KG is an HIV-positive male who complains of the appearance of a "sore" on his penis. He reports having unprotected sexual intercourse with another male approximately 5 to 7 days prior to the appearance of the lesion. He denies pain or itching at the site of the lesion, dysuria, or frequent urination. Additionally, there appears to be no vesicles in the genital area.

What information is suggestive of syphilis?

What potential risk factors for STIs are present?

How should the diagnosis of syphilis be confirmed in this patient?

If the diagnosis of syphilis is confirmed, what therapeutic options exist for this patient?

test), and treponemal exams (i.e., enzyme immunoassay, the *T. pallidum* hemagglutination test, the fluorescent treponemal antibody test, and the enzyme-linked immunosorbent assay).

TREATMENT

Desired Outcome

After confirming the diagnosis of syphilis, the desired outcome is a fourfold decrease in quantitative nontreponemal titers over a 6-month period and within 12 to 24 months after treatment of latent or late syphilis. An algorithm for the treatment of syphilis is shown in [Figure 80-1](#).

With regard to neurosyphilis, a reduction in neurologic manifestations is desired, which may include seizures, paresis, meningitis, stroke, hyperreflexia, visual disturbances, hearing loss, neuropathy, or loss of bowel and bladder function. In late neurosyphilis, vascular lesions (meningovascular neurosyphilis) may also be observed; thus a reduction in the number of observed lesions is warranted. A diminution in CSF white blood cell count (WBC) (less than $10 \times 10^3/\text{mm}^3$ [$10 \times 10^9/\text{L}$]) or protein levels (0.05 g/dL [0.5 g/L]) is also preferred.

Pharmacologic Therapy

- 4 **P** *Parenterally administered penicillin G is recommended for all stages of syphilis (Table 80-1).* Although penicillin G is the drug of choice, combinations of benzathine penicillin with procaine penicillin or oral penicillin preparations are not considered appropriate treatment regimens. Several reports have demonstrated the misuse of the benzathine–procaine combination (Bicillin C-R) instead of the standard benzathine penicillin (Bicillin L-A).^{20,22} Clinicians and purchasing agents should be aware of the similarities in product names to avoid errors in the prescribing and administration of these agents. Pertinent information germane to benzathine penicillin G is found in Table 80-1.

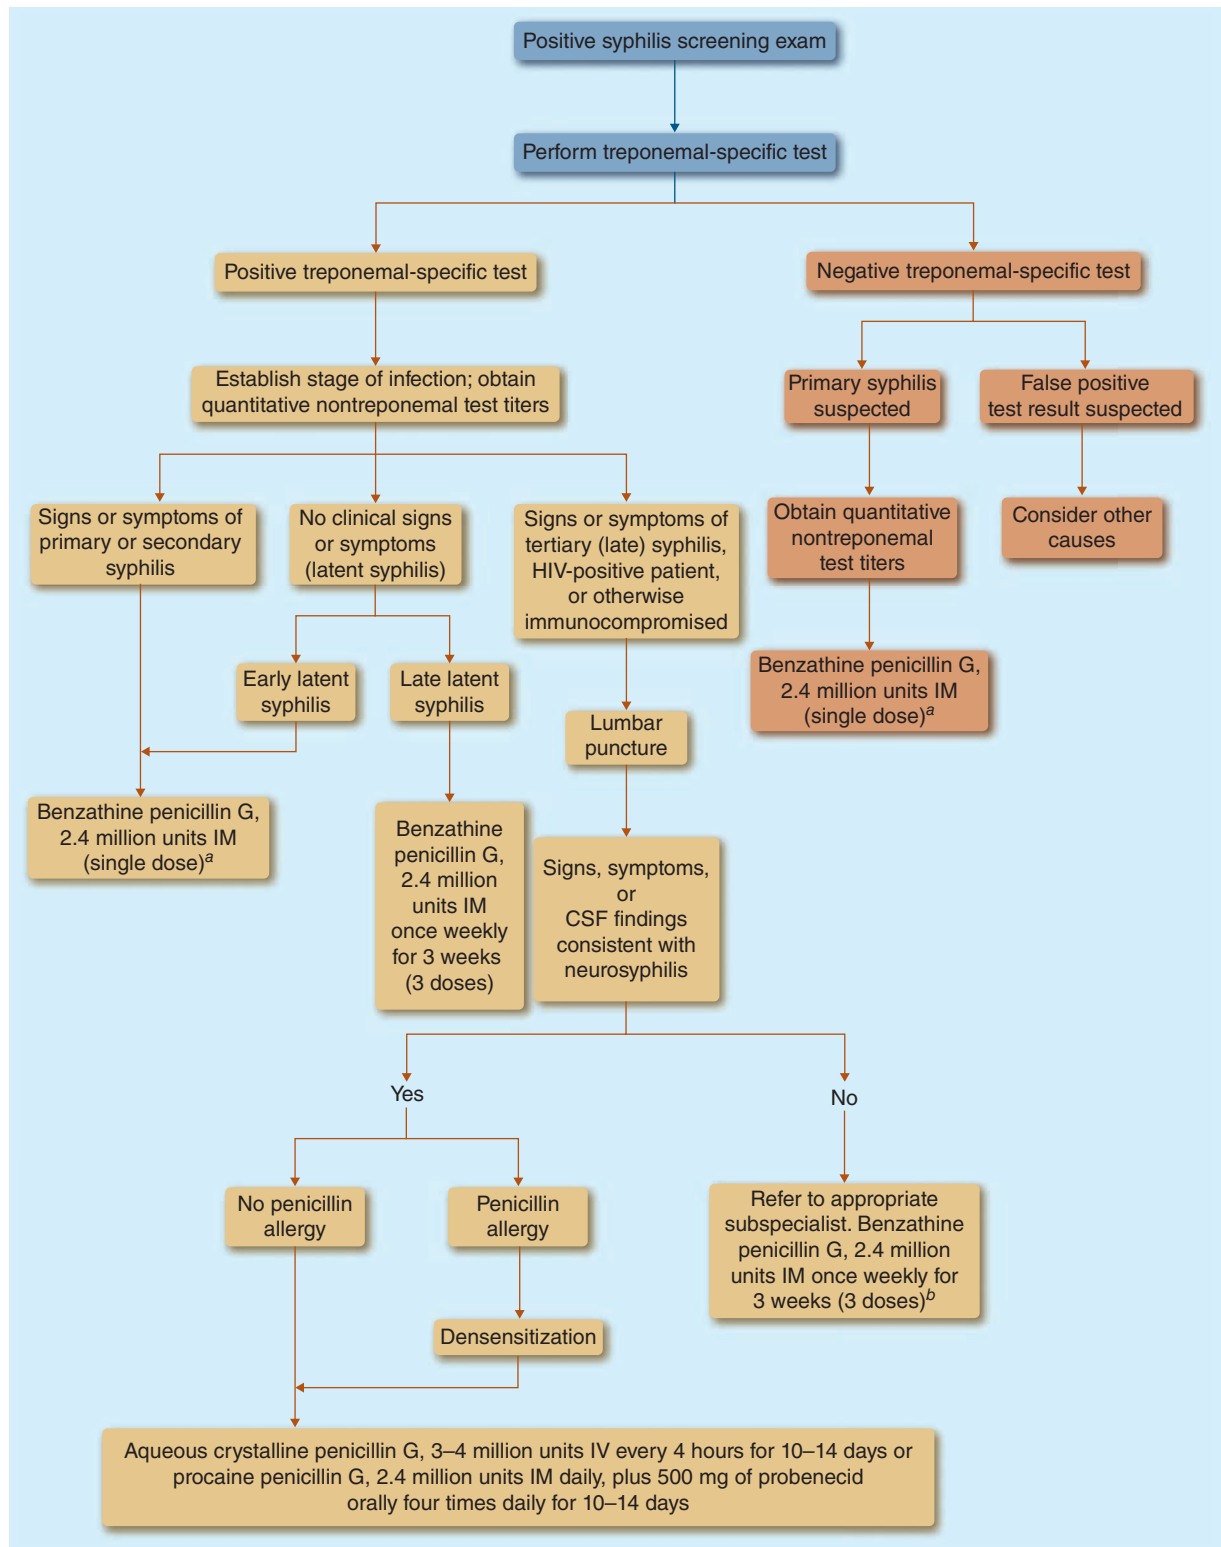

FIGURE 80-1. Treatment of syphilis. (CSF, cerebrospinal fluid; IM, intramuscularly.) (From Brown D, Frank J. Diagnosis and management of syphilis. *Am Fam Physician* 2003;68(2):283–290.) ^aAlternative treatments for nonpregnant penicillin-allergic patients: doxycycline 100 mg orally twice daily for 2 weeks or tetracycline 500 mg four times daily for 2 weeks; limited data support ceftriaxone 1 g once daily IM or IV for 8 to 10 days; or azithromycin 2 g orally (single dose). ^bAlternative treatments for nonpregnant penicillin-allergic patients: doxycycline 100 mg orally twice daily for 4 weeks, or tetracycline 500 mg orally four times daily for 4 weeks.

Table 80-1

Benzathine and Procaine Penicillin G Informational Chart

Categories	Benzathine Penicillin G	Procaine Penicillin G
Drug-related adverse reactions	CNS: convulsions, confusion, drowsiness, myoclonus, fever; dermatologic: rash; metabolic: electrolyte imbalance; hematologic: positive Coombs test, hemolytic anemia; local: pain, thrombophlebitis; renal: acute interstitial nephritis; miscellaneous: anaphylaxis, hypersensitivity, Jarisch-Herxheimer reaction	CNS: seizures, confusion, drowsiness, myoclonus, CNS stimulation Cardiovascular: myocardial depression, vasodilation, conduction disturbances Hematologic: positive Coombs test, hemolytic anemia, neutropenia Local: thrombophlebitis, sterile abscess at injection site Renal: interstitial nephritis Miscellaneous: pseudoanaphylactic reactions, hypersensitivity, Jarisch-Herxheimer reaction, serum sickness
Monitoring parameters	Observe for anaphylaxis during first dose	Observe for anaphylaxis during first dose. Remove the other reactions
Pregnancy category	B	B
Lactation	Enters breast milk	Enters breast milk
Availability	Bicillin L-A: 600,000 units/mL (1, 2, and 4 mL); Permapen Isoject: 600,000 units/mL (2 mL)	Injection, suspension: 600,000 units/mL (1, 2 mL)

CNS, central nervous system; IM, intramuscular.

From Lacy C, Armstrong L, Goldman M, Lance L. Lexi-Comp's Drug Information Handbook. 19th ed. Hudson, OH: Lexi-Comp; 2010:1128-1132.

Alternative agents may be used in allergic individuals and include doxycycline, minocycline, tetracycline, or erythromycin base or stearate. Some patients (e.g., young children or pregnant women) may not respond favorably to alternative modalities or should not receive tetracyclines. Therefore, in patients who must be administered penicillin (i.e., patients who are pregnant or have CNS involvement) or are allergic, **desensitization** should be performed before the drug is initiated.

Patients may experience fever, chills, tachycardia, and tachypnea, a condition commonly known as the Jarisch-Herxheimer reaction. This reaction is postulated to occur secondary to spirochete lysis and proinflammatory cytokine cascades. It may transpire as early as 2 hours after penicillin administration and usually resolves within 24 hours. Treatment is supportive and may include antipyretic and anti-inflammatory agents, as well as fluid resuscitation and bed rest.

► Primary Syphilis

Drug of Choice

Adults. Benzathine penicillin, 2.4 million units intramuscularly as a single dose. Additional doses of benzathine penicillin or other antibiotics do not enhance efficacy, regardless of HIV status.⁹

Children. Benzathine penicillin 50,000 units/kg intramuscularly, up to the adult dose of 2.4 million units in a single dose. Infants less than 1 month of age diagnosed with syphilis should have a CSF test to determine whether asymptomatic neurosyphilis is present. Patient records should be reviewed to decipher whether syphilis is congenital or acquired.

Alternatives Oral doxycycline 100 mg twice daily for 2 weeks *or* tetracycline 500 mg by mouth four times daily for 2 weeks. Limited literature also supports the use of ceftriaxone 1 g intramuscularly or IV once daily for 10 days *or* oral azithromycin as a single 2-g dose.^{9,21}

► Secondary and Early Latent Syphilis

Treatment modalities administered in primary syphilis are also effective in secondary syphilis and early latent syphilis (less than 1 year duration).

Children with early latent syphilis should receive benzathine penicillin G 50,000 units/kg intramuscularly, up to the adult dose of 2.4 million units in a single dose.

► Late Latent Syphilis

Benzathine penicillin, 7.2 million units total, administered as three doses of 2.4 million units intramuscularly each at 1-week intervals.

Children with late latent syphilis should be treated with benzathine penicillin G 50,000 units/kg intramuscularly, up to the adult dose of 2.4 million units, administered as three doses at 1-week intervals (total 150,000 units/kg up to the adult dose of 7.2 million units).

► Tertiary Syphilis

Drug of Choice Benzathine penicillin 2.4 million units administered intramuscularly once weekly for 3 weeks. A total of 7.2 million units should be administered.

Alternatives In nonpregnant patients with a penicillin allergy, alternative regimens include doxycycline 100 mg orally two times daily for 4 weeks *or* tetracycline 500 mg orally four times daily for 4 weeks.

► **Gummatous and Cardiovascular Syphilis**

As long as no evidence of CNS involvement exists, antibiotic therapy for **gummatous** and cardiovascular syphilis is identical to that for tertiary syphilis.

► **Neurosyphilis**

As an effective treatment for neurosyphilis, the Centers for Disease Control and Prevention (CDC) endorses two regimens of penicillin. Alternatively, ceftriaxone may also be prescribed.²⁵

The regimens of choice are aqueous penicillin G 3 to 4 million units administered IV every 4 hours or continuous infusion for 10 to 14 days *or* procaine penicillin G 2.4 million units administered intramuscularly once daily, plus probenecid 500 mg orally four times daily, both for 10 to 14 days. Limited data suggest that ceftriaxone 2 g daily either IM or IV for 10 to 14 days can be used as an alternative treatment for patients with neurosyphilis.

Congenital Syphilis^{23–25}

The decision to treat an infant should be based on a diagnosis of syphilis in the mother and confirmation of adequacy of maternal treatment. Clinical, laboratory, or radiographic evidence of syphilis in the infant should be documented. Maternal nontreponemal titers (at delivery) should be compared with the infant's nontreponemal titers. Because diagnosis based on neonatal serologic testing is complicated by the transplacental transfer of maternal IgG antibodies, which can cause a positive test in the absence of infection, neonatal titers are assessed. A titer greater than four times the maternal titer would not generally result from passive transfer, and diagnosis is considered confirmed or highly probable.

The following regimens are recommended for treatment of maternal syphilis: benzathine penicillin G 2.4 million units weekly or 7.2 million units intramuscularly over 3 weeks if the duration of syphilis has been at least a year. An alternative regimen is procaine penicillin 0.6 to 0.9 million units daily intramuscularly for 10 to 14 days, or ceftriaxone 1 g daily intramuscularly or IV for 8 to 10 days.

In women who experience uterine cramping, pelvic pain, or fever, administer acetaminophen to combat these symptoms. Additionally, the patient should be well hydrated and rested.

Treatment of asymptomatic neonates is with 50,000 units/kg of benzathine penicillin G in a single intramuscular dose. Symptomatic neonates should receive 50,000 units/kg of aqueous crystalline penicillin G every 12 hours intramuscularly for the first 7 days of life, then every 8 hours for 3 days *or* procaine penicillin G 50,000 IU/kg intramuscularly as a single dose daily for 10 days.

PATIENT CARE AND MONITORING

The CDC has provided patient care monitoring guidelines for syphilis (**Fig. 80–2**).^{9,11,20}

Primary and Secondary Syphilis

- After 6, 12, and 24 months of treatment, reexamine the patient and recommend a follow-up quantitative nontreponemal titer. More frequent assessment might be sensible if follow-up is uncertain. If the patient is asymptomatic, yet has a fourfold increase in nontreponemal titer or persistent or recurrent symptoms are observed, order an HIV test and a lumbar puncture; if the patient is HIV positive, suggest an infectious disease consult.
- In patients who are both negative for HIV and the lumbar puncture, administer benzathine penicillin G 2.4 million units intramuscularly once weekly for 3 weeks. Perform a patient follow-up in 6 months, including a clinical examination and another nontreponemal titer. In HIV-negative patients with lumbar puncture findings compatible with neurosyphilis, treat the patient accordingly for neurosyphilis.
- Six months after the original diagnosis, institute a standard clinical follow-up exam in patients who show no symptomatology and a fourfold decrease in nontreponemal titers. By testing and observing the patient for signs of remission, you may be able to initiate proper treatment or recommend a consult in a timely fashion, thereby decreasing the propensity of the patient's condition to advance to a higher stage.
 - If serologic titers do not decline despite a negative CSF examination and a repeated course of therapy, it is unclear whether additional therapy or CSF examinations are needed; additional testing or repeated therapy is not generally recommended.

Early and Late Latent Syphilis

- Order nontreponemal titers 6, 12, and 24 months after instituting treatment for early or late latent syphilis. Neurosyphilis should be strongly considered in patients who show a fourfold increase in titers, patients who have an initially high titer (1:32 or greater) that fails to decline at least fourfold within 12 to 24 months of therapy, HIV-infected patients, and patients who develop signs or symptoms associated with neurosyphilis.

Neurosyphilis

- Follow-up is dependent on the CSF findings. If **pleocytosis** is present, reexamine the CSF every 6 months until the WBC count normalizes. Consider recommending a second course of treatment if the CSF white count does not decline after 6 months or completely normalize after 2 years.^{4,9,20} Failure to normalize may require retreatment; most treatment failures occur in immunocompromised patients.

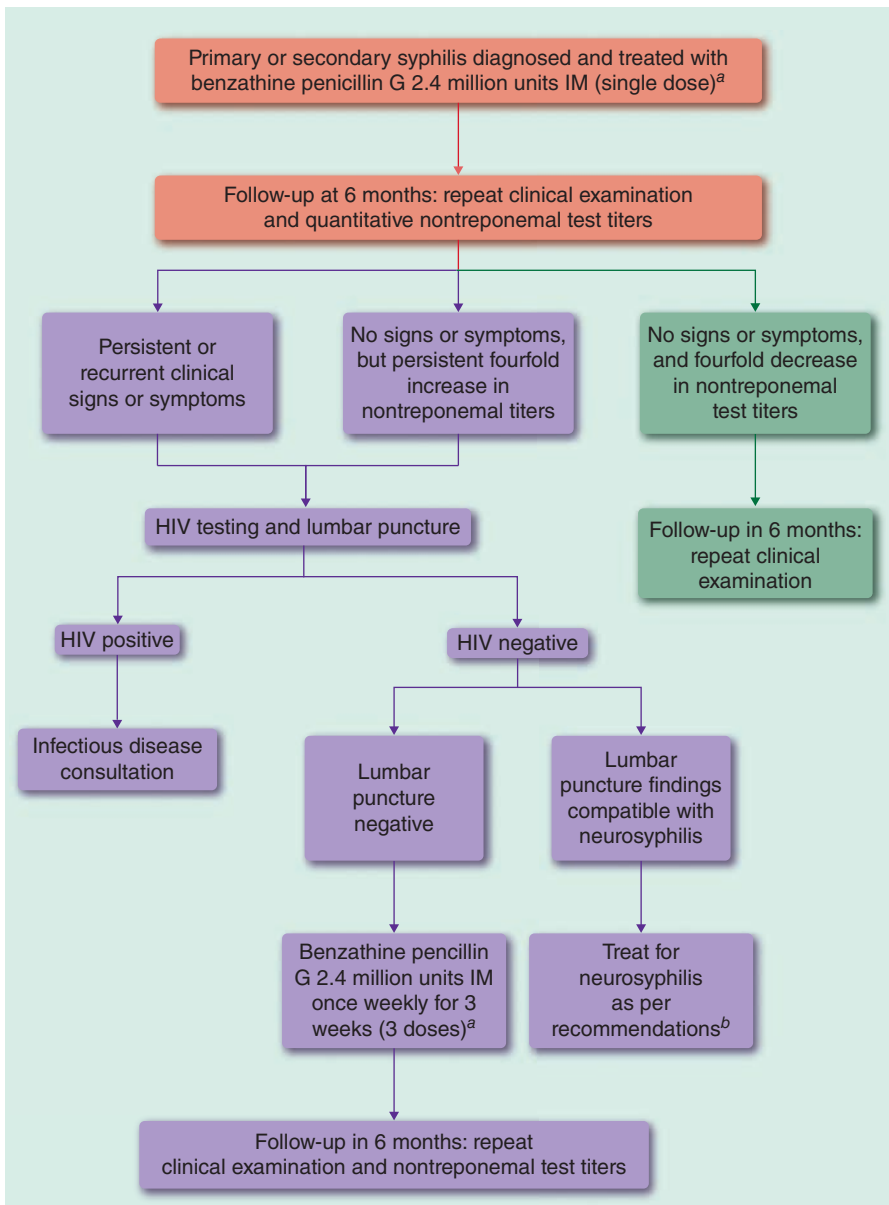

FIGURE 80-2. Patient care monitoring for syphilis. (From Brown D, Frank J. Diagnosis and management of syphilis. *Am Fam Physician* 2003;68(2):283–290.) (^aSee text for alternative treatment recommendations for nonpregnant penicillin-allergic patients. ^bSee text for treatment recommendations for neurosyphilis.)

Congenital Syphilis

- Observe the patient for changes in clinical features; hepatomegaly, jaundice, and bone changes will usually resolve in 3 months.
- Monitor elevated serologic markers (nontreponemal tests) for reduction in titer levels. Given effective treatment, clinical features will usually disappear after 6 months. On this basis, evaluate seropositive infants periodically for at least 6 months.²⁴

TRICHOMONIASIS

Trichomoniasis is caused by the protozoan *Trichomonas vaginalis* and is far more prevalent than *C. trachomatis* or *N. gonorrhoeae*. In the United States, approximately

5 million new cases appear annually, compared with 3 million chlamydial and 650,000 gonococcal cases annually.²⁶

PATHOPHYSIOLOGY

T. vaginalis, a protozoa, may be isolated from the vagina, urethra, and Bartholin's or Skene's glands. After attachment to the host cells, it ignites an inflammatory response exhibited as a discharge containing elevated levels of polymorphonuclear leukocytes. The protozoal pathogen causes direct damage to the epithelium, leading to microulcerations.

DIAGNOSIS

Diagnosis is usually performed with a wet mount or Papanicolaou smear. In women, symptoms are characterized

Clinical Presentation of Trichomoniasis^{9,26}

General

- Asymptomatic

Signs

- Strawberry cervix (women)
- Colpitis macularis (women)
- Prostatitis or epididymitis (men)

Symptoms

- Vaginal/vulvar erythema
- Excessive yellow-green discharge
- Vulvar itching
- Vaginal odor
- Urethral discharge or irritation
- Dysuria
- Vaginal pH greater than 4.5

by diffuse, malodorous, yellow-green vaginal discharge with vulvar irritation. Some women may be asymptomatic.

TREATMENT

Desired Outcome

The desired outcome is the complete eradication of *T. vaginalis* in the patient and sexual partner(s) and elimination of the signs and symptoms observed.

Pharmacologic Therapy

5 *The 5-nitroimidazoles have been the standard therapy for trichomoniasis for over 45 years.* Drugs included in this class are metronidazole, tinidazole, ornidazole, and secnidazole; metronidazole and tinidazole are the only drugs in this class available in the United States. When recommending the 5-nitroimidazoles, advise patients to avoid the consumption of alcohol.

► Metronidazole

Metronidazole may be administered orally as a single 2-g dose or 500 mg twice daily for 7 days.^{9,26} Pregnant women should be prescribed the single dose of metronidazole. Cure rates are greater than 90% when metronidazole is administered as either a single 2-g dose or a 7-day regimen. Possible adverse effects include an unpleasant metallic taste, reversible neutropenia, urticaria, rash, flushing, dry mouth, darkened urine, and a disulfiram-like reaction.

► Tinidazole

Tinidazole, a second-generation nitroimidazole with protozoal and anaerobic activity, has been available outside the United States for over 35 years.²⁷ As a single 2-g dose,

tinidazole has an efficacy equivalent to a 2-g dose of metronidazole. Tinidazole also has a longer half-life than metronidazole, 14 and 7 hours respectively, and penetrates into male reproductive tissue better than metronidazole.

Tinidazole is effective for metronidazole-resistant trichomoniasis.^{26,27} Possible side effects include an unpleasant metallic taste, dizziness, loss of coordination, seizures, severe diarrhea, darkened urine, nausea, vomiting, and a swollen or discolored tongue.

PATIENT CARE AND MONITORING

Monitoring for *T. vaginalis* is generally not required unless symptoms persist or recur.

GENITAL WARTS

- Genital warts, caused by the human papillomavirus (HPV), usually appear in the genital area as very contagious, small bumps. Responsible for various visible, keratotic, and nonkeratotic manifestations, HPV has more than 120 noted strains, some of which have been linked to squamous cell carcinoma.²⁸ More than 40 strains have been linked to the genital area.⁹

EPIDEMIOLOGY

Affecting more than 20 million Americans, HPV is the most common newly diagnosed STI in the United States, with prevalence just about 15.2%. Approximately 6.2 million new HPV infections occur every year in the United States.²⁹ The frequency of cervicovaginal HPV infection among sexually active women has been observed at 43%, with the greatest incidence noticed in men with three or more sex partners and women whose most recent regular sexual partner had two or more lifetime partners. Most people with HPV do not develop symptoms. At least half of sexually active persons will become infected at least once in their lifetime. In 90% of the cases, the body's immune system clears HPV naturally within 2 years. HPV types 16 and 18 cause over 70% of all cervical cancer, whereas HPV types 6 and 11 are responsible for about 90% of genital warts.³⁰

PATHOPHYSIOLOGY

HPV replicates in terminally differentiated squamous cells in the intermediate layers of the genital mucosa. Hence these effects of the viral early region genes on DNA synthesis are critical for viral survival. Genital warts are the clinical manifestation of active viral replication and virion production at the infection site.

DIAGNOSIS

- A definitive diagnosis of HPV is based on DNA or RNA or capsid protein detection.
- Diagnosis is generally made from the clinical presentation and may be classified into several categories: classic

Clinical Presentation of Genital Warts^{9,30,31}

General

- Appear as rough, thick, cauliflower-like lesions

Signs

- Black dots within warts
- Disrupted surface

Symptoms

- Anogenital pruritus
- Burning
- Vaginal discharge or bleeding
- Although rare, dyspareunia may occur with vulvovaginal condyloma

condyloma acuminata, which are pointed or cauliform; keratotic warts with a thick, horny surface resembling common skin warts; and flat warts, frequently observed on the *outer layer of skin*.

- Tissue biopsy or viral typing is only indicated if the diagnosis is uncertain and is not recommended for patients with routine or typical lesions.
- Since HPV is highly associated with cervical cancer and has more than 20 different cancer-associated HPV types, patients who are diagnosed with HPV should be tested for cervical cancer.

TREATMENT

Desired Outcome

Removal of visible warts and reduction of infectivity are the goals of treatment.

Pharmacologic Therapy^{9,31}

6 Currently, the choice of therapy is based on the size, site, and morphology of lesions, as well as patient preference, treatment costs, convenience, adverse effects, and clinician experience. Factors that might affect response include the presence of immunosuppression and patient compliance. Assuming that the diagnosis is correct, switching to alternate therapy is appropriate if there has been no response observed after three treatment cycles. A comparison of adverse effects related to treatment options may be found in [Table 80–2](#).

► Patient-Applied Treatment

Podofilox Available as a 0.5% gel or solution containing purified extract of the most active compound of podophyllin, podofilox arrests the formation of the mitotic spindle, prevents cell division, and may also induce damage in blood

Table 80–2

Comparison of Adverse Effects Seen with Treatments for Genital Warts

Treatment	Adverse Effects
Podofilox	Burning at site of application, pain, inflammation
Imiquimod	Erythema, irritation, ulceration, pain, burning, edema, pigmentary changes
Sinecatechins	Burning at site of application, erythema, pruritus, edema
Podophyllin resin	Local irritation, erythema, burning, soreness at application site; possibly oncogenic
Bichloroacetic and trichloroacetic acid	Local irritation and pain, minimal systemic effects
Cryotherapy	Pain or blisters at application site
Surgical excision	Pain, bleeding, scarring; possible burning or allergic reaction to local anesthetic
Vaporization	Pain, bleeding, scarring; risk of HPV spreading via smoke plumes
Intralesional interferon	Burning, itching, irritation at injection site, systemic myalgia, headache, fever, chills, leukopenia, elevated liver enzymes, and thrombocytopenia

HPV, human papillomavirus.

From Refs. 9, 28, and 31.

vessels within the warts. The surface area treated must not exceed 10 cm², and a maximum of 0.5 mL should be used on a daily basis.

Apply twice daily for 3 consecutive days followed by 4 consecutive days without treatment. This cycle may be repeated until there are no visible warts or for a maximum of 4 weeks. Side effects are generally local and may include erythema, swelling, and erosions. Podofilox is not recommended for use in the vagina, anus, or during pregnancy.

Imiquimod Imiquimod is a cell-mediated immune-response modifier, available as a topical 5% cream in single-dose application packets. Imiquimod is applied at bedtime, three times a week for up to 16 weeks.

The treatment area should be washed with soap and water 6 to 10 hours after application. Mild to moderate erythema has been noted with imiquimod use; however, this generally suggests that the drug is reaching a therapeutic range and may be clearing the lesion.^{32,33}

Sinecatechins A green tea extract with an active product (catechins) is available as a 15% ointment. Apply a thin layer (0.5 cm) using a finger to each wart three times a day until complete clearance of warts. Do not wash off after use, and all sexual contact should be avoided while ointment is on the skin. This product should not be continued for longer than 16 weeks.⁹

► Physician-Applied Treatments

Podophyllin Resin A 10% to 25% solution of podophyllin resin has been the standard in-office treatment for genital

warts. Because podophyllin is neurotoxic and easily systemically absorbed, only a small amount (no more than 0.5 mL) should be applied, avoiding normal tissue. Application should be limited to less than 0.5 mL of podophyllin on an area of less than 10 cm² of warts per session, and no open lesions or wounds should exist in the area to which treatment is administered. The affected area will likely become erythematous and painful within 48 hours of application.³⁴

Topical podophyllin is applied once weekly and the area should be allowed to dry. Immediately following treatment, the dried drug should be removed using alcohol or soap and water. It is contraindicated in pregnant patients.

Bichloroacetic and Trichloroacetic Acids These products are available in 80% to 90% concentrations and are not systemically absorbed. The products are effective when used to treat a few, small, moist lesions. They may be applied to both keratinized epithelial and mucosal surfaces and may be used in pregnancy.

A noted reaction to these medications is transient burning; contact with surrounding epithelium may prove to be painful, producing significant local erythema and swelling. To avoid these effects, place petroleum jelly around the external lesion, including unaffected skin, and carefully apply the agent with a small applicator. If an excess amount of acid is used, talc or sodium bicarbonate (baking soda) may be used to neutralize unreacted acid.

Other Treatments Additional treatments may include fluorouracil/epinephrine/bovine collagen gel, an intralesional injection that has been proven effective in clinical trials for refractory patients or an intralesional injection of interferon.³¹

► Ablative Therapy

Several ablative options have been employed in the treatment of genital warts and include cryotherapy, surgical removal, and vaporization.

► Special Therapeutic Issues^{31,34}

Large Warts Treat warts greater than 10 mm in diameter with surgical excision. Use imiquimod for three to four treatment cycles to reduce the number of warts and improve surgical outcomes. Fifty percent reduction in wart size after four treatment cycles warrants continued use of imiquimod until warts clear or eight cycles have been completed; less than 50% reduction warrants surgical excision or other ablative therapy.

Subclinical Warts Subclinical warts may be identified through colonoscopy, biopsy, acetic acid application, or laboratory serology. However, early treatment has not been linked to a favorable effect during the course of therapy in the index patient or the partner with regard to reduction of the transmission rate.

Pregnancy Agents contraindicated in pregnancy include podofilox, sinecatechins, fluorouracil, and podophyllin. Imiquimod is not approved for use in pregnancy, although it has been considered after signed consent has been obtained.

Bichloroacetic and trichloroacetic acids have been used without problems. Ablative therapy is also a viable option.

PATIENT CARE AND MONITORING

Monitor patients every 3 to 6 months for a reduction in lesions or disease remission. Monitoring parameters include patient compliance, disease remission, and benign or cancerous tumors. Sexually active people can lower their chances of getting HPV by limiting their number of partners.

Vaccinations

- Several HPV genotypes have been linked to the development of cervical cancer. Gardasil[®], developed to protect against HPV genotypes 6, 11, 16, and 18, was the first vaccine employed to prevent cervical cancer, precancerous genital lesions, and genital warts due to HPV. Cervarix[®] vaccine helps prevent cervical cancer and precancers caused by HPV types 16 and 18. The CDC recommends the HPV vaccine for all 11- and 12-year-old males and females. Vaccination is also recommended for all teens, girls, and women through 26 years who have not been previously vaccinated or who have not completed the full series of shots.⁴⁰

Both vaccines are given in a series of three injections over a 6-month period. The second and third doses should be given at 2 and 6 months (respectively) after the first dose. HPV vaccine may be given at the same time as other vaccines.

GENITAL HERPES

Genital herpes (GH) is caused by herpes simplex virus (HSV) types 1 and 2. HSV is a chronic, life-long viral infection for which there is no cure. Once latency is established, neither competent host immunity nor therapeutic agents can eradicate the virus.⁹ Currently, there is no vaccine available for HSV, and it seems that the development of one is unlikely in the near future.

EPIDEMIOLOGY

Approximately 50 million Americans have GH. HSV-2 is the most common cause of recurrent genital herpes. Roughly one in six people in the United States (16.2%) aged 14 to 49 is infected with HSV-2. Prevalence of HSV-2 infection has grown slightly since the late 1970s (16.4% to 17.2%), and currently more than 500,000 new cases of HSV-2 occur annually.

PATHOPHYSIOLOGY

Nearly all HSV-2 infections are sexually acquired. Since HSV is only found in humans, infection may only be transmitted from infectious secretions onto mucosal surfaces (i.e., cervix or urethra) or direct contact with an active lesion (abraded skin). The virus may survive for a limited amount of time on environmental surfaces.

Clinical Presentation of Genital Herpes^{9,38,39}

General

- Asymptomatic

Classic Sign

- A cluster of painful vesicles on an erythematous base

Symptoms

- Itching
- Burning
- Tingling
- Groin lump
- Dysuria
- Dyspareunia
- Increased urinary frequency

Other Symptoms

- Ulcerative lesions, fissures, cervicitis

Patient Encounter 3

MR is a 19-year-old white female who visits a clinic complaining of intense itching and burning in the genital area for the past few days. She informed the clinician that she engaged in frequent, unprotected sexual intercourse with two men within the past 4 months and has also noticed an eruption of painful vesicles in the genital area. She is not sure of her partners' sexual contacts.

What information is suggestive of genital herpes?

What potential risk factors for STIs are present?

What therapy should be recommended for this patient initially and how will this differ if episodic infection recurs?

uncomplicated course of infection, and in severe cases may require hospitalization. Several agents are effective during this period (Table 80–3).^{36–38} At the cited dosages, these agents have had excellent outcomes with regard to lesion healing time, viral shedding, and resolution of pain. Common adverse effects are nausea, headache, and diarrhea.

► Episodic Therapy

In a patient with a previous diagnosis of genital herpes, the appearance of new vesicular lesions is synonymous with HSV reactivation. For most patients, genital herpes recurrence is self-limiting and short-lived, lasting approximately 6 to 7 days.

► Suppressive Therapy

Suppressive therapy is effective for controlling all symptoms related to the disease and may impact troublesome complications of infection. Daily suppressive therapy is used in patients who have six or more episodes per year. Before beginning suppressive therapy, discuss patient expectations. Encourage patients to record any breakthrough episodes, as this may require treatment reevaluation and adjustment.

► Preventive Therapy

Valacyclovir 500 mg orally once daily has been implicated to prevent the sexual transmission of HSV to an uninfected partner. In addition to pharmacologic therapy, counsel patients regarding safe sex practices.

► Drug Resistance

All acyclovir-resistant strains are resistant to valacyclovir, and the majority are resistant to famciclovir. Foscarnet, cidofovir, and trifuridine have been administered in acyclovir-resistant patients.³⁹ These agents are usually reserved for use after other medications have failed because of their associated toxicities.

► Pregnancy

Women who are pregnant may transmit the virus to the neonate during delivery. There are two management strategies: cesarean section and antiviral therapy. A few

DIAGNOSIS

Ulcerative or multiple vesicular lesions are absent in many infected persons. Laboratory confirmation is vital to effective treatment of HSV, especially in individuals in whom a clinical diagnosis cannot be obtained. There are several methods by which a definitive diagnosis may be acquired, and these include virologic typing, serologic diagnosis, rapid point-of-care antigen detection, enzyme-linked immunosorbent assay (ELISA), immunoblot, and DNA polymerase chain reaction.³⁵ Additionally, the FDA recently approved glycoprotein G-based assays to aid in the diagnosis of HSV.

TREATMENT

Desired Outcome

The desired outcome is to curtail the number of episodic prodromes and to minimize any side effects experienced due to the antivirals. Counseling of infected persons and their partners is vital to the management of HSV.

Pharmacologic Therapy⁹

7 *Treatment is based on several factors, including likelihood of patient compliance, whether it is the first or a recurrent episode, host immunity, and pregnancy.* However, patient response has been linked to the time it takes to initiate treatment with acyclovir, or its analogues, after symptom onset.

► First Episode

The first episode is a systemic illness associated with the vesicular lesions, may last up to 21 days, usually has an

Table 80-3

Comparison of Antivirals Used for Herpes Simplex Infection

Agent	Dose	Side Effects
First Episode		
Acyclovir	<i>200 mg orally 5 times a day × 7–10 days</i> 400 mg orally 3 times daily × 7–10 days	Headache, confusion, nausea, vomiting, thrombocytopenia, renal insufficiency, rash, pruritus, fever, arthralgias, myalgia, thrombotic thrombocytopenic purpura, hallucinations, somnolence, depression
Valacyclovir	<i>1 g orally 2 times daily × 7–10 days</i>	Refer to acyclovir
Famciclovir	250 mg orally 3 times daily × 7–10 days	Refer to acyclovir
Episodic		
Acyclovir	<i>200 mg orally 5 times daily × 5 days</i> Or 400 mg orally every 8 hours × 5 days Or 800 mg orally 2 times daily × 5 days Or 800 mg orally 3 times daily × 2 days	Refer to acyclovir
Valacyclovir	<i>500 mg orally 2 times daily × 3 days</i> Or 1 g orally once daily × 5 days	Refer to acyclovir
Famciclovir	125 mg orally 2 times daily × 5 days 1000 mg orally twice daily × 1 day	Refer to acyclovir Or
Suppressive		
Acyclovir	400 mg orally 2 times daily continuously Or	Refer to acyclovir
Valacyclovir	500 mg orally once daily continuously Or	Refer to acyclovir
Valacyclovir	1000 mg orally once daily continuously Or	Refer to acyclovir
Famciclovir	250 mg orally 2 times daily continuously	Refer to acyclovir
Reserved Agents		
Foscarnet	40 mg/kg IV every 8 hours until clinical resolution is attained	Renal insufficiency, metabolic disturbances, hypophosphatemia
Cidofovir	1% topical agent (gel) used daily on a compassionate basis for acyclovir-resistant herpes lesions × 5 days	Application site reactions, lesion recrudescence
Imiquimod	Topical alternative used daily on a compassionate basis for acyclovir-resistant herpes lesions × 5 days	Application site reactions, lesion recrudescence

Italicized data indicate recommended dosages.

From Refs. 9 and 33.

studies indicate that acyclovir 200 to 400 mg every 8 hours has been administered from 38 weeks gestation until delivery. Suppressive treatment includes the use of acyclovir or valacyclovir from week 36 until delivery. The goal of therapy is to reduce the number of lesions and asymptomatic shedding at delivery.

► Neonates

The risk for transmission from an infected mother to a neonate is high among women who acquired GH near time of delivery. HSV infections should be considered in all neonates who present with nonspecific symptoms such as fever, poor feeding, lethargy, or seizures in the first month of life. Infants suspected to have or who are diagnosed with an HSV

infection should be treated parenterally. Acyclovir can be administered 20 mg/kg/day in three divided doses IV for 21 days for disseminated and CNS disease or 14 days for disease limited to skin, eyes, and mucous membranes.

PATIENT CARE AND MONITORING

Reevaluation of the patient's condition and therapy adjustment are key elements in effective monitoring. Parameters may include:

- The patient's psychosocial and psychosexual status
- Frequent reassessment of recurrent episodes and therapy adjustment

- Ordering tests for malignancy
- Yearly testing of HIV status
- Side effects of drugs

BACTERIAL VAGINOSIS

8 *Bacterial vaginosis (BV)* is a clinical syndrome categorized by an overgrowth of polymicrobial anaerobic organisms, such as *Gardnerella vaginalis*, *Prevotella species*, *Mycoplasma hominis*, and *Mobiluncus species*. BV infection leads to the replacement of the normal hydrogen peroxide-producing lactobacillus and an increase in vaginal pH from 4.5 to 7.⁴¹ BV is the most prevalent cause of vaginal discharge and malodor.

EPIDEMIOLOGY

BV is associated with having multiple male or female partners, a new sex partner, douching, lack of condom use, and lack of vaginal lactobacilli. It is estimated that one in three women will develop BV at some point in their lives. BV has been found in 12% to 25% of women in routine clinic populations, 10% to 26% of women in obstetrics clinics, and 32% to 64% of women in clinics for STIs. BV infection usually results from sexual activity, although some cases have been reported in women who are not sexually active.

PATHOPHYSIOLOGY

A complex and intricate balance of microorganisms maintains the normal vaginal flora (i.e., lactobacilli, corynebacteria, and yeast). The normal postmenarchal and premenopausal vaginal pH is 3.8 to 4.2. At this pH, growth of pathogenic organisms is usually inhibited; however, disturbance of the normal vaginal pH can alter the vaginal flora, leading to overgrowth of pathogens.

DIAGNOSIS

BV is diagnosed according to the Amsel criteria. In order for diagnosis to be confirmed, three of the four criteria must be present:

1. Thin, white, homogenous discharge
2. Clue cells on microscopy (clue cells are epithelial cells of the vagina that get their distinctive stippled appearance by being covered with bacteria)
3. pH of vaginal fluid greater than 4.5
4. Release of a fishy odor upon the addition of an alkali (10% potassium hydroxide) to a vaginal sample

Alternatively, a gram-stain vaginal smear may be used to diagnose BV using the Nugent criteria. This relies on estimating the proportions of bacteria morphotypes to

Clinical Presentation of Bacterial Vaginosis^{9,42,43}

General

- Offensive fishy-smelling vaginal discharge

Signs

- Thin, white, homogenous discharge, coating the walls of the vagina

Symptoms

- Many women are asymptomatic; usually not associated with soreness, itching, or irritation

provide a score between 0 and 10. A score of less than 4 is normal, 4 to 6 is intermediate, and greater than 6 is consistent with BV. Isolation of *G. vaginalis* may not be diagnostic because it can be cultured from the vagina in some normal women, although a high concentration may be indicative of infection.⁴²

TREATMENT

Desired Outcome

Reduction in the number of causative bacteria, cessation of vaginal discharge, and decrease in vaginal pH are the desired outcomes.

Pharmacologic Therapy^{9,43}

► Adults

Recommended adult regimens include metronidazole 500 mg orally twice daily for 7 days *or* metronidazole gel (0.75%), one full applicator (5 g) intravaginally once daily for 5 days *or* clindamycin cream (2%), one full applicator (5 g) intravaginally at bedtime for 7 days.

Alternative regimens include clindamycin ovules 100 mg intravaginally once at bedtime for 3 days, clindamycin 300 mg orally twice daily for 7 days, tinidazole 2 g orally once daily for 2 days, or Tinidazole 1 g orally daily for 5 days.

► Pregnancy

Pregnant symptomatic women should receive treatment. Treatment of BV in asymptomatic women at high-risk for preterm delivery with a recommended oral regimen mitigates preterm delivery. Screening should be performed during the first prenatal visit. Recommended regimens for pregnant women include metronidazole 500 mg orally twice daily for 7 days *or* metronidazole 250 mg orally three times daily for 7 days *or* clindamycin 300 mg orally twice daily for 7 days. Metronidazole is not recommended for use in the first trimester of pregnancy.

Patient Encounter 4, Part 1

SM is a sexually active 22-year-old Hispanic female who came to the clinic with vaginal discharge and a cauliflower-like lesion in the genital area. She had her first child at 17 years old and is currently on birth control pills. SM admits to having unprotected sex with her first baby's father and her current boyfriend within the past 3 weeks. Upon her visit, SM mentions that she experienced a similar breakout 2 years ago.

What information is suggestive of genital warts?

What potential risk factors for STIs are present?

How should the diagnosis of genital warts be confirmed in this patient?

PATIENT CARE AND MONITORING

- A test to determine whether the patient has been cured is generally not recommended, thus follow-up visits are unnecessary if symptoms resolve. However, in patients with recurrent symptomatic BV, a follow-up after the course of therapy may be warranted. If treatment has been prescribed during pregnancy to reduce preterm birth, perform a repeat exam in 1 month and advise further treatment for recurrent BV. Patients taking metronidazole should be cautioned not to consume alcohol while taking this medication for up to 24 hours after taking the last dose.

PELVIC INFLAMMATORY DISEASE

Pelvic inflammatory disease (PID) usually affects young, sexually active, reproductive-age women. PID includes a spectrum of inflammatory disorders of the upper female genital tract. In the majority of cases, the pathogens responsible are *C. trachomatis* and *N. gonorrhoeae*, although anaerobes, enteric gram-negative rods, and cytomegalovirus have also been implicated in the pathogenesis.⁴⁴ PID has been correlated with ectopic pregnancy, infertility, tubo-ovarian abscess, and chronic pelvic pain.⁴⁶

EPIDEMIOLOGY

More than 750,000 women are affected by PID each year in the United States. The highest rates of PID occur in teenagers and first-time mothers. Up to 10% to 15% of these women may become infertile as a result of PID. The CDC estimates that more than 1 million women experience an episode of PID every year. The disease leads to approximately 2.5 million office visits annually. Because many cases of PID go unrecognized and some episodes are asymptomatic, the potential for damage to the reproductive health of women is substantial.

PATHOPHYSIOLOGY

PID occurs when bacteria move upward from a woman's vagina into her reproductive organs. *Chlamydia* may produce a heat-shock protein that causes tissue damage through a delayed hypersensitivity reaction. *C. trachomatis* may also possess DNA evidence of toxin-like genes that code for high-molecular-weight proteins with structures similar to *Clostridium difficile* cytotoxins, enabling inhibition of immune activation. This may explain the observation of a chronic *C. trachomatis* infection in subclinical PID.

DIAGNOSIS^{44,45}

To be diagnosed with PID, patients must have uterine tenderness, cervical motion tenderness, lower abdominal pain, painful intercourse, and adnexal tenderness with no other cause of these signs. Additional criteria include:

- Oral temperature greater than 38.3°C (101°F)
- Abnormal cervical or vaginal discharge
- WBC presence on saline microscopy of vaginal secretions
- Elevated erythrocyte sedimentation rate
- Elevated C-reactive protein
- Laboratory documentation of cervical infection with *N. gonorrhoeae* or *C. trachomatis*

TREATMENT

Desired Outcome

The eradication of causative bacteria and reduction of any related sequelae are the desired goals of treatment.

Clinical Presentation of Pelvic Inflammatory Disease^{9,46}

General

- Signs and symptoms may vary from mild to severe

Signs

- Vague

Symptoms

- Lower abdominal or pelvic pain
- Malodorous vaginal discharge
- Abnormal uterine bleeding
- Dyspareunia
- Dysuria
- Nausea and/or vomiting
- Fever

Table 80-4

Treatment Regimens for Pelvic Inflammatory Disease**Parenteral Option A**

Cefotetan 2 g IV every 12 hours plus doxycycline 100 mg orally or IV every 12 hours

or

Cefoxitin 2 g IV every 6 hours plus doxycycline 100 mg orally or IV every 12 hours

Parenteral Option B

Clindamycin 900 mg IV every 8 hours plus gentamicin, loading dose IV or IM (2 mg/kg) followed by maintenance dose (1.5 mg/kg) every 8 hours. A single daily dose of gentamicin (3–5 mg/kg) may be used.

Alternative Parenteral treatment

Ampicillin-sulbactam 3 g IV every 6 hours plus doxycycline 100 mg orally or IV every 12 hours

Oral

Ceftriaxone 250 mg IM single dose plus doxycycline 100 mg orally twice daily for 14 days with or without metronidazole 500 mg orally twice daily for 14 days

Or

Cefoxitin 2 g IM single dose and probenecid 1 g single dose, plus doxycycline 100 mg orally twice daily for 14 days with or without metronidazole 500 mg orally twice daily for 14 days

Or

Third-generation cephalosporin (ceftizoxime or cefotaxime) plus doxycycline 100 mg orally twice daily for 14 days with or without metronidazole 500 mg orally twice daily for 14 days

From Refs. 9, 45, and 46.

Pharmacologic Treatment⁹

9 *Resolution of infection (i.e., N. gonorrhoeae, C. trachomatis, Streptococcus spp., and gram-negative facultative bacteria) and mitigation of sequelae should be the main goal of pharmacologic therapy.* CDC-approved treatment regimens are shown in **Table 80-4**.^{9,44} Optimal management of PID should be individualized based on clinical setting and patient characteristics. For some patients, hospitalizations, IV antibiotics, and surgical treatment of complications may be needed. Although outpatient management remains contentious, many feel that outpatient management should be limited to individuals who remain afebrile, have a WBC count less than $11 \times 10^3/\text{mm}^3$ ($11 \times 10^9/\text{L}$), have minimal evidence of peritonitis, have active bowel sounds, and can tolerate oral nourishment. Nonetheless, outpatient therapy with a parenteral cephalosporin followed by doxycycline and metronidazole is recommended.

PATIENT CARE AND MONITORING

If no clinical improvement has occurred within 3 days after parenteral or outpatient oral therapy, further assessment should be performed. The goals of monitoring patients with PID are related to reducing long-term complications. To this end, the primary approach should be prevention and education of at-risk women. Secondary prevention may include screening by conducting a pelvic exam during a routine checkup. The male sex partners of women with PID should be examined if the patient's onset of symptoms

occurred within the previous 60 days. It is imperative that women understand that the more sex partners she encounters, the greater her risk of developing PID.

PREVENTION STRATEGIES

A combination of prevention efforts is advised. Alteration in sexual behavior should undoubtedly be the first counseling concern, as promiscuous sexual activity has been shown to augment the probability of infection.

Abstinence is the best course of action, especially in patients with herpes during lesional episodes. However, compliance in some may be minimal, in which case, appropriate condom use should always be recommended. To alleviate any possible misconceptions about condom application, either demonstrate how to apply a condom or

Patient Encounter 4, Part 2

PMH: History of bacterial vaginosis 2 years ago. Allergy to clindamycin.

FH: Noncontributory.

SH: Has two children from two different fathers. Admits to having six sexual partners in the last 3 years. Smokes ½ pack of Newport cigarettes per day to remain calm.

ROS: Painful vesicles, frequent urination, and urticaria in the genital area. Recently developed a fishy smelling vaginal (white) discharge.

PE:

VS: BP = 135/85 mm Hg, Height = 5 ft 2 in (157 cm), Weight = 217 lb (98.6 kg), Temp = 97.8°F (36.6°C)

Lab: Vaginal pH = 4.7

What information is suggestive of bacterial vaginosis?

If the diagnosis of bacterial vaginosis is confirmed, what therapeutic options exist for this patient?

Patient Encounter 4, Part 3

SM is young and uneducated about the ramifications of her sexual actions. She continues to have unprotected sex with multiple men. Although taking birth control pills may protect her from pregnancy, they will not protect her from STIs. The incidence of STIs has increased dramatically over the last 25 years.

What impact will pregnancy have on the treatment plan for the two STIs?

What consideration should be given to other STIs?

ask the patient to demonstrate. During the demonstration, explicitly educate the patient with regard to application, storage, and the use of lubricants.⁴⁷

Abbreviations Introduced in This Chapter

BV	Bacterial vaginosis
CSF	Cerebrospinal fluid
ELISA	Enzyme-linked immunosorbent assay
GH	Genital herpes
HPV	Human papillomavirus
HSV	Herpes simplex virus
MSM	Men who have sex with men
PID	Pelvic inflammatory disease
RPR	Rapid plasma reagin
STI	Sexually transmitted infection
WSW	Women who have sex with women

Osteomyelitis

Melinda M. Neuhauser and Susan L. Pendland

LEARNING OBJECTIVES

● Upon completion of the chapter, the reader will be able to:

1. List common risk factors for osteomyelitis.
2. Discuss the pathophysiology of osteomyelitis.
3. Compare and contrast the classic signs and symptoms of acute and chronic osteomyelitis.
4. Evaluate microbiology culture data and other laboratory tests utilized for the diagnosis and treatment of bone infections.
5. List the most common pathogens isolated in acute and chronic osteomyelitis.
6. Develop a treatment plan for osteomyelitis.
7. Recommend parameters to monitor antimicrobial therapy for effectiveness and toxicity.
8. Educate patients regarding disease state and drug therapy.

KEY CONCEPTS

- 1 Osteomyelitis, an infection of the bone, can be an acute or chronic process.
- 2 Osteomyelitis is most often classified by duration of disease and route of infection.
- 3 *Staphylococcus aureus* is the predominant pathogen seen in all types of osteomyelitis, with methicillin-resistant *S. aureus* (MRSA) being increasingly reported. However, the spectrum of potential causative pathogens varies with patient-specific risk factors and route of infection.
- 4 The gold standard for diagnosis of osteomyelitis is a bone biopsy with isolation of microorganism(s) from culture and the presence of inflammatory cells and osteonecrosis on histologic exam. Due to the invasive nature of the bone biopsy, the diagnosis of osteomyelitis is often based on clinical findings, laboratory tests, and imaging studies rather than bone biopsy.
- 5 Typical signs and symptoms of osteomyelitis include local pain and tenderness over the affected bone, as well as inflammation, erythema, edema, and decreased range of motion. Patients with acute hematogenous osteomyelitis may also present with fever, chills, and malaise.
- 6 The treatment goals for acute and chronic osteomyelitis are to eradicate the infection and prevent recurrence. Higher cure rates are seen with acute compared with chronic osteomyelitis. Therefore, in chronic

osteomyelitis, a common treatment goal for many patients is to prevent complications such as amputation.

- 7 Treatment of osteomyelitis is dependent on the extent of bone necrosis. For acute osteomyelitis with minimal bone destruction, an extended course of antimicrobial therapy should effectively treat the infection; however, in chronic osteomyelitis, surgical intervention is also typically required.
- 8 Empiric antimicrobial therapy should target likely causative pathogen(s) based on patient-specific risk factors and route of infection. *With the increased incidence of MRSA, the use of anti-MRSA antimicrobials should be considered as first-line therapy for empiric coverage of suspected staphylococcal osteomyelitis.* However, therapy should be modified based on culture and sensitivity data.
- 9 The duration of antimicrobial therapy is usually 4 to 8 weeks.
- 10 Patients should be monitored for clinical and laboratory response, development of adverse drug reactions, and potential drug–drug interactions. Patients should also be closely monitored for adherence in the outpatient setting.

INTRODUCTION

- 1 *Osteomyelitis is an infection of the bone that is associated with high morbidity and increased healthcare costs. The inflammatory response associated with acute osteomyelitis*

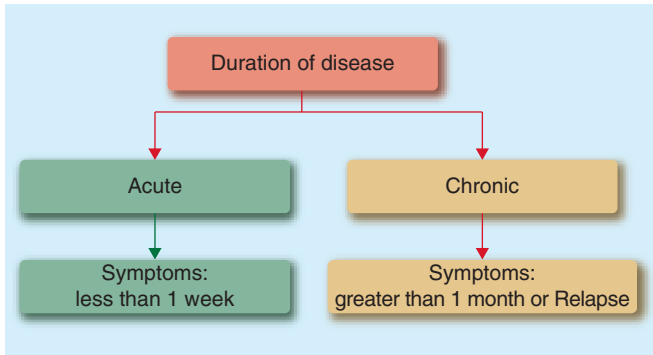

FIGURE 81-1. Classification by duration of disease.

can lead to bone necrosis and subsequently chronic infections. Bacterial pathogens, particularly *Staphylococcus aureus*, are the most common microorganisms implicated in these infections. Diagnosis and treatment are often difficult due to the heterogeneous nature of osteomyelitis. Medical management is the mainstay of treatment for acute infections; however, surgical intervention is necessary for chronic cases that involve bone necrosis. Outcomes may vary based on patient-specific risk factors, duration of disease, and site of infection.

2 There are multiple classification schemes for osteomyelitis.¹⁻⁵ Due to the heterogeneity of bone infections, no single classification system has been universally accepted.^{1,6} Two of the most common classification schemes are based on duration of disease and route of infection.^{1,3,4,6,7}

Historically, osteomyelitis has been classified as acute or chronic based on duration of disease (Fig. 81-1).^{1,2,6} However, there are no established definitions for acute and chronic infections.^{1,6} Acute infection has been defined as first episode or recent onset of symptoms (within 2 weeks).^{2,3,8} Chronic osteomyelitis is generally defined as relapse of the disease or symptoms persisting beyond 2 months.^{2,3} Because there is no abrupt demarcation, but rather a gradual shift from acute to chronic infection, others describe chronic osteomyelitis as the presence of necrotic bone.^{1,5,6,9}

Waldvogel classified osteomyelitis based on the route of infection and the presence of vascular insufficiency.⁷ In this classification scheme, the route of infection is categorized as either hematogenous or contiguous (Fig. 81-2). Osteomyelitis

secondary to a contiguous focus is further subdivided into infections with or without vascular insufficiency. This classification, based on etiology of the infections, does not provide therapeutic guidance.^{1,3}

An alternative classification, the Cierny-Mader staging system, is based on anatomic site and physiologic status of the patient.⁴ This classification scheme was developed for chronic osteomyelitis involving long bones, but has limited application for small bones and digits. The detailed stratification has the greatest utility in clinical trials since it permits comparison of treatment regimens in patients with diverse comorbidities and infection sites.

EPIDEMIOLOGY AND ETIOLOGY

Osteomyelitis due to contiguous spread accounts for approximately 80% of all cases and is the most common type in adults.³ Hematogenous spread accounts for the remaining 20% of bone infections and is the most common type of osteomyelitis in children.^{1-3,6,7,10} Hematogenous osteomyelitis is reported in older adults and IV drug users, with the spine (vertebral osteomyelitis) being the most common site of infection.^{1-3,11,12}

3 The etiology of osteomyelitis has remained relatively unchanged, with *S. aureus* being the predominant pathogen seen in all types of osteomyelitis.^{1-3,5,6,8,13-15} However, the susceptibility of *S. aureus* has been shifting from methicillin-sensitive to methicillin-resistant in both the healthcare and community settings.^{1,2,5,8,10,12-14,16-21} Although it is more common in skin and soft tissue infections,²² MRSA has been increasingly reported in osteomyelitis.^{1,2,5,8,10,12-14,16-21} Risk factors for healthcare-associated MRSA include previous antimicrobial therapy, prolonged hospitalization, hemodialysis, or presence of an indwelling catheter.²³ In contrast, community-associated MRSA has emerged in patients with no prior healthcare exposure or apparent risk factors.²³

Host factors such as age, comorbidities, medication, and presence of foreign devices can influence the spectrum of infection (i.e., bone and pathogen involvement).^{1,2,6,11,14,24}

- Patients with uncontrolled diabetes and/or peripheral vascular disease (PVD) have poor wound healing and often present with nonhealing skin ulcers.

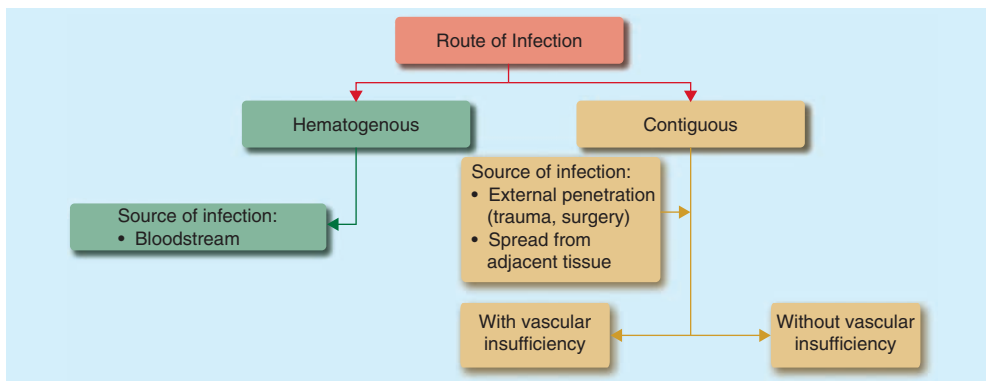

FIGURE 81-2. Classification by route of infection.

These wounds are typically colonized with a mixture of aerobic and anaerobic microorganisms, which can lead to polymicrobial osteomyelitis.^{1,2,6,14,25} Common aerobic pathogens in this setting may include MRSA, *Enterococcus* spp, Enterobacteriaceae, and *Pseudomonas aeruginosa*.²⁵ Therefore, if a wound is deep or extensive, these patients should be evaluated for underlying osteomyelitis.^{2,14,24}

- Other special populations with a varied pathogen spectrum include:
 - IV drug users (MRSA)^{1,2,6,11,14}
 - Elderly (*Escherichia coli* secondary to urinary tract infections)^{1,11,14}
 - Sickle cell patients (*Salmonella* spp)^{1,2,5,6,13,14}
 - Individuals with prosthetic implants (coagulase-negative staphylococci)^{1,5,14}
 - Neonates (*E. coli* or group B streptococci)^{2,5,13}
 - Patients with pressure sores (polymicrobial—aerobes and anaerobes)^{1,2,14}
- Typical bone involvement in osteomyelitis depends on the route of infection.
 - Hematogenous: long bones (femur, tibia) in neonates and prepubertal children and vertebra in the elderly^{1-3,5,10,11,13}
 - Contiguous with vascular insufficiency: lower extremities²⁵
 - Contiguous without vascular insufficiency: bones affected by trauma, surgery, or adjacent to soft-tissue infection⁶
 - Osteomyelitis of the jaw has been reported in patients receiving bisphosphonate therapy.²⁶ Risk factors include cancer, chemotherapy, corticosteroids, tooth extraction and poor oral hygiene. Bisphosphates may induce osteoclast apoptosis and slow wound healing, leaving oral lesions susceptible to infection from oral microflora.²⁶

PATHOPHYSIOLOGY

Both microbial and host factors are important determinants in the development of osteomyelitis.^{1,6,25} Healthy bone tissue is normally resistant to infection but may become susceptible under certain conditions.^{1,2,6,25} Bone can become infected: (a) via the presence of bacteria in the bloodstream, (b) by direct inoculation from trauma or surgery, and (c) by spread from an adjacent site (e.g., soft-tissue infection).^{1,6,25} The latter is particularly problematic in patients with foreign body implants (e.g., hip replacement) and chronic skin ulcers.¹ *Staphylococcus* species possess bacterial adhesins, which promote their attachment to tissues and foreign devices.^{1,13,25}

Microbial adherence to bone elicits an inflammatory response.¹ The subsequent release of leukocytes and cytokines leads to edema and ischemia. In some cases, these processes can lead to bone necrosis.^{1,25} Pieces of dead bone may become separated, forming sequestra (Fig. 81-3).^{1,25} These

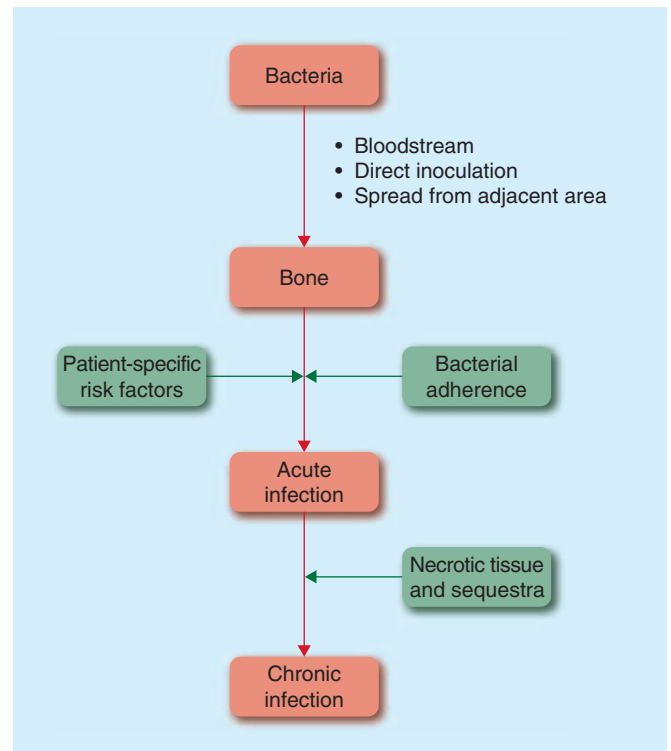

FIGURE 81-3. Pathogenesis of osteomyelitis.

areas typically cannot be penetrated by antimicrobials and phagocytic cells and thus require surgical intervention to eradicate the bacterial nidus.¹

CLINICAL PRESENTATION AND DIAGNOSIS

General

- The clinical presentations of osteomyelitis may vary depending on route and duration of infection, as well as patient-specific factors such as infection site, age, and comorbidities.^{1,5,6,10,13}
- **4** The gold standard for diagnosis of osteomyelitis is a bone biopsy with isolation of microorganism(s) from culture and the presence of inflammatory cells and osteonecrosis on histologic exam.^{1-3,6,13,24,25,27} Due to the invasive nature of the bone biopsy, the diagnosis of osteomyelitis is often based on clinical findings, laboratory tests, and imaging studies rather than bone biopsy.^{1,27} A thorough history and physical examination are especially important for diagnosis in patients with limited or atypical symptoms.^{1,24}

Symptoms and Signs

- **Systemic:** Fever, chills, malaise^{1,5,6,10,13}
- **Localized:** Pain or tenderness, edema, erythema, inflammation, decreased range of motion of infected area^{1,5,6,10,14}

- **5** Patients with acute osteomyelitis typically experience both systemic and localized signs and symptoms.^{5,6,8,13}
- **5** Patients with chronic infection typically present with only localized signs and symptoms.⁶
- A cardinal sign of chronic osteomyelitis is the formation of sinus tracts with purulent drainage.¹

Laboratory Tests

- No single noninvasive laboratory test is currently available for the diagnosis of osteomyelitis.^{1,3,6} Despite low specificity, several tests are commonly used to aid in the diagnosis and to monitor response to therapy.
- Nonspecific inflammatory markers for infection include^{1,3,5,6,9,11,12,21,25,28}:
 - White blood cell count (WBC)
 - Erythrocyte sedimentation rate (ESR)
 - C-reactive protein (CRP)
 - These tests may be elevated in osteomyelitis, as well as in other infections and noninfectious conditions
- WBC, ESR, and CRP are often elevated, but may also be within normal limits. An elevated WBC is mostly seen in patients with acute osteomyelitis.^{1,3,6}
- CRP rises faster than ESR during early stages of infection and also returns to normal levels more quickly than ESR. This makes CRP a more useful tool for both diagnosis and monitoring of therapeutic response.^{2,5,6,11,21}

Microbiologic evaluation

- Isolation of causative pathogen is essential for targeted antimicrobial therapy.^{1-3,6,24,25}
- Positive culture and histology from bone biopsy samples provide definitive diagnosis of osteomyelitis.^{1,5,14,25} However, bone biopsies are rarely performed due to the invasive nature of the procedure.^{1,3,6,25}
- If bone biopsy is not done, quality specimens (e.g., two consecutive samples with bone contact [deep samples] in patients with contiguous osteomyelitis^{3,24,29} or blood cultures in patients with acute hematogenous osteomyelitis^{1,5,11,13}) should be obtained to provide pathogen identification. Superficial swabs often represent colonization rather than infecting organism(s).^{1,3,14}
- *S. aureus* is the predominant pathogen in all types of bone infection.^{1-3,5,6,13-15}
- A single pathogen is most often isolated in hematogenous osteomyelitis, whereas multiple organisms are often isolated in contiguous osteomyelitis.^{2,3,6}

Imaging Studies

- A number of different imaging tests are used to assist in the diagnosis of osteomyelitis.^{2,6,25,28,30}
- Plain film radiographs (x-rays) are the initial imaging study of choice for skeletal infections.^{1,2,11,13,24,28} Although changes in soft tissue may appear within 3 days of

infection, bone lesions may not be visible for 10 to 21 days.^{1-3,6,28}

- Advantages: accessibility, cost, low radiation exposure, readily repeatable²⁸
- Disadvantages: inability to detect early bone infections^{1-3,5,13,28}
- Magnetic resonance imaging (MRI) is generally considered the best overall imaging modality for the diagnosis of osteomyelitis.^{1-3,5,8,13,21,27,28,30}
 - Advantages: early detection (i.e., 3 to 5 days after onset of infection), no radiation exposure, high resolution^{1-3,13,28,30}
 - Disadvantages: expense, inconvenience to patients (long examination time), movement artifacts, limitations to scanning patients with pacemakers and other implantable metal devices^{2,3,5,8,30}
- Computed tomography (CT) scans have high resolution and reproducibility.^{3,30} CT scans have reduced sensitivity compared with MRI and should not be routinely used to diagnose osteomyelitis.²⁸
 - Advantages: useful for the identification of sequestra, less expensive than MRI^{3,5,28,30}
 - Disadvantages: exposure of the patient to radiation, inability to use contrast medium to enhance images in patients with impaired renal function or previous allergic reactions^{5,28,30}
- Radionuclide imaging is also used for the early diagnosis of bone infections. The most widely used nuclear medicine test is the three-phase bone scan.^{28,30}
 - Advantages: early detection within 24 to 48 hours after onset of symptoms^{3,13,28}
 - Disadvantages: low specificity (increased risk of false positives) in patients with recent trauma, surgery, orthopedic prosthesis, diabetes, and ischemia^{1,3,13,28}

TREATMENT

Desired Outcomes

- **6** The treatment goals for osteomyelitis are to eradicate the infection and prevent recurrence.^{13,24} Cure rates of greater than

Patient Encounter, Part 1

A 38-year-old male with history of diabetes comes to the emergency department complaining of a painful ulcer on his right bottom foot. After questioning him, you determine that the wound has been present for several months and has not responded to multiple debridements and oral antibiotic therapy. On physical examination, a large wound with purulent drainage is seen.

What information is suggestive of osteomyelitis?

What risk factors, if any, does he have for osteomyelitis?

Patient Encounter, Part 2

The medical team suspected osteomyelitis and ordered laboratory tests and imaging studies and consulted orthopedic surgery service.

How would you classify the infection in this patient?

What imaging study(s) should be ordered for this patient?

85% have been reported for acute hematogenous osteomyelitis.⁸ In contrast, chronic osteomyelitis is associated with higher failure rates, largely due to the presence of necrotic bone.⁶ These patients typically require surgical intervention to remove the necrotic bone and tissue, and if applicable, to replace infected hardware.¹⁴ Comorbidities such as vascular insufficiency can further contribute to the poor outcomes seen with chronic osteomyelitis.¹⁴ Due to the high failure rates, treatment in this patient population may require prolonged therapy, with the primary goal of preventing amputation of infected areas.^{1,6}

General Approach to Treatment

7 Antimicrobial therapy alone is the mainstay of treatment for acute osteomyelitis.^{5,11,14} In comparison, treatment for chronic osteomyelitis typically requires a combination of antimicrobial therapy and surgical intervention.^{3,14} If the patient is not a candidate for surgical intervention, prolonged antimicrobial therapy is generally necessary.²⁵

► Nonpharmacologic Therapy

In addition to medical and surgical management, non-pharmacologic interventions that reduce risk factors for developing osteomyelitis should be communicated to the patient. Examples include smoking cessation, weight-control, exercise, and good nutrition.^{1,6} Additionally, a diabetic patient should be counseled regarding the necessity of controlled blood glucose, routine care and self-examination of lower extremities, and aggressive wound care.² Patients with chronic immobility should be counseled on skin care and techniques to prevent the development of pressure ulcers.

► Pharmacologic Therapy

8 Empiric antimicrobial therapy should target likely causative pathogen(s) based on patient-specific risk factors and route of infection.¹³ Empiric antimicrobial coverage against *S. aureus* should be considered for all classifications of osteomyelitis.² With MRSA increasingly being reported in both the hospital and community setting, the use of anti-MRSA antimicrobials (e.g., vancomycin) should be considered as first-line therapy for empiric coverage of suspected staphylococcal osteomyelitis.^{1,2,5,13–16,18,19} In addition to anti-MRSA coverage, patients with contiguous osteomyelitis with vascular insufficiency (e.g., diabetic) should also receive

empiric antimicrobial therapy to cover *P. aeruginosa* and anaerobes.^{2,24} Specific recommendations may vary based on factors such as patient allergies, potential for harboring a resistant organism, institution formulary, and cost considerations.^{10,14} Antimicrobial therapy should be modified based on culture and sensitivity data of appropriately collected specimens (Table 81–1).^{6,25}

Once culture and sensitivity results are available, therapy can be targeted against specific pathogens based on susceptibility data.^{5,13} If MRSA is isolated, vancomycin is considered first-line therapy unless the minimum inhibitory concentration is greater than 2 mcg/mL (2 mg/L).^{5,21,31} Alternate agents include daptomycin, linezolid, clindamycin, and trimethoprim-sulfamethoxazole in combination with oral rifampin.^{1,3,6,10,14,21,32–36} Clindamycin is commonly used in pediatric patients.^{5,8,10,15,21} However, microbiology laboratories must screen with a disk diffusion test (D-test) for inducible resistance via the macrolide-lincosamide-streptogramin (MLS) gene, as clindamycin failures have been associated with infections caused by these isolates.^{5,8,10,15,17,21,37} In addition, many experts recommend the use of oral rifampin in combination with an anti-MRSA antibiotic in patients with MRSA osteomyelitis.^{1–3,14,21} If methicillin-sensitive *S. aureus* is isolated and the patient has no β -lactam allergy, therapy should be changed to nafcillin/oxacillin or cefazolin (Table 81–1).^{1–3,11,13–15} Changes or addition of other antimicrobial agents should be based on the identification and susceptibility of other aerobic or anaerobic gram-positive and gram-negative bacteria isolated in appropriately collected cultures (Table 81–1).^{1,5,11,13–15}

Treatment is initiated with IV antimicrobials to optimize drug concentrations in bone.^{1,6} IV therapy can be administered in the inpatient or outpatient setting.^{6,14} Following 1 to 2 weeks of IV therapy, a switch to oral antibiotics may be considered in patients with good clinical response, strict adherence, and outpatient follow-up.^{5,6,13,21} Oral agents should possess such characteristics as high bio-availability, good bone penetration, and long half-life (i.e., extended dosing interval).^{1,6,13,14,21} Antimicrobials commonly used as oral therapy for osteomyelitis include fluoroquinolones, clindamycin, linezolid, and trimethoprim-sulfamethoxazole.^{1,3,6,8,13–15,21,37} Additionally, oral rifampin may be used in combination with another antibiotic in patients with foreign devices or MRSA osteomyelitis.^{1,14,21}

For chronic osteomyelitis, some clinicians recommend placement of antibiotic impregnated beads or cement.^{5,6,14} This enables antibiotics such as aminoglycosides and vancomycin to be delivered in high concentrations at the site of infection.^{5,6,14}

9 The duration of treatment had typically been 4 to 6 weeks for acute and chronic osteomyelitis.^{1,2,5,6,9,11,13} Recent guidelines recommend a minimum of 8 weeks for treatment of MRSA osteomyelitis.²¹ In patients who have undergone surgery, the total length of therapy should be counted after the last major surgical intervention.⁶ Therapy should be continued until the infection has resolved. Prolonged therapy (greater than 3 months) may be necessary for certain populations such as patients with vascular insufficiency or patients with

Table 81–1

Pathogen-Targeted Antimicrobial Therapy and Dosing Recommendations in Adults and Pediatrics

Microorganism	Antimicrobial Agent	Adult Dose	Pediatric Dose ^a
<i>S. aureus</i>			
MRSA	Vancomycin ^b	15–20 mg/kg IV every 8–12 hours	15 mg/kg IV every 6 hours
	Daptomycin ^b	6 mg/kg IV every 24 hours	6–10 mg/kg IV every 24 hours
	Linezolid	600 mg IV/oral every 12 hours	10 mg/kg IV/oral every 8 hours (less than 12 years old)
	Clindamycin ^c	600 mg IV/oral every 8 hours	10–13 mg/kg/dose IV/oral every 6–8 hours
	trimethoprim-sulfamethoxazole ^b (+ rifampin ^c 600 mg oral daily)	3.5–4.0 mg/kg of trimethoprim component IV/oral every 8–12 hours (trimethoprim-sulfamethoxazole single strength tablet is 80 mg/400 mg; double strength tablet is 160 mg/800 mg)	—
MSSA	Nafcillin ^d /oxacillin ^b	1–2 g IV every 4–6 hours	100–200 mg/kg/day IV in divided doses every 4–6 hours
	Cefazolin ^b	1–2 g IV every 6–8 hours	50–100 mg/kg/day IV in divided doses every 6–8 hours
<i>Enterococcus spp.</i>			
Ampicillin-sensitive	Ampicillin ^b	2 g IV every 4–6 hours	100–400 mg/kg/day IV in divided doses every 6 hours
Ampicillin-resistant Vancomycin-resistant	Vancomycin ^b Daptomycin ^b Linezolid	15–20 mg/kg IV every 8–12 hours 4–6 mg/kg IV every 24 hours 600 mg IV/oral every 12 hours	15 mg/kg IV every 6 hours — 10 mg/kg IV/oral every 8 hours (less than 12 years old)
<i>Streptococcus spp.</i>	Penicillin G ^b	2–4 million units IV every 4–6 hours	250,000–400,000 units/kg/day IV in divided doses every 4–6 hours
<i>P. aeruginosa</i>			
	Doripenem ^b	500 mg IV every 8 hours	—
	Imipenem/cilastatin ^b	500 mg IV every 6 hours	25 mg/kg IV every 6 hours
	Meropenem ^b	1 g IV every 8 hours	10–20 mg/kg IV every 8 hours
	Ceftazidime ^b	2 g IV every 8 hours	50 mg/kg IV every 8 hours
	Cefepime ^b	2 g IV every 12 hours	50 mg/kg IV every 8–12 hours
	Piperacillin/tazobactam ^b	4.5 g IV every 6 hours	100 mg/kg IV piperacillin component every 8 hours
	Ciprofloxacin ^{b,e}	400 mg IV every 8–12 hours; 750 mg oral every 12 hours	—
	Levofloxacin ^{b,e}	750 mg IV/oral every 24 hours	—
Enterobacteriaceae (in addition to antipseudomonal agents listed above)	Ceftriaxone ^d	1–2 g IV every 24 hours	50–100 mg/kg/day IV in divided doses every 12–24 hours
	Cefotaxime ^{b,d}	1–2 g IV every 8 hours	50–200 mg/kg/day IV in divided doses every 6–8 hours
	Ertapenem ^b	1 g IV every 24 hours	—
Anaerobes ^f	Moxifloxacin ^{c,e}	400 mg IV/oral every 24 hours	—
	Clindamycin ^c	600–900 mg IV every 8 hours; 300–450 mg oral every 6–8 hours	25–40 mg/kg/day IV in divided doses every 6–8 hours
	Metronidazole ^{b,c}	500 mg IV/oral every 6–8 hours	30 mg/kg/day IV/oral in divided doses every 6–8 hours

^aRefer to specialized pediatric reference for maximum neonatal and pediatric dosing recommendations.

^bDosage adjustment necessary in renal dysfunction.

^cDosage adjustment necessary in severe hepatic dysfunction.

^dDosage adjustment necessary in patients with concomitant renal and hepatic dysfunction.

^eFluoroquinolones: Not approved by the U.S. FDA for use in children except for anthrax (ciprofloxacin, levofloxacin) and complicated UTI and pyelonephritis (ciprofloxacin).

^fMay consider β -lactam/ β -lactamase inhibitor or carbapenem for broad-spectrum activity including anaerobes.

From Refs. 1, 6, 10, 11, 14, 17, 18, 21, 31, and 36–38.

recalcitrant infections that do not respond to 4 to 6 weeks of therapy.^{1,5,6,9,21,25}

OUTCOME EVALUATION

Therapeutic success is measured by the extent to which the care plan (a) resolves signs and symptoms, (b) eradicates the microorganism(s), (c) prevents relapses, and (d) prevents complications such as amputation.¹³ Patients should be evaluated for resolution of clinical signs and symptoms and normalization of laboratory tests (WBC, CRP, ESR, and cultures).¹³ Hospitalized patients should be examined daily. Improvement in clinical manifestations should be seen within 48 to 72 hours of initiation of IV antimicrobial therapy. In the outpatient setting, patients should be evaluated weekly during the initial 4 to 8 weeks of therapy.^{5,11} A reduction in CRP should be seen within 1 week of therapy and should be monitored weekly throughout therapy for a continued downward trend.^{5,8} ESR can also be monitored weekly, although normalization will be slower than for CRP.⁸ Patients should also be monitored for antimicrobial tolerability and toxicity (Table 81-2).

If poor response is noted, the following should be evaluated: (a) patient adherence, (b) significant drug–drug or drug–food interactions, (c) appropriate dosage to achieve therapeutic concentrations, (d) development of antimicrobial resistance necessitating a change in the treatment regimen, (e) need for additional imaging studies, and (f) diagnostic reevaluation. Treatment is considered successful if all clinical signs and symptoms are resolved and all laboratory tests have returned to normal following 4 to 8 weeks of appropriate treatment. Due to high rates of relapse, patients should have medical follow-up for at least 1 year following resolution of symptoms. Patients should be evaluated at 3- to 6-month intervals for any clinical manifestations of recurring infection and continued normalization of laboratory tests. Follow-up imaging studies at 1 to 2 years may be useful in some patients to confirm therapeutic success.

Table 81-2

Monitoring Considerations for Select Antistaphylococcal Agents

Antimicrobial	Monitoring Considerations
Daptomycin	Muscle pain or weakness particularly of the distal extremities; monitor CPK weekly with more frequent monitoring in patients with renal insufficiency or receiving (or recent discontinuation) of HMG-CoA reductase inhibitors Consider temporarily discontinuing HMG-CoA reductase inhibitors while patient receiving daptomycin
Linezolid	Myelosuppression: monitor CBC once weekly if more than 2 weeks of therapy Mild MAO inhibitor; evaluate for potential drug–drug or drug–food interactions Peripheral and/or optic neuropathy has been reported with long-term therapy; perform routine neurologic and ophthalmic evaluations in these patients
Vancomycin	Targeted steady state trough is 15–20 mcg/mL (15–20 mg/L; 10–14 μmol/L) for serious infections such as osteomyelitis Renal dysfunction: monitor weekly renal function (BUN/SCr) and troughs in stable patients Potential for additive renal toxicity if being coadministered with a nephrotoxic agent (e.g., aminoglycoside)

BUN, blood urea nitrogen; CBC, complete blood count; CPK, creatine phosphokinase; MAO, monoamine oxidase; SCr, serum creatinine.

From Refs. 1, 3, 5, 6, 10, 14, 18, 21, 31, 34, 35, and 38.

Patient Encounter, Part 3: The Medical History, Physical Exam, and Diagnostic Tests

PMH: Type 1 diabetes mellitus

SH: Tobacco smoker (2 packs per day for the past 20 years), denies alcohol and illicit drug use. Self-employed

Allergies: NKDA

Meds: Novolin 70/30: 40 units every morning and at bedtime

PE:

Gen: No apparent distress with tenderness and pain in the region of the nonhealing skin ulcer

Skin: 4 cm ulcer on the 5th metatarsal with purulent drainage

VS: BP 130/85 mm Hg, P 72 beats/min, RR 15 breaths/min, T 36.9°C (98.4°F), ht 5 ft 9 in (175 cm), wt 77.3 kg (170 lb)

Labs: WBC $7 \times 10^3/\text{mm}^3$ ($7 \times 10^9/\text{L}$), BUN 19 mg/dL (6.8 mmol/L), serum creatinine (Scr) 0.9 mg/dL (80 μmol/L), fasting blood glucose 290 mg/dL (16.1 mmol/L), ESR 70 mm/h, CRP 74 mg/dL (740 mg/L)

Microbiology: Culture from bone biopsy during debridement grew *S. aureus* (sensitive to linezolid, vancomycin, TMP/SMX but resistant to oxacillin, erythromycin, and clindamycin) and *P. aeruginosa* (sensitive to all antibiotics tested including amikacin, cefepime, levofloxacin, meropenem, piperacillin, tobramycin)

Based on the information presented, create a care plan for this patient's osteomyelitis. Your plan should include:

(a) Goals of therapy

(b) Patient-specific detailed therapeutic plan

(c) Nonpharmacologic interventions

(d) Follow-up plan to determine whether outcomes have been achieved

Patient Encounter, Part 4

The patient received 4 weeks of IV antimicrobial therapy following debridement. The patient has shown clinical and laboratory improvement. The multidisciplinary medical team plans to complete therapy with an oral antibiotic.

What oral antimicrobial therapy would you recommend for this patient?

Evaluate the patient's medication profile for drug–drug interactions.

Counsel the patient regarding this drug therapy.

Patient Care and Monitoring

- 10 Assess the patient's symptoms and laboratory test results to determine whether patient-directed therapy is appropriate.
2. Obtain a thorough history of prescription, nonprescription, and natural drug product use.
3. Educate the patient on lifestyle modifications that will reduce the risk of recurrent infections.
4. Develop a plan to assess the effectiveness of antimicrobial therapy.
5. Evaluate the patient for the presence of adverse drug reactions, drug allergies, and drug interactions.
6. Stress the importance of adherence to the therapeutic regimen.
7. Provide patient education with regard to disease state and drug therapy. Explain the following:
 - Causes of osteomyelitis
 - Complications associated with osteomyelitis
 - The drug, dose, duration, and route of administration of the patient's antimicrobial regimen
 - Optimal medication administration time for the patient's lifestyle and other concurrent medications
 - Available options for missed dose(s)
 - Adverse effects that may occur
 - Provide patient education monographs for antibiotic(s)

Disclaimer

The views expressed in this chapter are those of the authors and do not necessarily reflect the position or policy of the Department of Veterans Affairs or the United States government.

Abbreviations Introduced in This Chapter

BUN	Blood urea nitrogen
CBC	Complete blood count
CRP	C-reactive protein
CPK	Creatine phosphokinase
CT	Computed tomography
CYP	Cytochrome P-450 isoenzyme
ESR	Erythrocyte sedimentation rate
IV	Intravenous
LFT	Liver function test
MAO	Monoamine oxidase
MRI	Magnetic resonance imaging
MRSA	Methicillin-resistant <i>Staphylococcus aureus</i>
MSSA	Methicillin-sensitive <i>Staphylococcus aureus</i>
Scr	Serum creatinine
TMP-SMX	Trimethoprim-sulfamethoxazole
UTI	Urinary tract infection
WBC	White blood cell

Self-assessment questions and answers are available at <http://mhpharmacotherapy.com/pp.html>.

Sepsis and Septic Shock

S. Scott Sutton, Christopher M. Bland, and
Gowtham A. Rao

LEARNING OBJECTIVES

● **Upon completion of the chapter, the reader will be able to:**

1. Compare and contrast the definitions of syndromes related to sepsis.
2. Identify the pathogens associated with sepsis.
3. Discuss the pathophysiology of sepsis as it relates to pro- and anti-inflammatory mediators.
4. Identify patient symptoms as early or late sepsis and evaluate diagnostic and laboratory tests for patient treatment and monitoring.
5. Assess complications of sepsis and discuss their impact on patient outcomes.
6. Design desired treatment outcomes for septic patients.
7. Formulate a treatment and monitoring plan (pharmacologic and nonpharmacologic) for septic patients.
8. Evaluate patient response and devise alternative treatment regimens for nonresponding septic patients.

KEY CONCEPTS

- 1 Sepsis is a continuum of stages defined by physiologic measures and signs and symptoms of a sepsis process.
- 2 Gram-positive and gram-negative bacteria, fungal species, and viruses may cause sepsis.
- 3 Inflammation is the key factor in the development of sepsis. Patients with severe infections, trauma, debilitating conditions, or an immunocompromised status may experience an imbalance among inflammatory mediators that progresses to sepsis.
- 4 The cumulative burden of sepsis complications is the leading factor of mortality. The risk of death increases 20% with failure of each additional organ. Severe sepsis averages two failed organs, with a mortality rate of 40%.
- 5 Treatment is aimed at early goal-directed resuscitation; reducing or eliminating organ failures; treating and eliminating the source of infection; avoiding adverse reactions of treatment; and providing cost-effective therapy.
- 6 Appropriate empiric anti-infective therapy administered within 1 hour of the recognition of sepsis decreases complications and 28-day mortality.

Sepsis is a continuum of physiologic stages characterized by infection, systemic inflammation, and hypoperfusion with widespread tissue injury.¹ 1 The American College of Chest Physicians and the Society of Critical Care Medicine developed definitions to utilize for sepsis (Table 82-1).² *Physiologic parameters categorize patients as having bacteremia, infection, systemic inflammatory response syndrome (SIRS), sepsis, severe sepsis, septic shock, or multiple-organ dysfunction syndrome (MODS).*² Standardized definitions have been developed for infections in critically ill patients.³

EPIDEMIOLOGY AND ETIOLOGY

Sepsis is the leading cause of morbidity and mortality for critically ill patients and the tenth leading cause of death overall.^{1,4} Additionally, care of septic patients has a significant economic impact in the United States.^{1,4-6}

Risk factors for sepsis include age, cancer, immunodeficiency, chronic organ failure, genetic factors (male sex and nonwhite ethnic origin in North America), and bacteremic patients.^{4,7-10} Pulmonary, GI, genitourinary, and bloodstream infections account for the majority of sepsis cases.^{4,7,8}

Table 82-1

Definitions Related to Sepsis

Bacteremia (fungemia): Presence of viable bacteria or fungi in the bloodstream.

Infection: Inflammatory response to invasion of normally sterile host tissue by microorganisms.

SIRS: A systemic inflammatory response to a variety of clinical insults that can be infectious, but can have a noninfectious etiology. The response is manifested by two or more of the following conditions: temperature greater than 38.0°C (100.4°F) or less than 36.0°C (96.8°F); pulse greater than 90 beats/min; respiratory rate greater than 20 breaths/min or $Paco_2$ less than 32 torr or mm Hg (4.26 kPa); WBC count greater than $12 \times 10^3/mm^3$ ($12 \times 10^9/L$), less than $4 \times 10^3/mm^3$ ($4 \times 10^9/L$), or greater than 10% (0.10) immature (band) forms.

Sepsis: The SIRS and documented infection (culture or Gram stain of blood, sputum, urine, or normally sterile body fluid positive for pathogenic microorganisms).

Severe sepsis: Sepsis associated with organ dysfunction due to hypoperfusion or hypotension (systolic blood pressure less than 90 mm Hg). Hypoperfusion and perfusion abnormalities may include, but are not limited to, lactic acidosis, oliguria, or acute alteration in mental status.

Septic shock: Sepsis with hypotension, despite fluid resuscitation, along with the presence of perfusion abnormalities. Patients who are on inotropic or vasopressor agents may not be hypotensive at the time perfusion abnormalities are measured.

MODS: Presence of altered organ function requiring intervention to maintain homeostasis.

MODS, multiple-organ dysfunction syndrome; $Paco_2$, partial pressure of carbon dioxide; SIRS, systemic inflammatory response syndrome.

From American College of Chest Physicians, Society of Critical Care Medicine Consensus Conference. Definitions for sepsis and organ failure and guidelines for the use of innovative therapies in sepsis. Crit Care Med 1992;20:864–874.

2 Gram-positive and gram-negative bacteria, fungal species, and viruses cause sepsis (Table 82-2). Gram-positive infections account for 30% to 50% of sepsis and septic shock cases.^{4,7,8} The percentages of gram-negative, polymicrobial, and viral sepsis cases are 25%, 25%, and 4%, respectively.^{4,7,8,11} Multidrug-resistant (MDR) bacteria are responsible for approximately 25% of sepsis cases, are difficult to treat, and increase mortality.^{7,8} The rate of fungal infections has significantly increased.⁴ *Candida albicans* is the most common fungal species; however, non-*albicans* species (*C. glabrata*, *C. krusei*, and *C. tropicalis*) have increased from 24% to 46%.^{4,11,12} Other fungi identified as causes of sepsis include species of *Cryptococcus*, *Coccidioides*, *Fusarium*, and *Aspergillus*.

PATHOPHYSIOLOGY

The development of sepsis is complex and multifactorial. The normal host response to infection is designed to localize and control bacterial invasion and initiate repair of injured tissue through phagocytic cells and inflammatory mediators.¹ Sepsis results when the inflammatory response becomes

Table 82-2

Pathogens in Sepsis

Organism	Frequency (%)
Gram-positive bacteria	30–50
Methicillin-susceptible <i>Staphylococcus aureus</i>	14–24
Methicillin-resistant <i>Staphylococcus aureus</i>	5–11
Other <i>Staphylococcus</i> species	1–3
<i>Streptococcus pneumoniae</i>	9–12
Other <i>Streptococcus</i> species	6–11
<i>Enterococcus</i> species	3–13
Anaerobes	1–2
Other gram-positive bacteria	1–5
Gram-negative bacteria	25–30

exaggerated and extends to normal tissue distant from the initial tissue site.

Pro- and Anti-inflammatory Mediators

3 The key factor in the development of sepsis is inflammation, which is intended to be a local and contained response to infection or injury. Infection or injury is controlled through pro- and anti-inflammatory mediators. Proinflammatory mediators facilitate clearance of the injuring stimulus, promote resolution of injury, and are involved in processing of damaged tissue.^{1,13–16} To control the intensity and duration of the inflammatory response, anti-inflammatory mediators are released that act to regulate proinflammatory mediators.^{15,16} The balance between pro- and anti-inflammatory mediators localizes infection/injury of host tissue.^{13–16} However, systemic responses ensue when equilibrium in the inflammatory process is lost.

The inflammatory process in sepsis is linked to the coagulation system. Proinflammatory mediators may be procoagulant and antifibrinolytic, whereas anti-inflammatory mediators may be fibrinolytic. A key factor in the inflammation of sepsis is activated protein C, which enhances fibrinolysis and inhibits inflammation. Protein C levels are decreased in many septic patients.

CLINICAL PRESENTATION AND DIAGNOSIS

The clinical presentation of sepsis varies, and the rate of development of clinical manifestations may differ from patient to patient. Immunosuppressed patients and patients

Physical Examination Results in Sepsis

HEENT: Scleral icterus, dry mucous membranes, pinpoint pupils, dilated and fixed pupils, nystagmus

Neck: Jugular venous distention, carotid bruits

Lungs: Crackles (rales), consolidation, egophony, absent breath sounds

CV: Irregular rhythm, S₃ gallop, murmurs

Abd: Tense, distended, tender, rebound, guarding, hepatosplenomegaly

Rectal: Decreased tone, bright red blood

Exts: Swollen calf, disparity of blood pressure between upper extremities

Neurologic: Agitation, confusion, delirium, obtundation, coma

Skin: Cold, clammy, or warm; hyperemic skin; rashes

with meningococemia or *Pseudomonas aeruginosa* infections may progress to late sepsis more rapidly.

A physical examination should be performed rapidly and efficiently, with efforts directed toward uncovering the most likely cause of sepsis. The patient may not provide any

medical history; therefore, historical data may be obtained from medical records and/or family. The patient's medical condition, recent illnesses, infections, or activities may provide valuable information about the cause of sepsis.

Diagnostic and Laboratory Tests

- Microbiologic cultures should be obtained before anti-infective therapy is initiated. However, cultures take 6 to 48 hours for results to be completed and often are negative (no growth of bacterial organisms). Negative cultures do not rule out infection. Administering anti-infectives before obtaining cultures may lead to a false-negative culture.

Two sets of blood cultures should be obtained to rule out contamination. At least one set should be drawn percutaneously and one drawn through each vascular access device, unless the device was recently (less than 48 hours) inserted.

Cultures of urine (with urinalysis), respiratory secretions, cerebrospinal fluid, and wounds should be obtained if the clinical situation suggests infection of these specific fluids, tissues, or organs. Laboratory tests should be performed to evaluate infection or complications of sepsis, including complete blood count (CBC) with differential, coagulation parameters, basic metabolic panel, serum lactate concentration, and arterial blood gas.

The use of biomarkers of sepsis has been controversial. Measurement of endotoxin, procalcitonin, or other markers in blood or serum is not routinely recommended. Concentrations

Clinical Presentation and Diagnosis of Sepsis

The signs and symptoms of septic patients are referred to as early and late sepsis.

Signs and Symptoms

The initial clinical signs and symptoms represent early sepsis, and they include fever, chills, and change in mental status. Other signs and symptoms include:

- **Tachycardia**
- **Tachypnea**
- Nausea and vomiting
- Hyperglycemia
- Myalgias
- Lethargy and malaise
- **Proteinuria**
- Leukocytosis
- Hypoxia
- Hyperbilirubinemia

Septic patients may have an elevated, low, or normal temperature. The absence of fever is common in neonates and elderly patients. Hypothermia is associated with a poor prognosis. Hyperventilation may occur before fever and

chills and may lead to respiratory alkalosis. Disorientation and confusion may develop early in septic patients, particularly in the elderly and patients with preexisting neurologic impairment. Disorientation and confusion may be related to the infection or due to sepsis signs and symptoms (e.g., hypoxia).

- Late sepsis represents a slow process that develops over several hours of hemodynamic instability. Signs and symptoms of late sepsis include:

- Lactic acidosis
- **Oliguria**
- **Leukopenia**
- Thrombocytopenia
- Myocardial depression
- Pulmonary edema
- Hypotension
- Hypoglycemia
- GI hemorrhage

Oliguria often follows hypotension because of decreased perfusion. Metabolic acidosis ensues because of diminished clearance by the kidneys and liver of lactic acid.

Patient Encounter, Part 1

A 71-year-old man with a history of a stroke resides in a long-term care facility and is reported to have high fevers, shaking chills, and mental status changes. His providers state that he has been confused all day. The patient has a history of a chronic Foley catheter since his stroke in 2011.

What information is suggestive of infection and/or sepsis?

Does this patient have factors that could lead to the development of sepsis?

What information do we need in order to confirm or diagnose sepsis in this patient?

of procalcitonin in serum are usually increased in sepsis, but fail to differentiate between infection and inflammation. However, procalcitonin has a high negative predictive value and could allow for the discontinuation of antibiotics.

Complications of Sepsis

- 4 *Recognition and treatment of sepsis complications, particularly organ failure, is essential to improve outcomes. The cumulative burden of sepsis complications is the leading factor of mortality. The risk of death increases 20% with failure of each additional organ. Severe sepsis averages two failed organs, with a mortality rate of 40%. The most common complications are disseminated intravascular coagulation, acute respiratory distress syndrome (ARDS), acute kidney injury (AKI), and hemodynamic compromise.*

► Disseminated Intravascular Coagulation

- Disseminated intravascular coagulation (DIC) complicates 25% to 50% of septic patients and is an independent predictor of mortality.¹⁷ DIC is a syndrome characterized by coagulation and activation and production of proinflammatory **cytokines**, culminating in intravascular fibrin formation and deposition in the microvasculature. Bleeding results from consumption and exhaustion of coagulation proteins and platelets, because of continued activation of the coagulation system.¹⁷ DIC may produce AKI, hemorrhagic necrosis of the GI mucosa, liver failure, acute pancreatitis, ARDS, and pulmonary failure.¹⁷

► Acute Respiratory Distress Syndrome

- ARDS is an acute and persistent lung inflammatory process with increased vascular permeability leading to severe hypoxia that can affect 20% of septic shock patients.^{18,19} Lung deterioration is a multiphase process that begins after infection, injury, or exacerbation of the medical condition. The patient appears stable; however, the chest radiograph reveals parenchymal infiltrates. At this time the patient has pulmonary edema and may be hyperventilating.^{18,19} During the

next phase, the patient develops respiratory insufficiency and pulmonary edema can be seen on chest radiographs. Severe hypoxia may ensue, leading to mechanical ventilation.

► Acute Kidney Injury

- AKI occurs in 19% of septic patients, 25% of severe septic patients, and 51% of septic shock patients.²⁰ Sepsis and AKI together have a 70% mortality, compared with 45% among patients with AKI alone.²⁰ AKI leads to fluid in the extravascular space, including the lungs, followed by impairment in gas exchange and severe hypoxemia. Hypoxemia will exacerbate ischemia and organ damage. Renal replacement therapy with the use of continuous venovenous hemofiltration, continuous venovenous hemofiltration, and dialysis or intermittent hemodialysis can be used to manage volume and electrolytes.²⁰

► Hemodynamic Compromise

- Arterial vasodilatation is the hallmark of hemodynamic effects related to sepsis. High cardiac output and low systemic vascular resistance characterize sepsis. Inflammatory cytokines (i.e., tumor necrosis factor- α [TNF- α]) and endotoxin directly depress cardiovascular function. Persistent hypotension offsets the delivery of oxygen to tissues (DO_2) and oxygen consumption by tissues (VO_2).²¹ Certain tissues may receive adequate oxygen during sepsis; however, in other tissues, oxygen demands may not be met because of decreased perfusion. This perfusion defect is accentuated by increased precapillary atrioventricular shunt. If perfusion decreases, oxygen extraction increases, and the atrioventricular oxygen gradient widens. Cellular DO_2 is decreased, but VO_2 remains unchanged. If perfusion decreases significantly, reserve DO_2 will be exceeded, and tissue ischemia results. Tissue ischemia leads to organ failure. Therefore, increasing oxygen delivery or decreasing oxygen consumption in a hypermetabolic patient should optimize systemic DO_2 relative to VO_2 .²¹

TREATMENT AND OUTCOME EVALUATION

Desired Outcomes

- 5 *The primary treatment goal of sepsis is to prevent morbidity and mortality. Treatment is aimed at early goal-directed resuscitation, reducing or eliminating organ failures, treating and eliminating the source of infection, avoiding adverse reactions of treatment, and providing cost-effective therapy.*²²⁻²⁸

General Approach to Treatment

The speed and appropriateness of therapy administered in the initial hours after sepsis develops influences outcome, as is the case for acute myocardial infarction and cerebrovascular accidents.²²

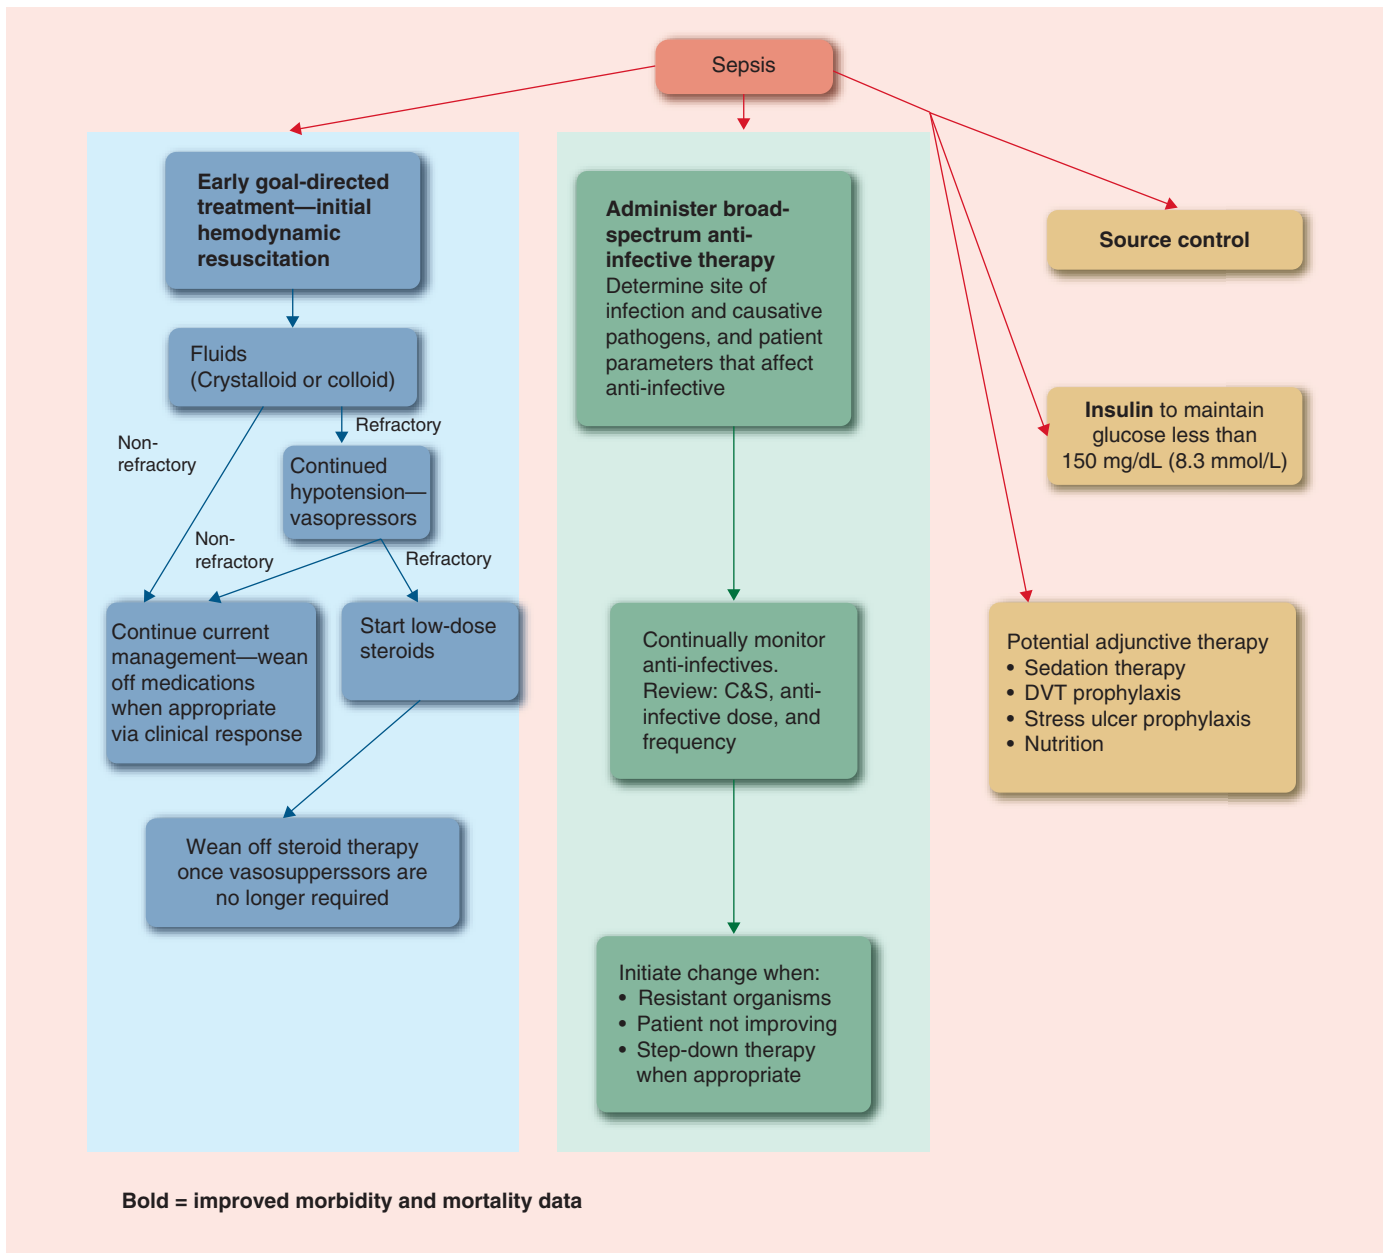

FIGURE 82-1. Therapeutic approach to sepsis. (C&S, culture and sensitivity.)

Pertinent issues in the management of septic patients are as follows (Fig. 82-1):²⁴

1. Early goal-directed resuscitation of septic patients during the first 6 hours after recognition.
2. Early administration of broad-spectrum anti-infective therapy.
3. Hydrocortisone for septic shock patients refractory to resuscitation and vasopressors.
4. Glycemic control via infusion of insulin and glucose, to maintain a glucose level less than 150 mg/dL (8.3 mmol/L).
5. Adjunctive therapies: nutrition, deep vein thrombosis (DVT) prophylaxis, stress ulcer prophylaxis, and sedation for mechanically ventilated patients.

Pharmacologic Therapy

- Treatment for sepsis focuses on infection, inflammation, hypoperfusion, and widespread tissue injury. Septic patients may require multiple simultaneous treatment regimens to achieve desired outcomes of decreased morbidity and mortality.

Initial Resuscitation

- 5** *Early goal-directed resuscitation decreases 28-day mortality in septic patients.* The treatment goals of sepsis-induced hypoperfusion (hypotension or lactic acidosis) during the first 6 hours include^{24,27–29}:

Patient Encounter, Part 2: Medical History, Physical Exam, and Diagnostic Tests

PMH: stroke (2011); hypertension; diabetes mellitus; chronic renal insufficiency (baseline serum creatinine 1.6 mg/dL [141 μmol/L])

FH: Father had stroke at age 62; mother has history of hypertension and diabetes mellitus

SH: Retired accountant; nonsmoker

Allergies: NKDA

Meds: Aspirin 81 mg daily; glipizide 10 mg once daily; hydrochlorothiazide 25 mg once daily; lisinopril 20 mg once daily

ROS: Unable to obtain; patient has become more confused

PE:

VS: BP 89/59 mm Hg, P 93 beats/min, RR 29 breaths/min, T 39.3°C (102.7°F)

Lungs: Decreased breath sounds

Labs: Serum creatinine 2.7 mg/dL (239 μmol/L); glucose 298 mg/dL (16.5 mmol/L); white blood cells: leukocytosis with left shift. APACHE II score 26.

Cultures: Blood, urine, and respiratory cultures pending.

Radiology: No pulmonary infiltrates seen on chest x-ray.

According to the patient's parameters, what does he have (i.e., systemic inflammatory response syndrome, sepsis, or septic shock)?

Identify treatment goals.

- Central venous pressure: 8 to 12 mm Hg (12 to 15 mm Hg for intubated patients)
- Mean arterial pressure greater than or equal to 65 mm Hg
- Urine output greater than or equal to 0.5 mL/kg/h
- Central venous or mixed venous oxygen saturation greater than or equal to 70% (0.70) or 65% (0.65), respectively.

• Crystalloid (such as 0.9% sodium chloride or lactated Ringer's solutions) or colloid fluids (5% albumin or 6% hetastarch) are used for resuscitation, and clinical studies comparing the fluids have found them to be equivalent.²⁹ Crystalloids require more fluids, which may lead to more edema (utilize caution in patients at risk for fluid overload, e.g., congestive heart failure and ARDS); however, colloids are significantly more expensive. Most patients require aggressive fluid resuscitation during the first 24 hours because of persistent venodilation and capillary leak.²⁴

Monitoring Parameters and Alternative Treatment for Resuscitation^{24,27-29}

- An elevated serum lactate concentration may be an early marker for tissue hypoperfusion.

- Administer a fluid challenge to hypovolemic patients (hypotension or lactic acidosis): crystalloids 500 to 1,000 mL; colloids 300 to 500 mL. Administer over 30 minutes and repeat based on response (increase in blood pressure and urine output).
- Patients will require maintenance fluid therapy.

Anti-infective Therapy

- **6** *Appropriate empiric anti-infective therapy decreases 28-day mortality compared with inappropriate empiric therapy (24% versus 39%).^{22,23,30} Additionally, appropriate therapy administered within 1 hour of sepsis recognition also decreases complications and mortality.^{22,23,30} Empiric anti-infective therapy should include one, two, or three drugs, depending on the site of infection and causative pathogens (Table 82-3). Anti-infective clinical trials in sepsis and septic shock patients are scarce and have not demonstrated differences among agents; therefore, factors that determine selection are:*

- Site of infection
- Causative pathogens
- Community- or nosocomial-acquired infection
- Immune status of patient
- Antibiotic susceptibility and resistance profile for the institution. Clinicians should be cognizant of growing prevalence of bacterial resistance in community and healthcare setting
- Patient history (underlying disease, previous cultures or infections, and drug allergy/intolerance)
- Adverse reactions
- Cost

Anti-infective regimens should be broad-spectrum since there is little margin for error in critically ill patients.

Monitoring and Treatment Strategies to Maximize Efficacy and Minimize Toxicity for Anti-infectives

- Administer broad-spectrum anti-infectives for initial therapy, as early as possible and within first hour of recognition of sepsis.
- Appropriate cultures should be obtained before initiating antibiotic therapy, but should not prevent prompt administration of treatment.
- Administer antibiotics that concentrate at the site of infection.
- Monitor patient parameters to ensure adequate dosing.
- Abnormal renal and hepatic function will increase drug concentration and predispose the patient to toxicity.
 - Ensure antibiotic dosing is changed to normal doses once renal dysfunction has resolved to limit the development of antimicrobial resistance.
- Septic patients may have altered volume of distribution due to initial resuscitation.

Table 82-3

Empirical IV Antimicrobial Regimens in Sepsis

Infection (Site or Type)	Community Acquired	Hospital Acquired
Urinary tract	Third-generation cephalosporin (ceftriaxone) or fluoroquinolone (levofloxacin or ciprofloxacin)	Antipseudomonal penicillin or antipseudomonal cephalosporin or antipseudomonal carbapenem plus aminoglycoside
Community-acquired pneumonia	Third-generation cephalosporin or ampicillin-sulbactam plus a macrolide or fluoroquinolone (levofloxacin or moxifloxacin)	
Healthcare-associated, ventilator-associated, or nosocomial pneumonia (early onset; no risk factors for MDR pathogens)		Third-generation cephalosporin or fluoroquinolone or ampicillin-sulbactam or ertapenem
Healthcare-associated, ventilator-associated, or nosocomial pneumonia (late onset and/or MDR pathogen risk factors)		Antipseudomonal penicillin or antipseudomonal cephalosporin or antipseudomonal carbapenem plus aminoglycoside or antipseudomonal fluoroquinolone plus vancomycin or linezolid
Intra-abdominal	Ertapenem or ciprofloxacin or levofloxacin + metronidazole or moxifloxacin	Piperacillin-tazobactam or imipenem or meropenem or cefepime plus metronidazole or ciprofloxacin or levofloxacin plus metronidazole
Skin and soft-tissue Catheter-related Unknown source of infection	Nafcillin or ceftazidim	Ceftriaxone ± vancomycin Vancomycin Antipseudomonal penicillin ± antipseudomonal cephalosporin or antipseudomonal carbapenem plus aminoglycoside plus vancomycin

MDR, multidrug resistant.

From Refs. 31–37.

Clinical Parameters for Aminoglycosides

Tobramycin is more active against *Pseudomonas aeruginosa* than gentamicin, whereas gentamicin is more active against *Serratia* species. Amikacin is the most potent aminoglycoside against the Enterobacteriaceae; however, it should be reserved for bacterial organisms resistant to gentamicin and tobramycin. Select an aminoglycoside based on:

- Local susceptibility patterns
- Patient parameters (infection and microbiologic culture history)
- Cost

Aminoglycosides may be administered by traditional methods (1.5 to 2 mg/kg every 8 hours) or by an extended-dosing interval method (7 mg/kg every 24 hours) in patients with normal renal function. The extended-dosing method maximizes the pharmacodynamic properties of aminoglycosides (concentration-dependent killing and postantibiotic effect) and reduces the incidence of nephrotoxicity. Extended-dosing interval aminoglycosides have prolonged drug-free periods, during which the saturable uptake of aminoglycosides into the proximal renal tubular cells can be completed. Extended-dosing interval aminoglycosides should not be used in pediatric patients, burn victims, pregnant patients, or patients with preexisting or progressive renal insufficiency.³⁸

- Reevaluate the initial regimen daily to optimize activity, prevent development of resistance, reduce toxicity, and decrease costs.
- Initiate step-down therapy based on microbiologic cultures to: prevent resistance, reduce toxicity, and cost.
- Monotherapy is equivalent to combination therapy once a causative pathogen has been identified. Empiric therapy should include combination regimens to ensure coverage of causative organisms.

Selection of Antimicrobial Agents

► Urinary Tract Infections

- Septic patients with a community-acquired urinary tract infection should be treated with a third-generation cephalosporin (ceftriaxone or cefotaxime) or a fluoroquinolone (ciprofloxacin or levofloxacin). **2** The causative pathogen is commonly an enteric gram-negative bacilli (i.e., *Escherichia coli*). Nosocomially acquired urinary tract infections are often related to catheters and are caused by fermenting and nonfermenting (*Pseudomonas*) gram-negatives and enterococci (see Table 82-3). β -Lactam/ β -lactamase inhibitor combinations (i.e., piperacillin-tazobactam), an antipseudomonal cephalosporin (i.e., cefepime or ceftazidime), or an antipseudomonal carbapenem (imipenem, meropenem, or doripenem), plus an aminoglycoside are recommended treatment options until susceptibilities are known (see Table 82-3).³¹

► Community-Acquired Pneumonia

- Septic patients with community-acquired pneumonia (CAP) are treated with a third-generation cephalosporin (ceftriaxone or cefotaxime) plus a macrolide (azithromycin or clarithromycin) or doxycycline, or a respiratory fluoroquinolone (levofloxacin, moxifloxacin, gemifloxacin) (see Table 82–3).³²
- 2** The causative organisms for CAP are *Streptococcus pneumoniae*, *Haemophilus influenzae*, *Moraxella catarrhalis*, and atypical organisms (*Mycoplasma pneumoniae*, *Chlamydia pneumoniae*, and *Legionella pneumophila*). *S. pneumoniae* accounts for 60% of the deaths associated with CAP and is resistant to penicillin and macrolides (multidrug resistant *S. pneumoniae*; MDRSP) 30% to 40% of the time.^{32,33} Controversy exists relating to the clinical significance of this resistance for nonmeningitis infections. Respiratory fluoroquinolones (levofloxacin, moxifloxacin, and gemifloxacin) may be utilized for MDRSP; however, clinical data have not shown them to be superior to cephalosporins plus a macrolide or doxycycline. The Centers for Disease Control and Prevention recommends reserving fluoroquinolones as last-line options in order to maintain their broad-spectrum antibacterial activity.³³ Treatment of methicillin-resistant *Staphylococcus aureus* (MRSA) or *P. aeruginosa* is a potential reason to modify the standard empirical regimen for CAP. Risk factors for the development of these pathogens are listed in Table 82–4.

► Hospital-, Ventilator-, and Healthcare-Associated Pneumonia

- Treatment for septic patients with hospital-acquired, ventilator-acquired, and healthcare-associated pneumonia is dependent on risk factors for MDR organisms (Fig. 82–2). Recommended treatment for patients with no MDR risk factors are third-generation cephalosporins (ceftriaxone or cefotaxime), fluoroquinolones (levofloxacin and moxifloxacin),

Table 82–4

Risk Factors for MRSA, *Pseudomonas*, and Gram-Negatives in Community-Acquired Pneumonia

Methicillin-Resistant *Staphylococcus aureus*
 End-stage renal disease
 Injection drug abuse
 Prior influenza
 Prior antibiotic therapy (especially fluoroquinolones)
Pseudomonas aeruginosa
 Structural lung disease
 Exacerbations of severe chronic obstructive pulmonary diseases leading to frequent steroid and/or antibiotic use, as well as prior antibiotic therapy
 Other Gram-negatives (*Klebsiella pneumoniae* or *Acinetobacter* species)
 Chronic alcoholism

From Heffelfinger JD, Dowell SF, Jorgensen JH, et al. Management of community-acquired pneumonia in the era of pneumococcal resistance: A report from the Drug-Resistant *Streptococcus pneumoniae* Therapeutic Working Group. *Arch Intern Med* 2000;160:1399–1408.

Clinical Dilemma About Antibiotic-Resistant Bacteria

- MRSA is a common hospital-acquired pathogen and is also increasing in the community. MRSA presented a problem in the past because it required treatment with vancomycin. Community-acquired MRSA presents a major therapeutic challenge. MRSA can cause pneumonia, cellulitis, and other infections. Clinicians should be aware of the rate of hospital and community MRSA in their geographic area. New treatment options are available for MRSA. They include linezolid, tigecycline, daptomycin, telavancin, and ceftaroline. Prospective clinical trials have not demonstrated improved efficacy of these agents over vancomycin.^{39,40}
- Extended-spectrum β -lactamase (ESBL) gram-negative bacteria are increasing in frequency. ESBLs most often occur in fermenting (lactose positive) Enterobacteriaceae and may be difficult to treat. ESBLs most commonly occur in urinary tract infections in patients with chronic Foley catheters, but they can occur in any infection. Carbapenem antibiotics are the most utilized agents for the treatment of ESBL infections.

ampicillin-sulbactam, or ertapenem (see Table 82–3).³⁴ Recommended treatment for patients with MDR risk factors are: β -lactam/ β -lactamase inhibitor combinations (piperacillin/tazobactam), antipseudomonal cephalosporin (cefepime or ceftazidime), or an antipseudomonal carbapenem (imipenem, meropenem, or doripenem), plus an aminoglycoside, plus vancomycin or linezolid (see Table 82–3).³⁴ If an aminoglycoside is undesirable, an antipseudomonal fluoroquinolone (ciprofloxacin or levofloxacin) may be utilized with a antipseudomonal β -lactam (piperacillin/tazobactam, cefepime, ceftazidime, imipenem, meropenem, or doripenem).

► Skin and Soft-Tissue Infections

- 2** Community-acquired skin and soft-tissue infections are caused by *Streptococcus pyogenes* and *S. aureus*. Treatment with nafcillin or cefazolin is recommended (see Table 82–3).³⁵ Local susceptibility rates may warrant empiric coverage for MRSA with anti-MRSA agents, especially in geographical areas with MRSA rates greater than 50%. Soft-tissue infections caused by *S. pyogenes* can lead to streptococcal toxic shock syndrome. Although penicillins and cephalosporins are efficacious, experimental models show clindamycin to be more effective than penicillin.³¹ Hospital-acquired skin and soft-tissue infections are caused by *S. pyogenes*, *S. aureus*, and enteric gram-negatives. Recommended treatment is a third-generation cephalosporin (cefotaxime or ceftriaxone), ampicillin-sulbactam, or ertapenem, plus vancomycin (see Table 82–3).³⁵

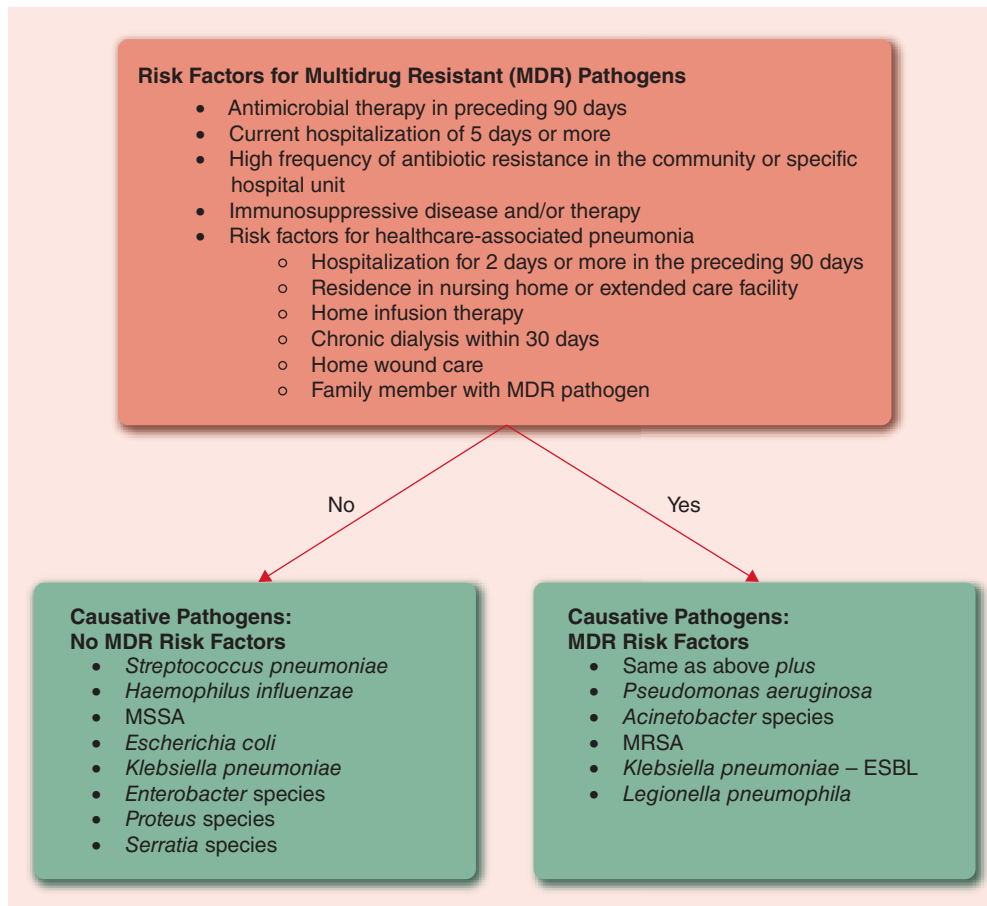

FIGURE 82-2. Risk factors for multidrug-resistant pathogens and causative pathogens for hospital-, ventilator-, and healthcare-associated pneumonia.³⁴ (ESBL, extended-spectrum β -lactamase; MDR, multidrug resistant; MRSA, methicillin-resistant *Staphylococcus aureus*; MSSA, methicillin-sensitive *Staphylococcus aureus*.)

► Intra-Abdominal Infections

2 Intra-abdominal infections are polymicrobial, including enteric aerobes and anaerobes. Patients with community-acquired intra-abdominal infections of mild to moderate severity should be administered antibiotics with activity against enteric gram-negative bacilli, gram-negative anaerobes, and gram-positive cocci. Recommended treatment agents for mild to moderate community-acquired intra-abdominal infections include cefoxitin, cephalosporins (ceftriaxone or cefotaxime) plus metronidazole, fluoroquinolones (levofloxacin, ciprofloxacin) plus metronidazole or moxifloxacin monotherapy, ticarcillin-clavulanic acid, and ertapenem (see Table 82-3).³⁶ Patients with nosocomial-acquired, high-severity intra-abdominal infections or immunosuppression should receive empiric treatment with broad-spectrum antibiotics. Broad-spectrum antibiotics such as antipseudomonal β -lactam/ β -lactamase inhibitor combinations (piperacillin/tazobactam), carbapenems (imipenem, meropenem, or doripenem), antipseudomonal cephalosporins (cefepime or ceftazidime) plus metronidazole, or antipseudomonal fluoroquinolones (ciprofloxacin or levofloxacin) plus metronidazole are recommended (see Table 82-3).³⁶

Antifungal Therapy

2 Septic patients not responding to conventional antibiotics should be evaluated for fungal infections. *Candida albicans* is the most common fungal species; however, the prevalence of nonalbicans species is increasing. Amphotericin B is utilized in septic patients with fungal or suspected fungal infections because of greater activity against nonalbicans *Candida*

Patient Encounter, Part 3

Treatment and Outcome Evaluation

The patient has continued hypotension despite previous intervention. Continued hypoxia has led to mechanical ventilation. The patient's serum creatinine has risen to 6.8 mg/dL (601 μ mol/L). Blood and urine cultures reveal lactose-positive gram-negative rods.

Design a therapeutic regimen for this patient. Include all necessary medications.

Clinical Controversy

Enterococcus species are normal inhabitants of the GI tract, but should empiric treatment of intra-abdominal infections have activity against *Enterococcus* species? Empiric treatment that covered *Enterococcus* species in intra-abdominal infections was equivalent to empiric treatment that lacked enterococcal coverage. Routine coverage for *Enterococcus* is not necessary for patients with community-acquired intra-abdominal infections. However, in patients with nosocomial or high-severity infections, enterococcal coverage is warranted.³⁶

compared with fluconazole.³⁷ However, amphotericin B has a significantly higher rate of adverse reactions. Lipid formulations of amphotericin B (amphotericin B cholesteryl sulfate complex, lipid complex, and liposomal amphotericin B) are available that are less nephrotoxic and have decreased infusion-associated side effects. Efficacy among the amphotericin products is equivalent, but the lipid formulations are significantly more expensive. Lipid products are recommended for patients intolerant of conventional amphotericin. Other alternatives for treatment of fungal infections include voriconazole and echinocandins (anidulafungin, caspofungin, micafungin). Data are lacking that demonstrate clinical superiority between agents.

Duration of Anti-Infective Therapy

- Average duration of anti-infective therapy for septic patients is 7 to 10 days. However, the durations vary depending on the site of infection and response to therapy. Step-down therapy from IV to oral anti-infectives is recommended for hemodynamically stable patients, patients afebrile for 48 to 72 hours, patients with normalized WBC, and patients able to take oral medications.

Vasopressors and Inotropic Therapy

- When fluid resuscitation does not provide adequate arterial pressure and organ perfusion, vasopressors and/or inotropic agents should be initiated. Vasopressors are recommended in patients with a systolic blood pressure less than 90 mm Hg or mean arterial pressure (MAP) lower than 60 to 65 mm Hg, after failed treatment with crystalloids.^{24,27,28} Vasopressors and inotropes are effective in treating life-threatening hypotension and improving cardiac index, but complications such as tachycardia and myocardial ischemia require slow titration of the adrenergic agents to restore MAP without impairing stroke volume. Vasopressor therapy may also be required transiently to sustain life and maintain perfusion in the face of life-threatening hypotension, even when fluid resuscitation is in progress and hypovolemia has not yet been corrected. Agents commonly considered for vasopressor or inotropic support include dopamine, dobutamine, norepinephrine, phenylephrine, and epinephrine. Norepinephrine

or dopamine are first-line vasopressors to correct hypotension in septic shock.^{24,27,28}

Norepinephrine is a potent α -adrenergic agent with less pronounced β -adrenergic activity. Doses of 0.01 to 3 mcg/kg/min can reliably increase blood pressure with small changes in heart rate or cardiac index. Norepinephrine is a more potent agent than dopamine in refractory septic shock.^{24,27,28} Norepinephrine induces less arrhythmias compared with dopamine.⁴¹

Dopamine is an α - and β -adrenergic agent with dopaminergic activity. Low doses of dopamine (1 to 5 mcg/kg/min) maintain renal perfusion; higher doses (greater than 5 mcg/kg/min) exhibit α - and β -adrenergic activity and are frequently utilized to support blood pressure and to improve cardiac function. Low doses of dopamine should not be used for renal protection as part of the treatment of severe sepsis.^{24,27,28}

Dobutamine is a β -adrenergic inotropic agent that can be utilized for improvement of cardiac output and oxygen delivery. Doses of 2 to 20 mcg/kg/min increase cardiac index; however, heart rate increases significantly. Dobutamine should be considered in septic patients with adequate filling pressure and blood pressure, but low cardiac index. If used in hypotensive patients, dobutamine should be combined with vasopressor therapy.^{24,27,28}

Milrinone is a phosphodiesterase inhibitor with vasodilatory as well as inotropic actions. Milrinone has a lower incidence of arrhythmias compared with dobutamine. Its vasodilatory properties limit its use in the setting of hypotension due to sepsis.

Phenylephrine is a fast-acting, short-duration α_1 agonist. Phenylephrine has primarily vascular effects and does not impair cardiac or renal function. Phenylephrine is useful when tachycardia limits the use of other vasopressors.^{24,27,28}

Epinephrine is a nonspecific α - and β -adrenergic agonist that can increase cardiac index and produce significant peripheral vasoconstriction. However, it can also increase lactate levels and impair blood flow to the splanchnic system. Because of these undesirable effects, epinephrine should be reserved for patients who fail to respond to traditional therapies.^{24,27,28}

Vasopressin levels are increased during hypotension to maintain blood pressure by vasoconstriction. However, there is a vasopressin deficiency in septic shock. Low, fixed doses of vasopressin increase MAP, leading to the discontinuation of vasopressors. However, routine use of vasopressin with norepinephrine is not recommended because of no difference in mortality compared with norepinephrine monotherapy.⁴² Vasopressin is a direct vasoconstrictor without inotropic or chronotropic effects and may result in decreased cardiac output and hepatosplanchnic flow. Vasopressin use may be considered in patients with refractory shock despite adequate fluid resuscitation and high-dose vasopressors.^{24,27,28}

Steroids

- Stress-induced adrenal insufficiency complicates 9% to 24% of septic patients and is associated with increased mortality.

Patient Encounter, Part 4

During medical rounds, you are asked to discuss clinical trials and resistant bacteria.

What antibiotics are found to be superior in septic patients?

What are examples of resistant bacteria?

Is this patient a candidate for antipseudomonal therapy?

Corticosteroid therapy's effect on mortality in the treatment of septic shock is conflicting. Septic shock patients refractory to resuscitation and vasopressors may be administered IV hydrocortisone 200 to 300 mg/day in three divided doses.^{24,43,44} Patients should be weaned from steroid therapy when vasopressors are no longer required.

Sedation and Neuromuscular Blockade

- Patients with ARDS and progressive hypoxia require mechanical ventilation. Critically ill patients may require sedation when high ventilator settings are used or when patients fight the ventilator. Mechanically ventilated patients should receive sedation by a protocol that includes a daily interruption or lightening of a sedative infusion until the patient is awake.²⁴ The utilization of sedation protocols decreases the duration of mechanical ventilation, length of hospitalization, and tracheostomy rates.

Paralysis usually is reserved for patients in whom sedation alone does not improve the effectiveness of mechanical ventilation. Neuromuscular blockers may lead to prolonged skeletal muscle weakness and should be avoided if possible. Patients requiring neuromuscular blockade should be monitored, and intermittent boluses or continuous infusion should be utilized. Monitor depth of neuromuscular blockade with train-of-four stimulation when using continuous infusion.

Glucose Control

- Glycemic control improves survival in postoperative surgical patients and is recommended in septic patients. Following initial stabilization of septic patients, current guidelines recommend maintaining blood glucose concentrations less than 150 mg/dL (8.3 mmol/L).^{24,45,46} There is an increase in mortality in tightly controlled patients (81 to 108 mg/dL [4.5 to 6.0 mmol/L]) versus moderately controlled patients (less than 180 mg/dL [10.0 mmol/L]). Septic patients with high glucose concentrations should receive insulin and glucose with frequent blood glucose monitoring (every 1 to 2 hours until glucose values and insulin infusion rates are stable, then every 4 hours).

Adjunctive Therapies

- Enteral nutrition is recommended in septic patients to meet the increased energy and protein requirements. Protein

requirements are increased to 1.5 to 2.5 g/kg/day. Nonprotein caloric requirements range from 25 to 40 kcal/kg/day (105 to 167 kJ/kg/day).²⁴

- DVT prophylaxis is recommended for septic patients. Low-dose unfractionated heparin, low-molecular-weight heparin (e.g., enoxaparin or dalteparin), or pentasaccharide therapy (e.g., fondaparinux) may be utilized. Graduated compression stockings or an intermittent compression device is recommended for patients with a contraindication to heparin products (thrombocytopenia, severe coagulopathy, active bleeding, or recent intracerebral hemorrhage).²⁴ Patients with severe sepsis and history of DVT, trauma, or orthopedic surgery should receive a combination of pharmacologic and mechanical therapy unless contraindicated or not practical.
- Stress ulcer prophylaxis is recommended in septic patients. Patients at greatest risk for stress ulcers include those who are coagulopathic, mechanically ventilated (more than 48 hours), and hypotensive. Histamine-receptor antagonists (e.g., ranitidine) are more efficacious than sucralfate, and proton pump inhibitors (e.g., omeprazole) have shown no added benefit over histamine-receptor antagonists. However, they do demonstrate equivalence in the ability to increase gastric pH.²⁴ The benefit of prophylaxis must be weighed against the potential effect of an increased stomach pH and development of hospital-acquired pneumonia.

Nonpharmacologic Therapy

- **5** Evaluate septic patients for the presence of a localized infection amenable to source control measures. Common source control measures include drainage and debridement, device removal, and prevention.^{24–26} Implementation of source control methods should be instituted as soon as possible following initial fluid resuscitation. The selection of optimal source control methods must weigh benefits and risks of the intervention. Source control measures may cause complications (bleeding, fistulas, and organ injury); therefore, the method with the least risk should be employed.²⁴

Prognosis

There are various factors that influence outcome. Gram-negative bacteria are more likely to produce septic shock than gram-positive bacteria (50% versus 25%) and have a higher mortality rate than other pathogens. This may be related to the severity of the underlying condition. Patients with rapidly fatal conditions, such as leukemia, aplastic anemia, and burns, have a worse prognosis than patients with nonfatal underlying conditions, such as diabetes mellitus or chronic renal insufficiency. Other factors that worsen the prognosis of septic patients include advanced age, malnutrition, resistant bacteria, utilization of medical devices, and immunosuppression. Data for long-term mortality are lacking (it is estimated that the mortality for sepsis survivors within the first year is 20%).⁵ Patients may have prolonged physical disability related to muscle weakness and posttraumatic stress.

Patient Care and Monitoring

1. Evaluate patient parameters and classify as infection, SIRS, sepsis, severe sepsis, septic shock, or MODS.
2. Review available diagnostic and laboratory data.
3. Evaluate early goal-directed resuscitation therapy. Understand what parameters define efficacy and failure of initial therapy. Recommend alternative resuscitation therapy if the patient does not respond to initial fluid challenge.
4. Evaluate the source of infection and make recommendations to remove potential source(s).
5. Analyze anti-infective therapy (dose, frequency, and duration) and revise as necessary based on clinical response, culture and sensitivity reports, and renal/hepatic function. Prepare an appropriate step-down therapy for the patient.
6. Determine the risk of sepsis complications and construct recommendations for treatment and monitoring.
7. Formulate appropriate doses of medications involved in patient therapy and revise as needed. Patient parameters may change frequently, thus requiring different doses and/or medications. Examples include antibiotic therapy, analgesics, sedatives, insulin, fluids, or vasopressors.
8. Continually monitor patient parameters to ensure optimal therapy to maximize outcomes.

Abbreviations Introduced in This Chapter

ARDS	Acute respiratory distress syndrome
AKI	Acute kidney injury
CAP	Community-acquired pneumonia
CBC	Complete blood count
DIC	Disseminated intravascular coagulation
Do ₂	Delivery of oxygen to tissues
DVT	Deep vein thrombosis
ESBL	Extended-spectrum β -lactamase
MAP	Mean arterial pressure
MDR	Multidrug resistant
MDRSP	Multidrug-resistant <i>Streptococcus pneumoniae</i>
MODS	Multiple-organ dysfunction syndrome
MRSA	Methicillin-resistant <i>Staphylococcus aureus</i>
MSSA	Methicillin-sensitive <i>S. aureus</i>
Paco ₂	Partial pressure of carbon dioxide
SIRS	Systemic inflammatory response syndrome
TNF- α	Tumor necrosis factor- α
Vo ₂	Oxygen consumption by tissues

Superficial Fungal Infections

Lauren S. Schlesselman

LEARNING OBJECTIVES

● Upon completion of the chapter, the reader will be able to:

1. Explain the underlying pathophysiology of vulvovaginal candidiasis, oropharyngeal candidiasis, esophageal candidiasis, and fungal skin infections.
2. Identify symptoms of vulvovaginal candidiasis, oropharyngeal candidiasis, esophageal candidiasis, and fungal skin infections.
3. Identify the desired therapeutic outcomes for patients with uncomplicated and complicated vulvovaginal candidiasis, oropharyngeal candidiasis, esophageal candidiasis, and fungal skin infections.
4. Recommend appropriate lifestyle modifications and pharmacotherapy interventions for patients with vulvovaginal candidiasis, oropharyngeal candidiasis, esophageal candidiasis, and fungal skin infections.
5. Recognize when long-term suppressive therapy is indicated for a patient with vulvovaginal candidiasis.
6. Recognize when topical versus oral treatment is indicated for a patient with oropharyngeal candidiasis, esophageal candidiasis, vulvovaginal candidiasis, and fungal skin infections.
7. Educate patients about the disease state, appropriate lifestyle modifications, and medication therapy required for effective treatment of vulvovaginal candidiasis, oropharyngeal candidiasis, esophageal candidiasis, and fungal skin infections.

KEY CONCEPTS

- 1 The predominant pathogen associated with vulvovaginal candidiasis is *Candida albicans*, although a small percentage of cases are caused by *Candida glabrata*, *Candida tropicalis*, *Candida krusei*, and *Candida parapsilosis*.
- 2 A variety of factors may increase the risk of developing symptomatic vulvovaginal candidiasis, including antibiotic use, diabetes, and immunosuppression. No risk factors are consistently associated with all cases of vulvovaginal candidiasis.
- 3 Asymptomatic vaginal colonization of *Candida albicans* is not diagnostic of vulvovaginal candidiasis since 10% to 20% of women are asymptomatic carriers of *Candida* species. Asymptomatic vaginal colonization does not require treatment.
- 4 Selection of antifungal agents to treat uncomplicated vulvovaginal candidiasis is influenced by patient preference, including route of administration, duration of therapy, cost, risk of adverse effects, and potential for medication interactions.
- 5 Recurrent vulvovaginal candidiasis, defined as four or more infections per year, requires long-term suppressive therapy for 6 months.
- 6 The occurrence of oropharyngeal and esophageal candidiasis is an indicator of immune suppression, often developing in infants, the elderly, and the immunocompromised.
- 7 Topical antifungal agents are first-line therapy for oropharyngeal candidiasis, although oral agents may be used for severe or unresponsive cases.
- 8 Esophageal candidiasis is a severe form of extension of oropharyngeal candidiasis that requires oral antifungal therapy.
- 9 Because dermatophyte hyphae seldom penetrate into the living layers of the skin, instead remaining in the stratum corneum, most mycotic infections of the skin can be treated with topical antifungals. Infections covering large areas of the body or infections involving nails or hair may require oral therapy.
- 10 Onychomycosis, fungal infections involving the nails, requires oral antifungal therapy. Topical agents do not adequately penetrate the nail.

VULVOVAGINAL CANDIDIASIS

Vulvovaginal candidiasis (VVC), whether symptomatic or asymptomatic, refers to infections in women whose vaginal cultures are positive for *Candida* species.

EPIDEMIOLOGY AND ETIOLOGY

Vulvovaginal candidiasis, also known as moniliasis, is a common form of vaginitis, accounting for 20% to 25% of vaginitis cases. Although VVC is uncommon prior to **menarche**, nearly 50% of women will experience one or more episodes by the age of 25 years.¹ A survey of women in the United States found that 6.5% of women over the age of 18 years reported experiencing at least one episode of vaginitis during the previous 2 months.²

According to the treatment guidelines of the Centers for Disease Control and Prevention (CDC),³ VVC can be classified as uncomplicated or complicated. Uncomplicated infections occur sporadically, cause mild to moderate symptoms, and occur in nonimmunocompromised women. Uncomplicated infections, most often caused by *Candida albicans*, often have no identifiable precipitating cause. Complicated infections, including recurrent, severe infections, and those in women with uncontrolled diabetes, debilitation, or immunosuppression, may be caused by nonalbicans or azole-resistant fungal organisms. Immunocompromise, including immunosuppression, uncontrolled diabetes, pregnancy, or debilitation, is also a risk factor for developing recurrent infection. Recurrent VVC, defined as four or more infections per year, occurs in less than 5% of women.³ Recurrent infection is distinguishable from a persistent infection by the presence of a symptom-free interval between infections.

① *Candida albicans* is the primary pathogen responsible for VVC, accounting for approximately 70% of cases.⁴ Other cases are caused by nonalbicans species including *Candida glabrata*, *Candida tropicalis*, *Candida krusei*, and *Candida parapsilosis*. In patients with recurrent vaginitis, the causative *Candida* is twice as likely to be nonalbicans.⁵ The incidence of nonalbicans VVC is increasing, possibly due to overuse of nonprescription vaginal antifungal products, short-course antifungal treatments, and long-term suppressive therapy with antifungals.

PATHOPHYSIOLOGY

The normal vaginal environment protects women against vaginal infections. Under the influence of estrogen, vaginal epithelium cornifies to reduce the risk of infection. Vaginal discharge, comprised of exfoliated cells, cervical mucus, and colonized bacteria, cleans the vagina. The volume of discharge varies during pregnancy, during oral contraceptive use, with age, and at midmenstrual cycle near ovulation. The normal pH of vaginal secretions, near 4.0, is maintained by *Lactobacillus acidophilus*, diphtheroids, and *Staphylococcus epidermidis*. The low pH is toxic to many pathogens.

Any alteration in the vaginal environment allows for overgrowth of organisms that are normally suppressed. Increases in the vaginal pH are associated with increased vulvovaginitis.

Clinical Presentation and Diagnosis of VVC

Patients with VVC may present with vulvar and/or vaginal symptoms. Symptoms often develop the week before menses and resolve with the onset of menses.

Symptoms include:

- Vaginal itching
- Vaginal soreness
- Vaginal burning
- Irritation
- External dysuria
- **Dyspareunia**

Signs include:

- Nonodorous vaginal discharge (may vary from watery to curd-like)
- Yellow or yellowish-green discharge
- Erythema and edema of the labia and vulva
- Fissures
- Pustulopapular lesions
- Normal cervix

Diagnostic Testing

- Microscopic investigation for the presence of **blastospores** or **pseudohyphae**; saline wet mount has a sensitivity of 40% to 50%, whereas a potassium hydroxide (KOH) preparation has a sensitivity of 50% to 70%.⁷ *Asymptomatic vaginal colonization of Candida albicans is not diagnostic of VVC since 10% to 20% of women are asymptomatic carriers of Candida species. Asymptomatic vaginal colonization does not require treatment; therefore the presence alone of Candida should not determine care.*
- Vaginal pH less than or equal to 4.5; pH should remain normal in cases of fungal infection, whereas an elevated pH suggests bacterial infection.
- *Candida* cultures should be obtained only if signs and microscopy are inconclusive or in cases of recurrent VVC.

pH changes are caused by stress, changes in hormone level, sexual activity, pregnancy, phases of the menstrual cycle, contraceptive use, presence of foreign bodies or necrotic tissue, use of douches, or the use of antibiotics. An increase in glycogen production, associated with altered estrogen and progesterone levels, can also increase the risk of infection through increased adherence of *Candida albicans* to epithelial cells.

RISK FACTORS

- ② *Although no risk factors are consistently associated with conversion to symptomatic infection, a variety of factors may increase the risk of developing symptomatic VVC in certain women (Table 83-1).*

Table 83–1

Possible Risk Factors Associated with VVC

Risk Factor	Proposed Mechanism
Broad-spectrum antibiotic use	Altered vaginal flora allowing overgrowth of <i>Candida</i> organisms; risk increases with duration of antibiotic use
Systemic corticosteroid or immunosuppressant use	Reduced vaginal protection by immunoglobulins
Sexual activity	VVC is often associated with the onset of sexual activity; partners may have penile or oral colonization; use of vaginal irritants or devices, including diaphragms and intrauterine systems, can irritate vaginal mucosa
Tight-fitting and nonabsorbent clothing	Promotes warm, moist environment for fungus growth
Elevated estrogen levels, hormonal contraceptives, and pregnancy	Estrogen enhances <i>Candida</i> adherence to vaginal epithelial cells and yeast-mycelial transformation; this is supported by the fact that infection rates are lower before menarche and after menopause (except in women taking hormone replacement therapy), whereas rates are higher during pregnancy
Vaginal pH	Changes in glycogen and lactic acid levels
Gastrointestinal reservoir of <i>Candida</i> organisms	Transfer of organism from rectum to vagina; irritation of the vulvovaginal area during sexual intercourse may enhance invasion of organisms
Diabetes	Enhanced binding of <i>Candida</i> to epithelial cells due to hyperglycemia; asymptomatic colonization is more common in patients with diabetes; elevated sugar levels may cause conversion to symptomatic infection

Patient Encounter 1

A 19-year-old woman presents to your clinic complaining of what she calls “itching and burning in my private areas.” After questioning her, you determine that she has vaginal burning, soreness, and itching, accompanied by a curd-like discharge. Although she has had vaginal infections before, she admits to recently becoming sexually active and is very concerned that she may have contracted a sexually transmitted disease. On examination, she has erythema of the labia and a nonodorous discharge.

What information is suggestive of VVC?

What additional information do you need to know before creating a treatment plan for this patient?

TREATMENT

The goals of treatment of VVC are as follows:

- Relief of symptoms
- Eradication of infection
- Reestablishment of normal vaginal flora
- Prevention of recurrent infections in complicated infections

Nonpharmacologic Treatments

- In combination with pharmacologic treatment, the practitioner should recommend basic nonpharmacologic approaches to treatment and prevention of VVC:

- Keep the genital area clean and dry
- Avoid prolonged use of hot tubs
- Avoid constrictive clothing
- Avoid vaginal douching
- Wear underwear made of breathable materials, such as cotton
- To reduce vulvar irritation, avoid soaps and perfumes in the genital area
- Although study results are conflicting, the daily consumption of active *Lactobacillus acidophilus* may reduce recurrence. One study found that the daily ingestion of oral *Lactobacillus* reduced fungal concentrations and produced a normal balance of colonized organisms,⁶ whereas other studies found no difference in infection rates in women who ingested yogurt^{7,8}

Pharmacologic Treatment of Uncomplicated VVC

Most cases of uncomplicated VVC will resolve with a single course of antifungal therapy. Treatment with an oral or vaginal antifungal agent, either prescription or nonprescription, is appropriate for most uncomplicated cases. Nonprescription azole antifungal products are available as 1-night, 3-night, and 7-night regimens in a variety of formulations, including cream, suppository, and vaginal tablets (Table 83–2). Oral fluconazole offers the option of treatment with one dose administered without regard to time of day. Some practitioners opt to re-treat with a second dose of fluconazole 3 days later. Due to the risk of severe hepatotoxicity, the use of oral ketoconazole should be reserved for severe fungal infections resistant to other antifungal options.

To avoid inappropriate use of nonprescription products, the practitioner should only recommend them to women who have previously been diagnosed with VVC. Estimates of how accurately women self-diagnose VVC are difficult to assess. One study found that only one-third of women accurately diagnosed an episode of vaginitis.⁹ Women with a previous clinically based diagnosis of VVC are no more accurate at self-diagnosing than women without prior clinical diagnosis.⁹

Table 83-2

Treatment Options for Uncomplicated VVC**1-Day Therapies**

Butoconazole 2% sustained-release cream, 5 g intravaginally as a single application
 Fluconazole 150 mg, one tablet orally as a single dose
 Tioconazole 6.5% ointment, 5 g intravaginally as a single application

3-Day Therapies

Butoconazole 2% cream, 5 g intravaginally for 3 nights
 Clotrimazole 100-mg vaginal tablet, two tablets for 3 nights
 Miconazole 200-mg vaginal suppository, one suppository for 3 nights
 Terconazole 0.8% cream, 5 g intravaginally for 3 nights
 Terconazole 80-mg vaginal suppository, one suppository for 3 nights

7- to 14-Day Therapies

Boric acid 600-mg vaginal suppository, one suppository intravaginally twice daily for 14 days
 Clotrimazole 1% cream, 5 g intravaginally for 7–14 nights
 Clotrimazole 100-mg vaginal tablet, one tablet for 7 nights
 Miconazole 2% cream, 5 g intravaginally for 7 nights
 Miconazole 100-mg vaginal suppository, one suppository for 7 nights
 Nystatin 100,000-unit vaginal tablet, one tablet for 14 nights
 Terconazole 0.4% cream, 5 g intravaginally for 7 nights

Inability to resolve an infection may indicate a mixed infection, infection owing to a nonalbicans strain, or an infection that is not fungal. Difficulty treating VVC can also be indicative of serious underlying conditions, such as diabetes or human immunodeficiency virus (HIV) infection. For these reasons, if infection does not resolve easily with a single course of antifungal therapy or if symptoms return within 2 months, practitioners should check cultures and further evaluate the patient's health status or refer the patient to a physician.

4 Due to the numerous treatment options available, a variety of factors can influence product selection, with patient preference playing a significant role. To improve adherence with therapy, the practitioner should discuss with the patient what options are available and what her preferences are.

Adherence rates are greater with oral treatment than with vaginal therapy. This may be due to the ease of administration, short duration, and flexibility on time of administration. Vaginal creams provide rapid relief of itching and burning. The practitioner may wish to advise a patient to apply a vaginal cream externally to reduce itching and burning if using an oral agent. The need to clean the vaginal applicator for reuse is unappealing for some women. Many nonprescription vaginal products are now packaged with sufficient disposable applicators to prevent the need for reuse with subsequent doses. Available regimens range from 1 to 7 days for topical preparations and fluconazole. Cure rates are similar among different durations of therapy.¹⁰ Most OTC products cost \$10 to \$20 per course of therapy. The cost of prescription products can vary based on if and what type of insurance coverage the patient has. If the patient does not have prescription coverage, nonprescription products may prove less expensive than even one or two fluconazole tablets.

Risk of Adverse Effects and Interactions

Systemic adverse effects associated with vaginal azoles are less frequent than with oral products. With topical products, local discomfort such as burning, itching, stinging, and redness may occur, particularly with the first application. In contrast, common adverse effects associated with fluconazole include headache, diarrhea, nausea, dizziness, abdominal pain, and taste alterations. Fifteen percent of patients experience gastrointestinal side effects with orally administered antifungal agents.¹¹ Oral ketoconazole is associated with hepatic toxicity at a rate of 1 in 15,000.¹²

Oral azoles are associated with significant interactions, particularly due to cytochrome P-450 isoenzymes. Medications that interact with azoles include warfarin, phenytoin, theophylline, rifampin, cyclosporine, and zidovudine. For patients receiving only a few doses, these interactions do not pose a significant risk. These interactions may pose a risk for patients receiving long-term suppressive therapy for recurrent infections.

TREATMENT OF RECURRENT VVC

The goal of treating recurrent VVC is control of the infection, rather than cure. First, any acute episodes are treated, followed by maintenance therapy. For the treatment of acute episodes, intravaginal or oral azoles can be utilized.

Although acute episodes of recurrent VVC will respond to azole therapy, some patients may require prolonged therapy to achieve remission. To achieve remission, a second dose of oral fluconazole 150 mg repeated 3 days after the first dose or 14 days of topical azole therapy can be used. The practitioner should consider that nonalbicans infections are more common in recurrent VVC; therefore, fluconazole and itraconazole resistance may make these agents less effective.

5 After achieving remission, recurrent VVC requires long-term suppressive therapy for 6 months (Table 83-3). To improve adherence to long-term suppressive therapy, oral therapy, typically with fluconazole, is preferred. Fluconazole 150 mg weekly for 6 months will prevent recurrence of

Table 83-3

Treatment Options for Maintenance Therapy**Daily**

Boric acid 600 mg in gelatin capsule vaginally daily during menses (5 days)
 Itraconazole 100 mg orally once daily
 Ketoconazole 100 mg orally once daily

Weekly

Clotrimazole 500 mg vaginal suppository once weekly
 Fluconazole 100 or 150 mg orally once weekly
 Terconazole 0.8% cream 5 g vaginally once weekly

Monthly

Fluconazole 150 mg orally once monthly
 Itraconazole 400 mg orally once monthly

infection in 90% of women.¹³ Cessation of suppressive therapy is associated with resurgence of symptomatic infection in 50% of women.¹⁴

TREATMENT OF NONALBICANS INFECTIONS

Treatment response rates are lower for nonalbicans infections. Although an optimal regimen is unknown, use of intravaginal azole therapy for 7 to 14 days is recommended. Terconazole may prove more effective than other azoles in the treatment of nonalbicans infections since *C. glabrata* and *C. tropicalis* are more susceptible to terconazole.¹⁵ For second-line therapy, boric acid 600 mg in a gelatin capsule administered vaginally twice daily for 2 weeks followed by once daily during menstruation is effective.¹⁶ Local irritation often limits the use of boric acid. Topical 4% flucytosine is also effective, but use should be limited due to the potential for resistance.

VVC DURING PREGNANCY

During pregnancy, VVC may prove difficult to treat due to elevated estrogen levels, accompanied by concern about harm to the fetus. Response rates are lower and recurrences are frequent during pregnancy. Vaginal antifungals remain the preferred treatment during pregnancy, although therapy should continue for 1 to 2 weeks to ensure effectiveness.¹⁴ Most topical antifungals are classified as risk category C, whereas clotrimazole is classified as risk category B. Fluconazole's risk category classification was recently changed to category D for all indications other than vaginal candidiasis, for which it remains a risk category C. Despite oral fluconazole's classification, studies have not demonstrated an increased risk to the fetus when the pregnant mother was exposed to low-dose fluconazole,^{17,18} although case studies have reported congenital limb deformities with doses of 400 to 800 mg daily during the first trimester.¹⁹

Cultural Awareness During Treatment of VVC

As with all gynecologic issues, the practitioner is faced with cultural perceptions of female genitalia. In particular, practitioners are treating an increased number of patients who have undergone female genital mutilation. More than 100 million women and girls worldwide have undergone such procedures for cultural and religious reasons.²⁰ Female genital mutilation, formerly known as female circumcision, describes the intentional alteration or injury of female genitalia. Some authorities suggest using the term "genital cutting" when dealing with patients to avoid appearing judgmental.²¹ Regardless of the terminology used, many immigrants are aware of common cultural views in the United States pertaining to female genital mutilation. Women who have undergone this procedure suffer acute and chronic complications. Within the scope of this chapter, the practitioner may find that patients with female genital mutilation suffer from recurrent VVC due to

inadequate drainage of vaginal fluids. Regardless of what the practitioner's opinion is about female genital mutilation, the practitioner must be sensitive to the patient's feeling and cultural values.

Patient Care and Monitoring of VVC

1. Assess the patient's symptoms to determine whether self-treatment with OTC antifungal therapy is appropriate or whether the patient should be evaluated by a practitioner or physician. OTC preparations should only be recommended for patients who have previously been diagnosed with VVC. Patients who experience more than four episodes per year should be referred to a physician for culturing and initiation of maintenance therapy.
2. Review any available diagnostic data, including cultures and KOH preps.
3. Obtain a thorough history of prescription, nonprescription, and natural drug product use. Is the patient taking any medications, such as steroids, antibiotics, or immunosuppressants, that may contribute to VVC? Is the patient taking any medications that may interfere with treatment?
4. If the patient has had VVC previously, determine what treatments were helpful to the patient in the past.
5. Educate the patient on lifestyle modifications that may prevent recurrence, including decreased consumption of sucrose and refined carbohydrates, increased consumption of yogurt containing live cultures, and wearing cotton underwear.
6. Develop a plan to assess effectiveness of antifungal therapy.
7. Determine whether long-term suppressive therapy is necessary.
8. Evaluate the patient for the presence of adverse drug reactions, drug allergies, and drug interactions.
9. Stress the importance of adherence with the antifungal regimen, including lifestyle modifications.
10. Provide patient education pertaining to vulvovaginal candidiasis and antifungal therapy.
 - Causes of vulvovaginal candidiasis
 - How to administer vaginal antifungal creams
 - Vaginal antifungal creams' and suppositories' adverse effects on latex condoms and diaphragms
 - Potential adverse effects that may occur with antifungal therapy
 - Medications that may interact with antifungal therapy
 - Preventing the spread of infection
 - Warning signs to report to a physician (recurrent or difficult-to-cure infections, infections with malodorous discharge)

OUTCOME EVALUATION

Whether using a topical or an oral agent, patients should notice relief of itching and discomfort within 1 to 2 days. The volume of discharge should also begin to decrease within a few days. The entire course of therapy should be continued even if symptoms have resolved. If the condition does not resolve or worsens, the patient should be referred to a physician for aggressive therapy. If the condition recurs within 4 weeks or more than four times per year, the patient should be further evaluated or referred to a physician for evaluation of possible non-*Candida* infections, resistant organism, or other complicating factors, along with assessment of need for long-term suppressive therapy.

OROPHARYNGEAL AND ESOPHAGEAL CANDIDIASIS

Oropharyngeal candidiasis (OPC) is a common fungal infection, usually associated with immune suppression. If left untreated, it will progress to more serious oral disease. Esophageal candidiasis, representing a serious progression of oropharyngeal candidiasis, is associated with increased morbidity.

EPIDEMIOLOGY AND ETIOLOGY

6 *The occurrence of oropharyngeal and esophageal candidiasis is an indicator of immune suppression, often developing in infants, the elderly, and the immunocompromised.* One-third to one-half of geriatric inpatients develop oropharyngeal candidiasis. Denture stomatitis is present in approximately 40% of denture wearers,²² more commonly in women than men. Oral candidiasis is the most commonly reported adverse drug event reported by patients receiving inhaled corticosteroids.²³ The prevalence of esophageal candidiasis is 37% among patients treated with inhaled corticosteroids.²⁴ The incidence is highest among patients receiving high doses of corticosteroids or those with diabetes.

The prevalence of HIV infection plays a significant role in the incidence of oropharyngeal and esophageal candidiasis. In the 1980s, the incidence of oropharyngeal candidiasis increased fivefold, in association with the spread of HIV infections.²⁵ Although HIV infection remains a risk factor for candidiasis, the introduction of highly active antiretroviral therapy precipitated a decline in the incidence of both infections by 50% to 60%.²⁶

Oropharyngeal candidiasis remains the most common opportunistic infection in patients with HIV. Ninety percent of HIV-positive patients develop oropharyngeal candidiasis.²⁷ For 70% of these patients, it is the first manifestation of HIV infection.²⁸ The incidence of oropharyngeal infection increases with decreasing CD4⁺ lymphocyte counts, with an incidence of 60% in patients with a CD4⁺ count less than 200 cells/mm³ (200 × 10⁶/L).

Although esophageal candidiasis represents the first manifestation of HIV infection in less than 10% of cases, it is the most common acquired immunodeficiency syndrome (AIDS)-defining disease.²⁹ As with oropharyngeal candidiasis, the incidence of esophageal candidiasis increases with decreasing CD4⁺ counts.

Candida albicans accounts for 80% of cases of OPC and esophageal candidiasis. Over the last 20 years, an increasing incidence of *C. albicans* resistance has been accompanied by an increased incidence of nonalbicans species infections, including *Candida glabrata*, *Candida tropicalis*, *Candida krusei*, and *Candida parapsilosis*. In patients with cancer, nonalbicans *Candida* species account for almost half of all cases.²⁷

PATHOPHYSIOLOGY

Similar to VVC, the development of OPC occurs when the normal environment is altered. *Candida* organisms frequently colonize the oropharynx and mucous membranes. These organisms do not become pathogenic until the environmental balance is disturbed. This occurs in the setting of broad-spectrum antibiotic use, tissue damage (due to chemotherapy, catheter tubing, trauma), or immune deficiency.

RISK FACTORS

Risk factors for OPC can be found in [Table 83-4](#).

Table 83-4

Risk Factors for Oropharyngeal and Esophageal Candidiasis

Factor	Proposed Mechanism
Extremes of age	Immature immunity in infants and reduced immunity in the elderly
Impaired mucosal integrity	Breaks in the protective barrier allows fungal invasion; often due to radiation, surgery, or mucositis
Dentures	Adherence of fungus to dentures, along with reduced salivary flow under dentures; ill-fitting dentures may impair mucosal integrity
Xerostomia	Reduced cleansing and defense factors of saliva
Use of antibiotics	Altered flora of mucosa allowing fungal overgrowth
Use of steroids	Suppression of immunity
Use of immunosuppressants	Suppression of immunity
HIV infection	Decreased CD4 T lymphocytes
Diabetes mellitus	Elevated glucose levels and defense factors in saliva
Nutritional deficiencies	Altered defense mechanisms, impaired mucosal integrity, or enhanced pathogenic potential of fungus

CLINICAL PRESENTATION AND DIAGNOSIS

- See text boxes for clinical presentation and diagnosis of OPC and esophageal candidiasis.

TREATMENT

- Along with selecting an effective treatment, selection of an appropriate antifungal agent requires consideration of

Clinical Presentation and Diagnosis of OPC

OPC is often a presumptive diagnosis based on signs and symptoms, along with the resolution of them after treatment with antifungal agents.

Symptoms

- Sore, painful mouth and tongue
- Burning tongue
- Dysphagia**
- Metallic taste

Signs

Signs vary depending on the type of oropharyngeal candidiasis.

- Diffuse erythema on the surface of buccal mucosa, throat, tongue, and gums
- White patches on tongue, gums, or buccal mucosa; removal of patches reveals erythematous and bloody tissue; ability to remove patches distinguishes OPC from oral hairy leukoplakia
- Angular cheilitis presents with small cracking lesions, erythema, and soreness at the corners of the mouth; associated with vitamin and iron deficiency
- Denture stomatitis presents with flat, red lesions on mucosa beneath dentures; signs of chronic erythema and edema on mucosa
- Hyperplastic OPC presents with discrete, transparent raised lesions on the inner mucosa of the cheek; typically found in men who smoke
- Pseudomembranous OPC presents with yellow-white plaques that may be small and discrete or confluent; most common form found in HIV patients

Diagnostic Testing

Diagnosis is primarily based on identification of characteristic lesions. Although rarely necessary, diagnostic testing is possible if a definitive diagnosis is required.

- Cytology, although presence of *Candida* is not diagnostic since colonization is common
- Culture to identify species of yeast or presence of resistance
- Biopsy

Clinical Presentation and Diagnosis of Esophageal Candidiasis

Symptoms

- Fever
- Odynophagia
- Dysphagia
- Retrosternal pain

Signs

- Fever
- Hyperemic or edematous white plaques
- Ulceration of esophagus
- Increased mucosal friability
- Narrowing of lumen

Diagnostic Testing

Unlike OPC, diagnosis of esophageal candidiasis is not based solely on clinical presentation, instead requiring endoscopic visualization of lesions and culture confirmation. Due to the invasive nature of these procedures, most practitioners opt to treat the infection presumptively, reserving endoscopic evaluation for patients who fail therapy.

- Cytology and culture to identify species of yeast or presence of resistance
- Barium esophagogram
- Endoscopy revealing whitish plaques with progression to superficial ulceration of the esophageal mucosa
- Mucosal biopsy

location and severity of infection, medication adherence, potential drug interactions, concomitant medical conditions, and presence of sucrose or dextrose. Topical agents require frequent dosing and prolonged contact time with oral mucosa. Rough surfaces of tablets and troches may irritate sensitive mucosa. Patients with **xerostomia** may have inadequate saliva to dissolve troches. Topical agents containing sucrose or dextrose may increase the risk of caries or cause elevated blood sugar in patients with diabetes. Along with being expensive, oral azoles exhibit an increased risk of toxicity and drug interactions due to cytochrome P-450.

Because oropharyngeal and esophageal candidiasis are signs of immunocompromise, the immune status of the patient should be considered in the therapeutic care plan. For HIV-infected patients, this should also include an evaluation of the patient's antiretroviral therapy since fungal infections may represent deterioration in immune status.

7 For low-risk patients, topical agents are first-line therapy for oropharyngeal candidiasis, although systemic agents may be used for severe or unresponsive cases. For patients with mild infections, nystatin suspension provides an inexpensive option for treatment of oropharyngeal

candidiasis, although it must be dosed 4 times per day. In small children, 0.5 to 1 mL of the suspension can be squirted into the cheeks using an oral syringe, whereas older children and adults can receive 5 mL per dose. Despite the convenience of once-daily dosing, fluconazole is typically reserved for more severe or unresponsive cases. For patients with severe OPC, oral fluconazole remains the agent of choice. Oral fluconazole administered for 2 weeks exhibits a mycological cure rate of 48% and a **clinical cure** rate of 84% in HIV patients.³⁰ Response occurs within 5 days in patients receiving 100 to 200 mg daily.¹⁴ Doses as low as 50 mg are effective, but clinical response is slow and potentially leads to resistance. Two weeks of oral itraconazole solution is as effective as fluconazole but is less well tolerated. Due to variable absorption, risk of toxicity, and potential for drug interactions, ketoconazole and itraconazole capsules are considered second-line alternatives to fluconazole.

For non-HIV-infected patients who have suppressed immune systems, the practitioner must consider the patient's risk of dissemination. Patients with cell-mediated immune deficiency but near-normal granulocyte function, such as patients with diabetes, solid organ transplant, or solid tumors, are at low risk for dissemination. The risk of dissemination is higher for patients who develop neutropenia, including patients with leukemia or bone marrow transplant. These patients should be treated aggressively to prevent invasive fungal infection.

For the treatment of OPC in HIV-infected individuals, initial episodes can be adequately controlled with topical agents, such as clotrimazole troches, so long as symptoms are not severe and no esophageal involvement is suspected.²⁶ Topical nystatin is the least effective agent, especially in severely immunocompromised patients.³¹ Topical clotrimazole appears to be the most effective topical antifungal, exhibiting clinical responses equivalent to oral fluconazole and itraconazole solution, but mycological cure rates are lower and relapse rates higher with clotrimazole.²⁹

8 *Representing a severe extension of oropharyngeal candidiasis, esophageal candidiasis requires systemic antifungal therapy.* The significant morbidity associated with esophageal candidiasis warrants aggressive treatment. The diagnosis of esophageal candidiasis requires endoscopic evaluation, but rather than employing invasive procedures, patients can be treated with an appropriate course of antifungal based on clinical presentation. If patients do not respond, endoscopy should be considered.

Two to 3 weeks of fluconazole or itraconazole solution are highly effective and demonstrate similar clinical response rates.³² Oral doses of 100 to 200 mg are effective in immunocompetent patients, but doses up to 400 mg are recommended for immunocompromised patients. Due to variable absorption, ketoconazole and itraconazole capsules should be considered second-line therapy. In severe cases, oral azoles may prove ineffective, warranting the use of IV amphotericin B for 10 days. Although echinocandins, voriconazole, and posaconazole are effective in treatment of esophageal candidiasis, experience remains limited and

Patient Encounter 2

An 89-year-old woman presents to the dental clinic complaining that her dentures must not be fitting correctly because “my mouth is very sore.” She comments that she noticed “these white spots” on her gums that “make everything taste funny.” On initial examination, she has white patches on her tongue, gums, and buccal mucosa. These patches are easily removed, revealing erythematous tissue underneath.

Her medical record shows that she recently completed a course of azithromycin and steroids for bronchitis.

What additional information do you need to know before creating a treatment plan for this patient?

What underlying medical conditions might make her susceptible to fungal infections?

How is the treatment care plan altered if the patient has a history of frequent and severe OPC? If the patient is HIV-positive? If the patient is neutropenic?

their role has yet to be established, particularly in light of less expensive alternatives

Fluconazole-Resistant Infections

Twenty percent of HIV-infected patients develop fluconazole-resistant *Candida albicans* isolates after repeated exposure to fluconazole.³³ To treat fluconazole-resistant oropharyngeal candidiasis, daily itraconazole for 2 to 4 weeks may be used. Oral itraconazole solution exhibits a mycological cure rate of 88% and a clinical cure rate of 97% in immunocompromised patients.³⁴ Fluconazole-resistant esophageal candidiasis should be treated with IV amphotericin B or caspofungin.

Recurrent Infections

If immunocompromised patients experience frequent or severe recurrences, particularly of esophageal candidiasis, chronic maintenance therapy with fluconazole 100 to 200 mg daily should be considered. In patients with infrequent or mild cases, secondary prophylaxis is not recommended. The rationale for not giving prophylaxis includes availability of effective treatments for acute episodes, risk of developing resistant organisms, potential for drug interactions, and the cost of therapy.

OUTCOME EVALUATION

- Patients should notice symptomatic relief within 2 to 3 days of initiating therapy. Complete resolution typically occurs within 7 to 10 days. The entire course of therapy should be continued even if symptoms have resolved. If the condition does not resolve or worsens, the patient should be referred to a specialist for aggressive therapy.

Patient Care and Monitoring of OPC

1. Assess the patient's symptoms to determine whether symptoms are consistent with oropharyngeal or esophageal candidiasis. All patients with suspected oropharyngeal or esophageal candidiasis should be referred to a practitioner or physician since no antifungal products appropriate for oral use are available without a prescription.
 2. Review any available diagnostic data, including cultures.
 3. Obtain a thorough history of prescription, nonprescription, and natural drug product use. Is the patient taking any medications that may contribute to candidiasis? Is the patient taking any medications that may interfere with treatment?
 4. If the patient has had oropharyngeal or esophageal candidiasis previously, determine what treatments were helpful to the patient in the past.
 5. If the patient has had oropharyngeal or esophageal candidiasis previously, determine whether the patient has risk factors for recurrent infection.
 6. Develop a plan to assess effectiveness of antifungal therapy.
 7. Determine whether long-term suppressive therapy is necessary.
 8. Evaluate the patient for the presence of adverse drug reactions, drug allergies, or drug interactions.
 9. Stress the importance of adherence with the antifungal regimen.
 10. Provide patient education pertaining to oropharyngeal or esophageal candidiasis and antifungal therapy.
 - Causes of oropharyngeal or esophageal candidiasis
 - Risk factors for developing candidiasis
 - How to administer topical antifungal agents, including cleaning the oral cavity prior to administration, shaking suspensions prior to use, administering after meals, how to dissolve troches, and how to swish suspensions
 - Importance of completing the course of therapy
 - Potential adverse effects that may occur with antifungal therapy
 - Medications that may interact with antifungal therapy
 - Warning signs to report to a physician (recurrent or difficult-to-cure infections, or worsening symptoms)
- Short courses of oral azoles are associated with gastrointestinal upset, whereas courses lasting longer than 7 to 10 days are associated with increased risk of hepatotoxicity. In patients receiving prolonged therapy lasting more than 3 weeks, periodic monitoring of liver function tests should be considered.

- Immunocompetent patients generally do not require reassessment after treatment. Patients with neutropenia exhibit an increased risk of dissemination of infection and therefore should be monitored for signs of systemic fungal infection. Due to an increased risk of recurrence, HIV-positive patients should routinely be evaluated for recurrence at each visit.

MYCOTIC INFECTIONS OF THE SKIN, HAIR, AND NAILS

Tinea infections are superficial fungal infections in which the pathogen remains within the keratinous layers of the skin or nails (Table 83–5). Typically these infections are named for the affected body part, such as tinea pedis (feet), tinea cruris (groin), and tinea corporis (body). Tinea infections are commonly referred to as ringworm due to the characteristic circular lesions. In actuality, tinea lesions can vary from rings to scales and single or multiple lesions.

EPIDEMIOLOGY AND ETIOLOGY

Tinea infections are second only to acne in frequency of reported skin disease.³⁵ The common tinea infections are tinea pedis, tinea corporis, and tinea cruris. Tinea pedis, the most prevalent cutaneous fungal infection, afflicts more than 25 million people annually in the United States.

Fungal skin infections are primarily caused by **dermatophytes** such as *Trichophyton*, *Microsporum*, and *Epidermophyton*. *Trichophyton rubrum* accounts for more than 75% of all cases in the United States.³⁶ To a lesser extent, *Candida* and other fungal species cause skin infections. With tinea infections, the causative dermatophyte typically

Clinical Presentation and Diagnosis of Mycotic Infections

Symptoms and Signs (see Table 83–5)

Diagnostic Testing

- KOH prep
- Wood's ultraviolet lamp
- Microscopic examination
- Fungal cultures
- Periodic acid-Schiff (PAS) staining of nail

Treatment of Skin and Hair Infections

The goals of treatment include:

- Providing symptomatic relief
- Resolution of infection
- Preventing spread of infection

Table 83-5

Signs, Symptoms, and Risk Factors of Superficial Fungal Infections

Infection	Symptoms, Signs, and Risk Factors
Tinea pedis	<ul style="list-style-type: none"> • Involves plantar surface and interdigital spaces of foot • Interdigital infections produce itching; presents as fissures, scaling, or macerated skin; can occur between any toes but most often between fourth and fifth toes; may cause foul smell due to superinfection with <i>Pseudomonas</i> or diphtheroids • Hyperkeratotic infections present with silvery white scales on a thickened, red base; usually covers entire foot; occasionally may also affect hand • Vesiculobullous tinea pedis presents as pustules or vesicles on soles of feet; associated with maceration, itching, and thickening of sole; may cause lymphangitis and cellulitis; most common during summer months • Ulcerative tinea pedis presents as macerated, denuded, and weeping ulcers on soles; may produce extreme pain and erosion of interdigital spaces; typically complicated by opportunistic gram-negative infections • Risk factors include occlusive footwear, foot trauma, and use of public showers
Tinea manuum	<ul style="list-style-type: none"> • Infection of the interdigital and palmar surfaces • Presents as white scales in palmar folds; may also develop scales on remainder of palm; may present as singular plaque • More commonly affecting only one hand • Presents with hyperkeratotic skin
Tinea cruris	<ul style="list-style-type: none"> • Presents with follicular papules and pustules on the medial thigh and inguinal folds • Ringed lesions may extend from inguinal fold over adjacent inner thigh • Lesions usually spare the penis and scrotum, in contrast to candidiasis • Frequency increases during summer • Primarily develops in young men • Risk factors include tight-fitting clothing, excessive sweating, poor hygiene, increased humidity and temperatures • Commonly referred to as “jock itch”
Tinea corporis	<ul style="list-style-type: none"> • Presents with circular, scaly patch with enlarged border • Lesions may have red papules or plaque in center that clears, leaving hypopigmentation or hyperpigmentation • Itching may be present • Commonly referred to as ringworm of the body • Risk factors include animal to human contact
Tinea versicolor	<ul style="list-style-type: none"> • Characterized by skin depigmentation but can present as hyperpigmentation, particularly in dark-skinned patients • Typically occurs in areas with sebaceous glands, including neck, trunk, and arms • Depigmentation may persist for years • Primarily develops in young and middle-aged adults • Risk factors include application of oil, greasy skin, high ambient temperature, high relative humidity, tight-fitting clothing, immunodeficiency, malnutrition, hereditary predisposition
Tinea barbae	<ul style="list-style-type: none"> • Infection of beard area
Tinea capitis	<ul style="list-style-type: none"> • Infection of the head and scalp • May be asymptomatic initially, then progresses to inflammatory alopecia • “Black dot” alopecia may develop due to breakage of hair at the root • May form kerions (nodular swellings) • Scaling or favus may develop on scalp • Cervical lymphadenopathy is common • Primarily found in infants, children, and young adolescents, often in African-American and Hispanic populations • Can be spread from person to person or animal to person
Onychomycosis (tinea unguium)	<ul style="list-style-type: none"> • Infection of nail plate and bed • Nail becomes opaque, thick, rough, yellow or brownish, and friable; nail may separate from bed • Toenails affected more frequently than fingernails • Prevalence increases with advanced age

invades the stratum corneum without penetration into the living tissues, leading to a localized infection.

PATHOPHYSIOLOGY

The primary mode of transmission of tinea infections is direct contact with other persons or surface reservoirs. Upon contact, the dermatophytes attach to the keratinized cells, leading to thickening of the cells. Although infection remains localized, bacterial superinfections may develop.

The pathophysiology of onychomycosis depends on the clinical type. With the most common form of onychomycosis, distal lateral subungual, the fungus spreads from the plantar skin. The fungus invades the underside of the nail through the distal lateral nail bed, leading to inflammation of the area. In cases of white superficial onychomycosis, the fungus invades the surface of the nail plate directly. With white superficial onychomycosis, the nail bed and hyponychium are infected secondarily. Proximal subungual onychomycosis infections begin in the cuticle and the proximal nail fold, then penetrate the dorsum of the nail plate.

RISK FACTORS

- Prolonged exposure to sweaty clothing
- Excessive skin folds
- Sedentary lifestyle
- Warm, humid climate
- Use of public pools
- Walking barefoot in public areas
- Skin trauma
- Poor nutrition
- Diabetes mellitus
- Immunocompromise
- Impaired circulation

TREATMENT

Nonpharmacologic Therapy

- Because fungi thrive in warm, moist environments, the practitioner should encourage patients to wear loose-fitting clothing and socks, preferably garments made of cotton or other fabrics that wick moisture away from the body. Avoid clothing made with synthetic fibers or wool.
- Clean the infected area daily with soap and water.
- The infected area should be dried completely prior to dressing, paying particular attention to skin folds.
- To allow circulation of air, the infected area should not be bandaged.
- For foot infections, cotton socks are recommended, although these should be changed two to three times a day to reduce moisture.

Patient Encounter 3

A mother presents to the clinic with her 15-year-old daughter. The mother explains that her daughter's feet "look awful—they are red and raw looking with cracks between her toes." The daughter adds that "it is starting to get embarrassing to take off my running shoes in the locker room after track practice."

What information is suggestive of tinea pedis?

What risk factors are present for tinea pedis?

What nonpharmacologic approaches can be recommended to prevent recurrence?

- To prevent spread, towels, clothing, and footwear should not be shared with other persons.
- Wear protective footwear in public showers and pool areas.

Pharmacologic Therapy of Tinea Infections

9 Since dermatophyte hyphae seldom penetrate into the living layers of the skin, instead remaining in the stratum corneum, most infections can be treated with topical antifungals. Infections covering large areas of the body or infections involving nails or hair may require systemic therapy. Treatment is typically initiated based on symptoms, rather than on microscopic evaluation. For infections accompanied by inflammation, combination therapy with a topical steroid can be considered (Tables 83–6 and 83–7). Patients with chronic infections or infections that do not respond to topical therapy are also candidates for systemic therapy (Table 83–8).

For the treatment of tinea pedis, corporis, and cruris, topical agents can be utilized unless the infection is refractory. Typically, tinea pedis requires treatment one to two times daily for 4 weeks, whereas tinea corporis and tinea cruris require treatment one to two times daily for 2 weeks. When applying treatment, the medication should be applied at least 1 in beyond the affected area. Treatment of any infection should continue at least 1 week after resolution of symptoms. Many practitioners opt to initiate therapy with nonprescription clotrimazole, tolnaftate, miconazole, or terbinafine, reserving prescription topical agents, such as naftifine, ciclopirox, and butenafine, for second-line therapy or refractory cases. For refractory cases or widespread lesions, systemic therapy can be prescribed.

When recommending topical therapy, the selection of vehicle is based on the type of lesion and location of the infection. Solutions and lotions are recommended for hairy areas and oozing lesions, whereas creams and ointments should be avoided in these areas. Creams are better for moderately scaling and nonoozing lesions. For hyperkeratotic lesions, ointments can be considered. The selected formulation should be applied to the affected area

Table 83-6

Available Topical Antifungal Agents

Medication	Rx/OTC	Cream/Ointment	Gel	Lotion	Spray/Solution	Powder
Butenafine	OTC	x				
Ciclopirox	Rx	x		x	Lacquer & shampoo	
Clotrimazole	OTC	x		x	x	x
Econazole	Rx	x				
Haloprogin	Rx	x			x	
Ketoconazole	Rx/OTC	x			Shampoo	
Miconazole	OTC	x		x	x	x
Naftifine	Rx	x	x			
Nystatin	Rx	x		x		x
Oxiconazole	Rx	x		x		
Sertaconazole	Rx	x				
Sulconazole	Rx	x				
Terbinafine	OTC	x	x		x	
Tolnaftate	OTC	x		x	x	

Table 83-7

Dosing of Topical Agents for Tinea Infections

Agents	Topical Dosing Frequency
Butenafine	Once daily
Ciclopirox	Twice daily; at bedtime (lacquer)
Clotrimazole	Twice daily
Econazole	Once daily
Haloprogin	Twice daily
Ketoconazole	Once daily
Miconazole	Twice daily
Naftifine	Once daily (cream); twice daily (gel)
Oxiconazole	Twice daily
Sertaconazole	Twice daily
Sulconazole	Twice daily
Terbinafine	Twice daily
Tolnaftate	2-3 times daily

Table 83-8

Dosing of Systemic Therapy for Tinea Infections

Medication	Adult Dosing	Pediatric Dosing
Fluconazole	150 mg/week	6 mg/kg/week
Griseofulvin	0.5-1 g/day	10-20 mg/kg/day
Itraconazole	200 mg twice daily	Not studied
Ketoconazole	200-400 mg/day	3.3-6.6 mg/kg/day
Terbinafine	250 mg/day	Less than 25 kg: 125 mg/day; 25-35 kg: 187.5 mg/day; more than 35 mg: 250 mg/day

after it is cleaned and dried. The medication should be rubbed into the infected area for improved penetration. Because most patients do not rub in sprays and powders, penetration of the epidermis is minimal, making them less effective than other formulations. Sprays and powders should be considered as adjuvant therapy with a cream or lotion or as prophylactic therapy to prevent recurrence (Table 83-7).

Due to the severity of infection and inflammation, tinea capitis does not adequately respond to topical agents. Oral agents for 6 to 8 weeks are recommended for eradication of tinea capitis. Griseofulvin has long been considered the treatment of choice due to its ability to achieve high levels within the stratum corneum. Itraconazole has also demonstrated effectiveness. Due to its lipophilicity, itraconazole achieves high levels in the skin. These levels are maintained for 4 weeks after medication is discontinued. Some practitioners recommend adjunct therapy with the oral agent to decrease dissemination, including ketoconazole or selenium sulfide shampoos.

Treatment of Onychomycosis

Onychomycosis is a chronic infection that rarely remits spontaneously. Adequate treatment is essential to prevent spread to other sites, secondary bacterial infections, cellulitis, or gangrene. ¹⁰ Due to the chronic nature and impenetrability of nails, topical agents have low efficacy rates for treating onychomycosis. Oral agents that can penetrate the nail matrix and nail base, such as itraconazole and terbinafine, are more effective than ciclopirox lacquer. Itraconazole and terbinafine demonstrate mycological cure rates of 62%³⁷ and 76%,³⁸ respectively, whereas ciclopirox has a cure rate of 29% to 36%.³⁹

Itraconazole can be administered continuously (200 mg orally daily) or as pulse therapy (200 mg orally twice daily for 1 week per month). Terbinafine is administered orally 250 mg per day as continuous therapy. Whether administered continuously or as pulse therapy, oral treatment for toenail infections should continue for at least 3 months, whereas treatment for fingernail infections should continue for at least 2 months. Terbinafine is an inhibitor of CYP450 2D6 isozyme. When administered with other medications metabolized via this isozyme, the other medication should be started at a low dose if it has a narrow therapeutic

range. Griseofulvin is also effective for the treatment of onychomycosis, but therapy must be continued for 4 months for fingernail infections or 6 months for toenail infections. For patients with liver disease or who are unable to use oral agents, ciclopirox nail lacquer remains a reasonable alternative, although it requires 48 weeks of therapy.

The FDA has released warnings pertaining to itraconazole and terbinafine as there is a small but real risk of developing congestive heart failure with itraconazole therapy due to its negative inotropic effects. Itraconazole should not be administered to patients with ventricular dysfunction such as congestive heart failure. The FDA also released warnings that itraconazole and terbinafine are associated with serious hepatic toxicity, including liver failure and death. Liver failure associated with these medications has occurred in patients with no preexisting living disease or serious underlying medical conditions. Treatment with itraconazole or terbinafine for prolonged periods requires laboratory monitoring of liver function tests before initiation of therapy and at monthly intervals.

Cultural Awareness When Treating Mycotic Infections

Awareness of cultural beliefs related to feet and hands is essential when treating patients with fungal infections. In Arab countries, showing the bottom of the foot is a grave insult. The foot is considered the dirtiest part of the body. As such, patients from these countries may be hesitant to show their feet to the practitioner. In other countries, the open palm “high five” gesture is considered insulting. When treating patients with infections on the hand, the practitioner should refrain from making this gesture while discussing the patient’s hand infection.

OUTCOME EVALUATION

- For infections of the skin, patients should notice relief of symptoms, including pruritus, scales, and inflammation, within 1 to 2 weeks. Therapy should be continued at least 1 week after complete resolution of symptoms. If the

Patient Care and Monitoring of Mycotic Infections

1. Assess the patient’s symptoms to determine whether self-treatment with OTC antifungal therapy is appropriate or whether the patient should be evaluated by a practitioner. Exclusions for self-treatment include infection of nails or hair, unsuccessful initial treatment, worsening condition, signs of secondary bacterial or systemic infection, large infected areas, or chronic medical conditions such as diabetes, immunosuppression, or impaired circulation.
2. Review any available diagnostic data, including cultures and KOH preps.
3. Obtain a thorough history of prescription, nonprescription, and natural drug product use.
4. If the patient has had a mycotic infection previously, determine what treatments were helpful to the patient in the past.
5. Educate the patient on lifestyle modifications that will prevent recurrence, including keeping the area dry, wearing shower shoes, washing clothing in hot water, using drying powders, avoiding sharing towels or clothing, and wearing loose-fitting clothing.
6. Develop a plan to assess effectiveness of antifungal therapy.
7. Determine whether long-term prophylactic therapy is necessary to prevent recurrence.
8. Evaluate the patient for the presence of adverse drug reactions, drug allergies, and drug interactions.
9. Stress the importance of adherence with the antifungal regimen.
10. Provide the patient education pertaining to mycotic infections and antifungal therapy.
 - Causes of mycotic infections of the skin, hair, or nails
 - Different types of OTC antifungal products, such as creams, sprays, shampoos, ointments, gel, lotions, solutions, and powders
 - How to apply various OTC antifungal products
 - How long therapy should be continued
 - How to avoid spread of infection
 - How to avoid recurrent infection
 - Potential adverse effects that may occur with antifungal therapy
 - Dietary modifications that are necessary with oral agents
 - Medications that may interact with antifungal therapy, particularly with oral agents used for nail infections
 - Warning signs to report to a physician (recurrent or difficult-to-cure infections, infections with malodorous discharge or bleeding)

condition worsens or does not resolve within 4 weeks, the patient should be treated with oral therapy.

For onychomycosis, relief of symptoms is slow. The infected nail will need months to grow out. The practitioner should advise the patient not to become frustrated by the slow resolution. Despite the slow progress, the antifungal agent is curing the infection. The practitioner should also advise the patient that even after the infection is cured, the nail may not look “normal.”

Abbreviations Introduced in This Chapter

AIDS	Acquired immunodeficiency syndrome
CDC	Centers for Disease Control and Prevention
HIV	Human immunodeficiency virus
KOH	Potassium hydroxide
OPC	Oropharyngeal candidiasis
OTC	Over the counter
PAS	Periodic acid-Schiff test
VVC	Vulvovaginal candidiasis

Invasive Fungal Infections

Russell E. Lewis

LEARNING OBJECTIVES

● Upon completion of the chapter, the reader will be able to:

1. Differentiate epidemiologic differences and host risk factors for acquisition of primary and opportunistic invasive fungal pathogens.
2. Recommend appropriate empiric or targeted antifungal therapy for the treatment of invasive fungal infections.
3. Describe the components of a monitoring plan to assess effectiveness and adverse effects of pharmacotherapy for invasive fungal infections.
4. Evaluate the role of antifungal prophylaxis in the prevention of opportunistic fungal pathogens.

KEY CONCEPTS

- 1 The diagnosis of endemic fungal infections is often prompted by a patient history of prolonged infectious symptoms, travel or residence in an endemic area, and/or participation in activities that result in exposures to soil contaminated by endemic fungi.
- 2 The approach to antifungal therapy in patients with endemic fungal infections is determined by the severity of clinical presentation, the patient's underlying immunosuppression, and potential toxicities and drug interactions associated with antifungal treatment.
- 3 Commensal or environmental fungi that are typically harmless can become invasive mycoses when the host immune defenses are impaired. Host immune suppression and risk for opportunistic mycoses can be broadly classified into three categories: (a) quantitative or qualitative deficits in neutrophil function, (b) deficits in cell-mediated immunity, and (c) disruption of integument and/or microbiologic barriers.
- 4 It is important to be familiar with the relative epidemiology and frequency of non-*albicans* *Candida* species in the institution or intensive care unit (ICU) before selecting empiric antifungal therapy for invasive candidiasis, as fluconazole is not recommended for the treatment of *C. glabrata* and *C. krusei* infections
- 5 If a patient is nonneutropenic, clinically stable (i.e., normotensive with relatively normal organ function), and has never received prior azole therapy, fluconazole 12 mg/kg/day loading dose followed by 6 mg/kg/day is still considered an appropriate first-line therapy for

invasive candidiasis in many centers until speciation of the *Candida* isolate is confirmed.

- 6 Clinical trials performed by the National Institute of Allergy and Infectious Diseases (NIAID) Mycoses Study Group demonstrated that 2 weeks of induction antifungal therapy with combination amphotericin B (0.7 mg/kg/day) plus flucytosine (100 mg/kg/day) achieved the highest clinical cure rates with reduced toxicity for cryptococcal meningitis.
- 7 Immunocompromised patients on fluconazole with progressive sinus or pulmonary disease by radiography should be considered to have a possible mold infection and receive empiric antifungal therapy directed (at minimum) against *Aspergillus species*.

Invasive fungal infection or invasive mycoses are general terms for diseases caused by invasion of living tissue by fungi. Unlike superficial mycoses (see Chap. 83), invasive mycoses invade internal organs, can disseminate throughout the body, and are associated with high rates of morbidity and mortality, particularly in the immunocompromised host.

● Invasive fungal infections are broadly categorized as either primary or opportunistic invasive mycoses. Primary invasive fungal infections are caused by fungal spores or conidia in the soil that, when disturbed, can become aerosolized and inhaled leading to infection, even in an immunocompetent patient. Because these fungi are often endemic to certain soil types and hence geographically restricted, primary invasive fungal pathogens are also known as endemic fungi. In the United States, three species (*Histoplasma capsulatum*, *Blastomyces dermatitidis*, and *Coccidioides immitis*) account

Table 84–1

for most of these infections (Table 84–1). In contrast, opportunistic fungal infections occur only in the setting of compromised host immune defenses and are caused by a wider spectrum of less virulent fungal species that are generally

incapable of causing infection in healthy patients (see Table 84–1). Hence, the spectrum, severity, and outcome of opportunistic fungal infections are heavily influenced by the degree, type, and severity of host immunosuppression. As a general rule, opportunistic fungal infections are difficult to diagnose, uniformly fatal if not treated early and aggressively, and associated with high rates of morbidity and mortality.

ENDEMIC MYCOSES**EPIDEMIOLOGY**

Endemic mycoses are capable of infecting otherwise healthy individuals. In immunocompromised patients, endemic fungal infections often present with a more fulminant course (in the case of primary infections) or reactivate to cause life-threatening infection. Because initial symptoms of an endemic fungal infection are nonspecific and produce symptoms indistinguishable from other slowly progressing infections (e.g., tuberculosis), a careful patient history concerning travel and activities associated with potential exposure to soil contaminated with endemic fungi is essential for the diagnosis.

- Two of the most common endemic fungal infections (histoplasmosis and North American blastomycosis) are found in overlapping regions in the eastern and central river basins of the United States (Fig. 84–1).¹ *Histoplasma capsulatum* var. *capsulatum*, the causative fungus of histoplasmosis, grows heavily in soil contaminated with bird or bat excreta, which serve to enhance sporulation of the fungus.² Activities

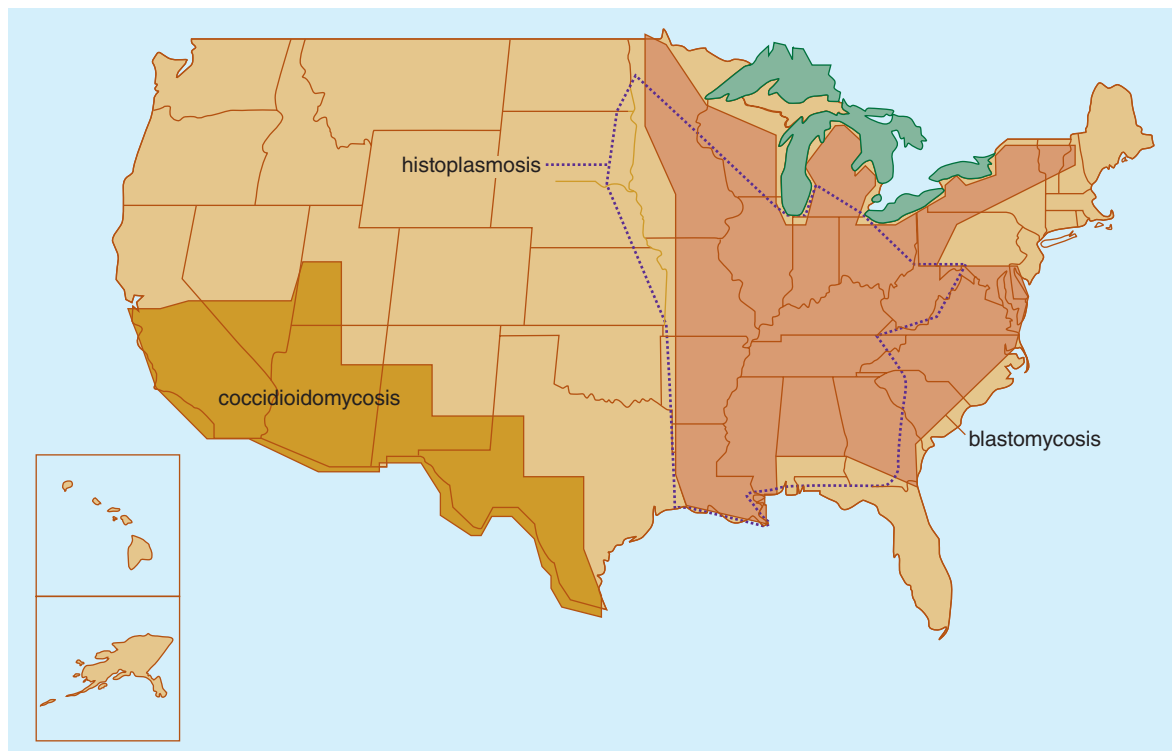

FIGURE 84–1. Geographic localization of primary (endemic) fungi in the United States.

in endemic regions that are classically associated with high exposures to *Histoplasma capsulatum* include cave exploration (spelunking), working in or demolishing chicken coops, or demolition of older buildings, woodcutting in forests with large bird roosts, or spreading avian excreta as fertilizer. For blastomycosis, decaying organic matter, warm humid conditions, and proximity to water or frequent rainfall seem to support growth of this fungus.³ Occupational or recreational activities that disturb soil heavily contaminated with *Blastomyces dermatitidis* are a common feature in the social history of patients who develop blastomycosis. Coccidioidomycosis differs from histoplasmosis and blastomycosis, as the fungus is associated with arid to semiarid climates, hot summers, low altitude, alkaline soil, and sparse flora. Hence the fungus is found in the southwestern regions of the United States stretching from western Texas to southern California (see Fig. 84–1).⁴ Epidemics of coccidioidomycosis have been reported in California following dust storms and earthquakes, including cycles of intense drought and rain, which favor the growth cycle of the fungus and enhance dispersion of its specialized spore forms, called arthroconidia.

PATHOPHYSIOLOGY

Endemic fungi share several key biologic and ecologic characteristics that contribute to their pathogenicity in humans. All endemic fungi exhibit temperature-dependent dimorphism, meaning they can propagate as either yeast (single cells that reproduce by budding into daughter cells) or molds (multicellular filamentous fungi that reproduce through production of conidia or spores). At environmental temperatures (25–30°C [77–86°F]), *H. capsulatum*, *B. dermatitidis*, and *C. immitis* grow in the mold form, producing 2- to 10- μ m round- to oval-shaped (*Histoplasma* and *Blastomyces*) or barrel-shaped conidia (*Coccidioides*) that are dispersed throughout the environment and in air currents. At physiologic temperatures, the conidia germinate into yeast (*Histoplasma* and *Blastomyces*) or in specialized cell forms called spherules (*Coccidioides*) that are resistant to killing by resident alveolar macrophages and neutrophils in the host lung. Control of infection is mediated by the development of antigen-specific T-lymphocyte response that enhances macrophage fungicidal activity and formation of a granuloma to contain the fungus.⁵ Not surprisingly, patients with T-cell-mediated immune deficiency (e.g., AIDS patients and transplant recipients) or suppressed cellular immunity due to drug therapy (e.g., chemotherapy, high-dose corticosteroids, or tumor necrosis- α blockers such as infliximab) are especially prone to severe reactivation of fungal disease.

The most common route of infection for endemic fungi is the respiratory tract, where conidia aerosolized from contaminated soil are inhaled into the lung. Once in the lung, conidia are phagocytosed but not destroyed by resident macrophages and neutrophils in the alveoli and bronchioles. Within 2 to 3 days, conidia germinate into **facultative** yeast resistant to phagocytosis and killing by macrophages and neutrophils

FIGURE 84-2. Histopathology of endemic mycoses in tissue. A. Histoplasmosis (yeast). B. Blastomycosis (broad-based budding yeast). C. Coccidioidomycosis (spherules with endospores).

(Fig. 84–2A and B). For *C. immitis*, germination of the arthroconidia results in the formation of a sac-like structure called a spherule filled with endospores (Fig. 84–2C). Spherules then rupture to release large numbers of endospores, which are the propagating form of the infection. Control of infection in the lungs is typically accomplished through formation of **granulomas**. However, in patients exposed to an overwhelming inoculum, or lower inocula in the setting of suppressed T-cell-mediated immunity, dissemination outside the lung to the skin and oral mucosa (especially blastomycosis), adrenal glands, bone, spleen, thyroid, GI tract, heart, and CNS is possible and uniformly fatal if left untreated.

CLINICAL PRESENTATION AND DIAGNOSIS

Histoplasmosis and coccidioidomycosis are frequently asymptomatic infections in immunocompetent patients or present as a self-limiting, influenza-like illness 1 to 3 weeks after inhalation of conidia. The clinical presentation of blastomycosis can range from asymptomatic infection, to acute or chronic pneumonia that develops 30 to 40 days after exposure, to full-blown disseminated disease.

Symptomatic endemic fungal infections often present as persistent pneumonia despite antibiotic therapy that is accompanied by fever, chills, cough, arthralgia, night sweats, and weight loss that is indistinguishable from other chronic infections such as pulmonary tuberculosis. **1** *The diagnosis of endemic fungal infection is often prompted by a patient history of prolonged infectious symptoms, travel or residence in an endemic area, and/or participation in activities that result in exposures to soil contaminated by endemic fungi.*

Radiographs

- Chest radiographs often reveal either diffuse or nodular infiltrates in the lung, accompanied by enlargement of the hilar and/or mediastinal lymph nodes.
- Fulminant pneumonia may be seen with high inoculum exposures, resulting in diffuse lung infiltrates that precede to acute respiratory distress syndrome (ARDS) and respiratory failure.

Signs and Symptoms

- Rheumatologic symptoms such as severe arthritis, pericarditis, and erythema nodosum may be seen in 10% to 30% of patients with endemic fungi.^{1,2,6}
- Dissemination outside the lung is common in patients with suppressed cellular immunity and frequently produces signs of progressing infection.
- Ulcerative oral and cutaneous lesions may also arise with any endemic fungal infections.
- Verrucous skin lesions on sun-exposed areas on the face are particularly suggestive of progressing blastomycosis and are frequently mistaken for cutaneous malignancy.⁶
- Dissemination of the fungi to bone marrow may result in anemia or thrombocytopenia.
- Hepatomegaly, splenomegaly, and adrenal insufficiency can also occur with dissemination of the endemic fungi to these internal organs.
- Seizures, meningeal signs, and hydrocephalus are common findings with dissemination of the infection to the CNS and portend an especially poor prognosis in the setting of disseminated coccidioidomycosis.

Definitive diagnosis of an endemic fungal infection requires growth of the fungus from body fluids or tissue, or evidence of cellular or tissue invasion in clinical samples by histopathology. However, cultures may only be positive in the setting of high inoculum exposures, pneumonia, or disseminated disease.⁷ Serologic testing is helpful in the diagnosis and management of patients with histoplasmosis or coccidioidomycosis but lacks sufficient specificity for diagnoses of *B. dermatitidis*.⁶ In general, a fourfold rise in antibody or complement fixation titers of *Histoplasma* or *Coccidioides* or any titer greater than 1:16 suggests active infection. However, many clinicians still consider titers as low as 1:8 as evidence

Patient Encounter 1, Endemic Fungal Infection, Part 1

A 64-year-old woman from Indianapolis, Indiana, with a history of rheumatoid arthritis chronically treated with prednisone and methotrexate presents with a 4-week history of cough, fever, and night sweats and 9-kg weight loss. Approximately 6 weeks before this presentation, she was treated with infliximab for an arthritis flare. The patient complained of fatigue but was afebrile (37°C), with a normal resting respiratory rate. Laboratory studies revealed anemia (hemoglobin less than 8.7 g/dL [87 g/L or 5.4 mmol/L]). Computer tomography (CT) of the chest revealed several pulmonary nodules.

What are this patient's risk factors for developing an endemic fungal infection?

What is the most likely endemic fungal pathogen based on this patient's area of residence?

of active disease because undetectable titers may be present in one-third of all active infections.⁴ Enzyme-linked immunosorbent assays (ELISAs) have been developed for detection of *Histoplasma* antigen in serum and urine, and a new radioimmunoassay directed against surface proteins of *B. dermatitidis* has shown promising sensitivity and specificity. Serial antigen testing can also provide a means for assessing response to antifungal therapy and early detection of relapse in patients with histoplasmosis or coccidioidomycosis.

The clinical presentation of blastomycosis covers a wide spectrum ranging from asymptomatic infections to flu-like illness resembling other upper respiratory tract illnesses; to infections resembling bacterial pneumonia with acute onset, high fever, lobar infiltrates, and cough; to subacute or chronic respiratory illness with complex symptoms resembling tuberculosis or lung cancer. At the other end of the spectrum, blastomycosis can also present with fulminant lung infections with high fever, diffuse infiltrates, and an ARDS-like presentation.⁶ As mentioned previously, the skin is the most common site of dissemination, typically involving sunlight exposed body areas (i.e., nose, face, and arms) and mucous membranes.

TREATMENT

General Approach

- 2 The approach to antifungal therapy in patients with endemic fungal infections is determined by the severity of clinical presentation, the patient's underlying immunosuppression, and potential toxicities and drug interactions associated with antifungal treatment. Immunocompetent patients with mild disease following exposure to *H. capsulatum* or *C. immitis* often experience a benign course of infection and rarely require antifungal therapy. Persons of Filipino or African descent have a higher risk for dissemination with *C. immitis*, and this may also be taken into consideration for more aggressive treatment.⁴ Typically, patients are followed in the outpatient setting with serial antigen testing to confirm resolving infection. Patients without clinical improvement within the first month are typically treated with oral itraconazole for 6 to 12 weeks (Table 84-2).^{1,4,6} Broader spectrum triazoles such as voriconazole and posaconazole appear to have good activity against endemic fungi; however, there are currently insufficient data to recommend their routine first-line use. Fluconazole (400 to 800 mg/day) is somewhat less effective than itraconazole (higher relapse rates) but has fewer GI adverse effects and drug interactions versus itraconazole.^{1,4,6}
- Patients with progressive symptoms for longer than 2 weeks or titers greater than 1:8 of histoplasmosis or coccidioidomycosis antigen are candidates for immediate antifungal therapy.^{1,4} Any patient with underlying immunosuppression should also receive immediate antifungal therapy. The following signs and symptoms are considered to be indicators of severe disease that require hospitalization and initial treatment with systemic amphotericin B (see Table 84-2).^{1,4,6}

- Hypoxia indicated by a partial pressure of oxygen less than 80 mm Hg (10.6 kPa)
- Hypotension (systolic blood pressure less than 90 mm Hg)

Table 84-2

Common Treatment Regimens for Endemic Fungal Infections

Mycosis	Recommended Treatment Regimens	Comments
Histoplasmosis Mild to moderate	Observation or itraconazole 200 mg 3 × daily for three days, then 1 to 2 × daily for 6–12 weeks Fluconazole 12 mg/kg/day PO for 6–12 weeks adjusted for renal function ^a	Fluconazole has a higher rate of relapse than itraconazole, but is better tolerated by many patients than itraconazole. Echinocandins are not clinically effective against endemic mycoses. Lipid formulation may be more effective than conventional formulations, especially for CNS disease. Patients initially treated with amphotericin B–based regimens are transitioned to itraconazole or fluconazole once they are clinically stable. Corticosteroid therapy should be considered in hypoxic patients with acute pulmonary infection. Itraconazole is less effective for CNS infections.
Severe including CNS disease or immunocompromised host	Amphotericin B 0.7 mg/kg per day IV or liposomal AMB 3–5 mg/kg per day for 12 weeks or until clinically stable	
Blastomycosis Mild to moderate	itraconazole 200 mg 3 × daily for 3 days, then 1 to 2 × daily for 6–12 weeks OR Fluconazole 6–12 mg/kg/day PO adjusted for renal function ^a	Relapses are common in immunocompromised host Suppressive therapy with itraconazole 200 mg/day PO or fluconazole 800 mg PO daily for 6 months is common in immunocompromised patients.
Severe including CNS disease or immunocompromised host	Amphotericin B 0.7 mg/kg per day IV until patient is clinically stable, then Itraconazole (non-CNS) or fluconazole 12 mg/kg/day PO adjusted for renal function ^a	
Coccidioidomycosis Mild to moderate	Observation or itraconazole 200 mg 3 × daily for three days, then 1 to 2 × daily for 6–12 weeks OR Fluconazole 6–12 mg/kg/day PO daily adjusted for renal function ^a	Itraconazole demonstrated trend toward superiority over fluconazole in a randomized controlled trial for progressive, nonmeningeal coccidioidomycosis; however, fluconazole is better tolerated than itraconazole.
Diffuse pneumonia or disseminated infection	Amphotericin B 1–1.5 mg/kg per day with dose and frequency decreased as improvement occurs OR Lipid Amphotericin B formulations 3–5 mg/kg per day	Fluconazole 800–1,000 mg/day adjusted for renal function ^a is often recommended after initial AMB therapy for meningitis.

CNS, central nervous system; IV, intravenous; PO, oral.

^aCrCl more than 50–90 mL/min (more than 0.83–1.50 mL/s), 100% of dose; CrCl 10–50 mL/min (0.17–0.83 mL/s), 50% of dose; CrCl less than 10 mL/min (less than 0.17 mL/s) 50%.

- Impaired mental status
- Anemia (hemoglobin less than 10 g/dL [100 g/L or 6.2 mmol/L])
- Leukopenia (less than $1 \times 10^3/\text{mm}^3$ [$1 \times 10^9/\text{L}$])
- Elevated hepatic transaminases (greater than five times upper limit of normal) or bilirubin (greater than 2.5 times upper limit of normal)
- Coagulopathy

- More than 10% loss in body weight with onset of illness
- Evidence of dissemination, including cutaneous manifestations
- Meningitis

The treatment of blastomycosis is heavily dependent on the severity of clinical manifestations. Generally, patients with mild disease can be managed as outpatients with oral itraconazole.⁶ Patients with evidence of severe pulmonary disease or

Patient Encounter 1, Endemic Fungal Infection, Part 2

Selecting Antifungal Therapy

The patient's serum titer for histoplasmosis returns as greater than 1:64. Based on the information presented, select an appropriate treatment plan for the patient's infection.

What antifungal treatment should the patient receive at this time?

What additional measures should be considered if the patient develops respiratory distress?

dissemination require initial treatment in the hospital with amphotericin B–based regimens until they are clinically stable, whereupon they can complete a 6- to 12-month treatment course as outpatients with oral triazoles.⁶ Methylprednisolone (0.5 to 1 mg/kg daily IV) during the first 1 to 2 weeks of antifungal therapy is recommended for patients who develop respiratory complications during initial treatment, including hypoxemia or significant respiratory distress.

PATIENT MONITORING

Response to antifungal therapy may be slow in patients with a prolonged history of infection or severe manifestations. However, gradual improvements in symptoms and reduction in fever are indicators of response to antifungal therapy. For histoplasmosis and coccidioidomycosis, decreasing antigen titers are also indicative of response to antifungal therapy.¹⁴

Antifungals used for the treatment of endemic mycoses can be associated with clinically significant drug interactions and toxicities, especially with the prolonged treatment courses that are often required in the management of endemic mycoses. Itraconazole is available as a capsule formulation and as a cyclodextrin-solubilized solution. The liquid formulation of itraconazole has several advantages over the capsule: It has a better oral bioavailability and does not require the low gastric pH that is required for dissolution and absorption of the capsule. However, the oral solution is somewhat dilute, has an unpalatable aftertaste (an issue when taking months of therapy), and has a much higher rate of GI intolerance. Therefore, the capsule formulation is often preferred provided patients are not on acid-suppression therapy (i.e., proton pump inhibitors, histamine antagonists, or antacids). Posaconazole is formulated as a micronized suspension that is best absorbed when taken with high-fat meals in divided doses up to 800 mg per day. Similar to the capsule formulation of itraconazole, the coadministration of posaconazole with acid-suppression therapy significantly reduces drug absorption, especially if the patient has poor appetite, nausea, or diarrhea. Absorption of voriconazole is not affected by gastric pH, but is generally administered 1 hour prior to or 2 hours after eating.

Drug interactions are an important concern in patients taking long-term triazole therapy. Itraconazole and voriconazole are substrates of the cytochrome P450 (CYP) 3A4 enzyme. Coadministration of itraconazole, voriconazole, and to lesser extent fluconazole and posaconazole, with inducers of this CYP 3A4 (e.g., rifampin, phenytoin, and phenobarbital) increases drug clearance resulting in ineffective plasma and tissue concentrations of the drug.^{8–11} In general, coadministration of the broader spectrum triazoles (itraconazole, voriconazole, posaconazole) with these inducers should be avoided. Itraconazole, voriconazole, and posaconazole are also potent inhibitors of CYP 3A4, which predisposes these agents to a large number of clinically significant pharmacokinetic drug–drug interactions. Posaconazole is also a substrate and inhibitor of P-glycoprotein, although the impact of this pathway on drug absorption is unknown. Even in the absence of drug interactions, serum drug levels of the broader spectrum triazoles (itraconazole, voriconazole, posaconazole) are often variable.¹² For voriconazole, pharmacokinetic variability results primarily from pharmacogenetic differences in CYP2C19 metabolism, with some patients classified as homozygous rapid metabolizers, heterozygous metabolizers, or homozygous poor metabolizers. Consequently, serum drug exposures are often difficult to predict from one patient to the next administered fixed drug doses. Impaired absorption is a primary factor influencing the variability of itraconazole and posaconazole serum concentrations. Serum drug concentration monitoring has been recommended in patients receiving triazole antifungals for documented infections, or when inadequate serum concentrations are suspected (Table 84–3).

As potent inhibitors of CYP3A4, itraconazole, voriconazole, and posaconazole can dramatically decrease the clearance of many medications with narrow therapeutic indices, leading to potentially dangerous drug interactions. Patients receiving anticoagulation therapy with warfarin, immunosuppressive therapy with cyclosporine or tacrolimus, those taking midazolam, HMG-CoA reductase inhibitors (statins), rifabutin, chemotherapy agents (e.g., vinca alkaloids, busulfan, and cyclophosphamide), and digoxin will require dosage adjustment and careful monitoring while receiving therapy with triazole antifungals.¹² Although fluconazole is not as potent an inhibitor of CYP3A4 as other triazoles, clinically significant drug interactions may still be observed at higher fluconazole dosages (i.e., 800 mg/day).¹²

All azole antifungals carry the potential for rash, photosensitivity, and hepatotoxicity. In general, hepatotoxicity is mild and reversible, presenting as asymptomatic increases in liver transaminases or with cholestatic toxicity with increases in total bilirubin. Fulminant hepatic failure is less common and typically mediated by immunologic mechanisms. Therefore, serial monitoring of liver function is recommended in all patients receiving triazole antifungals. Long-term therapy with itraconazole has also been associated with reversible adrenal suppression and cardiomyopathy associated with the drug's negative inotropic effects. These adverse effects can be prevented or managed with close monitoring and follow-up of patients on long-term therapy. Voriconazole has also been

Table 84-3

Recommendations for Antifungal Therapeutic Drug Monitoring

Drug	Indication for Monitoring	Time of First Measurement	Target Conc. for Efficacy (mcg/mL or mg/L)	Target Conc. for Safety (mcg/mL or mg/L)
Flucytosine	Routine during first week of therapy, renal insufficiency, or poor clinical response	3–5 days	Peak greater than 20 (greater than 155 $\mu\text{mol/L}$)	Peak less than 50 (less than 388 $\mu\text{mol/L}$) to reduce risk of marrow toxicity
Itraconazole	Routine during first week of therapy, GI dysfunction, suspected drug interactions	4–7 days	Prophylaxis greater than 0.5 (greater than 0.7 $\mu\text{mol/L}$); therapy trough greater than 1–2 (greater than 1.4–2.8 $\mu\text{mol/L}$)	Some evidence to suggest trough greater than 4 mcg/mL (greater than 5.7 $\mu\text{mol/L}$) increased cardiac toxicity
Voriconazole	Lacking response, GI dysfunction, suspected drug interactions, pediatrics, ^a IV to oral switch, unexplained neurological changes	4–7 days	Prophylaxis trough greater than 0.5 (greater than 1.4 $\mu\text{mol/L}$); therapy trough 1–2 (2.9–5.7 $\mu\text{mol/L}$)	Trough less than 6 (17.2 $\mu\text{mol/L}$) to reduce risk of CNS toxicities
Posaconazole	Lacking response, GI dysfunction, potent acid suppression therapy (i.e., proton pump inhibitor) therapy, suspected drug interactions	4–7 days	Prophylaxis trough greater than 0.5 (greater than 0.7 $\mu\text{mol/L}$); therapy trough 0.5–1.5 (0.7–2.1 $\mu\text{mol/L}$)	Not established

^aPediatric patients display accelerated linear clearance of voriconazole. Therefore, higher daily voriconazole dosing (7 mg/kg every 12 hours) without a loading dose are recommended to achieve similar exposures to adults. Some children may require doses as high as 12 mg/kg every 12 hours to achieve similar serum drug exposures to adults. Therefore, therapeutic drug monitoring is recommended.

associated with severe phototoxic reactions and cutaneous erythema in sun-exposed skin, which may not be preventable with sunscreen alone. These reactions have been recently linked to development of squamous cell carcinoma or melanoma. Therefore, patients should be instructed to avoid sun exposure while on voriconazole therapy and have frequent skin examinations by a dermatologist.

- Amphotericin B is the mainstay of treatment of patients with severe endemic fungal infections. The conventional deoxycholate formulation of the drug can be associated with substantial infusion-related adverse effects (e.g., chills, fever, nausea, rigors, and in rare cases hypotension, flushing, respiratory difficulty, and arrhythmias). As-needed premedication with low doses of hydrocortisone, acetaminophen, nonsteroidal anti-inflammatory agents, and meperidine can be used to reduce acute infusion-related reactions. Venous irritation associated with the drug can also lead to thrombophlebitis; hence central venous catheters are the preferred route of administration in patients receiving more than a week of therapy.

- The most severe adverse effect associated with amphotericin B therapy is nephrotoxicity, which occurs through the renal vascular effects of the drug (constriction of the afferent arterioles in the kidney tubule), and direct toxicity to the kidney tubular membrane.¹² Generally, nephrotoxicity with amphotericin B is reversible provided the drug is stopped. However, treatment interruptions can be problematic in patients with severe infections. Precipitous decreases in glomerular filtration may occur in patients with marked dehydration or during aggressive diuresis. Infusion of normal saline before and after amphotericin B, a practice known as “sodium loading,” can blunt precipitous decreases in renal

perfusion pressure and slow the rate of decline in the glomerular filtration rate. Administration of amphotericin B by continuous infusion has also been reported to reduce the nephrotoxicity of the drug, but is generally not advocated because of unproven efficacy when the drug is administered by this approach. Tubular toxicity can be delayed by avoiding the use of other drugs with known tubular toxicity such as aminoglycosides, cyclosporine, cisplatin, or foscarnet. Generally, tubular toxicity manifests in patients with severe wasting of potassium and magnesium in the urine. Therefore, patient electrolytes must be carefully monitored and potassium and magnesium supplementation is always necessary. Hypokalemia and hypomagnesaemia frequently precede decreases in glomerular filtration (increased serum creatinine), especially in patients who are adequately hydrated.¹² Continued tubular damage eventually results in decreases in renal blood flow and glomerular filtration through tubuloglomerular feedback mechanisms that further constrict the afferent arteriole.

- During the 1990s, amphotericin B was reformulated into three different lipid-based formulations (Abelcet, AmBisome, and Amphotec) that have reduced rates of nephrotoxicity compared with the conventional deoxycholate formulation (Fungizone). Two of the formulations (Abelcet and AmBisome) have also shown reductions in the rates of infusion-related reactions. Although these lipid formulations are generally considered to be as effective as conventional amphotericin B deoxycholate, they are not dosed equivalently to the standard formulation (Table 84-2).

Unlike conventional amphotericin B, which is administered at dosages ranging from 0.6 to 1.5 mg/kg/day, lipid formulation

doses are threefold to fivefold higher on a milligram-per-milligram basis, ranging from 3 to 6 mg/kg/day.¹² Only one prospective study has directly compared the efficacy of a lipid amphotericin formulation with that of the conventional formulation in AIDS patients with disseminated histoplasmosis.¹³ Liposomal amphotericin B (AmBisome) was found to be more effective than amphotericin B, with response rates of 84% and 64%, respectively. AmBisome may also be the preferred agent in patients with CNS infections over other lipid formulations, due to its improved CNS penetration.¹⁴

PROPHYLAXIS

Primary prophylaxis, before development of infection, is generally not recommended for endemic fungi but may be considered in specific situations, including the following:

1. Patients with HIV infection with CD4⁺ cell counts less than 150 cells/mm³ ($150 \times 10^6/L$) (histoplasmosis) or less than 250 cells/mm³ ($250 \times 10^6/L$) (coccidioidomycosis) living in regions with high endemic case rates (greater than 10 cases per 100 patient-years), or in any patient with positive IgM or IgG antibodies. The recommended regimen is itraconazole 200 mg daily.^{1,4,6}
2. Secondary prophylaxis or suppressive therapy with itraconazole 200 mg daily is recommended to prevent recurrence of blastomycosis in immunosuppressed patients if immunosuppression cannot be reversed.⁶
3. In patients with prior CNS disease, fluconazole or voriconazole are preferred over itraconazole due to the limited penetration of itraconazole into the CNS.

OPPORTUNISTIC MYCOSES

3 Commensal or environmental fungi that are typically harmless can become invasive mycoses when the host immune defenses are impaired. Host immune suppression and risk for opportunistic mycoses can be broadly classified into three categories:

1. Quantitative or qualitative deficits in neutrophil function
2. Deficits in cell-mediated immunity
3. Disruption of the integument and/or microbiologic barriers

Quantitative defects in neutrophils (neutropenia) resulting from neoplastic diseases, cytotoxic chemotherapy, marrow transplantation, or aplastic anemia are among the most common risk factors for opportunistic mycoses. Qualitative defects may be seen in certain disease states (e.g., advanced diabetes mellitus and chronic granulomatous disease) or with high-dose corticosteroid therapy. Deficits in T-cell-mediated immunity secondary to AIDS, high-dose corticosteroid therapy, cyclosporine or other immunosuppressive drugs, chemotherapy, transplantation, bone marrow failure, and various other disorders have become increasingly common with the prolonged survival of transplant patients on chronic immunosuppressive therapy.

Immune deficits arising from disruption of the integument or GI/genitourinary barriers can also predispose patients to

fungal infections. The most common types of barrier disruptions include surgery or infections/perforation of the abdominal viscus, use of central venous and urinary catheters, hyperalimentation, and mucositis associated with cytotoxic chemotherapy. Broad-spectrum antibacterial therapy can also predispose patients to fungal infections through disruption of the microbiologic flora in the gut, which allows overgrowth of *Candida* species. Successful management of opportunistic fungal pathogens, therefore, requires the reversal or reduction of underlying deficits in the host immune system.

All of the opportunistic mycoses are difficult to diagnose and often must be treated empirically before diagnosis is proven. Deciding when to initiate antifungal therapy and what opportunistic pathogens to cover is a decision governed largely by the cumulative immune deficits and clinical status of the host.

INVASIVE CANDIDIASIS

EPIDEMIOLOGY

Candida species are the most common opportunistic fungal pathogens encountered in hospitals, ranking as the third to fourth most common cause of nosocomial bloodstream infections in United States.¹⁵ The incidence of nosocomial candidiasis has increased steadily since the early 1980s, with the widespread use of central venous catheters, broad-spectrum antimicrobials, and other advancements in the supportive care of critically ill patients. In the 1980s, *C. albicans* accounted for more than 80% of all bloodstream yeast isolates cultured from patients. By the late 1990s, this relative frequency of *C. albicans* had decreased to 50% in national surveys of bloodstream infections without a corresponding decrease in infections caused by non-*albicans* species. Because of the inherent resistance (e.g., *C. krusei*) or diminished susceptibility (e.g., *C. glabrata*) of many of the non-*albicans* species, the introduction of fluconazole in the early 1990s is often cited as the key element driving the shift in the microbiology of invasive candidiasis.¹⁶ However, it is likely that other institution-specific factors (e.g., increasing use of central venous catheters and increasing intensity of cytotoxic/mucotoxic chemotherapy) and use of broad-spectrum antibiotic therapy have contributed equally to this trend. 4 It is important to be familiar with the relative epidemiology and frequency of nonalbicans *Candida* species in the institution or intensive care unit (ICU) before selecting empiric antifungal therapy for invasive candidiasis, as fluconazole is not recommended for the treatment of *C. glabrata* and *C. krusei* infections.

CLINICAL PRESENTATION AND DIAGNOSIS

Invasive candidiasis is not a single syndrome, rather a spectrum of infections that differ in terms of clinical presentation and course depending on the type of host immune immunosuppression. However, disseminated infection is associated

with crude mortality rates approaching 30% to 40%, underscoring the potential severity of infection.¹⁷ The most common form of invasive candidiasis is seen in nonneutropenic patients with disruption of the GI, skin, or microbiologic barriers giving rise to a bloodstream infection (fungemia) from, or seeding to, a central venous catheter. Catheter-related candidemia carries a good prognosis if appropriate antifungal therapy is instituted early with catheter removal.¹⁷ Fungemia can be of high density, however, leading to metastatic sites of infection and invasion of deep organs with increased morbidity. Therefore, the infection must be taken seriously, especially in patients with poor performance status (i.e., a high Acute Physiology, Age, and Chronic Health Evaluation [APACHE] II score) in the ICU.

Patients with acute disseminated candidiasis share many similar features as patients with catheter-related candidemia, except infection generally arises from the gut following mucotoxic chemotherapy, and the patients are often profoundly ill. Hematogenous spread to noncontiguous organs is common in patients with acute disseminated candidiasis, and outcome is heavily dependent upon recovery from neutropenia.¹⁷ Fluconazole prophylaxis has markedly decreased the incidence of acute disseminated candidiasis among high-risk patient groups such as bone marrow transplant and acute leukemia patients.¹⁷ However, breakthrough infections with fluconazole-resistant *C. glabrata* and *C. krusei* are still a concern.

Some forms of invasive candidiasis are dominated by deep-organ infection and may never be detected by blood cultures. Chronic disseminated candidiasis or hepatosplenic candidiasis is a unique presentation of candidemia seen after recovery from neutropenia. Candidemia during the period of neutropenia may be initially localized to the portal circulation with dissemination to contiguous organs. After recovery of neutrophils, an inflammatory response is seen against areas of focal infection in the liver and spleen. This inflammatory response produces abdominal pain that is associated with increases in alkaline phosphatase levels and hepatocellular enzymes.¹⁷ Diagnosis is typically confirmed by patient history (recent neutropenia), and multiple areas of lucency in the liver and spleen on CT.

Focal invasive candidiasis has been reported for virtually every organ, even following apparently uncomplicated catheter-related fungemia. The most common sites of infection are the kidney, eye, and bone. *Candida* in the urine can be an indication of renal candidiasis or an obstructing fungus ball; however, it must be distinguished from more benign colonization of the urinary tract, especially in patients with chronic indwelling urinary catheters.¹⁷ All patients with candidemia should undergo an eye exam to rule out *Candida* endophthalmitis, which can be sight-threatening if not recognized early.¹⁷

Laboratory diagnosis of invasive candidiasis is established by detection of the yeast in blood cultures or another sterile site (Fig. 84-3A).¹⁷ Growth of *Candida* from urine, sputum, or respiratory secretions (including bronchoalveolar lavage) is not considered to be evidence of invasive infection, as these areas frequently become colonized with *Candida*

species in patients receiving broad-spectrum antibiotics.¹⁷ Colonization at multiple body sites or with high density of *Candida* species, however, may precede invasive infection. Therefore, preemptive antifungal therapy may be indicated in colonized high-risk populations such as those with neutropenic fever, transplant recipients, or following major abdominal surgery.¹⁷ Although *Candida* are not particularly fastidious organisms, the sensitivity of blood cultures is relatively poor (less than 60%), and a negative culture does not rule out infection.¹⁷ The poor sensitivity of blood cultures for detecting invasive disease has led to the study of novel serodiagnostic tests to detect antibodies, fungal metabolites, fungal cell wall antigens, or nucleic acids of *Candida* species. Of the four approaches, testing of patient serum for fungal cell wall β -glucan polymers (i.e., Fungitell[®](1 \rightarrow 3)- β -D-glucan test, Associates of Cape Cod Inc.) appear most promising; however, these tests may not be routinely performed in many hospitals.

Laboratory identification of *Candida* in clinical samples must be performed to the species level whenever possible, as *Candida* species differ considerably in their susceptibility to antifungal agents.¹⁷⁻²⁰ Rapid discrimination of *C. albicans* from common nonalbicans *Candida* species can be accomplished by the germ-tube test, which presumptively identifies *C. albicans* by the early formation (less than 4 hours) of a hyphae-like structure when the yeast is incubated in serum at 37°C (98.6°F). Definitive species identification, however, may require an additional 48 to 72 hours after the organism is isolated on agar. Fluorescent in situ hybridization (FISH) of *Candida* species-specific DNA sequences can reduce the time needed for definitive species identification, but may not be offered in many clinical microbiology laboratories.

C. albicans remains the most common cause of invasive candidiasis and is the most virulent of *Candida* species, but is the most susceptible to commonly used antifungals including fluconazole.^{17,19,20} Like *C. albicans*, *C. tropicalis* is a relatively virulent species that has a tropism for causing deep tissue invasion. *C. tropicalis* is generally sensitive to antifungals, including fluconazole.^{17,19,20} *C. parapsilosis* is a less virulent species seen frequently in neonates and in adults with central venous catheters. Although *C. parapsilosis* is less virulent, many isolates form thick biofilms on prosthetic materials and catheters that make the organism difficult to eradicate.¹⁷ *C. parapsilosis* is generally susceptible to most antifungals, including fluconazole. However, this species is inherently less susceptible to echinocandin antifungals, although many patients still respond to treatment, perhaps due to the lower virulence of this species. *C. krusei* is a less common species associated with breakthrough infections in heavily immunocompromised patients and should always be considered resistant to fluconazole.^{17,19,20} Most fluconazole-resistant isolates of *C. krusei* retain susceptibility to itraconazole, voriconazole, and posaconazole based on laboratory testing.

C. glabrata has become a common cause of both de novo and breakthrough candidemia in heavily immunocompromised hosts and breakthrough infection in patients on fluconazole prophylaxis. Although *C. glabrata* is generally

Patient Encounter 2, Opportunistic Fungal Infection, Part 1

A 45-year-old man in the surgical ICU with necrotizing pancreatitis develops fever while receiving broad-spectrum antibacterial therapy (meropenem 1 g every 8 hours, gentamicin 120 mg every 8 hours, and linezolid 600 mg every 12 hours). The patient has a central venous catheter and a Foley catheter. Blood cultures are negative at the time, but the patient has yeast growing in the sputum and urine. A serum (1→3)-β-D-glucan test is positive at 90 pg/mL (90 ng/L). Laboratory studies reveal a white blood cell count of 12,500 cells/mm³ (12.5 × 10⁹/L).

What are this patient's risk factors for developing an invasive fungal infection?

What current evidence suggests that this patient has an invasive fungal infection?

If antifungal therapy is started in this patient, which species need to be treated?

less virulent than other *C. albicans*, infections with this organism are typically seen in patients with poor performance status, and therefore mortality remains high. The marginal susceptibility of *C. glabrata* to fluconazole dictates that other agents such as echinocandins and possibly amphotericin B be considered as first-line therapy until susceptibility to fluconazole can be documented.^{19,20} The effectiveness of voriconazole or posaconazole for fully fluconazole-resistant *C. glabrata* fungemia is not well established, and cross-resistance among these triazole antifungals has been documented in laboratory studies.^{19,20}

TREATMENT

Six antifungals (amphotericin B, fluconazole, voriconazole, caspofungin, micafungin, and anidulafungin) have been studied as monotherapy in prospective, randomized comparative clinical trials for the treatment of invasive candidiasis.^{16,21–25} Although these treatment options are considered to have relatively equivalent efficacy, they differ somewhat in toxicity and associated drug–drug interaction profiles. Lipid amphotericin B formulations are probably as effective as the aforementioned agents; however, evidence supporting their use is derived principally from open-label observational studies and empiric therapy trials of febrile neutropenia.¹⁷ Moreover, the acquisition cost of lipid amphotericin B formulations may be relatively higher in many institutions compared with fluconazole and the echinocandins. As a result, their first-line use is not prominently recommended in evidence-based guidelines for proven infection.¹⁷ No prospective randomized, controlled clinical trials have been published comparing antifungal therapies for proven acute disseminated candidiasis in neutropenic patients, chronic

disseminated candidiasis, or other forms of deep-organ candidiasis.¹⁷

A majority of patients are treated empirically for invasive candidiasis before conclusive evidence of infection is available to direct therapy. Empiric therapy for invasive candidiasis should be considered in any patient with persistent, unexplained fever and host deficits that predispose patients to candidemia, including broad-spectrum antibacterial therapy, presence of a central venous catheter, patients with severe organ dysfunction or on dialysis, recent history of surgery that damages or opens the GI viscera, patients with neutropenia or qualitative deficiencies in host immunity (e.g., due to high-dose corticosteroid therapy), or colonization with *Candida* at one or more body sites.

5 If a patient is nonneutropenic, clinically stable (i.e., normotensive with relatively normal organ function), and has never received prior azole therapy, fluconazole 12 mg/kg/day loading dose followed by 6 mg/kg/day is still considered an appropriate first-line therapy for invasive candidiasis in many centers until speciation of the *Candida* isolate is confirmed.¹⁷ However, echinocandins (caspofungin, micafungin, anidulafungin) are preferred as first-line agents in more critically ill patients with compromised renal function, hypotension/sepsis, or in institutions/ICUs with higher rates (greater than 10%) of *C. glabrata* or *C. krusei* (Table 84–4).¹⁹ Treatment is continued for at least 2 weeks for uncomplicated catheter infections that respond quickly to antifungals and catheter removal or at least 4 to 6 weeks for complicated infections arising from an endovascular source or infections associated with a high risk of metastatic seeding.

One caveat is that cryptococcosis, endemic fungi, or other rare yeast (e.g., *Trichosporon* species) occasionally produce fungemia in lymphopenic patients that may initially be mistakenly assumed to be *Candida*. Therefore, initial treatment with a lipid amphotericin B formulation may be judicious in profoundly lymphopenic patients (i.e., CD4⁺ less than 250/mm³ [250 × 10⁶/L]) with yeast in blood cultures until fungal identification is confirmed, as echinocandins have poor activity against non-*Candida* yeast. Timely initiation of appropriate antifungal therapy is critical, as any delay in the initiation of antifungal therapy once a patient has a positive blood culture significantly increases mortality and the potential for metastatic infections.²⁶

Amphotericin B deoxycholate 0.7 mg/kg/day or an echinocandin (i.e., caspofungin, micafungin, or anidulafungin); voriconazole; or a lipid amphotericin B formulation are recommended as empiric therapy in patients with neutropenic (i.e., absolute neutrophil count less than 500 PMN/mm³ [500 × 10⁶/L]) fever.^{17,21} If the neutropenia is of shorter duration and the patient is at lower risk for mold infections (e.g., solid tumor patients with 2 weeks or less of neutropenia), higher dose fluconazole (i.e., 800 mg/day or 12 mg/kg) could be considered.^{17,21} Lipid amphotericin B formulations, an echinocandin, or voriconazole are often the preferred agents in febrile patients with 3 weeks or more of neutropenia to expand coverage against molds.^{17,27} If the yeast is identified as *C. glabrata*, treatment guidelines recommend the use of an echinocandin or possibly amphotericin B formulations.^{17,27}

Table 84-4

Therapeutic Approach to Opportunistic Invasive Fungal Infections

Mycoses	Recommended Treatment Regimens	Comments
Candidiasis Catheter-related and acute hematogenous	Fluconazole 12 mg/kg loading dose, then 6–12 mg/kg/day IV every 24 hours adjusted for renal function ^a OR Echinocandin ^b OR Voriconazole 6 mg/kg every 12 hours IV for 1 day, then 3 mg/kg every 12 hours IV <i>Second line:</i> Lipid amphotericin B formulation 3–5 mg/kg per day ^c OR Amphotericin B 0.7 mg/kg per day IV OR Amphotericin B + fluconazole	Treat for 14 days after the last positive blood culture and resolution of signs and symptoms; catheter should be removed whenever possible Patients can be switched to oral fluconazole when clinically stable if isolate is susceptible The IV cyclodextrin formulation of voriconazole is not recommended in patients with estimated creatinine clearance less than 50mL/min (less than 0.83 mL/s) due to concerns of accumulation of the cyclodextrin vehicle Echinocandins and amphotericin B are preferred agents for fluconazole-resistant species. Voriconazole appears to be effective against fluconazole-resistant <i>C. krusei</i>
Empirical therapy in neutropenic patient	Fluconazole 6–12 mg/kg/day (low risk) adjusted for renal function ^a OR Liposomal amphotericin B 3 mg/kg every 24 hours OR Echinocandin OR Amphotericin B 0.7 mg/kg every 24 hours	Antifungals with coverage of <i>Aspergillus</i> should be used in higher risk patients or prolonged neutropenia (i.e., longer than 3 weeks)
Urinary candidiasis	Fluconazole 200 mg IV or PO for 7–14 days OR Amphotericin B 0.3 mg/kg per day IV for 1–7 days	Asymptomatic candiduria does not require therapy
Cryptococcosis Pulmonary-isolated	Fluconazole 6 mg/kg/day IV or PO for 6–12 mo adjusted for renal function ^a	Therapeutic drug monitoring is required for safe use of flucytosine, see Table 84-3.
Severe pulmonary infection and meningitis	<i>Induction:</i> Amphotericin B 0.7–1 mg/kg per day + flucytosine 100 mg/kg per day PO divided every 6 hours for 2 weeks adjusted for renal function ^c <i>Consolidation:</i> Fluconazole 6–12 mg/kg/day for 10 weeks adjusted for renal function ^a <i>Second line:</i> Fluconazole + flucytosine for 2 weeks, then fluconazole for 10 weeks adjusted for renal function ^{a,c} OR Amphotericin + fluconazole for 2 weeks, then fluconazole for 10 weeks adjusted for renal function ^a OR Liposomal amphotericin B 5 mg/kg per day × 2 weeks, then fluconazole for 10 weeks adjusted for renal function ^a	Amphotericin B +5-flucytosine, Amphotericin B + fluconazole, liposomal amphotericin B (4–6 mg/kg/day) Echinocandins have no activity against cryptococci

(Continued)

Table 84-4

Therapeutic Approach to Opportunistic Invasive Fungal Infections (Continued)

Mycoses	Recommended Treatment Regimens	Comments
Aspergillosis	Voriconazole 6 mg/kg IV every 12 hours × 2 doses, then 4 mg/kg IV every 12 hours OR Lipid formulations of amphotericin B OR Echinocandin ^b OR Posaconazole 200 mg PO 4 times daily × 14 days, then 400 mg PO twice daily OR Combination therapy	Voriconazole can be administered as oral therapy in patients taking oral medications. Therapeutic drug monitoring should be considered in patients receiving voriconazole or posaconazole, see Table 84-3. Preclinical studies suggest mold-active azoles (i.e., voriconazole) plus echinocandins ^c have enhanced activity vs. triazole monotherapy. <i>A. terreus</i> should be considered resistant to amphotericin B

^aFluconazole renal dosing adjustments: CrCl greater than 50–90 mL/min (0.83–1.50 mL/s), 100% of dose; CrCl 10–50 mL/min (0.17–0.83 mL/s), 50% of dose; CrCl less than 10 mL/min (less than 0.17 mL/s) 50%.

^bAnidulafungin 200 mg loading dose day 1, then 100 mg daily, caspofungin 70 mg loading dose day 1, then 50 mg daily; or micafungin 100 mg daily.

^cFlucytosine renal dosing adjustments: CrCl greater than 50–90 mL/min (0.83–1.50 mL/s), 25 mg/kg every 12 hours; CrCl 10–50 mL/min (0.17–0.83 mL/s), 25 mg/kg every 12–24 hours; CrCl less than 10 mL/min (less than 0.17 mL/s) 25 mg/kg every 24 hours. Therapeutic drug monitoring is required for safe use of flucytosine (see Table 84-3).

Voriconazole or posaconazole are generally avoided because of concerns of cross-resistance.^{19,20} *C. krusei* infections can be treated with an echinocandin, amphotericin B, or newer triazoles such as voriconazole and posaconazole, as cross-resistance among triazoles is less problematic than with *C. glabrata*.^{19,20} Patients who respond to therapy are medically stable, are not neutropenic, and are taking oral medications can be transitioned to oral fluconazole or voriconazole preferably after documentation of susceptibility to fluconazole with minimum inhibitory concentration testing.

Treatment recommendations for other forms of invasive candidiasis are based primarily on anecdotal evidence and expert opinion. Deep-organ candidiasis requires prolonged therapy to achieve a cure; therefore, importance is placed on the use of convenient and nontoxic long-term treatment regimens. Fluconazole (400 mg/day or 6 mg/kg/day) is the preferred regimen in clinically stable patients. Echinocandins, amphotericin B, or lipid amphotericin B formulations can be considered for refractory cases or clinically unstable patients. Infections of the eye, bone, pancreas, or gallbladder are typically treated with either amphotericin B, fluconazole, or possibly voriconazole. Although echinocandins are effective for intra-abdominal infections, their limited penetration into the eye makes them unsuitable agents for *Candida* endophthalmitis.

Urinary candidiasis is a term for an ill-defined group of syndromes that can range from benign colonization (candiduria) in the bladder to invasive disease of the renal parenchyma. Asymptomatic nonneutropenic patients with candiduria do not require antifungal therapy, as no study has demonstrated the value of transiently clearing *Candida* from the urine. Patients should receive 7 to 14 days of antifungal therapy for urinary candidiasis if they are (a) symptomatic, (b) have clinical or laboratory evidence of infection,

(c) are neutropenic, (d) are low-birth-weight infants; (e) will undergo urologic manipulations, or (f) have renal allografts. Removal of urinary tract instruments, including Foley catheters and stents, is essential to prevent relapse. The preferred therapy is fluconazole 200 mg daily, although IV amphotericin B deoxycholate 0.3 to 1 mg/kg/day is also effective. Other antifungal agents (with the exception of flucytosine) do not achieve appreciable concentrations in the urine and therefore should not be considered for urinary candidiasis. Irrigation with amphotericin B is not effective for infections above the bladder and should not be used in higher risk patients with the exception of its use as a diagnostic tool for confirming a localized infection of the bladder. *Candida* infections of the renal parenchyma secondary to metastatic seeding from the bloodstream are treated in a similar fashion to candidemia.

Mucocutaneous candidiasis is not invasive and can be treated with topical azoles (clotrimazole troches), oral azoles (fluconazole, ketoconazole, or itraconazole), or oral polyenes (such as nystatin or oral amphotericin B). Orally administered and absorbed azoles (ketoconazole, fluconazole, or itraconazole solution), amphotericin B suspension, IV echinocandins, or IV amphotericin B are recommended for refractory or recurrent infections.¹⁷

Although more severe than mucocutaneous candidiasis, esophageal candidiasis typically does not evolve into a life-threatening infection unless the esophagus is ruptured. However, topical therapy is ineffective. Triazole antifungals (fluconazole, itraconazole solution, or voriconazole), echinocandins, or IV amphotericin B (in cases of unresponsive infections) are effective treatment options. Parenteral therapy should be used in patients who are unable to take oral medications.¹⁷

Patient Encounter 2, Opportunistic Fungal Infection, Part 2

Selecting Antifungal Therapy

The patient is started on fluconazole 400 mg/day, but 3 days later has persistent fever and develops hypotension and decreased urine output. Blood cultures are now growing a germ tube–negative yeast. Laboratory studies revealed a white blood cell count of $14,200/\text{mm}^3$ ($14.2 \times 10^9/\text{L}$), aspartate aminotransferase 68 IU/L ($1.13 \mu\text{kat}/\text{L}$), alanine aminotransferase 75 IU/L ($1.25 \mu\text{kat}/\text{L}$), alkaline phosphatase 168 IU/L ($2.80 \mu\text{kat}/\text{L}$), and normal bilirubin. Serum creatinine has increased from 1.2 to 1.8 mg/dL (106 to $159 \mu\text{mol}/\text{L}$) over the last 3 days.

What factors suggest empiric antifungal therapy should be changed in this patient?

What other procedures should be recommended in this patient to improve response to antifungal therapy?

PATIENT MONITORING

- Response to antifungal therapy in invasive candidiasis is often more rapid than for endemic fungal infections. Resolution of fever and sterilization of blood cultures are indications of response to antifungal therapy with the caveat that the growth of *Candida* from blood cultures is often delayed by 48 to 72 hours. Adverse effects associated with antifungal therapy are similar in these patients as described earlier, except some toxicities may be more pronounced in critically ill patients with invasive candidiasis. Nephrotoxicity and electrolyte disturbances with amphotericin B can be especially problematic and may not be avoidable even with lipid amphotericin B formulations. Therefore, current treatment guidelines emphasize less toxic treatment options, such as the first-line use of fluconazole in lower-risk patients and echinocandins in higher risk patients. Decisions to use one class of antifungal agents over the other are principally driven by concerns of nonalbicans species, patient tolerability, or history of prior fluconazole exposure (risk factor for nonalbicans species.).

PROPHYLAXIS

Fluconazole (400 mg/day) has been extensively studied as a prophylactic regimen to prevent invasive candidiasis in patients with prolonged (greater than 2 weeks) neutropenia.^{28–32} Placebo-controlled, prospective randomized trials performed in the 1990s demonstrated that fluconazole was effective in reducing the frequency, morbidity, and, in some trials, mortality due to invasive candidiasis if administered until marrow recovery. However, the major limitation with fluconazole is its lack of mold coverage

needed for high-risk patients with persistent neutropenia. Studies have examined the use of itraconazole, voriconazole, posaconazole, or the echinocandin micafungin as prophylaxis in hematopoietic cell transplant recipients until engraftment to provide protection against both *Candida* and *Aspergillus* species.^{32–35} Although each of these studied antifungals has demonstrated a benefit in reducing fungal infections, all of the drugs have limitations with respect to prolonged administration in high-risk patients. Therefore, the approach toward antifungal prophylaxis is highly institution-specific depending on the patient population, epidemiology of invasive fungal infections, and options for outpatient IV drug therapy.

Use of antifungal prophylaxis for invasive candidiasis in nonneutropenic patients remains an area of controversy. Prophylaxis should be targeted toward clearly defined high-risk transplant populations (e.g., liver, pancreatic, or small-bowel transplantation) or ICU patients (i.e., neonatal intensive care) with rates of invasive candidiasis exceeding 10%, despite aggressive infection-control procedures.^{36,37} Fluconazole prophylaxis (400 mg/day) reduces the rate of *Candida* peritonitis in patients with refractory GI perforation and trended toward decreased rates of invasive candidiasis in select adult patients admitted to a surgical ICU for more than 3 days.^{36,37} Fluconazole is also effective in reducing the rate of invasive candidiasis in neonates.³⁷ However, prophylaxis can result in excessive antifungal use in lower-risk patients; therefore, many experts have advocated preemptive (i.e., starting therapy based on biomarkers of infection such as serum beta glucan) or empirical (symptoms of infection) treatment approaches in this population in lieu of prophylaxis. A multi-institutional prospective randomized trial of administering empirical fluconazole (800 mg/day versus placebo) in ICU patients with persistent fever, however, did not demonstrate a benefit for the nonneutropenic population.³⁸ It is hoped that ongoing studies will better define the risks versus benefits of routine antifungal prophylaxis or preemptive treatment approaches in the ICU setting.

CRYPTOCOCCOSIS

EPIDEMIOLOGY

Cryptococcus neoformans is an encapsulated yeast that can infect apparently normal hosts but is more frequently associated with severe infections in immunocompromised patients. *C. neoformans* is divided into two varieties based on serotype: *C. neoformans* var. *neoformans* (serotypes a and d) that is associated with infections in immunocompromised patients, and *C. neoformans* var. *gattii* (serotypes b and c) that is associated with infections in healthy hosts. *C. neoformans* var. *gattii* is found predominantly in tropical and subtropical climates with eucalyptus trees, and more recently has been linked to infectious outbreaks around Vancouver Island and the U.S. Pacific Northwest. *C. neoformans* var. *neoformans* is found worldwide and is associated with pigeon droppings and other avian excreta. Before the AIDS

pandemic, cryptococcosis was a relatively uncommon disease, but became a leading cause of meningitis among HIV-infected patients. Although the incidence of this infection has declined somewhat with the widespread use of highly active antiretroviral therapy (HAART), *C. neoformans* remains an important pathogen in the developing regions with high rates of AIDS and also in immunocompromised patients, including transplant and cancer patients who may present with the pulmonary form of the infection.

CLINICAL PRESENTATION AND DIAGNOSIS

C. neoformans is acquired primarily through inhalation of the desiccated yeast particles found in the environment. Inhaled cells reach distal alveolar spaces where they gradually rehydrate and form their characteristic polysaccharide capsules that enable resistance to phagocytosis. Defects in cellular immunity allow reconstitution of the protective capsule and multiplication of yeast in the lungs. Although alveolar macrophages phagocytose the yeast, containment and killing require a coordinated response between innate and adaptive humoral (complement and anticryptococcal antibodies) and T-cell-mediated host responses.⁵ Deficiencies in cell-mediated immunity allow the yeast to survive as a facultative intracellular pathogen in macrophages as they migrate from the lung to draining lymph nodes, leading to dissemination via the bloodstream to the meninges.

Unlike most opportunistic fungi, true virulence factors have been identified for *C. neoformans*. The capsules, including the soluble polysaccharides released from the yeast cells during infection, impair phagocytosis and binding of anticryptococcal antibodies. Primary cryptococcal infection begins in the lung, presenting as a mildly symptomatic or asymptomatic infection that resolves spontaneously or undergoes encapsulation in noncalcified lung nodules. It is common for these isolated nodules to be detected on chest x-rays during routine workup. Diagnosis of primary cryptococcosis is only made if the nodule is aspirated or removed because of concerns of primary lung cancer.

In the immunocompromised host, infection of the lung may present with more diffuse, bilateral, and interstitial disease that mimics the presentation of *Pneumocystis jirovecii* (carinii) pneumonia (PCP). Dissemination to other organs, particularly the CNS, eye, and possibly the skin, is more likely to occur in patients with severe deficits in cell-mediated immunity. Fever, cough, dyspnea, and pleural pain are common at presentation, with accompanying hypoxemia that can rapidly evolve to acute respiratory failure. Because the features of diffuse pulmonary cryptococcosis overlap with other opportunistic pathogens, early diagnosis requires bronchoalveolar lavage or transbronchial biopsy, which can effectively diagnose 80% to 100% of cases.³⁹ The clinical course of diffuse cryptococcal pneumonia can be as severe as PCP, with mortality rates approaching 100% in untreated patients by 48 hours.

C. neoformans is strongly neurotropic and readily disseminates from the lung to the CNS, specifically the leptomeninges, and occasionally the parenchyma of the brain. The clinical characteristics of cryptococcal meningitis differ somewhat, however, between patients with and without underlying AIDS. In patients without AIDS, disease presentation is more insidious, and symptoms such as dizziness, irritability, decreased comprehension, and unstable gait may present many weeks to months before the diagnosis is established.³⁹ Patients with AIDS generally present much later in the course of disease with severe meningoencephalitis.³⁹ The most common signs and symptoms on presentation are fever, headache, meningismus, photophobia, mental status changes, and seizures. CT or more sensitive MRI may reveal cerebral edema, multiple areas of enhanced nodules, or a single mass lesion (cryptococcoma). Examination of the cerebrospinal fluid (CSF) often reveals increased opening pressure upon lumbar puncture, but glucose, protein, and leukocyte levels can be normal.³⁹

LABORATORY DIAGNOSIS

Clinical diagnosis is confirmed by cultures from the blood, CSF, or other clinically relevant fluids or tissue. However, early diagnosis is suggested by either direct observation of *C. neoformans* in the CSF by India ink staining (Fig. 84-3B).³⁹ Similarly, detection of cryptococcal antigen in either serum or CSF can provide a rapid diagnosis with greater than 95% sensitivity and specificity and appears to correlate with fungal burden.³⁹ A positive serum antigen test of greater than 1:4 strongly suggests cryptococcal infection, and greater than or equal to 1:8 is indicative of active disease. Antigen titers in serum are positive in 99% of patients with cryptococcal meningitis and typically exceed titers of 1:2,048 in patients with

FIGURE 84-3. Opportunistic mycoses in clinical samples. A. Candidiasis (tissue). B. Cryptococcosis (India ink stain of CSF). C. Aspergillosis (tissue). D. Mucormycosis (tissue).

AIDS.³⁹ However, the time course of cryptococcal antigen elimination is unknown, and a positive test result can persist for many years. Changes in the CSF cryptococcal antigen titers have limited value in the monitoring of drug therapy for cryptococcal meningitis, although it is expected that a decrease should be seen after 2 or more weeks of antifungal therapy.³⁹

TREATMENT

Cryptococcal meningitis is fatal if left untreated. Because pneumonia frequently precedes dissemination of disease and subsequent meningitis, all patients with culture-, histopathology-, or serology-proven disease should receive antifungal therapy. In patients with isolated pulmonary cryptococcosis, fluconazole is generally considered to be the therapy of choice (see Table 84–2).³⁹ Alternatively, itraconazole, voriconazole, or combination therapy (fluconazole plus flucytosine) has also been used with some success, but these regimens are generally considered inferior to amphotericin B and are recommended only for persons unable to tolerate or unresponsive to standard treatment. Echinocandins do not have activity against *C. neoformans*.

Disseminated or CNS cryptococcosis requires a more aggressive treatment approach. Pretreatment predictors of poor outcome with antifungal therapy include the following:

- Progressive underlying disease or immune dysfunction
- Abnormal mental status at the time of presentation
- Increased opening pressure on lumbar puncture (greater than 260 mm H₂O [2.55 kPa])
- High fungal burden as reflected by a CSF antigen titer (in AIDS patients) of greater than 1:2,048

Prospective randomized trials completed prior to the recognition of AIDS demonstrated high response rates (approximately 80%) with the combined use of amphotericin B and flucytosine for 4 to 6 weeks. Although sterilization of the CSF could be achieved in most patients within 2 weeks with this regimen, a substantial number of patients (30% to 40%) developed dose-limiting toxicities, and relapse was seen in roughly 50% of patients. Therefore, a treatment approach was devised that consists of distinct treatment phases to minimize toxicity and reduce the risk of relapse. **6** *Clinical trials performed by the National Institute of Allergy and Infectious Diseases (NIAID) Mycoses Study Group after the recognition of AIDS showed that 2 weeks of induction antifungal therapy with combination amphotericin B (0.7 mg/kg/day) plus flucytosine (100 mg/kg/day) for cryptococcal meningitis, followed by consolidation therapy with fluconazole (400 mg daily) for 8 weeks, was as effective as 4 weeks of combination therapy, with fewer toxicities (see Table 84–2).*^{12,41} Lipid formulations of amphotericin B can be substituted in patients at higher risk for nephrotoxicity. Other studies have suggested that fluconazole plus amphotericin or high-dose fluconazole alone (more than 800 mg/day) may be an acceptable alternatives in patients who cannot tolerate therapy with flucytosine (see Table 84–2).³⁶

PROPHYLAXIS

- Fluconazole (200 mg/day) is recommended as maintenance therapy for life in patients with persistent underlying immune dysfunction to prevent recurrent cryptococcal meningitis.³⁶ Available data have demonstrated that it is safe to discontinue maintenance therapy in AIDS patients who have had a sustained immunologic response on effective antiretroviral therapy (i.e., CD4⁺ count greater than 100 cells/microliter (greater than 100 × 10⁶/L) with undetectable or very low viral RNA) if they have received at least 12 months of antifungal therapy.³⁶ Occasionally, initiation of HAART can result in the reactivation of a subclinical, immunologic manifestation of cryptococcal infection (or other opportunistic infections). Manifestations of this **immune reconstitution inflammatory syndrome (IRIS)** may include exacerbations of meningitis or necrotizing pneumonia. Antifungal therapy plus a non-steroidal anti-inflammatory agent or prednisone have been used successfully in patients with cryptococcal-associated immune reconstitution syndrome.³⁹ However, the optimal management of this recently defined clinical entity remains unknown.

INVASIVE ASPERGILLOSIS

EPIDEMIOLOGY

Invasive molds, particularly *Aspergillus*, are a common complication of intensive cancer chemotherapy required for hematologic malignancies as well as hematopoietic and solid organ transplant recipients. More than 180 species within the genus *Aspergillus* have been described, but only four species are commonly associated with invasive infection: *Aspergillus fumigatus*, *Aspergillus flavus*, *Aspergillus terreus*, and *Aspergillus niger*. Of these four species, *A. fumigatus* accounts for most of human infections. However, identification of *Aspergillus* mold in culture to the species level is still essential because the incidence of amphotericin B–resistant *Aspergillus terreus* and *Aspergillus flavus* have increased over the last 10 years in many centers. Additionally, less common mold infections such as fusariosis and mucormycosis often present with similar clinical features aspergillosis, but require different treatment approaches due to their inherent resistance to many antifungal agents. Early and accurate diagnosis of invasive aspergillosis (IA) improves the outcome of infection, reducing mortality rates by 30% to 50% with the timely administration of effective antifungal therapy.⁴⁰

CLINICAL PRESENTATION AND DIAGNOSIS

The pathogenesis of IA is defined largely by the underlying immune dysfunction of the host. The most common route of acquisition for *Aspergillus* is through the respiratory tract. Conidia dispersed in air currents are continuously

FIGURE 84-4. Pathogenesis of invasive aspergillosis (IA).

inhaled through the sinuses and mouth and penetrate down to distal alveolar spaces (see [Fig. 84-4](#)). Most conidia are rapidly phagocytosed and removed by resident macrophages and neutrophils in the upper and lower respiratory tract.⁵ However, macrophage function may be suppressed following transplantation, cytotoxic chemotherapy, or in patients who have received high-dose corticosteroid therapy. Conidia that escaped phagocytosis begin to germinate into hyphal forms that invade blood vessels or contiguous tissues or bone (in sinuses), resulting in hemorrhage and/or infarction and coagulative necrosis. Once in the bloodstream, viable hyphal fragments can break off and disseminate to distal organs including the brain. Control of the infection at this stage requires development of an adaptive Th1 or TH17 response to enhance the fungicidal activity of professional effector cells (i.e., neutrophils) against hyphal elements.⁵ Patients with dysregulated, suppressed T-cell-mediated immunity or prolonged neutropenia are unable to control fungal growth and are at high risk for dissemination of the infection. Without early diagnosis and antifungal therapy, IA in persistently immunosuppressed patients is uniformly fatal.

Signs and symptoms of IA are predictably muted in the immunocompromised host. Fever is common but nonspecific for infection and may be accompanied by pleuritic chest pain, cough, hemoptysis, and/or friction rub.⁴⁰ Neurologic signs, including seizures, hemiparesis, and stupor, may be present in patients with dissemination to the brain. Cutaneous plaques or papules characterized by a central

necrotic ulcer or eschar occur in up to 10% of patients with disseminated disease; however, concomitant blood cultures are often negative. Chest radiographs cannot detect early forms of disease and may remain negative in up to 10% of patients within 1 week of death.^{41,42} Nodular lesions detected by high-resolution computed tomography (HRCT) scans, along with fever, are often the first indication of invasive pulmonary aspergillosis in severely immunocompromised patients. Typically these radiographs reveal wedge-shaped or nodular lesions, surrounded by intermediate attenuation called the “halo sign” ([Fig 84-5](#)).^{40,43} These early lesions on CT scans represent hemorrhage and edema surrounding

FIGURE 84-5. Radiographic evolution of invasive pulmonary aspergillosis in a neutropenic patient. *A.* Early halo sign of ground glass opacity surrounding nodular lesions. *B.* Nonspecific infiltrate of increased diameter. *C.* Air crescent sign observed with neutrophil recovery, cavitation of infected lung in walled off cavity with air (arrow).

Patient Encounter 3

Invasive Mold Infection

A 53-year-old man with acute myelogenous leukemia at day 80 after matched-allogeneic donor hematopoietic stem-cell transplantation presents to the clinic with increasing complaints of nausea, stomach cramping, and rash on the back and chest. He also complains of sharp pain in the left side of his chest during deep inspiration. By laboratory examination, he is noted to have an alanine aminotransferase of 119 IU/L (1.98 μ kat/L), aspartate aminotransferase 107 IU/L (1.78 μ kat/L), and total bilirubin of 1.8 mg/dL (31 μ mol/L). The patient has an absolute neutrophil count of 950 cells/mm³ (950 \times 10⁶/L). His current medications include tacrolimus 5 mg twice daily (most recent level: 9 ng/mL [9 mcg/L; 11 nmol/L]), prednisone 20 mg daily, levofloxacin 500 mg daily, fluconazole 200 mg/day, valacyclovir 500 mg twice daily. He is admitted to the hospital for suspected graft-versus-host disease exacerbation. However, computed tomography scan of the chest reveals a single dense pleural-based lung nodule in the left lung. A serum galactomannan test is reported to be negative (index 0.4; positive when more than 0.5). The primary service wishes to start voriconazole.

What are the patient's risk factors for developing an invasive mold infection?

Is voriconazole an acceptable option in this patient? Are there any drug interaction concerns?

What mold infections need to be considered if the patient had presented to the hospital with these findings while already receiving voriconazole prophylaxis?

an infarcted blood vessel. Despite “effective” antifungal therapy, lesions on CT scan may continue to increase in size in neutropenic patients until neutrophil counts recover, at which time they begin to cavitate, forming the “air-crescent sign” on chest radiographs, indicative of resolving infection. **7** *Immunocompromised patients on fluconazole with progressive sinus or pulmonary disease by radiography should be considered to have a possible mold infection and receive empiric antifungal therapy directed (at minimum) against *Aspergillus* species.*⁴⁰

LABORATORY DIAGNOSIS

Like other invasive mycoses, definitive diagnosis of aspergillosis requires histopathologic evidence of hyphal invasion in tissue (Fig. 84–3). However, procedures needed to establish a definitive diagnosis by sampling of suspicious lesions (e.g., fine-needle aspiration or thoracoscopic lung biopsy) are not feasible in many patients with underlying thrombocytopenia secondary to hematologic malignancies or chemotherapy. Even if hyphae are observed in tissue, histopathology alone cannot distinguish *Aspergillus* from other angioinvasive

septate molds, such as *Fusarium*, which have different patterns of antifungal susceptibility (see Table 84–1).⁴⁰ Therefore, respiratory and/or wound cultures (if cutaneous or sinus/hard palate lesions are present) are important factors in the modification of empiric antifungal therapy.

Respiratory cultures including sputum, bronchial washings, or bronchoalveolar lavage have a low sensitivity for diagnosis of IA but a high positive predictive value in immunocompromised patients.⁴⁰ Therefore, a negative bronchoalveolar lavage culture does not rule out invasive pulmonary aspergillosis, but a positive culture in a high-risk patient (e.g., allogeneic hematopoietic cell transplant patients) indicates pulmonary aspergillosis in at least 60% of such patients. Blood cultures have little diagnostic value for IA but may reflect true disease with *A. terreus*. Patients with limited lung involvement or on prophylactic or empiric antifungal therapy may continue to be culture-negative for *Aspergillus* species, despite the appearance of progressing disease.⁴⁰ Therefore, negative cultures are never the sole indication for stopping antifungal therapy in patients with suspected or proven aspergillosis.

Considerable effort has been focused in the last decade to develop non-culture-based laboratory methods (antigen detection, polymerase chain reaction [PCR], and antigen detection) for the diagnosis of IA. The hope is that these surrogate tests could detect early evidence of *Aspergillus* infection before significant target organ damage eventually detected by CT scans occurs. The FDA has approved an enzyme-linked immunosorbent assay (ELISA)-based assay for the detection of a polysaccharide component of the *Aspergillus* cell wall called galactomannan. Although several large prospective studies have found that the sensitivity and specificity of the assay exceeded 90% in neutropenic patients with hematologic malignancies, the median time span between galactomannan detection and clinical signs and symptoms of IA averages less than 6 days.⁴⁰ The sensitivity of the galactomannan may be enhanced if the test is performed on bronchial lavage fluid. Other factors such as patient immune status (neutropenia versus graft-versus-host disease), antibacterial therapy, and diet may affect the interpretation of the galactomannan test.⁴⁰ For example, false-positive results have been reported to be higher in the pediatric population, patients receiving piperacillin-tazobactam for neutropenic fever, and following the ingestion of certain cereals, pastas, nutritional supplements, or soy sauce.⁴⁰ Accumulating clinical data suggest that rising galactomannan levels are a harbinger of breakthrough infection, and declining galactomannan concentrations are an early indicator of response to treatment. However, antifungal therapy is rarely stopped in patients once the serum galactomannan becomes negative, especially in persistently immunosuppressed patients. Hence, the galactomannan test and other non-culture-based strategies, such as serum β -glucan, which can also be detected during *Aspergillus* infection, serve as complementary methods to confirm results from microbiologic, histopathologic, and radiographic investigations directed toward diagnosing IA.

TREATMENT

To date, only two comparative randomized controlled clinical trials have evaluated antifungal therapies for the treatment of diagnosis-proven IA, and only one study was sufficiently powered to measure differences in response to antifungal therapy.⁴³ In that study, unblinded investigators compared patients initially randomized to the newer triazole, voriconazole, with patients initially treated with amphotericin B deoxycholate.⁴³ The study design was unique in that it allowed a change from the randomized drug to any other licensed antifungal therapy, without requiring that the patient be classified as a treatment failure on randomized therapy. Nearly 80% of patients randomized to receive amphotericin B deoxycholate were switched to other licensed antifungal therapies (mean duration 10 days) versus 36% of patients in the voriconazole arm (mean duration 77 days). The poor tolerability of amphotericin B deoxycholate was not surprising given the relatively higher dosages (1 mg/kg/day IV) and prolonged treatment courses required in the treatment of IA. At the end of the study (12 weeks), a higher proportion of patients in the voriconazole arm remained alive (70.8%) compared with amphotericin B deoxycholate-treated patients (57.9%). On the basis of these results, many experts now consider voriconazole as the initial drug of choice for IA in patients without significant contraindications (e.g., drug interactions or preexisting liver dysfunction) to azole therapy (see Table 84–2).⁴⁰ Voriconazole also appears to have some efficacy in CNS aspergillosis, a form of IA with historical mortality rates approaching 100%. Itraconazole has activity against *Aspergillus* and is sometimes used as prophylaxis, but is not considered a particularly effective treatment option for invasive disease.⁴⁰

Lipid formulations of amphotericin B, echinocandins, or posaconazole can be considered as possible alternatives to voriconazole therapy and may be preferred agents in patients with breakthrough infection on azole antifungals (including itraconazole or fluconazole). Several recent open-label case series have suggested that combination therapy, with an echinocandin and mold-active triazole such as voriconazole, may be more effective than voriconazole alone for patients with IA who have failed amphotericin B–based therapy.⁴⁰ An ongoing multicenter prospective trial comparing voriconazole monotherapy versus voriconazole plus anidulafungin should provide insights (if any) into the benefits of starting with combination regimens during the initial treatment of IA. Once antifungal therapy has begun, the duration and intensity of antifungal therapy is directed by host-specific factors, including clinical response, underlying immunosuppression, tolerability, and plans for future chemotherapy/immunosuppression. In the heavily immunocompromised patient, complete eradication of the fungus is unlikely, and suppressive therapy may be required until well after recovery of cellular immune function. Reactivation from residual infarcts or devitalized tissue in the sinus or lung harboring aspergillosis is a concern if the patient will receive further immunosuppressive therapy. Therefore, surgical debridement of the sinus or excision of large lung lesions is often

pursued if the patient is not profoundly thrombocytopenic. Relapsing or breakthrough *Aspergillus* infections respond less favorably to antifungal therapy than de novo IA and may require more aggressive measures (combination therapy, immunotherapy, or surgery) to stabilize the infection.

PROPHYLAXIS

Although recently published guidelines for preventing opportunistic infections in hematopoietic cell transplant recipients do not provide concrete recommendations for antifungal prophylaxis against *Aspergillus*, prophylaxis should be considered in certain high-risk subgroups with rates of IA exceeding 10%. These groups include (a) patients with prolonged pre-engraftment periods (e.g., cord-blood transplant recipients), (b) patients with a history of IA prior to transplantation, (c) patients receiving transplants with a high risk of graft-versus-host disease (e.g., haploidentical allogeneic transplant) or infection (e.g., T-cell-depleted transplant), any patient with graft-versus-host disease on high-dose corticosteroid therapy (greater than 1 mg/kg prednisone equivalent) with or without antithymocyte globulin or tumor necrosis factor blockade (i.e., infliximab), and (d) any transplant recipient with active cytomegalovirus disease, which is associated with an increased risk of subsequent mold infections due to the immunosuppressive effects of the virus. Posaconazole was shown in two prospective randomized trials to reduce *Aspergillus*-associated death in patients with acute high-risk leukemia and reduce mold infections in patients with graft-versus-host disease following hematopoietic stem cell transplantation.^{33,34} Similar data are available for voriconazole,³⁵ but less benefit was observed versus standard fluconazole prophylaxis plus intensive galactomannan monitoring in the hematopoietic stem cell transplant patients. Prophylactic approaches, however, are often institution and patient specific.

PATIENT MONITORING

Response to antifungal therapy in invasive molds is slow and difficult to judge by clinical signs alone. Resolution of fever and eventual clearing of CT scans (in the case of lung infections) are indications of response to antifungal therapy.

- Toxicity associated with antifungal therapy is similar in these patients as in those described earlier. In addition to the adverse effects mentioned earlier, voriconazole may cause transient visual changes (photopsia) in approximately one-third of patients with the first few doses of therapy. Occasionally, these visual disturbances are accompanied by hallucinations and may require discontinuation of therapy. The risk of phototoxic reactions and cutaneous malignancies with voriconazole is of special concern in transplant patients, who are often receiving calcineurin inhibitors that increase the risk for secondary malignancies. Voriconazole and posaconazole exhibit wide intrapatient and interpatient pharmacokinetic variability due to variable absorption and metabolism, respectively.^{44,45} Therefore, many experts advocate therapeutic drug monitoring in patients with

documented disease receiving the drugs as monotherapy, or in patients with suspected breakthrough infection (voriconazole, posaconazole) or toxicities (voriconazole) while on therapy (see Table 84–3).^{40,44–46} Patients who develop breakthrough infections on voriconazole should also undergo a careful clinical workup for other invasive mold pathogens such as mucormycosis (see Table 84–1), which are not susceptible to voriconazole. In most cases, antifungal therapy may be continued until immunosuppression has resolved.

Abbreviations Introduced in This Chapter

AIDS	Acquired immunodeficiency syndrome
ARDS	Acute respiratory distress syndrome
CNS	Central nervous system
CSF	Cerebrospinal fluid
CrCl	Estimated creatinine clearance
CT	Computed tomography
CYP	Cytochrome P-450 isoenzyme
ELISA	Enzyme-linked immunosorbent assay
FISH	Fluorescent in situ hybridization
HAART	Highly active antiretroviral therapy
HRCT	High-resolution computed tomography
IA	Invasive aspergillosis
ICU	Intensive care unit
IRIS	Immune Reconstitution Inflammatory Syndrome
IV	Intravenous
NIAID	National Institute of Allergy and Infectious Diseases
PCP	<i>Pneumocystis jiroveci</i> (<i>carinii</i>) pneumonia
PCR	Polymerase chain reaction
PO	Oral

Antimicrobial Prophylaxis in Surgery

Mary A. Ullman and John C. Rotschafer

LEARNING OBJECTIVES

● Upon completion of the chapter, the reader will be able to:

1. Discuss the epidemiology and impact of surgical site infections (SSIs) on patient outcomes and healthcare costs.
2. Name and differentiate the four different types of wound classifications.
3. Recognize at least three risk factors for postoperative SSIs.
4. Identify likely pathogens associated with different surgical operations.
5. Compare and contrast antimicrobials used for surgical prophylaxis and identify potential advantage and disadvantages for each antibiotic.
6. Discuss the importance of β -lactam allergy screening and how this could impact resistance and healthcare costs.
7. Identify nonantimicrobial methods that can reduce the risk of postoperative infection.
8. Discuss the possible impact of antimicrobial-impregnated bone cement and how this affects the use of antimicrobial prophylaxis in surgery.
9. Discuss the importance of timing, duration, and redosing in relation to antimicrobial prophylaxis in surgery.
10. Recommend appropriate prophylactic antimicrobial(s) given a surgical operation.

KEY CONCEPTS

- 1 Surgical site infections (SSIs) are a significant cause of morbidity and mortality.
- 2 The distinction between prophylaxis and treatment influences the choice of antimicrobial and duration of therapy.
- 3 Surgical operations are classified as clean, clean-contaminated, contaminated, or dirty.
- 4 Choosing the appropriate prophylactic antimicrobial relies on anticipating which organisms are likely to be encountered during the operation.
- 5 A thorough drug allergy history should be taken to discern true drug allergy (anaphylaxis) from other adverse events (stomach upset).
- 6 For prevention of SSIs, correct timing of antimicrobial administration is imperative so as to allow the persistence of therapeutic concentrations in the blood and wound tissues during the entire course of the operation.
- 7 The goal of antimicrobial dosing for surgical prophylaxis is to optimize the pharmacodynamic

parameter of the selected agent against the suspected organism for the duration of the operation.

- 8 The duration of antimicrobial prophylaxis should not exceed 24 hours (48 hours for cardiac surgery); additional doses of antimicrobial past this time point do not demonstrate added benefits.
- 9 According to Centers for Disease Control and Prevention criteria, SSIs may appear up to 30 days after an operation and up to 1 year if a prosthesis is implanted.

● **1 Surgical site infections (SSIs) are a significant cause of morbidity and mortality.** Approximately 2% to 5% of patients undergoing clean **extra-abdominal** operations and 20% undergoing **intra-abdominal** operations will develop an SSI.¹ SSIs have become the second most common cause of nosocomial infection, and these data are likely underestimated.¹ More than 70% of surgical procedures are now performed on an outpatient basis, creating a significant potential for under-reporting.²

SSIs negatively affect patient outcomes and increase health-care costs. Patients who develop SSIs are five times more likely to be readmitted to the hospital and have twice the mortality of patients who do not develop an SSI.¹ A patient with an SSI is also 60% more likely to be admitted to an ICU.¹ SSIs increase lengths of hospital stay and costs.^{1,3,4} The type of SSI can also affect the severity of a patient's negative outcome due to surgery. Deep SSIs, involving organs or spaces, result in longer durations of hospital stay and higher costs compared with SSIs that are limited to the incision.⁵ Additionally, since 2008, Medicare and Medicaid Services no longer reimburses the hospitals for any cost incurred from treating certain hospital-acquired infections, including SSIs.⁶ Thus, even greater importance is placed on preventing infection, and, if infection should occur, treatment of the infection should be for the shortest duration possible and in the most cost-effective manner.

SSIs are defined and reported according to Centers for Disease Control and Prevention (CDC) criteria.⁵ SSIs are classified as either incisional or organ/space. Incisional SSIs are further divided into superficial incisional SSI (skin or subcutaneous tissue) and deep incisional SSI (deeper soft tissues of the incision). Organ/space SSIs involve any anatomic site other than the incised areas. For example, a patient who develops meningitis after removal of a brain tumor could be classified as having an organ/space SSI. An infection is considered as SSI if any of the above criteria is met and the infection occurs within 30 days of the operation. If a prosthetic is implanted, the timeline extends out to 1 year.

EPIDEMIOLOGY AND ETIOLOGY

Numerous **risk factors** for SSIs have been identified in the literature.^{5,7,8} These factors can be divided into two categories: patient and operative characteristics. Patient risk factors for SSI include age, comorbid disease states (especially chronic lung disease and diabetes), malnutrition, immunosuppression, nicotine or steroid use, and colonization of the nares with *Staphylococcus aureus*. Many patients developing postoperative wound infections bring the organism with them into the hospital. Modifying risk factors may decrease the threat of SSI. Malnutrition can be corrected using enteral or parenteral feedings. Additional nonantimicrobial strategies to reduce SSIs will be discussed later.

Operative characteristics are based on the actions of both the patient and the operating staff. Shaving of the surgical site prior to operating can produce microscopic lacerations and increase the chance of SSI and is, therefore, not accepted as a method of hair removal.⁵ Maintaining aseptic technique and proper sterilization of medical equipment is effective in preventing SSI. Surgical staff should wash their hands thoroughly. In clean surgeries, most bacterial inoculums introduced postoperatively are generally small. However, subsequent patient contact between contaminated areas (nares or rectum) and the surgical site can lead to SSI. Finally, the appropriate use of **antimicrobial prophylaxis** can have a significant impact on decreasing SSIs.

PATHOPHYSIOLOGY

Prophylaxis Versus Treatment

Properly identifying the state of an infection is important when using antimicrobial prophylaxis in surgery. Antibiotic prophylaxis begins with the premise that no infection exists but that during surgery there can be a low-level inoculum of bacteria introduced into the body. However, if sufficient antimicrobial concentrations are present, the situation can be controlled without infection developing. This is the case when surgery is done under controlled conditions, there are no major breaks in sterile technique or spillage of GI contents, and perforation or damage to the surgical site is absent. An example would be an elective hysterectomy done with optimal surgical technique.

If an infection is already present, or presumed to be present, then antimicrobial use is for treatment, not prophylaxis, and the goal is to eliminate the infection. This is the case when there is spillage of GI contents, gross damage or perforation is already present, or the tissue being operated on is actively infected (pus is present and cultures are positive). An example would be a patient undergoing surgery for a ruptured appendix with diffuse peritonitis.

2 *The distinction between prophylaxis and treatment influences the choice of antimicrobial and duration of therapy.* Appropriate antimicrobial selection, dosing, and duration of therapy differ significantly between these two situations. A regimen for antimicrobial prophylaxis ideally involves one agent and lasts less than 24 hours. Treatment regimens can involve multiple antimicrobials with durations lasting weeks to months depending on desired antimicrobial coverage and the surgical site.

Types of Surgical Operations

3 *Surgical operations are classified at the time of operation as clean, clean-contaminated, contaminated, or dirty.* Antimicrobial prophylaxis is appropriate for clean, clean-contaminated, and contaminated operations. Dirty operations take place in situations of existing infection and antimicrobials are used for treatment, not prophylaxis (**Table 85-1**).

Microbiology

4 *Choosing the appropriate prophylactic antimicrobial relies on anticipating which organisms will be encountered during the operation.* SSIs associated with extra-abdominal operations are the result of skin flora organisms in nearly all cases. These organisms include gram-positive cocci, with *S. aureus* and *Staphylococcus epidermidis* being among the most frequently isolated SSI pathogens according to the National Nosocomial Infections Surveillance System (NNIS)⁵ (**Table 85-2**). *Streptococcus* spp. and other gram-positive aerobes may also be implicated.

Intra-abdominal operations involve a diverse flora with the potential for polymicrobial SSIs. *Escherichia coli* make up a large portion of bowel flora and are frequently isolated as pathogens according to the NNIS.⁵ Other enteric

Table 85-1

National Red Cross Wound Classification, Risk of SSI, and Antibiotic Indication

Classification	Description	SSI Risk	Antibiotic Prophylaxis
Clean	No acute inflammation or transection of GI, oropharyngeal, GU, biliary, or respiratory tracts; elective case, no technique break	Low	Indicated
Clean-contaminated	Controlled opening of aforementioned tracts with minimal spillage or minor technique break; clean procedures performed emergently or with major technique breaks	Medium	Indicated
Contaminated	Acute, nonpurulent inflammation present; major spillage or technique break during clean-contaminated procedures	High	Indicated
Dirty	Obvious preexisting infection present (abscess, pus, or necrotic tissue present)	—	Not indicated; antibiotics used for treatment

GU, genitourinary.

From Refs. 7 and 9.

gram-negative bacteria, as well as anaerobes (especially *Bacteroides* spp.), may be encountered during intra-abdominal operations.

Candida albicans is being implicated as the cause of a growing number of SSIs. According to the NNIS, from 1991 to 1995, the incidence of fungal SSIs rose from 0.1 to 0.3 per 1,000 discharges.⁵ Increased use of broad-spectrum antimicrobials and rising prevalence of immunocompromised and human immunodeficiency virus-infected individuals are factors in fungal SSIs. Despite this increase, antifungal prophylaxis for surgery is not currently recommended.

Table 85-2

Major Pathogens in Surgical Wound Infections

Pathogen	Percentage of Infections ^a
<i>Staphylococcus aureus</i>	20
Coagulase-negative staphylococci	14
Enterococci	12
<i>Escherichia coli</i>	8
<i>Pseudomonas aeruginosa</i>	8
<i>Enterobacter</i> spp.	7
<i>Proteus mirabilis</i>	3
<i>Klebsiella pneumoniae</i>	3
Other <i>Streptococcus</i> spp.	3
<i>Candida albicans</i>	3
Group D streptococci	2
Other gram-positive aerobes	2
<i>Bacteroides fragilis</i>	2

From Kanji S, Devlin JW. Antimicrobial prophylaxis in surgery. In: DiPiro JT, Talbert RL, Yee GC, et al. (eds.) *Pharmacotherapy: A Pathophysiologic Approach*. 6th ed. New York: McGraw-Hill; 2005: 2219; With permission.

Choosing an Antibiotic

An antimicrobial used in surgical prophylaxis should meet certain criteria. Selecting an antimicrobial with a spectrum that covers expected pathogens is crucial. The antimicrobial should be inexpensive, available in a parenteral formulation, and easy to use. Adverse-event potential should be minimal. Choosing an agent with a longer half-life reduces the likely need to redose unless the surgical procedure is prolonged.

Operations can be separated into two basic categories: extra-abdominal and intra-abdominal. SSIs resulting from extra-abdominal operations are frequently caused by gram-positive aerobes. Thus an antimicrobial with strong gram-positive coverage is useful. Cefazolin provides a benign adverse-event profile, simple dosing, and low cost, making cefazolin the mainstay for surgical prophylaxis of extra-abdominal procedures. For patients with a β -lactam allergy, clindamycin or vancomycin can be used as an alternative.

Intra-abdominal operations necessitate broad-spectrum coverage of gram-negative organisms and anaerobes. Anti-anaerobic cephalosporins, cefoxitin and cefotetan, are widely used. Fluoroquinolones or aminoglycosides, paired with clindamycin or metronidazole, should provide adequate coverage for intra-abdominal operations; these regimens are recommended as appropriate regimens for use in patients with β -lactam allergies.

The Hospital Infection Control Practices Advisory Committee allows for the use of vancomycin for surgical prophylaxis when methicillin-resistant *S. aureus* (MRSA) rates at an institution are “high.”¹¹ Unfortunately, a “high” rate of MRSA has not been standardized. Additionally, vancomycin use in institutions where MRSA rates are “high” may not translate into a lower incidence of SSI. Finkelstein and associates found that the incidence of SSI for patients on cefazolin or vancomycin did not differ despite a high MRSA rate at the study institution. However, patients who received cefazolin were more likely to develop an SSI due to MRSA.¹⁰ The increasing prevalence of community-associated methicillin-resistant *S. aureus* (CA-MRSA) in patients admitted to the hospital

creates an added concern, although this pathogen is often sensitive to clindamycin. Vancomycin should be considered appropriate surgical prophylaxis for those patients identified as being colonized with MRSA (prior to or at admission).¹

Due to antimicrobial shortages of the recommended antimicrobials and development of newer antimicrobials (e.g., carbapenems, third- and fourth-generation cephalosporins, and antipseudomonal penicillins), some interest has been generated in the use of these newer antimicrobials for surgical prophylaxis. Ertapenem was superior to standard cefotetan in the prevention of SSIs after elective colorectal surgery.¹¹ However, the ertapenem treatment group had a larger proportion of *Clostridium difficile* infections than those in the cefotetan treatment group. Ertapenem has been included as an approved antibiotic for colon surgery.¹² At this time, it is not considered appropriate to use these newer antimicrobials for surgical prophylaxis; overuse of these antimicrobials may contribute to **collateral damage** and the development of bacterial resistance. Further research is needed before any of these newer agents are routinely used for surgical prophylaxis. New guidelines are likely to be published soon and may offer guidance on the use of newer antimicrobials.

β -Lactam Allergy

Allergy to β -lactams such as penicillin is one of the most common reported drug allergies. Concerns over cross-reactivity may limit the use of β -lactams for surgical prophylaxis. **5** *A thorough drug allergy history should be taken to discern true allergy (e.g., anaphylaxis) from adverse event (e.g., stomach upset).* Allergy testing may be helpful in confirming a patient's penicillin allergy and could spare vancomycin. However, practitioners should be aware allergy testing may be difficult to perform due to the removal of a major component (penicilloyl-polylysine) of the testing from the commercial market.¹³ If a practitioner desires to perform allergy testing, the individual reagents required for penicillin allergy testing must be prepared at the healthcare facility, on a case-by-case basis. Cross-allergenicity between penicillin and cephalosporins is low. The increased risk of cephalosporin allergy in patients with a history of penicillin allergy may be as low as 0.4% for first-generation cephalosporins and nearly zero for second- and third-generation agents.¹⁴ Other studies also found the risk of cross-reactivity to be very low.¹⁵ However, in the case of severe penicillin allergy (anaphylaxis), cephalosporins should be avoided.

Alternative Methods to Decrease SSI

Several nonantimicrobial methods have been studied for reducing the risk of SSI.¹⁶ Providing supplemental warming to patients (36.7°C [98°F]) during the intraoperative period reduced infection rates compared with control patients (34.7°C [94.5°F]).¹⁷ Intensive glucose control (maintaining blood glucose to 80 to 110 mg/dL [4.4 to 6.1 mmol/L]) versus conventional control (blood glucose less than 220 mg/dL [less than 12.2 mmol/L]) reduced infections and improved outcomes in cardiac patients who received intensive insulin

control in the ICU after surgery.¹⁸ Also, patients randomized to 80% (0.80) inspired oxygen had lower SSI rates compared with patients on 30% (0.30) oxygen after colorectal resection.¹⁹ Despite these findings, there are insufficient data to make definitive recommendations on the use of these therapies.

Antimicrobial-impregnated bone cement is being used as an adjunct or alternative to traditional antimicrobial prophylaxis for orthopedic operations. Cefuroxime-impregnated cement lowered the risk of deep infection after primary total knee arthroplasty.²⁰ Other studies have been inconclusive regarding superiority of antimicrobial-impregnated bone cement versus conventional therapies.²¹ Confounding this issue is the lack of standards regarding antimicrobial-impregnated cements. An array of drugs, from aminoglycosides to macrolides, is used in these preparations. Some cements are produced commercially, whereas others are made in the operating room. The long-term durability of impregnated cements is also unknown, as the addition of antimicrobials may reduce the tensile strength of bone cement. Further study is needed before antimicrobial-impregnated bone cements can be recommended as an alternative to preoperative prophylaxis with traditional antimicrobials.

Antimicrobial irrigation may also be encountered in the surgical arena as an adjunct or alternative to traditional parenteral antimicrobial prophylaxis. Irrigation of wounds allows debris removal as well as an additional way to lessen bacterial contamination simply by dislodging, diluting, or evacuating possible microbes. However, as with the antimicrobial bone cement, evidence is mixed on the advantages of using this approach. Irrigation with detergent solutions, rather than antimicrobials, appears to provide the same results but with less wound-healing problems encountered with antimicrobial irrigation.²² Additionally, because antimicrobial irrigation solutions are not commercially available, irrigants are often made in the operation rooms, allowing for the possibility of higher than or lower than desired concentrations. If concentrations are higher than desired, local chemical irritation may occur as well as systemic absorption and toxicity. If concentrations fall below desired targets, development of resistant organisms may occur. Further study is required before antimicrobial irrigation is recommended for use in surgical prophylaxis.

With the increase of CA-MRSA, increased importance has been placed on screening for *S. aureus*, especially MRSA and decolonization. Surgical patients with nasal colonization of *S. aureus* have a higher risk of an SSI due to *S. aureus*, and decolonization leads to a lower incidence of SSIs.²³⁻²⁵ However, although this evidence may imply the opportunity for some real benefits in the surgical population, a clear consensus on how the nasal colonization should be approached has not been reached. British guidelines recommend an attempt at decolonization for patients undergoing planned surgical procedures to minimize the risk of infection.²⁶ Harbarth and colleagues suggest that MRSA screening should be targeted to patients undergoing elective surgical procedures that have a high risk of MRSA infection. In addition, each hospital's infection control team, along with the surgical team, should analyze their patient population and MRSA

epidemiology to appropriately select screening guidelines,²⁷ keeping in mind state and federal statutes regarding the use of active surveillance cultures. Screening methods that utilize rapid, polymerase chain reaction (PCR)-based testing may provide an advantage in quickly identifying colonized patients and allowing decolonization to occur prior to surgery.

The most studied approach to eradication of methicillin-sensitive *S. aureus* (MSSA) and/or MRSA has been mupirocin applied to the anterior nares for 5 days prior to surgery.²⁸ Additionally, skin decolonization with 4% chlorhexidine for 5 days prior to surgery has also been recommended. Although decolonization of the anterior nares is the most common and most studied, some controversy exists because patients may be colonized elsewhere (rectum, throat, vagina, etc.) and often do not receive complete decolonization.²⁸ Furthermore, decolonization usually does not lead to life-long eradication. Other drugs, both topical and systemic, have been studied for decolonization/eradication of MRSA, but a review of randomized controlled trials for the eradication of MRSA found insufficient evidence for the use of any agent for eradication of MRSA.²⁹ In one study, surgical patients were assessed for nasal colonization by *S. aureus*. A significantly lower incidence of infections was demonstrated in patients who were colonized with *S. aureus* and completed a 5-day treatment of intranasal mupirocin twice daily and chlorhexidine wash daily. Although no MRSA infections were noted in the patients included in this study, the authors suggest that this treatment strategy would be beneficial in MRSA-colonized patients as long as those strains were susceptible to mupirocin. Although MRSA screening has gained more acceptance, less than 10% of centers screen for mupirocin and/or chlorhexidine resistance.³¹ Mupirocin resistance rates have varied from 1.9 to 5.6% of *S. aureus* isolates.³² Further studies are needed to elucidate this area of surgical prophylaxis, including cost-effectiveness.

Principles of Antimicrobial Prophylaxis

► Route of Administration

IV antimicrobial administration is the most common delivery method for surgical prophylaxis. IV administration ensures complete bioavailability while minimizing the impact of patient-specific variables. Oral administration is also used in some bowel operations. Nonabsorbable compounds such as erythromycin base and neomycin are given up to 24 hours prior to surgery to cleanse the bowel. Note that oral agents are used adjunctively and do not replace IV agents.

► Timing of First Dose

6 For prevention of SSIs, correct timing of antimicrobial administration is imperative so as to allow the persistence of therapeutic concentrations in the blood and wound tissues during the entire course of the operation. The National Surgical Infection Prevention Project recommends infusing antimicrobials for surgical prophylaxis within 60 minutes of the first incision. Exceptions to this rule are fluoroquinolones and vancomycin, which can be infused 120 minutes prior to avoid

infusion-related reactions.¹ No consensus has been reached on whether the infusion should be complete prior to the first incision. However, if a proximal tourniquet is used, antimicrobial administration should be complete prior to inflation.

Administration of the antimicrobial should begin as close to the first incision as possible. This is important for antimicrobials with short half-lives so that therapeutic concentrations are maintained during the operation and reduce the need for redosing. Beginning the antimicrobial infusion after the first incision is of little value in preventing SSI. Administration of the antimicrobial after the first incision had SSI rates similar to patients who did not receive prophylaxis.³³

► Dosing and Redosing

7 The goal of antimicrobial dosing for surgical prophylaxis is to optimize the pharmacodynamic parameter of the selected agent against the suspected organism for the duration of the operation. Dosing recommendations can vary between institutions and guidelines. Clinical judgment should be exercised regarding dose modifications for renal function, age, and especially weight. Obese patients often require higher doses than do nonobese patients.¹ Morbidly obese patients (body mass index greater than 40 kg/m²) who received 2 g of ceftazolin had a lower incidence of SSI compared with patients receiving 1 g.³⁴ An advisory statement from the National Surgical Infection Prevention Project suggested that for patients weighing less than 80 kg, ceftazolin should be dosed at 1 g; patients who weigh 80 kg or more should receive 2 g of ceftazolin for adequate prophylaxis.¹

If an operation exceeds two half-lives of the selected antimicrobial, then another dose should be administered.¹ Repeat dosing reduces rates of SSI. For example, ceftazolin has a half-life of about 2 hours, thus another dose should be given if the operation exceeds 4 hours. The clinician should have extra doses of antimicrobial ready in case an operation lasts longer than planned.

► Duration

The National Surgical Infection Prevention Project and published evidence suggest that the continuation of antimicrobial prophylaxis beyond wound closure is unnecessary.¹

8 The duration of antimicrobial prophylaxis should not exceed 24 hours (48 hours for cardiac surgery); additional doses of antimicrobial past this time point do not demonstrate added benefits. Longer durations of antimicrobial prophylaxis are advocated by some guidelines and will be discussed later.

TREATMENT

Antimicrobial Prophylaxis in Specific Surgical Procedures

► Gynecologic and Obstetric

Enteric gram-negative bacilli, anaerobes, group B streptococci, and enterococci are all possible pathogens that may be encountered in gynecologic or obstetric surgeries. For

Table 85-3

Recommended Regimens for Antimicrobial Prophylaxis of Specific Surgical Procedures^a

Type of Operation	Recommended Prophylaxis Regimen	Alternative Regimen
Vascular	Cefazolin 1–2 g IV every 8 hours for a total of 24 hours or cefuroxime 1.5 g IV × 1, then 750 mg every 8 hours for a total of 24 hours	Clindamycin 600–900 mg IV every 6 hours for a total of 24 hours or vancomycin 1 g IV every 8–12 hours for a total of 24 hours
Neurosurgery	Cefazolin 1–2 g IV every 8 hours for a total of 24 hours	Vancomycin 1 g IV every 8–12 hours for a total of 24 hours
Head and neck	Cefazolin 1–2 g IV every 8 hours for a total of 24 hours	Clindamycin 600–900 mg IV every 6 hours for a total of 24 hours
Urologic	Cefazolin 1–2 g IV × 1	Ciprofloxacin 400 mg IV × 1
Cesarean section	Cefazolin 1–2 g IV × 1	See hysterectomy
Hysterectomy	Cefotetan 1 g IV × 1, cefazolin 1–2 g IV × 1, ceftioxin 1–2 g IV × 1	Antianaerobic agent (metronidazole 0.5–1 g IV × 1 or clindamycin 600–900 mg IV × 1 combined with gentamicin 1.5 mg/kg IV × 1, aztreonam 1–2 g IV × 1, or ciprofloxacin 400 mg IV × 1 Ampicillin/sulbactam 3 g IV × 1 Ciprofloxacin 400 mg IV × 1
Gastroduodenal (high-risk only: obstruction, acid suppression, morbid obesity, hemorrhage, malignancy)	Cefazolin 1–2 g IV × 1	Ciprofloxacin 400 mg IV × 1
Biliary tract (high-risk only: age greater than 70 years, acute cholecystitis, obstructive jaundice, duct stones, nonfunctioning gallbladder)	Cefazolin 1–2 g IV × 1 or ceftioxin 1–2 g IV × 1	Ciprofloxacin 400 mg IV × 1
Colorectal	^b Oral: neomycin 1 g plus erythromycin base 1 g (give 19, 18, and 9 hours prior to procedure) IV: ceftioxin 1–2 g × 1	Cefazolin 1–2 g IV plus metronidazole 0.5–1 g IV × 1 or hysterectomy regimens
Appendectomy	Ceftioxin 1–2 g IV × 1; cefotetan 1 g IV × 1	Ertapenem 1 g × 1 Metronidazole 0.5–1 g IV plus gentamicin 1.5 mg/kg IV × 1
Orthopedic	Cefazolin 1–2 g IV every 8 hours for a total of 24 hours	Vancomycin 1 g IV every 12 hours or clindamycin 600–900 mg IV q 6 h
Cardiothoracic	Cefazolin 1–2 g IV every 8 hours for a total of 48 hours or cefuroxime 1.5 g IV every 12 hours for a total of 48 hours	Vancomycin 1 g IV every 12 hours for a total of 48 hours or clindamycin 600–900 mg IV every 6 hours

^aDosing recommendations are based on common clinical doses for adult patients with normal renal function; dosing for individual patients and institutions may vary.

^bOral regimens should be used in conjunction with IV prophylaxis.

From Refs. 1, 9, and 15.

patients undergoing hysterectomy, ceftioxin or cefotetan are appropriate therapies (Table 85-3). Cefazolin or ampicillin/sulbactam may be used. In the case of β -lactam allergy, the following regimens are appropriate: clindamycin combined with gentamicin, aztreonam, or ciprofloxacin; metronidazole combined with gentamicin or ciprofloxacin, or clindamycin monotherapy. Metronidazole monotherapy is also indicated but is less effective than other regimens.¹

Cesarean sections are stratified into low- and high-risk groups. Patients who undergo emergency operations or have cesarean sections after the rupture of membranes and/or onset of labor are considered high risk. Prophylactic antimicrobials are most beneficial for high-risk patients but are used in both groups. Antimicrobial regimens similar to those for hysterectomy are appropriate. Antimicrobials should not be administered until after the first incision and the umbilical cord has

been clamped. This practice prevents potentially harmful antimicrobial concentrations from reaching the newborn.

► Orthopedic Surgery

Orthopedic operations are generally clean and are done under controlled conditions. Likely pathogens include gram-positive cocci, mostly staphylococci. In the case of total joint (knee and hip) arthroplasty, cefazolin is the antimicrobial of choice. Patients with a β -lactam allergy should receive either clindamycin or vancomycin. Antimicrobial prophylaxis should not exceed 24 hours and does not need to be continued until all drains and catheters have been removed. Antimicrobial-impregnated bone cement can be useful in lowering infection rates in orthopedic surgery but has not been approved for prophylaxis.

► Cardiothoracic and Vascular Surgery

Cefazolin or cefuroxime are appropriate for prophylaxis in cardiothoracic and vascular surgeries. In the case of β -lactam allergy, vancomycin or clindamycin are advised. Debate exists on the duration of antimicrobial prophylaxis. SSIs are rare after cardiothoracic operations, but the potentially devastating consequences lead some clinicians to support longer periods of prophylaxis. The National Surgical Infection Prevention Project cites data that extending prophylaxis beyond 24 hours does not decrease SSI rates and may increase bacterial resistance.¹ However, the Society of Thoracic Surgeons issued practice guidelines in 2006 to extend the duration of antibiotics to 48 hours following cardiac surgeries.³⁵ Duration of therapy should be based on patient factors and risk of development of an SSI.

► Colorectal Surgery

Antimicrobial prophylaxis for colorectal operations must cover a broad range of gram-positive, gram-negative, and anaerobic organisms. Strategies include oral antimicrobial bowel preparations, parenteral antimicrobials, or both. Oral prophylaxis combinations of neomycin and erythromycin or neomycin and metronidazole are common. Oral antimicrobials should be administered at 19, 18, and 9 hours prior to surgery. A delay in surgery may require a redose, depending on the length of postponement. For parenteral prophylaxis, cefoxitin, cefotetan, or ertapenem is appropriate. Cefazolin combined with metronidazole or ampicillin/sulbactam is an effective alternative

Patient Encounter Part 2

RP is transferred to the oncology ward after completion of his surgery. In the procedure notes, the surgeon notes that part of the small bowel was nicked and possible intra-abdominal contamination may have occurred.

Does this patient still require surgical site prophylaxis?

The surgeon asks for your opinion for which antibiotic the patient should receive. Which antibiotic do you recommend?

How long should this patient remain on antibiotics?

if antianaerobic cephalosporins are not available. For patients with β -lactam allergies, use clindamycin combined with gentamicin, aztreonam, or ciprofloxacin; metronidazole combined with gentamicin or ciprofloxacin is also appropriate.

Appendectomy is one of the most common intra-abdominal operations. Antimicrobial prophylaxis used for appendectomy is similar to that used for colorectal regimens. In the case of ruptured appendix, antimicrobials are used for treatment, not prophylaxis.

OUTCOME EVALUATION

The clinician should consistently follow up postoperative patients and screen for any sign of SSI. **9** According to CDC criteria, SSIs may appear up to 30 days after an operation and up to 1 year if a prosthesis is implanted.⁵ This period often extends beyond hospitalization, so patients should be educated on warning signs of SSI and be encouraged to contact a clinician immediately if necessary. The presence of fever or leukocytosis in the immediate postoperative period does not constitute SSI and should resolve with proper patient care. Distal infections, such as pneumonia, are not considered

Patient Encounter Part 1

RP is a 50-year-old man with a history of rectal bleeding and recent diagnosis of sigmoid colon cancer. He presents today for a colon resection (colorectal surgery). He has a history of nausea with cephalexin. You have been asked for recommendation for surgical prophylaxis.

Height: 68 in (173 cm)

Weight: 214 lb (97.3 kg)

VS: BP 127/83 mm Hg, HR 63 beats/min, RR 21 breaths/min, T 98.6°F (37°C)

Labs: WBC 3×10^3 mm³ (3×10^9 /L), serum creatinine 0.9 mg/dL (80 μ mol/L), glucose 95 mg/dL (5.3 mmol/L)

What organisms are likely to be encountered for this operation and why?

What agents need to be avoided considering this patient's previous reaction with cephalosporins?

What drug would you choose for this operation and why?

The surgeon agrees with your decision and wants to begin infusing the antibiotic 3 hours prior to the first incision.

Comment on this.

What other interventions besides antibiotic use could prove useful in lowering RP's risk of SSI?

Patient Encounter Part 3

RP was treated appropriately for his surgical complications based on your recommendations following his surgery. He presents to a 3-week follow-up appointment to the surgical clinic. He notes that his wound site has been increasing in redness over the past 1 to 2 days, accompanied by a slight discharge that started this morning prior to the clinic visit.

VS: BP 104/78 mm Hg, P 82 beats/min, RR 21 breaths/min, T 100.7°F (38.2°C)

Labs: WBC 13×10^3 /mm³ (13×10^9 /L) serum creatinine 1 mg/dL (88 μ mol/L)

Based on the available data, does RP have an SSI?

What further steps should be taken in regard to this possible SSI?

Patient Care and Monitoring

1. Conduct a thorough medication history, including prescription and nonprescription medications, as well as herbals and vitamins.
2. Verify the patient's allergy history and the type of reaction experienced. Attempt to discern between true allergy and adverse event. β -Lactam-allergic patients may receive clindamycin, vancomycin, or other antimicrobials. Cross-reactivity between penicillin allergy and cephalosporins is low, but cephalosporins should be avoided in patients with a history of anaphylaxis to penicillins.
3. Document the type of operation the patient is undergoing. Verify the surgical procedure with the patient.
4. Prophylactic antimicrobials should be started within an hour of the first incision to optimize patient outcomes. Exceptions to this include vancomycin and fluoroquinolones.
5. The patient should be monitored for signs of an allergic reaction during the operation. These include rash, hives, difficulty breathing, or substantial drops in blood pressure.
6. Major breaks in surgical technique may cause the classification of the operation to change and require adjustments in antimicrobial prophylaxis.
7. The patient should be monitored for signs and symptoms of infection postoperatively. These could include pus, erythema, and fever. If signs consistent with SSI appear, cultures should be taken and additional antimicrobial therapy should be considered.
8. Patients being discharged should be counseled on recognizing signs and symptoms of SSI. An SSI can appear up to 30 days after an operation is completed.

SSIs even if these infections occur in the 30-day period. The appearance of the surgical site should be checked regularly and changes should be documented (e.g., erythema, drainage, or pus). The presence of pus or other signs suggestive of SSI must be treated accordingly. Any wound requiring incision and drainage is considered an SSI regardless of appearance. Prompt cultures should be collected and appropriate antimicrobial therapy initiated to reduce any chance of morbidity and mortality.

Abbreviations Introduced in This Chapter

ASHP	American Society of Health-System Pharmacists
CA-MRSA	Community-associated methicillin-resistant <i>Staphylococcus aureus</i>

MIC	Minimum inhibitory concentration
MRSA	Methicillin-resistant <i>Staphylococcus aureus</i>
MSSA	Methicillin-sensitive <i>S. aureus</i>
NNIS	National Nosocomial Infections Surveillance System
SSI	Surgical site infection

Vaccines and Toxoids

Marianne Billeter

LEARNING OBJECTIVES

● Upon completion of the chapter, the reader will be able to:

1. Define vaccination and immunization.
2. Classify each of the routine vaccines as an inactivated, polysaccharide, conjugate, toxoid, or subunit vaccine.
3. Describe the effect of each routine vaccine on preventing infection.
4. Recommend an immunization schedule for a child, including immunocompromised children.
5. Recommend an immunization schedule for an adult based on comorbid conditions and lifestyle issues.
6. Evaluate an adverse reaction and its probable association with a vaccine.

KEY CONCEPTS

- 1 Vaccines provide active immunity against viral and bacterial pathogens.
- 2 Polysaccharide vaccines are poorly immunogenic in children younger than 2 years of age.
- 3 Combination vaccines decrease the number of injections and increase the likelihood of completing the immunization schedule.
- 4 Healthcare professionals should report vaccine-adverse events.
- 5 Live virus vaccines should not be given to an immunocompromised host.
- 6 Vaccines are cost effective in preventing disease.

The development and widespread use of vaccines is one of the greatest public health achievements of the 20th century. Other than safe drinking water, no other modality has had a greater impact on reducing mortality from infectious diseases. The first accounts of deliberate inoculation to prevent disease date back as far as the 10th century. However it wasn't until 1798 that Edward Jenner published his work on inoculation of natural cowpox as a means to prevent infection with smallpox. This was the first scientific attempt to prevent infection by inoculation. Since 1900, vaccines have been developed against more than 20 diseases, with half of these recommended for routine use. The widespread use of vaccines has resulted in the eradication of smallpox worldwide and wild-type poliovirus from

the Western hemisphere. There have also been dramatic declines in the incidence of diphtheria, pertussis, tetanus, measles, mumps, rubella, and *Haemophilus influenzae* type b.

1 Vaccines have traditionally been preparations of killed or attenuated microorganisms that provide active immunity against a variety of viral and bacterial infections. Most vaccines are designed to prevent acute infections that can be rapidly controlled and cleared by the immune system. Successful immunization involves activation of antigen-presenting cells with processing of the antigen by lysosomal or cytoplasmic pathways. T and B lymphocytes will be activated to replicate and differentiate to form large pools of memory cells for protection against subsequent exposure to the antigen.¹

Vaccines against viral infections may be **attenuated** live viruses or inactivated viral particles. Attenuation may be accomplished by several methods to decrease the viruses' virulence while retaining their **immunogenicity**. Bacterial vaccines utilize antigenic particles of the outer membrane to elicit an immune response. 2 Outer membrane polysaccharides are poorly immunogenic in children younger than 2 years of age unless conjugated with a carrier protein. Also, bacterial toxins may undergo chemical treatment to render them nontoxic to form **toxoids** against infectious agents.

● Often the terms *vaccination* and *immunization* are used interchangeably even though they are distinct concepts. Vaccination refers to the act of administering a vaccine, whereas immunization refers to the development of immunity to a pathogen. The delivery of a vaccine does not imply that the individual mounted an adequate immune response to the vaccine to elicit protection. However, immunization implies that the act of vaccination resulted in the development of protective immunity.

Patient Encounter 1

A mother is taking her 11-year-old girl to the pediatrician for a routine sports physical. The pediatrician notices that the girl is due for several vaccines.

Which vaccines should the girl receive?

Will any booster doses be required for the administered vaccines?

The mother voices concerns about vaccinating her daughter against a sexually transmitted disease. What is an appropriate response?

Herd immunity refers to high levels of immunization in one population, resulting in protection of another unvaccinated population. For example, concentrated vaccination of children with the 7-valent pneumococcal conjugate vaccine resulted in decreased invasive *Streptococcus pneumoniae* infection not only in the vaccinated children, but also in elderly persons within the same community.

Cocoon immunization is a strategy used to immunize all persons surrounding another high-risk individual, such as vaccinating parents, siblings, and grandparents of a new infant who is too young to be vaccinated. This strategy is used to protect individuals who are not able to be vaccinated themselves.

THE ROUTINE VACCINES

Diphtheria, Tetanus, and Pertussis Vaccines

► Diphtheria Toxoid

Diphtheria is a bacterial respiratory infection characterized by membranous pharyngitis. The membrane may cover the pharynx, tonsillar areas, soft palate, and uvula. Diphtheria may also cause anal, cutaneous, vaginal, and conjunctival infections. The impact of diphtheria is not from the causative bacteria, *Corynebacterium diphtheriae*, but rather from complications attributed to its exotoxin, such as **myocarditis** and peripheral **neuritis**. In the late 1800s, the annual death rate from diphtheria ranged from 46 to 196 cases per 100,000. Mortality from diphtheria dropped in the 1900s mostly due to the availability of diphtheria antitoxin, which elicited passive immunity. Diphtheria is rarely reported in the United States since the introduction of vaccination with diphtheria toxoid; however, diphtheria continues to be a major problem in developing countries.

In the early 1900s, a balanced mixture of diphtheria toxin and antitoxin was found to produce active immunity in both animals and humans. This preparation gained widespread acceptance and protected approximately 85% of recipients. Several years later, diphtheria toxoid was developed by treating the toxin with small amounts of formalin. This process caused the toxin to lose its toxic properties while maintaining its immunogenic properties. In the mid-1920s, the

addition of an alum precipitate enhanced the immunogenic properties of the toxoid.

In the 1940s, diphtheria toxoid was combined with tetanus toxoid and whole-cell pertussis vaccines and later with the acellular pertussis vaccine. The diphtheria toxoid, tetanus toxoid, and acellular pertussis vaccine are part of the routine childhood immunization schedule. Diphtheria toxoid is also combined with tetanus toxoid and is commonly used as a booster vaccine. The pediatric product (DT) has a higher amount of diphtheria toxoid than does the adult product (Td). Diphtheria toxoid is not available as an individual vaccine.

Recent outbreaks of diphtheria have demonstrated that immunity wanes in adulthood. Approximately 50% of all adults no longer have immunity to diphtheria. Regular boosters with tetanus and diphtheria toxoids every 10 years will provide adequate recall immunity to diphtheria provided the adult was previously immunized.²

► Tetanus Toxoid

The tetanus vaccine differs from others in that it does not protect against a contagious disease such as diphtheria, but rather against an environmental pathogen. *Clostridium tetani* is widely found in the environment, especially in dirt and soils. Additionally, animals and humans may harbor and excrete the organism. *C. tetani* produces two neurotoxins, tetanospasmin and tetanolysin, which are responsible for producing the painful muscular contractions associated with tetanus. Tetanus continues to be a major problem in the developing world, causing approximately 1 million deaths each year.³ Approximately 40% of the cases are neonatal tetanus and most likely associated with the use of nonsterile instruments or poultices on the umbilical cord. Tetanus is rarely seen in developed countries.

Immunity to tetanus decreases with increasing age; therefore, a regular booster every 10 years with tetanus toxoid is recommended. The preferred agent to use in adults is tetanus and diphtheria toxoid (Td) in order to give a booster for diphtheria. Tetanus immunization status should be assessed in the management of wounds in individuals seeking medical care. A tetanus booster should be administered if a tetanus-containing vaccine has not been given in the preceding 5 years for moderate and severe wounds or contaminated wounds. If the wound is minor and uncontaminated, then a tetanus booster is needed if the previous tetanus vaccination was more than 10 years ago.

► Pertussis

Pertussis is a highly contagious respiratory tract infection caused by the bacteria *Bordetella pertussis*. Pertussis is characterized by a protracted severe cough with or without posttussive vomiting, whoop, difficulty breathing, difficulty sleeping, and rib fractures. It is often referred to as “whooping cough” or the 100-day cough. In the prevaccine era, pertussis accounted for more than 250,000 cases of severe illness and 10,000 deaths per year in the United States. Pertussis has always been thought of as a pediatric disease since most cases occurred in preschool-aged children with

relatively no cases seen in adolescents and adults. The first pertussis vaccine was introduced in the 1940s and within 30 years resulted in a 99% reduction in disease. However, during the past two decades, there has been a steady increase in reported cases of pertussis among adolescents and adults, indicating a waning immunity after primary immunization.⁴

The first pertussis whole-cell vaccine was a mixture of killed organisms that was associated with frequent local and systemic reactions. In the late 1980s, an acellular pertussis (aP) vaccine was introduced that contains purified pertussis components that are immunogenic but associated with fewer adverse reactions. Acellular pertussis vaccine is available in combination with tetanus and diphtheria toxoids. Pertussis is not available as a separate vaccine component. In the spring of 2005, the FDA-approved tetanus toxoid, reduced diphtheria toxoid, and acellular pertussis vaccines for use in adolescents and adults.

► Use of Diphtheria, Tetanus, and Acellular Pertussis Vaccine

Diphtheria and tetanus toxoids and acellular pertussis (DTaP) vaccine should be administered in a five-shot series to all children beginning at 2 months of age (Table 86-1). The shots are given at 2, 4, 6, and 15 to 18 months, and 4 to 6 years. Complete immunity to diphtheria and tetanus is achieved after the third vaccination.

Tetanus toxoid, reduced diphtheria toxoid, and acellular pertussis vaccine (Tdap) is recommended as a single booster for the following groups in place of a tetanus booster.⁵

- *Adolescents 11 to 18 years of age:* regardless of the interval from the last tetanus-containing vaccine.
- *Adults 19 to 64 years of age:* Tdap should replace the next routine tetanus booster regardless of the interval from the last tetanus-containing vaccine.
- *Tetanus prophylaxis in wound management:* Adolescents and adults 11 to 64 years of age who have completed a primary series and require a tetanus-containing product should receive Tdap instead of Td if they have not already received Tdap.
- *Prevention of pertussis among infants younger than 12 months of age:* Adults who have close contact with infants younger than 12 months of age, especially parents, grandparents, and child care providers, should receive a single dose of Tdap. Ideally, Tdap should be given 2 weeks prior to contact with the infant.
- *Postpartum women:* Women should receive a single dose of Tdap in the immediate postpartum period if Tdap has not been previously received. Ideally this should be administered prior to discharge from the hospital or birthing center.
- *Healthcare workers with direct patient contact:* Such workers should receive a single dose of Tdap.

Haemophilus Influenzae Type b Vaccine

Haemophilus influenzae is a bacterial respiratory pathogen that causes a wide spectrum of disease ranging from

colonization of the airways to bacterial meningitis. It causes considerable morbidity and mortality, especially in children younger than 5 years of age. *H. influenzae* is either encapsulated or unencapsulated. The encapsulated strains can be further differentiated into six antigenically distinct serotypes, designated by the letters a through f. *H. influenzae* type b was primarily found in cerebrospinal fluid and blood of children with meningitis, whereas the unencapsulated strains were found in the upper respiratory tract of adults. Before the introduction of the vaccine, *H. influenzae* was responsible for 20,000 to 25,000 cases of invasive disease annually and was the most common cause of bacterial meningitis. Since the introduction of the vaccine, invasive disease due to *H. influenzae* type b has been nearly eliminated.

The *H. influenzae* type b vaccine is a protein conjugate that utilizes a carrier-hapten for antigen presentation. The polysaccharide is conjugated to an immunogenic protein carrier, which is recognized by T cells and macrophages, which stimulates T-dependent immunity. The conjugated vaccine elicits an immune response characterized by T-helper cell activation. The T-dependent antigens induce an enhanced immune response in younger children. Within 10 years of its introduction, the *H. influenzae* type b vaccine use has resulted in widespread herd immunity.

H. influenzae type b conjugate vaccine is a recommended routine childhood vaccine given at 2, 4, 6, and 12 to 15 months of age. Adolescents and adults with functional or anatomic asplenia should also receive a booster dose of *H. influenzae* type b vaccine. The currently available vaccines are labeled for pediatric use, but can be used in adults when vaccination is indicated. There are several *H. influenzae* type b vaccines on the market that differ in the size of the polysaccharide and type of carrier protein; however, the immune response to *H. influenzae* type b is similar among the different vaccines. The different brands are interchangeable without affecting the primary immune response or booster response.

H. influenzae type b and influenza vaccines have the potential for confusion and medication errors because of the similarity of the names. Care should be taken when ordering, dispensing, and administering these vaccines.

Hepatitis A Vaccine

Hepatitis A virus continues to be a frequent cause of illness despite the availability of a highly effective vaccine. Hepatitis A typically has an abrupt onset of symptoms including fever, malaise, nausea, abdominal discomfort, and jaundice. Frequently, children younger than 6 years of age are asymptomatic, whereas adults typically have symptomatic disease. Symptoms may persist for 2 months or longer. There is wide geographic variation in the incidence of hepatitis A infection, with the number of cases ranging from 50 to more than 700 cases per 100,000 persons annually. The economic burden of hepatitis A is greater than \$300 million annually in combined direct and indirect costs. Widespread use of the vaccine offers the opportunity to substantially decrease the disease burden caused by hepatitis A infection.⁶

Table 86-1

Vaccine Dosing

Vaccine	Common Abbreviation	Dose	Route	Cautions and Adverse Effects
Diphtheria and tetanus toxoid Diphtheria, tetanus, acellular pertussis	DT DTaP	0.5 mL 0.5 mL	Intramuscular Intramuscular	Systemic neurologic reaction from previous vaccine Brachial neuritis Cries for 3 hours nonstop after previous dose Temperature greater than 40.6°C (105°F)
<i>Haemophilus influenzae</i> type b Hepatitis A	HIB HAV	0.5 mL C: 0.5 mL A: 1 mL	Intramuscular Intramuscular	
Hepatitis B	HBV	C: 0.5 mL A: 1 mL	Intramuscular	Allergic reaction to yeast (baking yeast)
Human papillomavirus Inactivated influenza	HPV TIV	0.5 mL 0.5 mL	Intramuscular Intramuscular	Pregnant women Severe egg allergy History of Guillain-Barré syndrome
Live attenuated influenza	LAIV	0.5 mL	Intranasal	Severe egg allergy Asthma Chronic health problems Immunocompromised host Pregnant women History of Guillain-Barré syndrome
Measles, mumps, rubella	MMR	0.5 mL	Subcutaneous	Allergic reaction to gelatin or neomycin Pregnant women Immunocompromised host Recently received a blood transfusion Severe egg allergy
Meningococcal polysaccharide	MPSV4	0.5 mL	Subcutaneous	History of Guillain-Barré syndrome
Meningococcal conjugate Pneumococcal 13-valent conjugate Pneumococcal polysaccharide	MCV4 PCV13 PPV23	0.5 mL 0.5 mL 0.5 mL	Intramuscular Intramuscular Intramuscular route preferred; subcutaneous	History of Guillain-Barré syndrome Children younger than 2 years of age
Poliovirus, inactivated	IPV	0.5 mL	Intramuscular, subcutaneous	Allergic reaction to neomycin, streptomycin, polymyxin B
Rotavirus vaccine Tetanus and diphtheria toxoid Tetanus, reduced diphtheria, acellular pertussis	RV Td Tdap	2 mL 0.5 mL 0.5 mL	Oral Intramuscular Intramuscular	Immunocompromised host History of Guillain-Barré syndrome Systemic neurologic reaction from previous vaccine
Varicella	VAR	0.5 mL	Subcutaneous	Allergic reaction to gelatin or neomycin Pregnant women Immunocompromised host Recently received a blood transfusion Hematopoietic stem-cell transplant
Zoster	ZOS	0.65 mL	Subcutaneous	Allergic reaction to gelatin or neomycin Immunocompromised host Recently received a blood transfusion Hematopoietic stem-cell transplant

C, children; A, adult.

Hepatitis A vaccine was licensed in the United States in 1995. It is an inactivated whole virus vaccine that is administered in a two-dose series. More than 94% of children, adolescents, and adults will have protective antibodies 1 month after receiving the first dose and 100% following the second dose.⁶ Recommended use of the hepatitis A vaccine utilizes an incremental implementation schedule beginning with high-risk populations or those at increased risk for

serious complications from the disease. Currently, hepatitis A vaccine is recommended for all children following the first birthday, with the second dose administered 6 months later. Adults who are at high risk for hepatitis A should receive two doses at least 6 months apart. High-risk adults include persons with clotting disorders or chronic liver disease, men who have sex with men, illicit drug users, international travelers going to areas with high to intermediate endemicity

of hepatitis A, persons with anticipated close contact with an international adoptee, or any other person who wishes to become immune.

Hepatitis B Vaccine

Hepatitis B virus is a blood-borne or sexually transmitted virus. Most acute infections occur in adults, whereas chronic infections usually occur in individuals infected as infants or children. However, about 10% of adults who contract hepatitis B virus will fail to clear their infection and develop chronic hepatitis B infection. Individuals with chronic hepatitis B infection are at risk for cirrhosis or hepatocellular carcinoma. Vaccination with hepatitis B vaccine is the most effective way to prevent hepatitis B infection.⁷

Hepatitis B vaccine is manufactured using recombinant DNA technology to express hepatitis B surface antigen (HBsAg) in yeast. This is further purified with biochemical separation techniques to produce the vaccine. The vaccines are formulated to contain 10 to 40 mcg of HBsAg protein/mL. Hepatitis B vaccine is available as a single component or in combination vaccines.

Hepatitis B vaccine is recommended for routine use in children. The first dose should be given within 12 hours of birth. The second and third doses are given at 2 months and 6 months, respectively, after the first dose if using the single-component vaccine or at 2, 4, and 6 months if using a hepatitis B-containing combination vaccine. If the infant weighs less than 2,000 g at birth, the birth dose is not counted in the three-dose series. Infants less than 2,000 g do not produce an adequate immune response to the birth dose of hepatitis B vaccine. Adolescents should receive the three-dose series if not previously vaccinated.⁷

Adults at high risk for hepatitis B because of occupation or lifestyle should receive the hepatitis B vaccine series. The typical series has the second and third doses given 1 month and 6 months after the first dose. Accelerated schedules may also be used. Frequently, individuals do not follow through with the complete three-dose series and questions arise about restarting the series. Hepatitis B vaccine produces an amnesic response; therefore, the series may be continued at any time in order to complete the three doses.

Following vaccination with hepatitis B vaccine, hepatitis B virus serologic markers will remain negative, with the exception of anti-HBs (antibody to hepatitis B surface antigen), which will be positive indicating immunity. Persons with anti-HBs concentration greater than 10 mIU/mL (10 IU/L) after vaccination will have complete protection against acute and chronic infection.⁷ There is no need for booster doses in immunocompetent individuals when anti-HBs concentrations fall below 10 mIU/mL (10 IU/L), since a good memory response will occur following exposure to hepatitis B virus. However, a booster dose is warranted in immunocompromised individuals.

Human Papillomavirus Vaccine

Human papillomavirus (HPV) is the most common sexually transmitted virus and is associated with a wide range of

diseases, including genital warts and cervical cancer. More than 100 HPVs have been sequenced and classified as low-risk nononcogenic or high-risk oncogenic types based on their ability to cause malignant disease. The predominant low-risk types HPV 6 and 11 are associated with 90% of genital warts. High-risk types HPV 16 and 18 are associated with 70% of cervical cancer cases and cervical intra-epithelial neoplasia.⁸ HPV is also associated with other gynecologic cancers, such as vaginal and vulvovaginal tumors.

Two HPV L-1 virus-like particle vaccines have been developed. The quadrivalent vaccine contains HPV types 6, 11, 16, and 18. The bivalent vaccine contains HPV types 16 and 18. Both vaccines have shown greater than 95% efficacy in preventing precancerous lesions of the cervix, vulva, and vagina. Additionally, the quadrivalent vaccine is also effective against genital warts. Both HPV vaccines are safe and adverse events are similar to other vaccines administered to adolescents.

These vaccines are unique in that preventing infection by HPV will translate into prevention of cancer, making these the first cancer prevention vaccines. Clinical trials are utilizing surrogate markers, prevention of precancerous lesions, to determine efficacy of the vaccines. However, the true impact on preventing cancerous tumors will not be known for years. The HPV vaccine is recommended for use in girls and women 9 through 26 years of age.⁹ Ideally it should be administered to girls before they become sexually active. However, sexually active girls and women should still receive the vaccine. Additionally, girls and women who have been infected with HPV should still receive the vaccine since the vaccine provides protection against more than one type of HPV. The quadrivalent HPV vaccine is also recommended for use in boys and men aged 9 through 26 years to prevent genital warts.

Influenza Vaccine

Influenza is a contagious viral respiratory infection that usually occurs during the winter months in the Northern Hemisphere and all year round in the Southern Hemisphere. All age groups are affected by influenza; however, children have the highest rate of infection. Serious illness and death due to influenza usually occurs in extremes of age, those over 65 years or under 2 years. Influenza is responsible for approximately 36,000 deaths annually in the United States.¹⁰

Influenza A and B viruses are responsible for causing human disease. Influenza A is further categorized into subgroups by its surface antigens, hemagglutinin and neuraminidase (e.g., influenza A H1N1 virus). Influenza B virus is not subtyped. Both influenza A and B undergo frequent antigenic drift, creating new influenza variants. Immunity to the surface antigens decreases the likelihood of infection. Unfortunately, antibody to one influenza subgroup does not give complete protection against other influenza subtypes. Therefore, annual influenza vaccination is recommended from September through November, and continuing until the vaccine supply is exhausted.

The best way to protect against influenza is through vaccination. The influenza vaccine is composed of two influenza

A subtypes and one influenza B subtype. The viral subtypes contained in the vaccine usually changes each year. The exact composition is selected by a panel of experts and announced by the Centers for Disease Control and Prevention (CDC) in March or April each year. The vaccine becomes available for use in August. Two types of influenza vaccine are licensed for use in the United States; both vaccines contain the same viral subunits. The influenza viruses for both vaccine preparations are grown in eggs. Therefore, the vaccines are contraindicated in individuals with severe allergy to eggs.

The influenza vaccine should be administered to all persons aged 6 months and older. The trivalent inactivated influenza vaccine can be administered to all age groups and risk populations; high-dose influenza vaccine should be administered to persons 65 years and older. The live attenuated influenza vaccine may be administered to healthy individuals between the age of 2 and 49 years. If the child is less than 8 years old and is receiving influenza vaccine for the first time, two doses separated by 4 to 6 weeks should be given.¹⁰

Measles, Mumps, and Rubella Vaccine

► Measles

Measles, also known as rubeola, is characterized by a rash that is often complicated by diarrhea, middle ear infection, or pneumonia. Encephalitis occurs in 1 of every 1,000 reported cases. Individuals who recover from encephalitis usually have permanent brain damage. Death occurs in 1 to 2 of every 1,000 reported measles cases.¹¹

Prior to measles vaccine availability, the number of cases of measles approached the birth rate of approximately 3 to 4 million annually. The first measles vaccine was licensed in 1963. Since that time there has been a 99% reduction in reported measles cases. Currently, there is a goal to eliminate measles transmission in the United States through aggressive immunization programs.

There have been several types of measles vaccines used since its introduction. The current vaccine uses a live attenuated preparation of the Enders-Edmonston virus strain. Following vaccination with measles-containing vaccine, a mild noncommunicable infection develops. Approximately 95% of individuals will develop antibodies following a single dose if administered after 12 months of age. More than 99% of individuals who receive two inoculations will develop long-term, probably lifelong, immunity to measles.¹¹

► Mumps

Mumps is usually thought of as a disease of children, but it has also gained notoriety as a prominent illness affecting military units. Mumps produces a typical acute parotitis, but may also cause nonspecific respiratory symptoms. In postpubertal males, mumps may also cause orchitis in 38% of those infected, which may result in infertility.¹¹

Since the introduction of the mumps vaccine in 1967, there has been a 99% reduction in reported cases. The mumps vaccine is a live virus preparation of the Jeryl-Lynn strain. It produces a subclinical, noncommunicable infection following

vaccination. Single doses of mumps vaccine will elicit immunity in 75% to 95% of individuals. Vaccine-induced immunity lasts for more than 30 years.

► Rubella

German measles, also known as rubella, is a mild exanthematous illness in children and young adults; however, rubella infection in pregnant women can cause a variety of congenital malformations in the infant. Congenital rubella syndrome occurs in approximately 25% of infants whose mother acquires rubella during the first trimester. Congenital rubella syndrome is characterized by congenital cataracts, heart disease, deafness, thrombocytopenia, mental retardation, and numerous other abnormalities.¹¹

The first rubella vaccine was licensed in 1969. Initial vaccination campaigns were targeting young children, as this age group had the highest rate of rubella infection. This strategy significantly decreased rubella cases in children, but did not have the desired effect on infection in adolescents and adults or on congenital rubella syndrome. Adolescents, especially young girls, were then targeted for vaccination. This has resulted in a significant reduction in the number of cases of congenital rubella syndrome.

The live rubella vaccine available in the United States contains the RA 27/3 strain of the virus. Following a single dose of rubella vaccine after the first birthday, more than 90% of individuals will develop long-term immunity. Rarely has congenital rubella syndrome been reported in infants born to mothers with adequate rubella immunization.

► Use of Measles, Mumps, and Rubella Vaccine

Measles, mumps, and rubella vaccines are no longer available as single-component vaccines because authorities recommend use of the measles, mumps, and rubella combination. Two doses of the measles, mumps, and rubella vaccine are recommended for all individuals born after 1957. The first dose should be administered soon after the first birthday and the second prior to entering school. For high-risk adolescents and adults who do not have adequate immunity, two doses of the vaccine should be separated by a minimum of 28 days.¹¹

Measles, mumps, and rubella vaccine is a live virus vaccine that should be used with caution in immunosuppressed children, such as those with cancer receiving chemotherapy, undergoing solid organ or bone marrow transplantation, or receiving other immunosuppressive drugs, such as steroids in a dose equivalent to prednisone 1 mg/kg/day or higher or 20 mg/day for 2 weeks or longer. If possible, vaccines should be given prior to becoming immunosuppressed. Otherwise, it may be prudent to defer the vaccine until after the immunosuppression resolves.

Meningococcal Vaccines

Neisseria meningitidis is a significant cause of meningitis and severe sepsis. Meningococcus causes an estimated 2,500 cases of invasive disease each year in the United States. Invasive meningococcal disease is associated with

Patient Encounter 2

A mother brings her 4-year-old child to the pediatrician for a routine exam. The child is due for some vaccines.

Which vaccines should the child receive?

The mother is concerned about the number of shots. How can the number of shots be minimized?

The mother is concerned about her child developing autism from one of the vaccines. What is an appropriate response?

an estimated 15% mortality rate. Morbidity in survivors is substantial, with approximately 20% having loss of limb or neurologic sequelae. The highest rates of meningococcal disease are among young children; however, rates have been increasing in adolescents and young adults aged 16 to 21 years. Thirteen meningococcal serogroups have been identified; however, five serogroups, A, B, C, Y, and W-135, are responsible for epidemic and endemic disease worldwide. Despite the availability of highly active antibacterial agents against *N. meningitidis*, there has been little impact on decreasing the morbidity and mortality due to invasive meningococcal disease.¹²

A meningococcal polysaccharide diphtheria toxoid conjugate vaccine was approved by the FDA in 2005, and contains meningococcal serogroups A, C, Y, and W-135. Use of the conjugate meningococcal vaccine in adolescents has shown a significant decrease in meningococcal disease among person aged 11 to 14, but not among persons aged 15 to 18. This indicates waning immunity as adolescents become older.

The meningococcal conjugate vaccine is recommended for routine vaccination at age 11 to 12 years, with a booster dose at age 16 to 18 years. Persons aged 2 through 54 years with complement component deficiencies or asplenia should receive a two-dose primary series administered 2 months apart and a booster dose every 5 years.

Pneumococcal Vaccines

Streptococcus pneumoniae is the most common bacterial cause of community-acquired respiratory tract infections. *S. pneumoniae* causes approximately 3,000 cases of meningitis, 50,000 cases of bacteremia, 500,000 cases of pneumonia, and more than 1 million cases of otitis media each year. The increasing prevalence of drug-resistant *S. pneumoniae* has highlighted the need to prevent infection through vaccination. Both licensed pneumococcal vaccines are highly effective in preventing disease from the common *S. pneumoniae* serotypes that cause human disease.

The 23-valent pneumococcal polysaccharide vaccine contains 23 serotypes that are responsible for causing more than 80% of invasive *S. pneumoniae* infections in adults. The vaccine includes those serotypes that are associated with drug resistance. Use of the vaccine will not prevent the development of antibiotic-resistant *S. pneumoniae*, but is likely to prevent infection from drug-resistant strains. The 23-valent

pneumococcal polysaccharide vaccine has demonstrated good immunogenicity in adults, but an individual will not develop immunity to all 23 serotypes following vaccination.¹³

The 23-valent pneumococcal polysaccharide vaccine is recommended for use in all adults 65 years of age or older and adults less than 65 years who have medical comorbidities that increase the risk for serious complications from *S. pneumoniae* infection, such as chronic pulmonary disorders, cardiovascular disease, diabetes mellitus, chronic liver disease, chronic renal failure, functional or anatomic asplenia, immunosuppressive disorders, and cigarette smokers. Children over the age of 2 years may be vaccinated with the 23-valent pneumococcal polysaccharide vaccine if they are at increased risk for invasive *S. pneumoniae* infections, such as children with sickle cell anemia or those receiving cochlear implants.

Revaccination with the 23-valent pneumococcal polysaccharide vaccine is recommended for adults over the age of 65 years if the first dose was administered when they were less than 65 years of age and at least 5 years have passed. Revaccination results in a blunted immune response and increased local adverse reactions; therefore, routine revaccination is not recommended.¹³ Adults vaccinated at age 65 or greater do not require revaccination.

The 7-valent pneumococcal conjugate vaccine was licensed in February 2000 for use in children. Widespread use of the 7-valent pneumococcal conjugate vaccine has resulted in herd immunity and decreased the incidence of invasive *S. pneumoniae* disease among unvaccinated adults over 20 years of age.¹³ A 13-valent pneumococcal vaccine was introduced in 2010 and is part of the routine childhood immunization schedule beginning at 2 months of age. It is given at 2, 4, 6, and 12 to 18 months of age.

Poliovirus Vaccine

Poliomyelitis is a highly contagious disease that is often asymptomatic; however, approximately 1 in every 100 to 1,000 cases will develop a rapidly progressive paralytic disease. Polio is caused by poliovirus, which has three serotypes; type 1 is most frequently associated with paralytic disease. Poliovirus replicates in the oropharynx and intestinal tract and is excreted in oral secretions and feces, which can infect others. As a result, more than 90% of unvaccinated individuals will become infected with poliovirus following household exposure to wild-type poliovirus. Since the introduction of the first poliovirus vaccine, there has been a significant reduction in the number of polio cases. Today, polio caused by wild-type poliovirus has been eradicated from the Western hemisphere with the goal of eradicating it from the world.¹⁴

The first inactivated poliovirus vaccine was introduced in the 1950s in an injectable formulation, and replaced in the 1960s by a live oral poliovirus vaccine. The oral poliovirus vaccine not only elicits systemic immunogenicity but also a localized immune response in the intestinal tract. Unfortunately, the oral poliovirus vaccine has the risk of vaccine-associated paralytic poliomyelitis occurring in

approximately 1 case of every 2.4 million doses distributed. The risk with the first dose of oral poliovirus vaccine is 1 case in 750,000 doses.¹⁴

The last reported case of indigenous wild-type poliovirus in the United States was in 1979; subsequent cases were all vaccine-associated. In 1997, a transition period to the inactivated poliovirus vaccine was begun to reduce the risk of vaccine-associated paralytic poliomyelitis. By January 2000, the oral vaccine was no longer recommended for routine use. Currently, the inactivated poliovirus vaccine is recommended for routine use in the United States. The oral poliovirus vaccine is still widely used in some countries where poliovirus eradication has been more difficult.

The enhanced potency inactivated poliovirus vaccine contains all three serotypes. After two doses, more than 90% of those vaccinated will have immunity to the three serotypes, and 99% will have immunity after three doses. Inactivated poliovirus vaccine is recommended to be given at 2, 4, 6 to 18 months, and 4 to 6 years of age.

Rotavirus Vaccine

Rotavirus is the most common cause of diarrhea worldwide. Most children will become infected by the age of 5 years. In the United States, rotavirus is responsible for approximately 50,000 hospitalizations for severe diarrhea and dehydration, and 20 to 40 deaths annually. Most hospitalizations occur in children younger than 3 years. Rotavirus infections follow a winter–spring seasonal pattern. Rotavirus G1 is the most prevalent strain found in the United States. However, in any given year, other strains (G2, G3, G4, and G9) may predominate.

The first rotavirus vaccine was a tetravalent rhesus-based rotavirus strain. It was licensed in the United States in 1998 and subsequently withdrawn from the market within the first year due to an association with **intussusception**. A pentavalent human-bovine reassortant rotavirus vaccine was approved by the FDA in February 2006. This vaccine contains outer capsid proteins for G1, G2, G3, G4 and P1. A monovalent, G1 vaccine has been approved for use in the United States.¹⁵ The exact mechanism by which these vaccines produce an immune response is unknown; however, these live virus vaccines replicate in the small intestine and induce immunity.

The rotavirus vaccine is administered in either a two-dose or three-dose series that is orally administered. The first dose is given to infants between 6 and 12 weeks of age.¹⁵ One year after the introduction of the rotavirus vaccine, the CDC reported a 50% reduction in reported cases of rotavirus in the United States.

Varicella Vaccine

Varicella zoster virus is a herpes virus that infects nearly all humans. Primary infection with Varicella zoster causes chickenpox (varicella), which is one of the most common childhood diseases. Chickenpox has always been thought to be a benign disease causing few serious complications in

children. The rate of chickenpox prior to the vaccine becoming available was thought to approximate the birth rate, with 3 to 4 million cases annually resulting in 11,000 hospitalizations and 100 deaths. Adults who develop chickenpox have a 25% greater risk for developing serious complications from varicella compared with children. Chickenpox is highly contagious and has a secondary household transmission rate of 87%. Following resolution of the primary infection, varicella becomes latent in cranial nerve, dorsal roots, and autonomic ganglia.

The varicella vaccine is made up of an attenuated Oka strain of varicella zoster virus. This is a live attenuated vaccine. Attenuation was achieved by performing serial passages through human embryonic lung cells, embryonic guinea pig cells, and human diploid cells.

Children younger than 12 years will have a 97% seroconversion rate following a single vaccination. Adolescents and adults more than 13 years old will only have 78% seroconversion after a single inoculation, but will have 99% conversion after the second vaccination administered 4 to 8 weeks after the first. Antibody titers appear to persist for at least 20 years following immunization. Despite excellent seroconversion rates, breakthrough chickenpox is reported at a rate of 1 case per 10,000 doses distributed. Most cases occurred within the first year following vaccination, and were due to wild-type varicella zoster virus. The majority of breakthrough cases were mild and of short duration.¹⁶

Secondary transmission to household contacts is always a concern with administration of a live vaccine. There are a few cases of possible secondary transmission of varicella following vaccination. Of the cases that varicella typing was done, 62% were wild-type virus, indicating exposure to an unvaccinated person. There are fewer than 10 confirmed cases of secondary transmission of the Oka vaccine strain following vaccination. A mild rash occurring in less than 5% of persons has been reported following vaccination. The varicella virus may be shed from the rash. Rashes due to the Oka vaccine strain typically occur more than 20 days following vaccination.¹⁶

Varicella vaccine should be administered after 12 months of age and a second dose at 4 years of age. Adolescents and adults without evidence of immunity to varicella zoster should receive two doses of varicella vaccine given 4 to 8 weeks apart. Varicella vaccine is available as a single-component vaccine or in combination with measles, mumps, and rubella vaccine.

Zoster Vaccine

Later in life, approximately 15% of the population will develop herpes zoster (shingles). Zoster is the reactivation of latent varicella zoster virus in the sensory ganglia. It produces a classic rash along a single nerve track. Approximately 20% of persons with herpes zoster will develop postherpetic **neuralgia**, which is a painful debilitating condition that can persist for months after resolution of the herpes zoster rash. Adults get a boost in immunity with repeated exposure to children with the chickenpox. Zoster most frequently occurs in the

elderly and immunocompromised individuals who have decreased circulating antibodies to varicella zoster virus.¹⁷

Zoster vaccine is a more concentrated form of the varicella vaccine. It is recommended for use in individuals 60 years of age and older even if they have had a previous episode of shingles. Use of the zoster vaccine has shown a 60% reduction in the incidence of zoster and postherpetic neuralgia. There is decreased effectiveness of the vaccine with increasing age.

The varicella vaccine is relatively new and has only been recommended for use since 1996; therefore, its true impact on chickenpox and zoster is not yet known. Continued use of the varicella vaccine will undoubtedly change the epidemiology of both of these diseases. As the prevalence of chickenpox declines, the rate of zoster will likely increase in the elderly, making vaccination with the zoster vaccine more prudent.¹⁷

COMBINATION VACCINES

The childhood immunization schedule is complex and requires a large number of injections. In small infants, the large number of injections can be intolerable to the infant, parent, and healthcare provider. Limiting the number of injections at each visit can lead to missed vaccinations and increased expense for return visits. **3** *Use of combination vaccines decreases the number of injections and increases the likelihood that the immunization schedule will be completed.*

Many factors have to be considered when developing combination vaccines. First, the selected components need to be given on a similar schedule, and all components should already be licensed in the United States. The excipients contained in the individual vaccines may interfere with another component when combined, altering a component's immunogenicity. Finally, the immunogenicity of the combination must be similar (within 10%) to the immune response when the components are administered separately.¹⁸

There are several combination vaccines available in the United States. Two of the most popular pediatric combinations are Pediarix and Pentacel, which are used in the primary infant vaccination series. The only combination available for adults is Twinrix, which has hepatitis A and hepatitis B vaccines.

VACCINE ADMINISTRATION SCHEDULES

Most vaccines are administered in two- to four-shot series in order to elicit the best protection. Childhood and adult immunization schedules are revised frequently and published annually by the CDC Advisory Committee on Immunization Practices. Current immunization schedules can be found at www.cdc.gov. Recommendations will be published throughout the year in the *Morbidity and Mortality Weekly Report (MMWR)* as new vaccines are licensed or new information necessitates a change in previous recommendations.

VACCINE SAFETY

Vaccination is one of the most powerful tools used to prevent disease. As with all drugs, most vaccines have been reported to cause adverse reactions. The reactions are either acute, such as local reactions, or are related to the risk of developing another disease. Healthcare professionals are to give vaccine information sheets (VIS) to individuals or caregivers prior to vaccination; these provide information about the risks and benefits of each vaccine.

Vaccine safety is monitored by the FDA and CDC through a passive reporting system that allows anyone, health professionals or lay public, to report any event. **4** *Healthcare professionals are bound by federal regulation to report certain adverse events (Table 86-2).* Additionally, any serious, life-threatening or unusual reactions should also be reported. The Vaccine Adverse Event Reporting System (VAERS) can be found at <http://vaers.hhs.gov>.

The VAERS database is continually monitored to determine whether the prevalence of reactions is changing and to identify previously unreported reactions to a particular vaccine. One of the limitations of the VAERS data is that it does not contain denominator data. Therefore, it is not possible to calculate a true rate of reaction occurrence: the number of cases of reaction per dose of vaccine administered. Rates are usually calculated using the number of doses distributed from the manufacture as the denominator. This makes the assumption that each dose distributed is administered.

Local Reactions

Pain at the injection site is one of the most commonly reported adverse effects of vaccination. The reaction is usually mild, with complaints of pain and tenderness at the injection site that may or may not be accompanied by erythema. Local reactions tend to be more frequent with repeated doses or booster doses of vaccine. The frequency and degree of the reactions appear to be related to the amount of preformed antibodies and rapid immunologic responses reflective of priming from previous doses. More serious Arthus reactions are infrequently reported. Arthus reactions are classified as type III hypersensitivity reactions and are characterized by a massive local response involving the entire thigh or deltoid. Arthus reactions are also related to preformed antibody complexes that induce an inflammatory lesion.¹⁹

Tetanus-containing vaccines are well known for causing localized reactions; however, all vaccines can cause local reactions.

Fever

Fever is the most frequently reported adverse effect in children and adolescents. Fever associated with vaccination is defined as a temperature of greater than or equal to 38°C (100.4°F) measured at any site using a validated device. Fever is caused by a complex reaction induced by the production of cytokines that affect the hypothalamic neurons. This

Table 86-2

Vaccine Reportable Events

Vaccine/Toxoid	Event	Interval From Vaccination
Tetanus in any combination (DTaP, DTP, DTP-Hib, DT, Tdap, Td, or TT)	Anaphylaxis or anaphylactic shock	7 days
	Brachial neuritis	28 days
	Systemic allergic reaction	7 days
	Systemic neurologic reaction	
Pertussis in any combination (DTaP, DTP, DTP-Hib, or Tdap)	Anaphylaxis or anaphylactic shock	7 days
	Encephalopathy or encephalitis	7 days
	Progressive neurologic disorders, such as infantile spasms or uncontrolled epilepsy	7 days
Measles, mumps, and rubella in any combination (MMR, MR, M, or R)	Anaphylaxis or anaphylactic shock	7 days
	Encephalopathy or encephalitis	15 days
Rubella in any combination (MMR, MR, or R)	Chronic arthritis	42 days
Measles in any combination (MMR, MR, or M)	Thrombocytopenic purpura	7–30 days
	Vaccine strain measles in immunodeficient recipient	6 months
Oral polio (OPV)	Paralytic polio	30 days to 6 months
	Vaccine strain polio infection	30 days to 6 months
Inactivated polio (IPV)	Anaphylaxis or anaphylactic shock	7 days
	Systemic allergic reaction	7 days
Hepatitis B	Anaphylaxis or anaphylactic shock	7 days
	Systemic allergic reaction	7 days
<i>Haemophilus influenzae</i> type b (conjugate)	Anaphylaxis or anaphylactic shock	7 days
	Systemic allergic reaction	7 days
Varicella (chickenpox)	Anaphylaxis or anaphylactic shock	7 days
	Systemic allergic reaction	7 days
Rotavirus	Intussusception	30 days
Pneumococcal conjugate	Anaphylaxis or anaphylactic shock	7 days
	Systemic allergic reaction	7 days

results in raising the hypothalamic set point. Temperature elevations above 40°C (104°F) can result in cellular and multiorgan dysfunction. Excessive temperature elevations rarely result from fever alone, but are usually coupled with other thermoregulatory dysfunction.²⁰

The whole-cell pertussis vaccine has been highly associated with temperature elevations; however, the prevalence has significantly decreased since the introduction of the acellular pertussis vaccine. Live virus vaccines are also associated with fever.

Guillain-Barré Syndrome

Guillain-Barré syndrome is a transient neurologic disorder involving inflammatory demyelination of the peripheral nerves. The syndrome is characterized by progressive symmetric weakness of the legs and arms with loss of reflexes. Occasionally, sensory abnormalities and paralysis of respiratory muscles will occur.²¹

The etiology of Guillain-Barré syndrome is unknown, but increasing evidence suggests it is probably a humoral and cellular autoimmune disease induced by infection with a variety of microorganisms. The background rate of Guillain-Barré syndrome is 1 to 2 cases per 100,000 persons annually. Guillain-Barré syndrome has been associated with several vaccines. An influenza vaccine used in the mid-1970s (swine flu vaccine) increased the incidence of Guillain-Barré syndrome by a factor of eight.²¹ Warnings about Guillain-Barré

syndrome continue to be given with annual influenza vaccinations. The hepatitis B vaccine derived from pooled plasma was also associated with Guillain-Barré syndrome; however, Guillain-Barré has not been reported with use of the currently available hepatitis B vaccines produced through recombinant DNA technology. Most recently, Guillain-Barré syndrome has been reported to occur with the meningococcal conjugate vaccine.

Other Safety Concerns

A clear cause-and-effect relationship between vaccine administration and chronic diseases, such as diabetes mellitus, multiple sclerosis, and chronic arthritis, has never been scientifically proven.

Thimerosal is a preservative used in vaccines that has been purported to cause autism in children. The assumption is that thimerosal, also known as ethyl mercury, causes similar effects as methyl mercury, which has neurotoxic and nephrotoxic effects at high doses. Several epidemiologic studies have not shown a higher rate of autism among children receiving thimerosal-containing vaccines when compared with the normal background rate of autism. Additionally, the mercury exposure with vaccination is much lower than through many other environmental exposures. Despite the lack of evidence of thimerosal causing neurologic disorders, vaccine manufacturers are producing vaccines that are thimerosal-free or only contain trace amounts of thimerosal.¹⁹

SPECIAL POPULATIONS

Immunocompromised Host

The number of immunocompromised persons is continually increasing as advances are made in medicine. The life expectancy for persons with cancer, HIV infection, and solid organ or bone marrow transplantation is increasing. Vaccination provides one tool to prevent infection in the immunocompromised host; however, the individual's immunosuppressed state will alter the response to the vaccine. In general, all vaccinations should be updated prior to the person becoming immunosuppressed, if possible. **5** *Once a person becomes significantly immunosuppressed, live virus vaccines should be avoided.*

Adults with HIV infection should be vaccinated with the 23-valent pneumococcal polysaccharide and hepatitis B vaccines as early in the course of the disease as possible. Inactivated influenza vaccine should be given yearly. Children should continue to receive vaccinations on the standard childhood immunization schedule. The individual may experience a transient elevation in HIV viral load following vaccination.²²

Following hematopoietic stem-cell transplantation, the patient will need virtually all routine vaccines to be administered again; however, the patient will not be able to mount an adequate response for 6 to 12 months posttransplant. Diphtheria, tetanus, acellular pertussis, *H. influenzae* type b, hepatitis B, pneumococcal, and inactivated poliovirus should be given at 12, 14, and 24 months posthematopoietic stem cell transplantation. Inactivated influenza vaccine should be given yearly, starting 6 months after transplant. Measles, mumps, and rubella can be given 2 years after transplant and varicella and zoster vaccines are contraindicated.²²

Solid organ transplant recipients have a blunted immune response to vaccines because the immunosuppressive regimens used to prevent organ rejection inhibit both T- and B-cell proliferation. Many of these patients will also have secondary hypogammaglobulinemia posttransplantation. Prior to transplant, children should complete primary immunization schedules if possible; accelerated schedules may be used. Adults should have all vaccinations updated prior to transplantation.²²

Household contacts of immunocompromised persons should have all routine vaccines as scheduled, including yearly influenza vaccination. Children in the household may receive live virus vaccines without special precautions; however, if a rash develops following varicella vaccination, contact should be avoided with the immunocompromised host until the rash resolves.

Patient Encounter 3

A 70-year-old patient goes to the physician for a routine physical. The patient reports not seeing a doctor for more than 5 years. The last time he was at the doctor he had shingles.

Which vaccines should the patient be screened for?

Should this patient receive the zoster vaccine?

Pregnancy

Immunization during pregnancy is done to ensure that the infant has sufficient antibodies during the period the infant is most vulnerable to disease. Maternal antibodies are actively transported to the fetus throughout the pregnancy. However, in the last 4 to 6 weeks of gestation, the active transport of immunoglobulins substantially increases. Vaccines administered during pregnancy should produce high antibody concentrations following a single vaccination and are administered in the second and third trimester, but no later than 2 weeks prior to delivery. Maternal vaccination has not shown any harmful effects to the developing fetus. However, live virus vaccines are avoided due to theoretical concerns of the virus being transported across the placenta and infecting the fetus. It is recommended that pregnant women be up-to-date on tetanus vaccine and receive the influenza vaccine if the second and third trimester will occur during the winter months.²³

Healthcare Workers

Most healthcare workers are at risk for exposure to many diseases in the normal course of their work. Additionally, healthcare workers may transmit vaccine-preventable diseases to their patients. At the time of employment and on a regular basis, healthcare workers should be screened for immunity to measles, mumps, rubella, and varicella; if found to be nonimmune, the measles, mumps, and rubella, and varicella vaccines should be administered. The hepatitis B series should be given if not already completed. Tetanus should be updated and given every 10 years. Healthcare personnel in hospitals and ambulatory settings with direct patient contact should receive Tdap if not already received.

All healthcare personnel should receive the influenza vaccine yearly in order to prevent transmission of influenza within the healthcare facility and to decrease employee absenteeism for influenza-related reasons. The vaccine should be made available to employees at the workplace free of charge. Employees should be asked to sign a declination if refusing to receive the influenza vaccine. Additionally, healthcare facilities should report the number of healthcare personnel receiving influenza vaccine as a patient safety measure.²⁴

OUTCOME MEASURES

6 *Vaccines are a cost-effective means for disease prevention.* For every dollar spent on routine childhood vaccines, there will be a savings of \$0.90 to \$24.00 in direct medical expense. The rates of vaccination for children are well over 90%. This has been attributed to the requirements for proof of vaccination by states for enrollment into day care centers and school. Additionally, children (18 years of age or younger) may receive routine vaccinations free of charge through state health departments or other assistance programs, such as the national Vaccines for Children program. Many states have developed universal immunization databases to document pediatric and adult vaccination status. This eliminates the problems of lost immunization records if a child changes healthcare providers.

The vaccination rate in adults is much lower than that in children. Only 50% to 60% of adults who meet criteria have received pneumococcal or influenza vaccination. Comprehensive initiatives need to be implemented to increase the adult vaccination rate. Some proven concepts are providing reminders to patients that vaccines are due and implementation of standing orders for vaccines. This latter concept allows nurses and pharmacists to screen patients to determine whether pneumococcal, influenza, or other vaccines are needed and to vaccinate without a physician's order.

The Centers for Medicare and Medicaid Services has incorporated pneumococcal and influenza immunization rates into some of their quality standards. Patients admitted to a hospital for community-acquired pneumonia should be screened for, offered, and vaccinated with pneumococcal and influenza vaccines prior to discharge if not previously administered. In physicians' office practice, all persons older than 65 years who have been hospitalized in the past year should be screened for, offered, and vaccinated with pneumococcal and influenza vaccines if not previously administered. Both of these standards will affect payment if the standard is not met. The Joint Commission has also incorporated these standards into their accreditation reviews of healthcare facilities.

Abbreviations Introduced in This Chapter

anti-HBs	Antibody to hepatitis B surface antigen
CDC	Centers for Disease Control and Prevention
HBsAg	Hepatitis B surface antigen
TT	Tetanus toxoid
VAERS	Vaccine Adverse Event Reporting System
VIS	Vaccine information sheets

Self-assessment questions and answers are available at <http://mhpharmacotherapy.com/pp.html>.

Human Immunodeficiency Virus Infection

Jessica L. Adams, Julie B. Dumond,
Angela D.M. Kashuba, and Amanda Corbett

LEARNING OBJECTIVES

● Upon completion of the chapter, the reader will be able to:

1. Explain the routes of transmission for HIV and its natural disease progression.
2. Identify typical and atypical signs and symptoms of acute and chronic HIV infection.
3. Identify the desired therapeutic outcomes for patients with HIV infection.
4. Recommend appropriate first-line pharmacotherapy interventions for patients with HIV infection.
5. Recommend appropriate second-line pharmacotherapy interventions for patients with HIV infection.
6. Describe the components of a monitoring plan to assess effectiveness and adverse effects of pharmacotherapy for HIV infection.
7. Educate patients about the disease state, appropriate lifestyle modifications, and drug therapy required for effective treatment.

KEY CONCEPTS

- 1 The treatment goals for HIV infection are to maximally and durably suppress HIV replication, avoid the development of drug resistance, restore and preserve immune function, prevent opportunistic infections, and minimize adverse effects.
- 2 HIV RNA plasma concentrations and CD4⁺ T-cell counts are used to assess risk of progression to AIDS (or risk for opportunistic infection) and to monitor efficacy and durability of treatment.
- 3 Effective and complete treatment of HIV infection involves a multidisciplinary approach, which includes pharmacists, other clinicians, and social workers.
- 4 Treatment with two nucleoside reverse transcriptase inhibitors (NRTIs) *and* a nonnucleoside reverse transcriptase inhibitor (NNRTI) *or* a ritonavir-boosted protease inhibitor (PI) *or* an integrase strand transfer inhibitor (INSTI) is the mainstay of initial treatment for HIV infection.
- 5 All patients with HIV infection relapse if medication is withdrawn. Therefore, long-term maintenance treatment is required.
- 6 HIV mutates easily, and strict adherence to the drug regimen and avoidance of deleterious drug interactions is critical to preventing the development of drug resistance and treatment failure.

- 7 The majority of antiretroviral medications are metabolized by the cytochrome P-450 enzyme system (CYP). Therefore, it is important to review patient medication profiles for drugs that may interact with antiretroviral drugs.
- 8 Most antiretroviral medications cause acute and chronic adverse effects. Patients should be closely monitored for these toxicities so that interventions can occur quickly.

The acquired immune deficiency syndrome (AIDS) was first recognized in 1981 and was described in a cohort of young homosexual men with significant immune deficiency. Since then, human immunodeficiency virus type 1 (HIV-1) has been clearly identified as the major cause of AIDS. HIV-2 is much less prevalent than HIV-1, but also causes AIDS. HIV primarily targets CD4⁺ lymphocytes, which are critical to proper immune system function. If left untreated, patients experience a prolonged asymptomatic period followed by rapid, progressive immunodeficiency. Therefore, most complications experienced by patients with AIDS involve opportunistic infections and cancers.

- HIV is primarily transmitted by sexual contact, by contact with blood or blood products, and from mother to child during gestation, delivery, or breast-feeding. The prevalence and incidence of HIV is rising globally, and to date there are no treatments that eradicate HIV from the body. Combinations of potent antiretroviral agents (called highly

active antiretroviral therapy, or HAART) can suppress HIV replication to undetectable levels, delay the onset of AIDS, and prolong survival. However, there are a number of drug-induced, long-term toxicities that challenge effective patient management. This chapter addresses HIV treatment options and challenges and gives practical suggestions for patient management.

EPIDEMIOLOGY

Since the first cases of AIDS were identified in 1981, close to 30 million people have died as a result of HIV infection. This makes AIDS one of the most destructive epidemics in recorded history. The epidemic remains extremely dynamic, and no country in the world is unaffected. In 2009, HIV infected approximately 33 million people worldwide. Approximately 68% of these cases are in sub-Saharan Africa, with a prevalence of approximately 5%. East Asia, Central Asia, and Eastern Europe are also seeing rapidly rising infection rates.¹

In 2009 alone, approximately 1.8 million people died from AIDS and 2.6 million people were newly infected with HIV. Most of these infections were acquired through heterosexual transmission. As of December 2009, women accounted for 52% of all people living with HIV worldwide. Persons aged 15 to 24 years accounted for approximately 40% of new HIV infections worldwide.¹

In the United States, at the end of 2008, an estimated 1,000,000 persons were living with HIV/AIDS. Approximately 20% of these are undiagnosed and unaware of their HIV infection and could be unknowingly transmitting the virus to others. In 2008, of the total number of HIV-infected patients, approximately one-half were living with AIDS, whereas approximately 18,000 died with AIDS. The cumulative estimated number of diagnoses of AIDS through 2006 was 1,014,797, one-half of whom (565,927) had died. Approximately 56,300 people are newly infected with HIV each year.²

Compared with their distribution in the U.S. population, African American and Hispanic populations are disproportionately affected by HIV/AIDS, representing 46% and 17% of cases, respectively. HIV/AIDS is among the top four causes of death for African American men aged 25 to 44 years and is among the top three causes of death for African American women of the same age. In 2008, HIV/AIDS rates for African American males were six times those for white males and three times those for Hispanic males. HIV/AIDS rates for African American females were 15 times the rates for white females and four times the rates for Hispanic females.²

ETIOLOGY AND PATHOGENESIS

HIV-1 is a retrovirus and member of the genus *Lentivirus*. These viruses have a characteristically prolonged latency period. There are two molecularly and serologically distinct but related types of HIV: HIV-1 and HIV-2. HIV-2 is a less common cause of the epidemic and is found primarily in

West Africa. HIV-1 is categorized by phylogenetic lineages into three groups (M [main], N [new], and O [outlier]). HIV-1 group M can be further categorized into nine subtypes: A through D, F through H, and J and K. HIV-1 subtype B is primarily responsible for the North American and Western European epidemic.

HIV in humans is believed to result from cross-species transmission from primates infected with simian immunodeficiency virus (SIV). HIV-2 is closely related to the SIV found in sooty mangabeys in West Africa, and HIV-1 is similar to the SIV found in chimpanzees. The earliest known human HIV infection was in central Africa in 1959. Cultural practices such as the preparation and eating of bush-meat, or keeping primates as pets, may have allowed the virus to transmit from animal to human. The rapid spread of the virus throughout the world can be primarily attributed to sexual promiscuity, drug abuse, and high mobility due to modern transportation.

- HIV infection occurs through three primary modes of transmission: sexual, parenteral, and perinatal. The most common method for transmission is receptive anal and vaginal intercourse, with the probability of transmission up to 30% per sexual contact. The probability of transmission increases when the index partner has a high level of viral replication (which occurs at the beginning of infection or late in disease) or when the uninfected partner has ulcerative disease or compromised mucosal surfaces or (in the case of men) has not been circumcised.

Parenteral transmission of HIV primarily occurs through injection drug use by sharing contaminated needles or injection-related supplies. As a result of a comprehensive North American screening program, less than 1% of all cases of HIV infection occur as a result of transfusions of contaminated blood or blood products, or infected transplant organs. Healthcare workers have a 0.3% estimated risk of acquiring HIV infection through percutaneous needle-stick injury.

Perinatal infection (also known as vertical transmission or mother-to-child transmission [MTCT]) can occur during gestation, at or near delivery, and during breast-feeding. The risk of MTCT up to and including delivery is approximately 25%, whereas the risk of transmission during breast-feeding is approximately 15% to 20% within the first 6 months of life. Because a high rate of HIV replication in the blood is a significant risk factor for transmission of HIV, it is important to treat women for their HIV infection during pregnancy. After delivery, mothers are strongly recommended not to breast-feed if safe alternatives are available.

Understanding the life cycle of the virus is important to know how antiretroviral drugs are combined for optimal therapy (Fig. 87-1). Once HIV enters the body, an outer glycoprotein called gp120 binds to CD4 receptors found on the surface of dendritic cells, T lymphocytes, monocytes, and macrophages. This allows further binding to other chemokine receptors on the cell surface called CCR5 and CXCR4. Greater than 95% of newly infected patients have viruses that preferentially use CCR5 to enter the cell, and most patients with advanced disease have viruses that preferentially use

FIGURE 87-1. Life cycle of HIV and targets for antiretroviral drugs. (From Fletcher CV, Kakuda TN. Human immunodeficiency virus infection. In: DiPiro JT, Talbert RL, Yee GC, et al., eds. *Pharmacotherapy: A Pathophysiologic Approach*. 8th ed. New York: McGraw-Hill; 2005: 2258; With permission.)

CXCR4 to enter the cell. This becomes important in understanding the place in therapy for some of the new drugs in development.

After the virus has attached to CD4 and chemokine receptors, another viral glycoprotein (gp41) assists with viral fusion to the cell and internalization of the viral contents. The viral contents include single-stranded RNA, an RNA-dependent DNA polymerase (also known as reverse transcriptase), and other enzymes. Using the single-stranded viral RNA as a template, reverse transcriptase synthesizes a complementary strand of DNA. The single-stranded viral RNA is removed from the newly formed DNA strand by ribonuclease H, and reverse transcriptase completes the synthesis of double-stranded DNA. The viral reverse transcriptase enzyme is highly error-prone, and many mutations occur in the conversion of RNA to DNA. This inefficient reverse transcription activity is responsible for HIV's ability to rapidly mutate and develop drug resistance.

A chronic infection is established when the double-stranded DNA migrates to the host cell nucleus and is integrated into the host cell chromosome by an HIV enzyme called integrase. Once the cell becomes activated by antigens or cytokines, HIV replication starts: Host DNA polymerase transcribes viral DNA into messenger RNA, and messenger RNA is translated into viral proteins. These proteins assemble beneath the bilayer of the host cell, a nucleocapsid

forms containing these proteins, and the virus buds from the cell. After budding, the virus matures when an HIV protease enzyme cleaves large polypeptides into smaller functional proteins. Without this process, the virus is unable to infect other cells.

During the early stages of infection, approximately 10 billion virions can be produced each day. Most of the cells containing these viruses will be lysed as a result of budding virions, killed by cytotoxic T-lymphocytes, or undergo apoptosis. However, virus will be protected within some cells (macrophages, T cells in lymph nodes), which can stay dormant for years. The initial immune response against HIV is relatively effective, but it is unable to completely clear the infection, and the patient enters a latent, asymptomatic, or mildly symptomatic stage lasting 5 to 15 years. During this time, a high rate of viral replication can be seen in the lymph nodes. Eventually immune deficiency occurs when the body is no longer able to replenish helper T cells at a rate equal to that at which HIV is destroying them.

- 1 The goal of therapy is to maximally and durably suppress HIV replication to restore and preserve immune system function and minimize morbidity and mortality. Because HIV replication has been found in all areas of the body, it is important to use potent drug therapy that can achieve adequate concentrations in all tissues, including protected sites such as the brain and genital tract.

CLINICAL PRESENTATION AND DIAGNOSIS

HIV diagnosis is made either by a positive **HIV enzyme-linked immunosorbent assay (ELISA)** or rapid test (these tests may be positive as soon as 3 to 6 weeks after infection) and then confirmed by a positive confirmatory test, usually the **HIV Western blot (WB)** (Table 87-1). An at-home HIV-1 test kit (Home Access Systems) has been approved by the FDA, allowing patients to self-collect blood samples, mail to a diagnostic laboratory, and receive counseling and results over the telephone using a PIN number; positive results require confirmation by WB.

Patients who are acutely infected with HIV may be asymptomatic or present with signs and symptoms associated with any viral infection, such as fever, myalgias, lymphadenopathy, pharyngitis, or rash. Taken together, these are the “acute retroviral syndrome,” and 40% to 90% of acutely infected individuals will have symptoms. Providers should consider the possibility of HIV infection in any patient with these findings and inquire about recent high-risk sexual encounters or other modes of exposure. Risk factors for HIV/AIDS infection include men who have sex with men (MSM), history of or current IV drug use (needle or equipment sharing), unprotected sexual intercourse with high-risk individuals, the presence of other sexually transmitted infections (e.g., *Chlamydia trachomatis* or *Neisseria gonorrhoeae*), persons with coagulation/hemophilia disorders, and previous blood product recipients. In the United States, 20% of HIV-infected individuals are not aware of their status, thus identifying acutely infected patients

and providing referral into HIV care is critical for preventing HIV transmission.² This percentage is 59% in patients aged 13 to 24 years. In acute infection, HIV RNA concentrations in blood and the genital tract are very high, increasing the risk of transmission to others.³ Increased infectiousness coupled with undiagnosed HIV infection in these patients may account for a substantial proportion of sexual HIV transmission.

- If patients are not identified during acute infection, they may later present with various nonspecific symptoms such as myalgias, fatigue, weight loss, thrush, or symptoms associated with opportunistic infections. The U.S. Centers for Disease Control (CDC) currently recommends that patients aged 13 to 64 years in all healthcare settings undergo opt-out HIV testing, meaning that a separate consent form for testing is not needed after the patient has been informed that testing will be performed. For those patients in the high-risk groups mentioned above, HIV testing should be performed on an annual basis, and pregnant women should be tested with each pregnancy.⁴

The diagnosis of HIV infection is made either by a baseline serologic screening test such as the ELISA or a rapid test. If reactive, then a confirmatory test is performed. The WB is the gold standard confirmatory test and is commonly used. The WB is considered reactive if two of the three major bands (p24, gp41, and/or gp120/160) change color. The test is nonreactive if no viral bands are visible. If the test is indeterminate (one band visible), patients are retested in 2 to 3 months. This is most likely if a recent (i.e., less than 3 to 6 weeks) infection has occurred, and HIV antibodies have not yet been fully formed. In this case, a plasma HIV RNA concentration (reverse transcriptase polymerase chain reaction [RT-PCR])

Table 87-1

HIV Diagnostic Tests

Test	Minimum Time to Detection After Exposure	Sample(s) Tested	Comments
Initial Screening Tests			
ELISA	3–6 weeks	Plasma	If nonreactive, no further testing is required, unless acute infection suspected
HIV RNA assay	Up to 14 days	Plasma	Obtain if recent high-risk exposure; if initially negative, repeat at months 1, 3, and 6
<i>Rapid tests (currently FDA-approved products):</i>			
OraQuick ADVANCE	Detects HIV antibodies within minutes of sample application		
	3–6 weeks	Whole blood, plasma, or oral fluid	Detects HIV-1 and HIV-2
HIV 1/2 STAT-PAK	3–6 weeks	Whole blood, plasma, or serum	Detects HIV-1 and HIV-2
SURE CHECK HIV 1/2	3–6 weeks	Whole blood, plasma, or serum	Detects HIV-1 and HIV-2
Multispot HIV-1/HIV-2 Rapid Test	3–6 weeks	Plasma or serum	Detects HIV-1 and HIV-2
Reveal Rapid HIV-1 Antibody Test	3–6 weeks	Plasma or serum	Detects HIV-1
Uni-Gold Recombigen HIV Test	3–6 weeks	Whole blood, plasma, or serum	Detects HIV-1
INSTI™ HIV-1 Antibody Kit	3–6 weeks	Plasma or whole blood	Detects HIV-1
Confirmatory Tests			
Western blot (WB)	3–6 weeks	Plasma	Gold standard confirmatory test
Indirect immunofluorescence assay (IFA)	3–6 weeks	Plasma	Simple to perform, but requires expertise to interpret results

ELISA, enzyme-linked immunosorbent assay.

Clinical Presentation and Diagnosis of HIV

Patients with acute HIV infection may display symptoms described as “acute retroviral syndrome.” Patients with chronic HIV infection may present with these same nonspecific symptoms and/or opportunistic infections.

Acute Retroviral Syndrome

The majority of patients may present with fever, lymphadenopathy, pharyngitis, and/or rash. Other symptoms include:

- Myalgia or arthralgia
- Diarrhea
- Headache
- Nausea and vomiting
- Hepatosplenomegaly
- Weight loss
- Thrush
- Neurologic symptoms (meningoencephalitis, aseptic meningitis, peripheral neuropathy, facial palsy, or cognitive impairment or psychosis)

Opportunistic Infections

Depending on the severity of immunosuppression (the CD4⁺ T lymphocyte count), patients may present with the following opportunistic infections (grouped by CD4⁺ count):

Any CD4⁺ count

- *Mycobacterium tuberculosis* disease

- Bacterial pneumonia (commonly *Streptococcus pneumoniae*, *Haemophilus influenzae*, *Pseudomonas aeruginosa*, and *Staphylococcus aureus*)
- Herpes simplex virus disease
- Varicella zoster virus disease
- Bacterial enteric disease (most commonly *Salmonella*, *Campylobacter*, and *Shigella*)

- Syphilis

- Bartonellosis

Less than 250 cells/mm³ (250 × 10⁶/L)

- Coccidioidomycosis

- *Pneumocystis jiroveci* (formerly *carinii*) pneumonia (PCP)

- Oropharyngeal and esophageal candidiasis

- Kaposi's sarcoma or human herpesvirus-8 disease

Less than 150 cells/mm³ (150 × 10⁶/L)

- Disseminated histoplasmosis

Less than 100 cells/mm³ (100 × 10⁶/L)

- Cryptosporidiosis

- Microsporidiosis

Less than 50 cells/mm³ (50 × 10⁶/L)

- Disseminated *Mycobacterium avium* complex disease

- Cytomegalovirus disease

- Cryptococcosis, aspergillosis, and *Toxoplasma gondii* encephalitis

should be evaluated. Patients with acute infection will generally have HIV RNA concentrations greater than 10⁶ copies/mL (10⁹ copies/L). **2** HIV severity is determined by following: (a) the CD4⁺ lymphocyte count (CD4 count) and percentage and (b) HIV RNA (viral load). The CD4 percentage is followed because the absolute count may fluctuate and does not necessarily indicate a change in the patient's condition.

TREATMENT

1 The goals of treatment are to maximally and durably suppress viral replication, avoid the development of drug resistance, restore and preserve immune function, prevent opportunistic infections, and minimize drug adverse effects. Elimination of HIV is not possible with currently available therapies. Instead, maximal suppression of viral replication (defined as HIV RNA concentrations undetectable by the most sensitive assay available) is desired. After the initiation of antiretroviral therapy, a rapid decline to undetectable HIV RNA in 16 to 24 weeks is a predictor of improved clinical outcomes.⁵

2 Degree of immune function preservation is also correlated with decreased viral replication, and is measured by CD4⁺ T-cell counts. CD4 measures are the best predictor of

progression to AIDS and help clinicians determine when to initiate treatment. At CD4⁺ T-cell counts of 200 cells/mm³ (200 × 10⁶/L) and lower, patients require drug prophylaxis for opportunistic infections. **Table 87-2** details the monitoring end points of HIV treatment for HIV RNA and CD4⁺ T-cell counts. In addition to these parameters, basic blood chemistry tests, liver function tests, complete blood counts, and lipid profiles should be monitored every 3 to 6 months in patients receiving antiretroviral therapy.⁵

Six classes of drugs are available to treat HIV infection: nucleoside (NRTI)/nucleotide (NtRTI) reverse transcriptase inhibitor, protease inhibitor (PI), nonnucleoside reverse transcriptase inhibitor (NNRTI), fusion inhibitors, CCR5 inhibitors, and integrase strand transfer inhibitors (INSTI). **3** Currently, combination antiretroviral drug therapy with three or more active drugs is the standard of care, which increases the durability of viral suppression and decreases the potential for the development of resistance.

4 Two nucleoside (nucleotide) reverse transcriptase inhibitors AND a NNRTI OR a ritonavir-boosted PI OR an INSTI are the mainstay regimens of combination therapy in initial treatment. Use of two NRTIs/NtRTIs with a CCR5 inhibitor may also be considered as an initial regimen. In the late

Patient Encounter 1, Part 1

A 22-year-old African American man presents to the emergency department of your hospital complaining of a fever, malaise, and pharyngitis that has been present for about a week.

PMH: No significant past medical history

FH: Noncontributory

SH: College student; reports multiple sexual partners in the past few months with condom use about 50% of the time. He denies illicit drugs, but drinks 5 to 10 alcoholic drinks weekly.

Meds: None

ROS: (–) weight loss, decreased appetite, shortness of breath, and cough, chest pain, nausea, vomiting, diarrhea

PE: Within normal limits

VS: BP 124/84 mm Hg, P 73 beats/min, RR 18 breaths/min, T 39.3°C

HEENT: Within normal limits

CV: RRR, normal S1, S2; no murmurs, rubs, gallops

Abd: Soft, nontender, nondistended; (+) bowel sounds, no hepatosplenomegaly

Rectal: Deferred

Labs: Sodium 135 mEq/L (135 mmol/L), potassium 3.6 mEq/L (3.6 mmol/L), chloride 100 mEq/L (100 mmol/L), bicarbonate 24 mEq/L (24 mmol/L), blood urea nitrogen 14 mg/dL (5 mmol/L), creatinine 1.0 mg/dL (88 μmol/L), WBC $5.2 \times 10^3/\text{mm}^3$ ($5.2 \times 10^9/\text{L}$), hemoglobin 11.5 g/dL (115 g/L or 7.14 mmol/L), hematocrit 34.1% (0.341), platelets $151 \times 10^3/\text{mm}^3$ ($151 \times 10^9/\text{L}$), neutrophils 58% (0.58), bands 9% (0.09), lymphocytes 32% (0.32), monocytes 1% (0.01), eosinophils 0% (0.00), basophils 0% (0.00)

What information is suggestive of HIV?

What is the likely time frame of this patient's HIV infection?

What are the risk factors present for having HIV?

How can the diagnosis of HIV be made in this patient?

What additional laboratory measurements would be useful?

Table 87-2

Monitoring End Points for CD4⁺ T-Cell Counts and HIV RNA

CD4 ⁺ T Cell Counts			HIV RNA Concentration		
When to Monitor?	Why?	Goal	When to Monitor?	Why?	Goal
Initial diagnosis	Assess need for ART	Start therapy in appropriate patients	Initial diagnosis/evaluation	Establish baseline and assess need for ART	Start ART in appropriate patients
	Assess need for OI chemoprophylaxis	Start therapy when counts less than 200 cells/mm ³ (less than $200 \times 10^6/\text{L}$)	2–8 weeks after starting or changing ART ^a	Early assessment of regimen efficacy	Undetectable concentrations
Every 3–6 months	Receiving ART: monitor success of treatment ^b	Average increase of 100–150 cells/mm ³ /year (100×10^6 – $150 \times 10^6/\text{L}$ /year)	Every 3–6 months	Receiving ART: assess success and durability of virologic suppression with current regimen	Steadily decreasing and/or consistently undetectable concentrations
	Not receiving ART: assess need to begin therapy	Start ART in appropriate patients	Every 3–4 months	Not receiving ART: monitor changes in viral load	Start therapy in appropriate patients
	Assess need for OI chemoprophylaxis	Start therapy when counts less than 200 cells/mm ³ (less than $200 \times 10^6/\text{L}$)		Not receiving ART: monitor changes in viral load	Start therapy in appropriate patients

ART, antiretroviral therapy; OI, opportunistic infection.

^aIf viral load is detectable, repeat every 4 to 8 weeks until less than 200 copies/mL (less than $200 \times 10^3/\text{L}$), then resume every 3- to 6-months schedule.

^bIn clinically stable patients with viral loads less than 50 copies/mL (less than $50 \times 10^3/\text{L}$) for more than 2 years, monitoring can be extended to every 6 to 12 months.

Adapted from Panel on Antiretroviral Guidelines for Adults and Adolescents. Guidelines for the use of antiretroviral agents in HIV-1-infected adults and adolescents [online]. Department of Health and Human Services. October 14, 2011;1–166. [cited 2011 Oct 10]. Available from: <http://www.aidsinfo.nih.gov/ContentFiles/AdultandAdolescentGL.pdf>.

1980s, when only zidovudine was available, achieving and maintaining viral suppression for more than 4 months was rarely possible. As more agents became available in the mid-1990s (most notably the PIs), HIV RNA was suppressed to undetectable concentrations and maintained there for long periods of time. Currently recommended combination regimens decrease HIV RNA to less than 50 copies/mL (50×10^3 copies/L) in 80% to 90% of patients in clinical trials. Therefore, monotherapy with any agent or the use of NRTIs without another drug class are not routine treatment options. Fusion inhibitors are only FDA-approved for use in treatment experienced patients with drug resistance to NRTIs, NNRTIs, and/or PIs. Figure 87-1 details the mechanisms of action of the drug classes within the life cycle of HIV.

Nonpharmacologic Interventions

6 *Patient adherence is a key component in treatment success.* Drug therapy is required for a lifetime, as the virus begins to replicate at high levels when medications are stopped. Early HIV combination therapy was exceedingly complicated for patients, with multiple daily doses, varying food restrictions, and large pill burdens. Advances in delivery and formulations now make possible once- or twice-daily dosing with fewer pills per day. Currently, two combination tablets providing one pill, once daily NNRTI-containing regimens are available: tenofovir + emtricitabine + efavirenz (Atripla) and tenofovir + emtricitabine + rilpivirine (Complera). The use of low-dose ritonavir to enhance the concentrations of other PIs (known as pharmacokinetic enhancement, or “boosting”) allows for significantly fewer doses and lower pill burdens. Atazanavir or darunavir with ritonavir boosting are potent, once-daily PI options; once-daily lopinavir/ritonavir or fosamprenavir/ritonavir may be used in selected treatment-naïve patients.

These advances, however, do not replace the need for patient counseling by a trained pharmacist and a multidisciplinary approach to promoting adherence.

Counsel all patients initially and repeatedly on ways to prevent viral transmission. Preventing the spread of resistant virus is particularly important. Patients receiving antiretroviral therapy can still transmit virus to sexual partners and to those with whom they share needles or other drug equipment. Where both partners are HIV-positive, safe sex and needle practices reduce the risk of superinfection with differing strains of HIV and the transmission of other sexually transmitted diseases. General guidelines for preventing viral transmission include using condoms with a water-based lubricant for vaginal or anal intercourse, using condoms without lubricant or dental dams for oral sex, and not sharing equipment used to prepare, inject, or inhale drugs. Treating other sexually transmitted infections (STIs), particularly genital herpes, in HIV-infected patients may help to prevent HIV transmission. The presence of STIs increases genital tract HIV viral load and, correspondingly, the risk of HIV transmission to sexual partners.

3 *Nutrition and dietary counseling should also be included in the care of the HIV patient, as poor nutrition leads to poorer outcomes and complicates treatment.* Antiretroviral

therapy itself introduces a host of nutritional issues, including drug–food interactions, GI adverse effects that may affect appetite and limit dietary intake, lipid abnormalities, and fat redistribution. The American Dietetics Association currently recommends assessing HIV-infected patients for their level of nutritional risk and involving a registered dietician as part of the clinical team for optimal nutrition care.⁶

Pharmacologic Therapy for Antiretroviral-Naïve Patients

Two major panels of experts publish guidelines for the treatment of HIV-infected individuals. Although the recommendations are quite similar, slight differences do exist between the Department of Health and Human Services (DHHS) Guidelines⁵ and the International AIDS Society–USA (IAS-USA) Panel Recommendations.⁷ The DHHS Guidelines are updated frequently, and current and archived versions are available online at www.aidsinfo.nih.gov. The IAS-USA Guidelines were last updated in 2010, and in 2008 prior to that revision. Due to the intense research and constant modifications to therapeutic approaches in the treatment of HIV, the majority of the treatment algorithms and recommendations presented herein follow the most up-to-date information found in the October 2011 DHHS recommendations.

2 *The decision of when to begin antiretroviral therapy is complex. Recommendations are based on the CD4⁺ T-cell count, which predicts disease-free survival, and other comorbid conditions (Table 87-3).* Other factors to consider include the patient’s viral load, decline in CD4⁺ counts over time, hepatitis C status, risk for cardiovascular disease, risk of

Table 87-3

Summary of Recommendations for Initiating Antiretroviral Therapy

Clinical Indicator/CD4 ⁺ Count	Recommended Action
Symptomatic HIV disease or opportunistic infection	Start ART
Asymptomatic infection with CD4 ⁺ count less than 350 cells/mm ³ (less than 350×10^6 /L)	
CD4 count 200–350 cells/mm ³ ($200 \times 10^6 - 350 \times 10^6$ /L)	
Pregnant women	
HIV-associated nephropathy	
HBV coinfection, where HBV treatment is indicated	
CD4 ⁺ count greater than 350 mm ³	Currently panels of experts are divided; depends on the patient characteristics and individual risk-benefit assessment

ART: antiretroviral therapy; HBV, hepatitis B virus.

Adapted from Panel on Antiretroviral Guidelines for Adults and Adolescents. Guidelines for the use of antiretroviral agents in HIV-1-infected adults and adolescents [online]. Department of Health and Human Services. October 14, 2011;1–166. [cited 2011 Oct 10]. Available from: <http://www.aidsinfo.nih.gov/ContentFiles/AdultandAdolescentGL.pdf>.

transmission to sex partners, willingness to begin therapy and maintain medication adherence, and the risk versus benefit of treating an asymptomatic patient. The clinical evidence is strongest for beginning treatment at CD4⁺ counts less than 200 cells/mm³ (200 × 10⁶/L), but more recent evidence from long-term studies and the availability of potent drugs with improved tolerability support earlier treatment at higher CD4⁺ counts. Many experts recommend starting treatment at CD4⁺ counts greater than 500 cells/mm³ (greater than 500 × 10⁶/L), including the IAS-USA Panel. Once the decision is made to initiate treatment, the regimen is selected based on patient-specific factors. **4** *All recommended regimens for initial treatment contain an NNRTI, a ritonavir-boosted PI, or an INSTI in combination with tenofovir (NtRTI) and emtricitabine (NRTI).* The preferred agents are as follows:

1. NRTI/NtRTI combination:
 - a. Tenofovir *and* emtricitabine (dosed once daily)
2. PIs:
 - a. Atazanavir/ritonavir (dosed once daily)
 - b. Darunavir/ritonavir (dosed once daily)
3. NNRTI:
 - a. Efavirenz (dosed once daily)
4. INSTI:
 - a. Raltegravir (dosed twice daily)

The decision to choose an NNRTI- or PI-based regimen as initial therapy is based on many patient- and clinician-specific factors. Drug resistance testing should be performed at diagnosis and again prior to initiating treatment if time has elapsed between diagnosis and treatment (see Pharmacologic Therapy for Antiretroviral-Experienced Patients for further discussion of drug resistance testing). The results of resistance testing may dictate which drug class is preferred; a minimum of 6% to 16% of newly diagnosed patients will have drug-resistant virus. This initial resistance pattern often involves the NNRTIs, but may involve other drug classes. NNRTI-based regimens have low pill burdens and may have decreased incidences of long-term adverse effects (e.g., dyslipidemia) in comparison with some PI-based regimens. However, this class also has a low threshold for drug resistance (the K103N mutation causes high level cross-class resistance), and patient adherence is a critical consideration. In pregnant women, or women with the potential to become pregnant, a PI-based regimen is preferred due to the potential teratogenicity of efavirenz in early pregnancy (Pregnancy Category D). INSTI-based regimens have the advantage of avoiding many complex drug–drug interactions and toxicities seen with NNRTIs and PIs; however, raltegravir must be dosed twice daily and also has a low threshold for drug resistance. Transmitted INSTI resistance is not yet a major clinical concern, but may develop as raltegravir comes into wider use. If transmitted INSTI resistance is a concern, integrase resistance testing must be ordered separately from standard HIV genotyping, which only includes the protease and reverse transcriptase genes.

In patients who cannot tolerate the above preferred first-line therapies, or have a compelling reason to choose a different agent, the following alternative regimens are recommended.

1. PI-based:
 - a. Atazanavir/ritonavir + abacavir/lamivudine
 - b. Darunavir/ritonavir + abacavir/lamivudine
 - c. Fosamprenavir/ritonavir (dosed once or twice daily) + either tenofovir/emtricitabine OR abacavir/lamivudine
 - d. Lopinavir/ritonavir (dosed once or twice daily) + either tenofovir/emtricitabine OR abacavir/lamivudine
2. NNRTI:
 - a. Efavirenz + abacavir/lamivudine
 - b. Rilpivirine/tenofovir/emtricitabine in patients with viral load less than 100,000 copies/mL (less than 100 × 10⁶ copies/L) (due to a more frequent incidence of virologic failure with development of broad NNRTI resistance in patients with high viral loads)
 - c. Rilpivirine + abacavir/lamivudine in patients with viral load less than 100,000 copies/mL (less than 100 × 10⁶ copies/L)
3. INSTI:
 - a. Raltegravir + abacavir/lamivudine

If abacavir is included in a regimen, patients should undergo HLA-B*5701 testing prior to initiation to reduce the risk of abacavir hypersensitivity. Patients who test positive for the allele are at high risk (approximately 61%) of developing this reaction and should not be given abacavir. An abacavir allergy should also be documented in the patient's medical record to prevent future administration. Those patients with a negative test may receive abacavir, but should still be monitored for the development of hypersensitivity.

A number of acceptable regimens that have demonstrated efficacy but are less desirable than the preferred and alternative regimens are listed in the DHHS Guidelines. These regimens include CCR5-based regimens (maraviroc with lamivudine/zidovudine, tenofovir/emtricitabine, or abacavir/lamivudine), nevirapine-based regimens (with lamivudine/zidovudine, tenofovir/emtricitabine, or abacavir/lamivudine), and other first-line or preferred agents with zidovudine/lamivudine-based regimens (efavirenz, rilpivirine, raltegravir, darunavir/ritonavir, fosamprenavir/ritonavir, atazanavir/ritonavir, lopinavir/ritonavir) and unboosted atazanavir with non-tenofovir-based NRTI regimens. Boosted saquinavir with two NRTIs is acceptable, but should be used with caution. One of these regimens should only be selected if a first-line regimen is intolerable or the patient has a compelling reason to avoid drugs in a first-line regimen. If maraviroc is under consideration, viral tropism testing should be performed to ensure CCR5-tropic virus for optimal efficacy.

Therapies *not recommended* for initial treatment due to poor potency or significant toxicity include triple-NRTI regimens, delavirdine, nevirapine in patients with moderate to high CD4⁺ T-cell counts, indinavir ± ritonavir, saquinavir or fosamprenavir used without ritonavir (“unboosted”), ritonavir used without another PI, nelfinavir, tipranavir/ritonavir, and tenofovir, lamivudine, or emtricitabine with didanosine. Because of limited data in antiretroviral naïve patients, etravirine is not recommended in the DHHS Guidelines at this time.

Drugs that should *not be combined* due to overlapping toxicities include atazanavir plus indinavir (due to enhanced hyperbilirubinemia), two NNRTIs, and didanosine plus stavudine. Emtricitabine and lamivudine should not be combined because of their similar chemical structures, and antagonism can result when stavudine is combined with zidovudine.

Pharmacologic Therapy for Antiretroviral-Experienced Patients

6 *Ongoing viral replication, whether at low levels in the face of adequate drug concentrations or at higher levels due to inconsistent systemic concentrations (or low concentrations in sanctuary sites, e.g., male and female genital fluids, cerebrospinal fluid, or lymph nodes), will eventually lead to resistance to the prescribed medications.* There is no consensus on the optimal time to change therapy based on virologic or immunologic failure. **2** *Virologic failure is defined as the inability to obtain or maintain an HIV RNA less than 200 copies/mL (less than 200×10^3 copies/L), whereas incomplete virologic suppression is defined as two consecutive HIV RNA greater than 200 copies/mL (greater than 200×10^3 copies/L) after 24 weeks of therapy.*⁵ Immunologic failure is defined as the failure to achieve and/or maintain an adequate CD4⁺ count in the setting of virologic suppression. A typical CD4⁺ count should increase at least 150 cells/mm³ (150×10^6 /L) over the first year of therapy. The goal of therapy for patients with antiretroviral resistance is to reestablish virologic suppression or HIV RNA less than 48 copies/mL (less than 48×10^3 copies/L).

Treatment considerations for antiretroviral-experienced patients are much more complex than for patients who are naïve to therapy. Prior to changing therapy, the reasons for treatment failure should be identified. A comprehensive review of the patient's severity of disease, antiretroviral treatment history, adherence to therapy, intolerance or toxicity, concomitant drug therapies, comorbidities, and results of current and past HIV resistance testing should be performed. If patients fail therapy due to poor adherence, the underlying reasons must be determined and addressed prior to initiation of new therapy. Reasons for poor adherence include problems with medication access, active substance abuse, depression and/or denial of the disease, and a lack of education on the importance of 100% adherence to therapy. Medication intolerance or toxicity can be remedied with therapy for the adverse event, exchanging the drug causing the toxicity with another in the same class, or changing the entire regimen. Pharmacokinetics or systemic drug exposure can be optimized by ensuring maximal drug absorption (taking the drug with or without food can alter exposure by up to 30%) and avoiding interactions with concomitant prescription or nonprescription medications and dietary supplements or natural products. When causes for treatment failure are identified, appropriate strategies for therapy can be determined.

An additional consideration when stopping or changing therapy is a staggered discontinuation of antiretrovirals with different half-lives. For example, in patients taking

Atripla (tenofovir, emtricitabine, and efavirenz), tenofovir, and emtricitabine should be continued for at least 4 to 7 days after discontinuation of efavirenz due to the much prolonged half-life of efavirenz as compared with tenofovir and emtricitabine. Otherwise, the potential for monotherapy with efavirenz exists. If new antiretroviral therapy is to be initiated immediately, no overlap is necessary; however, it should be noted that efavirenz concentrations will persist for some period of time.

Drug interactions between antiretrovirals and between antiretrovirals and concomitant medications should be evaluated for each patient to avoid under- and/or overexposure of either therapy. **7** *NNRTIs and PIs are metabolized by CYP450 enzymes and are inducers and/or inhibitors of this enzyme system.* In addition, some of the antiretrovirals are substrates, inhibitors, and/or inducers of transporters such as P-glycoprotein and therefore may lead to drug interactions. Information provided in [Table 87-4](#) describes the drug interaction potential of each antiretroviral. Due to the ever-changing drug interactions with this class of medications, the regularly updated DHHS Guidelines for the Use of Antiretroviral Agents in HIV-1-Infected Adults and Adolescents are a recommended source of specific drug interactions.⁵

The goals of therapy differ for antiretroviral-experienced patients who have limited drug exposure (i.e., developing resistance to their first antiretroviral regimen) versus those with extensive exposure (i.e., developing resistance to their third or fourth antiretroviral regimen). It is reasonable to expect maximal viral suppression in those with limited drug exposure. However, this may not be feasible for patients with prior exposure to multiple medications. **1** *In antiretroviral-experienced patients, a reasonable goal is to simply preserve immune function and prevent clinical progression.*

Several issues need to be considered in choosing a salvage regimen for HIV infection. Knowing prior medication exposure can assist in identifying which drugs to avoid. However, direct HIV resistance testing can better identify the resistance and susceptibility patterns of the major viral strains. Because HIV may be susceptible to certain components of the failing antiretroviral regimen, these drugs can be recycled into future regimens. Resistance testing should be used when all patients enter into care, in patients with virologic failure on a current antiretroviral regimen, or with suboptimal suppression after initiation of antiretroviral therapy. Testing is generally preferred for antiretroviral naïve patients. For resistance testing to be useful, the patient should have a plasma HIV RNA of at least 1,000 copies/mL (1×10^6 copies/L) and should be currently taking their antiretroviral medications (or be within 4 weeks of discontinuing antiretroviral therapy). This viral concentration is necessary to yield reliable amplification of the virus, and the antiretroviral medications are needed because the dominant viral species reverts to wild-type within 4 to 6 weeks after medications are stopped.

Two types of HIV resistance testing are available, an HIV **genotype** and an HIV **phenotype**. Genotyping involves detecting mutations by genetically sequencing the virus, whereas phenotyping determines the ability of the virus to

Table 87-4

Summary of Currently Available Antiretroviral Agents

Generic Name [Abbreviation] (Trade Name)	Dosage Forms	Commonly Prescribed Doses	Dose Adjustments	Food Restrictions	Significant Adverse Events	Drug Interaction Potential
Nucleoside (tide) Reverse Transcriptase Inhibitors						
Abacavir (Ziagen)	300-mg tablet; 20 mg/mL oral solution	300 mg twice daily or 600 mg once daily	None	None (alcohol increases abacavir conc. by 41%)	Potentially fatal hypersensitivity reaction (rash, fever, malaise, nausea, vomiting, shortness of breath, sore throat, loss of appetite)	Alcohol dehydrogenase and glucuronyl transferase, 82% renal excretion of metabolites
Didanosine (Videx EC)	125-, 200-, 250-, 400-mg capsules	Greater than 60 kg: 400 mg daily	CrCl (mL/min [mL/s]): Greater than 60 kg: Less than 60 kg:	Take 30 minutes prior or 2 hours after meal (conc. decrease 55% with food)	Pancreatitis; peripheral neuropathy; nausea; diarrhea	Renal excretion
Generic didanosine EC	125-, 200-, 250-, 400-mg capsules	Less than 60 kg: 250 mg daily	30–59 [0.50–0.99] 10–29 [0.17–0.49] less than 10 [0.17]	200 mg 125 mg 125 mg	125 mg 100 mg 75 mg	
Emtricitabine (Emtriva)	200-mg capsule; 10 mg/mL oral solution	200 mg daily; 240 mg (24 mL) oral solution daily	CrCl (mL/min[mL/s]): Capsule: Solution:	None	Minimal	Renal excretion
			30–49 [0.50–0.82] 15–29 [0.25–0.49] Less than 15/HD [0.25/HD] (Dose after dialysis on dialysis days)	200 mg every 48 hours 200 mg every 72 hours 200 mg every 96 hours	120 mg every 24 hours 80 mg every 24 hours 60 mg every 24 hours	
Lamivudine (Epivir)	150-mg and 300-mg tabs or 10 mg/mL oral solution	150 mg twice daily or 300 mg once daily	CrCl (mL/min): Dose:	None	Minimal	Renal excretion
			30–49 [0.50–0.82] 15–29 [0.25–0.49] 5–14 [0.08–0.24] Less than 5/HD [0.08/ HD] (Dose after dialysis on dialysis days)	150 mg qday 150 mg, then 100 mg every day 150 mg, then 50 mg every day 50 mg, then 25 mg every day		
Stavudine (Zerit)	15-, 20-, 30-, 40-mg capsules or 1 mg/mL for oral solution	Greater than 60 kg: 40 mg twice daily Less than 60 kg: 30 mg twice daily	CrCl (mL/min): Greater than 60 kg: Less than 60 kg:	None	Peripheral neuropathy; lipodystrophy; rapidly progressive ascending neuromuscular weakness (rare); pancreatitis; lactic acidosis with hepatic steatosis (higher incidence with stavudine than with other NRTIs); hyperlipidemia	Renal excretion
			26–50 [0.43–0.83] 10–25/HD [0.17–0.42/ HD]	20 mg every 12 hours 20 mg every 24 hours	15 mg every 12 hours 15 mg every 24 hours	

Tenofovir disoproxil fumarate (Viread)	300-mg tablet	300 mg daily	CrCl (mL/min): 30–49 [0.50–0.82] 10–29 [0.17–0.49] ESRD/HD (Dose after dialysis on dialysis days)	Dose: 300 mg every 48 hours 300 mg twice weekly 300 mg every 7 days	None	Asthenia, headache, diarrhea, nausea, vomiting, and flatulence; renal insufficiency	Renal excretion
Zidovudine (Retrovir)	100-mg capsule, 300-mg tablet, 10 mg/mL IV solution, 10 mg/mL oral solution	300 mg twice daily	100 mg 3 times daily or 300 mg once daily in severe renal impairment or HD		None	Bone marrow suppression: macrocytic anemia or neutropenia; GI intolerance, headache, insomnia, asthenia	Glucuronyl transferase and renal
Zidovudine + lamivudine (Combivir)	Zidovudine 300 mg + Lamivudine 150-mg tablet	1 tablet twice daily	Do not use with CrCl less than 50 mL/min (0.83 mL/s)		None	See adverse events for zidovudine and lamivudine	See zidovudine and lamivudine
Abacavir + lamivudine + zidovudine [abacavir/lamivudine/zidovudine] (Trizivir)	Abacavir 300 mg + lamivudine 150 mg + zidovudine 300-mg tablet	1 tablet twice daily	Do not use with CrCl less than 50 mL/min (0.83 mL/s)		None	See adverse events for zidovudine, lamivudine, and abacavir	See zidovudine, lamivudine, and abacavir
Abacavir + lamivudine [abacavir/lamivudine] (Epzicom)	Abacavir 600 mg + lamivudine 300-mg tablet	1 tablet daily	Do not use with CrCl less than 50 mL/min (0.83 mL/s)		None	See adverse events for abacavir and lamivudine	See abacavir and lamivudine
Tenofovir + emtricitabine [Tenofovir/emtricitabine] (Truvada)	Tenofovir 300 mg + emtricitabine 200-mg tablet	1 tablet daily	CrCl (mL/min [mL/s]): 30–49 [0.50–0.82] less than 30 [less than 0.50]	Dose: 1 tablet every 48 hours Not recommended	None	See adverse events for tenofovir and emtricitabine	See tenofovir and emtricitabine
Nonnucleoside Reverse Transcriptase Inhibitors							
Delavirdine (Rescriptor)	100-, 200-mg tablets	400 mg 3 times daily (100-mg tablet can be dispersed in 3 oz or more of water to produce slurry); 200-mg tablet should be administered whole; separate dosing from buffered didanosine or antacids by 1 hour	Use with caution in patients with hepatic impairment		None	Rash; increased LFTs, headaches	Metabolized by cytochrome P-450 (CYP); CYP3A inhibitor; 51% excreted in urine (less than 5% unchanged); 44% in feces

(Continued)

Table 87-4

Summary of Currently Available Antiretroviral Agents (Continued)

Generic Name [Abbreviation] (Trade Name)	Dosage Forms	Commonly Prescribed Doses	Dose Adjustments	Food Restrictions	Significant Adverse Events	Drug Interaction Potential
Efavirenz (Sustiva)	50-, 100-, 200-mg capsules or 600-mg tablet	600 mg daily at or before bedtime	Use with caution in patients with hepatic impairment	Take on an empty stomach (high-fat/calorie meals increases C_{max} of capsule 39% and C_{max} of tablet 79%)	Rash; CNS symptoms (insomnia, irritability, lethargy, dizziness, vivid dreams) usually resolve in 2 weeks; increased LFTs; false-positive cannabinoid test; teratogenic in monkeys	Metabolized by CYP2B6 and CYP3A (3A mixed inducer/inhibitor); 14–34% excreted in urine (glucuronidated metabolites, less than 1% unchanged); 16–61% in feces
Etravirine (Intelence)	100-, 200-mg tablets	200 mg twice daily following a meal	No dosage adjustment for Child Pugh Class A or B. Has not been evaluated for Class C	Take following a meal. Fasting decreases by 50%	Rash, nausea	Metabolized by CYP3A, 2C9, and 2C19; Induces 3A4 and inhibits 2C9 and 2C19
Nevirapine (Viramune)	200-mg tablet or 50 mg/5 mL oral suspension	200 mg once daily for 14 days; then 200 mg twice daily	Use with caution in patients with hepatic impairment; avoid use with moderate to severe hepatic impairment	No food restrictions	Rash including Stevens-Johnson syndrome; symptomatic hepatitis, including fatal hepatic necrosis	Metabolized by CYP2B6 and CYP3A (3A inducer); 80% excreted in urine (glucuronidated metabolites; less than 5% unchanged); 10% in feces
Rilpivirine (Edurant)	25-mg tablet	25 mg daily	No dosage adjustment for Child Pugh Class A or B. Has not been evaluated for Class C; Use with caution in severe or end-stage renal impairment	Take with a normal- to high-calorie meal Absorption dependent on gastric pH-special considerations needed when coadministered with antacids	Rash; depressive disorders;	Metabolized by CYP3A4

Tenofovir + emtricitabine + efavirenz [tenofovir/emtricitabine/efavirenz] (Atripla)	Tenofovir 300 mg Emtricitabine 200 mg Efavirenz 600 mg	1 tablet daily	Do not use in patients with CrCl less than 50 mL/min (0.83 mL/s)		High-fat/high-caloric meals increase peak plasma concentrations of efavirenz capsules by 39% and efavirenz tablets by 79%; take on empty stomach	See adverse events of tenofovir, emtricitabine, and efavirenz	See tenofovir, emtricitabine, and efavirenz
Tenofovir + emtricitabine + rilpivirine [tenofovir/emtricitabine/rilpivirine] (Complera)	Tenofovir 300 mg Emtricitabine 200 mg Rilpivirine 25mg	1 tablet daily	Do not use in patients with CrCl less than 50 mL/min (0.83 mL/s)		Take with a meal (preferably high fat)	See adverse events of tenofovir, emtricitabine, and rilpivirine	See tenofovir, emtricitabine, and rilpivirine
Protease Inhibitors							
Atazanavir (Reyataz)	100-, 150-, 200-, 300-mg capsules	400 mg daily If taken with tenofovir use the following: atazanavir 300 mg daily + ritonavir 100 mg daily If taken with efavirenz in treatment of naïve patients only: atazanavir 400 mg daily + ritonavir 100 mg daily (do not use efavirenz in treatment of experienced patients)	Child-Pugh Class 7–9 Greater than 9	Dose 300 mg daily Not recommended; Treatment-naïve patients on hemodialysis: atazanavir 300 mg + ritonavir 100 mg daily; treatment-experienced patients on hemodialysis: Not recommended	Take with food (AUC increases 30%); pH-sensitive dissolution—special considerations needed when coadministered with antacids	Indirect hyperbilirubinemia; prolonged PR interval (asymptomatic first-degree AV block); use with caution in patients with underlying conduction defects or on concomitant medications that can cause PR prolongation; hyperglycemia; fat maldistribution; increased bleeding episodes in patients with hemophilia	CYP3A4 inhibitor and substrate; UGT1A1 inhibitor
Darunavir (Prezista)	400-, 600-mg tablets	Darunavir 600 mg + ritonavir 100 mg twice daily	Use with caution in patients with hepatic impairment		Should be given with food	Skin rash (has a sulfonamide moiety, Stevens Johnson and erythema multiforme have been reported); diarrhea, nausea; headache; hyperlipidemia; transaminase elevation; hyperglycemia; fat maldistribution; possible increased bleeding episodes in patients with hemophilia	CYP3A4 inhibitor and substrate

(Continued)

Table 87-4

Summary of Currently Available Antiretroviral Agents (Continued)

Generic Name [Abbreviation] (Trade Name)	Dosage Forms	Commonly Prescribed Doses	Dose Adjustments	Food Restrictions	Significant Adverse Events	Drug Interaction Potential	
Fosamprenavir (Lexiva)	700-mg tablet; 50 mg/mL oral suspension	ARV-naïve patients: fosamprenavir 1,400 mg twice daily, Fosamprenavir 700 mg + ritonavir 100 mg twice daily, or fosamprenavir 1,400 mg + ritonavir 200 mg once daily; PI-experienced patients: fosamprenavir 700 mg + ritonavir 100 mg twice daily Coadministration with efavirenz: fosamprenavir 700 mg + ritonavir 100 mg twice daily or fosamprenavir 1,400 mg + ritonavir 300 mg once daily	Child-Pugh Class 5-8 9-12 Ritonavir should not be used in patients with hepatic impairment	Dose 700 mg twice daily Not recommended	None	Skin rash; diarrhea, nausea and vomiting; headache; hyperlipidemia; LFT elevation; hyperglycemia; fat maldistribution; increased bleeding episodes in patients with hemophilia	CYP3A4 inhibitor, inducer, and substrate
Indinavir (Crixivan)	200-, 333-, 400-mg capsules	800 mg every 8 hours; indinavir 800 mg + ritonavir 100 twice daily; indinavir 800 mg + ritonavir 200 mg twice daily	Mild to moderate hepatic insufficiency due to cirrhosis: 600 mg every 8 hours	<i>For unboosted indinavir:</i> Take 1 hour before or 2 hours after heavy meals, or concomitantly with low-fat meal. No restrictions when used with ritonavir	Nephrolithiasis; GI intolerance, nausea; indirect hyperbilirubinemia; hyperlipidemia; headache, asthenia, blurred vision, dizziness, rash, metallic taste, thrombocytopenia, alopecia, hemolytic anemia; hyperglycemia; fat maldistribution; increased bleeding episodes in patients with hemophilia	CYP3A4 inhibitor (less than ritonavir)	

Lopinavir + ritonavir (Kaletra)	Lopinavir 200 mg + ritonavir 50-mg tablet, lopinavir 400 mg + ritonavir 100 mg/5 mL oral solution (contains 42% alcohol)	2 tablets or 5 mL twice daily 4 tablets once daily; with efavirenz or nevirapine: 3 tablets or 6.7 mL twice daily	Use with caution in patients with hepatic impairment	Take with food (AUC increases 48–80%)	Nausea, vomiting, diarrhea; asthenia; hyperlipidemia; LFT elevation; hyperglycemia; fat maldistribution; increased bleeding episodes in hemophiliacs	CYP3A4 inhibitor and substrate CYP2C9, 2C19, 1A2 inducer
Nelfinavir (Viracept)	250–625-mg tablets, 50 mg/g oral powder	1,250 mg twice daily or 750 mg 3 times daily	Use with caution in patients with hepatic impairment	Take with meal or snack	Diarrhea; hyperlipidemia; hyperglycemia; fat maldistribution; increased bleeding in hemophiliacs; LFT elevation	CYP3A4 inhibitor and substrate
Ritonavir (Norvir)	100-mg tablet, 600 mg/7.5-mL solution	600 mg twice daily (when ritonavir is used as sole PI); 100–200 mg/dose when used as pharmacokinetic enhancer	No dosage adjustment in mild hepatic impairment. No data for moderate to severe impairment; use with caution	Take with food to improve tolerability	GI intolerance, nausea, diarrhea; paresthesias; hyperlipidemia; hepatitis; asthenia; taste perversion; hyperglycemia; fat maldistribution; increased bleeding in hemophiliacs	CYP3A4 inhibitor (potent) and substrate; CYP2D6 substrate; mixed dose-dependent induction and inhibition of other phase I and II enzymes
Saquinavir tablets and hard gel capsules (Invirase)	200-mg capsule, 500-mg tablet	Unboosted saquinavir not recommended <i>With ritonavir:</i> (ritonavir 100 mg + saquinavir 1,000 mg) twice daily	Use with caution in patients with hepatic impairment	Take within 2 hours of a meal when taken with ritonavir	Nausea, diarrhea; headache; LFT elevation; hyperlipidemia; hyperglycemia; fat maldistribution; increased bleeding in hemophiliacs	CYP3A4 inhibitor and substrate

(Continued)

Table 87-4

Summary of Currently Available Antiretroviral Agents (Continued)

Generic Name [Abbreviation] (Trade Name)	Dosage Forms	Commonly Prescribed Doses	Dose Adjustments	Food Restrictions	Significant Adverse Events	Drug Interaction Potential
Tipranavir (Aptivus)	250-mg capsules	500 mg twice daily with ritonavir 200 mg twice daily	Contraindicated in patients with moderate to severe hepatic insufficiency	Take with food	Hepatotoxicity; skin rash; hyperlipidemia; hyperglycemia; fat maldistribution; possible increased bleeding in hemophiliacs	Tipranavir/ritonavir mixed CYP inhibitor/inducer; Tipranavir is CYP3A4 substrate
Fusion Inhibitors Enfuvirtide (Fuzeon)	Injectable, in lyophilized powder Each single-use vial contains 108 mg of enfuvirtide to be reconstituted with 1.1 mL of sterile water for injection for delivery of approximately 90 mg/1 mL	90 mg (1 mL) subcutaneously 2 times per day	No dosage recommendation	N/A	Local injection site reaction (pain, erythema, induration, nodules and cysts, pruritus, eachymosis) in most patients; increased rate of bacterial pneumonia; less than 1% hypersensitivity reaction (rash, fever, nausea, vomiting, chills, rigors, hypotension, or elevated serum transaminases); do not rechallenge	Catabolism to amino acids, with subsequent recycling in the body pool

Chemokine Receptor Antagonists (CCR5 Antagonists)

Maraviroc (Selzentry)	150-mg and 300-mg tablets	150 mg twice daily when given with strong CYP3A inhibitors (with or without CYP3A inducers) including PIs (except tipranavir/ritonavir) 300 mg twice daily when given with NRTIs, enfuvirtide, tipranavir/ritonavir, nevirapine and other drugs that are not potent P450 inhibitors 600 mg twice daily when given with CYP3A inducers, including efavirenz, rifampin, etc. (without a CYP3A inhibitor)	Patients with CrCl less than 50 mL/min (0.83 mL/s) should receive maraviroc with a CYP3A inhibitor only if benefit outweighs the risk	No food restrictions	Abdominal pain; cough; dizziness; musculoskeletal symptoms; pyrexia; rash; upper RTI; hepatotoxicity; orthostatic hypotension	CYP3A substrate
Integrase Inhibitors						
Raltegravir (Isentress)	400-mg tablet	400 mg twice daily	No dosage adjustment	No food restrictions	Nausea; headache; diarrhea; pyrexia; CPK elevation	UGT1A1 substrate (glucuronidation)

AUC, area under the time-concentration curve; ARV, antiretroviral; AV, atrioventricular; C_{max} , maximum concentration; CrCl, creatinine clearance; ESRD, end-stage renal disease; HD, hemodialysis; LFT, liver function test; NRTI, nucleoside reverse transcriptase inhibitor; UGT, uridine diphosphate-glucuronosyltransferase.

Adapted from the DHHS Guidelines for the Use of Antiretroviral Agents in HIV-1-Infected Adults and Adolescents, January 29, 2008.

replicate in the presence of varying ARV concentrations. Genotyping is more rapid and less costly than phenotyping, but results in a list of mutations that may be more difficult to interpret than phenotyping. An **HIV virtual phenotype** report may also be obtained when genotypes are ordered.⁵ This compares the patient's viral sequence to a database of matched genotypes and drug susceptibilities. Because the predictability of virtual phenotypes are dependent on the robustness of the database from which they are derived, some clinicians believe their utility is limited. Web-based tools are available to assist with interpretation of resistance mutations (e.g., Stanford University's HIV Drug Resistance Database; <http://hivdb.stanford.edu/index.html>). However, expert interpretation of genotype and phenotype reports is recommended.

Certain guiding principles should be considered when treating antiretroviral-experienced patients, and expert opinion is advised before selecting therapy. **4** *As with antiretroviral-naïve patients, three or more active drugs should be prescribed.*⁵ Because considerable cross-resistance can occur between medications within an antiretroviral class, simply using drugs to which the patient has not been exposed may be insufficient. Complete cross-resistance occurs within the first generation of NNRTIs, whereas the NRTIs and PIs have variable overlapping resistance patterns. For this reason, HIV resistance assays are important tools for choosing subsequent effective therapies. The following factors are associated with superior virologic response: lower viral load at the time therapy is changed, using a new class of antiretroviral agent, and using ritonavir-enhanced PIs in patients previously exposed to PIs.⁵

If patients fail therapy with resistance to only one drug, one or two active agents may be substituted for this drug while retaining the remaining drugs in the regimen. If patients fail therapy with resistance to more than one drug, changing classes of antiretrovirals and/or adding new active drugs is warranted. New NRTIs should be selected from resistance testing. If this is not available, the assumption should be made that resistance has developed to all NRTIs used in the failing regimen. In general, HIV that is resistant solely to lamivudine and/or emtricitabine will be susceptible to other NRTIs. If HIV develops resistance solely to tenofovir, then it may have reduced susceptibility to didanosine and likely abacavir but should remain susceptible to zidovudine, stavudine, lamivudine, and emtricitabine. Cross-resistance occurs between zidovudine and stavudine.

If a patient appears to fail an antiretroviral regimen without detectable HIV resistance, adherence should be investigated, and the adequacy of the plasma HIV RNA concentration in the resistance sample confirmed. Options include continuing the current regimen or starting a new regimen and repeating the resistance test 2 to 4 weeks after adherence is verified. An increasing number of patients have extensive HIV resistance, such that antiretroviral regimens cannot be designed to which the virus is fully susceptible. For these patients, continuing the current regimen may be beneficial because drug-resistant virus may have a compromised **replication capacity**. Other strategies may be considered for this type of patient, including pharmacokinetic enhancement with ritonavir, retreatment with prior antiretroviral agents, treatment with multidrug regimens (four or more

antiretroviral drugs), and the use of new agents through expanded access programs or clinical trials.

Treatment Considerations in Special Populations

► Acute HIV Infection

Diagnosis of acute HIV infection is difficult, since many patients are asymptomatic or have nonspecific clinical symptoms similar to other common respiratory infections. If acute HIV infection is suspected, HIV antibody tests and a plasma HIV RNA concentration should be obtained. A clear diagnosis is made when an HIV antibody test is negative and the plasma HIV RNA concentration is high. Some centers are utilizing pooled testing methods on HIV antibody-negative patients to test for HIV RNA in order to more readily diagnose acute infection. This method involves combining 50 to 100 patient samples that are negative for HIV antibody and testing the pooled sample for HIV RNA. This is a more complex and expensive test, and combining samples for initial screening limits the need to test all patient samples separately. If this pooled sample is negative for HIV RNA, no further testing is required. If the pooled sample is positive, individual patient samples will then be tested to determine which one is acutely infected with HIV (ie, HIV antibody negative, HIV RNA positive).

There are limited outcome data for treating acutely infected patients. Treatment of acute infection can decrease the severity of acute disease and decrease the viral set point; this may decrease progression rates and reduce the rate of viral transmission.⁵ Limitations include an increased risk of chronic drug-induced toxicities and the development of viral resistance. Resistance testing should be performed prior to initiation of therapy due to an increase in resistance of antiretroviral naïve patients.⁵

► Adolescent and Young Adult Patients

As a result of similar modes of HIV transmission, adolescents infected after puberty are treated as adults. In this population, dosing of antiretroviral drugs should not be based on age, but on the Tanner stage (which considers external primary and secondary sexual characteristics). Adolescents in early puberty should be dosed according to pediatric guidelines, whereas those in late puberty should be dosed as adults. During growth spurts, adolescents should be monitored closely for drug efficacy and toxicity, since rapid changes in weight can lead to altered drug concentrations. Adherence is of concern in this population due to denial of the disease, misinformation, distrust of healthcare professionals, low self-esteem, and lack of family and/or social support. Additionally, asymptomatic patients this age find it more difficult to adhere to therapy while feeling well.

► Pediatric Patients

There are unique considerations in the treatment of HIV-infected children. Specific treatment guidelines exist,⁸ but a thorough review is outside the scope of this chapter.

Most children acquire HIV infection through perinatal transmission either in utero, intrapartum, or postpartum through breast-feeding, although antiretroviral interventions have dramatically reduced transmission rates.⁵ Antiretroviral therapy is limited in pediatric patients, as some drugs have no dosing recommendations for this population or are not available in a formulation that can be easily administered to children. Additionally, drug exposures can change dramatically during early childhood development due to altered drug-metabolizing enzyme and drug transporter activities.

► **Illicit Drug Users**

Treatment challenges in illicit drug users include comorbidities (such as hepatitis infection), limited access to care, inadequate adherence to therapy, side effects and toxicities, and the need for treatment of substance abuse, which can lead to drug interactions. *Many drugs of abuse have the potential to interact with antiretroviral medications, and a number of case reports have documented drug overdose when combined with PI therapy.*⁹ In these populations, without addiction control, adherence is suboptimal and treatment failure is common. Most PIs and NNRTIs decrease methadone concentrations up to 50%. As this can result in the development of withdrawal symptoms, patients should be closely monitored for 4 to 8 weeks after initiation of antiretroviral therapy. Withdrawal symptoms can be alleviated with a methadone dose increase of 5 to 10 mg. Although there are fewer data, buprenorphine concentrations may be similarly affected, and therefore this drug requires close monitoring.

► **Pregnancy and Women of Reproductive Potential**

The goals of antiretroviral therapy for women of reproductive age and pregnant women are the same as for other adult patients. Specific guidelines for HIV-infected pregnant women are available.¹⁰ If a woman is already virally suppressed on an antiretroviral regimen at the time she becomes pregnant, it is recommended that she remain on that regimen unless it contains efavirenz, which is Pregnancy Category D. If not already on antiretroviral therapy, recommended therapies in pregnancy include zidovudine, lamivudine, lopinavir/ritonavir, and, if the CD4⁺ count is less than 250 cells/mm³ (250 × 10⁶/L), nevirapine. A dual nucleoside reverse transcriptase inhibitor (NRTI) backbone that includes one or more NRTIs with high levels of transplacental passage, if possible, is recommended. Drugs to be avoided include efavirenz (due to potential teratogenicity), the combination of didanosine and stavudine (due to a high incidence of lactic acidosis), and nevirapine in patients with a CD4⁺ count greater than 250 cells/mm³ (250 × 10⁶/L) (due to an increased risk of hepatotoxicity). The goal of therapy is to reduce plasma HIV RNA below 1,000 copies/mL (1 × 10⁶ copies/L) and prevent MTCT of HIV. Limited data are available on antiretroviral pharmacokinetics in pregnancy, and standard doses of antiretroviral drugs are currently recommended, with close HIV RNA and CD4⁺ monitoring in the third trimester of pregnancy.

Women of reproductive potential prescribed efavirenz should be counseled on its potentially teratogenic effects

Patient Encounter 1, Part 2

After receiving the diagnosis of HIV and assessing his laboratory values, the patient from Part 1 and his medical team decide to start antiretrovirals.

What is the guidance for when to start therapy in a treatment-naïve patient?

What are the recommended regimens according to the October 2011 DHHS Guidelines?

What is the drug interaction potential with each of the recommended regimens?

What adverse effects does the patient need to be counseled on with each of the recommended regimens?

and the importance of birth control. **7** *Additionally, efavirenz, nevirapine, ritonavir, lopinavir/ritonavir, and tipranavir/ritonavir, darunavir/ritonavir, fosamprenavir/ritonavir, and saquinavir/ritonavir decrease the concentrations of different estrogens and/or progestins in oral contraceptives, which could lead to failure.*⁵ For patients prescribed these drugs, barrier forms of contraception are preferred to prevent pregnancy. Atazanavir may be taken with oral contraceptives with caution, as it can increase or decrease the exposure to estrogen and progesterone, depending on whether it is used in combination with ritonavir. DepoProvera may be a safe alternative, as it does not affect nelfinavir, efavirenz, or nevirapine concentrations; although the effect of antiretrovirals on medroxyprogesterone concentrations has not been examined, no evidence of ovulation has been seen in women on these combinations.¹¹ Maraviroc and raltegravir have not shown clinically significant effects when used with oral contraceptive and are safe to use in combination.

► **Hepatitis B Coinfection**

HIV-infected patients coinfecting with hepatitis B virus (HBV) have higher concentrations of DNA and hepatitis B early antigen (HBeAg) and higher rates of HBV-associated liver disease. Therapy for HBV should be offered to patients who are HBeAg-positive or have HBV DNA greater than 10⁵ copies/mL (10⁸ copies/L) and have either liver serologies (serum alanine aminotransferase) greater than two times the upper limit of normal or histologic evidence of moderate disease or fibrosis. Options include interferon- α 2a or 2b and nucleoside/tide analogs. Nucleoside/tide analogs that treat HBV but not HIV are adefovir and entecavir. Nucleoside/tide analogs that treat HBV and HIV are lamivudine, emtricitabine, and tenofovir. These latter agents should be considered when treating HIV infection in HBV-coinfecting patients.¹² When changing HIV therapy in a patient with HBV viral suppression, the lamivudine, emtricitabine, or tenofovir should be continued for treatment of HBV in addition to the new HIV regimen.⁵

► Hepatitis C Coinfection

Patients coinfecting with hepatitis C virus (HCV) and HIV have a threefold increase in rate of progression to cirrhosis compared with those with HCV alone. Therapy for HCV is considered in patients with detectable plasma HCV RNA and results of liver biopsy and or liver imaging. Patients with HCV genotype 2 and 3 (and a CD4⁺ count greater than 200 cells/mm³ [200 × 10⁶/L]) treated with pegylated interferon plus ribavirin have a better sustained viral response at 48 weeks (60% to 70%) compared with those with HCV genotype 1 (15% to 28%). Comprehensive treatment guidelines for HIV/HCV-coinfecting patients are available.¹²⁻¹⁴ Important considerations addressed in these guidelines include avoiding the combination of ribavirin with didanosine, and stavudine (due to increased risk of pancreatitis and/or lactic acidosis) and ribavirin with zidovudine (due to increased risk of anemia). Growth factors and erythropoietin may be needed to treat neutropenia from interferon and anemia from ribavirin. Two new protease inhibitors, telaprevir and boceprevir, that inhibit HCV protease have been approved for use in combination with peg interferon- α and ribavirin to treat HCV genotype 1. These agents have potentially significant drug-drug interactions with antiretrovirals for which there are limited data available at this time.^{15,16} Careful consideration should be taken when deciding on HIV and HCV regimens in coinfecting patients. Antiretrovirals such as nevirapine, efavirenz, and tipranavir are hepatotoxic and in most cases should be avoided in HCV/HIV-infected patients.

OUTCOME EVALUATION

1 The success of antiretroviral therapy is measured by the degree to which the therapy (a) restores and preserves immunologic function, (b) maximally and durably suppresses HIV RNA, (c) improves quality of life, (d) reduces HIV-related morbidity and mortality, and (e) prevents opportunistic infections. 2 The major outcome parameters are CD4⁺ lymphocyte absolute count and percentage and plasma HIV RNA. Adequate immunologic response in antiretroviral-naïve patients consists of an increase in CD4⁺ cell count that

averages 50 to 150 cells/mm³ (50 × 10⁶ to 150 × 10⁶/L) (with a faster response in the first 3 months), and a 1-log decrease in HIV RNA by 2 to 8 weeks after starting medications, followed by concentrations less than 50 copies/mL (50 × 10³ copies/L) by 12 to 16 weeks (if HIV RNA less than 100,000/mL [100 × 10⁶/L] or by 16 to 24 weeks if HIV RNA greater than 100,000/mL [100 × 10⁶/L]). Upon initiating or changing antiretroviral therapy, HIV RNA should be measured after 2 to 8 weeks and every 4 to 8 weeks until undetectable. Once stable, HIV RNA and CD4⁺ count are monitored generally every 3 to 6 months. In highly treatment-experienced patients, adequate immunologic response may be only a stable, or slightly increased, CD4⁺ T-cell count and a stable HIV RNA. This may be enough to prevent clinical progression. However, with the new agents and new therapeutic classes of antiretrovirals available for treatment-experienced patients, the goal of treatment should be to reestablish maximal viral suppression to less than 50 HIV RNA copies/mL (50 × 10³ copies/L).⁵

Each patient should have a plan to assess the effectiveness of antiretroviral therapy after initiation. At each clinic visit, patients should be evaluated for the presence of adverse drug reactions, drug allergies, medication adherence, and potential drug interactions. 8 Antiretrovirals have both class-associated and drug-specific adverse effects (see Table 87-4). If the patient experiences any of the serious, life-threatening effects (Table 87-5), the offending agent should be discontinued promptly, and in most cases the patient cannot be rechallenged. Potential long-term complications that may reduce the quality of life are listed in Table 87-6. For drugs with a high likelihood of intolerance (such as nelfinavir-associated diarrhea), patients should be counseled to anticipate these effects and have concomitant prescriptions available for pre-emptive management (such as an antidiarrheal agent). Patients should have follow-up within the first week after initiating a new drug regimen. If the patient does not tolerate a medication despite all efforts to the contrary, consider changing the drug.⁵

5 Currently, treatment of HIV infection is lifelong. Unplanned short-term treatment interruptions may be necessary due to drug toxicity or illness that precludes administration of oral therapy. If a patient must interrupt therapy due to toxicity, all drugs of the regimen should be stopped at the same time, regardless of half-life. The strategy of scheduling elective treatment interruptions (where patients stop and start antiretroviral therapy based on CD4⁺ T-cell count criteria) has been evaluated in several clinical trials. Viral rebound occurs quickly after stopping therapy and worsens immune function, causes clinical progression, and may even result in death. If either short-term (less than 7 days) or long-term treatment interruption is needed, drug half-life must be taken into consideration. For regimens in which all components have similar half-lives, all drugs can be stopped simultaneously. If the regimen contains components with significantly different half-lives (e.g., Atripla), stopping all drugs at the same time could result in the drug with the longest half-life (usually NNRTIs) lingering in the body and functioning as monotherapy. The ideal time to stop the NNRTIs (efavirenz, etravirine, or nevirapine) is unknown, as these drugs can continue to be detectable 1 to 3+ weeks in patients. Options

Patient Encounter 2

A 43-year-old white woman presents to your clinic with significant psychiatric effects after starting a regimen consisting of emtricitabine, tenofovir, and efavirenz 2 weeks prior. Because the side effects have been interfering with her job, she has had intermittent adherence and would like to switch therapy.

What laboratory tests do you recommend?

What additional information do you need to know before creating a treatment plan for this patient?

What monitoring assessments and follow-up would you recommend?

Table 87-5

Serious Adverse Effects and Management

Adverse Effects	Drug	Signs and Symptoms	Risk Factors	Prevention/Monitoring	Management
Hepatotoxicity	Nevirapine	Onset: Up to 18 weeks postinitiation Symptoms: Abrupt onset of flu-like symptoms, abdominal pain, jaundice, fever ± rash	Increased CD4 ⁺ count at initiation Female Elevated baseline AST/ALT Any liver disease High nevirapine concentration	2-week dose escalation Avoid starting nevirapine in women with CD4 ⁺ greater than 250 cells/mm ³ (250 × 10 ⁶ /L), men with CD4 ⁺ greater than 400 cells/mm ³ (400 × 10 ⁶ /L) AST/ALT every 2 weeks for 1st month, monthly for 3 months, then every 3 months	D/C antiretrovirals; D/C all hepatotoxic agents; rule out other causes; do not rechallenge with nevirapine
	Other NNRTIs, PIs, most NRTIs, and MVC	Onset: NNRTI—60% within first 12 weeks PI—weeks to months NRTI—months to years Symptoms: NNRTI—asymptomatic to nonspecific symptoms, such as anorexia, weight loss, or fatigue PI—generally asymptomatic, some with anorexia, weight loss, jaundice Didanosine NRTI—zidovudine, didanosine, stavudine may cause hepatotoxicity associated with lactic acidosis; lamivudine, emtricitabine, or tenofovir may cause HBV flare when these drugs are withdrawn	HBV or HCV coinfection Alcoholism Concomitant hepatotoxic drugs	Monitor LFTs at least every 3–4 months	Rule out other causes. For symptomatic patients: D/C all antiretrovirals and other potential hepatotoxic agents; after symptoms and LFTs normalize, begin new antiretroviral regimen (without the potential offending agents). For asymptomatic patients: If ALT greater than 5–10 × ULN, may consider D/C antiretrovirals or continue with close monitoring; after symptoms and LFTs normalize, begin new antiretroviral regimen (without the potential offending agents)
Lactic acidosis/hepatic steatosis ± pancreatitis	NRTIs (esp. stavudine, didanosine, zidovudine)	Onset: Months after initiation Symptoms: Nonspecific GI (nausea, anorexia, abdominal pain, vomiting, weight loss, fatigue) Laboratory values: ↑ lactate, ↓ arterial pH, ↓ serum bicarbonate, ↑ AST/ALT, ↑ PT, ↑ T.bili, ↓ serum albumin, ↑ amylase/lipase (with pancreatitis)	Stavudine + didanosine Female sex Obesity Pregnancy Didanosine + hydroxyurea or ribavirin ↑ Duration of NRTI use	None unless symptoms present Consider lactate concentrations in patients with ↓ serum bicarbonate or ↑ anion gap	D/C all antiretrovirals; symptomatic support with fluids; some patients require IV bicarbonate, hemodialysis, parenteral nutrition, or mechanical ventilation; once syndrome resolves, consider using NRTIs with ↓ mitochondrial toxicity (abacavir, tenofovir, lamivudine, or emtricitabine); monitor lactate after restarting NRTIs; some clinicians use NRTI-sparing regimens

(Continued)

Table 87-5

Serious Adverse Effects and Management (Continued)

Adverse Effects	Drug	Signs and Symptoms	Risk Factors	Prevention/Monitoring	Management
Stevens-Johnson syndrome/toxic epidermal necrosis	Nevirapine greater than efavirenz, delavirdine, etravirine; also, amprenavir, abacavir, zidovudine, didanosine, indinavir lopinavir/r, atazanavir	Onset: 1st day–weeks after therapy start Symptoms: Skin eruption with mucosal ulcerations; fever, tachycardia, malaise, myalgia, arthralgia; for nevirapine may also have hepatic toxicity	Nevirapine—female, black, Asian, Hispanic	Nevirapine: use 2-week lead in 200 mg daily, then 200 mg twice a day Avoid corticosteroid use during dose escalation—may increase rash incidence Educate patients to report symptoms as soon as they appear	D/C all antiretrovirals as well as any other possible cause; aggressive symptom support; do not rechallenge patient with offending agent; if caused by nevirapine, avoid NNRTI class, if possible
Hypersensitivity reaction (HSR)	Abacavir	Onset: Median = 9 days; 90% within first 6 weeks Symptoms: Acute onset of symptoms (most frequent to least): high fever, diffuse skin rash, malaise, nausea, headache, myalgia, chills, diarrhea, vomiting, abdominal pain, dyspnea, arthralgia, respiratory symptoms	HLA-B*5701, HLA-DR7, HLA-DQ3 Antiretroviral-naïve patients Higher incidence with 600 mg every day compared with twice a day dosing	HLA-B*5701 screening prior to abacavir if (+), label as abacavir allergic in medical chart Educate patients about signs and symptoms of HSR and the need of prompt report	D/C abacavir and other antiretrovirals; rule out other causes of symptoms, most signs and symptoms resolve 48 hours after abacavir/DC; do not rechallenge with abacavir after suspected HSR
Lactic acidosis/rapidly progressive ascending neuromuscular weakness	Stavudine	Onset: Months, then striking motor weakness within days–weeks Symptoms: Rapidly progressive ascending demyelinating polyneuropathy (similar to Guillain-Barré); respiratory paralysis	Prolonged stavudine use	Early recognition and D/C of offending agent to avoid progression	D/C antiretrovirals; supportive care; recovery may take months, sometimes irreversible; do not rechallenge with offending agent
Bleeding events	Tipranavir/ritonavir: intracranial hemorrhage (ICH); other PIs: ↑ bleeding in hemophiliacs	Onset: ICH: median = 525 days on tipranavir/ritonavir Hemophiliacs: Few weeks Symptoms: ↑ Spontaneous bleeding tendency (in joints, muscles, soft tissues, and hematuria)	ICH: CNS lesions, head trauma, recent neurosurgery, coagulopathy, alcohol abuse, or on anticoagulant or antiplatelet agents Hemophiliac patients: PI use	ICH: Avoid tipranavir/ritonavir use in high risk patients Hemophiliacs: Consider using an NNRTI-based regimen; monitor for spontaneous bleeding	ICH: D/C tipranavir/ritonavir; supportive care Hemophiliacs: May require increased use of factor VIII products
Bone marrow suppression	Zidovudine	Onset: Few weeks–months Symptoms: Fatigue, risk of ↑ bacterial infections due to neutropenia; anemia, neutropenia	Advanced HIV High-dose zidovudine Preexisting anemia or neutropenia Concomitant use of bone marrow suppressants	Avoid in patients at high risk for bone marrow suppression; avoid other suppressing agents; monitor CBC with differential at least every 3 months	Switch to another NRTI; D/C concomitant bone marrow suppressant, if possible; for anemia: Identify and treat other causes; consider erythropoietin treatment or blood transfusion, if indicated; for neutropenia: Identify and treat other causes; consider filgrastim treatment, if indicated

Nephrolithiasis/ urolithiasis/crystalluria	Indinavir	<p>Onset: Any time after initiation of therapy, especially if ↓ fluid intake</p> <p>Symptoms: Flank pain and/or abdominal pain, dysuria, frequency; pyuria, hematuria, crystalluria; rarely, ↑ serum creatinine and acute renal failure</p>	<p>History of nephrolithiasis</p> <p>Patients unable to maintain adequate fluid intake</p> <p>High peak indinavir concentration</p> <p>↑ duration of exposure</p>	<p>Drink at least 1.5–2 L of noncaffeinated fluid per day; ↑ fluid intake at first sign of darkened urine; monitor urinalysis and serum creatinine every 3–6 months</p>	<p>Increased hydration; pain control; may consider switching to alternative agent; stent placement may be required</p>
Nephrotoxicity	Indinavir, tenofovir	<p>Onset: Indinavir—months after therapy Tenofovir—weeks to months after therapy</p> <p>Symptoms: Indinavir—asymptomatic; rarely develop end-stage renal disease; ↑ serum creatinine, pyuria; hydronephrosis, renal atrophy Tenofovir—asymptomatic to symptoms of nephrogenic diabetes insipidus, Fanconi syndrome; ↑ serum creatinine, proteinuria, hypophosphatemia, glycosuria, hypokalemia, non-anion gap metabolic acidosis</p>	<p>History of renal disease</p> <p>Concomitant use of nephrotoxic drugs</p>	<p>Avoid use of other nephrotoxic drugs; adequate hydration if on indinavir; monitor creatinine, urinalysis, serum potassium and phosphorus in patients at risk</p>	<p>D/C offending agent, generally reversible; supportive care; electrolyte replacement as indicated</p>
Pancreatitis	Didanosine; didanosine + stavudine; didanosine + hydroxyurea or ribavirin; tenofovir	<p>Onset: Usually weeks to months</p> <p>Symptoms: Postprandial abdominal pain, nausea, vomiting; ↑ serum amylase and lipase</p>	<p>High intracellular and/or serum Didanosine concentrations</p> <p>History of pancreatitis</p> <p>Alcoholism</p> <p>Hypertriglyceridemia</p> <p>Concomitant use of didanosine with stavudine, hydroxyurea, or ribavirin</p> <p>Use of didanosine + tenofovir without Didanosine dose reduction</p>	<p>Didanosine should not be used in patients with history of pancreatitis; avoid concomitant use of didanosine with stavudine, hydroxyurea, or ribavirin; ↓ didanosine dose when used with tenofovir</p>	<p>D/C offending agents; symptomatic management of pancreatitis—bowel rest, IV hydration, pain control, gradual resumption of oral intake</p>

AST, aspartate aminotransferase; ALT, alanine aminotransferase; CBC, complete blood cell count; CPK, creatine phosphokinase; D/C, discontinue; HBV, hepatitis B virus; HCV, hepatitis C virus; LFT, liver function tests; NNRTI, nonnucleoside reverse transcriptase inhibitor; NRTI, nucleoside reverse transcriptase inhibitor; PI, protease inhibitor; PT, prothrombin time; T.bili, total bilirubin; ULN, upper limit of normal.

Table 87-6

Other Adverse Effects and Management

Adverse Effects	Drug	Signs and Symptoms	Risk Factors	Prevention/Monitoring	Management
Potential Long-Term Complications					
Cardiovascular	Potentially all PIs and other antiretrovirals (efavirenz, stavudine—unfavorable lipid effect; abacavir, didanosine—unknown)	Onset: months to years after therapy initiation; symptoms: premature CVD	Other risk factors for CVD	Consider non-PI-based regimen; lifestyle modification, counseling	Early diagnosis, prevention, and pharmacologic therapy for hyperlipidemia, HTN, insulin-resistance/diabetes mellitus; assess cardiac risk factors; switch to NNRTI- or atazanavir-based regimen; avoid stavudine
Hyperlipidemia	All PIs (except atazanavir); stavudine; efavirenz (to a lesser extent)	Onset: weeks to months after therapy initiation; symptoms: all PIs except atazanavir—↑ LDL and total cholesterol (TC), ↓↑ HDL; lopinavir/r and ritonavir—disproportionate ↑ TG; stavudine—↑ TG; may also ↑ LDL and TC; efavirenz or nevirapine—↑ HDL, slight ↑ TG	Underlying hyperlipidemia PI: Tipranavir/r greater than lopinavir/r and ritonavir greater than nelfinavir and amprenavir greater than indinavir and saquinavir greater than atazanavir NNRTI: less than PIs; efavirenz greater than nevirapine, etravirine, or rilpivirine NRTI: stavudine greater than zidovudine and tenofovir most common	Use non-PI, non-stavudine-based regimens; use atazanavir-based regimen; monitor fasting lipid profile at baseline, 3–6 months after new regimen, then at least annually	Assess cardiac risk factor; lifestyle modification; switch to antiretrovirals with fewer lipid effects; total cholesterol greater than 200 mg/dL (5.17 mmol/L), LDL, TG 200–500 mg/dL (2.26–5.65 mmol/L) ⇒ pravastatin or atorvastatin; TG greater than 500 mg/dL (5.65 mmol/L) gemfibrozil or micronized fenofibrate
Insulin resistance/diabetes mellitus	All PIs	Onset: weeks to months after therapy initiation; symptoms: polyuria, polydipsia, polyphagia, fatigue, weakness; exacerbation of hyperglycemia in patients with underlying diabetes	Underlying hyperglycemia, family history of diabetes mellitus	Use PI-sparing regimens; monitor fasting blood glucose 1–3 months after starting new regimen, then at least every 3–6 months	Diet and exercise; consider switching to an NNRTI-based regimen; if need for pharmacologic therapy, consider metformin, sulfonyleurea, “glitazones,” or insulin, where indicated
Osteonecrosis	All PIs	Onset: insidious; symptoms: mild to moderate periarticular pain; 85% of cases involve one or both femoral heads	Diabetes Prior steroid use Advanced age Alcohol use Hyperlipidemia	Risk reduction (limit steroid and alcohol use): for asymptomatic cases with less than 15% bony head involvement, monitor with MRI every 3–6 months × 1 year, then every 6 months × 1 year, then annually	Conservative: reduce weight-bearing activity on affected joint; reduce risk factors; analgesics as needed; surgical: core decompression ± bone grafting (early disease); total joint arthroplasty (severe disease)
Quality-of-Life Complications					
CNS effects	Efavirenz	Onset: first few doses; symptoms: one or more of the following: drowsiness, insomnia, abnormal dreams, dizziness, impaired concentration, depression, hallucination; exacerbation of psychiatric disorders; psychosis; suicidal ideation	Preexisting or unstable psychiatric illness Use of other drugs with CNS effects May be more common in African Americans due to genetic predisposition of ↓ clearance	Take no earlier than 2–3 hours before bedtime; take on an empty stomach; counsel patients to avoid operating machinery during first 2–4 weeks of therapy	Symptoms usually diminish or resolve after 2–4 weeks; may consider discontinuing therapy if symptoms persist and significantly impair daily function or exacerbate psychiatric illness

Fat maldistribution	PIs, thymidine analogs (stavudine more common than zidovudine)	Onset: gradually, months after therapy initiation; symptoms: lipoatrophy—peripheral fat loss (facial thinning, thinning of extremities and buttocks); lipohypertrophy—increase in abdominal girth, breast size, and dorsocervical fat pad (buffalo hump)	Lipoatrophy—low baseline body mass index	DEXA scan; lipoatrophy: avoid thymidine analogs or switch from zidovudine or stavudine to abacavir or tenofovir	Switching to other agents may slow or stop progression, but may not reverse effects; injectable poly-L-lactic acid for facial lipoatrophy
GI intolerance	All PIs, zidovudine, didanosine	Onset: first few doses; symptoms: nausea, vomiting, abdominal pain; diarrhea commonly seen with nelfinavir, lopinavir/ritonavir, and didanosine-buffered formulations	All patients	Taking with food may reduce symptoms (not for didanosine or unboosted indinavir); may preemptively need antiemetics or antidiarrheals	May spontaneously resolve or become tolerable with time; nausea and vomiting: consider antiemetic prior to dosing; switch to less emetogenic agent; diarrhea: consider antimotility agents, calcium tablets, bulk-forming agents, and/or pancreatic enzymes
Injection site reactions	Enfuvirtide	Onset: first new doses; symptoms: pain, pruritus, erythema, ecchymosis, warmth, nodules, rarely injection site infection	All patients	Educate regarding use of sterile technique, solution at room temperature, rotation of injection sites, avoidance of sites with little subcutaneous fat or existing reactions	Massaging the area vigorously before and after injection may reduce pain; wear loose clothing around injection site areas; take warm shower or bath prior to injection; rarely, warm compact or analgesics may be necessary
Peripheral neuropathy	Didanosine, stavudine	Onset: weeks to months after therapy initiation; symptoms: begins with numbness and paresthesias of toes and feet; may progress to painful neuropathy; upper extremities less frequently involved; may be irreversible despite drug discontinuation	Preexisting peripheral neuropathy Combined use of these NRTIs or other drugs which may cause neuropathy Advanced HIV High dose of offending drugs or drugs that may increase didanosine intracellular activities (hydroxyurea, ribavirin)	Avoid using these agents in patients at risk, if possible; avoid combined use of these agents; ask patient at each encounter	Consider D/C offending agent prior to onset of disabling pain; pharmacologic treatment (variable effectiveness): gabapentin, tricyclic antidepressants, lamotrigine, oxcarbamazepine, topiramate, tramadol, narcotic analgesics, capsaicin cream, topical lidocaine

CVD, cardiovascular disease; D/C, discontinue; DEXA, dual-energy x-ray absorptiometry; HDL, high-density lipoprotein; HTN, hypertension; LDL, low-density lipoprotein; NNRTI, nonnucleoside reverse transcriptase inhibitor; NRTI, nucleoside reverse transcriptase inhibitor; PI, protease inhibitor; TG, triglyceride.

include either (a) stopping the NNRTI first and continuing the other drugs in the regimen for up to 4 weeks or (b) substituting the NNRTI with a PI and continuing the PI with dual NRTIs for up to 4 weeks. In this situation, therapeutic drug monitoring of the long half-life drug can be useful in determining when to stop the NRTI ± PI coverage.⁵

Patient Care and Monitoring

Patient Assessment

1. Medication history

- Get a thorough history of prescription, nonprescription, and natural drug product use. Determine what prior antiretroviral regimens, if any, were used in the past.
- *Is the patient taking the appropriate dose of each medication? Are the doses adjusted for renal or hepatic failure? Are the doses adjusted for drug interactions with concomitant medications?*
- Evaluate the patient for the presence of adverse drug reactions, drug allergies, and drug interactions.
- Assess improvement in quality-of-life measures such as physical, psychological, and social functioning and well-being. *Is the patient experiencing any drug-induced adverse effects? What can you do to help manage these adverse effects?*

2. Review any available diagnostic data to determine status of his HIV/AIDS.

3. Determine whether initiation of antiretroviral therapy is indicated. Evaluate the patient's ability to adhere to medications, daily routine, social support, and financial stability. *Is the patient taking any medications that may interfere with the individual components of potential regimens? Does the patient have medical insurance and prescription coverage?*

4. Develop a plan to assess the effectiveness and tolerability of antiretroviral therapy.

Patient Education

1. Educate the patient on HIV/AIDS disease and the importance of strict adherence to medication (the patient must ideally take his or her medications at the same time every day). Recommend a therapeutic regimen that is as easy as possible for the patient to take. Talk to the patient specifically about when and how the patient will be taking the medications. *What time do they eat meals? When do they wake up? What other medications are they taking at the same time?* Educate patients whether to take their medications with or without food.
2. Educate the patient on common adverse drug effects and a few of the key signs and symptoms of severe toxicity (i.e., jaundice and abacavir hypersensitivity reaction). Tell them to call their provider immediately if any of those symptoms occur. Make sure they have the correct telephone number for the clinic.

Abbreviations Introduced in This Chapter

AIDS	Acquired immunodeficiency syndrome
ALT	Alanine aminotransferase
ART	Antiretroviral therapy
AST	Aspartate aminotransferase
CPK	Creatine phosphokinase
CVD	Cardiovascular disease
CYP	Cytochrome P-450 isoenzyme
D/C	Discontinue
DEXA	Dual-energy x-ray absorptiometry
DHHS	Department of Health and Human Services
ELISA	Enzyme-linked immunosorbent assay
GERD	Gastroesophageal reflux disease
gp	Glycoprotein
HAART	Highly active antiretroviral therapy
HBeAg	Hepatitis B early antigen
HBV	Hepatitis B virus
HCV	Hepatitis C virus
HDL	High-density lipoprotein
HIV	Human immunodeficiency virus
HLA	Human leukocyte antigen
HSR	Hypersensitivity reaction
HTN	Hypertension
IAS-USA	International AIDS Society–USA
ICH	Intracranial hemorrhage
IFA	Indirect immunofluorescence assay
LDL	Low-density lipoprotein
LFT	Liver function tests
MSM	Men who have sex with men
MTCT	Mother-to-child transmission
NNRTI	Nonnucleoside reverse transcriptase inhibitor
NRTI	Nucleoside reverse transcriptase inhibitor
NtRTI	Nucleotide reverse transcriptase inhibitor
PCP	<i>Pneumocystis jiroveci</i> (formerly <i>carinii</i>) pneumonia
PI	Protease inhibitor
PT	Prothrombin time
RT-PCR	Reverse transcriptase polymerase chain reaction
SIV	Simian immunodeficiency virus
STI	Sexually transmitted infection
T.bili	Total bilirubin
TDF	Tenofovir disoproxil fumarate
TG	Triglyceride
ULN	Upper limit of normal
WB	Western blot

Cancer Chemotherapy and Treatment

Amy Robbins Williams

LEARNING OBJECTIVES

● Upon completion of the chapter, the reader will be able to:

1. Describe the etiology of cancer.
2. Define the tumor, nodes, metastases (TNM) system of cancer staging.
3. Classify each drug used in the treatment of cancer and compare and contrast the mechanisms of action, uses, and side effects.
4. Outline actions for all health care providers to prevent medication errors with cancer treatments.
5. Describe the role of health care practitioners in the care of cancer patients.

KEY CONCEPTS

- 1 The word *cancer* covers a diverse array of tumor types that affect a significant number of Americans and individuals worldwide and are a significant cause of mortality.
- 2 Numerous cellular changes occur in the genetic material of the cancer cell so that programmed cell death, or **apoptosis**, does not occur. Proliferation of cancer cells goes unregulated.
- 3 Most solid tumors are staged according to the tumor, nodes, metastases (TNM) classification system. The size of the primary tumor, extent of nodal involvement, and presence of metastases are used to determine the stage. Metastases are cancer cells that have spread to sites distant from the primary tumor site and have started to grow. The most frequently occurring sites of metastases of solid tumors are the brain, bone, liver, and lungs. After TNM staging, most cancers types are then classified by a more simplified staging (i.e., stages I to IV), which indicates disease severity.
- 4 Traditional chemotherapy agents have some similar side effects, usually manifested on the most rapidly proliferating cells of the body. However, various pharmacological categories of antineoplastic agents do possess unique toxicities. Anthracyclines (e.g., doxorubicin) have the potential to cause cardiac toxicity, which is related to the cumulative dose. Microtubule-targeting agents (e.g., vincristine) are associated with various forms of neurotoxicity. Alkylating agents (e.g., melphalan) are associated with secondary malignancies.
- 5 Because of the risk of severe toxicities associated with many of the chemotherapy agents, safety and handling precautions must be in place to prevent chemotherapy errors and/or accidental chemotherapy exposures to health care professionals or patients.
- 6 Clinicians should play a role in ensuring chemotherapy safety, patient education, and monitoring patient response to therapy. For example, cumulative doses of anthracyclines should be monitored along with signs and symptoms of heart failure. Clinicians should also monitor for drug interactions between other current medications and chemotherapy agents.

EPIDEMIOLOGY

1 *The word cancer covers a diverse array of tumor types that affect a significant number of Americans and individuals worldwide and are a significant cause of mortality. The term cancer actually refers to more than 100 different diseases. What is common to all cancers is that the cancerous cell is uncontrollably growing and has the potential for invading local tissue and spreading to other parts of the body, a process called metastases. Cancer is now the leading cause of death in Americans younger than the age of 85 years of age.¹ In 2011, it was projected that almost 1.6 million Americans will be diagnosed with cancer, and more than 570,000 Americans will die from the cancer.² Figure 88–1 describes cancers by gender, new cases, and deaths.*

- Once diagnosed, a cancer patient may encounter many different health care professionals. All health care professionals need to collaborate to ensure safe and appropriate

Leading Sites of New Cancer Cases and Deaths—2011 Estimates

FIGURE 88-1. Cancer incidences (*left*) and deaths (*right*) in the United States for males and females—2011 estimates. (Reproduced from American Cancer Society. Cancer facts and figures—2011. Atlanta: American Cancer Society; 2011.)

prescribing, preparation, administration, and monitoring of anticancer agents; management of toxicities; resolution of reimbursement issues; and participation in clinical trials.³

As a result of advances in research and technology, available cancer treatments have increased dramatically in the last couple of decades. The fields of radiation therapy, surgery, and drug development have made enormous progress over the years; therefore, patients may not only be receiving less toxic treatments but also treatments that have better outcomes than in the past. Supportive care therapies have improved, and patients now may be at less risk for toxicity and have a better **quality of life** than patients in the past. In the early 1990s, most patients received chemotherapy in the hospital because of side effects. Today, most patients are able to receive chemotherapy in the outpatient clinics and/or take oral anticancer agents at home.

Cancer Prevention

Because most cancers are not curable in advanced stages, cancer prevention is an important and active area of research. Both lifestyle modifications and chemoprevention agents may significantly reduce the risk of developing cancer. Although still an active area of investigation, the Food and Drug Administration (FDA) has approved two vaccines that can help prevent cancer. One of these vaccines prevents infection with human papillomavirus, which can cause cervical cancer and anal cancer. The other vaccine prevents infection with hepatitis B virus, which can cause liver cancer. In addition, both tamoxifen and raloxifene are approved for the prevention of breast cancer, and celecoxib is approved for the prevention of familial adenomatous polyposis (FAP) variant of colon cancer.

Tobacco

Tobacco smoking increases the risk of developing not only lung cancer but also many other types of cancer, including cancer of the bladder, mouth, pharynx, larynx, and esophagus as well as renal cell cancer. Smoking cessation is associated with a gradual decrease in the risk of cancer, but more than 5 years is needed before a major decline in risk is detected. In addition, most studies have found that passive smoking (i.e., secondhand smoke) also increases a person's risk of developing lung cancer.⁴

Sun Exposure

Ultraviolet light and increased skin exposure may increase the risk of melanoma and other skin cancers, especially in individuals who have a positive family history and who are fair skinned, and have light-colored eyes, high degrees of freckling, and a tendency to burn instead of tan. Practitioners can counsel patients on proper sun protection, including minimizing sun exposure, using sunscreens with a sun protection factor (SPF) of 15 or greater on exposed areas, wearing protective clothing, avoiding tanning beds, and the importance of early detection.

CARCINOGENESIS

- The exact cause of cancer remains unknown and is probably very diverse given the vast array of diseases called cancer. It is thought that cancer develops from a single cell in which the normal mechanisms for control of growth and proliferation are altered. Current evidence indicates that there are four stages in the cancer development process.

The first step, **initiation**, occurs when a carcinogenic substance encounters a normal cell to produce genetic damage and results in a mutated cell. The environment is altered by carcinogens or other factors to favor the growth of the mutated cell over the normal cell during **promotion**, the second step. The main difference between initiation and promotion is that promotion is a reversible process. Third, **transformation** (or **conversion**) occurs when the mutated cell becomes malignant. Depending on the type of cancer, up to 20 years may elapse between the carcinogenic phases and the development of a clinically detectable tumor. Finally, **progression** occurs when cell proliferation takes over and the tumor spreads or develops metastases.

There are substances known to have carcinogenic risks, including chemicals, environmental factors, and viruses. Chemicals in the environment, such as aniline and benzene, are associated with the development of bladder cancer and leukemia, respectively. Environmental factors, such as excessive sun exposure, can result in skin cancer, and smoking is widely known as a cause of lung cancer. Viruses, including human papilloma virus (HPV), Epstein-Barr virus, and hepatitis B virus, have been linked to cervical cancers, lymphomas, and liver cancers, respectively. Anticancer agents such as the alkylating agents (e.g., melphalan), anthracyclines (e.g., doxorubicin), and epipodophyllotoxins (e.g., etoposide) can cause secondary malignancies (e.g., leukemias) years after therapy has been completed. Additionally, factors such as the patient's age, gender, family history, diet, and chronic irritation or inflammation may be considered to be promoters of carcinogenesis.

Cancer Genetics

Because the human genome has been sequenced and with the great improvements in genetic technology, there is growing knowledge regarding the genetic changes of cancer. There are two major classes of genes involved in carcinogenesis, **oncogenes** and **tumor suppressor genes**. **Protooncogenes** are normal genes that, through some genetic alteration caused by carcinogens, change into oncogenes. Protooncogenes are present in all normal cells and regulate cell function and replication. Genetic damage of the protooncogene may occur through point mutation, chromosomal rearrangement, or an increase in gene function, resulting in the oncogene. The genetic damage may either be inherited from an individual's parents (germline mutations) or by way of carcinogenic agents (e.g., smoking). The oncogene produces abnormal or excessive gene product that disrupts normal cell growth and proliferation.⁵ As a result, this may cause the cell to have a distinct growth advantage, increasing its likelihood of becoming cancerous. **Table 88-1** provides examples of oncogenes by their cellular function and associated cancer.

Tumor suppressor genes inhibit inappropriate cellular growth and proliferation by gene loss or mutation. This results in loss of control over normal cell growth. The *p53* gene is one of the most common tumor suppressor genes, and mutations of *p53* may occur in up to 50% of all malignancies. This gene stops the cell cycle to enable "repairs" of the cell.

If *p53* is inactivated, then the cell allows the mutations to occur. Although mutations of the *p53* gene are found in many tumors, such as breast, colon, and lung cancer, it is also associated with drug resistance of cancer cells. DNA repair genes fix errors in DNA that occur because of environmental factors or errors in replication and can be classified as *tumor suppressor genes*. Mutations in DNA repair genes have been reported in hereditary nonpolyposis colon cancer and in some breast cancer syndromes.

② *Numerous cellular changes occur in the genetic material of the cancer cell so that programmed cell death, or apoptosis, does not occur. Proliferation of cancer cells goes unregulated.* If mutations persist and cells are not repaired or suppressed, cancer may develop. **Apoptosis**, or programmed cell death, may prevent the mutated cell from becoming cancerous. Loss of *p53* and overexpression of *bcl-2* are two examples of changes within the cell that occur to result in enhanced cell survival. Cellular senescence refers to cell death that occurs after a preset number of cell doublings. Telomeres are DNA segments at the ends of chromosomes that shorten with each replication to the point where senescence is triggered.

Identification of genes involved in cancer may be conducted for various reasons, including cancer screening to determine if an individual is at an increased risk of cancer, to develop new anticancer agents, to aid in diagnosis, and to predict response and/or the toxicity of the agents used in individual patients.

Principles of Tumor Growth

It takes about 10^9 cancer cells to be clinically detectable by palpation or radiography. **Figure 88-2** demonstrates the classic Gompertzian kinetics tumor growth cycle. From the diagram, one can see that malignant cell growth occurs many times before a mass may be detected. The number of malignant cells may decrease drastically because of surgery or in decreasing steps by each administration of chemotherapy. One dosing round, or cycle, of chemotherapy does not eliminate all malignant cells; therefore, repeated cycles of chemotherapy are administered to eliminate tumor cell burden. The cell kill hypothesis states that a fixed percentage of tumor cells will be killed with each cycle of chemotherapy. According to this hypothesis, the number of tumor cells will never reach zero. This theory assumes that all cancers are equally responsive and that anticancer drug resistance and metastases do not occur, which is not the case.⁶

Metastases

A **metastasis** is a growth of the same cancer cell found at some distance from the primary tumor site.⁷ The metastasis may be large, or it may be just a few cells that may be detected through polymerase chain reaction (PCR); however, the presence of metastasis at staging usually is associated with a poorer prognosis than the patient with no known metastatic disease. As the technology to detect malignant cells evolves, the dilemma exists on how to treat patients based on current guidelines that were not based on cellular detection technology.

Table 88-1

Examples of Oncogenes and Tumor Suppressor Genes

Gene	Function	Associated Human Cancer
Oncogenes		
Genes for growth factors or their receptors		
<i>EGFR</i> or <i>Erb-B1</i>	Codes for epidermal growth factor (EGFR) receptor	Glioblastoma, breast, head and neck, and colon cancers
<i>HER-2/neu</i> or <i>Erb-B2</i>	Codes for a growth factor receptor	Breast, salivary gland, prostate, bladder, and ovarian cancers
<i>RET</i>	Codes for a growth factor receptor	Thyroid cancer
Genes for cytoplasmic relays in stimulatory signaling pathways		
<i>K-RAS</i> and <i>N-RAS</i>	Code for guanine nucleotide-proteins with GTPase activity	Lung, ovarian, colon, pancreatic binding cancers Neuroblastoma, acute leukemia
Genes for transcription factors that activate growth-promoting genes		
<i>c-MYC</i> <i>N-MYC</i>		Leukemia and breast, colon, gastric, and lung cancers Neuroblastoma, small cell lung cancer, and glioblastoma
Genes for cytoplasmic kinases		
<i>BCR-ABL</i>	Codes for a nonreceptor tyrosine kinase	Chronic myelogenous leukemia
Genes for other molecules		
<i>BCL-2</i>	Codes for a protein that blocks apoptosis	Indolent B-cell lymphomas
<i>BCL-1</i> or <i>PRAD1</i>	Codes for cyclin D ₁ , a cell-cycle clock stimulator	Breast, head, and neck cancers
<i>MDM2</i>	Protein antagonist of p53 tumor suppressor protein	Sarcomas
Tumor-suppressor genes		
Genes for proteins in the cytoplasm		
<i>APC</i>	Step in a signaling pathway	Colon and gastric cancer
<i>NF-1</i>	Codes for a protein that inhibits the stimulatory Ras protein	Neurofibroma, leukemia, and pheochromocytoma
<i>NF-2</i>	Codes for a protein that inhibits the stimulatory Ras protein	Meningioma, ependymoma, and schwannoma
Genes for proteins in the nucleus		
<i>MTS1</i>	Codes for p16 protein, a cyclin-dependent kinase inhibitor	Involved in a wide range of cancers
<i>RB1</i>	Codes for the pRB protein, a master brake of the cell cycle	Retinoblastoma, osteosarcoma, and bladder, small cell lung, prostate, and breast cancers
<i>p53</i>	Codes for the p53 protein, which can halt cell division and induce apoptosis	Involved in a wide range of cancers
Genes for protein whose cellular location is unclear		
<i>BRCA1</i>	DNA repair, transcriptional regulation	Breast and ovarian cancers
<i>BRCA2</i>	DNA repair	Breast cancer
<i>VHL</i>	Regulator of protein stability	Renal cell cancer
<i>MSH2, MLH1, PMS1, PMS2, MSH6</i>	DNA mismatch repair enzymes	Hereditary nonpolyposis colorectal cancer

From DiPiro JT, Talbert RL, Yee GC, et al. (eds.) *Pharmacotherapy: A Pathophysiologic Approach*. 8th ed. New York: McGraw-Hill; 2011: Table 135-2.

Cancers spread usually by two pathways: hematogenous (through the bloodstream) or through the lymphatics (drainage through adjacent lymph nodes). The malignant cells that split from the primary tumor find a suitable environment for growth. It is believed that malignant cells secrete mediators that stimulate the formation of blood vessels for growth and oxygen, the process of angiogenesis. The usual metastatic sites for solid tumors are the brain, bone, lung, and liver.

PATHOPHYSIOLOGY

Tumor Origin

Tumors may arise from the four basic tissue types: epithelial, connective (i.e., muscle, bone, and cartilage), lymphoid, or

nerve tissue. The suffix *-oma* is added to the name of the cell type if the tumor cells are benign. A *lipoma* is a benign growth that resembles fat tissue.

Precancerous cells have cellular changes that are abnormal but not yet malignant and may be described as *hyperplastic* or *dysplastic*. Hyperplasia occurs when a stimulus is introduced and reverses when the stimulus is removed. Dysplasia is an abnormal change in the size, shape, or organization of cells or tissues.

Malignant cells are divided into categories based on the cells of origin. Carcinomas arise from epithelial cells, whereas sarcomas arise from muscle or connective tissue. Adenocarcinomas arise from glandular tissue. *Carcinoma in situ* refers to cells limited to epithelial origin that have not yet invaded the basement membrane. Malignancies of

FIGURE 88-2. The Gompertzian growth curve demonstrating symptoms and treatments versus tumor volume. (From Buick RN. Cellular basis of chemotherapy. In: Dorr RT, Von Hoff DD, eds. Cancer Chemotherapy Handbook. 2nd ed. New York: Elsevier; 1994: 3–14.)

the bone marrow or lymphoid tissue, such as leukemias or lymphomas, are named differently.

Tumor Characteristics

Tumors are either benign or malignant.⁸ Benign tumors often are encapsulated, localized, and indolent; they seldom metastasize; and they rarely recur once removed. Histologically, the cells resemble the cells from which they developed. Malignant tumors are invasive and spread to other locations even if the primary tumor is removed. The cells no longer perform their usual functions, and their cellular architecture changes. This loss of structure and function is called *anaplasia*. Despite improvements in screening procedures, many patients have metastatic disease at the time of diagnosis. Usually, once distant metastases have occurred, the cancer is deemed to be incurable.

DIAGNOSIS OF CANCER

Cancer can present as a number of different signs and symptoms as well as pain and loss of appetite. Unfortunately, many people fear a diagnosis of cancer and may not seek medical attention at the first warning signs when the disease is at its most treatable stage. After the initial visit with the physician, a variety of tests will be performed, which are somewhat dependent on the initial differential diagnosis. Appropriate laboratory tests, radiologic scans, and tissue samples are necessary. The sample of tissue may be obtained by a biopsy, fine-needle aspiration, or exfoliative cytology. No treatment of cancer should be initiated without

a pathologic diagnosis of cancer. During the pathologic workup, cytogenetics may be done. Depending on the type of cancer, the cytogenetics can provide the additional information on prognosis of the malignancy and whether certain therapies may be appropriate.

- Once the pathology of cancer is established, then the staging of the disease is done before treatment is initiated. Each chapter describing a cancerous disease state will discuss the specifics of staging of the disease. Cancer staging is usually done according to the primary tumor size, extent of lymph node involvement, and the presence or absence of metastases, also referred to as the tumor, nodes, metastases (TNM) system (Table 88-2). The stage of the disease is a compilation of the primary tumor size, the nodal involvement, and metastases and is usually referred to as stages I, II, III, or IV. Not all cancers can be staged according to this system, but many of the solid tumors are classified this way.

Why are tumors staged? First, the stage of the disease is an important part of determining the prognosis of the cancer. Second, staging of the cancers allows comparison of patient groups when examining data from clinical trials; staging reflects the extent of disease. Finally, the clinician uses it as a guide to treatment and may use restaging after treatment to guide further treatment.

Some cancers produce substances (e.g., proteins) that are detected by a blood test, that may be useful in following response to therapy or detecting a recurrence; these are referred to as tumor markers. An example of a clinically used tumor marker is the prostate-specific antigen (PSA). The PSA serum level can be used as a screening test for prostate cancer. Unfortunately, some tumor markers are nonspecific

Table 88-2

Tumor (T), Node (N), Metastasis (M) Staging for Non-Small Cell Lung Cancer

Primary Tumor		Description		
T ₁		Tumor 3 cm or less diameter, surrounded by lung or visceral pleura, without invasion more proximal than lobar bronchus		
	T _{1a}	Tumor 2 cm or less in diameter		
	T _{1b}	Tumor greater than 2 cm but 3 cm or less in diameter		
T ₂		Tumor greater than 3 cm but 7 cm or less, or tumor with any of the following features: –Involves main bronchus, 2 cm or less distal to carina –Invades visceral pleura –Associated with atelectasis or obstructive pneumonitis that extends to the hilar region but does not involve the entire lung		
	T _{2a}	Tumor greater than 3 cm but 5 cm or less		
	T _{2b}	Tumor greater than 5 cm but 7 cm or less		
T ₃		Tumor greater than 7 cm or any of the following: –Directly invades any of the following: chestwall, diaphragm, phrenic nerve, mediastinal pleura, parietal pericardium, main bronchus less than 2 cm from carina (without involvement of carina) –Atelectasis or obstructive pneumonitis of the entire lung –Separate tumor nodules in the same lobe		
T ₄		Tumor of any size that invades the mediastinum, heart, great vessels, trachea, recurrent laryngeal nerve, esophagus, vertebral body, carina, or with separate tumor nodules in a different ipsilateral lobe		
Regional lymph nodes (N)				
N ₀		No regional lymph node metastases		
N ₁		Metastasis in ipsilateral peribronchial and/or ipsilateral hilar lymph nodes and intrapulmonary nodes, including involvement by direct extension		
N ₂		Metastasis in ipsilateral mediastinal and/or subcarinal lymph node(s)		
N ₃		Metastasis in contralateral mediastinal, contralateral hilar, ipsilateral or contralateral scalene, or supraclavicular lymph node(s).		
Distant metastasis (M)				
M ₀		No distant metastasis		
M ₁		Distant metastasis		
	M _{1a}	Separate tumor nodule(s) in a contralateral lobe; tumor with pleural nodules or malignant pleural or pericardial effusion		
	M _{1b}	Distant metastasis		
Stage	T	N	M	5 Yr Survival
Stage IA:	T _{1a} -T _{1b}	N ₀	M ₀	73%
Stage IB:	T _{2a}	N ₀	M ₀	58%
Stage IIA:	T _{1a} , T _{1b} , T _{2a} , T _{2b}	N ₁ , N ₀	M ₀ , M ₀	46%
Stage IIB:	T _{2b} , T ₃	N ₁ , N ₀	M ₀ , M ₀	36%
	T _{1a} , T _{1b} , T _{2a} , T _{2b}	N ₂	M ₀	
Stage IIIA:	T ₃	N ₁ , N ₂	M ₀	24%
	T ₄	N ₀ , N ₁	M ₀	
Stage IIIB:	T ₄	N ₂	M ₀	9%
	Any T	N ₃	M ₀	
Stage IV:	Any T	Any N	M _{1a} or M _{1b}	13%

From DiPiro JT, Talbert RL, Yee GC, et al. (eds.) Pharmacotherapy: A Pathophysiologic Approach. 8th ed. New York: McGraw-Hill; 2011: Table 137-2.

and may be elevated from nonmalignant causes. In the case of PSA, nonmalignant causes such as prostatitis, trauma, surgery, ejaculation, some medications, benign prostatic hypertrophy, or riding on an exercise bicycle can all cause increased PSA levels.⁹ Some tumors may express a marker in some patients and not in others. The full role of tumor markers has not been fully elucidated.

TREATMENT

Desired Outcome

Surgery may be able to remove all macroscopic disease; however, microscopic cells may still be present near the surgical site or may have traveled to other parts of the body. When malignant cells have traveled to other parts of the body

and become established there and are able to grow in this new environment, they are called *metastatic cancer cells*. Thus, for chemotherapy-sensitive diseases, systemic therapies may be administered after surgery to destroy these microscopic malignant cells; this is called *adjuvant chemotherapy*. The goals of **adjuvant chemotherapy** are to decrease the recurrence of the cancer and to prolong survival. Chemotherapy may also be given before surgical resection of the tumor; this is referred to as **neoadjuvant chemotherapy**. Chemotherapy given before surgery should decrease the tumor burden to be removed (which may result in a shorter surgical procedure or less physical disfigurement to the patient) and make the surgery easier to perform because the tumor has shrunk away from vital organs or vessels. Neoadjuvant chemotherapy also gives the clinician an idea of the responsiveness of the tumor to that particular chemotherapy.

Chemotherapy may be given to cure cancers that are curable, or it may be given to help control the symptoms of an incurable cancer, which is referred to as **palliative therapy**.

Response

The responses to chemotherapy may be referred to as **complete response (CR)**, **partial response (PR)**, **stable disease (SD)**, or **disease progression**. A **cure** in oncology implies that the cancer is completely gone, and the patient will have the same life expectancy as a patient without cancer. The Response Evaluation Criteria in Solid Tumors (RECIST)

was developed in 2000 and revised in 2009 and is considered to be the standard criteria to evaluate a response to therapy (Table 88–3). A CR refers to complete disappearance of all cancer for 1 month after treatment. PR is defined as a 30% or greater decrease in tumor diameter along with no new disease for 1 month. The term **overall objective response rate** refers to the combination of PR and CR. SD occurs in a patient whose tumor size neither grows nor shrinks by the

Table 88–3

RECIST 1.1 Criteria

Term	Description
Complete response (CR)	Disappearance of all targeted lesions
Partial response (PR)	At least a 30% decrease in the sum of the longest diameter of target lesions from baseline
Progressive disease (PD)	At least a 20% increase in the sum of the longest diameter of target lesions from baseline, including new lesions discovered during treatment
Stable disease (SD)	Neither sufficient shrinkage to qualify for PR nor sufficient increase to qualify for PD

Adapted from Eisenhauer E, Therasse P, Bogaerts J, et al. New response evaluation criteria in solid tumours: Revised RECIST guideline (version 1.1). *Eur J Cancer* 2009;45:228–247.

Clinical Presentation and Diagnosis: Cancer Chemotherapy and Treatment

Signs and Symptoms

- The seven warning signs of cancer are:
 - Change in bowel or bladder habits
 - A sore that does not heal
 - Unusual bleeding or discharge
 - Thickening or lump in breast or elsewhere
 - Indigestion or difficulty in swallowing
 - Obvious change in a wart or mole
 - Nagging cough or hoarseness
- The eight warning signs of cancer in children are:
 - Continued, unexplained weight loss
 - Headaches with vomiting in the morning
 - Increased swelling or persistent pain in bones or joints
 - Lump or mass in abdomen, neck, or elsewhere
 - Development of a whitish appearance in the pupil of the eye
 - Recurrent fevers not caused by infections
 - Excessive bruising or bleeding
 - Noticeable paleness or prolonged tiredness

Diagnostic Procedures

- Laboratory tests: CBC, lactate dehydrogenase (LDH), renal function, and liver function tests
- Radiologic scans: x-rays, CT scans, MRI, position emission tomography (PET)
- Biopsy of tissue or bone marrow with pathologic evaluation
- Cytogenetics
- Tumor markers
- Staging determination of the primary tumor size, extent of lymph node involvement, and the presence or absence of metastases, referred to as the TNM system (see Table 88–2). **3** *Most solid tumors are staged according to the tumor, nodes, metastases (TNM) classification system. The size of the primary tumor, extent of nodal involvement, and presence of metastases are used to determine the stage. Metastases are cancer cells that have spread to sites distant from the primary tumor site and have started to grow. The most frequently occurring sites of metastases of solid tumors are the brain, bone, liver, and lungs.*

above criteria. **Disease progression** refers to tumor that has spread or the primary tumor that has increased in size by 20% while the patient is receiving treatment. Some cancers, such as leukemia, cannot be measured by size, so biopsy of the bone marrow provides a cellular indication of the absence or presence of disease.¹⁰

Cancer chemotherapy and the treatment of cancers are analogous to antiinfectives and the treatment of infections. Cancer cells may be **sensitive** to certain chemotherapy agents, but then with repeated exposure, the cells may become **resistant** to treatment. The resistant cells then may grow and multiply. A number of genetic mutations, including *EGFR*, *KRAS*, and *BRAF*, predict sensitivity to chemotherapy agents that target these mutations. These mutations will be discussed in the oncology disease-specific chapters where the agents are used.

Nonpharmacologic Therapy

The four primary treatment modalities of cancer are surgery, radiation, biotherapy, and pharmacologic therapy. Surgery is useful to gain tissue for diagnosis of cancer and for treatment, especially those cancers with limited disease. Radiation plays a key role not only in the treatment and possible cure of cancer but also in palliative therapy. Together, surgery and radiation therapy may provide local control of symptoms of the disease. However, when cancer is widespread, surgery may play little or no role, but radiation therapy localized to specific areas may palliate symptoms.

Pharmacologic Therapy

Chemotherapy of cancer started in the early 1940s when nitrogen mustard was first administered to patients with lymphoma. Since then, numerous agents have been developed for the treatment of different cancers.

Dosing of Chemotherapy

Chemotherapeutic agents typically have a very narrow therapeutic index. If too much is administered, the patient may suffer from fatal toxicities. If too little is given, the desired effect on cancer cells may not be achieved. Many chemotherapy agents have significant organ toxicities that preclude using steadily increasing doses to treat the cancer. The doses of chemotherapy must be given at a frequency that allows the patient to recover from the toxicity of the chemotherapy; each period of chemotherapy dosing is referred to as a *cycle*. Each cycle of chemotherapy may have the same dosages; the dosages may be modified based on toxicity; or a chemotherapy regimen may alternate from one set of drugs given during the first, third, and fifth cycles to another set of different drugs given during the second, fourth, and sixth cycles. The **dose density** of chemotherapy refers to shortening of the period between cycles of chemotherapy. This can accomplish two things: First, the tumor has less time between cycles of chemotherapy to grow, and second, patients receive

the total number of required cycles in a shorter time period. Administration of dose-dense chemotherapy regimens often requires the use of colony-stimulating factors (e.g., filgrastim also known as granulocyte colony-stimulating factor [G-CSF]) to be administered. These agents shorten the duration and severity of neutropenia. The chemotherapy regimens that are dose dense tend to be adjuvant regimens, and the goal of therapy is cure.

When a chemotherapy regimen is used as palliative therapy (to control symptoms), the dosages of chemotherapy may be decreased based on toxicity or the interval between cycles may be lengthened to maintain quality of life.

Patient and tumor biology also affect how cancer therapy is dosed. Patients with a uridine diphosphate-glucuronosyltransferase 1A1 enzyme deficiency can have life-threatening diarrhea and complications from irinotecan related to a decreased ability to metabolize the parent drug. The patient may have a blood test before irinotecan therapy to determine if this genetic mutation is present (**Table 88-4**). In the case of some monoclonal antibodies, flow cytometry results reveal whether the tumor has the receptor where the drug will bind and exert the pharmacologic effect.

Another consideration of chemotherapy administration is the patient. Factors that affect chemotherapy selection and dosing are age, concurrent disease states, and performance status. Performance status can be assessed through either the Eastern Cooperative Oncology Group (ECOG) Scale or the Karnofsky Scale (**Table 88-5**). Performance status is a very important prognostic factor for many types of cancer. If a patient has renal dysfunction and the chemotherapy is eliminated primarily by the kidney, dosing adjustments will need to be made. If a patient has had a myocardial infarction recently or preexisting heart disease, the clinician will weigh the risks of anthracycline therapy against the benefit of the treatment of the cancer.

Another important consideration for treatment of cancers is reimbursement by third-party payors for off-label use of chemotherapy agents because of the high expense. The American Association of Cancer Centers (www.accc-cancer.org) provides a drug compendium quarterly to which clinicians may refer to verify coverage by Medicare based on ICD-9 codes. Drugs used according to FDA-approved indications are usually reimbursed. If sufficient supportive literature exists, an insurer may pay for an off-label use.

During the time of chemotherapy administration, patients will likely experience various toxicities. The National Cancer Institute (NCI) has provided a standardized system for evaluating and grading the toxicity from chemotherapy to provide uniform grading of toxicity and evaluation of new agents and new regimens (**Table 88-6**).

Combination Chemotherapy

The underlying principles of using combination therapy are to use (1) agents with different pharmacologic actions, (2) agents with different organ toxicities, (3) agents that are

Table 88–4

Oncology Drugs With Valid Genomic Biomarkers

Biomarker	Drug	Approved Label Content
Biomarkers for Selection of Therapy		
ALK	Crizotinib	Crizotinib is specifically approved for the treatment of locally advanced or metastatic non–small cell lung cancer that is ALK positive as detected by an FDA-approved test.
BRAF	Vemurafenib	Vemurafenib is indicated for the treatment of unresectable or metastatic melanoma with BRAF ^{V600E} mutation (found in approximately 70% of malignant melanomas), as detected by an FDA-approved test. It is not recommended for treatment of wild-type BRAF.
CD20	Rituximab, tositumomab	Rituximab and tositumomab are indicated for the treatment of patients with CD20-positive lymphomas
CD30	Brentuximab	Brentuximab binds to CD-30–expressing cells and is indicated for the treatment of Hodgkin's lymphoma patients after failure of ASCT or after failure of at two prior multidrug regimens and not eligible for ASCT and for patients with anaplastic large cell lymphoma who have failed at least one chemotherapy regimen.
c-kit	Imatinib	Imatinib is indicated for the treatment of patients with kit (CD117)-positive unresectable and/or metastatic malignant GIST.
Chromosome 5 deletion	Lenalidomide	Lenalidomide is indicated for the treatment of patients with transfusion-dependent anemia caused by low- or intermediate-1-risk myelodysplastic syndromes associated with a deletion 5q cytogenetic abnormality with or without additional cytogenetic abnormalities.
EGFR expression	Erlotinib ^b , panitumumab ^a , Cetuximab ^a	Erlotinib is indicated for advanced NSCLC and advanced pancreatic cancer. EGFR expression was determined using the EGFR pharmDx kit. In contrast to the 1% cutoff specified in the pharmDx kit instructions, a positive EGFR expression status was defined as having at least 10% of cells staining for EGFR. Cetuximab is indicated for EGFR-expressing colorectal cancer and for cancers of the head and neck. Panitumumab is indicated for metastatic colorectal cancer after disease progression on other therapies. Patients enrolled in the clinical studies were required to have immunohistochemical evidence of positive EGFR expression using the DakoCytomation EGFR pharmDx test kit.
Fip1L1-PDGFR α	Imatinib	Imatinib is indicated in adult patients with HES and /or CEL who have this fusion kinase and for patients with HES and/or CEL who are negative or unknown.
HER-2/neu	Trastuzumab, lapatinib	Detection of HER-2 protein overexpression is necessary for selection of patients appropriate for trastuzumab and lapatinib therapy.
PDGFR	Imatinib	Imatinib is indicated in adult patients with MDS/MPD associated with PDGFR gene rearrangements.
Philadelphia chromosome	Busulfan, imatinib, dasatinib, nilotinib	Busulfan is clearly less effective in patients with CML who lack the Philadelphia (Ph1) chromosome. Imatinib is indicated for patients with newly diagnosed adult and pediatric patients with Ph ⁺ chronic CML in chronic phase, and in Ph ⁺ CML patients in blast crisis, accelerated phase, or chronic phase after failure of interferon- α therapy. It is also indicated in relapsed or refractory Ph ⁺ acute lymphoblastic leukemia. Dasatinib is indicated for the treatment of adults with Ph ⁺ ALL. Nilotinib is indicated for the treatment of adult patients with newly diagnosed Philadelphia Ph ⁺ CML in chronic phase. It is also indicated for the treatment of chronic phase and accelerated phase Ph ⁺ CML in adult patients resistant or intolerant to prior therapy that included imatinib.
PML/RAR fusion gene	Tretinoin, arsenic trioxide	Initiation of therapy with tretinoin may be based on the morphologic diagnosis of APL. Confirmation of the diagnosis of APL should be sought by detection of the t (15; 17) genetic marker by cytogenetic studies. If these are negative, PML/RAR (α) fusion should be sought using molecular diagnostic techniques. The response rate of other AML subtypes to tretinoin has not been demonstrated; therefore, patients who lack the genetic marker should be considered for alternative treatment. Arsenic trioxide is indicated for induction of remission and consolidation in patients with APL who are refractory to or have relapsed from retinoid and anthracycline therapy and APL that has demonstrated the presence of the t(15;17) translocation or PML/RAR- α gene expression.
Biomarkers for Preventing Toxicity		
TPMT	Azathioprine, Mercaptopurine	Thiopurine methyltransferase deficiency or lower activity caused by mutation at increased risk of myelotoxicity. TPMT testing is recommended and consideration be given to either genotype or phenotype patients for TPMT.
UGT1A1	Irinotecan, nilotinib	Individuals who are homozygous for the UGT1A*28 allele are at increased risk for neutropenia following initiation of irinotecan treatment. A reduced initial dose should be considered for patients known to be homozygous for the UGT1A*28 allele. Heterozygous patients may be at increased risk of neutropenia; however, clinical results have been variable that patients have been shown to tolerate normal starting doses.

(Continued)

Table 88-4

Oncology Drugs With Valid Genomic Biomarkers (Continued)

Biomarker	Drug	Approved Label Content
DPD deficiency	5-FU, Capecitabine	Nilotinib is a competitive inhibitor of UGT1A1 in vitro, which could increase the concentrations of nilotinib. In a pharmacogenetic analysis, patients with (TA)7/(TA)7 genotype (UGT1A1*28) had a statistically significant increase in bilirubin over other genotypes. Rarely, unexpected, severe toxicity (e.g., stomatitis, diarrhea, neutropenia, neurotoxicity) associated with 5-FU has been attributed to a deficiency of DPD activity. A link between decreased levels of DPD and increased, potentially fatal toxic effects of 5-FU therefore cannot be excluded.

ALK, anaplastic lymphoma kinase; ALL, acute lymphoblastic leukemia; APL, acute promyelocytic leukemia; ASCT, autologous stem cell transplant; CEL, chronic eosinophilic leukemia; CML, chronic myeloid leukemia; DPD, dihydropyrimidine dehydrogenase; EGFR, epidermal growth factor receptor; FDA, Food and Drug Administration; 5-FU, 5-fluorouracil; GIST, gastrointestinal stromal tumor; HES, hypereosinophilic syndrome; MDS, myelodysplastic disease; MPD, myeloproliferative disease; NSCLC, non-small cell lung cancer; PDGFR, platelet-derived growth factor receptor; TPMT, thiopurine S-methyltransferase.

^aPanitumumab and cetuximab are not recommended for the treatment of colorectal cancer with *KRAS* mutations in codon 12 or 13. Retrospective subset analyses have not shown a treatment benefit for these mutations.

^bErlotinib is recommended as first-line therapy in patients with activating EGFR mutations.

active against the tumor and ideally synergistic when used together, and (4) agents that do not result in significant drug interactions (although these can be studied carefully and the interactions addressed). When two or more agents are used together, the risk of development of resistance may be lessened, but toxicity may be increased.

4 Traditional chemotherapy agents have some similar side effects, usually manifested on the most rapidly proliferating cells of the body. However, there are unique toxicities of various

pharmacologic categories of antineoplastic agents. Anthracyclines (e.g., doxorubicin) have the potential to cause cardiac toxicity, which is related to the cumulative dose. Microtubule-targeting agents (e.g., vincristine) are associated with various forms of neurotoxicity. Alkylating agents (e.g., melphalan) are associated with secondary malignancies.

Currently, anticancer agents are categorized by the mechanism of action. As depicted in Figure 88-3, different agents work in different parts of the cell.

Table 88-5

Performance Status Scales

Description: Karnofsky Scale	Karnofsky Scale (%)	Zubrod Scale (ECOG)	Description: ECOG Scale
No complaints; no evidence of disease	100	0	Fully active; able to carry on all predisease activity
Able to carry on normal activity; minor signs or symptoms of disease	90		
Normal activity with effort; some signs or symptoms of disease	80	1	Restricted in strenuous activity but ambulatory and able to carry out work of a light or sedentary nature
Cares for self; unable to carry on normal activity or to do active work	70		
Requires occasional assistance but is able to care for most personal needs	60	2	Out of bed more than 50% of time; ambulatory and capable of self-care but unable to carry out any work activities
Requires considerable assistance and frequent medical care	50		
Disabled; requires special care and assistance	40	3	In bed more than 50% of time; capable of only limited self-care
Severely disabled; hospitalization indicated, although death not imminent	30		
Very sick; hospitalization necessary; requires active supportive treatment	20	4	Bedridden; cannot carry out any self-care; completely disabled
Moribund; fatal processes progressing rapidly	10		
Dead	0		

ECOG, Eastern Cooperative Oncology Group.

Table 88-6

Selected National Cancer Institute Common Toxicity Criteria

Toxicity	Grade 1	Grade 2	Grade 3	Grade 4	Grade 5
General Neutropenia	Mild Lowest baseline: 1,500/mm ³ (1.5 × 10 ⁹ /L)	Moderate Less than 1,500–1,000/ mm ³ (1.5–1 × 10 ⁹ /L)	Severe Less than 1,000–500/mm ³ (1–0.5 × 10 ⁹ /L)	Life threatening Less than 500/mm ³ (5 × 10 ⁹ /L)	Death
Thrombocytopenia	Lowest baseline: 75,000/mm ³ (75 × 10 ⁹ /L)	Less than 75,000–50,000/ mm ³ (75–50 × 10 ⁹ /L)	Less than 50,000–25,000/mm ³ (50–25 × 10 ⁹ /L)	Less than 25,000 mm ³ (25 × 10 ⁹ /L)	Death
Diarrhea	Increase of less than 4 stools per day over baseline or mild increase in ostomy output	Increase of 4–6 stools per day over baseline; IV fluids indicated less than 24 hours of moderate increase in ostomy output compared with baseline; not interfering with ADLs	Increase of greater than or equal to 7 stools per day over baseline; incontinence; IV fluids greater than or equal to 24 hours; hospitalization; severe increase in ostomy output compared with baseline; interfering with ADLs	Life-threatening consequences (e.g., hemodynamic collapse)	Death
Esophagitis	Asymptomatic pathologic, radiographic, or endoscopic findings only	Symptomatic altered eating or swallowing; IV fluids indicated less than 24 hours	Symptomatic and severely altered eating or swallowing; IV fluids, tube feedings, or TPN indicated 24 hours or more	Life-threatening consequences	Death
Nausea	Loss of appetite without alteration in eating habits	Oral intake decreased without significant weight loss, dehydration, or malnutrition; IV fluids indicated less than 24 hours	Inadequate oral caloric or fluid intake; IV fluids, tube feedings, or TPN indicated greater than 24 hours	Life-threatening consequences	Death
Vomiting	1 episode in 24 hours	2–5 episodes in 24 hours; IV fluids indicated less than 24 hours	6 episodes or more in 24 hours; IV fluids or TPN indicated greater than or equal to 24 hours	Life-threatening consequences	Death

ADL, activity of daily living; IV, intravenous; TPN, total parenteral nutrition.

Antimetabolites: Pyrimidine analogs

► Fluorouracil

5-Fluorouracil, commonly referred to as 5-FU, is a fluorinated analog of the pyrimidine uracil. Once administered, this prodrug is metabolized by dihydropyrimidine dehydrogenase. 5-FU ultimately is metabolized to fluorodeoxyuridine monophosphate (FdUMP), which interferes with the function of thymidylate synthase, which is required for synthesis of thymidine. The triphosphate metabolite of 5-FU is incorporated into RNA to produce the second cytotoxic effect of 5-FU. Inhibition of thymidylate synthesis occurs with the continuous infusion regimens, whereas the triphosphate form is associated with bolus administration. Patients with a low activity of dihydropyrimidine dehydrogenase appear to be at risk for life-threatening toxicities.¹¹ Folates appear to increase the stability of FdUMP–thymidylate synthase inhibition, which enhances the activity of the drug in certain cancers. 5-FU is metabolized extensively by the liver, but up to 15% of a dose may be found unchanged in the urine.

Age does not appear to alter the pharmacokinetics. 5-FU has shown clinical activity in the treatment of colorectal, breast, esophageal, pancreas, stomach, anal, and head and neck cancers. Adverse effects may include stomatitis, diarrhea, cardiac abnormalities, and rarely reported cerebellar toxicities. Esophagitis and gastric ulcerations also may occur. Some alopecia may occur, but hair regrowth may occur with subsequent doses. Cryotherapy (using ice chips in the mouth) for 30 minutes while receiving bolus 5-FU may decrease the severity of **mucositis**.¹² Neurotoxicity may consist of headaches, visual disturbances, and cerebellar ataxia. Cardiac toxicity may consist of ST-segment elevation, which appears to be more common in patients with a history of coronary artery disease.

► Capecitabine

Capecitabine is an orally active prodrug of 5-FU and has shown to be active in tumors of the colon, rectum, and breast. It not only shares the same mechanism but the toxicity profile is also similar to that of 5-FU. Toxicities include diarrhea,

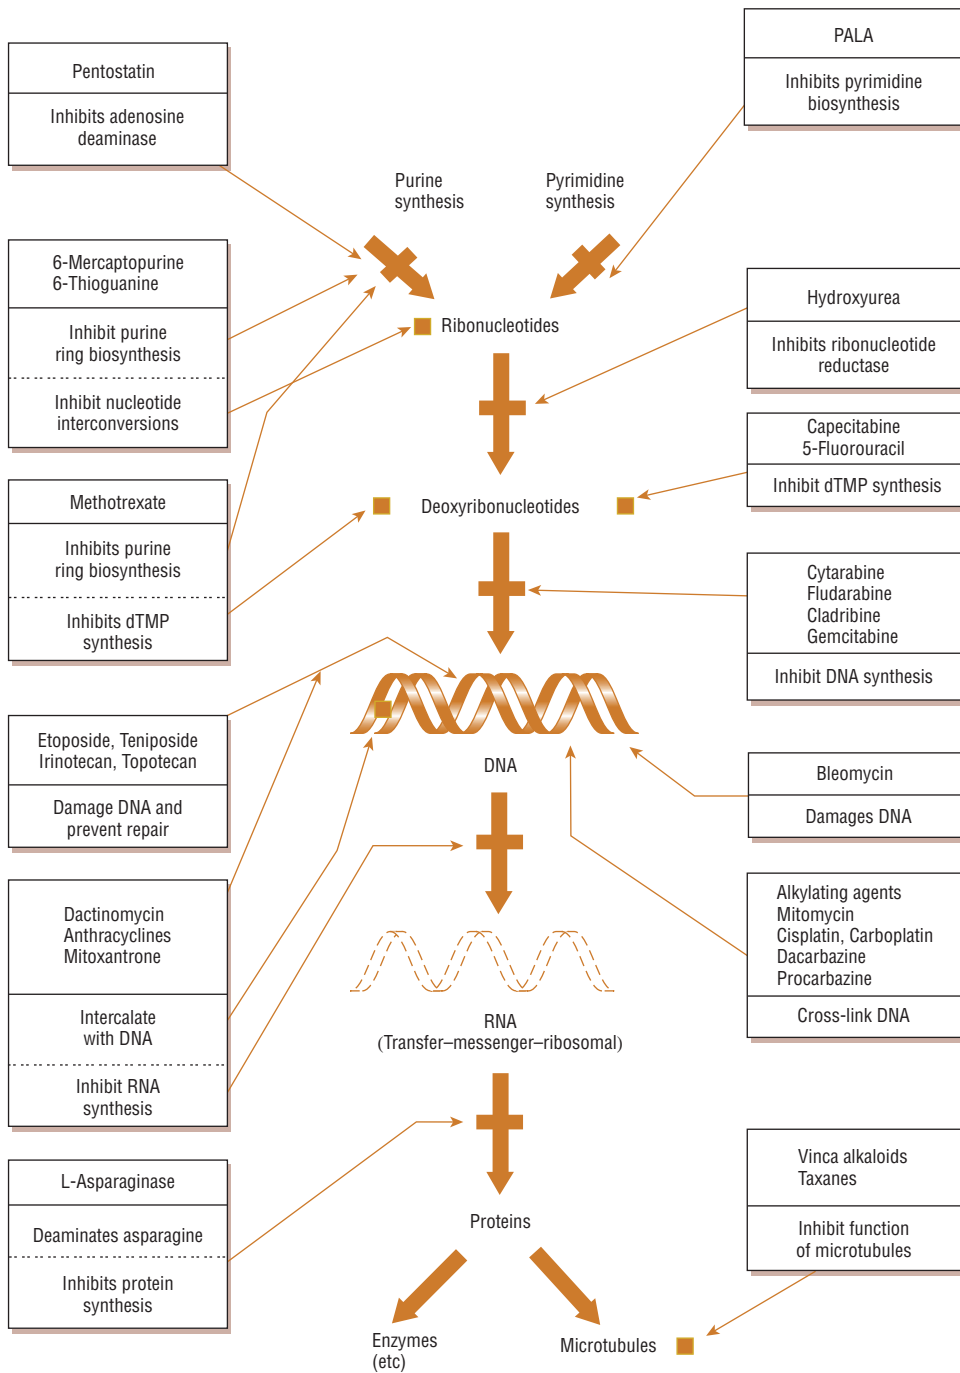

FIGURE 88-3. The mechanisms of action of commonly used antineoplastic agents. (dTMP, deoxythymidylic acid; PALA, *N*-phosphonacetyl-L-aspartate.) (From Chabner BA, Amrein PC, Druker BJ, et al. Antineoplastic agents. In: Brunton LL, Lazo JS, Parker KL, eds. Goodman & Gilman's The Pharmacologic Basis of Therapeutics, 11th ed. New York: McGraw-Hill; 2006: 1319.)

mucositis, palmar-plantar erythrodysesthesia, nausea, and **myelosuppression**. Palmar-plantar erythrodysesthesia, also referred to as hand-foot syndrome, refers to redness, itching, and blistering of the palms of the hands and soles of the feet. Patients should be counseled to notify the prescriber when this adverse effect occurs. Significant increases in international normalization ratio (INR) and prothrombin time may occur within several days when capecitabine is initiated in patients concomitantly receiving warfarin. The INR should be monitored closely or the patient may be switched to a low-molecular-weight heparin. Phenytoin levels

may become elevated related to possible CYP2C9 inhibition by capecitabine; therefore, plasma levels of phenytoin should be monitored. Patients should be instructed to take capecitabine within 30 minutes of a meal to increase absorption of the drug.

► Cytarabine

Cytarabine, also known as Ara-C, is a structural analog of cytosine and is phosphorylated intracellularly to the active triphosphate form, which inhibits DNA polymerase.

Patient Encounter 1, Part 1

BM is a 58-year-old previously healthy woman who has had symptoms of an upper respiratory tract infection for about 4 weeks. She has been treated with two courses of antibiotics without improvement of symptoms. She has also noticed an increase in bruising and bleeding gums after brushing her teeth. She reports feeling extraordinarily tired recently. Today, she presents to an urgent care center with worsening cough. Her complete blood count (CBC) reveals a high white blood cell (WBC) count ($39 \times 10^3 / \text{mm}^3$ [$39 \times 10^9 / \text{L}$]) and peripheral blasts (60% [0.60]). She is emergently admitted to the hospital for further evaluation.

After a bone marrow biopsy and further cytogenetic testing, a diagnosis of acute myeloid leukemia (AML) is made and treatment is planned to start as soon as possible.

What signs and symptoms does BM have that are consistent with a cancer presentation?

What is your desired outcome when treating this patient?

The triphosphate form also may be incorporated into DNA to result in chain termination to prevent DNA elongation. The drug may be administered as a low-dose continuous infusion, high-dose intermittent infusion, and into the subdural space via intrathecal or intraventricular administration. There is also a liposomal formulation available for less frequent administration into the central nervous system (CNS). Cytarabine is eliminated by the kidneys with a renal clearance of 90 mL/min (1.5 mL/s). Cytarabine has shown efficacy in the treatment of acute leukemias and some lymphomas. The toxicities of cytarabine in high doses include myelosuppression; cerebellar syndrome (i.e., nystagmus, dysarthria, and ataxia); and chemical conjunctivitis, an eye irritation that requires prophylaxis with steroid eye drops. The risk of neurotoxicity is increased with high doses (greater than 1 g/m²), advanced age, and renal dysfunction. If cerebellar toxicity does occur, the drug needs to be discontinued immediately, and decisions regarding further therapy need to be carefully considered.¹³

► Gemcitabine

Gemcitabine is a deoxycytidine analog that is structurally related to cytarabine. Gemcitabine inhibits DNA polymerase activity and ribonucleotide reductase to result in DNA chain elongation. Gemcitabine has shown activity in cancers of the pancreas, breast, lung, ovary, and some lymphomas. The toxicities include myelosuppression; flu-like syndrome with fevers during the first 24 hours after administration; rash that appears 48 to 72 hours after administration; and hemolytic uremic syndrome, a rare but life-threatening adverse effect. Patients should be counseled to use acetaminophen to treat the fevers during the first 24 hours; however, fevers occurring 7 to 10 days after gemcitabine are likely to be febrile neutropenias and need prompt treatment with broad-spectrum antibiotics.

► Azacitidine and Decitabine

Azacitidine and decitabine, both nucleoside analogs, were recently approved for the treatment of patients with myelodysplastic syndrome, a hematopoietic disorder that can transform into acute myeloid leukemia. Both of these agents cause cytotoxicity by directly incorporating in the DNA and inhibiting DNA methyltransferase, which causes hypomethylation of DNA. Hypomethylation of DNA appears to normalize the function of the genes that control cell differentiation and proliferation to promote normal cell maturation. The major side effects reported are myelosuppression and infections.

► Nelarabine

Nelarabine is indicated for the treatment of patients with T-cell acute lymphoblastic leukemia and T-cell lymphoblastic lymphoma, whose disease has been already treated with at least two other chemotherapy regimens. Nelarabine is a prodrug that accumulates as the active 5'-triphosphate form in leukemic blasts to result in inhibition of DNA synthesis and cell death. The most common adverse effects are hematologic toxicities, neutropenic fever, headaches, and gastrointestinal toxicities. Severe neurologic toxicities, including mental status change, convulsions, peripheral neuropathies, and effects similar to Guillain-Barré syndrome, have been reported.

Antimetabolites: Purine Analogs

► Mercaptopurine and Thioguanine

6-Mercaptopurine (6-MP) and thioguanine are oral purine analogues that are converted to ribonucleotides that inhibit purine synthesis. Mercaptopurine is converted into thiopurine nucleotides, which are catabolized by thiopurine S-methyltransferase (TPMT), which is subject to genetic polymorphisms and may cause severe myelosuppression. TPMT status may be assessed before therapy to reduce drug-induced morbidity and the costs of hospitalizations for neutropenic events. Both of these agents are used in the treatment of acute lymphocytic leukemia (ALL) and chronic myeloid leukemia (CML). Because the agents are similar structurally, cross-resistance is observed. Significant side effects include myelosuppression; mild nausea; skin rash; cholestasis; and rarely, veno-occlusive disease. Mercaptopurine is metabolized by xanthine oxidase, an enzyme that is inhibited by allopurinol. This represents a major drug-drug interaction. To avoid toxicities of mercaptopurine when these drugs are used concomitantly, the dose of mercaptopurine must be reduced by 66% to 75%.

► Fludarabine

Fludarabine is an analog of the purine adenine. It interferes with DNA polymerase to cause chain termination and inhibits transcription by its incorporation into RNA. Fludarabine is

dephosphorylated rapidly and converted to 2-fluoro-Ara-AMP (2-FLAA), which enters the cells and is phosphorylated to 2-fluoro-Ara-ATP, which is cytotoxic. Fludarabine is used in the treatment of chronic lymphocytic leukemia (CLL), some lymphomas, and refractory acute myeloid leukemia (AML). This drug is given intravenously (IV) usually daily for 5 days every 4 weeks. Significant myelosuppression may occur, along with immunosuppression, so patients are susceptible to opportunistic infections. Prophylactic antibiotics and antivirals are recommended until CD4 counts return to normal. Mild nausea and vomiting and diarrhea have been observed. Rarely, interstitial pneumonitis has occurred.

► **Cladribine**

Cladribine (2-chlorodeoxyadenosine, or 2-CDA) is a purine nucleoside that is a prodrug, activated via phosphorylation to a 5'-triphosphate derivative, which is incorporated into DNA, resulting in inhibition of DNA synthesis and chain termination. It may be administered as a continuous 7-day IV infusion or as a 2-hour infusion daily for 5 days; both regimens deliver the same total dose of drug. The primary indication for cladribine is hairy cell leukemia, although it has been used in the management of other hematologic conditions, including pediatric leukemias, and non-Hodgkin's lymphoma. Although fairly well tolerated, patients may experience myelosuppression and opportunistic infections. Fever, which is thought to be as a result of cell lysis and endogenous pyrogens being released into the bloodstream, can prompt the clinician to consider initiation of antibiotics. Even though it is likely drug induced, it may be difficult to rule out an infectious cause. Rash occurs in approximately 50% of patients.

► **Clofarabine**

Clofarabine was developed based on the structures of fludarabine and cladribine with the hope it would be resistant to deamination by adenosine deaminase. Clofarabine has shown activity in myeloid leukemia and myelodysplastic syndrome.¹⁴ Side effects include bone marrow suppression, severe but transient liver dysfunction in 15% to 25% of patients, skin rashes, and hand-foot syndrome.

► **Pentostatin**

Pentostatin is an inhibitor of adenosine deaminase, an enzyme important in purine base metabolism. Pentostatin irreversibly inhibits adenosine deaminase, which blocks DNA synthesis through inhibition of RNA ribonucleotide reductase. Side effects include bone marrow suppression, myalgias, conjunctivitis, and rash.

Antimetabolites: Folate antagonists

Folates carry one-carbon groups in transfer reactions required for purine and thymidylc acid synthesis. Dihydrofolate reductase is the enzyme responsible for supplying reduced folates intracellularly for thymidylate and purine synthesis.

► **Methotrexate**

Methotrexate inhibits dihydrofolate reductase of both malignant and nonmalignant cells. When high doses of methotrexate are given, the "rescue drug" leucovorin, a reduced folate, is administered to bypass the methotrexate inhibition of dihydrofolate reductase of normal cells and is usually initiated 24 hours after methotrexate administration. This is done to prevent potentially fatal myelosuppression and mucositis. For safety purposes, the term *folinic acid*, another term used for leucovorin, should not be used because of the potential for a medication error in which folic acid might be given instead. Methotrexate concentrations should be monitored to determine when to stop leucovorin administration. Generally, leucovorin administration may be stopped when methotrexate concentrations decrease to 5×10^{-8} M, although this may vary by the chemotherapy regimen. High dosages of methotrexate may cause methotrexate to crystallize out in the kidney, which may result in acute renal failure and decreased methotrexate clearance. Administration of IV hydration with sodium bicarbonate to maintain urinary pH greater than or equal to 7 is necessary to prevent methotrexate-induced renal dysfunction. Methotrexate is eliminated by tubular secretion; therefore, concomitant drugs (e.g., probenecid, salicylates, penicillin G, and ketoprofen) that may inhibit or compete for tubular secretion should be avoided. Methotrexate doses must be adjusted for renal dysfunction. A recommended dosing adjustment is to divide the creatinine clearance of the patient by 70 mL/minute (1.17 mL/s), which is the average creatinine clearance of patients who received methotrexate during clinical trials, and then to multiply this fraction by the dosage recommended for that disease state. Again, close monitoring of methotrexate concentrations in patients with renal impairment is advised. Methotrexate has shown activity in lymphoma, gastric, esophageal, bladder, and breast cancer and ALL. Side effects of methotrexate include myelosuppression, nausea and vomiting, and mucositis. Methotrexate also may be administered via the intrathecal route or via an Ommaya reservoir in very low doses as small as 12 mg to doses of 20 g IV, so it is crucial for the clinician to know the correct dose by the correct route in order to avoid substantial toxicity. The methotrexate used for intrathecal and intraventricular injection must be preservative-free to prevent CNS toxicity.

► **Pemetrexed**

Pemetrexed inhibits four pathways in thymidine and purine synthesis. Pemetrexed has shown activity in the treatment of mesothelioma and non-small cell lung cancer (NSCLC). Side effects include myelosuppression, rash, diarrhea, and nausea and vomiting. Patients should receive folic acid and cyanocobalamin to reduce bone marrow toxicity and diarrhea. Doses of folic acid of at least 400 mcg/day starting 5 days before treatment and continuing throughout therapy, as well as for 21 days after the last pemetrexed dose, have been used. Cyanocobalamin 1,000 mcg is given intramuscularly

the week before pemetrexed and then every 3 cycles thereafter. Dexamethasone 4 mg twice daily the day before, the day of, and the day after pemetrexed administration helps to decrease the incidence and severity of rash.¹⁵

► *Pralatrexate*

Pralatrexate is a folate analogue metabolic inhibitor that is transported into tumor cells via the reduced folate carrier (RFC-1) and competitively inhibits dihydrofolate reductase. It also competitively inhibits for polyglutamylation by the enzyme folylpolyglutamyl synthetase, resulting in the depletion of thymidine and other molecules. It is an intravenously administered agent indicated for the treatment of patients with refractory or relapsed peripheral T-cell lymphoma. Pralatrexate was approved based on overall response rates, not survival benefits. Common adverse reactions include mucositis, thrombocytopenia, nausea, and fatigue. In an effort to reduce the treatment-related mucositis and hematologic toxicity associated with pralatrexate, patients should be counseled to take low-dose oral folic acid on a daily basis and vitamin B₁₂ intramuscular injections every 8 to 10 weeks.

Microtubule-Targeting Agents

► *Vinca Alkaloids (Vincristine, Vinblastine, and Vinorelbine)*

The vinca alkaloids (vincristine, vinblastine, and vinorelbine) are derived from the periwinkle (vinca) plant and cause cytotoxicity by binding to tubulin, disrupting the normal balance between polymerization and depolymerization of microtubules, and inhibiting the assembly of microtubules, which interferes with the formation of the mitotic spindle. As a result, cells are arrested during the metaphase of mitosis. The vinca alkaloids are used primarily to treat hematologic malignancies (including Hodgkin's disease and ALL); lung, breast, and testicular cancers; Wilm's tumor; and sarcomas. Even though these agents have similar structures, the incidence and severity of toxicities vary among the agents. The dose-limiting toxicity of vincristine is neurotoxicity, which can consist of depressed tendon reflexes, paresthesias of the fingers and toes, toxicity to the cranial nerves, or autonomic neuropathy (constipation or ileus, abdominal pain, and/or orthostatic hypotension.) In contrast, the dose-limiting toxicity associated with vinorelbine and vinblastine is myelosuppression. All of the vinca alkaloids are vesicants and can cause tissue damage; therefore, the clinician must take precautions to avoid extravasation injury. Biliary excretion accounts for a significant portion of elimination of vincristine and its metabolites, so doses need to be adjusted for obstructive liver disease.

Vincristine, vinblastine, and vinorelbine have similar sounding names, which is a potential cause of medication errors. As with all chemotherapy prescribing, dispensing, and administration, the clinician must be very careful with sound-alike, look-alike medications. Unfortunately, vincristine has been involved in numerous cases of fatal

chemotherapy errors, including inadvertent intrathecal administration. Because the drug is a vesicant, intrathecal administration of the drug can cause widespread tissue damage in the brain and death. An example of a strategy that health systems can use to decrease the likelihood of an error such as this is for the pharmacy to only dispense vincristine in a mini-bag for IV administration. Many clinicians cap IV vincristine doses at 2 mg to prevent severe neuropathic side effects; however, if the intent of chemotherapy is curative, the vincristine dose may be dosed above the 2-mg cap.¹⁶

► *Taxanes (Paclitaxel, Docetaxel, and Cabazitaxel)*

Paclitaxel and docetaxel are taxane plant alkaloids that, similar to the vinca alkaloids, exhibit cytotoxicity during the M phase of the cell cycle by binding to tubulin. Unlike the vinca alkaloids, however, the taxanes do not interfere with tubulin assembly. Rather, the taxanes promote microtubule assembly and inhibit microtubule disassembly. Once the microtubules are polymerized, the taxanes stabilize against depolymerization.

Hepatic metabolism and biliary excretion account for the majority of paclitaxel's elimination. Paclitaxel has demonstrated activity in ovarian, breast, non-small cell lung, prostate, esophageal, gastric, and head and neck cancers. Considerable variability exists in paclitaxel dosing, from weekly 1-hour infusions to 24-hour infusions administered every 3 weeks. The diluent for paclitaxel, Cremophor EL, is composed of ethanol and castor oil. Infusions must be prepared and administered in non-polyvinyl chloride-containing bags and tubings, and solutions must be filtered. Patients receive dexamethasone, diphenhydramine, and an H₂ blocker to prevent hypersensitivity reactions caused by Cremophor EL. Patients also may have asymptomatic bradycardia during the infusion. Approximately 3 to 5 days after administration, patients may complain of myalgias and arthralgias that may last several days. Myelosuppression, flushing, neuropathy, ileus, and total-body alopecia are other common side effects. Because paclitaxel is a substrate for CYP 3A4, steady-state concentrations of paclitaxel were 30% lower in patients receiving phenytoin than in patients not receiving phenytoin. Paclitaxel clearance was decreased by 33% when it was administered after cisplatin, so paclitaxel is administered before cisplatin.

A nanoparticle albumin-bound paclitaxel product is also available for the treatment of metastatic breast cancer. This product does not have the serious hypersensitivity reactions encountered with paclitaxel solubilized in Cremophor EL, so premedication with H₁ and H₂ blockers and steroids is not necessary. The dose is infused over 30 minutes and does not require a special IV bag, tubing, or filter. The dosing of this product is different from that of the original paclitaxel, so practitioners need to be aware of which product is being prescribed. The pharmacokinetics of the albumin-bound paclitaxel display a higher clearance and larger volume of distribution than paclitaxel. The drug is eliminated primarily via fecal excretion.¹⁷ Bone marrow suppression, neuropathy, ileus, arthralgias, and myalgias still occur.

Docetaxel has activity in the treatment of breast, non-small cell lung, prostate, bladder, esophageal, stomach, ovarian, and head and neck cancers. Dexamethasone, 8 mg twice daily for 3 days starting the day before treatment, is used to prevent the fluid-retention syndrome associated with docetaxel and possible hypersensitivity reactions. The fluid-retention syndrome is characterized by edema and weight gain that is unresponsive to diuretic therapy and is associated with cumulative doses greater than 800 mg/m². Myelosuppression, alopecia, and neuropathy are other side effects associated with docetaxel treatment.

Cabazitaxel is a newer taxane used in combination with prednisone for the treatment of metastatic hormone-refractory prostate cancer in patients previously treated with a docetaxel-containing treatment regimen. Cabazitaxel has shown to have similar adverse effects as paclitaxel and docetaxel. Premedication with an antihistamine, corticosteroid, and H₂ antagonist to prevent hypersensitivity reactions is required.

► **Eribulin Mesylate**

Eribulin mesylate is classified as a nontaxane microtubule dynamics inhibitor. It is a synthetic analog of halichondrin B, which is a product isolated from the sea sponge *Halichondria okadai*. While taxanes inhibit cell division by stabilizing microtubules, eribulin arrests the cell cycle through inhibition of the growth phase of microtubules without interfering with microtubule shortening. The cytotoxicity results from its effects via a tubulin-based antimetabolic mechanism, resulting in G₂/M cell-cycle arrest and mitotic blockage. Apoptotic cell death results from prolonged mitotic blockage. Eribulin mesylate is an IV medication that is specifically indicated for the treatment of patients with metastatic breast cancer who have received at least two previous chemotherapy regimens (containing an anthracycline and taxane) for metastatic disease. The most common adverse effects reported are neutropenic fever, anemia, asthenia or fatigue, alopecia, peripheral neuropathy, nausea, and constipation. Eribulin has been reported to cause significant neutropenia and QT interval prolongation. It has vesicant properties. Dosages should be adjusted in renal and hepatic impairment.¹⁸

► **Estramustine**

Estramustine, an oral drug, also inhibits microtubule assembly and has weak estrogenic activity at the estradiol hormone receptors of the cell. This drug is used primarily for the treatment of prostate cancer, but its use is limited by the side effects, which include nausea and vomiting, diarrhea, thromboembolic events, and gynecomastia.

► **Ixabepilone**

Ixabepilone, an epothilone analog, binds to β -tubulin subunits on microtubules, which results in suppression of microtubule dynamics. Ixabepilone is primarily eliminated by the liver by oxidation through the CYP3A4 system.

Ixabepilone is indicated for the treatment of metastatic or locally advanced breast cancer after failures of anthracyclines and a taxane. Side effects include hypersensitivity reactions, myelosuppression, and peripheral neuropathy. To minimize the occurrence of hypersensitivity reactions, patients must receive both H1 and H2 antagonists before therapy. If a reaction still occurs, corticosteroids should be added to the premedications.

Topoisomerase Inhibitors

Topoisomerase is responsible for relieving the pressure on the DNA structure during unwinding by producing strand breaks. Topoisomerase I produces single-strand breaks, whereas topoisomerase II produces double-strand breaks.

► **Epipodophyllotoxins (Etoposide and Teniposide)**

Etoposide and teniposide are semisynthetic podophyllotoxin derivatives that inhibit topoisomerase II, causing multiple DNA double-strand breaks. Etoposide has shown activity in the treatment of several types of lymphoma, testicular and lung cancer, retinoblastoma, and carcinoma of unknown primary. The IV preparation has limited stability. Stability is concentration dependent, with a concentration of 0.4 mg/dL having 24 hours' stability. Oral bioavailability is approximately 50%, so oral dosages are approximate two times those of IV doses. Teniposide has shown activity in the treatment of ALL, neuroblastoma, and non-Hodgkin's lymphoma. Both of these agents should be slowly administered to prevent hypotension. Side effects of these agents include mucositis, myelosuppression, alopecia, phlebitis, hypersensitivity reactions, and secondary leukemias. Hypersensitivity reactions may be life threatening.

► **Camptothecin Derivatives (Irinotecan and Topotecan)**

Irinotecan and topotecan, both camptothecins, inhibit the topoisomerase I enzyme to interfere with DNA synthesis through the active metabolite SN38. Topoisomerase I enzymes stabilize DNA single-strand breaks and inhibit strand resealing. Irinotecan has shown activity in the treatment of cancers of the colon, rectum, cervix, and lung. Irinotecan-induced diarrhea is a serious complication and may be life threatening. One form of diarrhea (acute) can occur during or immediately after the infusion. This is a result of a cholinergic process in which the patient may experience facial flushing, diaphoresis, and abdominal cramping. IV atropine should be administered to treat diarrhea that occurs any time during the first 24 hours of administration. Another form of diarrhea (chronic) can occur several days after administration and can result in severe dehydration. This adverse effect should be treated immediately with loperamide at a dosage of 2 mg every 2 hours or 4 mg every 4 hours until diarrhea has stopped for 12 hours. Other side effects include myelosuppression, fatigue, and alopecia. Individuals homozygous for *UGT1A1**28 have an increased risk of febrile neutropenia and diarrhea.

and should be considered for an upfront dose reduction of one level; heterozygotes should receive closer monitoring, including more frequent complete blood counts (CBCs) to detect myelosuppression.

Topotecan has shown clinical activity in the treatment of ovarian and lung cancer, myelodysplastic syndromes, and AML. The IV infusion may be scheduled daily for 5 days or once weekly. Side effects include myelosuppression, mucositis, and diarrhea. Diarrhea is less common than with irinotecan.

Anthracene Derivatives

► *Daunorubicin, Doxorubicin, Idarubicin, and Epirubicin*

Anthracyclines (daunorubicin, doxorubicin, idarubicin, and epirubicin) are also referred to as antitumor antibiotics or topoisomerase inhibitors when considering their mechanism of action. All of the anthracyclines contain a four-membered anthracene ring, a chromophore, with an attached sugar portion. Free radicals formed from the anthracyclines combine with oxygen to form superoxide, which can make hydrogen peroxide. These agents are able to insert between base pairs of DNA to cause structural changes in DNA. However, the primary mechanism of cytotoxicity appears to be the inhibition of topoisomerase II. These drugs are widely used in a variety of cancers.

Oxygen-free-radical formation is a cause of cardiac damage and extravasation injury, which is common with these drugs. Daunorubicin, doxorubicin, epirubicin, and idarubicin can cause cardiac toxicity as manifested by a congestive heart failure or cardiomyopathy symptomatology, alopecia, nausea or vomiting, mucositis, myelosuppression, and urinary discoloration. These drugs are **vesicants**; significant tissue damage may occur with extravasation. Dosage alterations should be made in the presence of biliary dysfunction.²⁰

To reduce the risk of cardiotoxicity associated with doxorubicin, the maximum lifetime cumulative dose is 550 mg/m². Ventricular ejection fractions should be measured before therapy and periodically if therapy is continued. Therapy should be halted if there is a 10% to 20% decrease from baseline in ejection fraction. Patients at increased risk of cardiotoxicity include patients reaching the upper limit of cumulative lifetime dose; those taking concomitant or previous cardiotoxic drugs, concurrent paclitaxel, or bolus administration; patients with preexisting cardiac disease or mediastinal radiation; and the very young and elderly. Cardioprotectants (e.g., dexrazoxane) have been used to decrease risk in some cases. Clinical guidelines exist recommending when cardioprotective agents are warranted.¹⁹

Liposomal doxorubicin is an **irritant**, not a vesicant, and is dosed differently from doxorubicin, so clinicians need to be very careful when prescribing these two drugs. Liposomal doxorubicin has shown significant activity in the treatment of breast and ovarian cancer along with multiple myeloma and Kaposi's sarcoma. Side effects include mucositis, myelosuppression, alopecia, and palmar-plantar

erythrodysesthesia. The liposomal doxorubicin may be less cardiotoxic than doxorubicin.

► *Mitoxantrone*

This royal blue-colored drug is an anthracenedione that inhibits DNA topoisomerase II. Mitoxantrone has shown clinical activity in the treatment of acute leukemias, breast and prostate cancer, and non-Hodgkin's lymphomas. Myelosuppression, mucositis, nausea and vomiting, and cardiac toxicity are side effects of this drug. The total cumulative dose limit is 160 mg/m² for patients who have not received prior anthracycline or mediastinal radiation. Patients who have received prior doxorubicin or daunorubicin therapy should not receive a cumulative dose greater than 120 mg/m² of mitoxantrone. Patients should be counseled that their urine will turn a blue-green color.²¹

Alkylating Agents

Although still widely used for many malignancies, the alkylating agents are the oldest class of anticancer drugs. The agents cause cytotoxicity via transfer of their alkyl groups to nucleophilic groups of proteins and nucleic acids. The major site of alkylation within DNA is the N7 position of guanine, although alkylation does occur to a lesser degree at other bases. These interactions can either occur on a single strand of DNA (monofunctional agents) or on both strands of DNA through a cross-link (bifunctional agents), which leads to

Patient Encounter 1, Part 2

The decision to treat BM with a systemic chemotherapy regimen is made. She will be receiving the standard induction regimen of 7 + 3 (idarubicin 12 mg/m²/day IV every day for 3 days + cytarabine 100 mg/m²/day continuous IV infusion for 7 days).

Before initiating this chemotherapy regimen in the patient, what patient specific issues need to be addressed?

What adverse effects will BM likely experience with these two chemotherapy drugs?

Patient Encounter 1, Part 3

BM goes into complete remission (or a complete response), and now consolidation therapy with high-dose cytarabine (2 gm/m²/dose IV every 12 hr for 6 doses) will be initiated.

What is the mechanism of action of cytarabine?

How do the toxicities of high-dose cytarabine differ from those of conventional (low-dose) cytarabine? What are the risk factors, prophylaxis, and treatment for these toxicities?

strand breaks. The major toxicities of the alkylating agents are myelosuppression, alopecia, nausea or vomiting, sterility or infertility, and secondary malignancies.

► **Nitrogen Mustards (Cyclophosphamide and Ifosfamide)**

Cyclophosphamide and ifosfamide are commonly used bifunctional alkylating agents, therefore causing cross-linking of DNA. They each share similar adverse effects and spectrum of activity, being used in a variety of solid and hematologic cancers. Cyclophosphamide and ifosfamide are both prodrugs, requiring activation by mixed hepatic oxidase enzymes to get to their active forms, phosphoramide and ifosfamide mustard, respectively. During the activation process, additional byproducts (acrolein and chloroacetaldehyde) are formed. Acrolein has no cytotoxic activity but is responsible for the hemorrhagic cystitis associated with ifosfamide and high-dose cyclophosphamide. Acrolein produces cystitis by directly binding to the bladder wall. Prophylaxis is necessary with aggressive hydration, administration of 2-mercaptoethane sulfonate sodium (MESNA, which binds to and inactivates acrolein in the bladder), frequent voiding, and patient monitoring in patients receiving ifosfamide and high-dose cyclophosphamide. Patients should be counseled to drink plenty of fluids; void frequently; and report any hematuria, irritation, or flank pain. Dosing regimens of MESNA range from an equal milligram dose to the ifosfamide mixed in the same IV bag to 20% of the dose before ifosfamide and 20% of the dose repeated at 4 and 8 hours after the dose.

Chloroacetaldehyde, a metabolite of ifosfamide, can result in encephalopathy, especially in patients receiving ifosfamide that exhibit risk factors such as renal dysfunction or advanced age. This adverse effect can occur within 48 to 72 hours of administration and is usually reversible.

► **Busulfan**

Busulfan is an alkylating agent that forms DNA–DNA and DNA–protein cross-links to inhibit DNA replication. Oral busulfan is well absorbed, has a terminal half-life of 2 to 2.5 hours, and is eliminated primarily by metabolism. It is also available in an IV formulation, which is useful when using the high doses required in blood and marrow transplantation. Busulfan has shown significant clinical activity in the treatment of AML and chronic myelocytic leukemia. Side effects include bone marrow suppression; hyperpigmentation of skin creases; and rarely, pulmonary fibrosis. High doses used for bone marrow transplant preparatory regimens result in severe nausea and vomiting, tonic–clonic seizures, and sinusoidal obstruction syndrome (formerly known as *veno-occlusive disease*). Patients receiving high-dose busulfan should receive anticonvulsant prophylaxis.

► **Nitrosureas (Carmustine and Lomustine)**

Carmustine (BCNU) and lomustine (CCNU) are nitrosureas that are lipophilic in nature and therefore able to cross the

blood–brain barrier. Carmustine, which is reconstituted with ethanol, crosses the blood–brain barrier when given IV. It also comes as a biodegradable wafer formulation that may be implanted to treat residual tumor tissue after surgical resection of brain tumors. Lomustine is available in an oral formulation. Carmustine has shown clinical activity in the treatment of lymphoma, melanoma, and brain tumors. Lomustine has shown clinical activity in the treatment of non-Hodgkin's lymphoma and melanoma. Patients should receive only enough lomustine for one cycle at a time to prevent confusion with their drug regimens and the prolonged neutropenia that can occur. Side effects include myelosuppression, severe nausea and vomiting, and pulmonary fibrosis with long-term therapy.

► **Nonclassic Alkylating Agents (Procarbazine and Temozolomide)**

Although the exact mechanism of action remains unclear, dacarbazine and temozolomide appear to inhibit DNA, RNA, and protein synthesis. Dacarbazine has shown clinical benefit in the treatment of patients with melanoma, Hodgkin's lymphoma, and soft tissue sarcomas. Side effects include myelosuppression, severe nausea and vomiting, and a flu-like syndrome that starts about 7 days after treatment and lasts 1 to 3 weeks.

Temozolomide is an orally active agent that is well absorbed and crosses the blood–brain barrier. Temozolomide is converted via pH-dependent hydrolysis to the active metabolite 5-(3-methyltriazeno)-imidazole-4-carboxamide. Temozolomide may be used in the treatment of melanoma, refractory anaplastic astrocytoma, and glioblastoma multiforme. Nausea may be minimized by administering the drug at bedtime. Because patients receiving temozolomide may have confusion secondary to their brain tumors and because dosing can consist of multiple capsule sizes, care must be taken by all providers to simplify regimens to prevent chemotherapy overdose.²²

► **Procarbazine**

Although the exact mechanism of action of procarbazine is unknown, it does inhibit DNA, RNA, and protein synthesis. Procarbazine is used most often in the treatment of lymphoma. Myelosuppression is the major side effect. Nausea, vomiting, and a flu-like syndrome occur initially with therapy. Patients must be counseled to avoid tyramine-rich foods because procarbazine is a monoamine oxidase inhibitor. Patients should be provided a list of foods and beverages to avoid a hypertensive crisis. A disulfiram-like reaction can occur with the ingestion of alcohol.

► **Bendamustine**

Bendamustine has three chemically active groups: a 2-chlorethyl group, a butyric acid side chain, and a benzimidazole ring. The 2-chloroethyl group, which confers alkylating properties, is shared with chlorambucil and other agents from the nitrogen mustard class. The butyric acid

side chain, also common to chlorambucil, confers water solubility. The benzimidazole ring, structurally similar to a purine ring, occupies the position of the benzene ring in chlorambucil. Bendamustine has shown activity in chronic lymphocytic leukemia and non-Hodgkin's lymphoma. The recommended dose of bendamustine is 100 mg/m² given IV over 30 minutes on days 1 and 2 of a 28-day cycle. Side effects include nausea, vomiting, bone marrow suppression, headache and dyspnea.

► **Thiotepa**

Thiotepa is an alkylating agent that reacts with DNA phosphate groups to produce chromosomal cross-linkage. Thiotepa has shown clinical activity in the treatment of breast, bladder, and ovarian cancer, along with carcinomatous meningitis and malignant effusions, and usually is administered IV or as an intravesicular infusion. It also may be used intrathecally. Side effects include myelosuppression, nausea and vomiting, and venous irritation.

Heavy Metal Compounds

Platinum drugs form reactive platinum complexes that bind to cells, so the pharmacokinetics of the individual drug may be of the platinum, both free and bound, rather than of the parent drug.

► **Cisplatin**

Cisplatin forms inter- and intrastrand DNA cross-links to inhibit DNA synthesis. Cisplatin has shown clinical activity in the treatment of numerous tumor types, from head and neck cancers to anal cancer, including many types of lymphoma and carcinoma of unknown primary. Cisplatin is highly emetogenic, even when low doses are given daily for 5 days, and causes delayed nausea and vomiting as well; patients require aggressive antiemetic regimens for both delayed and acute emesis. Significant nephrotoxicity and electrolyte abnormalities can occur if inadequate hydration occurs. Ototoxicity, which manifests as a high-frequency hearing loss, and a glove-and-stocking neuropathy may limit therapy.

► **Carboplatin**

Although carboplatin has the same mechanism of action as cisplatin, its side effects are similar but less intense than those of cisplatin. Many chemotherapy regimens dose carboplatin based on an area under the curve (AUC), which is also called the *Calvert equation*. According to the Calvert equation, the dose in milligrams = (CrCl + 25) × AUC desired.²³ Carboplatin has shown clinical activity in the treatment of ovarian, lung, breast, testicular, esophageal, and head and neck cancers, as well as lymphomas. Thrombocytopenia, nausea and vomiting, and hypersensitivity reactions are side effects.

► **Oxaliplatin**

Oxaliplatin has shown clinical activity in the treatment of colorectal cancer. Oxaliplatin, although similar in action to

cisplatin and carboplatin, causes a cold-induced neuropathy. Patients should be counseled to avoid cold beverages, to use gloves to remove items from the freezer, and to wear protective clothing in cold climates for the first week after treatment. A glove-and-stocking neuropathy also occurs with long-term dosing. Hypersensitivity reactions and moderate nausea and vomiting are also side effects.²⁴

mTOR Inhibitors

► **Temsirolimus and Everolimus**

The mammalian target of rapamycin (mTOR) is a downstream mediator in the phosphatidylinositol 3-kinase/Akt signaling pathway that controls translation of proteins that regulate cell growth and proliferation but also angiogenesis and cell survival. The mTOR is an intracellular component that stimulates protein synthesis by phosphorylating translation regulators, and contributes to protein degradation and angiogenesis.

Temsirolimus is approved for the treatment advanced renal cell carcinoma. Temsirolimus and its metabolite sirolimus are substrates of the cytochrome P4503A4/5 isoenzyme system. The primary side effects of temsirolimus include mucositis, diarrhea, maculopapular rash, nausea, leucopenia, thrombocytopenia, and hyperglycemia.

Everolimus is an oral inhibitor of mTOR that is approved for the treatment of patients with advanced renal cell cancer after failure of treatment with sunitinib or sorafenib and most recently for the treatment of advanced pancreatic neuroendocrine tumors. Drug interactions and adverse reactions are similar to those of temsirolimus.

Miscellaneous Agents

► **Altretamine**

Altretamine, formerly known as hexamethylmelamine, is similar in structure to alkylating agents but is known to have anticancer activity in cancer cells resistant to alkylating agents. Altretamine has shown activity in the treatment of ovarian and lung cancer. This orally administered drug has the dose-limiting side effects of anorexia, nausea, vomiting, diarrhea, and abdominal cramping. Other side effects include neuropathy, agitation, confusion, and depression.

► **Bleomycin**

Bleomycin is a mixture of peptides with drug activity expressed in units, where 1 unit equals 1 mg. Bleomycin causes DNA strand breakage. Bleomycin has shown clinical activity in the treatment of patients with testicular cancer and malignant effusions, squamous cell carcinomas of the skin, and Kaposi's sarcoma. Hypersensitivity reactions and fever may occur, so premedication with acetaminophen may be required. The most serious side effect is the pulmonary toxicity that presents as a pneumonitis with a dry cough, dyspnea, rales, and infiltrates. Pulmonary function studies show decreased carbon monoxide diffusing capacity

and restrictive ventilatory changes. “Bleomycin lung” is associated with cumulative dosing greater than 400 units and occurs rarely with a total dose of 150 units. The pulmonary toxicity is potentiated by thoracic radiation and by hyperoxia. Additional side effects include fever with or without chills, mild to moderate alopecia, and nausea and vomiting. Bleomycin has been used to manage malignant effusions at doses of 15 to 60 units through installation into the affected area. The drainage tube of the effusion is clamped off for some period of time after administration of bleomycin (time varies based on the location of the effusion), and then the amount of drainage is monitored to determine efficacy of the bleomycin treatment.²⁵

► Hydroxyurea

Hydroxyurea is an oral drug that inhibits ribonucleotide reductase, which converts ribonucleotides into the deoxyribonucleotides used in DNA synthesis and repair. Hydroxyurea has shown clinical activity in the treatment of chronic myelocytic leukemia, polycythemia vera, and thrombocytosis. The major side effects are myelosuppression, nausea and vomiting, diarrhea, and constipation. Rash, mucositis, and renal tubular dysfunction occur rarely.

► L-Asparaginase

L-Asparaginase is an enzyme that may be produced by *Escherichia coli*. Asparaginase hydrolyzes the reaction of asparagine to aspartic acid and ammonia to deplete lymphoid cells of asparagine, which inhibits protein synthesis. L-Asparaginase has shown clinical activity in the treatment of ALL and childhood AML. Severe allergic reactions may occur when the interval between doses is 7 days or greater, so while a skin test result may be negative, patients should be observed closely after asparaginase administration. Pancreatitis and fibrinogen depletion may also occur during therapy. Repletion of fibrinogen should be done to prevent disseminated intravascular coagulation and fatal bleeding. If the patient suffers an allergic reaction to L-asparaginase, pegaspargase, which is L-asparaginase modified through a linkage with polyethylene glycol, which extends the half-life and allows for lower doses and less frequent administration, may be given. Cost and limited availability are some reasons pegaspargase may not be used first.

► Arsenic Trioxide

Arsenic trioxide, which is approved for the treatment of acute promyelocytic leukemia (APL), induces the growth of cancer cells into mature, more normal cells and induces programmed cell death, or apoptosis. Arsenic trioxide causes QT-interval prolongation, so frequent electrocardiograms need to be done before each dose, and other drugs that may prolong the QT interval need to be avoided during therapy. Monitoring of potassium and magnesium should be performed and active replacement undertaken to prevent QT prolongation. Other side effects include dry skin with itching, nausea and vomiting, loss of appetite, and elevations of serum

hepatic enzymes. A serious side effect is APL differentiation syndrome, which appears similar to pneumonia but is related to the arsenic therapy.²⁶

► Mitomycin C

Mitomycin C forms cross-links with DNA to inhibit DNA and RNA synthesis. Mitomycin C has shown clinical activity in the treatment of anal, bladder, cervix, gallbladder, esophageal, and stomach cancer. Side effects consist of myelosuppression and mucositis, and it is a vesicant.

► Tretinoin

Tretinoin, also referred to *ATRA*, which stands for all-trans-retinoic acid, is a retinoic acid that is not cytotoxic but promotes the maturation of early promyelocytic cells and is specific to the t(15;17) cytogenetic marker. The most significant side effect is the APL differentiation syndrome, which may occur anywhere from the first couple of days of therapy until the end of therapy and consists of symptoms of fever, respiratory distress, and hypotension. Chest radiographs are consistent with a pneumonia-like process. The syndrome can be confused easily with pneumonia in a patient with possible neutropenia. The treatment for retinoic acid syndrome is dexamethasone 10 mg IV every 12 hours; the syndrome may resolve within 24 hours of the start of dexamethasone therapy. However, the use of steroids in a febrile neutropenic patient may further compromise the treatment of infection.²⁷

► Thalidomide

Thalidomide was introduced into the market on October 1, 1957, as a sedative-hypnotic, and when it was taken by pregnant women, it resulted in severe limb deformities (phocomelia). Thalidomide is indicated for the treatment of leprosy and multiple myeloma. Thalidomide is an angiogenesis inhibitor, but the full the mechanism of action is still unknown. Possible mechanisms of action include free radical oxidative damage to DNA, inhibiting tumor necrosis factor α production, altering the adhesion of cancer cells, and altering cytokines that affect the growth of cancer cells.^{28,29} Thalidomide has shown clinical activity in the treatment of multiple myeloma and is still being studied for the treatment of several other cancers. Because of thalidomide’s potential to cause phocomelia, each patient must be counseled on the risks of thalidomide not only for the patient but also the patient’s reproductive partner. Physicians must be registered to prescribe thalidomide. Pharmacists can fill prescriptions only when both the patient and the physician have completed surveys on a monthly basis.

► Lenalidomide

Lenalidomide is approved for the treatment of myelodysplastic syndrome when the 5q deletion is present and multiple myeloma. Because lenalidomide is an analog of thalidomide, all of the same precautions must be taken to prevent phocomelia. Dosing adjustments are necessary for renal

dysfunction. Lenalidomide is used in the treatment of myelodysplastic syndrome and multiple myeloma. Other side effects are neutropenia, thrombocytopenia, deep vein thrombosis (DVT), and pulmonary embolus.

► **Bexarotene**

Bexarotene is a retinoid that selectively activates retinoid X receptors, which affects cellular differentiation and proliferation. Bexarotene is eliminated primarily by the hepatobiliary system. Bexarotene is indicated for the treatment of cutaneous manifestations of cutaneous T-cell lymphoma in patients who are refractory to other therapy. Side effects include hypercholesterolemia, elevations in triglycerides, pancreatitis, hypothyroidism, and leukopenia, headache, and dry skin.

► **Bortezomib**

The proteasome is an enzyme complex that exists in all cells and plays an important role in degrading proteins that control the cell cycle. When the proteasome is inhibited, the numerous pathways that are necessary for the growth and survival of cancer cells is disrupted. Bortezomib specifically inhibits the 26S proteasome, which is a large protein complex that degrades ubiquitinated proteins. This pathway plays an essential role in regulating the intracellular concentration of specific proteins, causing the cells to maintain homeostasis. Inhibition of the 26S proteasome prevents this to occur, ultimately causing a disruption in the homeostasis and cell death.

Bortezomib is approved for the treatment of multiple myeloma and mantle cell lymphoma. It is administered as an IV injection. The most commonly reported adverse effects are asthenia, gastrointestinal disturbances (nausea, diarrhea, decreased appetite, constipation, vomiting), thrombocytopenia, peripheral neuropathy, anemia, headache, insomnia, and edema. Reactivation of varicella zoster infection is also common with bortezomib, and antiviral prophylaxis with acyclovir should be considered.

► **HDAC Inhibitors (Vorinostat and Romidepsin)**

Vorinostat is indicated for the treatment of cutaneous T-cell lymphoma in patients with progressive, persistent, or recurrent disease after treatment with two systemic therapies. Romidepsin was approved in 2009 for the treatment of cutaneous or peripheral T-cell lymphoma in patients who have received at least one systemic therapy. These agents catalyze the removal of acetyl groups from acetylated lysine residues in histones, resulting in the modulation of gene expression. Vorinostat is an orally available agent, and romidepsin is only available in an IV formulation. These drugs are metabolized by CYP3A4, so caution should be exercised with monitoring for drug–drug interactions. Side effects include diarrhea, fatigue, nausea and anorexia, hypercholesterolemia, hypertriglyceridemia, and hyperglycemia. Despite anemia, thrombocytopenia, and neutropenia, patients have developed pulmonary embolism and DVT while on therapy.³⁰

Patient Encounter 2

RA is a 43-year-old man receiving doxorubicin and ifosfamide for a newly diagnosed osteosarcoma. While receiving chemotherapy, he begins to complain of flank pain and hematuria. His serum creatinine has risen from 0.9 mg/dL to 1.8 mg/dL (80 to 159 μ mol/L) in the last 3 days.

What is the likely diagnosis?

What drug should always be included as part of this regimen?

What should patients be counseled to do while receiving ifosfamide therapy?

Immune Therapies

► **Interferons**

The categories of α , β , and γ interferons exist; the α -interferons are used in the treatment of cancer. Interferon enhances the immune system's attack on cancer cells, can decrease new blood vessel formation, and can augment expression of antigen on tumor cell surfaces. Interferon has shown clinical activity in the treatment of melanoma, kidney cancer, Kaposi's sarcoma, and chronic myelocytic and lymphocytic leukemia. Unfortunately, interferon is not well tolerated by patients because it causes a flu-like syndrome that consists of fevers and chills; depression, malaise, and fatigue are other side effects. Premedication with acetaminophen helps alleviate the flu-like symptoms, which decrease with chronic administration.

► **Aldesleukin**

Aldesleukin, which is a human recombinant *interleukin-2 (IL-2)*, is a lymphokine that promotes B- and T-cell proliferation and triggers a cytokine cascade to attack the tumor. Aldesleukin has shown clinical activity in the treatment of kidney cancer and melanoma. Side effects of IL-2 vary by dose and route. IV high-dose IL-2 causes a drug-induced shocklike picture. Patients may develop hypotension despite aggressive IV hydration. Patients develop a red, itching skin; liver and kidney function tests change; via immune complex formation in the kidneys, fluid and electrolyte imbalances occur; and high fevers occur while receiving scheduled acetaminophen and nonsteroidal anti-inflammatory agents. Severe rigors and chills may require IV meperidine for symptom control. All the side effects reverse within 24 hours of stopping the drug. The toxicity profile is much less with subcutaneous administration. However, with subcutaneous administration, nodules form at the injection site and may take months to resolve. Corticosteroids should not be administered to patients while they are receiving aldesleukin unless a life-threatening emergency occurs. Steroids reverse all the symptoms and the antitumor effect even with topical administration. The itching, red skin may be treated with topical creams and antihistamines.

► **Denileukin Diftitox**

Denileukin diftitox is a combination of the active moieties of IL-2 and diphtheria toxin. It binds to high-affinity IL-2 receptors on the cancer cell (and other cells), and the toxin portion of the molecule inhibits protein synthesis to result in cell death. Denileukin diftitox is used for the treatment of persistent or recurrent cutaneous T-cell lymphoma whose cells express the CD25 receptor. Side effects include vascular leak syndrome, fevers or chills, hypersensitivity reactions, hypotension, anorexia, diarrhea, and nausea and vomiting.

► **Peginterferon Alfa-2b**

Sylatron, approved in April 2011, is a covalent conjugate of recombinant alfa-2b interferon with monomethoxy polyethylene glycol (PEG). The mechanism of cytotoxicity in patients with melanoma is unknown. This agent is specifically indicated for the adjuvant treatment of melanoma with microscopic or gross nodal involvement up to 84 days after definitive surgical resection (including complete lymphadenectomy). Adverse effects include fatigue, increased liver enzymes, pyrexia, headache, anorexia, myalgia, nausea, chills, and pain at the injection site.³¹

► **Sipuleucel-T**

Sipuleucel-T is a novel autologous cellular immunotherapy, approved in 2010, for the treatment of asymptomatic or minimally symptomatic metastatic hormone refractory prostate cancer. Sipuleucel-T is designed to induce an immune response targeted at prostatic acid phosphatase (PAP), which is an antigen expressed in greater than 95% of prostate cancers. Patients receiving sipuleucel-T undergo leukapheresis to collect their own antigen-presenting cells. These cells are then sent to a manufacturing facility and cultured with a recombinant antigen (PAP-GM-CSF, composed of PAP and GM-CSF, an immune cell activator). The cellular product, which is made specifically for each patient, is then delivered to the patient's clinic and infused intravenously into the patient on day 3 or 4. Each course consists of three infusions of activated cells given at 2-week intervals. Adverse effects include chills, fatigue, fever, back pain, nausea, joint pain, and headache.³²

Monoclonal Antibodies

The cell surface contains molecules, which are referred to as *CD*, which stands for "cluster of differentiation." The antibodies are produced against a specific antigen. When administered, usually by an IV injection, the antibody binds to the antigen, which may trigger the immune system to result in cell death through complement-mediated cellular toxicity, or the antigen-antibody cell complex may be internalized to the cancer cell, which results in cell death. Monoclonal antibodies also may carry radioactivity, sometimes referred to as *hot antibodies*, and are referred to as *radioimmunotherapy*, so the radioactivity is delivered to

Table 88-7

Syllable Source Indicators for Monoclonal Antibodies^a

U	Human
O	Mouse
A	Rat
E	Hamster
I	Primate
Xi	A cross between humanized and animal source

^aThese letters appear before *mab*, which stands for monoclonal antibody.

From Programme on International Nonproprietary Names (INN) Division of Drug Management and Policies, World Health Organization, Geneva. 1997.

the cancer cell. Antibodies that contain no radioactivity are referred to as *cold antibodies*.

All monoclonal antibodies end in the suffix *-mab*. The syllable before *-mab* indicates the source of the monoclonal antibody (Table 88-7). When administering an antibody for the first time, one should consider the source. The less humanized an antibody, the greater the chance for the patient to have an allergic-type reaction to the antibody. The more humanized the antibody, the lower the risk of a reaction. The severity of the reactions may range from fever and chills to life-threatening allergic reactions (which have resulted in death). Premedication with acetaminophen and diphenhydramine is common before the first dose of any antibody. If a severe reaction occurs, the infusion should be stopped and the patient treated with antihistamines, corticosteroids, or other supportive measures.

► **Alemtuzumab**

Alemtuzumab is an antibody to the CD52 receptor present on B and T lymphocytes. Alemtuzumab has shown clinical activity in the treatment of chronic lymphocytic leukemia. Severe and prolonged (6 months) immunosuppression may result, which necessitates pneumocystis carinii pneumonia (PCP) prophylaxis and antifungal and antiviral prophylaxis to prevent opportunistic infections.

► **Bevacizumab**

Bevacizumab is a humanized monoclonal antibody that binds to vascular endothelial growth factor (VEGF), which prevents it from binding to its receptors, ultimately resulting in inhibition of angiogenesis. Bevacizumab has shown clinical activity in the treatment of colorectal, kidney, lung, breast, and head and neck cancer. Patients may develop hypertension requiring chronic medication during therapy. Impaired wound healing, thromboembolic events, proteinuria, bleeding, and bowel perforation are serious side effects that occur with this drug.

► **Brentuximab**

Brentuximab vedotin is a CD30-directed antibody-drug conjugate (ADC) that consists of the antibody specific for

CD30, a microtubule disrupting agent called monomethyl auristatin E (MMAE), and a protease-cleavable linker that covalently attaches MMAE to the antibody. It is reported that the cytotoxic activity is a result of the binding of the ADC to CD30-expressing cells followed by internalization of the ADC-CD30 complex, and then proteolytic cleavage and release of MMAE into the cell. Binding of MMAE to tubulin disrupts the microtubule network, resulting in cell cycle arrest and apoptosis. This IV agent, which was granted accelerated approval in 2011, is indicated for Hodgkin's lymphoma patients after failure of autologous stem cell transplant (ASCT) or after failure of at least two multidrug regimens in patients who are not eligible for ASCT and for patients with systemic anaplastic large cell lymphoma who have failed at least one systemic chemotherapy regimen. In vitro data suggests that MMAE is a substrate and an inhibitor of CYP3A4/5; therefore, patients need to be monitored for drug-drug interactions. The most common adverse effects are neutropenia, peripheral neuropathy, fatigue, nausea and vomiting, diarrhea, anemia, thrombocytopenia, and upper respiratory infection. Dosing modifications guidelines for peripheral neuropathy can be found in the prescribing information.³³

► **Cetuximab**

Cetuximab is a chimeric antibody that binds to the epidermal growth factor receptor (EGFR) to block its stimulation. Tumors that have *KRAS* mutations do not respond to treatment with cetuximab; therefore, tumors should be tested for *KRAS* mutations before initiating therapy. Cetuximab has shown clinical activity in the treatment of colorectal and head and neck cancers. An acne-like rash may appear on the face and upper torso 1 to 3 weeks after the start of therapy. Other side effects include hypersensitivity reactions, interstitial lung disease, fever, malaise, diarrhea, abdominal pain, and nausea and vomiting.

► **Gemtuzumab Ozogamicin**

Gemtuzumab ozogamicin is a humanized antibody to the CD33⁺ receptor present on about 80% of AML cells. The antibody is linked to calicheamicin, a cellular toxin that is released intracellularly after the antigen-antibody complex is internalized. Inside the cell, calicheamicin binds to DNA in the minor groove, resulting in DNA double-strand breaks and cell death. Shortly after receiving accelerated approval in 2000 for elderly patients with relapsed CD33⁺ AML, hepatotoxicity (specifically veno-occlusive disease) and hypersensitivity reactions, including anaphylaxis, infusion reactions, and pulmonary events, were observed, which led to the addition of black box warnings. Unfortunately, the confirmatory postapproval clinical trial did not confirm the clinical benefit of gemtuzumab ozogamicin. Based on these safety and efficacy concerns, in 2010, gemtuzumab ozogamicin was voluntarily withdrawn from the market in the United States.

► **Ibritumomab Tiuxetan**

This "hot antibody" is linked to yttrium and binds to the CD20 receptor of B lymphocytes (see Rituximab later). Hematologic toxicity may occur several weeks after administration and may take weeks to resolve.

► **Ipilimumab**

Ipilimumab is a recombinant, human monoclonal antibody that binds to the cytotoxic T lymphocyte-associated antigen 4 (CTLA-4), which is a molecule on T cells that causes a suppression of the immune response. CTLA-4 is a negative regulator of T-cell activation. Ipilimumab binds to CTLA-4 and blocks the interaction of CTLA-4 with its ligands. This blockage has been reported to enhance T-cell activation and proliferation. Ipilimumab is approved for patients with unresectable or metastatic melanoma. The antitumor effects appear to be T-cell-mediated immune responses. This medication is given through IV administration and is dosed at 3 mg/kg over 90 minutes every 3 weeks for a total of four doses. Ipilimumab administration can result in severe and fatal immune-mediated adverse reactions, including enterocolitis, hepatitis, toxic epidermal necrolysis, neuropathy, and endocrine abnormalities. These symptoms can occur during treatment or weeks to months after discontinuation of the drug. Liver and thyroid function tests should be performed at baseline and before each dose. If this occurs, treatment should be initiated with systemic corticosteroids and the drug should be discontinued permanently. Progressive multifocal leukoencephalopathy has been reported. Additional less serious adverse effects include fatigue, diarrhea, pruritus, rash, and colitis.

► **Ofatumumab**

Ofatumumab is a fully human monoclonal antibody to CD20 that received accelerated approval as single-agent therapy in 2009 for patients with chronic lymphocytic leukemia that is refractory to fludarabine and alemtuzumab therapy. Data suggest that possible mechanisms of anticancer activity are through complement-dependent and antibody-dependent cell-mediated cytotoxicity. The most common adverse effects include infusion-related reactions, neutropenia, infections, pyrexia, anemia, diarrhea, and nausea. Serious adverse events, including fatal infections, progressive multifocal leukoencephalopathy, and reactivation of hepatitis B, have been reported.

► **Panitumumab**

Panitumumab binds to the EGFR to prevent receptor autophosphorylation and activation of receptor-associated kinases, which results in inhibition of cell growth and induction of apoptosis. Panitumumab has demonstrated activity against tumors of the colon and rectum. However, panitumumab is not recommended for the treatment of colorectal cancer with *KRAS* mutations in codon 12 or 13. Retrospective subset analyses have not shown a treatment benefit for these mutations. Side effects include dermatitis,

pruritus, exfoliative rash, infusion reactions, pulmonary fibrosis, diarrhea, hypomagnesemia, hypocalcemia, and photosensitivity.

► **Rituximab**

Rituximab is a monoclonal antibody to the CD20 receptor expressed on the surface of B lymphocytes; the presence of the antibody is determined during flow cytometry of the tumor cells. Cell death results from antibody-dependent cellular cytotoxicity. Rituximab has shown clinical activity in the treatment of B-cell lymphomas that are CD20 positive. Side effects include hypersensitivity reactions, hypotension, fevers, chills, rash, headache, and mild nausea and vomiting.

► **Tositumomab**

This “hot antibody” is linked to radioactive iodine and binds to the CD20 receptor present on B lymphocytes (see Rituximab earlier). Tositumomab has shown activity in non-Hodgkin’s lymphoma. Hematologic toxicity occurs several weeks after administration and may persist for months. Because radioactive iodine may have adverse effects on the thyroid, all patients must receive thyroid-blocking agents.

► **Trastuzumab**

Trastuzumab is the antibody directed against human epidermal receptor 2 (*HER-2*), which is overexpressed by 25% to 30% of breast cancers and is associated with aggressive disease and decreased survival. Breast cancer tissue must be tested for the presence of *HER-2* because patients who do not express *HER-2* do not respond to trastuzumab. Trastuzumab is also indicated for the treatment of gastric cancer. Severe congestive heart failure may occur with concurrent anthracycline administration. Cardiac toxicity may be seen when the drug is administered months after anthracycline administration, so patients must be counseled on the signs and symptoms of heart failure. Other side effects include hypersensitivity reactions, fever, diarrhea, infections, chills, cough, headache, rash, and insomnia.³⁴

Tyrosine Kinase Inhibitors

There are more than 100 different types of tyrosine kinases present in the body. Tyrosine kinase inhibitors (TKIs) are also referred to as small-molecule inhibitors. Each of the following drugs was developed to block either several or a specific tyrosine kinase.

► **Imatinib**

Imatinib was the first FDA-approved TKI. The drug was designed to block the breakpoint cluster region tyrosine kinase (BCR-ABL) produced by the Philadelphia chromosome associated with CML and ALL. Imatinib also has shown activity against gastrointestinal stromal tumors (GIST) that are positive for c-kit (CD117). Numerous drug interactions have been reported for imatinib. CYP450 3A4 inducers, such as rifampicin and St. John’s wort, increase the clearance of

imatinib.^{35,36} Ketoconazole, a CYP450 3A4 inhibitor, has been shown to decrease imatinib clearance by almost 30%.³⁷ Imatinib also may increase the exposure of simvastatin, a CYP450 3A4 substrate.³⁸

► **Dasatinib**

Dasatinib is a second-generation TKI that shares the same binding site on the BCR-ABL cluster region as imatinib but maintains activity despite imatinib resistance, with higher potency than imatinib. Dasatinib also inhibits SRC kinases, which are tyrosine kinases that mediate cellular differentiation, proliferation, and survival. Dasatinib is used front line in the treatment of CML and in CML with resistance or intolerance to imatinib, as well as for the treatment of Philadelphia-chromosome-positive acute lymphoblastic leukemia. Side effects of dasatinib include myelosuppression, nausea and vomiting, headache, fluid retention, hypocalcemia, and pleural effusions.

► **Nilotinib**

Nilotinib also blocks the breakpoint cluster region tyrosine kinase (BCR-ABL) produced by the Philadelphia chromosome associated with CML and ALL. Nilotinib is also indicated for the treatment of Philadelphia-chromosome-positive CML. Nilotinib is a competitive inhibitor of UGT1A1 in vitro, which could increase the concentrations of nilotinib. In a pharmacogenetic analysis, patients with (TA)7/(TA)7 genotype (UGT1A1*28) had a statistically significant increase in bilirubin over other genotypes.³⁹ Nilotinib should be administered on an empty stomach or 2 hours after a meal. Side effects include QT prolongation, bone marrow suppression, elevations in lipase, and hepatotoxicity.

► **Erlotinib**

Erlotinib, whose pharmacology is not entirely understood, is believed to inhibit the intracellular phosphorylation of the EGFR. Erlotinib is about 60% absorbed after oral administration. Food increases bioavailability to almost 100%, but this is variable, and experts recommend administering erlotinib on an empty stomach. Erlotinib is eliminated predominately by CYP450 3A4. Smoking increases the clearance of erlotinib by 24%, which may result in treatment failure.⁴⁰ Erlotinib is used in the treatment of NSCLC and cancer of the pancreas. Side effects include interstitial lung disease, rash, diarrhea, anorexia, pruritus, conjunctivitis, and dry skin. Again, significant drug interactions have been documented with CYP450 3A4 inducers and inhibitors.

► **Lapatinib**

Lapatinib inhibits the intracellular kinase domains of both EGFR and *HER-2* and has been shown to retain activity against breast cancer cells that have become resistant to trastuzumab. The drug is dosed at 1000 mg/day in combination with trastuzumab, 1250 mg/day in combination with capecitabine, and 1500 mg/day in combination with letrozole. Patients with Child-Pugh class C liver disease should have a dosage

reduction to 750 mg/day to adjust the AUC to the normal range. Lapatinib is indicated for the treatment of patients with breast cancer whose tumors overexpress *HER-2*. Side effects of lapatinib include decreased left ventricular ejection fraction, diarrhea, hepatotoxicity, rash, and QT prolongation.

► **Sorafenib**

Sorafenib is a multikinase inhibitor that inhibits both intracellular and extracellular kinases to decrease renal cell cancer proliferation. Sorafenib is metabolized primarily by the liver by CYP450 3A4. Sorafenib is used for the treatment of renal cell cancer. The primary side effects of sorafenib include rash, hand-foot skin reaction, diarrhea, pruritus, and elevations in serum lipase.

► **Sunitinib**

Sunitinib blocks several tyrosine kinases, including platelet-derived growth factor, VEGF receptor, stem cell factor receptor, fms-like receptor growth factor, colony-stimulating growth factor receptor type 1, and glial cell line-derived neurotrophic factor receptor. The active metabolite of sunitinib blocks these same enzymes with similar potency. It is indicated for the treatment of GISTs after disease progression or intolerance to imatinib. It is also indicated for the treatment of advanced renal cell cancer and pancreatic neuroendocrine tumors. Significant side effects include left ventricular dysfunction, hemorrhage, asthenia, hypertension, nausea and vomiting, and diarrhea. Approximately one-third of patients may develop a yellow color of the skin along with dryness and cracking of the skin. Also, hair may become depigmented with doses of 50 mg/day or more; the depigmentation is reversible when therapy is stopped. Clinically significant drug interactions exist with drugs metabolized via the CYP450 3A4 system; ketoconazole has been shown to increase concentrations of sunitinib, whereas rifampin has been shown to decrease concentrations of sunitinib.

► **Pazopanib**

Pazopanib is a vascular epidermal growth factor receptor (VEGFR) TKI that acts at VEGFR-1, VEGFR-2, and VEGFR-3. It is specifically indicated for the treatment of patients with advanced renal cell carcinoma. Pazopanib is metabolized through CYP3A4; therefore, drug-drug interactions should be monitored. Pazopanib is an orally administered agent that should be taken on an empty stomach. Common adverse effects include diarrhea, hypertension, hair color change, nausea and vomiting, fatigue, and anorexia. Serious toxicities that have been observed are increases in liver enzymes and bilirubin, including fatal hepatotoxicity, prolonged QT intervals and torsades de pointes, hemorrhagic events, arterial thrombotic events, gastrointestinal perforation, and proteinuria.

► **Vemurafenib**

Vemurafenib, formerly known as PLX4032, is a potent inhibitor of mutated *BRAF*. In August 2011, the agent

received FDA approval for the treatment of unresectable or metastatic melanoma in patients with documented *BRAFV600E* mutation as determined by an FDA-approved test. Vemurafenib produced improved rates of overall and progression-free survival in a phase III trial when compared with dacarbazine. Vemurafenib is not indicated for patients with wild-type *BRAF*. The orally administered vemurafenib is dosed at 960 mg twice daily without regards to meals. Common adverse effects include arthralgia, rash, fatigue, alopecia, keratoacanthoma or squamous cell cancer, photosensitivity, nausea, and diarrhea. Approximately 40% of patients require dosage modifications because of adverse effects.⁴¹

► **Crizotinib**

Crizotinib is a small-molecule inhibitor of the anaplastic lymphoma kinase gene (*ALK*) and mesenchymal epithelial transition growth factor (*c-MET*). This orally available agent was approved in August 2011 for the treatment of locally advanced or metastatic NSCLC that is *ALK* positive (about 2% to 7% of NSCLC patients) as detected by an FDA-approved test. Crizotinib is dosed at 250 mg orally twice daily without regards to meals. Adverse effects reported include mild gastrointestinal symptoms, edema, and visual disturbances, which have been described as trails of light following objects as they move.⁴²

► **Vandetanib**

Vandetanib is an orally available receptor TKI that blocks both the VEGF and EGF receptor kinase. This agent is indicated for the treatment of symptomatic or progressive medullary thyroid cancer in patients with unresectable locally advanced or metastatic disease. It is an orally administered agent dosed at 300 mg/day without regards to meals. Common adverse effects include diarrhea, rash, acne, nausea, hypertension, headache, fatigue, decreased appetite, and abdominal pain.

Hormonal Therapies

Hormonal therapies have shown activity in the treatment of cancers whose growth is affected by gonadal hormonal control. Hormonal treatments either block or decrease the production of endogenous hormones.

► **Antiandrogens: Bicalutamide, Flutamide, and Nilutamide**

The antiandrogens block androgen receptors to inhibit the action of testosterone and dihydrotestosterone in prostate cancer cells. Unfortunately, prostate cancer cells may become hormone refractory.

Side effects common to these agents are hot flashes, gynecomastia, and decreased libido. Flutamide tends to be associated with more diarrhea and requires three times daily administration, whereas bicalutamide is dosed once

daily. Nilutamide may cause interstitial pneumonia and is associated with the visual disturbance of delayed adaptation to darkness.

► **Luteinizing Hormone–Releasing Hormone Agonists: Goserelin and Leuprolide**

Initially, luteinizing hormone–releasing hormone (LHRH) agonists increase levels of luteinizing hormone and follicle-stimulating hormone, but testosterone and estrogen levels are decreased because of continuous negative-feedback inhibition. Major side effects are testicular atrophy, decreased libido, gynecomastia, and hot flashes. Goserelin is injected as a pellet under the skin, therefore, subcutaneous injection of lidocaine around the injection site before administration helps to decrease the pain associated with goserelin administration. Numerous dosage forms are available for leuprolide with varying strengths and dosing intervals. Antiandrogens may be administered during initial therapy to decrease symptoms of tumor flare (e.g., bone pain and urinary tract obstruction).

► **Ketoconazole**

Although ketoconazole is an antifungal agent, it has been used for treatment of prostate cancer. In high doses of 400 mg three times daily, ketoconazole blocks the production of testosterone.

► **Luteinizing Hormone–Releasing Hormone Antagonist: Degarelix**

Degarelix is a gonadotropin-releasing hormone (GnRH) receptor antagonist that works by binding reversibly to the pituitary GnRH receptors, thereby reducing the release of gonadotropins and consequently testosterone. Degarelix was approved in 2008 and is indicated for the treatment of advanced prostate cancer. Adverse events include hot flashes, injection site reactions, and an increase in liver enzymes. An advantage of degarelix over LHRH agonists is the lack of the tumor flare.⁴³

► **Abiraterone**

Abiraterone, approved in 2011, is an orally available androgen biosynthesis inhibitor that inhibits 17 α -hydroxylase/C17,20-lyase (CYP17), which is expressed in testicular, adrenal, and prostatic tumor tissues. Abiraterone is indicated in combination with prednisone for the treatment of metastatic castration–resistant prostate cancer who have received prior chemotherapy containing docetaxel. Adverse effects include joint swelling, hypokalemia, edema, muscle discomfort, hot flashes, diarrhea, urinary tract infections, nocturia, urinary frequency, dyspepsia, cough, hypertension, and arrhythmia. The patient must be counseled to take the oral medication on an empty stomach because food increases absorption and results in adverse reactions.⁴⁴

► **Anastrozole**

Anastrozole is a selective nonsteroidal aromatase inhibitor that lowers estrogen levels. Anastrozole is used for the adjuvant treatment of postmenopausal women with hormone-positive breast cancer and in breast cancer patients who have had disease progression following tamoxifen. Side effects include hot flashes, arthralgias, osteoporosis or bone fractures, and thrombophlebitis.

► **Exemestane**

Exemestane is an irreversible aromatase inactivator that binds to the aromatase enzyme to block the production of estrogen from androgens. Exemestane is indicated for the treatment of advanced breast cancer in postmenopausal women who have had disease progression following tamoxifen therapy. Side effects include hot flashes, fatigue, osteoporosis or bone fractures, and flu-like symptoms.

► **Letrozole**

Letrozole is another selective aromatase that inhibits the conversion of androgens to estrogen. Letrozole is used in the treatment of postmenopausal women with hormone receptor–positive or unknown advanced breast cancer. Side effects include bone pain, hot flashes, back pain, nausea, arthralgia, osteoporosis or bone fractures, and dyspnea.

► **Fulvestrant**

Fulvestrant is an estrogen receptor antagonist that binds to the estrogen receptor and is given as a monthly intramuscular injection. Fulvestrant is used for the treatment of hormone receptor–positive metastatic breast cancer in postmenopausal women with disease progression following antiestrogen therapy. Side effects are hot flashes, abdominal pain, depression, and myalgias.

► **Megestrol Acetate**

Megestrol is a synthetic progestin with antiestrogen properties that is used for breast cancer and in higher doses for weight gain. Side effects include fluid retention, hot flashes, vaginal bleeding and spotting, breast tenderness, and thrombosis.

► **Tamoxifen**

Tamoxifen is a selective estrogen receptor modulator (SERM). Tamoxifen is used for the treatment of metastatic hormone receptor–positive breast cancer, adjuvant and primary treatment of breast cancer, and prevention of breast cancer in high-risk women. Side effects include hot flashes, fluid retention, mood swings, thrombosis, endometrial and uterine cancer, and corneal changes and cataracts. Because tamoxifen is a substrate of CYP450 3A4, decreased tamoxifen levels have occurred with use of St. John's wort, and decreased tamoxifen levels have been observed with the use of rifampin. Tamoxifen is also a substrate for CYP450 2D6, and evidence suggests that those who are CYP2D6*4/*4 may have a poorer

response and more toxicity with tamoxifen.⁴⁵ Significant drug interactions exist with antidepressants that may be used to treat depression or help relieve hot flashes.

► **Raloxifene**

Raloxifene is an SERM usually used for the treatment of osteoporosis in postmenopausal women, although it is also indicated for the prevention of breast cancer in high-risk women at a dose of 60 mg/day. When compared head to head with tamoxifen for breast cancer prevention, it was demonstrated to have equal efficacy with less toxicity. The only advantage of tamoxifen for the prevention of breast cancer is that it can be used in premenopausal women. Hot flashes, arthralgias, and peripheral edema occur frequently with raloxifene, but thrombosis is a rare but serious adverse effect.

► **Toremifene**

Toremifene is an SERM. Toremifene is used for the treatment of metastatic breast cancer in postmenopausal women with estrogen receptor–positive or unknown tumors. Toremifene causes hot flashes, vaginal bleeding, thromboembolism, and visual acuity changes.

ADMINISTRATION ISSUES

Extravasation

One issue of chemotherapy safety is extravasation. Antineoplastic agents that cause severe tissue damage when they escape from the vasculature are called **vesicants**. Some examples of vesicants are the anthracyclines and the vinca alkaloids. The tissue damage may be severe, with tissue sloughing and loss of mobility, depending on the area of extravasation. Patients need to be educated to notify the nurse immediately if there is any pain on administration. If extravasation of a vesicant occurs, the injection should be stopped and any fluid aspirated out of the injection site. If an antidote should be administered, such as with nitrogen mustard extravasation, the pharmacy should be notified immediately so that the sodium thiosulfate can be prepared and delivered quickly. Cold compresses should be applied (heat should be used for vincas) to the affected area. The area of extravasation should be recorded and inked and followed closely to detect early signs of infection and to treat pain. Obviously, prevention of extravasation is very important. Good IV access is key, which may include the placement of a central venous catheter along with free-flowing IV fluids. During administration of a vesicant, blood return should be checked to be sure that the drug is going into the vein. Central venous catheters can be placed for patients needing infusions of vesicants or for patients with small, friable veins to prevent extravasation.

Hypersensitivity Reactions

Hypersensitivity reactions of cancer treatments is problematic because of cross-reactivity between agents and

the desire to continue active therapies against the cancer.⁴⁶ For documented immediate hypersensitivity reactions to a particular agent, further administration of the agent may be achieved through extensive premedication with H1 and H2 antihistamines and corticosteroids and through use of escalating doses of the offending agent given at doses of one-hundredth, one-tenth, and the balance of the dose (so the total dose administered is equivalent to the normally prescribed dose) administered over a much longer period of time. These treatments must be given in an environment where resuscitation is readily available in case of medical emergency.

Secondary Malignancies

Chemotherapy and radiation therapy treatments may cause cancers later in life; these are referred to as secondary cancers. The most common type of secondary cancer is myelodysplastic syndrome, or AML. The antineoplastic agents most commonly associated with secondary malignancies are alkylating agents, etoposide, teniposide, topoisomerase inhibitors, and anthracyclines. Although the risk for secondary cancers is extremely low, it must outweigh the risk of survival produced by treatment of the primary malignancy. Because secondary malignancies may not occur for several years after treatment, patients with relatively short-term survival owing to the primary malignancy should consider the more immediate benefits of chemotherapy. Radiation therapy rarely may cause solid tumors as secondary cancers decades after treatment. The most common example of radiation therapy–induced secondary malignancy is breast cancer, which rarely occurs after mantle field radiation therapy for Hodgkin's disease.

CHEMOTHERAPY SAFETY

One of the first Institute of Medicine reports, the health arm of the National Academy of Sciences, starts out with a patient who died from an overdose of chemotherapy; the patient did not have an immediately life-threatening cancer, so her death was hastened by a medication error. Chemotherapy agents may cause harm to patients, health care workers, and the environment if not handled correctly.

5 *Because of the risk of severe toxicities associated with many of the chemotherapy agents, safety precautions must be in place to prevent chemotherapy errors or accidental chemotherapy exposures of health care professionals or patients.* The Oncology Nursing Society and the American Society of Health-System Pharmacists have information to assist in the safe handling of chemotherapy agents.¹⁶ National, state, and local regulations regarding the safe disposal of chemotherapy agents and the equipment used to administer them need to be followed to protect the environment.

- Each organization should have chemotherapy safety checks built into the prescribing, preparation and administration of

chemotherapy.¹⁶ Dosing based on patient-specific information should be included on every order for chemotherapy, whether it is oral or parenteral. Many chemotherapy regimens are referred to by acronyms (e.g., AC, which is doxorubicin cyclophosphamide); these should not be allowed as the only reference to drugs in the prescribing of chemotherapy. Also, abbreviations for the names of chemotherapy agents should be avoided because one abbreviation may stand for two different drug entities. For drugs such as doxorubicin and liposomal doxorubicin, the names should be written out fully, and in this case, the addition of the brand name may help to prevent a mistake.

The measured height and weight, along with the body surface area (BSA), if applicable, should be readily available, along with the dosage in milligrams per meter squared or kilogram, so that the dosage may be checked. If a chemotherapy regimen is a continuous infusion of 800 mg/m²/day for 4 days, an added safety feature would be to include the total dosage of 3200 mg in order to prevent any ambiguity. In cases where the clinician wants to decrease the dosage based on a laboratory value or side effect, it is recommended that the clinician include that information with the order so that everyone understands what the correct dosage is for that patient. Chemotherapy dosages should be checked for route and dose to determine that the dosages prescribed are correct according to the regimen and do not

exceed dosing guidelines. Appropriate laboratory values should be checked to verify that dosages are correct for any organ dysfunction present, and drug interactions should be scrutinized closely (Tables 88–8 and 88–9). Health care practitioners administering chemotherapy should check the dosage calculation for the patient's weight or BSA along with the five Rs of administering medication (i.e., right patient, right medication, right dose, right route, at the right time). If there is any question about the safe dosage or safe administration of a chemotherapy agent, the chemotherapy should not be administered until the question is resolved.

An area of controversy with chemotherapy dosing: What weight should be used for patients who are morbidly obese? Currently, there is no consensus. Some clinicians cap BSA at some value; some clinicians will use an adjusted weight for the BSA calculation even though there is no recommendation on what adjusted weight to use. This is an area for future research.

Many of the newer agents used to treat cancer are orally administered agents. Clinicians need to be aware of drug-herbal interactions, timing of agents with respect to meals, patient education on correct dosing when multiple dosage forms are used, and reimbursement issues. Table 88–10 presents a summary of timing of oral chemotherapy with respect to food. Information should be provided to the patient both in writing and verbally, as well as to patient

Table 88–8

Empiric Dose Modifications in Patients with Renal Dysfunction

Agent	Organ Dysfunction	Dose Modification
Bleomycin	CrCl = 30–60 mL/min (0.50–1.0 mL/s)	25%–50% decrease
	CrCl = 10–30 mL/min (0.17–0.50 mL/s)	25%–50% decrease
	CrCl less than 10 mL/min (less than 0.17 mL/s)	50% decrease
Capecitabine	CrCl = 30–50 mL/min (0.50–0.84 mL/s)	25% decrease
	CrCl less than 30 mL/min (less than 0.50 mL/s)	Do not use
Carboplatin	Renal insufficiency	Total Dose = AUC × (CrCl
Cisplatin	Use with caution in patients with CrCl less than 50 mL/min (less than 0.84 mL/s)	[in mL/min] + 25)
Cyclophosphamide	Renal failure	Decrease dose 25%
Etoposide	Decrease in proportion to CrCl: 15–50 mL/min (0.25–0.84 mL/s)	Decrease dose 25%
Fludarabine, hydroxyurea	Use in caution in patients with CrCl less than 60 mL/min (less than 1.0 mL/s)	Decrease dose in proportion to CrCl
Ifosfamide	CrCl = 10–50 mL/min (0.17–0.84 mL/s)	Decrease dose 25%
	CrCl = less than 10 mL/min (less than 0.17 mL/s)	Decrease dose 50%
Methotrexate	Decrease in proportion to CrCl Monitor levels closely in all patients receiving high-dose therapy (e.g., 150 mg/m ² or greater)	80 mL/min (1.34 mL/s)–full dose 80 mL/min (1.34 mL/s)–75% 60 mL/min (1.00 mL/s)–63% 50 mL/min (0.84 mL/s)–56% Less than 50 mL/min (less than 0.84 mL/s)–use alternative chemotherapy
Pentostatin	Dose in proportion to CrCl	
Streptozocin	Renal Failure	Decrease dose 50%–75%
Topotecan	CrCl 20–39 mL/min (0.33–0.65 mL/s)	Decrease dose 50%
	CrCl less than 20 mL/min (less than 0.33 mL/s)	Do not use

Table 88-9

Empiric Dose Modifications for Patients with Hepatic Dysfunction

Anthracyclines	Bilirubin 1.2–3.0 mg/dL (20.5– 51.3 μ mol/L)	Decrease dose 50%
	Bilirubin 3.1–5.0 mg/dL (53.0– 85.5 μ mol/L)	Decrease dose 75%
	Bilirubin greater than 5.0 mg/dL (greater than 85.5 μ mol/L)	Omit
Docetaxel	Bilirubin greater than ULN	Do not give
	AST or ALT greater than 1.5 ULN and	Do not give
	Alk Phos greater than 2.5 ULN	
Etoposide	Bilirubin 1.5–3.0 mg/dL (25.7– 51.3 μ mol/L)	Decrease dose 50%
	Bilirubin 3.1–5.0 mg/dL (53.0– 85.5 μ mol/L)	Omit
Imatinib	Bilirubin greater than 3 \times ULN	Withhold until less than 1.5 ULN
Ixabepilone	As a monotherapy agent if AST or ALT greater than 10 \times ULN or bilirubin greater than 3 \times ULN	Contraindicated
	In combination with capecitabine AST or ALT greater than 2.5 \times ULN or bilirubin greater than 1 \times ULN	
	Child–Pugh class C hepatic dysfunction	Dose reduction to 750 mg/day
Lapatinib	Use with caution in hepatic failure	
Paclitaxel	Use with caution in hepatic failure	
Thiotepa	Use with caution in hepatic failure	
Vinblastine, vincristine	Bilirubin 1.5–3.0 mg/dL (25.7–51.3 μ mol/L)	Decrease dose 50%
	Bilirubin 3.1–5.0 mg/dL (53.0–85.5 μ mol/L)	Omit
Vinorelbine	Bilirubin 2.1–3.0 mg/dL (35.9–51.3 μ mol/L)	Decrease dose 50%
	Bilirubin greater than 3 mg/dL (51.3 μ mol/L)	Decrease dose 75%

Vorinostat	X		

caregivers. Particular attention should be paid to educating patients on regimens given Monday through Friday only, daily times 4 weeks and then off 2 weeks. Patients should be encouraged to bring in oral medications with visits so adherence can be checked.

OUTCOME EVALUATION

Once a pathologic diagnosis of cancer is made, the patient may be evaluated by a radiation oncologist, a surgical oncologist, and a medical oncologist. Options for treatment are presented that may include surgery, radiation, chemotherapy, biotherapy, or some combination of these modalities. The goals of treatment vary by the cancer and the stage of disease. For example, the patient who has metastatic kidney cancer could be presented with several options. They may have a possible cure with high-dose aldesleukin or receive palliative therapy with sorafenib or sunitinib, or the patient may decline any therapy because of fears of significant toxicity that would decrease quality of life. In this case, if the patient's performance status is poor, such as an ECOG performance status 3, then the patient would not be a candidate for aldesleukin therapy because of significant toxicity or even death from treatment. The patient with the poor performance status will receive palliative therapy to control symptoms of the disease to improve the quality of life at the end of life. For the patient with a poor performance status and extensive metastatic disease, no treatment of the cancer may be appropriate, and the patient may be enrolled in a hospice program or provided comfort care.

Patient Care and Monitoring

6 Clinicians should play a role in chemotherapy safety, patient education, and monitoring patient response to therapy.

Chemotherapy Administration

1. Evaluate the chemotherapy regimen to ensure the correct dose and route of administration.
2. Check patient laboratory values to ensure that the CBC and organ function studies are normal or within acceptable limits before administering chemotherapy.
3. If a patient has renal or hepatic impairment or a poor metabolizer genotype, adjust chemotherapy doses if necessary.
4. Ensure appropriate antiemetic therapy for the degree of emetogenicity.
5. Assess the regimen to determine if primary prophylaxis with colony-stimulating factors is needed.
6. Assess the patient's concurrent medications for the possibility of drug interactions and discontinue potentially interacting medications, if possible.
7. Use safe handling and disposal methods.

Monitoring

1. Efficacy:
 - Monitor CT scans or other imaging studies, and categorize patient with a complete response (CR), partial response (PR), stable disease (SD), or progressive disease.
2. Toxicity:
 - Monitor CBC and other laboratory tests
 - Monitor patient for other known toxicities of the chemotherapy regimen and decrease the dose or discontinue the regimen if necessary

Abbreviations Introduced in This Chapter

2-CDA	2-Chlorodeoxyadenosine
2-FLAA	2-Fluoro-Ara-AMP
5-FU	Fluorouracil
6-MP	6-Mercaptopurine
6-TG	6-Thioguanine
ADC	Antibody–drug conjugate
ALK	Anaplastic lymphoma kinase gene
ALL	Acute lymphocytic leukemia
AML	Acute myeloid leukemia
Ara-C	Cytarabine
ASCT	Autologous stem cell transplant
ATRA	All-trans-retinoic acid
AUC	Area under the-curve
CD	Cluster of differentiation
c-MET	Mesenchymal epithelial transition
CML	Chronic myeloid leukemia

CTC	Common toxicity criteria
CTLA-4	Cytotoxic T-lymphocytic-associated antigen 4
ECOG	Eastern Cooperative Oncology Group
EGFR	Epidermal growth factor receptor
FdUMP	Fluorodeoxyuridine monophosphate
GIST	Gastrointestinal stromal tumor
HER-2	Human epidermal receptor-2
HPV	Human papillomavirus
IL	Interleukin
LHRH	Luteinizing hormone releasing hormone
MMAE	Monomethyl auristatin E
NCI	National Cancer Institute
NSCLC	Non-small cell lung cancer
PCR	Polymerase chain reaction
PSA	Prostate Specific Antigen
TNM	Tumor, nodes, metastases
TPMT	Thiopurine S-methyltransferase
VEGFR	Vascular Epidermal Growth Factor Receptor

Breast Cancer

Gerald Higa

LEARNING OBJECTIVES

● Upon completion of the chapter, the reader will be able to:

1. List factors associated with an increased risk of breast cancer in the United States.
2. Assess patients for signs and symptoms related to breast cancer in early and late stages of the disease.
3. List all modalities that are appropriate screening tools for breast cancer and determine how they should best be used in the public domain.
4. Discuss available options for breast cancer prevention.
5. Critique available prognostic variables for clinical utility.
6. Determine which patient populations may benefit from systemic adjuvant therapy for breast cancer.
7. Determine the treatment goals for early stage, locally advanced, and metastatic breast cancer.
8. Determine appropriate indications for endocrine therapy, chemotherapy, and biologic therapy for patients with metastatic breast cancer.
9. Evaluate available chemotherapy options for patients with metastatic breast cancer based on pertinent patient and disease state characteristics.
10. Discuss the role of trastuzumab in the management of early and advanced stage breast cancer.

KEY CONCEPTS

- 1 Breast cancer is the most common neoplasm diagnosed in American women, although the disease risk varies by ethnicity.
- 2 Classic breast cancer risk factors, initially derived from epidemiologic studies, now include genetic and nongenetic components.
- 3 Most patients diagnosed with breast cancer have early stage, and potentially curable, disease.
- 4 Early breast cancer is now treated with less aggressive surgical procedures that involve the primary tumor and regional lymph nodes.
- 5 The presence of two receptors, estrogen and HER2/neu, guides the application of systemic therapy for both early and advanced breast cancers.
- 6 Appropriate application of adjuvant endocrine therapy with or without chemotherapy plus trastuzumab (if indicated) reduces the rates of relapse and death.
- 7 Goals of therapy differ between early and metastatic breast cancer—cure in the former and preserving or improving quality of life in the latter.

- 8 In the absence of acute life-threatening complications, initial therapy of estrogen receptor (ER)-positive advanced breast cancer is endocrine therapy.
- 9 Approximately 50% to 60% of women who have not received prior chemotherapy for metastatic disease will respond to chemotherapy regimens; anthracycline- and taxane-containing regimens are the most active.
- 10 Chemotherapy plus trastuzumab (if indicated) is the strategy of choice for ER-negative metastatic disease.

After a sharp increase in new breast cancer diagnoses during the early 1980s and a more modest rise during the latter half of the 1990s, the incidence of invasive disease has decreased slightly over the past 10 years.¹ Moreover, the 5-year survival rates has also improved significantly from 75% to 89% during the mid-1970s and 1996 to 2004, respectively. The latter finding is likely attributable to early detection and the development of effective treatment regimens. Treatment strategies for most breast cancer patients include surgical, radiologic, and pharmacologic therapies.

EPIDEMIOLOGY AND ETIOLOGY

Breast cancer is the most common type of cancer and is second only to lung cancer as a cause of cancer death in American women. In 2012 alone, an estimated 229,000 new cases of invasive breast cancer were diagnosed; and nearly 40,000 women died of complications of the disease.¹ The median age for the diagnosis of breast cancer is 63 years.² Notably, the annual incidence does not include approximately 40,000 patients diagnosed with DCIS or LCIS. **1** *Although the disease occurs more frequently in white women than any other ethnic group, the mortality rate is highest among African Americans.*

Most breast cancers diagnosed are small (2 cm or less), with disease localized in all racial and ethnic groups. However, African American and other minority women have proportionally more cases of advanced disease compared with white women. The reason for the latter finding is believed to be related to barriers in access to care, reduced screening mammography and biological factors.

Although the etiology of breast cancer is largely unknown, a number of factors that increase the risk of developing the disease have been identified. **2** *Additionally, information regarding breast cancer biology suggests that a complex interplay exists among one's sex hormones, genetic factors, environment, and lifestyle. These external and internal factors contribute to the pathogenesis of disease.*

The two variables most strongly associated with the development of breast cancer are gender and age. Although breast cancer is a disease primarily of women, about 1% of the total incidence occur in men.¹ When the stage and other known prognostic factors are controlled for, men have similar treatments and prognoses as women.

The incidence of breast cancer increases with advancing age. Perhaps the most frequently quoted breast cancer statistic is that one in seven women will develop the disease sometime during her lifetime. It should be emphasized that this is a cumulative lifetime risk from birth to 110 years of age and that the estimates are weighted by the probability of surviving through each decade of life.³ Feuer and colleagues developed a more useful method of presenting the risk data based on age intervals.³ As **Table 89-1** demonstrates, the risk of a woman developing breast cancer before the age of 40 years is about one in 250. It is apparent from this table that although the cumulative probability of developing breast cancer increases with age, more than half the risk occurs after the age of 60 years. It is also important to note that the cysts found in fibrocystic breast disease do not develop into breast cancer. As many as 85% of American women have "lumpy breasts," which are typically benign cysts and may have a clinical diagnosis of fibrocystic or benign breast disease. Data suggest that this condition is not typically associated with an increased risk for developing breast cancer.⁴ However, it must be noted that "lumpy breasts" may delay a diagnosis of breast cancer because of an inability of the patient or physician to detect a true malignant lesion.

Table 89-1

Risk of Developing Breast Cancer: SEER Areas, Women, All Races, 1998 to 2000

Age Interval (years)	Probability (%) of Developing Invasive Breast Cancer During the Interval
30-40	0.40 or 1 in 250
40-50	1.45 or 1 in 69
50-60	2.78 or 1 in 36
60-70	3.81 or 1 in 26
From birth to death	13.51 or 1 in 7

Endocrine Factors

2 *A number of endocrine factors have been linked to an increased risk for breast cancer.*^{5,6} Many of the risks relate to the total duration of estrogen exposure. Hence, early menarche (before age 12 years) and late menopause (after age 55 years) are associated with an increased risk of the disease. Support for this belief is the finding that bilateral oophorectomy before age 35 years decreases the relative risk of developing breast cancer.^{5,6} Nulliparity and a late age at first birth (30 years or older) have been reported to increase the lifetime risk of developing breast cancer twofold.^{5,6}

Long-term use of hormone replacement therapy and concurrent use of progestins appear to contribute to breast cancer risk.⁷ Use of postmenopausal estrogen replacement therapy in women with a history of breast cancer is generally contraindicated. However, most experts believe that the safety and benefits of low-dose oral contraceptives currently outweigh the potential risks and that changes in the prescribing practice for the use of oral contraceptives are not warranted. Oral contraceptives are known to reduce the risk of ovarian cancer by about 40% and the risk of endometrial cancer by about 60%.

Genetic Factors

2 *Both personal and family histories influence a woman's risk of developing breast cancer.* A medical history of breast cancer is associated with about a fivefold increased risk of contralateral breast cancer. Cancer of the uterus and ovary also has been associated with an increased risk of developing breast cancer.

For some time, it has been recognized that a family history of breast cancer is strongly associated with a woman's risk for developing the disease. The percentage of all breast cancers in the population that are attributed to family history ranges between 6% and 12%.⁸ Empirical estimates of the risks associated with particular patterns of family history of breast cancer indicate the following:

1. Having any first-degree relative (i.e., mother or sister) with breast cancer increases the risk up to threefold, depending on age.
2. The relative risk is even higher if the first-degree relative was diagnosed with breast cancer at an age younger than 45 years.
3. Having multiple first-degree relatives affected has been inconsistently associated with elevated risks.
4. Having a second-degree relative with breast cancer increases the risk of developing breast cancer by approximately 50% (relative risk, 1.5).
5. Affected family members on the maternal side and the paternal side contribute similarly to the risk.

2 In the early 1990s, the *BRCA1* gene on the long arm of chromosome 17 (17q21) was identified as abnormal in a large percentage of hereditary breast and ovarian cancer patients.^{9,10} A second breast cancer gene, called *BRCA2*, has been mapped to chromosome 13. Both *BRCA1* and *BRCA2* are tumor suppressors. A woman with a strong family history of breast or ovarian cancer, or both, who carries a germ-line mutation of *BRCA1* faces roughly an 85% lifetime risk of breast cancer and a 60% risk of ovarian cancer.¹¹ Carriers of the *BRCA2* mutation have similar risks for breast cancer but much lower risks for ovarian cancer. Jewish people of Eastern European descent (Ashkenazi Jews) have an unusually high (2.5%) carrier rate of germ-line mutations in *BRCA1* and *BRCA2* compared with the rest of the U.S. population.

Women with a strong family history of breast cancer are candidates for genetic testing. A genetic test that evaluates for *BRCA1* and *BRCA2* mutations is commercially available and should be done under the guidance of a genetic counselor. It is recommended for high-risk carriers of *BRCA1* and *BRCA2* mutations to undergo an oophorectomy at completion of childbearing. Bilateral total mastectomy does reduce the risk of breast cancer occurrence; however, both breast and ovarian cancer have been reported in patients who have had prophylactic removal of these organs. It is recommended for *BRCA* carriers who do not opt for surgical prophylaxis to have mammography every 6 months. Carriers may also consider tamoxifen therapy.

Environmental and Lifestyle Factors

2 Experimental and epidemiologic evidence suggests an association between breast cancer and the Western diet (high in calories, fat, and cooked meats). Obesity in postmenopausal women and distribution of body fat around the abdominal region also appear to increase the risk of breast cancer. A recent meta-analysis¹² indicates both a modest positive association between alcohol ingestion and breast cancer in a dose-response relationship. Cigarette smoking and augmentation mammoplasty do not appear to increase the risk of breast cancer. Exercise may provide modest protection against breast cancer¹².

Radiation, an environmental risk factor, is associated with an increased risk of breast cancer in survivors of the atomic

bomb, patients given radiation for postpartum mastitis, women receiving multiple fluoroscopic examinations during therapy for tuberculosis, and patients who receive mediastinal radiation for malignancies. Interestingly, this risk appears to be confined to radiation exposure before age 40 years, which suggests that a “window of initiation” for breast cancer occurs at a relatively early age. Exposure to diagnostic x-rays, including annual screening mammography, does not impart a sufficient dose of radiation for clinical concern.

It should be emphasized that more than 60% of women with breast cancer have no identifiable major risk factor, indicating that the search for the etiology of this disease is largely incomplete.

A number of calculators are available on the Internet to estimate a patient’s risk of developing breast cancer. The National Cancer Institute (NCI) has an online version of the Breast Cancer Risk Assessment Tool that is considered to be the most authoritative and accurate standard (www.cancer.gov/bcrisk-tool). The Breast Cancer Risk Assessment Tool was designed for health professionals to project a women’s individualized risk for invasive breast cancer over a 5-year period and over her lifetime.

PATHOPHYSIOLOGY

The pathologic evaluation of breast lesions serves to establish histologic diagnosis and confirm the presence or absence of other factors believed to influence prognosis. These **prognostic factors** include the presence of necrosis, lymphatic or vascular invasion, nuclear grade, hormone receptor status, proliferative index, amount of aneuploidy, and *HER-2/neu* gene amplification or protein expression.

Invasive Carcinoma

Invasive breast cancers are a histologically heterogeneous group of lesions. Most breast carcinomas are adenocarcinomas and are classified on the basis of their microscopic appearance as ductal or lobular, corresponding to the ducts and lobules of the normal breast. The various histologic types of breast cancer have different prognoses, but it is unknown whether their response to therapy differs because patients in therapeutic trials typically are not stratified according to histologic type. Infiltrating lobular carcinoma commonly metastasizes to meningeal and serosal surfaces, whereas ductal carcinomas usually metastasize to the bone, brain, or liver.

Noninvasive Carcinoma

As with invasive carcinoma, the noninvasive lesions may be divided broadly into ductal and lobular categories. During the past decade, the widespread use of screening mammography and subsequent biopsy, coupled with recognition of noninvasive breast carcinoma by pathologists, has resulted in a significant increase in diagnosis of in situ breast cancer. A detailed discussion of the biology and appropriate management of noninvasive breast cancer is beyond the scope of this chapter, but some of the more salient characteristics of ductal carcinoma in situ (DCIS) and lobular carcinoma in situ (LCIS)

are described below, and readers are referred to a number of excellent reviews for a more comprehensive discussion.^{13,14}

DCIS is diagnosed more frequently than LCIS. Simple or total mastectomy (without lymph node dissection) has been the standard treatment of DCIS for several decades. Breast conservation (i.e., wide local excision followed by irradiation of breast tissue) may be an effective alternative to mastectomy. Although radiation following lumpectomy does not appear to change the survival rate of patients with DCIS, it significantly reduces the incidence of local recurrences and enhances the breast preservation rate in these women. Axillary dissection generally is not indicated because there is only a 1% incidence of axillary node involvement. There is currently no proven benefit for the use of cytotoxic chemotherapy in patients who receive local therapy for DCIS. However, subgroups of patients with DCIS, such as hormone receptor-positive patients, may benefit from the addition of tamoxifen to lumpectomy plus radiation.¹⁵

CLINICAL PRESENTATION AND DIAGNOSIS

Prevention and Early Detection

Current efforts at breast cancer prevention are directed toward the identification and removal of risk factors. Unfortunately, a number of risk factors associated with the development of breast cancer, such as family history of breast cancer or personal history of breast or other gynecologic malignancies, cannot be modified. Isolation and cloning of breast cancer susceptibility genes allow screening of women with histories suggestive of “breast cancer families” and identification of appropriate candidates for prophylactic bilateral mastectomy. Currently, no absolute indications for prophylactic bilateral mastectomy exist. This surgery is

Patient Encounter, Part 1

In September 2005, AD, a 41-year-old business executive mother of two girls, ages 11 and 9 years, had a routine screening mammography. Upon radiographic review, an amorphous abnormality is seen in the upper outer quadrant of the right breast. Fine-needle aspirate of the abnormal area was performed the following day. Frozen section of the specimen indicated hyperplastic changes of ductal epithelial cells. Diagnosis was confirmed on complete pathologic review.

Plan: Repeat the mammogram in 6 months.

What factors are relevant when screening for any disease?

Why is close surveillance necessary in this patient?

considered for high risk, particularly if the woman’s breasts are difficult to evaluate by both physical examination and mammography and if she presents with persistent, disabling fears of breast cancer diagnosis.

The idea that prevention can be achieved pharmacologically is based on clinical trials of tamoxifen, an antiestrogen used as adjuvant therapy for early breast cancer. These trials demonstrate reduced development of contralateral breast cancer and a survival advantage in women who received tamoxifen for 2 to 5 years following mastectomy.^{16–18} Several clinical trials were conducted with tamoxifen, which provided proof of principle that breast cancer risk reduction could be achieved through chemoprevention.^{19–21} A recent meta-analysis of these trials indicates a consistent (and significant) benefit in reducing the risk of developing estrogen receptor (ER)-positive breast cancers in premenopausal and postmenopausal women.²²

Clinical Presentation and Diagnosis of Breast Cancer

Common early signs and symptoms include:

- Painless lump (90% of cases) that is:
 - Solitary
 - Unilateral
 - Solid
 - Hard
 - Irregular
 - Nontender
- Stabbing or aching pain (10% of cases) as the first symptom

Uncommon early signs and symptoms include:

- Nipple discharge (3% of women and 20% of men), retraction, or dimpling

- Eczema appearance of the nipple (Paget’s carcinoma)
- Prominent skin edema, redness, warmth, and induration of the underlying tissue (inflammatory carcinoma)

Metastatic signs and symptoms—tissues most commonly involved with metastases are lymph nodes (other than axillary or internal mammary), skin, bone, liver, lungs, and brain. The following symptoms of metastases will be present in about 10% of patients when they first seek treatment:

- Bone pain
- Difficulty breathing
- Abdominal enlargement
- Jaundice
- Mental status changes

Table 89–2

Guidelines for Early Detection of Breast Cancer

	American Cancer Society ¹⁸	U.S. Preventive Services Task Force ¹⁹	National Cancer Institute ²⁰
BSE	Age 20 years and older: Risk-to-benefit discussion	All ages: NR	NR
CBE	Age 20 to 30 years: Every 3 years	All ages: ± (recommended with mammography)	All ages: Every year
Mammography	Age 40 years and older: Every year Age 40 years and older: Interval not designated	Age 50 years or older: Every 1–2 years (with or without CBE)	Age 40–49: Every 1–2 years Age 50 years and older: Every 1–2 years

±, insufficient data to recommend for or against; BSE, breast self-examination; CBE, clinical breast examination; NR, not recommended.

However, results of the prevention trials also confirmed the increased incidence of tamoxifen-induced endometrial cancer. Because this outcome could have a direct impact on patient acceptance of chemoprevention, a search began for an agent with a better safety profile. A compound related to tamoxifen known as raloxifene was found to reduce the incidence of spinal fractures in postmenopausal women at high risk for osteoporosis.²³ Raloxifene is also an antiestrogen, so its effects on breast and endometrial tissue were closely monitored. After 3 years of raloxifene therapy, investigators found a significant decrease in the incidence of breast cancer without the carcinogenic effect on the endometrium.²⁴

The Study of Tamoxifen and Raloxifene (STAR) trial compared the two agents in postmenopausal women who were considered to be at increased risk (as determined by the Gail model)²⁵ for developing invasive breast cancer.²⁶ Although there was a similar reduction in the incidence of breast cancer, raloxifene had a superior safety profile with regards to uterine cancer and thromboembolic events. Thus, raloxifene is the chemopreventive agent of choice for high-risk postmenopausal women. Because premenopausal women were not included in the STAR trial, tamoxifen is the only agent approved for reducing the risk of breast cancer in younger patients.

The impressive data of the aromatase inhibitors (AIs) in the adjuvant setting provided the rationale and impetus for studying their potential as breast cancer chemoprevention agents. Exemestane is more effective than placebo in reducing the risk of breast cancer in high risk postmenopausal women, although it has not been compared with either tamoxifen or raloxifene. Based on indirect comparisons with tamoxifen and raloxifene, cardiovascular and endometrial toxicity with exemestane may be less, with hot flashes and arthralgias reported most frequently.²⁷

The rationale for early detection of breast cancer is based on the clear relationship between stage of breast cancer at diagnosis and probability of cure. Thus, if breast cancer is detected at a very early stage (i.e., small primary tumor and negative lymph nodes), then conceivably more patients with the disease could be cured. Screening guidelines for early detection of breast cancer have been put forward by the American Cancer Society, the United States Preventive

Services Task Force (USPSTF), and the NCI^{28–30} (Table 89–2). All include recommendations for women at average risk, with some general statements regarding screening for high-risk women as well. Nearly 75% of all breast cancer occurs in women 50 years of age or older, and regular use of screening mammography can reduce mortality from breast cancer by 20% to 40% in this age group. Controversy regarding the use of screening mammography is largely confined to women younger than 50 years of age. After many years of debate, three organizations recommended mammograms in this age group of women every 1 to 2 years except for the USPSTF, which modified its recommendation in 2009.^{28–31}

Patient Encounter, Part 2

HPI: In August of 2006, AD returns for her biannual mammogram. The abnormal area previously visualized appears to be calcified with the lesion measuring 1.2 cm. An ultrasound-guided core biopsy of the lesion was performed the following day. Frozen section of the specimen indicated dysplastic changes with focal nests of neoplastic cells invading the ducts. Pathological review of the tissue sample confirmed a diagnosis of invasive intraductal breast cancer.

PMH: No comorbid medical problems; oral contraceptives between 19 and 24 years of age and for the past 5 years.

FH: Mother with breast cancer at age 45 years (succumbed to disease 2 years after initial diagnosis). Father is alive.

Plan: Discuss management of the cancer with the multidisciplinary breast cancer team.

Is hyperplasia one of the steps in the tumorigenic process? What are the patient's risk factors for developing breast cancer?

What issues should be considered regarding testing for BRCA1 and BRCA2 mutations in this patient? In her two daughters?

Diagnosis

The initial workup for a woman presenting with signs or symptoms suggestive of breast cancer should include a careful history, physical examination of the breast, three-dimensional mammography, and possibly other imaging techniques such as magnetic resonance imaging. Most (80% to 85%) breast cancers are visualized on a mammogram as a mass, a cluster of calcifications, or a combination of both. A breast biopsy is indicated for a mammographic abnormality that suggests malignancy or for a palpable mass on physical examination.

Clinical Staging

Stage (anatomic extent of disease) is defined on the basis of the primary tumor size (T_{1-4}), presence and extent of lymph node involvement (N_{1-3} or pN_{1-3} if pathologic examination of lymph nodes is conducted), and presence or absence of distant metastases (M_{0-1}) (Table 89-3). For a more complete description of the **staging** system, readers are referred to the guidelines.³² Although many possible combinations of T and N are possible within a given stage, simplistically, stage 0

Table 89-3 Tumor, Nodes, Metastasis Stage Grouping for Breast Cancer			
Stage Grouping			
0	T_{is}	N_0	M_0
I	T_1^a	N_0	M_0
IIA	T_0^a	N_1	M_0
	T_1	N_1	M_0
IIB	T_2	N_0	M_0
	T_2	N_1	M_0

Table 89-4

Estimated Stage at Presentation and 5-Year Disease-Free Survival (DFS): Breast Cancer

	Percentage of Total Cases	5-Year DFS ^a (%)
Stage I	40	70–90
Stage II	40	50–70
Stage III	15	20–30
Stage IV	5	0–10 ^b

^aWith current conventional local and systemic therapy.

^bPatients in stage IV are rarely free of disease; however, 10% to 20% of these patients may survive with minimal disease for 5 to 10 years.

represents carcinoma in situ (T_{is}) or disease that has not invaded the basement membrane. Stage I represents small primary tumor without lymph node involvement, and the majority of stage II disease involves regional lymph nodes. Stages I and II are often referred to as early breast cancer. It is in these early stages that the disease is curable. Stage III, also referred to as locally advanced disease, usually represents a large tumor with extensive nodal involvement in which either node or tumor is fixed to the chest wall. Stage IV disease is characterized by the presence of metastases to organs distant from the primary tumor and is often referred to as advanced or metastatic disease, as described earlier. Most cancer today presents in early stages, when prognosis is favorable (Table 89-4).

Prognostic Factors

A number of potential prognostic factors have been identified for breast cancer. *Prognostic factors* are biological or clinical indicators associated with survival independent of therapy. Poor prognostic factors include:

- Age younger than 35 years
- Larger tumor size
- High nuclear grade signifies that a tumor is growing quickly
- Lymph node involvement
- Negative tumor receptor status (i.e., ER-, PR-, and HER2-)
- Over-expression of HER-2/neu

EARLY BREAST CANCER

TREATMENT

Desired Outcome

- 3 Most patients presenting with breast cancer today have an in situ tumor, a small tumor with negative lymph nodes (stage I), or a stage II cancer. The goal of therapy in early breast cancer is **cure**. Surgery alone can cure most, if not all, patients with in situ cancers and approximately half of all patients with stage II cancers.

Patient Encounter, Part 3

HPI: Four days after the diagnosis, AD's case is presented at the weekly meeting of the multidisciplinary breast cancer team to determine the best strategy to manage this patient's disease.

Plan: Discuss the treatment plan with the patient.

What factors should guide treatment of this patient's breast cancer?

Nonpharmacologic Local-Regional Therapy

Surgical procedures have changed drastically over the past 50 years. **4** *Less aggressive surgical options for early invasive breast cancer include the modified radical mastectomy (also termed total mastectomy with **ipsilateral** axillary lymph node dissection) and breast conservation.* In the modified radical mastectomy, the pectoralis minor muscle may be excised, divided, or left intact; more important, there may be variation in the extent of axillary lymph node dissection, ranging from sampling to full dissection. It is important to note that in the elderly patients with comorbid conditions, patients with particularly favorable tumors, or patients whose adjuvant therapy would not be affected by node status, axillary dissection is an optional. Breast conservation consists of lumpectomy, also referred to as segmental or partial mastectomy, and is defined as excision of the primary tumor and adjacent breast tissue followed by radiation therapy to reduce the risk of local recurrence. Removal of level I/II axillary lymph nodes is recommended for completeness of staging and prognostic information. The National Institutes of Health (NIH) Consensus Conference on the Treatment of Early-Stage Breast Cancer addressed the roles of modified radical mastectomy versus breast conservation and concluded that primary therapy for breast cancer stages I and II should be breast conservation.³³ The reason for favoring breast conservation therapy is that it achieves similar results to more extensive surgical procedures and cosmetically superior. Additionally, breast conservation helps to preserve a woman's emotional and psychological well-being.

In most instances, external-beam radiation therapy used in conjunction with breast-conserving procedures involves 4 to 6 weeks of therapy directed to eradicate residual disease. Complications associated with radiation therapy are minor and include erythema of the breast tissue and subsequent shrinkage of total breast mass beyond that predicted on the basis of breast tissue removal alone. Some clinical situations also require postmastectomy radiation therapy as well (see section on locally advanced breast cancer).

Several contraindications to breast conservation must be considered when selecting patients:

- Multiple sites of cancer within the breast
- Pregnancy (patient cannot receive radiation)

- Inability to attain negative pathologic margins on the excised breast specimen
- Preexisting collagen vascular diseases (e.g., scleroderma, systemic lupus erythematosus)
- Diffuse malignant-appearing microcalcifications on mammography
- Prior radiation treatment to the breast or chest wall
- Large tumor volume in a woman with small breasts (better cosmetic results often can be obtained with mastectomy and reconstruction).

The importance of stage I/II axillary dissection is being challenged. Although highly accurate, its morbidity rate is significant, with rates of acute complication and chronic lymphedema of 20% to 30%.^{34,35} Across the United States, a new procedure involving lymphatic mapping and **sentinel lymph node** biopsy is becoming more acceptable at many academic centers.³⁶ The sentinel lymph node is the first lymph node that drains a cancer. Injection of a dye around the primary breast tumor results in identification of the sentinel lymph node in the majority of patients, and the status of this lymph node may predict the status of the remaining nodes in the nodal basin. A sentinel lymph node can be identified in 90% of patients and can accurately predict the status of the remaining axillary nodes in 95% of patients.³⁷

Pharmacologic Systemic Adjuvant Therapy

Unfortunately, breast cancer cells often spread by contiguity, lymph channels, and through the blood to distant sites. This often occurs early in cancer growth, and deposits of tumor cells form in distant sites (**micrometastases**) that cannot be detected with current diagnostic methods and equipment. **Systemic adjuvant therapy** is defined as the administration of systemic therapy following definitive local therapy (i.e., surgery, radiation, or a combination of these) when there is no evidence of metastatic disease but a high likelihood of disease recurrence. **5 6** *Most published results confirm that chemotherapy (in all patients) and hormonal therapy (in patients with **hormone receptor-positive** disease) or chemotherapy plus trastuzumab (if tumor is HER2 positive) result in improved **disease-free survival (DFS)** and/or overall survival (OS) for patients with early-stage breast cancer.*

A standard approach was formalized at the NIH's 2000 Consensus Development Conference on adjuvant therapy for breast cancer.³³ The panel recommended the consideration of adjuvant hormonal therapy for women whose tumors contain hormone receptor protein regardless of age, menopausal status, involvement of axillary lymph nodes, or tumor size. They also recommended that adjuvant chemotherapy be given for essentially all patients with lymph node metastases or breast tumors 1 cm or larger in size.³³

Another group, the St. Gallen expert panel, is convened every 2 years to review new information and establish evidence-based recommendations regarding the treatment of patients with early breast cancer.³⁸ In 2007, the panel

Table 89-5

St. Gallen Risk Classification and Therapy Recommendations

Risk Classification	Low Risk	Intermediate Risk	High Risk
Tumor and patient criteria	Node negative (and all of the following): ER/PR positive; <i>HER-2</i> negative; 2 cm or smaller in size; grade 1; no vascular invasion; 35 years of age or older	1–3 nodes involved with tumor and <i>HER-2</i> negative <i>or</i> Node negative (and at least one of the following): <i>HER-2</i> overexpressed greater than 2 cm in size; grade greater than 1; presence of vascular invasion; younger than 35 years of age	Greater than 4 nodes involved with tumor <i>or</i> 1–3 nodes involved with tumor and <i>HER-2</i> positive
Adjuvant therapy	Endocrine or no therapy	Endocrine responsive: Endocrine therapy or chemotherapy followed by endocrine therapy; add trastuzumab if <i>HER-2</i> positive Endocrine uncertain: Chemotherapy followed by endocrine therapy; add trastuzumab if <i>HER-2</i> positive Endocrine nonresponsive: Chemotherapy; add trastuzumab if <i>HER-2</i> positive	Endocrine responsive or uncertain: Chemotherapy followed by endocrine therapy; add trastuzumab if <i>HER-2</i> positive Endocrine nonresponsive: Chemotherapy; add trastuzumab if <i>HER-2</i> positive

From Morrow M, Harris JR. Local management of invasive breast cancer. In: Diseases of the Breast, 2nd ed. Lippincott Philadelphia, Williams & Wilkins, 2000:515–560.

endorsed the concept and definition of “endocrine-responsive” tumors, as well as the classification of patients into three risk groups. Tumors are categorized as endocrine responsive (10% or greater number of ER-positive tumor cells), endocrine nonresponsive (0% ER-positive tumor cells), and endocrine responsive uncertain (1% to 9% ER-positive tumor cells). Risk classification is based on a number of tumor and patient characteristics with the regional lymph node status being the major criterion. The most prominent recommendation in 2007 was the addition of adjuvant trastuzumab for all patients with *HER-2*/neu overexpressing tumors. A summary of risk classification and therapy recommendations is provided in [Table 89-5](#).

The National Comprehensive Cancer Network (NCCN) also has developed practice guidelines for the treatment of early breast cancer.³⁹ These guidelines recommend, though the prognosis of patients with tumors 1 cm or smaller and negative or micro tumor-involved nodes is generally good, the decision to use trastuzumab must consider the relative clinical benefits and drug-associated toxicities. Additionally, adjuvant trastuzumab should be given for at least 1 year in the absence of treatment-limiting toxicity. Finally, the use of preoperative (*neoadjuvant*) systemic therapy is gaining favor in both early stage and locally advanced breast cancers. When used before surgery, treatments incorporating trastuzumab should be given for at least 9 weeks before the operation is performed.

Although **neoadjuvant therapy** most often consists of cytotoxic chemotherapy, hormonal agents may be preferable in patients with significant comorbidities. Nonetheless, this strategy can be used to determine tumor response in vivo (an important prognostic indicator) as well as

minimize the amount of breast tissue resected. Although this approach to therapy generally is reserved for patients with inoperable tumors (locally advanced), early-stage breast cancer patients who meet the criteria for breast-conserving therapy, excluding tumor size, may be considered for preoperative systemic therapy.

► Adjuvant Chemotherapy

6 Cytotoxic drugs that have been used most frequently in combination as adjuvant therapy of breast cancer include doxorubicin, epirubicin, cyclophosphamide, paclitaxel, docetaxel, methotrexate, and fluorouracil. The most common chemotherapy regimens used in the adjuvant and metastatic settings are listed in [Table 89-6](#). The dose-limiting toxicities and other significant toxicities are listed for each chemotherapeutic agent in [Table 89-7](#).

The basic principle of adjuvant therapy for any cancer type is that the regimen with the highest response rate in advanced disease should be the optimal regimen for use in the adjuvant setting. Theoretically, early administration of effective combination chemotherapy at a time when the tumor burden is low should increase the likelihood of cure and minimize the emergence of drug-resistant tumor cell clones. Anthracyclines (e.g., doxorubicin and epirubicin) historically have been referred to as the most active class of chemotherapy agents in the treatment of metastatic breast cancer. This has led to the assumption that anthracycline-containing regimens are associated with a higher cure rate than non-anthracycline-containing regimens.

The taxanes (e.g., paclitaxel and docetaxel) are a relatively newer class of agents that rival the anthracyclines in their

Patient Encounter, Part 4

HPI: Staging workup for the patient AD thus far included bone and CT scans, which were negative for objective evidence of distant disease. Liver function tests were normal. After presenting all of the information to the patient, it was decided (with the patient's concurrence) that management of the cancer would include surgery followed by external beam radiation, then systemic adjuvant therapy. Ten days after the diagnosis, a lumpectomy was performed with surgical margins free of tumor. The tumor measured 1.7 cm at its greatest dimension. Sentinel node biopsy was positive for tumor. Tumor ER and PR were both positive; HER2 gene amplification was negative by FISH. *BRCA1* and *BRCA2* mutations were present.

Plan: Complete staging and plans for managing the patient.

What is the stage of the breast cancer in this patient?

What would be the rationale for giving systemic adjuvant therapy?

If systemic therapy is used, what agents should this patient receive?

When should endocrine therapy begin?

Is there a role for oophorectomy in this patient?

Should the patient receive zoledronic acid?

activity in metastatic breast cancer, becoming the most active class of chemotherapy for this disease.

Although the optimal duration of adjuvant chemotherapy administration is unknown, it appears to be 12 to 24 weeks depending on the adjuvant regimen. Chemotherapy is usually initiated within 3 weeks of surgical removal of the primary tumor. Dose intensity and dose density appear to be critical factors in achieving optimal outcomes in adjuvant breast cancer therapy. *Dose intensity* is defined as the amount of drug administered per unit of time and typically is reported in milligrams per square meter of body surface area per week ($\text{mg}/\text{m}^2/\text{wk}$). Increasing dose, decreasing time, or both can increase the dose intensity. *Dose density* is equivalent to the concept of increasing dose intensity by decreasing the time between treatment cycles. Reducing the dose for standard treatment regimens should be avoided unless necessitated by severe toxicity. On the other hand, increasing doses beyond those contained in standard treatment regimens does not appear to add benefit because there is a threshold for dosing adjuvant chemotherapy above which only additional toxicity is seen without any improvement in patient outcomes. The short-term toxic effects of chemotherapy used in the adjuvant setting generally are well tolerated. Although a number of investigators have demonstrated a reduction in quality of life, most patients are able to maintain a reasonable level of functional, emotional, and social well-being during

treatment.⁴⁰ In general, supportive therapy of the patient receiving systemic adjuvant chemotherapy has improved in the past decade. Increased attention to the impact of symptoms on quality of life may account for some of this improvement. In addition, antiemetics that block serotonin and substance P have become available to assist in managing chemotherapy-induced nausea and vomiting, and colony-stimulating factors often are helpful in preventing febrile neutropenia, particularly in elderly patients or patients receiving dose-dense chemotherapy regimens. A number of side effects are common with the regimens used, and patients should be counseled appropriately regarding the likelihood of alopecia, weight gain, and fatigue. Patients who are menstruating usually experience a cessation of menses that may or may not return. Along with cessation of menses are accompanying signs and symptoms of menopause. Deep vein thrombosis has been reported in women receiving combination chemotherapy regimens.⁴¹ A recent study estimated that 1–10 of 10,000 patients treated for 6 months with cyclophosphamide-based regimens are expected to have leukemia within 10 years of diagnosis of breast cancer.⁴² Cardiomyopathy induced by doxorubicin occurs less than 1% of the time in women whose total dose of doxorubicin is less than $320 \text{ mg}/\text{m}^2$.⁴³ It should be noted that epirubicin in the adjuvant setting is given at a dose of 100 to $120 \text{ mg}/\text{m}^2$.⁴⁴ At this dose, epirubicin has an equal chance of causing cardiomyopathy as standard doxorubicin doses when both agents are given as bolus or short infusions. Taxanes often are associated with hypersensitivity reactions, peripheral neuropathy, and/or myalgias and arthralgias for a few days following the infusion.

It is important to note that the magnitude of survival benefit for chemotherapy appears to be small, with an absolute reduction in the mortality rate of only 5% at 10 years for patients with negative axillary lymph nodes and 10% for patients with positive axillary lymph nodes. Regardless, it has been reported that most patients with early breast cancer would accept drug-related toxicities to achieve the modest overall benefits.^{45,46} Because the risks are not insignificant, investigators have been searching for ways to identify patients who could avoid chemotherapy without altering the disease prognosis. Recently, three potential gene expression assays (e.g., Oncotype DX, MammaPrint, and H/I) have become commercially available. Of the three, Oncotype DX provides the strongest evidence that a subset of patients, especially those with ER-positive, lymph node-negative tumors, derive little or no benefit from adjuvant chemotherapy when compared with the use of hormonal therapy alone.⁴⁷ Newer data suggest this is also true for patients with lymph node-positive disease.⁴⁸ In essence, genomic analyses may play an important role in improving risk stratification and determining chemotherapy benefit.⁴⁹

► Adjuvant Biologic Therapy

Trastuzumab is a monoclonal antibody directed against the HER-2/neu receptor. HER-2/neu is a member of the erbB (or HER) growth factor receptor family and is expressed

Common Chemotherapy Regimens for Breast Cancer (Continued)

Metastatic Single-Agent Chemotherapy

Docetaxel

Docetaxel 60–100 mg/m² IV over 1 hour
Repeat cycles every 21 days^a
or
Docetaxel 30–35 mg/m²/wk IV over 30 minutes
Repeat dose every 7 days^p

Capecitabine

Capecitabine 2,000–2,500 mg/m²/day orally, divided twice daily
for 14 days
Repeat cycles every 21 days^{a,r}

Docetaxel + Capecitabine

Docetaxel 75 mg/m² IV over 1 hour, day 1
Capecitabine 2,000–2,500 mg/m²/day orally divided twice
daily for 14 days
Repeat cycles every 21 days^r

Epirubicin + Docetaxel^s

Epirubicin 70–90 mg/m² IV bolus
Followed by:
Docetaxel 70–90 mg/m² IV over 1 hour
Repeat cycles every 21 days^r

Gemcitabine

Gemcitabine 600–1,000 mg/m²/wk IV, days 1, 8, and 15
Repeat cycles every 28 days (may need to hold day-15 dose based on
blood counts)^q

Liposomal Doxorubicin

Liposomal doxorubicin 30–50 mg/m² IV over 90 minutes
Repeat cycles every 21–28 days^s

Doxorubicin + Docetaxel^s

Doxorubicin 50 mg/m² IV bolus, day 1
Followed by:
Docetaxel 75 mg/m² IV over 1 hour, day 1
Repeat cycles every 21 days^r

Pharmacokinetic interactions make these regimens more difficult to give.

IV, intravenous.

at low levels in the epithelial cells of normal breast tissue. Overexpression of HER-2/neu is associated with increased signaling in pathways that mediate cellular growth and division. Most experts agree that women whose tumors overexpress HER-2/neu appear to be relatively resistant to alkylating agent–based adjuvant therapy and may derive greater benefit from an anthracycline-based adjuvant therapy regimen.^{50–52}

Although HER-2/neu positively, though not absolutely, predicts response to trastuzumab therapy, receptor overexpression is also considered a poor prognostic factor. **6** *Currently, the use of trastuzumab is indicated for treatment of adjuvant and metastatic breast cancer in patients who have tumors that overexpress HER-2/neu.*³⁹ It is important to note that trastuzumab therapy should not be given concurrently with the anthracyclines because of increased risk of cardiotoxicity (see section on metastatic breast cancer).

► **Adjuvant Endocrine Therapy**

6 *Hormonal therapies that have been studied in the treatment of primary or early breast cancer include selective estrogen receptor modulators (SERMs), oophorectomy, ovarian irradiation, luteinizing hormone–releasing hormone (LHRH) agonists, and AIs.*

5 *Hormone receptors are used clinically as indicators of prognosis and to **predict response** to hormone therapy.* Hormone receptors are cytoplasmic proteins that transmit signals to the nucleus of the cell for growth and proliferation. The hormone receptors clinically useful in discussions of breast cancer include the ER and the progesterone receptor (PR). The presence of these proteins in the primary tumor is measured routinely by enzyme-linked immunochemical assays and radio assays (enzyme-linked immunosorbent assay). About 50% to 70% of patients with primary or

Table 89-7

Toxicities of Common Chemotherapies Used for Breast Cancer

Class	Drug	Dose-Limiting Toxicities	Other Toxicities
Anthracyclines	Doxorubicin, epirubicin	Myelosuppression, cardiomyopathy	Alopecia, nausea, vomiting, stomatitis, ulceration, and necrosis with extravasation, red-colored urine, radiation-recall effect
	Liposomal doxorubicin	Myelosuppression, palmar-plantar erythrodysesthesia (hand-foot syndrome)	Alopecia, infusion reactions, stomatitis, fatigue, nausea, vomiting
Taxanes	Paclitaxel	Neutropenia, peripheral neuropathy, hypersensitivity reactions	Alopecia, fluid retention, myalgia, skin reactions, ulceration, and necrosis with extravasation, bradycardia, stomatitis
	Docetaxel	Myelosuppression, severe fluid retention	Alopecia, fatigue, stomatitis, nausea, vomiting, diarrhea, peripheral neuropathy, nail disorder, skin reactions, hypersensitivity reactions
Antimetabolites	Capecitabine	Diarrhea, palmar-plantar erythrodysesthesia (hand-foot syndrome)	Myelosuppression, stomatitis, nausea, vomiting
	Gemcitabine	Myelosuppression (especially thrombocytopenia)	Flulike syndrome (fever, chills, myalgias, and arthralgias), nausea
	Fluorouracil	Myelosuppression	Stomatitis, diarrhea, alopecia
Vinca alkaloids	Methotrexate	Myelosuppression, stomatitis	Diarrhea, nausea, vomiting, renal toxicity
	Vinorelbine	Neutropenia	Fatigue, nausea, vomiting, ulceration, and necrosis with extravasation
Alkylating agents	Cyclophosphamide	Myelosuppression, hemorrhagic cystitis	Alopecia, stomatitis, amenorrhea, aspermia

metastatic breast cancer have hormone receptor–positive tumors. Tumors that are hormone receptor positive are associated with superior response to hormone therapy, a longer disease-free interval between primary and subsequent metastatic disease, and a favorable prognosis. Hormone receptor–positive tumors are more common in postmenopausal patients than in premenopausal patients. Many experts believe that breast cancer in postmenopausal women is substantially different from that occurring in premenopausal women.

Tamoxifen traditionally was the “gold standard” adjuvant hormonal therapy and has been used in the adjuvant setting for 3 decades. Tamoxifen is antiestrogenic in breast cancer cells, but it appears to have estrogenic properties in other tissues and organs.^{53,54} Newer information confirms that tamoxifen and other similar drugs have many estrogenic and antiestrogenic effects that depend on the tissue and the gene in question. Women receiving adjuvant tamoxifen therapy have a reduction in recurrence and mortality compared with women not receiving tamoxifen therapy.⁵⁵ This observation, coupled with evidence of tamoxifen’s tolerability, including beneficial estrogenic effects on the lipid profile and bone density, led to tamoxifen being the hormonal agent of choice.

Tamoxifen therapy is initiated shortly after surgery or as soon as pathology results are known. Because many patients receive chemotherapy, administration of tamoxifen should begin after completion of chemotherapy. This practice is supported by a study which showed after a median follow-up of 8.5 years, the administration of sequential tamoxifen resulted in an estimated DFS advantage of 18% (hazard

ratio [HR], 1.18) compared with the *concurrent* use of tamoxifen with chemotherapy.⁵⁶ Data suggest the growth-inhibitory effect of tamoxifen diminished the cytotoxic effect of chemotherapy, resulting in a shorter DFS in women who received these two agents concurrently.

Patient Encounter, Part 5

HPI: Five years have passed since the original diagnosis. AD returns for her annual checkup. She continues tamoxifen, and except for occasional hot flashes, she is doing very well. Laboratory tests are all within normal limits. There is no abnormal bleeding. Psychosocial evaluation reports a well-adjusted woman, devoted mother, and consummate professional.

Plan: Complete 5 years of tamoxifen. Monitor bone density. Judicious surveillance for disease recurrence.

Should the patient be continued on endocrine therapy for an additional 5 years?

If zoledronic acid was not used initially, should the agent be implemented if the patient chooses to continue endocrine therapy?

How much longer does the patient need to be followed for her breast cancer?

Table 89-8

Breast Cancer Pharmacogenomics

Gene or Gene Product	Drug	Effect on Drug	Comment
<i>CYP2D6</i>	Tamoxifen	Enzyme responsible for metabolic activation of tamoxifen	Genetic variants of <i>CYP2D6</i> with low metabolizing activity or co-prescribed drugs that inhibit <i>CYP2D6</i> (e.g., fluoxetine and paroxetine) are inconsistently associated with increased risk of disease recurrence and shorter DFS
<i>HER2/neu</i>	Anthracycline-containing chemotherapy regimens	Precise mechanistic effect on drug therapy not known	Clinical trial data indicate a differential benefit of the anthracyclines; these data also support the belief that the anthracyclines are one of the most active class of drugs for breast cancer
	Trastuzumab	Gene amplification and protein overexpression have predictive value	Predictive value relates to the likelihood of response to trastuzumab (conversely, the agent is of no benefit in patients with <i>HER-2</i> -negative disease)
	Lapatinib	Gene amplification and protein overexpression has predictive value	Beneficial in patients with trastuzumab resistant disease; may be beneficial in brain metastasis
Dihydropyrimidine dehydrogenase	5-FU	Inactivates 5-FU	Low DPD activity associated with increased normal tissue toxicity
Thymidine phosphorylase	Capecitabine	Converts drug to 5-FU	Oral TP/DPD ratio appears to determine tumor 5-FU levels

DFS, disease-free survival; 5-FU, 5-fluorouracil.

From Refs. 50, 51, 57–61, 83, and 89.

Adjuvant tamoxifen (20 mg/day) is currently given for 5 years,⁵⁷ but two ongoing clinical trials are evaluating whether tamoxifen treatment for 10 years results in improved patient outcome. Because of the significant side effects of tamoxifen, all patients must be counseled properly about warning signs of endometrial cancer (i.e., vaginal bleeding or groin pain or pressure) and thromboembolism (i.e., chest pain, trouble breathing, changes in vision, one-sided weakness, or pain or swelling in the legs).

An intriguing observation associated with the adjuvant tamoxifen trials is related to the role of pharmacogenomics in tailoring therapy to individual patients (Table 89-8). For example, evidence indicates that germline variants of *CYP2D6* are associated with substantially lower concentrations endoxifen, the metabolite of tamoxifen, significant disease recurrence, and shorter DFS.^{58,59} Consistent with these findings, additional data demonstrate that concomitant administration *CYP2D6* inhibitors result in reduced plasma levels of endoxifen and is an independent predictor of breast cancer outcome.⁶⁰⁻⁶² However, discordant results of a more recent study have been presented.⁶³

In premenopausal women, the use of LHRH agonists or other means of ovarian ablation have been shown beneficial in the adjuvant setting.⁶⁴ The use of goserelin, an LHRH agonist, alone or with tamoxifen, has been compared with standard chemotherapy regimens (see Table 89-6). As a single agent, goserelin appears to provide similar benefit to CMF for node-positive, ER-positive tumors in premenopausal breast cancer patients.⁶⁵ In another trial, a

significant advantage of endocrine therapy in terms of DFS over chemotherapy alone was demonstrated after a median follow-up of 6 years.⁶⁶ Retrospective reviews have found that premenopausal women who cease to menstruate with chemotherapy may have a better survival than women who continue to menstruate.⁶⁷ Therefore, the role of an LHRH agonist after chemotherapy in women who continue to menstruate is being investigated.

In postmenopausal women, the use of adjuvant AIs has been studied in three different ways: (a) direct comparison with tamoxifen for adjuvant hormonal therapy, (b) sequential use after 5 years of adjuvant tamoxifen therapy, and (c) sequential use after 2 to 3 years of adjuvant tamoxifen. Based on the positive results of several studies, oncology groups recommend AIs as the endocrine therapy of choice for postmenopausal women with ER-positive breast cancer.^{38,68} However, it is still unclear if AIs should be used instead of or sequentially when tamoxifen has been given for 2 to 5 years.³⁸ Nonetheless, a survival benefit appears to be emerging with sequential administration of anastrozole after 2 to 5 years of initial tamoxifen therapy.⁶⁹

The NCCN Practice Guidelines recommend “bone mineral density determination at initiation of AI therapy and periodically thereafter.”³⁹ Other concerns related to changes in blood lipids and cardiovascular disease requires further study. Successful coadministration of bisphosphonates with the AIs has been accomplished in many patients in the metastatic setting. The three available AIs are exemestane, anastrozole, and letrozole (Table 89-9).

Table 89–9

Endocrine Therapies Used for Metastatic Breast Cancer

Class	Drug	Dose	Side Effects	
Aromatase inhibitors	Nonsteroidal	Anastrozole Letrozole	1 mg/day PO 2.5 mg/day PO	Hot flashes, arthralgias, myalgias, headaches, diarrhea, mild nausea
	Steroidal	Exemestane	25 mg/day PO	
	Antiestrogens	SERMs	Tamoxifen Toremifene	
	SERDs	Fulvestrant	250 mg IM every 28 days	Hot flashes, injection-site reactions, possibly thromboembolism
LHRH analogs	Goserelin Leuprolide Triptorelin	3.6 mg SC every 28 days 7.5 mg IM every 28 days 3.75 mg IM every 28 days	Hot flashes, amenorrhea, menopausal symptoms, injection-site reactions	
Progestins	Megestrol acetate Medroxyprogesterone	40 mg PO 4 for a day 400–1,000 mg IM every week	Weight gain, hot flashes, vaginal bleeding, edema, thromboembolism	
Androgens	Fluoxymesterone	10 mg PO twice a day	Deepening voice, alopecia, hirsutism, facial or truncal acne, fluid retention, menstrual irregularities, cholestatic jaundice	
Estrogens	Diethylstilbestrol	5 mg PO 3 for a day	Nausea or vomiting, fluid retention, anorexia, thromboembolism, hepatic dysfunction	
	Ethinyl estradiol	1 mg PO 3 for a day		
	Conjugated estrogens	2.5 mg PO 3 for a day		

IM, intramuscular; LHRH, luteinizing hormone–releasing hormone; PO, oral; SC, subcutaneous; SERD, selective estrogen-receptor downregulator; SERM, selective estrogen-receptor modulator.

LOCALLY ADVANCED BREAST CANCER (STAGE III)

TREATMENT

Desired Outcome

Locally advanced breast cancer generally refers to breast carcinomas with significant primary tumor and nodal disease but in which distant metastases cannot be documented. A wide variety of clinical scenarios can be seen within this group of patients, including neglected tumors that have spread locally and inflammatory breast cancers that are a unique clinical entity. Patients with inflammatory breast cancer are often treated inappropriately for cellulitis for several weeks to months.

- Treatment of stage III breast cancer generally consists of a combination of surgery, radiation, and chemotherapy (i.e., **combined modality**) administered in an aggressive approach with the treatment goal of a cure. In patients with locally advanced breast cancer, systemic relapse and death are common even when local-regional control is accomplished.⁷⁰ These observations led to the use of neoadjuvant or primary chemotherapy as an approach to render inoperable tumors resectable even with the possibility of breast-conserving surgery. Theoretical advantages to this method include potential benefits related to early initiation of systemic therapy, delivery of drugs through an intact vasculature, in vivo assessment of treatment response, and an opportunity to evaluate the biologic effects of the systemic therapy. However, the use of this approach does not use well-validated pathologic prognostic markers, such as initial tumor size and involvement of axillary lymph nodes.

Pharmacologic Therapy

- For patients with inoperable breast cancer, including inflammatory breast cancer, the treatment objective is to obtain tumor resectability using neoadjuvant chemotherapy. After neoadjuvant chemotherapy, most tumors respond with more than a 50% decrease in tumor size, and about 70% of patients experience tumor downstaging. Chemotherapy regimens used in stage III breast cancer are similar to those used in the adjuvant setting. Supporting evidence for each individual regimen differs, but available data support the use of anthracycline-containing regimens, incorporation of the taxanes, and approaches to improve dose density or dose intensity.⁷⁰ Neoadjuvant endocrine therapy may be an option for patients who have unresectable, hormone receptor–positive tumors and unable to receive chemotherapy (e.g., multiple comorbid conditions). Even though not an approved indication, several preliminary clinical studies have demonstrated the efficacy of neo-adjuvant trastuzumab in patients with HER-2-overexpressing tumors. In terms of local therapy, the extent of surgery will be determined by a patient's response to chemo- or endocrine therapy, the wishes of the patient, and the cosmetic results likely to be achieved. Adjuvant radiation therapy should be administered to all patients with locally advanced breast cancer to minimize local recurrences regardless of the type of surgery used for that individual patient (e.g., mastectomy or segmental mastectomy). Inoperable tumors that are unresponsive to systemic chemotherapy may require radiation for local management; however, these tumors may be ineligible for subsequent surgical resection. Such patients have a very poor prognosis and are not commonly seen. For most patients in this category, cure is still the primary goal of therapy.

METASTATIC BREAST CANCER (STAGE IV)**TREATMENT****Desired Outcome**

7 The goal of therapy with early and locally advanced breast cancer is to cure the disease. Currently, breast cancer is incurable after it has advanced beyond local-regional disease.

Goals for treatment of metastatic breast cancer are to improve symptoms; maintain quality of life; and if possible, prolong survival. Thus, it is important to choose therapy with good activity while minimizing toxicities. Treatment of metastatic breast cancer with either cytotoxic or endocrine therapy often results in regression of disease and improvement in quality of life.

General Approach to Treatment

- 5 The choice of therapy for metastatic disease is based on the site of disease involvement and presence or absence of certain characteristics (i.e., hormone and HER-2 receptor status of the primary tumor). For example, patients with ER-positive tumors who experience a long DFS following local-regional therapy or have disease located primarily in bone or soft tissue often respond to endocrine therapy. Patients with asymptomatic visceral involvement (e.g., liver or lung) may be candidates for hormonal therapy.
- 8 Patients who are hormone receptor positive generally receive initial endocrine therapy followed by combination chemotherapy when endocrine therapy fails. Patients who respond to initial endocrine therapy often respond to a second (or even third) hormonal manipulation, although the response rate is lower and duration of response is shorter with second- and third-line hormonal therapies. About 50% to 60% of ER-positive patients and 75% to 80% of ER- and PR-positive patients respond to hormonal therapy; however, the response rate of ER- and PR-negative tumors is less than 10%. Thus, the primary factor determining the choice of endocrine versus cytotoxic chemotherapy is the presence of hormone receptors in the primary breast tumor.
- Patients who are hormone receptor negative with rapidly progressive or symptomatic disease involving the liver, lung, or central nervous system and those having progressed on initial endocrine therapy usually are treated with cytotoxic chemotherapy.
- 9 Chemotherapy results in an objective response in about 50% to 60% of patients previously unexposed to chemotherapy. Most patients have partial responses, but complete disappearance (i.e., **complete response**) of disease occurs in fewer than 20% of patients. The median duration of response is 5 to 12 months, although some patients have an excellent response to an initial course of chemotherapy and may live 5 to 10 years without evidence of disease. In general, survival of patients after treatment with commonly used drug combinations for metastatic breast cancer is a median of 14 to 33 months. The response rate to second- and third-line combination chemotherapy varies from 20% to 40% depending on the previous chemotherapy regimens the patients have received. Combinations of different hormonal

therapies or chemotherapy plus hormones are not used in the setting of metastatic breast cancer owing to the lack of increased efficacy and evidence of increased toxicity.

- 10 Patients with tumors that overexpress HER-2/neu should be considered for treatment with trastuzumab, usually in combination with chemotherapy.

Pharmacologic Systemic Therapy**► Endocrine Therapy**

The pharmacologic goals of endocrine therapy for breast cancer are to decrease circulating levels of estrogen and/or to prevent the effects of estrogen on the breast cancer cell (targeted therapy) through blocking the hormone receptors or downregulating the presence of those receptors. Achievement of these goals is independent of menopausal status. Many endocrine therapies are available to target these goals. Combination studies also have been conducted in an attempt to improve patient outcomes. Unfortunately, many combinations do not improve efficacy but they do increase toxicity. Therefore, therapy involving combinations of endocrine agents is not recommended outside the context of a clinical trial. Thus, patients are often treated with a series of endocrine agents over several years before chemotherapy is considered.

Until recently, there was little evidence supporting improved response or survival benefit from one endocrine therapy superior to that achieved with other therapies. Given this equality in efficacy, the choice of a particular endocrine therapy was primarily based on toxicity (Table 89–9), resulting in the use of tamoxifen as the preferred initial agent when metastasis is present. An exception to this occurs if a patient is receiving adjuvant tamoxifen at the time or within 1 year of occurrence of metastatic disease.

Over the past decade, new information has been published regarding the use of a new generation of AIs. These data have changed the way patients with metastatic breast cancer and early stage breast cancer are treated. In postmenopausal and women without functioning ovaries, the main source of estrogen is derived from peripheral conversion of androstenedione and testosterone produced by the adrenal gland to estrone and estradiol. This conversion process requires aromatase. This enzyme also catalyzes the conversion of androgens to estrogens in the ovary in premenopausal women and in extraglandular tissue, including the breast itself, in postmenopausal women. Therefore, AIs effectively reduce the level of circulating estrogens, as well as estrogens in the target organ. Their toxicity profile consists mainly of skeletal complications such as fractures, nausea, hot flashes, arthralgias or myalgias, and mild fatigue. Anastrozole and letrozole are nonsteroidal compounds that exhibit reversible, competitive inhibition of aromatase. Exemestane is a steroidal compound that binds irreversibly to aromatase, forming a covalent bond. However, clinical evidence does not demonstrate superior results with exemestane over the other agents in this class.

The AIs are used as first-line therapy for ER-positive advanced breast cancer in postmenopausal women. Large trials have

compared these agents with tamoxifen and have found similar response rates and a longer median time to progression for patients receiving the selective AIs.⁵⁰ A consistent finding in these trials was a lower incidence of thromboembolic events and vaginal bleeding in patients treated with an AI. This led to the conclusion that the new AIs were superior to tamoxifen as first-line therapy for advanced breast cancer in postmenopausal women. Use of exemestane after treatment with a nonsteroidal inhibitor may provide some benefit. This is a common practice based on small clinical trials investigating this sequential approach to therapy.⁷¹ The opposite sequence also has shown some benefit. Therefore, patients may receive two AIs (first and second line sequentially), especially patients who progress while on adjuvant tamoxifen therapy.

The AIs are only used in postmenopausal women. Premenopausal or perimenopausal women with functioning ovaries are not appropriate candidates for these therapies, at least based on the available evidence. Use of the AIs in addition to ovarian ablation (e.g., oophorectomy or LHRH agonists) is currently being investigated. The use of AIs in men with advanced breast cancer should be avoided. Available data suggest the use of these agents in men increases circulating levels of testosterone, which may negate the therapeutic effects of the drug.⁷²

Antiestrogens bind to ERs, preventing receptor-mediated gene transcription, and therefore are used to block the effect of estrogen on the end target. This class of agents now is subdivided into two pharmacologic categories, SERMs and pure antiestrogens. SERMs include tamoxifen and toremifene and demonstrate tissue-specific activity, both estrogenic and antiestrogenic, as described previously. The agonistic activity is thought to be responsible for many of the adverse reactions seen with these agents, including the increased risk of endometrial cancer. In an effort to minimize this agonistic activity, research has led to the development of pure estrogen receptor antagonists that lack estrogen agonist activity. Pure antiestrogens are a new class of agents that are also referred to as *selective estrogen-receptor downregulators* (SERDs). These molecules bind to ER and degrade the drug-ER complex. Fulvestrant is the only pure antiestrogen available commercially in the United States.

Tamoxifen can be used in both premenopausal and postmenopausal women with metastatic breast cancer who have tumors that are hormone receptor positive. The toxicities of tamoxifen are described in the section on adjuvant endocrine therapy. The only additional toxicity that one might expect to find in the setting of metastatic breast cancer (specifically bone metastases) is a tumor flare or hypercalcemia, which occurs in approximately 5% of patients following the initiation of any SERM therapy and is not an indication to discontinue SERM therapy. It is generally accepted that this is a positive indication that the patient will respond to endocrine therapy.

Fulvestrant is approved as second-line therapy of postmenopausal metastatic breast cancer patients who have tumors that are hormone receptor positive. Studies examining the role of fulvestrant in the treatment of metastatic breast cancer have compared this agent with anastrozole. Given anastrozole's mechanism of action, only postmenopausal

women were eligible for these trials. In the comparative trials with fulvestrant and anastrozole, similar efficacy and safety were demonstrated with both agents when given after patients progressed on tamoxifen therapy.^{73,74} Adverse events related to fulvestrant include injection-site reactions, hot flashes, asthenia, and headaches. This agent is a good option for patients who are unable to take an oral medication because it is given as an intramuscular injection every 28 days. There is no biological reason why fulvestrant should not produce similar outcomes in premenopausal women; however, data supporting this hypothesis have not been published confirming the safety or efficacy in this group. Another goal of antitumor treatment is to reduce estrogen production in premenopausal women using surgery, irradiation, or medication. Statistical significance was not found in two randomized trials evaluating the overall response rate between tamoxifen and oophorectomy in premenopausal women. However, the secondary response rate to oophorectomy after tamoxifen treatment was somewhat higher than the response to tamoxifen after primary oophorectomy (33% versus 11%).⁷⁵ Some experts interpret this as suggesting that tamoxifen does not completely antagonize available estrogen, particularly in premenopausal women. Ovarian ablation (surgically or chemically) is still used commonly in some parts of the United States and is considered by many specialists to be the endocrine therapy of choice in premenopausal women. The mortality rate with surgical oophorectomy is low (less than 2% to 3% in appropriately selected patients). Medical inhibition of estrogen production castration with LHRH analogs is used increasingly in lieu of oophorectomy in premenopausal women.

Medical inhibition of estrogen production castration with LHRH analogs has been used in premenopausal metastatic breast cancer patients and induces remission in about one-third of unselected patients. The mechanism of action of LHRH analogs in breast cancer is thought to result from downregulation of LHRH receptors in the pituitary. Decreased levels of luteinizing hormone (LH) subsequently results in a significant decrease in estrogen to castrate levels. The three agents available in the United States for medical inhibition of estrogen production are leuprolide, goserelin, and triptorelin, but only goserelin is approved for the treatment of metastatic breast cancer. These agents are administered as an injection and are associated with primarily nuisance side effects such as amenorrhea; hot flashes; and occasionally, nausea. A recent meta-analysis of premenopausal women reported on the combined use of tamoxifen and LHRH agonists versus LHRH agonists alone in patients with metastatic breast cancer.⁷⁶ With a median follow-up of 6.8 years, combined treatment demonstrated a significant survival benefit and progression-free survival (PFS) benefit. The overall response rate was also significantly higher on combined endocrine treatment. However, this analysis did not compare tamoxifen alone against the combination of an LHRH agonist with tamoxifen. LHRH agonists also may produce a flare response owing to an initial surge in LH and estrogen production for the first 2 to 4 weeks. This flare response is similar to that seen with tamoxifen, and patients should be monitored for increasing pain and/or hypercalcemia during the initiation period.

In randomized trials, progestins such as megestrol acetate and medroxy-progesterone acetate have been compared with tamoxifen and have been found to yield equal response rates. Medroxyprogesterone acetate is used more frequently in Europe, and megestrol acetate is used more frequently in the United States. Based on efficacy and tolerability, these agents generally are reserved as third-line therapy after patients have received an AI and an SERM (i.e., tamoxifen or toremifene). The most common side effect is weight gain, occurring in 20% to 50% of patients. Patients experiencing weight gain may have fluid retention, but fluid retention is not totally responsible for the weight gain. In cachectic cancer patients, the weight gain may be desirable, but this is not uniformly true of all patients with metastatic breast cancer. Additional side effects associated with progestins include vaginal bleeding in 5% to 10% of patients, either while patients are taking the progestational agent or when it is discontinued, and somewhat less than a 10% incidence of hot flashes. Thromboembolic complications are also significant with these agents. High-dose estrogens and androgens are rarely used because they are more toxic than other hormonal agents. About one-third of patients placed on high-dose estrogens will discontinue the use of these agents because side effects, the most important of which are thromboembolic events, vomiting, and fluid retention. Given the recent availability of the AIs, use of androgens and estrogens has become rare.

► Cytotoxic Chemotherapy

Cytotoxic chemotherapy is eventually required in most patients with metastatic breast cancer. Patients with hormone receptor–negative tumors require chemotherapy as initial treatment of symptomatic metastases. In general, the median survival time of patients after treatment with commonly used drug combinations for metastatic breast cancer is 14 to 33 months. In most studies, the median time to response has ranged from 2 to 3 months, but this period depends in large part on the site of measurable disease. The median time to appearance of response is between 3 and 6 weeks in patients whose disease is primarily in the skin and lymph nodes, 6 to 9 weeks in patients with metastatic lung involvement, 15 weeks in patients with hepatic involvement, and nearly 18 weeks in patients with bone involvement. Thus, an immediate response to therapy is often not apparent, and in general, once a chemotherapy regimen has been initiated, it is continued until there is unequivocal evidence of disease progression.

Currently well-defined clinical characteristics or established tests to identify patients likely to benefit from chemotherapy are not available. Factors associated with an increased probability of response include good performance status, limited number (one or two) of disease sites, and previous response to chemotherapy with a long disease-free interval. Patients who have progressive disease during chemotherapy have a lower probability of response to a different type of chemotherapy. Patients who do not respond to endocrine therapy are as likely to respond to chemotherapy as patients who are treated with chemotherapy as their initial

treatment modality. Age; menopausal status; and, in some instances, receptor status have not been associated with a favorable or unfavorable response to chemotherapy.

Although many chemotherapeutic agents have demonstrated activity in the treatment of breast cancer, the most frequently used agents include doxorubicin, epirubicin, paclitaxel, nab-paclitaxel, docetaxel, capecitabine, fluorouracil, cyclophosphamide, methotrexate, vinorelbine, ixabepilone, and gemcitabine. ¹⁰ *The most active classes of chemotherapy in metastatic breast cancer are the anthracyclines and the taxanes, producing response rates as high as 50% to 60% in patients who have not received prior chemotherapy for metastatic disease.*⁷⁷ In the metastatic setting the most effective weekly dose of paclitaxel appears to be 80 mg/m²/wk with no breaks in therapy. With this approach, the toxicity profile of paclitaxel changes with less myelosuppression and delayed onset of peripheral neuropathy but slightly more fluid retention and skin and nail changes. Patients should be premedicated with a steroid (dexamethasone), H₁ antagonist (diphenhydramine), and H₂ antagonist (ranitidine or famotidine) before treatment to minimize hypersensitivity reactions. A randomized study comparing doses of 60, 75, and 100 mg/m² docetaxel was published recently and demonstrates a dose–response relationship with regard to response rates only.⁷⁸ Time to progression and OS were similar among all dose levels. Therefore, dose remains important for symptomatic patients who require a rapid response to therapy. In asymptomatic patients requiring docetaxel chemotherapy, lower doses may be appropriate. Results from a single randomized trial indicate that docetaxel is associated with less neuropathy, myalgia, and hypersensitivity than paclitaxel given every 3 weeks, but febrile neutropenia, fluid retention, and skin reactions appear to occur more frequently with the newer taxane.⁷⁹ The median cumulative docetaxel dose to the onset of fluid retention is 400 mg/m² in nonpremedicated patients. Premedication with a steroid (dexamethasone) before beginning docetaxel and continued for 3 days helps to prevent hypersensitivity reactions and fluid retention.

Regardless of the minor controversy regarding whether a new formulation of an old drug can be considered a “new” drug, nanoparticle albumin-bound paclitaxel or nab-paclitaxel exhibits some advantages over conventional paclitaxel. In a clinical study designed to compare the efficacy and safety of nab-paclitaxel with the older formulation, patients with metastatic breast cancer were enrolled into a randomized trial.⁸⁰ Patients received either 260 mg/m² nab-paclitaxel or 175 mg/m² conventional paclitaxel. Because the albumin-bound drug does not require solvents, standard premedications to prevent acute drug reactions were not given to those randomized to the newly formulated product. Results of the trial indicated significantly better outcomes in patients treated with nab-paclitaxel than those receiving standard paclitaxel. The overall response rates of 33% and 19% favored patients in the nab-paclitaxel arm ($P = .001$); the median time to progression for the nab-paclitaxel group and conventional paclitaxel group was 23 weeks versus 16.9 weeks, respectively ($P = .006$). However, no survival advantage was noted. Despite the higher dosage, the incidence of severe neutropenia was significantly lower with nab-paclitaxel

than paclitaxel (9% versus 22%, respectively; $P < .001$). In addition, even in the absence of premedication, no acute hypersensitivity reactions were observed with nab-paclitaxel administration. Nab-paclitaxel is currently indicated for patients with metastatic breast cancer resistant to conventional chemotherapy or progressing within 6 months of receiving an adjuvant anthracycline-containing chemotherapy regimen.

Ixabepilone is a member of a distinct class of microtubule-targeted agents known as the epothilones. In vitro studies show that the antitumor activity of ixabepilone, similar to the taxanes, occurs primarily by blocking disassembly, thus kinetically “stabilizing” the microtubule structure. The results of an international phase III clinical trial demonstrated that the combination of ixabepilone plus capecitabine significantly prolonged PFS by approximately 1.6 months compared with capecitabine alone (median, 5.8 months versus 4.2 months, respectively; $P = 0.0003$).⁸¹ This relatively modest improvement represented a 38% overall increase in PFS. The objective response rate (ORR) was more than twice as high with the combination compared with capecitabine alone (35% versus 14%, respectively). Notably, the response rates were nearly identical to the ORRs (33% versus 14%) in patients who had disease that was intrinsically resistant to previous taxane therapy. The findings from this study support preclinical data that the antitumor activity between ixabepilone and capecitabine are at least additive and may in fact, be synergistic.⁸²

However, a much higher incidence of adverse effects involving the bone marrow and peripheral nervous system was apparent in those receiving ixabepilone plus capecitabine. Five infection-related deaths were associated with abnormal liver function at the time of enrollment. In addition, two-thirds of the patients developed variable grades of sensory neuropathy; 21% of the all patients discontinued treatment because of this adverse effect. Ixabepilone is approved for use in combination with capecitabine for patients with advanced breast cancer resistant to or progressing on previous anthracycline and taxane therapy or for patients in whom anthracyclines are contraindicated. The use of single-agent ixabepilone is approved for use in patients with disease resistant capecitabine as well as any drugs in the two classes mentioned earlier.

Capecitabine is a novel oral agent approved in the mid-1990s with significant activity in metastatic breast cancer patients who have progressed on an anthracycline-containing regimen as well as a taxane regimen. This agent is a prodrug for fluorouracil with somewhat targeted activity toward malignant cells. The parent compound undergoes a three-step enzymatic conversion to become fluorouracil (see Table 89–8).⁸³ The third and final step in this conversion is more likely to occur in malignant cells than normal cells owing to the presence of higher levels of the responsible enzyme in malignant tissues. Approximately 85% of fluorouracil is degraded by dihydropyrimidine dehydrogenase (see Table 89–8). In patients who have been exposed to an anthracycline and a taxane, capecitabine produces response rates of about 25%, which is impressive compared with other tested chemotherapy agents.⁸⁴

Vinorelbine, a microtubule interactive agent, also has shown impressive response rates in metastatic breast

cancer.⁸⁵ Vinorelbine was approved by the Food and Drug Administration (FDA) in 1994 for the treatment of non-small cell lung cancer. It is not approved for breast cancer, but response rates to vinorelbine range from 30% to 50%, with an overall 5% complete response rate in phase I and phase II studies in patients with advanced breast cancer. Importantly, paclitaxel, docetaxel, and vinorelbine do not appear to be cross-resistant with anthracyclines, which are arguably considered first-line treatment of metastatic breast cancer.

Gemcitabine is another agent that is used quite frequently in patients who have received the aforementioned chemotherapy regimens, who still have a good performance status and who may benefit from additional chemotherapy. This is a nucleotide analog that inhibits DNA synthesis. Response rates ranging from 13% to 42% have been reported in a number of phase II trials.⁸⁵ In patients who have been exposed to an anthracycline and a taxane, gemcitabine appears to provide similar benefit to capecitabine. This agent appears to affect platelets more frequently than other chemotherapy previously mentioned, and close monitoring is required for patients receiving this agent.

Combination chemotherapy regimens are associated with higher response rates than are single-agent therapies in the treatment of metastatic breast cancer, but the higher response rates usually have not translated into significant differences in time to progression and OS. The use of sequential single-agent chemotherapies versus the combination regimens has been debated widely for metastatic breast cancer. Current consensus is that first-line chemotherapy includes sequential single agents or combination chemotherapy.³⁹ In the palliative metastatic setting, using the least toxic approach is preferred when efficacy is considered equal. In clinical practice, patients who require a rapid response to chemotherapy (e.g., those with symptomatic bulky metastases) often receive combination therapy despite the added toxicity. This decision is complex and should be made on an individual patient basis.

Because most patients are given adjuvant chemotherapy, regimens chosen for first-line use in the metastatic setting often are different from those used in the adjuvant setting. If a patient’s cancer recurs within 1 year of finishing adjuvant chemotherapy, those chemotherapy agents are not considered effective for treatment of the metastatic disease. However, if the patient recurs more than 1 year after the end of her adjuvant chemotherapy, the same agents also may be helpful in the metastatic setting.

► Biologic Therapy

Trastuzumab is a humanized monoclonal antibody that binds with a specific epitope of the HER-2/neu protein. Single-agent treatment with trastuzumab has a response rate of 15% to 20% and a clinical benefit rate of nearly 40% in patients with HER-2/neu-overexpressing cancers.⁸⁶ Trastuzumab has additive and perhaps synergistic activity with other chemotherapeutic agents.⁸⁷ In the pivotal trial, patients who received the doxorubicin-trastuzumab combination had a very high incidence of cardiotoxicity (27%), leading to a black-box warning regarding this combination in the product

information for trastuzumab. Cardiotoxicity is reduced when trastuzumab is given after all cycles of the anthracyclines have been completed. An alternative regimen that may be considered is concurrent administration of docetaxel, carboplatin, and trastuzumab.⁸⁸

Other chemotherapy agents that are being evaluated in combination with trastuzumab include vinorelbine, gemcitabine, capecitabine, and the platinum agents (e.g., cisplatin and carboplatin).⁸⁹

Trastuzumab is reasonably well tolerated. The most common adverse effects (e.g., chills) are infusion related and occur in about 40% of patients during the initial infusion. To alleviate the symptoms, acetaminophen and diphenhydramine may be given and/or the infusion rate may be reduced. The rare adverse effects of severe hypersensitivity and/or pulmonary reactions have been reported. It is important to educate patients regarding the pulmonary reactions because they may occur up to 24 hours after the infusion and if not treated promptly can be fatal. Trastuzumab may increase the incidence of infection, diarrhea, and/or other adverse events when given with chemotherapy. When trastuzumab is given with an anthracycline, the rates of heart failure are unacceptably high, but even as a single agent, there is a 5% incidence of heart failure. Fortunately, the heart failure seen with trastuzumab is somewhat reversible with pharmacologic management. Some patients have continued therapy with trastuzumab after their left ventricular ejection fraction has returned to normal. Close monitoring for clinical signs and symptoms of heart failure is important in order to intervene with appropriate cardiac treatments. It should be noted that only 20% to 25% of patients with metastatic breast cancer overexpress HER-2/neu, and commercially available immunohistochemistry (IHC) tests that score 2+ for HER-2/neu are often negative by the more sensitive and specific fluorescence in situ hybridization (FISH) technique. To date, little benefit is associated with the administration of trastuzumab to the subset of patients who are HER-2/neu-negative and a very questionable benefit associated with administration of trastuzumab to women who are 2+ for HER-2/neu by IHC staining alone. The patients who benefit most from trastuzumab therapy include those whose tumors overexpress HER-2 protein at the 3+ level and/or demonstrate gene amplification by FISH testing.⁹⁰

Lapatinib is a dual inhibitor of HER-2/neu and the epidermal growth factor receptor (EGFR). In contrast to the extracellular recognition site of trastuzumab, the specific targets of lapatinib are the receptors' intracellular kinase domain. A critical phase III trial was conducted to assess the efficacy and safety of lapatinib plus capecitabine versus capecitabine alone in patients with trastuzumab-refractory advanced breast cancer.⁹¹ Of note, the trial was terminated early when a preplanned interim analysis indicated a significant reduction in risk of disease progression (time to progression [TTP], $P < 0.001$) that favored the group receiving the combination to capecitabine alone. Efficacy data were reanalyzed 4 months later. Based on an independent review, the median TTP was 27.1 weeks and 18.6 weeks ($P = 0.00013$; HR, 0.57), and response rates were 23.7% and 13.9% for the lapatinib combination arm and capecitabine monotherapy arm, respectively. Interestingly,

tumor cell expression of EGFR was not an eligibility criterion. This is especially notable because results from an earlier study of lapatinib suggested that clinical response may be higher in breast tumors that coexpressed EGFR and HER2.⁹² Another relevant outcome was the significantly lower incidence of brain metastasis in the lapatinib-treated group compared with capecitabine alone (2% versus 11%, respectively; $P = 0.0445$).⁹³

Clinical trials of lapatinib have revealed a remarkably similar side effect profile that included non-treatment-limiting diarrhea, rash, nausea, and fatigue among the most frequently reported side effects. The incidence of diarrhea, dyspepsia, and rash was higher when lapatinib was combined with capecitabine.⁸¹ Cardiac events were also monitored because severe toxicity related to blockade of the HER-2/neu signaling pathway has been previously reported.^{94,95} Although addition of lapatinib was not associated with any cardiac event resulting in subject withdrawal, the answer related to this issue is not final as the possibility of selection bias and the relatively short observation period.

Based on these data, lapatinib in combination with capecitabine was approved in March 2007 for patients with HER-2/neu-overexpressing metastatic breast cancer progressing on prior anthracycline, taxane, and trastuzumab therapy.

Bevacizumab is a humanized monoclonal antibody that targets vascular endothelial growth factor (VEGF), thereby preventing angiogenesis, which is a necessary process to support tumor growth and metastasis. Based on results from a phase III clinical trial,³⁹ the antibody received FDA approval in February 2008 as first-line therapy in combination with paclitaxel for metastatic HER-2-negative breast cancer. However, in late 2010, the FDA rescinded its prior approval after two clinical trials failed to reproduce the clinically meaningful benefit observed in the earlier study. Additional studies are being conducted to elucidate bevacizumab's role in the treatment of breast cancer and its efficacy in combination with trastuzumab.

A novel HER-2 targeted agent called pertuzumab was recently approved by the FDA for use as first-line therapy (in combination with docetaxel) for HER-2-positive metastatic breast cancer. Unlike the monoclonal antibody trastuzumab, pertuzumab binds to a specific epitope on the ectodomain of the receptor and sterically hinders the dimerization process.

► Bisphosphonates

For women whose breast cancer has metastasized to bone, bisphosphonates are recommended, in addition to chemotherapy or endocrine therapy, to reduce bone pain and fractures.^{39,96} Pamidronate (90 mg) and zoledronate (4 mg) can be given IV once each month. These bisphosphonates are given in combination with calcium and vitamin D.

Local-Regional Control

► Radiation Therapy

Radiation is an important modality in the treatment of symptomatic metastatic disease. The most common indication for treatment with radiation therapy is painful bone metastases

or other localized sites of disease refractory to systemic therapy. Approximately 90% of patients who are treated for painful bone metastases experience significant pain relief with radiation therapy. Additionally, radiation is an important modality in the palliative treatment of metastatic brain lesions and spinal cord lesions, which respond poorly to systemic therapy, as well as eye or orbit lesions and other sites where significant accumulation of tumor cells occurs. Skin and/or lymph node metastases confined to the chest wall area also may be treated with radiation therapy for palliation (e.g., open wounds or painful lesions).

OUTCOME EVALUATION

Early breast cancer is resected completely with curative intent and adjuvant chemotherapy and/or hormonal therapy with trastuzumab in selected patients are initiated to prevent recurrence. During adjuvant chemotherapy, laboratory values to monitor chemotherapy toxicity are obtained before each cycle of chemotherapy. After completion of adjuvant therapy, patients are monitored every 3 months for the first few years after diagnosis, with intervals between examinations extended as time from diagnosis lengthens.

- Physical examination to detect breast cancer recurrence
- Annual mammography
- Symptom-directed workup

Patients with locally advanced breast cancer are often treated with neoadjuvant therapy to make the tumor surgically resectable. During neoadjuvant chemotherapy, laboratory values to monitor chemotherapy toxicity are obtained before each cycle of chemotherapy, and a physical and ultrasound examinations to detect size of tumor are performed after the cycles of neoadjuvant therapy are completed. After complete surgical resection, monitoring proceeds as described for early breast cancer.

Metastatic breast cancer is not curable, and therapy is intended to palliate symptoms. In most cases, hormonal therapy is the mainstay for tumors that are ER positive. While on therapy, patients are monitored monthly for signs of disease progression or metastasis to common sites, such as the bones, brain, or liver. Evaluations include:

- Pain
- Mental status or other neurologic findings
- Laboratory tests
- Liver function tests
- Complete blood count
- Calcium, electrolytes

Patient Care and Monitoring

1. Review the patient's diagnostic information to determine the stage of disease, overall prognosis, and goals of therapy.
2. Obtain a thorough history of prescription, nonprescription, and natural drug product use. Is the patient taking any medications that may contribute to breast cancer and require discontinuation?
3. Review the patient's medical history to determine the risks associated with any potential therapies and/or surgery and/or radiation therapy.
4. Educate the patient on the chemotherapy or endocrine therapy regimen chosen for the patient, focusing on what adverse events to expect, when to expect them, and how to manage them if they do occur. Also include in the initial education an overall plan of care, including the duration of therapy, other treatment modalities that will follow (e.g., radiation therapy, surgery, endocrine therapy), and when the patient will receive them.
5. Develop a premedication and postmedication plan for the chemotherapy or endocrine therapy regimen chosen based on the patient's risk factors for adverse events; chemotherapy or endocrine therapy drugs chosen; and dose, route, and timing of administration chosen.
6. Develop a plan to assess effectiveness of the overall treatment plan, focusing on educating the patient on ways to monitor and track adverse events and/or disease-related symptoms throughout therapy.
7. Determine success of the overall treatment plan by obtaining a thorough history of adverse events experienced with the previous chemotherapy or endocrine therapy treatment and objective measures of response to therapy. Assess effects on quality of life measures such as physical, psychological, and social function and well-being.
8. Address any adverse events the patient experienced and alter the premedication and postmedication plan for the next treatment accordingly.
9. Provide follow-up patient education regarding the new plan for side effect management.
10. Stress importance of reporting adverse events and adherence with the prescribed medication regimen. Attempt to develop a therapeutic regimen that is easy for the patient to accomplish.

Abbreviations Introduced in This Chapter

AI	Aromatase inhibitor
DCIS	Ductal carcinoma in situ
DFS	Disease-free survival
ER	Estrogen receptor
HER2/neu	Human epidermal growth factor receptor 2
LCIS	Lobular carcinoma in situ
LHRH	Luteinizing hormone-releasing hormone
MRI	Magnetic resonance imaging
OS	Overall survival
PFS	Progression-free survival
PR	Progesterone receptor
SERM	Selective estrogen receptor modulator
TNM	Tumor, node, metastasis (staging system)

Self-assessment questions and answers are available at <http://mhpharmacotherapy.com/pp.html>.

Lung Cancer

Val Adams and Justin Balko

LEARNING OBJECTIVES

● **Upon completion of the chapter, the reader will be able to:**

1. Identify major risk factors for the development of lung cancer.
2. Explain the pathologic progression of lung cancer and its relationship with signs and symptoms of the disease.
3. Make appropriate recommendations for screening or preventive measures in high-risk patients.
4. Understand staging of lung cancer patients and how it influences treatment decisions.
5. List the rationale, advantages, disadvantages, and place in therapy for adjuvant and neoadjuvant chemotherapy.
6. Identify the chemotherapeutic regimens of choice for limited and extensive small cell lung carcinoma, as well as local, locally advanced, and advanced non-small cell lung carcinoma.
7. Monitor patients for chemotherapy-associated toxicity and recommend appropriate management.
8. Distinguish the treatment goals of palliative care versus those of first-line treatment.

KEY CONCEPTS

- 1 The most important risk factor for the development of lung cancer is smoking, and the most effective way for high-risk patients to reduce their risk is to stop smoking. Additional recommendations should include an increase in dietary intake of fruits and vegetables.
- 2 The signs and symptoms of lung cancer can be classified as pulmonary, extrapulmonary, and paraneoplastic. These classifications relate to disease progression.
- 3 The treatment goals in lung cancer are cure (early-stage disease), prolongation of survival, and maintenance or improvement of quality of life through alleviation of symptoms.
- 4 The performance status (PS) of the patient represents an important aspect of chemotherapy treatment decisions. Patients with a PS of 0 to 1 may be treated with chemotherapy. Patients with a PS of 2 may be treated with less aggressive regimens that have a decreased risk of major toxicities.
- 5 Surgical resection of the tumor is the mainstay of treatment in early-stage non-small cell lung cancer and produces the longest survival rates.
- 6 Doublet chemotherapy regimens offer superior response rates compared to single-agent regimens and should be used when the patient can tolerate the associated

toxicity. Platinum-containing doublets are first-line treatment in most cases.

- 7 Knowing when and how to treat adverse events from chemotherapy is an important aspect of patient care. Unmanaged events may cause delays in chemotherapy administration and reduced chemotherapy doses and may contribute to treatment failure.
- 8 Although some evidence suggest that the use of a colony-stimulating factor reduces the number of neutropenic fever episodes, hospital stay, and antibiotic administration in certain subsets of lung cancer patients, routine front-line (prophylactic) use of a colony-stimulating factor is not recommended owing to lack of a survival benefit.

Lung cancer has a major health impact both in the United States and worldwide. Before 1930, lung cancer was a relatively rare disease, but a sharp incline in industrialization and smoking in the early 1900s has bred an epidemic. Lung cancer has a high mortality rate, and although treatment can cure selected patients, most therapies only prolong survival for months. Recent advances in lung cancer research provide good reason for optimism. However, despite the emergence of new therapies, antismoking

campaigns still appear to offer the best opportunity to reduce lung cancer incidence and mortality.

EPIDEMIOLOGY AND ETIOLOGY

Incidence and Mortality

Cancer is the second leading cause of death in the United States. Cancers of the lung and bronchus rank first in cancer-related mortality, comprising more than 28% of cancer-related deaths.¹ In 2011, more than 220,000 new cases of lung cancer are expected. A close correlation exists between incidence and mortality of lung cancer, reflecting the reality that approximately 70% of lung cancer patients ultimately die of the disease.

Gender

Lung cancer incidence and mortality are slightly higher in men, but the rate in women is expected to match that of men in future years owing to changes in smoking patterns.² Typically, women with lung cancer are diagnosed at an earlier age, which has raised the question that there may be inherent genetic differences between men and women in their susceptibility to lung cancer. Furthermore, there are differences in the prevalence of histologic subtypes of tumors. Interestingly, historical studies have shown improved prognosis and survival times for women diagnosed with lung cancer.³

Race

Although no significant difference is noted in incidence or mortality between black and white women, black men have a markedly higher incidence and mortality rate than white men. Proposed contributions to this gap include differences in smoking habits, such as increased menthol cigarette use.² Black Americans also have a significantly lower 5-year survival rate than white Americans regardless of gender. They present with more advanced disease and are less likely to be treated, suggesting that genetic, psychosocial, and socioeconomic components contribute to this disparity. Although it remains a significant health care issue, Asians, Hispanics, and Native Americans have lower rates of lung cancer than both whites and African Americans.^{2,4,5}

Clinical Risk Factors

► Smoking

1 *The most important risk factor for the development of lung cancer is smoking.* One of the most predictive factors on lung cancer epidemiology is trends in population cigarette smoking. Because lung cancer is a fatal disease in most cases, both incidence and mortality strongly reflect the smoking trends of the population on a 20- to 30-year lag. In other words, decreases in tobacco use now would be expected to affect lung cancer incidence in 2030. With this knowledge, the current expectation is that lung cancer incidence and mortality will decrease steadily until 2020, reflecting decreases in cigarette smoking between 1970 and 1990. Because smoking has

continued at a steady rate since 1990, lung cancer incidence is expected to plateau.² Correlation between smoking and lung cancer continues to drive antismoking campaigns and should be considered an investment in the future health care of the nation. Furthermore, smoking cessation plays an important role in reducing lung cancer risk on a patient-to-patient basis, and appropriately guiding such therapy is a crucial part of treating at-risk patients.⁶ Both total smoke exposure and current use correlate with the individual's risk of developing malignancy. The risk of lung cancer decreases to near-normal levels 10 to 15 years following successful smoking cessation. Total smoke exposure is reported as pack-years. One pack-year is the equivalent of smoking 1 pack per day for 1 year. A patient who smokes 40 cigarettes per day (2 packs) for 5 years would have a 10 pack-year history (2 packs/day × 5 years).

► Other Air-Related Risks

In addition to direct inhalation of cigarette smoke, other environmental factors have been identified as risks for the development of primary lung tumors. Environmental tobacco smoke (ETS) presents a significant occupational hazard for nonsmokers working in environments that have a high smoking population, such as bars or restaurants. Most states have instituted laws banning public smoking in order to protect individuals working in these locations. Each year approximately 3000 cases of lung cancer in nonsmokers are caused by ETS. Other environmental factors linked to lung cancer include radon, arsenic, nickel, and chloromethyl ethers. Those who live in an urban environment are also at an increased risk for lung cancer owing to exposure to high concentrations of combustion fumes.⁴ Asbestos exposure increases the risk of developing a distinct type of lung cancer called **mesothelioma**, which is rare and beyond the scope of this chapter.

► Nutrition

Diet and nutrition have long been suspected to play a role in cancer susceptibility, and many studies have sought to define specific foods or nutrients that influence cancer risk. Because not all heavy smokers develop lung cancer, it is thought that nutritional factors may explain part of this variation. Epidemiologic studies focusing on diet and nutrition in lung cancer have shown reduced rates of lung cancer in individuals who report higher fruit and vegetable consumption. However, studies attempting to identify specific chemical components of fruits and vegetables that are responsible for this effect have not been successful. **1** *Recommendations to patients who are at risk owing to smoking or other factors or those who are simply interested in reducing their risk of cancer should include an increase in dietary intake of fruits and vegetables.*

Hereditary or Genetic Risk Factors

Although smoking is a key risk factor for lung cancer, the majority of people who smoke never develop lung cancer. Genetic risk factors may predispose certain smokers to lung cancer. After adjustments for age, smoke exposure, occupation,

- and gender, relatives of a lung cancer patient have approximately a twofold risk of developing lung cancer. The degree of inherited risk inversely correlates with the age of the relative at the time of diagnosis. First-degree relatives of a lung cancer patient diagnosed between the ages of 40 and 59 years have a sixfold relative risk for lung cancer. Familial lung cancer that develops at an early age in nonsmokers fits a Mendelian codominant inheritance model. However, a lung cancer gene has not been identified.
- Other genetic links to lung cancer involve metabolic enzymes that process carcinogens. The damaging effects of tobacco smoke are thought to be a result of bulky aromatic hydrocarbons that damage DNA. These chemicals are activated by certain phase I metabolic enzymes and are deactivated by phase II conjugating enzymes such as the glutathione-S-transferases. People with elevated cytochrome CYP 2D6, 1A1, or 1A2 have greater risk of DNA damage and subsequent cancer owing to higher formation rates of active carcinogens. Those with deficient phase II metabolism (*GSTM1* or *GSTT1*) similarly may have increased risk owing to lower clearance of carcinogens.

Chemoprevention

Chemoprevention refers to the use of prophylactic medications to prevent the development of cancer. Many studies of potential chemopreventatives, including nonsteroidal anti-inflammatory drugs (NSAIDs), retinoids, inhaled glucocorticoids, vitamin E, selenium, and green tea extracts, have been conducted, but none have been successful. Large randomized clinical trials have evaluated β -carotene and vitamin E as lung cancer chemopreventative agents in high-risk patients (older smokers). Although vitamin E has no influence on lung cancer, the trials show that older people who smoke have a higher risk of developing and dying of lung cancer if they take a β -carotene supplement. Nonsmokers do not appear to have an altered risk of lung cancer with β -carotene consumption. Interestingly, data from a placebo-controlled double blind study demonstrated that selective cyclooxygenase-2 (COX-2) inhibition with celecoxib reduces the proliferation of bronchial epithelial cells, lowers inflammatory markers, and may resolve benign or premalignant lung nodules in former smokers.⁷ Existing data suggest that bronchial epithelial cell proliferation may be a surrogate endpoint for chemopreventative lung cancer trials. Thus, COX-2 inhibition may be a viable strategy for lung cancer chemoprevention, but requires additional validation. In the absence of this validation, and given the long-term cardiovascular effects of selective COX-2 inhibitors, routine use of celecoxib as a chemopreventative agent is not warranted.

Screening and Early Detection

- Overall 5-year survival in lung cancer is only 15%, but those who are diagnosed at a localized stage exhibit a 5-year survival rate of 50%. Currently, more than three-quarters of newly diagnosed lung cancers present with locally advanced or metastatic disease, and therefore, very few patients are able to

undergo surgical resection.¹ In an attempt to identify tumors when they are localized and have higher cure rates, many investigators are evaluating different screening modalities. Effective screening methods have the potential to save thousands of lives. The use of spiral computed tomography (CT) has been shown to be more sensitive in detecting small nodules compared with chest radiography. However, spiral CT scanning alone has limited benefit owing to the high rate of false-positive results (i.e., lack of specificity) leading to excessive patient anxiety and workup, which can have a negative effect on morbidity and mortality. Nonetheless, a landmark trial, the National Lung Screening Trial, which randomized more than 53,000 patients at high risk for lung cancer to triannual CT or chest radiography demonstrated a significant impact (20% reduction) on lung cancer mortality using CT as a screening tool.⁸ However, the number of false-positive results in the CT arm was greater than triple that of the chest radiography arm. Thus, screening using CT can significantly reduce mortality but at the cost of higher false-positive results. Future trials will likely be aimed at reducing false-positive results associated with spiral CT using additional screening tools for follow-up of suspicious lesions.

Because lung cancer tumors are hypermetabolic, they can typically be visualized with 5-FDG (5-fluorodeoxyglucose) positron emission tomography (PET). The combination of spiral CT scanning and follow-up PET scanning for positive lesions is a promising method for the identification of false-positive results. In a recent study, this combination resulted in 90% specificity and 100% sensitivity for detection of cancer when a 3-month follow-up CT was used after a negative PET scan result. Furthermore, 92% of non-small cell tumors were diagnosed at stage IA or IB.⁹ Additional studies evaluating the benefits on mortality of this approach are underway. Spiral CT and PET scanning are currently the most promising screening tools for patients at a high risk for lung cancer. High-risk individuals should be encouraged to enter randomized controlled trials aimed at demonstrating a survival benefit from screening.

PATHOPHYSIOLOGY

Most lung cancers arise from the epithelium of the airways and are classified as **carcinomas**. There are four major and several rare histologic types of lung cancer. They appear to form through different mutagenic pathways; however, they all appear to transition through a premalignant state. The presence of a transitional state from normal tissue to cancerous tissue is important because the premalignant cells contain damage that is generally thought to be reversible. Researchers are currently trying to develop methods to identify people with premalignant lesions as well as drugs that can reverse the damage.

- Continued damage to premalignant cells can lead to cancer. The first appearance of cancer cells that have not yet become invasive is referred to as *carcinoma in situ*. Patients are rarely diagnosed with this early stage of cancer owing to a lack of symptoms and relatively rapid progression from

Table 90-1

Lung Tumor Histopathology⁴³

Tumor Type	Percent of Tumors	Approximate Cell Doubling Time (days)	Sensitivity to Chemotherapy and Radiotherapy	Relative Risk of Metastasis
Small cell	15–20	30	High	High
Non–small cell				
Adenocarcinoma	30–35	180	Low	Medium
Large cell (giant)	9	100	Low	Low
Squamous (epidermoid)	30–35	180	Low	Low

this state to larger invasive tumors. As the tumor grows, cells may become dislodged from the tumor bulk and enter the hematologic or lymphatic circulatory systems, where they can travel to either local or distant parts of the body. Hematologic spread usually results in metastatic sites in the bones, liver, and central nervous system (CNS). Lymphatic spread is more orderly in nature, with the hilar and mediastinal lymph nodes in the pleural cavity commonly being involved. Once the tumor has spread to multiple locations, curative treatment is rare because surgical excision and radiotherapy cannot remove all or nearly all of the cancer cells.

Histologic Classification

Histologic classification of lung cancer involves determining the cellular origin of the tumor. Knowing the histology of the tumor influences treatment decisions as well as prognosis. For histologic classification to be carried out, the pathologist must obtain a tissue sample. Methods of tissue sampling are discussed in the section on diagnostic principles.

There are four major histologic types of lung cancer that are divided into two classes based on response to treatment and prognosis: small cell lung cancer (SCLC) and non–small cell lung cancer (NSCLC). However, it is important to note that certain other rare malignancies can be seen and many lung cancers may consist of multiple histologic subtypes. Furthermore, a recent phenomenon has been observed where pharmacologic treatments may selectively kill different components of the

tumor, resulting in a conversion of the remaining tumor to a different subtype (i.e., NSCLC becomes SCLC after treatment). Therefore, repeat biopsies of lung tumors before each line of treatment may become a standard of care, although it is not routinely performed at this time. The four major types of lung cancer are outlined by class in [Table 90-1](#).

CLINICAL PRESENTATION AND DIAGNOSIS

Clinical symptoms are not commonly seen until lung cancer tumors become large and/or have metastasized. This is a key factor in the poor prognosis associated with lung cancer. Patients who are diagnosed at an earlier clinical stage have improved prognosis compared with those diagnosed at later stages. Therefore, diagnosing lung cancer earlier through screening and identification of initial signs and symptoms is important. Patients with multiple risk factors for lung cancer; including smoking, may be screened for suspicious lesions using spiral CT triannually because this method has been shown to beneficially impact lung cancer mortality in a high-risk population. However, it should be noted that screening using CT predisposes patients to a greater number of false-positive test results, which may lead to unnecessary evaluation procedures and patient anxiety and stress.

Diagnosis

The diagnosis of lung cancer requires both visualization of the cancerous lesion and tissue sampling for pathologic assessment. Visualization of the suspected tumor provides the clinician with the information necessary to choose the most appropriate sampling technique. Although some lung tumors may be apparent using relatively simple techniques such as a chest x-ray (CXR), many can be either too small to detect or located in an anatomically difficult area to visualize. Therefore, multiple methods of visualization are often used. Once the tumor has been located, sampling provides tissue to confirm malignancy and to determine the histology (e.g., squamous cell, adenocarcinoma, large cell, or small cell). The advantages and disadvantages of various sampling methods must be weighed carefully so that the procedure performed is the least invasive with a high likelihood of providing an accurate diagnosis. Tools used in the diagnosis of lung cancer are outlined in [Table 90-2](#).

Patient Encounter, Part 1

A 57-year-old Asian woman, LT, presents at your clinic complaining of new-onset cough. She has had several upper respiratory infections in the past 2 months with occasional hemoptysis. She smoked about a half a pack of cigarettes per day beginning in her early 30s but quit about 10 years later and has not smoked since. She lives downtown in the city and has worked at her own restaurant and bar since she bought the establishment 10 years ago.

What risk factors for lung cancer are present?

Calculate this patient's pack-year history.

Clinical Presentation and Diagnosis of Lung Cancer

2 Signs and symptoms of lung cancer can be classified into three subdivisions: pulmonary, extrapulmonary, and paraneoplastic syndromes. Distinguishing among these classes of symptoms is important because it can aid in determining the severity of the disease, guide treatment options, and affect prognosis.

Pulmonary Symptoms

Symptoms owing to the direct effects of the primary tumor are often the first to appear and are the most common. These include:

- Cough
- Chest pain
- Superior vena cava obstruction
- Shortness of breath
- Dysphagia
- Hemoptysis
- Pleural effusion

Extrapulmonary Symptoms

Once the tumor invades tissues outside the pleural cavity, it can produce a wide array of symptoms, including:

- General bone pain
- Adrenal insufficiency
- Nausea
- Focal neurologic symptoms

- Confusion
- Personality changes
- Enlarged lymph nodes
- Weight loss
- Seizures
- Horner's syndrome
- Fatigue
- Headache
- Vomiting
- Subcutaneous skin nodules

Paraneoplastic Syndromes

Symptoms that are not a result of the direct effects of the tumor are termed *paraneoplastic syndromes*. They may be caused by substances secreted by the tumor or in response to the tumor and often occur in tissues far from the site of malignancy. Paraneoplastic syndromes are numerous and affect a wide variety of systems, including the endocrine, neurologic, skeletal, renal, metabolic, vascular, and hematologic systems.

Diagnosis

Diagnosis requires visualization of one or more lesions as well as biopsy of the lesion to confirm malignancy. Both visualization and sampling can be performed by invasive or noninvasive methods. These methods are summarized in Table 90–2.

Table 90–2

Diagnostic Tools

	Technique	Description
Visualization	Chest x-ray	The least expensive visualization method in the diagnosis of lung cancer. Readily accessible and does not require systemic administration of contrast dye. However, it often detects lesions that are not cancerous and is not capable of assessing lymph node status.
	CT	More accurate when providing information on size, location, and invasion than chest radiography. It is recommended as part of the standard workup in most cases.
	PET scanning	Uses a substance called 5-FDG to produce a functional image of the lungs. Cells that are actively growing and dividing use greater amounts of glucose and therefore take up more 5-FDG. Focal regions of fluorescence can be visualized in cancerous lesions. PET scanning combined with a CT scan is more accurate than CT scan alone; however, the exact role of PET scanning in staging and monitoring is unclear. The apparent benefit and common role in staging is to evaluate mediastinal disease when it can influence the tumor resectability.
Tumor sampling	Fine-needle aspiration	A method of aspirating cells from the tumor via insertion of a small-bore needle into the lesion and aspirating. Commonly used to evaluate lymph nodes or other poorly accessible sites, it has the advantage of being faster and less invasive than other biopsy methods; however, it does not preserve the architecture of the tumor and may return cells that are undergoing cell death, which negates histologic analysis.
	Bronchoscopy	A fiberoptic camera is inserted through the airways to examine the site of the suspected lesion. Once the lesion is visualized, a tool attached to the camera allows for a tissue biopsy. Newer technologies incorporate fluorescence to differentiate malignant tissue from premalignant lesions.
	Core needle biopsy	A method of obtaining tissue and preserving the tumor architecture. A large-bore needle is inserted into a lesion, where it cuts a core of tissue out that then can be evaluated.
	Thoracentesis	Involves removal of fluid in the pleural cavity via a needle. The fluid then is assayed for presence cancerous cells. This procedure has low sensitivity and depends on the presence of a pleural effusion.
	Sputum cytology	Detects cancerous cells that become dislodged from the airways into the sputum. Sputum cytology is useful because it is not invasive, but it has much lower sensitivity for detecting cancer.

CT, computed tomography; 5-FDG, 5-fluorodeoxyglucose; PET, positron emission tomography.

Clinical Staging

Once the diagnosis of lung cancer is confirmed through visualization and biopsy, the extent of disease must be determined. NSCLC is staged using the American Joint Committee on Cancer (AJCC) tumor, node, and metastasis (TNM) staging system. SCLC is typically staged using the Veterans Administration Lung Cancer Study Group method. Clinical staging serves two primary purposes: predicting prognosis and guiding therapy.

► Non–Small Cell Lung Cancer

Clinical staging of NSCLC with the TNM system evaluates the size of the tumor (T), extent of nodal involvement (N), and presence of metastatic sites (M). The combination of these three evaluations determines the stage. Clinical stages and associated survival rates are outlined in [Table 90–3](#). Local disease includes tumors that are confined to a single **hemithorax** and those cancers which have spread to the ipsilateral hilar lymph nodes. Once malignancy invades the mediastinal lymph nodes or contralateral hilar nodes, the disease becomes locally advanced. When signs of cancer are detected outside the pleural cavity, it is classified as advanced disease. Local disease is associated with the highest cure and survival rates, whereas those with advanced disease have a 5-year survival rate of less than 5%.

► Small Cell Lung Cancer

The most common system for staging SCLC was developed originally by the Veterans Administration Lung Cancer Study Group. This system categorizes SCLC into two classifications, limited and extensive disease.¹⁰

- Limited disease: evidence of the tumor is confined to a single hemithorax and can be encompassed by a single radiation port
- Extensive disease: any progression beyond limited disease

TABLE 90–3

Clinical Stage and Prognosis¹⁰

Clinical Stage	TNM Staging			Survival Rate (%)	
	Tumor	Node	Metastasis	1 Year	5 Year
Local					
IA	1	0	0	94	67
IB	2	0	0	87	53
IIA	1	1	0	89	40
Locally Advanced					
IIB	2	1	0	73	30
	3	0	0		
IIIA	1	2	0	58	15
	2	2	0		
	3	1	0		
	3	2	0		
IIIB	Any	3	0	37	10
Advanced					
IIIB	4	Any	0	37	10
IV	Any	Any	1	18	Less than 5

Patient Encounter, Part 2: Medical History, Physical Examination, and Diagnosis

PMH: GERD (controlled with PPIs) and moderate hypertension (controlled)

FH: Father recently diagnosed with colorectal cancer, but alive, mother living and healthy.

Meds:

- Lisinopril 20 mg/day
- Lansoprazole 30 mg/day

ROS: (+)chest pain, shortness of breath, hemoptysis; (–) recent weight loss

PE

VS: BP 125/69, RR 26, P 80, T 99°F (37.2°C)

CV: RRR

Labs:

Slightly elevated ionized calcium and LFTs; all others WNL.

Chest radiograph reveals a solitary nodule in right lower lobe.

Fine-needle aspiration confirms adenocarcinoma of the lung.

Further evaluation with CT and PET scans reveal a 3-cm mass with possible ipsilateral lymph node involvement.

What clinical stage is this patient's disease?

What is the estimated survival time for this stage of NSCLC?

Does this patient have any factors that may negatively or positively influence survival?

TREATMENT

Desired Outcome and General Approach to Patient

The treatment of lung cancer depends on tumor histology; stage of disease; and patient characteristics such as age, gender, history, and performance status (PS). All of these aspects must be assessed before appropriate treatment can be recommended. The general approach to treatment of lung cancer is outlined in [Figure 90–1](#). In the development of a patient care plan, keep in mind the ultimate goals of therapy.

③ *In patients with early stage disease, a definitive cure is the primary goal of treatment, although this end point is not always met. Additional goals of treating lung cancer patients include prolongation of survival and improvement of quality of life through alleviation of symptoms.* The goals of treatment must be considered when selecting a therapeutic plan. Some treatments may prolong survival by a few months but at the expense of significant decreases in patient quality of life. Treatment decisions must include both the health care team and an informed and well-counseled patient.

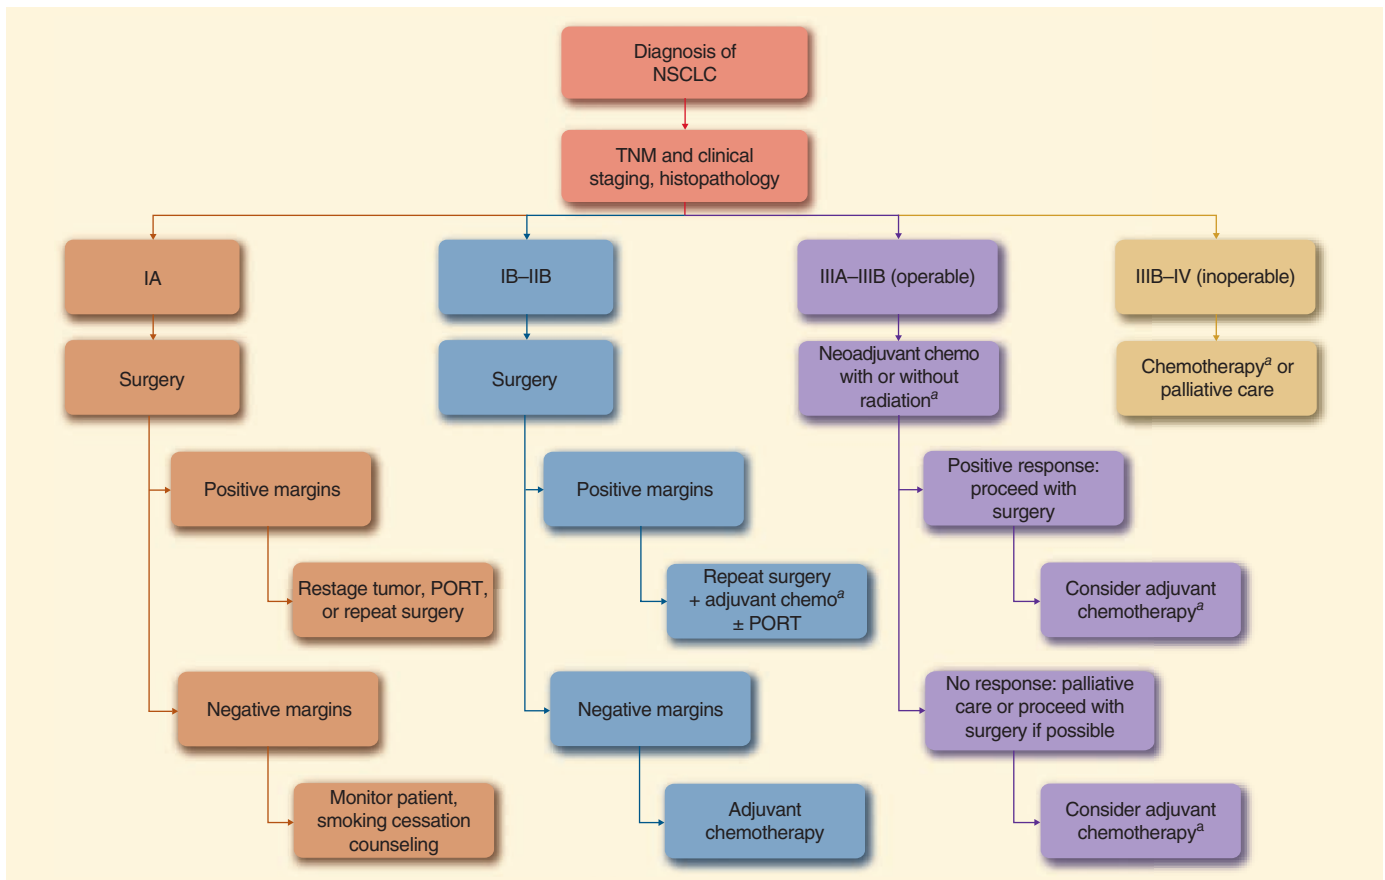

FIGURE 90-1. Clinical pathway for non-small cell lung cancer. ^aSee text for specific treatment recommendations. (chemo, chemotherapy; NSCLC, non-small cell lung cancer; PORT, postoperative radiotherapy; TNM, tumor, node, metastasis.)

► Performance Status

The PS of an individual patient predicts response and likelihood of toxicity to chemotherapy as well as overall survival. The PS scaling system used most frequently was developed by the Eastern Cooperative Oncology Group (ECOG) (see Chap. 88). **4** *Categorizing patients by their ECOG PS allows for an objective measure of capability to tolerate systemic therapies that may severely compromise the patient's health. patients with a good PS (0 to 1) are more likely to tolerate intense therapy. PS 2 may receive chemotherapy, and PS 3-4 may receive supportive therapy or treatment with targeted therapies if they have activating mutations.* Patients with less advanced disease may be treated more aggressively in this scenario because the intent of treatment is curative.

Nonpharmacologic Therapy

► Surgery

5 *Of all treatment modalities, surgical resection of the affected lobe or lung leads to the greatest improvement in survival for patients with early stage and locally advanced NSCLC tumors (clinical stage IA, IB, or IIA).* The candidacy of the tumor for resection should only be determined by an experienced

thoracic surgeon who routinely works with cancer patients. During surgery, peripheral lymph nodes may be removed if they are thought to be involved, and mediastinal nodes are often dissected for biopsy to determine their involvement. In patients with advanced disease NSCLC, surgery is not curative and as a general approach does not prolong survival. However, surgery for advanced disease is an important palliative treatment that can improve quality of life in some patients. In this respect, surgery is limited to local sites where the tumor is causing significant morbidity (e.g., spinal cord compression). Patients with small cell carcinomas are rarely treated with surgery because the results of a randomized trial published in 1969 showed that surgery did not result in any 5- or 10-year survivors, but radiation produced a 4% survival rate at 5 and 10 years.¹¹ With improved imaging and surgical techniques as well as the use of effective adjuvant therapy, some clinicians believe that surgery does have a role in early stage SCLC. However, this has yet to be proven in a clinical trial.

► Radiotherapy

As mentioned earlier, radiotherapy is the treatment of choice for limited-stage SCLC. Optimal patient outcomes are achieved when radiation is administered concurrently with chemotherapy because of synergy between the

two modalities. Limited- and extensive-stage SCLC patients who respond to therapy should also receive prophylactic cranial irradiation (PCI), which prevents brain metastasis and improves cure rates for limited-stage disease. Patients with localized NSCLC are best treated with surgery; however, many of these patients are inoperable because of comorbidities (e.g., lung disease from smoking). In these situations, radiation therapy can be used with curative intent in place of surgery, and the success rate is approximately 50% that of surgery.¹² Similar to SCLC, patients with late stage NSCLC can receive radiation therapy to palliate symptomatic metastases. Although radiation is less invasive than surgery, it can have marked toxicity on normal tissue, and patients may experience esophagitis, pneumonitis, cardiac abnormalities, myelopathies, and skin irritation. These adverse events can be decreased by using stereotactic radiation and/or hyperfractionated administration.¹³

Postoperative radiotherapy (PORT) is thought to eliminate remnants of the resected tumor that might be deposited in nearby tissue. In clinical trials, PORT decreases local recurrence; however, a survival benefit has never been shown. A meta-analysis of investigations evaluating PORT suggested that it may actually be detrimental to patients with stage I or II NSCLC.¹⁴ The meta-analysis evaluated older studies that used outdated radiation techniques, and consequently, some argue that the meta-analysis does not apply to current practice. Nonetheless, no studies to date have demonstrated a survival advantage with the use of PORT. When local recurrence is a significant risk, PORT still may be a viable option. In fact, current guidelines recommend that patients with positive surgical margins (i.e., cancerous cells are detected on the surface of the excised tissue) undergo re-resection or systemic chemotherapy or PORT.¹⁵ Outside of this recommendation, adjuvant radiotherapy without concurrent chemotherapy is not considered beneficial, especially in early-stage disease.

Pharmacologic Therapy

► Chemotherapy

Traditional chemotherapeutic agents interfere with processes during cell division or affect DNA replication in nondividing cells, resulting in cell death. Unfortunately, these agents are not specific for cancer cells, and other tissues in the body often are affected. Rapidly cycling cells, both tumor

and normal tissue such as bone marrow, epithelial cells of the gastrointestinal (GI) tract, and hair follicles, are most susceptible to chemotherapy toxicity. Because the dose of traditional chemotherapy agents is determined in phase I studies in which the maximum tolerated dose is considered the best dose, toxicity is seen with each of these agents. Preventing and managing chemotherapy toxicity are crucial to optimizing patient outcomes (e.g., curing, prolonging life, or palliating symptoms). The decision to start chemotherapy depends greatly on the overall patient picture, with emphasis on PS and comorbid conditions. Knowledge of the major adverse effects of individual regimens is important for anticipation and prophylaxis of such toxicities. Many regimens require appropriate pre-medication and hydration. Furthermore, decisions to start chemotherapy must include the full consent and understanding of risks by the patient. Counseling on the chemotherapy and risk of toxicity is imperative before dosing. Lung cancer regimens and their associated toxicities are shown in [Table 90–4](#). Refer to Chapter 88 for dosing recommendations in renal and hepatic failure.

► Combination Therapy

6 *Doublet chemotherapy regimens offer superior response rates compared with single-agent regimens and should be used when the patient can tolerate the increased toxicity. Platinum-containing regimens are the mainstay of multidrug regimens. Several regimens contain either cisplatin or carboplatin combined with another chemotherapy agent; these are known as platinum doublets. Cisplatin and carboplatin are structurally related but have distinct toxicity profiles, and it is unclear if they are equally efficacious.*

Non–Small Cell Lung Cancer Both carboplatin and cisplatin show the most pronounced improvements in survival in patients with advanced stage NSCLC when combined with newer agents such as gemcitabine, vinorelbine, docetaxel, or paclitaxel. Because of reduced neurotoxicity, nephrotoxicity, and GI toxicity, many clinicians favor carboplatin over cisplatin.¹⁶ There is also interest in developing non-platinum-containing doublets. Recent studies suggest that gemcitabine combined with paclitaxel or docetaxel is just as effective in advanced stage NSCLC as a platinum doublet; however, guidelines maintain that a platinum-containing doublet should be used when feasible.¹⁵

Small Cell Lung Cancer In SCLC, a platinum agent combined with an older agent (e.g., etoposide) is the treatment of choice. There are also a number of non-platinum-containing three-drug anthracycline-containing regimens that are as effective as a platinum doublet in extensive-stage disease. However, the three-drug regimens are more toxic and are rarely used in the United States. In limited-stage disease, cisplatin and etoposide are superior to the three-drug anthracycline-containing regimens and provide optimal outcomes when combined with concurrent radiation.¹⁷

A direct comparison of etoposide combined with either cisplatin or carboplatin in SCLC found similar results.

Patient Encounter, Part 3

LT's condition has interfered with her ability to work, but she is able to complete daily activities and has been working to this point, managing her restaurant.

What is this patient's ECOG PS score?

Are there any nonpharmacologic interventions you would suggest?

Table 90-4

Chemotherapy Regimens in Lung Cancer and Associated Toxicities^{19,23,31,44-50}

Dose	Neutropenia		
	Cycle Length (days)	Grade III (%)	Grade IV (%)
Non-Small Cell			
Paclitaxel-carboplatin-bevacizumab	Carboplatin, dose targeted to AUC of 6 IV (day 1), paclitaxel 200 mg/m ² IV over 3 hours (day 1), bevacizumab 15 mg/kg IV (day 1)	21	24
Cisplatin-paclitaxel	Paclitaxel 135 mg/m ² IV over 24 hours (day 1) and cisplatin 75 mg/m ² IV (day 2)	21	18 57
Cisplatin-docetaxel	Cisplatin 75 mg/m ² IV (day 1) and docetaxel 75 mg/m ² IV (day 1)	21	21 48
Cisplatin-gemcitabine	Cisplatin 100 mg/m ² IV (day 1) and gemcitabine 1000 mg/m ² IV (days 1, 8, and 15)	28	24 39
Cisplatin-vinorelbine-cetuximab	Cisplatin 80 mg/m ² (day 1) and vinorelbine 25 mg/m ² (days 1 and 8) +/- cetuximab 400 mg/m ² initial dose; then 250 mg/m ² /wk	21	14 38
Cisplatin-vinorelbine	Cisplatin 80 mg/m ² (day 1) and vinorelbine 25 mg/m ² weekly (days 1 and 8)	21	14 38
Carboplatin-paclitaxel	Carboplatin, dose targeted to AUC of 6 IV (day 1), and paclitaxel 225 mg/m ² IV over 3 hours (day 1)	21	20 43
Gemcitabine-paclitaxel	Paclitaxel 200 mg/m ² IV (day 1) and gemcitabine 1000 mg/m ² (days 1 and 8)	21	10 5
Gemcitabine-docetaxel	Gemcitabine 1100 mg/m ² IV (days 1 and 8) and docetaxel 100 mg/m ² IV (day 8)	21	11 11
Gemcitabine	Gemcitabine 1125 mg/m ² (days 1 and 8)	21	19
Pemetrexed	Pemetrexed 500 mg/m ² (day 1), vitamin B ₁₂ 1 mg IM 1-2 weeks before treatment initiation and every 9 weeks thereafter; folic acid 1 mg/day beginning 3 weeks before treatment initiation	21	5-6
Paclitaxel	Paclitaxel 200 mg/m ² IV over 3 hours (day 1)	21	34 3
Docetaxel	Docetaxel 35 mg/m ² IV over 1 hour (days 1, 8, 15)	28	5
Small Cell			
EP	Etoposide 100 mg/m ² IV (days 1-3) and cisplatin 100 mg/m ² IV (day 2)	28	85 18
CAV	Cyclophosphamide 800 mg/m ² IV (day 1), doxorubicin 50 mg/m ² (day 1), and vincristine 1.4 mg/m ² (maximum, 2 mg) IV (day 1)	21-28	15 72
EC	Etoposide 100 mg/m ² IV (days 1-3) and carboplatin AUC 5-6 IV (day 1)	21	10-20 5-15
IC	Irinotecan 60 mg/m ² (days 1, 8, 15) and cisplatin 60 mg/m ² (day 1)	28	40 25
Topotecan	Topotecan 1.5 mg/m ² IV over 30 minutes (days 1-5)	21	18 70
Other Significant Toxicities		Nausea/Vomiting Potential	
Non-Small Cell			
Paclitaxel-carboplatin-bevacizumab	Diarrhea, fever, headache, hypertension, hemoptysis, infection, leukopenia, nausea, neuropathy, peripheral neuritis, vomiting, thrombocytopenia, thrombotic events, bleeding, proteinuria	High (day 1 only)	
Cisplatin-paclitaxel	Febrile neutropenia or infection, thrombocytopenia, nausea, vomiting, diarrhea, cardiac toxicity, renal toxicity, neuropathy, weakness, hypersensitivity reactions, anemia	High (day 2 only)	
Cisplatin-docetaxel	Infection, thrombocytopenia, nausea, vomiting, diarrhea, cardiac, renal, neuropathy, weakness, hypersensitivity, anemia	High (day 1 only)	
Cisplatin-gemcitabine	Febrile neutropenia or infection, thrombocytopenia, nausea, vomiting, diarrhea, cardiac, renal, neuropathy, weakness, anemia	High (day 1) mild (days 8/15)	
Cisplatin-vinorelbine-cetuximab	Data not available	High (day 1 only)	
Cisplatin-vinorelbine	Neutropenia, infection, anorexia, thrombocytopenia, nausea, vomiting, dyspnea, constipation, neuropathy, anemia	High (days 1 and 8)	
Carboplatin-paclitaxel	Infection, thrombocytopenia, nausea, vomiting, diarrhea, cardiac, renal, neuropathy, weakness, hypersensitivity, anemia	High (day 1 only)	
Gemcitabine-paclitaxel	Alopecia, nausea and vomiting, neurotoxicity, thrombocytopenia	Moderate	
Gemcitabine-docetaxel	Nausea and vomiting, diarrhea, thrombocytopenia, asthenia, neurotoxicity	Moderate	
Gemcitabine	Thrombocytopenia	Mild	
Pemetrexed	Anemia	Mild	
Paclitaxel	Infection, nausea, vomiting, diarrhea, mucositis, arthralgia, asthenia, peripheral neuropathy, alopecia, cardiovascular	Mild (day 1 only)	
Docetaxel	Fatigue, nausea, vomiting, skin toxicity, neuropathy, anemia, hypersensitivity, alopecia	Mild	

(Continued)

Table 90-4

Chemotherapy Regimens in Lung Cancer and Associated Toxicities^{19,23,31,44-50} (Continued)

	Other Significant Toxicities	Nausea/Vomiting Potential
Small Cell		
EP	Infection, nausea, vomiting, thrombocytopenia, anemia	High (day 2 only)
CAV	Nausea, vomiting, thrombocytopenia, neuropathy, hepatic, renal, alopecia	High
EC	Infection, thrombocytopenia, alopecia	High (day 1 only)
IC	Fever, infection, thrombocytopenia, anemia, diarrhea, nausea and vomiting, elevated liver enzymes	High (day 1), moderate (days 8/15)
Topotecan	Neutropenic fever, neutropenic sepsis, anemia, thrombocytopenia, nausea, fatigue, vomiting, stomatitis, anorexia, diarrhea, fever	Mild (days 1-5)

AUC, area under the curve; CAV, cyclophosphamide–doxorubicin–vincristine; EC, etoposide–carboplatin; EP, etoposide–cisplatin; IM, intramuscular; IC, irinotecan–cisplatin; IV, intravenous.

See Chapter 88 for dose reductions for hepatic and renal dysfunction.

This leads some clinicians to consider the agents interchangeable; however, this trial primarily enrolled patients with extensive-stage disease. A direct comparison in patients with limited-stage disease has not been performed, and most clinicians consider cisplatin and etoposide to be the treatment of choice because this combination has been used in nearly all the large comparative trials.

Single-Agent Chemotherapy First-line therapy for advanced-stage NSCLC and SCLC is best done with a two-drug regimen. However, patients who have a recurrence after the initial regimen are best treated with a single chemotherapy agent. Single-agent therapy is also acceptable for patients with poor health and advanced disease because toxicities tend to be lower with one-drug regimens. Chemotherapeutic agents used in monotherapy in lung cancer include pemetrexed, docetaxel, gemcitabine, paclitaxel, topotecan, and vinorelbine (see Table 90-4).

• **Adjuvant Chemotherapy** Surgery has a limited role in the treatment of SCLC, making adjuvant chemotherapy primarily applicable to NSCLC. The rationale behind adjuvant chemotherapy is to eradicate micrometastases or other tumor cells that may have been missed during removal of the primary tumor. The recent results of five relatively large prospective trials ($n = 344$ to 1867) suggest that there is benefit from adjuvant chemotherapy. The largest study, the International Adjuvant Lung Trial (IALT),¹⁸ led to the conclusion that adjuvant chemotherapy following surgical resection of non-small cell tumors results in a 4% improvement in survival. However, the majority of patients in IALT were treated with a cisplatin and etoposide, which has been proven inferior to newer combinations of cisplatin in the advanced disease setting. In support of this criticism, the intergroup JBR-10 study evaluated adjuvant cisplatin–vinorelbine (a current standard regimen for advanced stage disease) and found a survival advantage of 15%.¹⁹ Consequently, adjuvant therapy has become the standard of care in resectable NSCLC and should be offered to patients after resection, particularly those with stage II to III disease. Although the regimen of choice is unclear, cisplatin–vinorelbine appears to be the regimen with the most evidence.

• **Neoadjuvant Therapy** *Neoadjuvant or induction therapy* refers to the use of chemotherapy regimens or radiotherapy before surgery. Again, because surgery has a limited role in SCLC, this section applies primarily to NSCLC. The rationale behind neoadjuvant therapy is to decrease the size of the tumor so that it can be extracted more easily with clean margins, as well as to eliminate distant micrometastases before invasive local treatment. Furthermore, patients with marginally resectable or nonresectable tumors may respond sufficiently to induction therapy that surgery becomes an option. Neoadjuvant chemotherapy has been shown to yield benefits in NSCLC (i.e., increase in median survival and disease-free survival and decreased risk of metastasis) for both local and locally advanced disease. One concern is that the toxicity of induction regimens may delay surgery, and if the tumor does not respond to the treatment, there is a risk of disease progression. Nonetheless, current data suggest that more than 90% of patients who are treated with neoadjuvant therapy maintain their scheduled surgery.²⁰ This approach is most common in patients with locally advanced tumors (stage III).²¹ Current studies are aimed at comparing neoadjuvant with adjuvant therapy in earlier stage NSCLC patients. The benefit of combining adjuvant therapy with induction therapy and surgery is also being investigated but is of unknown value at this time.

► Monoclonal Antibodies

Bevacizumab and cetuximab are IgG monoclonal antibodies that have activity in NSCLC. Bevacizumab targets vascular endothelial-derived growth factor (VEGF), which facilitates **angiogenesis**, a process contributing to growth and maintenance of the tumor environment. Bevacizumab has been shown to improve survival of advanced stage non-squamous cell NSCLC patients in a large phase III trial²² and has been incorporated into current guidelines.¹⁵ Squamous cell carcinoma of the lung should not be treated with bevacizumab due to the increased risk of bleeding events (an adverse event associated with bevacizumab administration) in this histologic subtype.

Cetuximab targets epidermal growth factor receptor (EGFR), a cytokine receptor on tumor cells that is frequently

involved with tumor survival and proliferation. This monoclonal antibody has a different and less extensive toxicity profile than traditional chemotherapy agents and appears to be synergistic when combined with chemotherapy. Cetuximab has recently been shown to be beneficial in NSCLC when added to cisplatin and vinorelbine in recurrent or metastatic NSCLC (stages IIIB–IV).²³

► Tyrosine Kinase Inhibitors

The tyrosine kinase inhibitors (TKIs) work by targeting specific intracellular messenger proteins that transmit growth and survival signals. The three TKIs are currently available for treatment of lung cancer are erlotinib, gefitinib, and crizotinib. Erlotinib and gefitinib, similar to cetuximab, target the EGFR, which has been shown to be mutated or overexpressed in some lung tumors. Both gefitinib and erlotinib are structurally related and presumably have the same mechanism of action; however, data show that erlotinib prolongs survival, but gefitinib does not in unselected patient populations. Consequently, gefitinib availability is currently restricted in the United States.

Crizotinib targets the *EML4-ALK* fusion gene, which results from a chromosomal translocation that fuses *EML4* gene to the ALK kinase, resulting in a constitutively active oncogenic protein product which is not present in normal cells. *EML4-ALK* fusions occur in about 5% of lung cancer patients and are also more common in never smokers. *EML4-ALK* fusion-positive lung cancer patients benefit significantly from crizotinib, which selectively targets the ALK kinase.²⁴

Pharmacogenomics and pharmacogenetics now play a major role in the selection of NSCLC patients who should receive oral EGFR inhibitors such as gefitinib or erlotinib. Large bodies of preclinical and clinical data demonstrate that certain mutations in the kinase domain of EGFR (L858R and del746-750) are associated with significant responses to such agents.²⁵ The presence of other mutations in EGFR (T790M) are associated with resistance to such inhibitors through decreased drug binding to the receptor. EGFR mutations are more frequent in women, Asians, patients with adenocarcinoma histology, and nonsmokers. Additionally, the presence of activating mutations in KRAS, another oncogene known to play a role in lung cancer, is also associated with clinical resistance to EGFR inhibitors. These findings have prompted clinical guidelines to suggest that assessment of the mutation status of EGFR and/or KRAS is critical in selecting patients for EGFR kinase inhibitor therapy.¹⁵ Patients with mutations in exons 19 or 21 of EGFR demonstrate the greatest likelihood of benefit, while those with mutations in exon 20 of EGFR or those with mutations in exons 1 or 2 of KRAS demonstrate the lowest likelihood of benefit. Furthermore, advanced stage NSCLC patients with EGFR mutations in exons 19 or 21 demonstrate improved survival and tolerability of therapy when treated with gefitinib or erlotinib versus chemotherapy. Therefore, use of genotyping KRAS and EGFR should now be routinely used in selecting lung cancer

patients who will benefit from EGFR TKIs. In addition to erlotinib and gefitinib, several “multitargeted” TKIs that target the EGFR and other cell-signaling cascades are in clinical trials and show promise for the treatment of patients with lung cancer. Likewise, fluorescence in situ hybridization techniques to detect the *EML4-ALK* fusion event are also now approved and required for selection of patients to receive crizotinib.

Small Cell Lung Cancer

Small cell lung cancer typically presents as extensive disease (approximately 60% to 70% of new cases) and progresses very quickly. Small cell carcinomas are very responsive to chemotherapy and radiation but have a short duration of response. Radiotherapy became the standard in 1969, when a randomized trial showed that it offered the potential for cure, whereas surgery did not.²⁶ In the vast majority of patients, chemotherapy with or without radiotherapy is the treatment of choice. Even after a complete response to therapy, the cancer usually recurs within 6 to 8 months, and the survival time following recurrence is typically short (approximately 4 months). This yields a typical survival rate of 14 to 20 months for limited disease and 8 to 13 months for extensive disease.²⁷ **Figure 90–2** illustrates the general treatment path of SCLC.

► Limited Disease

- The regimen of choice for limited-disease SCLC is etoposide–cisplatin (EP). In patients who are able to tolerate combined modality therapy, concomitant chemoradiotherapy offers the greatest survival benefit. Carboplatin may be substituted for cisplatin in patients who cannot tolerate cisplatin toxicity. Cisplatin is preferred over carboplatin because of a small study that randomized patients to cisplatin or carboplatin plus etoposide. There was a numerically higher complete response rate with cisplatin, which is believed to be requisite for cure. In European countries, a three-drug combination containing an anthracycline has been the mainstay of therapy; however, mounting clinical evidence shows that these regimens are inferior to EP plus concurrent radiation and have more toxicity. Consequently, the guidelines recommend that the EP regimen be used with concurrent radiotherapy.²⁷

Because patients with SCLC commonly have a recurrence in the CNS, trials have been performed to evaluate the benefit of PCI. A pivotal study showed that PCI reduces the incidence of brain metastasis and increases the 3-year survival rate from 15% to 21%.²⁸ Patients with limited stage SCLC who achieve a complete response with treatment should be offered PCI.

► Extensive Disease

- Platinum regimens, particularly EP, are the treatment of choice in extensive disease. In one Japanese study, a combination of irinotecan and cisplatin demonstrated an increased median survival time by approximately 3 months over the EP regimen. This irinotecan–cisplatin regimen also had a lower incidence of severe neutropenic side effects but exhibited higher rates of middle- to high-grade diarrhea.

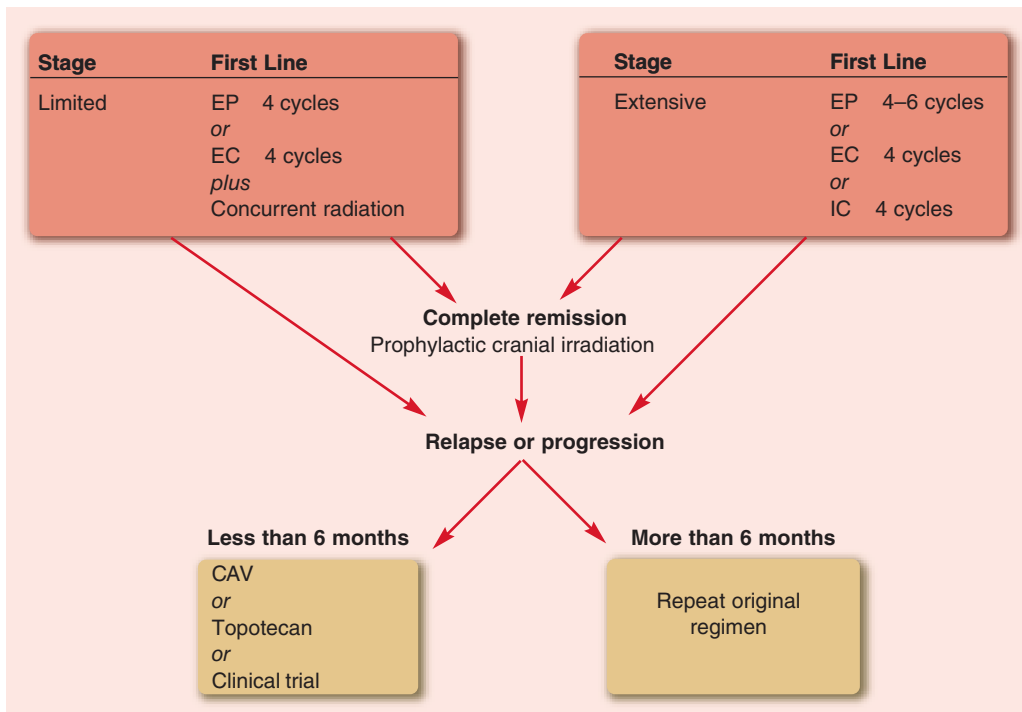

FIGURE 90-2. Small cell lung cancer treatment overview.²⁷ (CAV, cyclophosphamide, doxorubicin [Adriamycin], and vincristine; EC, etoposide–carboplatin; EP, etoposide–cisplatin; IC, irinotecan–cisplatin.)

However, this study was repeated in the United States and did not show a similar improvement over the EP regimen.²⁹ Therefore, EP remains the regimen of choice for treating extensive SCLC in the United States. Because of the high sensitivity of treatment-naïve SCLC to chemotherapy, it is imperative that these patients be monitored for signs of tumor lysis syndrome and possibly treated with prophylactic therapy.

Concurrent radiotherapy is not used routinely in extensive disease; however, PCI provides significant benefit in patients responding to chemotherapy. A pivotal study demonstrated that median survival from the time of randomization increased from 5.4 to 6.7 months and 1-year survival rates increased from 13.3% to 27.1% with PCI. An additional benefit was a lower rate of brain metastasis (14.6% versus 40.4%).³⁰

► Recurrent Disease

- The treatment of recurrent SCLC depends on the time to recurrence. If the time to recurrence is less than 6 months, second-line therapy should be considered if the patient has an acceptable PS (see Patient Care and Monitoring). The most widely accepted second-line therapies in SCLC are topotecan alone or CAV (cyclophosphamide, doxorubicin [Adriamycin], and vincristine). Relapses occurring more than 6 months after treatment warrant a repeat of the initial regimen. Patients with a poor PS (3 to 4) are typically managed with best supportive care, including palliative care therapies.

Non–Small Cell Lung Cancer

The first step in treatment of NSCLC involves confirmation of the clinical stage and determination of resectability

of the tumor. This decision should always be made by a thoracic surgeon who routinely performs lung cancer surgery. Treatment options depend on the advancement of disease (i.e., local, locally advanced, or metastatic), PS, and eligibility for resection.

► Local Disease (Stages 1A, 1B, and IIA)

- Local disease encompasses stages IA through IIA and is associated with a favorable prognosis because approximately 40% to 60% of patients are expected to live more than 5 years from diagnosis. Goals of therapy are curative in local disease, and surgery is the mainstay of treatment. Stage IA tumors are rarely seen clinically and may be treated with surgery alone. In this case, neoadjuvant or adjuvant therapy has not been adequately studied to know if it conveys a benefit. If surgical margins are positive, radiotherapy or re-resection is recommended.¹⁵ Stage IB, IIA, and locally advanced IIB NSCLC are treated with adjuvant chemotherapy. Patients who have positive or questionable margins may receive radiation therapy, which typically is administered with the adjuvant chemotherapy. The regimen of choice in this setting is not clear; however, clinical trials demonstrating the most benefit used cisplatin–vinorelbine.

► Locally Advanced Disease (Stages IIB and IIIA)

- Patients with locally advanced disease should also be considered for surgery. Neoadjuvant chemotherapy with or without concurrent radiotherapy can be used before surgery, although this practice varies from institution to institution. Progression of disease during induction therapy may preclude surgery, and the regimen should be altered. If there is a response, surgical resection can be attempted,

with or without additional adjuvant chemotherapy. Nonresectable locally advanced disease may be treated with both an active platinum-containing regimen and radiotherapy.

► **Advanced or Metastatic Disease (Stages IIIB and IV)**

- Advanced disease is treated with chemotherapy if the patient has an acceptable ECOG PS score (0–1). Historically, platinum-containing doublets have produced the highest overall response rates (25% to 35%) and survival times (30% to 40% 1-year survival) in well-performing patients with advanced disease. A number of different platinum doublet treatment regimens have been used in this setting. In some patients with stage IIIB disease, cisplatin and etoposide may be given concurrently with radiotherapy. However, treating unresectable stage III patients with a platinum-containing doublet regimen and omitting the radiation is common. The optimal regimen has yet to be determined. NSCLC chemotherapy doublets that are considered generally equivalent include:

- Paclitaxel–cisplatin
- Paclitaxel–carboplatin
- Cisplatin–gemcitabine
- Cisplatin–docetaxel
- Carboplatin–docetaxel
- Cisplatin–vinorelbine
- Gemcitabine–paclitaxel
- Gemcitabine–docetaxel
- Cisplatin–pemetrexed

A large randomized trial comparing the first four regimens reported similar response rates and survival with all treatments, although there were less life-threatening toxicity and treatment-related deaths associated with paclitaxel–carboplatin.³¹ Consequently, one may argue that paclitaxel–carboplatin is the treatment of choice. However, the carboplatin–paclitaxel regimen used in the trial infused paclitaxel over 24 hours, which is uncommon in clinical practice. The most common carboplatin–paclitaxel regimen infuses a higher dose of paclitaxel over 3 hours in the clinic rather than admit patients to the hospital for a 24-hour infusion. It is unfair to extrapolate the toxicity advantage from this trial to the commonly used 3-hour paclitaxel infusion, and consequently, there is not a single best regimen. A subset analysis of the cisplatin–pemetrexed data shows that only patients with a nonsquamous histology benefit from pemetrexed. Additionally, two non-platinum-containing regimens have been shown to have similar survival benefits. Both gemcitabine–paclitaxel and gemcitabine–docetaxel produce response durations and survival times similar to the platinum-containing doublet regimens. These regimens may be substituted when patients are unlikely to tolerate the toxicity of platinum regimens owing to comorbidities or other factors.³²

- **Targeted agents** Although it is unclear which chemotherapy combination is the best, research aimed at integrating targeted agents into therapy have proven successful but only in defined subgroups. Adding bevacizumab to the carboplatin–paclitaxel

(3-hour infusion) regimen increases response rates and prolongs progression-free survival by 1.7 months and overall survival by 2.3 months.²² Consequently, carboplatin–paclitaxel and bevacizumab are arguably the new standard of care. However, bevacizumab is only appropriate for patients with non-squamous cell histology because of a high risk of fatal hemoptysis seen in patients with squamous histology.³²

Interestingly, bevacizumab does not show the same level of synergy with all regimens; when combined with cisplatin and gemcitabine, better progression-free survival and response were seen, but there was no difference was in overall survival. Early data suggest a large benefit from combining bevacizumab with a platinum and pemetrexed, but it is not currently the standard of care. Based on the current peer review data, bevacizumab should only be used with carboplatin and paclitaxel as the initial treatment.³²

The anti-EGFR monoclonal antibody cetuximab has been shown to improve survival when combined with cisplatin and vinorelbine. The FLEX trial demonstrated a 1.2-month survival advantage of cetuximab when added to cisplatin and vinorelbine in recurrent or metastatic NSCLC (stages IIIB–IV).²³ The study population consisted of chemotherapy-naïve patients with PSs of 0 to 2 that demonstrated positive tumor staining for EGFR by immunohistochemistry. It is unclear how this regimen compares with bevacizumab plus carboplatin and paclitaxel. Because bevacizumab was proven effective first and the survival advantage appears superior, cisplatin, vinorelbine, and cetuximab will likely only be used in patients with a contraindication to bevacizumab (e.g., squamous cell histology).

Individualized therapy has blossomed with the use of EGFR TKIs. Demographic, pathology, and genetic markers can help identify patients most likely to respond to these treatments. Early studies showed that nonsmokers with adenocarcinoma were most likely to benefit from therapy; correlative studies demonstrated that patients with mutations in exon 19 and/or 21 also defined a population likely to respond to treatment. This knowledge has now been tested prospectively. Gefitinib, an EGFR TKI, was compared with carboplatin–paclitaxel as first-line therapy in patients with adenocarcinoma who were never smokers or light former smokers. They reported that gefitinib was noninferior and improved quality of life. A subset analysis showed that those with a mutation in exon 19 or 21 had the highest objective response rates and appeared to have the most benefit.³³ A similar trial comparing erlotinib to a platinum-based doublet in patients with an exon 19 or 21 mutation found that erlotinib improved progression free survival.³⁴ Based on this data, erlotinib is recommended as first-line therapy in patients with an activating EGFR mutation.

Crizotinib is a new targeted therapy that appears to be very effective for a subset of patients with an ALK rearrangement (approximately 5% of patients). It recently received accelerated approval based on a single arm trial in the salvage setting that resulted in a 55% survival rate at 2 years.²⁴ Despite the lack of data in the first-line setting, the NCCN guidelines recommend that patients with a known ALK rearrangement can be treated with crizotinib in the

first-line setting, which is based on its activity as salvage treatment.

In summary, targeted therapy as monotherapy or in combination with chemotherapy has become a mainstay in first-line treatment of advanced NSCLC.

- **Poorly Performing Patients** Treating patients with a PS of 2 is a subject of debate. Although patients with a PS of 2 typically have inferior survival rates and higher toxicity to platinum chemotherapy than higher performing patients, low-toxicity single-agent regimens may offer a survival advantage in this subset. Use of these regimens also presents a method of providing symptomatic care for advanced stage patients. Agents such as pemetrexed, gemcitabine, and docetaxel may be used in this scenario. In patients with a PS of 3 or 4, chemotherapy typically results in high rates of toxicity and fails to convey a survival benefit. Consequently, treatment should be aimed at relief of symptoms instead of a definitive cure. Because targeted agents typically have less severe toxicity, they also have been used in appropriate subsets of patients with a poor PS (ECOG PS of 2 or 3). Unfortunately, we do not have peer review clinical trial data regarding the efficacy and toxicity of targeted agents in these patients. In summary, debilitated patients should not be treated with combination chemotherapy with or without targeted agents because of historically high rates of toxicity without benefit. Single-agent therapy with less toxicity can be used to help palliate symptoms.

Duration of Therapy Because advanced stage NSCLC is not curable, an argument can be made that the goal is to extend the number of quality days, rather than just overall survival. With this goal in mind and an assumption that quality of life is lower during chemotherapy treatment, it is important to consider the duration of therapy. Over the last decade, treatment has moved toward fewer chemotherapy cycles. Typical therapy regimens have decreased from planning eight cycles to six cycles, to four cycles, which was the standard until several years ago. It was at this time that positive data were reported from two studies using pemetrexed, erlotinib, and bevacizumab as maintenance therapy. Both key studies included patients who had a response or stable disease after 4 cycles of a platinum-based doublet who were then randomized to placebo or treatment.³⁵ The pemetrexed study reported a 3-month survival advantage with maintenance therapy. A subgroup analysis of this study demonstrated that patients with squamous histology did not benefit from therapy leaving an overall survival benefit of 5 months for the non-squamous cell group. Similarly, the erlotinib maintenance study reported a 1-month overall survival advantage, which does not appear as robust; however, the subset analysis showed benefit was much more likely in nonsmokers and those with adenocarcinoma histology and particularly in patients who had an activating mutation (exon 19 or 21). Similar to the pemetrexed study, patients whose tumor was of squamous cell histology did not appear to benefit from maintenance. In summary, the duration of therapy depends highly on histology; patients with squamous

cell histology will likely be treated for four cycles, but patients with non-squamous cell histology will be treated until progression.³⁵

► **Recurrent and Progressive Disease**

- Although patients frequently experience a response to initial therapy, disease recurs in most cases. If the recurrence is localized, surgery options may be assessed. If the patient's PS remains acceptable (0 to 1), second-line systemic chemotherapy has been shown to improve survival. Although platinum doublets may be used at this point in care, a single-agent therapy with docetaxel, pemetrexed, erlotinib, or crizotinib is recommended.^{24,36} Recurrences in poorly performing patients (3–4) usually are not treated with chemotherapy and are instead treated with supportive care. Additional recurrences (e.g., third-line therapy) may be treated with single-agent therapy not previously used or best supportive care.

PATIENT CARE AND MONITORING

Management of Toxicity

7 *Knowing when and how to treat adverse events from chemotherapy is an important aspect of patient care. Unmanaged events may cause delays in chemotherapy administration and reduced chemotherapy doses and may contribute to treatment failure.* Given the fatal nature of untreated lung cancer, patients and health care professionals are willing to tolerate high risks of severe and life-threatening side effects provided that the therapy has been shown to benefit the patient. There are multiple methods of preventing or reducing toxicity from chemotherapeutic agents. These methods usually are agent specific but commonly include maintenance of adequate hydration, use of appropriate premedications, dose reduction of the causative agent, and use of growth factors to combat toxicities associated with cytopenias.

► **Grading Toxicity**

- In order to standardize grading of adverse events, the National Cancer Institute (NCI) has developed the Common Toxicity Criteria for Adverse Events (CTC, V4.0) (see Chap. 88). In most cases, patients who experience grade 3 or 4 toxicity require a change in therapy with the next cycle of treatment. Common changes include a chemotherapy dose reduction or pharmacologic intervention to prevent or treat the toxicity. The CTC is an invaluable tool to determine what serious toxicity is most likely with a particular regimen and improves the pharmacist's ability to counsel the patient as well as determine appropriate toxicity-prevention measures.

► **Dose Intensity and Growth Factors**

- The term *dose intensity* refers to the percent of drug delivered compared with the planned amount as measured by milligrams per meter squared per week. Maintaining dose

intensity (i.e., delivering the planned dose according to the scheduled time course) has been shown to influence survival in some cancers, such as breast cancer; however, the importance of dose intensity in lung cancer is not well established. In order to maintain dose intensity, pharmacologic agents are sometimes used to combat serious toxicities that may prohibit or delay administration of subsequent doses.

With most lung cancer chemotherapy regimens, the most common grade 3 or 4 toxicity is neutropenia. Patients who experience grade 3 or 4 neutropenia are at a high risk of developing a severe or life-threatening bacterial infection. Consequently, patients with neutropenia who develop a fever are empirically given broad-spectrum antibiotics. If a patient experiences neutropenic fever, dose reduction, or intervention with growth factors (e.g., pegfilgrastim, filgrastim, or sargramostim) to maintain dose intensity should occur before the next cycle of chemotherapy. In lung cancer patients, no survival benefit has been demonstrated by using a colony-stimulating factor to maintain dose intensity. **8** *Although some evidence suggest that the use of a colony-stimulating factor reduces the number of neutropenic fever episodes, hospital stay, and antibiotic administration in certain subsets of lung cancer patients, routine front-line (prophylactic) use of a colony-stimulating factor is not recommended owing to a lack of a survival benefit.*^{37,38}

► Nausea and Vomiting

Platinum agents are the most active lung cancer agents and historically have very high rates of nausea and vomiting. This is particularly true of high-dose cisplatin, which is used

in many regimens. Understanding how to prevent and treat chemotherapy-induced nausea and vomiting (CINV) in lung cancer patients is crucial because nearly all the regimens are highly emetogenic. Although the pathology of CINV is not fully understood, there are three classifications of CINV based on the time of occurrence in relationship to chemotherapy administration: acute CINV (1–24 hours after the dose), delayed (24 hours to 5 days after the dose), and anticipatory (before the dose following one or more previous cycles).

Acute CINV appears to be influenced predominantly by serotonin binding to 5-HT₃ receptors on the vagal nerve, where it innervates the GI tract. Delayed CINV has been attributed to a variety of mechanisms but appears to be influenced by substance P stimulation of neurokinin-1 (NK-1) receptors in the CNS, as well as a corticosteroid-responsive element. Anticipatory CINV is thought to be a learned or conditioned behavior. The major influencing factors appear to be prior acute or delayed CINV and anxiety. Anticipatory CINV may be prevented or treated with benzodiazepines such as lorazepam or alprazolam not because they possess antiemetic properties but rather because they contain amnesic and antianxiety properties.

The three main drug targets that are antagonized to prevent or treat acute and delayed CINV are 5-HT₃ receptors, dopamine type 2 receptors (D₂), and NK-1 receptors. 5-HT₃ receptor antagonists are the most effective agents for preventing acute CINV. However, they are only recommended for moderate to high emetogenic potential regimens, primarily owing to cost (see [Table 90–5](#) for a comparison of agents). Because ondansetron's patent has expired, several generics are available, and the cost for this class of agents has dropped significantly. Aprepitant is the only available NK-1 receptor

Table 90–5

Pharmacotherapy for Chemotherapy-Induced Nausea and Vomiting

Class	Indication	Drug	Dose	Half-life
NK-1 inhibitors	Acute or delayed NV	Aprepitant	125 mg PO on day 1 80 mg PO daily on days 2–3	9–13 hours
		Fosaprepitant	115 mg IV on day 1	9–13 hours
5-HT ₃ inhibitors	Acute NV	Ondansetron	80 mg PO aprepitant daily on days 2–3 16–24 mg PO or 8–12 mg IV on day 1 16 mg PO daily or 8 mg IV daily on days 2–4	3–6 hours
		Palonosetron	0.25 mg IV on day 1	40 hours
		Granisetron	1–2 mg PO or 0.01 mg/kg IV on days 1–4	4–12 hours
		Dolasetron	100 mg PO or 100 mg IV daily on days 1–4	8 hours (active metabolite)
D ₂ antagonists	Acute or delayed NV, PRN breakthrough treatment	Haloperidol	1–2 mg PO q4–6 hours or 1–3 mg IV q4–6 hours	20 hours
		Olanzapine	Olanzapine 2.5–5 mg PO twice a day PRN	20–50 hours
Corticosteroids	Adjunctive treatment for acute or delayed NV	Dexamethasone	12 mg IV or PO on day 1 8 mg IV or PO daily on days 2–4	2–4 hours biologic half-life of 36–54 hours
Benzodiazepines	Anticipatory NV	Lorazepam	0.5–2 mg PO once on night before and once on morning of treatment	12–16 hours
	Anticipatory NV	Alprazolam	0.5–2 mg PO three times a day starting the night before treatment	12–16 hours

5-HT₃, 5-hydroxytryptamine receptor; IV, intravenous; NK-1, neurokinin-1; NV, nausea and vomiting; PO, oral; PRN, as needed.

antagonist that is approved to prevent CINV. It has modest but additive activity in acute CINV and appears to be highly active in preventing delayed CINV. It was approved for use in highly emetogenic regimens but also works in patients receiving moderately emetogenic chemotherapy. The use of aprepitant is somewhat limited by the cost. Dopamine type 2 receptor antagonists, which are approved for schizophrenia, also have antiemetic activity in both acute and delayed CINV. As a group, these agents do not appear to be as effective as 5-HT₃ receptor antagonists in acute CINV or as effective as aprepitant in delayed CINV. Consequently, their use is frequently limited to patients receiving mild emetogenic chemotherapy as prevention or as treatment following full-dose 5-HT₃ receptor antagonist and/or aprepitant. They are attractive owing to their relatively low cost but cause a significant number of side effects. Interestingly, corticosteroids, most commonly dexamethasone, is an active antiemetic agent that can be used as monotherapy to prevent acute CINV in patients receiving mild to moderate emetogenic chemotherapy. They are also synergistic with 5-HT₃ receptor antagonists, aprepitant, and D₂-receptor antagonists in acute and delayed CINV. Although antiemetic choices typically are guided by chemotherapy, patient-specific risk factors that may play a role include the following high-risk features: very young age, very old age, female gender, emesis associated with pregnancy or motion sickness, and those with low alcohol intake.³⁹

► Diarrhea

- Chemotherapy-induced diarrhea can be a significant toxicity in cancer patients and should be managed pharmacologically when necessary. The most common offending agent in the treatment of lung cancer is irinotecan. Treatment may include loperamide (4 mg at the onset followed by 2 mg every 2 hours until resolution; may use 4 mg every 4 hours during sleep) or octreotide (starting at 100 mcg subcutaneously every 8 hours and titrated to effect). The goals of therapy are resolution of diarrhea and improvement in quality of life.

Surveillance

Following response to surgery or pharmacologic treatment, the patient should be monitored regularly to detect recurrence. NCCN guidelines suggest a physical examination and chest x-ray every 3 to 4 months for 2 years. If no disease is detected during this time, follow-up frequency can be prolonged to every 6 months for 3 years and then annually. Low-dose spiral CT scanning is also recommended annually. Additionally, smoking cessation counseling with or without pharmacologic treatment should be a priority. Although studies have shown that patients who continue to smoke through treatment in NSCLC do not perform more poorly compared with those that quit before treatment, those who respond to treatment and continue to smoke probably have an increased risk of developing secondary malignancies.⁴⁰ In contrast to NSCLC, some data suggest that SCLC patients with limited stage disease have poorer outcomes if they continue to smoke during treatment.⁴¹

Complications

► Cachexia and Anorexia

Cachexia is a severe wasting syndrome that is seen in many cancer patients. Although it is more common in advanced disease, it is often seen in localized disease as well. Cachexia is characterized by a catabolic state that leads to significant loss of body mass, both lean muscle and fat. The causes of cachexia are poorly understood, but it is thought that they involve inflammatory cytokines such as tumor necrosis factor alpha (TNF- α , originally described as cachexin). **Anorexia** is a patient's loss of appetite or willingness to eat. The presence of anorexia can aggravate cachexia and contribute to morbidity. When anorexia contributes to cachexia, it is important to assess the patient for the underlying cause of the anorexia.

Causes for anorexia in lung cancer patients can be widespread and include CINV, esophagitis and mucosal irritation from combined radiotherapy and chemotherapy, GI obstruction owing to tumors, constipation from opioid analgesics, and psychological factors such as anxiety or depression. Many of these issues may be improved with pharmacologic treatment of the underlying cause (i.e., antidepressant therapy for psychological factors) or with palliative treatment of the offending tumor.⁴² Additionally, appetite stimulants such as the cannabinoid, dronabinol (2.5 mg twice daily with meals, titrated to a maximum of 20 mg/day) and megestrol acetate (400–800 mg/day orally) can aid in increasing caloric intake.

Cachexia is more difficult to treat, although it may resolve following treatment of the underlying malignancy. Nutritional consultation may be of aid, although cachexia is thought to be more attributable to internal pathophysiologic processes than malnutrition.

► Paraneoplastic Syndromes

Paraneoplastic syndromes are clinical syndromes caused by nonmetastatic systemic effects of cancer. Tumors make and secrete biologically active products that can stimulate or inhibit hormone production, autoimmunity, immune complex production, or cause immune suppression. Lung cancer, particularly SCLC, is associated with a high rate of paraneoplastic syndromes. Pharmacologic therapy is necessary when the abnormality causes the patient acute physical or psychological stress or adversely affects his or her health. When possible, therapy should be directed at the primary tumor, and a response often leads to resolution of symptoms.

► Palliative Care

Ultimately, most lung cancer patients succumb to their disease. Palliative care involves management of symptoms and improvement of quality of life when curative treatment options are no longer available. Often, problematic metastases can be removed by surgery (depending on location) or can be treated with radiotherapy to reduce tumor size. In selecting options at this point in treatment, it is important to keep the goals of therapy (i.e., maximizing the duration and quality of life)

Patient Encounter, Part 4

LT undergoes surgery for her disease, which is successful, with negative margins. After 1 year, however, the patient returns for routine follow-up and is found to have recurrent disease, with metastases present in both the brain and in the liver. Molecular diagnostics reveals a mutation in exon 19 of the *EGFR* gene.

What is the patient's new clinical stage?

Discuss the significance of the mutation identified in the tumor.

Based on the information provided, develop a care plan for this patient. Include (a) treatment goals, (b) monitoring parameters for anticipated toxicities, and (c) a follow-up plan to determine response to treatment and surveillance.

Patient Care and Monitoring

1. Review the patient's medical and social history. Was the patient exposed to clinical risk factors for lung cancer?
2. Verify the histology and clinical stage of disease. Evaluate the patient's performance status. Is the patient a surgical candidate? How does this influence your treatment recommendations?
3. Develop a care plan based on treatment goals. If the goal is palliative care, how does treatment-related toxicity influence therapy?
4. If chemotherapy is the treatment of choice, counsel the patient on the risks and benefits of undergoing such therapy. Be sure that the patient understands the issues fully before moving forward.
5. Verify dosing of all agents in the chemotherapy regimen. What are the major expected toxicities?
6. Evaluate toxicity as treatment progresses. Is the toxicity severe enough to warrant dose reduction or pharmacologic treatment? Record graded toxicities according to the NCI CTC V4.0 criteria.
7. Evaluate the response to treatment. Did the patient experience a complete response, partial response, stable disease, or disease progression? How does this change future treatment?
8. If the patient is in remission, develop a monitoring plan. What signs or symptoms denote disease progression?
9. Recommend a smoking cessation program or other risk reduction plan for the patient.

in mind. Low-toxicity single-agent chemotherapy, targeted therapy, and best supportive care (including fatigue and pain management) are commonly the mainstays of palliative care.

OUTCOME EVALUATION

Following treatment, evaluate the goals of therapy versus the response that was achieved. Was there response to treatment or progression of disease? If the patient is being treated with supportive care, then alleviation of symptoms and improvement in quality of life should be of primary importance. Be sure to document objective evaluations of the outcome in the care plan.

Abbreviations Introduced in This Chapter

5-FDG	5-Fluorodeoxyglucose
CAV	Cyclophosphamide, doxorubicin, vincristine
CT	Computed tomography
ECOG	Eastern Cooperative Oncology Group
EGF	Epidermal growth factor
EGFR	Epidermal growth factor receptor
EP	Etoposide, cisplatin
ETS	Environmental tobacco smoke
NSCLC	Non-small cell lung cancer
PCI	Prophylactic cranial irradiation
PET	Positron-emission tomography
PS	Performance status
SCLC	Small cell lung cancer
TNM	Tumor, node, and metastasis staging
VEGF	Vascular endothelial-derived growth factor

Self-assessment questions and answers are available at <http://www.mhpharmacotherapy.com/pp.html>.

Colorectal Cancer

Emily B. Borders and Patrick J. Medina

LEARNING OBJECTIVES

● Upon completion of the chapter, the reader will be able to:

1. Identify the risk factors for colorectal cancer.
2. Recognize the signs and symptoms of colorectal cancer.
3. Describe the treatment options for colorectal cancer based on patient-specific factors, such as stage of disease, age of patient, genetic mutations, and previous treatment received.
4. Outline the pharmacologic principles for agents used to treat colorectal cancer.
5. Develop a monitoring plan to assess the efficacy and toxicity of agents used in colorectal cancer.
6. Educate patients about the adverse effects of chemotherapy that require specific patient counseling.
7. Outline preventive and screening strategies for individuals at average and high risk for colorectal cancer.

KEY CONCEPTS

- 1 Although there are numerous risk factors for developing colorectal cancer, age is the biggest risk factor for sporadic colorectal cancer.
- 2 Diets high in fat and low in fiber are associated with increased colorectal cancer risk, whereas the regular use of aspirin (and nonsteroidal anti-inflammatory drugs [NSAIDs]) and calcium supplementation may decrease the risk of colorectal cancer.
- 3 Effective colorectal cancer screening programs incorporate annual fecal occult blood testing in combination with regular examination of the entire colon starting at age 50 years for average-risk individuals and should be recommended by all health care providers.
- 4 Most patients with colorectal cancer are asymptomatic early but may develop changes in bowel or eating habits, fatigue, abdominal pain, and blood in stool.
- 5 The stage of colorectal cancer is determined by the tumor-node-metastasis (TNM) staging system and is the most important prognostic factor for patient survival. Disease stages I to III are curable, but patients with stage IV disease are treated with the goal of palliation.
- 6 Adjuvant chemotherapy is not needed in patients with stage I colon cancer, may be beneficial in selective high-risk patients with stage II colon cancer, and is standard of care in patients with stage III colon cancer. 5-Fluorouracil (5-FU), leucovorin and oxaliplatin chemotherapy (FOLFOX) is the standard regimen used in adjuvant colon cancer. It is usually given for 6 months.
- 7 Triple-drug therapy consisting of 5-FU and leucovorin with oxaliplatin or irinotecan improves survival compared with 5-FU plus leucovorin alone and is considered standard first-line therapy for metastatic disease. The addition of bevacizumab is recommended to be added to 5-FU-based regimens based on improvements in overall survival.
- 8 Pharmacogenetic testing for KRAS mutation status should occur in all patients before starting an epidermal growth factor receptor (EGFR) targeted agent. EGFR inhibitors should be considered for addition to standard chemotherapy regimens only in patients with metastatic disease and a wild-type KRAS mutation status.
- 9 Treatment of relapsed or refractory metastatic disease uses agents not given in the first-line setting; patients who receive all effective chemotherapy options have improved outcomes compared with those who do not.
- 10 Adjuvant therapy consisting of 5-FU-based chemotherapy in combination with radiation therapy should be offered to patients with stage II or III cancer of the rectum. Metastatic rectal cancer is treated similar to metastatic colon cancer.

INTRODUCTION

Colorectal cancer is one of the three most common cancers diagnosed in the United States and includes cancers of the colon and rectum. It was projected that, in 2011, an estimated 141,210 new cases would be diagnosed and an estimated 49,380 deaths would occur, making colorectal cancer the second leading cause of cancer-related deaths in the United States.¹ The prognosis is primarily determined by the stage of disease with the majority of patients with early stage (I or II) disease cured. Treatment options for colorectal cancer include surgery, radiation, chemotherapy, and new targeted molecular therapies.

EPIDEMIOLOGY AND ETIOLOGY

Colorectal cancer occurs at a much higher rate in industrialized parts of the world such as North America and Europe, while the lowest rates are seen in less-developed areas, suggesting that environmental and dietary factors influence the development of colorectal cancer. In addition to these environmental factors, colorectal cancers are known to develop more frequently in certain families, and genetic predisposition to this cancer is well known.

The incidence of colorectal cancer is greatest among men, who have an approximately 1.5 times greater risk for developing colorectal cancer than women. Overall, colon and rectal cancers make up approximately 10% of all cancer diagnoses in men and women in the United States.¹ The median age at diagnosis is 72 years with very few cases occurring in individuals younger than 45 years of age.² **1** *Age appears to be the biggest risk factor for the development of colorectal cancer with 70% of cases diagnosed in adults older than 65 years of age.*

Although still the third leading cause of cancer death, mortality rates for colorectal cancer have declined over the past 30 years as a result of better and increasingly used screening modalities and more effective treatments.

RISK FACTORS

Besides age, the development of colorectal cancer appears to be caused by variety of dietary or environmental factors, inflammatory bowel disease, and genetic susceptibility to the disease. **Table 91-1** lists well-known risk factors for developing colorectal cancer. Epidemiologic studies of the worldwide incidence of colorectal cancer suggest that dietary habits strongly influence its development.

2 *High-fat, low-fiber diets, which usually occur in tandem, have been associated with an increased risk of colorectal cancer.* The association between red meat consumption and colorectal cancer is strongest, possibly a result of the heterocyclic amines formed during cooking or the presence of specific fatty acids in red meat such as arachidonic acid. Although data indicate that animal meat and saturated fat intake are associated with an increased risk of colorectal cancer, the exact increase in risk is unknown. The evidence

for low-fiber diets as a risk factor is based on the ingestion of large amounts of dietary fiber being associated with a small, inconsistent, reduced colorectal cancer risk. Foods that are high in fiber include vegetables, fruit, grains, and cereals. The protective effects of fiber may be a result of reduced absorption of carcinogens in the bowel, reduced bowel transit time, or a reduction in dietary fat intake associated with high-fiber diets.³

The degree of colorectal cancer risk reduction associated with increased consumption of vegetables and fruit is variable but generally modest and has ranged from no difference to a 25% decrease in cancer risk in prospective studies.³ A large pooled analysis of 13 prospective cohort studies found dietary fiber intake to be inversely associated with the risk of colorectal cancer; however, upon multivariate analysis for other dietary risk factors, the benefit was no longer observed.³ This analysis does not consider for the known benefits of a fiber-rich diet for noncancerous conditions such as diabetes and coronary artery disease.

2 *The risk of colorectal cancer appears to be inversely related to calcium and folate intake.* Higher intake of calcium and vitamin D has been associated with a reduced risk of colorectal cancer in epidemiologic studies and polyp recurrence in polyp-prevention trials. However, daily supplementation of calcium (1,000 mg) with vitamin D3 (400 IU) for 7 years had no effect on the incidence of colorectal cancer among postmenopausal women compared with a placebo group in the randomized trial involving 18,106 women. The benefit of calcium and vitamin D for preventing colon cancer may require longer follow-up.⁴

Calcium's protective effect may be related to a reduction in mucosal cell proliferation rates or through its binding to bile salts in the intestine, and dietary folate helps maintain normal bowel mucosa. Based on its role in DNA methylation, folate intake has been associated with modifying the risk of colorectal cancer. Epidemiologic evidence suggests that higher intake

of folate decreases the risk for the development of colorectal cancer. However, studies are inconsistent, and whether benefit is limited to certain patient populations requires further study. In addition, the timing of folate intake may be important with early intake preventing colorectal cancer and later intake promoting the progression of disease.⁵ Micronutrient deficiencies, including selenium, vitamin C, vitamin D, vitamin E, and β -carotene, appear to increase colorectal cancer risk; however, the benefit of dietary supplementation of these micronutrients does not appear to be substantial.⁶

Chronic use of several medications has been shown to influence the risk of developing colorectal cancer. **2** *Studies have consistently demonstrated that regular (at least two doses per week) nonsteroidal anti-inflammatory drug (NSAID) and aspirin use is associated with a reduced risk of colorectal cancer.*^{7,8} Additional studies support these findings that regular aspirin or NSAID use may decrease the risk of colorectal cancer by as much as 50%.^{7,8} The potential mechanisms by which these agents exert their protective effects appear to be linked primarily to their inhibition of cyclooxygenase-2 (COX-2), and protective effects may be limited to those precancerous lesions that overexpress COX-2.⁹ Colorectal cancers with weak or absent expression of COX-2 may not derive the same benefit from long-term COX-2 inhibition.⁹ Exogenous hormone use, particularly postmenopausal hormone replacement therapy, is associated with a significant reduction in colorectal cancer risk in most studies with the greatest benefit in women who are on current hormone replacement therapy.¹⁰ Unfortunately, the known risks of hormone replacement therapy outweigh this benefit, and routine use of hormone replacement therapy to prevent colorectal cancer is not recommended.

Physical inactivity and elevated body mass index (BMI) are associated with up to a twofold increase in the risk of colorectal cancer. Decreased bowel transit time and exercise-induced alterations in body glucose, insulin levels, and perhaps other hormones may reduce tumor cell growth.^{6,11} Type 2 diabetes mellitus, independent of body mass size and physical activity level, is also associated with an increased risk of colorectal cancer in women and supports a role for hyperinsulinemia as a possible link between obesity, sedentary lifestyle, diabetes mellitus, and colorectal cancer.¹¹ Additional lifestyle choices that increase the risk of colorectal cancer include alcohol consumption and smoking that may increase the risk of colorectal cancer by generating carcinogens or their direct toxic effects on bowel tissue.⁶

Inflammatory bowel diseases, such as chronic ulcerative colitis, particularly when it involves the entire large intestine, and to lesser extent Crohn's disease, confer increased risk for colorectal cancer. Overall, persons diagnosed with either disease constitute about 1% to 2% of all new cases of colorectal cancer each year.

Finally, as many as 10% of cases are thought to be hereditary, resulting from genetic mutations. The two most common forms of hereditary colorectal cancer are familial adenomatous polyposis (FAP) and hereditary nonpolyposis colorectal cancer (HNPCC). FAP is a rare autosomal dominant trait

that is caused by mutations of the **adenomatous polyposis coli (APC)** gene and accounts for 1% of all colorectal cancers. The disease is manifested by hundreds to thousands of **polyps** arising during adolescence.¹² The risk of developing colorectal cancer for individuals with untreated FAP is virtually 100%, and patients require early screening for the disease and likely prophylactic total colectomy. HNPCC, also an autosomal dominant syndrome, accounts for up to 5% of colorectal cancer cases.¹² In contrast to FAP, juvenile polyps occur rarely, and the average age of colorectal cancer in these patients is closer to that of average risk patients, with most patients diagnosed in their forties. Testing for HNPCC mutations is available but reserved for individuals who meet strict diagnostic criteria.

Up to 25% of patients who develop colorectal cancer have a family history of colorectal cancer unrelated to a mutation described earlier.⁸ First-degree relatives of patients diagnosed with colorectal cancer have an increased risk of the disease that is at least two to four times that of persons in the general population without a family history.

Summary of Risk Factors

- In summary, the true association between most dietary factors and the risk of colorectal cancer is unclear. The protective effects of fiber, calcium, and a diet low in fat are not completely known at this time. NSAID use and hormonal use appear to decrease the risk of colorectal cancer while physical inactivity, alcohol use, and smoking appear to increase the risk of colorectal cancer. Clinical risk factors and genetic mutations are well-known risks for colorectal cancer.

SCREENING

3 *Health care professionals must be aware of and promote appropriate screening recommendations for colorectal cancer in their patients.* Effective screening programs incorporate fecal occult blood tests (FOBTs) and regular examinations. Appropriate screening of patients at normal and high risk for colorectal cancer leads to the detection of smaller, localized lesions and higher cure rates.¹³ Screening techniques include FOBTs and imaging of the colon. The use of FOBTs annually in combination with digital rectal examinations has led to earlier diagnosis of early stages of disease and may reduce colorectal cancer mortality by up to one-third.¹³ However, FOBT using a single stool sample collected during a digital rectal examination is not a recommended option for screening because this method has a decreased sensitivity for detecting advanced disease.⁸ Recommendations for adequate FOBT require the patient to collect two stool samples from three consecutive specimens using at-home testing procedures.¹³ Two main methods are available to detect occult blood in the feces: guaiac dye and immunochemical methods. The Hemoccult II is the most commonly used FOBT in the United States and is a guaiac-based test. Proper counseling by health care providers is required to receive accurate test results. **Table 91-2** lists common reasons for inaccurate results with the guaiac tests and requires appropriate counseling on the

Table 91–2

^aAvoid these foods and medications for 3 days before the test.

use of these tests. Fecal immunochemical tests (FITs) (InSure and others), which use antibodies to detect hemoglobin, are also available for use. One advantage of FITs is that they do not react with dietary factors or medications. Both FOBTs can be recommended in screening protocols for patients.

In addition, imaging of the colon with a sigmoidoscopy, colonoscopy, or double-contrast barium enema is required every 5 to 10 years in most individuals. Colonoscopy is the preferred procedure as it allows for greater visualization of the entire colon and simultaneous removal of lesions found during screening.¹³ A sigmoidoscopy only examines the lower half of the colon, and a double-contrast barium enema requires a supplemental colonoscopy to remove any lesions found during the screening process. Several revisions to the colorectal cancer screening guidelines have been made in an attempt to increase the compliance to screening guidelines. These include the use of computed tomographic colonography (CTC) and stool DNA testing as acceptable screening methods. CTC, also known as “virtual colonoscopy,” uses integrated two- and three-dimensional images to detect and characterize polyps. Although noninvasive compared with colonoscopy, adequate

Patient Encounter, Part 1

HB is a 68-year-old man who presents to your clinic with a chief complaint of abdominal discomfort and blood in his stool for the past 3 months. He also states he has felt tired and has had diarrhea and a reduced appetite over the past month. HB has a medical history positive for hypercholesterolemia, gastroesophageal reflux disease (GERD), and obesity. He states that he consumes a moderate amount of alcohol (3 or 4 beers most days of the week after work), quit smoking a few weeks ago (previously smoked ½ pack per day for 40 years), and does not follow any particular diet (mostly red meat and fried foods).

What risk factors does HB have for colon cancer?

Does he have clinical symptoms suggestive of colon cancer?

What additional tests need to be ordered to diagnosis colon cancer?

Table 91–3

Colon Cancer Screening Guidelines

Average risk	Annual FOBT or FIT after age 50 years Stool DNA testing may be used as an alternative <i>and</i> One of the following after age 50 years: Sigmoidoscopy every 5 years Colonoscopy every 10 years Barium enema every 5 years CTC every 5 years
Family history	Screening at ages 35–40 years
HNPCC	Screening at age 30 years
FAP	Screening at ages 10–12 years

CTC, computed tomographic colonography; DRE, digital rectal examination; FAP, familial adenomatous polyposis; FIT, fecal immunochemical tests; FOBT, fecal occult blood tests; HNPCC, hereditary nonpolyposis colorectal cancer.

bowel preparation, which is often cited as the reason for noncompliance, is still required. In addition, any lesions found on examination require a follow-up colonoscopy.

Stool DNA testing detects molecular markers associated with advanced colorectal cancer. Because this test is not dependent on the detection of bleeding, which can be sporadic, it requires only a single stool collection. How often and what molecular markers to test for are undergoing further evaluation. **3** Table 91–3 is a summary of the current American Cancer Society guidelines for screening and surveillance for early detection of colorectal polyps and cancer.¹³

COLORECTAL CANCER PREVENTION

Strategies to prevent colorectal cancer can be done with pharmacologic or surgical interventions and involve either preventing the initial development of colorectal cancer (primary prevention) or preventing cancer in patients who demonstrate early signs of colorectal cancer (secondary prevention).

The most widely studied agents for the chemoprevention of colorectal cancer are agents that inhibit COX-2 (aspirin, NSAIDs, and selective COX-2 inhibitors) and calcium supplementation.¹⁴ COX-2 appears to play a role in polyp formation, and COX-2 inhibition suppresses polyp growth. In 1999, the Food and Drug Administration (FDA) approved the use of celecoxib to reduce the number of colorectal polyps in patients with FAP as an adjunct to usual care. This may delay the need for surgical intervention in these patients, but the results cannot be extrapolated to the general population. The dose of celecoxib for this indication is 400 mg orally twice daily, and the risk of cardiovascular damage from COX-2 inhibition needs to be assessed carefully in these patients. The use of aspirin as both a primary and secondary chemoprevention agent has also been studied. In a prospective, randomized trial, low-dose (81 mg/day) aspirin was shown to decrease the incidence of additional polyps by 19% in patients with a previous history of at least one polyp.¹⁵

Calcium supplementation appears to be associated with a moderate reduction in risk of recurrent colorectal adenomas with prospective studies demonstrating a nonstatistical decrease in adenoma recurrence, and its role as a chemoprevention agent remains under investigation.¹⁴

Additional agents, including selenium and folic acid, show promise as chemopreventive agents in colorectal cancer and preliminary, and confirmatory studies evaluating their effectiveness have been completed or are ongoing.¹⁴

Surgical resection remains an option to prevent colorectal cancer in individuals at extremely high risk for its development such as patients diagnosed with FAP. Individuals with FAP who are found to have polyps on screening examinations require total abdominal colectomy. In addition, removal of noncancerous polyps detected during screening colonoscopy is considered the standard of care to prevent the progression of premalignant polyps to cancer.

PATHOPHYSIOLOGY

Anatomy and Bowel Function

The large intestine consists of the cecum; ascending, transverse, descending, and sigmoid colon; and rectum (Fig. 91-1). The function of the large intestine is to receive contents from the ileum, absorb water, and package solid waste for excretion. Absorption of materials occurs in segments of the colon proximal to the middle of the transverse colon, with movement and storage of fecal material in the left colon and distal segments of the colon.

Four major tissue layers, from the lumen outward, form the large intestine: the mucosa, submucosa, muscularis externa, and serosa (Fig. 91-2). Complete replacement of surface epithelial cells occurs every 7 to 10 days with the

FIGURE 91-1. Colon and rectum anatomy. (From DiPiro JT, Talbert RL, Yee GC, et al., eds. *Pharmacotherapy: A Pathophysiologic Approach*, 6th ed. New York: McGraw-Hill, 2005; Fig. 127-2.)

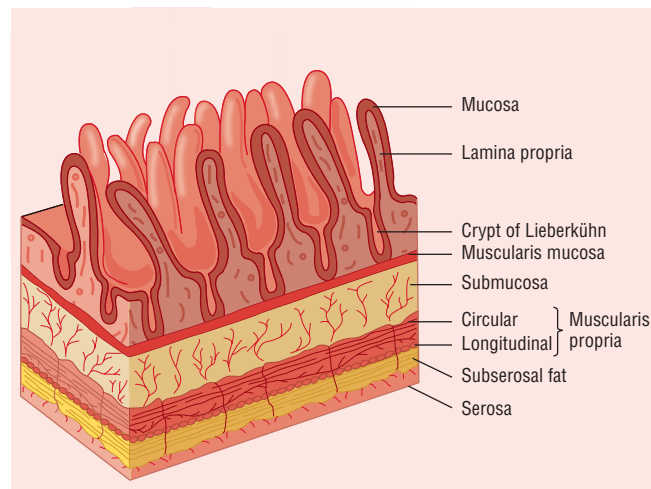

FIGURE 91-2. Cross-section of bowel wall. (From DiPiro JT, Talbert RL, Yee GC, et al., eds. *Pharmacotherapy: A Pathophysiologic Approach*, 6th ed. New York: McGraw-Hill, 2005; Fig. 127-3.)

total number of epithelial cells remaining constant in normal colonic tissue. As patients age, abnormal cells accumulate on the surface epithelium and protrude into the stream of fecal matter; their contact with fecal mutagens can lead to further cell mutations and eventual adenoma formation.¹²

Colorectal Tumorigenesis

The development of a colorectal neoplasm is a multistep process of several genetic and phenotypic alterations of normal bowel epithelium leading to unregulated cell growth, proliferation, and tumor development. A genetic model has been proposed for colorectal tumorigenesis that describes a process of transformation from adenoma to carcinoma. This model of tumor development reflects an accumulation of mutations within colonic epithelium that give a selective growth advantage to the cancer cells.¹² Genetic changes include activating mutations of **oncogenes**, mutations of **tumor suppressor genes**, and defects in **DNA mismatch repair genes**.

Additional genes and protein receptors are believed important in colorectal tumorigenesis. COX-2, which is induced in colorectal cancer cells, influences apoptosis and other cellular functions in colon cells, and overexpression of the EGFR, a transmembrane glycoprotein involved in signaling pathways that affect cell growth, differentiation, proliferation, and angiogenesis, occurs in the majority of colon cancers.¹⁶ These mechanisms are potentially important because of the availability of pharmacologic agents targeted to inhibit these processes.

More than 90% of colorectal cancers that develop are adenocarcinomas and are assigned a grade of I to III based on how similar they are compared with normal colorectal cells. Grade I tumors most closely resemble normal cellular structure, but grade III tumors have frequently lost the characteristics of mature normal cells. Grade III tumors are associated with a worse prognosis than grade I tumors.¹⁷

Clinical Presentation and Diagnosis of Colorectal Cancer

General

Patients are often asymptomatic in early stages of disease

Symptoms

Changes in bowel habits, abdominal pain, anorexia, nausea and vomiting, weakness (if anemia is severe), and tenesmus

Signs

Blood in stool and weight loss

Laboratory Tests

- Patients may have a low hemoglobin level from blood loss
- Positive FOBT
- Liver function tests (INR, activated partial thromboplastin time, and bilirubin) may be abnormal if disease has metastasized to the liver
- CEA level may be high; normal level is less than 2.5 ng/mL (2.5 mcg/L) in nonsmokers and less than 5 ng/mL (5 mcg/L) in smokers

Imaging Tests

Chest x-ray, CT scan, or PET scan results may be positive if cancer has spread to the lungs, liver, or peritoneal cavity

TREATMENT

Desired Outcome

Staging is required to determine the extent of disease and is necessary in developing patient treatment options and determining patient prognosis. The tumor, node, metastasis (TNM) classification system that takes into account T (tumor size and depth of tumor invasion), N (lymph node involvement), M (presence or absence of metastases) is used to stage patients from stage I to stage IV. Computed tomography (CT) and appropriate assessment of lymph node involvement during surgical resection are essential in determining the stage of disease and subsequent treatment options. At this time, routine magnetic resonance imaging and positron emission tomography (PET) scans for initial staging are not recommended. **Figure 91-3** depicts how the three categories are used in combination to determine the stage of disease. **5** *The stage of colorectal cancer upon diagnosis is the most important prognostic factor for survival and disease recurrence. Stages I, II, and III disease are considered potentially curable and are aggressively treated in an attempt to cure these patients. Patients who develop stage IV disease are treated to reduce symptoms, avoid disease-related complications, and prolong survival.*

General Approach to Treatment

The treatment approaches for colorectal cancer reflect two primary treatment goals: curative therapy for localized disease (stages I to III) and palliative therapy for metastatic cancer (stage IV). Surgical resection of the primary tumor is the most important part of therapy for patients in whom cure is possible.¹⁸ Depending on the stage of disease and whether the tumor originated in the colon or rectum, further **adjuvant** chemotherapy or chemotherapy plus radiation may be needed after surgery to cure these patients. In the metastatic setting, pharmacologic intervention is the main treatment option.

CLINICAL PRESENTATION AND DIAGNOSIS

- 4** *The signs and symptoms associated with colorectal cancer can be extremely varied, subtle, and nonspecific. Most patients are asymptomatic but may develop changes in bowel or eating habits, fatigue, abdominal pain, and blood in the stool.*

FIGURE 91-3. Stage I: cancer is confined to the lining of the colon. Stage II: cancer may penetrate the wall of the colon into the abdominal cavity but does not invade any local lymph nodes. Stage III: cancer invades one or more lymph nodes but has not spread to distant organs. Stage IV: cancer has spread to distant locations in the body, which may include the liver, lungs, or other sites. (From <http://www.cancer.gov/cancertopics/pdq/treatment/colon/Patient/page2>.)

Pharmacogenetic and pharmacogenomic testing has become an integral component to designing the optimal pharmacologic intervention for patients with colorectal cancer. The choice of treatment agents is largely dictated by individualized patient and tumor specific factors. For example, recent data have demonstrated specific tumor characteristics that may assist clinicians in predicting who will respond to EGFR inhibitors. Early immunohistochemical staining for EGFR status is not useful in predicting response because both EGFR-positive and -negative patients respond at the same rate. **Fluorescence in situ hybridization (FISH)** of EGFR copy number and **KRAS** gene mutation status have demonstrated predictive value. Patients with high EGFR gene copy number and wild-type (WT) (nonmutated) **KRAS** are more likely to benefit from cetuximab or panitumumab therapy.¹⁷ In particular, testing for **KRAS** mutational status is now part of the disease workup to define patients who may derive benefit from cetuximab or panitumumab. Characteristics of the tumor are also vital in making treatment decisions for patients with stages II and III disease. The degree of **microsatellite instability (MSI)** within a tumor tells clinicians information about both prognosis and treatment options. More detail on specific pharmacogenetic and pharmacogenomic information is provided the pertinent pharmacologic therapy sections.

Nonpharmacologic Therapy

► Operable Disease (Stages I–III)

● **Surgery** Individuals with stage I to III colorectal cancer should undergo a complete surgical resection of the tumor mass with removal of regional lymph nodes as a curative approach for their disease.¹⁸ Surgery for rectal cancer depends

on the region of tumor involvement with attempts to retain rectal function as a goal of the surgical procedure. Overall, surgery for colorectal cancer is associated with low morbidity and mortality rates. Common complications associated with colorectal surgery include infection, anastomotic leakage, obstruction, adhesion formation, and malabsorption syndromes.

Radiation Therapy There is currently no role for adjuvant radiation in colon cancer. However, patients who receive surgery for rectal cancer receive radiation therapy to reduce local tumor recurrence. Adjuvant radiation plus chemotherapy is considered standard treatment for patients with stage II or III rectal cancer after the surgical procedure is complete.¹⁹ Preoperative radiation may be used to reduce the initial size of rectal cancers to make the surgical procedure easier.

► Metastatic Disease (Stage IV)

● **Surgery** Unlike stages I to III disease, the benefit of surgical resection in most patients with metastatic disease is limited to symptomatic improvement. Select patients who have from one to three small nodules isolated to the liver, lungs, or abdomen may have a prolongation of survival, although cure is rare. Five-year survival for patients who undergo surgical resection of metastases isolated to the liver is approximately double that of patients who are not surgical candidates with approximately 33% of patients alive at 5 years.²⁰ Alternatives to surgery include destroying the tumor through freezing and thawing (cryoablation), heat (radiofrequency), or alcohol injection, although these appear to be less successful than surgical resection.^{18,20} Because the majority of these patients will relapse, many practitioners offer adjuvant chemotherapy

Patient Encounter, Part 2

PMH: Hypercholesterolemia and GERD since age 40 years; obesity; the patient is 60% over his ideal body weight

FH: Father died at age 60 years following a stroke. Mother died at age 75 years with breast cancer; older sister with breast cancer; maternal aunt died at age 47 years from rectal cancer.

SH: Works on a farm. Widowed with three children.

Meds: Simvastatin 20 mg daily, omeprazole 20 mg daily, aspirin 81 mg daily

ROS: (+) Abdominal cramping, loss of appetite, blood in stool, and fatigue

PE:

VS: 164/88 mm Hg, P 80, RR 17, T 37.1°C (98.8°F), ht 190 cm (75 in), wt 125 kg (275 lb)

Abd: Distended and tender to touch, (+) bowel sounds, and heme (+) stools

Labs: Positive hemoglobin 11.6 g/dL (116 g/L or 7.20 mmol/L) decreased from 14.6 g/dL (146 g/L or 9.06 mmol/L) last year.

Imaging and Diagnostic Studies

- Colonoscopy revealed multiple polyps in his transverse colon.
- Biopsy revealed three polyps positive for adenocarcinoma of the colon
- Staging CT scan negative for disease outside of his colon.
- Four lymph nodes positive for disease.

Because HB has stage III colon cancer, how does this affect the goal of your treatment plan compared with stage IV disease?

What nonpharmacologic and pharmacologic options are available to HB?

to select patients following potentially curative resection, but further studies are needed to determine an optimal treatment regimen.²⁰ Additionally, **neoadjuvant** approaches to patients with isolated hepatic lesions are discussed later in the chapter.

Radiation Symptom reduction is the primary goal of radiation for patients with advanced or metastatic colorectal cancer.

Pharmacologic Therapy

Table 91–4 lists common chemotherapy regimens used in colorectal cancer and the abbreviations used in the literature to describe them.

► Operable Disease (Stages I–III)

6 *Adjuvant chemotherapy is administered after tumor resection to decrease relapse rates and improve survival in patients with colon cancer by eliminating micrometastatic disease that is undetected on imaging studies. Patients diagnosed with stage*

*I colon or rectal cancer are usually cured by surgical resection, and adjuvant chemotherapy is not indicated in these patients.*¹⁸

The role of adjuvant chemotherapy for stage II colon cancer is controversial but may benefit certain high-risk groups. **Table 91–5** lists adjuvant treatment regimens based on stage and performance status (PS). Adjuvant chemotherapy for patients with stage II disease has not been shown to be superior to surgery alone with the exception of high-risk patients. High-risk patients who may benefit include those with inadequate nodes sampled for staging, bowel perforation upon diagnosis, T4 lesions, and those with unfavorable histology.¹⁷ The risks and benefits of adjuvant chemotherapy should be discussed with medically fit patients who have stage II disease with high-risk features. However, the American Society of Clinical Oncology does not recommend the routine use of adjuvant chemotherapy in the general patient population unless part of a clinical trial.²¹

The use of tumor gene profiling may predict patients with stage II disease that would benefit from adjuvant chemotherapy but requires further validation in prospective trials.¹⁷

Table 91–4

Dosing Schedules of Chemotherapy Regimens for Colon Cancer^a

Regimen	Dosing
5-FU + leucovorin (bolus)	Leucovorin 500 mg/m ² IV 5-FU 500 mg/m ² IV Every week × 6 weeks followed by 2-week rest
5-FU + leucovorin (continuous infusion)	Leucovorin 200 mg/m ² IV 5-FU 400 mg/m ² IV bolus and then 600 mg/m ² of 5-FU as a 22-hour continuous infusion On days 1 and 2; repeat every 2 weeks
FOLFIRI	Irinotecan 180 mg/m ² IV day 1 Folinic acid (leucovorin) 400 mg/m ² IV day 1 5-FU 400–500 mg/m ² IV bolus after folinic acid; then 2,400–3,000 mg/m ² of 5-FU IV over 46 hours Repeat every 14 days
FOLFOX4	Oxaliplatin 85 mg/m ² IV + leucovorin 200 mg/m ² IV followed by 5-FU 400 mg/m ² IV bolus and then 5-FU 600 mg/m ² IV over 22 hours day 1 Leucovorin 200 mg/m ² , followed by 5-FU 400 mg/m ² IV bolus and then 5-FU 600 mg/m ² IV over 22 hours day 2 Repeat every 2 weeks
mFOLFOX6	Oxaliplatin 85 mg/m ² IV day 1 Leucovorin 400 mg/m ² IV over 2 hrs, followed by 5-FU 400 mg/m ² IV bolus day 1 followed by 2400 mg/m ² IV over 46 hours Repeat every 2 weeks
Bevacizumab + 5-FU regimen	Bevacizumab 5 mg/kg every 2 weeks + a 5-FU-containing regimen (FOLFOX, FOLFIRI, or 5-FU + leucovorin) Bevacizumab 7.5 mg/kg every 3 weeks with CapeOX
Cetuximab ± irinotecan	Cetuximab 400 mg/m ² first infusion, then 250 mg/m ² weekly ± irinotecan 125 mg/m ² every week for 4 weeks Repeat irinotecan every 6 weeks (after a 2-week break)
Panitumumab	6 mg/kg every 2 weeks
Capecitabine	1,250 mg/m ² twice a day orally for 14 days Repeat every 3 weeks
CapeOX	Capecitabine 1,000 mg/m ² twice a day orally for 14 days Oxaliplatin 130 mg/m ² IV on day 1 Repeat every 3 weeks
CAPIRI	Capecitabine 1,000 mg/m ² twice a day for 14 days Irinotecan 100 mg/m ² IV days 1 and 8 Repeat every 22 days

CAPIRI—capecitabine and irinotecan; CapeOX, capecitabine—oxaliplatin; 5-FU, 5-fluorouracil; IV, intravenous.

^aNote that many variations exist, and current literature should be checked before administering any chemotherapy regimen.

Table 91-5

Treatment Regimens for Adjuvant Colon Cancer

Stage II ^a	Stage III
High Risk <ul style="list-style-type: none"> • Capecitabine or 5-FU plus leucovorin • FOLFOX 	Good Performance Status <ul style="list-style-type: none"> • FOLFOX • Capecitabine or 5-FU plus leucovorin
Low Risk^b <ul style="list-style-type: none"> • Observation or clinical trial • Capecitabine or 5-FU plus leucovorin 	Poor Performance Status <ul style="list-style-type: none"> • Capecitabine

5-FU, 5-fluorouracil.

^aIndividualized assessment of patient risk is necessary to determine if treatment is required. Clinical trials or observation may be an appropriate option.

^bT3 lesions may be considered high risk by some clinicians.

- An additional consideration for deciding on adjuvant therapy is the status of MSI within the tumor. MSI results from defective **DNA mismatch repair (dMMR) genes** leading to damaged DNA. Tumors that display high-levels of MSI appear to be associated with better prognosis for patients than those with microsatellite-stable (MSS) tumors. Despite being associated with a better prognosis, tumors that display high-levels of MSI do not respond as well to certain chemotherapy, including 5-fluorouracil (5-FU).²² It is recommended that stage II patients should be tested for the status of MSI if 5-FU alone is being considered for therapy, and an alternative therapy should be considered if high levels of MSI are displayed.¹⁷ In general, patients with stage II colon cancer should be enrolled into carefully controlled clinical trials to assess the impact of new agents and prognostic models. **6** *Adjuvant chemotherapy is standard therapy for patients with stage III colon cancer.* The presence of lymph node involvement in the resected specimen places patients with stage III colon cancer at high risk for relapse; the risk of death within 5 years of surgical resection alone is as high as 70%.¹⁸ In this population of patients, adjuvant chemotherapy significantly decreases the risk of cancer recurrence and death and is considered the standard of care.

6 5-FU, leucovorin, and oxaliplatin (FOLFOX)-based chemotherapy is the standard regimen used in adjuvant colon cancer. It is usually given for 6 months. 5-FU alone results in a small improvement in survival that can vary based on the method of 5-FU administration and the status of MSI. Studies suggest that continuous IV 5-FU infusion treatment schedules are more effective as adjuvant therapy and tumors with high levels of MSI display increased resistance to the single agent.²²

More often, 5-FU is administered as part of a combination regimen. The most frequently used combination is that of 5-FU, oxaliplatin, and leucovorin. The combination of 5-FU plus leucovorin has undergone extensive study in the adjuvant setting with decreased rates of recurrence and improved survival seen in patients receiving 5-FU plus leucovorin

compared with surgery alone. A pooled analysis demonstrated that 5-year disease-free survival (DFS) and overall survival were increased by 12% and 7% with adjuvant 5-FU-based chemotherapy, respectively.²³ 5-Fluorouracil and leucovorin can be administered in a variety of treatment schedules, but none has proven superior with regard to overall patient survival. In the past, the United States has favored bolus regimens based on patient convenience. However, improved availability and comfort in use of portable infusion pumps has led to an increase in use of the continuous IV schedule of 5-FU commonly advocated in Europe. Patients are treated with 6 months of adjuvant therapy. Longer regimens do not improve patient outcomes. No standard exists for the best schedule of 5-FU and leucovorin administration, although continuous infusions may be less toxic and have improved response rates (although no survival advantage) compared with bolus regimens.

Oxaliplatin added to the combination of 5-FU and leucovorin has further improved response rates in the adjuvant setting. The MOSAIC trial, conducted in more than 2,200 patients, demonstrated that the addition of oxaliplatin to 5-FU and leucovorin decreases disease recurrence and improves DFS and overall survival in patients with stage III disease.²⁴ These results led to the approval of the FOLFOX4 regimen, given for 6 months, for the adjuvant treatment of colon cancer. FOLFOX is considered standard of care for patients with stage III disease unless their PS is so poor that clinicians do not believe the patients could tolerate intensive combination therapy. Age alone should not determine whether patients receive combination adjuvant therapy or not because elderly patients have been found to equally benefit from this approach with minimal addition of adverse effects.

- Every effort should be made to minimize adverse treatment effects and use this regimen in patients with stage III colon cancer because this is the only regimen demonstrated to improve overall survival in these patients.^{18,24} Several variations on the original FOLFOX regimen have been studied with mFOLFOX6 being the most routinely used in clinical practice. Table 91-4 displays selected variations of the FOLFOX regimen.

Capecitabine is an oral prodrug of 5-FU that is also effective in the adjuvant setting and is being evaluated as a replacement in certain regimens for 5-FU for patient convenience and possible economic and safety reasons.

- Data suggest that capecitabine is at least equivalent to bolus 5-FU and leucovorin in efficacy and is better tolerated by patients.²⁵ An increase in hand-foot syndrome and decreased mucositis and neutropenia are seen with capecitabine compared with bolus 5-FU. Consequently, most practitioners feel that capecitabine is an acceptable alternative to IV 5-FU plus leucovorin. The role of capecitabine in combination with additional chemotherapy agents such as oxaliplatin has been investigated. The addition of oxaliplatin to capecitabine resulted in improved DFS compared with bolus 5-FU-leucovorin in stage III patients and is considered an acceptable adjuvant regimen in this patient population.^{17,26} Use of capecitabine as part of additional chemotherapy regimens should not be done outside of clinical trials.

Targeted therapies are being evaluated for their role in their adjuvant treatment of colon cancer. In particular, cetuximab and bevacizumab are in or have recently completed phase III trials. Trials comparing mFOLFOX6 with and without bevacizumab have failed to show a benefit of bevacizumab in the adjuvant setting.²⁷ At this time, no targeted agents are approved for use as adjuvant therapy in stage II or III colorectal cancer patients. Additionally, irinotecan should not be used in the adjuvant setting because its addition to 5-FU-based regimens has increased toxicity without therapeutic benefit.¹⁷

► Metastatic Disease (Stage IV)

Traditional chemotherapy and targeted biological therapies are the mainstay of treatment for metastatic colon or rectal cancer and have improved the median survival time of these patients to more than 20 months.¹⁸ Most often, a combination of chemotherapy agents with biological therapies is administered to these patients. Currently, metastatic colorectal cancer is incurable, and treatment goals are to reduce patients' symptoms, improve quality of life, and extend survival. Combination chemotherapy regimens have been demonstrated to result in prolongation of survival with tolerable adverse effects. Similar to the adjuvant setting, 5-FU plus leucovorin continues to be in most first-line chemotherapy regimens used for metastatic colorectal cancer. A variety of continuous intravenous (IV) infusion 5-FU and bolus regimens can be used; however, compared with IV bolus 5-FU, response rates with continuous infusion 5-FU are approximately doubled. In a meta-analysis of six randomized trials evaluating more than 1,200 patients with advanced colorectal cancer, continuous infusions of 5-FU had a significantly higher tumor response rate, a small increase in survival, and lower incidence of myelosuppression, diarrhea, and mucositis when compared with bolus regimens.²⁸

Additional agents have been added to the 5-FU and leucovorin regimen with superior response and survival rates compared to the two drugs used alone. The addition of irinotecan to 5-FU plus leucovorin (IFL) significantly improves response rates and survival without adversely affecting quality of life. This regimen was superior to 5-FU plus leucovorin with regard to tumor response, survival, and quality of life.²⁹ As a result, irinotecan received approval from the FDA in 2000 as first-line therapy for metastatic colorectal cancer in combination with 5-FU and leucovorin. Soon thereafter, oxaliplatin in combination with 5-FU and leucovorin (FOLFOX4) demonstrated improvement in median survival compared with the IFL regimen described earlier. A comparison of oxaliplatin plus 5-FU and leucovorin (FOLFOX4) with weekly IFL showed superior efficacy with FOLFOX4 compared with IFL with regard to response rates and survival.³⁰ Several study design questions including the crossover design and differing methods of 5-FU administration led several practitioners to debate the significance of these results. Patients in the IFL arm received weekly IV bolus 5-FU, and FOLFOX4 patients received 5-FU as IV bolus followed by continuous infusion IV, which is

thought to increase response rates. A larger European study validated these concerns when it compared a combined bolus and infusional 5-FU regimen plus irinotecan (FOLFIRI) with the FOLFOX regimen (using a slightly different schedule) with crossover to the opposite arm upon relapse.³¹ No difference in patient survival was seen with either regimen, and toxicity was as expected. Neuropathy and neutropenia were more common with FOLFOX, and diarrhea, nausea, vomiting, dehydration, and febrile neutropenia were more common with FOLFIRI. Based on improved survival data with the FOLFOX and FOLFIRI regimens, irinotecan administered in a bolus fashion, as described in the IFL regimens, is no longer recommended for routine use. When irinotecan-based combination chemotherapy is to be given for the metastatic treatment of colon cancer, it should be as FOLFIRI described in Table 91-4.

Capecitabine also has activity in the metastatic setting. When combined with oxaliplatin in regimens known as CapeOx or XELOX, capecitabine appears to be as safe as 5-FU-based regimens.¹⁷ Additionally, **progression-free survival** (PFS) with capecitabine and oxaliplatin is similar to that of FOLFOX and is considered noninferior to the FOLFOX regimen as first-line therapy in advanced disease.³² This noninferiority with capecitabine may be specific to its use with oxaliplatin because capecitabine in combination with irinotecan (CAPIRI) demonstrated decreased PFS compared with FOLFIRI and the routine substitution of 5-FU with capecitabine in irinotecan-based regimens is not recommended.^{17,33}

5-Fluorouracil plus leucovorin or capecitabine alone is appropriate first-line treatment only for individuals for whom three-drug combination regimens are believed to be toxic. The site(s) of tumor involvement, history of prior chemotherapy, and patient-specific factors help define the appropriate management strategy. **9** *The most important factor in patient survival is not the initial regimen but whether or not patients receive all three active chemotherapy drugs (5-FU, irinotecan, and oxaliplatin) at some point in their treatment course.*³⁴

Targeted or biologic agents have been approved for use in metastatic colorectal cancer. Bevacizumab in combination with IV 5-FU-based chemotherapy is approved by the FDA for initial treatment of patients with metastatic colorectal cancer. Results from randomized trials show increased benefit compared with chemotherapy alone. One phase III trial of bevacizumab in combination with IFL as first-line therapy in patients with metastatic colorectal cancer has also been completed with a 5-month increase in median survival seen with the addition of bevacizumab with manageable adverse effects.³⁵ The results of this study show the relevance of **angiogenesis** as an important target for the treatment of metastatic colorectal cancer. Similar to when used without bevacizumab, FOLFIRI is superior to IFL in combination with bevacizumab. Survival time was improved by approximately 9 months with FOLFIRI plus bevacizumab compared with IFL plus bevacizumab.³³

The addition of bevacizumab when added to first-line oxaliplatin-based chemotherapy has also been demonstrated

to improve PFS but did not positively impact response rates or overall survival.³⁶ Similar results were demonstrated with bevacizumab in combination with capecitabine and oxaliplatin.⁴⁷

Based on these results, bevacizumab is recommended as part of all 5-FU–based chemotherapy regimens used for the first-line treatment of metastatic colorectal cancer unless contraindicated. Bevacizumab should not be used in patients who present with or develop the following conditions until they are stabilized or treated, including patients with gastrointestinal (GI) perforation or fistulas involving a major organ, recent (within 28 days) major surgeries or open wounds, wound dehiscence requiring medical intervention, hypertensive crisis or uncontrolled severe hypertension, hypertensive encephalopathy—serious bleeding, a severe arterial thromboembolic event, moderate or severe proteinuria (2 g or higher of proteinuria/24 hours); nephrotic syndrome, and reversible posterior leukoencephalopathy syndrome.

The EGFR inhibitors, cetuximab and panitumumab, demonstrate improved PFS as first-line therapy in the metastatic setting when individually combined with either the FOLFOX or FOLFIRI regimens.^{37–40} **8** *Before using these agents, testing for KRAS mutation status should occur. Extensive literature exists documenting evidence demonstrating failure of EGFR inhibitors in patients whose tumors have a mutation in codon 12 or codon 13 of the KRAS gene.*¹⁷ To illustrate the importance of KRAS mutation status, in a retrospective analysis of data from a large phase III trial investigating panitumumab versus best supportive care in the metastatic setting, patients with WT KRAS had a 17% response rate, but those with mutant KRAS had a 0% response rate to panitumumab.⁴¹ Similar findings have been replicated with cetuximab as well. Consequently, cetuximab or panitumumab may be used in the first-line setting in combination with traditional chemotherapy agents in KRAS WT patients only.¹⁷

Attempts to combine the vascular endothelial growth factor (VEGF) inhibitor bevacizumab with cetuximab and panitumumab as part of traditional chemotherapy regimens have resulted in inferior outcomes to regimens with bevacizumab alone.⁴² Based on these results, the use of bevacizumab with either EGFR inhibitor is not recommended.¹⁷

7 *In summary, most practitioners select first-line treatment for metastatic colorectal cancer from among these currently approved treatments: oxaliplatin plus 5-FU plus leucovorin (FOLFOX); irinotecan plus 5-FU plus leucovorin (FOLFIRI); capecitabine plus oxaliplatin (CapeOx or XELOX); bevacizumab plus 5-FU– or capecitabine-based chemotherapy (FOLFIRI or FOLFOX or CapeOx); or cetuximab or panitumumab plus 5-FU based chemotherapy (FOLFOX or FOLFIRI) in KRAS WT patients.*¹⁷

► Second-Line Therapy

9 *Treatment of relapsed or refractory metastatic disease uses agents not given in the first-line setting.* Because most patients will have received a combination of 5-FU or capecitabine with either irinotecan or oxaliplatin, second-line therapy

with the alternate regimen should be considered.¹⁷ For example, a patient who received FOLFOX plus bevacizumab as first-line therapy for metastatic disease should be offered FOLFIRI as part of their second-line regimen. EGFR inhibitors are an additional option for use in the second-line setting in patients with WT KRAS *only*. Patients who did not have an EGFR inhibitor in their first-line regimens are candidates for single-agent cetuximab or panitumumab or either agent in combination with 5-FU and irinotecan (FOLFIRI + EGFR inhibitor). Additionally cetuximab plus irinotecan can be used without the inclusion of 5-FU. The use of EGFR inhibitors may be beneficial as monotherapy, but response rates and PFS appear to be increased in combination with irinotecan-based chemotherapy.^{43–47} The results appear to be best when irinotecan is continued because of synergy demonstrated between the two classes of agents.^{17,43}

If targeted agents such as bevacizumab were not part of the initial regimen, addition to the second-line regimen should be strongly considered. In the phase III randomized Eastern Cooperative Oncology Group trial, patients with metastatic colorectal who had failed first-line therapies were randomized into three treatment arms: FOLFOX4, FOLFOX4 plus bevacizumab, and single-agent bevacizumab. The addition of bevacizumab to FOLFOX increased the overall survival time from 10.8 to 12.9 months.⁴⁸ Bevacizumab as monotherapy was shown to be inferior to FOLFOX4 in efficacy and should not be considered as a treatment option in the second-line setting.

► Salvage Therapy

Third-line options for patients with metastatic colorectal cancer are limited. Panitumumab is approved for patients who have progressed after 5-FU, oxaliplatin, and irinotecan. Compared with best supportive care, it was demonstrated to improve disease progression.¹⁷ Patients who fail standard treatment for metastatic colorectal cancer should be encouraged to participate in a clinical trial evaluating new treatment approaches for this incurable disease. **Table 91–6** lists treatment options for first- and second-line treatment of metastatic colorectal cancer. Patients with good PS are treated more aggressively than those with poor PS because of their ability to better tolerate chemotherapy.

► Metastatic Patients With Isolated Hepatic Metastasis

Patients with metastatic lesions in the liver that remain unresectable have a poor outcome with limited chance for long-term survival. One approach to treating these patients is to resect the lesion and then give adjuvant chemotherapy. Unfortunately, the majority of patients with hepatic lesions have unresectable lesions at diagnosis. For these patients, neoadjuvant chemotherapy should be considered in attempt to convert their tumors unresectable to resectable.¹⁷

FOLFOX and FOLFIRI have both been demonstrated to allow for an increase in surgical resection and increase the potential for long-term survival.¹⁷ A systematic review

^bBevacizumab may be given if not part of the first-line therapy.

^cIf KRAS wild type.

published on the outcomes of surgical resection in patients with colorectal liver metastasis found that a subgroup of patients with hepatic metastases receive a large benefit from surgical resection.²⁰ Five year-survival rates in the reviewed studies ranged from 15% to 67% (median, 30%). Recent studies have added bevacizumab to combination chemotherapy regimens with success. No more than 8 to 10 weeks of chemotherapy should be given to avoid liver complications associated with it, and health care practitioners should take precautions to ensure that bevacizumab is not given within 6 weeks of surgery in this setting.¹⁷ Additionally, EGFR inhibitors can be considered for part of the neoadjuvant regimen in patients with WT status.

Hepatic arterial infusion pumps have been used in the setting of isolated liver metastases, but this practice has fallen

out of favor given improvements in local therapy such as radiofrequency ablation, cryoablation, and chemoembolization.

SPECIFIC AGENTS USED IN COLORECTAL CANCER

- **Table 91-7** lists all FDA-approved drugs used in colorectal cancer along with their mechanisms of action, common toxicities, and recommended dose adjustments for hepatic and renal dysfunction.

5-Fluorouracil

- 5-Fluorouracil acts as a “false” pyrimidine inhibiting the formation of the DNA base thymidine.¹⁸ The main mechanism by which it accomplishes this is by inhibiting the enzyme thymidylate synthase, the rate-limiting step in thymidine formation. 5-Fluorouracil must first be metabolized to its active metabolite, fluoro-deoxy-uridine monophosphate (F-dUMP). Additionally, metabolites of 5-FU may incorporate into RNA inhibiting its synthesis.

5-Fluorouracil is commonly used in the adjuvant and metastatic treatment of colon and rectal cancers. Various dosing administration techniques and schedules have been developed with 5-FU, including IV bolus every 3 to 4 weeks, IV continuous infusion, weekly IV boluses, and IV boluses followed by continuous infusions of 5-FU. Clinical studies comparing efficacy of bolus and continuous infusion schedules generally favor continuous infusion of 5-FU. This is consistent with evidence that suggests that the duration of infusion may be an important determinant of the biologic activity of 5-FU, particularly because of its short plasma half-life, S-phase specificity, and relatively slow growth of colon tumors.^{18,49}

Clinically significant differences in toxicity also differ based on the dose, route, and schedule of 5-FU administration. Leukopenia and mucositis are the primary dose-limiting toxicities of bolus 5-FU, whereas palmar-plantar erythrodysesthesia (“hand-foot syndrome”) and diarrhea occur most frequently with continuous infusions of 5-FU.^{18,49} Health care practitioners can offer valuable patient advice to decrease the impact of these adverse effects. Patients can be informed to suck on ice chips before and for up to 30 minutes after 5-FU boluses to decrease the incidence of mucositis. Hand-foot syndrome, characterized by painful swelling and redness of the soles of the feet and palms of the hand, can be minimized with loose-fitting clothing and keeping skin moist. Additional toxicities include moderate nausea and vomiting, skin discoloration, nail changes, photosensitivity, and neurologic toxicity.

An additional determinate of 5-FU toxicity, regardless of the method of administration, is related to its catabolism and **pharmacogenomic** factors. Dihydropyrimidine dehydrogenase (DPD) is the main enzyme responsible for the catabolism of 5-FU to inactive metabolites.⁵⁰ A number of polymorphisms in DPD have been identified in which patients have a complete or near-complete deficiency of this enzyme. This results in unusually severe toxicity, including

Patient Encounter, Part 3

Based on the information presented, create a care plan for this patient's colon cancer.

Your plan should include:

- The patient's drug- and nondrug-related needs and problems*
- The goals of therapy*
- A treatment plan specific to HB that includes strategies to prevent adverse effects of chemotherapy*
- A follow-up plan to determine whether the goals have been achieved and the adverse effects of chemotherapy have been minimized*
- A plan for treatment options when the initial therapy is no longer achieving the goals of therapy.*

Table 91-7

FDA-Approved Drugs Used in Colon Cancer

Generic Name (Trade Name)	Mechanism of Action	Common Toxicities	Dosing Adjustments for Renal or Hepatic Dysfunction or Pharmacogenetic Considerations
5-FU	Inhibition of the enzyme thymidylate synthase, the rate-limiting step in thymidine formation	<i>Dose limiting:</i> Myelosuppression and mucositis with bolus administration Diarrhea and hand-foot syndrome with continuous infusion <i>Additional toxicities:</i> Skin discoloration, nail changes, photosensitivity, and neurologic toxicity	Do not give if bilirubin greater than 5 mg/dL (86 μmol/L) DPD deficiency may result in increased toxicity. Testing not routine, but may be considered in those with excessive toxicity.
Capecitabine (Xeloda)	Orally active prodrug of 5-FU. Once activated, the mechanism of action is the same	Similar to continuous infusion 5-FU	CrCl 30–50 mL/min (0.50–83 mL/s) decrease starting dose to 75% of the original dose Do not give if CrCl less than 30 mL/min (0.50 mL/s)
Irinotecan (Camptosar)	Topoisomerase inhibitor that forms a complex with the covalently bound DNA topoisomerase enzyme and interferes with the DNA breakage-resealing process	<i>Dose limiting:</i> Early and late diarrhea <i>Additional toxicities:</i> Neutropenia, nausea, and vomiting	Decrease dose one level in patients with a homozygous UGT1A1*28 allele. Having this allele decreases the hepatic metabolism of irinotecan and increases the toxicity
Oxaliplatin (Eloxatin)	Similar to other platinum analogs (cisplatin) in that it binds to the N-7 position of guanine, which results in cross-linking of DNA and double-stranded DNA breaks	<i>Dose limiting:</i> Acute (within first 2 days) and persistent (greater than 14 days) neuropathies <i>Additional toxicities:</i> Anaphylactic-like reactions, dyspnea, nausea, vomiting	No formal dose adjustment, though use with caution in patients with mild to moderate renal dysfunction
Bevacizumab (Avastin)	Monoclonal antibody that binds to VEGF and inhibits angiogenesis	<i>Dose limiting:</i> Hypertension, bleeding episodes, thrombotic events <i>Additional toxicities:</i> Rare perforation of the bowel, proteinuria	None
Cetuximab (Erbix)	Binds to the cell surface EGFR, preventing EGF and TGF-α binding. This decreased cell proliferation of cancer cells	<i>Dose limiting:</i> Infusion-related reactions, acneiform skin rash <i>Additional toxicities:</i> Diarrhea, hypomagnesemia, hypocalcemia, interstitial lung disease	KRAS WT only
Panitumumab (Vectibix)	Similar to cetuximab	<i>Dose limiting:</i> Acneiform skin rash <i>Additional toxicities:</i> Infusion-related reactions, diarrhea, hypomagnesemia, hypocalcemia, interstitial lung disease	KRAS WT only

CrCl, creatinine clearance; EGF, epidermal growth factor; EGFR, epidermal growth factor receptor; 5-FU, 5-fluorouracil; TGF, transforming growth factor; VEGF, vascular endothelial growth factor; WT, wild type.

death, after the administration of 5-FU. Approximately 3% of patients have a complete lack of DPD activity with other patients demonstrating a partial deficiency in enzyme activity. Although patients may be tested for level of DPD activity, it is not routinely done but may be considered in patients who develop severe toxicity after 5-FU administration. The response to 5-FU is also influenced by the status of MSI within the tumor. Tumors with high levels of MSI are generally more resistant to 5-FU despite being associated with better prognosis.

Leucovorin is commonly given with 5-FU. Leucovorin acts to increase the affinity of 5-FU to thymidine synthase,

thus increasing the pharmacologic activity of 5-FU.¹⁸ Leucovorin is most effective when administered before 5-FU and can be given by IV bolus or as a continuous infusion. Health care practitioners can also expect an increase in 5-FU toxicities (leukopenia, mucositis, and diarrhea) when leucovorin is given in combination with 5-FU.

Capecitabine

Capecitabine (Xeloda) is an oral prodrug of 5-FU that is designed to be selectively activated by tumor cells. Capecitabine undergoes a three-step conversion to 5-FU, the last step

being phosphorylation by thymidine phosphorylase (TP). TP levels are reported to be higher in tumor cells than normal tissues; therefore, the systemic exposure of active drug is minimized, and tumor concentrations of the active drugs are optimized.^{18,25} After the drug is converted to 5-FU, it has the same mechanism of action. The current FDA-approved indication for capecitabine is for use in metastatic and adjuvant colorectal cancer when monotherapy is desired, although it is actively being investigated as a replacement for 5-FU in most combinations of colon and rectal cancer regimens. Capecitabine has been demonstrated to be at least equivalent to bolus IV 5-FU in the metastatic and adjuvant setting with improved patient tolerability.^{25,51} Hand-foot syndrome and diarrhea are common with capecitabine because its toxicities (and pharmacologic activity) appear to mimic those of continuous infusions of 5-FU. Both irinotecan and oxaliplatin have been combined with capecitabine. Capecitabine in combination with oxaliplatin appears to be as safe and effective as IV-based 5-FU in the treatment of patients with colorectal cancer.^{17,49} Combinations with irinotecan have had mixed results and are not routinely recommended.^{17,33}

The dose of capecitabine ranges from 1,000 to 1,250 mg/m² twice a day when used by itself; lower doses are often used when it is given in combination with irinotecan or oxaliplatin or in patients with renal insufficiency. The dose should be taken on a full stomach with breakfast and dinner. Capecitabine administered with warfarin can result in significant increases in patients' international normalized ratio (INR) and requires close monitoring. The convenience of oral administration, potentially requiring fewer clinic visits, and an improvement in toxicity make capecitabine a useful alternative to IV 5-FU both by itself and incorporated into other regimens used in colorectal cancer.

Irinotecan

- Irinotecan (Camptosar) is a **topoisomerase-I** inhibitor that forms a complex with the covalently bound DNA topoisomerase I enzyme and interferes with the DNA breakage–resealing process.⁴⁹ Binding permits uncoiling of the double-stranded DNA, but it prevents subsequent resealing of the DNA, resulting in double-stranded DNA breaks. Irinotecan is a prodrug that is converted by carboxylesterases to its active form, SN-38. Irinotecan is indicated for the first-line treatment of metastatic colorectal cancer in combination with 5-FU and leucovorin or as a single agent in patients who fail first-line therapies. Irinotecan is not recommended as part of the adjuvant treatment of colorectal cancer at this time.

The major toxicity of irinotecan is diarrhea, which can occur both early and late in therapy.^{17,49} The early diarrhea is a cholinergic reaction that occurs in the first 24 hours (often during the infusion) in up to 10% of patients and responds to atropine 0.25 to 1 mg IV. The late diarrhea seen in a larger percent of patients occurs 7 to 14 days after the irinotecan infusion. Health care practitioners have to be diligent in counseling patients on this adverse reaction and counseling them on the proper use of antidiarrheals. At the first change

in bowel habits, an intensive loperamide regimen should be started by patients (4 mg initially followed by 2 mg every 2 hours until diarrhea free for 12 hours). If diarrhea does not stop or if it worsens, patients should be instructed to call their health care provider immediately. Late-onset diarrhea may require hospitalization or discontinuation of therapy, and fatalities have been reported. Additional toxicities with irinotecan include leukopenia (including neutropenic fever) and moderate nausea and vomiting. Toxicities of irinotecan appear to be greater when the drug is given weekly compared with other administration schedules.

Similar to 5-FU, a pharmacogenomic abnormality is associated with irinotecan toxicity. UDP-glucuronosyltransferase (UGT1A1) is an enzyme that is responsible for the glucuronidation of SN-38 to inactive metabolites, and reduced or deficient levels of this enzyme correlate with irinotecan-induced diarrhea and neutropenia.^{17,49} Recently, the FDA approved a blood test that detects variations in this gene. This test may assist health care providers in predicting which patients may develop severe toxicities from “normal” doses of irinotecan and can be ordered before patients receive irinotecan.¹⁷ The package insert recommends dose reductions of one level in patients who are UGT1A1 homozygous variants. Irinotecan is administered as an IV bolus over 60 to 90 minutes in a variety of dosing schedules.

Oxaliplatin

- Oxaliplatin (Eloxatin) is similar to other platinum analogs (cisplatin) in that it binds to the N-7 position of guanine that results in cross-linking of DNA and double-stranded DNA breaks.⁴⁹ Oxaliplatin differs from cisplatin in that the DNA damage induced by oxaliplatin may not be as easily recognized by DNA repair genes often seen in colorectal cancer. Oxaliplatin, in combination with 5-FU-based regimens, is indicated for the first- and second-line treatment of metastatic colorectal cancer as well as the adjuvant treatment of colorectal cancer.

The dose-limiting toxicity of oxaliplatin is acute and chronic neuropathy.¹⁸ Acute neuropathies occur within 1 to 2 days of dosing, resolve within 2 weeks, and usually occur peripherally. These acute neuropathies occur in almost all patients to some degree and are exacerbated by exposure to cold temperature or cold objects. Health care providers should instruct patients to avoid cold drinks, avoid use of ice, and cover skin before exposure to cold or cold objects. In addition, carbamazepine, gabapentin, amifostine, and calcium and magnesium infusions have been used to both prevent and treat oxaliplatin-induced neuropathies, although use of these agents is not widely accepted.¹⁸ Persistent neuropathies generally occur after eight cycles of oxaliplatin and are characterized by defects that can interfere with daily activities (e.g., writing, buttoning, swallowing, and walking). Patients may receive predefined breaks from oxaliplatin to decrease the onset of these toxicities with reinitiation of therapy.³⁰ This strategy varies among protocols but involves administering a certain number of predefined oxaliplatin cycles and then stopping. Maintenance therapy with another

agent is usually administered and then the oxaliplatin-based regimen is restarted based on the protocol. These neuropathies occur in up to half of patients receiving oxaliplatin but usually resolve with dosage reductions or after oxaliplatin is stopped.¹⁸ A recent phase III trial in the adjuvant setting demonstrated a decrease in greater than grade 2 chronic sensory neuropathies in patients receiving IV calcium and magnesium infusions before and after oxaliplatin infusion.⁵² Oxaliplatin has minimal renal, myelosuppressive effects, and nausea and vomiting when compared with other platinum drugs. Oxaliplatin is given IV in a variety of dosing schedules with a typical dose of 85 mg/m² IV every 2 weeks.

Bevacizumab

Bevacizumab (Avastin) is a recombinant, humanized monoclonal antibody that inhibits VEGF. VEGF is a proangiogenic growth factor found in many cancers, including colorectal, and is thought to promote blood vessel formation and metastasis of the tumor by binding to VEGF receptors on tumors. Bevacizumab inhibits circulating VEGF, preventing it from binding to receptors and decreasing the formation of new blood vessels.^{17,18} Additionally, bevacizumab may allow for increased concentrations of traditional chemotherapy such as irinotecan to reach the tumor to exert its pharmacologic effect. Bevacizumab is not effective alone and must be used in combination with other agents effective in colorectal cancer. It is indicated for first-line treatment of patients with metastatic colorectal cancer in combination with IV 5-FU-based regimens. Bevacizumab has also been shown to increase survival in the second-line setting when used in combination with the FOLFOX regimen in patients who have not yet received bevacizumab.¹⁷

Adverse effects associated with bevacizumab include hypertension, which is common but easily managed with oral antihypertensive agents.^{35,53} Thrombotic events (including myocardial infarctions, pulmonary embolisms, and deep vein thrombosis) occur more frequently in the elderly patients with cardiovascular risk factors and need to be monitored routinely. Because bevacizumab interferes with normal wound healing, it should not be given shortly before or after surgical procedures.⁵³ Initiation within 28 days of surgery is not recommended to allow for proper wound healing and decrease the risk of bleeding. The amount of time needed after bevacizumab discontinuation to perform elective surgical procedures is less clear, but health care providers should take into consideration bevacizumab's half-life of approximately 20 days when making clinical decisions.³⁸ Patients should have their urine checked for protein before each dose of bevacizumab to check for potential kidney damage. Patients who have developed 2+ protein on the urinalysis require additional testing before receiving therapy. These patients will have their 24-hour urine collected and assessed for protein. Therapy is interrupted for 2 g or more of proteinuria/24 hours and resumed when proteinuria was less than 2 g/24 hours.

Finally, there is a risk of GI perforation that is rare but potentially fatal. Patients complaining of abdominal pain

associated with vomiting or constipation should be counseled to call their physician immediately. Bevacizumab is commonly given at a dose of 5 mg/kg IV every 14 days until disease progression. Once disease progresses and salvage chemotherapy is initiated, the benefit of continuing bevacizumab is unclear.

Cetuximab and Panitumumab

Cetuximab (Erbix) and panitumumab (Vectibix) are monoclonal antibodies directed against the EGFR. Cetuximab is a chimeric antibody, whereas panitumumab is a fully human monoclonal antibody. EGFR is overexpressed in colorectal cancers and leads to an increase in tumor proliferation and growth.⁴⁹ Cetuximab received FDA approval for use in EGFR-expressing metastatic colorectal cancer in irinotecan-relapsed or -refractory patients. Cetuximab should be administered in combination with irinotecan but can be used as a single agent in patients who cannot tolerate irinotecan-based chemotherapy. Panitumumab is approved as monotherapy agent and should not be used in combination with other agents outside of clinical trials.

Both agents are well tolerated with infusion-related reactions being cetuximab's dose-limiting toxicity and rash most commonly seen with panitumumab. Patients receiving cetuximab require premedication with acetaminophen and diphenhydramine and may require modifications to their administration schedule or permanent discontinuation if they develop severe allergic toxicity. A skin rash and diarrhea are also commonly seen with both agents, and health care practitioners should provide counseling to patients about these adverse effects. Treatment options include common medications used to treat acne (doxycycline), topical and systemic steroids, and general skin care. Development of rash may be a surrogate marker of response, and clinicians should attempt to minimize the complications of the rash before discontinuing therapy.¹⁷ Other toxicities common to both agents include low magnesium, calcium, and potassium levels that require checking levels and replacement therapy as clinically indicated. A rare (less than 1%) interstitial lung disease is seen with all agents that inhibit EGFR, and patients should be instructed to report any new-onset shortness of breath. Cetuximab has an initial loading dose of 400 mg/m² IV infusion. Weekly doses of 250 mg/m² are then administered starting the following week. Panitumumab is given 6 mg/kg every 2 weeks.

Patient Encounter, Part 4

Despite completing 6 cycles of adjuvant chemotherapy, HB's disease progresses, and a CT scan reveals metastases to his bone and liver. The tumor is sent for pharmacogenomic profiling and is found to have a mutation in the *KRAS* gene.

What pharmacologic treatment options are available for the treatment of his metastatic disease?

RECTAL CANCER

Although often treated similarly to colon cancer, there are some important differences in the treatment of rectal cancer, especially in the adjuvant setting. Rectal cancer involves tumors found in the distal 15 cm of the large bowel and, as such, is very distinct from colon cancer in that it has a propensity for both local and distant recurrence. The higher incidence of local failure and poorer overall prognosis associated with rectal cancer are attributable to limitations in surgical techniques. Therefore, multimodality therapies with a combination of chemotherapy, radiation, and surgery are at the forefront in the treatment of rectal cancer with the main goal of survival and quality of life by preserving the function of the anal sphincter. In addition, because treatment with surgery, radiation, or systemic chemotherapy at the time of the recurrence is often suboptimal, adjuvant therapy after tumor resection is an important aspect of treatment of the primary tumor. Similar to adjuvant therapy for colon cancer, 5-FU provides the basis for chemotherapy regimens for rectal cancer. **10** *Adjuvant therapy consisting of 5-FU–based chemotherapy in combination with radiation therapy should be offered to patients with stage II or III cancer of the rectum.*⁵⁴ Radiation therapy decreases the rate of local recurrences, but the 5-FU decreases the risk of distant tumor recurrence as well as acting as a radiosensitizer. Toxicities from combined modality therapy include severe hematologic toxicity, enteritis, and diarrhea. Additional trials have sought to determine optimal combinations of concurrent radiation and 5-FU. Similar to tumors in the colon, continuous infusions of 5-FU appear to be superior to bolus doses. However, leucovorin does not appear to improve efficacy of adjuvant treatment for rectal cancer. Use of oral alternatives to 5-FU that are also known to enhance radiation effects, such as capecitabine, are under investigation with preliminary data suggesting the combination of capecitabine and radiation will be safe and effective. In addition, based on the efficacy in colon cancer, FOLFOX regimens have moved into clinical trials in the adjuvant setting.

Another unique aspect of rectal cancer is the use of neoadjuvant therapy. Preoperative radiation (with or without chemotherapy) is given to downstage the tumor before surgical resection to improve sphincter preservation.⁵⁴ The issue of pre- versus postoperative radiation is a subject of debate and investigation in the United States and requires further data to determine the superiority of a specific neoadjuvant protocol.

10 *Finally, once rectal cancer is metastatic, similar regimens as outlined in the colon cancer section are used for palliation of symptoms.*⁵⁴

OUTCOME EVALUATION

The goals of monitoring are to evaluate whether the patient is receiving any benefit from the management of the disease, detect recurrence, and minimize the adverse effects of treatment. During treatment for active disease, patients should undergo monitoring for measurable tumor response,

progression, or new metastases; these tests may include chest CT scans or x-rays, abdominal or pelvic CT scans or x-rays, depending on the site of disease being evaluated for response; and carcinoembryonic antigen (CEA) measurements every 3 months if the CEA level is or was previously elevated.¹⁷ A PET scan can be considered to identify localized sites of metastatic disease when a rising CEA level suggests metastatic disease but results of CT scans and other imaging studies are negative. Symptoms of recurrence such as pain, changes in bowel habits, rectal bleeding, pelvic masses, anorexia, and weight loss develop in fewer than 50% of patients. Patients who undergo curative surgical resection, with or without adjuvant therapy, require close follow-up because early detection and treatment of recurrence could still result in patient cures. In addition, early treatment for asymptomatic metastatic colorectal cancer appears superior to delayed therapy. Colorectal cancer surveillance guidelines published by the American Society of Clinical Oncology recommend against routinely monitoring liver function tests, complete blood count (CBC), FOBT, CT scans, annual chest x-rays, or pelvic imaging in asymptomatic patients.⁵⁵

In addition, a CBC should be obtained before each course of chemotherapy administration to ensure that hematologic values are adequate. In particular, white blood cell counts and absolute neutrophil counts can be decreased in patients receiving chemotherapy such as irinotecan and 5-FU. Baseline liver function tests and an assessment of renal function should be evaluated before and periodically during therapy. Other selected laboratory tests include checking for the presence of protein in the urine in patients receiving bevacizumab and monitoring of magnesium, calcium, and potassium in patients receiving cetuximab or panitumumab.

Patients should be evaluated during every treatment visit for the presence of anticipated side effects from their treatment, and health care practitioners should anticipate these adverse reactions and aggressively treat and prevent them from occurring. These generally include loose stools or diarrhea from irinotecan, 5-FU, and capecitabine; hand-foot syndrome from 5-FU and capecitabine; nausea or vomiting from irinotecan, 5-FU, and oxaliplatin; mouth sores from 5-FU; neuropathies from oxaliplatin; bleeding and hypertension from bevacizumab; and skin rash associated with cetuximab and panitumumab.

SUMMARY

Recent advances in the treatment of cancer of the colon and rectum now offer the potential to improve patient survival, but for many patients, improved DFS and PFS represent equally important therapeutic outcomes. In the absence of the ability of a specific treatment to demonstrate improved survival, important outcome measures should include the effects of the treatment on patient symptoms, daily activities, PS, and other quality-of-life indicators. Individualized patient care to balance the risks associated with treatment and benefits of a specific treatment regimen is necessary to optimize patient outcomes.

Patient Care and Monitoring

1. Review any available diagnostic data to determine the status of the colon cancer.
2. Obtain a thorough history of prescription, nonprescription, and natural drug product use.
3. Evaluate patient-specific factors that may dictate treatment regimen. Does the patient have a known pharmacogenomic deficiency? What lifestyle issues are important to the patient?
4. Determine if any dose modifications are required in the chemotherapy regimen prescribed. Does the patient have adequate blood counts to receive chemotherapy?
5. Educate the patient on drug therapy and possible treatment-related adverse effects and counsel the patient on appropriate recommendations to prevent or minimize these adverse effects. What medications are for the treatment of cancer, and what medications are to prevent the adverse effects of chemotherapy?
6. Develop a plan to prevent treatment-related adverse effects. Are the antiemetics appropriate? Does the patient understand the possible adverse effects and when to call the physician versus when patient-directed care is appropriate?
7. Warning signs to report to the physician (depends on regimen used) include fever, diarrhea, mucositis, and hand-foot syndrome.
8. Evaluate the patient for the presence of adverse drug reactions, drug allergies, and drug interactions.

INR	International normalized ratio
MSI	Mircrosatellite instability
NSAID	Nonsteroidal anti-inflammatory drug
PET	Positron emission tomography
PFS	Progression-free survival
TNM	Tumor, node, metastasis
TP	Thymidine phosphorylase
UGT	UDP-glucuronosyltransferase
VEGF	Vascular endothelial growth factor

Abbreviations Introduced in This Chapter

APC	Adenomatous polyposis coli
CapeOX	Capecitabine and oxaliplatin
CBC	Complete blood count
CEA	Carcinoembryonic antigen
COX-2	Cyclooxygenase-2
CTC	Computed tomographic colonoscopy
DFS	Disease-free survival
DPD	Dihydropyrimidine dehydrogenase
EGFR	Epidermal growth factor receptor
FAP	Familial adenomatous polyposis
F-dUMP	Fluoro-deoxy-uridine monophosphate
FISH	Fluorescence in situ hybridization
FIT	Fecal immunochemical test
FOBT	Fecal occult blood test
FOLFIRI	Folinic acid, fluorouracil, and infusional irinotecan
FOLFOX	Folinic acid, fluorouracil, and oxaliplatin
HNPCC	Hereditary nonpolyposis colorectal cancer
IFL	Irinotecan, fluorouracil, and leucovorin

LEARNING OBJECTIVES

● Upon completion of the chapter, the reader will be able to:

1. List the risk factors associated with the development of prostate cancer.
2. Compare placebo versus finasteride for the prevention of prostate cancer.
3. Recommend an initial treatment for prostate cancer on the basis of stage, Gleason score, prostate-specific antigen, patient age, and symptoms.
4. Select an initial and secondary hormonal manipulation for newly diagnosed advanced prostate cancer
5. Understand the role of chemotherapy and immunotherapy in the treatment of metastatic castrate-resistant prostate cancer.

KEY CONCEPTS

- 1 Prostate cancer is the most frequent cancer in U.S. men. Increasing age and family history are the primary risk factors for prostate cancer.
- 2 Prostate-specific antigen (PSA) is a useful marker for predicting outcome for localized disease and monitoring response to androgen-deprivation therapy or chemotherapy for advanced-stage disease. An elevated PSA may detect asymptomatic prostate cancer at an early stage.
- 3 The prognosis for prostate cancer patients depends on the histologic grade, tumor size, and disease stage. More than 85% of patients with stage 1 disease but fewer than 1% of those with stage D can be cured.
- 4 Androgen ablation with a luteinizing hormone-releasing hormone (LHRH) agonist plus an antiandrogen should be used before radiation therapy for patients with locally advanced prostate cancer to improve outcomes over radiation therapy alone.
- 5 Androgen ablation therapy with orchiectomy, an LHRH agonist alone or an LHRH agonist plus an antiandrogen (combined hormonal blockade) can be used to provide palliation for patients with advanced (stage D) prostate cancer. The effects of androgen deprivation are most pronounced in patients with minimal disease at diagnosis.
- 6 For patients having progressive disease while receiving combined hormonal blockade with an LHRH agonist plus an antiandrogen, antiandrogen withdrawal can

provide additional symptomatic relief. Mutations in the androgen receptor have been documented that cause antiandrogen compounds to behave like receptor agonists.

- 7 Chemotherapy with docetaxel and prednisone improves survival in patients with castrate-resistant prostate cancer (CRPC).
- 8 Chemotherapy with cabazitaxel and prednisone improves survival in patients with CRPC who have either progressed or are intolerant to docetaxel
- 9 Hormonal manipulation with abiraterone and prednisone improves survival in patients previously treated with docetaxel and prednisone.
- 10 Immunotherapy with sipuleucel-T improves survival in patients with minimally symptomatic CRPC.

INTRODUCTION

Prostate cancer is the most commonly diagnosed cancer in U.S. men.¹ The disease course varies from a slow growing, asymptomatic tumor that may not require treatment to a rapidly progressing, aggressive tumor resulting in mortality. Prostate cancers are hormonally sensitive, and their growth is increased by androgen signaling. In most men, prostate cancer has a prolonged course. The treatment of clinically localized prostate cancer is based on risk features that may predict a more aggressive cancer. Treatment options for clinically localized disease include active surveillance (also referred to as observation, or watchful waiting) for low-risk patients to surgery, and/or radiation for higher risk patients.

With active surveillance, patients are monitored for disease progression or development of symptoms. In patients with certain high-risk features, a course of adjuvant androgen deprivation therapy may be used after surgery or radiation. Although clinically localized prostate cancer can be cured by surgery or radiation therapy, advanced prostate cancer is not yet curable. Treatment for advanced prostate cancer can provide significant disease palliation for many patients for several years after diagnosis. Advances in the understanding of the biology of the disease resulted in the availability of multiple treatment options and improved survival for patients with advanced prostate cancer.

EPIDEMIOLOGY AND RISK FACTORS

1 Prostate cancer is the most frequently diagnosed cancer among U.S. men and represents the second leading cause of cancer-related deaths in all men.¹ In the United States alone, it was predicted that more than 240,000 new cases of prostatic carcinoma will be diagnosed and more than 33,000 men would die from this disease in 2011.¹ Although prostate cancer incidence increased during the late 1980s and early 1990s owing to widespread prostate-specific antigen (PSA) screening, deaths from prostate cancer have been declining since 1995.

Table 92-1 summarizes the possible factors associated with risk for prostate cancer.^{2,3} The widely accepted risk factors for prostate cancer are age, race or ethnicity, and family history of prostate cancer. The disease is rare under the age of 40, but the incidence sharply increases with each subsequent decade of life, most likely because with older age an individual has had a greater lifetime exposure to testosterone, a known growth signal for the prostate. In an evaluation of autopsies from men in Michigan dying of unrelated causes, prostate cancer was identified in 2%, 29%, 32% 55%, and 64% of men in their third, fourth, fifth, sixth and eighth decades of life, respectively.

Race and Ethnicity

The incidence of clinical prostate cancer varies across geographic regions. Scandinavian countries and the United States report the highest incidence of prostate cancer, but the disease is relatively rare in Japan and other Asian countries.⁵ African American men have the highest rate of prostate cancer in the world, and in the United States, prostate cancer mortality in African Americans is approximately twice that seen in the white population.¹ Hormonal, dietary, and genetic differences, as well as differences in access to health care, may contribute to the altered susceptibility to prostate cancer in these populations.^{2,3} Testosterone, commonly implicated in the pathogenesis of prostate cancer, is 15% higher in African American men compared with white men. Activity of 5- α -reductase, the enzyme that converts testosterone to its more active form, dihydrotestosterone (DHT), in the prostate, is decreased in Japanese men compared with African Americans and whites.^{2,3} In addition, genetic variations in

Table 92-1

Risk Factors Associated With Prostate Cancer

Factor	Possible Relationship
Probable Risk Factors	
Age	More than 70% of cases are diagnosed in men older than 65 years
Race	African Americans have a higher incidence and death rate
Genetic	Familial prostate cancer inherited in an autosomal dominant manner Mutations in <i>p53</i> , <i>Rb</i> , E-cadherin, α -catenin, androgen receptor, <i>KAI1</i> , and microsatellite instability; loss of heterozygosity at 1, 2q, 12p, 15q, 16p, and 16q; <i>BRCA1</i> and <i>BRCA2</i> mutations Candidate prostate cancer gene locus identified on chromosome 1
Possible Risk Factors	
Environmental	Clinical carcinoma incidence varies worldwide Latent carcinoma similar between regions' nationalized men adopt intermediate incidence rates between that of the United States and their native country
Occupational	Increased risk associated with cadmium exposure
Dietary	Increased risk associated with high-meat and high-fat diets Decreased intake of 1,25-dihydroxyvitamin D, lycopene, and β -carotene increases risk
Hormonal	Does not occur in castrated men Low incidence in cirrhotic patients Up to 80% are hormonally dependent African Americans have 15% increased testosterone Japanese have decreased 5- α -reductase activities Polymorphic expression of the androgen receptor

the androgen receptor exist. Activation of the androgen receptor is inversely correlated with trinucleotide (CAG) repeat length. Shorter CAG repeat sequences have been found in African Americans. Therefore, the combination of increased testosterone and increased androgen receptor activation may account for the increased risk of prostate cancer in African American men.^{2,3} The Asian diet generally is considered to be low in fat and high in fiber with a high concentration of phytoestrogens, potentially explaining their decreased risk.^{5,6}

Family History

Men with a brother or father with prostate cancer have twice the risk for prostate cancer compared to the rest of the population.⁶ Genome-wide scans have identified potential prostate cancer susceptibility candidate genes, and there appears to be a familial clustering of a prostate cancer syndrome. Male carriers of germline mutations of *BRCA1* and *BRCA2* are known to have an increased risk for developing prostate cancer.⁷ Common exposure to

environmental and other risk factors may also contribute to increased risk among patients with first-degree relatives with prostate cancer.⁶

An alternative explanation for the familial clustering may be polymorphisms in genes important for prostate cancer function and development.⁸ Candidate **polymorphisms** include a polymorphism in the androgen receptor, which has two different nucleotide repeat variants, the CAG or the GCC. The CAG repeat varies in repeat number from 11 to 31 repeats in healthy individuals, and the number of repeats is inversely proportional to the activity of the androgen receptor. Some studies have demonstrated that shorter CAG repeats are associated with increased prostate cancer risk. Another candidate polymorphism is *SRD5A2*, which is the gene that codes for 5- α -reductase, the enzyme that converts testosterone to the more active DHT. A variant in *SRD5A2*, the Ala49Thr, increases the activity and may increase prostate cancer risk.⁸

Diet

A number of epidemiologic studies support an association between high fat intake and risk of prostate cancer. A strong correlation between national per capita fat consumption and national prostate cancer mortality has been reported, and prospective case-control studies suggest that a high-fat diet doubles the risk of prostate cancer.⁶ This relationship between high fat intake and prostate cancer may be explained by differences in insulin-like growth factor-1 (IGF-1). High-calorie and high-fat diets stimulate production of IGF-1 by the liver. This factor is involved in the regulation of proliferation of cancer cells and may also prevent them from undergoing apoptosis. High levels of IGF-1 are associated with an increased risk of prostate cancer.⁸

Other dietary factors implicated in prostate cancer include retinol, carotenoids, lycopene, and vitamin D consumption.⁵ Retinol, or vitamin A, intake, especially in men older than 70 years, is correlated with an increased risk of prostate cancer, but intake of its precursor, β -carotene, has a protective or neutral effect. Lycopene, obtained primarily from tomatoes, decreased the risk of prostate cancer in small cohort studies. Men who developed prostate cancer in one cohort study had lower levels of 1,25(OH)₂-vitamin D than matched control participants, although a prospective study did not support this. Clearly, dietary risk factors require further evaluation, but because fat and vitamins are modifiable risk factors, dietary intervention may be promising in prostate cancer prevention. Investigations of selenium and vitamin E supplementation are discussed further in the chemoprevention section.

Other Factors

Benign prostatic hyperplasia (BPH) is a common problem among elderly men, affecting more than 40% of men older than the age of 70 years. BPH results in the urinary symptoms of hesitancy and frequency. Because prostate cancer affects a similar age group and often has similar

presenting symptoms, the presence of BPH often complicates the diagnosis of prostate cancer, although it does not appear to increase the risk of developing prostate cancer.^{2,9}

Smoking has been associated with an increased risk of aggressive prostate cancer and smokers with prostate cancer have an increased mortality resulting from the disease compared with nonsmokers with prostate cancer (relative risk [RR], 1.5 to 2).¹⁰

PATHOPHYSIOLOGY

The prostate gland is a solid, rounded, heart-shaped organ positioned between the neck of the bladder and the urogenital diaphragm (**Fig. 92-1**). The normal prostate is composed of acinar secretory cells arranged in a radial shape and surrounded by a foundation of supporting tissue. The size, shape, or presence of acini is almost always altered in a gland that has been invaded by prostatic carcinoma. Adenocarcinoma, the major pathologic cell type, accounts for more than 95% of prostate cancer cases.^{11,12} Much rarer tumor types include small cell neuroendocrine cancers, sarcomas, and transitional cell carcinomas.

Prostate cancer can be graded systematically according to the histologic appearance of the malignant cell and then grouped into well, moderately, or poorly differentiated grades.^{11,12} Gland architecture is examined and then rated on a scale of 1 (well differentiated) to 5 (poorly differentiated). Two different specimens are examined, and the score for each specimen is added. Groupings for total Gleason score are 2 to 4 for well differentiated, 5 or 6 for moderately differentiated, and 7 to 10 for poorly differentiated tumors. Poorly differentiated tumors grow rapidly (poor prognosis), while well-differentiated tumors grow slowly (better prognosis).

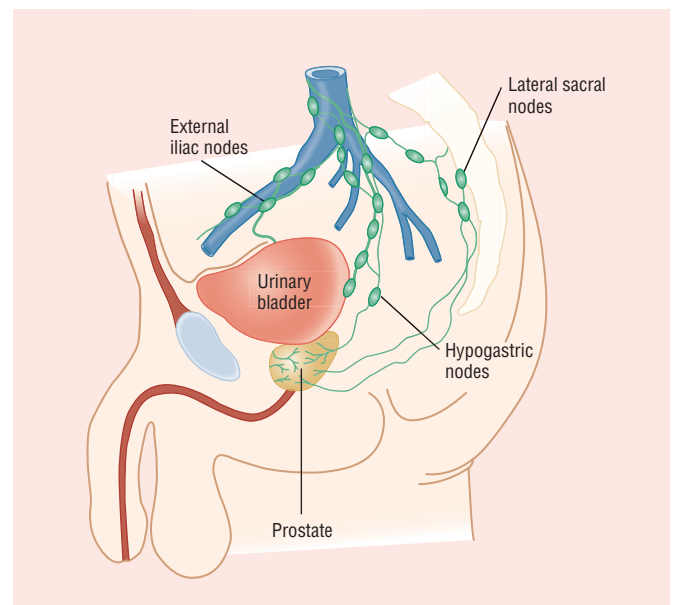

FIGURE 92-1. The prostate gland. (From DiPiro JT, Talbert RL, Yee GC, et al, eds. *Pharmacotherapy: A Pathophysiologic Approach*, 6th ed. New York: McGraw-Hill, 2005:1856.)

Metastatic spread can occur by local extension, lymphatic drainage, or hematogenous dissemination.^{11,12} Lymph node metastases are more common in patients with large, undifferentiated tumors that invade the seminal vesicles. The pelvic and abdominal lymph node groups are the most common sites of lymph node involvement (Fig. 92-1). Skeletal metastases from hematogenous spread are the most common sites of distant spread. Typically, the bone lesions are osteoblastic or a combination of osteoblastic and osteolytic. The most common site of bone involvement is the lumbar spine. Other sites of bone involvement include the proximal femurs, pelvis, thoracic spine, ribs, sternum, skull, and humerus. The lung, liver, brain, and adrenal glands are the most common sites of visceral involvement, although these organs usually are not involved initially. About 25% to 35% of patients have evidence of lymphangitic or nodular pulmonary infiltrates at autopsy. The prostate is rarely a site for metastatic involvement from other solid tumors.

Normal growth and differentiation of the prostate depends on the presence of androgens, specifically DHT.^{13,14} The testes and the adrenal glands are the major sources of circulating androgens. Hormonal regulation of androgen synthesis is mediated through a series of biochemical interactions among the hypothalamus, pituitary, adrenal glands, and testes (Fig. 92-2). Luteinizing hormone–releasing hormone (LHRH) released from the hypothalamus stimulates the release of luteinizing hormone (LH) and follicle-stimulating

hormone (FSH) from the anterior pituitary gland. LH complexes with receptors on the Leydig cell testicular membrane and stimulates the production of testosterone and small amounts of estrogen. FSH acts on the Sertoli cells within the testes to promote the maturation of LH receptors and to produce an androgen-binding protein. Circulating testosterone and estradiol influence the synthesis of LHRH, LH, and FSH by a negative feedback loop operating at the hypothalamic and pituitary level.^{15,16} Prolactin, growth hormone, and estradiol appear to be important accessory regulators for prostatic tissue permeability, receptor binding, and testosterone synthesis.

Testosterone, the major androgenic hormone, accounts for 95% of the androgen concentration. The primary source of testosterone is the testes; however, 3% to 5% of the testosterone concentration is derived from direct adrenal cortical secretion of testosterone or C19 steroids such as androstenedione.^{13,17}

In early stage prostate cancers, aberrant tumor cell proliferation is promoted by the presence of androgens. For these tumors, blockade of androgens induces tumor regression in most patients. Hormonal manipulations to ablate or reduce circulating androgens can occur through several mechanisms (Table 92-2).^{15,16} The organs responsible for androgen production can be removed surgically (orchiectomy, hypophysectomy, or adrenalectomy). Hormonal pathways that modulate prostatic growth can be interrupted at several steps (see Fig. 92-2). Interference with LHRH or LH (by estrogens, LHRH agonists, progesterones, and cyproterone acetate) can reduce testosterone secretion by the testes. Estrogen administration reduces androgens by directly inhibiting LH release, acting directly on the prostate cell, or decreasing free androgens by increasing steroid-binding globulin levels.^{15,16}

FIGURE 92-2. Hormonal regulation of the prostate gland. (ACTH, adrenocorticotropic hormone; DHT, dihydrotestosterone; FSH, follicle-stimulating hormone; GH, growth hormone; LH, luteinizing hormone; LHRH, luteinizing hormone–releasing hormone; PROL, prolactin; R, receptor.) Hormonal Manipulations in Prostate Cancer

Androgen source ablation	Antiandrogens
Orchiectomy	Flutamide
Adrenalectomy	Bicalutamide
Hypophysectomy	Nilutamide
LHRH or LH inhibition	Cyproteroneacetate ^b
Estrogens	Progesterones
LHRH agonists	5- α -Reductase inhibition
Progesterones ^a	Finasteride ^b
Cyproteroneacetate ^b	Dutasteride ^b
Gonadotropin receptor antagonists	
Abarelix	
Degarelix	
Androgen synthesis inhibition	
Abiraterone	
Aminoglutethimide	
Ketoconazole	
Progesterones ^a	

LH, luteinizing hormone; LHRH, luteinizing hormone–releasing hormone.

^aMinor mechanisms of action.

^bInvestigational compounds or use.

Isolation of the naturally occurring hypothalamic decapeptide hormone LHRH has provided another group of effective agents for advanced prostate cancer treatment. The physiologic response to LHRH depends on both the dose and the mode of administration. Intermittent pulsed LHRH administration, which mimics the endogenous release pattern, causes sustained release of both LH and FSH, but high dose or continuous intravenous administration of LHRH inhibits gonadotropin release caused by receptor downregulation.¹⁴⁻¹⁶ Structural modification of the naturally occurring LHRH and innovative delivery have produced a series of LHRH agonists that cause a similar downregulation of pituitary receptors and a decrease in testosterone production.¹⁶

Androgen synthesis can also be inhibited in the testes or adrenal gland. Aminoglutethimide inhibits the desmolase-enzyme complex in the adrenal gland, thereby preventing the conversion of cholesterol to pregnenolone. Pregnenolone is the precursor substrate for all adrenal-derived steroids, including androgens, glucocorticoids, and mineralocorticoids. Ketoconazole, an imidazole antifungal agent, causes a dose-related reversible reduction in serum cortisol and testosterone concentration by inhibiting both adrenal and testicular steroidogenesis.¹⁵ Megestrol is a synthetic derivative of progesterone that exhibits a secondary mechanism of action by inhibiting the synthesis of androgens. This inhibition appears to occur at the adrenal level, but circulating levels of testosterone also are reduced, suggesting that inhibition at the testicular level also may occur.¹⁵

Antiandrogens inhibit the formation of the DHT-receptor complex and thereby interfere with androgen-mediated action at the cellular level. Megestrol acetate, a progestational agent, also is available and has antiandrogen actions.¹⁸ Finally, the conversion of testosterone to DHT may be inhibited by 5- α -reductase inhibitors.⁹

In advanced stages of the disease, prostate cancer cells may be able to survive and proliferate without the signals normally provided by circulating androgens.¹⁸ When this occurs, the tumors are no less sensitive to therapies that are dependent on androgen blockade. These tumors are referred to as *castrate resistant* and were formally known as *hormone refractory* or *androgen independent*.

PREVENTION AND EARLY DETECTION

Chemoprevention

Significant decreases in the risk of prostate cancer have been demonstrated by the 5- α -reductase inhibitors finasteride and dutasteride.^{9,19} These medications work by inhibiting 5- α -reductase, an enzyme that converts testosterone to its more active form, DHT, which is involved in prostate epithelial proliferation. There are two types of 5- α -reductase, types I and II; both are implicated in the development of prostate cancer. Finasteride selectively inhibits the 5- α -reductase type-II isoenzyme, whereas dutasteride inhibits both isoenzymes. Both finasteride and dutasteride lower the PSA by approximately 50% within 1 year.^{9,19} However this lowering may vary across individuals or within the same individual

over time. Although no prospective studies have validated a specific threshold for PSA monitoring in patients receiving a 5- α -reductase inhibitor, common clinical practice is to lower the PSA threshold by one-half.

The Prostate Cancer Prevention Trial compared 5 mg/day of finasteride for 7 years with placebo for the prevention of prostate cancer in men 55 years of age or older with normal digital rectal examination findings and a PSA of 3.0 ng/mL (3.0 mcg/L) or less.^{9,20} When compared with placebo, the prevalence of prostate cancer was reduced for those on finasteride by 24.8% (95% confidence interval [CI], 18.6% to 30.6%) (hazard ratio, 0.75). However, in those who did develop prostate cancer, there was an increase in the number of high-grade (Gleason grade, 7 to 10) tumors detected at biopsy in the finasteride group. Overall, finasteride did reduce the frequency of prostate cancer; however, the prostate cancers that were diagnosed in the finasteride group were more aggressive. There were no differences in overall survival. Common adverse events included decreased libido, erectile dysfunction, and gynecomastia.

Dutasteride was evaluated in a different population of men.¹⁹ They randomized men that were 50 to 75 years of age with PSA levels of 2.5 to 10 ng/mL (2.5 to 10 mcg/L) and a recent negative prostate biopsy result to dutasteride 0.5 mg/day or placebo. Treatment with dutasteride resulted in a significant reduction in the risk for prostate cancer (RR reduction of 22.8%) as well as a reduction in acute urinary retention. There were no significant differences in overall survival.²⁰

The use of finasteride to prevent prostate cancer is the subject of a joint consensus statement. The American Society of Clinical Oncology (ASCO) and the American Urological Association (AUA) used the results from a systematic review of the literature to develop evidence-based recommendations for the use of 5- α -reductase inhibitors for prostate cancer chemoprevention.²¹ 5- α -Reductase inhibitors decrease the period prevalence of prostate cancer by approximately 26% (RR, 0.74; 95% CI, 0.67 to 0.83). The absolute risk reduction is about 1.4% (4.9% in controls versus 3.5% in the treatment arms), although this may vary with the age of the treated population. On the basis of these outcomes, the ASCO and AUA recommend that asymptomatic men with a PSA less than or equal to 3 ng/mL (3 mcg/L) who are regularly screened with PSA may benefit from a discussion of both the benefits of 5- α -reductase inhibitors for 7 years for the prevention of prostate cancer and the potential risks (including the possibility of high-grade prostate cancer). Men who are taking 5- α -reductase inhibitors for benign conditions such as lower urinary tract symptoms may benefit from a similar discussion, understanding that the improvement of symptoms should be weighed with the potential risks of high-grade prostate cancer.

Selenium and vitamin E alone or in combination were evaluated in the Selenium and Vitamin E Cancer Prevention Trial (SELECT), a clinical trial investigating their effects on the incidence of prostate cancer. The data and safety monitoring committee found that after 5 years, selenium and vitamin E taken alone or together did not prevent prostate cancer.

On the basis of these data and safety concerns, the trial was halted.²² Other agents, including vitamin D, lycopene, green tea, nonsteroidal anti-inflammatory agents, isoflavones, and statins, are under investigation for prostate cancer and show promise; however, none are currently recommended for routine use outside of a clinical trial.²³

Screening

Early detection of potentially curable prostate cancers is the goal of prostate cancer screening. For cancer screening to be beneficial, it must reliably detect cancer at an early stage, and identify those cancers that would benefit from an early intervention and decrease mortality. Whether prostate cancer screening fits these criteria has generated considerable controversy.^{24,25} Digital rectal examination (DRE) has been recommended since the early 1900s for the detection of prostate cancer. The primary advantage of DRE is its specificity, reported at greater than 85%, for prostate cancer. Other advantages of DRE include low cost, safety, and ease of performance. However, DRE is relatively insensitive and is subject to interobserver variability. DRE as a single screening method has poor compliance and had little effect on preventing metastatic prostate cancer in one large case-control study.²⁶

② *Prostate-specific antigen is a useful marker for detecting prostate cancer at early stages, predicting outcome for localized disease, monitoring disease-free status, and monitoring response to androgen-deprivation therapy or chemotherapy for advanced-stage disease.* PSA is used widely for prostate cancer screening in the United States, with simplicity as its major advantage and low specificity as its primary limitation.^{24,27} Although PSA is often elevated in men with prostate cancer, the PSA may also be elevated in men with acute urinary retention, acute prostatitis, and prostatic ischemia or infarction, as well as BPH, a nearly universal condition in men at risk for prostate cancer. PSA elevations between 4.1 ng/mL (4.1 mcg/L) and 10 ng/mL (10 mcg/L) cannot distinguish between BPH and prostate cancer, limiting the utility of PSA alone for the early detection of prostate cancer. Additionally, only 38% to 48% of men with clinically significant prostate cancer have a serum PSA outside the reference range.²⁸

Neither DRE nor PSA is sensitive or specific enough to be used alone as a screening test. Although the relative predictability of DRE and PSA is similar, the tumors identified by each method are different. Catalona and associates²⁹ confirmed that the combination of a DRE plus PSA determination is a better method of detecting prostate cancer than DRE alone.

The common approach to prostate cancer screening today involves offering a baseline PSA and DRE between the age of 40 and 50 years with annual evaluations beginning at the age of 50 years to all men of normal risk with a 10-year or greater life expectancy. Men with an increased risk of prostate cancer, including men of African American ancestry and men with a family history of prostate cancer, may begin screening earlier, at age 40 to 45 years.

Patient Encounter 1: Prevention and Screening

OC is a 56-year-old white man who comes into the pharmacy for a refill of his finasteride, which he is taking for BPH. He wants to know what he can do to reduce his risk of prostate cancer.

OC does not have a family history of prostate cancer. He has never been screened for prostate cancer.

What do you recommend for prostate cancer screening?

What do you recommend for prostate cancer chemoprevention?

Despite this common practice, the benefits of prostate cancer screening are unproven.^{24,30} PSA measurements can identify small, subclinical prostate cancers, in which no intervention may be required. Detecting prostate cancer in those not needing therapy not only increases the cost of care through unnecessary screening and workups but also increases the toxicity of therapy, by subjecting some patients to unnecessary therapy.^{31,32} Currently, the American College of Physicians recommends that rather than screening all men for prostate cancer as a matter of routine, physicians should describe the potential benefits and known risks of screening, diagnosis, and treatment; listen to the patient's concerns; and then decide on an individual's screening method. The United States Preventative Task Force recently downgraded PSA screening for prostate cancer to a grade D, intended to "discourage the use of the service."²⁴

CLINICAL PRESENTATION AND DIAGNOSIS

Before the implementation of routine screening, prostate cancers were frequently identified on the investigation of symptoms that included urinary hesitancy, retention, painful urination, hematuria, and erectile dysfunction. With the introduction of screening techniques, most prostate cancers are now identified before the development of symptoms.³³

There are two commonly recognized staging classification systems (Table 92-3). The formal international classification system (tumor, node, metastases [TNM]), adopted by the International Union Against Cancer in 1974, was last updated in 2002. The AUA classification is also commonly used in the United States (Table 92-4). Patients are assigned to stages A through D and corresponding subcategories based on the size of the tumor (T), local or regional extension, presence of involved lymph node groups (N), and presence of metastases (M). Some studies classify patients who have progressed after hormonal therapy as stage D₃. On the basis of men diagnosed with prostate cancer at Walter Reed Army Medical Center from 1988 to 1998, including

Clinical Presentation of Prostate Cancer

Localized Disease

Asymptomatic

Locally Invasive Disease

Ureteral dysfunction, frequency, hesitancy, and dribbling
Impotence

Advanced Disease

Back pain
Cord compression
Lower extremity edema
Pathologic fractures
Anemia
Weight loss

more than 2,042 prostate cancer diagnoses, localized prostate cancer (stage T₁ and T₂) was diagnosed more frequently (89% versus 68%), and advanced disease (stages T₃, T₄, and D) was diagnosed less frequently (11% versus 32%) when comparing the incidence rates in 1998 with the 1988 rates, respectively. This largely reflects the impact of widespread PSA screening. Prostate cancer is usually initially diagnosed by PSA and DRE and confirmed by a biopsy when the Gleason score is assigned.

3 The prognosis for patients with prostate cancer depends on the histologic grade, tumor size, and local extent of the primary tumor and PSA.^{11,34} One of the most important prognostic criteria appears to be the histologic grade, assessed by Gleason score. Poorly differentiated tumors are highly associated with both regional lymph node involvement and distant metastases. Once the tumor has spread into locoregional lymph nodes, there is a significantly increased risk of recurrence of disease after curative intent therapy.¹¹ The 10-year cancer-specific survival is estimated as 95% for stage A₁, 80% for stages A₂ to B₂, 60% for stage C, 40% for stage D₁, and 10% for stage D₂.³² It is estimated that more than 85% of patients with stage A₁ can be cured, but fewer than 1% of patients with stage D₂ will be cured.

TREATMENT

Desired Outcome

The desired outcome in early stage prostate cancer is to minimize morbidity and mortality from prostate cancer with special consideration that some degree of morbidity may be caused by the toxicity of treatment.³⁴ The most appropriate therapy of early stage prostate cancer is a matter of debate. Early stage disease may be treated with surgery, radiation, or watchful waiting. Although surgery and radiation are curative, they are associated with significant morbidity and mortality. Because the overall goal is to minimize morbidity and mortality associated with the disease, watchful waiting is appropriate in selected individuals with a low risk of rapid disease progression.³⁴ Advanced prostate cancer (metastatic spread) is not currently curable, and treatment should focus on providing symptom relief and maintaining quality of life.³⁵

Table 92-3

Diagnostic and Staging and Classification Systems Workup for Prostate Cancer

Initial tests	DRE PSA TRUS if either DRE is positive or PSA is elevated
Staging tests	Biopsy Gleason score on biopsy specimen Bone scan CBC Liver function tests Serum phosphatases (acid/alkaline) Excretory urography Chest radiography
Additional staging tests (depends on tumor classification, PSA, and Gleason score)	Skeletal films Lymph node evaluation Pelvic CT ¹¹¹ In-labeled capromab pendetide scan Bipedal lymphangiogram Transrectal MRI

CBC, complete blood count; CT, computed tomography; DRE, digital rectal examination; MRI, magnetic resonance imaging; PSA, prostate-specific antigen; TRUS, transrectal ultrasonography.

General Approach to Treatment

The initial treatment for prostate cancer depends on the disease stage, Gleason score, presence of symptoms, and life expectancy of the patient.³³ For asymptomatic patients determining risk for disease progression and recurrence are critical for determining treatment options. Asymptomatic patients with a low risk of recurrence, those with a T₁ or T_{2a} tumor, with a Gleason score of 2 through 6, and a PSA of less than 10 ng/mL (10 mcg/L) may be managed by active surveillance, radiation, or radical prostatectomy (Table 92-5). Because patients with asymptomatic, early stage disease generally have an excellent 10-year survival rate, immediate morbidities of treatment must be balanced with the lower likelihood of dying from prostate cancer. In general, more aggressive treatments of early stage prostate cancer are reserved for younger men, although patient preference is a major consideration in all treatment decisions. In a patient with a life expectancy of less than 10 years, expectant management or radiation therapy may be offered. In those with a life expectancy of equal to or greater than 10 years, expectant management, radiation (**external beam** or **brachytherapy**), or radical **prostatectomy** with a pelvic

Table 92-4

Staging and Classification Systems for Prostate Cancer

AUA ^a Stage (A–D)	AJCC-UICC ^b Classification (TNM)
A (occult, nonpalpable) A ₁ : Focal A ₂ : Diffuse	T _x N _x M _x (cannot be assessed) T ₀ N ₀ M ₀ (nonpalpable) T _c : Focal or diffuse
B (confined to prostate) B ₁ : Single nodule in 1 lobe, less than 1.5 cm B ₂ : Diffuse involvement of whole gland, greater than 1.5 cm	T ₁ N ₀ M ₀ , T ₂ N ₀ M ₀ T ₁ (Clinically inapparent tumor not palpable or visible by imaging) T _{1a} : Tumor incidental histologic finding in 5% or less of tissue resected T _{1b} : Tumor incidental histologic finding in 5% or more of tissue resected T _{1c} : Tumor identified by needle biopsy (e.g., because of elevated PSA) T ₂ : (Tumor confined within the prostate ^c) T _{2a} : Tumor involves half of a lobe or less T _{2b} : Tumor involves more than half a lobe, but not both lobes T _{2c} : Tumor involves both lobes
C (localized to periprostatic area) C ₁ : No seminal vesicle involvement, less than 70 g C ₂ : Seminal vesicle involvement, greater than 70 g	T ₃ N ₀ M ₀ , T ₄ N ₀ M ₀ T ₃ : (Tumor extends through the prostatic capsule ^d) T _{3a} : Unilateral extracapsular extension T _{3b} : Bilateral extracapsular extension T _{3c} : Tumor invades the seminal vesicle(s) T ₄ : Tumor is fixed or invades adjacent structures other than the seminal vesicles T _{4a} : Tumor invades any of bladder neck, external sphincter, or rectum T _{4b} : Tumor invades levator muscles and/or is fixed to the pelvic wall
D (metastatic disease) D ₁ : Pelvic lymph nodes or ureteral obstruction D ₂ : Bone, distant lymph node, organ, or soft tissue metastases	Any T, N ₁₋₄ , M ₀ or N ₀₋₄ , M ₁ N ₁ : Metastasis in a single lymph node, 2 cm or less in greatest dimension N ₂ : Metastasis in single lymph node more than 2 cm but not more than 5 cm in greatest dimension; or multiple lymph node metastases, none more than 5 cm in greatest dimension N ₃ : Metastasis in lymph node more than 5 cm in greatest dimension M _{1a} : Nonregional lymph node(s) M _{1b} : Bone(s) M _{1c} : Other site(s)

^aAmerican Urologic Association.^bAmerican Joint Committee on Cancer–International Union Against Cancer.^cTumor found in one or both lobes by needle biopsy, but not palpable or visible by imaging, is classified as T_{1c}.^dInvasion into the prostatic apex or into (but not beyond) the prostatic capsule is not classified as T₃ but as T₂.

Table 92-5

Management of Prostate Cancer With Low and Intermediate Recurrence Risk

Recurrence Risk	Expected Survival (years)	Initial Therapy
Low T ₁ -T _{2a} and Gleason 2–6 and PSA less than 10 ng/mL (10 mcg/L) and less than 5% tumor in specimen	Less than 10 10 or more	Expectant management or radiation therapy Expectant management or radical prostatectomy with or without pelvic lymph node dissection or radiation therapy
Intermediate T _{2b} or Gleason 7 or PSA 10–20 ng/mL (10–20 mcg/L)	Less than 10 10 or more	Expectant management or radical prostatectomy with or without pelvic lymph node dissection or radiation therapy with or without 4–6 months of androgen deprivation therapy Radical prostatectomy with or without pelvic lymph node dissection or radiation therapy with or without 4–6 months of androgen deprivation therapy

PSA, prostate-specific antigen.

lymph node dissection may be offered. Radical prostatectomy and radiation therapy generally are considered therapeutically equivalent for localized prostate cancer, although neither has been proven to be better than observation alone.^{35,36} Complications from radical prostatectomy include blood loss, stricture formation, incontinence, lymphocele, fistula formation, anesthetic risk, and impotence. Nerve-sparing radical prostatectomy can be performed in many patients; 50% to 80% regain sexual potency within the first year. Acute complications from radiation therapy include cystitis, proctitis, hematuria, urinary retention, penoscrotal edema, and impotence (30% incidence).¹¹ Chronic complications include proctitis, diarrhea, cystitis, enteritis, impotence, urethral stricture, and incontinence.¹¹ Because radiation and prostatectomy have significant and immediate morbidity compared with expectant management alone, many patients may elect to postpone therapy until symptoms develop.

Individuals with T_{2b} disease or a Gleason score of 7 or a PSA ranging from 10 to 20 ng/mL (10 to 20 mcg/L) are considered at intermediate risk for prostate cancer recurrence.³⁴ Individuals with less than a 10-year expected survival may be offered expectant management, radiation therapy, or radical prostatectomy with or without a pelvic lymph node dissection, and those with a greater than or equal to 10-year life expectancy may be offered either radical prostatectomy with or without a pelvic lymph node dissection or radiation therapy (see [Table 92-5](#)).

The patients at high risk of recurrence (stages T_{2c}, a Gleason score ranging from 8 to 10, or a PSA value greater than 20 ng/mL [20 mcg/L]) should be treated with androgen ablation for 2 to 3 years combined with radiation therapy ([Table 92-6](#)).³⁴ Selected individuals with a low tumor volume may receive a radical prostatectomy with or without a pelvic lymph node dissection.

Table 92-6**Management of Prostate Cancer With High and Very High Recurrence Risk**

Recurrence Risk	Initial Therapy ^a
High T _{2c} or T _{3a} , Gleason 8–10, PSA greater than 20 ng/mL (20 mcg/L)	Androgen ablation ^b (2–3 years) and radiation therapy, or radiation therapy or radical prostatectomy with or without pelvic lymph node dissection
Locally Advanced, Very High T _{3b–T4}	Androgen ablation ^b (2–3 years) or radiation therapy + androgen ablation (2–3 years)
Very High Any T, N ₁	Androgen ablation ^b or radiation therapy + androgen ablation
Any T, Any N, M ₁	Androgen ablation ^b

^aAndrogen ablation = serum testosterone levels less than 50 ng/mL (1.74 nmol/L).

^bLuteinizing hormone–releasing hormone agonist (medical castrations or surgical are equivalent).

Patient Encounter 2: Initial Presentation and Treatment

CM is a 58-year-old man who presents to the clinic complaining of impotence for the past 1 to 2 months and requesting a prescription for sildenafil. Upon questioning, he gives a history of fatigue, gradual weight loss of 10 lb, and difficulty with urination that began about 6 months ago.

Physical examination is positive for a 1-cm nodule in the prostate, and his laboratory study results reveal the following: PSA, 12 ng/dL (12 mcg/L); PSA from 2 years ago was 2 ng/dL (2 mcg/L).

A prostate biopsy by TRUS reveals adenocarcinoma of the prostate with a Gleason score of 8. CT scanning and bone scan reveal disease that is metastatic to the bone.

What stage is this patient's prostate cancer?

Based on his stage, what are treatment options for this patient?

Patients with T_{3b} and T₄ disease have a very high risk of recurrence and are not candidates for radical prostatectomy because of extensive local spread of the disease.³³

4 *Androgen ablation with an LHRH agonist plus an antiandrogen should be used before radiation therapy for patients with locally advanced prostate cancer to improve outcomes over radiation therapy alone.* Recent evidence suggests that a course of androgen ablation therapy should be instituted at diagnosis rather than waiting disease recurrence. In a clinical trial enrolling 500 men with locally advanced prostate cancer who were randomized to either immediate initiation of androgen ablation with either **orchiectomy** or androgen ablation or deferred hormonal therapy, individuals with immediate therapy had a median actuarial cause-specific survival duration of 7.5 years for immediate treatment and 5.8 years for deferred treatment.³⁷

5 *Androgen ablation therapy, with either orchiectomy, an LHRH agonist alone or an LHRH agonist plus an antiandrogen (combined androgen blockade), can be used to provide palliation for patients with advanced (stage D2) prostate cancer.* Secondary hormonal manipulations, cytotoxic chemotherapy, or supportive care is used for patients who progress after initial therapy.³⁷ Estrogens were once widely used; however, the primary estrogen, diethylstilbestrol (DES), was withdrawn from the U.S. market in 1997 because of an increased cardiovascular risk.

Nonpharmacologic Therapy**► Expectant Management**

Active surveillance, also known as observation or watchful waiting, involves monitoring the course of disease and initiating treatment if the cancer progresses or the patient becomes symptomatic. A PSA and DRE are performed

every 6 months with a repeat biopsy at any sign of disease progression. The advantages of expectant management are avoiding the adverse effects associated with definitive therapies such as radiation and radical prostatectomy and minimizing the risk of unnecessary therapies. The major disadvantage of expectant management is the risk that the cancer progresses and requires a more intensive therapy or metastasizes, making the disease incurable.³³

► Orchiectomy

Bilateral orchiectomy, or removal of the testes, rapidly reduces circulating androgens to castrate levels (i.e., serum testosterone levels less than 50 ng/dL [1.74 nmol/L]).¹² However, many patients find this procedure psychologically unacceptable, and others are not surgical candidates owing to their advanced age.¹² Orchiectomy is the preferred initial treatment in patients with impending spinal cord compression or ureteral obstruction.

► Radiation

The two commonly used methods for radiation therapy are external-beam radiotherapy and brachytherapy.³³ In external-beam radiotherapy, doses of 70 to 75 Gy are delivered in 35 to 41 fractions in patients with low-grade prostate cancer and 75 to 80 Gy for those with intermediate- or high-grade prostate cancer. Brachytherapy involves the permanent implantation of radioactive beads of 145 Gy 125-iodine or 124 Gy of 103-palladium and is generally reserved for individuals with low-risk cancers.

► Radical Prostatectomy

Radical prostatectomy is performed in patients who are surgical candidates and in disease that requires definitive therapy based on risk factors and patient preference; additionally, the disease must be amenable to complete surgical resection. Complications from radical prostatectomy include blood loss, stricture formation, incontinence, lymphocele, fistula formation, anesthetic risk, and impotence. Nerve-sparing radical prostatectomy can be performed in many patients; 50% to 80% regain sexual potency within the first year. Acute complications from radical prostatectomy and radiation therapy include cystitis, proctitis, hematuria, urinary retention, penoscrotal edema, and impotence (30% incidence).^{12,26} Chronic complications include proctitis, diarrhea, cystitis, enteritis, impotence, urethral stricture, and incontinence.¹² Because radiation and prostatectomy have significant and immediate mortality when compared with observation alone, many patients may elect to postpone therapy until symptoms develop.

Pharmacologic Therapy

► LHRH Agonists

LHRH agonists are a reversible method of androgen ablation and are as effective as orchiectomy in treating prostate cancer (Table 92-7).³⁸ Currently available LHRH agonists

Table 92-7

Luteinizing Hormone–Releasing Hormone Agonists

LHRH Agonist	Usual Dose	Adverse Effects (Similar for All Agents)
Leuprolide depot	7.5 mg every 28 days 22.5 mg every 12 weeks 30 mg every 16 weeks	Gynecomastia Hot flashes Decreased libido, impotence, Fatigue
Goserelin implant	3.6 mg every 28 days 10.8 mg every 12 weeks	Tumor flare in first 2 weeks and increased risk of cardiovascular disease Osteopenia with long-term use
Triptorelin depot	3.75 mg every 28 days 11.25 mg every 84 days	

LHRH, luteinizing hormone–releasing hormone.

include leuprolide, leuprolide depot, leuprolide implant, triptorelin depot, triptorelin implant, and goserelin acetate implant. Leuprolide acetate is administered once daily, whereas leuprolide depot and goserelin acetate implant can be administered once monthly, once every 12 weeks, or once every 16 weeks (leuprolide depot, every 4 months). The leuprolide depot formulation contains leuprolide acetate in coated pellets. The dose is administered intramuscularly, and the coating dissolves at different rates to allow sustained leuprolide levels throughout the dosing interval. Goserelin acetate implant contains goserelin acetate dispersed in a plastic matrix of D,L-lactic and glycolic acid copolymer and is administered subcutaneously. Hydrolysis of the copolymer material provides continuous release of goserelin over the dosing period. Another formulation of leuprolide is a mini-osmotic pump implanted intramuscularly that delivers 120 mcg of leuprolide daily for 12 months. After 12 months, the implant is removed, and a different implant can be placed. Triptorelin LA is administered as an intramuscular injection of 11.25 mg every 84 days. Triptorelin depot is administered once every 28 days as a 3.75-mg dose.

Several randomized trials have demonstrated that leuprolide, goserelin, and triptorelin are effective agents when used alone in patients with advanced prostate cancer.¹⁴ Response rates around 80% have been reported, with a lower incidence of adverse effects compared with estrogens.¹⁴ There are no direct comparative trials of the currently available LHRH agonists or the dosage formulations, but a recent meta-analysis reported that there is no difference in efficacy or toxicity between leuprolide and goserelin. Triptorelin is a more recent addition but is generally considered equally effective. Therefore, the choice between the three agents is usually made on the basis of cost and patient and physician preference for a dosing schedule.

The most common adverse effects reported with LHRH agonist therapy include a disease flare-up during the first week of therapy, hot flashes, erectile impotence, decreased libido, and injection-site reactions.¹⁴ The disease flare-up is

caused by an initial induction of LH and FSH by the LHRH agonist, leading to an initial phase of increased testosterone production. It manifests clinically as an exacerbation of disease-related symptoms, usually increased bone pain or urinary symptoms.¹⁴ This flare reaction usually resolves after 2 weeks and has a similar onset and duration pattern for the depot LHRH products.^{39,40} Initiating an antiandrogen before the administration of the LHRH agonist and continuing for 2 to 4 weeks is a frequently used strategy to minimize this initial tumor flare.¹⁶

LHRH agonist monotherapy can be used as initial therapy, with response rates similar to orchiectomy. There is a lower incidence of cardiovascular-related adverse effects associated with LHRH therapy than with estrogen administration. Patients should be counseled to expect worsening symptoms during the first week of therapy; appropriate pain and symptom management is required during this period, and a short course of concomitant antiandrogen therapy may need to be considered before initiating the LHRH agonist. Caution should be exercised if initiating LHRH agonist therapy in patients with widely metastatic disease involving the spinal cord or having the potential for ureteral obstruction because irreversible complications may occur.

Another potentially serious complication of androgen deprivation therapy is a resultant decrease in bone-mineral density, leading to an increased risk for osteoporosis, osteopenia, and an increased risk for skeletal fractures. Most clinicians recommend that men starting long-term androgen deprivation therapy should have a baseline bone mineral density test and be initiated on a calcium and vitamin D supplement.¹⁶

► Gonadotropin-Releasing Hormone Antagonists

An alternative to LHRH agonists is the recently approved GnRH antagonist degarelix. Degarelix works by binding reversibly to gonadotropin-releasing hormone (GnRH) receptors on cells in the pituitary gland, reducing the production of testosterone to castrate levels. The major advantage of degarelix over LHRH agonists is the speed at which it can achieve the drop in testosterone levels; castrate levels are achieved in 7 days or less with degarelix, compared with 28 days with leuprolide, eliminating the tumor flare seen and need for antiandrogens with LHRH agonists.

In a trial of 610 men with advanced prostate cancer, degarelix was shown to be equivalent to leuprolide in lowering testosterone levels for up to 1 year and is approved by the Food and Drug Administration for the treatment of advanced prostate cancer. Degarelix is available as 40-mg/mL and 20-mg/mL vials for subcutaneous injection, and the starting dose is 240 mg followed by 80 mg every 28 days. The starting dose should be split into two injections of 120 mg.

The most frequently reported adverse reactions were injection-site reactions, including pain (28%), erythema (17%), swelling (6%), induration (4%), and nodule (3%). Most were transient and mild to moderate, leading to discontinuation in fewer than 1% of study subjects. Other adverse effects included elevations in liver function tests, which occurred in approximately 10% of study subjects.

Similar to other methods of androgen deprivation therapy, osteoporosis may develop, and calcium and vitamin D supplementation should be considered.

Degarelix is not approved in combination with antiandrogens, and routine use of the combination cannot be recommended.

Antiandrogens

Three antiandrogens—flutamide, bicalutamide, and nilutamide—are currently available (Table 92–8). Cyproterone is another agent with antiandrogen activity but is not available in the United States. Antiandrogens have been used as monotherapy in previously untreated patients, but a recent meta-analysis determined that monotherapy with antiandrogens is less effective than LHRH agonist therapy.⁴⁰ Therefore, for advanced prostate cancer, all currently available antiandrogens are indicated only in combination with androgen-ablation therapy, flutamide and bicalutamide are indicated in combination with an LHRH agonist, and nilutamide is indicated in combination with orchiectomy.⁴¹

The most common antiandrogen-related adverse effects are listed in Table 92–7. In the only randomized comparison of bicalutamide plus an LHRH agonist versus flutamide plus an LHRH agonist, diarrhea was more common in

Table 92–8

Antiandrogens

Antiandrogen	Usual Dose	Adverse Effects
Flutamide	750 mg/day	Gynecomastia Hot flushes GI disturbances (diarrhea) Liver function test abnormalities Breast tenderness Methemoglobinemia
Bicalutamide	50 mg/day	Gynecomastia Hot flushes GI disturbances (diarrhea) Liver function test abnormalities Breast tenderness
Nilutamide	300 mg/day for first month; then 150 mg/day	Gynecomastia Hot flushes GI disturbances (nausea or constipation) Liver function test abnormalities Breast tenderness Visual disturbances (impaired dark adaptation) Alcohol intolerance Interstitial pneumonitis

GI, gastrointestinal.

flutamide-treated patients. Antiandrogens can reduce the symptoms from the flare phenomenon associated with LHRH agonist therapy.¹⁶

Combined Androgen Blockade

Although up to 80% of patients with advanced prostate cancer respond to initial hormonal manipulation, almost all patients progress within 2 to 4 years after initiating therapy.¹² Two mechanisms have been proposed to explain this tumor resistance. The tumor could be heterogeneously composed of cells that are hormone dependent and hormone independent, or the tumor could be stimulated by extratesticular androgens that are converted intracellularly to DHT. The rationale for combination hormonal therapy is to interfere with multiple hormonal pathways to more completely eliminate androgen action. In clinical trials, combination hormonal therapy, sometimes also referred to as maximal androgen deprivation or total androgen blockade, or **combined androgen blockade** (CAB), has been used. The combination of LHRH agonists or orchiectomy with antiandrogens is the most extensively studied CAB approach.

Many studies comparing CAB with conventional medical or surgical castration have been performed.⁴²⁻⁴⁴ In studies with LHRH agonists, the results have varied, with no consistent benefit demonstrated for CAB. A National Cancer Institute (NCI) intergroup trial involving 1,387 evaluable stage D₂ prostate cancer patients failed to show any significant survival benefits for the combination of orchiectomy plus flutamide over orchiectomy alone.⁴⁵ Similar to other studies of CAB, overall survival was longest in patients with minimal disease. Diarrhea, elevated liver function test results, and anemia were more common in those patients who received flutamide.

A meta-analysis of 27 randomized trials in 8,275 patients (4,803 treated with flutamide, 1,683 treated with nilutamide, and 1,784 treated with cyproterone) comparing CAB with conventional medical or surgical castration showed a small survival benefit at 5 years for those treated with flutamide or nilutamide (27.6%) compared with those with castration alone (24.7%; $P = 0.0005$).

In one of the few combination androgen-deprivation studies comparing two different antiandrogens (bicalutamide versus flutamide), the time to treatment failure (the main study end point), time to progression (as defined by appearance of new or worsening bone or extraskelatal lesions), and time to death were equivalent, suggesting that the two treatments are equally effective.

Although some investigators now consider CAB to be the initial hormonal therapy of choice for newly diagnosed advanced prostate cancer patients, clinicians are left to weigh the costs of combined therapy against potential benefits in light of conflicting results in the randomized trials⁴¹ and the modest benefit seen in the meta-analysis.⁴³ For trials that did show an advantage for CAB, whether these effects are specific to the testosterone-deprivation method (orchiectomy vs. leuprolide vs. goserelin), the antiandrogen, the duration of therapy, or patient selection is not clear. Until further carefully designed studies that use survival, time

to progression, quality of life, patient preference, and cost as end points are conducted, it is appropriate to use either LHRH agonist monotherapy or CAB as initial therapy for metastatic prostate cancer. CAB may be most beneficial for improving survival in patients with minimal disease and for preventing tumor flare, particularly in those with advanced metastatic disease. All other patients may be started on LHRH monotherapy, and an antiandrogen may be added after several months if androgen ablation is incomplete.

There is considerable debate concerning when to start hormonal-deprivation therapy in patients with advanced prostate cancer.¹⁴ The original recommendation to start therapy when symptoms appeared was based on the Veterans Administration Cooperative Urologic Research Group (VACURG) trials in which no overall survival difference was demonstrated in patients who either started DES initially or crossed over to active treatment when symptoms appeared; the excess mortality rate was attributed to estrogen administration. Because LHRH agonists and antiandrogens are viable therapies with less cardiovascular toxicity, it is not clear whether delaying therapy is justified with these agents. Reanalysis of the original VACURG data and recent combined androgen-deprivation trials demonstrate a survival advantage for young, good-performance status, minimal-disease patients treated initially with hormonal therapy, suggesting that early intervention before symptoms appear may be appropriate. The issue of when best to start hormonal therapy is the subject of several ongoing clinical trials.⁴⁶

Secondary Therapies

Secondary or salvage therapies for patients who progress after their initial therapy depend on what was used for initial management. For patients initially diagnosed with localized prostate cancer, radiotherapy can be used in the case of failed radical prostatectomy. Alternatively, androgen ablation can be used in patients who progress after either radiation therapy or radical prostatectomy.

In patients treated initially with one hormonal modality, secondary hormonal manipulations may be attempted. This may include adding an antiandrogen to a patient who incompletely suppresses testosterone secretion with an LHRH agonist. In patients who have progression while receiving CAB, withdrawing antiandrogens, or using agents that inhibit androgen synthesis may be attempted.

For patients who initially received an LHRH agonist alone, castration testosterone levels should be documented. Patients with inadequate testosterone suppression (greater than 20 ng/dL [0.7 nmol/L]) can be treated by adding an antiandrogen or performing an orchiectomy. If castration testosterone levels have been achieved, the patient is considered to have castrate-resistant disease, and palliative salvage therapy can be used. Supportive care, chemotherapy, immunotherapy, and local radiotherapy can be used in patients who have failed all forms of androgen-ablation manipulations because these patients are considered to have castrate-resistant prostate cancer

6 *Antiandrogen withdrawal for patients having progressive disease while receiving combined hormonal blockade with an*

LHRH agonist plus an antiandrogen can provide additional symptomatic relief. Mutations in the androgen receptor have been documented that cause antiandrogen compounds to act like receptor agonists.

If the patient initially received CAB with an LHRH agonist with an antiandrogen, then androgen withdrawal is the first salvage manipulation.³³ Objective and subjective responses have been noted following the discontinuation of flutamide, bicalutamide, or nilutamide in patients receiving these agents as part of combined androgen ablation with an LHRH agonist. Mutations in the androgen receptor have been demonstrated that allow antiandrogens such as flutamide, bicalutamide, and nilutamide (or their metabolites) to become agonists and activate the androgen receptor. Patient responses to androgen withdrawal manifest as significant PSA reductions and improved clinical symptoms. Androgen withdrawal responses lasting 3 to 14 months have been noted in up to 35% of patients, and predicting response seems to be most closely related to longer androgen exposure times.⁴⁴ Incomplete cross-resistance has been noted in some patients who received bicalutamide after they had progressed while receiving flutamide, suggesting that patients who fail one antiandrogen may still respond to another agent. Adding an agent that blocks adrenal androgen synthesis, such as aminoglutethimide, at the time that androgens are withdrawn may produce a better response than androgen withdrawal alone. Because of the potential for response immediately after antiandrogen withdrawal, a sufficient observation and assessment period (usually 4 to 6 weeks) is usually required before a patient can be enrolled on a clinical trial evaluating a new agent or therapy for advanced prostate cancer.

Androgen synthesis inhibitors, such as aminoglutethimide 250 mg orally every 6 hours or ketoconazole 400 mg orally three times a day, can provide symptomatic relief for a short time in approximately 50% of patients with progressive disease despite previous androgen-ablation therapy.³⁷ Adverse effects during aminoglutethimide therapy occur in approximately 50% of patients.³⁷ Central nervous system effects that include lethargy, ataxia, and dizziness are the major adverse reactions. A generalized morbilliform, pruritic rash has been reported in up to 30% of patients treated. The rash is usually self-limiting and resolves within 5 to 8 days with continued therapy. Adverse effects from ketoconazole include gastrointestinal intolerance, transient rises in liver and renal function tests, and hypoadrenalism. Additionally, ketoconazole is a strong inhibitor of CYP1A2 and CYP3A4 and is contraindicated in combination with a number of medications that are commonly used in men with prostate cancer, including cisapride, lovastatin, midazolam, and triazolam because ketoconazole inhibits their metabolism and leads to increased toxicity. Arrhythmias often fatal have been reported with the combination of cisapride and ketoconazole. Absorption of ketoconazole requires gastric acidity; therefore, ketoconazole should not be administered with H₂-blockers, proton pump inhibitors, or antacids. Additionally, ketoconazole should not be administered with strong CYP3A4 inducers, such as rifampin, because this

may reduce the effectiveness of ketoconazole because it is also a substrate for CYP3A4. Ketoconazole is combined with replacement doses of hydrocortisone to prevent symptomatic hypoadrenalism.³⁷

After all hormonal manipulations are exhausted, the patient is considered to have androgen-independent disease, also known as hormone-refractory prostate cancer. At this point, either chemotherapy or palliative supportive therapy is appropriate. Palliation can be achieved by pain management, using radioisotopes such as strontium-89 or samarium-153 lexidronam for bone-related pain, analgesics, corticosteroids, bisphosphonates, or local radiotherapy.^{47,48}

Skeletal metastases from hematogenous spread are the most common sites of distant spread of prostate cancer. Typically, the bone lesions are osteoblastic or a combination of osteoblastic and osteolytic. Bisphosphonates may prevent skeletal related events and improve bone mineral density. A randomized, controlled trial of zoledronic acid at a dose of 4 mg every 3 weeks reduced the incidence of skeletal-related events by 25% ($P = 0.021$) compared with placebo.⁴⁹ The usual dose of pamidronate is 90 mg every month, and the usual dose of zoledronic acid is 4 mg every 3 to 4 weeks. A trial of pamidronate or zoledronic acid can be initiated in prostate cancer patients with bone pain; if no benefit is observed, the drug may be discontinued.⁵⁰

Patient Encounter 3: Progressive Disease

JM is a 66-year-old man who was initially diagnosed with metastatic prostate cancer 5 years ago. He was initially started on leuprolide and has progressed through treatment as described in the treatment summary below.

Treatment Summary

Date	PSA	Intervention
9/2/10	25 ng/mL (25 mcg/L)	Started leuprolide 7.5 mg IM every month
12/2/10	2 ng/mL (2 mcg/L)	Continued leuprolide
6/2/11	22 ng/mL (22 mcg/L)	Added bicalutamide 50 mg PO daily
9/2/11	5 ng/mL (5 mcg/L)	Continued leuprolide and bicalutamide
10/2/12	32 ng/mL (32 mcg/L)	Continued leuprolide; stopped bicalutamide
11/1/12	7 ng/mL (7 mcg/L)	Continued leuprolide

Today he presents to the clinic with bone pain and a serum PSA of 67 ng/mL (67 mcg/L).

Why was bicalutamide discontinued on 10/2/12?

How would you characterize the patient's disease?

What treatments are options for him?

Table 92-9

First-Line Chemotherapy for Metastatic Castrate-Resistant Prostate Cancer

Chemotherapy	Usual Dose	Adverse Effects	Dose Adjustments
Docetaxel	75 mg/m ² every 3 weeks	Fluid retention, alopecia, mucositis, myelosuppression, hypersensitivity	<i>Hepatic</i> If AST/ALT is greater than 1.5 × the upper limit of normal and ALP is greater than 2.5 upper limit of normal, do not administer <i>Hematologic</i> Ensure CBC recovered
Estramustine	280 mg three times a day on days 1–5	Edema, gynecomastia, leukopenia, increased risk of thromboembolic events	<i>Hematologic</i> Ensure CBC recovered

ALP, alkaline phosphatase; ALT, alanine aminotransferase; AST, aspartate aminotransferase; CBC, complete blood count.

7 *Chemotherapy with docetaxel and prednisone improves survival in patients with castrate-resistant prostate cancer.*

Docetaxel 75 mg/m² every 3 weeks combined with prednisone 5 mg twice a day improves survival in hormone-refractory metastatic prostate cancer.⁵¹ The most common adverse events reported with this regimen are nausea, alopecia, and bone marrow suppression. In addition, fluid retention and peripheral neuropathy, known effects of docetaxel, are observed. Docetaxel is hepatically eliminated; patients with hepatic impairment may not be eligible for treatment with docetaxel because of an increased risk for toxicity.⁵¹

The combination of estramustine (280 mg three times a day, days 1 to 5) and docetaxel 60 mg/m² on day 2 every 3 weeks also improves survival in hormone-refractory metastatic prostate cancer.⁵² Estramustine causes a decrease in testosterone and a corresponding increase in estrogen; therefore, the adverse effects of estramustine include an increase in thromboembolic events, gynecomastia, and decreased libido (Table 92-9). Estramustine is an oral capsule and should be refrigerated. Calcium inhibits the absorption of estramustine. Although both the docetaxel–prednisone and the docetaxel–estramustine regimens are effective in hormone-refractory prostate cancer, most clinicians prefer the docetaxel/prednisone regimen because of the cardiovascular adverse effects associated with estramustine and the improved survival seen with docetaxel–prednisone. In addition, androgen ablation is usually continued when chemotherapy is initiated.

The regimen of mitoxantrone plus prednisone has been shown to be effective in reducing pain from bone metastasis and was a standard therapy before the development of docetaxel and prednisone. The effectiveness of mitoxantrone after failure of docetaxel-based therapy has not been scientifically evaluated. Treatment options now include continued chemotherapy with cabazitaxel, additional hormonal manipulation with abiraterone, immunotherapy with sipuleucel-T, or radiation for palliation of local symptoms.

8 *Chemotherapy with cabazitaxel and prednisone improves survival in patients with castrate-resistant prostate cancer who have either progressed or are intolerant to docetaxel.*

Cabazitaxel is a taxane with demonstrated activity in docetaxel resistant cell lines and animal models of human cancer. A partial explanation is that docetaxel is a substrate for P-glycoprotein multidrug resistance transporter while cabazitaxel has low affinity.⁵³ In patients previously treated with docetaxel and prednisone, treatment with cabazitaxel 25 mg/m² every 3 weeks with prednisone 10 mg/day significantly improved progression-free survival and overall survival compared with mitoxantrone and prednisone. Neutropenia, febrile neutropenia, neuropathy and diarrhea are the most significant toxicities. Hypersensitivity reactions may occur, and premedication with an antihistamine, a corticosteroid, and an H₂ antagonist is recommended. Cabazitaxel is extensively hepatically metabolized and should be avoided in patients with hepatic dysfunction (Table 92-10).

9 *Hormonal manipulation with abiraterone and prednisone improves survival in patients previously treated with docetaxel and prednisone.*

An upregulation of androgen synthesis has been noted in castration-resistant prostate cancer, and further inhibition of androgen synthesis after failure of androgen deprivation therapy and antiandrogens can provide benefit for patients. Abiraterone is an inhibitor of CYP17, an enzyme critical for testosterone synthesis. In patients previously treated with docetaxel, compared with prednisone alone, treatment with abiraterone 1000 mg orally once daily and prednisone 5 mg orally twice daily lead to increases in overall survival and progression-free survival of 3.9 months and 2 months, respectively. Abiraterone should be administered on an empty stomach either 2 hours after or 1 hour before a meal. The most significant adverse effects with abiraterone were fluid retention, hypokalemia, and hypertension (Table 92-10).⁵⁵

10 *Immunotherapy with sipuleucel-T improves survival in patients with castrate-resistant prostate cancer with minimally symptomatic disease.*

Table 92–10

Second-Line Therapy for Metastatic Castrate Resistant Prostate Cancer

Chemotherapy	Usual Dose	Adverse Effects	Dose Adjustments
Cabazitaxel	25 mg/m ² every 3 weeks	Myelosuppression, neuropathy, diarrhea	<i>Hepatic</i> Extensively hepatically metabolized, usage should be avoided in hepatic dysfunction (ALT/AST greater than 1.5 × ULN or bilirubin > ULN) <i>Hematologic</i> Ensure CBC recovered
Abiraterone	1000 mg once daily	Edema, hypokalemia, hypertension, hepatotoxicity	<i>Hepatic</i> Moderate hepatic impairment (Child-Pugh class B), reduce the starting dose to 250 mg once daily; for development of hepatotoxicity during treatment, hold until recovery; retreatment may be initiated at a reduced dose

ALT, alanine aminotransferase; AST, aspartate aminotransferase; CBC, complete blood count.

The approval of sipuleucel-T ushered in a new era of cancer treatment. Sipuleucel is a patient-specific anticancer vaccine.⁵⁶ Patients eligible for treatment first undergo a leukapheresis procedure to collect dendritic cells. These are then cultured at a central manufacturing facility and stimulated with a fusion protein of prostatic phosphatase and granulocyte macrophage colony-stimulating factor. These are then injected into the patient. This procedure is performed three times, at 0, 2, and 4 weeks. Treatment is well tolerated with the most common adverse effects reported being moderate and transient chills, fever, and influenza-like symptoms. In the pivotal clinical trial, the patient population was limited to minimally symptomatic men and, although most men in the trial had not received chemotherapy, approximately 15% had been previously treated with docetaxel. Patients with long-bone fractures, spinal cord compression, or visceral metastases were excluded. Although disease progression was not improved by sipuleucel-T, overall survival was significantly improved from 21.7 months with placebo to 25.8 months with sipuleucel-T.⁵⁶ High cost and limited production capacity limit the availability of this therapy. In patients who are minimally symptomatic and are able to receive treatment, sipuleucel-T is a valid treatment option. However, because disease progression was not slowed, it may not offer significant relief from disease-related symptoms. In highly symptomatic patients, a treatment that delays tumor progression may be more appropriate.

OUTCOME EVALUATION

Monitoring of prostate cancer depends on the stage of the cancer. When definitive, curative therapy is attempted, objective parameters to assess tumor response include assessment of the tumor size, evaluation of involved lymph nodes, and the response of tumor markers such as PSA to

the treatment. Following definitive therapy, the PSA level is checked every 6 months for the first 5 years and then annually. Local recurrence in the absence of a rising PSA may occur, so the DRE is also performed. In the metastatic setting, clinical benefit responses can be documented by evaluating performance status changes, weight changes, quality of life, and analgesic requirements, in addition to the PSA or DRE at 3-month intervals and radiologic studies to objectively measure tumor response.

Patient Care and Monitoring

1. Obtain complete past medical history, family history, and social history.
2. Obtain complete list of any concomitant prescription and over-the-counter medications; be sure to include herbal, vitamin, and mineral supplements.
3. Verify completion of prostate cancer workup and staging.
4. Using information obtained, identify appropriate treatment options.
5. Discuss the benefits and risks of appropriate treatment options with the health care team and patient.
6. If drug therapy is selected, review patient medical history for drug–drug and drug–herbal interactions.
7. Initiate therapy. If patient is asymptomatic, monitor PSA and circulating androgens for castration level of testosterone. If patient is symptomatic, monitor symptoms for improvement or worsening.
8. Monitor for any new symptoms and adverse events from therapy.

Abbreviations Introduced in This Chapter

ASCO	American Society of Clinical Oncology
AUA	American Urological Association
BPH	Benign prostatic hyperplasia
CAB	Combined androgen blockade
CI	Confidence interval
DES	Diethylstilbestrol
DHT	Dihydrotestosterone
DRE	Digital rectal examination
FSH	Follicle-stimulating hormone
GnRH	Gonadotropin-releasing hormone
IGF-1	Insulin-like growth factor-1
IM	Intramuscular
LH	Luteinizing hormone
LHRH	Luteinizing hormone-releasing hormone
NCI	National Cancer Institute
PSA	Prostate-specific antigen
SELECT	Selenium and Vitamin E Cancer Prevention Trial
TRUS	Transrectal ultrasonography

Skin Cancer

Trinh Pham

LEARNING OBJECTIVES

● Upon completion of this chapter, the reader will be able to:

1. Identify the risk factors associated with skin cancer.
2. Devise a plan of lifestyle modifications for the prevention of skin cancer.
3. Explain the goals of therapy for the treatment of the different stages of nonmelanoma and melanoma skin cancer.
4. Discuss the role of mutation testing in patients with newly diagnosed metastatic melanoma and the impact of the test on choosing drug therapy.
5. Compare and contrast the pharmacologic treatment options that are available for patients diagnosed with nonmelanoma and melanoma skin cancer.
6. Suggest management options for patients experiencing adverse effects of pharmacologic therapy.

KEY CONCEPTS

- 1 Exposure to ultraviolet radiation from the sun is recognized as one of the primary triggers for skin cancer development.
- 2 Staging of malignant melanoma is important to determine prognosis, categorize patients with regard to metastatic potential and survival probability, and aid in clinical decision making.
- 3 Determination of lymph node status is important in melanoma staging because it is an independent prognostic factor, and it provides the oncologist with guidance for therapy decisions.
- 4 Stages IIB, IIC, and III melanoma are considered to be high risk because of their potential for recurrence and distant metastasis. The primary treatment modality is surgical excision of the tumor and a lymphadenectomy for patients with positive lymph nodes.
- 5 Stage IV melanoma is not curable, and the primary goal of therapy is local control of the disease and relief of identifiable symptoms.
- 6 Melanoma is an immunogenic tumor and strategies to enhance the patient's immune response to treat the cancer are an area of active research. Ipilimumab is an immunotherapy agent that has a major role in the treatment of unresectable or metastatic melanoma.
- 7 Interferon alfa 2b is indicated as adjuvant therapy for patients with bulky stages IIB, IIC, and stage III melanoma because they are at high risk for recurrence after curative surgical resection of the cancer.
- 8 Advances in molecular profiling and genome sequencing have led to the identification of the *BRAF V600E* gene mutation in patients with melanoma. Genetic testing for this mutation should be performed in patients with unresectable or metastatic melanoma to determine the patient's eligibility to start targeted therapy with vemurafenib.
- 9 In patients diagnosed with basal cell carcinoma and squamous cell carcinoma, the primary goal of therapy is to cure the patient and to prevent recurrence.

Skin cancer is the most prevalent of all malignancies occurring in humans, and in the United States, it accounts for more than 50% of all cancers.¹ The most common cutaneous malignancies are basal cell carcinoma (BCC), squamous cell carcinoma (SCC), and malignant melanoma (MM). BCC and SCC are categorized as nonmelanoma skin cancer (NMSC). It is estimated that more than 3.5 million cases (in more than 2 million people) of BCC and SCC and more than 100,000 cases of melanomas are diagnosed in the United States each year.¹ Ultraviolet radiation (UVR) exposure is the leading environmental factor causing skin cancer.² This is a modifiable risk factor, and

prevention of skin cancer development is possible through a sun protection regimen that includes wearing protective clothing; avoidance of prolonged, intense sun exposure and sunburns; and regular application of sunscreen. If skin cancer is detected in its early stage, survival is improved, and the disease is curable. Therefore, campaigns for primary and secondary prevention of skin cancer are important in combating this tumor. NMSC and MM differ with regard to prognosis, metastatic potential, mortality, curability, and treatment options. This chapter reviews the pathogenesis and risk factors for the development of skin cancer and provides current data on the recommendations for the prevention and treatment of both NMSC and MM.

MELANOMA

EPIDEMIOLOGY AND ETIOLOGY

Malignant melanoma is the most common serious form of skin cancer, and the lifetime risk of developing it is 1 in 37 for men and 1 in 56 for women.¹ Approximately 70,230 new cases of invasive melanoma were predicted to occur in 2011.¹ Melanoma represents about 2% of all skin cancers in the United States, but it accounts for 75% of all skin cancer deaths.¹ It was estimated that in 2011, 8,790 deaths would be attributable to melanoma.¹ The incidence of melanoma is not evenly distributed among all populations; race, gender, and age confer different rates. The rate of MM is 10 times higher in whites than in African Americans or Hispanics, and it is 50% higher in white men than white women.³ In patients older than 65 years, the incidence is 10 times higher than in patients younger than 40 years.⁴ The median age of diagnosis for cutaneous melanoma is 59 years, and the median age of death is 68 years.⁵ The trend in 5-year survival rates for melanoma has improved from 82% to 93% in the past 4 decades; however, MM is still a major public health problem in the United States because of its dramatic rise in incidence in the past 3 decades.³ Data from the National Cancer Institute Surveillance Epidemiology and End Results (SEER) show that the incidence of melanoma nearly tripled from 1975 to 2005.⁵

RISK FACTORS

Environmental

The risk factors for developing MM can be categorized as environmental factors and host factors. **1** *Exposure to UVR from the sun is recognized as one of the primary triggers for skin carcinogenesis.* UV radiation (specifically UVB) is absorbed by DNA in the cells in the epidermal layer and may induce DNA damage. Gene mutations, such as UVR-induced mutation to the p53 tumor suppressor gene, may transpire, resulting in dysregulation of apoptosis, expansion of mutated keratinocytes, and initiation of skin cancer.² Other mechanisms of UV radiation–induced DNA damage include the generation of reactive oxygen species, which

create breaks in DNA, leading to genetic mutations and skin cancer.² It is estimated that 65% to 90% of MMs are attributable to UV exposure, particularly when a person has a history of intense and blistering sunburns in childhood. If a person experienced more than one severe sunburn in childhood, the risk of developing melanoma is increased twofold.² Since the mid 1980s, depletion of the ozone layer has been of concern because this allows more UVR to penetrate the atmosphere. Melanoma mortality may increase by 1% to 2% when there is an approximate 1% decrease in ozone levels.² Exposure to sources of artificial UV radiation such as tanning beds has also been linked to increased risk of skin cancer.²

Host Factors

Host risk factors for developing MM include individuals with phenotypic characteristics of red hair, light skin, blue eyes, sun sensitivity, and freckling. Family history of MM in a first-degree relative is another risk factor for developing MM, with a twofold likelihood compared with patients with no family history.² In individuals without a family history of MM (sporadic MM), the presence of benign melanocytic nevi (benign moles) is consistently identified as the strongest risk factor for the future development of MM. It has been found that the greater the number of benign nevi a person possess, the greater the susceptibility to MM growth. A personal history of MM or NMSC also increases the risk of developing subsequent MM.⁵ The dysplastic nevus syndrome is another

Patient Encounter, Part 1

DM is a 55-year-old woman who presented to her dermatologist with a pigmented skin lesion on her left shoulder that she noticed had enlarged and changed color recently in the past few months.

History: She has the lesion since youth, and it was measured at 3 mm. She noticed the change in color and size in the past few months.

DM reports being a “sun worshiper” all her life; she spends her weekends outdoors or at the pool and vacations at the beach. DM notes that she burns initially and then eventually tans with excessive freckling. She reports using an indoor tanning bed 3 to 5 days a week for the past 20 years. She does not use sunscreen or practice sun protection measures.

What are DM's risk factors for developing malignant melanoma?

What primary prevention measures are recommended to prevent skin cancer?

What is the recommendation to detect melanoma early in a patient?

risk factor. A person with five or more dysplastic nevi has six times the risk of developing MM than a person with no dysplastic nevi.⁵ Larger nevi, as in the case of congenital melanocytic nevi (greater than 20 cm), is also associated with a greater risk of developing MM.⁵

Compared with other cancers, MM occur at a younger age with a median of 62 years in men and 54 years in women, and as a person ages, the risk increases further, especially in men.⁶ The risk of MM is also increased in patients with immunosuppression due to cancer, AIDS, a history of chronic lymphocytic leukemia, non Hodgkin's lymphoma, and after organ transplants.² Rare genetic syndromes such as xeroderma pigmentosum (XP) increases the risk of developing MM and NMSC 100-fold compared with the general population.⁶ MM has been reported in breast-ovarian cancer families with a 2.6-fold risk in carriers of *BRCA2* mutations.⁶ An association has been found between pancreatic cancer and MM with mutation in *CDKN2A*.⁶

PRIMARY PREVENTION OF SKIN CANCER

Ultraviolet radiation exposure from the sun is the major cause of NMSC and MM. **Primary prevention** strategies for skin cancer aim at educating people against excessive exposure to the sun and are spearheaded by the American Academy of Dermatology, American Cancer Society, Environmental Protection Agency, and Centers for Disease Control and Prevention. The aims of these programs are to increase public awareness about the harmful effects of sun exposure and the risk of skin cancer, change attitudes about the social norms related to sun protection and tanned skin, and decrease the incidence of skin cancer and deaths related to this malignancy. Recommendations for prevention of skin cancer are universal and include a variety of simple strategies to minimize exposure to UV rays:

- Avoid direct exposure to the sun between the hours of 10 AM and 4 PM, when UV rays are most intense.
- Wear hats with a broad enough brim to shade the face, ears, and neck.
- Wear protective clothing (especially tightly woven apparel) that covers as much as possible the arms, legs, and torso.
- Cover skin with a sunscreen lotion with a skin protection factor (SPF) of at least 15, protecting against UV radiation (both UVA and UVB).
- Reapply sunscreens every 2 hours (especially if sweating or swimming).
- Avoid sun lamps and tanning beds, which provide an additional source of UV radiation.
- Seek shade when outdoors.

The use of chemical sunscreen is only one of many strategies, and it should not be the sole agent used for cancer prevention. The lay public should be warned not to use sunscreen with a higher SPF with the intent to extend the

duration of exposure because it is observed that DNA damage can occur long before sunburn appears, and the long-term effects of increased sun exposure are not known. Sunscreen protective agents have been proven only to reduce the risk of actinic keratosis (AK) and SCC. There is no convincing evidence that sunscreen application has protective effect against BCC or MM.⁷

SECONDARY PREVENTION OF SKIN CANCER

Secondary prevention of skin cancer involves early detection of premalignant cancers for early intervention with the hope that it will reduce mortality and increase cure. Regular screening for melanoma either by skin self examination or total skin examination performed by health care providers consistently identify smaller and thinner lesions in high-risk patients.⁸ However, recommendations for melanoma screening are conflicting because there are no randomized, controlled, prospective melanoma trials demonstrating that routine screening reduces mortality. For this reason, the US Preventive Services Task Force (USPSTF) recommends neither for nor against routine screening for the general population. On the other hand, the American Cancer Society and the National Institutes of Health promote skin self-examination and recommend routine clinic-based screening for skin cancer for all individuals beginning at age 20 years. The American Academy of Dermatology, Skin Cancer Foundation, and 1992 National Institutes of Health Consensus Conference on Early Melanoma recommend annual screening for all patients.⁸ The American Academy of Family Physicians and American College of Preventive Medicine recommend screening for high-risk populations with family or personal history of skin cancer, clinical evidence of precursor lesions, or increased occupational or recreational exposure to sunlight.⁸ Pamphlets and online information describing the method of skin self-examination are available from agencies such as the American Cancer Society (www.cancer.org), American Academy of Dermatology (www.aad.org), and Skin Cancer Foundation (www.skincancer.org).

PATHOPHYSIOLOGY

Malignant melanoma is a cancer that arises from melanocytes, which are cells that synthesize melanin and contribute to hair and skin pigmentation. The overwhelming majority of MMs originate from the skin, although they may also arise less commonly from mucosal epithelial tissues such as the conjunctiva, oral cavity, esophagus, vagina, female urethra, penis, and anus. The pathway that leads to the development of melanoma is complex, and the processes by which melanocytes transform to malignant melanoma cells are thought to occur through germline predisposition, multistep accumulation of genetic and molecular alterations, and environmental factors such as UV exposure. Exposure to UVR is an important factor in MM development; however,

the relationship between risk and exposure is not clear. MM may occur in individuals with either inherent genetic susceptibility or low genetic susceptibility for melanocyte proliferation. The distinguishing characteristic is that MM may develop with less solar damage and on intermittent sun exposed body sites such as the trunk for individuals with high genetic susceptibility. Conversely, in individuals with low genetic susceptibility, melanoma occurs with chronic UV exposure on commonly exposed areas such as the face and neck.¹⁰

Genetic Pathway to the Development of Melanoma

Recent advances in molecular profiling and genome sequencing have enabled the identification of oncogenic mutations that drive MM progression. Much attention has been focused on the BRAF melanoma oncogene and its role in MM. BRAF is a serine/threonine protein kinase that is a member of the RAF kinase family, which is a part of the RAF/MEK/ERK serine threonine cascade (also known as ERK/MAP kinase pathway or “classical” MAPK pathway).¹¹ Mutations in BRAF activates the ERK/MAP pathway and thus trigger melanocyte proliferation and clonal expansion. BRAF mutation is found in approximately one half of all MM, and BRAF mutant melanomas tend to occur on intermittent sun-exposed skin areas, skin phenotypes that have poor UV protection (e.g., pale skin, poor tanning response, red hair, and freckling), and younger individuals (younger than 55 years) with lower cumulative UV exposure.¹² There are more than 50 mutations in BRAF described, but the valine to glutamic acid (*BRAF V600E*) substitution accounts for 80% of all *BRAF* mutations. Furthermore, this *V600E* mutation is the most common BRAF mutation in MM.¹³ The development of potent and selective BRAF kinase inhibitors has demonstrated early evidence of tumor regression and disease control in metastatic MM.

CLINICAL PRESENTATION, DIAGNOSIS, AND STAGING

There are four major subtypes of cutaneous MM: superficial spreading, nodular, lentigo maligna melanoma, and acral lentiginous (Table 93-1). They each vary in clinical and growth characteristics.^{14,15}

Data from SEER show that 84% of diagnosed MM are locally confined, 8% are diagnosed after the cancer has spread regionally, 4% are diagnosed with distant metastasis, and the remaining 4% are not staged.¹⁶ **2** *Once skin cancer is diagnosed, it is important to determine the stage of the cancer to find out if the cancer is confined to the original tumor site or has spread to other sites, such as the lymph nodes, liver, brain, lungs, or bone. The purpose of staging is to determine prognosis, categorize patients with regard to metastatic potential and survival probability, and aid in clinical decision making.* As with most solid tumors, the tumor, node, metastasis (TNM) classification is used to stage MM,

and the latest guidelines for staging MM proposed by the American Joint Committee on Cancer were implemented in 2010 (Table 93-2).¹⁷

3 *Determination of lymph node status is important in melanoma staging because it is an independent prognostic factor, and it provides the oncologist with guidance for therapy decisions.* For patients with MM that are at risk of spreading to the lymph nodes, a **sentinel lymph node** (SLN) biopsy is performed. The SLN, the first lymph node to receive lymph draining from the tumor, is identified by injecting a radioactive material, technetium-99m-labeled radiocolloids, and vital blue dye into the skin next to the tumor and tracing the flow of lymph from the tumor site to the nearest lymph node chain. Once the SLN is located, it is removed and analyzed for the presence of MM cells. If it is positive for the presence of MM, then the whole lymph node basin in that area is dissected; this is also known as **lymphadenectomy**. An SLN biopsy is the initial procedure to assess the status of lymph node involvement to prevent the morbidity associated with a total lymphadenectomy.

In addition to the stage of the disease and the status of disease involvement in the lymph nodes, other prognostic factors for outcome in MM include primary tumor thickness (Fig. 93-1), the presence of ulceration in the primary melanoma, mitotic activity, the presence of tumor infiltrating lymphocytes (TIL), and gender. Tumor thickness is defined as thin (less than 1 mm), intermediate (1 to 4 mm), and thick (greater than 4 mm). The 10-year survival rate is 92% for thin tumors and 63% to 80% for intermediate tumors and decreases further to 50% in patients with thick tumors.¹⁷ *Ulceration* is defined as the lack of an intact dermis overlying the primary tumor on histologic evaluation. Survival rates for patients with an ulcerated melanoma are proportionately lower than those with a nonulcerated melanoma of equivalent thickness, but the survival rate is similar for a nonulcerated melanoma of the next highest level of thickness. The male sex is associated with poor prognosis and adverse outcome in MM.¹⁸

Skin Examination

The *ABCDE* acronym is a helpful mnemonic for recognizing the signs and symptoms of early MM (Fig. 93-2). It was devised in 1985 by clinicians working in the Melanoma Clinical Cooperative Group at New York University School of Medicine and is used to educate health care professionals who are not dermatologists in differentiating common moles from cancer.⁸ It is also a useful tool to educate the lay public to assess pigmented lesions and screen for suspicious moles to help identify the MM in its early stage when it is curable. Not all MMs, including nodular melanoma, have all *ABCDE* characteristics, and it is not meant to provide a comprehensive list of all MM features. The characteristics for each of the letters are described in the Clinical Presentation and Diagnosis box. It should be noted that evolution of a lesion is one of the most important warning signs of danger in the assessment of moles for MM.

Table 93-1

Characteristics of Different Types of Skin Cancer

	Malignant Melanoma				Nonmelanoma Skin Cancer	
	Superficial Spreading	Nodular	Lentigo Maligna Melanoma	Acral Lentiginous	Basal Cell Carcinoma	Squamous Cell Carcinoma
Frequency	70%	10–15%	10%	Less than 10%	75%	20%
Location	Head, neck Legs in women Trunk in men	Trunk, head, neck	Sun-exposed areas, face, head, neck	Palms of the hands, soles of feet, nailbeds	Head and neck	Face, hands, forearms
Age	Fifth decade	Seventh decade	Eighth decade	Sixth decade	Incidence increases after age 40	Incidence increases after age 40
Ethnicity	White	White	White	Most frequent in ethnic groups of color	Similar between whites and African Americans	Most common in African descendants
Clinical features	Long horizontal growth phase (5–7 years); better prognosis	Very aggressive without identifiable horizontal growth phase; deeply invasive at the time of diagnosis; associated with poor prognosis	Long horizontal growth phase (10 years); lentigo maligna is the in situ form of lentigo maligna melanoma (only 5% transform to malignant melanoma)	Aggressive, rapid progression from horizontal to vertical growth; poorer prognosis	Rarely metastasize Circumscribed types: A: Nodular BCC, most common subtype B: Adenoid BCC C: Fibroepithelioma D: Basosquamous (metatypical) Diffuse types: plaque-like with horizontal spread and poorly defined margins A: Superficial BCC; second most common type of BCC, least aggressive B: Morpheaform, most aggressive C: Micronodular	Metastasize to lymph nodes and blood Have premalignant precursors and in situ variant; usually presents as raised pink papule or plaque, often scaly and sometimes ulcerated

From Refs. 14 and 15.

Table 93-2

2009 AJCC Melanoma Staging System and Classification (7th Edition)

Stage	Histologic Features	Overall Survival	
		5 Years (%)	10 Years (%)
0	Melanoma in situ (involves only the epidermis layer)	100	100
IA	Less than or 1 mm thickness, no ulceration, and mitosis less than 1/mm ²	95	88
IB	Less than or 1 mm with ulceration or mitosis greater than or 1/mm ² or between 1.01 and 2 mm with no ulceration	89–91	79–83
IIA	Between 1.01 and 2 mm with ulceration	77–79	64
IIB	Between 2.01 and 4 mm with ulceration	63–67	51–54
IIC	Greater than 4 mm with ulceration	45	32
IIIA	Any tumor thickness with no ulceration with one lymph node involved and micrometastases or any tumor thickness with no ulceration with two to three lymph nodes involved and micrometastases	63–70	57–63
IIIB	Any tumor thickness with ulceration and one to three lymph nodes involved and micrometastases or any tumor thickness without ulceration and one to three lymph nodes involved and macrometastases or any tumor thickness with ulceration with in-transit metastases or satellite lesions without metastatic lymph nodes	46–59	36–48
IIIC	Any tumor thickness with ulceration with one lymph node involved and macrometastases	24–29	15–24
IV	Any tumor thickness with ulceration with two to three lymph nodes involved and macrometastases	7–19	3–16
	Any tumor thickness with four or more metastatic lymph nodes or in-transit metastases or satellite lesions with metastatic lymph nodes		
	M _{1a} : Skin, subcutaneous tissue, or distant lymph nodes with normal LDH M _{1b} : Lung with normal LDH M _{1c} : To all other visceral sites (liver) or distant metastasis at any site with elevated serum LDH

TREATMENT

Early diagnosis of skin cancer is the key to improved prognosis. On presentation to a clinician's office, patients may offer a history of a new growth or an area of irritation. Conversely, the skin cancer may have been present for years undetected by the patient. The definitive diagnosis of any suspected cutaneous malignancy should be confirmed by a **biopsy** before treatment.

The modality of treatment for skin cancer depends on the size, location, and stage of the tumor; the age of the patient; and the type of skin cancer. Treatment options for skin cancer include surgery, radiation, chemotherapy, **immunotherapy**, and **targeted therapy**.

Desired Outcome

The primary goals of therapy for MM are to completely eradicate the tumor and minimize the risk of tumor recurrence and metastasis. Secondary goals of therapy include preserving normal tissue, maintaining function, and providing optimal cosmetic outcomes. Patients with local disease MM (stages I and IIA) are curable with surgical resection of the tumor. Thus, the aim is to diagnose patients at the earliest stage to increase the probability of cure.

Patients with regional disease (stages IIB, IIC, and III) have a high recurrence risk, and the goal of therapy is to prevent relapse of the disease. Disseminated, metastatic MM is not curable, and the goal of therapy is local control of the disease and palliation of symptoms.

The outcome of patients diagnosed with MM depends on the stage of the disease at diagnosis. The overall 5-year survival rate for patients with localized disease (stages I and IB) is the best at 89% to 95%.¹⁷ For patients with stage IIA to IIIA disease, the 5-year survival rate is greater than 50%, ranging from 63% to 79%.¹⁷ In patients with more advanced regional metastatic disease (stage IIIB to IIIC), the 5-year survival rate ranges from 24% to 59%. Patients with stage IV distant metastatic disease have the worst 5-year survival rate at only 7% to 19%.¹⁷

Treatment Options for Malignant Melanoma

► Surgery

4 The primary treatment modality for local/regional (stage I to III) MM is surgical excision of the tumor and a lymphadenectomy for patients with positive lymph nodes. The goals of therapy are to optimize local control, achieve potential cure, and minimize morbidity. Achieving adequate

Patient Encounter, Part 2

PMH: Otherwise healthy

FH: Father experienced multiple SCCs but no melanoma. Mother has diabetes and hypertension.

SH: Patient is an administrative assistant. Married with two children.

Examination: Reveals an asymmetric pigmented lesion of 6 mm on the left shoulder with no other suspicious lesions noted. Lymph nodes are not palpable.

Biopsy: Excisional biopsy of lesion reveals melanoma, Breslow thickness 5.4 mm, positive for ulceration, and mitosis 3/mm²

CT scan: no distant metastases

Laboratory data: normal

DM underwent a surgical wide excision of the lesion with a 2-cm margin and sentinel lymph node biopsy. Pathology revealed negative margins and one of three nodes positive for melanoma. Her melanoma is diagnosed as stage IIIB. She underwent a lymphadenectomy of the left axilla.

What is the treatment goal for DM at this stage of her disease?

Should DM receive adjuvant therapy?

If it is decided that DM should receive adjuvant treatment, which is the preferred option, high-dose interferon or pegylated interferon?

surgical margins for the primary tumor is important in preventing local recurrence and improving overall survival. The thickness of the tumor dictates the extent of the surgical margin (Table 93-3).¹⁹ The most common first site of recurrence in primary melanoma after excision of the tumor is in the lymph nodes. **5** For patients with metastatic MM, surgical excision is not curative. The primary goal of

therapy is local control of the disease and relief of identifiable symptoms. In highly selected patients, such as those with good performance status, less aggressive tumor biology, prolonged period of disease-free interval from the time of primary tumor treatment, and limited disease that is contained within a single location, complete surgical resection results in a median survival time of 2 years and a 5-year survival rate of 10% to 25%.²⁰ For most other patients with stage IV MM, unfortunately, the survival rate is measured in months rather than years, with an overall median survival of 5 to 8 months and a 5-year survival rate of less than 5%.²⁰

Surgical resection is also an option for patients with melanoma brain metastasis that is amenable to surgery. It is best considered for solitary brain lesion without systemic disease or a single metastatic brain lesion. For patients with symptomatic or life-threatening brain lesions, surgical resection allows for relief of symptoms such as intracranial hypertension, seizures, and a reduction of neurologic deficits.²¹

► Radiation

Radiation is generally not indicated for the treatment of primary melanoma except when surgery is impossible or not reasonable. It also may be administered as adjuvant therapy in areas where complete excision of the tumor is difficult, such as the face.²² It is indicated for the lymph nodes only when a lymph node dissection is not complete. For patients with bone metastasis, radiation may be indicated as palliative therapy for pain, fracture risks, or spinal cord compression.²²

Melanoma is the third cancer most commonly associated with central nervous system (CNS) metastasis after lung and breast cancer, and 10% to 40% of melanoma patients present with cerebral metastasis.²² Patients with brain metastasis have a life expectancy of 3 to 5 months, and 1-year survival is less than 10% to 15%.²² Headaches and seizures are the most common presenting symptoms. Radiation therapy is indicated for palliation of CNS symptoms and as adjuvant therapy after resection of the CNS metastasis.²²

Whole-brain radiation therapy (WBRT) is indicated for patients with multiple (more than three) CNS metastases, surgically inaccessible lesions, and extensive systemic disease.²³ WBRT for metastatic CNS MM does not improve survival or provide a cure; however, it is effective in relieving neurologic symptoms,²³ preventing new metastasis, reducing symptomatic recurrence, and decreasing the need for salvage therapy.²² It improves neurologic deficits in 50% to 75% of cases and relieves headaches in 80% of patients.²⁴ There are some data to suggest that surgical resection followed by WBRT in patients with a single CNS metastasis decreases the risk of local recurrence compared with resection alone.²²

Stereotactic radiosurgery (SRS) delivers high doses of focused ionizing external-beam radiation to a well-defined target area in one session of radiation therapy.²³ This technique maximizes the dose of radiation to the tumor with a rapid dose falloff outside the target area, resulting in sparing of the surrounding nontarget normal tissue. SRS may be considered over surgery for patients with fewer than three

Table 93-3

Excision Margin Based on Tumor Thickness

Tumor Thickness (mm)	Excision Margin (cm)
<i>In situ</i>	0.5–1
0–1	1
1–2	1 or 2 ^a
2–4	2
Greater than 4	2

^aA 2-cm margin is preferred, but a 1-cm margin is acceptable in anatomic locations where a 2-cm margin may compromise function or significantly affect cosmesis.

From Ross M, Gershenwald J. Evidence-based treatment of early-stage melanoma. *J Surg Oncol* 2011;104:341–353.

Clinical Presentation of MM

Patients with skin cancer generally present with a lesion that may be located anywhere on the body. The most common sites are the head, neck, trunk, and extremities. Changes in any characteristics of a lesion are important danger warning signals. Abnormal presentations of a mole or lesion indicate the need for further assessment.

- *Asymmetry*: Half the lesion does not mirror the other half
- *Border*: Sharp, ragged, uneven, and irregular borders
- *Color*: Multiple colors of various hues of light brown, dark brown, black, red, blue, or gray
- *Diameter*: Larger than 6 mm or the size of a pencil head eraser
- *Evolving*: Significant change in shape, size, symptoms, surface, or shades of color

Other signs and symptoms to monitor for in a lesion, in addition to ABCDE, include:

- Sudden or continuous enlargement of a lesion or elevation of a lesion
- Changes in the skin surrounding the nevus
- Redness, swelling, itching, tenderness, or pain
- Ulceration: friability of the lesion with bleeding or oozing. This is a danger signal.

Less Common Sites and Manifestations of MM

It is important to examine these sites for “hidden” MM:

- Nailbed
- Mucosal tissue

- Scalp
- Eye

In the nailbed, a black streak or wide variegated brown streak, elevation of nailbed, skin next to nail becomes darker, nail looks deformed or is being destroyed; size of nail streak increases over time.

Diagnostic Tests

- Dermoscopy
- Biopsy

Staging Tests (Depending on Patient’s Presentation)

- Baseline chest radiography
- LDH level
- CT of chest, abdomen, pelvis
- SLN biopsy: **3** The status of the SLN is one of the most powerful independent prognostic factors predicting survival. It also provides the oncologist with guidance for therapy decisions and accurate staging.
- PET
- MRI

From Rigel D, Russak J, Friedman R. The evolution of melanoma diagnosis: 25 years and beyond the ABCDs. *CA Cancer J Clin* 2010;60(5):301–316.

metastatic CNS lesions that are deep, nonsymptomatic, and smaller than 3 cm in size.²³

► Chemotherapy

In general, cytotoxic chemotherapy is not considered a standard of care for metastatic melanoma even though this is an area of active research to identify the optimal chemotherapy regimen. The following review highlights the current status of the most promising chemotherapy agents in the treatment of melanoma.

The major indication for systemic chemotherapy is in patients with metastatic or inoperable MM who are not candidate for vemurafenib. The goal of chemotherapy is to reduce tumor size, and it is an accepted palliative therapy for stage IV melanoma. Dacarbazine, an alkylating agent, is the most active single-agent chemotherapy against MM, achieving response rates of 15% to 25% in older clinical trials.²⁵ More recent large-scale clinical trials have shown response rates of 5% to 12%.²⁶ It is the only chemotherapy agent approved by the Food and Drug Administration (FDA) for the treatment of metastatic MM. Temozolomide

(TMZ) is an oral chemotherapy agent that is structurally and functionally similar to dacarbazine that yields the same active intermediate. TMZ possesses activity against MM cells and the ability to cross the blood–brain barrier because of its lipophilicity, thus making it an appropriate chemotherapy agent to be investigated for the treatment of MM with CNS metastases. A phase III clinical trial comparing single-agent TMZ versus dacarbazine demonstrated that TMZ is at least as effective as dacarbazine against advanced metastatic MM without CNS involvement.²⁵ Combining other chemotherapy agents with dacarbazine has been investigated in phase III clinical trials and has not shown improvement in median or long-term survival over single-agent dacarbazine at the risk of greater toxicity.²⁷ Therefore, combination chemotherapy is not a standard of care for stage IV MM. The role of TMZ, either alone or as combination therapy in the prevention and treatment of MM CNS metastasis is an area of active research (Table 93–4).

Paclitaxel with or without cisplatin or carboplatin demonstrate response rates below 20% as first- or second-line treatment for stage III or IV MM.^{28,29} The combination of cisplatin, paclitaxel, and dacarbazine (CTD regimen)

Table 93-4

Dosing^a RecommendationsInterferon^a Regimens Used in Clinical Trials

High dose (HDI)	20 million units/m ² IV daily × 5 days/week for 4 weeks followed by 10 million units/m ² SC 3 times/week for 48 weeks
Intermediate dose (IDI)	10 million units × 5 days/week for 4 weeks followed by 10 million units SC 3 times/week for varying durations
Low dose (LDI)	3 million units SC 3 times/week for varying durations
	1 million units SC every other day for 1 year
Peginterferon	6 mcg/kg/week SC for 8 weeks followed by 3 mcg/kg/week for up to 5 years

Interleukin-2^a Dosing Regimens

IL-2 600,000 or 720,000 IU/kg by 15-minute infusion every 8 hours for 14 consecutive doses over 5 days as tolerated

IL-2 720,000 IU/kg IV over 15 minutes beginning at 6 PM on day 1 and subsequently at 8 AM and 6 PM up to a maximum of eight total doses on days 1 to 5 (first treatment course) and repeated on days 15 to 19 (second treatment course)

Ipilimumab^a

Ipilimumab 3 mg/kg every 3 weeks for four doses

Vemurafenib^a

Vemurafenib 960 mg PO twice daily with the first dose in the morning and the second dose in the evening approximately 12 hours later.

Continue treatment until disease progression or unacceptable toxicity occurs

Caution should be used in patients with severe renal or hepatic impairment; no specific guidelines exist

Vemurafenib is only indicated in patients with a BRAF mutation

Chemotherapy^a Dosing

Dacarbazine 250 mg/m²/day IV, days 1 to 5, every 21 days

No guidelines exist for dose adjustment in patients with renal or hepatic impairment

Temozolomide 150 to 200 mg/m²/day by mouth × 5 days, every 28 days

Caution should be used in patients with severe renal or hepatic impairment; no specific guidelines exist

Measure ANC and platelets on days 22 and 29

If ANC is less than 1,000/mm³ ($1.0 \times 10^9/L$) or platelet is less than 50,000/mm³ ($50 \times 10^9/L$), postpone therapy until ANC is greater than 1,500/mm³ ($1.5 \times 10^9/L$) and platelet is greater than 100,000/mm³ ($100 \times 10^9/L$); reduce dose by 50 mg/m² for subsequent cycle

If ANC is 1,000 to 1,500/mm³ (1.0×10^9 – $1.5 \times 10^9/L$) or platelet is less than 50,000–100,000/mm³ (50×10^9 – $100 \times 10^9/L$), postpone therapy until ANC is greater than 1,500/mm³ ($1.5 \times 10^9/L$) and platelet is greater than 100,000/mm³ ($100 \times 10^9/L$); maintain initial dose

If ANC is greater than 1,500/mm³ ($1.5 \times 10^9/L$) and platelet is greater than 100,000/mm³ ($100 \times 10^9/L$), increase dose to or maintain dose at 200 mg/m²/day for 4 subsequent cycles

^aThe doses presented here are general. Clinicians should refer to clinical trials to determine the specific dose based on the regimen the patient is receiving.

ANC, absolute neutrophil count; IV, intravenous; PO, oral; SC, subcutaneous.

From Refs. 26, 28, 37, 41, and 43.

demonstrated overall response rates of 41% as first-line therapy in patients with stage III or IV disease. Sensory neuropathy and myelosuppression occur with cumulative dosing of CTD and may require dose reduction.³⁰ A nanoparticle albumin bound paclitaxel (nab-paclitaxel) formulated in a solvent free vehicle to avoid the toxicities associated with Cremophor has been studied in combination with carboplatin for patients with stage IV MM. This regimen has shown promising activity as first line therapy in chemotherapy naïve patients and may have role in the treatment of MM³¹ (see Table 93-4).

Enrollment in clinical trials is encouraged in patients with MM because there is little consensus regarding standard chemotherapy for patients with metastatic melanoma.

► Immunotherapy

6 Melanoma is an immunogenic tumor and strategies to enhance the patient's immune response to treat the cancer are an area of active research. The relationship between melanoma and the immune system was also established

after spontaneous regression of melanoma was observed, and spontaneous serologic and cellular immunity can be documented in a high proportion of patients with advanced melanoma.³² Strategies to enhance patients' immune response for the treatment of MM have focused on cytokine therapy, immune-modulating therapy, adoptive T-cell therapy, and vaccines.

Interferon- α 2b Interferon- α 2b (IFN- α 2b) has diverse mechanisms of action, including antiviral activity, impact on cellular metabolism and differentiation, and antitumor activity. The antitumor activity is attributable to a combination of direct antiproliferative effect on tumor cells and indirect immune-mediated effects.³³ 7 IFN and pegylated IFN (peginterferon alfa-2b) are both approved by the FDA as adjuvant therapy for patients who are free of disease after curative surgical resection but are at high risk of MM recurrence. This includes patients with bulky disease or regional lymph node involvement such as stage IIB, IIC, or III disease. The doses of IFN used in clinical trials can be

classified into three groups: high-dose (HDI), intermediate-dose (IDI), and low-dose (LDI) interferon (see Table 93–4).

The optimum dose, schedule, and duration of IFN alfa-2b in high-risk melanoma remain to be defined. A recent meta-analysis of clinical trials of IFN in patients at high risk of recurrence after surgical resection showed improvements in relapse-free survival and overall survival.³⁴ However, IFN is associated with substantial toxicities, and the National Comprehensive Cancer Network (NCCN) Melanoma Guidelines recommend that the decision for IFN therapy should be made on an individual basis after explaining to the patient the potential benefits and side effects of the therapy. The NCCN Melanoma Guidelines recommend high-dose IFN for 1 year or peginterferon alfa-2b for up to 5 years if the decision is made to initiate IFN (see Table 93–4). Encouragement to participate in clinical trials is also reasonable for eligible patients.³⁵

HDI has substantial side effects (Table 93–5) that can be divided into acute and chronic manifestations and categorized into four major side effect groups: constitutional, neuropsychiatric, hematologic, and hepatic.³⁶ Patients should be educated on the side effects to expect and counseled of the interventions available to minimize the toxicities. Peginterferon alfa-2b has a longer duration of action than IFN alfa-2b and may be administered once a week. The side effects are similar to IFN alfa-2b, although the incidence may be less. The monitoring recommendations for peginterferon alfa-2b are the same as for IFN.

● **Interleukin 2** Interleukin-2 (IL-2) therapy is approved by the FDA for the treatment of metastatic MM. IL-2 indirectly causes tumor cell lysis by proliferating and activating cytotoxic T lymphocytes (CTLs). The overall objective response rate for patients with metastatic MM receiving high-dose IL-2 is 16%, with a complete response in 6% of patients and a partial response in 10% of patients. The median duration of response is 8.9 months for all responding patients and 5.9 months for patients with a partial response.³⁷ The median duration of complete response has not been reached but is at least 59 months. Disease progression is not observed in any patient responding for longer than 30 months. The data are encouraging because for the small number of patients who responded to therapy, the effect is of a long duration, and some patients may be considered to be cured of the disease. (Refer to Table 93–4 for dosing.)

● High-dose IL-2 therapy is associated with significant severe toxicities and morbidity.^{38,39} This treatment option is generally only considered in patients with good performance status who will have a better chance of tolerating and completing the therapy. With the availability of new therapies such as ipilimumab and vemurafenib, IL-2 is no longer the primary option for patients with metastatic melanoma. Table 93–6 lists the most common side effects experienced by patients receiving IL-2 therapy and recommendations for management. All clinicians involved with the care of patients receiving IL-2 should be well educated on the monitoring and management of IL-2-specific side effects.

Table 93–5

IFN Toxicities**Common Acute Toxicity****Management****Flu-Like Symptoms**

Fever, rigors, chills, headaches, myalgia, nausea, emesis

Last 1–12 hours after dose and tolerance develops with continued therapy
Bedtime administration helps with tolerating side effects
Premedicate with acetaminophen or NSAID and administer meperidine for severe chills and rigors

Neutropenia

Hepatic enzyme elevation

5-HT₃ antagonist, prochlorperazine, metoclopramide, fluids helps with nausea and vomiting
Weekly CBC; reduce dose by 30–50%
LFTs at baseline, weekly during induction, monthly during first 3 months of maintenance, then every 3 months; withhold treatment until LFTs normalize; restart at 30–50% dose reduction; reversible on dose reduction or cessation

Cutaneous: alopecia; transient, mild rashlike reaction

INF is contraindicated in patients with psoriasis because exacerbation of psoriasis has been noted during IFN therapy

Common Chronic Toxicity**Management**

Fatigue, weight loss, anorexia

Reported in 70–100% of patients and increase in intensity as therapy continues
Increase aerobic activity, light exercise, improve nutrition, increase noncaffeinated fluid intake, stress management technique; pharmacologic intervention—megestrol acetate, methylphenidate, to help with either fatigue or anorexia

Depression, cognitive dysfunction. Rare—mania, mood instability

Psychiatric history before therapy and reassess every 4 to 6 weeks; antidepressants: SSRIs, mood stabilizer, bupropion, psychostimulants

Thyroid dysfunction

Initial thyroid function test (TSH), then monthly; if three sequential values are stable or normal, bimonthly or quarterly TSH

CBC, complete blood count; 5-HT₃, serotonin; INF, interferon; LFT, liver function test; NSAID nonsteroidal anti-inflammatory drug; SSRI, selective serotonin reuptake inhibitor; TSH, thyroid-stimulating hormone.

From Hauschild A, Gogas H, Tarhini A, et al. Practical guidelines for the management of interferon- α -2b side effects in patients receiving adjuvant treatment for melanoma. Expert opinion. Cancer 2008;112:982–994.

Table 93-6

IL-2 Toxicities

Toxicity (% of Patients)	Management
Cardiovascular Hypotension (64%), supraventricular tachycardia (17%)	Discontinue antihypertensive medications; IV fluids to maintain systolic blood pressure greater than 80–90 mm Hg or vasopressor support with an α -agonist such as phenylephrine as indicated; be judicious in use of IV fluids for hypotension
GI Vomiting and diarrhea (55%), nausea (24%), stomatitis (14%)	5-HT ₃ antagonist, prochlorperazine for emesis (avoid corticosteroids), H ₂ blocker for gastritis, antidiarrheal as needed (loperamide, diphenoxylate/atropine, codeine)
Neurologic Confusion (30%), somnolence	Haldol for agitation, lorazepam for anxiety, zolpidem for insomnia
Pulmonary Dyspnea (31%), pulmonary edema, and ARDS	Advise smokers to quit 2 weeks before therapy; discontinue therapy if requiring greater than 4 L O ₂ or 40% O ₂ mask for saturation greater than 95%
Hepatic Elevated bilirubin (51%), transaminase (39%), ALP	Consider discontinuing therapy if severe
Renal Oliguria (49%), elevated serum creatinine (35%), anuria (8%)	Normal saline or dopamine at renal perfusion dose of 2 mcg/kg/min for oliguria; monitor for electrolyte abnormalities and replace as indicated
Hematologic Thrombocytopenia (43%), anemia (29%), leukopenia (21%)	Transfuse with packed red blood cells and platelets as needed
Skin Rash (27%), exfoliative dermatitis (15%), pruritus	Hydroxyzine, diphenhydramine, oatmeal powder baths, Lubriderm lotion
General Fever and or chills (47%), malaise (34%), infection (15%)	Acetaminophen and NSAIDs around the clock for fever and chills; add meperidine if chills are severe; clindamycin or cefazolin to prevent infection
Hypothyroidism	May occur in one-third of patients; thyroid function tests

ALP, alkaline phosphatase; ARDS, adult respiratory distress syndrome; 5-HT₃, serotonin; IV, intravenous; NSAID, nonsteroidal anti-inflammatory drug.

From Refs. 38 and 39.

Antibody Blockade of CTLA-4 with Ipilimumab

► T-Cell Activation and Inhibition

T-cell activation involves two different signals: (a) the binding of the T-cell receptor to a peptide presented by the major histocompatibility complex (MHC) on the antigen presenting cell (APC) and (b) the interaction of a costimulatory receptor (CD28) on the T-cell surface with a costimulatory ligand (B7) on the APC. The costimulatory molecules enhance the immune response by promoting T-cell activation and proliferation.⁴⁰

CTLA-4 is expressed in CD⁴⁺ and CD⁸⁺ T cells and regulatory T cells. It is a member of the immunoglobulin super family. After T-cell activation occurs, CTLA-4 migrates to the surface of the T cell, where it has higher affinity for the B7 ligand than CD28 and preferentially binds to B7. This results in an inhibitory signal to the T-cell and causes a downregulation on the immune response; in other words, CTLA-4 acts as a “brake” on the activation of the immune system.⁴⁰

Ipilimumab is a fully human monoclonal immunoglobulin (IgG1 κ) specific for CTLA-4. It has a high affinity for CTLA-4 and impedes binding of CTLA-4 to B7, preventing downregulation of the immune response. This results in increased proliferation of activated T cells and increases the interactions of T cells and cancer cells.⁴⁰ Ipilimumab is approved by the FDA for the treatment of unresectable or metastatic melanoma based on a phase III study demonstrating improved survival.⁴¹ The onset of response and regression of tumor size are slow after ipilimumab administration and may take at least 12 weeks of therapy for the response to be measurable. Furthermore, in the initial weeks of therapy, there may be apparent growth of the tumor probably because of drug-related inflammatory infiltrate from activation of T lymphocytes.⁴²

- The most common adverse effects observed with ipilimumab are immune related, and they follow a characteristic pattern of onset.⁴² The skin side effects are seen after an average of 3 to 4 weeks with improvement in 6 weeks, the gastrointestinal tract and liver side effects occur after 6 to 7 weeks with improvement after a median of 2 weeks for

Table 93-7

Ipilimumab Toxicities^a

Toxicity (% of patients)	Management
Dermatologic (47–68%) Maculopapular rash Pruritus Vitiligo	Do not need to stop or dose reduce ipilimumab Topical corticosteroid Urea-containing cream Antipruritic agent such as hydroxyzine For grade 3 or 4: oral corticosteroid with prednisone 1 mg/kg or dexamethasone 4 mg every 4 hours with a 4-week taper
GI (31–46%) Mild diarrhea, severe diarrhea, or colitis	Loperamide, hydration, electrolyte replacement Budesonide 9 mg/day or prednisone 1 mg/kg or high-dose IV steroids: methylprednisolone 2 mg/kg once or twice daily or dexamethasone 4 mg every 4 hours; then taper over 4 weeks after symptom resolution; some patients may require 6 to 8 weeks; taper; too rapid taper may result in recrudescence or worsening of symptoms If no response to steroids in 48 to 72 hours: Infliximab 5 mg/kg every 2 weeks. NOTE: infliximab is contraindicated in patients with bowel perforation or sepsis Discontinue ipilimumab for severe symptoms such as colitis Methylprednisolone 2 mg/kg/day 1–2 times daily for LFT greater 8 × ULN or total bilirubin greater 5 × ULN Mycophenolate 1 g IV or 1.5 g orally two times daily if symptoms persist
Inflammatory hepatotoxicity (3–9%)	Obtain thyroid function tests, serum cortisol levels, ACTH, testosterone, FSH, LH, prolactin Dexamethasone 4 mg every 4 hours for 7 days and taper over at least 4 weeks Hormone substitution as needed Endocrinologist consult
Endocrine (4–6%) Hypophysitis	Obtain thyroid function tests, serum cortisol levels, ACTH, testosterone, FSH, LH, prolactin Dexamethasone 4 mg every 4 hours for 7 days and taper over at least 4 weeks Hormone substitution as needed Endocrinologist consult
Neurologic (1%) Guillain–Barré syndrome Sensory or motor neuropathy Myasthenia gravis	If symptoms persist for more than 5 days, evaluate for neurologic disorders Corticosteroids May need to interrupt or discontinue therapy if symptoms are severe

^aIn general, for severe grade 3 or 4 ipilimumab toxicities, therapy should be discontinued permanently.

ACTH, adrenocorticotropic hormone; FSH, follicle-stimulating hormone; LH, luteinizing hormone; ULN, upper limit of normal

From Kähler C, Hauschild A. Treatment and side effect management of CTLA-4 antibody therapy in metastatic melanoma. *J Dtsch Dermatol Ges* 2011;9:277–285.

GI and 4 weeks for liver toxicity, and the endocrine effects are apparent after an average of 9 weeks with improvement occurring 20 weeks later. The skin side effect is manifested as a maculopapular rash with associated pruritus. The most common GI side effect is diarrhea, which is usually mild but in some cases may be prolonged or severe and may worsen to colitis and the risk of bowel perforation. The hepatotoxicity presents as an asymptomatic increase in transaminases or as immune-related hepatitis with fever and malaise. Hypophysitis (inflammation of the pituitary gland) is the presenting endocrine disorder, and it is a rare side effect of ipilimumab. Clinical symptoms of hypophysitis include headache, nausea, dizziness, vision disturbances, and weakness. Severe ophthalmologic (episcleritis and uveitis) side effects have also been reported with ipilimumab. It appears on average 2 months after beginning therapy and resolved within 1 week regardless of therapy. Fewer than 1% of patients experience neurologic side effects such as Guillain–Barré syndrome, sensory or motor neuropathy, or myasthenia gravis.⁴²

- Corticosteroids are the treatment of choice for ipilimumab-induced irAE. The administration of steroids to treat the side effects did not appear to result in decreased effectiveness of ipilimumab. Interestingly, there may be a correlation between immune-related adverse events and treatment success⁴² (see [Table 93-7](#) for side effects management).

Targeted Therapy with Vemurafenib

BRAF is an intermediary in signal transduction through the MAPK pathway. Activation of BRAF is associated with downstream activation of ERK, elevation of cyclin D1, and an increase in cellular proliferation.⁴³ BRAF is mutated in approximately 50% of melanomas, and 80% of these mutations are the *BRAF V600E* mutation.¹² Vemurafenib is an oral competitive small molecule serine threonine kinase inhibitor that functions by binding to the adenosine triphosphate binding domain of mutant BRAF.⁴³ **8** *Vemurafenib selectively targets the mutated BRAF V600E isoform and it is approved by the FDA as first-line therapy for unresectable stage IIIC or*

Patient Encounter, Part 3

DM presents 3 years later after treatment of her stage III melanoma with high-dose interferon. At her routine follow-up visit, a chest x-ray showed bilateral lung metastases. DM also reports a history of increasing nonproductive cough and exertional shortness of breath in the past few weeks.

Laboratory Data: LDH two times above normal level; all other lab data are normal

CT scan: Confirms metastasis in lung and paraaortic lymph nodes

What is the treatment of choice for DM?

What test is used to determine if DM should receive vemurafenib?

What are the most common side effects associated with vemurafenib?

metastatic melanoma that is BRAF V600 mutation positive. The Cobas 4800 BRAF V600 Mutation Test is the companion FDA-approved diagnostic tool used to test for the BRAF V600 mutation (see Table 93–4 for dosing).

A phase III clinical trial compared vemurafenib with dacarbazine in patients with previously untreated, unresectable stage IIIC or metastatic melanoma possessing the BRAFV600 E mutation.⁴⁴ Data analysis at 6 months showed that overall survival was 84% and median progression-free survival was 5.3 months for patients receiving vemurafenib compared with 64% overall survival and 1.6 months progression-free survival for patients receiving dacarbazine. The most common side effects associated with vemurafenib were arthralgia, photosensitivity, rash, diarrhea, nausea, fatigue, and alopecia. Some patients may require dose reduction for severe side effects, but doses lower than 480 mg twice daily are not recommended. Eighteen percent of patients in the phase III clinical trial reported at least one squamous cell carcinoma or keratoacanthoma. These lesions were excised, and no patients required dose modification of vemurafenib.⁴⁴ Rare side effects that led to discontinuation of the drug in some patients include liver function abnormalities, prolonged QTc, and retinal vein thrombosis.

OUTCOME EVALUATION

After diagnosis and treatment of skin cancer, the next phase of management is appropriate follow-up with the purpose of detecting recurrent disease or new malignant melanomas. Patients need to understand the importance of scheduling regular follow-up visits with the oncologist or dermatologist after the diagnosis and treatment of skin cancer. The NCCN Melanoma Guidelines recommend that patients with stage IA to IIA disease to be seen every 3 to 12 months for 5 years and then annually for life. Patients with stage IIB to IV

disease should be followed up every 3 to 6 months for 2 years, then every 3 to 12 months for 3 years, and then annually for life. Chest x-ray, computed tomography, or positron emission tomography scans every 6 to 12 months and annual brain magnetic resonance imaging may be considered for patients with stage IIB to IV disease. Routine radiologic screening for asymptomatic recurrence is not recommended after 5 years.³⁵

Recurrence of MM occurs after complete resection in 30% of patients diagnosed with stage I to III disease, and 80% of the patients develop recurrence within 3 years of their diagnosis of primary MM.⁴⁵ Among patients whose melanoma recurred, the site of recurrence is local in 20% to 28% of patients; in 26% to 60%, recurrence is in regional lymph nodes; and 15 to 50% experience distant recurrence. The rate of recurrence detection by patients is reported to be 33% to 99%; thus, patients should be educated on how to perform self-examination of the skin and lymph nodes and the importance of ongoing sun protection measures.⁴⁵

Patients who received immunotherapy for stage III or IV MM may experience fatigue and other chronic side effects. Develop a plan to order laboratory tests such as liver function tests, thyroid-stimulating hormone, and white blood cell count at baseline and on a weekly or monthly basis as indicated. Monitor and evaluate patients for side effects of IL-2, IFN, ipilimumab, and vemurafenib and educate patients on what to expect and how the side effects will be managed. Assess patients' psychological, physical, and social functioning. Counsel patients to contact the hospital's social service department or the American Cancer Society for assistance in dealing with the disease emotionally and recommend that patients consider attending support group meetings or talking to a counselor if or before they become overwhelmed with the diagnosis.

Patient Encounter, Part 4

DM was negative for BRAF mutation with analysis using the Cobas 4800 BRAF V600 Mutation Test.

The decision was made to initiate DM on ipilimumab. She is scheduled to receive 3 mg/kg every 3 weeks for a total of 4 cycles. At week 4, it was noted that DM has new subcutaneous lesions and enlargement of the preexisting lesions. Furthermore, a few days after DM received her second dose of ipilimumab, she experienced severe grade 3 diarrhea. She reports mild abdominal pain with no fever and no blood in her stool.

When is it appropriate to assess if DM has responded to the therapy?

What are the most common side effects associated with ipilimumab?

What should be done to manage the side effects of ipilimumab?

Patient Encounter, Part 5

Create a care plan for DM while she is receiving ipilimumab. The plan should include (a) the goal of therapy and (b) a plan related to dealing with the side effects of ipilimumab.

For how long should DM be monitored for side effects if they should occur?

What laboratory parameters need to be monitored?

What are the indications to discontinue ipilimumab?

What does it mean if DM develops new lesion in the first few weeks of therapy?

NONMELANOMA SKIN CANCER

EPIDEMIOLOGY AND ETIOLOGY

NMSC accounts for more than half of all newly diagnosed cancers in the United States each year, and it was estimated that more than 3.5 million new cases of BCC and SCC (in more than 2 million people) would be diagnosed in 2011.¹ The true prevalence of NMSC may be underestimated because it is treated in outpatient settings, and no formal reporting to cancer registries is required. The incidence rate of NMSC is increasing worldwide with a yearly rise of 3% to 8% since 1960.⁴⁶ BCC is the most common form of NMSC and comprises 75% of NMSC with SCC accounting for 20%.¹⁵ The majority of NMSCs are curable, and the mortality rate is low; cure rates approach 98%, and the overall 5-year survival rate is greater than 95%.⁴⁷ Metastasis occurs in fewer than 0.1% of BCCs compared with an average of 3.6% of SCCs. Seventy-five percent of all NMSC deaths are attributed to SCC.⁴⁷ NMSC is associated with considerable morbidity related to functional and cosmetic deformity. In addition, it is an economic burden to the health care system because costs associated with NMSC treatment are estimated at approximately \$426 million per year.¹⁵

RISK FACTORS

The risk of developing NMSC is multifactorial (**Table 93–8**). The most important risk factor for NMSC is UV radiation exposure, and data from epidemiologic studies indicate that greater cumulative lifetime sun exposure is associated with a higher risk of developing SCC, but intermittent and childhood sun-exposure correlates more with BCC.⁴⁶ Most cases of BCC are sporadic; however, it occurs frequently in the rare individuals with hereditary disorders such as basal cell nevus syndrome (also known as Gorlin's syndrome). It is also common in patients with genetic syndromes such as XP. The *patched* gene (*PTCH*), a tumor-suppressor gene, has been shown to be mutated in 68% of sporadic BCCs.⁴⁶ There is clear evidence linking defects of the immune system to the development of NMSC. For example, it is observed that

Table 93–8

From Refs. 46 and 48.

patients receiving chronic immunosuppressant therapy for organ transplantation have a 65-fold increase in developing SCC and 10-fold increase in developing BCC.⁴⁸

PATHOPHYSIOLOGY

NMSCs arise from epidermal keratinocytes and involve primarily squamous cells and basal cells of the epidermis and dermis skin layers. BCCs arise from interfollicular basal cells or keratinocytes in hair follicles or sebaceous glands.⁴⁸

CLINICAL PRESENTATION, PROGNOSIS

BCC is characterized as circumscribed or diffuse, and within these two groups, it is further classified according to type, degree of differentiation, and depth of invasion (see Table 93–1).¹⁴ The nodular BCC is the most common type of BCC followed by superficial BCC. The morpheiform BCC is the most aggressive subtype.¹⁴ BCC has indolent growth characteristics with a very low metastatic and mortality rate.⁴⁶ Paradoxically, BCCs can cause extensive local destruction and significant disfigurement. Approximately 80% of BCCs occur on the head and neck. Superficial BCC occurs predominantly on the trunk. Early stage BCC is usually small, translucent or pearly with raised telangiectatic edges.⁴⁶ BCC may also appear as raised, yellowish-reddish lesions with a border resembling a string of pearls and telangiectasia. Dermatoscopy may distinguish between a benign and

malignant lesion; however, clinical examination is usually sufficient for diagnosis of BCC. Depending on the size of the tumor, subtype, and treatment planned, a biopsy may be needed.

SCC usually presents on sun-exposed sites because of UVR damage to the skin. Unlike BCC, SCCs are preceded by premalignant lesions such as leukoplakia, actinic keratosis (AK) (a small papule that appears on areas of sun damage on the skin), or SCC in situ (Bowen's disease).⁴⁶ The rate of AK progression to SCC is 1% to 10% in 10 years and may be higher if a patient has more than five AKs.⁴⁶ Patients with Bowen's lesion present with slowly enlarging erythematous scaly or crusted plaques and have a 3% to 5% risk of progressing to SCC. A typical SCC lesion has an adherent crust and ill-defined edges; the first sign of malignant SCC is induration of the lesion. The rate of metastasis for SCC is 2% to 6% and may be as high as 10% to 14% in high-risk sites such as the ear and lip and 30% in the genital area.⁴⁷ Metastasis most commonly presents 1 to 2 years after diagnosis of the primary SCC with 80% of metastasis involving the regional lymph nodes.⁴⁹ The Skin Cancer Foundation (www.skincancer.org) provides images and descriptions of the various presentations of BCC and SCC.

High-risk factors for NMSC are outlined in Table 93–7. If a patient possesses these factors, he or she is at high risk for disease recurrence and subsequent metastasis. Patients with NMSC have a 10-fold increased risk of developing subsequent NMSC compared with the general population.⁴⁶

Staging for NMSC uses the TNM staging system recommended by the American Joint Committee on Cancer. It is seldom done for patients with BCC because nodal and visceral metastasis is rare for this diagnosis.⁴⁶

TREATMENT

9 *In patients diagnosed with BCC and SCC, the primary goal of therapy is to cure the patient and to prevent recurrence.* Although NMSC has a low mortality rate, morbidity related to tissue destruction, functional impairment, and disfigurement is a significant issue. Therefore, secondary goals of therapy for NMSC are preservation of function and restoration of cosmesis. The treatment options for NMSC involve surgery, pharmacologic therapy, or a combination of both. The choice of treatment depends on factors such as tumor size, the site of the lesion, patient comorbidities, and the histologic and clinical nature of the cancer.

Nonpharmacologic Therapy

► Surgery

Surgery is the primary treatment modality for all patients diagnosed with either BCC or SCC. Full-thickness ablative procedure in the form of surgical excision of the tumor along with a margin of normal tissue surrounding the tumor is the preferred method for high-risk tumors. Obtaining negative surgical margins is critical for cure and decreasing the risk

of tumor recurrence. A margin of 4 to 5 mm in well-defined BCC and SCC ensures peripheral clearance in 95% of cases. Depending on the tumor size, degree of differentiation, and invasion of surrounding structures, larger margins of resection may be necessary.⁴⁶ The two most common surgical techniques used are electrodesiccation and curettage (ED&C) and Mohs' micrographic surgery (MMS). The indications of each of these procedures are described below.

Low-risk tumors defined as small, well-differentiated, and slow growing can be treated with superficial ablative techniques, including ED&C and cryotherapy.⁴⁶ ED&C is a simple, cost-effective technique that uses repeated cycles of using a curette to cut through malignant tissue followed by electrodesiccation, which involves the application of high voltage, low current to the skin, causing drying or desiccation of the tissue. ED&C is most appropriate for well-defined superficial lesions that are not located in areas with increased risk for metastasis. The disadvantage of this technique is that histologic confirmation of complete tumor removal is not possible.⁴⁸ This procedure is not recommended for treatment of recurrent disease, tumors of the face, and high-risk tumors.⁴⁸

For high-risk NMSC or for tumors located in cosmetically or anatomically sensitive areas, MMS is the procedure of choice. The goal of this therapy is complete removal of the cancer with preservation of as much surrounding normal tissue as possible. MMS involves careful dissection, staining of frozen sections, and anatomic mapping of the tumor specimen. Sections are assessed immediately under the microscope by the surgeon, and the process is repeated until a tumor-free margin is attained. MMS cures 93% of primary NMSC and 90% to 94% of recurrent disease compared with 92% and 77% cure rate with standard excision for primary and recurrent disease, respectively.⁴⁹ Cure rates for all modalities decrease with the presence of high-risk features but are still superior with MMS.⁴⁹

Cryotherapy is a procedure used primarily for smaller, low-risk NMSCs with clearly defined margins. It involves delivering liquid nitrogen at subzero temperatures as a spray or with a supercooled metal probe to destroy the malignant tissue in a single cycle or multiple cycles.⁴⁸ This technique can achieve comparable results to conventional surgery for well-differentiated, not too large, superficial tumors in older patients with BCC.⁴⁸ The procedure is contraindicated in the hair-bearing scalp, upper lip, and distal portion of lower leg because of delayed healing and high rates of recurrence.⁴⁸

► Radiation

Radiation is not standard therapy for the treatment of skin cancer; however, there are circumstances in which radiation may be preferred. It may be offered to patients in whom surgery is not possible because the tumor is inoperable or surgery would lead to unacceptable cosmetic or functional impairment.⁴⁹ Radiation to the lip, ear, and nasal entrance for SCC may provide the best cosmetic and functional

result. On the other hand, some patients may develop dyspigmentation, radiodystrophy, or telangiectasia at the site of radiation, resulting in poorer cosmetic outcomes. Radiation is contraindicated in treating BCC that recurred after radiotherapy. It should be used with caution in patients younger than 65 years because latent NMSC can develop after 15 to 20 years of radiation exposure.⁴⁶

► Photodynamic Therapy

Photodynamic therapy (PDT) involves the topical application of a photosensitizing agent that is activated after exposure to a light source and causes tumor cell damage and death. The photosensitizer is converted to protoporphyrin IX after it is preferentially taken up by active tumor cells. Damage to cell membranes, organelles, and surrounding vasculature occurs when protoporphyrin IX is activated after exposure to a light source. Protoporphyrin IX has absorption bands at 408, 510, 543, 583, and 633 nm; therefore, blue light (corresponding to 408-nm band) and red light (corresponding to 633-nm band) are the most commonly used light source.⁴⁸ Blue light is used for superficial lesions because of its shorter wavelength and because it does not penetrate the skin as well as red light.⁴⁸

δ -Aminolevulinic acid (ALA) and methyl aminolevulinate (MAL) are two photosensitizing agents that have FDA approval for the treatment of AK⁵⁰ (see **Table 93–9** for dosing). PDT has also been shown to be effective in the treatment of SCC in situ, but it is not indicated for SCC because of its extensive invasiveness and metastatic potential.⁵⁰ In patients with superficial BCC, MAL-PDT may be considered when surgery may result in suboptimal cosmetic outcomes or complications.⁵⁰ For patients with nodular BCC, MAL-PDT may be considered but not ALA-PDT.^{48,50}

Pharmacologic Therapy

► Fluorouracil

Nonsurgical treatment is used frequently for superficial NMSCs. Topical 5-fluorouracil has been used for the treatment of dermatologic disorders for approximately 45 years, and it has FDA approval for the treatment of AK and superficial BCC⁵⁰ (Table 93–4). Fluorouracil is available as solution and cream with strengths ranging from 1% to 5%. There is also a microsphere-encapsulated 0.5% cream that has reduced systemic absorption with enhanced skin retention to reduce systemic side effects. The microsphere formulation is applied only once a day, providing patient preference and convenience over the twice-daily application with the other formulations.⁵⁰ The optimal strength of fluorouracil is still under investigation, but the FDA has approved 2% to 5% cream or solution and 0.5% microsphere formulation for AK. For superficial BCC, only the 5% strength is FDA approved for this indication.⁵⁰ The most common side effects with topical fluorouracil are expected to occur within the initial 5 to 10 days of treatment, and it presents as erythema, irritation, burning sensation, pruritus, and pain along with hypo- or hyperpigmentation.⁵⁰ Patients also experience inflammatory

Table 93–9

Topical Therapy for Nonmelanoma Skin Cancer

Methyl Aminolevulinate Hydrochloride

Actinic keratosis: apply up to 1 g (half tube) of cream *topically* on lesion(s) during PDT session (2 sessions 1 week apart) followed by occlusive dressing for 3 hr (at least 2.5 hr and no more than 4 hr in duration) and then red light illumination for 7 to 10 min; maximum, 1 g (half tube) per treatment session

Aminolevulinic Acid

Actinic keratosis: apply *topically* to target lesion(s) on face or scalp and let dry and then repeat once; 14 to 18 hr later, gently rinse area with water and pat dry; follow by illumination from the BLU-U(R) Blue Light Photodynamic Therapy Illuminator; may retreat a second time after 8 wk

Protect treated lesions from sunlight or prolonged or intense light for at least 40 hr by covering with light-opaque material; sunscreen will not protect against photosensitivity reactions caused by visible light.

Topical Fluorouracil

Actinic keratosis: cover lesions *topically* with 2% or 5% solution or cream twice daily for 2 to 6 weeks or with 0.5% microsphere formulation once daily for up to 4 weeks.

Superficial basal cell carcinoma: cover lesions *topically* with 5% cream or solution twice daily for 3 to 6 weeks up to 10 to 12 weeks.

Imiquimod

Superficial basal cell carcinoma on trunk, neck, or extremities when surgical methods are less appropriate and follow-up is assured: Aldara 5% apply *topically* formulation once daily five times per week for 6 weeks; apply at bedtime and leave on skin for 8 hr

The doses presented here are general. Clinicians should refer to clinical trials to determine the specific dose based on the regimen the patient is receiving.

PDT, photodynamic therapy.

From National Comprehensive Cancer Network. Basal Cell and Squamous Cell Skin Cancer. Version 1. 2012, <http://www.nccn.org>.

reactions that include crusting, edema, and oozing. If the reactions are severe, the fluorouracil strength or frequency of application may be reduced. To reduce inflammation, topical steroids may be used concurrent with fluorouracil application and for 1 to 2 weeks after treatment.⁵⁰ Caution should be used in administering fluorouracil to patients with dihydropyrimidine dehydrogenase deficiency, an enzyme critical in the metabolism of fluorouracil, because increased toxicity may be observed.

► Imiquimod

Imiquimod is an immune-modulating agent that works by stimulating innate and cell-mediated immune responses. It has FDA approval for the treatment of AK and for when surgical procedure is not appropriate for superficial BCC located on the trunk, neck, or extremities and when follow up is assured. Imiquimod has been shown to have complete

clearing of AK in 50% of patients and partial clearing in 75% of patients with AK compared with 5% for those treated with placebo. Cure rates for imiquimod 5% in patients with superficial BCC are greater than 90%. The response rate is much lower for nodular BCC at 75%; therefore, it should be used in these patients only if they are not able to undergo surgery, radiation, or cryotherapy and the tumor is small and in a low-risk area. Imiquimod is not recommended for the treatment of invasive SCC, but data for SCC in situ showed a 93% cure rate; thus, it may be considered for this patient population.

Imiquimod is available in 3.75% strength, which may be applied daily on larger areas of skin, the balding scalp, or the full face, and 5% strength, which may be used on areas of skin that are 25 cm² or smaller⁵⁰ (see Table 93–4). Imiquimod should be applied before bedtime and left on the skin for 6 to 10 hours. The most common side effects with imiquimod involve the area of application and present as erythema, pruritus, a burning or stinging sensation, and tenderness. Less commonly, hypopigmentation, fever, diarrhea, and fatigue may also occur. Temporary discontinuation of imiquimod and application of topical steroids may be necessary to alleviate the irritation symptoms. Imiquimod may be resumed at a decreased frequency after the symptoms have resolved.⁵⁰

► Vismodegib

Genetic alterations in hedgehog signaling pathway cause loss of function of patch homolog 1 (PTCH1), which normally acts to inhibit signaling activity of Smoothed, a transmembrane protein involved in Hedgehog signal transduction. Vismodegib is a first-in-class, oral small molecule inhibitor of the Hedgehog signaling pathway; it binds to and inhibits Smoothed (SMO). Vismodegib is approved by the FDA for the treatment of adults with metastatic BCC or locally advanced BCC that has recurred following surgery or who are not candidates for surgery or radiation.

OUTCOME EVALUATION

BCC and SCC have excellent outcomes, with cure rates approaching 98%.⁴⁷ Recurrence of NMSC is around 30% to 50% during a 5-year follow-up, and 70% to 80% of recurrence develops within the first 2 years after initial therapy.⁴⁷ Therefore, it is crucial to advise patients to schedule routine follow-up visits with their dermatologist and to educate them about the value of sun protection and total-body skin self-examination. Patients with SCC at high risk for recurrence should be monitored every 1 to 3 months for the first year, every 2 to 4 months in the second year, every 4 to 6 months for years 3 to 5, and then every 6 to 12 months annually for life.⁵⁰ The follow-up recommendation for low-risk SCC patients is every 3 to 6 months for 2 years, every 6 to 12 months for year 3, and then annually for life. For patients with BCC, the recommendation is for physician follow-up with complete

skin examination every 6 to 12 months for life.⁵⁰ Patients may be directed to the following websites that discuss skin cancer prevention: <http://www.aafp.org/afp/2000/0715/p375.html>, <http://www.skincancer.org/Guidelines/>, and <http://www.aad.org/skin-care-and-safety/skin-cancer-prevention/skin-cancer-prevention>.

Patients receiving topical agents such as fluorouracil or imiquimod should be educated to wash the treatment area with mild soap and water before applying the cream, use gloves to apply enough to cover the area with a 1-cm margin, and wash their hands thoroughly after each application. They should avoid sun exposure and be counseled to monitor for side effects such as pain, itching, and inflammation. They should consult their dermatologist if the side effects are intolerable.

Patient Care and Monitoring

1. Obtain a thorough patient medication history, both prescription and nonprescription, to prevent drug interactions with the current therapy the patient is receiving.
2. Obtain the appropriate baseline laboratory tests and determine a time interval for reevaluation of specific laboratory tests to determine toxicity.
3. Provide education on the side effects of therapy:
 - What to administer or take to prevent side effects
 - When to administer or take the medication to decrease side effects
 - Nonpharmacologic recommendations to minimize side effects
 - Drugs that may interact with therapy
 - Lab tests that need to be monitored on a regular basis
 - The parameters for discontinuing or holding therapy
 - If therapy is to be reinitiated, the new dose of therapy
4. Assess the patient for adverse drug reactions and drug–drug interactions.
5. Educate the patient on the signs and symptoms of infection.
6. Assess for changes in the patient's quality of life owing to side effects of drug therapy.
7. Educate the patient on measures that should be undertaken to limit sun exposure and prevent skin cancer.
8. Educate the patient on how to do skin self-examination for suspicious moles.
9. Educate the patient on follow-up recommendations after treatment for skin cancer is completed.

Abbreviations Introduced in This Chapter

AK	Actinic keratosis
BCC	Basal cell carcinoma
CNS	Central nervous system
CTL	Cytotoxic T lymphocyte
CTLA-4	Cytotoxic T-lymphocyte antigen-4
ED&C	Electrodessication and curettage
HDI	High-dose interferon- <i>a</i> 2b
IDI	Intermediate-dose interferon- <i>a</i> 2b
IFN	Interferon- <i>a</i> 2b
IL-2	Interleukin 2
LDI	Low-dose interferon- <i>a</i> 2b
LFT	Liver function test
MM	Malignant melanoma
MMS	Mohs' micrographic surgery
NMSC	Nonmelanoma skin cancer
SCC	Squamous cell carcinoma
SEER	Surveillance, Epidemiology, and End Results
SLN	Sentinel lymph node
SPF	Skin protection factor
SRS	Stereotactic radiosurgery
TMZ	Temozolamide
TNM	Tumor, node, metastasis
UVR	Ultraviolet radiation
WBRT	Whole-brain radiation therapy
XP	Xeroderma pigmentosum

Self-assessment questions and answers are available at <http://www.mhpharmacotherapy.com/pp.html>.

Ovarian Cancer

Judith A. Smith

LEARNING OBJECTIVES

● **Upon completion of the chapter, the reader will be able to:**

1. Demonstrate understanding the etiology and risk factors associated with the development of ovarian cancer.
2. Justify the risk and benefits of the surgical and chemoprevention options available for decreasing the potential risk of developing ovarian cancer.
3. Interpret and understand the utility of the screening tests and serologic markers for diagnosing ovarian cancer.
4. Distinguish the nonspecific physical signs and symptoms of ovarian cancer.
5. Recommend the appropriate surgical and chemotherapy treatment options for newly diagnosed and relapsed ovarian cancer patients.
6. Compare and contrast chemotherapy options for women with recurrent platinum-resistant ovarian cancer.
7. Compare and contrast the treatment options for management of hot flushes in ovarian cancer patients.
8. Devise a plan for the management of common complications associated with advanced and recurrent ovarian cancer.

KEY CONCEPTS

- 1 Ovarian cancer is a sporadic disease; fewer than 10% of ovarian cancers can be attributed to heredity.
- 2 Because CA-125 is a nonspecific marker, there is no standard recommendation for routine screening for prevention of ovarian cancer.
- 3 Ovarian cancer is denoted “the silent killer” because of its nonspecific signs and symptoms.
- 4 Surgery is the primary treatment intervention for ovarian cancer.
- 5 Ovarian cancer is staged surgically using the International Federation of Gynecology and Obstetrics (FIGO) staging algorithm.
- 6 After initial surgery, the gold standard of care is six cycles of a taxane/platinum-containing regimen.
- 7 Although majority of patients will initially achieve a complete response, disease will recur within the first 2 years in more than 50% of patients.
- 8 Because the efficacy of the agents is similar, the selection of agent for treatment of recurrent platinum-resistant ovarian cancer depends on residual toxicities, clinician preference, and patient convenience.

- 9 Precaution should be used in removal of ascites because of the potential complications associated with rapid fluid shifts.
- 10 In ovarian cancer patients, small bowel obstruction (SBO) is a common complication of progressive disease (PD). In general, laxatives should not be used in patients with SBOs.

INTRODUCTION

Ovarian cancer is relatively uncommon but is the most fatal gynecologic cancer. The primary reason for the high mortality rate associated with ovarian cancer is the nonspecific symptoms and difficulty for early detection or screening that result in patients presenting with advanced disease. The majority of ovarian cancers are of epithelial origin. Each time ovulation occurs, the epithelium of the ovary is broken followed by occurrence of cell repair. The *incessant ovulation hypothesis* proposes that the increasing number of times the ovary epithelium undergoes cell repair is associated with the increasing risk of mutations and ultimately ovarian cancer. Ovarian cancer is often denoted as the “silent killer” because although the majority of patients will achieve a complete response (CR) to primary surgery and chemotherapy, disease

Patient Encounter 1, Part 1

BN, a 63-year-old active woman, has been in good health up until recently (about 4 months or so). She has had significant indigestion after meals and feels “nausea” frequently throughout the day. Her general physician completed upper and lower GI series, which both had normal results. One month later, her symptoms persisted, so her physician ordered a CT scan, which came back positive for an abdominal mass and thickening of the omentum. Of note, she has been married for 35 years with only one sexual partner in her lifetime. They have one child who is now 20 years old. Her first menses was when she was 12 years old and menopause was at age 57 years. She denies any alcohol or tobacco use.

Based on the CT scan, what additional diagnostic tests would be recommended to complete her workup?

In the context of BN, discuss why ovarian cancer is often denoted the “silent killer” and what needs to be done for earlier diagnosis of ovarian cancer.

Compare and contrast the treatment options for BN after her initial surgery.

recurs in more than 50% of patients in the first 2 years after completion of primary treatment. Ovarian cancers often cause **metastasis** via the lymphatic and blood systems to the liver, and/or lungs. Common complications of advanced and progressive ovarian cancer include **ascites** and small bowel obstruction (SBO), which often are associated with the end of life.

EPIDEMIOLOGY AND ETIOLOGY

In 2012, there were an estimated 22,280 new cases of ovarian cancer diagnosed with an associated 15,500 deaths.¹ Ovarian cancer remains the number one gynecologic killer and the fifth leading cause of cancer-related death in women. Despite great efforts and extensive research, there has been little change in the mortality rate associated with ovarian cancer over the past 4 decades. The high mortality rate associated with ovarian cancer can be attributed to its insidious onset of nonspecific symptoms, resulting in the majority of patients not presenting until the cancer has progressed to stages III to IV disease.

As with many other disease states, a significant risk factor associated with ovarian cancer is aging. A woman’s risk increases as her age advances from 40 to 79 years, with the mean age at diagnosis being 63 years and the majority of women being diagnosed between 55 and 64 years.²

① *Ovarian cancer is a sporadic disease; fewer than 10% of ovarian cancers can be attributed to heredity.* The majority of cases of ovarian cancer occur sporadically, thus making it difficult to screen and prevent. Although hereditary accounts for fewer than 10% of all ovarian cancer cases, when there is a family history, it appears to be an important risk factor in the development of ovarian cancer in some patients.³ If

one family member has a diagnosis of ovarian cancer, the associated risk is about 9%, but this risk increases to greater than 50% if there are two or more first-degree relatives (i.e., mother and sister) with a diagnosis of ovarian cancer or multiple cases of ovarian and breast cancer.³ Both breast cancer activator gene 1 (*BRCA1*) and breast cancer activator gene 2 (*BRCA2*) mutations have been associated with ovarian cancer. However, *BRCA1* is more prevalent, being associated with 90% of hereditary and 10% of sporadic cases of ovarian cancer.³ Hereditary breast and ovarian cancer (HBOC) syndrome is one of the two different forms of hereditary ovarian cancer and is associated with germline mutations in *BRCA1* and *BRCA2*.^{3,4} The hereditary nonpolyposis colorectal cancer (HNPCC) or Lynch syndrome is a familial syndrome with germline mutations causing defects in enzymes involved in DNA mismatch repair, which has been associated with up to 12% of hereditary ovarian cancer cases.⁴

Although it is not clearly defined, hormones and reproductive history are associated with the risk of developing ovarian cancer. **Nulliparity**, infertility, early menarche, or late menopause is associated with an increased risk of ovarian cancer.⁵

Ovarian cancer is associated with certain dietary and environmental factors as well. A diet that is high in galactose and animal fat and meat increases the risk of ovarian cancer, whereas a vegetable-rich diet is suggested to decrease the risk.⁶ Although controversial, exogenous factors such as asbestos and talcum powder use on the perineal area have also been suggested to increase the risk of ovarian cancer.⁶

Screening and Prevention

► Screening

- Currently there is no standard effective screening tool that is adequately predictive or sensitive for early detection.
- Pelvic examinations are effective for detecting obvious tumors present with a sensitivity of 67% for detecting all tumors; however, minimal or microscopic disease cannot be detected on physical examination.⁸ Pelvic examinations are noninvasive and well accepted, but they do not usually detect ovarian cancer until it is in advanced stage. Therefore, routine pelvic examinations will not improve earlier diagnosis or help decrease overall mortality.⁸
- Serum cancer antigen-125 (CA-125) is the most extensively evaluated tumor marker for ovarian cancer. Unfortunately, CA-125 is nonspecific, and elevated levels can be associated with a number of other gynecologic and GI-related diseases. CA-125 levels in a woman without ovarian cancer are static or tend to decrease over time, but levels associated with malignancy continue to rise.^{9,10} ② *Because CA-125 is a nonspecific marker, there is no standard recommendation for routine screening for prevention of ovarian cancer.*

Transvaginal ultrasound (TVUS) is a component of current screening practices. Typically, it is used in combination with CA-125 or could be used as a single modality. TVUS releases sonic sound waves that create an image of the ovary to evaluate the size and shape and detect the presence of cystic or solid masses. Limitations of this technique are lack

Patient Encounter 2

ST, a 34-year-old woman who has been in good health, presents to your clinic complaining of constipation and abdominal pain. She explains to you that she is concerned about her cancer risk because her 54-year-old mother had breast cancer and underwent surgery and chemotherapy approximately 20 years ago after the birth of her third child. Last month, her cousin was diagnosed with stage I ovarian cancer and underwent TAH-BSO and had genetic testing completed that revealed she was BRCA1 positive. She is requesting to check her CA-125 level today in clinic.

Explain the association between hereditary and ovarian cancer risk.

Discuss why monitoring CA-125 is not used as a screening tool for ovarian cancer.

Describe the potential advantages and disadvantages of using oral contraceptives for prevention of ovarian cancer for ST.

of specificity and an inability to detect peritoneal cancer or cancer in normal size ovaries.^{2,9} Most prevention clinics use this multimodality approach to screen high-risk women and recommend yearly ultrasound in combination with CA-125 blood test every 6 months.

► Prevention

Ovulation is considered a hostile event to the ovarian epithelium, making it more susceptible to damage and cancer. Interventions or conditions that limit the number of ovulations in a woman's reproductive history, including multiparity, have a protective effect.

Chemoprevention Investigational chemoprevention strategies used for ovarian cancer include oral contraceptives (OCs), aspirin and nonsteroidal anti-inflammatory agents, and retinoids, although none of these is currently accepted as standard treatment for the prevention of ovarian cancer. The theory that OCs reduce the number of ovulatory events is a basic explanation of its protective effect. Recent studies have suggested that progestin-induced apoptosis of the ovarian epithelium is responsible for the chemopreventive effect of OCs. The theory is that cells that have genetic damage but are not yet neoplastic have an increased chance of undergoing apoptosis.¹¹ OCs decrease the relative risk to less than 0.4% in women that use OCs for longer than 10 years.¹² However, the maximum protective effect of OC use in women with BRCA mutations has been reported to be between 3 and 5 years.¹² At the same time, OC use has been associated with an increased risk of breast cancer.^{11,13} Thus, women with a family history of breast cancer would not be ideal candidates for this preventive measure.

Nonsteroidal antiinflammatory agents, aspirin, and acetaminophen have been suggested for use in the prevention of different cancers, especially hereditary nonpolyposis

colon cancer.¹³ Although observational studies have linked these to a reduction of ovarian carcinoma risk, evidence is still lacking. Potential mechanisms include effects on normal ovulation shed and inhibition of ovulation.¹³ Other pharmacologic interventions that have been suggested but are still being evaluated include vitamin A, lutein, and other carotenoids.¹⁴⁻¹⁵ The protective effect of these agents is associated with inhibition of cell growth as well as promotion of cellular differentiation.¹⁴

Prophylactic Surgery Surgical strategies are also used in the prevention of ovarian cancer. The goal is to remove healthy, at-risk organs and ultimately reduce the risk of developing cancer. These surgeries include prophylactic **bilateral salpingo-oophorectomy** (BSO) or tubal ligation (see Fig. 94-1).

Prophylactic oophorectomy should be considered in any woman with a high risk of developing ovarian cancer.¹⁶ The criteria for defining high risk includes any woman with two or more first-degree relatives with epithelial ovarian carcinoma; a family history of multiple occurrences of **nonpolyposis** colon cancer, endometrial cancer, and ovarian cancer; and a family history of multiple cases of breast and ovarian cancer.¹⁷

- Patients undergoing prophylactic oophorectomy need to be made aware that complete protection is not guaranteed.¹⁷⁻¹⁹ Although a 67% reduction in risk has been shown, a potential 2% to 5% risk of peritoneal **carcinomatosis** remains.¹⁸⁻²⁰

Tubal ligation is another procedure that has shown potential for risk reduction. However, it is not recommended as a sole procedure in prophylaxis. Protective effect may be attributable to the limiting exposure of the ovary to environmental carcinogens. A case-control study conducted by Narod and colleagues¹⁹ found that a history of tubal ligation in BRCA-positive women was associated with a statistically significant 63% reduction in risk.

Genetic Screening Genetic screening is another option available for high-risk patients. Patients can be screened for genes such as BRCA1 and BRCA2 or other genes such as those associated with HNPCC or the HBOC syndrome.^{3,21} Patient

FIGURE 94-1. Diagram of female reproductive tract (uterus, fallopian tubes, ovaries, vagina). The *dashed line box* outlines what is removed during the total abdominal hysterectomy with bilateral salpingo-oophorectomy (TAH/BSO).

and family counseling and genetic counseling should be available for the patient and family to prepare and deal with the health and psychosocial implications of the genetic test results. Before this decision, the potential preventive options should be discussed, such as prophylactic BSO and/or total **hysterectomy**. Patients specifically positive for *BRCA1* or *BRCA2* may also consider a mastectomy to reduce the risk of breast cancer.¹⁸⁻²⁰ Cancer risk and patient's health need to be balanced, but typically surgery can be held off until after the childbearing years.^{20,21}

PATHOPHYSIOLOGY

The three current theories are the incessant ovulation hypothesis, the pituitary gonadotropin hypothesis, and the chronic inflammatory processes hypothesis.² The incessant ovulation hypothesis proposes that the pathogenesis of ovarian cancer is connected to continual ovulation. Ovulation is considered a “hostile” event to the ovaries, perhaps with not enough time for adequate repair. Each time ovulation occurs, the ovary epithelium is disrupted, and cell damage occurs. Thus, repeated ovulations may lead to a greater number of repairs of the ovarian epithelium and

increase the possibility of aberrant repairs, mutation, and **carcinogenesis**.²² The pituitary gonadotropin hypothesis associates the disease with elevations in gonadotropin and estrogen levels.² This leads to an increase in the number of follicles and therefore an increased risk of malignant changes. Finally, the chronic inflammatory processes may be involved with various environmental carcinogens to cause cancer.^{2,13}

The three major pathologic categories of ovarian tumors include sex-cord stromal, germ cell, and epithelial. About 85% to 90% of ovarian cancers are of epithelial origin. Epithelial ovarian tumors are composed of cells that cover the surface of the ovary such as serous, mucinous, endometrioid, clear cell, and poorly differentiated adenocarcinomas. Germ cell tumors involve the precursors of ova with the most common type being dysgerminoma, which are most commonly diagnosed in women younger than the age of 40 years and generally have a better prognosis.² Sex-cord stromal tumors are indolent tumors that produce excess estrogen and androgens but also have a better overall prognosis.² Although the histologic type of the tumor is not a significant prognostic factor, it is important to know the histopathologic grade. Undifferentiated tumors are associated

Clinical Presentation and Diagnosis of Ovarian Cancer

General

3 *Ovarian cancer has often been denoted the “silent killer” because of the nonspecific signs and symptoms.* By the time symptoms become unrelenting and bothersome, patients most likely have advanced stage disease.

Symptoms

Patients may experience episodes or persistent symptoms such as abdominal pain, constipation or diarrhea, flatulence, urinary frequency, or incontinence.

Signs

The degree of abdominal swelling secondary to fluid accumulation may present like “pregnant abdomen” and irregular vaginal bleeding.

Laboratory Test

- **CA-125.** The normal level is less than 35 U/mL (35 kU/L). Note: This test is associated with a lack of specificity. CA-125 can be elevated in a number of other states such as different phases of the menstrual cycle, endometriosis, and nongynecologic cancers.
- **NOTE:** It is important to rule out other cancers associated with the abdominal cavity.
- **Carcinoembryonic antigen (CEA).** CEA is marker for colon cancer. A normal value is less than 3 ng/mL (3 mcg/L).
- **CA-19-9** is a marker for many GI tumors such as cholangiocarcinomas.

Chemistries With Liver Function Tests (LFTs)

- LFTs and serum creatinine might be suggestive of extent of disease. The majority of this information is needed to determine if patient is a surgical candidate. Laboratory study results should be within normal limits.

Complete Blood Count (CBC)

- Abnormalities in CBC are not associated with ovarian cancer; however, this information is needed to determine if patient is a surgical candidate. Laboratories should be within normal limits.

Other Diagnostic Tests

To characterize local disease, one or both of the following are completed:

- TVUS
- Abdominal ultrasound

To evaluate the extent of disease, only one of the following is completed:

- CT scan
- MRI
- PET scan

Chest x-ray is also often done as part of clearance for surgery.

with a poorer prognosis than lesions that are considered to be well or moderately differentiated.

Ovarian cancer is usually confined to the abdominal cavity, but spread can occur to the lung and liver and less commonly to the bone or brain. Disease is spread by direct extension, peritoneal seeding, lymphatic dissemination, or bloodborne metastasis. Lymphatic seeding is the most common pathway and frequently causes ascites.

Mechanisms of Resistance

The common mechanisms of drug resistance in ovarian cancer include (a) alteration of drug inactivation by agents such as glutathione S-transferase (GST), (b) enhanced DNA repair, (c) dysregulation of apoptotic pathways through activation of oncogenes or the loss of tumor suppressor gene functions, (d) *p*-glycoprotein (Pgp) multidrug resistance that leads to decreased drug accumulation, and (e) steroid xenobiotic receptor (SXR) that leads to enhanced drug metabolism. At this time, our understanding about the mechanism of drug resistance in ovarian cancer is incomplete and limited mostly to in vitro studies. Ongoing improvements in current technology have allowed development of in vivo studies to evaluate mechanisms of drug resistance in ovarian cancer. MDR has been one of the major limitations and is one of the ongoing challenges for the successful therapeutic treatment on recurrent and persistent ovarian cancer.

TREATMENT

Desired Outcomes

- Health care providers use a multimodality approach, including surgery and chemotherapy, in initial treatment of patients with ovarian cancer with a curative intent, or restoring a normal life span. **7** *Although the majority of patients initially achieve a complete response, disease will recur within the first 2 years in more than 50% of patients.*^{2,23} CR to treatment is defined as no evidence of disease can be detected by physical examination or diagnostic tests and patient has a normalized CA-125.

The stage of disease at the time of diagnosis is the most important prognostic factor affecting overall survival in ovarian cancer patients.²⁴ The estimated 5-year survival rates of patients with localized, regional, distant, and unstaged ovarian cancer are 92.7%, 71.1%, 30.6%, and 26%, respectively.²⁴ The histology of the disease is another predominant prognostic factor influencing treatment outcomes. Clear cell and undifferentiated tumors do not respond as well to chemotherapy.² The extent of residual disease and tumor grade are also predictive of response to chemotherapy and overall survival.² There are other prognostic factors that may predict how well a patient will respond to adjuvant chemotherapy.

Generally, younger patients with a better performance status tolerate chemotherapy better than elderly patients. White women tend to have a worse prognosis and response to therapy compared to women of other ethnic backgrounds.^{2,4,5}

The treatment goals shift when a patient presents with recurrent ovarian cancer. The desired outcomes focus on relief of symptoms such as pain or discomfort from ascites, slowing disease progression, and prevention of serious complications such as SBO. When a patient relapses, the prognostic factors are similar as after initial surgery except that the amount of time that has lapsed since the completion of chemotherapy should be considered to determine if drug resistance is emerging in the tumor. Recurrent platinum-sensitive ovarian cancer patients generally have a better prognosis than platinum-resistant patients.

Nonpharmacologic Therapy

- 4** *Surgery is the primary treatment intervention for ovarian cancer.*²⁵⁻²⁷ A total abdominal hysterectomy with BSO (TAH-BSO) (Fig. 94-1), **omentectomy**, and lymphonectomy (or lymph node dissection) is the standard initial surgical treatment of ovarian cancer.²⁵ The objective of the surgery is to debulk the patient to less than 1 cm of residual disease remains. Residual disease less than 1 cm correlates with better CR rates to chemotherapy and better overall survival compared with patients with bulky residual disease (greater than 1 cm).^{26,27} Indeed, the size of residual tumor masses after primary surgery is found to be another important prognostic factor in patients with advanced ovarian cancer.²⁷

A thorough exploratory **laparotomy** is essential for the accurate staging of the patient.²⁵⁻²⁷ **5** *Ovarian cancer is staged surgically using the International Federation of Gynecology and Obstetrics (FIGO) staging algorithm (Fig. 94-2).* For certain patients with limited stage disease, surgery may be curative.

Other surgical procedures have been evaluated to improve overall survival. Debulking surgery is intended to relieve symptoms associated with complications such as SBO and help improve the patient's quality of life but does not have a curative intent. Interval debulking that is completed after two to three cycles of chemotherapy has not translated to an improved survival benefit. Often debated, the benefit of the "second-look laparotomy" to evaluate residual disease after the patient has completed chemotherapy remains controversial because it has been difficult to establish any impact on patients' overall survival. It has questionable benefit because although approximately 40% of patients with advanced disease have a negative second look, 50% still relapse.² The role of **laparoscopic** surgery is somewhat controversial for initial surgery but is more often considered in debulking of recurrent or advanced disease when the intent is palliative rather than curative.²⁵

Pharmacologic Therapy

► First-Line Chemotherapy

- 6** *After initial surgery, the gold standard of care is six cycles of taxane/platinum-containing regimen for patients with*

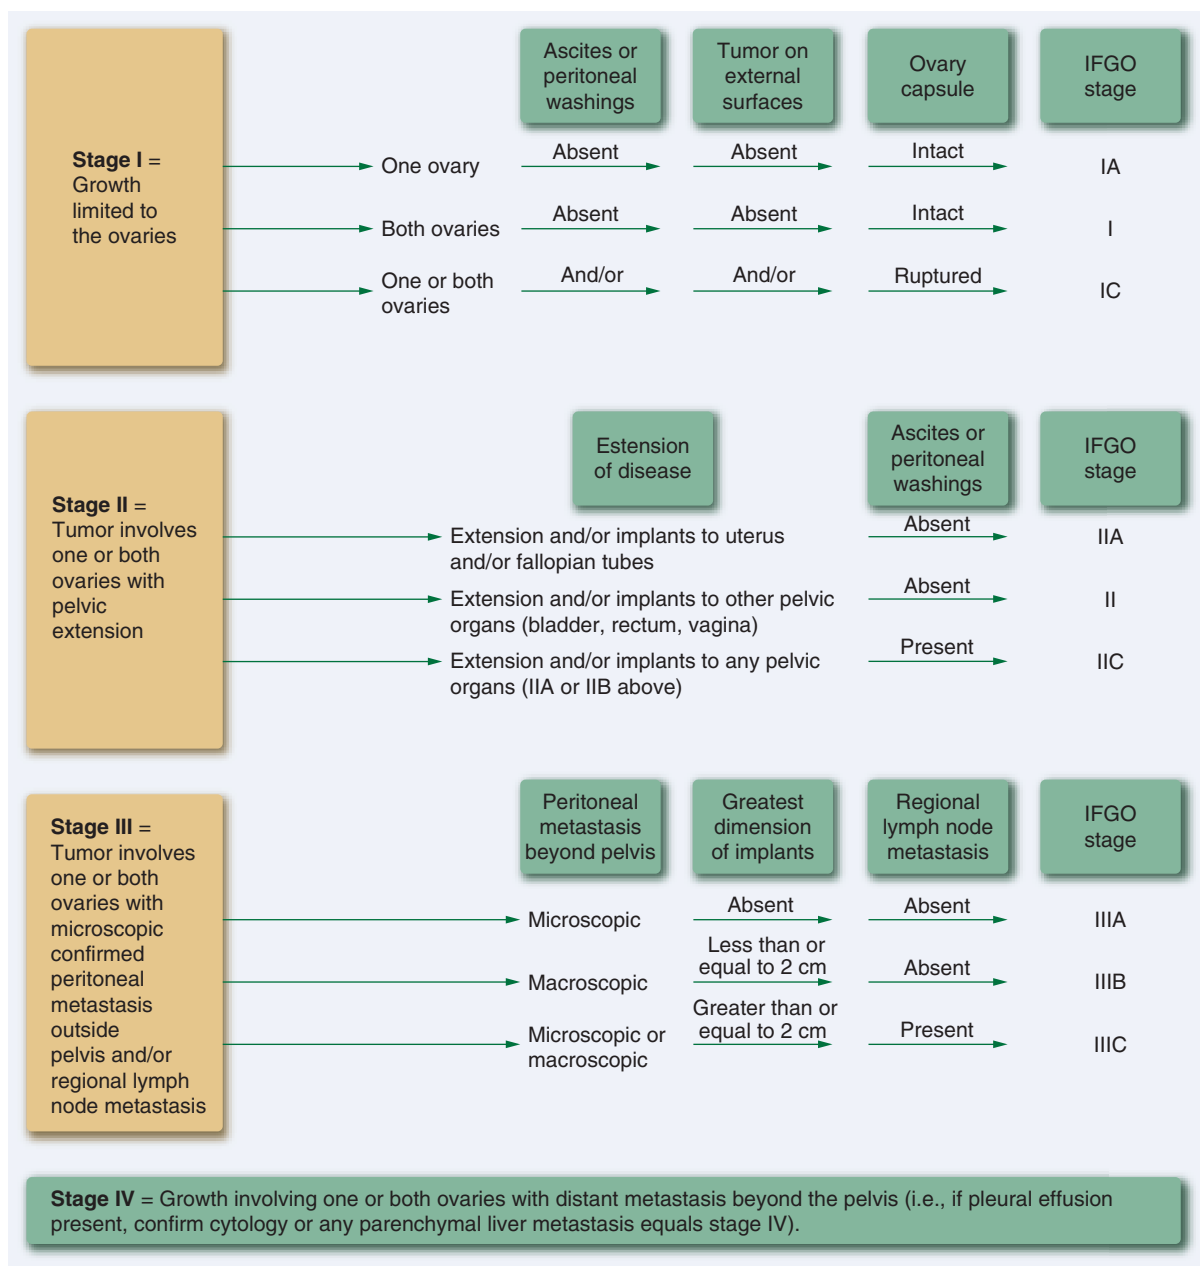

FIGURE 94-2. International Federation of Gynecology and Obstetrics (FIGO) staging algorithm for ovarian cancer.

advanced ovarian cancer.²⁸⁻³⁰ Patients with limited disease will have observation alone after surgery (Fig. 94-3). Most often, paclitaxel is the taxane agent used in combination with carboplatin as the preferred platinum agent.²⁸⁻³⁰ Depending on patients' preexisting comorbidities and how well they tolerate chemotherapy regimens, substitution with docetaxel or cisplatin might be considered. The route of administration should also be discussed. Although intravenous (IV) administration is often used, **intraoperative** (IP) administration has been shown to improve overall survival and should be considered for first-line treatment; however, patient selection for IP therapy is critical³¹ (Table 94-1). Close monitoring of organ function, nausea/vomiting, myelosuppression, and neuropathies is necessary for all taxane/platinum regimens (Table 94-2).

► Intraoperative Chemotherapy

For more than 3 decades, numerous investigators have evaluated the IP route for administration of chemotherapy; however, it was not until the third report of an improvement in overall survival that brought its use to the forefront in the first-line setting.³² The principal theory supporting IP administration is to increase drug concentration in the site of disease, specifically the abdominal cavity. Patient characteristics greatly influence response and tolerability of IP chemotherapy. To be selected to receive IP chemotherapy for first-line treatment of ovarian cancer, the patient should have tumor optimally debulked and no bowel resection with primary surgery, normal renal and liver function, younger age, and no significant comorbidities.

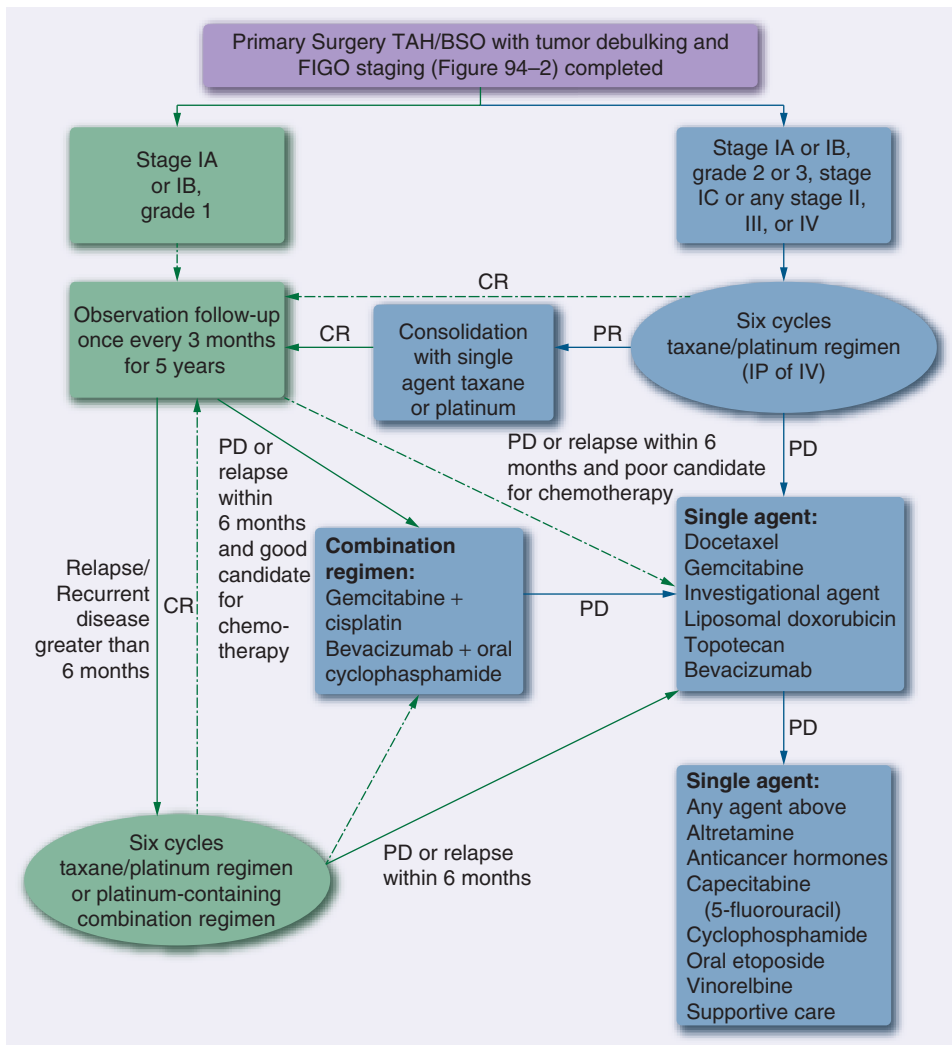

FIGURE 94–3. Summary of a chemotherapy treatment algorithm for epithelial ovarian cancer. (CR, complete response; FIGO, Federation of Gynecology and Obstetrics; PR, partial response; PD, progressive disease; TAH-BSO, total abdominal hysterectomy with bilateral salpingo-oophorectomy.)

Table 94–1

Summary of First-Line Chemotherapy Regimens for Advanced Ovarian Cancer

Gold standard first-line chemotherapy after initial surgery for treatment of ovarian cancer:

Paclitaxel 175 mg/m² IV infused over 3 hours + carboplatin AUC = 5 IV infused over 1 hour. Regimen is given once every 21 days × 6 cycles

Alternative first-line regimen: Paclitaxel IV with substitution of carboplatin IV with cisplatin IP and addition of paclitaxel IP therapy: Patient selection is critical: must have optimally debulked disease (less than 1 cm) and no significant comorbidities; younger patients tolerate better

Day 1: paclitaxel 135 mg/m² IV infused over 24 hours + day 2: cisplatin 100 mg/m² IP infused over 1 hour + day 8: paclitaxel 60 mg/m² IP infused over 1 hour. Regimen is given once every 21 days × 6 cycles

Alternative first-line regimen: Dose density. Consider for patients with optimal debulking, no comorbidities, good performance status: Paclitaxel 80 mg/m² IV infused over 1 to 3 hours once a week with carboplatin AUC = 6 IV infused over 1 hour on day 1 only of 21-day cycle.

Alternative first-line regimen: Substitution of cisplatin in place of carboplatin. Consider for patients experiencing difficulty with maintaining platelet counts:

Paclitaxel 135 mg/m² IV infused over 24 hours + day 2: cisplatin 75 mg/m² IV infused over 4 hours. Regimen is given once every 21 days × 6 cycles

Alternative first-line regimen: Substitution of docetaxel in place of paclitaxel. Consider for patients with preexisting or increased risk of neuropathies:

Docetaxel 75 mg/m² IV infused over 1 hour + carboplatin AUC = 5 IV infused over 1 hour. Regimen is given once every 21 days × 6 cycles

AUC, area under the curve; IV, intravenous.

Table 94-2

Summary of Chemotherapy Agents Used for First-Line Treatment of Advanced Ovarian Cancer

Mechanism of Action of First-Line Agents

Platinum analogues: Produce intra- and interstrand cross-links and DNA adducts to disrupt DNA replication

Taxanes agents: Stabilize microtubules and prevents depolymerization of tubulin

Agent	Common Adverse Effects	Monitoring/Comments
Paclitaxel	Peripheral neuropathy (DLT), nausea/vomiting, alopecia, hypersensitivity reactions	<ol style="list-style-type: none"> 1. Use caution with any elevation in AST (SGOT) 2. Give proper dosing for liver dysfunction. At least a 50% dose reduction generally recommended 3. Do not give if total bilirubin is greater than 5 mg/dL (85 μmol/L) 4. Premedicate for hypersensitivity reactions: dexamethasone, diphenhydramine, and cimetidine
Docetaxel	Neutropenia (DLT) hyperlacrimation, fluid retention, nail disorders, myelosuppression	<ol style="list-style-type: none"> 1. Use with caution in liver dysfunction. Patients with bilirubin greater than the ULN and/or liver transaminases greater than 1.5 times, the ULN should not receive docetaxel 2. Do not give if biliary tract is obstructed 3. Premedicate for hypersensitivity reactions: dexamethasone
Carboplatin	Myelosuppression (DLT), nephrotoxicity, nausea/vomiting, electrolyte wasting, diarrhea, stomatitis, hypersensitivity reactions	<ol style="list-style-type: none"> 1. Prehydration not required 2. If using BSA dosing, then give proper dosing for renal dysfunction CrCl greater than or equal to 60 mL/min (1.00 mL/s): no dosage adjustment needed. CrCl 41–59 mL/min (0.68–0.99 mL/s): give 250 mg/m² CrCl 16–40 mL/min (0.26–0.67 mL/s): give 200 mg/m² CrCl less than or equal to 15 mL/min (0.25 mL/s): do not give NOTE: Calvert formula (AUC dosing) is based on renal function, so no additional dose adjustment is needed 3. Premedicate for hypersensitivity reactions: dexamethasone, diphenhydramine, and cimetidine
Cisplatin	Neurotoxicity (DLT), nausea/vomiting, ototoxicity, nephrotoxicity, myelosuppression, electrolyte wasting, diarrhea	<ol style="list-style-type: none"> 4. Appropriate antiemetic regimen for prevention of acute and delayed nausea 1. Prehydration and posthydration with electrolyte replacement (i.e., potassium chloride 10 mEq [10 mmol] and magnesium sulfate 16 mEq [8 mmol]) required 2. Do not use if SrCr greater than 1.5 mg/dL (133 μmol/L) or BUN greater than 25 mg/dL (8.9 mmol/L) 3. Give proper dosing for renal dysfunction CrCl 46–60 mL/min (0.77–1.00 mL/s): decrease dose by 50%. CrCl 31–50 mL/min (0.51–0.83 mL/s): decrease dose by 75%. CrCl less than or equal to 30 mL/min (0.50 mL/s): do not use 4. Appropriate antiemetic regimen for prevention of acute and delayed nausea

AST, aspartate aminotransferase; AUC, area under the curve; BSA, body surface area; BUN, blood urea nitrogen; CrCl, creatinine clearance; DLT, dose-limiting toxicity; SrCr, serum creatinine; ULN, upper limit of normal.

If IP therapy is going to be considered, the placement of an IP catheter should occur at the time of surgery unless otherwise contraindicated. During IP administration, chemotherapy is delivered to the peritoneal space in 1 L of normal saline (NS) that has been warmed followed by another liter of NS to enhance drug distribution as tolerated.^{33,34} In addition, it is recommend to alternate the position of patient every 15 minutes for the first hour after drug IP administration to ensure proper distribution.^{33,34} The current standard IP regimen includes the administration of paclitaxel IV on day 1 followed by cisplatin IP on day 2 and then paclitaxel IP on day 8 given on a 21-day cycle for a total of six cycles (see Table 94-2). The most common toxicities associated with IP administration include abdominal pain, myelosuppression, neurotoxicity, and catheter-related infections. The substitution of carboplatin IP in place of cisplatin remains investigational and should not be recommended outside a clinical trial protocol.

► Neoadjuvant Chemotherapy

Neoadjuvant chemotherapy is first-line treatment for patients who are poor surgical candidates or patients with bulky or significant tumor burden.²³ For patients who are poor surgical candidates because of significant comorbidities, a combination of taxane with platinum agent is administered every 21 to 28 days as tolerated with the intent to relieve symptoms and slow progression of disease. In some cases, especially in elderly patients, single-agent carboplatin is used as palliative treatment instead. Chemotherapy alone has not been curative for patients with advanced ovarian cancer.²³

In patients with bulky disease or significant tumor burden, neoadjuvant chemotherapy can be used to decrease tumor burden to increase the likelihood of optimal tumor debulking during surgery.³¹ Typically, three cycles of the standard combination taxane/platinum regimen is administered once

every 21 days. After surgery, patient will receive another three to six cycles depending on their response to chemotherapy.

► Consolidation and Maintenance Chemotherapy

Consolidation chemotherapy is the addition of cycles of the taxane/platinum regimen or the addition of single-agent platinum or single taxane after completion of first-line chemotherapy.³⁶ If the tumor has a partial response (PR) to first-line chemotherapy evident by a significant decline in CA-125 by greater than 50% presurgery level and/or tumor regression or decrease in size, then cancer is still considered taxane/platinum sensitive. Additional cycles of chemotherapy are given until CR is achieved (see Fig. 94–3). Maintenance chemotherapy is similar to consolidation chemotherapy except maintenance chemotherapy is given to patients who have achieved a clinically CR.³⁷ Maintenance chemotherapy is used to hopefully extend progression-free and overall survival by eliminating any microscopic disease present after completion of primary chemotherapy.

► Agents Used in First-Line, Consolidation, and Maintenance Chemotherapy of Ovarian Cancer

Taxanes

Paclitaxel. Paclitaxel is a taxane that is naturally derived from the bark of the yew tree. Paclitaxel is cytotoxic to cells by stabilizing microtubules to prevent depolymerization of tubulin, causing cell cycle arrest in the M-phase. The two most common regimens used in ovarian cancer is a 3-hour infusion of 175 mg/m² or a 24-hour infusion of 135 mg/m². In addition, dose-dense paclitaxel 80 mg/m² once a week is also becoming more common in practice.³⁵

Paclitaxel is a water-insoluble drug, so an alcohol-based diluent, Cremophor, is used in the formulation and is associated with increase hypersensitivity reactions. Patients are pretreated with an H₂ blocker, diphenhydramine, and steroids. The dose-limiting toxicity (DLT) of paclitaxel is infusion dependent. For shorter infusion (e.g., 3 hours), the DLT is neuropathy, and for longer infusions, the DLT is myelosuppression. Additional common adverse effects can be found in Table 94–2.

Docetaxel. Docetaxel is another agent in the class of taxanes with a similar mechanism of action as paclitaxel but with differences in affinity for α -tubulin-binding sites and is hence more potent.

Because the experience with docetaxel in the treatment of ovarian cancer is limited, it is often considered a second-line option. However, ongoing clinical trials are comparing the efficacy and toxicity of docetaxel with paclitaxel in the combination with platinum agents for first-line treatment of ovarian cancer.³⁸ The dose of docetaxel typically used is 75 mg/m² given every 21 days and is reasonably well tolerated. To avoid severe fluid retention or hypersensitivity reactions, patients are premedicated with corticosteroids. The DLT associated with docetaxel primarily is neutropenia. Additional common adverse effects can be found in Table 94–2.

Platinum Analogues

Cisplatin. Cisplatin forms Platinum (Pt) DNA adducts that intercalate the DNA interrupting DNA synthesis.

The typical dose of cisplatin used for the treatment of ovarian cancer is 75 mg/m² when administered via the IV route or 100 mg/m² if administered via the IP route. Because cisplatin is nephrotoxic, regardless of route of administration, prehydration with 1 to 3 L of NS with replacement of electrolytes such as magnesium and potassium is required, which often requires an inpatient stay. The DLT of cisplatin is neurotoxicity that is nonreversible in many patients. Cisplatin is highly emetogenic but can be minimized with serotonin (5HT₃) antagonists and neurokinin 1 (NK1) receptor antagonist plus dexamethasone. Additional common adverse effects can be found in Table 94–2.

Carboplatin. Carboplatin has a similar mechanism of action as cisplatin, forming Pt-DNA adducts that intercalate the DNA interrupting DNA synthesis to ultimately cause cell death.

Carboplatin dose is determined using the Calvert formula: $\text{Carboplatin dose (mg)} = \text{Target AUC} * (\text{CrCl} + 25)$. The Calvert formula uses the calculated glomerular filtration rate (GFR) for the estimated creatinine clearance (CrCl) in this equation to individualize the dose and minimize dose-related toxicity. For the first-line treatment of ovarian cancer, the target area under the curve (AUC) is 5 to 7.5. Individualized dosing has decreased the incidence and degree of nephrotoxicity associated with carboplatin compared with cisplatin, eliminating the need for intensive prehydration, thus allowing for outpatient administration. Myelosuppression, primarily thrombocytopenia, is the DLT of carboplatin. Additional common adverse effects can be found in Table 94–2.

Recurrent Chemotherapy

In the recurrent setting, platinum sensitivity of the tumor is assessed first. If recurrence occurs in less than 6 months or disease progresses while the patient is receiving a platinum-based regimen, the cancer is considered platinum resistant (see Fig. 94–3). These parameters are also used to determine if tumors are taxane sensitive or resistant. However, patients resistant to paclitaxel may still respond to docetaxel.³⁹ If the treatment goal is palliative care, then often single therapy will be used, but curative care typically is an aggressive combination regimen (see Fig. 94–3 and Table 94–3). Sometimes an investigational agent may achieve responses equivalent or surpassing standard therapy, and should be considered for most patients.

► Platinum Sensitive

In patients who experienced a CR to first-line chemotherapy and have had greater than a 6-month platinum-free interval, retreatment with a platinum-containing regimen is appropriate. Current National Comprehensive Cancer Network (NCCN) guidelines recommend the combination of carboplatin with gemcitabine, liposomal doxorubicin, or

Table 94-3

Summary of Combination Chemotherapy Regimens Used for Treatment of Recurrent Ovarian Cancer

Drug(s)	Regimen Dosing	Drug Monitoring Comments ^b
Combination Regimens		
<i>Platinum Sensitive</i>		
Paclitaxel and carboplatin	175 mg/m ² IV (3-hr infusion) AUC 5–7.5 IV every 21 days	<ul style="list-style-type: none"> • Monitor closely for hypersensitivity reactions
Paclitaxel and cisplatin	135 mg/m ² IV (24-hr infusion) 75 mg/m ² IV	<ul style="list-style-type: none"> • Monitor closely for hypersensitivity reactions
Docetaxel and carboplatin	75 mg/m ² IV AUC 5 IV every 21 days	<ul style="list-style-type: none"> • Monitor closely for hypersensitivity reactions
Gemcitabine and carboplatin	800 mg/m ² IV days 1 and 8 AUC 5 IV day 1 every 21 days	<ul style="list-style-type: none"> • Monitor platelet counts closely • Monitor closely for hypersensitivity reactions
Liposomal doxorubicin and carboplatin	30 mg/m ² IV over 1–3 hr AUC 5 IV every 28 days	<ul style="list-style-type: none"> • Monitor closely for hypersensitivity reactions • Liposomal doxorubicin infusion start over 3 hr and decrease to 1 hr as tolerated • Counsel patient for PPE prevention
<i>Platinum-Resistant^a</i>		
Gemcitabine and cisplatin	1000 mg/m ² IV days 1 and 8 40 mg/m ² IV days 1 and 8 every 21 days	<ul style="list-style-type: none"> • Monitor renal function closely • Monitor ANC closely, consider primary use of growth factor • Monitor closely for hypersensitivity reactions
Cyclophosphamide and bevacizumab	50 mg PO once daily 10 mg/kg IV once every 2 weeks every 28 days (continuous)	<ul style="list-style-type: none"> • Monitor for hypertension; hold therapy blood pressure greater than 140/90 mm Hg • Monitor urine-to-creatinine baseline and every two cycles; hold therapy if the ratio is greater than 2 • Use caution in patients with history of thrombosis

^aPlatinum resistance = disease progression while on platinum agent or recurrence within 6 months of completion of platinum-based therapy.

^bSee Table 94-2 for specific monitoring parameters.

ANC, absolute neutrophil count; AUC, area under the curve; IV, intravenous; PO, oral; PPE, palmar-plantar erythrodysesthesia.

paclitaxel for the treatment of platinum-sensitive recurrent ovarian cancer with a curative intent^{31,40,41} (see Table 94-3). However, in patients who are unable to tolerate additional combination chemotherapy regimens, carboplatin alone or any one of the second-line agents would be appropriate⁴² (see Table 94-2).

► Platinum Resistant

Recurrent or persistent ovarian cancer after platinum-based regimens has a discouraging prognosis. Second-line agents have not been successful to date, but any active agent that has not been used during initial treatment is available to use. **8** *Single-agent chemotherapy is standard practice for recurrent platinum-resistant ovarian cancer.* However, two combination regimens have demonstrated promising activity in the recurrent setting: (a) gemcitabine plus cisplatin because gemcitabine modulates platinum resistance allowing it to regain its cytotoxic activity, and (b) bevacizumab with metronomic oral cyclophosphamide.^{43,44} Active agents include altretamine (formerly hexamethylmelamine), anastrozole, capecitabine (5-fluorouracil), cyclophosphamide, docetaxel, gemcitabine, liposomal doxorubicin, oral etoposide, vinorelbine, topotecan, bevacizumab, or investigational agents. Numerous ongoing

investigational studies are evaluating the benefit of addition of bevacizumab with other cytotoxic agent to improve outcomes in the recurrent ovarian cancer setting (see Fig. 94-3).

8 *Because the efficacy of the agents is similar, the selection of agent for treatment of recurrent platinum-resistant ovarian cancer is dependent upon residual toxicities, clinician preference, and patient convenience.* Table 94-4 gives a short summary of the adverse effects and monitoring parameters for chemotherapy agents commonly used for the treatment of recurrent ovarian cancer.

OUTCOME EVALUATION

Overall survival is impacted by success of initial surgery to debulk tumor to less than 1 cm of disease and response to first-line chemotherapy. The CA-125 level should be monitored with each cycle, and at least a 50% reduction in CA-125 after four cycles of taxane/platinum chemotherapy is related to an improved prognosis. Patients who achieve CR should have follow-up examinations once every 3 months, including CA-125, physical examination, and pelvic examination, and appropriate diagnostic scans (i.e., computed tomography [CT], magnetic resonance imaging

Table 94-4

Summary of Chemotherapy Single-Agent Regimens Used for Treatment of Progressive and Recurrent Platinum-Resistant Ovarian Cancer

Agent	Dose	Response Rate (%)	Common Adverse Effects	Monitoring/Comments
Docetaxel	75 mg/m ² IV over 1 hour repeat every 21–28 days vs. 30–40 mg/m ² IV over 1 hr once every week	22 NR	Neutropenia (DLT) hyperlacrimation, fluid retention, nail disorders, myelosuppression	<ol style="list-style-type: none"> 1. Premedicate for hypersensitivity reactions with dexamethasone 2. Use with caution in liver dysfunction. Patients with bilirubin greater than the ULN and/or liver transaminases greater than 1.5 times the ULN should not receive docetaxel 3. Do not give if the biliary tract is obstructed
Gemcitabine	800 mg/m ² IV infused over 30 minutes once a week on days 1, 8, and 15 followed by 1 week of rest	13.9–27	Myelosuppression (DLT), flulike symptoms, headache, somnolence, nausea/vomiting, stomatitis, diarrhea, constipation, rash	<ol style="list-style-type: none"> 1. Use with caution in renal or liver dysfunction. No specific guidelines available
Liposomal doxorubicin	40 mg/m ² IV infused over 3 hours cycle 1 and 2; then infused over 1 hr; thereafter repeat every 28 days	12.3–18	Myelosuppression, stomatitis, mucositis, alopecia, flushing, shortness of breath, hypotension, headaches, cardiotoxicity, hand–foot syndrome	<ol style="list-style-type: none"> 1. Give proper dosing for liver dysfunction; total bilirubin 1.2–3 mg/dL (21–51 μmol/L): reduce dose by 50%; total bilirubin greater than or equal to 3 mg/dL (51 μmol/L): reduce dose by 75% 2. Do not give if total bilirubin is greater than 5 mg/dL (86 μmol/L)
Topotecan	1.5 mg/m ² IV infused over 30 minutes on days 1, 2, 3, 4, and 5; repeat every 21 days OR 4 mg/m ² IV infused over 30 minutes once a week for 3 consecutive weeks followed by 1-week rest	6.5–17 31	Myelosuppression (DLT), nausea/vomiting, diarrhea, stomatitis, abdominal pain, alopecia, AST/ALT elevation	<ol style="list-style-type: none"> 1. Summary of Chemotherapy Single-Agent Regimens Used for Treatment of Progressive and Recurrent Platinum-Resistant Ovarian Cancer (Continued)

Agent	Dose	Response Rate (%)	Common Adverse Effects	Monitoring/Comments
Vinorelbine	30 mg/m ² IV infused over 15 minutes on days 1 and 8; repeat every 21 days	29	Constipation, neutropenia, anemia, thrombocytopenia, neurotoxicity	1. Consider bowel regimen to prevent constipation
Bevacizumab	15 mg/kg IV infused over 30–90 minutes every 21 days		Hypertension, proteinuria, infusion-related reactions, fluid retention, increase risk of thrombosis, myelosuppression	1. Monitor urine-to-creatinine baseline and every two cycles; hold therapy if ratio greater than 2 2. Use caution in patients with a history of thrombosis

CrCl, creatinine clearance; DLT, dose-limiting toxicity; IV, intravenous; NR, not reported; PD, progressive disease; PO, oral; PPE, palmar-plantar erythrodysesthesia; ULN, upper limit of normal.

Patient Encounter 1, Part 2: Completion of Primary Treatment

BN was optimally debulked. After surgery, she completed four cycles of paclitaxel IV plus cisplatin IP and IP paclitaxel on day 8 given every 21 days but then had to discontinue IP therapy because of catheter complications. To complete adjuvant chemotherapy she was given two cycles of paclitaxel IV plus carboplatin IV. Her CT scan findings were negative and CA-125 had decreased but was still above the normal range (48 U/mL [48 kU/L]) upon completion of her chemotherapy. She feels great and has no symptoms of ovarian cancer at this time.

Compare and contrast the possible advantages and disadvantages of consolidation chemotherapy versus “watchful waiting” for this patient.

Describe the role of second-look surgery for this patient.

Explain the challenges of using bevacizumab for consolidation treatment in this patient.

In the PD or recurrent setting, CA-125 levels should still be monitored with each cycle, but no change in therapy is recommended until after minimum of three cycles of chemotherapy. In addition, appropriate diagnostic scans (i.e., CT scan, MRI, or PET scan) should be evaluated once every three cycles. Patients should also have routine physical examinations with each cycle of chemotherapy to evaluate for any physical toxicity associated with chemotherapy such as neuropathies, fluid retention, palmar-plantar erythrodysesthesia, myelosuppression, or nausea/vomiting.

Unfortunately, most patients will eventually progress through all chemotherapy options, and supportive care measures should be provided to maintain patient comfort and quality of life. Common complications while developing a plan for treatment of advanced or progressive ovarian cancer include ascites, uncontrollable pain, and SBO. **9** *Precaution should be used in removal of ascites because of the potential complications associated with rapid fluid shifts.* Liberal use of opioids to control pain is appropriate as ovarian cancer patients cope with PD and approaching end of life. Appropriate bowel regimens with laxatives and stool softeners should be used to prevent constipation. However, when a patient with a well-controlled bowel regimen presents with new onset of constipation, additional workup is required before altering the bowel regimen. **10** *In ovarian cancer patients, SBO is a common complication of progressive disease. In general, laxatives should not be used in patients with SBOs.* Before treating constipation, patients should have a physical examination and abdominal x-ray to rule out SBO. Often, palliative surgery is required to correct SBO and alleviate patient pain. Patients should not eat any solid or liquids until resolution of SBO. If inoperable SBO exists, then parenteral nutrition can be considered but weighed against ultimate treatment objectives. Overall, providing any measures needed to maintain patient comfort is the priority for patients with progressive ovarian cancer.

[MRI], positron emission tomography [PET] scan) should be evaluated for the detection of disease. Side effects while evaluating patient for resolution of any residual chemotherapy include neuropathies, nephrotoxicity, ototoxicity, myelosuppression, or nausea/vomiting. Younger patients with an active menstrual cycle before surgery will encounter “surgical menopause” and often experience intense hot flashes. Because there are concerns about potential of hormones in the pathogenesis of ovarian cancer, the use of hormone replacement therapy is controversial.

The use of phytoestrogen supplements, such as black cohosh or soy, is also controversial. An effective alternative has been the use of the class of serotonin reuptake inhibitors such as venlafaxine controlled-released once daily.

Patient Care and Monitoring

1. Assess patient history of nonspecific symptoms to determine if the patient should be evaluated by a gynecologist.
2. Determine if patient is at high risk for development of ovarian cancer and make appropriate recommendations for screening and prevention.
3. Evaluate patient comorbidities and medications to determine if additional workup is necessary before tumor debulking surgery. Do any medications need to be stopped or changed before surgery (i.e., aspirin, warfarin, nonsteroidal antiinflammatory agents)?
4. Develop a plan for preventing and treatment of nausea and vomiting for patient receiving emetogenic chemotherapy.
5. Monitor patient for signs of hypersensitivity reactions to taxane or platinum chemotherapy regimens.
6. Monitor appropriate laboratories to determine
 - a. Changes in organ function: Adjust chemotherapy doses as indicated
 - b. Electrolyte wasting: Replace and supplement electrolytes IV or oral as indicated.
7. Provide appropriate patient education on respective chemotherapy agents that will be given for treatment of recurrent ovarian cancer.
 - a. What chemotherapy is and how it works
 - i. Explain the plan for monitoring response to treatment.
 - b. What side effects to expect during chemotherapy?
 - i. Precautions to take to prevent infection when neutropenic.
 - ii. Monitor for signs and symptoms of infection
 - c. When to contact physician or clinic between cycles of chemotherapy
 - d. Drug or food interactions with chemotherapy to avoid

CA-125	Cancer antigen 125
CA-19	Cancer antigen 19
CEA	Carcinoembryonic antigen
CR	Complete response
CrCl	Creatinine clearance
DLT	Dose-limiting toxicity
FIGO	International Federation of Gynecology and Obstetrics
GFR	Glomerular filtration rate
GST	Glutathione S-transferase
HBOC	Hereditary breast and ovarian cancer
HNPCC	Hereditary nonpolyposis colorectal cancer
IP	Intraperitoneal
LFT	Liver function test
NCCN	National Comprehensive Cancer Network
NS	Normal saline
OC	Oral contraceptive

Acute Leukemia

Nancy Heideman and Richard Heideman

LEARNING OBJECTIVES

● Upon completion of the chapter, the reader will be able to:

1. Describe the pathogenesis of acute leukemia.
2. Compare the classification systems for acute lymphocytic leukemia (ALL) and acute myelogenous leukemia (AML).
3. Identify the risk factors associated with a poor outcome for the acute leukemias.
4. Explain the importance of minimal residual disease (MRD) and its implication on early bone marrow relapse.
5. Explain the role of induction, consolidation, and maintenance phases for acute leukemia.
6. Define the role of CNS preventive therapy for acute leukemia.
7. Recognize the treatment complications associated with therapy for acute leukemias.
8. Describe the late effects associated with the treatment of long-term survivors of acute leukemias.

KEY CONCEPTS

- 1 The acute leukemias are hematologic malignancies of bone marrow precursors characterized by excessive production of immature hematopoietic cells. This proliferation of “blast” cells eventually replaces normal bone marrow and leads to the failure of normal hematopoiesis and the appearance of leukemia cells in peripheral blood as well as infiltration of other organs.
- 2 Acute leukemias are classified according to their cell of origin. Acute lymphocytic leukemia (ALL) arises from the lymphoid precursors. Acute nonlymphocytic leukemia (ANLL) or acute myelogenous leukemia (AML) arises from the myeloid or megakaryocytic precursors.
- 3 The goal is to match treatment to risk and minimize over- or undertreatment. Children and adults with leukemia are sorted into prognostic categories based on clinical and biological features that mirror their risk of relapse. Risk assessment is an important factor in the selection of treatment.
- 4 Minimal residual disease (MRD) is a quantitative assessment of subclinical remnant of leukemic burden remaining at the end of the initial phase of treatment (induction) when a patient may appear to be in a complete morphologic remission. This measure has become one of the strongest predictors of outcome for patients with acute leukemia. The elimination of MRD is a principal objective of postinduction leukemia therapy.
- 5 The initial treatment for acute leukemias is called **induction**. The purpose of induction is to induce a **remission**, a state in which there is no identifiable leukemic cells in the bone marrow or peripheral blood with light microscopy.
- 6 The current induction therapy for ALL typically consists of vincristine, L-asparaginase, and a steroid (prednisone or dexamethasone). An anthracycline is added for higher risk patients.
- 7 Leukemic invasion of the CNS is considered to be an almost universal event in patients, even in those whose cerebrospinal fluid (CSF) cytology shows no apparent disease. Thus, all patients with ALL and AML receive intrathecal chemotherapy. Although this is often referred to as “prophylaxis,” it more realistically represents treatment.
- 8 Bone marrow relapse is the major form of treatment failure in 15% to 20% of patients with ALL. Most relapses have the same immunophenotype and cytogenetic changes seen in the original disease.
- 9 The current induction therapy for AML usually consists of a combination of cytarabine and an anthracycline daunorubicin or idarubicin, with the frequent addition of a steroid and/or an antimetabolite such as 6-thioguanine. The second phase of treatment for AML

is called **consolidation**. The purpose of this phase is to further enhance remission with more cytoreduction. This period is also a time to consider hematopoietic stem cell transplantation for patients in first remission.

- 10 Despite this significant increase in survival, many patients, particularly pediatric cancer survivors, have disease- or treatment-related disabilities. As many as 50% to 60% of these survivors are estimated to have at least one chronic or late-occurring complication of treatment.

INTRODUCTION

1 *The acute leukemias are hematologic malignancies of bone marrow precursors characterized by excessive production of immature hematopoietic cells. This proliferation of “blast” cells eventually replaces normal bone marrow and leads to the failure of normal hematopoiesis and the appearance in peripheral blood as well as infiltration of other organs. These blast cells proliferate in the marrow and inhibit normal cellular elements, resulting in anemia, neutropenia, and thrombocytopenia. Leukemia also may infiltrate other organs, including the liver, spleen, bone, skin, lymph nodes, testis and central nervous system (CNS). Virtually anywhere there is blood flow, the potential for extramedullary (outside the bone marrow) leukemia exists.*

2 *Acute leukemias are classified according to their cell of origin. Acute lymphocytic leukemia (ALL) arises from the lymphoid precursors. Acute nonlymphocytic leukemia (ANLL) or acute myelogenous leukemia (AML) arises from the myeloid or megakaryocytic precursors. As a result of clinical trials defining various prognostic (risk) factors that helped guide treatment modifications, the outcomes of acute leukemias, especially ALL, has improved dramatically over the past 30 years.¹ Risk-based treatment strategies that consider multiple **phenotypic** and biological risk factors and attempt to match the aggressiveness of therapy with the presumed risk of relapse and death are now the standard of care.*

EPIDEMIOLOGY AND ETIOLOGY

Epidemiology

Leukemia is a relatively uncommon disease overall. The current overall age-adjusted annual incidence of acute leukemia in the United States has remained relatively stable at 10 per 100,000 in children and 1 to 2 per 100,000 in adults.² It was projected that of the estimated 1.5 million new cancers diagnosed in 2010, only 1.2% would be acute leukemia, with 5,330 cases of ALL and about 12,330 cases of AML.^{3,4}

In the pediatric population, leukemia is a common disease, accounting for almost one-third of all childhood malignancies. ALL accounts for 75% to 80% of all cases of childhood leukemia, whereas AML accounts for no more than 20%. Males generally are affected more often than females in all but the infant age group, and its incidence is higher in whites than among other racial groups.

The incidence of AML in children is bimodal: It peaks at 2 years of age, decreases steadily thereafter to age 9 years, and then increases again at around age 16.⁴ The average age of diagnosis for AML is about 65 years and is a result of an increasing incidence of AML with age.

Etiology

The causes of the acute leukemias is unknown; multiple influences related to genetics, socioeconomic, infection, environment, hematopoietic development, and chance all may play a role.⁴ **Table 95–1** lists the major conditions that have been associated with the acute leukemias. In most cases, however, there is no identifiable cause of the leukemia.

Although leukemia is rarely a hereditary disease, some genetic associations are evident. For example, among identical twins, the concordance for ALL in the initially unaffected twin is 20% to 25% within 1 year. Although the incidence in fraternal twins is much less, there is still a fourfold increase in the risk of leukemia in the initially unaffected twin compared with the normal population. One explanation for this association may be a shared placental circulation, which allows for transmission of disease from one twin to the other. Additionally, leukemia is known to have an increased incidence in several chromosomally abnormal populations. Patients with Down’s syndrome have a 20 times increased risk of developing leukemia compared with the rest of the population. Patients with Klinefelter’s syndrome and Bloom’s syndrome also have an increased incidence of leukemias.⁴

Exposure to environmental agents such as agricultural chemicals, pesticides, and radiation have also been periodically associated with leukemia, but none is conclusively related to the development of leukemia. An increased frequency of ALL is associated with higher socioeconomic status. It is

Clinical Conditions Associated With an Increased Frequency of Acute Leukemias

Drugs

Alkylating agents
Epipodophyllotoxins

Genetic Conditions

Down’s syndrome
Bloom’s syndrome
Fanconi’s anemia
Klinefelter’s syndrome
Ataxia telangiectasia
Langerhans’ cell histiocytosis
Shwachman’s syndrome
Severe combined immunodeficiency syndrome
Kostmann’s syndrome
Neurofibromatosis type 1
Familial monosomy 7
Diamond-Blackfan anemia

Chemicals

Benzene

Radiation

Ionizing radiation

Viruses

Epstein-Barr virus
Human T-lymphocyte virus (HTLV-1 and HTLV-2)

Social Habits

Cigarette smoking
Maternal marijuana use
Maternal ethanol use

Adapted from Pieters R, Carroll WL. Biology and treatment of acute lymphoblastic leukemia. *Pediatr Clin North Am* 2008;55(1):1–20

postulated that less social contact in early infancy and thus a late exposure to some common infectious agents may have some impact.⁴

Risk factors for the development of AML include exposure to environmental toxins, Hispanic ethnicity, and genetics.⁵ Of greater concern is the increased prevalence of AML as a secondary malignancy, resulting from chemotherapy and radiation treatment for other cancers. Alkylating agents, such as ifosfamide and cyclophosphamide, and topoisomerase inhibitors, such as etoposide, are linked to an increased risk of AML and **myelodysplastic syndrome** (MDS).⁵

PATHOPHYSIOLOGY

Hematopoiesis is defined as the development and maturation of blood cells and their precursors. In utero, hematopoiesis may occur in the liver, spleen, and bone marrow; after birth, this process occurs exclusively in the bone marrow. All blood cells are generated from a common hematopoietic precursor, or *stem cell*. These stem cells are self-renewing and pluripotent and thus are able to commit to any one of the different lines of maturation that give rise to platelet-producing megakaryocytes, lymphoid, erythroid, and myeloid cells. The myeloid cell line produces monocytes, basophils, neutrophils, and eosinophils, whereas the lymphoid stem cell differentiates to form circulating B and T lymphocytes, natural killer (NK) cells, and dendritic cells. In contrast to the ordered development of normal cells, the development of leukemia seems to represent an arrest in differentiation at an early phase in the continuum of stem cell to mature cell.¹

Both AML and ALL are presumed to arise from clonal expansion of these “arrested” cells. As these cells expand, they acquire one and often more chromosomal aberrations, including translocations, inversions, deletions, point mutations, and amplifications.⁴ The translocation t(12;21) or *TEL-AML1* is found in approximately 25% of cases of pediatric ALL and is associated with a favorable prognosis.⁶ This translocation is uncommon in adults. Another example is the t(9;22) translocation (Philadelphia

chromosome, Ph⁺), which results in the *BCR-ABL* fusion protein. This translocation produces a novel kinase that leads to uncontrolled proliferation, survival, and self-renewal of cells. It is uncommon in childhood ALL and commonly found in adult ALL, especially in older patients.

Patients with MDS or AML as a secondary neoplasm are often characterized by having had prior alkylator-based or etoposide-based chemotherapy. Patients who have received treatment for Hodgkins disease or solid tumors are most at risk for this problem because they often treated with these agents. Patients with MDS have an abnormal bone marrow and a variety of cytopenias involving one or more of their marrow cell lines. They are at high risk of converting to overt leukemia over time. A variety of complex cytogenetic findings and monosomies of chromosome 5 or 7, and 11q26 translocations are often present in this population.⁵

Leukemia Classification

Classification methods for leukemia have evolved from simple schemes that were largely phenotypic and considered only age, gender, white blood cell (WBC) count, and blast morphology to now-complex methods that include biological features such as cell-surface receptors, DNA content (ploidy; more or less than normal chromosomal DNA content), and a variety of cytogenetic abnormalities.

For all newly diagnosed patients with leukemia, an aspirate of the liquid marrow and a bone marrow core biopsy are obtained. Analysis of the leukemic cell surface markers (immunophenotyping) establish three types of ALL, pre-B, mature B, and T-cell precursor ALL. There are eight subtypes of AML (M0 to M7) as classified by the French-American-British (FAB) scheme (Tables 95-2 and 95-3).

Immunophenotyping by **flow cytometry** has taken on an increasingly important role in the diagnosis of leukemia. Owing to the ease of application, sensitivity, and quantifiable results, flow cytometry is the preferred method for leukemic lineage as well as prognostic assignment.⁷ This approach takes advantage of the development of diagnostic

Table 95-2

Morphologic (FAB) Classification of AML

Subtype		Frequency of FAB Subtype		
		Adults (%)	Children Older Than 2 Years (%)	Children Younger Than 2 Years (%)
M0	Acute myeloblastic leukemia without maturation	5	Low	Low
M1	Acute myeloblastic leukemia with minimal maturation	15	17	25
M2	Acute myeloblastic leukemia with maturation	25		27
M3	Acute promyelocytic leukemia	10		5
M4	Acute myelomonocytic leukemia	25	30	26
M5a	Acute monoblastic leukemia, poorly differentiated	5	52	16
M5b	Acute monoblastic leukemia, well differentiated	5		
M6	Acute erythroleukemia	5		2
M7	Acute megakaryoblastic leukemia	10		5-7

FAB, French-American-British.

Table 95-3

WHO Classification of AML

AML with recurrent genetic abnormalities:
 AML with t(8;21)(q22;q22), (*AML1/ETO*)
 AML with abnormal bone marrow eosinophils and inv(16) (p13q22) or t(16;16)(p13;q22), (*CBFB/MYH11*)
 Acute promyelocytic leukemia with t(15;17)(q22;q12), (*PML/RARα*) and variants
 AML with 11q23 (*MLL*) abnormalities
 AML with multilineage dysplasia
 After MDS or MDS/MPD
 Without antecedent MDS or MDS/MPD but with dysplasia in at least 50% of cells in two or more myeloid lineages
 AML and MDSs, therapy related
 Alkylating agent- or radiation-related type
 Topoisomerase II inhibitor-related type (some may be lymphoid)

Others:
 AML not otherwise categorized

Classify as:
 AML, minimally differentiated
 AML without maturation
 AML with maturation
 Acute myelomonocytic leukemia
 Acute monoblastic/acute monocytic leukemia
 Acute erythroid leukemia (erythroid/myeloid and pure erythroleukemia)
 Acute megakaryoblastic leukemia
 Acute basophilic leukemia
 Acute panmyelosis with myelofibrosis
 Myeloid sarcoma

AML, acute myeloid leukemia; MDS, myelodysplastic syndrome; MPD, myeloproliferative disorders.

Adapted from Pieters R, Carroll WL. Biology and treatment of acute lymphoblastic leukemia. *Pediatr Clin North Am* 2008;55(1):1-20.

monoclonal antibodies (MABs) to many cell-surface antigens that are differentially expressed during hematopoietic differentiation. The antigens are referred to as antibody *cluster determinants* (CDs) that define cells at various stages of development and can easily separate ALL from AML and T-cell from pre-B-cell ALL.^{4,7} The combined approach of flow cytometric identification and cytogenetic DNA content, much of which is also revealed by flow cytometry and fluorescent in situ hybridization (**FISH**; microscopic, fluorescence identification of chromosomal features) has facilitated diagnosis and delineation of specific subtypes of the acute leukemias. Common immunophenotypic markers seen in AML and ALL are provided in **Table 95-4**.

Prognostic Factors

3 *The goal of treatment is to match treatment to risk and minimize over- or undertreatment. Patients with leukemia are sorted into prognostic categories based on clinical and biological features that mirror their risk of relapse. Risk assessment is an important factor in the selection of treatment. Age, WBC, leukemic cell-surface markers, DNA content, and specific cytogenetic abnormalities predict response to therapy and are used to assign risk and associated treatment.*⁴

Patient Encounter, Part 1

MV is a 8-year-old boy who presents to the pediatric emergency department with his father with a history of aches, chills, and fevers for the past 4 to 5 days. He has had several colds over the past few weeks that do not seem to be improving. He has also had diffuse body and bone pain in his legs over the past couple of weeks. Physical examination reveals pallor, cervical lymphadenopathy, and hepatosplenomegaly. Electrolytes and uric acid are within normal limits. A CBC shows a normochromic, normocytic anemia with a hemoglobin of 7.0 g/dL (70 g/L, 4.34 mmol/L; reference range, 11.7 to 15.7 g/dL, 7.26 to 9.74 mmol/L), hematocrit of 21% (0.21; reference range, 35% to 47% or 0.35 to 0.47), and WBC count of 4.1 $10^3/\text{mm}^3$ ($4.1 \times 10^9/\text{L}$). The differential on the WBC count reveals 65% (0.65) lymphocytes (reference range, 20% to 40% or 0.2 to 0.4), 13% (0.13) neutrophils (reference range, 55% to 62% or 0.55 to 0.62), and 22% (0.22) lymphoblasts (normal amount, 0%). Flow cytometry from the peripheral blood is consistent with pre-B-cell ALL.

What information is consistent with the diagnosis of ALL?

What are the prognostic factors for MV?

What is the role of flow cytometry in identifying ALL?

On the basis of these prognostic variables, patients are assigned to standard-, high-, or very-high-risk groups that determine the aggressiveness of treatment.

► Prognostic Factors in ALL

- In both children and adults with ALL, clinical trials have identified several risk factors that correlate with outcome (**Table 95-5**). Prognostic features include age, WBC count, cytogenetic abnormalities, ploidy (DNA content), leukemic cell immunophenotype, and degree of initial response to therapy, and minimal residual disease (MRD; the degree of subclinical disease remaining at various times after starting treatment)^{4,7,8} When these factors are combined, they predict groups of patients with varying degrees of risk for treatment failure.

Table 95-4

Common Immunophenotypes in Acute Leukemia

Leukemia	Common Immunophenotypes
AML	CD13, CD15, CD33, CD14, CD64, and C-KIT
B-cell ALL	CD19, CD20, CD10, and CD22
T-cell ALL	CD2, CD3, CD4, CD5, and CD7

ALL, acute lymphoblastic leukemia; AML, acute myeloid leukemia; CD, cluster determinants.

Adapted from Pieters R, Carroll WL. Biology and treatment of acute lymphoblastic leukemia. *Pediatr Clin North Am* 2008;55(1):1-20.

Table 95-5

Prognostic Factors in ALL

Factor	Risk for Leukemic Relapse	
	Low	High
Immunologic phenotype	Early pre-B cell	Null cell, T cell, pre-B cell, B cell
WBC count at diagnosis	Less than $10 \times 10^3/\text{mm}^3$ ($10 \times 10^9/\text{L}$)	Greater than $50 \times 10^3/\text{mm}^3$ ($50 \times 10^9/\text{L}$)
Platelets	Greater than $100 \times 10^3/\text{mm}^3$ ($100 \times 10^9/\text{L}$)	Less than $30 \times 10^3/\text{mm}^3$ ($30 \times 10^9/\text{L}$)
Patient age	3–7 years	Less than 1 year or greater than 10 years
Cytogenetics	Normal karyotype	t(9;22); t(4;11); -7; +8
Myeloid markers	Absent	Present
CNS leukemia	Absent	Present
Node/liver/spleen enlargement	Absent	Massive
Mediastinal mass	Absent	Present
Time to remission	Less than 4 weeks	Greater than 4 weeks

WBC, white blood cell.

Adapted from Pieters R, Carroll WL. Biology and treatment of acute lymphoblastic leukemia. *Pediatr Clin North Am* 2008;55(1):1–20.

The importance of age is seen is evident in both children and adults. Children younger than 1 year or older than 10 years of age have a poorer outcome than others. Likewise, in adults, there is a steady decline in the rate survival with increasing age.

Similar to age, the WBC count at presentation is a reliable indicator of complete response (CR) rate and outcome. The WBC count is indicative of tumor burden, although the underlying biological mechanisms that account for the unfavorable outcomes associated with an elevated WBC count are unclear. Patients with WBC counts of less than $50 \times 10^3/\text{mm}^3$ ($50 \times 10^9/\text{L}$) are considered being at standard risk and have a better outcome than those with a higher WBC counts at presentation, which is associated with higher risk of treatment failure (Table 95–5).

Specific chromosomal abnormalities in leukemic cells also possess prognostic significance. Blast cells with a translocation of parts of chromosome 12 and 21 (the *TEL-AML1* fusion) or trisomies of 4, 10, and 17 are considered to have favorable genetic features.⁴ The presence of the Philadelphia chromosome (Ph⁺), the result of a specific translocation between chromosome 9 and 22, **t(9;22)(q34;q11.2)**, is a high-risk feature, which is present in about 5% of children but is much more common in adults with ALL. This translocation results in a novel tyrosine kinase that drives cell proliferation.^{7,8}

Among children younger than 1 year of age, as many as 80% possess a poor prognostic genotype represented by the presence of the *MLL* (11q22) gene rearrangement. This finding is rare among older patients. Leukemias with the *MLL* gene rearrangement are highly resistant to the key antileukemic drugs such as glucocorticoids and L-asparaginase.⁹

The DNA content of blast cells, hyper-, hypo-, or diploid, corresponding to increased, decreased, or normal chromosome numbers, has been considered prognostic. Lower risk patients with hyperdiploidy (greater than 50 chromosomes per leukemic cell) generally include approximately 25% of children who have B-cell lineage ALL.⁶ These children are between the ages of 1 and 9 years, but the higher risk patients with normal diploidy (50 chromosomes) generally are older.

Patients with cell-surface markers indicating that the blasts are early in the B-cell lineage (CD markers) are considered favorable and standard risk, whereas those with mature B-cell and T-cell blasts are considered high risk. T-cell ALL is found in approximately 15% of childhood ALL. Compared with B-lineage ALL, T-cell ALL is relatively resistant to different classes of drugs, including methotrexate and cytarabine.

Patients completing induction treatment and in apparent remission still harbor malignant cells in their bone marrow even though they appear disease free by peripheral blood and bone marrow morphology. Assuming that most patients present with about a 10^{11} leukemic cell burden at diagnosis, at least 10^9 cells remain after initial treatment. These residual leukemic cells are below the limits of detection using standard morphologic examination. Measurement of this population of cells has become an increasingly significant prognostic factor and a determinant of the aggressiveness of postinduction therapy. Through flow cytometric analysis and **polymerase chain reaction**, it is possible to detect one leukemic cell among 10^6 normal cells, representing 1,000-fold greater sensitivity than morphologic examination.^{10,11}

4 Minimal residual disease (MRD) is a quantitative assessment of subclinical remnant of leukemic burden remaining at the end of the initial phase of treatment (induction) when a patient may appear to be in a complete morphologic remission. This measure has become one of the strongest predictors of outcome for patients with acute leukemia. The elimination of MRD is a principal objective of postinduction leukemia therapy. Several studies in children, in whom ALL is common, have evaluated disease levels at the end of induction and correlated these values with event-free survival (EFS). For a patient with detectable MRD less than 0.1% at the end of induction, EFS is 88% at 3 years. Conversely, a patient with high MRD (more than 1%) has a 3-year EFS of only 30%.¹² Assessment of MRD is also emerging as an important indicator of disease recurrence in the adult population and in patients with AML.

► Prognostic Factors in AML

The major prognostic factors in newly diagnosed AML are age, subtype, chromosome status, ethnicity, and body mass index.

Older adults with AML (older than 60 years), compared with younger patients with the same disease, have a dismal prognosis and represent a distinct population in terms of disease biology, treatment-related complications, and overall survival (OS). These older patients have a higher incidence of unfavorable chromosomal abnormalities, such as aberrations

Patient Encounter, Part 2

MV is admitted to the pediatric oncology service. A bone marrow biopsy and aspirate is done, which shows 85% replacement with precursor B-cell blasts. FISH analysis performed on the peripheral blood is positive for the BCR/ABL translocation (Ph⁺) in 5.5% of the cells examined. He is started on intravenous hydration with sodium bicarbonate and allopurinol. A diagnostic lumbar puncture (LP) is performed, which is negative for CNS leukemia. During the LP, MV receives IT cytarabine.

What is the role of CNS prophylaxis for MV?

What is the BCR/ABL translocation?

How does the presence of this chromosomal abnormality change MV's risk status?

of chromosomes 5, 7, or 8, and fewer abnormalities that are associated with a more favorable outcome, such as t(8;21) or inv(16) (see [Table 95-6](#)).^{5,12}

Recent studies suggest that ethnicity may be an important predictor of outcome in children with AML. Investigators

found that African Americans treated with chemotherapy had a significantly worse outcome than whites, perhaps suggesting race-related pharmacogenetic differences. Body mass index may also affect the prognosis of children with AML. Underweight patients and overweight patients were less likely to survive than normal weight patients because of a greater risk of treatment-related deaths.¹³

TREATMENT

Desired Outcome

The primary objective in treating patients with acute leukemia is to achieve a continuous complete remission (CCR). **Remission** is defined as the absence of all clinical evidence of leukemia with the restoration of normal hematopoiesis. For both ALL and AML, remission induction is achieved with the use of myelosuppressive chemotherapy that initially induces a state of bone marrow aplasia as the leukemic cells die followed by a slow return and proliferation of normal cells. After this period, hematopoiesis is restored. Failure to achieve remission in the first 7 to 14 days of therapy is highly predictive of later disease recurrence. This again represents the growing importance of MRD in prognosis and treatment.

Clinical Presentation and Diagnosis of ALL^{3,6,11}

General

Typically, patients have symptoms for 1 to 3 months before presentation. These include fatigue, fever, and pallor, but patients generally are in no obvious distress.

Symptoms

- The patient may present with weakness, malaise, bleeding, and weight loss.
- Neutropenic patients are often febrile and highly susceptible to infection.
- Anemia usually presents as pallor, tiredness, and general fatigue.
- Patients with thrombocytopenia usually present with bruising, petechiae, and ecchymosis.
- Patients often present with bone pain secondary to expansion of the marrow cavity from leukemic infiltration.
- CNS involvement is common at diagnosis.

Signs

- Temperature may be elevated secondary to an infection associated with a low WBC count.
- Petechiae and bleeding are indicative of thrombocytopenia.
- Patients may present with organ involvement, such as peripheral adenopathy, hepatomegaly, and splenomegaly.
- T-lineage ALL may present with a mediastinal mass.

Laboratory Tests

- CBC with differential is performed.
- The anemia is usually normochromic and normocytic. Approximately 50% of children present with platelet counts of less than $50 \times 10^3/\text{mm}^3$ ($50 \times 10^9/\text{L}$). The WBC count may be normal, decreased, or high. About 20% of patients have WBC counts over $100 \times 10^3/\text{mm}^3$ ($100 \times 10^9/\text{L}$), which places them at risk for leukostasis.
- Uric acid is increased in approximately 50% of patients secondary to rapid cellular turnover.
- *Electrolytes*: Potassium and phosphorus often are elevated. Calcium usually is low.
- *Coagulation disorders*: Elevated prothrombin time, partial thromboplastin time, D-dimers; hypofibrinogenemia

Other Laboratory Tests

Flow cytometric evaluation of bone marrow and peripheral blood is performed to characterize the type of leukemia as well as to detect specific chromosomal rearrangements. The bone marrow at diagnosis usually is hypercellular, with normal hematopoiesis being replaced by leukemic blasts. At diagnosis, a lumbar puncture is performed to determine if CNS leukemia is present.

Table 95-6

Risk Category According to Cytogenetic Abnormalities Present

Disease	Risk Category		
	Good Risk	Intermediate Risk	High Risk
AML	t(8;21)(q22;q22); inv(16); t(15;17); t(9;11) trisomy 21	Normal karyotype; trisomy 8; 11q23; del(7q); del(9q); trisomy 22	Complex karyotype; -5; -7; del(5q); inv(3P)
Probability of relapse	Less than or equal to 25%	50%	Greater than 70%
4-Year survival	Greater than or equal to 70%	40%–50%	Less than or equal to 20%
ALL	Hyperdiploidy; t(10;14); or 6q		t(9;22); t(8;14); t(4;11); t(1;9)

ALL, acute lymphocytic leukemia; AML, acute myelogenous leukemia.

Nonpharmacologic Therapy

This year, roughly 1.6 million people will be diagnosed with cancer in the United States and Canada. With improvements in detection and treatment, approximately two-thirds of those diagnosed with the disease can expect to be alive in 5 years. With improving longevity, the cumulative adverse effects of both the disease and treatment are becoming an increasingly important issue. “Late-effects” data show that both adult and pediatric cancer survivors are at greater risk for developing second malignancies, cardiovascular disease, diabetes, and osteoporosis than those in the general population. With respect to the growing population of pediatric cancer survivors, data confirm that they are eight times more likely than their siblings to have a severe or life-threatening chronic health condition. For example, the survivors of pediatric ALL have an increased onset of obesity, osteopenia, and associated comorbidities. Thus, it is important to provide supportive care and intervention and counseling related to nutrition, smoking cessation, and exercise as a part of their active treatment. Health care professionals should think beyond the immediate treatment-related issues of their patients and provide appropriate, active assistance to promote healthy lifestyles and encourage patients to take active roles in pursuing general preventive health strategies.¹⁴

Pharmacologic Therapy: ALL

The treatment for ALL consists of four main elements: remission induction (the initial tumor reduction leading to morphologic remission), CNS-directed treatment, and intensive postremission consolidation regimens, followed by a prolonged maintenance phase (Table 95-7).

► Remission Induction

- 5 The initial treatment for acute leukemias is called **induction**. The purpose of induction is to induce a **remission**, a state in which there is no identifiable leukemic cells in the bone marrow or peripheral blood with light microscopy.
- 6 Current induction therapy for ALL typically consists of vincristine, L-asparaginase, and a steroid (prednisone or dexamethasone). An anthracycline is added for higher risk

- patients. Although induction treatment produces 95% CR in children, it declines to no more than 60% in patients older than 60 years of age.

Adults, unlike children, are universally considered to be at high risk for relapse; therefore, their induction regimens include an anthracycline (daunorubicin or doxorubicin) in addition to the standard steroid and vincristine treatment that have been the backbone of treatment for this disease for the last 40 years.^{14,15} Dexamethasone is often replacing prednisone as the steroid of treatment because of its longer half-life and better CNS penetration.¹⁵ Even though dexamethasone possesses more favorable pharmacologic characteristics than prednisone, its use may be associated with more aseptic osteonecrosis of the femoral and humeral heads as well as an increase in life-threatening infections and septic deaths.¹⁵

► CNS Prophylaxis

- 7 Leukemic invasion of the CNS is considered to be an almost universal event in patients even in those whose cerebrospinal fluid (CSF) cytology shows no apparent disease. Thus, all patients with ALL and AML leukemia receive intrathecal (IT) chemotherapy. Although this is often referred to as “prophylaxis,” it more realistically represents treatment. CNS prophylaxis relies on IT chemotherapy (e.g., methotrexate, cytarabine, and corticosteroids), systemic chemotherapy with dexamethasone and high-dose methotrexate, and craniospinal irradiation (XRT) in selected high-risk patients.¹⁶ Cranial radiation was once a common intervention, but it is now reserved for only high-risk patients in whom IT treatment is inadequate. Its use has diminished substantially once the efficacy of IT treatment was evident, and the toxicities associated with radiation, learning disabilities, growth retardation, and secondary malignancies (particularly with the use of 6-mercaptopurine), were recognized. IT therapy has replaced cranial XRT as CNS prophylaxis for all except the very high-risk patients and those with T-cell ALL who are at higher risk of CNS disease.

Inexplicably, the treatment of CNS leukemia has not had the same remarkable impact on the OS of adults as it has for childhood ALL. With IT chemotherapy alone, the incidence of CNS relapse in adults is 9% to 13% compared with less than 3% in children.^{5,11}

Clinical Presentation and Diagnosis of AML^{3,6,11}

General

Patients may have symptoms of AML for 1 to 3 months before presentation. These include fatigue, fever, and pallor, but patients generally are in no obvious distress.

Symptoms

- The patient may present with weakness, malaise, bleeding, and weight loss.
- Neutropenic patients are often febrile and highly susceptible to infection.
- Anemia usually presents as pallor, tiredness, and general fatigue.
- Patients with thrombocytopenia usually present with bruising, petechiae, and ecchymosis.
- Chloromas (localized leukemic deposits named after their color) may be seen, especially in the periorbital regions and as skin infiltrates.
- Gum hypertrophy is indicative of AML M4 and AML M5 subtypes.
- Disseminated intravascular coagulation is common in AML M3 and is associated with generalized bleeding or hemorrhage.
- Lymphadenopathy, massive **hepatosplenomegaly**, and bone pain are not as common in AML as in ALL.

Signs

- Temperature may be elevated secondary to an infection associated with a low WBC count.

- Petechiae and bleeding are indicative of thrombocytopenia.

Laboratory Tests

- CBC with differential is performed.
- The anemia is usually **normochromic** and **normocytic**.
- Approximately 50% of children present with platelet counts of less than $50 \times 10^3/\text{mm}^3$ ($50 \times 10^9/\text{L}$).
- The WBC count may be normal, decreased, or high. About 20% of patients have WBC counts of over $100 \times 10^3/\text{mm}^3$ ($100 \times 10^9/\text{L}$), which places them at risk for leukostasis.
- Uric acid is increased in approximately 50% of patients secondary to rapid cellular turnover.
- *Electrolytes*: Potassium and phosphorus are often elevated. Calcium is usually low.
- *Coagulation disorders*: Elevated prothrombin time, partial thromboplastin time, D-dimers; hypofibrinogenemia

Other Diagnostic Tests

Flow cytometric evaluation of bone marrow and peripheral blood to characterize the type of leukemia, as well as to detect specific chromosomal rearrangements. The bone marrow at diagnosis usually is hypercellular, with normal hematopoiesis being replaced by leukemic blasts. The presence of greater than 20% blasts in the bone marrow is diagnostic for AML. At diagnosis, a lumbar puncture is performed to determine if CNS leukemia is present.

► Postremission Consolidation Regimens

Consolidation After completion of induction and restoration of normal hematopoiesis, patients begin consolidation.

The goal of consolidation is to administer dose-intensive chemotherapy in an effort to further reduce the burden of residual leukemic cells. It is in this and subsequent treatment phases that the remaining leukemic burden is eliminated. Several regimens use agents and schedules designed to minimize the development of drug cross-resistance. Studies have demonstrated that this phase of treatment has proven to be an effective strategy in the prevention of relapse in children with ALL, but its benefits in adults are less clear.

In children, the intensity of the consolidation treatment is now determined not only by the child's risk classification but also by the degree of cytoreduction during induction (MRD). Patients who respond slowly to induction therapy (as determined by bone marrow examination early in induction) are at higher risk of relapse and are treated with more aggressive regimens.¹⁶

Delayed Intensification The Berlin-Frankfurt-Munster (BFM) Study Group introduced a treatment element called

delayed intensification (or *reinduction*) *therapy*. This therapy consisted of repetition of the initial remission induction therapy administered approximately 3 months after remission. This, similar to consolidation, has been adopted as a component of treatment for children by virtually all institutions.¹³

Intensification regimens may vary in their aggressiveness and the drugs they use depending on the patient's risk group and immunophenotype. For example, the use of high-dose methotrexate (5 g/m^2) appears to improve outcome in patients with T-cell ALL. The use of intensive asparaginase treatment in T-cell ALL patients also has improved outcomes significantly.¹⁵

► Maintenance

- The purpose of maintenance therapy is to further eliminate leukemic cells and produce an enduring CCR. The two most important agents in maintenance chemotherapy are a combination of oral methotrexate and 6-mercaptopurine. Improved outcome has been associated with increasing 6-mercaptopurine doses to the limits of individual tolerance

Table 95-7

based on absolute neutrophil count (ANC). The benefit of adding intermittent “pulses” of vincristine and a steroid (usually dexamethasone) to the antimetabolite backbone remains unclear, but it is common practice in most modern treatment regimens.¹⁵ The goal is to induce a moderate immunosuppression and leukemic cell kill.

6-Mercaptopurine is a key agent in maintenance therapy. It has a complex metabolism and is initially cleared by thiopurine methyltransferase (TPMT). TPMT activity is variable with about 90% of patients having normal activity, about 10% having intermediate activity, and fewer than 1% having very low or no activity. These enzymatic polymorphisms are inherited in an autosomal recessive fashion and have a profound influence on 6-mercaptopurine tolerance.^{18,19}

TPMT screening is recommended for children starting therapy with 6-mercaptopurine. Children who possess alleles that have diminished activity require 6-mercaptopurine dose reductions of 50% to 90% to prevent severe immunosuppression and infection. Despite these reductions, these children have equivalent OS when compared with those receiving full-dose 6-mercaptopurine. The optimal duration of maintenance therapy in both children and adults is unknown, but most regimens are given for 2 to 3 years; extension of the regimen beyond 3 years has not shown any additional benefit.

ALL in Infants and Young Children

Infants and children younger than 1 year of age account for approximately 5% of all children with ALL and have the worst outcome of any group with this disease. These patients have several poor prognostic features at diagnosis, including hyperleukocytosis, hepatomegaly, splenomegaly, and CNS leukemia.⁹

A characteristic finding in up to 70% this group is a chromosomal translocation involving the *MLL* gene located at 11q23. There are multiple possible rearrangements of this gene with other chromosomes, and all confer a poor prognosis. In vitro, blasts these patients showed greater drug resistance to prednisolone and L-asparaginase than those from other patients, although they are more sensitive to cytarabine.²⁰ Based on this information, several studies are

testing the efficacy of intensified chemotherapy that includes high-dose cytarabine. Another achievement is the prevention of CNS relapse using IT cytarabine in conjunction with high-dose systemic cytarabine. This combination has eliminated the need for cranial XRT in this young population. Even with major advances in cure rates for the general pediatric ALL population, in whom survival is 80% or more, the long-term survival of infants is only about 40% (Tables 95–8 and 95–9).

ALL in Adolescents and Young Adults

As noted previously, age is an important prognostic factor in ALL. Adolescents and adult patients have generally been shown to have poorer survival than children. However, the group of patients between late adolescence and age 30 years (adolescents and young adults) has recently been shown to have a substantially better outcome than older adult patients. This appears to be the result of using treatment regimens that are the same as or closely resemble pediatric ALL regimens. Retrospective studies show that outcome is improved from the range of 30% to 40% with standard adult therapy to as high as 65% with pediatric protocols.^{2,21} The reasons for this are not entirely clear, and multiple factors are likely to play a role. Among the likely explanations is that pediatric protocols use more aggressive and prolonged postremission consolidation therapy before maintenance. Other proposed explanations are the potential differences in disease biology in this versus older age patients, more intense CNS prophylaxis, and the greater degree of social support and better compliance fostered in a pediatric environment. Current and planned trials are focusing on the potential of extending this treatment approach to patients age 40 years and possibly older.

ALL in Adults

The incidence of ALL in adults ages 30 to 60 years is only two per 100,000 persons per year compared with almost 10 per 100,000 in children. The conventional risk factors such as high WBC counts, older age, and CNS disease hold true in adults as in children. However, the significance of cytogenetic and molecular markers that are so important in children seem to be less predictive of outcome in adults. An exception is the adverse prognostic factor, the presence of the *BCR-ABL* translocation (Ph⁺) just as in childhood ALL. This occurs in 15% to 30% of adults and is even more common in patients older than 60 years of age.²¹ The use of imatinib or dasatinib, both potent inhibitors of the Ph⁺-associated *BCR-ABL* tyrosine kinase, has now become a standard of practice for all patient groups with Ph⁺ disease.⁷ Results show that the combination of these agents with conventional chemotherapy improves remission rates as well as OS compared with the use of conventional chemotherapy alone.^{7,8,21}

Currently, the induction and consolidation regimens in adults is similar to the regimens in pediatric patients, but the more aggressive postinduction regimens are not as well tolerated in this population, particularly in elderly patients (age older than 60 years) and are associated with

Patient Encounter, Part 3

MV begins induction therapy with vincristine, prednisone, daunorubicin, and asparaginase. According to his protocol, he will begin dasatinib in the middle of his induction treatment, on day 15. MV has a bone marrow on day 29 showing a morphologic remission, and his MRD on day 29 was less than 0.1%. He is now ready to begin consolidation.

What is the role of dasatinib for Ph⁺ ALL?

What is the significance of an MRD of 0.1%?

What is the purpose of consolidation therapy?

Table 95-8

Representative Chemotherapy Regimens for Pediatric ALL**Induction (1 month)**

IT cytarabine on day 0

Prednisone 40 mg/m²/day or dexamethasone 6 mg/m²/day PO for 28 days

Vincristine 1.5 mg/m²/dose (maximum, 2 mg) IV weekly for 4 doses

Pegaspargase 2,500 units/m²/dose IM for 1 dose or asparaginase 6,000 units/m²/dose IM Monday, Wednesday, and Friday for 6 doses

IT methotrexate weekly for 2–4 doses

Consolidation (1 month)

Mercaptopurine 50–75 mg/m²/dose PO at bedtime for 28 days

Vincristine 1.5 mg/m²/dose (maximum, 2 mg) IV on day 0

IT methotrexate weekly for 1–3 doses

Patients with CNS or testicular disease may receive radiation

Interim Maintenance (1 or 2 cycles) (2 months)

Methotrexate 20 mg/m²/dose PO at bedtime weekly

Mercaptopurine 75 mg/m²/dose PO daily on days 0–49

Vincristine 1.5 mg/m²/dose (maximum, 2 mg) IV on days 0 and 28

Dexamethasone 6 mg/m²/day PO on days 0–4 and 28–32

Delayed Intensification (1 or 2 cycles) (2 months)

Dexamethasone 10 mg/m²/day PO on days 0–6 and 14–20

Vincristine 1.5 mg/m²/dose (maximum, 2 mg) IV weekly for 3 doses

Pegaspargase 2,500 units/m²/dose IM for 1 dose

Doxorubicin 25 mg/m²/dose IV on days 0, 7, and 14

Cyclophosphamide 1,000 mg/m²/dose IV on day 28

Thioguanine 60 mg/m²/dose PO at bedtime on days 28–41

Cytarabine 75 mg/m²/dose SC or IV on days 28–31 and 35–38

IT methotrexate on days 0 and 28

Consolidation Option (2- to 3-week intervals for 6 courses on weeks 5–24)

Mercaptopurine 50 mg/m²/dose PO at bedtime

Prednisone 40 mg/m²/day for 7 days on weeks 8 and 17

Vincristine 1.5 mg/m²/dose (maximum, 2 mg) IV on the first day of weeks 8, 9, 17, and 18

Methotrexate 200 mg/m²/dose IV + 800 mg/m²/dose over

24 hours on day 1 of weeks 7, 10, 13, 16, 19, and 22

IT methotrexate on weeks 5, 6, 9, 12, 15, and 18

Late Intensification (weeks 25–52)

Methotrexate 20 mg/m²/dose IM weekly or 25 mg/m²/dose PO every 6 hours for 4 doses every other week

Mercaptopurine 75 mg/m²/dose PO at bedtime

Prednisone 40 mg/m²/day PO for 7 days on weeks 25 and 41

Vincristine 1.4 mg/m²/dose (maximum, 2 mg) IV on the first day of weeks 25, 26, 41, and 42

IT methotrexate on day 1 of weeks 25, 33, 41, and 49

Maintenance (12-week cycles)

Methotrexate 20 mg/m²/dose PO at bedtime or IM weekly with dose escalation as tolerated

Mercaptopurine 75 mg/m²/dose PO at bedtime on days 0–83

Vincristine 1.5 mg/m²/dose (maximum, 2 mg) IV on days 0, 28, and 56

Dexamethasone 6 mg/m²/day PO on days 0–4, 28–32, and 56–60

IT methotrexate on day 0

IM, intramuscular; IT, intrathecal; PO, oral; SC, subcutaneous.

a much higher incidence of toxicity and treatment-related deaths.⁷ Some investigators are studying “moderate-dose” consolidation regimens that are better tolerated. These studies are yet too early to have meaningful data. Even though remissions are achieved in 80% to 90% of adult patients, 5 years disease-free survivals are only in the 30% to 40% range. Among elderly patients, the outcome is even poorer with no more than 20% having long-term survival.

Relapsed ALL

Relapse is the recurrence of leukemic cells at any site after remission has been achieved. **8** *Bone marrow relapse is the major form of treatment failure in 15% to 20% of patients with ALL. Most relapses have the same immunophenotype and cytogenetic changes seen of the original disease.* Bone marrow relapse is the principal form of treatment failure in patients with ALL. Extramedullary sites of relapse include the CNS and the testicles.²² Extramedullary relapse, although once common, has decreased to 5% or less because of effective prophylaxis. Site of relapse and the length of the first remission are important predictors of second remission and OS. Marrow relapses occurring less than 18 to 24 months into first remission are associated with a poor survival, but longer periods of remission (greater than 36 months) have a much higher chance of survival.²² Treatment strategies for relapsed ALL include chemotherapy or allogeneic hematopoietic stem cell transplant (allo-HSCT). Even though patients undergoing allo-HSCT are less likely to relapse, treatment-related toxicity leads to a higher incidence of morbidity and mortality compared with chemotherapy alone.⁶ Clofarabine, a next-generation deoxyadenosine analog, has shown considerable activity in children and adults with refractory acute leukemias. Of interest, this is the only anticancer drug to receive primary indication for use in pediatrics in the past 10 years.²³

Treatment of AML

As with ALL, the primary aim in treating patients with AML is to induce remission and thereafter prevent relapse. Treatment of AML is conventionally divided into two phases: induction and consolidation. Despite several strategies to increase the intensity of therapy, the OS rate has reached a plateau at 50% to 60%, suggesting that further intensification of therapy may not improve survival rates greatly; conventional treatment of AML already uses drug doses that are at or near those maximally tolerable.

9 *The current induction therapy for AML usually consists of a combination of cytarabine and daunorubicin, with the frequent addition of a steroid and/or an antimetabolite such as 6-thioguanine. The second phase of treatment for AML is called **consolidation**. The purpose of this phase is to further enhance remission with more cytoreduction. This period is also a time to consider HSCT for patients in first remission.*

► Remission Induction

The goal of induction chemotherapy in AML is essentially identical to that in ALL—“empty” the bone marrow of

Table 95-9

Chemotherapy for the Acute Leukemias

Agent and Major Uses	Class and Mechanism	Major Side Effects	Drug Interactions
Asparaginase (L-asparaginase, Elspar) Pegaspargase (Oncaspar): ALL	Antitumor enzyme, hydrolyzes L-asparaginase in bloodstream, depriving tumor cells of the essential amino acid; results in inhibition of protein, DNA, and RNA synthesis and cell proliferation; derived from <i>Escherichia coli</i>	Hypersensitivity reactions (fever, hypotension, rash, dyspnea in 25%), much lower risk with polyethylene glycol form; low emetogenic potential; pancreatitis; decreased synthesis of proteins, clotting factors; CNS: lethargy	Increased toxicity has been noted when given concurrently with vincristine and prednisone; decreased metabolism when used with cyclophosphamide; increased hepatotoxicity when used with mercaptopurine
Cytarabine (Ara-C, cytosine arabinoside, Cytosar-U): ANLL, ALL, lymphomatous meningitis, NHL, MDS High-dose Ara-C (HiDAC) liposomal cytarabine (DepoCyt) for IT use for lymphomatous meningitis	Antipyrimidine antimetabolite; inhibits DNA polymerase with inhibition of DNA strand elongation and replication; activated in tumor cells in triphosphate form; competes with conversion of cytidine to deoxycytidine nucleotides, further blocking polymerization of DNA; leads to production of short DNS strands; cell-cycle specific (S phase): acts only on proliferating cells	Myelosuppression; alopecia; moderate emetogenic; worse with high dose (greater than 1 g/m ²) or IT administration; diarrhea; mucositis; flulike syndrome with fever and arthralgias; rash often followed by desquamation on palms and soles HiDAC toxicities; cerebellar direct neurotoxicity: ataxia, slurred speech, nystagmus; conjunctivitis (drug is excreted into tears and blocks corneal DNA synthesis)	Possible increased toxicity when given concurrently with alkylating agents, radiation, purine analogs, and methotrexate
Daunorubicin (daunomycin, Dauno, Cerubidine) Liposomal daunorubicin (DaunoXome): ANLL, ALL, KS	Antitumor antibiotic; topoisomerase II inhibitor; DNA intercalator; free radical formation (thought to be related to cardiac toxicity and tissue injury)	Myelosuppression (dose related); mucositis (worse with continuous infusion); moderate emetogenic potential; alopecia; vesicant: severe extravasation injury; cardiac toxicities: acute—not related to cumulative dose; arrhythmias, pericarditis; chronic—cumulative injury to myocardium (total dose greater than 550 mg/m ² ; lower total cumulative doses cause damage to myocardium in children (e.g., 350 mg/m ²))	
Etoposide (VP-16, Vepesid), etoposide phosphate (Etopophos): testicular cancer, SCLC, NSCLC, ANLL, KS, HD, NHL, BMT preparative chemotherapy, gastric cancer	Plant alkaloid, epipodophyllotoxin; inhibits DNA binding activity of topoisomerase II, resulting in multiple DNA double-strand breaks	Myelosuppression; moderately emetogenic: may be worse with oral and high-dose regimens; alopecia; mucositis; hypotension: infusion rate related; etoposide phosphate can be given IV push without hypotension risk; hypersensitivity reactions: especially common in children	Substrate of MDR; cyclosporine may increase levels of etoposide
Gemtuzumab ozogamicin (Mylotarg)	Humanized antiCD33 antibody linked to calicheamicin, a potent toxin; binding to the CD33 receptor results in internalization of the antibody-antigen complex; calicheamicin is then released intracellularly and exerts cytotoxicity by causing DNA double-strand breaks, resulting in cell death	Infusion reactions: fevers, chills, nausea, vomiting, hypotension, dyspnea; myelosuppression may be severe and prolonged; tumor lysis syndrome: WBC counts should be reduced to less than 30 × 10 ³ /mm ³ (30 × 10 ⁹ /L) before administration, if possible, to decrease risk; increased liver function tests and bilirubin, hepatic veno-occlusive disease	
Imatinib mesylate (Gleevec, STI 571) CML (adults and children), GIST, Ph+ ALL	Tyrosine kinase inhibitor; relatively specific for the tyrosine kinase coded for by the BCR-abl translocation in CML patients	Moderate emetogenic potential: take with meals and a full glass of water; edema; periorbital edema is characteristic; pleural effusions, ascites, or pulmonary edema also occur; rash; diarrhea; neutropenia, thrombocytopenia (sometimes difficult to distinguish from CML-induced cytopenias); increased liver function tests	Drug interactions are minimal; substrate of CYP 3A4; serum concentrations of imatinib may be increased by drugs that inhibit CYP3A4

(Continued)

Table 95-9

Chemotherapy for the Acute Leukemias (Continued)

Agent and Major Uses	Class and Mechanism	Major Side Effects	Drug Interactions
6-Mercaptopurine (Purinethol, 6-MP): ALL	Antipurine antimetabolite; purine analog; inhibits DNA, RNA, protein synthesis; metabolized by xanthine oxidase	Myelosuppression: mild, anorexia, low emetogenic potential; dry skin rash, photosensitivity; hepatotoxicity: jaundice and hyperbilirubinemia occur after 1–2 months of therapy and may be dose limiting	Allopurinol can increase levels of mercaptopurine; aminosaliclates may inhibit TPMT
<i>Methotrexate (MTX)</i> : ALL CNS leukemia (IT), breast cancer, NHL, osteosarcoma, head and neck cancer, bladder cancer, rheumatoid arthritis	Folic acid antagonist; inhibits DHFR; blocks reduction of folate to tetrahydrofolate; inhibits de novo purine synthesis; results in arrest of DNA, RNA, and protein synthesis Leucovorin provides reduced folate to bypass the metabolic block	Myelosuppression: can be prevented with leucovorin rescue Mucositis: can be prevented with leucovorin Renal dysfunction: (high-dose regimens) caused by precipitation of drug in renal tubules; hydration (3 L/m ² /day) and alkalization of urine	Salicylates, sulfonamides, probenecid, and high-dose penicillin may decrease clearance of methotrexate
<i>Vincristine (VCR, Oncovin)</i> ALL, HD, NHL, multiple myeloma, breast cancer, SCLC, KS, brain tumors, soft tissue sarcomas, osteosarcomas, neuroblastoma, Wilms' tumor	Antimicrotubule agent or vinca alkaloid; derived from periwinkle plant; disrupts formation of microtubules	Peripheral neuropathy: primary dose-limiting toxicity; motor sensory, autonomic, and cranial nerves may all be affected (paresthesias, ileus, urinary retention, facial palsies); may be irreversible; mild emetogenic; SIADH; vesicant: extravasation injury	Vincristine levels may be increased when given with drugs that inhibit cytochrome CYP3A enzyme (itraconazole)

ALL, acute lymphocytic leukemia; ANLL, acute nonlymphocytic leukemia; BMT, bone marrow transplant; C, cytarabine; CD, cluster determinants; CML, chronic myeloid leukemia; CNS, central nervous system; CYP, cytochrome; DHFR, dihydrofolate reductase; DNS, DNS strands; GIST, gastrointestinal stromal tumor; HD, Hodgkin's disease; HiDAC, high-dose Ara-C; IT, intrathecal; KS, Kaposi's sarcoma; MDS, myelodysplastic syndrome; MTX, methotrexate; NHL, non-Hodgkin's lymphoma; NSCLC, non-small cell lung cancer; Ph⁺, Philadelphia chromosome; SIADH, syndrome of inappropriate antidiuretic hormone; SCLC, small cell lung cancer; VCR, vincristine; VP, etoposide.

Adapted from McManus Balmer C, Wells Valley A, Iannucci A. Cancer Treatment and Chemotherapy. In: DiPiro JT, Talbert RL, Yee GC, et al, eds. Pharmacotherapy: A Pathophysiologic Approach, 6th ed. New York: McGraw-Hill; 2005:2458–2511.

all hematopoietic precursors and allow repopulation with normal cells. The combination of an anthracycline (e.g., daunorubicin, doxorubicin, or idarubicin) and the antimetabolite cytarabine forms the backbone of AML induction therapy. The most common induction regimen (7 + 3) combines daunorubicin for 3 days with cytarabine on days 1 to 7.¹² The remission rate for this combination is approximately 80% in children and younger adults but declines to 40% to 50% in patients older than 60 years of age.^{5,12} Despite studies that have used alternative anthracyclines or substituted high-dose for conventional-dose cytarabine and added etoposide and/or thioguanine, the 7 + 3 regimen remains the standard induction regimen. Paving the way for more innovative therapies, gemtuzumab ozogamicin, a humanized anti-CD33 antibody, has shown it improved the outcome of pediatric and younger adults patient (age younger than 60 years) when added to conventional 7 + 3 chemotherapy.^{24,25}

► Postremission Chemotherapy

In AML, postremission chemotherapy is often referred to as *consolidation therapy*. Several cycles of intensive postremission chemotherapy combining non-cross-resistant

agents given every 4 to 6 weeks substantially improves DFS. Without postremission treatment, all patients would relapse within several weeks. This is analogous to the consolidation and other phases of postremission chemotherapy in ALL. One of three cytarabine-based regimens has been used in current treatment programs, either alone or in combination with L-asparaginase, mitoxantrone, or etoposide. The following cytarabine dosing schedule is used: 100 mg/m²/day for 5 days by continuous infusion (standard-dose arm); 400 mg/m²/day for 5 days by continuous infusion (intermediate-dose arm); or 3 g/m² twice daily over 3 hours on days 1, 3, and 5 (high-dose arm). The higher dose regimen for cytarabine can be tolerated only by younger patients (younger than 60 years of age). Although the optimal number of courses remains to be determined, at least three are probably required.¹²

Allogeneic Hematopoietic Stem Cell Transplantation

Allo-HSCT has been used in the treatment of pediatric AML in first complete remission. In HSCT, very high doses of chemotherapy with or without total-body irradiation (TBI) are given in an attempt to potentiate leukemia cell kill. Hematopoiesis is restored by the infusion of stem cells harvested from a human leukocyte antigen (HLA)-compatible donor, thereby rescuing the patient from the

consequences of total aplasia.^{5,6} It may be the most effective antileukemic therapy currently available.

The availability of HLA-matched sibling donors determined whether patients underwent HSCT as postremission treatment. To facilitate this process, it is important to obtain HLA typing on all younger patients and siblings shortly after diagnosis. Patients who do not have an HLA-matched sibling proceed to postremission therapy with chemotherapy alone.

Transplantations from nonidentical sources have many complications, including graft-versus-host disease (GVHD), delayed or incomplete engraftment, and an increased likelihood of opportunistic infections that substantially increase morbidity and mortality. A benefit of allo-HSCT is an immunologic effect of the donor marrow on residual host leukemic cells that seems to improve antileukemic activity. This is evidenced by the lower relapse rates in patients with GVHD.

Transplant-related mortality following matched-sibling allo-HSCT is 20% to 30% in most series. Complications from transplantation increase with age; therefore, patients older than 60 years of age are uncommonly considered to receive a myeloablative allo-HSCT. Because the average age of AML patients is 65 years, most patients with this disease are not candidates for this form of therapy. For older patients up to 70 years of age, a reduced-intensity (mini or nonmyeloablative allogeneic) transplant may be an option. These transplants use less intensive preparative regimens and rely on the allogeneic graft-versus-leukemia effect to eliminate their disease.¹²

HSCT in first remission is often recommended for patients with a matched-sibling donor because of the lower relapse rate with transplant versus postremission chemotherapy. However, only 30% of patients have an HLA-matched sibling. Some types of AML patients may be curable with conventional-dose chemotherapy alone. Thus indiscriminate use of allo-HSCT could reduce the rate and quality of survival in these individuals.

Autologous Hematopoietic Stem Cell Transplantation

Because the majority of AML patients lack a HLA-identical donor, investigators began to consider the use of the patient's own bone marrow, obtained while in CR, as a source of hematopoietic regeneration. However, relapse continues to be a problem secondary to the presence of residual disease in the graft. Despite the reduced morbidity and mortality associated with auto-HSCT, this type of transplant does not compare favorably to standard postremission chemotherapy.¹²

► CNS Therapy

The prevalence of CNS disease at diagnosis of AML ranges from 5% to 30% in various clinical series. Features associated with the risk of CNS leukemia include hyperleukocytosis, monocytic, or myelomonocytic leukemia (FAB M4 or M5), and young age. Adequate CNS prophylaxis is an essential component of therapy. Studies have shown that patients with CNS disease at diagnosis can be cured with IT therapy

alone without the use of cranial XRT. In most cases, IT cytarabine with or without methotrexate and systemic high-dose cytarabine provide effective treatment.

AML in Infants

AML in infants younger than 12 months of age shows clinical and biological characteristics different from those of older children. The disease phenotype is more commonly monoblastic or myelomonoblastic (M4, M5), and the patients usually present with hyperleukocytosis. Extramedullary involvement is common, often involving skin and other organs. As in infant ALL, there is a high incidence of translocations involving the *MLL* gene in infant AML. The number of infant AML trials reported is limited, but the EFS of this population is similar to that of older children with AML. This is in marked contrast to the outcomes for infants with ALL for whom the EFS is much lower than in older children.²⁶

AML in the Elderly

AML is the most common acute leukemia in the elderly. Compared with younger patients with the same disease, older adults have a poor prognosis and represent a distinct population with regard to the biology of their disease. Older adults have a lower incidence of favorable chromosomal aberrations and a higher incidence of unfavorable aberrations.^{5,12} They also have a much higher incidence of comorbidities, such as type 2 diabetes, obesity, and other physiologic limitations. Thus, the poor prognostic significance of older age is only partly a result of unfavorable biology.

In older adults, in contrast to AML in children, AML is more likely to arise from a proximal bone marrow–stem cell disorder, such as MDS, or present as a secondary, prior treatment-related leukemia. These forms of AML are notoriously poorly responsive to conventional chemotherapy and thus have a lower CR rate and poorer survival.²⁷

As previously noted, age is an important prognostic factor. Older adults are not as tolerant of or as responsive to remission induction and consolidation chemotherapy as younger patients. Using a standard induction regimen of cytarabine and anthracycline, patients older than 60 years of age have only a 38% to 62% probability of remission. In contrast, younger adults treated with a similar standard-induction regimen have approximately 70% probability of attaining a CR. Furthermore, long-term survival for patients older than 60 years is only 5% to 15% compared with 30% DFS for younger adults.^{5,12}

Relapsed AML

Even though 75% to 85% of patients with AML achieve a remission, only about 50% survive. Patients who relapse usually respond poorly to additional treatment and have a shorter duration of remission. This is probably related to drug resistance induced during induction and certain chromosomal abnormalities.

Even though there is no standard therapy for relapse, most studies have shown that high-dose cytarabine-containing regimens have considerable activity in obtaining a second remission. Cytarabine has been used in combination with mitoxantrone, etoposide, fludarabine, 2-chlorodeoxyadenosine, and (more recently) clofarabine.^{5,12} After a patient has achieved a second remission with conventional chemotherapy, allo-HSCT is the therapy of choice. For patients without an HLA-matched sibling, a matched unrelated donor (MUD) or cord blood transplant may be a reasonable alternative. The combination of myeloablative high-dose chemotherapy and the GVL effect is thought to offer the best chance of survival in AML.

Complications of Treatment

► Tumor Lysis Syndrome

- Tumor lysis syndrome (TLS) is an oncologic emergency that is characterized by metabolic abnormalities resulting from the death of blast cells and the release of large amounts of purines, pyrimidines, and intracellular potassium and phosphorus. Uric acid, the ultimate breakdown product of purines, is poorly soluble in plasma and urine. Deposition of uric acid and calcium phosphate crystals in the renal tubules can lead to acute renal failure. Many patients with acute leukemia, especially those with a high tumor burden, are at risk for TLS during the first several days of chemotherapy. Measures to prevent TLS include aggressive hydration, alkalinization to help solubilize uric acid, and allopurinol to promote other purine metabolites other than uric acid. Hyperhydration and alkalinization is generally an effective method of dealing with this issue. However, on some occasions, the use of rasburicase is indicated. Rasburicase is an enzyme that catalyzes the oxidation of uric acid to allantoin, which is much more soluble than uric acid and excreted more easily.^{28,29} Given its high cost, rasburicase generally is restricted to patients with high WBC counts (greater than $50 \times 10^3/\text{mm}^3$, $50 \times 10^9/\text{L}$) and uric acid levels greater than 8 mg/dL (476 $\mu\text{mol/L}$).

► Infection

- Infection is a primary cause of death in acute leukemia patients. Both the disease and aggressive chemotherapy cause severe myelosuppression, placing the patient at risk for sepsis. The therapy for AML is extremely myelosuppressive. Children with AML have a 10% to 20% induction mortality rate secondary to infection and bleeding complications. Therefore, patients receiving induction therapy usually are hospitalized for the first 4 to 6 weeks of therapy. The induction therapy for ALL is far less myelosuppressive, and these patients recover their neutrophil counts quicker and usually do not require prolonged hospitalizations.⁶ It is important to recognize that symptoms and signs of infection may be absent in a severely immunosuppressed or neutropenic patient. Fever (greater than 38.3°C [100.9°F]) in a neutropenic patient is a medical emergency. Because the progression of infection in neutropenic patients can be rapid,

empirical antibiotic therapy should be administered quickly when fever is documented. Currently, the most commonly used initial antibiotic agent is cefepime, a fourth-generation cephalosporin that has good antipseudomonal coverage as well as adequate coverage against *Streptococcus viridans* and pneumococci.³⁰

Trimethoprim-sulfamethoxazole is started in all patients with any acute leukemia for the prevention of *Pneumocystis jiroveci* pneumonia (PJP). Patients normally continue this therapy for 6 months after completion of treatment. The use of additional antibiotic prophylaxis is not encouraged because of concerns for antibiotic resistance.

Of note is that up to 10% of patients seem to exhibit excessive myelosuppression with trimethoprim-sulfamethoxazole (presumably the result of the antifolate trimethoprim in combination with other systemic cytotoxic agents). Changing to another anti-PJP agent such as dapsone or inhaled pentamidine may help to alleviate this problem.

► Secondary Malignancies

- Secondary malignancies are a risk of the successful treatment of a prior cancer or the use of cytotoxic agents in a variety of autoimmune diseases. The chemotherapy agents used, especially alkylating agents and topoisomerase II inhibitors, predispose patients to secondary hematopoietic neoplasms. As the aggressiveness of treatment and the number of survivors of AML increase, the risk of secondary neoplasms also may rise. There are two different types of second malignancies: acute leukemia, which is generally myeloid in origin, or MDS. There are also reports of secondary solid tumors, especially within regions of prior radiation exposure. The latency period between the end of treatment and the development of a secondary leukemia is generally in the range of 5 to 10 years. For those patients who develop secondary solid malignancies, the latency may be as long as 10 to 20 years.

The incidence of second cancers attributed to alkylators peaks 4 to 6 years after exposure and plateaus after 10 to 15 years. Higher cumulative doses and older age at the time of treatment are risk factors for this type of cancer.

Epipodophyllotoxins (etoposide and others) can induce a second malignancy characterized by balanced chromosomal translocations and short latency periods (2 to 4 years). The risk of this leukemia is related to schedule (dose intensity) and the concomitant use of other agents (L-asparaginase, alkylating agents, and possibly antimetabolites). The prognosis for topoisomerase II inhibitor-related secondary leukemia is extremely poor. Only about 10% of these patients survive after salvage chemotherapy, and only 20% survive after HSCT.

Ionizing radiation therapy is also a cause of secondary malignancies. These secondary tumors generally develop within or adjacent to the previous radiation field. These cancers often have a prolonged latency, typically 15 or more years, but shorter latencies (5 to 14 years) are known. Higher doses of radiation and younger age are associated with an increased risk of secondary malignancy.

Unlike children, adults may have other factors that predispose them to secondary malignancies. Lifestyle

choices such as tobacco use, alcohol use, and diet have been implicated in influencing the development of secondary neoplasms in the adult population.

Now that 80% or more of children survive their primary cancers, the incidence of secondary neoplasms may increase. Recognizing this potential, many treatment regimens for children are being modified appropriately to reduce exposure to alkylators, topoisomerase inhibitors, and radiation. Late effects clinics screen for secondary malignancies and other disease and treatment-related disabilities that accompany childhood cancer. Similar screening and educational opportunities are not as established in adult survivors. The Lance Armstrong Foundation focuses much of its efforts on these issues and the concerns of adult and pediatric cancer survivors.

► Late Effects

With increased success in pediatric clinical trials, the OS rate for pediatric cancers has increased markedly over the last 35 years. For some diseases (acute lymphoblastic leukemia, Wilms' tumor, low-grade and common germ cell tumors), the OS rate is now at or above 80%. ¹⁰ *Despite this significant increase in survival, many patients, particularly pediatric cancer survivors, have disease- or treatment-related disabilities. As many as 50% to 60% of these survivors are estimated to have at least one chronic or late-occurring complication of treatment.*³¹ In leukemia, the intensified use of methotrexate may be responsible for some sporadic neurotoxicity seen in children and adults. Likewise, the use of pharmacologic doses of glucocorticoids has been associated with avascular necrosis of bone in older children and adults. High cumulative doses of anthracyclines can cause irreversible cardiomyopathy. Cranial XRT is now less frequently used for CNS leukemia prophylaxis but can cause neuropsychological and neuroendocrine abnormalities that may lead to obesity, short stature, or precocious puberty.⁴ As newer and more intensive treatments enter clinical trials, close observation for long-term side effects will assume even greater importance.

Supportive Care

Because of the need for repeated venous access, a central venous catheter or infusion port is placed before starting treatment. These devices are useful not only for delivery of chemotherapy but also to support patients during periods of myelosuppression. Infection and bleeding complications are the primary causes of mortality in patients with leukemia.

Platelet transfusions are a common tool to prevent hemorrhage. Patients with uncomplicated thrombocytopenia can be transfused when the platelet count falls below $10 \times 10^3/\text{mm}^3$ ($10 \times 10^9/\text{L}$). Patients who are either highly febrile or actively bleeding may require transfusions at higher levels. Red blood cell transfusions generally are not necessary for a hemoglobin concentration greater than 8 g/dL (80 g/L, 4.97 mmol/L).

There is much controversy regarding the routine use of colony-stimulating factors (e.g., granulocyte colony-stimulating factor [G-CSF] and granulocyte-macrophage colony-stimulating factor [GM-CSF]) in neutropenic patients. Even though several

clinical trials have shown the time to ANC recovery is decreased with a colony-stimulating factor, none have demonstrated that CSFs statistically influence infection-related mortality. At present, the use of colony-stimulating factors (G-CSF most commonly) generally is limited to those chemotherapy regimens that place the patient at highest risk for prolonged neutropenia.

OUTCOME EVALUATION

Developing strategies for the treatment and monitoring of acute leukemias begins with risk stratification. Understanding the likely risk of relapse determines the aggressiveness and length of therapy. Remission status and MRD after the induction phase of treatment must be closely observed. Failure to obtain morphologic bone marrow remission by day 28 is a very adverse prognostic sign and dictates further induction treatment. For those who have a morphologic remission, quantification of MRD has become an increasingly important prognostic factor. *Levels of residual less than 0.01% appear to be associated with better outcomes.*

A clinician is generally charged with developing a plan to educate patients and families about their drugs and doses. This is a critical responsibility; it is imperative that the patients and their families understand why they are receiving their medications and how to take them. Frank, open discussion (with the family or patient in possession of their prescriptions) go a long way toward

Patient Care and Monitoring

1. Evaluate the patient for response to therapy during induction, consolidation, and maintenance by following hematologic indices closely.
2. Review the treatment plan closely with the patient.
3. Educate the patient on potential adverse reactions and drug interactions.
4. Stress the importance of medication compliance.
5. Provide patient education regarding disease state and drug therapy:
 - Possible complications of leukemia, especially infections.
 - Potential side effects of drug therapy
 - Warning signs to report to the physician (e.g., temperature, bruising, or bleeding)
6. Based on WBC counts during ALL maintenance, is the patient receiving the appropriate dose of mercaptopurine?
7. Provide education regarding the long-term sequelae associated with the treatment for the acute leukemias.

preventing errors that occur as a result of “assuming” that they understand their medications. If modifications are necessary secondary to toxicity or inadequate response, establish a plan for treatment change. Remember that individual patients often do not fit the “average” patient profile, and dose modifications are frequently needed. The practitioner should be familiar with dosing ranges, WBC count, and other parameters that indicate appropriate treatment response. Based on response to prior phases of treatment, the clinician should recognize potential toxicities in subsequent phases of treatment with the same or different drugs at similar or different doses.

Abbreviations Introduced in This Chapter

ALL	Acute lymphocytic/lymphoblastic leukemia
allo-HSCT	Allogeneic hematopoietic stem cell transplantation
AML	Acute myelogenous leukemia
ANC	Absolute neutrophil count
ANLL	Acute nonlymphocytic leukemia
BFM	Berlin-Frankfurt-Munster
CCR	Continuous complete remission
CD	Cluster determinants
CML	Chronic myelogenous leukemia
CR	Complete remission
CSF	Cerebrospinal fluid
CSF	Colony-stimulating factor
DFS	Disease-free survival
EFS	Event-free survival
FISH	Fluorescent in situ hybridization
G-CSF	Granulocyte colony-stimulating factor
GM-CSF	Granulocyte-macrophage colony-stimulating factor
GVHD	Graft-versus-host disease
GVL	Graft-versus-leukemia
HLA	Human leukocyte antigen
HSCT	Hematopoietic stem cell transplantation
MAB	Monoclonal antibody
MDS	Myelodysplastic syndrome
MPD	Myeloproliferative disorder
MRD	Minimal residual disease
MUD	Matched unrelated donor
OS	Overall survival
Ph ⁺	Philadelphia chromosome
TBI	Total-body radiation
TLS	Tumor lysis syndrome
XRT	Irradiation

Chronic Leukemias and Multiple Myeloma

Amy M. Pick

LEARNING OBJECTIVES

● Upon completion of the chapter, the reader will be able to:

1. Explain the role of the Philadelphia chromosome in the pathophysiology of chronic myelogenous leukemia (CML).
2. Describe the natural history of CML.
3. Identify the clinical signs and symptoms associated with CML.
4. Discuss treatment options for CML with special emphasis on tyrosine kinase inhibitors.
5. Describe the clinical course of chronic lymphocytic leukemia (CLL).
6. Describe patients who may be observed without treatment and those who receive aggressive treatment for CLL.
7. Discuss the various treatment options available for CLL.
8. Describe the clinical presentation of multiple myeloma.
9. Discuss the treatment options available for multiple myeloma.

KEY CONCEPTS

- 1 The Philadelphia chromosome (Ph) is a chromosomal translocation responsible for chronic myelogenous leukemia (CML).
- 2 The Ph results in the formation of an abnormal fusion gene, *BCR-ABL*, which encodes an overly active tyrosine kinase.
- 3 Allogeneic stem cell transplantation is the only curative treatment option for CML.
- 4 Nearly all patients with CML are treated initially with a tyrosine kinase inhibitor (TKIs).
- 5 Dasatinib and nilotinib are two second-generation TKIs that can overcome imatinib resistance or intolerance.
- 6 Chronic lymphocytic leukemia (CLL) can have a variable disease course, but most patients survive for many years.
- 7 Chemotherapy does not improve overall survival in early stage CLL.
- 8 Fludarabine-based chemotherapy is commonly used as first-line therapy for younger patients with CLL.
- 9 Autologous transplant either as a single or double transplant offers younger patients with myeloma longer disease-free survival.

- 10 Newer therapies for multiple myeloma, including thalidomide, lenalidomide, and bortezomib in combination with dexamethasone, produce major responses.

INTRODUCTION

Several diseases comprise chronic leukemia. The two most common forms are chronic myelogenous leukemia (CML) and chronic lymphocytic leukemia (CLL). The slower progression of the disease contrasts it from acute leukemia, with the survival of chronic leukemia often lasting several years without treatment. This chapter covers CML and CLL. The chapter also discusses multiple myeloma and provides a brief discussion of Waldenström macroglobulinemia.

CHRONIC MYELOGENOUS LEUKEMIA

- CML is a hematologic cancer that results from an abnormal proliferation of an early myeloid **progenitor** cell. The clinical course of CML has three phases: chronic phase, accelerated phase, and **blast** crisis.¹ Chemotherapy can be used to control white blood cell (WBC) counts in the chronic phase, but as CML slowly progresses, the cancer becomes resistant

Table 96-1

Clinical Course of CML

Phase	Characteristics	Median Duration (With Treatment)
Chronic	Elevated WBC Responsive to treatment	4–6 years ^a
Accelerated	Elevated WBC count Unresponsive to treatment	6–9 months
Blast	Increased symptoms Disease transformation to acute leukemia	3–6-month

^aBefore imatinib therapy.

CBC, complete blood count; WBC, white blood cell.

to treatment. Blast crisis resembles acute leukemia, and immediate aggressive treatment is required. Table 96-1 describes each of the phases of CML.

EPIDEMIOLOGY AND ETIOLOGY

It was estimated that 5,150 new cases of CML would be diagnosed in 2011, accounting for 12% of all adult leukemias.² The incidence of CML increases with age, with the median age of diagnosis being 67 years.^{3,4} In most newly diagnosed cases, the etiology cannot be determined, but high doses of ionizing radiation and exposure to solvents such as benzene are recognized risk factors.

PATHOPHYSIOLOGY

Cell of Origin

CML arises from a defect in an early progenitor cell. The pluripotent (noncommitted) stem cell is implicated as the origin of the disease; therefore, multiple cell lineages of hematopoiesis may be affected, including myeloid, erythroid, megakaryocyte, and (rarely) lymphoid lineages. These cells remain functional in chronic phase CML, which is why patients in this phase are at low risk for developing infections.

Ph Chromosome

1 The Philadelphia chromosome (Ph) results from a translocation between chromosomes 9 and 22, leaving a shortened chromosome 22. 2 The Ph results in the formation of an abnormal fusion gene between the breakpoint cluster region and the abelson proto-oncogene (BCR-ABL), which encodes an overly active tyrosine kinase. The loss of control of tyrosine kinase activity causes abnormal cellular proliferation and inhibition of apoptosis.^{1,4} Molecular tools such as quantitative and qualitative polymerase chain reaction (Q-PCR) and fluorescence in situ hybridization (FISH) are used in the detection and monitoring of CML.⁵

Clinical Presentation and Diagnosis of CML

Signs and Symptoms

- 30–50% are asymptomatic at diagnosis
- Symptoms may include fatigue, fever, weight loss, bleeding.
- Organomegaly consisting of splenomegaly and hepatomegaly

Diagnostic Procedures

- Peripheral blood smear
- Bone marrow biopsy (percentage of blasts)
- Cytogenetic studies
- Molecular testing (Q-PCR and FISH to detect *BCR-ABL* transcripts)

Laboratory Findings

Peripheral blood smear

- Leukocytosis (most present with WBC count more than $100 \times 10^9/L$, [$100 \times 10^9/mm^3$])
- Thrombocytosis (approximately 50% of patients in chronic phase)
- Anemia
- Presence of blasts

Bone marrow

- Hypercellularity with presence of blasts
- Presence of Ph

Poor Prognostic Factors

- Older age
- Splenomegaly
- High percent blasts in the blood
- High or low platelet count
- Increased eosinophils or basophils

TREATMENT

Desired Outcome

The primary goal in the treatment of CML is to eradicate the Ph positive clones. Elimination of the Ph is termed *cytogenetic complete remission*. If treatment produces Q-PCR–negative disease (no *BCR-ABL* transcripts detected), it is termed *molecular complete remission* and indicates a several log reduction over cytogenetic complete remission. An early goal of therapy is to achieve hematologic complete remission or to normalize peripheral blood counts. A cure from CML can only come from complete eradication of the Ph clone.

General Approach to Treatment

There have been significant advances in the treatment of CML since the discovery of the Ph in 1960. The success of

therapy is partially dependent on the clinical phase of the disease. Treatment decisions are based on patient's age, phase of CML, comorbidities, and availability of a donor for transplant. Nearly all patients with CML are treated initially with a tyrosine kinase inhibitor (TKI). Three TKIs—imatinib, dasatinib, and nilotinib—are available for first-line therapy. Hydroxyurea may be used after diagnosis to rapidly reduce high WBC counts and prevent potentially serious complications (respiratory and neurologic) associated with large numbers of circulating neutrophils. Hydroxyurea, though, does not alter the disease process. TKIs can also reduce peripheral WBC counts over several weeks; therefore, many patients are started on a TKI alone. Before the development of imatinib, interferon- α (INF- α) was the treatment of choice. With the emergence of more effective therapies in CML, today INF- α 's role is minimal. INF- α should be reserved for use in patients who do not respond to TKI therapy and do not enroll in a clinical trial. Although **allogeneic** stem cell transplant is the only curative therapy for CML, the effectiveness and survival benefit of TKIs have decreased the use of transplantation. Transplantation is reserved for patients with the T315I mutation (i.e., TKI resistance) or patients who have failed TKIs. **Figure 96-1** illustrates one common method of clinically managing newly diagnosed CML patients.

Nonpharmacologic Therapy

► Hematopoietic Stem Cell Transplantation

3 *Allogeneic stem cell transplantation is the only curative treatment option for CML.* The National Comprehensive Cancer Network (NCCN) recommends that allogeneic stem cell transplant be considered for patients with the ABL kinase domain mutation known as T315I, which confers resistance to the TKIs imatinib, dasatinib, and nilotinib. Transplant should also be considered for patients who progress on a TKI in accelerated phase or blast crisis.³ Patients who undergo an allogeneic stem cell transplant require a human leukocyte antigen (HLA)-matched donor. Cure rates are superior when patients are transplanted in chronic phase within the first year of diagnosis and may be as high as 75%.³ Unfortunately, only 30% to 40% of patients will be candidates for transplantation. Significant risks are associated with allogeneic transplant with a 10% to 20% early mortality rate or within 100 days of transplant.⁶ Patients may also have a significant decline in quality of life from chronic **graft-versus-host disease** and other long-term complications associated with allogeneic stem cell transplantation. For patients who do not achieve a molecular complete remission or have a relapse after transplant, the infusion of donor lymphocytes may place the patient back into a durable remission.³

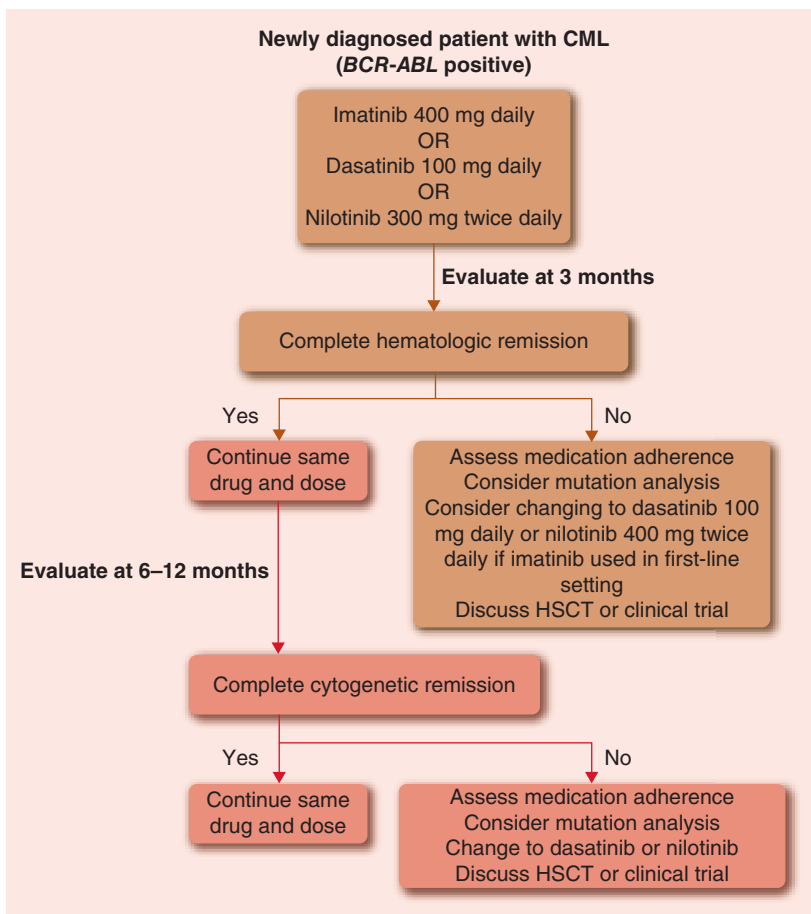

FIGURE 96-1. Algorithm for tyrosine kinase inhibitor therapy in newly diagnosed chronic myeloid leukemia (CML) patients. (HSCT, hematopoietic stem cell transplantation.)

Pharmacologic Therapy (Table 96–2)

The treatment of CML has dramatically changed since the introduction of the first- and second-generation TKIs.

4 Nearly all patients with CML are treated initially with TKIs. These oral agents do not cure CML but are able to produce long-term disease control in the vast majority of patients.

► Imatinib Mesylate (Gleevec)

Imatinib mesylate (STI-571; Gleevec) was the first TKI to show efficacy in the treatment of CML. Imatinib inhibits phosphorylation of various proteins involved in cell proliferation. In CML, imatinib works by binding to the

adenosine triphosphate-binding pocket of *BCR-ABL*.⁴ Data show that the use of imatinib in chronic phase CML results in 88% of patients reaching 6-year survival.⁷ The drug induces complete hematologic responses in more than 97% of patients and complete cytogenetic responses in about 87% of patients in chronic phase.⁸ As expected with more aggressive disease, lower response rates are reported in accelerated phase and blast crisis.⁹ Disease progression is typically attributed to imatinib primary or secondary resistance.¹⁰ The ABL mutation T315I is one such mechanism of secondary resistance that results in reactivation of *BCR-ABL* activity. The T315I mutation renders imatinib and the second-generation TKIs ineffective; therefore, alternative therapy such as allogeneic

Table 96–2

Drugs Used in CML

Drug	Adverse Effects	Comments	Renal Dosing	Hepatic Dosing
Dasatinib (Sprycel)	Thrombocytopenia, neutropenia, headache, rash, edema, pleural effusions	Dose: 100 mg PO once daily for chronic phase CML or 140 mg PO daily for accelerated phase or blast crisis Avoid concomitant medications that prolong the QT-interval; low levels of potassium and magnesium should be corrected before initiating therapy Drug interactions: metabolized by CYP 3A4 (e.g., cyclosporine, erythromycin, itraconazole, phenytoin, St. John's wort) Dasatinib exhibits pH-dependent absorption; avoid medications that alter gastric pH (e.g., H ₂ antagonists and PPIs)	No reductions	No reductions
Imatinib mesylate (Gleevec, STI 571)	Neutropenia, thrombocytopenia, diarrhea, rash, nausea, edema, fatigue, arthralgias, myalgias, headache, increased liver function tests, congestive heart failure (rare)	Dose range: 400–800 mg PO per day depending on phase Take with meals and a full glass of water Drug interactions: metabolized by CYP 3A4; weak inhibitor of CYP 2D6 and 2C9 (e.g., warfarin) Avoid taking with acetaminophen to reduce hepatic toxicity Diarrhea usually responds to loperamide	CrCl 20–39 mL/min (0.33–0.66 mL/s): 50% reduction in dose CrCl less than 20 mL/min (0.33 mL/s): use with caution	Mild to moderate impairment: no adjustment Severe impairment: reduce dose by 25% Discontinue imatinib if liver transaminases are greater than 5 × upper limit of normal or if serum bilirubin greater than 3 × upper limit of normal
Interferon- α (Intron A, Roferon-A, IFN)	Flulike symptoms: fever, chills, myalgias, fatigue; depression; insomnia; thrombocytopenia	Premedicate with acetaminophen or an NSAID to lessen flulike symptoms Dose is given subcutaneously or intramuscularly daily	No reductions	No reductions
Nilotinib (Tasigna)	Thrombocytopenia, neutropenia, elevated bilirubin, elevated serum lipase	Dose: 400 mg PO twice daily Take on an empty stomach Black box warning for QT prolongation; avoid concomitant medications that prolong the QT interval; low levels of potassium and magnesium should be corrected before initiating therapy Drug interactions: metabolized by CYP 3A4; competitive inhibitor of CYP 2C8, 2C9, 2D6, and UGT1A1. Pharmacogenomic testing of UGT1A1 polymorphisms can be used to identify patients who may have hyperbilirubinemia	No reductions	Child-Pugh class A, B, or C: 200 mg PO twice daily for chronic phase CML; may increase to 300 mg if tolerating nilotinib therapy; discontinue nilotinib if experiencing grade 3 or 4 elevations in bilirubin or liver transaminases

CML, chronic myeloid leukemia; CrCl, creatinine clearance; IV, intravenous; PO, oral; PPI, proton pump inhibitor; NSAID, nonsteroidal anti-inflammatory drug.

stem cell transplant or clinical trials should be considered.^{3,10} In addition, agents that circumvent this mutation are in clinical development.

Imatinib may be used as first-line therapy in patients with CML. Standard dosing of imatinib is 400 mg/day in chronic phase CML. Because lower response rates are seen with advanced disease, studies are investigating the use of 600 to 800 mg/day of imatinib in accelerated phase and blast crisis. Although these higher doses are used quite often in clinical practice, increased efficacy over standard dose imatinib has not been demonstrated.¹¹

Therapy with imatinib is generally well tolerated. Common side effects include **myelosuppression** (phase and dose related), rash, gastrointestinal disturbances, edema, fatigue, arthralgias, myalgias, and headaches. Congestive heart failure is a rare but serious side effect (1.7% of patients) and requires careful monitoring in patients with preexisting cardiac conditions.³ Imatinib is metabolized by CYP450 3A4, and possible drug interactions include agents that inhibit or induce 3A4, such as erythromycin, ketoconazole, and phenytoin.¹²

► **Dasatinib (Sprycel) and Nilotinib (Tasigna)**

5 *Dasatinib and nilotinib are two second-generation TKIs that can overcome imatinib resistance or intolerance.* These inhibitors are anywhere from 10 to 325 times more potent than imatinib in inhibiting *BCR-ABL* and are able to overcome most *BCR-ABL* mutations that lead to imatinib resistance.¹⁰ The one exception is that neither drug can overcome the T315I mutation. Dasatinib and nilotinib were initially indicated for use in CML when patients failed imatinib therapy. Their indication has now expanded to include first-line therapy. Several phase II trials have compared dasatinib or nilotinib with imatinib. These study results suggest that dasatinib and nilotinib are comparable to, if not better than, imatinib.^{13,14} Common side effects are similar to those of imatinib. A significant and potentially severe side effect of pleural effusions has been reported with the use of imatinib and dasatinib but not with the use of nilotinib. Additional side effects include QT prolongation (dasatinib and nilotinib) and increases in indirect bilirubin (nilotinib).^{3,10}

► **Interferon- α and Cytarabine**

Before the introduction of TKIs, the combination of INF- α and low-dose cytarabine was the nontransplant treatment of choice for patients in chronic phase CML. The precise mechanism of action of INF- α remains unknown. The addition of cytarabine to INF- α improves the response compared with INF alone. This combination produces cytogenetic response rates of 30%, much lower than imatinib.¹⁵ One of the major drawbacks, in addition to the low response rates, is INF's toxicity, including flulike symptoms, depression, and thrombocytopenia. Today, INF- α and cytarabine should only be considered in rare circumstances for patients who do not respond to any TKI and are not candidates for stem cell transplantation or a clinical trial.

OUTCOME EVALUATION

Successful treatment for CML depends on the elimination of the Ph. Nearly all newly diagnosed CML patients will initially be placed on a TKI. Although historically imatinib has been used as first-line therapy, dasatinib and nilotinib are also viable options, receiving their first-line indications in 2010. Which agent to use depends on several factors, including mutational status, disease risk score, age, comorbid conditions, and medication safety profile. Patients should be counseled on the importance of medication adherence. Patients should understand that poorer outcomes may result if they are not adherent to daily TKI therapy. If patients fail to obtain a cytogenetic response within 6 to 12 months, a change in therapy is recommended. If imatinib was used as first line, a change to dasatinib or nilotinib is recommended.³ If dasatinib or nilotinib was chosen as first line, then a switch to the other second-generation TKI is recommended. If the T315I mutational status is present, the patient should consider transplantation or a clinical trial without trying another TKI. Patients who do not respond to a TKI and cannot be transplanted should be encouraged to enroll in a clinical trial. Some patients will not respond to treatment and will progress to blast crisis when they will receive treatment for acute leukemia. Although its use is limited, allogeneic

Patient Encounter 1

KC is a 32-year-old man who presents to his ophthalmologist with complaints of blurry vision when looking at a distance. KC's medical history consists of gastroesophageal reflux disease treated with twice daily famotidine and bipolar depression treated with ziprasidone. An eye examination reveals retinal infiltrates. A CBC is drawn and shows the following:

Total WBC: $225 \times 10^9/L$ ($225 \times 10^3/mm^3$), (4% [0.04] blasts, 86% [0.86] segs, 10% [0.10] lymphs)

HgB/HCT: 8.3 g/dL (83 g/L; 5.15 mmol/L)/25% (0.25)

Platelets: $65 \times 10^9/L$ ($65 \times 10^3/mm^3$)

KC is referred to an oncologist for further workup. A bone marrow biopsy is performed and reveals hypercellular marrow with 5% (0.05) blasts. FISH analysis is positive for Ph.

What are the first-line treatment options for chronic phase CML patient?

Which specific treatment do you recommend for this patient and why?

Identify your treatment goals for this patient.

If this patient has suboptimal response to your initial therapy, what would you recommend?

What factors may contribute to this patient's having a suboptimal response?

transplant offers the only cure for CML. Allogeneic stem cell transplantation may be discussed with the minority of patients who have a matched donor and are young enough to tolerate transplant.³

CHRONIC LYMPHOCYTIC LEUKEMIA

CLL is a cancer that results in the accumulation of functionally incompetent lymphocytes.¹⁶ CLL is considered an indolent, incurable disease, and treatment should only be initiated when patients have symptoms. A subset of patients has

aggressive disease, and these individuals need to be treated aggressively.

EPIDEMIOLOGY AND ETIOLOGY

CLL is the most common type of leukemia diagnosed in adults, accounting for 30% of all adult leukemias. It was estimated that in 2011, 14,570 new cases would be diagnosed in the United States.² The median age at diagnosis is the sixth decade of life with the incidence increasing with age. The etiology of CLL is unknown, but hereditary factors may have a role, with family members of CLL patients having a two- to sevenfold increased risk of CLL.¹⁶

PATHOPHYSIOLOGY

Cell of Origin

CLL is characterized by small, relatively incompetent B lymphocytes that accumulate in the blood and bone marrow over time. The lack of apoptotic mechanisms leads to the persistence and accumulation of B lymphocytes. The exact cell of origin is controversial but has been described as an antigen activated B lymphocyte.¹⁶ Chromosomal abnormalities have been identified in 40% to 50% cases of CLL. Detection of some of these markers may predict clinical course and prognosis and may influence treatment decisions.^{16,17}

Clinical Course

- 6 *CLL can have a variable clinical course with survival ranging from months to decades. Low-risk disease is asymptomatic, and median survival times exceed 10 years. Intermediate risk is associated with lymphadenopathy and has median survival times of about 7 years. High-risk patients with anemia have median survival times of only 3 years.¹⁸ The typical low-risk patient is an elderly patient without symptoms who is diagnosed on routine blood draw. The typical high-risk patient is a middle-aged patient in which symptoms have brought him or her to a physician.*

PROGNOSTIC FACTORS

Two staging systems, Rai's and Binet's, have been developed to help practitioners determine the overall prognosis of patients with CLL. They are comparable systems and are useful when broadly determining good, intermediate, and poor prognostic disease.^{16,17} Risk stratification criteria included in these systems are the presence of lymphadenopathy, splenomegaly, hepatomegaly, and cytopenias. Increasingly, a number of biological markers of the disease such as deletions of chromosome 17p and 13q and mutational status of immunoglobulin heavy chain variable region gene (IgVH) are being used to predict the likely clinical course.¹⁸ These biological markers are not included in the Rai or Binet staging systems.

Clinical Presentation and Diagnosis of CLL

Signs and Symptoms (40% are asymptomatic at diagnosis)¹⁶

- Lymphadenopathy
- Organomegaly consisting of splenomegaly and hepatomegaly
- Fatigue, weight loss, night sweats, fevers
- Chronic infections caused by immature lymphocytes

Diagnostic Procedures

- Peripheral blood smear
- Bone marrow biopsy
- Cytogenetic studies
- Molecular testing

Laboratory Findings

Peripheral-blood

- Leukocytosis (WBC count more than $100 \times 10^9/L$ [more than $100 \times 10^3/mm^3$])
- Lymphocytosis (absolute lymph count more than $5 \times 10^9/L$, [more than $5 \times 10^3/mm^3$])
- Anemia
- Thrombocytopenia
- Hypogammaglobulinemia

Bone marrow

- Must have at least 30% (0.30) lymphocytes

Poor Prognostic Factors

- Lymphocytosis with accompanying:
 - Anemia (hemoglobin less than or equal to 11.0 g/dL [less than or equal to 110 g/L; less than or equal to 6.83 mmol/L])
 - Thrombocytopenia (platelets less than $100 \times 10^9/L$ [less than $100 \times 10^3/mm^3$])
- ZAP-70 and CD38 antigen expression
- Cytogenetics such as deletions of chromosomes 17p and 13q

TREATMENT

Desired Outcomes

The primary goals in the treatment of CLL are to provide palliation of symptoms and improve overall survival. Because the current treatments for CLL are not curative, reduction in tumor burden and improvement in disease symptoms are reasonable end points, particularly in older patients. A complete response (CR) to therapy can be defined as a resolution of lymphadenopathy and organomegaly, normalization of peripheral blood counts, and elimination of lymphoblasts in the bone marrow.

Nonpharmacologic Therapy

7 *Chemotherapy does not improve overall survival in early stage CLL.* In addition, deferring therapy until a patient becomes symptomatic does not alter overall survival.^{19,20} For this reason, the notion of “watch and wait” (observation) is considered reasonable for older patients with indolent disease. Several factors will influence this approach, including the patient’s life expectancy, disease characteristics, and the patient’s ability to tolerate therapy.²¹

► Hematopoietic Stem Cell Transplantation

The use of hematopoietic stem cell transplantation (HSCT) in CLL is limited. Allogeneic transplantation offers longer disease-free remissions than **autologous** transplantation but is associated with high treatment morbidity and mortality. Several factors must be considered before allogeneic stem cell transplantation. The lack of a donor, older age, and poor performance status make transplant an uncommon procedure in this population. Allogeneic transplantation may be an option for younger patients who have aggressive disease. NCCN guidelines suggests that patients younger than 70 years of age with the deletion of chromosome 17p or who relapse after initial treatment consider allogeneic stem cell transplantation because these patients have a poor response to conventional therapies.²² Although its use is currently limited, HSCT may someday be an important component in achieving a cure for CLL.¹⁶

Pharmacologic Therapy (Table 96–3)

Numerous agents can be used as initial therapy in the treatment of symptomatic or advanced CLL. The discussion below focuses on the common agents used in the treatment of CLL. Because many of these chemotherapy regimens have never been compared directly with one another, there is not one preferred regimen. Selection of the appropriate chemotherapy depends on the individual patient and practitioner’s preference. **Figure 96–2** illustrates one approach for initial therapy in newly diagnosed patients with CLL.

► Single-Agent Chemotherapy

Historically, chlorambucil (Leukeran), an alkylating agent, was considered the standard treatment for CLL. Today, the

treatment for CLL has changed with the development of the purine analogs. There are three purine analogs used in the treatment of CLL: fludarabine (Fludara), pentostatin (Nipent), and cladribine (Leustatin) with fludarabine being the most studied. 8 *Today, fludarabine-based chemotherapy is often used as first-line therapy for younger patients with CLL.* Randomized clinical trials have shown that fludarabine is superior to chlorambucil in achieving higher response rates and producing a longer duration of response (CR 20% versus 4%, respectively).²³ Fludarabine is effective in previously untreated patients as well as patients who have chlorambucil-resistant disease.²⁴ Although fludarabine is one of the most effective agents in the treatment of CLL, it is rarely used as a sole agent. Instead fludarabine is given in combination with other drugs.^{16,22,23}

The most common dose for fludarabine is 20 mg/m² intravenously (IV) daily for 5 consecutive days, but chlorambucil can be taken daily as an oral tablet with the dose ranging from 4 to 10 mg/day.²⁴ Fludarabine is associated with more toxicities than chlorambucil, including myelosuppression and prolonged immunosuppression.²³ Resultant infectious complications may occur during the periods of prolonged immunosuppression. NCCN guidelines recommend that clinicians consider antibacterial and antiviral prophylaxis for *Pneumocystis carinii* and varicella zoster when using fludarabine-based therapy.²² Today, chlorambucil remains a practical option for symptomatic elderly patients who require palliative therapy because of the ease of oral administration and limited side effects profile.

Bendamustine (Treanda) is an alkylating agent approved in 2008 for the treatment of CLL. As first-line therapy for CLL, bendamustine was shown to have superior overall response rates, CRs, and longer progression-free survival than chlorambucil.²² The efficacy of bendamustine has not been compared to fludarabine-based combination therapy. NCCN guidelines suggest that bendamustine may be given as first-line therapy with rituximab.²² The dosing for bendamustine is 100 mg/m² given IV on days 1 and 2 of a 28-day cycle. Table 96–3 lists some of the adverse effects seen with bendamustine.

► Monoclonal Antibodies

Rituximab (Rituxan) Rituximab is a naked chimeric monoclonal antibody directed against the CD20 antigen on B-lymphocytes.²⁵ Similar to other B-cell malignancies, CLL expresses CD20 antigens. Dose escalation studies suggest that higher doses are required than those used in non-Hodgkin’s lymphoma.²⁵ The higher dose required in CLL is probably a combined effect of lower CD20 antigen expression and higher concentrations of soluble CD20 antigen than in non-Hodgkin’s lymphoma.^{16,25} Rituximab is typically given in combination with other therapies since these combinations result in higher CRs than rituximab alone.²⁶ The most commonly observed side effects of rituximab include infusion reactions consisting of fever, chills, hypotension, nausea, vomiting, and headache.¹⁶ Premedication with diphenhydramine

Table 96-3

Drugs Used in CLL

Drug	Adverse Effects	Comments	Renal Dosing	Hepatic Dosing
Alemtuzumab (Campath)	Infusion reactions: fever, chills, nausea, vomiting; hypotension; prolonged immunosuppression (resulting in infectious complications)	Antiviral and PCP prophylaxis should be initiated during treatment Consider antifungal prophylaxis Premedicate with acetaminophen, diphenhydramine with or without a steroid to alleviate infusion-related reactions SC dosing may lessen acute toxicity	No reductions	No reductions
Bendamustine (Treanda)	Myelosuppression, fever, nausea, vomiting, infusion reactions, tumor lysis syndrome	Consider using allopurinol for tumor lysis syndrome during first few cycles of therapy	CrCl less than 40 mL/min (0.67 mL/s): do not use	Mild impairment: use with caution Moderate to severe impairment: do not use
Chlorambucil (Leukeran)	Myelosuppression; allergic reactions (skin rash); secondary malignancies	Take on an empty stomach because food decreases absorption Dose range: 4–10 mg PO daily	No reductions	No reductions
Fludarabine (Fludara)	Myelosuppression; prolonged immunosuppression, resulting in secondary infectious complications; edema; neurotoxicity	Dose: 20 mg/m ² IV daily for 5 days Often given in combination	CrCl 30–70 mL/min (0.50–1.17 mL/s): 20% reduction of dose (IV and PO) CrCl less than 30 mL/min (0.50 mL/s): do not use IV; reduce dose of oral by 50%	No reductions
Ofatumumab (Arzerra)	Severe infusion-reactions: bronchospasm, edema, fever, chills, rigors, hypotension; prolonged myelosuppression	Premedicate with acetaminophen, IV antihistamine, and an IV steroid to alleviate infusion-related reactions Rate of infusion should be increased gradually to minimize reactions Monitor for reactivation of hepatitis B	No reductions	No reductions
Pentostatin (Nipent)	Myelosuppression; infectious complications	Fatal pulmonary toxicity when given with fludarabine	Hold dose if serum creatinine increases	No reductions
Rituximab (Rituxan)	Infusion reactions: fever, chills, rigors, hypotension	Premedicate with acetaminophen, diphenhydramine with or without a steroid to alleviate infusion related reactions Rate of infusion should be increased gradually to minimize reactions Monitor for reactivation of hepatitis B	No reductions	No reductions

CrCl, creatinine clearance; IV, intravenous; PO, oral; PCP, pneumocystitis pneumonia; SC, subcutaneous.

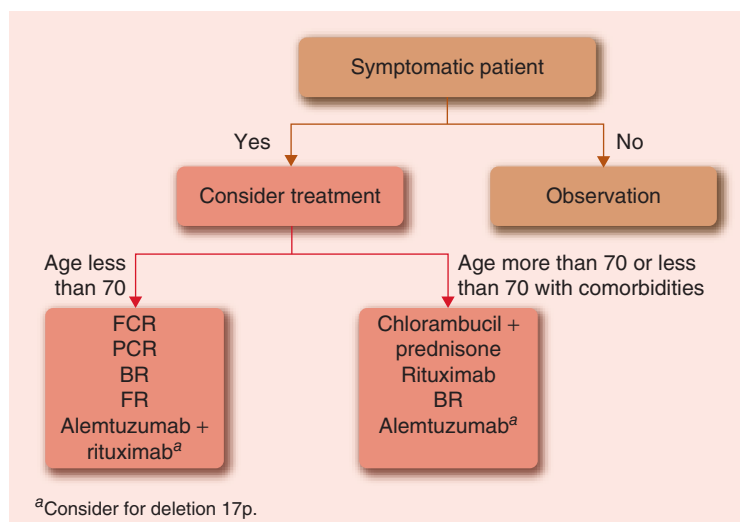

FIGURE 96-2. Algorithm for initial therapy in newly diagnosed chronic lymphocytic leukemia (CLL) patients. B, bendamustine; C, cyclophosphamide; F, fludarabine; P, pentostatin; R, rituximab.

and acetaminophen is recommended to minimize infusion reactions.

Ofatumumab (Arzerra) Ofatumumab is a newer CD20 antigen-directed monoclonal antibody that is approved in CLL patients who fail fludarabine and alemtuzumab.²² Premedications are similar to rituximab with the addition of a corticosteroid to reduce the incidence of infusion reactions. The rate of infusion depends on patient tolerability of ofatumumab. Although it is currently used in refractory patients, its use in CLL may expand in the future. Table 96–3 lists some of the adverse effects seen with ofatumumab.

Alemtuzumab (Campath) Alemtuzumab is a humanized monoclonal antibody directed against the CD52 antigen.²⁷ CD52 antigen is expressed on the majority of B and T lymphocytes. Alemtuzumab is approved by the Food and Drug Administration for single-agent use in the treatment of CLL. Studies have shown alemtuzumab to be effective in fludarabine-resistant disease, in patients with the deletion of 17p, and as front-line therapy.²³ Infusion-related reactions can be significant and typically occur with the initial dose and lessen in severity with subsequent doses. To limit acute allergic reactions, subcutaneous administration may be given instead of IV dosing.^{16,23} Premedication with oral antihistamines and acetaminophen is recommended. Alemtuzumab also suppresses the T cells, resulting in prolonged immunosuppression. Infectious complications may occur from the reactivation of cytomegalovirus and herpes virus and from infection with *Pneumocystis carinii*. These infections have been shown to occur with both the IV and subcutaneous routes of administrations. Guidelines recommend that patients receive trimethoprim–sulfamethoxazole and acyclovir or an equivalent antiviral to prevent these infections.^{16,28}

- **Fludarabine-Based Combination Therapy** Fludarabine-based combination therapy may improve long-term disease-free survival. The combination of fludarabine, cyclophosphamide, and rituximab improves CR rates compared with fludarabine alone (70% versus 20%, respectively) but at the expense of increased infections.^{28,29} The combination of fludarabine and alemtuzumab is also being investigated, with the hopes of improving overall survival.¹⁶ No fludarabine-based regimen has been shown to be superior to another.²³

OUTCOME EVALUATION

Successful outcomes depend on the appropriate treatment selection for a specific patient. A risk-versus-benefit analysis should be done in the treatment of older CLL patients.

- Because CLL is not curable, watch and wait is a reasonable approach for those with indolent disease. Treatment can then begin when the patient becomes symptomatic. Aggressive fludarabine-based therapy is often reserved for younger patients with high-risk CLL, with the goal being prolonged disease-free survival. A desirable response to therapy includes

Patient Encounter 2

JR is a 72-year-old man who is admitted to the hospital for fever, chills, and shortness of breath. His medical history includes chronic obstructive pulmonary disease, type 2 diabetes mellitus, and hypertension. A thorough workup is performed with the following results reported:

Chest x-ray: right upper lobe infiltrates and a right lung base nodule

Chest CT with contrast: stable noncalcified mass in the peripheral right lower lobe; bilateral airspace infiltrates in lower lobes compatible with pneumonia; stable mediastinal adenopathy; splenomegaly

Abdominal ultrasound: hepatosplenomegaly; prior cholecystectomy

Bone marrow biopsy: extensive bone marrow and peripheral blood involvement by chronic lymphocytic leukemia; CD20 essentially negative; cytogenetics report: deletions of 13q, 17p, and 11q

Peripheral blood smear: macrocytic anemia, marked thrombocytopenia, and marked absolute lymphocytosis with atypical lymphocytes and smudge cells consistent with chronic lymphocytic leukemia

What information supports the diagnosis of CLL?

Identify your treatment goals for this patient.

What treatment approach do you recommend?

Would your treatment options change if this patient were an otherwise healthy 46-year-old man? If so, what would be your new treatment?

a reduction in lymphocytes, decrease in stage of the disease, and resolution of symptoms.

MULTIPLE MYELOMA

Multiple myeloma is a malignancy of the **plasma cell** and is characterized by an abnormal production of a monoclonal protein in the bone marrow. Features of the disease include bone lesions, anemia, and renal insufficiency.³⁰ Multiple myeloma is an incurable disease; however, advancements in the treatment of myeloma have significantly extended survival.

EPIDEMIOLOGY AND ETIOLOGY

Multiple myeloma is the second most common hematologic malignancy. It is estimated that approximately 20,520 new cases of multiple myeloma would be reported in 2011, accounting for 1% to 2% of all cancers.² The median age at diagnosis is 70 years, and fewer than 2% are diagnosed before the age of 40 years.^{30,31} The incidence of myeloma is highest

in African Americans, lowest in Asians, and occurs more frequently in men than women.³¹ The etiology of multiple myeloma is unknown.

PATHOPHYSIOLOGY

The pathogenesis of multiple myeloma is quite complex with multiple-step models created to postulate the process. Myeloma must be distinguished from a condition called monoclonal gammopathy of unknown significance (MGUS), which is characterized by a monoclonal immunoglobulin without malignant plasma cells. Yearly, about 1% of patients with MGUS will develop multiple myeloma. Chromosomal abnormalities and changes in gene expression lead to cell cycle dysregulation and appear to be involved early in the disease process.³⁰ The pathophysiology of multiple myeloma involves complex bone marrow microenvironment, and cytokine interactions. Interleukin-6, tumor necrosis factor, vascular endothelial growth factor, and stroma-derived factor-1 support the establishment and proliferation of myeloma cells.^{30,31} The understanding of these interactions has led to novel agents used in the treatment of multiple myeloma.

PROGNOSTIC FACTORS

Prognostic factors for myeloma include extent of tumor burden and patient performance status. The International Staging System is used to predict outcomes after therapy. Staging is stratified based on the levels of serum β_2 -microglobulinemia and serum albumin. High β_2 -microglobulinemia and low albumin are poor prognostic factors and are indicative of high tumor load.³⁴ Although cytogenetic abnormalities are not included in the International Staging System, many abnormalities are associated with poor outcomes. Chromosomal changes are being used to predict high-risk patients with perhaps the most important being deletions of the long arm of chromosome 13 and translocation of chromosomes 4 and 14.^{30,32,33} Older patients, renal impairment, and other comorbidities also predict for poorer outcomes.³⁴

TREATMENT

Desired Outcomes

The primary goal in the treatment of multiple myeloma is to decrease tumor burden and minimize complications

Clinical Presentation and Diagnosis of Multiple Myeloma

Signs and Symptoms

- “CRAB”
 - “C”—hyperCalcemia
 - “R”—Renal failure (serum creatinine greater than 2 mg/dL [greater than 177 μ mol/L])
 - “A”—Anemia (fatigue)
 - “B”—Bone disease (pain, lesions, fractures)
- Weight loss
- Recurrent infections

Diagnostic Procedures

- Laboratory
 - CBC, chemistry panel, β_2 microglobulin
 - Peripheral blood smear
 - Serum protein electrophoresis and immunofixation
 - Urine protein electrophoresis and immunofixation
 - Serum free light chains
- Radiologic evaluation (MRI, bone densitometry)
- Bone marrow biopsy
 - Cytogenetic studies
 - Molecular testing

Laboratory Findings

- Peripheral blood
 - Monoclonal protein in serum (usually IgG or IgA)
 - High β_2 microglobulin
 - Low platelets and hemoglobin
 - High creatinine, urea, lactate dehydrogenase, C-reactive protein, and calcium
 - Rouleaux formation
- Urinalysis
 - Urinary free light chains (Bence-Jones Protein)
- Bone marrow
 - Plasma cells (10% or more)
 - Abnormal cytogenetics
- Radiologic findings
 - Bone lesions, fractures, osteoporosis

Poor Prognostic Factors

- High serum β_2 -microglobulin and low serum albumin
- Elevated C-reactive protein
- Elevated lactate dehydrogenase
- IgA isotype
- Low platelet count
- Chromosome 13 deletions and other cytogenetic abnormalities

Patient Encounter 3

A 52-year-old woman presents with her health care provider with complaints of upper left leg and hip pain. Her medical history is irrelevant with the exception of a recent fall (2 months ago) while ice skating. Workup reveals:

Radiologic data:

X-ray of left hip: Osteolytic lesions

Laboratory data:

Hemoglobin: 6.7 g/dL (67 g/L; 4.16 mmol/L)

Platelets: $180 \times 10^9/L$ ($180 \times 10^3/mm^3$)

Corrected calcium: 12.6 mg/dL (3.15 mmol/L)

Serum creatinine: 2.4 mg/dL (212 μ mol/L)

Serum IgG: 3700 mg/dL (37 g/L) (normal, 620–1500 mg/dL [6.2–15 g/L])

Serum IgM: 100 mg/dL (1 g/L) (normal 50–200 mg/dL [0.5–2 g/L])

Bone marrow: 90% (0.90) plasma cell infiltrates

What information is suggestive of multiple myeloma?

What treatment options are available for this patient?

Assuming this patient is a candidate for autologous stem cell transplantation, what would be an appropriate induction regimen?

Assuming this patient is not a candidate for autologous stem cell transplantation, what would be an appropriate induction regimen?

What may be used for maintenance therapy after an autologous stem cell transplantation?

associated with the disease. A watch and wait approach is an option for asymptomatic patients (smoldering myeloma) who have no lytic lesions in the bone. When symptoms occur, treatment is required. All patients should be evaluated to see if they are eligible candidates for transplant. Autologous stem cell transplantation prolongs overall survival in patients who can tolerate high-dose chemotherapy. Immunomodulators such as thalidomide

should be incorporated into initial therapy to reduce tumor burden in patients with symptomatic disease. Almost all patients become refractory to initial treatment and require the use of salvage therapies. Maintenance therapy with immunomodulators or bortezomib is frequently being used to prolong the duration of response. **Figure 96-3** illustrates possible treatment approaches for transplant-eligible and -ineligible patients.

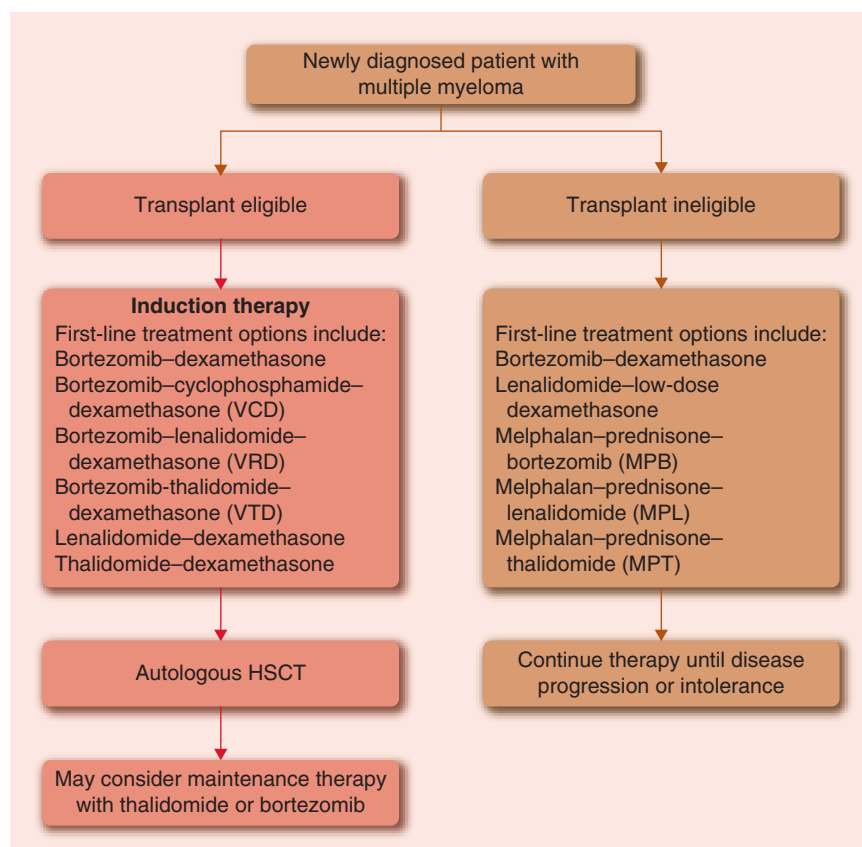

FIGURE 96-3. Possible approach for treatment in newly diagnosed patients with multiple myeloma. (HSCT, hematopoietic stem cell transplantation.)

Nonpharmacologic Therapy

► Autologous Stem Cell Transplantation

9 Autologous stem cell transplantation results in higher response rates and extends overall survival compared with those who receive conventional therapy such as vincristine–doxorubicin–dexamethasone (VAD). Because overall median survival is prolonged from 42 to 54 months, stem cell transplant should be considered in all patients who can tolerate high-dose chemotherapy.^{34,35} High-dose melphalan is the most common preparative regimen. Two sequential transplants (tandem transplants) improve overall survival in patients who do not have a good partial response after

one transplant.³¹ The use of maintenance therapy after autologous transplantation with thalidomide or bortezomib may be used in select patients to extend progression-free survival.³³ It should be noted that the studies supporting the use of transplant were done before the development of many of the novel agents used in the treatment of myeloma; thus, the future role of stem cell transplantation may evolve.

Pharmacologic Therapy (Table 96–4)

► Conventional-Dose Chemotherapy

When patients present with symptomatic disease, they are started on therapy. The use of conventional-dose chemotherapy

Table 96–4

Drugs Used in Multiple Myeloma

Drug	Adverse Effects	Comments	Renal Dosing	Hepatic Dosing
Bortezomib (Velcade)	Constipation; decreased appetite; asthenia; fatigue; fever; thrombocytopenia; dose related, reversible peripheral neuropathy	Dose: 1.3 mg/m ² IV bolus twice weekly for 2 weeks; week 3 off; repeat SC administration is being studied Consider herpes zoster prophylaxis with daily acyclovir	No reductions	Bilirubin greater than 1.5 × the upper limit of normal: reduce dose to 0.7 mg/m ²
Dexamethasone	Hyperglycemia, edema, adrenal cortical insufficiency	Dose given PO once daily	No reductions	No reductions
Doxorubicin (Adriamycin)	Myelosuppression; alopecia; cumulative dose-limiting toxicity: myocardium damage	Given in combination with VAD	No reductions	Bilirubin 1.2–3 mg/dL (21–51 μmol/L): 50% reduction in dose Bilirubin 3.1–5 mg/dL (53–85 μmol/L): 75% reduction in dose Bilirubin greater than 5 mg/dL (85 μmol/L): use with caution
Lenalidomide (Revlimid)	Possible birth defects (because it is an analogue of thalidomide), neutropenia, thrombocytopenia, DVT, PE, pruritus, fatigue	Dose: 25 mg taken with water once daily Women of childbearing age must use two forms of contraception before and during use Pregnancy test must be taken before and during use Enrollment into monitoring program required	CrCl 30–60 mL/min (0.50–1.00 mL/s): 10 mg/day CrCl less than 30 mL/min (less than 0.50 mL/s): 15 mg every 48 hours Dialysis and CrCl less than 30 mL/min (less than 0.50 mL/s): 5 mg every 24 hours given after dialysis	No reductions
Melphalan (Alkeran)	Myelosuppression, secondary malignancies, pulmonary fibrosis, sterility, alopecia	Dose given PO once daily IV formulation used for stem cell transplantation	No recommendation but may consider an initial dose reduction	No reductions
Thalidomide (Thalomid)	Severe birth defects, peripheral neuropathy, DVT, somnolence, constipation	Titrate initial doses; doses are taken nightly Women of childbearing age must use two forms of contraception Pregnancy test must be taken before and during use Enrollment into monitoring program required	No reductions	No reductions
Vincristine (Oncovin)	Dose-limiting toxicity: peripheral neuropathies; paresthesias, constipation, alopecia	Given in combination with doxorubicin and dexamethasone (VAD)	No reductions	Bilirubin greater than 3 mg/dL (51 μmol/L): 50% reduction in dose

DVT, deep venous thrombosis; IV, intravenous; PE, pulmonary embolism; PO, oral; SC, subcutaneous; VAD, vincristine–dexamethasone.

has declined with the advent of immunomodulators and bortezomib. The combination of melphalan and prednisone (MP) was once the most common initial treatment combination for myeloma. Today, MP is often used in combination therapy with immunomodulators as front-line therapy for patients who are not eligible for transplant. VAD is another combination chemotherapy regimen that was often used in patients with myeloma. VAD may be an alternative option for induction therapy in patients who are transplant eligible because it avoids the alkylating agent melphalan, thus minimizing the risk of secondary malignancies that are associated with chronic alkylating therapy.³²

► **Thalidomide (Thalomid)**

Thalidomide as monotherapy or combination therapy is effective in the treatment of multiple myeloma. The precise mechanism of action of thalidomide is unknown, but its antimyeloma activity may be attributable to its **antiangiogenic** and anticytokine properties.³⁶ **10** *The combination of thalidomide, bortezomib, and dexamethasone has emerged as the one of the most commonly used induction regimens in the treatment of transplant-eligible patients with myeloma.* Thalidomide and steroid combinations produce responses in 60% to 80% of previously untreated patients.³⁷ Responses can be improved to 94% with the addition of a third agent, bortezomib, but adding a fourth agent does not further improve responses.^{38,39} The addition of thalidomide to MP also improves overall response and overall survival in newly diagnosed patients.⁴⁰ This combination (MPT) can be used as initial therapy in patients who are not transplant eligible. Common side effects of thalidomide therapy include somnolence, constipation, peripheral neuropathy, and deep venous thrombosis (DVT). Standard dose warfarin or low-molecular-weight heparins are recommended to prevent DVT.^{34,41} There are substantial teratogenic effects of thalidomide if it is used during pregnancy, so distribution of the drug is closely monitored through the STEPS program.

► **Lenalidomide (Revlimid)**

Lenalidomide is an immunomodulating agent related to thalidomide that is approved for the treatment of relapsed myeloma in combination with dexamethasone. **10** *Lenalidomide and dexamethasone with or without bortezomib may be used for induction therapy before a transplant.* Phase III trials showed that lenalidomide in combination with dexamethasone produced higher response rates and a longer time to progression than dexamethasone alone in relapsed and refractory myeloma.^{34,42} Low-dose dexamethasone with lenalidomide offers improved overall survival compared with high-dose dexamethasone.⁴³ The combination of melphalan, prednisone, and lenalidomide (MPL) may be used as initial therapy in patients not eligible for transplant. The response rate appears to be quite high at 81% with 24% achieving a CR.⁴² A randomized trial comparing MPL with MPT is currently underway. Lenalidomide has a more favorable safety profile over thalidomide because it

lacks the common side effects of somnolence, constipation, and peripheral neuropathy. Significant adverse effects of lenalidomide include myelosuppression and DVT. Similar to thalidomide–dexamethasone, DVT prophylaxis is recommended with lenalidomide–dexamethasone combinations.^{34,41} Stem cells should be collected shortly after starting lenalidomide because CD34-positive stem cell counts tend to decrease with prolonged lenalidomide exposure.³⁴ In addition, maintenance lenalidomide after stem cell transplantation has been associated with an increased incidence of secondary malignancies, so alternatives such as thalidomide should be considered.³⁴

► **Bortezomib (Velcade)**

Bortezomib is a **proteasome** inhibitor approved for the treatment of multiple myeloma. Proteasome inhibitors induce myeloma cell death by modulating **nuclear factor kappa-B** products, including inflammatory cytokines and adhesion molecules that support myeloma cell growth. Bortezomib also disrupts the myeloma microenvironment by inhibiting the binding of myeloma cells to the bone marrow stromal cells.³¹ Initially approved in the treatment of relapsed disease, bortezomib produces response rates of 35% in heavily pretreated individuals.⁴⁴ **10** *Today, bortezomib is frequently given in combination with dexamethasone and thalidomide or lenalidomide as induction therapy before a transplant.* The response rates have been reported as high as 97% in newly diagnosed myeloma.³⁰ Bortezomib can also be given in combination with prednisone and melphalan (MPB) in patients who are not transplant eligible. Superior response rates and survival are seen with the combination of MPB compared with MP.⁴² Side effects of bortezomib include fatigue, nausea, peripheral neuropathy, and hematologic effects.⁴² The incidence of DVT is lower than the immunomodulators; thus, bortezomib does not routinely require prophylactic anticoagulation. However, prophylactic acyclovir should be considered to reduce the risk of herpes zoster infections.³⁴

► **Bisphosphonates**

Bone disease is a common manifestation of multiple myeloma. Bisphosphonates should be initiated in symptomatic patients with bone lesions to slow osteopenia and reduce the fracture risk associated with the disease. Pamidronate 90 mg and zoledronic acid 4 mg have equivalent efficacy in the management of osteolytic lesions.⁴⁶ The use of zoledronic acid decreases pain and bone-related complications and improves quality of life. Osteonecrosis of the jaw is a major concern with bisphosphonate therapy. Risk factors are unclear, but osteonecrosis of the jaw is more common in patients receiving IV administration of bisphosphonates and having dental procedures performed. It is recommended that patients have dental restoration work before starting bisphosphonate therapy. Several consensus guidelines have been published on the use of bisphosphonates and myeloma. Recommendations on the duration of therapy and which bisphosphonate to use have largely been left up to the practitioner.^{47,48}

Patient Care and Monitoring

Chronic Myeloid Leukemia

1. Patients are placed on a TKI at the time of diagnosis. Imatinib, dasatinib, and nilotinib are all viable options for first-line therapy. If patients do not have a complete cytogenetic response at 6 to 12 months, then either dasatinib or nilotinib should be tried if imatinib was used in the first line setting.
2. Patients should be monitored for a dose-dependent myelosuppression, gastrointestinal intolerance, edema, and rash. Drug interactions with CYP 3A4 inducers are clinically important and should be monitored.
3. Patients should avoid acid suppression while taking dasatinib, and the QT interval should be monitored while the patient is taking dasatinib and nilotinib.
4. HSCT may be considered when the patient fails to respond or is intolerant to TKIs. Ideal candidates include younger patients in chronic phase CML that have an HLA-matched related or unrelated donor.

Chronic Lymphocytic Leukemia

1. Observation is a reasonable approach if the patient is asymptomatic.
2. Monitor WBC count and monitor for signs of infection if the patient is receiving fludarabine-based chemotherapy.
3. Monitor for infusion reactions with rituximab, ofatumumab and alemtuzumab. Premedicate with

acetaminophen and diphenhydramine to prevent these reactions. IV corticosteroid should also be used with ofatumumab. Titrating the rate of infusion may lessen the risk of severe reactions.

4. Prophylactic trimethoprim–sulfamethoxazole and an antiviral (acyclovir, famciclovir, or valacyclovir) are recommended for all patients receiving alemtuzumab. Consider adding an antifungal (fluconazole) if warranted.

Multiple Myeloma

1. During therapy, monitor myeloma monoclonal protein in urine and serum, renal function, hemoglobin, and platelets. Caution using NSAIDs in patients with renal dysfunction.
2. Monitor peripheral neuropathy with bortezomib, thalidomide and vincristine. Dose reduction may be necessary to prevent permanent neurologic damage.
3. Prophylactic anticoagulation is prescribed with thalidomide or lenalidomide with dexamethasone.
4. Bisphosphonates should be initiated in symptomatic patients. Renal function must be monitored. Patients may need pain medication for bone pain.
5. If a reduction in myeloma protein is not seen with one chemotherapy regimen, another regimen should be used

OUTCOME EVALUATION

Newly diagnosed, asymptomatic patients with myeloma may be observed without treatment. This asymptomatic period may last for months to a couple years. All patients with multiple myeloma become symptomatic, and when this occurs, treatment is required. All patients should be evaluated for an autologous stem cell transplant. For patients who are eligible for transplant, induction therapy often consists of thalidomide or lenalidomide, bortezomib, and dexamethasone. For those patients who are not transplant eligible, therapy may consist of MPT, MPB, or MPL. Nearly all patients progress at some point, and second-line therapy usually includes bortezomib. Monthly bisphosphonates should be given to patients who have bone lesions with the hope of reducing pain and fractures.

WALDENSTRÖM MACROGLOBULINEMIA

Waldenström macroglobulinemia is a rare immunoglobulin disorder that is associated with non-Hodgkin's lymphoma. Approximately 4 in 1 million individuals are affected with the disease. Waldenström macroglobulinemia is characterized by an elevation of serum immunoglobulin M and involvement

of the lymph nodes, bone marrow, and spleen. Patients are typically asymptomatic at the time of diagnosis, with the disease being discovered by routine laboratory examination. Similar to indolent lymphomas, the watch and wait approach is used for asymptomatic patients. Symptomatic patients experience anemia, fatigue, hepatosplenomegaly, lymphadenopathy, and hyperviscosity syndrome.⁴⁹ When these symptoms arise, treatment is necessary with the goal being palliation. Systemic therapy includes alkylating agents, nucleoside analogs, rituximab, thalidomide, or bortezomib. Treatment is often continued until a desired response (reduction in symptoms) is achieved. **Plasmapheresis** may be required in addition to systemic therapies to alleviate symptoms associated with hyperviscosity syndrome.⁵⁰

Abbreviations Introduced in This Chapter

CD	Cluster of differentiation
CLL	Chronic lymphocytic leukemia
CML	Chronic myelogenous leukemia
CR	Complete response
DVT	Deep venous thrombosis
FISH	Fluorescence in situ hybridization
HLA	Human leukocyte antigen

HSCT	Hematopoietic stem cell transplantation
MGUS	Monoclonal gammopathy of unknown significance
MP	Melphalan–prednisone
MPB	Melphalan–prednisone–bortezomib
MPL	Melphalan–prednisone–lenalidomide
MPT	Melphalan–prednisone–thalidomide
NCCN	National Comprehensive Cancer Network
Ph	Philadelphia chromosome
Q-PCR	Qualitative and quantitative polymerase chain reaction
TKI	Tyrosine kinase inhibitor
VAD	Vincristine–doxorubicin–dexamethasone
WBC	White blood cell

Self-assessment questions and answers are available at REF <http://www.hpharmacotherapy.com/pp.html>.

Malignant Lymphomas

Keith A. Hecht and Susanne E. Liewer

LEARNING OBJECTIVES

● **Upon completion of the chapter, the reader will be able to:**

1. Discuss the underlying pathophysiologic mechanisms of the lymphomas and how they relate to presenting symptoms of the disease.
2. Differentiate the pathologic findings of Hodgkin's lymphoma (HL), follicular indolent non-Hodgkin's lymphoma (NHL), and diffuse aggressive NHL and how this information yields a specific diagnosis.
3. Describe the general staging criteria for the lymphomas and how it relates to prognosis; evaluate the role of the prognostic systems such as the International Prognostic Score for HL, the Follicular Lymphoma International Prognostic Index (FLIPI), and the International Prognostic Index (IPI) for diffuse, aggressive NHL.
4. Compare and contrast the treatment algorithms for early and advanced stage disease for HL.
5. Delineate the clinical course of follicular indolent and diffuse aggressive NHL and the implications for disease classification schemes and treatment goals.
6. Outline the general treatment approach to follicular indolent and diffuse aggressive NHL for localized and advanced disease.
7. Interpret the current role for monoclonal antibody therapy in NHL.
8. Assess the role of autologous hematopoietic stem cell transplantation (SCT) for relapsed lymphomas.

KEY CONCEPTS

- 1 There are two broad classifications of lymphoma, Hodgkin's lymphoma (HL) and non-Hodgkin's lymphoma (NHL), and both contain numerous histologic subtypes that are pathologically distinct disease entities.
- 2 Specific pathologic characteristics distinguishing HL from NHL include morphology, cell surface antigens, and chromosomal mutations.
- 3 Classic signs and symptoms of the lymphomas include lymphadenopathy and B symptoms (i.e., fever, night sweats, and weight loss).
- 4 The diagnosis of malignant lymphomas is established by tumor biopsy sample, analysis of the biopsy tissue, and determination of the extent of the disease in the patient.
- 5 The goal of treatment of HL is cure for all stages of disease and first relapse.
- 6 Initial treatment of HL includes combination chemotherapy, these regimens have demonstrated efficacy and have an acceptable long-term toxicity profile.
- 7 Follicular indolent NHL is incurable, so therapy goals focus on inducing and maintaining remission duration while minimizing treatment-related toxicities.
- 8 Diffuse, aggressive NHL centers on curative-intent therapy using anthracycline-based combination chemotherapy for initial treatment and high-dose chemotherapy with autologous stem cell transplantation for relapsed disease.
- 9 The recombinant monoclonal antibody rituximab is an effective treatment option for patients with B-cell origin CD20+ NHL as a single agent and enhances the efficacy of combination chemotherapy regimens.

INTRODUCTION

The malignant lymphomas are a clonal disorder of hematopoiesis with the primary malignant cells consisting of lymphocytes of B-, T-, or natural killer (NK) cell origin. These cells originate from a small population of lymphocytes that have undergone malignant transformation from a series of genetic mutations. Lymphoma cells predominate in the lymph nodes; however, they can infiltrate lymphoid and nonlymphoid tissues, such as the bone marrow, central nervous system (CNS), gastrointestinal (GI) tract, liver, mediastinum, skin, and spleen. An overview of the lymph node regions is depicted in **Figure 97-1**. **1** There are two broad classifications of lymphoma, *Hodgkin's lymphoma (HL)* and *non-Hodgkin's lymphoma (NHL)*, and both contain numerous histologic subtypes that are pathologically distinct disease entities. HL is distinguished from NHL by the presence of the pathognomonic Reed-Sternberg (RS) cell. Other lymphomatous disease entities are classified as types of NHL.

The clinical course varies widely among histologies of HL and NHL. More aggressive lymphoma subtypes are highly

proliferating tumor cells that require aggressive therapeutic intervention with chemotherapy, radiation therapy, or both. By contrast, certain subtypes of NHL are characterized by a disease course that flares and remits intermittently over a period of years regardless of treatment.

EPIDEMIOLOGY AND ETIOLOGY

Hodgkin's Lymphoma

Approximately 8,830 new cases of HL were estimated to be diagnosed in the United States in 2011, with 1,300 deaths attributed to the disease.¹ The incidence of HL is bimodal, with its peaks occurring in the third decade of life and in patients older than 50 years of age.² The precise cause of HL is unknown, but certain associations have been reported and provide insight about into possible etiologic factors. Epstein-Barr virus (EBV) has been associated with HL in various studies. The viral genome has been detected in RS cells in up to 40% of cases in developed countries. Other viruses (cytomegalovirus, human herpesviruses, and adenoviruses) have been associated with HL; however, conflicting data have been reported regarding their association with HL.² The risk of HL has also been associated with HIV. However, the reason for this association remains unclear. Other possible risk factors identified include woodworking and a familial history of HL.

Non-Hodgkin's Lymphoma

Approximately 66,360 cases of NHL were estimated to be diagnosed in the United States in 2011, with an estimated 20,620 deaths. These figures represent a stabilization in the incidence of NHL since 1998 that follows a dramatic increase that had nearly doubled the number of cases in the United States since 1950.^{1,3} The previous increase is thought to have been related to the development of aggressive NHL in young men with HIV, although the overall increase is independent of HIV disease, particularly for patients older than 65 years of age. The median age for diagnosis is 50 years, although children and young adults may also be affected. The etiology of certain aggressive NHL subtypes is related to specific endemic geographic factors. Follicular or low-grade lymphoma is more common in the United States and Europe and is relatively uncommon in the Caribbean, Far East, Middle East, or Africa. The human T-cell leukemia virus I induces T-cell lymphoma or leukemia in both Japan and the Caribbean. Kaposi's sarcoma-associated herpes virus, or human herpes virus 8, and hepatitis C have been implicated in inducing NHL. Lymphomas of the GI tract are more prevalent in patients with celiac sprue, inflammatory bowel disease, or *Helicobacter pylori* infection. The incidence of Burkitt's NHL is seven cases per 100,000 people in Africa compared with 0.1 per 100,000 in the United States. Malaria or EBV is thought to contribute to the chronic B-lymphocyte stimulation that leads to malignant transformation in Burkitt's NHL. EBV has been shown to transform lymphocytes in vitro to a monoclonal malignant

FIGURE 97-1. Representation of the anatomic regions used in the staging of Hodgkin disease. (From Rosenberg SA. Staging of Hodgkin disease. *Radiology* 1966;87:146.)

population, which is believed to drive the development of disease in patients who have received a solid organ transplant or bone marrow transplant or have other chronic immunosuppressed states. Patients with congenital diseases such as Wiskott-Aldrich syndrome, common variable hypogammaglobulinemia; X-linked lymphoproliferative syndrome; and severe combined immunodeficiency, including drug-induced immunosuppression, are also at risk.⁴ Environmental factors have been identified as contributing to the development of NHL. Certain occupations such as wood and forestry workers, butchers, exterminators, grain millers, machinists, mechanics, painters, printers, and industrial workers have a higher prevalence of disease. Industrial chemicals such as pesticides, herbicides, organic chemicals (e.g., benzene), solvents, and wood preservatives are also associated with NHL.

PATHOPHYSIOLOGY

- Pluripotent stem cells in the bone marrow are able to differentiate to both lymphoid and myeloid progenitor cells. Lymphoid progenitor cells undergo gene rearrangement to yield either B-cell or T-cell lineage precursor cells. Normal maturation for naive B cells includes expression of cell surface antibody or the cells typically undergo **apoptosis**. These cells are differentiated from other B cells, such as memory cells, by virtue of cell surface antigen (CD5⁺ or CD5⁻ and CD27⁻) and bound antibody (IgM⁺ and IgD⁺). When naive B cells recognize antigen with their cell surface antibody, they accumulate in the lymph nodes, spleen, or other lymphoid tissue. The DNA of these B cells is susceptible to three different types of genetic modification: **receptor editing**, **somatic hypermutation**, and class switching within the germinal center of the lymph node. Germinal centers are microanatomic structures located within lymph nodes that develop with clonal B-cell expansion secondary to antigen stimulation. Under normal circumstances, these genetic changes allow for adaptation of the immune system to the repeated exposure to environmental antigens.

Hodgkin's Lymphoma

The pathophysiology of HL is defined by the presence of the RS cell in a grouping of lymph nodes. The RS cell is a morphologically large cell with a multinucleated structure possessing pronounced eosinophilic nucleoli.⁵ In the affected lymph nodes, the RS cells are contained in a reactive milieu of B cells, T cells, plasma cells, eosinophils, and mast cells. It is believed this microenvironment is essential for the survival of RS cells.⁶

- RS cells are genetically derived preapoptotic germinal center B cells. The majority of these cells demonstrate numerous chromosome abnormalities.⁷ Despite their origin, RS cells have lost the expression of most B-cell markers. Common cell-surface antigens expressed by RS cells include CD30 and CD15, but other common B-cell antigens, such as CD20 are inconsistently expressed.⁸ The overexpression of a proliferative and antiapoptotic transcription factor nuclear

factor kappa-B (NF- κ B) is believed to contribute to the expansion and survival of RS cells.⁶

HL is classified into disease subtypes based on the number and morphologic appearance of RS cells and the background cellular milieu. These are listed in the World Health Organization (WHO) classification of lymphoid neoplastic diseases in **Table 97-1**.⁹ Nodular sclerosing is the most common form of HL, representing 70% of cases. It is more common in young adults and is marked by the presence of the RS variant cell, the lacunar cell. The second most common form of HL, accounting for approximately 20% of cases, is the mixed-cellularity variant, with others accounting for the

Table 97-1

WHO Classification of Lymphoid Neoplasms

B-Cell Neoplasms

Precursor B-cell neoplasm
 Precursor B-lymphoblastic leukemia/lymphoma
 Mature (peripheral) B-cell neoplasms
 B-cell chronic lymphocytic leukemia/small lymphocytic lymphoma
 B-cell prolymphocytic leukemia
 Lymphoplasmacytic lymphoma
 Splenic marginal zone B-cell lymphoma (+/- villous lymphocytes)
 Hairy cell leukemia
 Plasma cell myeloma/plasmacytoma
 Extranodal marginal zone B-cell lymphoma of MALT type
 Nodal marginal zone B-cell lymphoma (+/- monocytoid B cells)
 Follicular lymphoma
 Mantle cell lymphoma
 Diffuse large B-cell lymphoma
 Mediastinal large B-cell lymphoma
 Primary effusion lymphoma
 Burkitt's lymphoma/Burkitt's cell leukemia

T-Cell and NK-Cell Neoplasms

Precursor T-cell neoplasm
 Precursor T-lymphoblastic lymphoma/ALL
 Mature (peripheral) T-cell neoplasms
 T-cell prolymphocytic leukemia
 T-cell granular lymphocytic leukemia
 Aggressive NK cell leukemia
 Adult T-cell lymphoma/leukemia (HTLV1+)
 Extranodal NK/T-cell lymphoma, nasal type
 Enteropathy-type T-cell lymphoma
 Hepatosplenic gamma-delta T-cell lymphoma
 Subcutaneous panniculitis-like T-cell lymphoma
 Mycosis fungoides/Sézary syndrome
 Anaplastic large-cell lymphoma, T/null cell, primary cutaneous type
 Peripheral T-cell lymphoma, not otherwise characterized
 Angioimmunoblastic T-cell lymphoma
 Anaplastic large-cell lymphoma, T/null cell, primary systemic type

HL

Nodular lymphocyte-predominant HL
 Classical HL
 Nodular sclerosing HL (grades 1 and 2)
 Lymphocyte-rich classical HL
 Mixed cellularity HL
 Lymphocyte depletion HL

ALL, acute myeloid leukemia; HL, Hodgkin's lymphoma; MALT, mucosa-associated lymphoid tissue; NK, natural killer.

Table 97-2	
Negative Prognostic Factors for HL	
International Prognostic Score—Advanced HL	
Albumin less than 4 g/dL (40 g/L)	
Hemoglobin less than 10.5 g/dL (105 g/L; 6.52 mmol/L)	
Male sex	
Age older than 45 years	
Stage IV disease	
WBC greater than or equal to 15,000/mm ³ ($15 \times 10^9/L$)	
Lymphocytopenia (count less than 600/mm ³ ($0.6 \times 10^9/L$), less than 8% (0.08) of WBC count, or both)	

WBC, white blood cell.

remainder of cases.⁸ Factors identified as negative disease prognostic indicators are listed in **Table 97-2**. Patients with advanced HL who have at least four of the criteria may warrant more aggressive treatment.¹⁰

Non-Hodgkin's Lymphoma

The pathophysiology of NHL is governed by numerous environmental and genetic events culminating with a monoclonal population of malignant lymphocytes. B cells represent the cells of origin in excess of 90% of cases of NHL. **Figure 97-2** outlines normal B-cell maturation with accompanying cell-surface antigens. Evolving data are correlating chromosomal mutations with specific disease subtypes. Cytogenetic abnormalities involving translocations of antigen receptor genes are prevalent in NHL. These include T-cell receptor genes in T-cell lymphomas and immunoglobulin genes in B-cell lymphomas. The principal defect appears to be an error in the assembly of the regulatory gene segment of an antigen receptor gene, resulting in inappropriate binding to an **oncogene**. This results in dysregulation of cell growth and proliferation, leading to the malignant clone of lymphocytes. Oncogenes that have been identified in different lymphomatous diseases include

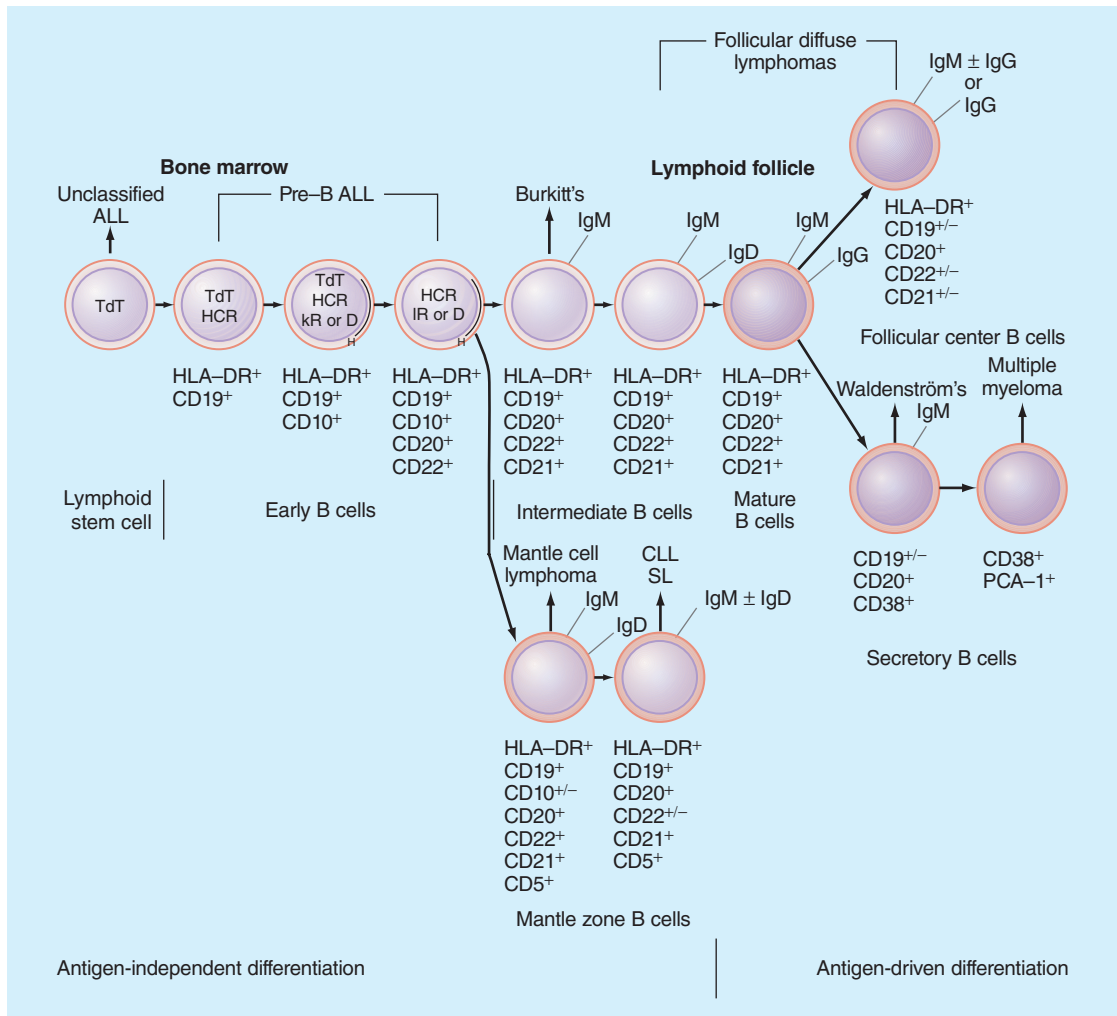

FIGURE 97-2. Pathway of normal B-cell differentiation and relationship to B-cell lymphocytes. (ALL, acute lymphoblastic leukemia; HLA, human leukocyte antigen; HCR, human chemokine receptor; Ig, immunoglobulin; TdT, terminal deoxynucleotidyl transferase.) (From Armitage JO, Longo DL. Malignancies in lymphoid cells. In: Kasper DL, Braunwald E, Fauci AS, et al., eds. Harrison's Principles of Internal Medicine, 16th ed. New York: McGraw-Hill, 2005:544.)

c-myc, a regulator of gene transcription; *bcl-1* important in the regulation of mitosis; *bcl-2*, a regulator of apoptosis; and *bcl-3*, *NF-κB*, and *bcl-6*, which regulate cell differentiation.¹¹ Classic translocations for NHL include t(8;14) in Burkitt's lymphoma, t(14;18) in follicular lymphomas, t(11;14) mantle cell lymphoma, and t(11;18)/t(1;14) in mucosa-associated lymphoid tissue (MALT).

2 **Characterization of the morphology of the lymphocytes, the reactivity of the other cells in the lymph node, and the lymph node architecture is essential in obtaining a diagnosis and predicting disease course.** The nodal presentation of NHL is divided into two main categories: follicular, corresponding to low-grade disease, and diffuse, corresponding to aggressive disease. A follicular disease pattern in the inspected lymph node is indicative of a more indolent or low-grade progression that has survival measured in years if left untreated. In contrast, a diffuse pattern of lymph node infiltration is a marker of highly aggressive disease, resulting in death within weeks to months if untreated. Follicular NHL is the most common indolent subtype, comprising 22% of NHL cases, in which diffuse, large B-cell lymphoma is the most common aggressive histology, 31% of NHL. The cells of origin for follicular NHL tend to be more mature, nondividing lymphocytes, whereas aggressive NHL is derived from rapidly dividing lymphoid precursors, such as immunoblasts, lymphoblasts, and centroblasts. A unique feature of the biology of NHL is that follicular low-grade histologies can undergo further malignant transformation, transforming further into a diffuse, large B-cell lymphoma population. This syndrome, called *Richter's transformation*, may occur in up to 20% of follicular low-grade lymphoma patients and involves multiple genetic events, including abnormalities of chromosomes 11 and 12 and tumor suppressor genes. Richter's transformation may also occur in patients with chronic lymphocytic leukemia, which results in a transformation to diffuse lymphoma.¹²

The classification of NHL has undergone several revisions as the histology, molecular biology, and clinical course of the disease have been more precisely defined. Classification schemes such as the *Working Formulation* categorize disease on aggressiveness into three general categories: low grade—survival estimated in years without treatment, intermediate grade—survival estimated in months without treatment, and high grade—survival measured in days to weeks for untreated disease. This scheme is limited in its clinical applicability because the large number of distinct clinical diseases that are not categorized by this classification. The Working Formulation classification of NHL and diseases unclassifiable by that system are presented in [Table 97-3](#). The WHO has updated a classification scheme published in 1994 by the International Lymphoma Study Group called the *Revised European American Classification of Lymphoid Neoplasms* (REAL) that broadly categorizes histologic subtypes into B- and T-cell subtypes. This newer classification incorporates immunologic morphologic and genetic and clinical attributes of various NHL histologies.

Prognostic factors present at diagnosis have been identified for NHL. Age, the presence of B symptoms, performance status,

Table 97-3

Working Formulation for NHL

Classification	Immunophenotype
Low Grade	
Small lymphocytic	100% B cell
Follicular, small cleaved cell	100% B cell
Follicular, mixed small cleaved cell and large cell	100% B cell
Intermediate Grade	
Follicular, large cell	100% B cell
Diffuse, small cleaved cell	75% B cell, 20% T cell, 5% null cell
Diffuse, mixed small and large cell	75% B cell, 20% T cell, 5% null cell
Diffuse, large cell	70% B cell, 20% T cell, 10% null cell
Diffuse, large cell	70% B cell, 20% T cell, 10% null cell
High Grade	
Immunoblastic	50% B cell, 50% T cell
Lymphoblastic	5% B cell, 95% T cell
Diffuse, small noncleaved cell	100% B cell

^aLymphomas not included in the working formulation: *Mycosis fungoides*, mantle cell lymphoma, monocytoid B-cell lymphoma, mucosa-associated lymphoid tissue, anaplastic large cell lymphoma, angiocentric lymphoma, angioimmunoblastic lymphadenopathy, Castleman's disease, adult T-cell leukemia/lymphoma.

number of nodal and extranodal sites, lactate dehydrogenase (LDH) concentration, bulky disease (greater than 10 cm), advanced stage, and β_2 -microglobulin concentration have been shown to be important prognostic features in NHL. [Table 97-4](#) shows the International Prognostic Index (IPI), a predictive model for aggressive NHL to be treated with doxorubicin-containing chemotherapy regimens.¹³ This index is used as a tool for selecting therapy for patients who may warrant a more intense treatment regimen based on known poor prognostic factors. Additionally, patients with diffuse aggressive B-cell lymphoma that is of germinal center type carry a better prognosis than other patients.¹⁴ A model similar to the IPI, the Follicular Lymphoma International Prognostic Index (FLIPI), is used to help guide treatment decisions in follicular lymphoma.¹⁵

TREATMENT OF HL

Desired Outcome

Staging of HL with a standard classification is necessary to guide appropriate treatment. The number of involved sites, disease involvement on one or both sides of the diaphragm, localized or disseminated extranodal disease, and B symptoms are factors in assignment of stage. The Cotswold staging system, a revision of the original Ann Arbor classification, is outlined in [Table 97-5](#).¹⁶

Table 97-4

Negative Prognostic Factors for NHL**International Prognostic Index—Diffuse, Aggressive NHL**

Criteria	Risk Assessment	
Age 60 years or older	Risk group	Number of criteria
Stage III/IV disease	Low	0-1
Extranodal disease greater than one site	Low-intermediate	2
ECOG performance status 2 or greater	High-intermediate	3
Serum LDH greater than 1 × normal limit	High	4-5

Follicular Lymphoma International Prognostic Index

Criteria	Risk Assessment	
Age 60 years or older	Risk group	Number of criteria
Stage III/IV disease	Low	0-1
Hemoglobin less than 12.0 g/dL (120 g/L; 7.45mmol/L)	Intermediate	2
Serum LDH greater than 1 × normal limit	High	3 or more
Number of nodal sites greater than or equal to 5 ^a		

^aThe nodal map used in the Follicular Lymphoma International Prognostic Index is different than the nodal map used in conventional staging.

Table 97-5

Cotswold Staging Classification for Hodgkin Disease (1989 Revision of Ann Arbor Staging)^a

Stage	Description
I	Involvement of a single lymph node region or lymphoid structure (e.g., spleen, thymus, Waldeyer's ring)
II	Involvement of two or more lymph node regions on the same side of the diaphragm; the number of anatomic sites is indicated by a subscript
III	Involvement of lymph node regions or structure on both sides of the diaphragm
III ₁	With or without involvement of splenic, hilar, celiac, or portal nodes
III ₂	Involvement of para-aortic, iliac, or mesenteric
IV	Involvement of extranodal site(s) beyond that designated E

Designations Applicable to All Stages

A	No symptoms
B	Fever, night sweats, and weight loss
X	Bulky disease: greater than one-third the width of the mediastinum or greater than 10 cm maximal dimension of nodal mass
E	Involvement of a single extranodal site, contiguous or proximal to a known nodal site
CS	Clinical stage
PS	Pathologic stage

^aAlso used for non-Hodgkin's lymphoma.

Clinical Presentation and Diagnosis of Malignant Lymphomas**General**

Nonspecific; can range from an asymptomatic patient with a less aggressive lymphoma to a patient who is gravely ill with advanced disease

3 Symptoms

- Lymphadenopathy, generally in the cervical, axillary, supraclavicular, or inguinal lymph nodes
- Splenomegaly
- Shortness of breath, dry cough, chest pressure (patients with mediastinal mass)
- GI complications (nausea, vomiting, early satiety, constipation, and diarrhea)
- Back, chest, or abdominal pain

Signs

- Fever^a
- Night sweats^a
- Weight loss greater than 10% within last 6 months^a
- Pruritus

Laboratory Tests

- LDH
- ESR

- Serum chemistries
- CBC with differential

4 Other Diagnostic Tests

- Physical exam with careful attention to lymph node inspection
- Imaging—chest x-ray, chest CT, abdominal or pelvic CT; integrated PET and CT is recommended as part of the initial workup
- Bone marrow biopsy
- Biopsy of suspected lymph node(s)—either open lymph node biopsy (preferred) or core biopsy; fine-needle aspiration should only be performed if preferred biopsy methods are unobtainable
- Hematopathology evaluation of biopsy specimen—morphologic inspection, immunohistochemistry for cell surface antigens to characterize lymphoma cells, cytogenetic analysis

^aKnown collectively as B symptoms.

CBC, complete blood count; CT, computed tomography; ESR, erythrocyte sedimentation rate; LDH, lactate dehydrogenase; PET, positron emission tomography.

Patient Encounter 1, Part 1

A 63-year-old man with a medical history of hypertension and diabetes mellitus presents to the oncologist's office for suspicion of new onset lymphoma. He states that he was in his usual state of health until 3 months ago when he started experiencing fevers and night sweats.

A recent lymph node examination by his primary physician revealed palpable lymph nodes in the right axilla, right inguinal, and right cervical areas. He indicates he has no impairment of his activities of daily living. Complete evaluation, including imaging, laboratory studies, and excisional lymph node biopsy, revealed stage III diffuse large B-cell lymphoma. Complete blood count and chemistry panel were unremarkable. The patient's lactate dehydrogenase was 2300 IU/L (38.3 μ kat/L).

Based on the information provided, what is his International Prognostic Index score, and how does it impact treatment selection?

5 The principal goal in treating HL is to cure the patient of the primary malignancy. HL is sensitive to both radiation and chemotherapy, resulting in an 80% rate of cure with modern therapy. Treatment strategy is generally divided into approaches for early stage I/II localized disease and stage III /IV advanced disease. Patients with early stage I/II disease are further classified into favorable, unfavorable with bulky disease, and unfavorable with nonbulky disease. Regardless of the stage of the disease, all patients are treated with curative intent. Other goals during treatment include:

- Complete resolution of symptoms of disease
- Minimization of acute and long-term treatment-related toxicity
- Incorporation of supportive care measures to optimize quality of life during chemotherapy and/or radiation therapy
- Selection of palliative therapy for refractory disease.

Nonpharmacologic Therapy

Radiation therapy is an effective single agent in the treatment of HL and has cured patients of their disease. Historically, patients with favorable early stage I/II disease were treated with subtotal lymphoid radiation as the only modality of therapy. However, the long-term toxicities associated with the larger fields of irradiation have precluded the use of radiation therapy alone. Current treatment strategies combine radiation therapy with chemotherapy. This has been reported to reduce the irradiated volume and dose as well as the number of cycles of chemotherapy.

Historically in the treatment of HL, the radiation fields were large and often included the lungs, liver, heart, and breast. Today, the use of involved-field radiotherapy (IFRT) limits radiation to the involved area. It is estimated that

compared with larger radiation areas such as total lymphoid irradiation, the involved field will reduce the volume by more than 80%. In addition to the smaller radiation volumes, other organs such as the breast, heart, and lungs have reduced exposure.¹⁷

Treatment with radiotherapy produces significant toxicity. Both acute and late effects of radiotherapy occur. Acute effects of mantle-field irradiation include nausea, vomiting, anorexia, xerostomia, dysgeusia, pharyngitis, dry cough, fatigue, diarrhea, and rash. Prophylaxis with antiemetics such as dexamethasone or prochlorperazine helps to prevent or treat nausea. These effects generally are transient and resolve shortly after completion of treatment. Delayed effects from radiotherapy are more concerning in that they may be permanent and present months to years after therapy is complete. Pneumonitis, pericarditis, hypothyroidism, infertility (with pelvic field irradiation), coronary artery disease, deformities in bone and muscle growth in adolescents and children, herpes zoster reactivation, **Lhermitte's sign**, and secondary malignancies are not uncommon. Patients cured with radiotherapy are at increased risk for breast cancer, lung cancer (particularly in smokers), stomach cancer, melanoma, and NHL depending on the involved radiation field.

Pharmacologic Therapy

► Early Stage Disease

6 Initial treatment of HL includes combination chemotherapy, these regimens have demonstrated efficacy and have an acceptable long-term toxicity profile. Combined modality therapy of ABVD (doxorubicin, bleomycin, vinblastine, and dacarbazine) (2–4 cycles) plus 20 to 30 Gy (Gray, the absorbed radiation dose) of IFRT or Stanford V chemotherapy (2 cycles) plus 30 Gy of IFRT is the preferred treatment of patients with favorable stage I/II HL. Patients with favorable disease have: an erythrocyte sedimentation rate (ESR) less than 50 mm/h, no extralymphatic lesions, and one or two lymph nodes involved. Only patients who are unable to tolerate combination chemotherapy because of comorbidities should be treated with radiation alone. Restaging should occur after a minimum of two cycles of chemotherapy. IFRT should be initiated within 3 weeks and is recommended for all patients who achieve a complete response (CR) or a partial response (PR). After completion of IFRT, no further treatment is necessary for patients with a CR, but further restaging is required for patients with PR to therapy.

ABVD or Stanford V followed by IFRT is recommended for patients with unfavorable, bulky disease. Two cycles of ABVD are given before restaging. For patients with a CR, an additional two to four more cycles of ABVD are given before IFRT without restaging between cycles. Patients with a PR will receive 2 cycles of chemotherapy followed by restaging for up to 6 total cycles of chemotherapy. If there is a chemotherapy response (CR or PR), patients then receive IFRT followed by end of treatment restaging to determine disease response. The use of the Stanford V regimen should

Table 97-6

Common Treatment Regimens in HL**MOPP—Every 28 Days**

Mechlorethamine 6 mg/m² IV × 1, days 1 and 8
 Vincristine 1.4 mg/m² IV × 1, days 1 and 8
 Procarbazine 100 mg/day PO, days 1–14
 Prednisone 40 mg/day PO, days 1–14

ABVD—Every 28 Days

Doxorubicin 25 mg/m² IV × 1, days 1 and 15
 Bleomycin 10 units IV × 1, days 1 and 15
 Vinblastine 6 mg/m² × 1, days 1 and 15
 Dacarbazine 375 mg/m² IV, days 1 and 15

MOPP/ABV Hybrid—Every 28 Days

Mechlorethamine 6 mg/m² IV × 1 day 1
 Vincristine 1.4 mg/m² IV × 1; day 1
 Procarbazine 100 mg orally daily, days 1–7
 Prednisone 40 mg orally daily, days 1–14
 Doxorubicin 35 mg/m² IV × 1 day 8
 Bleomycin 10 units IV × 1 day 8
 Vinblastine 6 mg IV × 1 day 8

Stanford V

Doxorubicin 25 mg/m² IV weeks 1, 3, 5, 7, 9, and 11
 Vinblastine 6 mg/m² IV weeks 1, 3, 5, 7, 9, and 11
 Mechlorethamine 6 mg/m² IV weeks 1, 5, and 9
 Etoposide 60 mg/m² IV weeks 3, 7, and 11
 Vincristine 1.4 mg/m² IV weeks 2, 4, 6, 8, 10, and 12
 Bleomycin 5 mg/m² IV weeks 2, 4, 6, and 8
 Prednisone 40 mg PO every other day for 12 weeks, start taper at week 10

BEACOPP (Escalated)—Every 21 Days

Bleomycin 10 mg/m² IV, day 8
 Etoposide 200 mg/m² IV daily × days 1–3
 Doxorubicin 35 mg/m², day 1
 Cyclophosphamide 1,200 mg/m² IV, day 1
 Vincristine 1.4 mg/m² IV, day 8
 Procarbazine 100 mg/m² orally daily, days 1–7
 Prednisone 40 mg orally daily, days 1–14

BCV (High-Dose with Autologous SCT)^a

Carmustine 400 mg/m² IV × 1 day
 Etoposide 800 mg/m² IV daily × 3 days
 Cyclophosphamide 1,800 mg/m² IV daily × 4 days

BEAM (High-Dose With Autologous SCT)^a

Carmustine 300 mg/m² IV × 1 day
 Etoposide 100–200 mg/m² IV every 12 hours × 4 days
 Cytarabine 100–200 mg/m² IV every 12 hours × 4 day
 Melfalan 140 mg/m² IV × 1 day

^aUsed for both Hodgkin's lymphoma and non-Hodgkin's lymphoma.

IV, intravenous; PO, oral; SCT, stem cell transplantation

be considered for patients with mediastinal disease, bulky disease, B symptoms, or unfavorable nonbulky disease.¹⁸ A listing of chemotherapy regimens used in HL is presented in [Table 97-6](#).

► Advanced Disease

Treatment of advanced stage (bulky disease greater than 10 cm, presence of B symptoms and/or stage III/IV) HL has been associated with treatment failure rates as high as 40%.¹⁹ Trials have focused on the use of multiagent chemotherapy for six to eight total cycles. The combination chemotherapy regimen MOPP (mechlorethamine, vincristine, procarbazine, and prednisone) is of historical significance because it was the first

chemotherapy regimen to cure HL when it was introduced in the 1960s. However, significant toxicity, including sterility and secondary leukemia, prompted investigators to evaluate other regimens. ABVD was compared with MOPP or ABVD–MOPP alternating.²⁰ This pivotal phase III Cancer and Leukemia Group B (CALGB) trial comparing these regimens in 361 patients with stage III/IV HL documented a higher CR in the ABVD containing arms (82% and 83%) versus MOPP (65%). There was increased hematologic toxicity in the MOPP arm. A recent update of the data shows the 18-year freedom from progression of 35% in the MOPP arm and 43% in the ABVD containing arms.²¹ A survival advantage has yet to be demonstrated. ABVD is now considered standard therapy for initial treatment of stage III or IV HL. Further information on ABVD may be found in [Table 97-7](#).

Additional regimens such as Stanford V and BEACOPP were developed to improve the outcomes of patients with advanced HL. The Stanford V regimen has demonstrated similar response rates to ABVD reported for event-free survival, overall survival, and toxicity. A dose-escalated regimen of BEACOPP (with colony-stimulating factor [CSF] support) was compared with a standard-dose of BEACOPP and also COPP (cyclophosphamide substituted for mechlorethamine for MOPP) alternating with ABVD. The dose-escalated BEACOPP was superior to the other arms in both freedom from treatment failure and overall survival at 10 years.²² However, the escalated BEACOPP regimen has been associated with a higher number of cases of secondary leukemia and an increased risk of infertility. Currently, neither BEACOPP regimen is widely used in the United States but is considered for advanced stage HL with a high number of poor prognostic factors.

Despite the high success rate in treating HL, approximately 5% to 10% of patients will be refractory to initial treatment and 10% to 30% will have disease relapse after CR. Patients relapsing after treatment should be offered additional therapy as durable responses have been reported in these patients. The duration of remission after chemotherapy remains a vital prognostic factor for likelihood of response to future treatment.²³ For healthy patients, the definitive therapy after relapse is high-dose chemotherapy with autologous stem cell transplantation (SCT).²⁴ This treatment offers a cure rate of approximately 40%.

Several studies have reported the importance of giving conventional chemotherapy before SCT. The purpose of the initial treatment after relapse is to decrease the tumor bulk before the high-dose chemotherapy. High-dose chemotherapy given to patients who are in first relapse has provided encouraging results. A series of 58 patients had a progression-free survival (PFS) of over 60% with a median follow-up of 2.3 years. The safety profile of autologous SCT continues to improve as refinements in supportive care are realized. Current estimates of mortality from autologous SCT for HL are approximately 5%. Morbidity commonly associated with the preparative regimens in HL, aside from infectious and bleeding complications, includes the additive pulmonary toxicity of bleomycin coupled with carmustine, inducing potentially fatal pulmonary pneumonitis.

Table 97-7

Practical Information for ABVD and CHOP

Regimen	Drug Class	Pharmacokinetics	Unique Toxicities
ABVD			
Doxorubicin	Anthracycline	Hepatic metabolism ^a	Cardiomyopathy Maximum lifetime dose, 550 mg/m ²
Bleomycin	Antitumor antibiotic	Renal clearance ^a	Pulmonary fibrosis Maximum lifetime dose, 400 mg
Vinblastine	Vinca alkaloid	CYP 3A4/5 metabolism ^a	Neuropathy, constipation
Dacarbazine	Alkylating agent	Hepatic metabolism ^a	Myelosuppression
CHOP			
Cyclophosphamide	Alkylating agent	Prodrug; CYP3A4/5, 2D6	Hemorrhagic cystitis
Doxorubicin	Anthracycline	Hepatic metabolism	Cardiomyopathy
Vincristine	Vinca alkaloid	CYP3A4/5	Neuropathy, constipation
Prednisone	Corticosteroid	100% oral bioavailability	Hyperglycemia, osteopenia See dose adjustments ^a (Chap. 88)

Patients who are not deemed candidates for high-dose chemotherapy with autologous SCT may receive standard multiagent salvage chemotherapy, such as etoposide, methylprednisolone, cytarabine, and cisplatin (ESHAP) or dexamethasone, cytarabine, and cisplatin (DHAP). Newer regimens such as GVD (gemcitabine, vinorelbine, and pegylated liposomal doxorubicin), IGEV (ifosfamide, gemcitabine, and vinorelbine) and GCD (gemcitabine, carboplatin, and dexamethasone) have also been effective for relapsed refractory HL. Recently, a new monoclonal antibody, brentuximab, was approved for the treatment of relapsed or refractory HL. This novel agent targets CD-30 and is linked to a microtubule-disrupting agent, monomethylauristatin E.²⁵

TREATMENT OF NHL

Desired Outcome

Treatment of NHL depends primarily on histologic subtype (follicular low grade versus diffuse aggressive) and staging (local stage I/II versus advanced stage III/IV) to guide appropriate treatment strategy with observation, chemotherapy, radiotherapy, or chemotherapy and radiation. The Cotswold modification of the Ann Arbor staging system for HL is generally used in NHL as well.

Treatment goals depend on the patient's specific subtype of NHL. For follicular low-grade NHL, the disease is considered to be incurable with standard therapies. There is a small prospect for cure using allogeneic SCT owing to the graft-versus-lymphoma effect of donor T cells. Many patients with follicular low-grade NHL are older than 60 years of age, making allogeneic SCT impractical because of the high treatment-related mortality for older patients.

7 The treatment goals for low-grade NHL include:

- Observation of the disease until the patient exhibits obvious progression that limits functional capacity or is life-threatening for low-grade NHL

- Treatment that induces the disease into remission with resolution of disease symptoms and manageable toxicity
- Judicious selection of treatment options to avoid long-term toxicity
- Prevention of infectious complications of treatment

The intent of treatment for patients with aggressive histologies is cure of the malignancy. Some histologic subtypes exhibit an aggressive clinical course and are not considered to be curable. These patients are still treated with curative-intent chemotherapy or may be considered for a clinical trial.

Nonpharmacologic Therapy

For patients with low-grade follicular NHL, deferring initiation of therapy until progression of disease is a standard approach. The median survival time is 6 to 10 years. Some patients may be asymptomatic for several years after initial diagnosis, making observation a reasonable front-line therapy for most of these patients. Radiation therapy has a limited role in NHL relative to HL. NHL is more often a systemic disease, and radiation typically has been reserved for consolidation therapy after chemotherapy in patients presenting with a large extranodal mass. However, IFRT without systemic therapy is a treatment option for patients with stage I/II follicular lymphoma.

For early-stage diffuse, aggressive NHL, combined-modality therapy was tested versus a longer course of chemotherapy.²⁶ Overall survival favored the CHOP–radiation arm for 5 years (82% versus 72%). There was a trend toward increased toxicity, particularly hematologic and cardiac toxicity, in the CHOP alone arm. The results of this trial have established combined-modality therapy as first-line treatment for early stage NHL. Unique presentations of NHL, such as primary CNS disease, may incorporate radiation into treatment algorithms.²⁷

Pharmacologic Therapy

► Follicular Low-Grade NHL

The management of low-grade lymphomas is an area of controversy, especially in patients who present with early stage disease. In patients with localized disease, observation alone can be an appropriate treatment strategy. Typical indications for treatment in this population include cytopenias, recurrent infections, threatened end-organ function, disease progression over at least 6 months, or patient preference. In these patients, single-agent chemotherapy such as fludarabine or bendamustine, a unique alkylating agent with a novel chemical structure, is often offered initially. In patients in whom a more rapid response is desired, such as patients with advanced disease, multiagent chemotherapy such as CVP (cyclophosphamide, vincristine, and prednisone or prednisolone) or CHOP may be used. These regimens, detailed in [Table 97-8](#), have not been associated with an improvement in overall survival, making it impossible to select an unequivocal first-line regimen.²⁸⁻³⁰

Rituximab has become an integral component in drug therapy for this disease. Rituximab is a chimeric monoclonal antibody that binds specifically to the antigen CD20 expressed on pre-B and mature B lymphocytes.³¹ NHL of B-cell origin expresses CD20 in greater than 90% of cases. CD20 is believed to play a role in early differentiation and activation of the cell cycle. Rituximab exerts its activity through antibody-dependent cytotoxicity activation of complement and induction of apoptosis. The initial clinical experience with rituximab involved 166 patients with CD20+ low-grade lymphoma treated with four doses of 375 mg/m² of rituximab weekly.³² The overall response rate was 48%, with CR in 6% of patients. The median follow-up of 12 months

demonstrated a median time to progression of 13 months by intent-to-treat analysis. These data established the role of rituximab as a viable treatment option in patients with indolent follicular NHL and is added to chemotherapy in most patients. Additionally, rituximab was examined as maintenance therapy administered every 8 weeks for to 2 years after rituximab-containing multiagent chemotherapy. Compared with observation, rituximab increased 3-year PFS (74.9 versus 57.6 months).³³

Novel strategies for treatment of low-grade lymphomas include the combination of monoclonal antibodies directed against CD20 with a radioactive moiety attached. Two such entities—ibritumomab-yttrium 90 and tositumomab-iodine¹³¹—are now approved by the Food and Drug Administration (FDA). The radiation component necessitates compounding both medications in a nuclear medicine pharmacy. Bendamustine has also been studied in a phase III trial of rituximab-refractory indolent lymphomas. Among 62 patients with follicular lymphoma, there was an overall response rate of 74% with a median duration of response of 9.2 months.³⁴ High-dose chemotherapy is being evaluated for low-grade follicular NHL, but its role is currently limited to clinical trials.

► Diffuse, Aggressive NHL

8 *The mainstay of therapy for diffuse, aggressive NHL has been the administration of anthracycline-based combination chemotherapy, which generally consists of four or more drugs. Therapy options for intermediate- and high-grade NHL generally are segregated between localized (stage I/II) and advanced (stage III/IV) disease. Combined-modality therapy with an abbreviated course of CHOP and local radiation is considered a standard of care for stage I/II disease.*

The standard therapy for disseminated disease since the 1970s has been CHOP. This regimen conferred a response of 50% to 60%, with long-term survival of approximately 30%. However, the 1980s were notable for the development of newer combination chemotherapy regimens that incorporated increasing numbers of agents with varying schedules. More complex chemotherapy regimens were shown in phase II trials to have higher response rates than CHOP. The CALGB designed a phase III randomized four-arm trial to assess the impact on survival of three more intensive regimens compared with CHOP.³⁵ This trial randomized 899 patients with intermediate- or high-grade (Working Formulation classification) NHL to CHOP or one of the three more intensive advanced-generation regimens. There were no significant differences in response rate or overall survival, which was consistent among all subgroups. Severe toxicity and death were higher in the advanced-generation treatment programs relative to CHOP. This pivotal trial has cemented CHOP as first-line chemotherapy in diffuse NHL.

Rituximab has also come to play a vital role in treating diffuse, aggressive NHL. A French study randomized patients 60 to 80 years of age with newly diagnosed diffuse, large B-cell NHL to either CHOP for eight cycles or CHOP plus

Table 97-8

Chemotherapy Regimens for Low-Grade, Follicular NHL

Fludarabine/Rituximab

Fludarabine 25 mg/m² IV days 1–5 every 28 days
Rituximab 375 mg/m² IV, days 1 and 5 of week 1 and 26; single dose 72 hours before fludarabine cycles 2, 4, and 6

Bendamustine/Rituximab—Every 28 Days

Bendamustine 90 mg/m² IV days 1 and 2
Rituximab 375 mg/m² IV, day 1

rCVP—Every 21 Days

Rituximab 375 mg/m² IV, day 1
Cyclophosphamide 750 mg/m² IV, day 1
Vincristine 1.4 mg/m² IV, day 1
Prednisone 40 mg/m² PO daily, days 1–5

rCHOP—Every 21 Days

Rituximab 375 mg/m² IV, day 1
Cyclophosphamide 750 mg/m² IV, day 1
Doxorubicin 50 mg/m² IV, day 1
Vincristine 1.4 mg/m² IV, day 1
Prednisone 100 mg/day PO, days 1–5

IV, intravenous; PO, oral.

Table 97-9

Treatment Regimens for Diffuse, Aggressive NHL**CHOP—Every 21 Days**

Cyclophosphamide 750 mg/m² IV, day 1
 Doxorubicin 50 mg/m² IV, day 1
 Vincristine 1.4 mg/m² IV, day 1
 Prednisone 100 mg orally daily, days 1–5

rCHOP—Every 21 Days

Rituximab 375 mg/m² IV, day 1
 Cyclophosphamide 750 mg/m² IV, day 1
 Doxorubicin 50 mg/m² IV, day 1
 Vincristine 1.4 mg/m² IV, day 1
 Prednisone 100 mg/day PO, days 1–5

m-BACOD—Every 21 Days

Methotrexate 200 mg/m² IV, days 8 and 15
 Bleomycin 4 mg/m² IV, day 1
 Doxorubicin 45 mg/m², day 1
 Cyclophosphamide 600 mg/m² IV, day 1
 Vincristine 1.4 mg/m² IV, day 1
 Dexamethasone 6 mg orally daily, days 1–5
 Leucovorin 10 mg PO every 6 hours, 24 hours after
 methotrexate × 8 doses

ProMACE-CytaBOM—Every 28 Days

Prednisone 60 mg/day PO, days 1–14
 Doxorubicin 25 mg/m² IV, day 1
 Cyclophosphamide 650 mg/m² IV, day 1
 Etoposide 120 mg/m² IV, day 1
 Cytarabine 300 mg/m² IV, day 8
 Bleomycin 5 units IV, day 8
 Vincristine 1.4 mg/m² IV, day 8
 Methotrexate 120 mg/m², day 8
 Leucovorin 25 mg/m² IV every 6 hours, 24 hours after methotrexate
 × 5 doses

MACOP-B

Methotrexate 400 mg/m² IV, day 8
 Doxorubicin 50 mg/m² IV, days 1 and 15
 Cyclophosphamide 350 mg/m² IV, days 1 and 15
 Vincristine 1.4 mg/m² IV, days 8 and 15

Prednisone 75 mg/day PO × 12 weeks

Bleomycin 10 units IV, day 28

Leucovorin 15 mg PO every 6 hours, 24 hours after methotrexate ×
 6 doses

Hyper-CVAD

Cyclophosphamide 300 mg/m² IV every 12 hours, days 1–3 (with
 Mesna)

Doxorubicin 50 mg/m² IV, day 1

Vincristine 1.4 mg/m² IV, days 1,11

Dexamethasone 40 mg/day PO, days 1–4 and 11–14

Methotrexate 15 mg intrathecal, day 2

Cytarabine 30 mg intrathecal, day 2

Hydrocortisone 15 mg intrathecal, day 2

Above Drugs Given on Courses 1, 3, 5, and 7

Methotrexate 1,000 mg/m² IV over 24 hours, day 1

Cytarabine 3,000 mg/m² IV every 12 hours, days 2 and 3

Leucovorin 25 mg IV × 1; then 25 mg PO every 6 hours for 7 doses

Methotrexate 15 mg intrathecal, day 2

Above Drugs Given on Courses 2, 4, 6, and 8

Relapsed Disease

ESHAP

Etoposide 40 mg/m² IV per day continuous infusion, days 1–4

Cisplatin 25 mg/m² IV per day continuous infusion, days 1–4

Cytarabine 2,000 mg/m² IV × 1, day 5

Methylprednisone 250 mg IV every 12 hours, days 1–4

DHAP

Dexamethasone 40 mg PO or IV daily, days 1–4

Cisplatin 100 mg/m² IV continuous infusion, day 1

Cytarabine 2,000 mg/m² IV every 12 hours for 2 doses on day 2

ICE

Etoposide 100 mg/m² IV daily, days 1–3

Carboplatin AUC 5 (maximum dose, 800 mg) IV, day 2

Ifosfamide 5,000 mg/m² IV continuous infusion × 1 on day 2 (with
 100% replacement with Mesna)

AUC, area under the curve; IV, intravenous; Mesna, 2-mercaptoethane sulfonate; PO, oral.

rituximab for eight cycles.³⁶ Initial 2-year follow-up showed that rituximab improved CR (76% versus 63%) and median event-free survival (57% versus 38%). Long-term follow-up also showed an increase in 10-year survival (43% versus 27.6%).

Similar findings in younger patients have been reported recently, making CHOP plus rituximab first-line therapy for advanced-stage diffuse, aggressive NHL (Table 97-9).

► Special Populations

There are certain histologic subtypes of diffuse, aggressive NHL that respond less well to treatment with conventional regimens such as CHOP. Burkitt's lymphoma, lymphoblastic lymphoma, mantle cell lymphoma, and primary CNS lymphoma are examples of disease that benefit from more intensive therapy. Regimens such as hyper-CVAD, which alternate cycles of hyperfractionated cyclophosphamide, doxorubicin, vincristine, and dexamethasone with high-dose cytarabine and methotrexate, may be substituted for CHOP.

Patients with CNS NHL have disease that is poorly responsive to therapy because of inadequate penetration of standard doses of chemotherapy across the blood-brain barrier. High-dose methotrexate, ranging from 2,500 to

Patient Encounter 1, Part 2

Based on the patient's diagnosis of stage III diffuse large B-cell lymphoma, the patient is to start treatment immediately.

What therapy (or therapies) is (are) most appropriate for this patient?

What other information (e.g., laboratory studies, diagnostic tests) is needed before the patient can start chemotherapy?

8,000 mg/m² is a mainstay of therapy. Treatment may also include direct instillation of intrathecal chemotherapy into the cerebrospinal fluid. Drugs that are commonly instilled intrathecally include methotrexate, cytarabine (conventional formulation and liposomal products), and corticosteroids.

The recent appreciation of the etiology of *Helicobacter pylori* in the etiology of peptic ulcer disease and the association between colonization and MALT has spurred the more aggressive treatment of this organism with antibiotics. In patients with localized disease, aggressive, combination therapy targeted at *H. pylori* has been shown to induce MALT remission. Patients with advanced disease may require combination chemotherapy, such as CHOP.

Mantle cell lymphoma, which comprises 6% of NHL cases, is defined by a chromosomal translocation of t(11;14)(q13;32). This translocation results in the overexpression of cyclin D1 coupled with NF- κ B, which plays a critical role in intracellular protein regulation and protranscription factors leading to increased cell survival. Bortezomib, a novel proteasome inhibitor, disrupts the regulation and degradation of proteins required for cell cycle regulation. Bortezomib is approved by the FDA for the treatment of patients with mantle cell lymphoma who have failed prior chemotherapy. A study conducted in 155 patients demonstrated that bortezomib resulted in 31% overall response rate with a median survival of 9.3 months.³⁷ Bortezomib is well tolerated, with peripheral neuropathy, thrombocytopenia, neutropenia, and nausea reported most frequently.

With more than half of patients with NHL expected to relapse with disease, salvage therapy plays a major role in the attempt to cure patients with recurrence. Multiple drug regimens such as ESHAP and DHAP can induce a CR, but the long-term cure rate with these regimens is less than 10%. Salvage therapy can induce remissions with subsequent relapses; however, the chance for a CR and the duration of remission is further diminished.

High-dose chemotherapy with autologous SCT has been studied as an alternative to standard dose regimens in the setting of first relapse.³⁸ The best-studied indication for SCT is for patients with intermediate- or high-grade disease that fails to respond to first-line therapy. A 3- to 5-year survival of greater than 40% is achieved in patients who have good performance and disease that demonstrates a significant response to one or two cycles of salvage chemotherapy. The procedure-related mortality rate has ranged from 5% to 10% in published reports. However, as with HL, with more broad application of peripheral blood stem cells and improved

supportive care, the mortality rate continues to decline. The role of allogeneic SCT in this setting is limited because of donor availability, the older age of patients, and the high treatment-related morbidity and mortality. Additionally, outcomes between autologous and allogeneic transplant appear similar.

Patients with HIV-related lymphoma represent a therapeutic dilemma considering many have high-grade disease of B-cell origin. A common presentation is that of extranodal disease, frequently in the GI tract, CNS, and bone marrow. Therapy for this population thus far has fared poorly, with a median survival time of 6 to 12 months, which decreases to 3 months with CNS involvement.³⁹ It remains to be seen if improved antiretroviral therapy will have an impact on the incidence and treatment options for these patients. The addition of rituximab to chemotherapy has failed to improve overall survival in this patient population and is associated with increased infectious complications.⁴⁰

OUTCOME EVALUATION

Treatment success in lymphoma is measured in successive stages, the first being inducing tumor regression and the degree of that regression: CR versus PR versus stable disease (SD) versus progressive disease (PD). The response evaluation criteria in solid tumors (RECIST) is a uniform criteria assessing tumor response developed by the National Cancer Institute is the standard methodology that physicians use to gauge treatment efficacy. HL and NHL may have residual masses after completion of treatment, adding to the difficulty in establishing a definitive remission from treatment. Clinical trials with limited numbers of patients have been published suggesting the value of positron emission tomography (PET) scans or gallium scans to rule out whether residual tumor masses after treatment contain viable tumor.⁴¹ The National Comprehensive Cancer Network recommends using integrated PET-computed tomography (CT) scanning as part of the initial workup and to evaluate for residual disease at the end of treatment.⁴²

Long-term follow-up monitors patients for continued disease remission or relapse with careful physical examination of the lymph nodes and sites of prior disease involvement and imaging studies. Patients will have routine chest x-rays and CT scans to screen for disease recurrence. Patients require long-term monitoring for toxicities of their primary treatment, either chemotherapy or radiation therapy.

Most patients treated for lymphoma with chemotherapy or radiation notice a regression of palpable lymphadenopathy within days. This is because of the high sensitivity of the rapidly proliferating malignant lymphocytes to chemotherapy and radiotherapy. This necessitates implementation of tumor lysis syndrome precautions with aggressive intravenous fluid resuscitation and allopurinol. Rasburicase should be considered for patients with moderate to high tumor burdens. Most chemotherapy treatments for lymphoma have a significant risk of infectious complications. Combination regimens for both HL and NHL are associated with rates of

Patient Encounter 1, Plan 3: Creating a Care Plan

Based on the information presented, create a care plan for this patient, including the goals of therapy, antineoplastic therapy plan, and necessary supportive care.

severe leukopenia and/or neutropenia ranging from 20% to 100% of patients. Consideration must be given to supportive care with prophylactic antibiotics and CSFs. Published guidelines recommend CSFs be used as primary prevention when the incidence of febrile neutropenia with chemotherapy is approximately 20% and no other equally effective and less myelosuppressive regimen is available or for secondary prevention where the patient already has experienced febrile neutropenia.⁴³ Effective antiemetic support is currently available that can control chemotherapy-induced nausea and vomiting reasonably well for most standard-dose regimens.⁴⁴

Advances in the treatment of lymphoma have increased the number of long-term survivors. Identification of long-term side effects associated with lymphoma therapy are vital to patient follow-up and may influence treatment decisions in newly diagnosed patients. Outcomes associated with the treatment of HL make up the majority of data. However, advances in NHL treatment have provided more information regarding long-term toxicities. Two leading causes of death associated with HL are secondary malignancies and cardiovascular disease. Secondary malignancies after HL are classified into leukemia, NHL, and solid tumors. Several studies have reported that cardiac mortality is the leading cause of non-malignancy-related death in HL survivors. The use of combined modality of irradiation with doxorubicin-based therapy has been reported to increase the risk of cardiac dysfunction. Treatment-related pulmonary toxicity, hypothyroidism, and infertility have all been associated with HL therapy. The most common solid tumors include cancers of the breast, lung, and GI tract. NHL survivors have an increased risk for developing myelodysplasia, acute myelogenous leukemia, and various solid tumors. The most common non-malignancy-based toxicities associated with NHL includes cardiac disease, infertility, neuropathy, renal insufficiency, GI toxicities, and lung fibrosis.⁴⁵

A limitation of rituximab is the severe, potentially fatal infusion-related reactions. Deaths have been reported resulting from the profound hypotension and circulatory collapse seen with the drug, particularly on the first dose. The package labeling recommends premedication with acetaminophen and diphenhydramine before each infusion. For the first infusion, the drug should be administered at 50 mg/h. The infusion rate may be increased by 50 mg/h every 30 minutes to a maximum of 400 mg/h if tolerated. If infusion-related reactions do occur, the infusion should be stopped temporarily until symptoms resolve. The infusion should be reinstated at a rate that is one-half the previous rate. For subsequent infusions, the rate may commence at 100 mg/h and be increased at 100-mg/h increments every 30 minutes for a maximum of 400 mg/h as tolerated. Tumor lysis syndrome is reported frequently with rituximab, and patients with a high tumor burden should be considered for prophylaxis with allopurinol and hydration. Reactivation of hepatitis B infections have occurred in patients treated with rituximab, so patients at high risk for hepatitis B should be screened and monitored carefully for reactivation of hepatitis. If hepatitis occurs, rituximab should be discontinued, and

Patient Care and Monitoring

1. Verify chemotherapy regimen doses with a standardized reference and assess for dose adjustment for height, weight, and body surface area and organ dysfunction (renal or hepatic).
2. Assess appropriateness of supportive care for each chemotherapy regimens such as antiemetics or colony-stimulating factors.
3. Before initiation of treatment with chemotherapy, determine if tumor lysis syndrome precautions need to be implemented.
4. Take a thorough medication history with particular attention to nonprescription or herbal medications.
5. Provide patient education regarding common toxicities associated with chemotherapy such as nausea/vomiting, mucositis, myelosuppression, and alopecia.
6. For doxorubicin-containing regimens, total the cumulative dosage received by the patient to monitor for cardiac toxicity.
7. For bleomycin-containing regimens, total the cumulative dosage received by the patient to monitor for pulmonary fibrosis.
8. Educate patients regarding the short- and long-term complications associated with radiation therapy.
9. Monitor patient for signs and symptoms of response of tumor to chemotherapy.
10. Provide contact numbers for patient in the event of a fever and a response plan if the patient is considered to be at risk for neutropenic fever

patients should be treated with antivirals. Other associated toxicities of rituximab include fever, chills, headache, asthenia, nausea, vomiting, angioedema, bronchospasm, and skin reactions. 9 *Rituximab is an effective treatment option for patients with various forms of NHL in combination with chemotherapy or as a single agent as long as patients are monitored appropriately.* Radiolabeled rituximab causes more myelosuppression than rituximab alone and, similar to combination cytotoxic chemotherapy regimens, has a long-term risk of inducing secondary leukemias.⁴⁶

Abbreviations Introduced in This Chapter

<i>Bcl-1</i>	Important in the regulation of mitosis
<i>Bcl-2</i>	A regulator of apoptosis
<i>Bcl-3</i>	A regulator of nuclear transcription factor
<i>Bcl-6</i>	Regulates cell differentiation
<i>c-myc</i>	Regulator of gene transcription
ABVD	Doxorubicin, bleomycin, vinblastine, and dacarbazine

CALGB	Cancer and leukemia group B
CD	Cluster of differentiation
CHOP	Cyclophosphamide, doxorubicin, vincristine, and prednisone
CSFs	Colony-stimulating factors
CVP	Cyclophosphamide, vincristine, and prednisone or prednisolone
EBV	Epstein-Barr virus
ESR	Erythroid sedimentation rate
FLIPI	Follicular lymphoma international prognostic index
HL	Hodgkin's lymphoma
IPI	International Prognostic Index
IFRT	Involved field radiation therapy
LDH	Lactate dehydrogenase
MALT	Mucosa-associated lymphoid tissue
MOPP	Mechlorethamine, vincristine, procarbazine, and prednisone
NHL	Non-Hodgkin's lymphoma
PET	Positron emission tomography
RECIST	Response evaluation criteria in solid tumors
RS	Reed-Sternberg
SCT	Stem cell transplant

Hematopoietic Stem Cell Transplantation

Amber P. Lawson

LEARNING OBJECTIVES

● Upon completion of the chapter, the reader will be able to:

1. Explain the rationale for using hematopoietic stem cell transplant (HSCT) to treat cancer.
2. Compare the different types of HSCTs, specifically (a) the types of donors (i.e., autologous and allogeneic), (b) the source of hematopoietic cells (i.e., umbilical cord, peripheral blood progenitor cells [PBPCs], and bone marrow), and (c) the type of preparative regimen (i.e., myeloablative and nonmyeloablative).
3. List the nonhematologic toxicity to high-dose chemotherapy used in myeloablative preparative regimens, specifically busulfan-induced seizures, hemorrhagic cystitis, GI toxicities, and sinusoidal obstruction syndrome.
4. Develop a plan for monitoring and managing engraftment of hematopoiesis.
5. Explain graft-versus-host disease (GVHD).
6. Recommend a prophylactic and treatment regimen for GVHD.
7. Choose an appropriate regimen to minimize the risk of infectious complications in HSCT patients.
8. Evaluate the long-term health care of HSCT survivors.

KEY CONCEPTS

- 1 Hematopoietic stem cell transplantation (HSCT) is a procedure used mainly to treat hematologic malignancies via high-dose chemotherapy and/or a graft-versus-tumor effect.
- 2 An autologous HSCT involves the infusion of a patient's own hematopoietic cells and allows for the administration of higher doses of chemotherapy, radiation, or both to treat the malignancy. Infusion of another's hematopoietic cells is an allogeneic HSCT; these cells can be from donors related or unrelated to the recipient.
- 3 Umbilical cord blood, peripheral blood progenitor cells (PBPCs), and bone marrow can serve as the source of hematopoietic cells. The optimal cell source differs based on the donor and recipient characteristics.
- 4 A myeloablative preparative regimen involves the administration of sublethal doses of chemotherapy to the recipient to eradicate residual malignant disease. The recipient will not regain his or her own hematopoiesis and will be at risk for substantial life-threatening nonhematologic toxicity.
- 5 A nonmyeloablative preparative regimen is less toxic than a myeloablative regimen in hopes of being able to offer the benefits of an allogeneic HSCT to more patients. A nonmyeloablative HSCT is based on the concept of donor immune response having a graft-versus-tumor effect.
- 6 Nonhematologic toxicity differs based on the preparative regimen administered.
- 7 Engraftment is the reestablishment of functional hematopoiesis. It is commonly defined as the point at which a patient can maintain a sustained absolute neutrophil count (ANC) of greater than 500 cells/mm³ ($0.5 \times 10^9/L$) and a sustained platelet count of greater than 20,000/mm³ ($20 \times 10^9/L$) lasting for 3 or more consecutive days without transfusions.
- 8 Graft-versus-host disease (GVHD) is caused by the activation of donor lymphocytes, leading to immune damage to the skin, gut, and liver in the recipient. An immunosuppressive regimen is administered to prevent GVHD in recipients of an allogeneic graft; this regimen is based on the type of preparative regimen and the source of the graft.
- 9 Recipients of HSCT are at higher risk of bacterial, viral, and fungal infections and usually receive a prophylactic or preemptive regimen to minimize the morbidity and mortality owing to infectious complications.

- 10 Long-term survivors of HSCT should be monitored closely, particularly for infections and secondary malignant neoplasms.

INTRODUCTION

Hematopoietic stem cell transplantation (HSCT) is a procedure used mainly to treat hematologic malignancies via high-dose chemotherapy and/or a graft-versus-tumor effect. An essential component of this procedure is the infusion of hematopoietic cells into the recipient to facilitate an immunologic response against the residual malignancy and/or restore normal hematopoiesis and lymphopoiesis. The first HSCTs were performed using allogeneic bone marrow, which involved administration of high-dose chemotherapy and/or radiation aimed at eradicating residual malignant disease followed by transplantation of bone marrow from one individual to another to “rescue” the recipient’s immune system from the myelotoxic effects of the treatment. Bone marrow contains pluripotent stem cells and postthymic lymphocytes, which are responsible for long-term hematopoietic reconstitution, immune recovery, and its associated **graft-versus-host disease** (GVHD). Subsequently, the dose-intensity concept for cancer treatment was expanded to using **myeloablative preparative regimens** followed by autologous HSCT.

The type of HSCT performed depends on a number of factors, including the type and status of disease, availability of a compatible donor, patient age, performance status, and organ function. In addition to bone marrow, hematopoietic stem cells may be obtained from the peripheral blood progenitor cells (PBPCs) and umbilical cord blood. The essential properties of the hematopoietic cells are their ability to engraft, the speed of **engraftment**, and the durability of engraftment.

Examples of diseases treated with HSCT are listed in **Table 98-1**. ② **Autologous HSCT**, or infusion of a patient’s own hematopoietic cells, allows for the administration of higher doses of chemotherapy, radiation, or both to treat the malignancy or autoimmune disorder. In this setting, the hematopoietic cells “rescue” the recipient from otherwise dose-limiting hematopoietic toxicity. Autologous HSCT is used to treat intermediate- and high-grade non-Hodgkin’s lymphoma (NHL), multiple myeloma (MM), autoimmune diseases, and relapsed or refractory Hodgkin’s disease.¹

② **Allogeneic HSCT** involves the transplantation of hematopoietic cells obtained from a different person’s (donor) bone marrow, peripheral blood, or umbilical cord blood to the recipient. Unless the donor and the recipient are identical twins (referred to as a *syngeneic HSCT*), they are dissimilar genetically. Allogeneic HSCT is used to treat both nonmalignant conditions and hematologic malignancies such as acute and chronic leukemias.¹

The infusion of hematopoietic cells follows the administration of a combination of chemotherapy and/or radiation, termed the *conditioning* or *preparative regimen*. ④ A **myeloablative preparative regimen** involves the administration of sublethal doses of chemotherapy to the recipient to eradicate residual malignant disease. The recipient will not regain his or her own hematopoiesis and will be at risk for substantial

Table 98-1

Diseases Commonly Treated With HSCT

	Autologous Graft	Allogeneic Graft
Cancers	Multiple myeloma Non-Hodgkin’s lymphoma Hodgkin’s disease Neuroblastoma Germ cell tumors	Acute myeloid leukemia Acute lymphoblastic leukemia Chronic myeloid leukemia Myelodysplastic syndrome Myeloproliferative disorders Non-Hodgkin’s lymphoma Hodgkin’s disease Chronic lymphocytic leukemia Multiple myeloma
Other diseases	Autoimmune diseases Amyloidosis	Aplastic anemia Paroxysmal nocturnal hemoglobinuria Fanconi’s anemia Thalassemia major Sickle cell anemia Severe combined immunodeficiency Inborn errors of metabolism

life-threatening nonhematologic toxicity. For those undergoing an autologous HSCT, their hematopoietic cells must be harvested and stored before the myeloablative preparative regimen is administered. After the administration of the myeloablative preparative regimen, these hematopoietic cells serve as a rescue intervention to reestablish bone marrow function and avoid long-lasting, life-threatening bone marrow aplasia. In the setting of an allogeneic HSCT, the preparative regimen is designed to suppress the recipient’s immunity, eradicate residual malignancy, or create space in the marrow compartment. Improved survival outcomes have been observed with both autologous and allogeneic HSCT when the hematologic malignancy is in complete remission at the time of HSCT.² At most HSCT centers, age younger than 65 years and normal renal, hepatic, pulmonary, and cardiac function are considered eligibility requirements for myeloablative allogeneic HSCT. A myeloablative or **nonmyeloablative preparative regimen** may be used for allogeneic HSCT; only myeloablative preparative regimens are used for autologous HSCT. Allogeneic HSCT offers the potential for a **graft-versus-tumor effect** in which immune effector cells from the donor recognize and eliminate residual tumor in the recipient.¹

The recognition of graft-versus-tumor effect, which likely is caused by cytotoxic T lymphocytes in the donor stem cells, led to investigations with nonmyeloablative transplants, in which less toxic preparative regimens are used in the hope of expanding the availability of HSCT to recipients whose medical condition or age prohibits use of myeloablative regimens.

EPIDEMIOLOGY AND ETIOLOGY

Each year, the number of allogeneic HSCTs is less than the number of autologous HSCTs. Worldwide, approximately 35,000 autologous HSCTs and 25,000 allogeneic HSCTs

are performed per year, with approximately one-third of allogeneic HSCTs using reduced-intensity preparative regimens. In the late 1990s, the number of allogeneic HSCTs reached a plateau, most likely related to the introduction of imatinib (Gleevec) for treatment of newly diagnosed chronic-phase chronic myelogenous leukemia (CML). Furthermore, the limited availability of suitable donors may have contributed to the plateau effect. Recently, however, the number of allogeneic transplants for hematologic malignancies other than CML appears to be increasing.²

Autologous PBPC use has increased and essentially has replaced bone marrow as a graft source in many transplant centers. From years 2004 through 2008, approximately 98% of autologous HSCTs in adults and 91% in children used PBPCs as the source of hematopoietic cells.² Patients do not benefit from an immunologic graft-versus-tumor effect while undergoing an autologous transplant; instead, the administration of high-dose chemotherapy followed by an autologous stem cell transplant in chemotherapy-sensitive malignancies relies on the preparative regimen alone to eradicate the malignant disease. Autologous HSCT is used to treat a variety of malignancies; Hodgkin's lymphoma, NHL, and MM are the most common indications for this procedure.² Autologous HSCT circumvents the need for histocompatible donors, is associated with a lower mortality rate, and is not restricted to younger patients.³ The use of allogeneic PBPCs is increasing; from years 2004 through 2008, 80% of allogeneic HSCTs performed worldwide used PBPCs as the source of hematopoietic cells rather than bone marrow in adult patients.³

PATHOPHYSIOLOGY

For an allogeneic HSCT, the recipient and the donor are dissimilar genetically unless they are identical twins (a transplant between twins is referred to as a *syngeneic HSCT*). The transplanted tissue is immunologically active, and thus there is potential for bidirectional graft rejection. In the first scenario, cytotoxic T cells and natural killer (NK) cells belonging to the host (recipient) recognize minor histocompatibility (MHC) antigens of the graft (donor hematopoietic stem cells) and lead to a rejection response. In the second scenario, immunologically active cells in the graft recognize host MHC antigens and elicit an immune response. The former is referred to as *host-versus-graft disease*, and the latter is referred to as GVHD. Host-versus-graft effects are more common in solid-organ transplantation. When host-versus-graft effects occur in allogeneic HSCT, they are referred to as *graft failure* or *rejection*, which results in ineffective hematopoiesis (i.e., adequate ANC and/or platelet counts were not obtained). **7** *Engraftment is defined as the point at which a patient can maintain a sustained absolute neutrophil count (ANC) of greater than 500 cells/mm³ (0.5 × 10⁹/L) and a sustained platelet count of greater than or equal to 20,000/mm³ (20 × 10⁹/L) lasting greater than or equal to 3 consecutive days without transfusions.*⁴ Therefore, an essential first step for patients eligible for HSCT is finding a human leukocyte antigen (HLA)-compatible graft with an acceptable risk of graft failure and GVHD.

Histocompatibility

Histocompatibility differences between the donor and the recipient necessitate immunosuppression after an allogeneic HSCT because considerable morbidity and mortality are associated with graft failure and GVHD. Rejection is least likely to occur with a syngeneic donor, meaning that the recipient and host are identical (monozygotic) twins. In patients without a syngeneic donor, initial HLA typing is conducted on family members because the likelihood of complete histocompatibility between unrelated individuals is remote. Siblings are the most likely individuals to be histocompatible within a family. The chance for complete histocompatibility occurring in an individual with only one sibling is 25%. Approximately 40% of patients with more than one sibling will have an HLA-identical match. Having a matched-sibling donor is no longer a requirement for allogeneic HSCT because improved immunosuppressive regimens and the National Marrow Donor Program have allowed an increase in the use of unrelated or related matched or mismatched HSCTs. The use of alternative sources of allogeneic hematopoietic cells, such as related donors mismatched at one or more HLA loci or phenotypically (i.e., serologically) matched unrelated donors, has been evaluated.⁵ Establishment of the National Marrow Donor Program has helped to increase the pool of potential donors for allogeneic HSCT. Through this program, an HLA-matched unrelated volunteer donor might be identified. Recipients of an unrelated graft are more likely to experience graft failure and acute GVHD relative to recipients of a matched-sibling donor. Determination of histocompatibility between potential donors and the patient is completed before allogeneic HSCT. Initially, HLA typing is performed using blood samples and compatibility for class I MHC antigens (i.e., HLA-A, HLA-B, and HLA-C) is determined through serologic and DNA-based testing methods. In vitro reactivity between donor and recipient also can be assessed in mixed-lymphocyte culture, a test used to measure compatibility of the MHC class II antigens (i.e., HLA-DR, HLA-DP, and HLA-DQ). Currently, most clinical and research laboratories are also performing molecular DNA typing using polymerase chain reaction (PCR) methodology to determine the HLA allele sequence.⁶

The preparative regimen or GVHD prophylaxis may be altered based on the mismatch between the donor and the recipient. The risk of graft failure decreases with better matches such that those with a class I (i.e., HLA-A, -B, or -C) antigen mismatch have the highest risk of rejection; those with just one class I allele mismatch have a minimal risk. Graft failure does not appear to be associated with mismatch at a single class II antigen or allele.⁶ GVHD and survival have been associated with disparity for classes I and II antigens and alleles.⁷

Stem Cell Sources

Autologous hematopoietic stem cells are obtained from bone marrow or peripheral blood. The technique for harvesting autologous hematopoietic cells depends on the anatomic

source (i.e., bone marrow or peripheral blood). A surgical procedure is necessary for obtaining bone marrow. Multiple aspirations of marrow are obtained from the anterior and posterior iliac crests until a volume with a sufficient number of hematopoietic stem cells is collected (i.e., 600 to 1,200 mL of bone marrow). The bone marrow then is processed to remove fat or marrow emboli and usually is infused intravenously into the patient similar to a blood transfusion.

The shift to the use of PBPCs over bone marrow for autologous HSCT is primarily because of the more rapid engraftment and decreased health care resource use. Because the harvest occurs before administering the preparative regimen, autologous hematopoietic cells must be cryopreserved and stored for future use.

Transplantation with PBPCs essentially has replaced bone marrow transplantation (BMT) as autologous rescue after myeloablative preparative regimens. Autologous PBPCs are obtained by administering a mobilizing agent(s) followed by apheresis, which is an outpatient procedure similar to hemodialysis. Hematopoietic growth factors (HGFs) alone or in combination with myelosuppressive chemotherapy are used for **mobilization** of autologous PBPCs with similar results. The HGFs granulocyte-macrophage colony-stimulating factor (sargramostim, Leukine) and granulocyte colony-stimulating factor (filgrastim, Neupogen) are used as mobilizing agents. The use of pegylated granulocyte colony-stimulating factor (pegfilgrastim, Neulasta) for mobilization of PBPCs appears more convenient and is promising as a mobilization agent; however, further data are needed regarding graft composition, HSCT outcomes, and donor safety in allogeneic donations before widespread use of this agent can be recommended.

The combination of chemotherapy with an HGF enhances PBPC mobilization relative to HGF alone.¹ In addition to treating the underlying malignancy, this approach lowers the risk of tumor cell contamination and the number of apheresis collections required, but there is a greater risk of neutropenia and thrombocytopenia. The HGF is initiated after completion of chemotherapy and is continued until apheresis is complete. Many centers monitor the number of cells that express the CD34 antigen (i.e., CD34+ cells) to determine when to start apheresis. The CD34 antigen is expressed on almost all unipotent and multipotent colony-forming cells and on precursors of colony-forming cells but not on mature peripheral blood cells. Apheresis is continued daily until the target number of PBPCs per kilogram of the recipient's weight is obtained. For adult recipients, the number of CD34+ cells correlates with time to engraftment. Lower yield of CD34+ cells is associated with administration of stem cell toxic drugs (e.g., carmustine and melphalan) and intensive prior chemotherapy or radiotherapy.

If patients are unable to obtain an adequate yield of CD34+ cells per kilogram after mobilization attempts fail, then allogeneic transplant may be considered as an alternative. Plerixafor (Mozobil) is approved by the Food and Drug Administration (FDA) for use in combination with granulocyte colony-stimulating factor to mobilize PBPCs for collection and subsequent autologous transplantation

in patients with NHL and MM. Plerixafor is an inhibitor of the CXCR4 chemokine receptor that results in more circulating PBPCs in the peripheral blood because of the inability of CXCR4 to assist in anchoring hematopoietic stem cells to the bone marrow matrix. Because administration of plerixafor with granulocyte colony-stimulating factor results in increased yield of CD34+ cells per kilogram compared to granulocyte colony-stimulating factor alone, this combination may serve as an alternative mobilization strategy in patients deemed to be at risk for mobilization failure with conventional methods.

TREATMENT

Desired Outcome

The desired outcome with HSCT is to cure the patient of his or her underlying disease while minimizing the short- and long-term morbidity associated with HSCT.

Nonpharmacologic Therapy

► **Harvesting, Preparing, and Transplanting Allogeneic Hematopoietic Cells**

3 *Bone marrow, PBPCs, and umbilical cord blood can serve as the source of hematopoietic cells. The optimal cell source differs based on the donor and recipient characteristics.*

Bone Marrow Harvesting the bone marrow from an allogeneic donor is conducted via the same process as for an autologous HSCT. The harvest occurs on day 0 of the HSCT such that it is infused into the recipient immediately after processing. The bone marrow may need additional processing if the donor and recipient are ABO incompatible, which occurs in up to 30% of HSCTs. Red blood cells (RBCs) may need to be removed before infusion into the recipient to prevent immune-mediated hemolytic anemia and thrombotic microangiopathic syndromes.

• **Peripheral Blood Progenitor Cells** The allogeneic donor first undergoes mobilization therapy with an HGF to increase the number of hematopoietic cells circulating in the peripheral blood. The most commonly used regimen to mobilize allogeneic donors is a 4- to 5-day course of filgrastim, 10 to 16 mcg/kg/day, administered subcutaneously followed by leukophereses on the fourth or fifth days when peripheral blood levels of CD34+ cells peak. An adequate number of hematopoietic cells usually are obtained with one to two apheresis collections, with the optimal number of CD34+ collected being a minimum of 5×10^6 cells/kg of recipient body weight. Higher numbers of CD34+ cells are associated with more rapid neutrophil and platelet engraftment; patients who receive less than 2×10^6 /kg CD34+ cells experience a higher mortality rate and a decreased overall survival than patients who receive at least 2×10^6 /kg CD34+ cells.⁸ Hematopoietic stem cells obtained from the peripheral blood are processed like bone marrow-derived stem cells and may be infused immediately into the recipient or frozen for future use. Compared with bone marrow donation,

allogeneic PBPC donation leads to quicker hematopoietic recovery. Neutrophil engraftment occurs 2 to 6 days earlier, and platelet engraftment occurs approximately 6 days earlier with PBPC grafts than bone marrow grafts.⁹ The donor may experience musculoskeletal pain, headache, and mild increases in hepatic enzyme or lactate dehydrogenase levels related to filgrastim administration. Hypocalcemia may also occur owing to citrate accumulation, which decreases ionized calcium concentrations during apheresis.

Allogeneic PBPC grafts contain approximately 10 times more T and B cells than bone marrow grafts. Historically, there has been significant concern that the greater T- and B-cell content of PBPCs could increase the risk of acute and/or chronic GVHD. In patients with a hematologic malignancy who have an HLA-matched sibling donor, a PBPC graft is optimal relative to bone marrow graft because the PBPC graft is associated with quicker neutrophil and platelet engraftment and potentially improved disease-free survival rates.¹⁰ Grafts from PBPCs are likely associated with a higher incidence of acute GVHD and an approximately 20% increase in the incidence of extensive-stage and overall chronic GVHD.¹⁰ Similar trends for engraftment and GVHD have been found with unrelated donors.¹¹

Umbilical Cord Blood Transplant with umbilical cord blood offers an alternative stem cell source to patients who do not have an acceptable matched related or unrelated donor. When allogeneic hematopoietic cells are obtained from umbilical cord blood, the cord blood is obtained from a consenting donor in the delivery room after birth and delivery of the placenta. The cord blood is processed, a sample is sent for HLA typing, and the cord blood is frozen and stored for future use. Numerous umbilical cord blood registries exist, with the goal of providing alternative sources of allogeneic stem cells. One potential limitation to the use of umbilical cord blood transplants is the inability to use donor-lymphocyte infusions in the event of relapse. Engraftment is slower in umbilical cord blood transplants, with a potential lower risk of GVHD and similar survival rates relative to BMT.^{11,12} In children receiving an umbilical cord blood graft from an unrelated donor, cell dose (e.g., nucleated cells) is related to engraftment, transplant-related morbidity, and survival.¹³ Although there were initial concerns regarding whether a umbilical cord blood transplant could provide enough nucleated cells to engraft adequately within an adult, there is growing experience to indicate that a umbilical cord blood transplant is feasible when at least 1×10^7 nucleated cells per kilogram of recipient body weight are administered.¹³ The prospective use of dual umbilical cord units and ex vivo expansion of umbilical cord units to obtain adequate engraftment are methods currently under exploration.

T-Cell Depletion Immunocompetent T lymphocytes may be depleted from the donor bone marrow ex vivo before infusion (referred to as *T-cell-depleted hematopoietic cells*) into the recipient as a means of preventing GVHD. Depletion of T lymphocytes in donor hematopoietic cells is completed ex vivo using physical (e.g., density-gradient fractionation) and/or immunologic (e.g., antithymocyte globulin [ATG]

antibodies) methods. Functional recovery of T cells in the recipient is delayed, and the risk of Epstein-Barr virus-associated lymphoproliferative disorders is higher with the use of T-cell-depleted bone marrow. The use of T-cell-depleted grafts reduces the incidence of GVHD, but graft failure and relapse are more common. The use of donor lymphocyte infusion in patients who relapse after receiving a T-cell-depleted HSCT is being investigated.

Engraftment After chemotherapy and radiation, pancytopenia lasts until the infused stem cells reestablish functional hematopoiesis. The median time to engraftment is a function of several factors, including the source of stem cells such as PBPCs, which can result in earlier engraftment than bone marrow.⁹ Myeloablative preparative regimens have significant regimen-related toxicity and morbidity and thus usually are limited to healthy, younger (i.e., usually younger than 50 years) patients. Alternatively, nonmyeloablative transplants are being performed with the hope of curing more patients with cancer by increasing the availability of HSCT with less regimen-related toxicity and by using the graft-versus-tumor effect.¹

A delicate balance exists between host and donor effector cells in the bone marrow environment. Residual host-versus-graft effects may lead to graft failure, which is also known as graft rejection. *Graft failure* is defined as the lack of functional hematopoiesis after HSCT and can occur early (i.e., lack of initial hematopoietic recovery) or late (i.e., in association with recurrence of the disease or reappearance of host cells after initial donor cell engraftment). Engraftment usually is evident within the first 30 days in patients undergoing an HSCT; however, rejection can occur after initial engraftment. Therapeutic options for the treatment of graft rejection are limited; a second HSCT is the most definitive therapy, although the toxicities are formidable.¹⁴

► Graft-Versus-Tumor Effect

A graft-versus-tumor effect occurs owing to the donor lymphocytes, as supported by three observations after myeloablative allogeneic HSCT; namely, (a) lower relapse rates in patients with GVHD relative to those who did not have GVHD; (b) a higher rate of leukemia relapse after T-cell-depleted, autologous, or syngeneic HSCT; and (c) the effectiveness of donor lymphocyte infusions in reinducing a remission in patients who relapsed after allogeneic HSCT. Rapid taper of immunosuppression in patients with residual disease may induce a graft-versus tumor effect. In donor lymphocyte infusion, lymphocytes are collected from the peripheral blood of the donor and administered to the recipient. Eradication of the recurrent malignancy is caused by either specific targeting of the tumor antigens or GVHD, which may affect cancer cells preferentially. Patients with hematologic malignancies (e.g., CML and acute myelogenous leukemia [AML]) and certain solid tumors (e.g., renal cell carcinoma) appear to benefit from a graft-versus-tumor effect. These data gave rise to the use of nonmyeloablative preparative regimens.

Patient Encounter, Part 1

ZN is a 52-year-old woman diagnosed with acute myeloid leukemia with complex cytogenetics. The patient achieved complete remission with induction therapy and is now being evaluated for an allogeneic stem cell transplant with a peripheral blood stem cell graft from a full HLA-matched sibling. She has no other siblings. Her preparative regimen consists of busulfan and cyclophosphamide (BU-CY) and her GVHD prophylaxis consists of tacrolimus and methotrexate.

What nonhematologic toxicities are associated with the preparative regimen?

What are the advantages and disadvantages of obtaining and infusing hematopoietic stem cells from a peripheral blood stem cell source as opposed to a bone marrow source?

What are the implications for ZN if the sibling was not an HLA match?

and radiation, suppressing the host immune system, and creating space in the marrow compartment to facilitate engraftment. The preparative regimen is designed to eradicate immunologically active host tissues (lymphoid tissue and macrophages) and to prevent or minimize the development of host-versus-graft reactions. Most allogeneic preparative regimens for the treatment of hematologic malignancies contain cyclophosphamide, radiation, or both. The combination of cyclophosphamide and total-body irradiation (TBI) was one of the first preparative regimens developed and is still used widely today. This regimen is immunosuppressive and has inherent activity against hematologic malignancies (e.g., leukemias and lymphomas). TBI has the added advantage of being devoid of active metabolites that might interfere with the activity of donor hematopoietic cells. In addition, TBI eradicates residual malignant cells at sanctuary sites such as the central nervous system. Modifications of the cyclophosphamide–TBI preparative regimen include replacing TBI with other agents (e.g., busulfan) or adding other chemotherapeutic or monoclonal agents to the existing regimen in hopes of minimizing long-term toxicities. In the case of a mismatched allogeneic HSCT with a substantially increased chance of graft rejection, ATG also may be added to the preparative regimen to further immunosuppress the recipient.

The optimal myeloablative preparative regimen remains elusive. The long-term outcomes of busulfan–cyclophosphamide (BU-CY) and cyclophosphamide–TBI (CY-TBI) in patients with AML and CML, the more common indications for allogeneic HSCT, have been compared in a meta-analysis of four clinical trials.¹⁸ Equivalent rates of long-term complications were present between the two preparative regimens except that there was a greater risk of cataracts with CY-TBI and alopecia with BU-CY. Overall and disease-free survivals were similar in patients with CML, but there was a

Pharmacologic Therapy**► Preparative Regimens for HSCT**

Examples of commonly used preparative regimens are included in **Table 98–2**. **6** *The nonhematologic toxicity differs based on the preparative regimen administered.*

- **Myeloablative Preparative Regimens** In both autologous and allogeneic HSCT, infusion of stem cells circumvents dose-limiting myelosuppression, maximizing the potential value of the steep dose–response curve to alkylating agents

Table 98–2**Commonly Used Preparative Regimens for HSCT^a**

Type of HSCT	Preparative Regimen	Dose and Schedule for Adults	Dose and Schedule for Pediatric Patients
Allogeneic ¹⁵	Myeloablative CY-TBI	CY 60 mg/kg/day IV on 2 consecutive days before TBI 1,000–1,575 rads (10–15.75 Gy) fractionated over 1–7 days	CY 60 mg/kg/day IV on 2 consecutive days before TBI 1,000–1,575 rads (10–15.75 Gy) fractionated over 1–7 days
Allogeneic, autologous ¹⁶	Myeloablative BU-CY	BU 1 mg/kg per dose PO or 0.8 mg/kg per dose IV every 6 hours × 16 doses; CY 60 mg/kg/day IV daily × 2 days after BU	BU 1 mg/kg per dose PO or 0.8 mg/kg per dose IV every 6 hours × 16 doses; CY 120–200 mg/kg IV given over 2–4 days after BU
Autologous ¹⁷	Myeloablative BEAM (carmustine/etoposide/-cytarabine/melphalan)	Carmustine 300 mg/m ² IV Etoposide 400–800 mg/m ² IV given over 4 days Cytarabine 400–1,600 mg/m ² IV given over 4 days	Carmustine 300 mg/m ² IV Etoposide 400–800 mg/m ² IV given over 4 days Cytarabine 400–1,600 mg/m ² IV given over 4 days
Allogeneic ³	Nonmyeloablative BU-FLU	Melphalan 140 mg/m ² IV Fludarabine 30 mg/m ² /day IV on day –10 to day –5 followed by busulfan 1 mg/kg/dose PO every 6 hours × 8 doses on days –6 and –5	Melphalan 140 mg/m ² IV Fludarabine 30 mg/m ² /day IV on day –10 to day –5 followed by busulfan 1 mg/kg/dose PO every 6 hours × 8 doses on days –6 and –5

BEAM, carmustine, etoposide, cytarabine, and melphalan; BU-CY, busulfan and cyclophosphamide; BU-FLU, busulfan and fludarabine; CY-TBI, cyclophosphamide–total-body irradiation; IV, intravenous; PO, oral; TBI, total-body irradiation.

trend for improved disease-free survival with CY-TBI in AML patients. Thus, the preparative regimen can be tailored to the primary disease and to the degree of HLA compatibility.

Nonmyeloablative Preparative Regimens ⁵ A nonmyeloablative preparative regimen is less toxic than a myeloablative regimen in the hope of being able to offer the benefits of an allogeneic HSCT to more patients. A nonmyeloablative HSCT is based on the concept of donor immune response having a graft-versus-tumor effect.

Because of the severe regimen-related toxicity of a myeloablative preparative regimen, the use of HSCT traditionally was limited to younger patients with minimal comorbidities. Most patients diagnosed with cancer are elderly; therefore, myeloablative HSCT could not be offered to a substantial portion of cancer patients. The concept of donor immune response having a graft-versus-tumor effect gave rise to the theory that a strongly immunosuppressive, but not myeloablative, preparative regimen (i.e., a nonmyeloablative transplant may result in a state of chimerism in which the recipient and donor are coexisting). The toxicity and efficacy of nonmyeloablative transplants are being evaluated in patients with malignant and nonmalignant conditions who are not eligible for a myeloablative HSCT.

A nonmyeloablative preparative regimen allows for development of mixed chimerism (defined as 5% to 95% peripheral donor T cells) between the host and recipient to allow for a graft-versus-tumor effect as the primary form of therapy (Fig. 98-1). Chimerism is assessed within peripheral blood T cells and granulocytes and bone marrow using conventional (e.g., using sex chromosomes for opposite-sex

donors) and molecular (e.g., variable number of tandem repeats) methods for same-sex donors.

The nonmyeloablative preparative regimen does not completely eliminate host normal and malignant cells. Donor cells eradicate residual host hematopoiesis, and the graft-versus-tumor effects generally occur after the development of full donor T-cell chimerism. After engraftment, mixed chimerism should be present and is shown by the presence of both donor- and recipient-derived cells. Autologous recovery should occur promptly if the graft is rejected. The intensity of immunosuppression required for engraftment depends on the immunocompetence of the recipient and the histocompatibility and composition of the HSCT.¹⁹ More intensive conditioning regimens that are required for engraftment in the setting of unrelated-donor- or HLA-mismatched-related HSCT have been termed *reduced-intensity myeloablative transplants*. After chimerism develops, donor-lymphocyte infusion can be administered safely in patients without GVHD to eradicate malignant cells.

Nonmyeloablative preparative regimens typically consist of a purine analog (e.g., fludarabine) in combination with an alkylating agent or low-dose TBI. Adverse effects in the early posttransplant period are decreased because of the lower intensity preparative regimen, thus making HSCT available to patients who in the past were not healthy or young enough to receive a myeloablative preparative regimen. The risk of GVHD remains with nonmyeloablative transplant; the GVHD prophylaxis regimens are reviewed in the GVHD section below. Presently, nonmyeloablative transplant is not indicated as first-line therapy for any malignant or nonmalignant conditions, although research is ongoing.

FIGURE 98-1. Schema for nonmyeloablative transplantation. Recipients (R) receive a nonmyeloablative preparative regimen and an allogeneic hematopoietic stem cell transplantation (HSCT). Initially, mixed chimerism is present with the coexistence of donor (D) cells and recipient-derived normal and leukemia or lymphoma (R_L) cells. Donor-derived T cells mediate a graft-versus-host hematopoietic effect that eradicates residual recipient-derived normal and malignant hematopoietic cells. Donor-lymphocyte infusions (DLIs) may be administered to enhance graft-versus-tumor effects. (From Champlin R, Khouri I, Anderlini P, et al. Nonmyeloablative preparative regimens for allogeneic hematopoietic transplantation. *Biology and current indications*. *Oncology (Williston Park)* 2003;17:94–100; discussion 103–107.)

Nonmyeloablative transplantation is being evaluated for cancers sensitive to a graft-versus-tumor effect (e.g., CML and AML), in older patients, or for those with comorbidities who would not be able to tolerate a myeloablative HSCT.

Toxicities and Management of Preparative Regimens

Myelosuppression is a frequent dose-limiting toxicity for antineoplastics when administered in the conventional doses used to treat cancer. However, because myelosuppression is circumvented with hematopoietic rescue in the case of patients receiving HSCT, the dose-limiting toxicities of these myeloablative preparative regimens are nonhematologic and vary with the preparative regimen used. Most patients undergoing HSCT experience toxicities commonly associated with chemotherapy (e.g., alopecia, mucositis, nausea and vomiting, and infertility), albeit these toxicities are magnified in the HSCT population.

Busulfan Seizures Seizures have been reported in both adult and pediatric patients receiving high-dose busulfan for HSCT preparative regimens. Anticonvulsants are used to minimize the risk of seizures. Anticonvulsants are begun shortly before busulfan, with the loading dose completed at least 6 hours before the first busulfan dose. Oral loading and maintenance regimens generally are sufficient because target phenytoin concentrations of 10 to 20 mcg/mL (10 to 20 mg/L; 40 to 79 μ mol/L) can be achieved by the peak time of seizure risk. If patients are experiencing significant vomiting or have difficulty maintaining therapeutic phenytoin concentrations, intravenous (IV) phenytoin should be substituted. Benzodiazepines such as lorazepam or clonazepam also have been used for seizure prophylaxis during high-dose busulfan therapy before HSCT. Antiseizure medications usually are discontinued 24 to 48 hours after administration of the last dose of busulfan. Seizures still can occur despite the use of prophylactic anticonvulsants and usually do not result in permanent neurologic deficits.

Adaptive Dosing of Busulfan The considerable interpatient variability in the clearance of both oral and IV busulfan along with the identified concentration–effect relationships, has led to the adaptive dosing of busulfan. Adjusting the oral busulfan dose to achieve a target concentration minimizes the toxicities of the BU-CY regimen, particularly hepatic sinusoidal obstruction syndrome (SOS; formerly referred to as *veno-occlusive disease*) while improving engraftment and relapse rates. Complete reviews of these relationships after oral busulfan administration are available elsewhere.²⁰ An IV busulfan product, Busulfex, was approved by the FDA in February 1999 in combination with cyclophosphamide as a preparative regimen before allogeneic HSCT for CML. Data with Busulfex in combination with either cyclophosphamide or fludarabine suggest that therapeutic drug monitoring may be needed.²¹

Hemorrhagic Cystitis High-dose cyclophosphamide causes moderate to severe hemorrhagic cystitis; acrolein, a metabolite of cyclophosphamide, is the putative bladder toxin. Preventive measures to lower the risk of hemorrhagic cystitis include vigorous hydration, continuous bladder irrigation,

or concomitant use of the uroprotectant mesna. The American Society of Clinical Oncology (ASCO) Guidelines for the Use of Chemotherapy and Radiotherapy Protectants recommends the use of Mesna (2-mercaptoethane sulfonate) plus saline diuresis or forced saline diuresis to lower the incidence of urothelial toxicity with high-dose cyclophosphamide in the setting of HSCT.²²

Chemotherapy-Induced Gastrointestinal Effects Preparative regimens for myeloablative HSCT result in other end-organ toxicities, such as renal failure and idiopathic pneumonia syndrome. In addition, recipients of myeloablative preparative regimens are at risk for severe gastrointestinal (GI) toxicity, specifically chemotherapy-induced nausea and vomiting (CINV), diarrhea, and mucositis. CINV can be caused by administration of highly emetogenic chemotherapy over several days, TBI, and poor control of CINV before HSCT. Thus, patients who are undergoing a myeloablative HSCT should receive a prophylactic corticosteroid with a serotonin antagonist, with higher doses of serotonin antagonists potentially being needed in this patient population. In addition, these patients are at high risk for delayed CINV in the immediate posttransplant period, and these issues should be addressed accordingly as per published clinical practice guidelines.²³

Diarrhea is also an adverse effect experienced by a majority of patients undergoing HSCT. Chemotherapy-induced diarrhea occurs because of the effects of the preparative regimen, which results in inflammation and damage to the cells lining the GI tract. Diarrhea caused by the preparative regimen is usually apparent within the first week after the initiation of chemotherapy and/or radiation. Treatment strategies for chemotherapy-induced diarrhea include the administration of antidiarrheals after excluding infectious causes of diarrhea and the prevention of dehydration.

Virtually all patients receiving a myeloablative preparative regimen experience severe mucositis owing to its effects on rapidly dividing cells of the oral epithelium and subsequent inflammation of the oropharyngeal cavity. Routine oral care protocols are indicated to reduce the severity of mucositis, which may onset within the first week of HSCT and persist for up to approximately 2 weeks. Palifermin (Kepivance) is a recombinant human form of keratinocyte growth factor that has been shown to lower the incidence and average duration of severe oral mucositis as well as the incidence and duration of opioid use in autologous HSCT recipients receiving TBI-based preparative regimens.²⁴ Palifermin use is recommended to decrease severe mucositis in autologous HSCT for hematologic malignancies with TBI-based preparative regimens and may be considered for patients undergoing myeloablative allogeneic HSCT with TBI-based preparative regimens, although data are limited in the allogeneic setting.²² Patients still may require parenteral opioid analgesics for pain relief owing to mucositis, and total parenteral nutrition may be necessary to prevent the development of nutritional deficiencies.

Sinusoidal Obstruction Syndrome Hepatic SOS is a life-threatening complication that may occur secondary to

preparative regimens or radiation. The pathogenesis of SOS is not understood completely, but several mechanisms have been proposed. The key event appears to be endothelial damage caused by the preparative regimen. The primary site of the toxic injury is the sinusoidal endothelial cells; the endothelial damage initiates the coagulation cascade, induces thrombosis of the hepatic venules, and eventually leads to fibrous obliteration of the affected venules.²⁵

The clinical manifestations of SOS are hyperbilirubinemia, jaundice, fluid retention, weight gain, and right upper quadrant abdominal pain. To make a clinical diagnosis of SOS, these features must occur in the absence of other causes of posttransplant liver failure, including GVHD, viral hepatitis, fungal abscesses, or drug reactions. Most cases of SOS occur within 3 weeks of HSCT, and the clinical diagnosis can be confirmed histologically via liver biopsy.

Patients with mild SOS have an excellent prognosis, but those with more severe disease (i.e., bilirubin greater than 20 mg/dL [342 μmol/L] or weight gain greater than 15%) have a high mortality rate. Pretransplant risk factors for SOS include a mismatched or unrelated graft, increased age, prior abdominal radiation or stem cell transplant, and increased transaminases before HSCT.²⁵ Interpatient variability in the metabolism and clearance of the chemotherapy (i.e., busulfan and cyclophosphamide) used within the preparative regimen also may be associated with a poor outcome, although the relationships vary within the various preparative regimens.²⁰ The association of SOS with busulfan concentrations is discussed in the section on adaptive dosing of busulfan. Preliminary data suggest that IV busulfan may be associated with a lower risk of SOS, although more data are needed.²⁶ Use of ursodiol, unfractionated heparin, or low-molecular-weight heparin has been associated with a lower incidence of SOS in a limited number of small, randomized studies and may be recommended for SOS prophylaxis.²⁵

The mainstay of treatment for established SOS is supportive care aimed at sodium restriction, increasing intravascular

volume, decreasing extracellular fluid accumulation, and minimizing factors that contribute to or exacerbate hepatotoxicity and encephalopathy. Recombinant tissue plasminogen activator administered with or without heparin has been investigated for treatment of SOS, but the life-threatening risk of bleeding precludes any potential benefit.²⁵ Defibrotide, an oligonucleotide with antithrombotic, anti-ischemic, and anti-inflammatory activity, has shown promising results in the treatment of SOS in clinical trials.²⁵

Myelosuppression and Hematopoietic Growth Factor

Use Hematopoietic growth factors (HGFs) may be administered to mobilize PBPCs before an HSCT, to hasten hematopoietic recovery during the period of aplasia after an autologous HSCT, and to stimulate hematopoietic recovery when the patient fails to engraft.²⁷

Autologous HSCT is associated with profound aplasia owing to the myeloablative preparative regimen. Aplasia typically lasts 7 to 14 days after an autologous PBPC transplant. During this period of aplasia, patients are at high risk for complications such as bleeding and infection. Filgrastim and sargramostim exert their effects by stimulating the proliferation of committed progenitor cells and accelerating recovery on hematopoiesis. Once engraftment occurs, HGFs may be discontinued. The anatomic source of hematopoietic cells predicts the degree of benefit, with the greatest benefit reached when bone marrow is the graft source. With autologous PBPC transplant, the effect of HGF on neutrophil recovery is variable.

The use of HGF after allogeneic HSCT—whether from bone marrow or PBPC grafts—is controversial. The amount of data with sargramostim is limited in this setting; data with filgrastim have shown more rapid neutrophil but slower platelet engraftment in those receiving grafts from bone marrow or PBPCs.²⁸ The effects of post-HSCT filgrastim use on acute and chronic GVHD have been conflicting, with either no effect or increases in both the incidence of acute

Clinical Presentation and Diagnosis of Sinusoidal Obstructive Syndrome

General

- Sinusoidal obstructive syndrome (SOS) usually occurs within the first 3 weeks after HSCT
- Busulfan, cyclophosphamide, pretransplant exposure to gemtuzumab, TBI-containing preparative regimens, and pretransplant abnormalities in liver function tests may increase the risk for SOS

Symptoms

- Patients may complain of weight gain and abdominal pain

Signs

- Fluid retention: Weight gain caused by ascites greater than 2% compared with pretransplant weight

- Hepatomegaly: May result in right upper quadrant pain
- Hepatic: Jaundice caused by hyperbilirubinemia defined as a bilirubin greater than 2 mg/dL (34.2 μmol/L)

Laboratory Tests

- Hepatic: Elevation of bilirubin, alkaline phosphatase, and γ-glutamyltransferase (GGT)
- Hematologic: Complete blood count with differential may reveal thrombocytopenia, elevated plasminogen activator-1 levels, decreased antithrombin III, protein C, and protein S

Other Diagnostic Tests

- Reversal of blood flow in portal and hepatic veins on Doppler ultrasonography
- Liver biopsy for pathologic review

and chronic GVHD and treatment-related mortality.²⁸ Thus, there is little reason to treat allogeneic BMT with filgrastim as prophylaxis after HSCT.

Graft Failure A delicate balance between host and donor effector cells in the bone marrow is necessary to ensure adequate engraftment because residual host-versus-graft effects may lead to graft rejection. The incidence of graft rejection is higher in patients with aplastic anemia and those undergoing HSCT with histoincompatible marrow or T-cell–depleted marrow.¹ Graft rejection is uncommon in leukemia patients receiving myeloablative preparative regimens with a histocompatible allogeneic donor.

Therapeutic options for the treatment of graft rejection or graft failure are limited. A second HSCT is the most definitive therapy, although the associated complications and toxicities may preclude its use. Graft rejection is best managed with immunosuppressants such as ATG. Primary graft failure occasionally can be treated successfully using HGFs, although patients who received purged autografts are less likely to respond.

Patient Encounter, Part 2

PMH: Coronary artery disease, hypertension, type 2 diabetes, hyperlipidemia, hypothyroidism, sleep apnea, and gout

FH: Father died at age of 56 years of myocardial infarction. Mother has history of hypertension. One younger sister with a history of hypertension.

SH: She is a high school teacher and is married with no children. She drinks alcohol occasionally and does not smoke or use illicit drugs.

Allergies: NKDA

Medications:

- Metformin 500 mg by mouth twice daily
- Lisinopril 20 mg by mouth once daily
- Carvedilol 12.5 mg by mouth twice daily
- Clopidogrel 75 mg by mouth once daily
- Aspirin 81 mg by mouth once daily
- Atorvastatin 40 mg by mouth once nightly at bedtime
- Levothyroxine 75 µg by mouth once daily
- Allopurinol 300 mg by mouth once daily

ROS: (+) fatigue

PE:

VS: 134/82, P 69, RR 18, T 37.6°C

Physical exam reveals no acute findings.

Laboratory analysis is within normal limits except for serum creatinine of 1.3 g/dL (115 µmol/L) and hemoglobin of 10.2 g/dL (102 g/L; 6.33 µmol/L).

Given this additional information, what is your assessment of the planned preparative regimen?

► Graft-Versus-Host Disease

- **8** GVHD is caused by the activation of donor lymphocytes, leading to immune damage to the skin, gut, and liver in the recipient. Immune-mediated destruction of tissues, a hallmark of GVHD, disrupts the integrity of protective mucosal barriers and thus provides an environment that favors the establishment of opportunistic infections. **8** An immunosuppressive regimen is administered to prevent GVHD in recipients of an allogeneic graft; this regimen is based on the type of preparative regimen and the source of the graft. The combination of GVHD and infectious complications are leading causes of mortality for allogeneic HSCT patients.
- GVHD is divided into two forms (i.e., acute and chronic) based on clinical manifestations. Traditionally, the boundary between acute and chronic GVHD was set at 100 days after HSCT; however, more recent definitions hinge upon different clinical symptoms rather than the time of onset.²⁹

Acute GVHD The degree of histocompatibility between donor and recipient is the most important factor associated with the development of acute GVHD. The pathophysiology for acute GVHD is a multistep phenomenon, including (a) the development of an inflammatory milieu that results from host tissue damage induced by the preparative regimen; (b) both recipient and donor antigen-presenting cells and inflammatory cytokines triggering activation of donor-derived T cells; and (c) the activated donor T cells mediate cytotoxicity through a variety of mechanisms, which leads to tissue damage characteristic of acute GVHD.³⁰

Clinically relevant grades II to IV acute GVHD occurs in up to 30% of HLA-matched sibling grafts and 50% to 80% of HLA-mismatched sibling or HLA-identical unrelated donors.³⁰ Other factors that increase the risk of acute GVHD include increasing recipient or donor age (older than 20 years), female donor to a male recipient, and mismatches in minor histocompatibility antigens in HLA-matched transplants.³⁰ T-cell depletion or receipt of an umbilical cord blood graft appears to lower the risk of acute GVHD.¹

- **Clinical Presentation and Staging of Acute GVHD** Acute GVHD must be distinguished accurately from other causes of skin, liver, or GI toxicity in HSCT patients. Other causes of toxicities affecting the skin, liver, or GI tract may include a drug reaction or an infectious process. A staging system based on clinical criteria is used to grade acute GVHD (Fig. 98–2). The severity of organ involvement is scored on an ordinal scale from 0 (no symptoms) to IV (severe symptoms), and then an overall grade is established based on the number and extent of involved organs.

Immunosuppressive Prophylaxis of Acute GVHD GVHD is a leading cause of morbidity and mortality after allogeneic HSCT and thus, efforts have focused on preventing acute GVHD. The donor graft and preparative regimen influence the prophylactic regimen for acute GVHD, with two approaches having been taken by clinicians over time. One approach involves T-cell depletion, which was discussed more fully in the section on T-cell depletion earlier.

Grading by Organ System			Overall Clinical Grade			
Organ	Extent of Involvement	Code	I	II	III	IV
Skin	Rash (% of body surface)	Less than 25	1+	■	■	■
		25–50	2+			
	Desquamation	Greater than 50	3+			
			4+			
Liver	Bilirubin (mg%)	2–3	1+	■	■	■
		3–6	2+			
		6–15	3+			
		Greater than 15	4+			
Intestine	Diarrhea (mL/day)	500–1000	1+	■	■	■
		1000–1500	2+			
	Pain/ileus	Greater than 1500	3+			
			4+			
—	Impairment of performance		1+	■	■	■
			2+			
			3+			

FIGURE 98-2. Clinical grading of acute graft-versus-host disease. The left *panel* summarizes the grading of one organ system; the *right panel* shows the overall clinical grade. With grade I, only the skin can be involved. With more extensive involvement of the skin or involvement of liver and intestinal tract and impairment of the clinical performance status, either alone or in any combination, the severity grade advances from II to IV. (From Perkins JB, Yee GC. Hematopoietic stem cell transplantation. In: DiPiro JT, Talbert RL, Yee GC, et al, eds. *Pharmacotherapy: A Pathophysiologic Approach*, 6th ed. New York: McGraw-Hill; 2005:2552.)

Clinical Presentation and Diagnosis of Acute Graft-Versus-Host Disease

General

- Patients may present with any or all of the following: skin rash, GI complaints, or jaundice
- Signs and symptoms present after engraftment when donor lymphoid elements begin to proliferate

Symptoms

- Patients may complain of nausea, vomiting, bloody diarrhea, or itching from skin rash

Signs

- Skin: Maculopapular skin rash on the face, trunk, extremities, palms, soles, and ears, which may progress to generalized total-body erythroderma, bullous formation, and skin desquamation

- GI: Ileus, malnutrition, dehydration, and electrolyte abnormalities caused by nausea, vomiting, and diarrhea
- Hepatic: Jaundice caused by hyperbilirubinemia

Laboratory Tests

- Hepatic: Elevation of bilirubin, alkaline phosphatase, and hepatic transaminases
- GI: send stool for bacterial, viral, and parasitic cultures to rule out infectious causes

Other Diagnostic Tests

- Biopsy of affected site for pathologic review

- The more common method is to use two-drug immunosuppressive therapy that typically consists of a calcineurin inhibitor (i.e., cyclosporine or tacrolimus) with methotrexate after myeloablative HSCT and a calcineurin inhibitor with mycophenolate mofetil after nonmyeloablative HSCT.

After myeloablative conditioning, acute GVHD rates have been similar or lower with triple-drug regimens, but infectious complications are higher and overall survival is similar to that with two-drug regimens.³¹ With the two-drug regimen, a short-course of low-dose methotrexate (e.g., on days +1, +3, +6, and day +11) is used and thus, can delay engraftment, increase the incidence and severity of mucositis, and cause liver function test (LFT) elevations. The methotrexate dose is reduced in the setting of renal or liver impairment. The calcineurin inhibitors (i.e., cyclosporine and tacrolimus) should be initiated before

donor cell infusion (e.g., day -1) when used for GVHD prophylaxis. This schedule is recommended because of the known mechanism of action of cyclosporine, which entails blocking the proliferation of cytotoxic T cells by inhibiting production of T helper cell-derived interleukin-2 (IL-2). Administering cyclosporine before the donor cell infusion allows inhibition of IL-2 secretion to occur before a rejection response has been initiated. Studies comparing cyclosporine and tacrolimus in combination with methotrexate have shown that tacrolimus administration is associated with a lower incidence of grade II to IV acute GVHD and a similar incidence of chronic GVHD but variable effects on overall survival.^{32,33} Because of the mucosal toxicity from myeloablative preparative regimens, the calcineurin inhibitors are administered IV until the GI toxicity from a myeloablative preparative regimen has resolved (e.g., for 7 to 21 days).

Most centers use a 1:2 to 1:3 ratio for conversion of IV to oral cyclosporine with the Neoral formulation; the ratio for tacrolimus conversion from IV to oral is often 1:4. Different conversion ratios for IV to oral regimens may be used when patients are receiving concomitant medications that affect CYP 3A or p-glycoprotein; these pathways are involved in the metabolism and transport of the calcineurin inhibitors (e.g., voriconazole).

Prophylaxis of acute GVHD for nonmyeloablative preparative regimens is varied, but a calcineurin inhibitor with either methotrexate or mycophenolate mofetil is used.³ To date, trials evaluating the optimal acute GVHD prophylaxis regimen have not been conducted.

Adaptive Dosing of the Calcineurin Inhibitors Most HSCT centers have their own standardized approach to dose adjust the calcineurin inhibitors cyclosporine and tacrolimus to target concentration ranges. Cyclosporine trough concentrations are associated with the acute GVHD and nephrotoxicity. Cyclosporine trough concentrations usually are maintained between 150 and 400 ng/mL (125 to 333 nmol/L) in patients undergoing allogeneic HSCT. Tacrolimus trough concentrations are targeted to a range of 10 to 20 ng/mL (10 to 20 mcg/L; 12.4 to 24.8 nmol/L).³⁴ Dosage adjustments to either calcineurin inhibitor also should be made for elevated serum creatinine (SCr) regardless of their serum concentrations. Nephrotoxicity can occur despite low or normal concentrations of the calcineurin inhibitor cyclosporine and may be a consequence of other drug- or disease-related factors known to influence the development of nephrotoxicity (e.g., genetic risk factors, concurrent use of other nephrotoxic agents, and sepsis). Careful monitoring for drug interactions via CYP 3A4 and p-glycoprotein is also warranted. The calcineurin inhibitor doses are adjusted based on serum drug levels and the calculated creatinine clearance. Common adverse effects to these agents include neurotoxicity, hypertension, hyperkalemia, hypomagnesemia, and/or nephrotoxicity (which may lead to an impaired clearance of methotrexate).

Tapering schedules for the calcineurin inhibitors after myeloablative HSCT vary widely. In patients without GVHD, the calcineurin inhibitor doses usually are stable to day +50 and then are tapered slowly with the intent of discontinuing all immunosuppressive agents by 6 months after HSCT. By this time, immunologic tolerance has developed, and patients no longer require immunosuppressive therapy. There is a paucity of information regarding the optimal duration of GVHD prophylaxis after nonmyeloablative HSCT, with data suggesting that a 2-month duration of cyclosporine with a 4-month taper lowers the rate of severe acute GVHD.³⁵

Treatment of Acute GVHD The most effective way to treat GVHD is to prevent its development. Corticosteroids, usually in combination with a calcineurin inhibitor, are the first-line therapy for treatment of established acute GVHD. Corticosteroids indirectly halt the progression of immune-mediated destruction of host tissues by blocking macrophage-derived IL-1 secretion. IL-1 is a primary stimulus for T helper cell-induced secretion of IL-2, which,

in turn, is responsible for stimulating proliferation of cytotoxic T lymphocytes. The recommended dosage of methylprednisolone in this setting is 2 mg/kg/day; there is no advantage to higher corticosteroid doses (i.e., 10 mg/kg/day).³⁰ A partial or complete response is seen in approximately 50% of patients treated with corticosteroids. Once a clinical improvement occurs, there is no consensus on the optimal method for tapering the corticosteroids. Patients with steroid-refractory acute GVHD have a poor prognosis, and a number of medications are being studied for salvage therapy.

Chronic GVHD Occurring in 20% to 70% of HSCT recipients surviving longer than 100 days, chronic GVHD is the most frequent and serious late complication of allogeneic HSCT.³⁶ Chronic GVHD is the major cause of nonrelapse mortality and morbidity. The clinical course of chronic GVHD is multifaceted, involving almost any organ in the body, and its symptoms resemble autoimmune and immunologic disorders (e.g., scleroderma). Chronic GVHD symptoms usually present within 3 years of allogeneic HSCT and often are preceded by acute GVHD.²⁹ Traditionally, the boundary between acute and chronic GVHD was set at 100 days after HSCT; however, more recent definitions hinge on different clinical symptoms rather than the time of onset.³⁶ A consensus document regarding the diagnosis and scoring of chronic GVHD has been published that proposes a clinical scoring system to describe chronic GVHD as opposed to historical descriptions of chronic GVHD, which described the phenomenon as being “limited” versus “extensive” in nature.²⁹ The diagnosis of chronic GVHD requires (a) distinction from acute GVHD, (b) the presence of at least one diagnostic clinical sign of chronic GVHD or presence of at least one distinctive manifestation confirmed by pertinent biopsy or other relevant tests, and (c) exclusion of other possible diagnoses.

Prevention and Treatment of Chronic GVHD Chronic GVHD is not a continuation of acute GVHD, and separate approaches are needed for its prevention and management. Prevention of chronic GVHD through prolonged use of immunosuppressive medications has been unsuccessful.³⁶ Thus, its prevention is focused on minimization of factors associated with higher rates of chronic GVHD. Several recipient, donor, and transplant factors are relevant. Recipient risk factors that are not modifiable include older age, certain diagnoses (e.g., chronic myeloid leukemia), and lack of an HLA-matched donor. Modifiable factors that may lower the risk of chronic GVHD include selection of a younger donor, avoidance of a multiparous female donor, use of umbilical cord blood or bone marrow grafts rather than PBPCs, and limitation of CD34+ and T-cell dose infused.³⁶ Development of acute GVHD is a major predictor for chronic GVHD, with 70% to 80% of those with grade II to IV acute GVHD developing chronic GVHD.³⁶

Relative to no treatment, survival in those with chronic GVHD is improved by extended corticosteroid therapy; however, multiple long-term adverse effects are associated with corticosteroid use. The prednisone dosage is 1 mg/kg/day administered orally in divided doses for 30 days and then

slowly converted to an alternate-day therapy by increasing the “on day” and decreasing the “off day” dose until a total of 2 mg/kg/day on alternate days is administered. Once therapy is initiated, 1 to 2 months may pass before an improvement in clinical symptoms is noted, and therapy usually is continued for 9 to 12 months. Therapy can be tapered slowly after resolution of signs and symptoms of chronic GVHD. If a flare of chronic GVHD occurs during the tapering schedule or after therapy is discontinued, immunosuppressive therapy is restarted. Other potential approaches for patients who are refractory to initial therapy include etanercept (Enbrel), infliximab (Remicade), mycophenolate mofetil (Cellcept), rituximab (Rituxan), extended use of calcineurin inhibitors, or extracorporeal photochemotherapy.³⁶ When immunosuppressive therapy is administered for long periods, the patient must be monitored closely for chronic toxicity. Cushingoid effects, aseptic necrosis of the joints, and diabetes can develop with long-term corticosteroid use. Other severe complications include a high incidence of infection with encapsulated organisms and atypical pathogens such as *Pneumocystis jiroveci*, cytomegalovirus (CMV), and varicella zoster virus (VZV).

► Infectious Complications

9 Recipients of HSCT are at higher risk of bacterial, viral, and fungal infections and usually receive a prophylactic or preemptive regimen to minimize the morbidity and mortality owing to infectious complications. After myeloablative and nonmyeloablative HSCT, opportunistic infections are a major source of morbidity and mortality. There are three periods of infectious risks, early (days 0–30), middle (engraftment to day +100), and late (after day +100). From days 0 to 30 after HSCT, particularly for patients undergoing myeloablative HSCT, the primary pathogens are aerobic bacteria, *Candida* spp., and herpes simplex virus (HSV). Respiratory viruses such as respiratory syncytial virus (RSV), influenza, adenovirus, and parainfluenza virus are recognized increasingly as pathogens causing pneumonia, particularly during community outbreaks of infection with these organisms. To reduce potential exposure of HSCT recipients to such respiratory viruses, visitors and staff members with respiratory signs and symptoms of a viral illness may not be allowed direct contact with patients.

The second period of infectious risk occurs after engraftment to posttransplant day +100. Bacterial infections are still of concern, but pathogens such as CMV, adenovirus, and *Aspergillus* spp. are common. A common manifestation of infection is interstitial pneumonitis (IP), which can be caused by CMV, adenovirus, *Aspergillus*, and *P. jiroveci*. Suppression of the immune system from acute GVHD and corticosteroids contributes to the risk of such infections during this period. Therefore, patients undergoing nonmyeloablative transplant who are receiving corticosteroids to treat GVHD can be expected to have a similar risk for infection as those undergoing myeloablative HSCT.³⁷ Invasive fungal infections over the first year after HSCT occur at a similar rate in nonmyeloablative transplant

compared with historical control participants receiving a myeloablative preparative regimen.³⁸

During the late period (after day +100), the predominant organisms are the encapsulated bacteria (e.g., *Streptococcus pneumoniae*, *Haemophilus influenzae*, and *Neisseria meningitidis*), fungi, and VZV. The encapsulated organisms commonly cause sinopulmonary infections. The risk of infection during this late period is increased in patients with chronic GVHD as a result of prolonged immunosuppression.

Prevention and Treatment of Bacterial and Fungal Infections

Because of the need to administer chemotherapy, blood products, antibiotics, and other adjunctive medications, the placement of a semipermanent double- or triple-lumen central venous catheter is necessary before HSCT. However, the indwelling IV central catheters put HSCT recipients at increased risk for *Staphylococcus* infections.

Between the time of administration of the preparative regimen and successful engraftment, allogeneic myeloablative HSCT patients undergo a period of pancytopenia that can last from 2 to 6 weeks. During this time, multiple transfusions of blood and platelet products are needed to support the patient through the pancytopenic period. Transfusions with multiple blood products place patients at risk for blood product-derived infection (e.g., CMV and hepatitis) and sensitization to foreign leukocyte HLA antigens (i.e., alloimmunization), which can lead to immune-mediated thrombocytopenia. Thus, blood product support in myeloablative allogeneic HSCT patients must incorporate strategies that reduce the risk of viral infection and alloimmunization by minimizing the number of pretransplant infusions, using of single-donor (rather than pooled-donor) blood products, irradiating blood products to inactivate T cells in the product, or filtering blood products with leukocyte-reduction filters. The risk of infection in autologous and allogeneic myeloablative HSCT patients is minimized through a variety of measures. Private reverse isolation rooms equipped with positive-pressure HEPA filters and adherence to strict hand hygiene techniques reduce the incidence of bacterial and fungal infections.⁴ To reduce exposure to exogenous sources of bacteria, immunosuppressed-patient (low-microbial) diets are used, and live plants or flowers are not allowed in the patient’s room. Chemotherapy-induced mucosal damage serves as a portal of entry for many organisms (e.g., *Streptococcus viridans*, aerobic gram-negative bacteria, and fungi) into the bloodstream. The mouth should be kept clean by using frequent (at least four to six times daily) mouth rinses with sterile water, normal saline, or sodium bicarbonate.⁴ Soft toothbrushes may be used for oral hygiene during periods of neutropenia and thrombocytopenia. The risk of infection is also reduced by aggressive use of antibacterial, antifungal, and antiviral therapy both prophylactically and for the treatment of documented infection. The antibacterial prophylactic regimens vary substantially among HSCT centers. Some HSCT centers use a prophylactic fluoroquinolone (e.g., levofloxacin) on admission for HSCT and then switch to a broad-spectrum IV antibiotic (e.g., meropenem) when the patient experiences his or her first neutropenic fever. Although fluoroquinolones

reduce the incidence of gram-negative bacteremia, they have not been shown to affect mortality; the possibility of developing clostridium difficile-associated diarrhea exists with fluoroquinolone use and infectious causes should be ruled out if diarrhea occurs.⁴ Concerns with fluoroquinolone use in the prophylactic setting during HSCT include the emergence of resistant organisms and an increased risk for streptococcal infection.⁴ Broad-spectrum IV antibiotics should be initiated immediately at the time of the first neutropenic fever under the treatment guidelines endorsed by the Infectious Disease Society of America for management of fever of unknown origin in the neutropenic host.³⁹

Prevention of HSV and VZV Patients who are HSV antibody seropositive before HSCT are at high risk for reactivation of their HSV infection. Acyclovir is highly effective in preventing HSV reactivation, and thus, prophylactic acyclovir is used commonly in HSV-seropositive patients who are undergoing an allogeneic or autologous HSCT.⁴ In the setting of HSV prophylaxis, dosing regimens for prophylactic acyclovir vary widely and most centers discontinue acyclovir at the time of hematopoietic recovery.⁴ Valacyclovir (Valtrex), a prodrug of acyclovir with improved bioavailability, may allow for adequate serum concentrations to prevent HSV in patients undergoing HSCT as well.

In those with a history of VZV infection, VZV disease occurs in 30% of allogeneic HSCT recipients.⁴⁰ The appropriate duration of VZV prophylaxis is controversial. Although VZV infections are reduced by prophylactic acyclovir administered from 1 to 2 months until 1 year after HSCT, the risk of VZV persists in those on continued immunosuppression.⁴⁰

Prevention and Preemptive Therapy of CMV Disease

After allogeneic HSCT, CMV disease is common and has high morbidity and mortality rates. Allogeneic patients are at greater risk than autologous recipients primarily because the latter more efficiently reconstitute their immune system after transplantation. However, autologous HSCT recipients who are CMV seropositive before HSCT are at risk for CMV infection, and prophylaxis should be considered in a select minority of patients.⁴ Infection caused by CMV is usually asymptomatic and develops when CMV replication occurs primarily in body fluids such as the blood (viremia), bronchoalveolar fluid, or urine (viruria). Cytomegalovirus disease is symptomatic and occurs when the virus invades an organ or tissue. Pneumonia and gastritis are the most common types of CMV disease after allogeneic HSCT. The presence of a CMV infection substantially increases the risk for developing invasive CMV disease. Strategies to prevent CMV infection have resulted in dramatic reductions in the incidence of CMV disease.

Primary CMV can be prevented with CMV seromatching, which includes transplanting PBPCs or bone marrow from CMV-seronegative donors and infusing CMV-negative blood products to CMV-negative recipients. Antivirals are essential in those who are CMV seropositive or have a CMV-seropositive graft, with two available approaches to minimize the morbidity associated with CMV. The first is universal prophylaxis, in which ganciclovir is begun at the

time of engraftment and is continued until approximately day +100. The second approach is called preemptive therapy, for which ganciclovir is selectively administered based on detection of CMV reactivation.

Preemptive therapy is the most commonly used strategy for preventing CMV disease after allogeneic HSCT because ganciclovir is used only in patients at highest risk for developing CMV disease. This approach minimizes administration of ganciclovir, thus lowering the risk of ganciclovir-induced neutropenia with its subsequent increased risk of invasive bacterial and fungal infections. With a decreased risk of ganciclovir-induced neutropenia, fewer interruptions of ganciclovir therapy because of myelosuppression may occur with a preemptive approach and the subsequent use of filgrastim to maintain adequate neutrophil counts may be limited. Preemptive therapy hinges on the ability to detect early reactivation of CMV using shell vial cultures, assays of blood for CMV antigens (such as pp65), or viral nucleic acids using PCR. Antigenemia-based preemptive therapy has similar efficacy in preventing CMV disease as universal ganciclovir prophylaxis, and preemptive therapy also has been associated with a significant reduction in CMV mortality. Preemptive strategies typically use an induction course of ganciclovir for 7 to 14 days followed by a maintenance course until 2 or 3 weeks after the last positive antigenemia result or until day +100 after HSCT.⁴ Oral valganciclovir (Valcyte) is an orally bioavailable prodrug of ganciclovir that is converted to ganciclovir in vivo after intestinal absorption and has been used for preemptive therapy. Foscarnet may be given as an alternative to ganciclovir to prevent CMV disease, although its use is complicated by nephrotoxicity and electrolyte wasting.

Fungal Infections

Prevention of Fungal Infections. The widespread use of fluconazole prophylaxis since the early 1990s has led to a significant decline in the morbidity and mortality associated with invasive candidiasis in HSCT recipients. However, invasive aspergillosis (IA); zygomycetes; and fluconazole-resistant *Candida* spp., such as *Candida krusei* and *Candida glabrata*, have increased markedly in incidence.⁴¹ Itraconazole, another azole antifungal agent, has better in vitro activity against fluconazole-resistant fungi (e.g., *Aspergillus* and some *Candida* spp.) and is more effective than fluconazole for long-term prophylaxis of invasive fungal infections after allogeneic HSCT; however, itraconazole is used less often because of frequent GI side effects and concern for potential drug interactions.⁴² Posaconazole (Noxafil) is a triazole antifungal that has been approved by the FDA for prophylaxis against IA in HSCT patients with GVHD and is now the recommended prophylactic agent for this subset of HSCT patients on immunosuppression.⁴³ Posaconazole should be given with food for adequate absorption. Micafungin (Mycamine), an agent of the newer class of antifungals known as the echinocandins, has been FDA approved for prophylaxis of *Candida* infections in patients undergoing HSCT.

Risk Factors for Invasive Mold Infections. Invasive mold infections (e.g., *Aspergillus* spp., *Fusarium* spp., *Zygomycetes*, and

Scedosporium spp.) are an increasing cause of morbidity and death after allogeneic and autologous HSCT. It has been estimated that up to one-third of febrile neutropenic patients who do not respond to antibiotic therapy after 1 week are harboring a fungal infection.³⁹ In HSCT recipients, risk factors for invasive fungal infections include (a) previous history of IA; (b) recipient factors, including older age, CMV seropositivity, and type of stem cell transplant; (c) treatment factors (e.g., a fludarabine-based preparative regimen); (d) transplant complications (e.g., prolonged neutropenia, graft failure, and higher grade GVHD); and (e) host factors (e.g., diabetes, iron overload).⁴⁴ Infections with *Aspergillus* spp. remain the most common mold infections diagnosed in the HSCT population and optimal treatment must be promptly initiated if indicated.

Treatment of Invasive Aspergillosis. Early diagnosis and initiation of appropriate therapy may reduce the high mortality rate of IA. Outcomes also depend on recovery of the recipient's immune system and reduction of immunosuppression. Diagnosis is difficult with the use of computed tomography scans and cultures. Research is ongoing to evaluate the benefit of using nonculture-based methods, such as galactomannan and (1,3)- β -D-glucan antigen detection, which are components of the fungal cell wall that can be detected by commercially available assays.

Practice guidelines are available for the treatment of invasive *Aspergillus* infections in immunocompromised patients.⁴³ Available mold-active agents include triazole antifungals (itraconazole, voriconazole, and posaconazole), echinocandins (caspofungin, micafungin, and anidulafungin), and amphotericin B formulations. Historically, conventional amphotericin B (c-AmB) has been considered the “gold standard” antifungal therapy for any IA infection, although the majority of responders eventually died of their infection. Significant toxicity occurs with c-AmB administration, with nephrotoxicity, electrolyte wasting (e.g., potassium and magnesium), and infusion-related reactions being the most troublesome side effects. Lipid analogs of amphotericin B were developed with the specific intent of reducing nephrotoxicity associated with conventional amphotericin B while retaining therapeutic efficacy, albeit at a higher acquisition cost.⁴⁵ These products include amphotericin B lipid complex (Abelcet, ABLC), liposomal amphotericin B (Ambisome, L-Amb), and amphotericin B colloidal dispersion (Amphotec, ABCD).

With significant toxicity limiting the overall utility of conventional amphotericin B, voriconazole (Vfend) was compared with c-AmB for treatment of IA. For initial therapy of IA, voriconazole had higher response and survival rates than c-AmB and is now considered the primary option for patients with IA.⁴⁶ An advantage of voriconazole is its 96% oral bioavailability, making use of this oral drug an attractive alternative. Common toxicities reported with voriconazole include infusion-related reactions, transient visual disturbances, skin reactions, elevations in hepatic transaminases and alkaline phosphatase, nausea, and headache. In addition, voriconazole increases the serum concentrations of medications cleared by cytochrome P-450

2C9, 2C19, and 3A4 (e.g., cyclophosphamide and calcineurin inhibitors); concomitant use of voriconazole and sirolimus should be carefully monitored. Because of pharmacokinetic and pharmacodynamic relationships, antifungal therapy with triazole antifungals such as voriconazole may be optimized for efficacy and toxicity through the practice of therapeutic monitoring of serum levels of these agents.⁴³

In patients who have failed initial therapy (i.e., salvage), lipid formulations of amphotericin products, itraconazole, posaconazole or an agent from the echinocandin class may be used. The echinocandins have a unique target for their antifungal activity—specifically, β -1,3-glucan synthase, an enzyme that produces an important component of the fungal cell wall. Three agents in the echinocandin class (caspofungin, micafungin, and anidulafungin) are currently FDA approved and are only available as IV formulations. Caspofungin (Cancidas) is the only member of the echinocandin class approved for use in pediatric patients, for patients with persistent neutropenic fever, and for patients with probable or proven IA that is refractory to or intolerant of other approved therapies. The most common adverse effects observed include increased liver aminotransferase enzyme levels; mild to moderate infusion reactions; and headache, with a smaller number of patients experiencing dermatologic reactions related to histamine release (e.g., flushing, erythema, and wheals).

The optimal duration of appropriate antifungal therapy for treating IA is individualized to the reconstitution of the patient's immune system and his or her response to antifungal treatment. Most clinicians continue aggressive antifungal therapy until the infection has stabilized radiographically and may continue with less aggressive “maintenance” therapy (e.g., oral voriconazole) until immunosuppression is lessened or completed. In general, it is common to require several months of antifungal therapy to treat IA.

***Pneumocystis jiroveci*.** After allogeneic HSCT, prophylaxis for *P. jiroveci* (formerly *P. carinii*) pneumonia (PCP) is used because *Pneumocystis* is a common infection with a high mortality rate if left untreated. The optimal prophylactic regimen in this setting is unclear, with most centers using cotrimoxazole for 6 to 12 months after HSCT.⁴ Aerosolized or IV pentamidine and oral dapsone are alternatives for patients who are allergic to sulfa drugs or who do not tolerate cotrimoxazole. Because PCP most often occurs after engraftment, cotrimoxazole usually is begun after neutrophil recovery because of its myelosuppressive effects. Patients receiving prophylactic cotrimoxazole should be monitored closely for rash and unexplained neutropenia or thrombocytopenia. Cotrimoxazole usually is avoided on days of methotrexate administration because the sulfonamides can displace methotrexate from plasma binding sites and decrease renal methotrexate clearance, resulting in higher methotrexate concentrations. Autologous HSCT patients do not receive posttransplant immunosuppression, and thus, their risk of developing PCP is lower.⁴ PCP prophylaxis is used often after autologous HSCT in patients with a hematologic malignancy.

Patient Encounter, Part 3

ZN is admitted for allogeneic HSCT with a reduced-intensity preparative regimen consisting of fludarabine and melphalan. Her hospital course was complicated for neutropenic fever and gastrointestinal toxicities associated with melphalan. Neutrophil engraftment occurred on day +12 after HSCT, and the patient was discharged from the hospital on day +14 with minimal complaints. She presents to the transplant clinic on day +22 complaining of several watery stools in the past 24 hours. She does not report nausea, vomiting, or any other symptoms.

What is the differential diagnosis for the patient's current condition?

It is determined that ZN has 1600 mL of liquid stool output in a 24-hour period. How should ZN be managed until a diagnosis is made?

► Issues of Survivorship After HSCT

The number of long-term HSCT survivors is increasing as 5-year disease-free survival rates improve. Because nonmyeloablative preparative regimens were developed over the past decade, the late effects reported in HSCT survivors describe those resulting from myeloablative preparative regimens.⁴⁷ HSCT recipients—with either an autologous or an allogeneic graft—have a higher mortality rate than the general population.⁴⁸ **10** *Long-term survivors of HSCT should be monitored closely, particularly for infections and secondary malignant neoplasms.*

Survivors of HSCT are at higher risk for secondary malignant neoplasms.⁴⁷ Long-term impairment of end-organ function, including the kidneys, liver, and lungs, may be caused by the preparative regimen, infectious complications, and/or posttransplant immunosuppression. Many HSCT recipients experience endocrine dysfunction, such as hypothyroidism from TBI, adrenal insufficiency from long-term corticosteroids to treat GVHD, and infertility from radiation and/or high doses of alkylating agents in myeloablative preparative regimens. Osteopenia has been found in more than half of HSCT recipients, most likely from gonadal dysfunction and/or corticosteroid administration.

Close monitoring of HSCT recipients for infections is necessary because recovery of immune function is slow, sometimes requiring more than 2 years, even in the absence of immunosuppressants.⁴⁷ Fevers should be assessed and treated rapidly to minimize the likelihood of a fatal infection. HSCT recipients—both autologous and allogeneic—lose protective antibodies to vaccine-preventable diseases; international guidelines have been published regarding recommendations for reimmunization of HSCT recipients.⁴⁹

Survivors of HSCT should be monitored routinely for signs of relapse and, if an allogeneic graft was used, chronic

GVHD. They should be advised regarding revaccination and obtaining prompt medical care for fevers or signs of infection. Routine evaluations of organ function (i.e., renal, hepatic, thyroid, and ovarian) and osteopenia should occur and the appropriate management strategies initiated if necessary.

OUTCOME EVALUATION

Monitor for symptoms and signs of the disease that is being treated by HSCT to assess the effectiveness of the HSCT. For example, the monitoring plan for a patient with CML would be to monitor disease response by PCR of the *BCR-ABL* transcript. The actual clinical outcome monitored, along with the frequency of monitoring, is based on the underlying disease.

Monitor for nonhematologic toxicity of the preparative regimen during its administration. Monitor these symptoms at least daily, with more frequent monitoring if the patient is experiencing these nonhematologic effects. The goal is to prevent or minimize these adverse effects. Specifically:

- **Busulfan:** Seizures, busulfan concentrations if being used with the BU-CY preparative regimen, number of vomiting episodes, and nausea by patient self-report, total bilirubin, and sudden weight changes (SOS)
- **Cyclophosphamide:** Electrocardiography during IV administration, RBCs in urine, frequency of urination, pain on urination, urinary output, number of vomiting episodes, and nausea by patient self-report, total bilirubin, and sudden weight changes (SOS)
- **Etoposide:** Blood pressure, respiratory rate, serum pH, serum bicarbonate with arterial blood gases, and evaluation of anion gap if necessary
- **Total-body irradiation:** Number of vomiting episodes, nausea by patient self-report, sudden weight changes (SOS), total bilirubin, and skin assessment for the presence of irritation or blister formation

Until the patient has achieved engraftment, monitor the patient for engraftment with at least daily complete blood counts with differentials; these tests may be needed more often if the patient is critically ill or had a prior low hemoglobin. Patients will require transfusion support with blood products and platelets until engraftment occurs if hemoglobin and/or platelets drop below unsafe levels. Transfusion parameters may differ for individual patients, but typically patients are transfused if the hemoglobin drops below 8.0 g/dL (80 g/L; 4.97 mmol/L); platelets are maintained at least above 10,000/mm³ (10 × 10⁹/L) to prevent spontaneous bleeding.

Until engraftment has occurred, monitor the patient's temperature every 4 to 8 hours for signs of infection. Also guide monitoring signs of focal point of infection based on clinical symptoms. For example, if the patient develops shortness of breath, then imaging of the lungs should occur to assess pulmonary infection. Monitor for the toxicity of prophylaxis and/or treatment of bacterial, fungal, or viral infections.

Patient Care and Monitoring

1. Assess the patient regarding the indication for HSCT, the type of preparative regimen, and the type of donor. Determine the nonhematologic toxicity of the preparative regimen, the expected timing of engraftment after the graft is infused, and the need for GVHD prophylaxis.
2. Determine the supportive care needs during administration of the preparative regimen, including use of indwelling central venous catheters; blood product support; and pharmacologic management of CINV, mucositis, and pain.
3. After the graft is infused, monitor the complete blood count with differential at least daily to evaluate engraftment. Allogeneic HSCT patients experience an initial period of pancytopenia followed by a more prolonged period of immunosuppression, which substantially increases the risk of bacterial, fungal, viral, and other opportunistic infections.
4. Counsel the patient regarding adherence to prophylactic antibiotic, antifungal, and antiviral regimens. Evaluate the patient for infection and adverse drug reactions to antibiotics, antifungals, and antivirals. Ensure that the patient is appropriately immunized after recovery from HSCT.
5. Counsel the patient regarding adherence to GVHD prophylaxis and treatment. Monitor and manage for adverse drug reactions.

Monitor for acute nonhematologic toxicity to the preparative regimen to approximately day +30. Specifically,

- Monitor the inside of the mouth and assess the patient's mouth pain for signs and symptoms of mucositis.
- Monitor weight and skin color daily to observe sudden weight changes suggesting SOS. Obtain a total bilirubin determination at least twice weekly or more frequently if SOS is suspected based on weight change.

Monitor for signs of acute GVHD at least daily during engraftment and more often if GVHD is suspected or diagnosed. The patient and his or her caregivers should be educated regarding the signs and symptoms to self-monitor for GVHD. The signs and symptoms for acute GVHD that occur between day +0 and day +100 are rash, nausea, diarrhea, jaundice, elevated liver function test results, and elevated bilirubin.

Abbreviations Introduced in This Chapter

AML	Acute myelogenous leukemia
ANC	Absolute neutrophil count
ASCO	American Society of Clinical Oncology

ATG	Antithymocyte globulin
BMT	Bone marrow transplantation
BU-CY	Busulfan–cyclophosphamide
CINV	Chemotherapy-induced nausea and vomiting
CML	Chronic myelogenous leukemia
CMV	Cytomegalovirus
CY-TBI	Cyclophosphamide–total-body irradiation
GVHD	Graft-versus-host disease
HGF	Hematopoietic growth factors
HLA	Human leukocyte antigen
HSCT	Hematopoietic stem cell transplant
IA	Invasive aspergillosis
IL-2	Interleukin-2
MHC	Minor histocompatibility
MM	Multiple myeloma
NHL	Non-Hodgkin's lymphoma
NK	Natural killer
PBPC	Peripheral blood progenitor cells
PCP	Pneumocystis pneumonia
SOS	Sinusoidal obstruction syndrome
SCr	Serum creatinine
TBI	Total-body irradiation
VZV	Varicella zoster virus

Self-assessment questions and answers are available at <http://www.mhpharmacotherapy.com/pp.html>.

Supportive Care in Oncology

Sarah L. Scarpace

LEARNING OBJECTIVES

● Upon completion of the chapter, the reader will be able to:

1. Describe the impact of various supportive care interventions on the prognosis of patients with cancer.
2. Discuss the scientific basis for providing various supportive care interventions in the oncology patient population.
3. Identify patient-related and disease-related risk factors in defining a population for whom supportive care interventions would be of benefit.
4. Recognize typical presenting signs and symptoms of common complications and emergencies that require supportive care interventions.
5. Outline an appropriate prevention and management strategies for various supportive care interventions.
6. Prepare a monitoring plan to evaluate the efficacy and toxicity of pharmacotherapy interventions for supportive care problems.

KEY CONCEPTS

- 1 The optimal method of managing chemotherapy-induced nausea/vomiting (CINV) is to provide adequate pharmacologic prophylaxis given a patient's risk level for emesis.
- 2 The fundamental approach to lessen the severity of mucositis begins with basic, good oral hygiene.
- 3 A risk assessment should be performed at presentation of febrile neutropenia (FN) to identify low-risk patients for potential outpatient treatment. Patients who do not meet low-risk criteria should be hospitalized for immediate parenteral administration of broad-spectrum antibacterials before culture results are obtained.
- 4 The primary goal of treatment of superior vena cava syndrome (SVCS) is to relieve obstruction of the superior vena cava (SVC) by treating the underlying malignancy.
- 5 Because patients with spinal metastases are generally incurable, the primary goal of treatment of spinal cord compression is palliation. The most important prognostic factor for patients presenting with spinal cord compression is the underlying neurologic status.
- 6 The goals of treatment of brain metastases are to manage symptoms and improve survival by reducing cerebral edema, treating the underlying malignancy both locally and systemically.
- 7 The use of effective prevention strategies can decrease the incidence of hemorrhagic cystitis to less than 5% in patients receiving cyclophosphamide or ifosfamide. There are three methods to reduce the risk: administration of Mesna, hyperhydration, and bladder irrigation with catheterization.
- 8 The primary goal of treatment for hypercalcemia is to control the underlying malignancy. Therapies directed at lowering the calcium level are temporary measures that are useful until anticancer therapy begins to work.
- 9 The primary goals of management of tumor lysis syndrome (TLS) are (a) prevention of renal failure and (b) prevention of electrolyte imbalances. Thus, the best treatment for TLS is prophylaxis to enable delivery of cytotoxic therapy for the underlying malignancy.
- 10 Chemotherapy extravasation may be avoided in many cases by the use of successful prevention strategies. The most important preventative measure is proper patient education.

INTRODUCTION

Patients with cancer are at risk for serious adverse events that result from their treatment, the cancer, or both.

The management of these complications is generally referred to as supportive care (or symptom management). Treatment-related complications include chemotherapy-induced nausea and vomiting (CINV), febrile neutropenia (FN), extravasation, hemorrhagic cystitis, mucositis, and tumor lysis syndrome (TLS). Tumor or cancer-related complications include superior vena cava (SVC) obstruction, spinal cord compression, and hypercalcemia and brain metastases. In some cases, these events can be life threatening. SVC obstruction, spinal cord compression, TLS, and hypercalcemia have traditionally been defined as oncologic emergencies. Although some of these conditions are not imminently life threatening (i.e., chemotherapy extravasation), as a group of treatment- and disease-related complications in the oncology population, they do require rapid assessment and supportive care interventions and treatment. The onset of oncologic emergencies may herald the onset of an undiagnosed malignancy or progression or relapse of a preexisting malignancy. Optimal management of patients with various oncologic emergencies and complications requiring supportive care interventions can significantly decrease morbidity and mortality in patients with cancer. This chapter provides an overview of these issues. First, an overview of the management of common side effects of treatment is given. Later, a summary of common oncologic emergencies is presented.

CHEMOTHERAPY-INDUCED TOXICITIES: NAUSEA/VOMITING

Nausea and vomiting are among the most commonly feared toxicities by patients undergoing chemotherapy. One study demonstrated that both nausea and vomiting ranked in the top five bothersome side effects of chemotherapy.¹ ① *The optimal method of managing CINV is to provide adequate pharmacologic prophylaxis given a patient's risk level for emesis.* Studies have demonstrated that insufficient control during the first cycle of chemotherapy leads to more difficulty in controlling emesis for subsequent cycles.²

EPIDEMIOLOGY AND ETIOLOGY

Although it is widely known that chemotherapy causes nausea and vomiting, the rate of emesis varies depending on individual patient risk factors and drug therapy regimen. Therefore, cancer treatments are stratified into varying risk levels: high, moderate, low, and minimal. Agents with a “high” emetic risk cause emesis in more than 90% of cases if not given any prophylaxis. The rates of emesis for “moderate,” “low,” and “minimal” are 30% to 90%, 10% to 30%, and less than 10%, respectively. **Table 99-1** lists the individual agents and their risk category.³ With proper prophylaxis using antiemetics, the rate of emesis when receiving a highly emetogenic regimen can decrease to about 30%.⁴

PATHOPHYSIOLOGY

The pathophysiology of nausea and vomiting is described in Chapter 20. Specific to CINV, the key receptors include

Table 99-1

Emetogenic Potential of Chemotherapy

Risk	Agent	
High emetic risk (more than 90% of patients will vomit without appropriate antiemetics)	Altretamine	
	Carmustine greater than 250 mg/m ²	
	Cisplatin equal to or greater than 50 mg/m ²	
	Cyclophosphamide greater than 1,500 mg/m ²	
	Dacarbazine	
	Mechlorethamine	
	Streptozocin	
	Moderate emetic risk (30–90%)	Aldesleukin greater than 12–15 million units/m ²
		Amifostine greater than 300 mg/m ²
		Arsenic trioxide
		Azacitidine
		Bendamustine
		Busulfan greater than 4 mg/m ²
		Carboplatin
		Carmustine less than or equal to 250 mg/m ²
		Cisplatin less than 50 mg/m ²
		Cyclophosphamide less than or equal to 1,500 mg/m ²
Cyclophosphamide (oral)		
Cytarabine greater than 1 g/m ²		
Dactinomycin		
Daunorubicin		
Doxorubicin		
Epirubicin		
Etoposide (PO)		
Idarubicin		
Ifosfamide		
Irinotecan		
Imatinib (PO)		
Lomustine		
Melphalan		
Methotrexate greater than 1,000 mg/m ²		
Oxaliplatin greater than 75 mg/m ²		
Temozolamide (PO)		
Vinorelbine (PO)		
Low emetic risk (10–30%)	Amifostine less than 300 mg/m ²	
	Bexarotene	
	Capecitabine	
	Docetaxel	
	Etoposide	
	Fludarabine (PO)	
	5-Fluorouracil less than 1,000 mg/m ²	
	Gemcitabine	
	Ixabepilone	
	Methotrexate greater than 50 mg/m ² and less than 250 mg/m ²	
	Mitomycin	
	Nilotinib	
	Paclitaxel	
	Pemetrexed	
	Topotecan	
	Vorinostat	
	Minimal risk (less than 10%)	Most other agents

From Hesketh PJ. Chemotherapy-induced nausea and vomiting. *N Engl J Med* 2008;358:2482–2494.

serotonin (5-HT₃) receptors (located in the chemoreceptor trigger zone, emetic center of the medulla, and gastrointestinal [GI] tract) and neurokinin-1 (NK1) receptors (located in the emetic center of the medulla). Serotonin plays an important

role in the genesis of acute vomiting because some cancer drug therapies can stimulate a release of serotonin from enterochromaffin cells in the GI tract. Serotonin then activates the emetic response by binding to 5HT₃ receptors in the emetic center. This short-lived release of serotonin likely explains why serotonin antagonists are more beneficial for preventing acute versus delayed vomiting.⁵ Other sites that are targeted by antiemetics include dopamine, muscarinic (acetylcholine), histamine, and cannabinoid receptors.

CLINICAL PRESENTATION AND DIAGNOSIS

CINV, although frequently discussed as one syndrome, includes two distinct clinical entities. Nauseous patients may present with general GI upset and reflux and may report a sensation or desire to vomit without being able to do so (patients may describe this as having “dry heaves”). Patients with chemotherapy-induced vomiting may experience vomiting with the first 24 hours of chemotherapy administration (“acute” nausea/vomiting) or several days after chemotherapy (“delayed” nausea/vomiting).³ Patients may additionally experience nausea/vomiting before chemotherapy administration (“anticipatory” nausea/vomiting).³ In all cases, it is important that other causes of nausea and vomiting are ruled out before diagnosing chemotherapy as the source.⁶ Other causes of nausea and vomiting may include bowel obstruction, opioids, electrolyte imbalances, brain metastases, and vestibular dysfunction.⁶

Clinical Presentation and Diagnosis of CINV

Acute Nausea/Vomiting

- Occurs within the first 24 hours after chemotherapy administration

Delayed Nausea/Vomiting

- Occurs between 24 hours and 5 days after chemotherapy administration

Anticipatory Nausea/Vomiting

- A learned, conditioned reflex response to a stimulus (sight, sound, smell) often associated with poor emetic control in a previous cycle of chemotherapy

Breakthrough Nausea/Vomiting

- Occurs despite prophylaxis with an appropriate antiemetic regimen

Differential Diagnosis

- Surgery, radiation
- Gastric outlet or bowel obstruction, constipation
- Hypercalcemia, hyperglycemia, hyponatremia, uremia
- Other drugs (opioids)

TREATMENT

Desired Outcomes

The desired outcome is to completely prevent or minimize the severity of nausea, vomiting, and the use of breakthrough antiemetic medications. In clinical trials, a common end point is “complete response,” defined as having no emesis and no breakthrough medication use within a defined period of time. If patients experience nausea or emesis, the goal is to quickly relieve the episode and prevent future nausea or vomiting, whether in the next few days or for the next cycle of chemotherapy.

General Approach to Treatment

Treatment-related factors and patient-related factors can help define a patient population at risk for developing CINV. Treatment-related factors include those chemotherapy agents with high levels of emetogenicity (see Table 99–1 for a complete listing). CINV is typically a cyclical occurrence. Although this section focuses on CINV, it can be helpful for practitioners to remember that patients undergoing concomitant radiation therapy and chemotherapy are at risk for more severe nausea and vomiting. Radiation (particularly total-body irradiation as part of a conditioning regimen for stem cell transplant) can cause a more cumulative (versus cyclical) nausea/vomiting phenomenon.

Specific patient-related factors such as female gender, age (children), history of motion sickness, pregnancy-induced nausea or vomiting, and poor emetic control in previous chemotherapy cycles increase the risk of emesis. Interestingly, patients with a history of alcohol abuse have a reported decreased risk of emesis.³ It is important to design an antiemetic regimen with consideration of these patient-specific risk factors.

- A well-designed regimen includes a prophylactic regimen and a breakthrough antiemetic drug “as needed.” Although many drugs are recommended as “breakthrough” drugs, choose a drug with a different mechanism of action compared with the drugs used for prophylaxis.⁶

► Nonpharmacologic Therapy

Nonpharmacologic therapy for nausea and vomiting can be useful adjuncts to drug therapy, particularly in the setting of anticipatory nausea and vomiting. The National Comprehensive Cancer Network (NCCN) recommends behavior therapies such as relaxation, guided imagery, and music therapy as well as acupuncture or acupressure as useful in this setting.⁶ Other general measures that can be taken include ensuring adequate sleep before treatment, eating smaller meals, and avoiding greasy foods and foods with strong odors.⁷ Nonprescription medications such as antacids, histamine-2-receptor blockers, and proton pump inhibitors can be helpful in reducing gastroesophageal reflux associated with some cancer treatments that may trigger or exacerbate CINV.⁸

Nonprescription antihistamines marketed for nausea associated with motion sickness are not usually helpful in managing CINV.

► Pharmacologic Therapy

According to the American Society of Clinical Oncology's antiemesis guidelines, three drug classes have a "high therapeutic index" to treat CINV: corticosteroids (dexamethasone), serotonin receptor antagonists, and NK1 receptor antagonists (aprepitant or fosaprepitant).⁹ A drug in these three classes will be used either in combination with drugs from the other classes or as a single agent for prophylaxis, depending on the emetic risk level (Table 99-2). Dexamethasone, serotonin antagonists, and fosaprepitant are usually administered 30 minutes before chemotherapy, and oral aprepitant is administered 60 minutes before chemotherapy. Dexamethasone is the preferred agent to prevent CINV in the delayed setting and is recommended to be scheduled at a dose of 4 mg orally twice daily (or 8 mg once daily) for 3 to 4 days after chemotherapy to prevent delayed nausea vomiting. In some cases, the serotonin antagonists may also be continued orally for 3 to 4 days after chemotherapy. For patients in whom aprepitant is used prechemotherapy (as either 125 mg orally or 115 mg intravenously as fosaprepitant), the aprepitant is continued as 80 mg orally once daily on days 2 and 3 of the chemotherapy cycle. The other antiemetics are usually prescribed "as needed" for breakthrough nausea or vomiting. The dopamine antagonists prochlorperazine and metoclopramide are usually recommended because they antagonize a different receptor than the drugs already given for prophylaxis. However, the NCCN guidelines state that other drugs, including serotonin receptor antagonists, cannabinoids, dexamethasone, scopolamine, or olanzapine, may be used.⁶ For those in any risk group who experience anticipatory nausea and vomiting, the addition of lorazepam for prophylaxis and breakthrough is recommended for its antiemetic and

Emetic Risk Category (Incidence of Emesis Without Antiemetics)	Antiemetic Regimens and Schedules
High (greater than 90%)	5-HT ₃ serotonin receptor antagonist: day 1 Dexamethasone: days 1–4 Aprepitant: days 1, 2, 3 or fosaprepitant 150 mg IV day 1 only
Moderate (30–90%)	5-HT ₃ serotonin receptor antagonist: day 1 Dexamethasone: day 1
Moderate (30–90%) but getting anthracycline, carboplatin, cisplatin, irinotecan cyclophosphamide, methotrexate	5-HT ₃ serotonin receptor antagonist: day 1 Dexamethasone: days 1, 2, and 3 Aprepitant: days 1, 2, and 3
Low (10–30%)	Dexamethasone: day 1
Minimal (less than 10%)	As needed

From Kris MG, Hesketh PJ, Somerfield MR, et al. American Society of Clinical Oncology Guidelines for Antiemesis in Oncology: Update 2006. *J Clin Oncol* 2006;24:2932–2947.

Antiemetic	Single Dose Administered Before Chemotherapy	Daily Schedule
5-HT₃ Serotonin Receptor Antagonists		
Dolasetron	PO: 100 mg IV: 100 mg or 1.8 mg/kg	100 mg PO daily
Granisetron	PO: 2 mg IV: 1 mg or 0.01 mg/kg Topical: 34.3-mg patch (apply 24–48 hours before chemotherapy, leave on for 7 days)	1–2 mg PO daily or 1 mg two times a day
Ondansetron	PO: 16–24 mg IV: 8 mg or 0.15 mg/kg	8 mg PO two times a day or 16 mg PO daily
Palonosetron	IV: 0.25 mg PO: 0.5 mg	
Others		
Aprepitant	PO: 125 mg	80 mg PO days 2 and 3
Fosaprepitant	IV: 150 mg	No aprepitant on days 2 or 3
Dexamethasone	PO: 12 mg	12 mg PO days 2–4

From Kris MG, Hesketh PJ, Somerfield MR, et al. American Society of Clinical Oncology Guidelines for Antiemesis in Oncology: Update 2006. *J Clin Oncol* 2006;24:2932–2947.

anxiety properties. Table 99-3 lists the doses of the antiemetic agents for prophylaxis and breakthrough use.

A prophylactic antiemetic regimen for high emetic risk levels should be with a triple-drug combination using dexamethasone, aprepitant, and 5-HT₃ antagonist to prevent both acute and delayed emesis. Dexamethasone should be continued until day 4, and aprepitant is also administered on days 2 and 3 if the oral formulation is used. When fosaprepitant 150 mg intravenous (IV) is administered on day 1, no oral aprepitant is needed on days 2 and 3 of therapy. If fosaprepitant 115 mg IV is administered on day 1, then oral aprepitant 80 mg once daily on days 2 and 3 is needed.

For moderately emetogenic regimens, acute emesis is still of major concern, but the incidence of delayed emesis is less. Therefore, dexamethasone plus a 5-HT₃ antagonist should be given on day 1. On days 2 to 4, choose to continue either the dexamethasone or the 5-HT₃ antagonist to prevent delayed emesis. One exception is when palonosetron is given as the 5-HT₃ antagonist on day 1. Because its half-life is long, no redosing is necessary on subsequent days. Aprepitant and fosaprepitant 115 mg IV are also approved by the Food and Drug Administration (FDA) for the prevention of CINV in the moderate setting and can be prescribed as a 3-day regimen. Of note, fosaprepitant 150 mg is not FDA approved for use in the moderately emetogenic setting. For patients with additional risk factors or who had uncontrolled emesis with previous chemotherapy cycles, the same regimen for "high-" risk levels may be used.

For low emetic risk regimens, single antiemetic prophylaxis with either dexamethasone or a dopamine antagonist

(prochlorperazine, metoclopramide) is recommended. For minimal emetic risk groups, guidelines do not recommend routine prophylaxis with antiemetics; instead, patients should be provided something as needed for nausea and vomiting. Table 99–2 summarizes the NCCN guidelines for antiemetic prophylaxis for the different risk levels.

OUTCOME EVALUATION

It is often difficult to evaluate nausea and vomiting when chemotherapy is given as an outpatient. After drug

administration, patients return home and may or may not report inadequate control of emesis. Subsequent chemotherapy cycles may also be poorly controlled, especially if patients do not state their experience with the previous cycle. To ameliorate this problem, patients' experiences with CINV should be assessed, particularly after the first and second cycles of chemotherapy. Patients should be asked about their previous emesis control with subsequent cycles of chemotherapy, and a prophylaxis regimen may need to be adjusted. Patients should also be encouraged to self-report poor control of emesis while at home. Side effects of the antiemetic regimen should also be assessed and reported.

Patient Encounter 1: CINV

RK is a 62-year-old man who presents to the clinic today to receive his first dose of cisplatin 100 mg/m² with concurrent radiation for his aggressive head and neck supraglottic squamous cell carcinoma. He is status post laryngectomy for pathological T4aN2C. He had disease progression soon after resection. He appears to be tolerating radiation very well with no obvious adverse side effects. He has a poor appetite and has difficulty swallowing, but he is keeping very well with his nutrition via percutaneous endoscopic gastrostomy (PEG) tube. He takes all of his regular medication through the PEG tube. He has some secretion from the tracheostomy tube. He denies any worsening shortness of breath, cough, hemoptysis, and palpitations. RK also denies any abdominal pain, melena, diarrhea, or constipation. He denies any dysuria, hematuria, or change in frequency of urine.

How would you approach the prevention and monitoring of RK for CINV?

Patient Care and Monitoring: CINV

Monitoring

- Using a visual analogue or numerical rating scale (0–10), have the patient rate the severity of nausea (assess nausea first; then move on to emesis)
- Daily, ask about the number of emesis episodes in the last 24 hours
- Assess scheduled and breakthrough medication adherence

Counsel the patient regarding his or her antiemetics

- Explain which drugs are taken as prophylaxis to prevent nausea and vomiting and which are taken as needed to treat it.
- Have the patient journal when a dose is taken in relation to the chemotherapy. Encourage journaling the severity and frequency of nausea, vomiting, diet, and antiemetic adherence.
- Discuss expected or common side effects of antiemetic medications.

MUCOSITIS

Mucositis is the degradation of mucosal lining in the oral cavity and GI tract caused by damage from radiation or chemotherapy.¹⁰ Mucositis is a common supportive care issue that deserves attention and is associated with many negative health consequences, including pain, inadequate nutritional intake, and risk for infection. Patients with mucositis often require parenteral analgesics, nutrition supplementation, and antiinfectives to treat concomitant bacterial, fungal, or viral infections. Furthermore, mucositis is associated with economic consequences, primarily increased lengths of hospital stay.¹¹ An understanding of the current guidelines for prevention and treatment of mucositis can help improve patient outcomes.

EPIDEMIOLOGY AND ETIOLOGY

- The incidence of chemotherapy or radiation-induced mucositis depends mostly on the type and area of radiation, the type of chemotherapy, and the specific cancer. Studies have reported an incidence of about 80% in head and neck cancer patients receiving chemoradiation.¹² The World Health Organization estimates that approximately 75% of patients who are treated with high-dose chemotherapy for stem cell transplantation developed oral mucositis.¹⁰ Specific chemotherapy agents associated with mucositis include taxanes, anthracyclines, platinum analogues, methotrexate, and the fluoropyrimidines.

PATHOPHYSIOLOGY

The classical concept of mucositis pathophysiology asserts that direct cytotoxicity from chemotherapy or radiation to basal epithelial cells results in ulcerative lesions caused by a lack of regeneration. These lesions are further complicated by trauma or microorganism growth. However, the most recent theory of mucositis pathophysiology is more detailed and involves a multistage, dynamic process that builds upon the historical model.¹³ According to this theory, there are five stages of mucositis: initiation, primary damage response, signal amplification, ulceration, and healing. It is important to note that these stages do not occur sequentially. Rather, they are dynamic and may overlap.

CLINICAL PRESENTATION AND DIAGNOSIS

Patients with mucositis may present along a continuum of mild, painless, erythematous ulcers to those that are painful and/or bleeding that may interfere with eating and swallowing or that may require treatment with hydration, antibiotics, or even parenteral nutrition in its most severe forms.¹³

TREATMENT

Nonpharmacologic Treatment

The goal of nonpharmacologic measures to prevent mucositis is to reduce the bacterial load of organisms in the mouth to prevent infection of the inflamed mucosa. Prevention of mucositis with good basic oral hygiene (brushing with a soft-bristled toothbrush at least twice daily, flossing, bland rinses, and saline substitutes) is key. 2 *The fundamental approach to lessen the severity of mucositis begins with basic, good oral hygiene.*^{10,13,14}

Pharmacologic Treatment

In the setting of radiation therapy, amifostine at doses equal to or greater than 340 mg/m² IV before each dose of radiation therapy may be considered.¹⁴ Cryotherapy, such as with ice chips, is recommended as a prophylactic measure for patients treated with both standard-dose and high-dose chemotherapy regimens.¹⁴ Antimicrobial lozenges, sucralfate and chlorhexidine rinses, and “magic-mouthwash” compounded rinses are not generally recommended by clinical practice guidelines for mucositis prevention even though they are sometimes used in practice.^{10,13,14}

Unfortunately, little evidence is available to recommend specific treatments for mucositis. Pain assessment and appropriate management are important.^{10,13,14} Pain management may be achieved with oral morphine, topical anesthetic products, and compounded rinses that incorporate

lidocaine.^{10,13,14} In more severe cases in which infection of the oral mucosa is suspected, appropriate antibiotic therapy is necessary to prevent systemic infection.^{10,13,14}

Palifermin is FDA approved for the prevention and treatment of mucositis in patients receiving high-dose chemotherapy for stem cell transplant or leukemia induction. Palifermin is administered as an IV bolus injection at a dosage of 60 mcg/kg/day for 3 consecutive days before and three consecutive days after myelotoxic therapy for a total of six doses. Administering Palifermin within 24 hours of chemotherapy can result in an increased sensitivity of rapidly dividing epithelial cells to the cytotoxic agent. For this reason, Palifermin should not be administered for 24 hours before, 24 hours after, or during the infusion of myelotoxic chemotherapy to avoid increasing the severity and the duration of oral mucositis.

OUTCOME EVALUATION

Based on these goals, outcomes measured in clinical trials often assess the incidence, duration, and severity of mucositis with a given intervention intended to prevent or treat mucositis. Agents that are intended to palliate the symptoms of mucositis are usually assessed by measures in pain scales and the ability to eat or drink.

HEMATOLOGIC COMPLICATIONS: FN

INTRODUCTION

FN is a common adverse effect after administration of cytotoxic chemotherapy. The mortality rate in neutropenic patients caused by infectious complications currently remains between 5% and 10%; therefore, FN is considered a true oncologic emergency. Patients frequently require hospitalization for prompt administration of broad-spectrum antibiotics that are critical to avoid morbidity and mortality.

EPIDEMIOLOGY AND ETIOLOGY

The microorganisms responsible for infections in neutropenic patients have changed significantly in the last 50 years. From the 1960s through the mid-1980s, gram-negative organisms were the most common bacteria isolated. This pattern shifted to the gram-positive organisms in the late 1980s, which remain the most common isolates. Recent data indicate that gram-positive organisms account for 62% to 76% of all bloodstream infections.¹⁵ The causes of this change are attributed to the widespread use of central venous catheters and more aggressive chemotherapy regimens as well as the use of prophylactic antibiotics with relatively poor gram-positive coverage (quinolones). Commonly isolated pathogens are shown in [Table 99-4](#). Although gram-negative infections are less common, they cause the majority of infections in sites other than the blood and are particularly virulent. It should be noted that isolates vary considerably among institutions; thus, attention to institutional isolation patterns is prudent.

Clinical Presentation and Diagnosis of Mucositis

- Painful, erythematous ulcers develop on the lips, cheeks, soft palate, floor of mouth.
- Assess mucositis using validated scales, either oral mucositis assessment scale (OMAS) or University of Nebraska oral assessment score (MUCPEAK).
- Symptoms appear within 5 to 7 days after chemotherapy and resolve in 2 to 3 weeks.
- Pain may affect ability to swallow and eat.
- The patient may have concomitant localized or systemic infection.
- Diarrhea can lead to electrolyte imbalances.

Patient Encounter 2: FN

NB is a 73-year-old man with a history of AML in remission s/p first of two cycles of cytarabine consolidation, dose adjusted based on renal function. He presents today 8 days later for follow-up and laboratory check. Relevant laboratory study results include WBC count, $0.7 \times 10^3/\text{mL}$ ($3 \times 10^9/\text{L}$); HgB 9.0 g/dL (0.09 g/L); HCT 26.6% (0.266); PLT, $6 \times 10^3/\text{mL}$ ($6 \times 10^9/\text{L}$); serum chemistries within normal limits except; SCr, 1.3 mg/dL (115 mmol/L); and estimated GFR 54 mL/min. Vitals: temperature, 98.2°F (36.6°C); pulse, 71 beats/min; respiratory rate, 18 breaths/min; BP 116/64 mm Hg. NB has no known drug allergies.

*What risk factors for FN does this patient have?
How would you approach NB?*

Fungal infections caused by *Candida* spp. (especially *Candida albicans*) have emerged as significant pathogens, especially in patients with hematologic malignancies and those undergoing bone marrow transplantation (BMT).

Table 99-4

Commonly Isolated Pathogens in Patients With FN

Type of Organism	Comments
Bacteria	
Gram-positive organisms	Most common isolates in FN
Coagulase-negative staphylococci (i.e., <i>Staphylococcus epidermidis</i>)	Between 70% and 90% resistant to methicillin; indolent course with low mortality
<i>Staphylococcus aureus</i>	Some centers report greater than 50% resistance to methicillin
<i>Enterococcus</i> spp.	Resistance to vancomycin greater than or equal to 30%
<i>Viridans streptococci</i>	Increasing resistance to penicillin; result of fluoroquinolone prophylaxis; associated with mucositis
Gram-negative organisms	Infections rapidly fatal
<i>Pseudomonas aeruginosa</i>	High mortality rate; increasing resistance to quinolones
<i>Escherichia coli</i>	Increased incidence of β -lactamase-producing strains
<i>Klebsiella</i> spp.	Increased incidence of β -lactamase-producing strains
<i>Enterobacter</i> spp.	Occur primarily after prolonged neutropenia (longer than 1 week)
Fungi	
Yeasts	
<i>Candida albicans</i>	Increasing incidence (~10%); high mortality rate
Non- <i>albicans Candida</i> (<i>Candida krusei</i> , <i>Candida glabrata</i>)	Resistant to fluconazole; high mortality rate
Molds	Resistant to fluconazole; high mortality
<i>Aspergillus</i> spp.	Pulmonary infection common
<i>Fusarium</i> spp.	Emerging pathogen
<i>Scedosporium</i> spp.	Emerging pathogen

FN, febrile neutropenia.

From Refs. 16 and 17.

In addition, *Aspergillus* spp. are important pathogens in patients with prolonged and severe neutropenia.

PATHOPHYSIOLOGY

The neutrophils are the primary defense mechanism against bacterial and fungal infection. Most infections in neutropenic patients are a result of organisms contained in endogenous flora, both on the skin and within the GI tract. These organisms are provided access to the bloodstream through breakdowns in host defense barriers (**mucositis**, use of central venous catheters). Mucositis in particular is a significant risk factor for sepsis and is increasingly more common because of the widespread use of aggressive chemotherapy regimens.¹⁸

Neutropenia is defined as an absolute neutrophil count (ANC) less than 500/ μL ($0.50 \times 10^9/\text{L}$) cells or an ANC less than 1,000/ μL ($1.00 \times 10^9/\text{L}$) cells with a predicted decrease to less than 500/ μL ($0.50 \times 10^9/\text{L}$) cells. The ANC is calculated by multiplying the total WBC by the percentage of neutrophils (segmented neutrophils plus “bands”). Fever is defined as a single oral temperature greater than or equal to 38.3°C (101°F) or a temperature greater than or equal to 38.0°C (100.4°F) for at least 1 hour. The combination of these two factors defines FN.¹⁹ The risk of infection during the period of neutropenia depends primarily on two factors:

- The duration of the neutropenia (time period of ANC less than 500/ μL ($0.50 \times 10^9/\text{L}$) cells)
 - The severity of the neutropenia (lowest ANC level reached [nadir])
- A multitude of other risk factors for FN have been identified (**Table 99-5**). Many of these are also risk factors for poor outcome in patients who experience FN. Cancer drug therapy regimens are also categorized as being high

Table 99-5

Risk Factors for FN

Patient Related	Therapy Related
Age 60 years or older	History of extensive chemotherapy
Poor performance status	Planned full dose intensity of chemotherapy
Bone marrow involvement by tumor	High-dose chemotherapy (i.e., bone marrow transplant)
Poor nutritional status	Greater than 20% incidence of FN reported in clinical trials with treatment regimen
Hematologic malignancy	10% to 20% incidence of FN reported in clinical trials with treatment regimen plus presence of patient-specific risk factors
Elevated LDH	
Decreased hemoglobin level	
Baseline or first-cycle low neutrophil counts	
History of previous FN	
Uncontrolled or advanced stage cancer	

FN, febrile neutropenia; LDH, lactate dehydrogenase.

Table 99–6

MASCC Risk-Index for Identifying Low-Risk Patients With FN^a

Characteristic	Score
Burden of illness ^b	
No symptoms	5
Mild symptoms	5
Moderate symptoms	3
No hypotension	5
No COPD	4
Solid tumor or hematologic malignancy without fungal infection	4
No dehydration	3
Outpatient onset of fever	2
Age less than 60 years ^c	

^aNote: A risk-index score of 21 or higher indicates that the patient is likely to be at low risk for complications and morbidity.

^bChoose one item only.

^cDoes not apply to patients 16 years of age or younger.

COPD, chronic obstructive pulmonary disease; FN, febrile neutropenia; MASCC, Multinational Association for Supportive Care in Cancer.

From Klastersky J, Paesmans M, Rubenstein EB, et al. The Multinational Association for Supportive Care in Cancer risk index: A multinational scoring system for identifying low-risk febrile neutropenic patients. *J Clin Oncol* 2000;18:3038–3051.

risk (greater than 20% incidence of FN reported in clinical trials) or intermediate risk (10% to 20% risk of FN reported in clinical trials). Similar to the approach to the prevention of CINV, it is important to consider both the regimen and patient-specific risk factors when determining whether a patient should receive prophylactic therapy for FN.

It is clear that patients with FN represent a heterogeneous group. Some patients are at lower risk and could potentially be treated as outpatients, thereby avoiding the risk and cost of hospitalization. The Multinational Association for Supportive Care in Cancer (MASCC) has validated a risk assessment tool that assigns a risk score to patients presenting with FN (Table 99–6).²¹ Patients with a risk-index score greater than or equal to 21 are identified as low-risk and are candidates for outpatient therapy (discussed under Treatment).

CLINICAL PRESENTATION AND DIAGNOSIS

Patients with suppressed immune systems are often unable to mount the same response to infection as normal individuals, thus limiting the expression of typical presenting signs and symptoms.²² Often fever is the only indicator of infection, and diagnosis is made empirically based on the patient's temperature; ANC; and coexisting risk factors for infection such as presence of an indwelling catheter, inpatient status, history of chemotherapy or radiotherapy, peripheral blood stem cell or bone marrow transplant, renal or hepatic compromise, and older age.^{22,23}

PREVENTION

Three primary modalities for preventing infection in patients who are expected to become neutropenic have been utilized, the first of which is the least expensive and simplest:

- Vigilant hand hygiene
- Prophylactic antibiotics
- Colony-stimulating factors (CSFs)

The advantages and disadvantages of these strategies are discussed individually in the following section.

Hand Hygiene

As previously discussed, most infections in neutropenic patients are a result of endogenous flora; however, prevention of further acquisition of environmental pathogens is also important. Patients who are or will become neutropenic should practice careful handwashing and avoid contact with people who neglect hand hygiene. In addition, ingestion of certain fresh fruits and vegetables as well as unprocessed dairy products should be avoided during the neutropenic period.

Prophylactic Antibiotics

Routine antibacterial prophylaxis is controversial and has been attempted primarily with sulfamethoxazole-trimethoprim (SMZ-TMP) and quinolones. SMZ-TMP offers improved prophylaxis for gram-positive organisms compared with quinolones; quinolones are more effective prophylaxis against gram-negative infections. The 2010

Clinical Presentation and Diagnosis of FN

General

- Only 50% of patients with FN have a clinically documented infection.
- Only 25% of patients with FN have a microbiologically documented infection.

Signs and Symptoms

- Fever is typically the only sign of infection, although septic patients may have chills.
- Infected catheter sites may be erythematous and tender to the touch.

Laboratory Tests

- CBC with differential
- Two blood cultures from each access site (peripheral and central), urinalysis, urine culture, chest x-ray, sputum cultures

Other Diagnostic Tests

- Detailed physical exam of the oral mucosa, sinuses, skin, catheter access sites, perineal area (no rectal examination because of the risk of bacteremia)

Infectious Diseases Society of America (IDSA) guidelines recommend fluoroquinolone prophylaxis in patients who are at high risk for “prolonged and profound” neutropenia.¹⁹ The IDSA does not recommend routine antibiotic prophylaxis for low-risk patients because of the lack of a clear benefit on mortality rates and concerns regarding increasing antibiotic resistance. One exception is that SMZ-TMP is recommended for prophylaxis of *Pneumocystis jirovecii* (formerly *Pneumocystis carinii*) pneumonitis (PCP) in all at-risk patients (i.e., bone marrow transplant recipients, AIDS), regardless of the presence of neutropenia.

Two recent meta-analyses add fuel to the controversy of routine antibiotic prophylaxis.^{24,25} Decreases in infection-related mortality and gram-negative bacteremia were demonstrated with the use of quinolones; however, overall adverse events were higher, and most of the studies were conducted in patients with hematologic malignancies (an inherently high-risk group). Although two additional randomized trials in patients with both solid tumors and hematologic malignancies demonstrated lower rates of FN, infection, and hospitalization with oral prophylactic levofloxacin compared with placebo, both the NCCN and IDSA only recommend prophylactic levofloxacin for patients with expected duration of neutropenia (defined as an ANC less than 1,000/ μL [$1.00 \times 10^9/\text{L}$]) for more than 7 days because of the:

- Unknown long-term consequences on the development of resistant organisms
- Emergence of *Clostridium difficile* and methicillin-resistant *Staphylococcus aureus* (MRSA) from fluoroquinolone overuse
- Ability to treat lower risk patients on an outpatient basis^{26–28}

Therefore, the use of prophylactic quinolones in patients who are at high risk for infection (i.e., hematologic malignancies) is reasonable; however, use should not be routine for low-risk patients. If prophylactic quinolone use is adopted, changes in local patterns of resistance should be closely monitored.

Colony-Stimulating Factors

The CSFs stimulate the maturation and differentiation of neutrophil precursors. Three agents are currently approved for use in the United States (Table 99–7). The prophylactic use of these agents decreases days of hospitalization and use of empiric antibiotics by shortening the duration of severe neutropenia (defined as ANC less than 500/ μL [$0.50 \times 10^9/\text{L}$]). There is little to no effect on the depth of neutrophil nadir.

- A recent meta-analysis found that the use of prophylactic granulocyte CSF (either filgrastim or pegfilgrastim) results in a 46% risk reduction of FN and a 48% risk reduction in infectious mortality, although absolute differences are small (3.3% versus 1.7%).²⁹ It is critical to note that patients who receive these agents may still experience FN despite the risk reduction. The primary limitation of the use of these agents is cost. Clinical practice guidelines for the use of CSFs have been developed by the NCCN.²³ These guidelines recommend the use of CSFs beginning with the first cycle (primary prophylaxis) of chemotherapy when the risk of FN is greater than or equal to 20%, regardless if the goal of therapy is curative or palliative. This is the point where the use of CSFs is cost effective when balanced against the cost of hospitalization and antimicrobials. Secondary prophylaxis refers to the subsequent prophylactic use of a CSF after a

Table 99–7

Overview of CSF

Agent	Effector Cell(s)	Dosage	Common Adverse Effects	Comments ^a
Filgrastim (Neupogen G-CSF)	Neutrophil	5 mcg/kg/day SC or IV or round to 300- or 480-mcg vial size	Bone pain (approximately 25%)	Begin 1–3 days after chemotherapy
Pegfilgrastim (Neulasta)	Neutrophil	6 mg SC once	Bone pain (approximately 25%)	Self-mediated clearance via neutrophils Once per cycle dosing Administer 1–3 days after chemotherapy
Sargramostim (Leukine GM-CSF)	Neutrophil, eosinophil, macrophage	250 mcg/m ² /day SC or IV or round to 250- or 500-mcg vial size	First dose effect (hypotension, flushing) Low-grade fever Bone pain Injection-site skin reaction	Indicated for use after induction chemotherapy in older patients with AML Limited experience and lack of FDA approval for prevention of FN

AML, acute myeloid leukemia; FDA, Food and Drug Administration; FN, febrile neutropenia; GC-SF, granulocyte-colony stimulating factor; GM-CSF, granulocyte-macrophage colony stimulating factor; SC, subcutaneous.

^aNo renal or hepatic dose adjustments are required for any product listed in this table.

From National Comprehensive Cancer Network [Internet]. Fort Washington, PA: National Comprehensive Cancer Network. Clinical practice guidelines in oncology: Myeloid growth factors. version, v.1.2011, accessed 10/4/2011. Available at: http://www.nccn.org/professionals/physician_gls/PDF/myeloid_growth.pdf.

patient has had an episode of FN. This strategy should be used especially when the chemotherapy is being given in patients with the intention of cure (i.e., Hodgkin's lymphoma, early breast cancer). In this circumstance, administration of full doses of chemotherapy on time without delays has been shown to improve patient outcomes.

Although generally well tolerated, CSFs may cause bone pain in around 25% of patients. This may be managed with acetaminophen or nonsteroidal anti-inflammatory drugs (NSAIDs), although attention to the platelet count is warranted with the use of NSAIDs. Sargramostim in particular may result in low-grade fever and myalgias, perhaps as a result of its wider pattern of effector cell stimulation.

TREATMENT

Desired Outcomes

Because rapid death may occur with certain infections in neutropenic patients, prompt and emergent treatment is indicated. The primary goal is to prevent morbidity and mortality during the neutropenic period. This is accomplished by effectively treating subclinical or established infections.

General Approach to Treatment

3 A risk assessment should be performed at presentation of FN to identify low-risk patients for potential outpatient treatment (see Table 99–6). Patients who do not meet low-risk criteria should be hospitalized for parenteral administration of broad-spectrum antibacterials. The IDSA has published evidence-based guidelines for the management of FN (Fig. 99–1).^{19,30} The choice of initial antimicrobial agent(s) depends on the following factors:

- Presence of a central venous catheter
- Drug allergies
- Concurrent renal dysfunction or use of nephrotoxic agents
- Use of prophylactic antibiotics
- Institutional and/or community susceptibility patterns
- Cost

3 The administration of empiric therapy should begin immediately after cultures are taken. Therapy should not be withheld until after culture results are obtained.

As illustrated in Figure 99–1, specific criteria exist for the addition of vancomycin for coverage of resistant gram-positive organisms or agents for coverage of fungal infections. Additional agents are necessary in the setting of continued fever or declining clinical status in neutropenic patients. In general, all empiric therapy is continued until recovery of the ANC to levels above 500/ μ L (0.500×10^9 /L) cells in patients with negative culture results. If a specific etiology is identified, appropriate therapy should be continued until 7 days after neutropenia resolves. Specific regimens with recommended dosages are summarized in Table 99–8.

► Nonpharmacologic Therapy

Prevention of infection is key. Handwashing is critical in the prevention of disease transmission.²⁶ It is also important to ensure that patients receive annual influenza vaccines and have had a pneumonia vaccine, and neutropenic patients should avoid individuals with active respiratory infections.³¹ Plants and animal secretions are also sources of infection and should be avoided.³¹ Indwelling catheters are often sources of infection; however, the Infectious Disease Society of America acknowledges that catheters do not always need to be removed. Catheters should be removed in the following circumstances: established tunnel infection (subcutaneous tunnel or periport infection, septic emboli, hypotension associated with catheter use, or a nonpatent catheter), recurrent infection, or no response to antibiotics within 2 or 3 days.¹⁹ Wound debridement should also be performed upon catheter removal. In the setting of peripheral blood stem cell or bone marrow transplant, the Centers for Disease Control and Prevention recommends the use of high-efficiency particulate air (HEPA) filtration systems in patient rooms, and the NCCN suggests that HEPA filters are reasonable to be considered for other patients who experience prolonged neutropenia.²⁶ HEPA filters are likely to be most useful in preventing mold infections. Although several small studies have attempted to evaluate the effectiveness of isolation of neutropenic patients as a mechanism for infection prevention, no clear data are available to support this practice.³¹

► Pharmacologic Therapy

There are two primary choices for the initial management of high-risk FN: monotherapy and dual therapy (see Fig. 99–1). Both regimens have been shown to be equivalent in randomized studies and meta-analyses. Monotherapy avoids the nephrotoxicity of the aminoglycosides and is potentially less expensive but lacks significant gram-positive coverage and may increase selection of resistant organisms. Dual therapy provides synergistic activity, decreased resistance, and dual coverage of *Pseudomonas aeruginosa* but requires therapeutic monitoring for aminoglycosides.

Vancomycin adds broad-spectrum gram-positive coverage; however, the increasing emergence of vancomycin-resistant organisms (i.e., *Enterococcus* spp.) prompts conservative use of this medication. Furthermore, the European Organization for the Research and Treatment of Cancer (EORTC) found that although empiric vancomycin decreased the number of days of fever, it did not improve survival, and it resulted in increased renal and hepatic toxicities.³² Thus, vancomycin should only be included as part of the initial therapy in the following cases:

- Severe mucositis
- Soft tissue infection
- Quinolone or TMP-SMX prophylaxis
- Hypotension or septic shock
- Colonization with resistant gram-positive organisms (i.e., MRSA)
- Evidence of central venous catheter infection

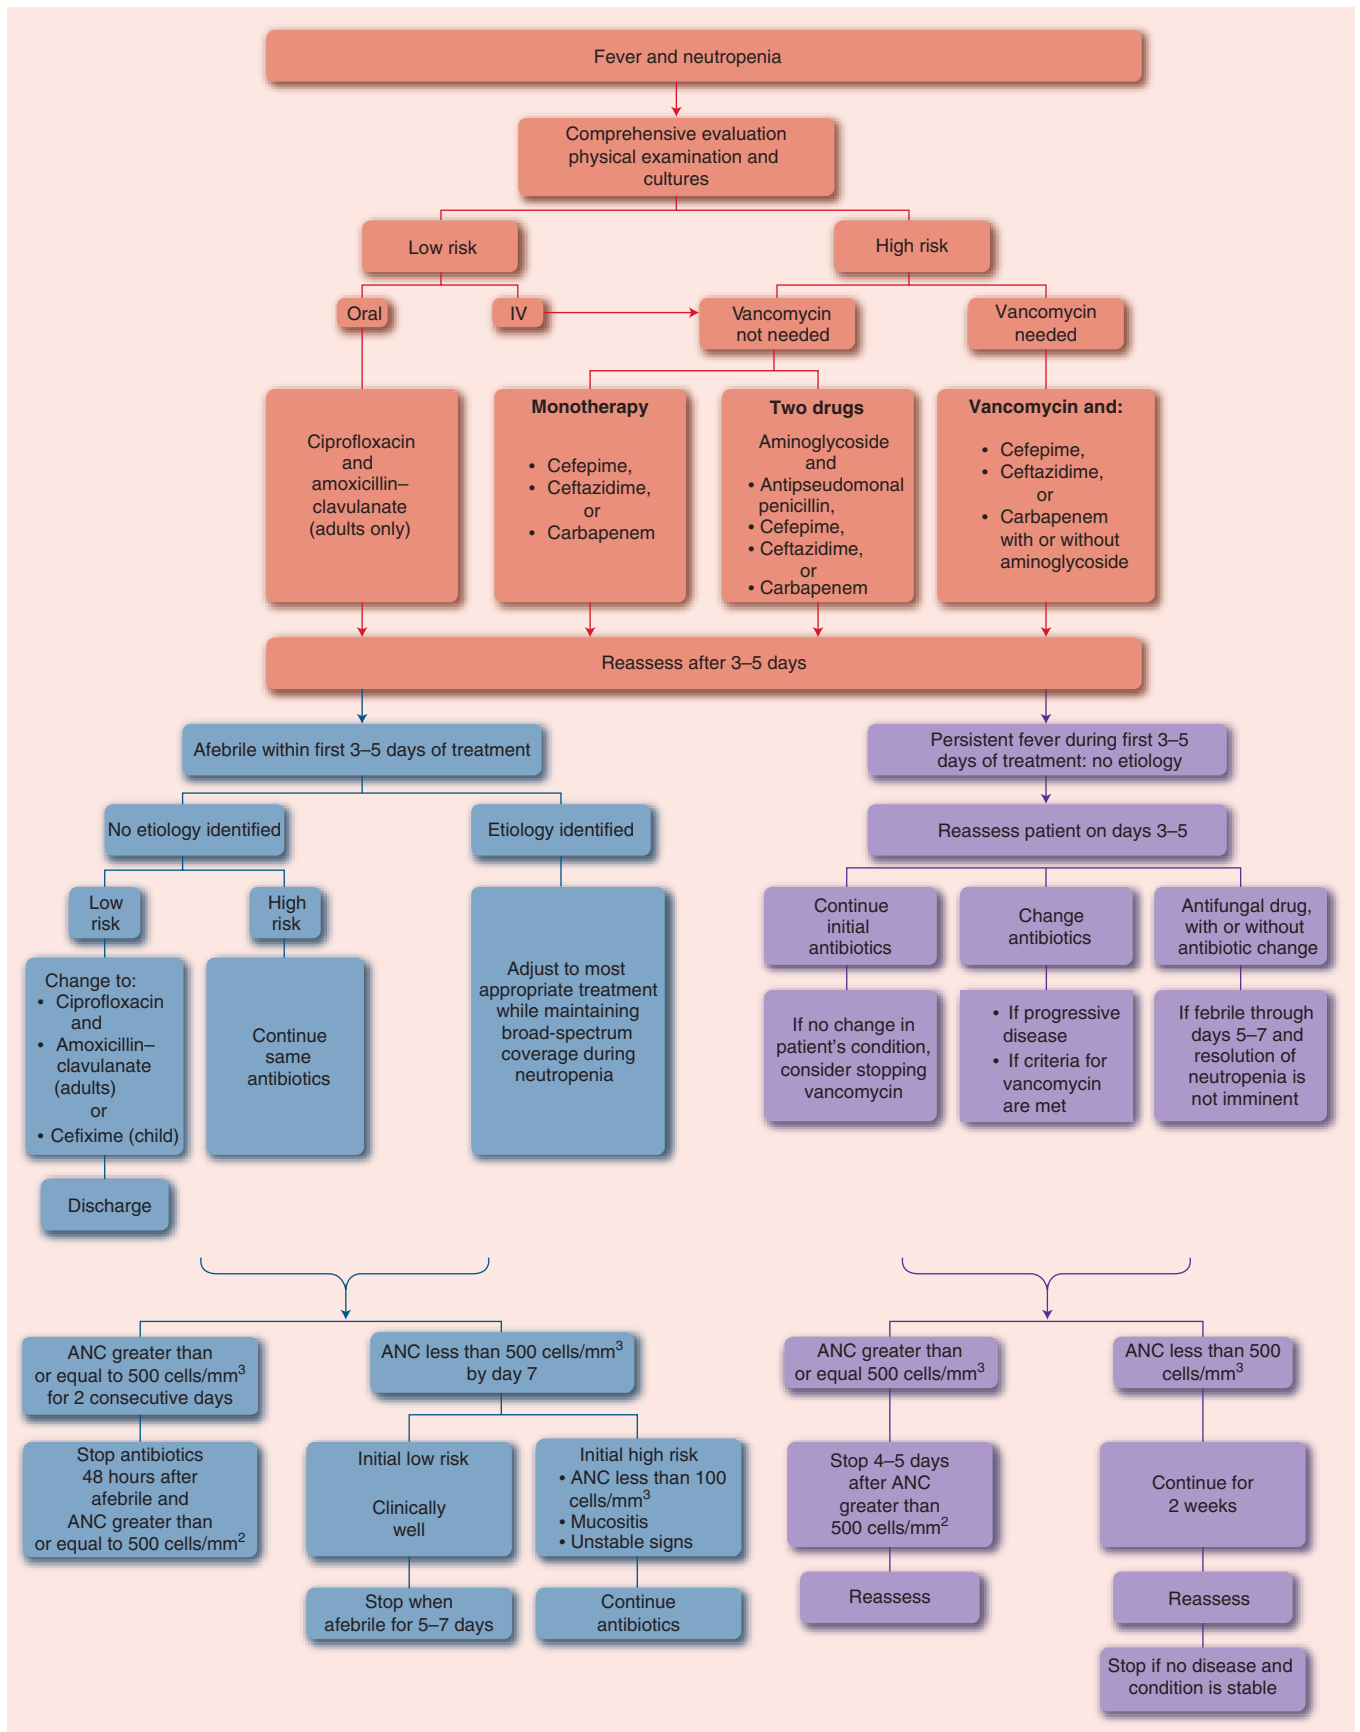

FIGURE 99-1. Management of febrile episodes in neutropenic cancer patients. (ANC, absolute neutrophil count.) (From Refs. 5 and 12.)

Table 99–8

Dosing Guidelines for Empiric Antimicrobial Agents in FN

Regimen Type	Agents and Dosing ^a	Comments
Antibacterial		
β -Lactam monotherapy	Cefepime 2 g IV every 8 hours Ceftazidime 2 g IV every 8 hours Imipenem 500 mg IV every 6 hours Meropenem 1 g IV every 8 hours Piperacillin–tazobactam 4.5 g IV every 8 hours	Although piperacillin–tazobactam is not recommended in the IDSA guidelines, recent data demonstrate equivalence to other monotherapy and dual therapy regimens. All of these agents require renal dose adjustment, and none requires adjustment in hepatic dysfunction. All except meropenem require adjustment during dialysis.
Dual therapy with antipseudomonal β -lactam plus aminoglycoside	Cefepime, ceftazidime, imipenem, meropenem, piperacillin–tazobactam (above dosages), ticarcillin–clavulanic acid 3.1 g IV every 6 hours and gentamicin or tobramycin	Gentamicin or tobramycin 2 mg/kg loading dose followed by doses adjusted by serum concentrations; once-daily dosing of aminoglycosides may be used. Both gentamicin and tobramycin require renal dose adjustment but are dosed based on serum levels. Neither gentamicin nor tobramycin requires hepatic dose adjustment.
Empiric regimens containing vancomycin	Cefepime, ceftazidime, imipenem, meropenem (above dosages) and vancomycin 0.5–1 g every 6–12 hours with or without aminoglycoside	Vancomycin dosages may be adjusted based on serum levels and are adjusted for renal disease and dialysis. No dose adjustment is recommended for hepatic dysfunction.
Dual therapy containing fluoroquinolone	Ciprofloxacin 400 mg IV every 8 hours and piperacillin–tazobactam, ceftazidime (above dosages)	Cannot be used in patients who receive fluoroquinolone prophylaxis. Dose adjusted in renal disease and dialysis but not for hepatic dysfunction.
Low-risk PO regimen	Ciprofloxacin 750 mg PO every 12 hours and amoxicillin–clavulanate 500–875 mg PO every 12 hours	For patients with MASCC scores greater than or equal to 21 not receiving fluoroquinolone prophylaxis. Amoxicillin–clavulanate is adjusted in renal disease and dialysis but not hepatic dysfunction.
Antifungal		
Amphotericin B deoxycholate	0.5–1 mg/kg IV daily	Premedication with acetaminophen and diphenhydramine; 500 mL normal saline boluses before and after. No dose adjustments are recommended for renal or hepatic dysfunction or during dialysis.
Liposomal amphotericin B	3 mg/kg IV daily	Lower incidence of nephrotoxicity and infusion reactions; more expensive. No dose adjustments are recommended for renal or hepatic dysfunction or during dialysis.
Caspofungin	70 mg/kg IV loading dose on day 1 followed by 50 mg/kg IV daily	Dosage adjustment in hepatic dysfunction but not for renal disease or dialysis.
Voriconazole	6 mg/kg IV loading dose every 12 hours on day 1 followed by 4 mg/kg PO or IV every 12 hours	Dosage adjustment in hepatic dysfunction; IV formulation contraindicated if creatinine clearance less than 50 mL/min; multiple drug interactions.
Posaconazole	Prophylactic: 200 mg PO three times a day with food Salvage: 200 mg PO four times a day with food; then 400 mg PO two times a day when stable	Not FDA approved for primary or salvage therapy for invasive fungal infections but used clinically; drug of choice per NCCN for prophylaxis in neutropenic patients with AML or MDS. No dose adjustments required for renal or hepatic dysfunction or during dialysis.

AML, acute myeloid leukemia; FDA, Food and Drug Administration; IDSA, Infectious Diseases Society of America; IV, intravenous; MDS, myelodysplastic syndrome; NCCN, National Comprehensive Cancer Network; PO, oral.

^aDosing for adult patients; adjust doses for renal dysfunction.

Vancomycin may be added to the empiric regimen after 3 to 5 days in persistently febrile patients or if cultures reveal gram-positive organisms. Vancomycin should be changed if the gram-positive organism is susceptible to other antibacterials or discontinued in patients with persistent fever after 3 days with negative culture results. Linezolid, quinupristin–dalfopristin, tigecycline, and daptomycin may be used in cases of vancomycin-resistant organisms or if vancomycin is not an option because of drug allergy or intolerance.

Empiric antifungal agents are typically added in persistently febrile patients after 5 to 7 days, especially if continued

neutropenia is expected. Amphotericin B has historically been the drug of choice because of its broad-spectrum activity against both yeast (*Candida* spp.) and mold (*Aspergillus* spp.) infections. Because frequent toxicity (nephrotoxicity, infusion reactions) limits the use of amphotericin B, less toxic alternatives have been studied. Lipid formulations of amphotericin provide decreased toxicity, and liposomal amphotericin B (AmBisome) has been shown to be equivalent to conventional amphotericin B as empiric therapy but is significantly more expensive. The role of voriconazole is unclear at this time; however, caspofungin has been shown to be equivalent with less toxicity compared with

liposomal amphotericin B in a randomized trial and is FDA approved for this indication.³³ Itraconazole has also been used in some institutions, but its use is complicated by poor bioavailability of oral preparations and numerous drug interactions. Posaconazole is a newer azole that is preferred by the NCCN for prophylactic use in neutropenic patients with acute myeloid leukemia or myelodysplastic syndrome and for patients with graft-versus-host disease while receiving intensive immunosuppressive therapy. It is not FDA approved as primary or salvage therapy for the treatment of invasive fungal infections but it is approved by the European Union for invasive aspergillosis and other fungal infections that are refractory to standard antifungal agents.

As stated earlier, low-risk patients fulfilling the MASCC criteria (see Table 99–6) may be treated empirically as an outpatient with a regimen combining amoxicillin–clavulanic acid and ciprofloxacin. Ciprofloxacin and clindamycin are reasonable alternatives for penicillin-allergic patients.

The CSF should not routinely be used for treatment of FN in conjunction with antimicrobial therapy.¹⁹ However, the use of CSFs in certain high-risk patients with hypotension, documented fungal infection, pneumonia, or sepsis is reasonable. A recent meta-analysis demonstrated that hospitalization and neutrophil recovery are shortened and

infection-related mortality is marginally improved.³⁴ As with prophylactic use of these agents, cost considerations limit their use to high-risk patients.

OUTCOME EVALUATION

The success of the treatment of FN depends on the adequate recovery of the ANC and either optimal antimicrobial coverage of identified organisms or empiric coverage of unidentified organisms. Monitor the complete blood count (CBC) with differential and T_{max} (maximum temperature during previous 24 hours) daily. Assess renal and hepatic function at least twice weekly, especially in patients receiving nephrotoxic agents. Vital signs should be taken every 4 hours. Follow-up on blood and urine culture results daily because many cultures do not become positive for several days. Assess the patient daily for pain that may indicate an infectious source. Conduct daily physical examination of common sites of infection. Repeat cultures and chest x-ray in persistently febrile patients and culture developing sources of infection (i.e., stool cultures for diarrhea).

CARDIOVASCULAR COMPLICATIONS: SVCS

INTRODUCTION

Superior vena cava syndrome (SVCS) is a relatively rare complication that, although nonmalignant, may occur in patients with cancer. SVCS is rarely immediately life threatening except in patients with airway compromise and/or laryngeal or cerebral edema. However, rapid recognition of typical presenting symptoms facilitates referral for tissue diagnosis (if unknown) and treatment.

EPIDEMIOLOGY AND ETIOLOGY

- SVCS occurs in around 15,000 patients per year, 90% of which are caused by malignancy. Specific cancers most commonly associated with SVCS are listed in [Table 99–9](#). Lung cancer is the most frequent cause, of which small cell lung cancer (SCLC) is the most frequent subtype associated

Patient Care and Monitoring: FN

- Counsel patients receiving cytotoxic chemotherapy or alemtuzumab to promptly report fever. Provide patients with a diet to use during the neutropenic period. Counsel patients to avoid close contact with sick friends and relatives and remind patients and caregivers of the importance of handwashing.
- If FN occurs, patient history is important:
 - What chemotherapy did the patient receive and when? Is the ANC on the way down (before nadir) or on the way up (after nadir)? Was the patient receiving prophylactic antibiotics, filgrastim, sargramostim, or pegfilgrastim?
 - Did the patient have previous episodes of FN? What were the previous culture results to determine colonization status?
- Assess the patient daily for any new signs or symptoms of infection. Evaluate the patient for adverse drug reactions, drug allergies, and interactions. Have all antibiotics been dose adjusted for renal or hepatic dysfunction?
- For patients receiving oral antibiotics either prophylactically or as treatment of FN: Counsel patients that initial or persistent fever should be promptly reported and that compliance with the regimen is critical. Patients should also have easy access to medical care and adequate caregiver support. Provide information on drug interactions and adverse effects.

Table 99–9

Tumors Most Commonly Associated With SVCS

Cause	Frequency (%)
Non–small cell lung cancer	50
Small cell lung cancer	22
Lymphoma	12
Metastatic cancer (especially breast)	9
Germ cell tumor	3
Thymoma	2
Mesothelioma	1

From Wilson LD, Detterbeck FC, Yahalom J. Superior vena cava syndrome with malignant causes. *N Engl J Med* 2007;356(8):1862–1869.

with SVCS. This is thought to be because of its predilection for the central and **perihilar** areas of the lung. Interestingly, right-sided lung cancers are four times more likely than left-sided lesions to cause SVCS. Mediastinal masses from lymphomas are the second most common cause.

The most common nonmalignant etiology of SVCS is catheter-related thrombosis, primarily caused by the increasing use of central access devices. Other causes include benign teratoma, tuberculosis, silicosis, and sarcoidosis.

PATHOPHYSIOLOGY

The SVC is the primary drainage vein for blood return from the head, neck, and upper extremities. It is a relatively thin-walled vein that is particularly vulnerable to obstruction from adjacent tumor invasion or thrombosis. The obstruction leads to elevated venous pressure, although collateral veins partially compensate. This is one reason for the relatively slow onset of the classic symptoms of SVCS. In fact, 75% of patients have signs and symptoms for more than 1 week before seeking medical attention.³⁵

CLINICAL PRESENTATION AND DIAGNOSIS

- Visible swelling of the face, neck, chest, and upper limbs with obvious venous distention are the usual presenting symptoms of SVCS.³⁵ Patients may also report coughing, hoarseness, sleep disturbances, dyspnea, headache, and confusion.³⁵ Diagnosis is made with consideration of these symptoms in conjunction with imaging studies that show unusual narrowing of the upper airway.³⁵

TREATMENT

Desired Outcomes

4 *The primary goal of treatment of SVCS is to relieve the obstruction of the SVC by treating the underlying malignancy.* In the case of SVCS caused by thrombosis, the goal is to eliminate the thrombus and prevent further clot formation. Resolution of the obstruction will rapidly relieve symptoms and restore normal SVC function. The final goal of therapy is to avoid potentially fatal complications of SVCS such as cerebral edema from rapid increases in intracranial pressure (ICP) and intracranial thrombosis or bleeding.

General Approach to Treatment

Because the majority of SVCS is not immediately life threatening, a tissue diagnosis (if malignancy is unknown) to specifically identify the cancer origin is critical because treatment approaches vary considerably according to tumor histology. Thus, therapy can typically be withheld until a definitive tissue diagnosis is established. While biopsy results are pending, supportive measures such as head elevation, diuretics, corticosteroids, and supplemental oxygen may be used.

Clinical Presentation and Diagnosis of SVCS

General

- Presentation depends on the degree of SVCS obstruction
- Almost complete obstruction is necessary to demonstrate classic symptoms

Signs and Symptoms

- Most common: face, neck, and upper extremity edema; dyspnea; cough; dilated upper extremity veins; orthopnea
- Less common: hoarseness, dysphagia, dizziness, headache, lethargy, chest pain
- Patients with elevated ICP may have mental status changes.
- Patients with airway obstruction may have shortness of breath.

Diagnostic Tests

- Tissue biopsy to determine underlying malignancy (if unknown), chest x-ray, CT scan, bronchoscopy, mediastinoscopy

► Nonpharmacologic Therapy

- Radiation therapy is the treatment of choice for chemotherapy-resistant tumors such as NSCLC or in chemotherapy-refractory patients with SVCS. Between 70% and 90% of patients experience relief of symptoms. Radiation therapy may also be combined with chemotherapy for chemotherapy-sensitive tumors such as SCLC and lymphoma. In the rare emergency situations of airway obstruction or elevated ICP, empiric radiotherapy before tissue diagnosis should be used. In most patients, symptoms resolve within 1 to 3 weeks.

Surgical options for the management of SVCS include stent placement and surgical bypass. SVC stenting may provide longer term relief of symptoms than radiotherapy, so it is often used in the palliative care setting when chemotherapy has failed.³⁶ One disadvantage of SVC stenting is the need for anticoagulation, especially in patients at high risk for thrombosis. The role of surgical bypass is limited to patients with complete SVC obstruction or patients who are refractory to chemotherapy and radiotherapy; thus, it is rarely indicated.

► Pharmacologic Therapy

- Cytotoxic chemotherapy is the treatment of choice for chemotherapy-sensitive tumors such as SCLC and lymphoma. As indicated earlier, chemotherapy may also be combined with radiotherapy, especially in patients with lymphoma who have bulky mediastinal lymphadenopathy.

Corticosteroids play a key role in the management of SVCS, particularly in cases of lymphoma, because

Patient Care and Monitoring: SVCS

Surgery provides rapid relief of symptoms within 1 to 7 days of stent placement.³² Patients who receive chemotherapy and/or radiotherapy generally experience symptom relief within 1 to 2 weeks. Monitor the patient for relief of symptoms by:

- Daily physical assessment of signs and symptoms
- Daily monitoring of fluid status
- For corticosteroid use: Daily serum glucose, insomnia, fluid retention, GI upset, mental status changes, signs and symptoms of infection.
- Repeat CT scans of the chest after the first cycle of chemotherapy, surgical stenting, or radiotherapy to assess tumor response.

these tumors inherently respond to corticosteroid therapy. They are also helpful in the setting of respiratory compromise. Corticosteroids benefit patients who are receiving radiation therapy by reduction of local radiation-induced inflammation and patients with increased ICP. Dexamethasone 4 mg IV or by mouth every 6 hours is a frequently used regimen. The dosage should be tapered upon completion of radiation therapy or resolution of symptoms.

The role of diuretics in the management of SVCS is controversial. Although patients may derive symptomatic relief from edema, complications such as dehydration and reduced venous blood flow may exacerbate the condition. If diuretics are used, furosemide is most frequently used with diligent monitoring of the patient's fluid status and blood pressure.

In the case of thrombosis-related SVCS, anticoagulation is controversial because there is a lack of survival benefit. However, thrombolytics (i.e., alteplase) and anticoagulation with heparin and warfarin may be beneficial in patients with thrombosis caused by indwelling catheters if used within 7 days of onset of symptoms, although catheter removal may be required.

OUTCOME EVALUATION

The major measure of outcome of treatment of SVCS is the relief of symptoms, regardless of the therapy used.

NEUROLOGIC COMPLICATIONS: SPINAL CORD COMPRESSION

INTRODUCTION

Although not typically life threatening, spinal cord compression is a true oncologic emergency because delays in treatment by mere hours may lead to permanent neurologic dysfunction. Practitioners must quickly recognize the signs and symptoms of this condition to facilitate rapid management strategies.

Clinical Presentation and Diagnosis of Spinal Cord Compression

General

- Once neurologic deficits appear, progression to irreversible paralysis may occur within hours to days.
- Around 10% to 38% of patients present with multiple sites of spinal involvement.

Signs and Symptoms

- Back pain is present in more than 90% of patients.
- Initially localized and increases in intensity over several weeks
- Aggravated by movement, supine positioning, coughing, sneezing, neck flexion, straight leg raise, Valsalva maneuver, palpation of spine
- Sensory deficit
 - Cervical spine compression: quadriplegia
 - Thoracic spine compression: paraplegia
 - Upper lumbar spine compression: bowel and bladder dysfunction (constipation and urinary retention) and abnormal extensor plantar reflexes
- Weakness

Diagnostic Tests

- MRI with gadolinium enhancement is the gold standard.
- X-rays may be helpful to identify bone abnormalities.

EPIDEMIOLOGY AND ETIOLOGY

Around 20,000 cancer patients experience spinal cord compression in the United States every year, most of which involves the thoracic spine (approximately 70%). Cancers that inherently metastasize to the bone (i.e., breast, prostate, and lung) are the most frequent underlying malignancies associated with this complication. Most spinal cord compression occurs in patients with a known malignancy; however, 8% to 34% of cases occur as the initial presentation of cancer, especially in patients with non-Hodgkin's lymphoma, multiple myeloma, and lung cancer.³⁷

PATHOPHYSIOLOGY

The spinal cord emerges from the brain stem at the base of the skull and terminates at the second lumbar vertebra. The thoracic spine is most vulnerable to cord compression because of natural kyphosis and because the width of the thoracic spinal canal is the smallest among the vertebrae. Most spinal cord compression is caused by adjacent vertebral metastases that compress the spinal cord or from pathologic compression fracture of the vertebra. This results in significant edema and inflammation in the affected area.

Patients with spinal cord compression are in acute, severe back and/or neck pain and may present to the emergency department for evaluation. Diagnosis is made based on symptoms and imaging studies that show fractured vertebrae.

TREATMENT

Desired Outcomes

5 Because patients with spinal metastases are generally incurable, the primary goal of treatment of spinal cord compression is palliation. The most important prognostic factor for patients presenting with spinal cord compression is the degree of underlying neurologic dysfunction. Only around 10% of patients who present with paralysis are able to ambulate after treatment.³⁷ Therefore, the goals of treatment are recovery of normal neurologic function, local tumor control, pain control, and stabilization of the spine. Therapeutic options depend primarily on the following factors:

- Underlying malignancy
- Prior therapies
- Stability of the spine at presentation
- Overall patient prognosis

► Nonpharmacologic Therapy

Radiation therapy is generally considered to be the treatment of choice for most patients. Exceptions to this include patients with prior radiation to the treatment site and patients with inherently radio-resistant tumors (i.e., melanoma, renal cell carcinoma). The radiation field should include two vertebral bodies above and below the involved area.

Surgery for spinal cord compression typically involves either **laminectomy** for posterior lesions or decompression with fixation. Surgery is the treatment of choice for the following patients: (a) patients with unstable spine requiring stabilization, (b) immediately impending sphincter dysfunction requiring rapid spinal decompression, (c) patients who do not respond to or have received their maximum dose of radiotherapy, and (d) direct compression of the spinal cord caused by spinal bony fragments.³⁷ Recent evidence suggests that surgery followed by radiation therapy may be superior to radiotherapy alone in terms of increased ambulation time after treatment, maintenance of continence, and rates of nonambulatory patients becoming ambulatory.³⁸ Surgery is also useful for establishing a tissue diagnosis in cases of unknown malignancy. Overall, the risks and benefits of surgery must be weighed against the expected prognosis of the patient in light of the significant rehabilitation required after surgery.

► Pharmacologic Therapy

Corticosteroids play a vital role in the management of spinal cord compression. Dexamethasone is most frequently used to reduce edema, inhibit inflammation, and delay the

Patient Care and Monitoring: Spinal Cord Compression

Monitor patients for:

1. Improved symptoms of sensory loss using physical exam every 4 hours until symptoms improve then daily
2. Improved autonomic system function, including urine and bowel control, every 4 hours until symptoms improve; then daily
3. Improved pain control using detailed pain assessment every 2 to 4 hours during initial titration then daily thereafter
4. For corticosteroid use: serum glucose, insomnia, fluid retention, GI upset, mental status changes, signs and symptoms of infection daily

onset of neurologic complications. Dexamethasone has been shown to improve ambulation in combination with radiation compared with radiation alone.³⁹ Significant controversy exists regarding the optimal dosing of dexamethasone. Oral loading doses of 10 to 100 mg followed by 4 to 24 mg orally four times daily have been used. Higher doses may be used in cases of rapidly progressing symptoms, but adverse effects, including GI bleeding and psychosis, are more severe. Steroids should be continued during radiation therapy and then tapered appropriately.

Pain management is also of critical importance in patients with spinal cord compression. Although dexamethasone will provide some benefit, opioid analgesics should also be used and titrated rapidly to achieve adequate pain control.

OUTCOME EVALUATION

Patients who receive definitive treatment with radiation and/or surgery generally derive benefit within days.

COMPLICATIONS OF BRAIN METASTASES

INTRODUCTION

Brain metastases are among the most feared complications of cancer and generally carry a poor prognosis. One serious consequence of brain metastases is elevated ICP, which can rapidly lead to fatal intracranial herniation and death. Rapid identification of the signs and symptoms of brain metastases is critical to improve long-term outcome and avoid mortality. The signs and symptoms of brain metastasis can be confused with common psychological distress or other neurologic problems (e.g., headaches) that may go unrecognized. It is important that patients who are suspected to have brain metastasis are quickly referred for appropriate management.

EPIDEMIOLOGY AND ETIOLOGY

Brain metastasis is the most common neurologic complication seen in patients with cancer. Approximately 170,000 patients develop brain metastases in the United States each year.⁴⁰ Many malignancies are frequently associated with brain metastases (Table 99–10). Although melanoma is the tumor type most likely to metastasize to the brain, brain metastases caused by lung and breast cancer are seen more often because they are among the most common cancers. In addition, brain metastases may be diagnosed at the same time as the primary malignancy in around 20% of cases.⁴¹ Around 80% of brain metastases occur in the cerebral hemispheres, 15% in the cerebellum, and 5% in the brain stem.

PATHOPHYSIOLOGY

A delicate balance of normal pressure is maintained in the brain and spinal cord by brain, blood, and cerebrospinal fluid. Because the brain is contained within a confined space (skull), any foreign mass contained within that space causes adverse sequelae. This results in either destruction or displacement of normal brain tissue with associated edema. Most brain metastases occur through hematogenous spread of the primary tumor and around 80% of patients have multiple sites of metastases within the brain.

CLINICAL PRESENTATION AND DIAGNOSIS

Patients with brain metastases may have no symptoms. Alternatively, they may have severe headaches, vision changes, and personality or mood disturbances depending on the location of the metastasis. Diagnosis is made based on physical signs and symptoms and brain computed tomography (CT) or magnetic resonance imaging (MRI) indicating a mass.

TREATMENT

Desired Outcomes

Therapeutic modalities used for the management of brain metastases may be divided into symptomatic management

Table 99–10

Cancers Most Frequently Associated With Brain Metastases

Type of Cancer	Frequency (%)
Lung cancer	18–64
Breast cancer	2–21
Melanoma	4–16
Colorectal cancer	2–11
Hematologic malignancies (i.e., leukemia)	Approximately 10 (primarily caused by leptomeningeal spread)

From Lassman AB, DeAngelis LM. Brain metastases. *Neurol Clin North Am* 2003;21:1–23.

Clinical Presentation and Diagnosis of Brain Metastasis

General

- Almost all patients with brain metastases are symptomatic.
- New cerebral neurologic symptoms in a cancer patient should initiate evaluation for brain metastases.
- Other causes of brain lesions, including hemorrhage, infection, and infarct, should be ruled out.

Signs and Symptoms

- Mental status changes (most common): loss of consciousness, irritability, confusion
- Hemiparesis, aphasia, papilledema, weakness, seizure, nausea, and vomiting
- Headache: may be of gradual onset or sudden in the case of hemorrhage

Diagnostic Tests

- MRI with contrast enhancement is the gold standard.
- CT scans may be used in patients with pacemakers, but may miss small metastases.

and definitive management. **6** *The goals of treatment of brain metastases are to manage symptoms by reducing cerebral edema, treat the underlying malignancy both locally and systemically, and improve survival.*

General Approach to Treatment

Patients with brain metastases have a poor prognosis. Untreated patients generally have a median survival of 1 month. The choice of treatment depends primarily on the status of the patient's underlying malignancy and the number and sites of brain metastases. The primary definitive treatments for brain metastases are surgery and radiation therapy. Pharmacologic modalities are primarily used to control symptoms, although cytotoxic chemotherapy plays a limited role in the management.

► Nonpharmacologic Therapy

- Radiation therapy is the treatment of choice for most patients with brain metastases. Most patients receive whole-brain radiation because the majority of brain metastases are multifocal. Another method known as stereotactic radiosurgery provides intense focal radiation, typically using a **linear accelerator** or **gamma knife**, in patients who cannot tolerate surgery or have lesions that are surgically inaccessible (i.e., brain stem). Because brain metastases can occur in up to 50% of patients with small cell lung cancer, prophylactic cranial irradiation is recommended in patients with good performance status who at least partially respond to chemotherapy to both prevent the development of brain metastases and to prolong survival.⁴² Although other

cancers can metastasize to the brain, the benefits of routine prophylactic cranial irradiation have only been demonstrated in studies conducted in patients with small cell lung cancer.⁴²

Surgery plays a key role in the management of patients with brain metastases, particularly in patients whose systemic disease is well controlled and in patients with solitary lesions. Surgery may also benefit patients with multiple metastatic sites who have a single dominant lesion with current or impending neurologic sequelae.

In cases of elevated ICP caused by cerebral herniation, mechanical hyperventilation to decrease the arterial PCO₂ down to 25 mm Hg (3.33 kPa) acutely decreases ICP by causing cerebral vasoconstriction. Elevation of the patient's bed may also quickly reduce the ICP. It should be noted that these strategies only relieve symptoms, and definitive therapy is still required.

► Pharmacologic Therapy

Corticosteroids are a mainstay in the management of brain metastases. They reduce edema that typically surrounds sites of metastases thereby reducing ICP. A loading dose of dexamethasone 10 mg IV followed by 4 mg by mouth or IV every 6 hours is typically used. Symptom relief may occur shortly after the loading dose, although the maximum benefit may not be seen for several days (after definitive therapy).

Mannitol is an agent that may be used in patients with impending cerebral herniation. Mannitol is an osmotic diuretic that shifts brain osmolarity from the brain to the blood. Doses of 100 g (1 to 2 g/kg) as an IV bolus should be used. Repeated doses are typically not recommended because mannitol may diffuse into brain tissue, leading to rebound increased ICP.⁴³

Twenty percent of patients with brain metastases may present with seizures and require anticonvulsant therapy. Phenytoin is the most frequently used agent with a loading

dose of 15 mg/kg followed by 300 mg by mouth daily (titrated to therapeutic levels between 10 and 20 mcg/mL [40 and 79 μmol/L]). Diazepam 5 mg IV may be used for rapid control of persistent seizures. Prophylactic anticonvulsants have frequently been used; however, a recent metaanalysis did not support their use.⁴⁴ Thus, because adverse effects and drug interactions are common, the routine use of prophylactic anticonvulsants is not recommended.

OUTCOME EVALUATION

The success of therapy is based on the ability to decrease symptoms, treat the underlying sites of disease within the brain, and prolong survival.

UROLOGIC COMPLICATIONS: HEMORRHAGIC CYSTITIS

INTRODUCTION

Hemorrhagic cystitis is defined as acute or insidious bleeding from the lining of the bladder. Although therapy with certain medications is the most common cause, it is also the most preventable. Once it occurs, hemorrhagic cystitis causes significant morbidity and mortality rates between 2% and 4%. This section focuses on preventive strategies for chemotherapeutic agents, which rely heavily on pharmacotherapeutic approaches.

EPIDEMIOLOGY AND ETIOLOGY

- Numerous etiologies have been linked to hemorrhagic cystitis (Table 99-11).⁴⁵ Of these, the oxazaphosphorine alkylating agents (cyclophosphamide and ifosfamide) are most frequently implicated. Incidence rates vary considerably but generally range between 18% and 40% with ifosfamide and 0.5% to 40% with high-dose cyclophosphamide in the absence of prophylactic measures.⁴⁶ Chronic, low-dose oral cyclophosphamide as typically used in autoimmune disorders and chronic lymphocytic leukemia is also infrequently associated with hemorrhagic cystitis.

Patient Care and Monitoring: Brain Metastasis

- Assess the patient's symptoms for prompt referral for radiation or surgery.
- For patients receiving corticosteroids, monitor for adverse effects and drug interactions. Does the patient need GI prophylaxis for long-term treatment? Slowly taper once symptoms improve and/or radiation or surgery is completed.
- Evaluate the patient for drug interactions, allergies, and adverse effects with phenytoin or corticosteroid therapy.
- Instruct patients receiving phenytoin about symptoms of elevated serum concentrations (nystagmus, blurred vision, dizziness, drowsiness, lethargy).
- Provide patient education regarding when to take medications and the importance of compliance and to promptly report symptoms of recurrence (mental status changes, seizures).

Table 99-11

Primary Causes of Hemorrhagic Cystitis

Pharmacologic	Nonpharmacologic
Cyclophosphamide	Pelvic irradiation
Chronic low doses	Viral infection
High-doses used in BMT	CMV
Ifosfamide	Papovavirus
Intravesicular thiotepa	Herpes simplex virus
Chronic oral busulfan	Adenovirus
Anabolic steroids	

BMT, bone marrow transplantation; CMV, cytomegalovirus.

From West NJ. Prevention and treatment of hemorrhagic cystitis. *Pharmacotherapy* 1997;17:696-706.

Twenty percent of patients receiving pelvic irradiation may experience hemorrhagic cystitis, especially with concurrent cyclophosphamide. Viral infections commonly associated with this condition most frequently occur in bone marrow transplant recipients who may also receive cyclophosphamide.

PATHOPHYSIOLOGY

Cyclophosphamide- or ifosfamide-induced damage to the bladder wall is primarily caused by their shared metabolite known as acrolein. Acrolein causes sloughing and inflammation of the bladder lining, leading to bleeding and hemorrhage. This is most common when urine output is low because higher concentrations of acrolein come into contact with the bladder urothelium for longer periods of time.

CLINICAL PRESENTATION AND DIAGNOSIS

- Patients with hemorrhagic cystitis from treatment may present with dysuria, anuria, or hematuria. Diagnosis is made based on symptoms and urinalysis, which shows the presence of red blood cells in the urine.

PREVENTION

- 7** The use of effective prevention strategies can decrease the incidence of hemorrhagic cystitis to fewer than 5% in patients receiving cyclophosphamide or ifosfamide. Three methods are used to reduce the risk: administration of Mesna (2-mercaptoethane sulfonate), hyperhydration, and bladder

irrigation with catheterization. Mesna is the primary method used with ifosfamide; all three strategies are used with cyclophosphamide.

Mesna is a thiol compound that is rapidly oxidized in the bloodstream after administration to dimesna, which is inactive. However, after being filtered through the kidneys, dimesna is reduced back to Mesna, which binds to acrolein, leading to inactivation and excretion. The American Society of Clinical Oncology (ASCO) has published evidence-based guidelines for the dosing and administration of Mesna (Table 99–12).⁴⁶ The dose of oral Mesna must be double the IV dose because of oral bioavailability between 40% and 50%. Because the half-life of Mesna (approximately 1.2 hours) is much shorter than that of ifosfamide or cyclophosphamide, prolonged administration of Mesna beyond the end of the chemotherapy infusion is critical (Fig. 99–2). Patients should receive at least 2 L of IV fluids beginning 12 to 24 hours before and ending 24 to 48 hours after the last dose of chemotherapy.

Hyperhydration with normal saline at 3 L/m²/day with IV furosemide to maintain urine output greater than 100 mL/h has also been used with cyclophosphamide. Continuous bladder irrigation by catheterization uses normal saline at 250 to 1,000 mL/h to flush acrolein from the bladder. Mesna is equivalent to both strategies in patients receiving high-dose cyclophosphamide and avoids the discomfort and infection risk with catheterization and the intensity of hyperhydration. Thus, Mesna is the preventive method of choice.

TREATMENT

Desired Outcomes

If hemorrhagic cystitis occurs, the goals of treatment are to decrease exposure to the offending etiology, establish and maintain urine outflow, avoid obstruction and renal compromise, and maintain blood and plasma volume. Restoration of normal bladder function is the ultimate goal following acute treatment.

General Approach to Treatment

The treatment of hemorrhagic cystitis first involves discontinuation of the offending agent. Agents such as anticoagulants and inhibitors of platelet function should also be discontinued. IV fluids should be aggressively administered to irrigate the bladder. Blood and platelet transfusions may be necessary to maintain normal hematologic values. Pain should be managed with opioid analgesics. Local **intravesicular** therapies may be necessary if hematuria does not resolve (Fig. 99–3).

► Nonpharmacologic Therapy

A large-diameter, multihole urethral catheter should be inserted to facilitate saline lavage and evacuation of blood clots. Surgical removal of blood clots under anesthesia may be required if saline lavage is ineffective. Active bleeding

Clinical Presentation and Diagnosis of Urologic Complications

General

- Presentation may be mild (microscopic hematuria) or severe (massive hemorrhage) and develops during or shortly after chemotherapy infusion.

Signs and Symptoms

- Suprapubic pain and cramping, urinary urgency and frequency, dysuria and burning, hematuria
- Urinary retention leading to **hydronephrosis** and renal failure may occur if large blood clots obstruct the ureters or bladder outlet.

Laboratory Tests

- Urine dipsticks for blood
- Urinalysis reveals more than 3 RBCs per high-power field: microscopic hematuria
- CBC with differential, prothrombin time or international normalized ratio, activated partial thromboplastin time, blood urea nitrogen, creatinine

Table 99–12

ASCO Guidelines for the Use of Mesna With Ifosfamide and High-Dose Cyclophosphamide

Chemotherapy Schedule	Dosing Schedule for Mesna	Comments
Low-dose ifosfamide 2 g/m ² /day	Oral: 100% of total daily dose of ifosfamide given 20% IV 15 minutes before and 40% PO 2 and 6 hours after start of ifosfamide	Available in 400-mg tablets Peak urinary thiol concentrations with oral Mesna is at 3 hours If patient vomits within 2 hours of administration, repeat dose PO or IV
Standard-dose ifosfamide 2.5 g/m ² /day	Bolus: 60% of total daily dose of ifosfamide given IV in 20% increments 15 minutes before and 4 and 8 hours after start of ifosfamide Infusion: 60% of total daily dose of ifosfamide given 20% IV 15 minutes before and 40% by continuous infusion during and for 12–24 hours after end of ifosfamide	Peak urinary thiol concentrations with IV Mesna is at 1 hour Compatible with ifosfamide and cyclophosphamide by Y-site administration or when admixed in the same bag
High-dose ifosfamide greater than 2.5 g/m ² /day	Lack of evidence for dosing, but higher doses for longer duration recommended based on longer half-life of ifosfamide at high doses	
Standard-dose cyclophosphamide	Use of Mesna is not routinely necessary	Should be combined with saline diuresis (1.5 L/m ² /day of normal saline)
High-dose cyclophosphamide (BMT)	Bolus: 40% of cyclophosphamide dose given IV at hours 0, 3, 6, and 9 after cyclophosphamide Infusion: 100% of cyclophosphamide dose given by continuous infusion until 24 hours after cyclophosphamide

from isolated areas may be cauterized with an electrode or laser. In severe cases that are unresponsive to local or systemic pharmacologic intervention, urinary diversion with percutaneous **nephrostomy** or surgical removal of the bladder may be required.

► **Pharmacologic Therapy**

A number of local or systemic agents are used in the treatment of hemorrhagic cystitis.⁴⁵ Local (direct instillation into the bladder), one-time administration of hemostatic agents

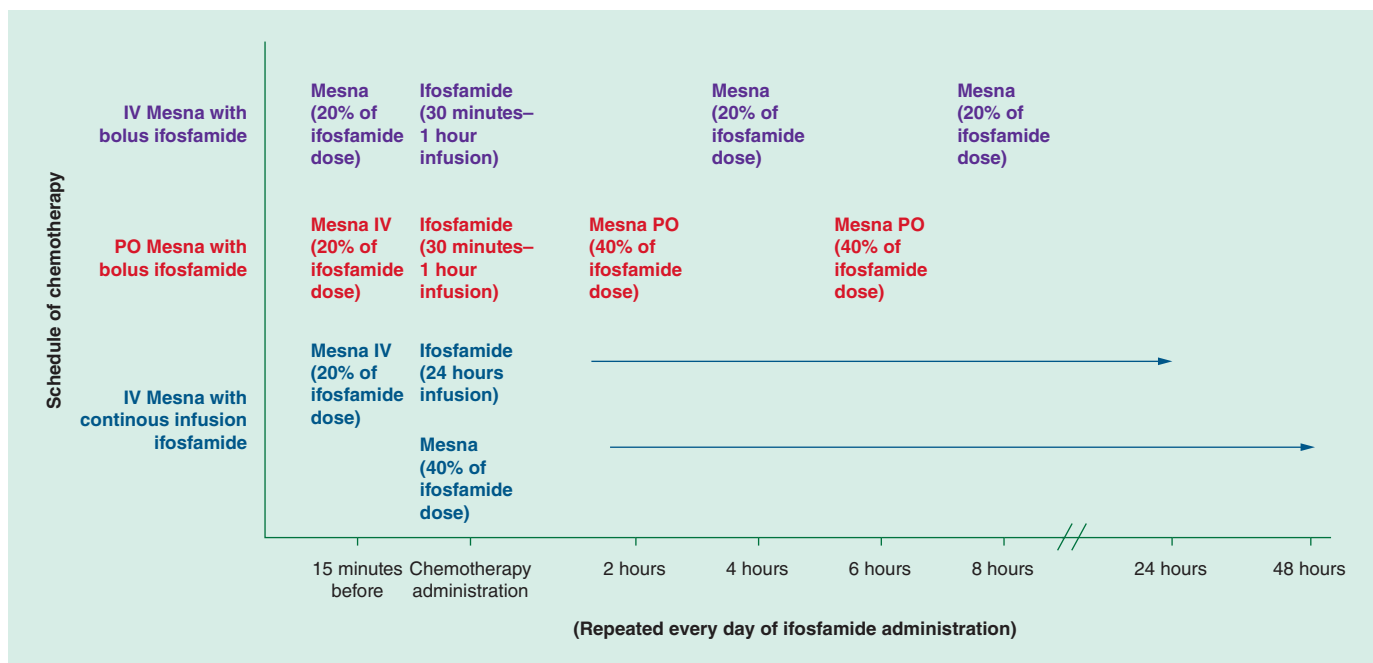

FIGURE 99–2. Examples of Mesna (2-mercaptoethane sulfonate) administration with ifosfamide. (IV, intravenous; PO, oral.)

**FIGURE 99-3.**

Treatment of hemorrhagic cystitis. (From Bucavene G, Micuzzi A, Menichetti F, et al. Levofloxacin to prevent bacterial infection in patients with cancer and neutropenia. *N Engl J Med* 2005;353:977-987.)

such as alum, prostaglandins, silver nitrate, and formalin may be used; however, general anesthesia is required, especially with formalin, because of pain. Systemic agents, including estrogens, vasopressin, and aminocaproic acid, may be used in patients who are refractory to local therapy, although they introduce the risk of systemic side effects. These agents should be continued until bleeding stops.

Antispasmodic agents such as oxybutynin 5 mg by mouth two to three times daily may be used for bladder spasms. In patients with refractory pain, opioid analgesics should be titrated to adequate pain control.

OUTCOME EVALUATION

The goal of treatment is resolution of bladder symptoms and appropriate pain management.

Monitor the patient for resolution of hematuria after each successive therapeutic intervention. The frequency of monitoring is based on the severity of hemorrhaging. Monitor urinary output and serum chemistries (including sodium,

Patient Care and Monitoring: Urologic Complications

1. Assess the patient receiving ifosfamide or cyclophosphamide at least daily for the development of hematuria.
2. Ensure administration of adequate hydration and proper doses of Mesna.
3. Counsel patient receiving oral Mesna on the importance of compliance, when to take doses, and to immediately report any episodes of vomiting for IV readministration.
4. Assess the quantity of urinary bleeding and promptly refer to a urologist for local or surgical management.
5. Patients receiving systemic treatment should be monitored every 4 hours for resolution of hematuria. Promptly refer to urologist for refractory hematuria.
6. Evaluate the patient for drug interactions, allergies, and adverse effects with chemotherapy, Mesna, or systemic therapies for management.

potassium, chloride, blood urea nitrogen, and serum creatinine) daily for renal dysfunction. Check the CBC at least daily to monitor hemoglobin and platelet count.

METABOLIC COMPLICATIONS: HYPERCALCEMIA OF MALIGNANCY

INTRODUCTION

Hypercalcemia is the most common metabolic abnormality experienced by patients with cancer. A small percentage of as yet undiagnosed patients present with hypercalcemia. Once hypercalcemia occurs, it is associated with a very poor prognosis because of the frequent association with advanced or metastatic disease.⁴⁷

EPIDEMIOLOGY AND ETIOLOGY

- Hypercalcemia occurs in 10% to 30% of patients with cancer during the course of their disease. The most common tumor types associated with hypercalcemia are breast cancer; squamous cell carcinomas of the head and neck, lung, and renal cancer. Hematologic malignancies such as multiple myeloma and, rarely, lymphomas are other underlying malignancies associated with hypercalcemia.

PATHOPHYSIOLOGY

Around 99% of calcium is contained in the bones; the other 1% resides in the extracellular fluid. Of this extracellular calcium, approximately 40% is bound to albumin, and the remainder is in the ionized, physiologically active form. Normal calcium levels are maintained by three primary factors: parathyroid hormone (PTH), 1,25-dihydroxyvitamin D, and calcitonin. PTH increases renal tubular calcium resorption and promotes bone resorption. The active form of vitamin D, 1,25-dihydroxyvitamin D, regulates absorption of calcium from the GI tract. Calcitonin serves as an inhibitory factor by suppressing osteoclast activity and stimulating calcium deposition into the bones.

The delicate balance maintained by these factors is altered in patients with cancer by two principal mechanisms: tumor production of **humoral** factors that alter calcium metabolism (humoral hypercalcemia) and by local osteolytic activity from bone metastases.⁴⁸ Humoral hypercalcemia causes around 80% of all hypercalcemia cases and is primarily mediated by systemic secretion of PTH-related protein (PTHrP). This protein mimics the action of endogenous PTH on bones. Local osteolytic activity causes 20% to 30% of hypercalcemia cases, although local osteolytic activity may also have a humoral component. Local production of various factors directly stimulates osteoclastic bone resorption, which releases growth factors and cytokines (i.e., transforming growth factor- β) that are necessary for tumor growth. Thus, these metastatic tumors perpetuate their own growth through this mechanism. Calcium is also released by the

osteolytic activity, resulting in hypercalcemia (Fig. 99–4). A third and less common mechanism is production of 1,25-dihydroxyvitamin D by tumor cells (usually lymphoma), which increases GI absorption of calcium and enhances osteoclastic bone resorption.

CLINICAL PRESENTATION AND DIAGNOSIS

- Patients with hypercalcemia may present with confusion, dehydration and elevated calcium levels.⁴⁷ Diagnosis is made based on symptoms, consideration of history of malignancy, and measurement of total calcium, ionized calcium, or corrected calcium levels.⁴⁷

TREATMENT

Desired Outcomes

- 8** *The primary goal of treatment for hypercalcemia is to control the underlying malignancy. Therapies directed at lowering the calcium level are temporary measures that are useful until anticancer therapy begins to work.* The goals of calcium-lowering therapy are to (a) lower the corrected calcium to normal levels, (b) regain fluid and electrolyte balance, (c) relieve symptoms, and (d) prevent life-threatening complications. Patients who are refractory to available therapies may have calcium-lowering therapy withheld (usually resulting in coma and death), which may be a humane approach.⁴⁷

General Approach to Treatment

Therapeutic options for the treatment of hypercalcemia should be directed toward the level of corrected serum calcium and the presence of symptoms (Fig. 99–5). Hypercalcemia may be classified as mild (corrected calcium equal to 10.5 to 11.9 mg/dL [2.6 to 3.0 mmol/L]), moderate (12 to 13.9 mg/dL [3.0 to 3.5 mmol/L]), and severe (greater than 14 mg/dL [3.5 mmol/L]).⁴⁷ Adequate treatment of mild or asymptomatic hypercalcemia may be achieved on an outpatient basis with nonpharmacologic measures. Moderate to severe or symptomatic hypercalcemia almost always requires pharmacologic intervention.

► Nonpharmacologic Therapy

- Calciuric therapy in the form of hydration is a key component in the treatment of hypercalcemia, regardless of severity or presence of symptoms.⁴⁹ Mild or asymptomatic patients may be encouraged to increase their oral fluid intake (3 to 4 L/day). Patients with moderate to severe or symptomatic hypercalcemia should receive normal saline at 200 to 500 mL/h according to their dehydration and cardiovascular status. Patients should be encouraged to ambulate as much as possible because immobility enhances bone resorption. Although calcium should be discontinued from parenteral feeding solutions, oral calcium supplementation minimally contributes to hypercalcemia unless it is mediated by vitamin D. In these cases, oral calcium should be discontinued. Finally,

FIGURE 99–4. Pathophysiology of the hypercalcemia of malignancy. (Ca^{2+} , calcium; IL-1, interleukin-1; IL-2, interleukin-2; PTHrP, parathyroid hormone–related protein; TGF- β , transforming growth factor β ; TNF- α , tumor necrosis factor α .)

agents that may contribute to hypercalcemia (thiazide diuretics, vitamin D, lithium) or decrease renal function (NSAIDs) should be discontinued. Dialysis may be used in refractory cases or patients who cannot tolerate aggressive saline hydration.

► Pharmacologic Therapy

- Multiple pharmacologic interventions are available for the treatment of hypercalcemia ([Table 99–13](#)). Furosemide 20 to 40 mg/day may be added to hydration after rehydration has been achieved to avoid fluid overload and enhance renal

Clinical Presentation and Diagnosis of Hypercalcemia

General

- Presence of symptoms depends not only on the calcium level but the rapidity of onset
- Normal calcium level is 8.5 to 10.5 g/dL (2.1–2.6 mmol/L) (varies by lab)
- Serum calcium level *must* be corrected for albumin level using the following formula:

$$\text{Corrected calcium} = \text{Serum calcium} + 0.8 (4 - \text{Serum albumin})$$

Signs and Symptoms

- Five primary organ systems may be affected:
 - GI: anorexia, nausea, vomiting, constipation
 - Musculoskeletal: weakness, bone pain, fatigue, ataxia
 - CNS: confusion, headache, lethargy, seizures, coma
 - Genitourinary: polydipsia, polyuria, renal failure
 - Cardiac: Bradycardia, ECG abnormalities, arrhythmias

Laboratory Tests

- Elevated corrected serum calcium level (greater than or equal to 10.5 g/dL [2.6 mmol/L]), serum albumin, low to normal serum phosphate
- Patient may have elevated blood urea nitrogen and serum creatinine
- Elevated alkaline phosphatase may indicate bone destruction
- ECG may indicate prolonged PR interval, shortened QT interval, widened T wave

Other Diagnostic Tests

- Rule out other causes of hypercalcemia, including primary hyperparathyroidism, hyperthyroidism, vitamin D intoxication, chronic renal failure

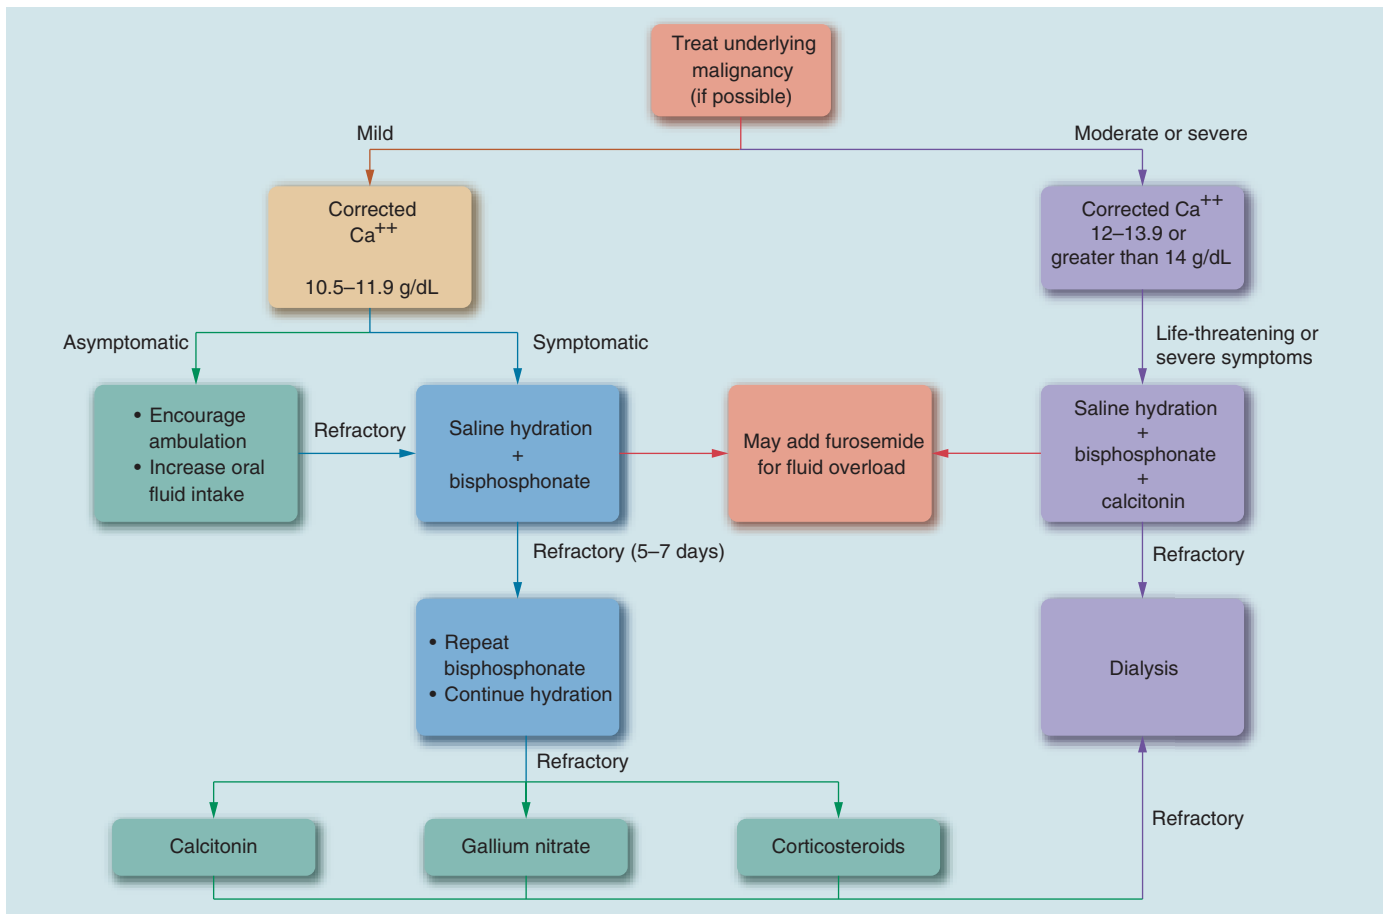

FIGURE 99-5. Treatment algorithm for the hypercalcemia of malignancy.

Table 99-13 Treatment Options for Hypercalcemia of Malignancy						
Agent	Dosage	Onset	Duration	Reduction in Serum Calcium Concentration	Comments	
Calciuric therapy	IV normal saline Furosemide 20–40 mg IV	200–500 mL/h 4 hours	24–48 hours 2–3 days	0.5–2 mg/dL —	Avoid fluid overload, monitor electrolytes Monitor for hypokalemia, dehydration	
Antiresorptive therapy	Pamidronate 60–90 mg IV over 2–24 hours ^a	24–72 hours	3–4 weeks	Greater than 1 mg/dL	Nadir not seen until after 4–7 days; may cause fever, renal dysfunction; pamidronate less expensive	
	Zoledronic acid 4 mg IV over 15 minutes	24–48 hours	4+ weeks	Greater than 1 mg/dL		
	Corticosteroids Prednisone (or equivalent) 50–100 mg/day	5–7 days	3–4 days	0.5–3 mg/dL	Monitor for hyperglycemia, insomnia, immunosuppression	
	Calcitonin 4–8 IU/kg SC or IM every 6–12 hours	2–4 hours	1–3 days	2–3 mg/dL	Salmon-derived formulation preferred; 1-unit test dose recommended; can be given in renal failure; may cause flushing, nausea	
	Gallium nitrate 100–200 mg/m ² CIV daily for 5 days	24–48 hours	—	—	Do not administer if creatinine greater than 2.5 mg/dL; may cause renal failure	

CIV, continuous intravenous infusion; IM, intramuscular; IV, intravenous; SC, subcutaneous.

^a60 mg of pamidronate may be used in smaller patients or in patients with mild hypercalcemia or renal dysfunction. May use longer infusion time in patients with renal dysfunction.

From Refs. 47 and 49.

excretion of calcium. Although effective in relieving symptoms, hydration and diuretics are temporary measures that are useful until the onset of antiresorptive therapy; thus, hydration and antiresorptive therapy should be initiated simultaneously.

The antiresorptive therapy of choice for hypercalcemia of malignancy is a bisphosphonate. Because of poor oral bioavailability, only IV agents should be used. Pamidronate and zoledronic acid are most commonly used and are potent inhibitors of osteoclast activity.⁵⁰ The choice of bisphosphonate is a difficult one; zoledronic acid is more efficacious in terms of response rate and longer duration of normocalcemia but is approximately four times more expensive.⁵¹ Regardless of selection, the bisphosphonates should be administered at diagnosis because of their delayed onset of action.

Calcitonin is the drug of choice in cases of emergent hypercalcemia (patients with life-threatening electrocardiographic (ECG) changes, arrhythmias, or central nervous system [CNS] effects) because of its rapid onset of action. Calcitonin inhibits osteoclast activity and decreases renal tubular calcium resorption. Corticosteroids are useful in patients with steroid-responsive malignancies,

Patient Care and Monitoring: Hypercalcemia

1. Determine the disease status of the patient: Is the patient newly diagnosed or has the patient had multiple episodes of hypercalcemia and is becoming refractory to calcium-lowering therapy?
2. Assess the patient's symptoms and serum calcium level to determine appropriate therapy. Is the patient taking any medications that may elevate the calcium level, inhibit its excretion, or affect renal function?
3. Educate the patient regarding the importance of oral hydration and ambulation if an outpatient. Counsel to immediately report any worsening signs or symptoms.
4. Develop a plan to maintain normocalcemia chronically using monthly bisphosphonates.
 - Monitor patients for relief of symptoms and restoration of fluid balance.
 - Monitor the serum calcium level, serum albumin, serum blood urea nitrogen and creatinine, and electrolytes daily during therapy.
 - Assess the fluid balance by daily input and output, weights, and signs of fluid overload.
 - Monitor the ECG in patients with cardiac manifestations until normalized.
 - Repeat doses of bisphosphonate after 5 to 7 days if the patient does not become normocalcemic.
 - Reassess patient status in terms of refractoriness to treatment to determine if treatment should be changed.
5. Evaluate the patient for drug interactions, allergies, and adverse effects with calcium-lowering therapy.

Patient Encounter 3: Hypercalcemia of Malignancy

LP is a 79-year-old man with stage IV moderately differentiated adenocarcinoma with features suggestive of a combined hepatocellular cholangiocarcinoma. The patient feels well but is fatigued and has a headache. He presents today to discuss treatment options for his disease. Relevant labs today are: calcium, 11.1 mg/dL (2.76 mmol/L) and albumin, 3.2 g/dL (32 g/L).

What is LP's corrected calcium level?

How would you approach LP's hypercalcemia?

such as lymphomas or multiple myeloma, and may delay **tachyphylaxis** to calcitonin. Gallium nitrate was also recently reapproved for treatment, although the 5-day administration regimen and risk of nephrotoxicity limit its use.

OUTCOME EVALUATION

The long-term success of therapy for hypercalcemia is determined primarily by the success of treatment of the underlying malignancy. The goal of treatment is to reduce serum calcium levels to normal range and to relieve patient symptoms if present.

METABOLIC COMPLICATIONS: TLS

INTRODUCTION

Although not as common as hypercalcemia, TLS may cause significant morbidity and mortality if adequate prophylaxis and treatment are not instituted. TLS is the result of rapid destruction of malignant cells with subsequent release of intracellular contents into the circulation.

EPIDEMIOLOGY AND ETIOLOGY

- The overall incidence of TLS is unknown but has been linked to a number of patient- and tumor-related risk factors (**Table 99-14**).⁵² TLS typically occurs in malignancies with high tumor burdens or high proliferative rates. Because of this, children are most frequently affected because they frequently have aggressive malignancies. TLS is typically induced by cancer treatment modalities, including chemotherapy, hormonal therapy, radiation, biologic therapy, or corticosteroids, although some patients may present spontaneously before treatment.

PATHOPHYSIOLOGY

Patients with TLS experience a wide range of metabolic abnormalities. The massive cell lysis that occurs leads to the release of intracellular electrolytes, resulting in hyperkalemia

Table 99–14

Risk Factors for TLS

Disease Related

High risk

Acute lymphoblastic leukemia
High-grade non-Hodgkin's lymphoma (i.e., Burkitt's lymphoma)

Intermediate risk

Chronic lymphocytic leukemia (especially bulky lymphadenopathy)
Acute myeloid leukemia (especially WBC count greater than 50,000 $10^3/\mu\text{L}$ ($500 \times 10^9/\text{L}$))
Multiple myeloma

Low risk

Low- and intermediate-grade non-Hodgkin's lymphoma
Hodgkin's disease
Chronic myeloid leukemia (blast crisis)
Rare
Breast cancer
Small cell lung cancer
Testicular cancer

Patient Related

Decreased urinary output, dehydration, or renal failure
Preexisting hyperuricemia
Acidic urine
WBC count greater than 50,000 $10^3/\mu\text{L}$ ($500 \times 10^9/\text{L}$)
LDH levels greater than 1500 IU/L (1500 units/L)
High tumor sensitivity to treatment modalities

LDH, lactate dehydrogenase; WBC, white blood cell.

From Refs. 52 and 54.

and hyperphosphatemia. High concentrations of phosphate bind to calcium, leading to hypocalcemia and calcium phosphate precipitation in the renal tubule. Purine nucleic acids are also released, which are subsequently metabolized to uric acid through multiple enzyme-mediated steps (Fig. 99–6). Uric acid is poorly soluble at urinary acidic pH, leading to crystallization in the renal tubule. The precipitation of uric acid and calcium phosphate leads to metabolic acidosis, facilitating further uric acid crystallization. Acute renal failure may be the end result.

Clinical Presentation and Diagnosis of TLS

General

- Patients present primarily with laboratory abnormalities.
- Normal uric acid is equal to 2 to 8 mg/dL (119–476 $\mu\text{mol/L}$).
- Most often occurs within 12 to 72 hours of initiation of cytotoxic therapy

Signs and Symptoms

- Most patients are asymptomatic.
- Patients may develop edema, fluid overload, and oliguria, which may progress to anuria with acute renal failure.
- Some patients with hyperuricemia may have nausea, vomiting, and lethargy.
- Hyperkalemia: lethargy, muscle weakness, **paresthesia**, ECG changes, bradycardia
- Hypocalcemia: muscle cramps, **tetany**, irritability, paresthesias, arrhythmias

Laboratory Tests (Adults)

- Serum uric acid level greater than 8 mg/dL (476 $\mu\text{mol/L}$)
- Serum potassium greater than 6 mEq/L (6 mmol/L)
- Serum phosphorus greater than 4.5 mg/dL (1.45 mmol/L)
- Serum calcium less than 7 mg/dL (1.75 mmol/L)
- Elevated blood urea nitrogen and creatinine once renal dysfunction develops

or

- A change of greater than 25% from baseline in the above lab values³⁵

FIGURE 99–6. The role of allopurinol and rasburicase in the enzymatic degradation of purine nucleic acids.

CLINICAL PRESENTATION AND DIAGNOSIS

Patients with TLS are diagnosed based on laboratory monitoring indicating hyperuricemia, hyperkalemia, hyperphosphatemia, hypocalcemia, and renal dysfunction.⁵³ As a result of these electrolyte abnormalities, patients may present with uremia, visual disturbances, muscle cramping, edema, hypertension, cardiac arrhythmias, seizures, and even sudden death.⁵³

TREATMENT

Desired Outcomes

9 The primary goals of management of TLS are (a) prevention of renal failure and (b) prevention of electrolyte imbalances. Thus, the best treatment for TLS is prophylaxis to enable delivery of cytotoxic therapy for the underlying malignancy. For patients who present with or develop TLS despite prophylaxis, treatment goals include (a) decreasing uric acid levels, (b) correcting electrolyte imbalances, and (c) preventing compromised renal function. These goals should be achieved in a cost-effective manner.

General Approach to Treatment

Prevention of TLS is generally achieved by increasing the urine output and preventing accumulation of uric acid. Prophylactic strategies should begin immediately upon presentation, preferably 48 hours prior to cytotoxic therapy. Treatment modalities primarily increase uric acid solubility, maintain electrolyte balance, and support renal output.

► Nonpharmacologic Therapy

Vigorous IV hydration with dextrose 5% in water with $\frac{1}{2}$ normal saline at 3 L/m²/day to maintain a urine output greater than or equal to 100 mL/m²/h is necessary unless the patient presents with acute renal dysfunction. Alkalinization of the urine to a pH greater than or equal to 7.0 with 50 to 100 mEq/L (50 to 100 mmol/L) of sodium bicarbonate has been used to promote uric acid solubility for excretion. This measure is controversial because xanthine and hypoxanthine are less soluble at alkaline pH, potentially leading to crystallization, especially during and after allopurinol therapy (see Fig. 99–6).⁵⁴ Medications that increase serum potassium (angiotensin-converting enzyme inhibitors, spironolactone) or block tubular resorption of uric acid (probenecid, thiazides) should be discontinued. Nephrotoxic agents such as amphotericin B or aminoglycosides should also be avoided. Hemodialysis may be required in patients who develop anuria or uncontrolled hyperkalemia, hyperphosphatemia, hypocalcemia, acidosis, or volume overload.

► Pharmacologic Therapy

Pharmacologic prevention strategies for TLS are aimed at low- and high-risk patients (Fig. 99–7). Allopurinol is a xanthine oxidase inhibitor that is used for prevention only because it has no effect on pre-existing elevated uric acid. Rasburicase is a recombinant form of urate oxidase that is useful for both prevention and treatment, but is extremely expensive (Table 99–15). Although the approved dose is 0.2 mg/kg/day for 5 days, recent studies using abbreviated courses (1–3 days) and/or lower doses (0.05–0.1 mg/kg/day) may be equally efficacious with significantly reduced cost.⁵⁴

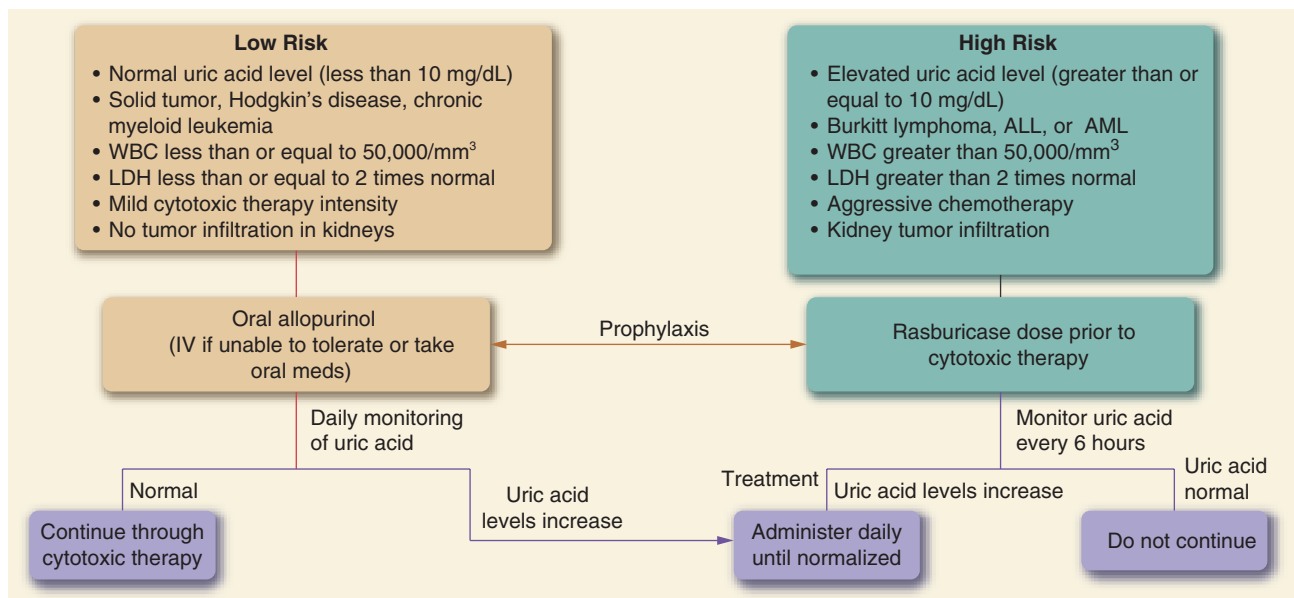

FIGURE 99-7. Prophylaxis and treatment of hyperuricemia associated with tumor lysis syndrome. (ALL, acute lymphoblastic leukemia; AML, acute myelogenous leukemia; IV, intravenous; LDH, lactate dehydrogenase; WBC, white blood cell.) (From Refs. 35 and 36.)

Table 99–15

Comparison of Allopurinol and Rasburicase in TLS

Drug	Dosing	AWP ^a	Comments
PO allopurinol (Zyloprim)	Adult: 600–800 mg/day in 2–3 divided doses Pediatric: 10 mg/kg/day or 200–300 mg/m ² /day	\$0.48/day (generic)	Adjust dose for renal impairment Avoid drug interactions (mercaptopurine) Monitor for skin rash
IV allopurinol (Aloprim)	Adult: 200–400 mg/m ² /day Pediatric: 200 mg/m ² /day	\$625–\$1,250/day	As above Reserve for patients who cannot tolerate or take oral medications Maximum dose = 600 mg/day
Rasburicase (Elitek)	0.2 mg/kg/day for up to 5 days	\$12,000/day	Lower doses and abbreviated schedules may be used to decrease cost (0.05–0.1 mg/kg/day) May rarely cause nausea and vomiting Contraindicated in patients with G6PD deficiency → hemolytic anemia Rare cases of hypersensitivity and antibody formation

AWP, average wholesale price; G6PD, glucose-6-phosphate dehydrogenase; PO, oral.

^aNormalized for 70-kg patient or body surface area = 1.73 m²; all costs are estimated and may vary.

From Yim BT, Sims-McCallum RP, Chong PH. Rasburicase for the treatment and prevention of hyperuricemia. *Ann Pharmacother* 2003;37:1047–1054.

Patient Care and Monitoring: TLS

1. Monitor daily at-risk patients who present with normal laboratory values daily for serum uric acid, electrolytes (Na, K, Ca, Mg, Cl, PO₄), blood urea nitrogen, creatinine, and urine output.
2. Monitor for signs of fluid overload during aggressive hydration.
3. Continue hydration and prophylaxis until 2 to 3 days after cytotoxic therapy.
4. In patients undergoing urinary alkalinization with sodium bicarbonate, assess the urine pH every 6 hours and maintain above 7.
5. For patients who present with or develop signs of TLS, monitor these parameters every 6 hours until stable.
6. Order an ECG for patients with hyperkalemia and monitor serially until resolution.
7. Adjust the dose of allopurinol and other renally eliminated medications for patients who develop renal dysfunction.
8. In patients receiving rasburicase, monitor the hemoglobin and hematocrit for signs of hemolysis.

Because uric acid levels generally fall within 4 hours of the first dose, one dose may be administered with frequent, serial monitoring of the uric acid level for repeat dosing if necessary (Fig. 99–7). Of note, rasburicase continues to break down uric acid in blood samples drawn from patients.

This can be avoided by immediately placing the sample in an ice bath for processing to avoid falsely lowered uric acid levels.

Electrolyte disturbances that develop in patients with TLS should be aggressively managed to avoid renal failure and cardiac sequelae. One exception pertains to the use of IV calcium for hypocalcemia. Adding calcium may cause further calcium phosphate precipitation in the presence of hyperphosphatemia and should be used cautiously.

OUTCOME EVALUATION

The most successful outcome in TLS is prevention. If the condition is not able to be prevented, the goal of therapy is to avoid renal failure and quickly return electrolytes to normal.

MISCELLANEOUS CHEMOTHERAPY TOXICITIES: EXTRAVASATION

INTRODUCTION

Extravasation is generally defined as leakage of IV fluids into the interstitial tissue.⁵⁶ Although extravasation does not cause death, significant morbidity may result from local tissue destruction, and immediate management is necessary.

EPIDEMIOLOGY AND ETIOLOGY

The incidence of chemotherapy extravasation is generally reported to be between 0.5% and 6% of all chemotherapy-related adverse events.⁵⁷ A number of risk factors have been identified for chemotherapy extravasation (Table 99–16). Chemotherapy agents are generally classified into three groups: vesicants,

Table 99–16

Risk Factors for Chemotherapy Extravasation

Presence of multiple venipunctures (common in cancer patients)
 Poor needle insertion technique
 Poor catheter location (dorsum of the hand, antecubital fossa)
 Inability to communicate symptoms (children, sedated patients, language barrier between patient and nurse)
 Presence of peripheral neuropathy
 Nurse experience and training
 Young age or elderly patients (small or fragile veins)
 Gross obesity

irritants, and nonvesicants (Table 99–17).⁵⁸ Either vesicants or irritants may cause local symptoms, however vesicants cause local tissue necrosis upon extravasation whereas irritants do not. The degree of tissue injury depends on the concentration and amount of fluid extravasated. It is important to note that some agents are well-known vesicants; however, for many agents, only isolated case reports of tissue necrosis exist. Therefore, it is imperative to use caution when administering

Table 99–17

Chemotherapeutic Agents With Vesicant or Irritant Properties

Vesicants	Irritants
<i>Common</i>	Camptothecins
Anthracyclines	Carmustine
Daunorubicin	Cyclophosphamide
Doxorubicin	Dacarbazine
Epirubicin	Epipodophyllotoxins
Idarubicin	Etoposide
Dactinomycin	Fluorouracil
Mechlorethamine	Gemcitabine
Mitomycin C	Ifosfamide
Vinca alkaloids	Irinotecan
Vincristine	Melphalan
Vinblastine	Pentostatin
Vinorelbine	Streptozocin
<i>Rare^a</i>	Teniposide
Cisplatin	Topotecan
Liposomal doxorubicin	
Mitoxantrone	
Oxaliplatin	
Taxanes	
Docetaxel	
Paclitaxel	

^aAgents for which there are isolated case reports of local tissue necrosis.

From Ener RA, Meglathery SB, Styler M. Extravasation of systemic hemato-oncological therapies. *Ann Oncol* 2004;15:858–862.

Clinical Presentation and Diagnosis of Extravasation**General**

- Anthracycline, mechlorethamine, and vinca alkaloid extravasations typically cause immediate pain.
- Patients may be asymptomatic at the time of extravasation but return within days to weeks with signs of tissue damage (particularly with mitomycin C).
- Exposure to ultraviolet light may worsen some lesions.

Signs and Symptoms

- Local pain (burning, tingling, stinging), swelling, erythema, induration
- Lack of blood return
- Ulceration may not develop until after 1 to 2 weeks or longer.

Diagnostic Tests

- Usually based on clinical history and presenting symptoms, but tissue biopsy may reveal definitive findings

any chemotherapeutic agent, especially new or investigational agents that have unknown vesicant properties.

PATHOPHYSIOLOGY

The mechanism of tissue injury is related to the pharmacodynamic characteristics of the extravasated drug. These agents may be classified into DNA binding and non-DNA binding. Examples of DNA-binding agents include the anthracyclines, mechlorethamine, and mitomycin C. These agents first cause cell death through interactions with DNA and are then released into the surrounding tissue and taken up by adjacent cells. This repeating cycle is perpetuated by the lipophilic nature of these drugs, resulting in chronic, slow-healing tissue injury because of long tissue retention. Doxorubicin in particular may remain in tissues for weeks to months.⁵⁸

Non-DNA-binding agents include the vinca alkaloids and etoposide. These agents tend to cause injury in the pattern of a thermal burn and are more easily cleared from interstitial spaces. Thus, they are more readily neutralized and tend to have a better healing prognosis.

CLINICAL PRESENTATION AND DIAGNOSIS

Patients who experience extravasation report burning pain and discomfort in the limb of the infusion site, which can be severe. The area may be erythematous at first. If not quickly treated, the tissue will become necrotic and require amputation. Diagnosis is made based on symptoms.

Table 99–18

Prevention Strategies for Chemotherapy Extravasation

Central venous catheters should be placed for vesicant administration whenever possible, especially in high-risk patients.

Avoid the dorsum of the hand, antecubital fossa, and limbs with significant lymphedema.

Use uncovered plastic cannulas or a butterfly needle for peripheral administration.

Always test the line with IV fluids before chemotherapy administration and observe site for swelling.

Check for blood return before and frequently during administration.

If venipuncture is repeated, should be proximal to before needle insertion site.

Vesicants given via peripheral vein should be given by IV push rather than by infusion to enable immediate cessation and withdrawal of fluids if extravasation occurs.

IV, intravenous.

From Oncology Nursing Society. Cancer Chemotherapy and Biotherapy Guidelines and Recommendations for Practice: Module XXII. Pittsburgh, PA: Oncology Nursing Press, 2002.

PREVENTION

10 Chemotherapy extravasation may be avoided in many cases by the use of successful prevention strategies. The most important preventive measure is proper patient education.

- Patients must be instructed to promptly report any local symptoms not only during administration but also days to weeks later. Another key factor is the exclusive use of highly trained personnel who are trained to administer chemotherapeutic drugs. The Oncology Nursing Society has developed guidelines for the administration of vesicant drugs as summarized in Table 99–18.⁵⁹ Although placement of a central venous catheter is recommended, extravasations may still occur because of dislodged or poorly placed needles or nicked catheters.

TREATMENT

Desired Outcomes

Once extravasation occurs, the primary goals of treatment are to (a) avoid further tissue damage by using appropriate nonpharmacologic and pharmacologic strategies and (b) promptly refer patients for surgery if required. Optimal pharmacologic and nonpharmacologic treatment of the extravasation allows the cancer patient to continue with chemotherapy (Table 99–19).

► Nonpharmacologic Therapy

- If extravasation occurs, the infusion should be stopped immediately with aspiration of fluid from the site, needle, and tubing as much as possible. The affected limb or area should be elevated (if possible). The site should be documented photographically, as should the time, date, site,

Table 99–19

Management of Chemotherapy Extravasation

Drug	Application of Heat or Cold	Pharmacologic Antidote	Dose	Comments
Anthracyclines	Cold packs	DMSO 50–99% Alternative: dexrazoxane	Apply 1–2 mL to area of skin twice the size of lesion every 6–8 hours for 7–14 days 1,000 mg/m ² IV within 5 hours of extravasation followed by 1,000 mg/m ² on day 2 and 500 mg/m ² on day 3	Allow to air dry Do not cover Promising new agent; expensive and may not be reimbursed by payors
Mitomycin C Mechlorethamine; concentrated cisplatin	Cold packs Cold packs	DMSO 50%–99% Sodium thiosulfate	As above Prepare 1/6M solution by adding 4 mL of 10% solution to 6 mL of sterile water; inject 2 mL for each mg of mechlorethamine. Follow with 1 mL SC (0.1-mL doses clockwise around area); may repeat every 3–4 hours if needed	Sodium thiosulfate must be diluted before administration
Vinca alkaloids	Hot packs	Hyaluronidase	Inject 1–6 mL of 150 units/mL concentration (150–900 units) through IV line or SC if removed; may repeat every 3–4 hours if needed	Dilute with normal saline
Paclitaxel	Cold packs	Hyaluronidase	As above	Hot packs paradoxically shown to worsen lesions in some case reports

DMSO, dimethylsulfoxide; IV, intravenous; SC, subcutaneous.

From Ener RA, Meglathery SB, Styler M. Extravasation of systemic hemato-oncological therapies. *Ann Oncol* 2004;15:858–862.

patient complaints, and estimated volume of extravasated drug.⁵⁸ Both hot and cold packs have been used to manage extravasations; however, the use of the proper therapy for certain agents is critical. For example, warm compresses have been shown to worsen doxorubicin extravasations, but cold packs may exacerbate vinca alkaloid lesions. Pressure should not be applied to the area because this may facilitate spread. Finally, patients should be referred to a plastic surgeon if pain persists or ulceration develops despite treatment.

► Pharmacologic Therapy

Therapeutic modalities to treat extravasation events consist of specific antidotes to halt or decrease the severity of local tissue necrosis. It should be noted that only one-third of extravasation events lead to local tissue necrosis, and most studies of antidotes are in animal models or isolated case reports. Antidotes either disperse or bind the chemotherapy agent and accelerate the removal of the agent from the tissues. Specific antidotes and their uses are presented in Table 99–19.

Dimethylsulfoxide (DMSO) is the antidote of choice for anthracycline and mitomycin C extravasations. It readily penetrates tissues and increases diffusion in the tissue area. In addition, DMSO is a free radical scavenger that functions to block this principle mechanism of anthracycline and mitomycin C–mediated tissue injury. DMSO is generally well tolerated but may cause some mild burning and redness. Dexrazoxane is a free-radical scavenger typically used for cardioprotection from anthracyclines. A special formulation of dexrazoxane (Totect) is the only commercially available product that is FDA approved to treat doxorubicin extravasation, although much controversy exists surrounding whether generic dexrazoxane may be equally efficacious than the newer, more expensive alternative.

Hyaluronidase is the antidote of choice for vinca alkaloid and high-concentration epipodophyllotoxin extravasations. Hyaluronidase breaks down hyaluronic acid, which functions as “tissue cement.” This promotes the absorption of the extravasated drug away from the local site. Hyaluronidase may also be used for paclitaxel extravasations; however, there are conflicting reports regarding its efficacy.⁶⁰ Hyaluronidase should not be used with anthracycline extravasations because enhancement of local spread may occur.

The antidote of choice for mechlorethamine extravasations is sodium thiosulfate. This agent binds alkylating agents, resulting in neutralization to inactive compounds that are then excreted. Sodium thiosulfate may also be effective for high-concentration cisplatin or dacarbazine extravasations.

OUTCOME EVALUATION

The primary outcome is the prevention of extravasation events using proper administration techniques. Instruct patients to promptly report any symptoms of extravasation. If extravasation occurs, select the proper antidote and thermal application for immediate administration. Promptly refer the patient for plastic surgery if pain persists or ulceration develops.

Patient Care and Monitoring: Extravasation

1. Upon diagnosis, determine the need for administration of chemotherapy with vesicant properties. Refer the patient for surgical placement of a central access device.
2. Insure proper training and certification of all personnel in institution who administer chemotherapeutic agents.
3. Educate the patient regarding signs and symptoms of extravasation and instruct to immediately relate to caregiver.
4. Educate the patient to promptly report increasing pain, spread of the lesion or ulceration.
5. Educate the patient regarding proper application of hot or cold packs as well as topical antidotes. Should the area be allowed to air dry or be covered?
6. Evaluate the patient for allergies and adverse effects of pharmacologic antidotes.

Abbreviations Introduced in This Chapter

ANC	Absolute neutrophil count
AWP	Average wholesale price
BMT	Bone marrow transplantation
BUN	Blood urea nitrogen
CIV	Continuous intravenous infusion
CSF	Colony-stimulating factor
DMSO	Dimethylsulfoxide
G6PD	Glucose-6-phosphate dehydrogenase
ICP	Intracranial pressure
LDH	Lactate dehydrogenase
NSAID	Nonsteroidal anti-inflammatory drug
NSCLC	Non–small cell lung cancer
PCP	<i>Pneumocystis jiroveci</i> pneumonitis (formerly <i>Pneumocystis carinii</i>)
PTHrP	Parathyroid hormone–related protein
SCLC	Small cell lung cancer
SVCS	Superior vena cava syndrome

Parenteral Nutrition

Michael D. Kraft, Imad F. Btaiche,
and Melissa R. Pleva

LEARNING OBJECTIVES

● Upon completion of the chapter, the reader will be able to:

1. List appropriate indications for the use of parenteral nutrition (PN) in adult patients.
2. Describe the components of PN and their role in nutrition support therapy.
3. List the elements of nutrition assessment and factors considered in assessing an adult patient's nutritional status and nutritional requirements.
4. Explain the pharmaceutical and compounding issues with PN admixtures.
5. Develop a plan to design, initiate, and adjust a PN formulation for an adult patient based on patient-specific factors.
6. Describe the etiology and risk factors for PN macronutrient-associated complications, including hyperglycemia, hypoglycemia, hyperlipidemia, and azotemia, in adult patients receiving PN.
7. Describe the etiology and risk factors for the refeeding syndrome.
8. Describe the etiology and risk factors for liver complications and metabolic bone disease in adult patients receiving PN.
9. Design a plan to monitor and correct fluid, electrolyte, vitamin, and trace element abnormalities in adult patients receiving PN.
10. Design a plan to assess the efficacy and monitor the safety of PN therapy.

KEY CONCEPTS

- 1 Parenteral nutrition (PN), also called total parenteral nutrition (TPN), is the intravenous (IV) administration of fluids, macronutrients, electrolytes, vitamins, and trace elements for the purpose of weight maintenance or gain, to preserve or replete lean body mass and visceral proteins, and to support anabolism and nitrogen balance *when the oral or enteral route is not feasible or adequate.*
- 2 Amino acids are provided in PN to preserve or replete lean body mass and visceral proteins, to promote protein anabolism and wound healing, and as an energy source.
- 3 Dextrose (D-glucose) is the major immediate energy source in PN and is vital for cellular metabolism, body protein preservation, tissue formation, and cellular growth.
- 4 IV lipid emulsions are used as an energy source in PN and to prevent or treat essential fatty acid deficiency.
- 5 PN should not be used to treat acute fluid and electrolyte abnormalities. Rather, PN should be adjusted to meet maintenance requirements and to minimize worsening of underlying fluid and electrolyte disturbances.
- 6 Electrolytes, vitamins, and trace elements are essential for numerous biochemical and metabolic functions and should be added to PN daily unless otherwise not indicated.
- 7 PN can be administered via a small peripheral vein [as peripheral PN (PPN)] or via a larger central vein (as central PN).
- 8 PN admixtures can be prepared by mixing all components into one bag [3-in-1 admixture or a total nutrient admixture (TNA)] or by mixing and infusing dextrose, amino acids, and all other components together and infusing IV lipid emulsion separately (2-in-1 admixture).
- 9 PN is associated with significant complications with both short- and long-term therapy.
- 10 Patients receiving PN should have specific laboratory parameters periodically monitored as indicated clinically. These mainly include fluid and electrolyte status, organ function, nutritional status, and micronutrient levels.

INTRODUCTION

Malnutrition in hospitalized patients is associated with significant complications, including increased infection risk, poor wound healing, prolonged hospital stays, and increased mortality, especially in surgical and critically ill patients.¹ Maintaining adequate nutritional status, especially during periods of illness and metabolic stress, is an important part of patient care. *Nutrition support therapy* refers to the administration of nutrients via the oral, enteral, or parenteral route for therapeutic purposes.¹ **1** *Parenteral nutrition (PN), also called total parenteral nutrition (TPN), is the intravenous (IV) administration of fluids, macronutrients, electrolytes, vitamins, and trace elements for the purpose of weight maintenance or gain, to preserve or replete lean body mass and visceral proteins, and to support anabolism and nitrogen balance when the oral or enteral route is not feasible or adequate.* PN is a potentially lifesaving therapy in patients with intestinal failure but can be associated with significant complications.

Desired Outcomes and Goals

The goals of nutrition support therapy include:

- Correction or avoidance of nutritional deficiencies
- Weight maintenance (or weight gain in malnourished patients and growing children)
- Preservation or repletion of lean body mass and visceral proteins
- Support of anabolism and nitrogen balance and improvement of healing
- Correction or avoidance of fluid and electrolyte abnormalities
- Correction or avoidance of vitamin and trace element abnormalities
- Improving clinical outcomes

Indications for PN

PN can be a lifesaving therapy in patients with intestinal failure, but the oral or enteral route is preferred when providing nutrition support therapy (“when the gut works, use it”). Compared with PN, enteral nutrition is associated with a lower risk of hyperglycemia and fewer infectious complications (e.g., pneumonia, intra-abdominal abscess, catheter-related infections).^{1,3} However, if used appropriately, PN can be safe and effective and can improve nutrient delivery. Indications for PN are listed in **Table 100-1**.^{1,2} In general, PN should be reserved for patients with altered intestinal function or absorption or when the gastrointestinal (GI) tract cannot be used. In addition, the anticipated duration of adequate PN therapy should be at least 5 to 7 days because shorter durations of therapy are unlikely to have a beneficial effect on a patient’s clinical and nutritional outcomes but may increase infection risk.^{1,2}

Table 100-1

Indications for Parenteral Nutrition in Adults^{1,2,a}

- Bowel obstruction
 - Physical or mechanical (e.g., tumor compressing intestinal lumen)
 - Functional (e.g., ileus, colonic pseudo-obstruction)
- Major small bowel resection (e.g., short-bowel syndrome)
 - Adult patients with less than 100 cm of small bowel distal to the ligament of Treitz without a colon
 - Adult patients with less than 50 cm of small bowel if the colon is intact
- Diffuse peritonitis
- Intestinal fistulas if EN cannot be provided above or below the fistula
- Pancreatitis—if patients have failed EN beyond the ligament of Treitz or cannot receive EN (e.g., because of intestinal obstruction)
- Severe intractable vomiting
- Severe intractable diarrhea
- Preoperative nutrition support in patients with moderate to severe malnutrition who cannot tolerate EN and in whom surgery can be delayed safely for at least 7 days
- In critically ill patients without malnutrition who cannot receive oral or EN in the first 7 days of ICU admission, PN should only be initiated after the first 7 days of admission and if oral or EN is still not feasible

^aWhen adequate oral or enteral nutrition will not be possible for ~5 to 10 days in patients with malnutrition or for ~7 to 14 days in most other cases, unless noted otherwise; anticipated duration of PN should be at least 5 to 7 days.

EN, enteral nutrition; ICU, intensive care unit; PN, parenteral nutrition.

PN COMPONENTS

PN should provide a *balanced* nutrition formula, including macronutrients, micronutrients, fluids, and electrolytes. **•** Macronutrients, including amino acids, dextrose, and IV lipid emulsions, are important sources of structural and energy-yielding substrates. Total daily calories in a balanced PN formulation for adult patients are typically provided as 10% to 20% from amino acids, 50% to 60% from dextrose, and 20% to 30% from IV lipid emulsion. Amino acids may provide more than 20% of the total daily calories in patients with conditions that increase protein requirements (e.g., severe thermal injury, healing wounds, cachexia, treatment with continuous renal replacement therapy, hypocaloric feeding—discussed later). Electrolytes and micronutrients, including vitamins and trace elements, are required to support essential biochemical reactions. PN also provides a significant source of fluid. Patients require individual adjustments of PN components based on their nutritional status, nutritional requirements, underlying disease state(s), level of metabolic stress, clinical status, and organ functions.

Patient Encounter, Part 1

WS is a 26-year-old woman admitted to the hospital with chief complaints of constipation, abdominal pain, abdominal distention, nausea, and vomiting for 4 days. She also reports decreased appetite and decreased oral intake for the past 3 to 4 days and gradual unintentional weight loss of about 10 lb (4.5 kg) over the past month. WS reports a history of chronic constipation and chronic abdominal pain and that she has had several abdominal surgeries in the past due to obstructions and severe constipation. She also states that she usually “doesn’t eat much” because she starts to “feel full” quickly. She has had multiple hospital admissions over the past 2 or 3 years for abdominal pain, constipation, and intestinal obstructions.

Medical History

Possible [Hirschsprung’s disease](#), chronic constipation, chronic abdominal pain, recurrent bowel obstructions, malnutrition

Surgical History

Colon resection with colostomy and mucus fistula, colostomy takedown with anastomosis, two small bowel resections for obstruction and lysis of adhesions (greater than 100 cm of small intestine remaining, ileocecal valve intact, part of the colon remaining)

Family History

Grandmother with chronic constipation and presumed [Hirschsprung’s disease](#)

Social History

Nonsmoker; patient reports only occasional alcohol; no recreational drugs but does require chronic prescription opioid therapy for chronic abdominal pain

Medications Before Admission

Hydrocodone—acetaminophen 5/325, 1 tablet every 4 to 6 hours as needed for abdominal pain (patient states taking 1 tablet about every 4 to 5 hours around the clock)

Docusate 100 mg PO twice daily

Polyethylene glycol 3,350, 17 g PO once daily

Physical Exam

Height, 163 cm (~5 ft, 4 in); actual body weight, 41 kg (90 lb); ideal body weight, 54.5 kg (120 lb); temperature 36.7°C (98°F); heart rate, 95 beats/min; blood pressure, 100/62 mm Hg; respiratory rate 25 breaths/min; alert and oriented × 3; mucous membranes and skin appear cool and dry; **tachycardic; tachypneic**; lungs clear

Abdomen: Tense, distended, diffuse crampy abdominal pain, bowel sounds absent

Diagnoses

Likely recurrent intestinal obstruction related to chronic constipation or possibly Hirschsprung’s disease, mild dehydration, and malnutrition

Plan

Admit to the hospital (non-ICU) for fluid resuscitation and treatment; evaluate for possible surgical intervention ([exploratory laparotomy](#)).

Is PN therapy indicated in this patient? Why or why not?

Amino Acids

- 1 Amino acids are the building blocks of proteins and an essential component of PN admixtures. 2 *Amino acids are provided to preserve or replete lean body mass and visceral proteins, to promote protein anabolism and wound healing, and as a source of energy.* Amino acids have a caloric value of 4 kcal/g (17 kJ/g).
- 3 Parenteral crystalline amino acid solutions are supplied by various manufacturers in various concentrations (e.g., 7%, 8%, 8.5%, 10%, 15%, and others). Different formulations are tailored for specific age groups (e.g., adults, infants) and disease states (e.g., kidney or liver dysfunction). Specialized formulations for patients with acute kidney injury contain higher proportions of essential amino acids. Formulations for patients with hepatic encephalopathy contain higher amounts of branched-chain and lower amounts of aromatic amino acids. However, these specialized formulations

have not been clearly shown to improve patient outcomes and therefore are not routinely used in clinical practice. Crystalline amino acid solutions have an acidic pH (pH ≈ 5 to 7) and may contain inherent electrolytes (e.g., sodium, potassium, acetate, phosphate).

Dextrose

- 3 *Dextrose (D-glucose) is the major energy source, and it is vital for cellular metabolism, body protein preservation, and cellular growth.* Body tissues that depend primarily on dextrose as a source of energy include the central nervous system, red blood cells, and the renal medulla. Typically, a 70% (70 g/100 mL) parenteral dextrose (hydrous dextrose) stock solution is used in PN compounding (a 50% stock solution is also available). Hydrous dextrose provides 3.4 kcal/g (14.2 kJ/g). A dextrose infusion rate of 2 mg/kg/min in adult patients is typically sufficient to suppress gluconeogenesis

and spare body proteins from being used for energy.⁴ Dextrose infusion rate in hospitalized adult patients generally should not exceed 4 to 5 mg/kg per minute.^{5,6}

Intravenous Lipid Emulsions

4 *Intravenous lipid emulsions have two main clinical uses, which are to prevent or treat essential fatty acid deficiency and provide an energy source.* IV lipid emulsions marketed in the United States consist of long-chain triglycerides. Lipid particles consist of a triglyceride core surrounded by a layer of egg phospholipids (emulsifiers). These particles carry a negative charge on their surface that creates repulsive electrostatic forces between droplets and maintains the stability of the emulsion. Glycerol is added to adjust the tonicity, and water is the solvent. The negative charges on the surface of lipid particles can be disrupted by cations, especially divalent cations, such as calcium, magnesium, and iron,⁷ and extreme pH changes, particularly acidic pH. **Creaming** of the emulsion occurs when lipid particles begin to aggregate and migrate to the surface of the emulsion but can be reversed with mild agitation. If these particles continue to aggregate, **coalescence** may occur and destabilize the emulsion. A coalesced emulsion should not be infused into a patient because this can result in fat emboli. If coalescence continues, irreversible separation of the emulsion can occur (**oiling out**, also called “breaking” or “cracking” of the emulsion). If there is any apparent disruption to a lipid emulsion, it should *not* be infused into a patient.

Intravenous lipid emulsions differ in their concentration (10%, 20%, and 30%), caloric density by volume, natural source of lipids, and ratio of phospholipids to triglycerides (PL:TG ratio). **Table 100–2** shows a comparison of commercially available IV lipid emulsions in the United States. Because of the addition of phospholipid emulsifiers and glycerol, the caloric density of IV lipid emulsions by weight is approximately 10 kcal/g (42 kJ/g; dietary fat is ~ 9 kcal/g [38 kJ/g]). Compared with the 10% lipid emulsion, 20% and 30% lipid emulsions have a lower PL:TG ratio and lower phospholipid content; this translates to better plasma

clearance of the 20% and 30% lipid emulsions compared with the 10% lipid emulsion.⁸ The 30% lipid emulsion is only approved by the Food and Drug Administration (FDA) for infusion in a total nutrient admixture (TNA) and should not be infused directly into patients nor via Y-site injection.

Lipid particles are hydrolyzed in the bloodstream by **lipoprotein lipase** to release free fatty acids and glycerol. Fatty acids are taken up into adipose tissue for storage (triglycerides), oxidized to energy in various tissues (e.g., skeletal muscles), or recycled in the liver to make lipoproteins. The typical daily dose of IV lipid emulsions in adults is about 0.5 to 1 g/kg/day. The maximum dose is 2.5 g/kg/day⁶ or 60% of total daily calories, although doses this high are rarely used in practice and should be avoided to prevent complications.

The essential fatty acids that cannot be produced endogenously in humans are linoleic acid (C18:2 n-6) and α -linolenic acid (C18:3 n-3). Arachidonic acid (C20:4 n-6) is also essential but can be synthesized in vivo from linoleic acid. Adult patients should receive a minimum of 2% to 4% of total daily calories as linoleic acid and 0.25% to 0.5% of total daily calories as α -linolenic acid to prevent **essential fatty acid deficiency**.⁶ This can be achieved by providing a minimum of about 500 mL of 20% (100 g) IV lipid emulsion once a week (or 250 mL twice a week on separate days) for most adult patients. Biochemical evidence of essential fatty acid deficiency (e.g., decreased serum linoleic acid, α -linolenic acid, and arachidonic acid concentrations; elevated mead acid concentrations; elevated triene-to-tetraene ratio) can develop in nonmalnourished adult patients within about 2 to 4 weeks of receiving lipid-free PN, and clinical manifestations (e.g., dry skin, skin **desquamation**, hair loss, hepatomegaly, anemia, thrombocytopenia, poor wound healing) may appear after an additional 1 to 2 weeks, although skin changes may take longer to develop.⁹

Complications and safety concerns related to the administration of IV lipid emulsions include severe hypertriglyceridemia, systemic infection, **anaphylactic** reactions, and infusion-related reactions. Patients with a history of hypertriglyceridemia, acute kidney injury, chronic kidney disease, hepatic dysfunction, severe

Caloric density ^a (kcal/mL)	1.1	2	1.1	2	3	1.1	2	3
Approximate osmolarity (mOsm/L)	276	258	284	292	293	300	350	310
Approximate mean pH (range)	8.0 (6.0–9.0)	8.3 (6.0–9.0)	8.3 (6.0–9.0)		8.4 (6.0–9.0)	8.0 (6.0–8.9)		

PL, phospholipid; TG, triglyceride.

^aOne kcal/mL is equivalent to 4.19 kJ/mL.

metabolic stress, or **pancreatitis** (particularly if caused by hypertriglyceridemia) may have reduced lipid clearance and be at risk of developing hypertriglyceridemia. IV lipid emulsions should be withheld in adult patients with serum triglyceride concentrations exceeding 400 mg/dL (4.52 mmol/L).

Intravenous lipid emulsions support the growth of bacterial and fungal pathogens, but bacterial growth is slower in TNAs than in IV lipid emulsions alone.^{10,11} This is because of the acidic pH of amino acid solutions and higher osmolarity of PN formulations. The Centers for Disease Control and Prevention (CDC) recommends that infusion of IV lipid emulsions separately from PN (i.e., 2-in-1) be completed within 12 hours of initiation (e.g., two lipid containers can be used with each container infused over 12 hours). If fluid or volume considerations prohibit a reduced infusion time, the lipid infusion can be completed within 24 hours, although there is debate about the appropriateness of this approach. Because TNAs support microbial growth at a slower rate than IV lipid emulsions, the CDC recommends that TNA infusion be completed within 24 hours of initiation. A 0.22-micron bacterial retention filter cannot be used on the TNA infusion line; the average size of lipid particles is approximately 0.4 to 0.5 microns, which cannot pass through the smaller filter intact. Strict aseptic technique must be used when handling IV lipid emulsions to minimize the risk of PN contamination and possible infectious complications.

Patients with an allergy to eggs or specific legumes (e.g., soy beans, broad beans, lentils) may develop cross-allergic reactions to IV lipid emulsions. Rarely, infusion-related adverse effects may occur with rapid infusion, including fever, chills, headache, palpitations, dyspnea, chest tightness, and nausea. Extending the IV lipid infusion time (e.g., over 12 to 24 hours) can minimize infusion-related adverse events and improves lipid clearance. Infusion rate of IV lipid emulsions should not exceed 0.12 g/kg/h.⁶

Fluid

5 Parenteral nutrition should not be used to treat acute fluid abnormalities. PN should be adjusted to provide maintenance fluid requirements and to minimize worsening of underlying fluid disturbances, taking into account other fluids the patient is receiving. Daily maintenance fluid requirements for adults can be estimated with the following equation:

$$\text{Total daily maintenance fluid requirements} = 1,500 \text{ mL} + (20 \text{ mL/kg} \times [\text{Wt (kg)} - 20])^*$$

For patients with significant fluid deficits, it is safer and more cost effective to correct fluid abnormalities using standard IV fluids (e.g., 0.9% sodium chloride in water, dextrose 5% and sodium chloride 0.45% in water, lactated Ringer's solution). Minimizing PN fluid volume may be indicated in patients with fluid overload, such as those who receive large volumes of resuscitation fluid and/or multiple IV medications (e.g., critically ill, bone marrow transplant),

* For elderly patients (e.g., greater than 60 years old), use 15 mL/kg for every kilogram above 20 kg.

patients with oliguric (urine output less than 400 mL/day, or less than 0.5 mL/kg/h) or anuric (urine output less than 50 mL/day) acute kidney injury, or those with congestive heart failure or symptomatic pleural effusion. It is reasonable to provide total daily fluid requirements (maintenance requirements and replacement for GI or other abnormal losses) in the PN admixture in patients who depend on long-term PN. However, caution should be exercised when the PN admixture is diluted to an extent that may alter the stability and compatibility of the components. Diluting a PN admixture may affect its physical and chemical properties (e.g., pH, which could affect lipid emulsion stability and calcium-phosphate compatibility); therefore, stability and compatibility data should first be confirmed.

Electrolytes

6 Electrolytes are essential for many metabolic and homeostatic functions, including enzymatic and biochemical reactions, maintenance of cell membrane structure and function, neurotransmission, hormone function, muscle contraction, cardiovascular function, bone composition, and fluid homeostasis. The causes of electrolyte abnormalities in patients receiving PN may be multifactorial, including altered absorption and distribution; excessive or inadequate intake; altered hormonal, neurologic, and homeostatic mechanisms; altered excretion and losses via the GI tract and kidneys; changes in fluid status and fluid shifts; and medication therapies. PN should not be used to treat acute electrolyte abnormalities but should be adjusted to meet maintenance requirements and to minimize worsening of underlying electrolyte disturbances.

Electrolytes that are included routinely in PN admixtures include sodium, potassium, phosphorus (as phosphate), calcium, magnesium, chloride, and acetate. Always assess the patient's kidney function when determining electrolytes in PN admixtures. Typical daily electrolyte maintenance requirements for adults with normal kidney function are listed in **Table 100-3**.

► Sodium

Sodium is the most abundant extracellular cation in the body and is the major osmotically active ion in the extracellular fluid. Sodium concentration determines distribution of water in extracellular space, and sodium disorders can be caused by many factors. Patients with abnormal GI losses (e.g., gastric, diarrhea, **ostomy**, enterocutaneous **fistula**) have increased sodium requirements. Patients with fluid overload and hypervolemic hypotonic hyponatremia may require sodium and fluid restriction. Sodium in PN can be provided in the forms of chloride, acetate, and phosphate salts (see Table 100-3). Total sodium concentration in PN should not exceed 154 mEq/L (154 mmol/L, the equivalent of normal saline).

► Potassium

Potassium is the most abundant intracellular cation in the body. Potassium has many important physiologic functions, including regulation of cell membrane electrical

Table 100–3

Approximate Daily Maintenance Electrolyte Requirements for Adults⁶

Electrolyte	Approximate Daily Maintenance Requirements ^a	Electrolyte Salts Used in PN
Sodium	1–2 mEq/kg	Chloride, acetate, phosphate
Potassium	1–2 mEq/kg	Chloride, acetate, phosphate
Phosphorus	20–40 mmol	Sodium phosphate, potassium phosphate
Calcium	10–15 mEq	Gluconate
Magnesium	8–20 mEq	Sulfate
Chloride	^b	Sodium, potassium
Acetate	^b	Sodium, potassium
Conversions	1 mmol potassium phosphate = 1.47 mEq potassium 1 mmol sodium phosphate = 1.33 mEq sodium	

^aElectrolyte requirements are adjusted based on serum electrolyte concentrations and vary depending on kidney function, gastrointestinal losses, nutritional status, specific metabolic and endocrine functions, and medication therapy that affect electrolyte losses or retention.

^bAs needed to maintain acid–base balance; linked to amounts of sodium and potassium provided (as chloride and acetate salts).

action potential, muscular function, cellular metabolism, and glycogen and protein synthesis. Potassium in PN can be provided as chloride, acetate, and phosphate salts (see Table 100–3). Generally, concentrations of potassium in PN admixtures should not exceed 120 mEq/L (120 mmol/L) for safety reasons and to avoid excessive potassium infusion. This may also decrease the risk of **thrombophlebitis** when administered as peripheral PN (PPN) via a peripheral vein (refer to the section Route of PN Administration). In addition, when admixed with IV lipid emulsion, high concentrations of cations can destabilize the emulsion (refer to the section Types of PN Formulations).⁶ IV potassium should be infused at a maximum of 10 mEq/h (10 mmol/h) via a peripheral vein in patients who are not on a cardiac monitor, and 20 mEq/h (20 mmol/h) via a central vein if the patient is on a cardiac monitor (nonemergent situations). Patients with abnormal potassium losses (e.g., loop or thiazide diuretic therapy, diarrhea) may have higher potassium requirements, and patients with acute kidney injury or chronic kidney disease or those who receive medications that can cause potassium retention (e.g., spironolactone, tacrolimus) may require potassium restriction.

► Calcium and Phosphorus

Calcium and phosphorus are essential electrolytes for many physiologic processes and biochemical reactions. Phosphorus in PN is provided as sodium or potassium phosphate (see Table 100–3), and phosphate is essential for energy and adenosine triphosphate (ATP). Approximately 10 to 15 mmol of phosphate is needed per 1,000 kilocalories (4,186 kJ) to maintain normal serum phosphorus concentrations in well-nourished adult patients (with normal kidney function).¹² Patients with impaired kidney function typically require phosphorus restriction.

The FDA published a safety alert in response to two deaths associated with calcium–phosphate precipitation in PN.¹³ Autopsy reports from these patients revealed diffuse **microvascular pulmonary emboli** containing calcium–phosphate precipitates. Because calcium and phosphate can bind and precipitate in solution, caution must be exercised

when mixing these two electrolytes in PN admixtures. Several factors can affect calcium–phosphate solubility, including:

- **pH.** Largely affected by the final amino acid concentration, to a lesser extent by the dextrose concentration (unless the final amino acid concentration is very low); the lower the solution pH, the less chance for calcium–phosphate precipitation. Monobasic phosphates predominate at low pH, leaving fewer free dibasic phosphates for precipitation with divalent calcium; monobasic calcium phosphate is more soluble than dibasic calcium phosphate.
- **Amino acid concentration.** Primary factor that affects pH of the PN admixture. The pH of amino acid stock solutions may vary between commercial products and thus differently affects the final pH of PN admixtures, but in general, the higher the final amino acid concentration, the lower the pH of the final admixture. Phosphates can also bind with amino acids, leaving fewer phosphates available to bind with calcium.
- **Calcium salt.** Calcium gluconate is the preferred calcium salt in PN because it has a low dissociation constant in solution with less free calcium available at a given time to bind phosphate (as opposed to calcium chloride, which dissociates rapidly in solution). One gram of calcium gluconate provides 4.5 mEq (2.2 mmol) of elemental calcium.
- **Time.** The longer calcium and phosphate are in solution, the more calcium and phosphate will dissociate over time and increase the risk for calcium–phosphate precipitation.
- **Temperature.** As temperature increases, more calcium and phosphate dissociate and increase the risk of calcium-phosphate precipitation.
- **Order of mixing.** Calcium and phosphate should not be added simultaneously or consecutively when compounding PN admixtures (e.g., add phosphate first, then add other PN components, and then add calcium near the end of compounding). The volume in the PN admixture at the time calcium is added (not necessarily the final volume) must be used to determine the maximum calcium that can be added.

When compounding PN admixtures, specific calcium-phosphate solubility curves must be used to determine safe and appropriate calcium and phosphate concentration limits.

► Magnesium

- Magnesium is the second most abundant intracellular cation after potassium. Magnesium is an essential cofactor for numerous enzymes and in many biochemical reactions, including reactions involving ATP.¹⁴ Magnesium disorders are multifactorial and can be related to kidney function, GI losses, disease states, and medication therapy. Magnesium in PN is typically provided as magnesium sulfate. One gram of magnesium sulfate provides 8.1 mEq (4.0 mmol) of elemental magnesium.

► Chloride and Acetate

- Concentration limits for chloride and acetate in PN typically are linked to limitations of sodium and potassium. The usual ratio of chloride to acetate in PN is about 1:1 to 1.5:1. Chloride and acetate play a role in acid-base balance. Serum chloride concentrations that exceed 130 mEq/L (130 mmol/L) may cause hyperchloremic acidosis. Acetate is converted to bicarbonate at a 1:1 molar ratio, and this conversion appears to occur mostly outside the liver. Acetate conversion to bicarbonate is rapid, but not immediate, and thus acetate salts should not be used to correct acute severe acidemia. Bicarbonate should *never* be added to or co-infused with PN admixtures. This can lead to the release of carbon dioxide and result in the formation of insoluble calcium or magnesium carbonate salts.

Vitamins

- **6** *The water-soluble and fat-soluble vitamins in the parenteral multivitamin mix are essential cofactors for numerous biochemical reactions and metabolic processes. Parenteral multivitamins are added daily to the PN admixture.* Patients with chronic kidney disease are at risk for vitamin A accumulation and potential toxicity. Serum vitamin A concentrations should be measured in patients with chronic kidney disease when vitamin A accumulation is a concern. Previously, vitamin K was administered either daily or once weekly because IV multivitamin formulations did not contain vitamin K. However, reformulated parenteral multivitamin products contain 150 mcg of vitamin K in accordance with FDA recommendations. A parenteral adult

multivitamin formulation is available without vitamin K (e.g., for patients who require warfarin therapy), but standard compounding of PN formulations should include a parenteral multivitamin that contains vitamin K unless otherwise clinically indicated. Water-soluble vitamins, with the exception of vitamin B₁₂, are generally readily excreted and not stored in the body in significant amounts. Deficiencies of water-soluble vitamins can occur rapidly in the absence of adequate vitamin supplementation in PN. For example, severe refractory lactic acidosis and deaths were reported in patients who received PN without added thiamine. Thiamine is an essential cofactor in carbohydrate metabolism, specifically a cofactor of the pyruvate dehydrogenase enzyme that is involved in the aerobic metabolism of pyruvate to acetyl-CoA (via the tricarboxylic acid cycle). Deficiency of thiamine pyrophosphate prevents the formation of acetyl-CoA from pyruvate, which is instead converted to lactate via anaerobic metabolism, resulting in lactic acidosis.

Trace Elements

- **6** *Trace elements are essential cofactors for numerous biochemical processes. Trace elements added routinely to PN include zinc, selenium, copper, manganese, and chromium (Table 100-4).* Various individual and multi-ingredient parenteral trace element formulations can be added to PN admixtures. Trace element supplementation in PN should be individualized, especially for long term PN-dependent patients, rather than using a fixed dose of multi-trace element products.¹⁵ Zinc is important for wound healing, and patients with high-output enterocutaneous fistulas, diarrhea, burns, and large open wounds may require additional zinc supplementation. Patients may lose as much as 12 to 17 mg zinc per liter of GI output (e.g., diarrhea, enterocutaneous fistula); however, 12 mg/day may be adequate to maintain these patients in positive zinc balance.¹⁶ Patients with chronic severe diarrhea, malabsorption, high-output enterocutaneous fistula, or short-bowel syndrome may also have increased selenium losses and may require additional selenium supplementation. Chromium is a cofactor for glucose metabolism, and patients with chromium deficiency may exhibit glucose intolerance; however, chromium deficiency is a rare cause of hyperglycemia. Patients who are chronically dependent on PN may accumulate chromium⁶ and manganese, resulting in high serum levels because these are known contaminants of parenteral products that are used in

Table 100-4

Approximate Daily Maintenance Trace Element Requirements for Adults^{6,a}

Zinc (Zn)	Selenium (Se)	Copper (Cu)	Manganese (Mn)	Chromium (Cr)
2.5–5 mg	20–60 mcg	0.3–0.5 mg	0.06–0.1 mg	10–15 mcg

^aTrace element requirements may vary based on patients' trace element levels, kidney function, liver function, gastrointestinal losses, nutritional status, specific metabolic and endocrine functions, and medication therapy. In addition, contamination of some parenteral nutrition (PN) ingredients with trace elements (e.g., chromium, manganese) can contribute significantly to the total amount the patient receives. Serum trace element levels should be monitored in patients receiving long-term PN therapy.

the making of PN.^{6,15} Patients with **cholestasis** (serum direct bilirubin concentrations that exceed 2 mg/dL [34.2 μmol/L]) should have manganese and possibly copper restricted to avoid accumulation and possible toxicity because both elements undergo biliary elimination. Manganese-induced neurotoxicity has been reported in PN patients with cholestasis and those receiving chronic PN. However, copper deficiency resulting in anemia, pancytopenia, and death has occurred in PN-dependent patients when copper was omitted from the PN admixture. Because copper deficiency has been reported to occur anywhere between 6 weeks and 12 months after copper elimination from PN,¹⁷ serum copper concentrations need to be regularly monitored (e.g., every 6 weeks at first and then every 2 to 3 months thereafter) when copper is omitted from PN admixtures. Trace element status should initially be monitored periodically (e.g., every 3 months) in patients at risk for trace element deficiency or accumulation. When stable, serum trace element concentrations can be monitored less frequently (e.g., every 6 to 12 months).

PN Additives

► Heparin

Heparin (0.5 to 1 unit/mL of final PN volume) may be added to PN admixtures for three reasons:

- Maintain catheter patency (although this effect is debated)
- Reduce **thrombophlebitis** (with PPN infusion)
- Enhance lipid particle clearance as a cofactor for the lipoprotein lipase enzyme

The benefits and necessity of adding heparin to PN are unclear. Although practices vary, the addition of heparin to PN admixtures for adult patients is becoming less common. There are also concerns about the stability and compatibility of IV lipid emulsions with heparin added at concentrations above 1 unit/mL. Heparin should be omitted in patients with active bleeding, **thrombocytopenia**, heparin-induced thrombocytopenia (HIT), or heparin allergy.

► Regular Insulin

Regular insulin may be added to PN admixtures for glycemic control. The dose depends on the severity of hyperglycemia, predisposing factors for hyperglycemia, renal function, and daily insulin requirements. Generally, after the patient is receiving his or her goal dextrose dose in PN, about 50% to 70% of the total insulin doses administered over the previous 24 hours as sliding scale or continuous infusion can be added to the next PN admixture. The insulin dose should be adjusted based on frequent capillary blood glucose evaluation. Caution should be used when insulin is added to PN to avoid hypoglycemia, especially when reversible causes of hyperglycemia have resolved (e.g., stress, acute pancreatitis, corticosteroids therapy) or more than one form of insulin therapy is concurrently used. Adding insulin to PN rather than administering as a continuous IV infusion does not provide the flexibility of frequent titration of the insulin dose to the desired target blood glucose concentration.

As such, severe uncontrolled hyperglycemia is best treated with a continuous insulin infusion.

► Histamine-2 Receptor Antagonists

Intravenous histamine-2 receptor antagonists such as ranitidine, famotidine, and cimetidine are compatible with PN and can be added to the daily PN when indicated (e.g., prevention of stress-related mucosal damage). This provides continuous acid suppression and reduces pharmacy and nursing time by avoiding intermittent scheduled infusions.

► Human Albumin

Human albumin is a colloid used as a plasma volume expander and *not* a source of nutrition. Albumin should not be added to the PN admixture and should be administered separately from PN because it may increase microbial growth and infectious risk when mixed in the PN admixture. Furthermore, co-infusion of human albumin at the Y-site injection of IV lipid emulsion and TNAs may cause disruption and creaming of the IV lipid emulsion.

► Parenteral Iron

Iron-deficiency anemia in chronic PN-dependent patients may be caused by underlying clinical conditions and the lack of regular iron supplementation in PN. Parenteral iron therapy becomes necessary in iron-deficient patients who cannot absorb or tolerate oral iron. Parenteral iron should be used with caution owing to its infusion-related adverse effects. A test dose of 25 mg of iron dextran should be administered first, and the patient should be monitored for adverse effects for at least 60 minutes. Iron dextran then may be added to lipid-free PN at a daily dose of 100 mg until the total iron dose is given. Iron dextran is not compatible with IV lipid emulsions and can cause oiling out of the emulsion. Other parenteral iron formulations (e.g., iron sucrose, ferric gluconate) have not been evaluated for compounding in PN and should NOT be added to PN admixtures.

NUTRITION ASSESSMENT AND NUTRIENT REQUIREMENTS

The first step before delivering nutrition support therapy is to perform a nutrition assessment and determine nutrient requirements based on the patient's nutritional status and clinical conditions. Collect subjective and objective data of dietary intake, functional capacity, anthropometrics, weight changes, GI function, medical history, medication therapy, and laboratory data to determine a patient's nutritional status, identify patients with malnutrition or at risk for malnutrition, identify risk factors that may put a patient at risk for nutrition-related problems, and identify or rule out specific nutrient deficiencies.¹ A nutrition assessment should include:^{1,18}

- Patient history
- Physical assessment including height, weight, ideal body weight (IBW), body mass index (BMI = weight [kg]/height [m²]), and recent weight loss (intentional or unintentional)

BMI relates a person's body weight to height and is a vague indicator of total body fat mass in adults. BMI categories do not account for frame size, muscle mass, bone, and water weight. Furthermore, BMI is not an indicator of body nutrient stores. Classifications of weight status in relation to BMI are underweight, less than 18.5 kg/m²; normal, 18.5 to 24.9 kg/m²; overweight, 25 to 29.9 kg/m²; obese, greater than or equal to 30 kg/m².

- Physical examination of the musculoskeletal system (e.g., biceps, triceps, quadriceps, temporalis, deltoid, and interosseus muscles) for loss of muscle mass, and examination of the skin and mucous membranes for abnormalities (e.g., noting dry or flaky skin, bruising, edema, ascites, poorly healing wounds) and loss of subcutaneous fat (e.g., triceps, chest)
- Changes in eating habits and GI function and associated GI symptoms
- Presence and severity of underlying and concurrent disease(s)
- Serum visceral protein concentrations (e.g., albumin, prealbumin). Hypoalbuminemia at baseline or before hospitalization may be indicative of malnutrition, and severe hypoalbuminemia may be associated with poor patient outcome. Serum albumin and prealbumin are negative acute phase proteins and therefore are not sensitive or specific indicators of nutritional status and protein stores in hospitalized patients under metabolic stress (e.g., postsurgery, organ failure, severe burns, trauma, sepsis). Synthesis and distribution of these proteins may be altered, and serum concentrations are affected by non-nutritional factors, including hydration status, kidney function, and liver function. Because prealbumin has a shorter half-life (~2 days) than albumin (~20 days), serum prealbumin concentrations are measured usually once weekly to help evaluate the net anabolism in response to nutrition support therapy.
- Serum concentrations of vitamins, trace elements, and iron studies as indicated

Several methods may be used to conduct a nutrition assessment, but one validated approach in adult patients is the Subjective Global Assessment (SGA).¹ Application of the SGA requires gathering the data listed above and assessing these parameters (i.e., weight change, dietary changes, GI symptoms, functional capacity, and physical examination) and then assigning a subjective rating (A = well nourished, B = moderately malnourished or suspected of being malnourished, and C = severely malnourished).¹⁸

After performing a nutrition assessment, estimate the patient's daily energy and protein requirements (Table 100-5). Indirect calorimetry involves measuring the volumes of oxygen consumption (VO₂) and carbon dioxide production (VCO₂) to determine the resting metabolic rate (RMR) or resting energy expenditure (REE) and respiratory quotient (RQ = VCO₂/VO₂). The REE or RMR is the amount of calories required during 24 hours by the body in a non-active state and is approximately 10% higher than the basal energy expenditure (BEE, metabolic

activity required to maintain life) as it adjusts for the thermic effect of food and awake state. Because critically ill patients may have variable energy expenditure (EE), indirect calorimetry is a valuable tool in assessing EE in mechanically ventilated patients with multiple and changing clinical conditions. Indirect calorimetry requires expensive equipment and trained personnel to use and therefore is not feasible in all institutions. More than 200 equations have been developed to predict EE for adults. The Harris-Benedict equations, Penn State equations (for non-obese critically ill patients), and Mifflin-St. Jeor equations (for obese noncritically ill patients) are some of the most widely used. Harris-Benedict equations take into account a patient's sex, weight, height, and age to determine the BEE. A "stress" or "injury" factor is then applied to estimate the daily total EE (TEE). Daily energy requirements are about 100% to 130% of the RMR with adequate protein intake. Alternatively, EE can be estimated based on EE per body weight (i.e., kilocalories per kilogram or in kilojoules per kilogram). However, dry weight or hospital admission weight should be used, and this estimation may not be appropriate in obese or elderly patients. There is debate over the best method to estimate energy requirements for obese patients. Indirect calorimetry would be the preferred method to estimate energy requirements for obese patients but may not always be available. Several equations have been developed to estimate EE in obese patients. Although there is no consensus on the weight used to estimate EE in obese patients, it is reasonable to use an adjusted body weight (AdjBW) in obese patients to avoid overfeeding. AdjBW can be calculated with 25% to 50% of the difference between the actual weight and IBW added to the IBW. Using a 25% difference in calculating the AdjBW further avoids overfeeding when estimating energy requirements:

$$\text{AdjBW} = \text{IBW} + (0.25 \times [\text{Actual weight} - \text{IBW}])$$

Amino acid requirements are based on the patient's nutritional status, clinical condition(s), kidney function, and liver function. Amino acids are needed in adequate amounts to facilitate anabolism, restore lean body mass, or promote wound healing while avoiding adverse effects from excessive amino acid loading (e.g., azotemia). No evidence-based data are available on the optimal body weight (actual, ideal, or adjusted) to use for dosing amino acids in adult patients. It is, however, suggested to dose amino acids based on actual body weight for normal body sized or malnourished adult patients (i.e., when actual weight is at or below IBW) and based on IBW for obese patients.

Hypocaloric nutrition support therapy for obese patients (BMI greater than or equal to 30 kg/m² or actual weight greater than 130% of IBW) is a promising approach. Hypocaloric feeding involves providing high amounts of protein (greater than or equal to 2 to 2.5 g/kg IBW/day) to support anabolism with lower amounts of total calories (average ~11 to 14 kcal/kg actual weight/day [~46 to 59 kJ/kg actual weight/day] or ~22 to 25 kcal/kg IBW/day [~92 to 105 kJ/kg IBW/day]) with primary goals to promote net protein anabolism and avoid hyperglycemia or exacerbation of metabolic stress in critically ill patients.^{2,19} Secondary benefits of hypocaloric feeding could be avoiding fat weight gain or possibly promoting fat

Table 100–5

Estimating Daily Nutritional Requirements in Adults^{1,6,18}

Determining Energy Expenditure:

Harris-Benedict equations	Men: BEE = 66.42 + 13.75 (W) + 5 (H) – 6.78 (A) Women: BEE = 655.1 + 9.65 (W) + 1.85 (H) – 4.68 (A) W = weight in kg, H = height in cm, A = age in years Energy expenditure should then be multiplied by a stress factor. To estimate the TEE: Bed rest ≈ 1.2 × BEE Ambulatory ≈ 1.3 × BEE Anabolic ≈ 1.5 × BEE Energy requirements should also be increased ~12% with each degree of fever above 37°C (98.6°F).
Penn State equations (for critically-ill non-obese adult patients)	RMR = (0.85 × BEE ^a) + (33 × V _E) + (175 × T _{max}) – 6,433 RMR = (0.96 × BMR ^b) + (31 × V _E) + (167 × T _{max}) – 6,212
Mifflin-St. Jeor equations (for non-obese, overweight and obese noncritically ill adult patients)	Men BMR = (10 × Wt) + (6.25 × Ht) – (5 × Age) + 5 Women BMR = (10 × Wt) + (6.25 × Ht) – (5 × Age) – 161
Energy expenditure per body weight (i.e., kcal/kg) ^c	Range of ~20–30 kcal/kg/day, possibly up to 35 kcal/kg/day Maintenance ~20–25 kcal/kg/day Repletion, postoperative wound healing, critical illness, sepsis, severe trauma, severe burns ~25–30 kcal/kg/day, possibly up to 35 kcal/kg/day
Determining Amino Acid Requirements	
Patient Clinical Condition	Daily Amino Acid Requirements^d (g/kg)
Maintenance or nonstressed	0.8–1
Repletion	1.3–2
Trauma, burns, sepsis, critical illness, wound healing	1.5–2
Hepatic failure with encephalopathy	0.8–1
Acute kidney injury, predialysis	0.8–1
Acute kidney injury receiving IHD	1.2–1.5
Chronic kidney disease receiving CAPD	1.2–1.5
Acute kidney disease receiving CRRT	1.5–2.5

BMR, basal metabolic rate; CAPD, continuous ambulatory peritoneal dialysis; CRRT, continuous renal replacement therapy; Ht, height (cm); IHD, intermittent hemodialysis; RMR, resting metabolic rate; TEE, total energy expenditure; T_{max}, maximum body temperature in degrees Celsius; V_E, minute ventilation in liters per minute; Wt, weight (kg).

^aBEE calculated using the Harris-Benedict equation.

^bBMR calculated using Mifflin-St. Jeor equation.

^cOne kcal/kg is equivalent to 4.186 kJ/kg.

^dAmino acid requirements are based on actual body weight for normal body sized or malnourished adult patients and on ideal body weight (IBW) for obese patients.

weight loss. The role of hypocaloric feeding in patients with kidney dysfunction or in patients with end-stage liver disease and hepatic encephalopathy is unknown. Also, the optimal safe duration of hypocaloric feeding in critically ill obese patients is unknown.

Permissive underfeeding refers to providing a lower calorie nutrition support regimen to critically ill adult patients for a short period of time during the initial phase of high metabolic stress. The aims of permissive underfeeding are to avoid the burden of caloric intake on worsening metabolic stress and the negative effects of carbohydrate loading and associated hyperglycemia, increased carbon dioxide production, and fat accumulation. Typically, a permissive underfeeding PN regimen provides about 60% to 80% of daily energy requirements. Because the optimal amounts of calories for critically ill patients is not well defined, strong clinical evidence to support the use

of permissive underfeeding is also lacking. Furthermore, severe underfeeding should be avoided because it can result in energy deficit to the patient with the consequences of increased infectious complications with negative patient outcomes.

Special Patient Considerations: Ethical and Personal Beliefs

When assessing a patient for PN, attention should be given to patients with special personal dietary choices (e.g., vegetarians, vegans) or religious beliefs (e.g., Jehovah's Witness). These situations may present unique challenges for clinicians. Most nutrients used in PN formulations are usually from synthetic sources (e.g., crystalline amino acids) or vegetable sources (e.g., triglycerides used in IV lipid emulsions), with the only exception usually being egg phospholipids used in IV lipid

emulsions. Discuss these issues for patients with specific needs who require PN so that a plan can be developed to provide appropriate nutrition support therapy.

AMERICAN SOCIETY FOR PARENTERAL AND ENTERAL NUTRITION SAFE PRACTICES FOR PN

Because serious and sometimes fatal adverse events have occurred with inappropriate use of PN, the American Society for Parenteral and Enteral Nutrition (A.S.P.E.N.) has published updated safe practice guidelines for PN.⁶ These practice guidelines provide a tool and reference for health professionals for the safe and efficacious use of PN. The guidelines represent the standards of practice as they relate to PN prescribing, compounding, stability, compatibility, labeling, administration, and quality assurance. Although application of these guidelines is voluntary, pharmacists who handle PN should review and apply them to their practice sites whenever possible.

PREPARING THE PN PRESCRIPTION: ADMINISTRATION, COMPOUNDING, AND PHARMACEUTICAL ISSUES

After performing a nutrition assessment and estimating nutritional requirements, determine the optimal route to provide nutrition support therapy (e.g., oral, enteral, or parenteral). If PN is deemed necessary, venous access (i.e., peripheral or central; see below) for PN infusion must be obtained. Finally, formulate a PN prescription and administer PN according to safety guidelines.

Route of PN Administration: Peripheral versus Central Vein Infusion

- 7 PN can be administered via a smaller peripheral vein (e.g., cephalic or basilic vein) or via a larger central vein (e.g., superior vena cava) (Fig. 100–1). Peripheral PN (PPN) is infused via a peripheral vein and generally is reserved for short-term administration (up to 7 days) when central venous access is not available. PN formulations are hyperosmolar, and PN infusion via a peripheral vein can cause thrombophlebitis. Factors that increase the risk of phlebitis include high solution osmolarity, extreme pH, rapid infusion rate, vein properties, catheter properties (e.g., diameter, material), and infusion time via the same vein.²⁰ The osmolarity of PPN admixtures should be limited to 900 mOsm/L or less to minimize the risk of phlebitis. The approximate osmolarity of a PN admixture can be calculated from the osmolarity of the individual components:
- Amino acids ~10 mOsm/g (or 100 mOsm/L% final concentration in PN)
 - Dextrose ~5 mOsm/g (or 50 mOsm/L% final concentration in PN)
 - Sodium (chloride, acetate, and phosphate) = 2 mOsm/mEq
 - Potassium (chloride, acetate, and phosphate) = 2 mOsm/mEq
 - Calcium gluconate = 1.4 mOsm/mEq
 - Magnesium sulfate = 1 mOsm/mEq
- PPN admixtures should be co-infused with IV lipid emulsion when using the two-in-one PN because this may decrease the risk of phlebitis caused by the iso-osmolarity and near-neutral pH of IV lipid emulsions (see Table 100–2). Infectious and mechanical complications may be lower with

PPN compared with central venous PN administration. However, because of the risk of phlebitis and osmolarity limit, PPN admixtures have low macronutrient concentrations and therefore usually require large fluid volumes to meet a patient's nutritional requirements. Given these limitations, every effort should be made to obtain central venous access and initiate central PN in patients who have an indication for PN (see Table 100-1).

Central PN refers to the administration of PN via a large central vein, and the catheter tip must be positioned in the superior vena cava (Fig. 100-2). Central PN allows the infusion of a highly concentrated, hyperosmolar nutrient admixture. The typical osmolarity of a central PN admixture is about 1,500 to 2,000 mOsm/L. Central veins have much higher blood flow and the PN admixture is diluted rapidly on infusion, so phlebitis is usually not a concern. Patients who require PN therapy for longer periods of time (greater than 7 days) should receive central PN. One limitation of central PN is the need for placing a central venous catheter and an x-ray to confirm placement of the catheter tip. A commonly used central catheter for PN infusion is a peripherally inserted central venous catheter (PICC), which is inserted into a peripheral vein but the catheter tip is placed in the superior vena cava (Fig. 100-3). Central venous catheter placement may be associated with complications, including pneumothorax, arterial injury, air embolus, venous thrombosis, infection, chylothorax, and brachial plexus injury.^{1,20}

Types of PN Formulations: 3-in-1 versus 2-in-1

- 8 PN admixtures can be prepared by mixing all components into one bag, or instead, IV lipid emulsion may be infused separately (via a Y-site infusion or through a separate IV catheter or lumen). When all components are mixed together, it is referred to as a 3-in-1 admixture or a TNA.²¹ When dextrose, amino acids, and all other PN components are mixed together without IV lipid emulsion, this is referred to as a 2-in-1 PN admixture. There are various advantages and disadvantages to using either 3-in-1 or 2-in-1 PN admixtures (Table 100-6). With a 2-in-1 PN admixture, IV lipid emulsion can be infused separately on a daily or intermittent basis. When lipid emulsion is mixed in the PN, the 3-in-1 admixture becomes an emulsion with respect to physical and chemical characteristics. The final concentration of IV lipid emulsion in a 3-in-1 admixture should be greater than or equal to 2% (20 g/L) to prevent compromising the stability of the emulsion.²¹

A primary concern when administering PN is safety, as described throughout this chapter (e.g., calcium–phosphate solubility). The FDA has provided recommendations for safe infusion of PN admixtures containing calcium and phosphate:

- A 0.22-micron air-eliminating in-line filter should be used for infusion of non-lipid-containing PN.
- A 1.2-micron in-line filter should be used for the infusion of 3-in-1 PN (i.e., a TNA) because it can remove large and unstable lipid droplets and particulate matter.²²

Table 100–6

Advantages and Disadvantages of Using 3-in-1 (TNA) or 2-in-1 PN Admixtures

	3-in-1 (TNA)	2-in-1
Advantages	<ul style="list-style-type: none"> Simplified regimen for patient Increased patient compliance at home Decreased labor (less nursing time) Decreased costs (fewer supplies and equipment needed) Decreased risk of contamination (caused by less manipulation and all components aseptically compounded) Inhibited bacterial growth vs. separate IV lipid emulsion Minimize infusion-related reactions from IV lipid emulsions and possibly improved lipid clearance (if infused over 12 hours) Decreased vein irritation (with PPN) 	<ul style="list-style-type: none"> Improved stability compared with TNA Increased number of compatible medications Decreased bacterial growth (in dextrose–amino acid component) compared with TNA Easier visual inspection Can use 0.22-micron bacterial retention filter Cost savings if unused (i.e., not spiked or opened) IV lipid emulsion can be reused
Disadvantages	<ul style="list-style-type: none"> Decreased stability compared to 2-in-1 PN Cannot use 0.22-micron bacterial retention filter; must use 1.2-micron filter Increased bacterial growth compared with 2-in-1 PN Visual inspection is difficult Limited compatibility with medications 	<ul style="list-style-type: none"> Increased labor and costs (if IV lipid emulsion infused separately) Increased vein irritation, especially if PPN is not co-infused with IV lipid emulsion

PN, parenteral nutrition; PPN, peripheral parenteral nutrition; TNA, total nutrient admixture.

Another concern is the co-infusion of IV medications with PN admixtures. Many IV medications have limited compatibility with 3-in-1 formulations but may be co-infused with a 2-in-1 formulation.^{23,24} Some medications can be co-infused at the Y-site, few medications can be mixed directly into the PN admixture or co-infused with IV lipid emulsion, and some cannot be mixed or co-infused with the PN admixture.^{23,24} *Always* consult compatibility data before adding a medication to a PN admixture or co-infusing it with PN. Medications should only be added to or co-infused with PN if there is evidence documenting compatibility and if it reasonable and safe (i.e., based on toxicity profile, pharmacokinetic and pharmacodynamic considerations).

United States Pharmacopeia, Chapter <797>

The U.S. Pharmacopeia, Chapter <797> (USP <797>) is a document that provides guidelines and best practices for pharmaceutical compounding of sterile products.²⁵ These guidelines address many aspects of compounded sterile preparations (CSPs), including (but not limited to) appropriate training of personnel; appropriate environments for compounding; appropriate storage, handling, and labeling of ingredients and final products; and quality assurance. The purpose of USP <797> is to prevent patient harm from CSPs as a result of contamination (including physical, chemical, and bacterial or fungal pathogens); inappropriate ingredients (variability in strength or quality); or inappropriate preparation, compounding, handling, transportation, or storage. CSPs are classified either as low-, medium-, or high-risk level or for immediate use. CSPs are also assigned an appropriate beyond-use date (BUD), which is the date or time after which a CSP shall not be stored or transported, and it is determined from the date or time the

CSP is compounded. PN admixtures are usually classified as medium-risk products, and they are assigned a BUD of 30 hours at controlled room temperature or 9 days at a cold (refrigerated) temperature. The full details of USP <797> are beyond the scope of this chapter. Pharmacists and other healthcare professionals involved in the preparation of CSPs should review this document along with institutional policies and procedures regarding CSPs.

Standardized, Commercially Available (Premixed) PN Formulations

- A standardized, commercially available PN formulation (also referred to as premixed PN) is a product available from a manufacturer that requires fewer compounding steps before administration.²⁶ These products usually contain amino acids and dextrose in a two-chamber bag, with or without electrolytes. Vitamins and trace elements must be manually added. Lipids can be added to create a TNA or infused separately. Potential advantages to the use of premixed PN include improvements in safety (both decreased compounding errors and microbiologic contamination) and reduced costs.²⁶ The safety advantages are logically related to fewer manual manipulations of the system but remain theoretical with no clinical trial confirmation. Cost advantages have been demonstrated in some trials, with others finding no difference or increased costs. Limitations with the use of premixed PN in the United States are related to the limited number of products available, including a lack of formulations containing lipids (in a three-chamber bag), relatively low amino acid concentration, only 1- and 2-L volumes, limited variability in electrolyte content, and no formulations available for neonatal patients (less than 1 year old).²⁶ These limitations may make premixed PN less appropriate for critically ill patients, obese patients, or those who have organ dysfunction or require fluid restriction.

Patient Encounter, Part 2

WS was diagnosed with recurrent intestinal obstruction related to chronic constipation or possible Hirschsprung's disease, mild dehydration, and malnutrition. A nasogastric (NG) tube was placed for intestinal decompression and to relieve symptoms; the tube initially drained approximately 1,000 mL of gastric or bilious fluid and then remained in place on low continuous suction.

Laboratory Data

Na = 135 mEq/L (135 mmol/L), K = 3.4 mEq/L (3.4 mmol/L), Cl = 96 mEq/L (96 mmol/L), HCO₃ = 27 mEq/L (27 mmol/L), BUN = 15 mg/dL (5.4 mmol/L), serum creatinine = 0.5 mg/dL (44 μmol/L), blood glucose = 78 mg/dL (4.3 mmol/L), total Ca = 8.1 mg/dL (2.03 mmol/L), ionized Ca = 2.28 mEq/L (1.14 mmol/L), Mg = 1.6 mg/dL (0.66 mmol/L), phosphorus = 2.2 mg/dL (0.71 mmol/L), TG = 141 mg/dL (1.59 mmol/L), albumin = 2.7 g/dL (27 g/L), WBC count = 7,700/mm³ (7.7 × 10⁹/L), hemoglobin = 11.2 mg/dL (112 g/L or 6.95 mmol/L), hematocrit = 32.9% (0.33), and platelets = 188,000/mm³ (188 × 10⁹/L)

The surgical team decided to manage WS conservatively (NG tube, plan to manage pain and wean opioids, antiemetic therapy as needed, nutrition support) given her medical condition, medical and surgical histories (chronic constipations, multiple bowel obstructions and abdominal surgeries), and high risk for complications. Because of these factors and possible need for surgical intervention, a peripherally inserted central catheter (PICC) was placed, and the team decided to initiate central PN.

Determine appropriate nutritional goals for WS (calorie and protein requirements).

What other patient data should be collected to help formulate a PN prescription?

Patient Encounter, Part 3

The surgical team plans to initiate the PN, and they ask for your recommendation for WS.

Develop a plan for a complete and balanced PN prescription for amino acids (including fluid, total calories, dextrose, amino acids, lipid emulsion, electrolytes, vitamins, trace elements, and any additives) and explain the rationale supporting your PN formulation and plan.

How should this PN admixture be initiated and titrated to goal?

Would you recommend any other treatments before initiating PN? (Hint: Is this patient at risk for refeeding syndrome?)

control is maintained and the patient does not experience any significant fluid or electrolyte abnormalities. Monitor electrolytes daily and correct as needed. Patients with severe malnutrition should have their PN advanced to goal more slowly and cautiously, and they should be monitored for refeeding syndrome (see Complications of PN).

Cycling PN

PN should be administered over 24 hours in most hospitalized patients to minimize glucose, fluid, and electrolyte abnormalities. However, administering PN via a cyclic infusion over less than 24 hours, or *cycling PN*, may be advantageous in certain patients and situations. Cycling PN typically involves administering the same PN volume over a goal infusion time, usually over 12 hours rather than over 24 hours. Begin with PN infusion over 24 hours; then taper the PN infusion to the goal cycle over 2 to 4 days (e.g., 24 hours, then 18 to 20 hours the next day, then 14 to 16 hours the next day, and then 12 hours the next day). Titrate the PN infusion rate up over 1 to 2 hours to goal rate to avoid hyperglycemia and taper down over 1 to 2 hours at the end of the cycle to avoid reactive hypoglycemia. Most home infusion pumps can be programmed to cycle a given PN volume automatically over a given time. However, the pharmacist may have to develop an appropriate PN cycle if the infusion pump cannot be programmed for an automatic cycle.

Cyclic PN has the following advantages:

- It helps prevent and alleviate PN-associated liver disease by avoiding continuous compulsive nutrient overload on the liver.²⁷
- It improves the quality of life of patients receiving home PN by allowing the patient time off of PN to engage in normal activities of daily living.

Concerns with cycling PN include hyperglycemia with high infusion rates, reactive hypoglycemia when PN infusion is stopped, and fluid and electrolyte abnormalities (refer to the Complications of PN section for more information). Random capillary blood glucose concentrations should be checked 4 hours into the PN cycle (~2 hours after reaching

Formulating a PN Admixture and Regimen

After completing a full nutrition assessment (e.g., SGA)^{1,18}; estimating the patient's daily fluid, energy, and protein requirements (see Table 100–5); and determining if PN is indicated (see Table 100–1), develop an appropriate PN prescription.

Initiating PN

Exercise caution when initiating PN to avoid hyperglycemia and fluid and electrolyte abnormalities. After the goal daily PN volume has been determined, infuse the PN admixture first over 24 hours. For safety, initiate PN at a lower infusion rate (e.g., ~50% of goal for anywhere from ~12 to 24 hours) on day 1 with no more than 150 to 200 g of dextrose per day (or a maximum dextrose infusion rate of ~2 mg/kg per minute for the first 24 hours). Then increase PN to goal over about the following 12 to 24 hours, provided that glycemic

goal rate), 15 to 60 minutes after PN stops, and intermittently during the PN cycle as needed for glycemic control. During cyclic PN infusion, the potassium infusion rate should not exceed 10 mEq/h (10 mmol/h) if the patient is not on a cardiac monitor. If nocturnal cyclic PN infusion interferes with patient's sleep pattern by causing overdiuresis, the PN cycle can be extended over a longer infusion time or PN can be infused during other times of the day that are most convenient to the patient.

Transition to Oral or Enteral Nutrition

The goal is to transition the patient to enteral or oral nutrition and taper off PN as soon as indicated clinically. After initiation of enteral or oral nutrition, monitor the patient for glucose, fluid, and electrolyte abnormalities. When oral nutrition intake is inconsistent, perform calorie counts to determine the adequacy of nutrition via the oral route. When the patient is tolerating more than 50% of total estimated daily calorie and protein requirements via the oral or enteral route, wean PN by about 50%. PN can be stopped when the patient is tolerating at least 75% of total daily calorie and protein requirements via the oral or enteral route, assuming that intestinal absorption is maintained.

COMPLICATIONS OF PN

9 *PN therapy is associated with significant complications, both with short- and long-term therapy.* Many complications are related to overfeeding (Table 100-7). Metabolic complications include hyperglycemia, hypoglycemia, hyperlipidemia, **hypercapnia**, electrolyte abnormalities, refeeding syndrome, and acid-base disturbances. Long-term metabolic complications include liver toxicity, vitamin abnormalities, trace element abnormalities, and metabolic bone disease. Other complications include infectious and mechanical complications that relate to venous catheters.

Hyperglycemia

Hyperglycemia is one of the most common complications associated with PN therapy. The rate of dextrose oxidation

may be reduced in patients with stress and hypermetabolism, patients with diabetes or acute pancreatitis, and patients receiving certain medications (e.g., corticosteroids, **vasopressors**, octreotide, and tacrolimus).^{28,29} Uncontrolled hyperglycemia can lead to fluid and electrolyte disturbances, **hyperglycemic hyperosmolar nonketotic syndrome**, hypertriglyceridemia, and an increased risk of infection.³⁰

Hyperglycemia in critically ill patients may be more a reflection of illness severity than from dextrose infusions, provided that the patient is not being overfed with dextrose.³¹ Critical illness is associated with increased endogenous glucose production (caused by increased glycogenolysis and gluconeogenesis) and insulin resistance. Therefore, critically ill patients have lower tolerance for dextrose infusion compared with nonstressed patients. In patients with hyperglycemia, it is reasonable to initiate PN with a continuous dextrose infusion rate of approximately 2 mg/kg/min until glycemic control is achieved and then advance to goal.⁴ Dextrose infusion rate typically ranges between approximately 2 and 4 mg/kg per minute but should not exceed 5 mg/kg/min in adult patients.^{1,5} Use AdjBW rather than actual weight in obese patients when calculating the dextrose infusion rate. A portion of daily calories (~20% to 30%) can be administered with IV lipid emulsion to help decrease hyperglycemia, provided that the patient does not have hypertriglyceridemia. Overfeeding (with dextrose and with total calories) always must be avoided.

Hyperglycemia can impair cellular and humoral host defenses and can lead to the development of nosocomial and wound infections.³⁰ Historically, hyperglycemia was defined as blood glucose concentrations of more than 200 to 220 mg/dL (11.1 to 12.2 mmol/L), and concentrations of 150 to 200 mg/dL (8.3 to 11.1 mmol/L) were considered "acceptable" in critically ill patients. Early clinical evidence evaluating tight glucose control (e.g., 80 to 110 mg/dL or 4.4 to 6.1 mmol/L) with intensive insulin therapy using continuous insulin infusion in surgical critically ill patients appeared to be associated with reduced infection rates, patient comorbidities, and mortality.^{32,33} However, these results were not replicated in later studies of critically ill medical intensive care unit (ICU) patients³⁴ and mixed medical and surgical ICU patients,³⁵ and tight glycemic control was associated with increased mortality.³⁵ The higher mortality rate may have been related to a higher incidence of hypoglycemia (blood glucose concentrations less than or equal to 40 mg per dL [less than or equal to 2.2 mmol/L]).³⁵ These data suggest that more moderate glucose control is indicated in critically ill patients (e.g., capillary glucose concentrations between ~140 and 180 mg per dL [8.0 and 10.0 mmol/L]).³⁵

The use of regular insulin as a continuous infusion rather than adding insulin to PN reduces the risk of prolonged hyperglycemia or hypoglycemia because the insulin drip can be readily titrated as insulin requirements change. In patients with diabetes, IV insulin doses in the PN admixture to maintain euglycemia range from 0.05 to 0.2 unit of insulin per each gram of dextrose in PN. Starting with a low insulin dose and adjusting the dose daily based on capillary

Table 100-7

Consequences of Overfeeding

Source of Overfeeding	Consequences
Dextrose	Hyperglycemia, hypertriglyceridemia, hepatic steatosis, hypercapnia; hyperglycemia may cause fluid and electrolyte disturbances and increased infection risk
IV lipid emulsions	Hypertriglyceridemia, hyperlipidemia, hepatic steatosis
Amino acids	Azotemia
Total calories	Hepatic steatosis, cholestasis, hypercapnia

blood glucose concentrations is indicated in order to avoid hypoglycemia. Careful adjustments or reductions should be made to the insulin dose as guided by frequent capillary blood glucose monitoring when metabolic stress decreases, acute pancreatitis resolves or when corticosteroid doses are tapered off or discontinued.

Hypoglycemia

- Hypoglycemia can occur in patients when PN is interrupted suddenly (reactive hypoglycemia), especially when patients are treated with insulin or as a result of insulin overdosing in PN.¹ It is essential to prevent hypoglycemia and, if it occurs, identify and treat it promptly. Reactive hypoglycemia typically is rare and usually can be avoided by tapering PN over 1 to 2 hours before discontinuation rather than abruptly stopping the infusion (especially if the patient is receiving insulin in PN or if the patient is not receiving oral or enteral nutrition). Reactive hypoglycemia generally occurs within 15 to 60 minutes after stopping PN (especially in neonatal patients), although it can occur later than this after discontinuing PN.¹ Capillary blood glucose concentrations should be monitored about 15 to 60 minutes after stopping PN infusion to detect any potential hypoglycemia. If PN is interrupted abruptly (e.g., because of lost IV access), infusing dextrose 10% in water at the same rate as PN should prevent hypoglycemia. In patients with poor venous access, reduce the PN infusion rate by 50% for 1 hour before discontinuing. Another alternative to prevent reactive hypoglycemia is to provide a glucose source via the oral route (by mouth or sublingually) when feasible. Monitor capillary blood glucose concentrations regularly in patients receiving insulin in PN and adjust insulin doses accordingly.

Hyperlipidemia

- Patients receiving IV lipid emulsion may be at risk for hyperlipidemia and hypertriglyceridemia. Hyperlipidemia in patients receiving PN may lead to a reduction in pulmonary gas diffusion and pulmonary vascular resistance (especially in patients with underlying pulmonary and vascular disease).³⁶ Severe hypertriglyceridemia (especially when serum triglyceride concentrations exceed 1,000 mg/dL or 11.30 mmol/L) can precipitate acute pancreatitis.³⁷
- Hypertriglyceridemia may develop as a result of increased fatty acid synthesis caused by hyperglycemia or impaired lipid clearance or in patients with history of hyperlipidemia, obesity, diabetes, alcoholism, kidney failure, liver failure, multiorgan failure, sepsis, or pancreatitis or as a result of medications (e.g., propofol, corticosteroids, cyclosporine, and sirolimus).³⁸ Hyperglycemia is probably the most common cause of hypertriglyceridemia in patients receiving PN. Propofol is formulated in a 10% lipid emulsion and may lead to hypertriglyceridemia. It also has been proposed that propofol could have direct effects on lipid metabolism, given that hypertriglyceridemia associated with propofol infusion has been observed with lipid doses that are lower than those typically given in PN.^{38,39}

A higher PL:TG ratio in the 10% lipid emulsion has been proposed to cause the appearance of the abnormal lipoprotein X particles (rich in phospholipids [~60%] and cholesterol [~25%], small amounts of triglycerides) in the blood.^{8,38} Lipoprotein X may compete with lipid particles for metabolism by lipoprotein lipase. Therefore, it is preferred to use IV lipid emulsions with a lower PL:TG ratio (i.e., 20% or 30% lipid emulsions), especially in patients with hypertriglyceridemia, because they have improved clearance compared with emulsions with a higher PL:TG ratio (i.e., 10% lipid emulsion).^{8,38}

Monitor serum triglyceride concentrations regularly during PN therapy (e.g., at the initiation of PN, then once per week initially, and monthly thereafter depending on clinical condition). If a patient develops hypertriglyceridemia, identify and correct the underlying cause(s) if possible (e.g., treatment of hyperglycemia or reduction of dextrose and/or lipid dose). Prolonging the infusion of IV lipid emulsion (e.g., over 24 hours) may improve lipid clearance; however, this may require hanging two containers daily because each container of lipid emulsion should infuse for only 12 hours based on USP <797> and infection control policies and practices. If a patient is receiving propofol, take into account the calories administered from the 10% lipid emulsion in propofol (1.1 kcal/mL or 4.6 kJ/mL). For safety reasons, IV lipid emulsion should be withheld in patients receiving propofol. It also should be held when the serum is lipemic or when serum triglyceride concentrations are greater than 400 mg/dL (4.52 mmol/L). When this occurs, restart IV lipid emulsions when the serum triglyceride concentration is approximately 200 to 400 mg/dL (2.26 to 4.52 mmol/L) (or less) and administer only two to three times per week to prevent essential fatty acid deficiency.

Hypercapnia

Hypercapnia (abnormally high concentration of carbon dioxide in the blood) can develop as a result of overfeeding with dextrose and/or total calories.^{1,40} Excess carbon dioxide production and retention can lead to acute respiratory acidosis. The excess carbon dioxide will also stimulate compensatory mechanisms, resulting in an increase in respiratory rate in order to eliminate the excess carbon dioxide via the lungs. This increase in respiratory workload can cause respiratory insufficiency that may require mechanical ventilation. Reducing total calorie and dextrose intake would result in resolution of hypercapnia if due to overfeeding.

Acid–Base Disturbances

Acid–base disturbances associated with PN are usually related to the patient's underlying condition(s). However, acid–base abnormalities may develop as a result of changes in chloride or acetate concentrations in PN admixtures. Because acetate is converted to bicarbonate in the body, excessive acetate salts in PN can lead to metabolic alkalosis;

excessive chloride salts in PN can lead to hyperchloremic metabolic acidosis. PN should not be used to treat or correct acute underlying acid–base disorders. However, adjusting chloride or acetate salts in the PN admixture may help to prevent or minimize exacerbation of acid–base disorders.

Liver Complications

The incidence of liver complications associated with PN ranges from approximately 7% to 84%, and end-stage liver disease develops in as many as 15% to 40% of adult patients on long-term PN.³⁸ Patients may develop a mild increase in liver transaminases within 1 to 2 weeks of initiating PN, but this generally resolves as PN continues, provided overfeeding is avoided. Severe liver complications include hepatic **steatosis**, **steatohepatitis**, cholestasis, and **cholelithiasis**.³⁸

- Hepatic steatosis usually is a result of excessive administration of carbohydrates or lipids, but deficiencies of carnitine, choline, and essential fatty acids also may contribute. Hepatic steatosis can be minimized or reversed by avoiding overfeeding, especially from dextrose and lipids.³⁸ Carnitine is an important amine that transports long-chain triglycerides into the mitochondria for oxidation, but carnitine deficiency in adults is extremely rare and is mostly a problem in premature infants and patients receiving chronic dialysis. Choline is an essential amine required for synthesis of cell membrane components such as phospholipids. Although a true choline deficiency is rare, preliminary studies of choline supplementation to adult patients' PN caused reversal of steatosis. Compelling evidence for routine carnitine or choline supplementation to prevent or treat steatosis in PN patients is lacking.

- Cholestasis is a common and potentially serious complication in PN-dependent patients. Factors that predispose PN patients to cholestasis include overfeeding, bowel rest (decrease in cholecystokinin secretion), long duration of PN, short-bowel syndrome, bacterial overgrowth and translocation, and sepsis.³⁸ Patients may exhibit increased liver transaminases, increase alkaline phosphatase and gamma-glutamyl transferase concentrations, and mainly increased bilirubin concentrations with jaundice. The most sensitive marker of cholestasis is increased serum conjugated bilirubin concentration of greater than 2 mg/dL (34.2 μ mol/L).³⁸ Cholestasis generally is reversible if PN is discontinued before permanent liver damage occurs. Serum liver function tests may take up to 3 months to return to normal after discontinuing PN. Steps to prevent cholestasis associated with PN include early enteral or oral feedings, using a balanced PN formulation, avoiding overfeeding, using cyclic PN infusion, and treating and avoiding sepsis.³⁸ Limiting soy-based IV lipid emulsion infusion to one or two times weekly at a dose no less than that required to prevent essential fatty acid deficiency may also decrease serum bilirubin concentrations and improve cholestasis.⁴¹ The use of ω -3-fatty acid-rich fish oil-based IV lipid emulsions may hold promise in preventing or reversing PN-associated cholestasis.⁴² However, these formulations

are not yet commercially available in the United States. Pharmacologic treatments include ursodeoxycholic acid (ursodiol), which may improve bile flow and reduce the signs and symptoms of cholestasis. However, ursodiol is only available in an oral dosage form, and absorption may

- be limited in patients with intestinal resections. If other measures are not successful and bacterial overgrowth is thought to be contributing to cholestasis, courses of oral metronidazole, oral gentamicin, or oral neomycin have been used to reduce bacterial overgrowth.
- Cholelithiasis can develop as a result of decreased gallbladder contractility, especially in the absence of enteral or oral intake. Lack of intestinal stimulation reduces secretion of cholecystokinin, a peptide hormone secreted in the duodenum that induces gallbladder contractility and emptying. The best prevention of cholelithiasis is early initiation of enteral or oral feeding (to stimulate secretion of cholecystokinin and intestinal motility). Pharmacologic treatment with cholecystokinin–octapeptide (sincalide) to stimulate gallbladder contraction and bile flow does not prevent PN-associated cholestasis or improve serum conjugated bilirubin concentrations.
- Monitor liver function tests, including serum aspartate aminotransferase (AST), alanine aminotransferase (ALT), alkaline phosphatase, total bilirubin, conjugated bilirubin, unconjugated bilirubin, and γ -glutamyl transferase at the initiation of PN therapy and regularly thereafter during PN therapy. The frequency of monitoring liver function tests depends on the presence or absence of liver disease. This varies from one to two times weekly in the acute setting to once weekly to once monthly in stable home PN patients.

Manganese Toxicity

- Manganese is a trace element that serves as a coenzyme in multiple biochemical reactions. Manganese accumulation can occur in patients with cholestasis or in patients receiving long-term PN therapy. The most common toxicity is neurotoxicity, but liver toxicity also may occur. Neurologic symptoms associated with manganese toxicity include headache, somnolence, weakness, confusion, tremor, muscle rigidity, altered gait, and masklike face (a Parkinson's-like syndrome).³⁸ Conversely, some patients with hypermagnesemia may not exhibit symptoms of toxicity.
- Periodically monitor blood manganese concentrations in patients on long-term PN. Patients with cholestasis receiving PN may require restriction of manganese in PN to prevent its accumulation and possible toxicity.

Metabolic Bone Disease

- Metabolic bone disease is a condition of bone demineralization leading to **osteomalacia**, **osteopenia**, or **osteoporosis** in patients receiving long-term PN. Metabolic bone disease may occur to some degree in as many as 40% to 100% of patients receiving long-term PN.³⁸ Often patients are asymptomatic, although symptoms can include bone pain, back pain, and

fractures. Patients often have increased serum alkaline phosphatase concentrations, low to normal parathyroid hormone (PTH) concentrations, normal 25-hydroxyvitamin D and low 1,25 dihydroxyvitamin D concentrations, hypercalcemia or hypocalcemia, and hypercalcuria.⁴³ Because patients may be asymptomatic, diagnosis can be incidental. Radiographic techniques commonly used in diagnosing bone disease include quantitative computed tomography (CT) and bone mineral density.⁴³

Factors that can predispose patients to developing metabolic bone disease include deficiencies of phosphorus, calcium, and vitamin D; aluminum toxicity; amino acids and hyperosmolar dextrose infusions; chronic metabolic acidosis; corticosteroid therapy; and lack of mobility.^{38,43} Calcium deficiency (caused by decreased intake or increased urinary excretion) is one of the major causes of metabolic bone disease in patients receiving PN. Provide adequate calcium and phosphate with PN to improve bone mineralization and help to prevent metabolic bone disease. Administration of amino acids and chronic metabolic acidosis also appear to play an important role. Provide adequate amounts of acetate in PN admixtures to maintain acid–base balance.

Aluminum toxicity appears to play a role in the development of metabolic bone disease in patients on long-term PN, possibly by impairing calcium bone fixation, inhibiting the conversion of 25-hydroxyvitamin D to the active 1,25-dihydroxyvitamin D, and/or reducing PTH secretion.^{38,43} Measure serum aluminum concentrations in PN patients with suspected metabolic bone disease to rule out aluminum toxicity. The FDA has investigated aluminum contamination in parenteral products and issued a rule specifying acceptable aluminum concentrations in large-volume parenterals in 2000.⁴⁴ The rule further stated that the package insert (“Precautions”) for large-volume parenterals used in making PN should indicate that the product contains no more than 25 mcg/L (0.93 μ mol/L) of aluminum and defined a safe upper limit for parenteral aluminum intake at less than 4 to 5 mcg/kg/day. This has required a great amount of effort by manufacturers to meet these limits and requires pharmacy policies for monitoring aluminum concentrations in PN admixtures. Pharmacies should use products with the lowest labeled aluminum content for the making of PN. Patients who are chronically dependent on PN should have their serum aluminum concentrations routinely monitored or whenever metabolic bone disease is suspected or diagnosed.

Encourage patients on long-term PN to engage in regular low-intensity exercise. Yearly bone density measurements also should be performed on patients on long-term PN and when metabolic bone disease is suspected.

Refeeding Syndrome

Refeeding syndrome describes the metabolic derangements that occur during nutritional repletion of patients who are starved, underweight, or severely malnourished.⁴⁵ Hypophosphatemia and hypokalemia (along with associated complications) are the classic signs and symptoms, but refeeding syndrome encompasses a constellation of fluid

and electrolyte abnormalities affecting neurologic, cardiac, hematologic, neuromuscular, and pulmonary systems. The most severe cases of refeeding syndrome have resulted in cardiac failure, seizures, coma, and death.⁴⁵ The reintroduction of energy substrates, especially carbohydrates or glucose, increases metabolism and the utilization of glucose as the predominant fuel source. This increases insulin secretion and the demand for phosphorylated intermediates of glycolysis (e.g., ATP and **2,3-diphosphoglycerate** [2,3-DPG]), inhibits fat metabolism, and causes an intracellular shift of phosphorus, potassium, and magnesium. These changes, in combination with preexisting low total body stores of phosphorus, potassium, and magnesium and enhanced cellular uptake of phosphorus during anabolic refeeding, result in hypophosphatemia, hypokalemia, and hypomagnesemia. Vitamin deficiencies (e.g., thiamine) also may exist or be precipitated during refeeding. High carbohydrate intake increases the demand for thiamine, which can precipitate thiamine deficiency and cause lactic acidosis and neurologic abnormalities,⁴⁵ as well as myocardial dysfunction and congestive heart failure. Other metabolic alterations that may occur include expansion of the extracellular water compartment and fluid intolerance.

The primary goal is preventing refeeding syndrome when initiating PN in high-risk patients (e.g., prolonged lack of adequate nutritional intake, significant weight loss, or moderate to severe malnutrition). When initiating nutrition support, the rule of thumb to prevent refeeding syndrome is to “start low and go slow.” Initiate PN cautiously (e.g., ~25% of estimated nutritional requirements on day 1) and gradually increase to goal over 3 to 5 days. Correct electrolyte abnormalities (e.g., hypophosphatemia, hypokalemia, and hypomagnesemia) before initiating PN and provide supplemental phosphate, potassium, and magnesium in or outside of PN (if the patient has normal kidney function). Well-nourished patients require 10 to 15 mmol of phosphate per 1,000 kcal (4,186 kJ) to avoid hypophosphatemia,¹² but patients with moderate to severe malnutrition who are at risk for refeeding syndrome require more aggressive supplementation. Doses of IV phosphate up to 0.64 to 1 mmol/kg may be used to treat severe hypophosphatemia (in patients with normal kidney function), and doses can be repeated as needed until serum phosphorus concentration has normalized.⁴⁶ Provide vitamin supplementation in addition to the multivitamin administered in PN (e.g., provide supplemental oral or IV thiamine 100 mg/day and folic acid 1 mg/day for about 1 week). In addition, minimize fluid and sodium intake during the first few days of PN (e.g., total fluid of 1,000 mL/day or less).⁴⁵ Assess patients for fluid balance, signs of edema, fluid overload, and weight gain because any gain of more than 1 kg per week likely represents fluid retention. Monitor patients closely for signs and symptoms of refeeding syndrome until they are tolerating PN at goal for a few days:

- Monitor vital signs (i.e., heart rate, blood pressure, and respiratory rate), mental status, and neurologic and neuromuscular function routinely (e.g., at least every 4–8 hours).

- Monitor pulse oximetry and any electrocardiographic changes when indicated clinically.
- Monitor serum laboratory values (including basic metabolic panel, phosphorus, and magnesium) at least once a day.

Infectious Complications

Patients receiving central PN are at increased risk of developing infectious complications caused by bacterial and fungal pathogens.^{1,47} In addition, patients without malnutrition who receive early PN (e.g., within 48 hours of ICU admission) may have a higher incidence of infectious complications than patients who do not receive PN or receive late PN initiation (e.g., greater than 7 days after ICU admission).^{2,10} Infections may be related to several factors, including placement of a central venous catheter, contamination of a central venous catheter or IV site (catheter-related infection), persistent hyperglycemia, and lack of stimulation of the intestinal tract. Strict aseptic techniques must be used when placing the catheter along with continuous care of the catheter and infusion site. Catheter-related bloodstream infections are a common complication in long-term PN patients, often requiring hospital admission for parenteral antimicrobial therapy and/or removal of the catheter. Contamination of the PN admixture is possible but rare if protocols are followed for aseptic preparation of PN admixtures. Lack of use of the intestinal tract also may increase the risk of infection possibly by reducing gut immunity, leading to intestinal bacterial overgrowth and subsequent systemic bacterial translocation.

Mechanical Complications

Mechanical complications of PN are related to venous catheter placement and the equipment used to administer PN. A central venous catheter must be placed by a trained professional, and risks associated with placement include pneumothorax, arterial puncture, bleeding, hematoma formation, venous thrombosis, and air embolism.¹ Over time, the venous catheter may require replacement. Problems with the equipment include malfunctions of the infusion pump, IV tubing sets, and filters.

MONITORING PN THERAPY

- **10** When initiating PN, patients should have important baseline laboratory values checked to assess electrolyte status, organ function, and nutritional status (Table 100–8). Baseline laboratory monitoring should include:

- Basic metabolic panel (i.e., serum sodium, potassium, chloride, bicarbonate, blood urea nitrogen, creatinine, glucose, and calcium), serum phosphorus, and magnesium
- Liver function, including AST, ALT, alkaline phosphatase, lactate dehydrogenase (LDH), total and conjugated bilirubin; a comprehensive metabolic panel can be ordered (i.e., serum sodium, potassium, chloride, bicarbonate, blood urea nitrogen, creatinine, glucose, calcium, AST, ALT, alkaline phosphatase, albumin, and total bilirubin), but phosphorus, magnesium, and fractionated or conjugated bilirubin are not included on this panel and must be ordered separately

Table 100–8

Suggested Frequency of Monitoring Parameters in Hospitalized Patients Receiving PN

Parameters	Initial	Daily (Unstable)	2–3 × Weekly (Stable)	Weekly	As Indicated
BUN, creatinine	X	X	X		
Sodium, potassium, chloride, bicarbonate	X	X	X		
Glucose	X	X	X		
Calcium, phosphorus, magnesium albumin, AST, ALT, LDH, alkaline phosphatase, total bilirubin	X	X	X		
Conjugated bilirubin	X			X	X
Prealbumin	X			X	X (once weekly)
Triglycerides	X			X	X
RBC count, hemoglobin, hematocrit, WBC count ± differential, platelets, PTT	X				X
PT or INR				X	X
Nitrogen balance					X
Zinc, selenium, chromium, copper, manganese, iron					X
TIBC, ferritin					X
Vitamin concentrations					X
Ammonia					X
Blood cultures					X
Body weight	X	X	X		

ALT, alanine aminotransferase; AST, aspartate aminotransferase; BUN, blood urea nitrogen; INR, international normalized ratio; LDH, lactate dehydrogenase; PT, prothrombin time; PTT, partial thromboplastin time; RBC, red blood cell; TIBC, total iron-binding capacity; WBC, white blood cell.

Patient Encounter, Part 4

The surgical team plans to initiate PN for WS per your recommendations. Laboratory data were listed previously.

What monitoring parameters related to PN therapy should you follow in WS after initiating PN? List monitoring parameters and frequency.

What potential complications of PN should you monitor for in WS?

What special considerations must be made when developing a plan for nutrition support therapy and a PN formulation for patients with severe malnutrition?

- Serum albumin, prealbumin, and triglycerides
- Complete blood count (including hemoglobin, hematocrit, red blood cell count, and white blood cell count) with differential and platelets
- **10** *Thereafter, these and other nutritional parameters should be monitored routinely or as indicated (see Table 100–8). Random capillary blood glucose concentrations also should be monitored every 6 to 8 hours when initiating PN, and regular insulin should be administered to control blood glucose concentrations as needed.*

SUMMARY AND CONCLUSION

PN is an effective and potentially lifesaving method of administering nutrition support therapy in patients who cannot receive adequate oral or enteral nutrition. Preparation and administration of PN are associated with significant adverse effects and metabolic, infectious, and mechanical complications. Optimal design, compounding, and administration of a PN regimen is essential to minimize the risk of adverse effects and complications, and patients must be monitored closely while receiving PN to optimize outcomes.

Abbreviations Introduced in This Chapter

ALT	Alanine aminotransferase
ASPEN	American Society for Parenteral and Enteral Nutrition
AST	Aspartate aminotransferase
ATP	Adenosine triphosphate
CT	Computed tomography
2,3-DPG	2,3-Diphosphoglycerate
FDA	Food and Drug Administration
GI	Gastrointestinal
HIT	Heparin-induced thrombocytopenia
IBW	Ideal body weight
kcal	Kilocalorie(s)
kJ	Kilojoule(s)

LDH	Lactate dehydrogenase
mEq	Milliequivalents
mmol	Millimoles
mOsm	Milliosmoles
PL	Phospholipid(s)
PN	Parenteral nutrition
PPN	Peripheral parenteral nutrition
PTH	Parathyroid hormone
TG	Triglyceride
TNA	Total nutrient admixture
TPN	Total parenteral nutrition

Self-assessment questions and answers are available at <http://www.mhpharmacotherapy.com/pp.html>.

LEARNING OBJECTIVES

● Upon completion of this chapter, the reader will be able to:

1. Discuss how gut structure and function impact choice of feeding route and outcome of feeding.
2. Estimate kilocalorie and protein requirements of an enteral feeding candidate and design an enteral nutrition (EN) regimen to meet these.
3. Evaluate patient-specific parameters to determine whether EN is appropriate.
4. Compare clinical efficacy, complications, and costs of EN versus parenteral nutrition (PN).
7. Formulate a monitoring plan for an EN patient.
8. Select appropriate medication administration techniques for an EN patient.

KEY CONCEPTS

- 1 EN is the preferred route if the gut can be used safely in a patient who cannot meet nutritional requirements by oral intake.
- 2 EN is associated with fewer infectious complications than PN.
- 3 For patients intolerant of gastric feedings or in whom the risk of aspiration is high, feedings delivered with the tip of the tube in the jejunum are preferred.
- 4 Standard EN formulas are polymeric formulas; these are appropriate for most patients.
- 5 When choosing an EN formula, the patient's fluid status should dictate the caloric density selected.
- 6 Robust clinical trial data supporting the use of specialty formulas in niche populations typically remain lacking in terms of improved patient outcomes.
- 7 Acceptance of enteral immunonutrition in certain clinical settings is gaining momentum.
- 8 Gastrointestinal complications are the most common complications of EN limiting the amount of feeding patients receive.
- 9 An important practice to help prevent medication-related occlusion is adequate water flushing of the tube before, between, and after each medication is given through the tube.
- 10 Compatibility of medications with an EN formula is of concern when administering medications through feeding tubes.

Enteral nutrition (EN) is broadly defined as delivery of nutrients via the gastrointestinal (GI) tract. This includes normal oral feeding as well as delivery of nutrients in liquid form by tube. Sometimes when the term *enteral nutrition* is used, only tube feedings are included; hence, the terms *enteral nutrition* and *tube feedings* are often used synonymously. The bulk of this chapter includes information regarding delivery of feedings via tubes. Formulas for EN usually are delivered in the form of commercially prepared liquid preparations, although some products are produced as powders for reconstitution. Modern techniques for enteral access, both placement of the tubes and the materials for making pliable, comfortable tubes, were developed in the 1960s to 1980s. Nonvolitional feedings in patients who cannot meet nutritional requirements by oral intake include EN and **parenteral nutrition** (PN), which are collectively known as *specialized nutrition support* (SNS).

Several organizations have issued clinical guidelines on the use of EN. These include the American Society for Parenteral and Enteral Nutrition (A.S.P.E.N.), European Society for Clinical Nutrition and Metabolism (ESPEN), and Canadian team known as Critical Care Nutrition.¹⁻⁴ A.S.P.E.N. and the Society for Critical Care Medicine (SCCM) have jointly issued guidelines for SNS in critically ill patients.⁵

GI TRACT STRUCTURE AND FUNCTION

Anatomy and Absorptive Function

With normal volitional feeding, food is ingested via the mouth. There, the process of breaking down complex foodstuffs into simpler forms that can be absorbed by the small bowel begins.

Segment	Length (ft) ^a
Total	12–20
Duodenum	1
Jejunum	5–8
Ileum	7–12

^aOne ft is equivalent to approximately 0.31 m.

Solid food is chewed in the mouth, and enzymes begin digestion. The trigger for release of many enzymes and GI hormones is the presence of food in specific regions of the GI tract. Food is swallowed and passes through the esophagus and the esophageal sphincter to the stomach, where additional digestive enzymes and acids further break it down. The stomach also serves a mixing and grinding function.

The food, now in a liquid form known as *chyme*, passes through the pyloric sphincter into the duodenum, where stomach acid is neutralized. There is wide variation in lengths of the components of the small intestine (i.e., duodenum, jejunum, and ileum) among individuals (Table 101-1). Most absorption of digested carbohydrate and protein occurs within the jejunum. Most fat absorption occurs within the jejunum and ileum. In the small bowel, breakdown of macronutrients (i.e., carbohydrate, protein, and fat) occurs both within the lumen and at the intestinal mucosal membrane surface. The absorptive units on the intestinal mucosal membrane are infoldings known as *villi*. These villi are made up of epithelial cells called *enterocytes*. Projections

(striations) from these enterocytes called *microvilli* increase the surface area of the small bowel and make up what is known as the *brush-border membrane*.

Digestive substances secreted by the pancreas play a role in food breakdown. The pancreas secretes large amounts of sodium bicarbonate that neutralize stomach acid. These substances flow from the pancreas through the pancreatic duct. The pancreatic duct typically joins the hepatic duct to become the common bile duct that empties through the **sphincter of Oddi** into the duodenum. Bile secreted by the liver does not contain digestive enzymes, but bile salts help to emulsify fat and facilitate fat absorption. Bile flows through bile ducts into the hepatic duct and common bile duct. Bile is stored in the gallbladder until needed in the gut to aid fat digestion, at which time it empties through the cystic duct to the common bile duct to the duodenum. Pathways through which carbohydrate, protein, and fat are digested and absorbed through the small bowel are illustrated in **Figure 101-1**.

After absorption in the small bowel, remaining undigested food passes from the ileum through the ileocecal valve to the colon. A major role of the colon is fluid absorption. Some of the water and sodium absorption achieved by the colon is facilitated by short-chain fatty acids (SFCAs) formed from digestion of certain dietary fibers by colonic bacterial enzymes.

Gut Immune Function

In addition to roles in digestion and absorption, the gut plays significant immune roles. The distal small bowel and colon host many bacteria and their endotoxins, and it is important that these organisms not gain access to the internal systems of the body. This function is known globally as the *gut barrier*.

FIGURE 101-1. Schematic of carbohydrate, fat, and protein digestion. (From Kumpf VJ, Chessman KH. Enteral nutrition. In: DiPiro JT, Talbert RL, Yee GC, et al, eds. *Pharmacotherapy: A Pathophysiologic Approach*, 8th ed. New York: McGraw-Hill, 2011:2528.)

function and can be divided into several components.⁶ Normal flora of the gut comprise one component. The normal flora, particularly some anaerobes, help to prevent overgrowth of potential pathogens. A second component involves mechanical factors. These include an epithelial mucus gel layer that prevents adherence of bacteria and peristalsis of the small bowel that prevents stasis of bacteria. **Gut-associated lymphoid tissue** (GALT) and **mucosa-associated lymphoid tissue** (MALT), prominent in the small bowel, serve as local immune systems. Secretory immunoglobulin A produced at the mucosal surface in response to food in the gut prevents bacteria from invading the surface. Bile salts and the **reticuloendothelial system** of the liver are believed to bind bacterial endotoxin and help clear it from the blood if it is absorbed into the portal circulation.

PATIENT SELECTION

In general, **1** EN is the preferred route if the gut can be used safely in patients who cannot meet nutritional requirements by oral intake. If the gut functions, EN is usually preferred over PN. The timing of SNS (either EN or PN) is controversial, but definitive guidelines for these therapies state that SNS should be started when intake has been inadequate for 7 to 14 days or if inadequate oral intake is anticipated to last at least 7 to 14 days.¹ The prior nutritional status of the patient should be considered. Previously well-nourished patients can better afford not being fed for longer periods than previously poorly nourished patients. Patients in the intensive care unit (ICU) setting probably benefit from early EN started within 24 to 48 hours of admission to the ICU.^{3,5} Ethical questions sometimes come into play when consideration is given to starting (or stopping) EN in seemingly futile situations. Methods for assessing nutritional status and designing SNS regimens are covered in Chapter 100. In general, non-obese hospitalized patients require 20 to 35 total kcal/kg of body weight/day (84 to 147 kJ/kg body weight/day) and 1 to 2 g protein/kg of body weight/day.

Indications

Many potential indications for EN exist (**Table 101-2**). PN was used extensively in the past for many of these conditions. Advances in EN technology now allow many patients with these conditions to receive EN. EN is administered in both institutional and home settings.

Contraindications and Precautions

EN should not be used or should be used with extreme caution in certain conditions (**Table 101-3**). It is possible to use EN in some patients with these conditions depending on severity of illness, location of abnormality, and experience of practitioners delivering care. Controversy surrounds some of these contraindications and precautions. For example, whereas some clinicians deliberately avoid enteral feedings in the hemodynamically unstable patient for fear of worsening intestinal ischemia, others believe that early feeding may

Table 101-2

Potential Indications for EN

Neoplastic Disease	GI Disease
Chemotherapy	IBD
Radiation therapy	Short-bowel syndrome
Upper GI tumors	Esophageal motility disorder
Cancer cachexia	Pancreatitis
Organ Failure	Fistulas
Hepatic	Gastroesophageal reflux disease
Renal	Esophageal atresia
Cardiac cachexia	Neurologic Impairment
Pulmonary	Comatose state
Bronchopulmonary dysplasia	Cerebrovascular accident
Congenital heart disease	Demyelinating disease
Hypermetabolic States	Severe depression
Closed head injury	Failure to thrive
Burns	Cerebral palsy
Trauma	Other Indications
Postoperative major surgery	AIDS
Sepsis	Anorexia nervosa
	Complications during pregnancy
	Geriatric patients with multiple chronic disease
	Organ transplantation
	Inborn errors of metabolism
	Cystic fibrosis
	Extreme prematurity

IBD, inflammatory bowel disease.

From Kumpf VJ, Chessman KH. Enteral nutrition. In DiPiro JT, Talbert RL, Yee GC, et al, eds. *Pharmacotherapy: A Pathophysiologic Approach*, 8th ed. New York: McGraw-Hill, 2011.

facilitate intestinal perfusion and is beneficial.^{5,7-9} Still others might avoid jejunal feedings in this setting but would proceed with cautious gastric feedings.

Enteral Versus Parenteral Feeding

With the advent of the technique of PN by a large central vein in the late 1960s, this modality of feeding quickly became popular. PN was used originally in patients with inflammatory bowel disease (IBD) or congenital bowel abnormalities but was incorporated quickly into care of

Table 101-3

Contraindications and Precautions for EN

Severe hemorrhagic pancreatitis
Severe necrotizing pancreatitis
Necrotizing enterocolitis
Diffuse peritonitis
Small bowel obstruction
Paralytic ileus
Severe hemodynamic instability
Enterocutaneous fistulae
Severe diarrhea
Severe malabsorption
Severe GI hemorrhage
Intractable vomiting

other types of patients such as critically ill patients. The relative ease of PN administration, along with the perception that critically ill patients had prolonged high-energy expenditures, led to complications of overfeeding. In the United States, where no intravenous (IV) fat emulsion was available commercially for several years during the 1970s, the impact of dextrose overfeeding was observed. Complications included hyperglycemia, carbon dioxide overproduction leading to delays in weaning from mechanical ventilation, and liver abnormalities owing to **hepatic steatosis**.

The pendulum began to swing toward EN in the late 1980s and early 1990s as clinical studies showed better clinical outcomes with EN compared with PN. Some of the potential advantages of EN over PN are included here. First, EN is expected to preserve the gut barrier function better than PN. This could prevent **translocation** of bacteria and endotoxin from the gut lumen into the lymphatic system and systemic circulation, thus preventing infections. Studies from the same era support that **2 EN is associated with fewer infectious complications than PN**. EN is cited frequently as having a better overall safety profile than PN. Whereas PN is associated with more severe complications, such as pneumothorax and catheter sepsis, EN is associated with more nuisance complications, such as GI side effects that delay or limit delivery of nutrients. Another major frequently cited advantage of EN over PN is that EN is less expensive. It is true that EN formulas typically are cheaper and less labor intensive to prepare than PN, although some specialty EN formulas approach the cost of PN formulas. Depending on the method of feeding tube placement, EN costs can mount if the tube must be placed by a radiologist or gastroenterologist rather than a nurse or if the tube must be replaced for some reason.

Arguments in support of EN over PN have been questioned. Part of this questioning relates to the question of whether EN is beneficial compared with PN or whether PN as commonly administered may be detrimental. Overfeeding and hyperglycemia occur easily with PN administration, and the potential harm of hyperglycemia, especially in critical care populations, has been demonstrated poignantly, although the exact range optimal for glycemic control in ICU patients remains controversial.^{10,11} A study published in 1991 demonstrated in a mildly malnourished perioperative population that there were more infectious complications in patients randomized to receive PN compared with those randomized to receive no SNS; there was no difference in noninfectious complications between the two groups.¹² Only in severely malnourished perioperative patients were fewer noninfectious complications seen with PN; in these patients, no difference in infectious complications was seen between groups. Whether EN truly prevents infections and improves clinical outcomes or whether PN is detrimental continues to be debated and probably depends on the specific patient population. However, at present, EN is preferred by most experts over PN when the gut is functional. In Europe (more so than in North America), PN has been used to supplement EN during the first week of intensive care therapy when EN is not yet being tolerated at full rates.² This approach

is currently discouraged by the American and Canadian ICU guidelines and the A.S.P.E.N./SCCM guidelines for SNS in critically ill patients, and a recent randomized controlled trial from Europe corroborates the prudence of this recommendation.^{3,4,13} One meta-analysis did indicate that PN may be superior to delayed EN in critical care.¹⁴ The Algorithms for Critical-Care Enteral and Parenteral Therapy (ACCEPT) trial showed that use of an evidence-based algorithm for SNS in critical care patients in community and teaching hospitals improved provision of EN and was associated with reduced hospital stays.¹⁵ A more recent study showed that although feeding guidelines resulted in earlier and more successful feeding, they did not result in decreases in mortality or hospital length of stay.¹⁶

ROUTES OF ACCESS¹⁷

There are several access sites for EN (**Fig. 101-2**). Nasogastric (NG), orogastric (OG), nasoduodenal (ND), and nasojejunal (NJ) routes generally are for short-term use (less than 1 month), whereas gastrostomy, **percutaneous endoscopic gastrostomy** (PEG), jejunostomy, and **percutaneous endoscopic jejunostomy** (PEJ) tubes are preferred for longer term treatment. Esophagostomy or pharyngostomy is used rarely. Both advantages and disadvantages exist for each EN route (**Table 101-4**).

Gastric Feeding

- Gastric feedings are used commonly. They require an intact gag reflex and normal gastric emptying for safety and success. Certain patients, such as those who have suffered head trauma, may not empty their stomachs efficiently and therefore may not be good candidates for gastric feedings. In these patients, it may be impossible to achieve a gastric tube feeding rate to provide adequate nutrients. In addition, pooling of formula in the stomach could increase risk of aspirating feeding formula into the lungs.

The NG route is used most commonly for short-term (less than 1 month) enteral access. The major advantage of this route is that the tube can be placed quickly and inexpensively by the nurse at the bedside.

Gastrostomy tubes, in which an incision is made directly through the abdominal wall, are indicated for patients who can tolerate gastric feedings but in whom long-term (longer than 1 month) feedings are anticipated. The most commonly placed gastrostomy tubes are PEG tubes placed endoscopically. Gastrostomy tubes also can be placed laparoscopically or during an open procedure by a surgeon. Placement of a gastrostomy tube either endoscopically or surgically is more expensive than bedside OG or NG placement but can result in placement of a larger bore tube.

An advantage of feeding into the stomach is that the feedings can be delivered either intermittently or continuously. This is unlike feeding directly into the small bowel, where continuous feedings must be used. Intermittent feedings into the small bowel result in GI intolerance in most patients.

FIGURE 101-2. Access sites for tube feeding. (From Kumpf VJ, Chessman KH. Enteral nutrition. In DiPiro JT, Talbert RL, Yee GC, et al, eds. *Pharmacotherapy: A Pathophysiologic Approach*, 8th ed, New York: McGraw-Hill, 2011:2531.)

Table 101-4

Options and Considerations in the Selection of Enteral Access

Access	Indications	Tube Placement Options	Advantages	Disadvantages
Nasogastric or orogastric	Short term Intact gag reflex Normal gastric emptying	Manually at bedside	Ease of placement Allows for all methods of administration Inexpensive Multiple commercially available tubes and sizes	Potential tube displacement Potential increased aspiration risk
Nasoduodenal or nasojejunal	Short term Impaired gastric motility or emptying High risk of GER or aspiration	Manually at bedside Fluoroscopically Endoscopically	Potential reduced aspiration risk Allows for early postinjury or postoperative feeding Multiple commercially available tubes and sizes	Manual transpyloric passage requires greater skill Potential tube displacement or clogging Bolus or intermittent feeding not tolerated
Gastrostomy	Long term Normal gastric emptying	Surgically Endoscopically Radiologically Laparoscopically	Allows for all methods of administration Large-bore tubes less likely to clog Multiple commercially available tubes and sizes Low-profile buttons available	Attendant risks associated with each type of procedure Potential increased aspiration risk Requires stoma site care
Jejunostomy	Long term Impaired gastric motility or gastric emptying High risk of GER or aspiration	Surgically Endoscopically Radiologically Laparoscopically	Allows for early postinjury or postoperative feeding Potential reduced aspiration risk Multiple commercially available tubes and sizes	Attendant risks associated with each type of procedure Bolus or intermittent feeding not tolerated Requires stoma site care

GER, gastroesophageal reflux.

From Kumpf VJ, Chessman KH. Enteral nutrition. In DiPiro JT, Talbert RL, Yee GC, et al, eds. *Pharmacotherapy: A Pathophysiologic Approach*, 8th ed. New York: McGraw-Hill, 2011.

Postpyloric Feedings

3 For patients intolerant of gastric feedings or in whom the risk of aspiration is high, feedings delivered with the tip of the tube in the jejunum are preferred. This bypasses the problem of poor gastric emptying and adds another barrier (the pyloric sphincter) through which tube feedings must traverse before they are aspirated into the lungs. It should be noted that **postpyloric feedings** do not preclude the possibility of aspiration. Many patients with this complication are not aspirating tube feeding formula but rather their own nasopharyngeal secretions.

Nasoduodenal and NJ feeding tubes can be placed by trained, experienced nurses at the bedside. Although such placements typically take more time than NG or OG placements, this is still a relatively inexpensive method of placement. Bedside electromagnetic transmitter devices (e.g., CORTAK, Corpak Medsystems) may be helpful in attaining postpyloric tube placement. Many institutions have not been able to achieve placements consistently at the bedside. In some institutions, ND or NJ placements are done in radiology by a radiologist using fluoroscopy to visualize tube advancement. This procedure increases the cost of EN therapy. NJ tubes generally are preferred over ND tubes; placement of the tip of the tube distal to the **ligament of Treitz** (located near the junction of the duodenum and the jejunum) may reduce risk of aspiration. Alternatively, during a laparotomy, the surgeon can place an ND or NJ tube.

Surgically placed jejunostomy tubes are an option; similar to surgically placed gastrostomy tubes, they are placed through an incision in the abdominal wall, precluding the need for a tube down the nose or mouth. These tubes frequently are placed during laparotomy following abdominal trauma. Alternatively, jejunal access can be obtained by placing a jejunal extension through a PEG tube; the resulting tube is sometimes referred to as a *PEGJ tube* or *G-J tube*. Another option is to place a PEJ tube directly; this is more technically difficult than PEG placement. Tubes with both gastric and jejunal lumens are sometimes used, the gastric lumen for suctioning stomach contents and the jejunal lumen for delivery of feedings.

METHODS OF DELIVERY

Enteral feedings are delivered by several different methods. Continuous infusion must be used when duodenal or jejunal feedings are administered. For gastric feedings, bolus or intermittent feedings could be administered instead of continuous feedings. Each method has advantages and disadvantages.

In many hospitals, EN is delivered most commonly as a continuous infusion over 24 hours at a constant rate regulated by an infusion pump. A variation of continuous infusion is cyclic feeding, in which a constant rate is maintained by a pump over a certain number of hours daily. This method of administration is used commonly in long-term care or home settings. Often EN is administered overnight, giving the patient “freedom” from the infusion pump during the day, although

this may not be practical for patients with high nutritional needs because it may be difficult to increase the rate of feedings while trying to maintain GI tolerance with cyclic feeding.

Intermittent feedings are used commonly in long-term care or home settings because of easier administration. Patients frequently are started with continuous feedings; transitioned to intermittent feedings given several times a day over about 30 to 45 minutes for each feeding; and eventually changed to bolus feedings, in which feeding is administered several times a day over less than 10 minutes per feeding. An advantage of intermittent feedings is that they may be administered by gravity flow adjusted with a roller clamp, although some institutions may use an infusion pump. Bolus feedings can be administered using a 60-mL syringe, although, again, in some circumstances, an infusion set and pump may be used. Intermittent and bolus feedings often are given in amounts of 240 to 480 mL per feeding, corresponding to one to two cans (8 oz each) of formula.

EN FORMULAS

One advantage of EN over PN is the availability in the United States of certain nutrients in some EN formulations (e.g., glutamine, fish oils) that are not available for parenteral use. A number of EN formulas are marketed commercially. Hospitals and long-term care facilities usually limit formularies of EN formulas, stocking only a limited number of products.

Polymeric versus Oligomeric Formulas

A major criterion for categorizing EN products is whether they contain more intact (polymeric) macronutrients (particularly the protein component) or their macronutrient ingredients are present in simpler forms (oligomeric). 4 *Standard EN formulas are polymeric formulas; these are appropriate for most patients.* Oligomeric formulas should be reserved for patients with GI dysfunction.

Polymeric formulas typically contain intact proteins (most commonly casein). They have low osmolality of 300 to 500 mOsm/kg (300 to 500 mmol/kg). These formulas usually supply essential vitamins and minerals in amounts similar to the Adequate Intakes (AI) or Recommended Dietary Allowances (RDA) for these nutrients when the formula is delivered in amounts adequate to meet macronutrient requirements of most patients. Many polymeric formulas are inexpensive relative to oligomeric formulas. Most polymeric formulas are lactose free and gluten free, as are most modern tube feeding products. Products designed to be used as oral supplements generally are polymeric and often have sucrose or other simple sugars added to improve taste.

The oligomeric formulas are also known as *chemically defined formulas*. These can be subcategorized based on whether the formula contains all free amino acids (elemental formulas) or peptides (peptide based) as the protein source. Some formulas contain a combination of free amino acids and small peptides. Dipeptides and tripeptides are absorbed more efficiently than free amino acids. Oligomeric formulas

may be better tolerated than polymeric formulas for patients with defects in GI function and may be particularly useful with severe pancreatic dysfunction or significantly decreased GI surface area (e.g., short-bowel syndrome).

Oligomeric formulas typically are more expensive than polymeric formulas and have higher osmolality because they contain more osmotically active particles. However, the osmolality of these products usually does not exceed 700 mOsm/kg (700 mmol/kg), a value less than that of many oral medications or a regular diet. In the past, there was concern that higher osmolality EN formulas could cause GI intolerance, particularly diarrhea. This led to dilution of formulas and gradually increasing both the strength and rate of formula administration. This practice is unnecessary and serves only to delay attainment of goal nutritional support. Sometimes enteral feedings are diluted to deliver extra water required by the patient; this practice generally is discouraged because of potential risk of formula contamination. Instead, it is better to give extra water as boluses through the tube. If medications are administered through the feeding tube, generous amounts of water should be used to flush the tube before and after each medication; this practice helps provide extra fluid and prevent problems with occlusion of the tube.

Oligomeric formulas usually are less palatable than polymeric formulas and are not designed for use as oral supplements. Many of the oligomeric formulas provide some fat calories as medium-chain triglycerides (MCTs), a fat source that is more readily absorbed and metabolized than long-chain triglycerides (LCTs) typically found in polymeric formulas. The MCTs do not require bile salts or pancreatic enzymes for absorption. Some of the elemental formulas contain a low proportion of fat (less than 10% of total calories), which makes them useful in certain situations where fat needs to be restricted. The carbohydrate source in oligomeric formulas is also less complex than in polymeric formulas, consisting of oligosaccharides rather than hydrolyzed starch.

Fiber Content

Another distinguishing factor of enteral formulas is whether or not they contain fiber. Both soluble and insoluble fibers may be included in the formula. Insoluble fiber exerts an effect on gut motility by drawing water into the intestine and decreasing transit time, thus preventing constipation. Soluble fiber can help to lower blood cholesterol levels, regulate blood sugar, and prolong gastric emptying. Soluble fiber may also help control diarrhea. Cellulose gum is an example source of insoluble fiber. Oat fiber and guar gum provide primarily soluble fiber. Soy fiber provides primarily insoluble fiber but also some soluble fiber and is the most commonly used fiber source in tube feeding products. Fiber has been useful for regulating gut motility in some but not all clinical studies; it certainly can be useful in selected patients.¹⁸ Some patients may experience GI discomfort secondary to gas production with introduction of fiber-containing formulas.

Fructooligosaccharides (FOS) are a form of fiber that pass through the stomach and small bowel undigested and are fermented by colonic bacteria to the SCFA butyrate,

propionate, and acetate. The SCFAs serve as a major fuel source for colonocytes and facilitate water and sodium reabsorption in the colon.¹⁹ The FOS are thus *prebiotics* that serve as fermentable substrates for the normal flora of the colon. The SCFAs are not added directly to EN products because they would be absorbed completely before reaching the colon; rather, FOS are added, allowing bacterial degradation to form SCFAs.

Caloric Density

Enteral feeding formulas can be categorized based on caloric density. Standard caloric density is 1 to 1.3 kcal/mL (4.2 to 5.4 kJ/mL). More calorically dense formulas containing 1.5 to 2 kcal/mL (6.3 to 8.4 kJ/mL) are available and have a higher osmolality. **5** *When choosing an EN formula, the patient's fluid status should dictate the caloric density selected.*

- Fluid-overloaded patients may benefit from more calorically dense formulas. As caloric content of a formula increases, the amount of free water decreases. For example, whereas 1-kcal/mL (4.2 kJ/mL) formulas contain about 850 mL of free water/L, the 2-kcal/mL (8.4 kJ/mL) formulas contain about 710 mL of free water/L.²⁰

Protein Content

Protein content is an important factor in choosing an EN formula. Standard protein content in EN formulas is up to about 15% of total calories as protein. High-protein formulas containing up to 25% of total calories as protein are available for highly stressed patients with elevated protein needs. So are low-nitrogen formulas containing less than 10% of total calories as protein for use in patients requiring protein restriction. A wide range of protein is available, from about 35 to 85 g/L.

Carbohydrate Content

The most common carbohydrate source in tube feeding products is maltodextrin, a partially hydrolyzed starch that is easily digestible. Corn syrup solids are another hydrolyzed starch found in many products. Products containing simple sugars (often those intended for oral use) tend to be higher in osmolality.

Fat Content

Both MCTs and LCTs are used in tube feeding products. Corn, soy, and safflower oils have been the mainstay sources of fat, providing mainly ω -6 polyunsaturated fatty acids (PUFAs). Some newer EN products contain higher quantities of ω -3 PUFAs from sources such as fish oil (i.e., docosahexanoic acid [DHA] and eicosapentaenoic acid [EPA]). Other formulas contain higher quantities of monounsaturated fatty acids (MUFAs) from canola oil and high-oleic safflower or sunflower oils. The essential fatty acid (EFA) content (mainly linoleic acid) of EN formulas is important because EFA deficiency can be induced if at least 1% to 4% of total calories are not supplied as EFAs. MCT oil does not contain any EFAs.

Vitamin, Mineral, and Electrolyte Content

Most EN products contain vitamins and minerals, including the major electrolytes, in amounts adequate to deliver the RDA or AI when a standard volume of the formula is delivered daily. Some of the specialty formulas (e.g., renal formulas) may have altered amounts of certain micronutrients.

Specialty Formulas

Specialty formulas designed for use in specific clinical situations generally are much more expensive than standard polymeric formulas. **6** *Robust clinical trial data supporting use of these specialty formulas in niche populations typically remain lacking in terms of improved patient outcomes.*

► Stress and Trauma Formulas

Historically, formulas aimed specifically for highly stressed, critically ill patients, including those who have sustained significant trauma and those undergoing major surgical procedures, were enriched with branched-chain amino acids (BCAAs). The rationale was that skeletal muscle BCAAs are preferentially used for energy in critical illness. Provision of BCAAs might limit breakdown of muscle in these patients. Clinical data failed to support or refute benefit of these formulas unequivocally in terms of clinical outcomes.³

The newer generation of enteral feeding formulas marketed for use in these populations covers a broad spectrum of characteristics (Table 101–5). Whereas some are polymeric, others are oligomeric to address malabsorption that may accompany high stress. Some formulas marketed for use in critical illness are calorically dense (1.5 to 2 kcal/mL [6.3 to 8.4 kJ/mL]) to address fluid restrictions seen in this population, and others are less calorically dense. Most products contain generous amounts of protein to address requirements of highly stressed patients (**nonprotein kilocalorie to nitrogen ratios** typically between 75:1 and 125:1). Many products contain ingredients purported to increase immune function; the term *immunonutrition* is sometimes attached to these products.

Immune-enhancing ingredients present in some enteral feeding products include arginine, glutamine, ω -3 fatty acids, nucleic acids, and antioxidants. Few products contain all of these (see Table 101–5). Arginine is an important substrate for nitric oxide (NO) synthesis, and small amounts of NO have beneficial effects on immune function under certain conditions. Arginine has been purported to have a positive influence on lymphocyte and macrophage function. Glutamine is considered to be conditionally essential in critical illness. This amino acid is a preferred fuel source for enterocytes of the small bowel. Supplementation with glutamine, either parenterally or enterally, may help to maintain the integrity of the gut mucosa, preventing translocation of bacteria and endotoxin from the gut lumen into the lymphatic system and systemic circulation. However, the importance of translocation in humans remains controversial. The ω -3 fatty acids, primarily from fish oils, are included in many immunonutrition products.

Metabolites of ω -6 fatty acids include mediators such as prostaglandins, leukotrienes, and thromboxanes that are primarily proinflammatory and increase coagulation. On the other hand, mediators produced from ω -3 fatty acids are less proinflammatory and decrease coagulation. Thus ω -3 fatty acids may help preserve the antimicrobial capacity of critically ill patients by downregulating inflammation.²¹ Limited data support nucleic acids as immunomodulators. Quantities of antioxidants (particularly vitamin C, vitamin E, and β -carotene) higher than those traditionally found in standard enteral formulas are added to some immunonutrition formulas to protect body systems, including the immune system, from damage by oxygen-free radicals.²² Oxygen-free radicals may be produced in high quantities in the setting of injury or infection.

7 *Acceptance of enteral immunonutrition in certain clinical settings is gaining momentum.* Several meta-analyses of the commercial immunonutrition products and/or specific ingredients (e.g., arginine and glutamine) found in these products have been conducted.^{3,23} In general, these analyses have found no benefit in terms of mortality rates. However, several have concluded that infection rates, length of stay, and length of time on a ventilator may be decreased with these products. The 2009 A.S.P.E.N./SCCM ICU Guidelines support use of these formulas in major elective surgery, trauma, burns, head and neck cancer, and mechanically ventilated patients.⁵ The best timing (initiation and duration) of delivery remains to be determined. There is some concern that supplementation with arginine may be detrimental in septic patients.³

► Pulmonary Formulas

Enteral feeding formulas designed for use in patients with chronic obstructive pulmonary disease or receiving mechanical ventilation contain higher amounts of fat (40% to 55% of total kilocalories) than most formulas. The rationale for high fat content is that burning of fat for energy is associated with less carbon dioxide production compared with burning of carbohydrate. Less carbon dioxide production theoretically would be advantageous in patients with retention of this substance and might facilitate weaning from mechanical ventilation. Because part of the market targeted by the manufacturers of these products comprises mechanically ventilated patients, these products are included in Table 101–5. Carbon dioxide retention owing to carbohydrate administration was a problem previously when feeding was overzealous. However, at conservative calorie levels, even standard enteral formulas usually can be given without fear of excess carbon dioxide production.

One formula, Oxepa (Nestle), has been studied specifically in critically ill patients with acute respiratory distress syndrome (ARDS), acute lung injury (ALI), and sepsis. This formula contains high quantities of the ω -3 fatty acids (EPA) and γ -linolenic acid (GLA). GLA is metabolized to a prostaglandin with vasodilatory properties. EPA is converted to prostaglandins and leukotrienes with primarily an anti-inflammatory profile. This formula contains large quantities of antioxidants. Patients receiving this formula had improved

^aOne kcal is equivalent to 4.186 kJ.

^bFormula considered enriched if following criteria met: arginine—greater than 10 g/1,500 kcal (6,279 kJ); glutamine—greater than 10 g/1,500 kcal (6,279 kJ); MCT—greater than 30% of total fat; and ω -3 fatty acid—ratio of ω -6 to ω -3 less than or equal to 2:1 or greater than 1.5 g/L ω -3 fatty acids.

^cPolymeric vs. oligomeric/monomeric designation based on protein content.

outcomes, including fewer days of mechanical ventilation, compared with patients receiving a high-fat enteral feeding product as a control.²⁴ A more recent study using a standard enteral feeding product as a control did not show clear benefit in septic patients with ARDS or ALI.²⁵ However, another recent study demonstrated benefit from Oxepa in patient with early sepsis even when using a standard enteral feeding control product.²⁶ The timing and duration of use of this product for optimum benefit in these populations remains to be determined.

► Diabetic Formulas

Similar to pulmonary formulas, formulas designed for patients with diabetes or stress-induced hyperglycemia are relatively high in fat and low in carbohydrates (Table 101-6). The macronutrient content of these products does not follow the recommendations of the American Diabetes Association for patients with diabetes (lower carbohydrate content and higher fat content than recommended), which could be an issue if used for a long period of time. These formulas

Table 101-6

Selected Enteral Feeding Formulas Marketed for Use in Diabetes and Stress-Induced Hyperglycemia^a

Product Name/Manufacturer	kcal/mL	% kcal as Fat	% kcal as Carbohydrate	Fiber (g/L)

Diabetisource AC/Nestle Nutrition	1.2	44	36	15

^aOne kcal is equivalent to 4.186 kJ.

typically contain fiber (primarily soluble) because it plays some role in glycemic control. They also may contain fructose and MUFAs. Data support improved blood sugar control with use of these formulas in patients with diabetes.²⁷ Whether or not a diabetic EN formula is chosen, avoidance of overfeeding and maintenance of good glycemic control with insulin or other hypoglycemic medications are important in these populations.

► Renal Formulas

Products designed for use in renal failure have high caloric density (1.8 to 2 kcal/mL [7.5 to 8.4 kJ/mL]) to decrease administered fluid (Table 101-7). The products vary in amounts of nutrients of interest in renal failure patients such as protein, potassium, phosphorus, and magnesium. Products low in protein (20 to 35 g/L) may be appropriate in chronic renal failure patients not yet receiving dialysis. On the other hand, removal of nitrogen by dialysis, coupled with the hypercatabolic, hypermetabolic condition seen in many acute renal failure patients, makes use of higher protein formulas (70 to 85 g/L) appropriate in these situations. Potassium, phosphorus, and magnesium contents of EN formulas designed for use in renal failure tend to be lower than standard formulas because these renally excreted electrolytes accumulate during renal failure.

Historically, elemental formulas designed for renal failure were enriched with essential amino acids (EAAs) and contained lesser amounts of nonessential amino acids (NEAAs) than standard formulas. Theoretically, EAAs could combine with urea nitrogen in the synthesis of NEAAs, leading to a decrease in blood urea nitrogen (BUN). The only situation in which such formulas may be appropriate is in patients with chronic renal failure who are not candidates for dialysis. Even in this setting, use of these products should be limited to no more than 2 or 3 weeks owing to the risk of increased serum ammonia levels.¹ These EAA-enriched formulas have been supplanted largely by polymeric formulas with protein content similar to standard EN formulas. Many dialysis patients tolerate standard, high-protein EN formulas, although electrolytes must be monitored closely.

► Hepatic Formulas

Specialized formulas for patients with hepatic insufficiency are limited in number. These are enriched with BCAAs while containing a reduced quantity of aromatic amino acids (AAAs) and methionine compared with standard enteral formulas. These changes address the high levels of AAAs and low levels of BCAAs found in the blood of patients with hepatic insufficiency. Theoretically, these products might help patients with hepatic encephalopathy (HE). One of the mechanisms postulated as a cause of HE is the “false neurotransmitter” hypothesis. According to this hypothesis, high levels of AAA in the blood allow large quantities of these amino acids to cross the blood–brain barrier and form false neurotransmitters. Administration of high amounts of BCAAs could competitively inhibit some AAAs from crossing the blood–brain barrier, thus decreasing formation of false neurotransmitters. Hepatic formulas have low AAA content, and this distinguishes them from the BCAA-enriched formulas historically used in patient with critical illness and stress. Improvement in mortality attributable to these products has not been consistent.¹

The A.S.P.E.N./SCCM guidelines for the ICU recommend against the use of protein restriction to reduce risk of development of hepatic encephalopathy.⁵ These guidelines recommend use of standard EN formulas for ICU patients with acute or chronic liver disease but state that the hepatic specialty formulas may be useful in improving coma grade in HE patients refractory to standard treatment with locally acting antibiotics and lactulose. An example of a specialized hepatic formula is Hepatic-Aid II, a product supplied as a powder for reconstitution that requires vitamin, mineral, and electrolyte supplementation. A second product is NutriHep (Nestle), supplied as a liquid formula containing the recommended amounts of key vitamins, minerals, and electrolytes.

► Wound Healing Formulas

Tube feeding and oral supplement formulas designed for use in patients with wounds or decubitus ulcers typically supply high amounts of protein and calories. The antioxidant vitamins A, C, and E are frequently also found in high quantities as is zinc.

Table 101-7

Selected Enteral Feeding Products Designed for Use in Renal Failure

Product Name/Manufacturer	Protein/L	Characteristics
Renalcal/Nestle	34.4	Enriched with EAAs, arginine, histidine; incomplete ^a formula because of negligible electrolytes and lack of fat-soluble vitamins
Nepro with Carb Steady/Abbott	80.6	Complete formula ^b similar to Novasource Renal
Novasource Renal/Nestle	74	Complete formula similar to Nepro with Carb Steady
Suplena with Carb Steady/Abbott	44.7	Complete formula with low amounts of protein for patients not yet receiving dialysis

^aIncomplete formula—contains insufficient amounts of one or more essential nutrients.

^bComplete formula—contains all nutrients in amounts sufficient to meet needs of most patients in a volume equal to or less than that usually administered.

EAA, essential amino acid.

Patient Encounter, Part 1

FH is a 40-year-old paraplegic woman admitted to the hospital with increasing shortness of breath, fever, and hypotension. She is intubated and placed on mechanical ventilation in the ICU. A diagnosis of sepsis and septic shock is made; her lactic acid level is elevated, as is her white blood cell count. Several sources of the sepsis are possible; in addition to pneumonia, she also has a significant sacral ulcer and a suprapubic catheter with urinalysis positive for leukocyte esterase and a few white blood cells. She is placed on a sepsis protocol to include fluid resuscitation, pressors, antibiotics, and stress-dose corticosteroids. She is given propofol for sedation while on the ventilator and is receiving an insulin drip.

FH responds well to treatment of her sepsis and by day 2 of hospitalization is receiving a stable low dose of pressors. A decision is then made to start EN. Her current weight is 57 kg, her height is 67 inches (170 cm), and her body mass index is 19.5 kg/m².

Is there any concern regarding starting EN at this time?

How does the propofol that the patient is receiving affect the EN prescription?

Design an enteral feeding regimen appropriate for this patient at this time.

What are this patient's risk factors for hyperglycemia, and is the insulin drip a good method of management?

Is there any indication for additional micronutrient supplementation for this patient beyond what is included in the EN formula?

► Modular Components

Single nutrient components are frequently administered through feeding tubes to augment the composition of the EN formula. Protein modules are probably the most commonly used. These may be supplied by the manufacturer as a powder that must be reconstituted with water or as a liquid product. Other commonly used modular components include fiber and glutamine supplements.

MONITORING AND COMPLICATIONS

Although complications of EN generally are considered less serious than those of PN, some complications nevertheless can be dangerous or can lead to impaired delivery of desired nutrient load. Complications of EN can be divided into four categories: GI, technical, infectious, and metabolic. The first three of these categories, along with common causes, are listed in **Table 101–8**. Patients on EN must be monitored for prevention of complications (**Table 101–9**). Note that monitoring of many parameters can become less frequent as the patient's condition stabilizes. Monitoring for efficacy of EN is also important.

Table 101–8

Complications of Tube Feeding

GI Complications

8 GI complications are the most common complications of EN limiting the amount of feeding that patients receive. Although diarrhea frequently is blamed on the tube feeding formula or the method of EN administration, other possible causes of diarrhea usually exist (see Table 101–8).

Table 101–9

Suggested Monitoring for EN Patients to Prevent the Development of Complications

Parameter	During Initiation of EN Therapy	During Stable EN Therapy
Vital signs	Every 4–6 hours	As needed with suspected change (i.e., fever)
Clinical assessment		
Weight	Daily	Weekly
Length and height (children)	Weekly–monthly	Monthly
Head circumference (less than 3 years of age)	Weekly–monthly	Monthly
Total intake or output	Daily	As needed with suspected change in intake or output
Tube feeding intake	Daily	Daily
Enterostomy tube site assessment	Daily	Daily
GI tolerance		
Stool frequency and volume	Daily	Daily
Abdomen assessment	Daily	Daily
Nausea or vomiting	Daily	Daily
Gastric residual volumes	Every 4–8 hours (varies)	As needed when delayed gastric emptying is suspected
Tube placement	Before starting; then ongoing	Ongoing
Laboratory		
Electrolytes, BUN/S _{cr} , glucose	Daily	Every 1–3 months
Calcium, magnesium, phosphorus	3–7 times/week	Every 1–3 months
Liver function tests	Weekly	Every 1–3 months
Trace elements, vitamins	If deficiency or toxicity is suspected	If deficiency or toxicity is suspected

BUN, blood urea nitrogen; EN, enteral nutrition; S_{cr}, serum creatinine.

From Knopf VS, Chessman KH. Enteral nutrition. In DiPiro JT, Talbert RL, Yee GC, et al, eds. *Pharmacotherapy: A Pathophysiologic Approach*, 8th ed. New York: McGraw-Hill, 2011.

In the inpatient setting, patients receiving EN frequently are some of the sickest patients. Along these lines, *Clostridium difficile* colitis must be considered as a possible cause of diarrhea, especially in patients who have been receiving antimicrobial therapy or proton pump inhibitors.^{28–30} Antibiotic therapy is a major cause of diarrhea in acutely ill patients, including those receiving EN. A medication-related cause of diarrhea is the sorbitol content of medications.³¹ Large quantities of this substance present in many oral liquid medications (often considered the dosage form of choice for administration through a feeding tube) can cause diarrhea. Unfortunately, the sorbitol content of many medications is not listed on their labeling, and some manufacturers frequently reformulate these preparations to contain varying amounts of excipients, such as sorbitol.

Determining the cause of the diarrhea is important to know how to address the problem. Whereas *C. difficile* colitis should be treated with metronidazole or vancomycin, sorbitol- or other medication-induced diarrhea can be addressed by removal of the offending agent. Likewise, diarrhea secondary to malabsorption sometimes can be addressed by changing to an oligomeric EN formula. Antiperistaltic agents such as loperamide may be useful in some cases of noninfectious diarrhea.

On the other hand, constipation may occur in some patients receiving tube feedings, especially the elderly. Increased provision of fluid or fiber may be useful in attaining bowel regularity. Constipation may be drug related, in which case

discontinuation or replacement of the offending drug may help alleviate the problem.

Impaired gastric emptying is seen commonly in EN patients receiving gastric feedings and may be associated with nausea and vomiting. Impaired gastric emptying may be related to a disease process (e.g., diabetic gastroparesis or sequelae to head injury) or to drug therapy, most notably narcotics. Gastric residual checks frequently are measured in patients receiving gastric feedings (see Table 101–9). To accomplish such a check, a syringe is attached to the feeding device, and as much liquid as possible is aspirated into the syringe. Debate is ongoing as to what constitutes a significant gastric aspirate, with numbers between 100 and 500 mL most commonly defended; some experts would even argue that residual checks are not necessary.^{4,32–34} Approaches to the patient with delayed gastric emptying might include changing to an enteral formula containing less fat because dietary fat is associated with slower gastric emptying. Metoclopramide often is given to patients receiving gastric feedings to facilitate gastric emptying. Erythromycin is an alternative medication that may be useful in stimulating gastric motility, although it can be associated with drug–drug interactions. Feedings by a PEG tube may be associated with a decreased risk of aspiration compared with NG feedings.³² Patients with consistently high gastric aspirates are considered to be at higher risk of aspirating feedings into their lungs and should be considered for transition to postpyloric feedings. Postpyloric feedings may help relieve EN-related nausea and vomiting and are preferred for patients without an intact gag reflex.

An important practice to help prevent aspiration is elevation of the head of the bed to at least 30 degrees during continuous feedings and during and for 30 to 60 minutes after intermittent and bolus feedings.

Technical Complications

Technical or mechanical complications are encountered frequently in EN patients. Tube occlusion most commonly is related to formula occlusion or medication administration through the tube. **9** *An important practice to help prevent medication-related occlusion is adequate water flushing of the tube before, between, and after each medication is given through the tube.* If intermittent feedings are used, water flushing after each feeding is recommended. Tube occlusion can increase cost of EN significantly if the tube has to be removed and replaced. Clearing of the occlusion using water or pancreatic enzymes plus sodium bicarbonate can be attempted, and special devices and kits (e.g., DeClogger, Bionix) are available for this purpose.³⁵

Tube displacement is a potentially significant complication of EN. This may be seen secondary to an agitated patient pulling at the tube, or in some cases, the tip of the tube migrates spontaneously. The danger of this complication arises if the tip of the tube is positioned in the tracheobronchial tree and feeding is delivered to this area, potentially leading to pneumonia, pneumothorax, and other problems. Location of the tip of the feeding tube should be confirmed initially by chest radiograph after placement and before use. For ongoing assessment of tube placement, auscultation and measurement of aspirate pH can be used.

Endoscopic and surgical feeding tubes can be complicated by erosion of the exit site caused by leakage of gastric or intestinal contents onto the skin. This complication must be addressed by good wound care and repair or replacement of the access device. Similarly, NG, ND, and NJ tubes can be complicated by nasopharyngeal irritation or necrosis. This is one reason why such tubes should be considered for short-term use only.

Infectious Complications

Infectious complications of EN include aspiration pneumonia and infections related to delivery of contaminated EN formula. Aspiration is a complication with GI, mechanical, and infectious implications. Although GI infections owing to contamination of enteral formulas have been reported uncommonly, there is ample opportunity for these formulas to be seeded with organisms during the processes of transferring from the can to the delivery bag with ready-to-use formulas and during the process of reconstitution with powdered formulas. The so-called closed systems of delivery, wherein the formulas come from the manufacturer premixed in a delivery bag, should help to decrease the chance of formula contamination. Practice recommendations from A.S.P.E.N. state that sterile water should be used for formula reconstitution, medication dilution, tube flushing, and additional water provision in acute or chronically ill patients requiring EN.⁴ This recommendation

can be difficult to implement into practice, especially in the home care setting.

Metabolic Complications

Metabolic complications of EN most commonly include disorders of fluid and electrolyte homeostasis and hyperglycemia. More severely ill patients require more frequent monitoring (see Table 101–9). Both dehydration and fluid overload can occur with tube feeding. Careful monitoring of fluid inputs and outputs as well as body weight is important. Dehydration may be caused by either excessive fluid losses or inadequate fluid intake. The trend in the ratio of BUN to serum creatinine can be useful in helping monitor for this complication; a ratio of greater than about 15:1 may be an indicator of dehydration. Attention should be paid to the free-water content of EN formulas. Free-water content of EN formulas varies from about 65% to 85%, with the percentage of free water typically dropping as caloric density of the formula rises. If dehydration develops, switching to a less calorically dense formula or using more water flushes may be appropriate. Fluid overload is reflected by increases in weight, lower extremity edema, and pulmonary rales and particularly may be a problem in patients with renal or cardiac insufficiency. Use of an EN formula that is more calorically dense may be helpful, and diuretic therapy may be necessary. Fluid imbalances often are associated with abnormalities of sodium homeostasis that should be addressed in concert with fluid imbalance.

Hypokalemia, hypomagnesemia, and hypophosphatemia are some of the most common electrolyte abnormalities in sick, hospitalized patients. These can occur in the context of the so-called refeeding syndrome. This syndrome occurs in chronically malnourished patients when they are aggressively started on a feeding regimen. Although more classically associated with PN, refeeding syndrome can also occur with aggressive EN. Careful monitoring of these electrolytes, coupled with a feeding regimen increased gradually to goal rate over a period of several days to a week, should help protect at-risk patients from this potentially harmful complication. Hypokalemia and hypomagnesemia also may be associated with excessive losses through the GI tract or urine and may be associated with various medication therapies, including diuretics. Repletion of these conditions may be accomplished enterally in nonsymptomatic patients or parenterally if the patient is symptomatic or the abnormality is severe. Enteral repletion with magnesium and phosphate can be associated with diarrhea. Hyperkalemia, hypermagnesemia, and hyperphosphatemia are encountered less commonly and usually are associated with renal insufficiency and decreased excretion. Hyperkalemia also is associated with several medications, including potassium-sparing diuretics, angiotensin-converting enzyme inhibitors, and angiotensin receptor blockers.

Although hyperglycemia is less common with EN than with PN, it can occur. Many severely ill patients (e.g., septic, highly stressed) receiving EN have a metabolic milieu promoting hyperglycemia. For ICU patients with hyperglycemia receiving

continuous EN, an IV insulin drip may be the most effective way to achieve good glycemic control. Administration of scheduled intermediate or long-acting insulin is preferred over sliding-scale insulin alone in patients requiring insulin after they have been stabilized on their enteral feeding regimen.^{36,37} Administration of a higher fat, lower carbohydrate EN formula may be useful in selected patients.

Monitoring for Efficacy and Outcome Evaluation

- The most useful physical measurement of efficacy of EN in the long-term patient is typically body weight. Depending on the clinical situation, the goal may be weight gain, weight maintenance, or weight loss. Whereas day-to-day fluctuations in weight generally reflect fluid changes, week-to-week variations are more useful in determining if caloric provision is appropriate.

The amount of EN actually administered is often less than the amount ordered owing to interruptions in therapy, especially in hospitalized patients. It is imperative to monitor volume of feedings actually received and to make adjustments in rates or amounts of EN as necessary.

Biochemical markers have been used historically to help interpret the adequacy of EN. However, use of visceral proteins such as albumin or prealbumin is limited by the effects of inflammation on serum levels of these biomarkers. In the acute phase of illness characterized by a proinflammatory state, proteins known as *acute-phase reactants* are preferentially synthesized. One of these acute-phase reactants measured clinically is C-reactive protein (CRP). In some patients with significant illness, prealbumin may not rise, even though the patients are receiving appropriate EN, until CRP begins to fall. Collection of urine to measure nitrogen balance can help analyze the adequacy of caloric and protein provision.

In patients with wounds (e.g., decubitus ulcers), a goal of nutritional therapy is to facilitate wound healing. Monitoring status of the wound becomes part of the ongoing nutritional assessment. In debilitated patients, particularly those on long-term EN, measures of functional status such as grip strength and ability to perform activities of daily living become important components of nutritional assessment.

MEDICATION ADMINISTRATION IN PATIENTS RECEIVING EN

Medication Administration Through Feeding Tubes

If a patient receiving EN is alert and can swallow oral medications, then medications should be given by mouth. Many patients are not able to receive medications by this route, and the feeding tube may be considered as a delivery route. Although used widely, the effects of medication administration through feeding tubes on the delivery of

Patient Encounter, Part 2

FH is extubated and transferred out of the intensive care unit on day 4 of hospitalization. The tube feeding is changed to a nocturnal feeding only, and a general diet including protein shakes is ordered. Unfortunately, FH's respiratory status deteriorates on the morning of day 5, prompting readmission to the ICU and reintubation with suspicion of adult respiratory distress syndrome; propofol is restarted. She has also developed loose stools and been found to be positive for *Clostridium difficile* toxin. The tube feeding is changed back to a continuous feeding around the clock.

What is the rationale for nocturnal tube feedings?

Should any changes be made to the tube feeding regimen based on the patient's current status?

Is Clostridium difficile infection a contraindication to EN?

Would this patient benefit from glutamine supplementation?

both the drug and the EN formula nutrients have been inadequately studied.³⁸

- 10 *Compatibility of medication with an EN formula is of concern when administering medications through feeding tubes.* An important technical complication of EN is tube occlusion, which is related most commonly to medication administration. Not only must compatibility of the medication and the EN formula be considered, but interactions between these components and the feeding tube itself must be considered. Because either medication or EN formula or some combination thereof can physically stick to the tube itself, strict protocols for flushing the tube before, between, and after administration of medications are important.⁵ The best fluid for flushing feeding tubes is warm water. Carbonated beverages and fruit juices are not recommended. Between 10 and 30 mL of water should be used as a flush before and after any medication administration through a feeding tube. Medications should be administered one at a time sequentially rather than being mixed together for simultaneous administration down the tube; about 5 mL of water should be used as a flush between each medication. This should help prevent interactions between drugs within the feeding tube itself that could lead to tube occlusion.

- Different dosage forms present unique challenges for administration through feeding tubes. Certain solid dosage forms should not be crushed because crushing would alter release characteristics.³⁹ For example, controlled-release, extended-release, and sustained-release preparations should not be crushed. Sublingual dosage forms should not be crushed. Enteric-coated dosage forms generally are designed to protect acid-labile medications from stomach acid; when these dosage forms reach the small bowel with its higher

pH, the drug then is released into an environment in which it is more stable. Alternatively, enteric-coated dosage forms protect the stomach from medications that could cause irritation. Thus, crushing of the enteric coating defeats the purpose of the dosage form and could lead to decreased efficacy or increased adverse events.

Medications available commercially as compressed tablets can be crushed for administration through feeding tubes. After such a tablet is crushed into a fine powder, it should be mixed with 10 to 30 mL of fluid (usually warm water) for administration. A powdered dosage form inside a hard-gelatin capsule similarly can be poured out and mixed with water for administration through feeding tubes. Soft-gelatin capsules can be dissolved in warm water. Some enteric-coated and delayed-release microencapsulated products can be opened, and the individually coated particles can be administered through the tube without crushing if the tube has a large enough diameter.

If a liquid dosage form of a medication exists, it would seem rational to use this dosage form for administration through a feeding tube. This may decrease the potential for tube clogging but may in some instances decrease tolerability of medication administration. Sorbitol is an excipient found in many liquid medications in amounts sufficient to cause diarrhea. If diarrhea secondary to sorbitol in a liquid medication is suspected, contact with the manufacturer to ascertain sorbitol content may be necessary.

Another potential problem with administration of liquid medications through feeding tubes is high osmolality of some products. Dilution of hypertonic medications with 30 to 60 mL of water (depending on osmolality of the medication and dosage volume of the undiluted medication) or administration of smaller dosages more frequently may help prevent diarrhea. Although administration of IV medications through feeding tubes sometimes may be entertained, these dosage forms frequently are hypertonic and contain excipients that can be problematic when given via the GI tract.

It is generally not recommended to mix medications directly into the EN formula because of concerns that physical incompatibilities might lead to tube occlusion. There is some evidence that polymeric formulas are more likely to demonstrate physical incompatibility with medications compared with monomeric formulas, although most of the work in this area has used casein or caseinate-based formulas, and other proteins may act differently.³⁸ Limited data currently available indicate that acidic syrups and elixirs may be most harmful, causing physical incompatibility when admixed with EN formulas. This incompatibility may be caused by changes in the protein structure after exposure to acid or alcohol.³⁸

It would seem logical that medications considered being absorbed to a greater extent in the fasted state either should be given between feedings on an intermittent feeding schedule or the feedings should be held before and after medication administration. However, results of one provocative study with the antihypertensive medication hydralazine indicated that continuous feeding into the stomach resulted in a situation

mimicking fasting in terms of rate of gastric emptying and drug absorption.³⁸ This issue deserves further study.

The location of the tip of the feeding tube is important when considering medication administration down a feeding tube. This is particularly true if the medication acts locally in the GI tract. For example, sucralfate and antacids act locally in the stomach; therefore, administration through a duodenal or jejunal tube is illogical. Likewise, for medications that require acid for best absorption, administration directly into the duodenum or jejunum would be expected to result in suboptimal absorption. Absorption of drugs when administered directly into the small bowel, especially the jejunum, is a topic where more research would be useful.

Problem Medications

► Phenytoin

Certain medications present specific challenges when administered through feeding tubes. The medication studied most thoroughly is phenytoin. Most studies have shown significant decreases in phenytoin absorption when the medication was administered enterally to patients receiving EN. Several mechanisms have been proposed for this apparent interaction. Many institutions have adopted a policy of holding tube feedings for 1 or 2 hours before and after administration of phenytoin to decrease the interaction, although some EN patients subjected to this routine still will require relatively high dosages of phenytoin to achieve therapeutic serum concentrations. Holding the feeding around medication administration can make meeting nutritional requirements difficult with continuous feedings, especially if the phenytoin is administered several times daily. Diligent monitoring of phenytoin serum concentrations is necessary for the patient on EN receiving this medication. In some cases, use of IV phenytoin or another anticonvulsant medication may be prudent.

► Warfarin

EN formulas contain vitamin K, which can antagonize the pharmacologic activity of warfarin. Vitamin K content of EN formulas generally has been adjusted down over the past several decades, resulting in products today that contain amounts of vitamin K unlikely to affect anticoagulation by warfarin significantly. However, inadequate warfarin anticoagulation in EN patients receiving formulas containing minimal vitamin K has been reported. There is some thought that a component of certain tube feedings, perhaps protein, may bind warfarin and result in suboptimal activity. One small study indicated a better response in terms of the international normalized ratio (INR) when feedings were held for 1 hour before and after warfarin administration compared with administration of the drug without holding the feedings.⁴⁰ When tube feedings are started, changed, or discontinued, the INR should be monitored closely.

Patient Encounter, Part 3

FH is extubated on day 9 but remains in the ICU because of difficulty clearing respiratory secretions. She is finally transferred out of the ICU on hospital day 11.

How should the transition from EN to oral feedings be accomplished?

► Fluoroquinolones

Absorption of antimicrobial agents such as fluoroquinolones and tetracyclines that can be bound by divalent and trivalent cations potentially could be compromised by administration with EN formulas containing these cations. The fluoroquinolones (e.g., levofloxacin and ciprofloxacin) have been best studied in this regard, and results of studies are not consistent.^{41,42} Some institutions hold tube feedings for 30 to 60 minutes or more before and after enteral dosages of fluoroquinolones. Because ciprofloxacin absorption has

been shown to be decreased with jejunal administration, this drug probably should not be given by jejunal tube.⁴²

SUMMARY AND CONCLUSION

EN is an important method of feeding patients who cannot or should not eat enough to meet nutrient requirements for a prolonged time. When the GI tract can be used safely, EN is preferred over PN. Various types of enteral access devices are available. Whereas tubes inserted through the nose often are adequate for patients expected to receive EN for a short time, more permanent devices (endoscopically or surgically placed) are preferred for longer term patients. The choice of whether to feed into the stomach or postpylorically is patient specific. Although numerous EN formulas are available commercially, many products are very similar, making a limited formulary feasible. Data supporting many of the specialized types of EN formulas are limited. Although complications of EN tend to be less serious than those of PN, the adverse effects encountered can be significant, and diligent ongoing monitoring is necessary. Although medications can be administered through feeding tubes, various factors must be taken into account in each individual patient.

Patient Care and Monitoring

1. Assess the patient's condition to estimate the amount of time he or she is expected to be unable to eat adequately to meet nutritional requirements. If inadequate intake has occurred or is anticipated for 7 to 14 days, start SNS. The threshold for starting SNS is lower for previously malnourished patients than for previously well-nourished patients. Also, critically ill patients should generally be started on EN within 24 to 48 hours of ICU admission.
2. Assess whether the GI tract is functional. If not, then PN is the SNS therapy of choice. If the GI tract is functional and no contraindication to EN exists, then EN is the SNS therapy of choice.
3. Does the patient have any condition precluding gastric feeding? If so, then postpyloric feeding should be initiated.
4. Choose the appropriate type of enteral access device based on the expected duration of SNS.
5. Choose an appropriate feeding formula based on patient-specific factors. This necessitates assessing nutritional requirements. Standard polymeric formulas are appropriate for the majority of patients.
6. Choose the method of feeding administration (e.g., intermittent or continuous) based on the type of feeding access (i.e., gastric versus postpyloric) and other patient factors. For example, in a patient with a gastric access, starting with or later transitioning to intermittent feedings may be preferred if it is anticipated that the patient still receiving these feedings will be discharged to a long-term care facility or to home.
7. Develop a plan to include monitoring at appropriate intervals for metabolic, GI, technical, and infectious complications.
8. Start the tube feeding at full strength and at a low rate and increase the rate as tolerated to the goal that will meet the patient's nutritional requirements.
9. Develop a monitoring plan for adequacy of the nutritional regimen.
10. If the patient is to be discharged to home on EN, educate the patient or caregiver on
 - Enteral access device care
 - Feeding delivery
 - Troubleshooting
 - Complications to observe for (e.g., fluid overload, dehydration)

Abbreviations Introduced in This Chapter

ALI	Acute lung injury
AI	Adequate intake
AAA	Aromatic amino acid(s)
ACCEPT	Algorithms for Critical-Care Enteral and Parenteral Therapy
ARDS	Acute respiratory distress syndrome
ASPEN	American Society for Parenteral and Enteral Nutrition
BCAA	Branched-chain amino acid(s)
BUN	Blood urea nitrogen
CRP	C-Reactive protein
DHA	Docosahexanoic acid
EAA	Essential amino acid(s)
EFA	Essential fatty acid(s)
EN	Enteral nutrition
EPA	Eicosapentaenoic acid
ESPEN	European Society for Clinical Nutrition and Metabolism
FOS	Fructooligosaccharide
GALT	Gut-associated lymphoid tissue
GI	Gastrointestinal
GLA	γ -Linolenic acid
HE	Hepatic encephalopathy
IBD	Inflammatory bowel disease
ICU	Intensive care unit
INR	International normalized ratio
LCT	Long-chain triglyceride
MALT	Mucosa-associated lymphoid tissue
MCT	Medium-chain triglyceride
MUFA	Monounsaturated fatty acid
ND	Nasoduodenal
NEAA	Nonessential amino acid
NG	Nasogastric
NJ	Nasojejunal
NO	Nitric oxide
OG	Orogastric
PEG	Percutaneous endoscopic gastrostomy
PEJ	Percutaneous endoscopic jejunostomy
PN	Parenteral nutrition
PUFA	Polyunsaturated fatty acid
RDA	Recommended Dietary Allowance
SCFA	Short-chain fatty acid
SCCM	Society for Critical Care Medicine
SNS	Specialized nutrition support

LEARNING OBJECTIVES

● Upon completion of the chapter, the reader will be able to:

1. Explain the underlying causes of overweight and obesity.
2. Identify parameters used to diagnose obesity and other objective information that indicates the severity of disease.
3. Identify desired therapeutic goals for patients who are overweight or obese.
4. Recommend appropriate nonpharmacologic and pharmacologic therapeutic interventions for overweight or obese patients.
5. Implement a monitoring plan that will assess both the efficacy and safety of therapy initiated.
6. Educate patients about the disease state and associated risks, appropriate lifestyle modifications, drug therapy, and surgical options necessary for effective treatment.

KEY CONCEPTS

- 1 Body mass index (BMI), waist circumference, comorbidities, and readiness to lose weight are used in the assessment of overweight or obese patients.
- 2 The presence of comorbidities (coronary heart disease [CHD], atherosclerosis, type 2 diabetes mellitus, and sleep apnea) and cardiovascular risk factors (cigarette smoking, hypertension, elevated low-density lipoprotein cholesterol, low high-density lipoprotein cholesterol, impaired fasting glucose, family history of premature CHD, and age) requires identification and aggressive management for overall effective treatment of the overweight or obese patient.
- 3 The treatment goals for overweight and obesity are to prevent additional weight gain, reduce and maintain a lower body weight, and control related risks.
- 4 Weight loss is indicated for patients with a BMI of 25 to 29.9 kg/m² or a high-risk waist circumference with two or more comorbidities or for any patient with a BMI of 30 kg/m² or greater.
- 5 Weight maintenance occurs after successful achievement of weight loss.
- 6 Treatment of obesity includes lifestyle changes (e.g., dietary modification, enhanced physical activity, and behavioral therapy), pharmacologic treatment, surgical intervention, or a combination of modalities.

- 7 Pharmacotherapy, in addition to lifestyle modifications, is reserved for patients with a BMI of 30 kg/m² or greater or a BMI of 27 kg/m² or greater with other obesity-related risk factors.
- 8 Weight likely will be regained if lifestyle changes are not continued indefinitely.
- 9 Surgery is warranted when other treatment attempts have failed in severely obese patients (BMI of 40 kg/m² or greater, or 35 kg/m² or greater with other obesity-related risk factors).

Overweight and obesity are terms used to describe weight measurements greater than what is considered healthy for a given height.¹ 1 **Body mass index (BMI), waist circumference, comorbidities, and readiness to lose weight are used in the assessment of overweight or obese patients.** The primary modality in defining overweight and obesity is the BMI, a measure of body fat based on height and weight that applies to both adult men and women. BMI does not reflect distribution of body fat; therefore, the measurement of **waist circumference** is a more practical method to evaluate abdominal fat before and during weight loss treatment. Abdominal fat poses a greater health risk over peripheral fat and may be an independent risk predictor when BMI is not elevated significantly.^{2,3} Both BMI and waist circumference should be used in the diagnosis and management of weight loss. Evaluation of the patient's risk status

involves not only calculation of the BMI and measurement of waist circumference but also determination of comorbidities or the presence of cardiovascular disease (CVD) risk factors.

2 *The presence of comorbidities (coronary heart disease [CHD], atherosclerosis, type 2 diabetes mellitus, and sleep apnea) and cardiovascular risk factors (cigarette smoking, hypertension, elevated low-density lipoprotein cholesterol, low high-density lipoprotein cholesterol, impaired fasting glucose, family history of premature CHD, and age) requires identification and aggressive management for overall effective treatment of the overweight or obese patient.* Obese patients may be at very high risk for mortality if concomitant risk factors exist; therefore, high-risk patients require aggressive modification of risk factors in addition to obesity treatment.⁴

ETIOLOGY AND EPIDEMIOLOGY

Obesity is a multifactorial, complex disease that occurs because of an interaction between genotype and the environment. Although the etiology is not known completely, it involves overlapping silos of social, behavioral, and cultural influence; pathophysiology; metabolism; and genetic composition.⁵ The majority of overweight or obese individuals are adults, but these diseases are also prevalent in children between 2 and 19 years of age. Approximately 34% of adults 20 years of age and older are considered obese. Almost 6% meet the criteria for extreme obesity. The prevalence of obesity in men and women of various racial and ethnic origins differ. Thirty-three percent of non-Hispanic white adults are considered obese, where approximately 39% of Mexican Americans and 44% of non-Hispanic black Americans are obese.⁶

Among children and adolescents, 17% are obese where 32% are considered overweight.⁷ Overweight children typically mature to overweight adults, but most obese adults were not overweight as children.⁸ Overweight and obesity, when present in young adults, may be a better predictor of prevalence.⁸ Additionally, adulthood overweight and obesity contribute to an increased risk of death in the presence of hypertension, hyperlipidemia, diabetes mellitus, coronary artery disease (CAD), stroke, sleep apnea, gallbladder disease, osteoarthritis, and certain cancers.⁴ Psychosocial functioning also may be hindered because obese patients may be at risk for discrimination if negatively stereotyped.⁴ Pediatric obesity is also associated with significant health-related problems and thus is a risk factor for much of the adult morbidity and mortality discussed previously.^{9,10} Cardiovascular (e.g., dyslipidemia and hypertension), endocrine (e.g., hyperinsulinemia, impaired glucose tolerance, type 2 diabetes mellitus, and menstrual irregularities), and mental (e.g., low self-esteem and depression) health problems exist for obese children and adolescents.¹¹

PATHOPHYSIOLOGY

Although a correlation between body weight in parents and children exists, the specific gene or genes contributing to obesity are unknown.¹² Syndromes in which obesity is a major

component collectively contribute very little to the incidence of obesity.¹³ The key factor in the development of overweight and obesity is the imbalance that occurs between energy intake and energy expenditure. The extent of obesity is determined by the length of time this imbalance has been present. Energy intake is affected by environmental influences, including social, behavioral, and cultural factors, whereas genetic composition and metabolism affect energy expenditure.¹⁴

Energy Intake

Food intake is regulated by various receptor systems.

Direct stimulation of serotonin 1A subtype (5-HT_{1A}) and noradrenergic α_2 -receptors increases food intake, serotonin 2C subtype (5-HT_{2C}) and noradrenergic α_1 - or β_2 -receptor activation decreases food intake. Stimulation of histamine receptor subtypes 1 and 3 and dopamine receptors 1 and 2 results in lower food consumption. Recently, the cannabinoid receptor (CB1), which is a G protein-coupled receptor in the endocannabinoid system, has been identified and associated with food intake and regulation of energy homeostasis.^{15,16} Inhibition of CB1 is shown to decrease the craving for food, resulting in weight loss when coupled with dietary and lifestyle modifications.¹⁷ In addition to receptor-modulated food consumption, higher levels of the protein leptin are associated with decreased food intake.¹⁸ In contrast, elevated levels of neuropeptide Y increase food intake.¹⁸

It is debatable whether obesity is related to total calorie intake or composition of macronutrients. Of the three macronutrients (i.e., carbohydrate, protein, and fat), fat has received the most attention, given its desirable texture and its ability to augment the flavor of other foods. Food high in fat promotes weight gain, in comparison with the other macronutrients, because fat is more energy dense. When compared with carbohydrate and protein, more than twice as many calories per gram are contained in fat. In addition, fat is stored more easily by the body compared with protein and carbohydrate.¹⁹

Energy Expenditure

A person's metabolic rate is the primary determinant of energy expenditure. The metabolic rate is enhanced after food consumption and is directly related to the amount and type.¹³ Physical inactivity may predispose an individual to overweight and obesity. In addition, endocrine-related disorders (e.g., hypothyroidism and Cushing's syndrome) may lower the metabolic rate, further contributing to the development of overweight and obesity.

CLINICAL PRESENTATION AND DIAGNOSIS

Any interaction between a patient and a healthcare provider presents an opportunity to evaluate the patient's height and weight. From these parameters, the BMI should be determined as well as waist circumference and the presence of comorbidities or associated risks. 1 *BMI, waist circumference, comorbidities, and readiness to lose weight are used in the*

Table 102-1

BMI Classification

Adult

Underweight	Less than 18.5 kg/m ²
Normal weight	18.5–24.9 kg/m ²
Overweight	25–29.9 kg/m ²
Obesity (class 1)	30–34.9 kg/m ²
Obesity (class 2)	35–39.9 kg/m ²
Extreme obesity (class 3)	Greater than or equal to 40 kg/m ²

Children (Does Not Pertain to Those Less Than 2 Years of Age^a)

Underweight	Less than 5th percentile
Healthy weight	5th–84th percentiles
Overweight	85th–94th percentiles
Obesity	Greater than or equal to the 95th percentile

^aWeight for height values should be plotted and monitored over time for children younger than 2 years of age.

From Refs. 4 and 19.

assessment of overweight or obese patients. The BMI is calculated using the measured weight in kilograms divided by the height in meters squared (kg/m²) for all adult patients regardless of gender. The BMI distribution changes with age for children just as height and weight. Percentiles specific for age and gender are used to classify pediatric patients as overweight and obese as well as healthy and underweight. The BMI is classified according to [Table 102-1](#). Waist circumference should also be determined for adult patients by placing a measuring tape at the top of the right iliac crest and proceeding around the abdomen, ensuring that the tape is tight but not constricting the skin. The value is measured after normal expiration.⁴ [Table 102-2](#) defines high-risk waist circumference.⁴ Measurement of waist circumference is not recommended for children and adolescents because reference values identifying risk are unavailable.²⁰ After obtaining patient appropriate parameters, further assess the adult patient for the presence of comorbidities and cardiovascular risk factors. ② *The presence of comorbidities (CHD, atherosclerosis, type 2 diabetes mellitus, and sleep apnea) and cardiovascular risk factors (cigarette smoking, hypertension, elevated low-density lipoprotein cholesterol, low high-density lipoprotein cholesterol, impaired fasting glucose, family history*

Table 102-2

High-Risk Waist Circumference

Adult

Men	Greater than 40 in (102 cm)
Women	Greater than 35 in (89 cm)

Table 102-3

Risk Factors

- Cigarette smoking
- Hypertension (systolic blood pressure greater than or equal to 140 mm Hg or diastolic blood pressure greater than or equal to 90 mm Hg) or current use of blood pressure-lowering medication(s)
- LDL cholesterol greater than or equal to 160 mg/dL (4.14 mmol/L)
- LDL cholesterol greater than or equal to 130–159 mg/dL (3.36–4.11 mmol/L) plus two additional risk factors
- HDL cholesterol less than 40 mg/dL (1.03 mmol/L)
- Impaired fasting glucose (fasting blood glucose, 100–125 mg/dL [5.6–6.9 mmol/L])
- Family history of premature CHD (first-degree male relative less than 55 years of age or first-degree female relative less than 65 years of age)
- Men 45 years or older
- Women 55 years or older

CHD, coronary heart disease; HDL, high-density lipoprotein; LDL, low-density lipoprotein

From U.S. Department of Health and Human Services, NIH-NHLBI. Clinical guidelines on the identification, evaluation and treatment of overweight and obesity in adults. NIH publication no. 00-4084. Bethesda, MD: National Institutes of Health, 2000.

of premature CHD, and age) requires identification and aggressive management for overall effective treatment of the overweight or obese patient. A patient is at very high absolute risk if diagnosed with CHD or other atherosclerotic diseases, type 2 diabetes mellitus, or sleep apnea or if three or more of the risk factors listed in [Table 102-3](#) are present.⁴ Aggressive disease management should be initiated and not limited to weight loss. If the patient is a child or adolescent and the BMI is greater than the 85th percentile, determine the patient's risk for future obesity-related problems or presence of obesity-related medical problems such as sleep, respiratory, gastrointestinal (GI), endocrine, cardiovascular, and psychiatric disorders.^{20,21}

TREATMENT

Desired Outcome

General management of obesity in adult patients is directed at weight reduction, maintenance of weight loss, and prevention of weight regain. ③ *The treatment goals for overweight and obesity are to prevent additional weight gain, reduce and maintain a lower body weight, and control related risks.* A 10% weight loss as derived from the patient's current weight is the initial goal of obesity management because favorable outcomes on the negative effects of obesity have been documented.^{4,22} Weight loss should occur at a rate of 0.45 to 0.9 kg (1–2 lb) per week, meeting the initial goal within the first 6 months of therapy. Overweight patients should lose weight at a rate of 0.23 kg (0.5 lb) per week. ④ *Weight loss is indicated for patients with a BMI of 25 to 29.9 kg/m² or an elevated waist circumference with two or more comorbidities or for any patient with a BMI of 30 kg/m² or greater.* Weight then

Patient Encounter 1, Part 1

A 45-year-old woman presents to your clinic wanting to lose weight. She reports not currently following any specific diet but has enrolled at Slim-4-Life in the past, which resulted in significant weight loss. However, the products used in the program are expensive, and thus she prefers to lose weight the “old fashion way.” She admits to eating foods high in sugar content such as sweetened beverages and candy bars, as well as foods that contain large amounts of starch (potatoes, bread, and chips). This patient is not currently exercising but has adhered to a daily walking regimen in the past. The patient does not smoke but consumes alcohol, 1 to 2 glasses of wine on the weekend. Her BMI is 30.8 kg/m², and her waist circumference is 42 in (107 cm).

What classification of overweight and obesity is appropriate for this patient?

Does this patient have a high-risk waist circumference?

Does she have other risk factors that may contribute to morbidity or mortality?

What are the treatment goals for the patient?

What additional information do you need to know before creating a treatment plan for this patient?

should be maintained (minimal regain of less than 3 kg [6.6 lb] and reduction in waist circumference of 1.6 in [4 cm]) sustained. If weight loss has been achieved and/or maintained for 6 months, therapy promoting further weight loss may be considered. When maximal weight loss has been attained, any therapy used to promote the weight loss must be continued in order to prevent weight regain.⁴ **5** *Weight maintenance occurs after successful achievement of weight loss.*

It is desirable to achieve a goal of improved long-term physical health for a child or adolescent. A BMI below the 85th percentile is warranted but is difficult to assess in frequent or short time periods. Thus, serial weight measurements may better quantify energy balance. Goals are most likely accomplished through adaptation of lifelong healthy lifestyle habits. In doing so, weight loss or maintenance can be attained for some children. Others may need to incorporate changes that result in a negative energy balance or energy input less than energy output.^{20,21}

General Approach to Treatment

Because the goals for obesity management in the adult population are multifactorial, it should be considered a chronic illness in which treatment is maintained for life.

- Any implemented therapy promoting weight loss should focus on behavior modification directed toward both dietary restriction and increased activity in conjunction with the selective use of pharmacologic or surgical intervention. Before initiating therapy, secondary causes of obesity

(e.g., hypothyroidism and Cushing’s syndrome) must be considered. Current treatment with medications that negatively alter weight should be determined and if present, alternative therapies should be suggested.^{23–25} **Table 102–4** provides a list of drugs commonly associated with weight gain. If no secondary cause exists, the presence of other cardiovascular risk factors and comorbidities must be determined to guide clinical decisions. **2** *The presence of comorbidities (CHD, atherosclerosis, type 2 diabetes mellitus, and sleep apnea) and cardiovascular risk factors (cigarette smoking, hypertension, elevated low-density lipoprotein cholesterol, low high-density lipoprotein cholesterol, impaired fasting glucose, family history of premature CHD, and age) requires identification and aggressive management for overall effective treatment of the overweight or obese patient.* Therapy implemented to minimize associated risk(s) may not enhance weight loss, but weight loss will positively address risk factors. Weight loss should not be initiated in pregnant or lactating patients, decompensated psychiatric patients, or patients in whom reduced caloric intake can exacerbate an acute, serious illness.⁴ **6** *Treatment of obesity includes lifestyle changes (dietary modification, enhanced physical activity, and behavioral therapy), pharmacologic treatment, surgical intervention, or a combination of modalities.*

Four stages have been suggested for the treatment of obesity in children and adolescents. Stage 1 or Prevention Plus is the first step for overweight or obese patients and includes adherence to healthy eating and activity habits. Patients should be encouraged to eat more than or equal to five servings of fruits and vegetables daily, limit consumption of sweetened drinks, decrease television or other screen time behaviors, and increase physical activity to greater than or

Table 102–4**Drugs Contributing to Weight Gain**

Anticonvulsants and mood stabilizers
Carbamazepine
Gabapentin
Valproic acid
Lithium
Antidepressants
Monoamine oxidase inhibitors (phenelzine)
Presynaptic α -2 antagonist (mirtazapine)
Selective serotonin reuptake inhibitors
Tricyclics (amitriptyline, imipramine, nortriptyline)
Antidiabetics
Insulin
Meglitinides
Sulfonylureas (glyburide, glipizide)
Thiazolidinediones
Antipsychotics
Atypical (clozapine, olanzapine, risperidone, paliperidone, quetiapine)
Others
Antihistamines
Corticosteroids
Hormonal Contraceptives (depot injections)

From Refs. 23 to 25.

- equal to 1 h/day. Stage 2 or Structured Weight Management incorporates Prevention Plus habits while setting specific eating and activity goals. Responsibilities include meal planning, observed physical activity or play daily for 1 hour, and documentation of energy consumption and expenditure.
- Comprehensive Multidisciplinary Interventions (stage 3) is directed at increasing the intensity of healthy behaviors. To accomplish goals, the child or adolescent should work closely with the primary care provider, registered dietician, exercise specialist, and behavioral counselor. Stage 4, Tertiary Care Intervention, may be needed for severely obese adolescents. A very low-calorie diet (LCD), medication or weight control surgery may be warranted.^{26,27}

Nonpharmacologic Therapy

► Dietary

- An LCD is essential for weight-loss management in overweight and obese patients. The Step-1 Diet (Table 102-5) is an LCD recommended as part of an obesity education initiative from the National Heart, Lung, and Blood Institute.⁴ In general, the Step-1 Diet restricts daily calories to a range of 1,000 to 1,200

kcal (4,186–5,023 kJ/day) for women weighing less than 75 kg (165 lb) and 1,400 to 1,600 kcal (5,860–6,697 kJ/day) for all others. However, this daily limit should be considered after assessing a patient's normal daily caloric intake and ensuring that the initial caloric restriction does not exceed 500 to 1,000 kcal (2,093–4,186 kJ/day). For example, a male patient who consumes 3,000 kcal (12,557 kJ/day) should not reduce his daily caloric intake to less than 2,000 kcal (8,372 kJ/day) when initially implementing a dietary program. Further reduction to the target of 1,600 kcal (6,697 kJ/day) can be attempted when the patient has reduced calories successfully as initially recommended for a period agreeable by the provider and the patient.⁴ Diets that are too restrictive in calorie reduction are successful initially but fail in the long term because compliance is difficult to sustain.²⁶ Therefore, this less aggressive approach promotes gradual weight loss and weight maintenance.

Dietary consumption should be balanced in carbohydrates, protein, and fat. Several diet plans exist that promote weight loss through strict limitation or overabundance of only one macronutrient (e.g., low-fat, low-carbohydrate, or high-protein diets); however, overall energy consumption and expenditure will determine the amount of weight alteration. Consultation

Table 102-5

Low-Calorie Step I Diet

Nutrient	Recommended Intake
Calories ^a	~500–1,000 kcal/day (2,093–4,186 kJ/day) reduction from usual intake
Total fat ^b	30% or less of total calories
Saturated fatty acids ^c	8–10% of total calories
Monounsaturated fatty acids	Up to 15% of total calories
Polyunsaturated fatty acids	Up to 10% of total calories
Cholesterol ^c	Less than 300 mg/day
Protein ^d	~15% of total calories
Carbohydrate ^e	55% or more of total calories
Sodium chloride	No more than 100 mmol/day (~2.4 g of sodium or ~6 g of sodium chloride)
Calcium ^f	1,000–1,500 mg/day
Fiber ^e	20–30 g/day

^aA reduction in calories of 500–1,000 kcal/day (2,093–4,186 kJ/day) will help achieve a weight loss of 1–2 lb/wk (~0.5–0.9 kg/wk). Alcohol provides unneeded calories and displaces more nutritious foods. Alcohol consumption not only increases the number of calories in a diet but also has been associated with obesity in epidemiologic studies as well as in experimental studies. The impact of alcohol calories on a person's overall caloric intake needs to be assessed and appropriately controlled.

^bFat-modified foods may provide a helpful strategy for lowering total fat intake but will only be effective if they are also low in calories and if there is no compensation by calories from other foods.

^cPatients with high blood cholesterol levels may need to use the Step II diet to achieve further reductions in LDL cholesterol levels; in the Step II diet, saturated fats are reduced to less than 7% of total calories, and cholesterol levels to less than 200 mg/day. All of the other nutrients are the same as in Step I.

^dProteins should be derived from plant sources and lean sources of animal protein.

^eComplex carbohydrates from different vegetables, fruits, and whole grains are good sources of vitamins, minerals, and fiber. A diet rich in soluble fiber, including oat bran, legumes, barley, and most fruits and vegetables, may be effective in reducing blood cholesterol levels.⁵ A diet high in all types of fiber may also aid in weight management by promoting satiety at lower levels of calorie and fat intake. Some authorities recommend 20–30 g of fiber daily with an upper limit of 35 g.

^fDuring weight loss, attention should be given to maintaining an adequate intake of vitamins and minerals. Maintenance of the recommended calcium intake of 1,000–1,500 mg/day is especially important for women who may be at risk for osteoporosis.

From U.S. Department of Health and Human Services, NIH-NHLBI. Clinical guidelines on the identification, evaluation and treatment of overweight and obesity in adults. NIH publication no. 00-4084. Bethesda, MD: National Institutes of Health, 2000.

with a dietician is recommended when implementing a healthy meal plan tailored to the individual's nutritional needs.

► Exercise

- Although diet and exercise contribute to weight loss, combining an LCD with physical activity results in greater weight loss compared with either therapy alone.²² In addition, physical activity can help to prevent weight regain and reduce related cardiovascular risks.⁴ Slow titration of both the amount and intensity of physical activity is recommended for most overweight and obese patients.⁴ A program that incorporates daily walking is a viable option for most patients (Table 102–6). Consider 10 min/day 3 days/week with a target of 30 to 45 minutes most days, if not every day.⁴ This type and amount of activity equate to a 100 to 200 kcal (419–837 kJ/day) caloric expenditure.⁴

► Behavioral

Nonadherence with recommended lifestyle changes may result in unsuccessful weight loss for adults.^{4,22} Therefore, eliminating these barriers through behavior modification is necessary to gain maximal benefit from both dietary modification and exercise. Components of successful behavioral modification include, but are not limited to, the following steps:⁴

- Determine the patient's readiness to lose weight and willingness to implement a weight-loss plan.
- Build and nurture the patient–provider partnership.
- Restructure cognitive abilities.
- Set achievable goals.
- Contact the patient frequently.
- Instruct the patient on the importance and technique of self-monitoring.

- Control stimuli that negatively affect weight loss or weight maintenance.
- Reward the patient for any amount of weight loss or avoidance of weight regain.

Targeted behaviors should be recommended to pediatric patients and their families because healthy habits help prevent excessive weight gain. These include, but are not limited to:^{20,21}

- Limit the consumption of sugar-sweetened beverages.
- Meet daily fruit and vegetable requirements set forth by the U.S. Department of Agriculture.
- Limit the amount of time watching television to 2 hours or less. Other screen time activities, such as computer play, should also be limited.
- Consume a healthy breakfast daily.
- Limit the number of times the family eats at restaurants, especially those that serve fast food.
- Parents should eat dinner with their children and limit portion size when preparing and serving meals.

Pharmacologic Therapy

- Pharmacotherapy is not recommended for individuals with BMIs of less than 27 kg/m². If lifestyle changes do not result in a 10% weight loss after 6 months, drug therapy in addition to a healthy lifestyle is warranted for overweight individuals with other related risks and for obese patients. **7** *Pharmacotherapy in addition to lifestyle modification is reserved for patients with a BMI of 30 kg/m² or greater, or a BMI of 27 kg/m² or greater with other obesity-related risk factors.* Pharmacologic products promoting weight loss are classified according to their mechanisms of action,

Table 102–6

Examples of Moderate Physical Activity

Common Chores^{a,b}

Washing and waxing a car for 45–60 minutes
 Washing windows or floors for 45–60 minutes
 Gardening for 30–45 minutes
 Wheeling self in wheelchair for 30–40 minutes
 Pushing a stroller 1½ miles (2.4 km) in 30 minutes
 Raking leaves for 30 minutes
 Walking 2 miles in 30 minutes (15 min/mile [9.3 min/km])
 Shoveling snow for 15 minutes
 Stair walking for 15 minutes

Sporting Activities^{a,b}

Playing volleyball for 45–60 minutes
 Playing touch football for 45 minutes
 Walking 1¾ miles in 35 minutes (20 min/mile [~12 min/km])
 Basketball (shooting baskets) for 30 minutes
 Bicycling 5 miles (8 km) in 30 minutes
 Dancing fast (social) for 30 minutes
 Water aerobics for 30 minutes
 Swimming laps for 20 minutes
 Basketball (playing a game) for 15–20 minutes
 Jumping rope for 15 minutes
 Running 1½ miles (2.4 km) in 15 minutes (15 min/mile)

^aA moderate amount of physical activity is roughly equivalent to physical activity that uses approximately 150 calories of energy/day (628 J/day) or 1,000 calories/week (4186 J/week).

^bSome activities can be performed at various intensities; the suggested durations correspond to expected intensity of effort.

From U.S. Department of Health and Human Services, NIH-NHLBI. Clinical guidelines on the identification, evaluation and treatment of overweight and obesity in adults. NIH publication no. 00-4084. Bethesda, MD: National Institutes of Health, 2000.

Table 102-7

Summary of Approved Pharmacologic Weight Loss Agents

Drug	Class	Daily Dose (mg)	Duration of Therapy
Orlistat	Lipase inhibitor	360	More than 3 months ^a
Phentermine	Noradrenergic agent	15–37.5	Up to 6 months
Diethylpropion	Noradrenergic agent	75	Up to 12 months

^aEfficacy and safety have not been determined beyond 4 years of use.

From U.S. Department of Health and Human Services, NIH-NHLBI. Clinical guidelines on the identification, evaluation and treatment of overweight and obesity in adults. NIH publication no. 00-4084. Bethesda, MD: National Institutes of Health, 2000.

including the suppression of appetite and the suppression of fat absorption (Table 102-7). Pharmacotherapy was indicated previously for short-term use; however, because obesity-related risks resurface with weight regain, long-term treatment is recommended to minimize these sequelae.

8 *Weight likely will be regained if lifestyle changes are not continued indefinitely.* Prolonged use of both fenfluramine and dexfenfluramine monotherapy and fenfluramine and phentermine in combination resulted in cardiac valvular disease.²⁷ Long-term treatment with sibutramine resulted in an increased risk for nonfatal heart attacks and nonfatal strokes in patients with preexisting cardiovascular disease.²⁸ Therefore, orlistat is the only drug currently approved for long-term use in promoting weight loss and preventing weight regain.

► Orlistat

Orlistat promotes and maintains weight loss by acting locally in the GI tract. Orlistat is a chemically synthesized derivative of lipstatin, a natural product of *Streptomyces toxytricini* that inhibits pancreatic and gastric lipases, as well as triglyceride hydrolysis. As a result, undigested triglycerides are not absorbed, causing a caloric deficit and weight loss.²⁹

Several studies have reported significant weight loss for patients receiving orlistat 120 mg three times a day compared with placebo.^{30,31} Weight maintenance or prevention of weight regain also has been documented with continued orlistat use.^{30,32} After 1 year of treatment, 57% of orlistat-treated patients lost at least 5% of their baseline weight.²⁹ The long-term weight-loss effect on one obesity-related comorbidity was assessed in a large placebo-controlled study. In 3,000 obese patients, 21% had impaired glucose tolerance at enrollment. After 4 years, weight loss was greater and the incidence of new diabetes was lower in patients receiving orlistat.³³

One study evaluated the longer term effect of orlistat in adolescents. In a group of 12- to 16-year-old individuals, orlistat (120 mg three times daily) in combination with diet, exercise, and behavior modification resulted in a significant reduction in BMI and waist circumference compared with placebo. In addition, orlistat-treated subjects exhibited

minimal weight increase after 1 year (0.53 kg) compared with placebo-treated patients (3.14 kg). Common adverse reactions observed were fatty or oily stools, oily spotting, oily evacuation, or abdominal pain and/or flatulence with bowel movements. Soft stools, nausea, increased defecation, and fecal incontinence also were noted.³⁴

The safety and efficacy of orlistat have not been determined beyond 4 years of use. Minimal systemic effects exist because orlistat acts locally in the GI tract. Thus, common side effects reported include oily spotting, flatus with discharge, fecal urgency, fatty or oily stools, oily evacuation, increased defecation, and fecal incontinence.²⁹ Other adverse events include bloating, abdominal pain, dyspepsia, nausea, vomiting, diarrhea, and headache.³⁵ Thirty-two reports of severe liver injury have been reported to the Food and Drug Administration (FDA), including six cases of liver failure.³⁶ After a complete review by the FDA, 13 reports of severe liver injury were identified. Of the 13 cases, only 1 occurred within the United States. Although a cause-and-effect relationship has not been established, the FDA has added serious liver injury information to orlistat's product label that includes signs, symptoms, and when to seek medical attention for severe liver disease. Signs and symptoms include itching, yellowing of the eyes or skin, dark urine, decreased appetite and light-colored stools. Orlistat should be stopped if the patient complains of these signs and symptoms. In addition, liver function tests, including aspartate transaminase (AST) and alanine aminotransferase (ALT), should be assessed.³⁷

Orlistat reduces the absorption of some fat-soluble vitamins and β -carotene. Daily intake of a multivitamin containing fat-soluble vitamins, as well as β -carotene, is recommended. Patients should take the multivitamin 2 hours before or after the dose of orlistat.²⁹ Because the availability of vitamin K may decline in patients receiving orlistat therapy, close monitoring of coagulation status should occur with concomitant administration of warfarin.²⁹ Hypothyroidism has been observed in patients taking both orlistat and levothyroxine. Patients taking both medications should separate the drug doses by 4 hours (administer levothyroxine 4 hours before or after the orlistat dose). These patients should also be monitored for changes in thyroid function. Administration of orlistat in conjunction with cyclosporine

can result in decreased cyclosporine plasma levels. To avoid this interaction, cyclosporine should be taken 2 hours before or after the dose of orlistat. Additionally, cyclosporine levels should be monitored more frequently.²⁹

Pregnant or lactating women should not take orlistat because no data exist to establish safety. Orlistat is contraindicated in patients with chronic malabsorption syndrome or cholestasis.²⁹

Initiate orlistat 120 mg three times a day with a well-balanced but reduced-caloric meal containing no more than 30% of calories from fat. Orlistat may be taken during or up to 1 hour after the meal. If a meal is missed or contains little fat, the dose of orlistat may be omitted. Doses above 360 mg/day provide no greater benefit and thus are not recommended.²⁹

► **Sibutramine**

Sibutramine and its two active metabolites (M_1 and M_2) induce weight loss by inhibiting the reuptake of serotonin, norepinephrine, and dopamine.³⁸ Appetite becomes suppressed because patients feel a sense of satiety.

The Sibutramine Cardiovascular Outcomes (SCOUT) trial was designed to evaluate the long-term, cardiovascular event rate, including death, in patients with preexisting cardiovascular disease, type 2 diabetes mellitus or both. An increased risk for nonfatal myocardial infarction (MI) and nonfatal stroke was observed for sibutramine-treated patients.²⁸ Results from the study prompted the FDA to ask Abbott Laboratories to withdraw sibutramine from the U.S. market.³⁹

► **Phentermine**

Phentermine decreases food intake, and hence weight, by increasing norepinephrine and dopamine release in the central nervous system (CNS). This drug is indicated for short-term use—no more than a few weeks—in addition to lifestyle modifications in obese patients with a BMI of 30 kg/m² or greater, or a BMI of 27 kg/m² or greater in the presence of other risk factors.⁴⁰

A recent meta-analysis evaluated patients at doses of 15 and 30 mg/day. Patients were analyzed for periods of 2 to 24 weeks. The majority of patients enrolled were female, and more than 80% of the patients evaluated received adjunctive modification in lifestyle. An average weight loss of 3.6 kg (7.9 lb) was demonstrated for patients treated with phentermine compared with placebo. Although modest in amount, this value was statistically significant.³⁵

Safety and efficacy have not been determined in pediatric patients less than 16 years of age.⁴⁰

Common adverse reactions seen with phentermine use include heart palpitations, tachycardia, elevated blood pressure, stimulation, restlessness, dizziness, insomnia, **euphoria**, **dysphoria**, tremor, headache, dry mouth, constipation, and diarrhea. Phentermine should be avoided in patients with unstable cardiac status, hypertension, hyperthyroidism, agitated states, or glaucoma. In combination with fenfluramine or dexfenfluramine, primary pulmonary

hypertension and valvular heart disease have been reported. The risk of developing either serious adverse effect cannot be ruled out with use of phentermine alone. Because phentermine is related to the amphetamines, the potential for abuse is high; thus, this should be kept in mind when selecting this agent as an aid for weight loss.⁴⁰

Phentermine use should be avoided in patients concomitantly receiving or having received a monoamine oxidase inhibitor (MAOI) within the preceding 14 days. Combination therapy with any stimulant or MAOI has the potential for causing hypertensive crisis. Alcohol is not recommended for patients prescribed phentermine.⁴⁰

Because no studies have been conducted in pregnant women, phentermine should be administered only when clearly indicated. Owing to the potential for severe adverse effects in nursing infants, a decision to stop the drug or discontinue nursing must be made.⁴⁰

Phentermine is available as an immediate- and a sustained-release product. In conjunction with a healthy lifestyle, 30 to 37.5 mg of phentermine is administered once daily, typically before breakfast or 1 to 2 hours after the morning meal. The dosage should be individualized; some patients may be managed adequately at 15 to 18.75 mg/day, but a dose of 18.75 mg twice daily may be used to minimize side effects, excluding insomnia. To lessen the risk of insomnia, dosing phentermine in the evening should be avoided. Timed-release preparations of phentermine are not recommended because phentermine's half-life is approximately 20 hours.⁴¹

► **Diethylpropion**

This sympathomimetic amine exudes similar pharmacologic activity as the amphetamines, resulting in CNS stimulation and appetite suppression. This drug is indicated for short-term use in conjunction with a reduced-calorie diet and exercise in obese patients with BMIs of 30 kg/m² or greater after failed attempts of diet and exercise alone.⁴²

One meta-analysis reviewed patients receiving doses of 75 mg/day during periods of 6 to 52 weeks. Similar to study characteristics for phentermine, the majority of patients enrolled were female, and all patients implemented adjunctive lifestyle modifications. The average additional weight loss observed was 3 kg (6.6 lb) compared with diet and exercise alone, resulting in a borderline statistically significant difference.³⁵

The safety and effectiveness of diethylpropion have not been established in patients under the age of 16; therefore, its use is not recommended.⁴²

Use of diethylpropion for a period longer than 3 months is associated with an increased risk for development of pulmonary hypertension. When used as directed, reported common CNS adverse effects included overstimulation, restlessness, dizziness, insomnia, **euphoria**, **dysphoria**, tremor, headache, jitteriness, anxiety, nervousness, depression, drowsiness, malaise, **mydriasis**, and blurred vision. In addition, diethylpropion can decrease the seizure threshold, subsequently increasing a patient's risk for an epileptic event. Other organ systems also can adversely be affected, resulting

in tachycardia, elevated blood pressure, palpitations, dry mouth, abdominal discomfort, constipation, diarrhea, nausea, vomiting, impotence or change in libido, gynecomastia, bone marrow suppression, agranulocytosis, and leukopenia. Diethylpropion is contraindicated in patients with pulmonary hypertension, advanced arteriosclerosis, severe hypertension, hyperthyroidism, agitated states, or glaucoma. Because diethylpropion is related to the amphetamines, the potential for abuse is high; therefore, its use is contraindicated in patients with a history of substance abuse.⁴²

As with phentermine, use of diethylpropion should be avoided in patients concomitantly receiving or having received an MAOI within the preceding 14 days to prevent hypertensive crisis. Combination with other anorectic agents should be avoided.⁴²

No adequate studies have been conducted using diethylpropion in pregnant women; therefore, the drug should be used only if the benefit outweighs potential fetal risk. Use with caution in nursing mothers because the drug is excreted in breast milk.⁴²

Diethylpropion is available as both an immediate- and a controlled-release product. In conjunction with a reduced-calorie diet and/or exercise, dose diethylpropion (immediate release) 25 mg three times a day before meals or 75 mg (controlled release) once a day, usually midmorning.⁴²

► Other Pharmacologic Therapy

Rimonabant diminishes food cravings by selectively inhibiting the cannabinoid (CB1) receptor.^{16,19} Taranabant is another drug with a mechanism of action similar to rimonabant. Unfortunately, the increased neuropsychiatric risk (suicide) demonstrated during clinical trials halted the anticipated use of the CB1 receptor antagonists.^{46,47}

Noradrenergic agents not approved by the FDA and subsequently not recommended for weight loss include amphetamine salts (e.g., ephedrine and phenylpropanolamine), methamphetamine, and benzphetamine. Although the selective serotonin reuptake inhibitors (e.g., fluoxetine and sertraline) appear to promote weight loss, further study is warranted given the inconsistent results available to date. Dietary supplements containing ephedra or ephedrine alkaloids are banned from sale following the FDA's final ruling.⁴⁸ However, ephedrine is available in nonprescription and prescription formulations for the treatment of bronchospasm, nasal congestion, hypotension or shock, and cardiac arrhythmias. Herbal products lack consistency in labeling, vary in effect, and present potentially dangerous health risks. Herbal products for weight loss are not recommended.

► Surgical Intervention

Weight reduction (bariatric) surgery is an option for patients whose BMIs are 40 kg/m² or greater, or 35 kg/m² or greater in the presence of other comorbid conditions and who have failed more conventional approaches to weight loss.^{4,49} **9** *Surgery is warranted when other treatment attempts have*

Patient Encounter 1, Part 2: Medical History, Physical Exam, and Diagnostic Tests

PMH: Occasional headaches, occasional heartburn

FH: Father alive and 68 years of age. Mother also alive with history of obesity and CVD (MI in 2008).

SH: (-) Tobacco, (+) alcohol, 1 to 2 drinks on the weekend

Med: Ibuprofen 400 mg PO as needed, ranitidine 75 mg PO as needed

ROS: (+) Heartburn, regurgitation; (-) chest pain, nausea, vomiting, diarrhea, change in appetite, shortness of breath, or cough

PE:

VS: BP 124/82 mm Hg, P 72 beats/min, RR 16 breaths/min, T 98.6° F (37° C)

Weight: 185 lb (84 kg); ht: 65 in (165 cm)

Waist circumference: 42 in (107 cm)

Cardiovascular: Normal S₁S₂; no murmurs, rubs, gallops

Abdominal: Obese, soft, nontender, nondistended; (+) bowel sounds

Extremities: (-) Edema

Labs: All values are within normal limits.

ECG: No evidence of past ischemia

Given this additional information, do you recommend weight loss? If so, how much weight should the patient lose and how fast?

What nonpharmacologic and pharmacologic alternatives are available for the patient?

*failed in severely obese patients (BMI of 40 kg/m² or greater, or 35 kg/m² or greater with obesity-related risk factors). There are two basic surgical techniques: (a) **gastric bypass**—the full partitioning of the proximal gastric segment into a jejunal loop of the intestine—whereby weight loss is induced through both malabsorption of food and limited gastric capacity, and (b) **gastroplasty**—incomplete partitioning at the proximal gastric segment with the placement of a gastric outlet stoma of set diameter—which promotes weight loss by limiting gastric capacity.^{4,49}*

A meta-analysis of surgical options for obesity reported that surgical treatment produces a weight loss of 20 to 30 kg (44–66 lb) that is maintained for 5 to 10 years. Additionally, favorable outcomes for comorbid conditions are observed after surgery. When evaluating the various types of surgery available, pooled data concluded that gastric bypass produces a 10-kg (22-lb) greater weight loss at 12 and 36 months than gastroplasty procedures. Complications are inherent to any surgical procedure. The more common bariatric surgery complications are respiratory problems, wound formation, wound infections, hernia development, deep venous thrombosis, and pulmonary

embolism. No differences were observed in mortality rates among various surgical procedures. Postoperative weight loss is much greater compared with pharmacologic therapies, but no comparative trials exist.⁵⁰

Gastric surgery, either banding or bypass, is an alternative offered to adolescents because it results in substantial weight loss and medical health improvement. Patients with a BMI greater than or equal to 40 kg/m² and an associated medical condition or BMI greater than or equal to 50 kg/m² at or after the age of 13 and 15 years for girls and boys, respectively; display emotional and cognitive maturity; and have implemented a behavioral-based weight-loss program are candidates for surgery.¹⁹

All patients undergoing bariatric surgery should be part of an integrated program of health education, diet, exercise, and behavioral modification before and after surgery.⁴ Patients must understand and commit to a substantial change in eating patterns to maintain long-term weight reduction.^{19,50}

SPECIAL POPULATION CONSIDERATION

Elderly Patients with Obesity

The majority of obese female patients are 40 to 59 years of age where more male patients aged 60 and older are considered obese.⁶ Therefore, it should not be surprising that more cardiovascular risk factors are present in this group of individuals. Additionally, obesity is a major predictor of functional limitation and mobility problems in older persons.

Age alone should not prejudice clinicians from treating geriatric patients; instead, the benefits of cardiovascular health and functionality should be considered. Treatments should be initiated that minimize adverse effects on bone health and nutritional status and should include dietary and activity modifications.⁴

OUTCOME EVALUATION

Successful management of overweight and obesity is determined by the ability the treatment plan has to (a) prevent weight gain, (b) reduce and maintain a lower body weight, and (c) decrease the risk of obesity-related comorbidities. Because weight is necessary to calculate the BMI, the patient's weight as well as the waist circumference should be determined. Obesity management may encompass more than weight loss or maintenance in the presence of other conditions; other pertinent parameters should be assessed at baseline. The presence of hypertension, type 2 diabetes mellitus, hyperlipidemia, CAD, sleep apnea, hypothyroidism, osteoarthritis, gallbladder disease, gout, or cancer should be determined. Blood pressure and heart rate should be measured before implementation of any therapy. Certain laboratory parameters also should be assessed. A basic metabolic panel, liver function tests, complete blood count, fasting lipid profile,

full thyroid function tests, and other laboratory studies as deemed necessary should be obtained. An electrocardiogram should be performed if recent results are unknown.⁴

The patient should be assessed in 2 to 4 weeks after the implementation of therapy to determine effectiveness of and intolerance to treatment. Monthly visits are encouraged during the first 3 months. More frequent follow-up may be necessary in the presence of other medical conditions. Less frequent follow-up occurs after 6 months of effective weight loss therapy.⁴

At each follow-up visit, compliance with a healthy lifestyle should be determined, as well as measurement of physical parameters, including weight, blood pressure, and heart rate. Waist circumference should be measured intermittently. A complete assessment also includes identification of adverse drug reactions or drug interactions if weight loss medications have been initiated.⁴

When the patient has achieved the recommended weight loss, he or she then enters the weight maintenance phase, which includes continued contact for education, guidance, and risk factor assessment. If weight loss is not attained, further assessment is required to determine why the goals of therapy have not been met. The interaction should be directed toward determining the motivation to lose weight, balance between caloric intake and physical activity, adherence to behavioral therapy, and determination of psychological stressors present.⁴

Patient Encounter 2, Part 1

A 54-year-old white man presents to your CVD Risk Reduction Clinic. The patient currently denies chest pain, shortness of breath, dizziness, and lightheadedness. Upon review of progress notes, you discover that the patient's blood pressure has been elevated during the past three office visits. As an electrician, he frequently eats fast food for lunch. Evenings are spent at a nearby country club, where he eats dinners that vary from steak and potatoes to fried chicken to occasional fish. He reports playing golf two days a week (Saturday and Sunday). The patient's BMI is 32.6 kg/m², and his waist circumference is 47 in (119 cm).

What classification of overweight and obesity is appropriate for this patient?

Does this patient have a high-risk waist circumference?

Does he have other risk factors that may contribute to morbidity or mortality?

What are the treatment goals for the patient?

What additional information do you need to know before creating a treatment plan for this patient?

Patient Encounter 2, Part 2: Medical History, Physical Exam, and Diagnostic Tests

PMH: Hypertension diagnosed 4 years ago

FH: Father alive and 78 years of age. Mother also alive and 77 years of age.

SH: Drinks alcohol most days (socially) but denies any alcohol-related problems

Meds: Hydrochlorothiazide 12.5mg PO every morning

ROS: (-) Heartburn, regurgitation; (-) chest pain, nausea, vomiting, diarrhea, change in appetite, shortness of breath, or cough

VS: BP 154/92 mm Hg, P 76 beats/min, RR 15 breaths/min, T 98.7° F (37.1° C)

Weight: 208 lb (94.5 kg)

Height: 67 in (170 cm)

Waist circumference: 47 in (119 cm)

PE:

General: Well developed, in no acute distress

HEENT: Conjunctiva clear

CV: Regular rhythm, no S₃ or S₄ noted

Lungs: Clear to auscultation (CTA) bilaterally

Abd: Obese, soft, nontender, nondistended; (+) bowel sounds

Neuro: Normal gait, normal speech

Ext: (-) Edema

Labs:

Na: 142 mEq/L (142 mmol/L); **K:** 4.6 mEq/L (4.6 mmol/L); **Cl:** 107 mEq/L (107 mmol/L); **CO₂:** 23 mEq/L (23 mmol/L); **BUN:** 18 mg/dL (6.4 mmol/L); **creatinine:** 0.9 mg/dL (80 μmol/L); **glucose:** 72 mg/dL (4.0 mmol/L)

TC: 213 mg/dL (5.51 mmol/L); **LDL:** 153 mg/dL (3.96 mmol/L);

HDL: 30 mg/dL (0.78 mmol/L); **TG:** 152 mg/dL (1.72 mmol/L)

AST: 24 U/L (0.40 μkat/L); **ALT:** 30 U/L (0.50 μkat/L)

Given this additional information, do you recommend weight loss? If so, how much weight should the patient lose and how fast?

What nonpharmacologic and pharmacologic alternatives are available for the patient?

Patient Encounter 2, Part 3: CVD Risk Reduction 6-Month Follow-up Clinic Visit

The patient present for his 6-month follow-up visit in the CVD Risk Reduction Clinic. He states that he has been adhering to the Step 1 diet and currently jogs on a treadmill 30 minutes a day 5 days a week.

SH: Continues to drink 3 to 4 beers nightly

Meds: Hydrochlorothiazide 12.5 mg PO every morning, lisinopril 20 mg PO every morning, and aspirin 81 mg PO daily

ROS: (-) Heartburn, regurgitation; (-) chest pain, nausea, vomiting, diarrhea, change in appetite, shortness of breath, or cough

VS: BP 126/74 mm Hg, P 76 beats/min, RR 16 breaths/min, T 98.5° F (36.9° C)

Wt: 199 lb (90 kg)

Ht: 67 in (170 cm)

Waist circumference: 45 in (114)

PE:

General: Well developed, in no acute distress

HEENT: Conjunctiva clear

CV: Regular rhythm, no S₃ or S₄ noted

Lungs: CTA bilaterally

Abd: Obese, soft, nontender, nondistended; (+) bowel sounds

Neuro: normal gait, normal speech

Ext: (-) Edema

Labs:

Na: 142 mEq/L (142 mmol/L); **K:** 4.7 mEq/L (4.7 mmol/L); **Cl:** 107 mEq/L (107 mmol/L); **CO₂:** 23 mEq/L (23 mmol/L); **BUN:** 18 mg/dL (6.4 mmol/L); **creatinine:** 1.0 mg/dL (88 μmol/L); **glucose:** 84 mg/dL (4.7 mmol/L)

TC: 218 mg/dL (5.64 mmol/L); **LDL:** 155 mg/dL (4.01 mmol/L); **HDL:** 34 mg/dL (0.88 mmol/L); **TG:** 145 mg/dL (1.64 mmol/L)

AST: 20 U/L (33 μkat/L), **ALT:** 32 U/L (0.53 μkat/L)

Calculate the patient's BMI.

What is the best weight loss therapeutic option for the patient?

Should any other medication(s) be implemented?

Patient Care and Monitoring

1. Determine if history of BMI greater than or equal to 25 kg/m². If unavailable or BMI unknown, obtain weight, height, and waist circumference. Calculate the BMI. Assess the patient's willingness to lose weight.
2. If the BMI is greater than 25 kg/m² or waist circumference greater than 35 in for females or 40 in for male patients, determine the presence of risk factors.
3. Prevention of weight gain is recommended in all patients with a BMI greater than or equal to 25 kg/m². Weight loss is indicated for patients with a BMI 25 to 29.9 kg/m², or an elevated waist circumference with two or more risk factors, or for any patient with a BMI greater than or equal to 30 kg/m².
4. Educate the patient regarding a healthy lifestyle, one that includes a balance between caloric intake and energy expenditure as well as suggest methods to modify behavior.
5. If the patient presents with a desire to lose weight, develop treatment goals and weight loss strategies (nonpharmacologic, drug therapy, or surgical intervention), including control of associated risks.
6. Close monitoring should follow to assess weight, BMI, waist circumference, and the presence of complications related to the treatment plan. If weight loss goals are not attained, determine reasons for failure.

Abbreviations Introduced in This Chapter

AST	Aspartate transaminase
ALT	Alanine transaminase
BMI	Body mass index
CAD	Coronary artery disease
CBI	Cannabinoid receptor
CHD	Coronary heart disease
CNS	Central nervous system
CVD	Cardiovascular disease
FDA	Food and Drug Administration
5-HT _{1A}	Serotonin 1A subtype
5-HT _{2C}	Serotonin 2C subtype
GI	Gastrointestinal
LCD	Low-calorie diet
MAOI	Monoamine oxidase inhibitor
MI	Myocardial infarction
NIH-NHLBI	National Institute of Health-National Heart Lung and Blood Institute
SCOUT	Sibutramine Cardiovascular Outcomes

Appendix A: Conversion Factors and Anthropometrics*

CONVERSION FACTORS

SI Units

SI (*le Système International d'Unités*) units are used in many countries to express clinical laboratory and serum drug concentration data. Instead of using units of mass (e.g., micrograms), the SI system uses moles (mol) to represent the amount of a substance. A molar solution contains 1 mole (the molecular weight of the substance in grams) of the solute in 1 L of solution. The following formula is used to convert units of mass to moles (mcg/mL to $\mu\text{mol/L}$ or, by substitution of terms, mg/mL to mmol/L or ng/mL to nmol/L).

► Micromoles per Liter

Micromoles per liter ($\mu\text{mol/L}$)

$$= \frac{\text{drug concentration (mcg/mL)} \cdot 1,000}{\text{molecular weight of drug (g/mol)}}$$

► Milliequivalents

An equivalent weight of a substance is the weight that will combine with or replace 1 g of hydrogen; a milliequivalent is 1/1,000 of an equivalent weight.

Milliequivalents per Liter

Milliequivalents per liter (mEq/L)

$$= \frac{\text{weight of salt (g)} \cdot \text{valence of ion} \cdot 1,000}{\text{molecular weight of salt}}$$

$$\text{Weight of salt (g)} = \frac{\text{mEq/L} \cdot \text{molecular weight of salt}}{\text{valence of ion} \cdot 1,000}$$

Approximate Milliequivalents: Weight Conversions for Selected Ions

Salt	mEq/g Salt	mg Salt/mEq
Calcium carbonate (CaCO_3)	20.0	50.0
Calcium chloride ($\text{CaCl}_2 \cdot 2\text{H}_2\text{O}$)	13.6	73.5
Calcium gluceptate ($\text{Ca}[\text{C}_7\text{H}_{13}\text{O}_8]_2$)	4.1	245.2
Calcium gluconate ($\text{Ca}[\text{C}_6\text{H}_{11}\text{O}_7]_2 \cdot \text{H}_2\text{O}$)	4.5	224.1
Calcium lactate ($\text{Ca}[\text{C}_3\text{H}_5\text{O}_3]_2 \cdot 5\text{H}_2\text{O}$)	6.5	154.1
Magnesium gluconate ($\text{Mg}[\text{C}_6\text{H}_{11}\text{O}_7]_2 \cdot \text{H}_2\text{O}$)	4.6	216.3
Magnesium oxide (MgO)	49.6	20.2
Magnesium sulfate (MgSO_4)	16.6	60.2
Magnesium sulfate ($\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$)	8.1	123.2
Potassium acetate ($\text{K}[\text{C}_2\text{H}_3\text{O}_2]$)	10.2	98.1
Potassium chloride (KCl)	13.4	74.6
Potassium citrate ($\text{K}_3[\text{C}_6\text{H}_5\text{O}_7] \cdot \text{H}_2\text{O}$)	9.2	108.1
Potassium iodide (KI)	6.0	166.0
Sodium acetate ($\text{Na}[\text{C}_2\text{H}_3\text{O}_2]$)	12.2	82.0
Sodium acetate ($\text{Na}[\text{C}_2\text{H}_3\text{O}_2] \cdot 3\text{H}_2\text{O}$)	7.3	136.1
Sodium bicarbonate (NaHCO_3)	11.9	84.0
Sodium chloride (NaCl)	17.1	58.4
Sodium citrate ($\text{Na}_3[\text{C}_6\text{H}_5\text{O}_7] \cdot 2\text{H}_2\text{O}$)	10.2	98.0
Sodium iodide (NaI)	6.7	149.9
Sodium lactate ($\text{Na}[\text{C}_3\text{H}_5\text{O}_3]$)	8.9	112.1
Zinc sulfate ($\text{ZnSO}_4 \cdot 7\text{H}_2\text{O}$)	7.0	143.8

Valences and Atomic/Molecular Weights of Selected Ions

Substance	Electrolyte	Valence	Atomic/Molecular Weight
Calcium	Ca^{2+}	2	40.1
Chloride	Cl^-	1	35.5
Magnesium	Mg^{2+}	2	24.3
Phosphate	HPO_4^- (80%)	1.8	96.0 ^a
(pH = 7.4)	H_2PO_4^- (20%)		97.0
Potassium	K^+	1	39.1
Sodium	Na^+	1	23.0
Sulfate	SO_4^-	2	96.0 ^a

^aThe atomic/molecular weight of phosphorus is only 31; that of sulfur is only 32.1.

*This appendix contains information from Appendices 1 and 2 of Smith KM, Riche DM, Henyan NN (eds). Clinical Drug Data, 11th ed. New York: McGraw-Hill, 2010:1239–1246; With permission.

Anion Gap

The anion gap is the concentration of plasma anions not routinely measured by laboratory screening. It is useful in the evaluation of acid–base disorders. The anion gap is greater with increased plasma concentrations of endogenous species (e.g., phosphate, sulfate, lactate, and ketoacids) or exogenous species (e.g., salicylate, penicillin, ethylene glycol, ethanol, and methanol). The formulas for calculating the anion gap are as follows:

$$\text{Anion gap} = (\text{Na}^+ + \text{K}^+) - (\text{Cl}^- + \text{HCO}_3^-)$$

or

$$\text{Anion gap} = \text{Na}^+ - (\text{Cl}^- + \text{HCO}_3^-)$$

where the expected normal value for the first equation is 11 to 20 mmol/L and for the second equation is 7 to 16 mmol/L. Note that there is a variation in the upper and lower limits of the normal range.

Temperature

Fahrenheit to Centigrade: $(^{\circ}\text{F} - 32) \times 5/9 = ^{\circ}\text{C}$

Centigrade to Fahrenheit: $(^{\circ}\text{C} \times 9/5) + 32 = ^{\circ}\text{F}$

Centigrade to Kelvin: $^{\circ}\text{C} + 273 = ^{\circ}\text{K}$

Calories

1 calorie = 1 kilocalorie = 1,000 calories = 4.184 kilojoules (kJ)

1 kilojoule = 0.239 calories = 0.239 kilocalories = 239 calories

Weights and Measures

► Metric Weight Equivalents

1 kilogram (kg) = 1,000 grams

1 gram (g) = 1,000 milligrams

1 milligram (mg) = 0.001 gram

1 microgram (mcg, μg) = 0.001 milligram

1 nanogram (ng) = 0.001 microgram

1 picogram (pg) = 0.001 nanogram

1 femtogram (fg) = 0.001 picogram

► Metric Volume Equivalents

1 liter (L) = 1,000 milliliters

1 deciliter (dL) = 100 milliliters

1 milliliter (mL) = 0.001 liter

1 microliter (μL) = 0.001 milliliter

1 nanoliter (nL) = 0.001 microliter

1 picoliter (pL) = 0.001 nanoliter

1 femtoliter (fL) = 0.001 picoliter

► Apothecary Weight Equivalents

1 scruple (\mathfrak{s}) = 20 grains (gr)

60 grains (gr) = 1 dram (\mathfrak{d})

8 drams (\mathfrak{d}) = 1 ounce (\mathfrak{z})

1 ounce (\mathfrak{z}) = 480 grains (gr)

12 ounces (\mathfrak{z}) = 1 pound (lb)

► Apothecary Volume Equivalents

60 minims (m) = 1 fluidram (fl \mathfrak{d})

8 fluidrams (fl \mathfrak{d}) = 1 fluid ounce (fl \mathfrak{z})

1 fluid ounce (fl \mathfrak{z}) = 480 minims (m)

16 fluid ounces (fl \mathfrak{z}) = 1 pint (pt)

► Avoirdupois Equivalents

1 ounce (oz) = 437.5 grains

16 ounces (oz) = 1 pound (lb)

► Weight/Volume Equivalents

1 mg/dL = 10 mcg/mL

1 mg/dL = 1 mg%

1 ppm = 1 mg/L

► Conversion Equivalents

1 gram (g) = 15.43 grains (gr)

1 grain (gr) = 64.8 milligrams (mg)

1 ounce (\mathfrak{z}) = 31.1 grams (g)

1 ounce (oz) = 28.35 grams (g)

1 pound (lb) = 453.6 grams (g)

1 kilogram (kg) = 2.2 pounds (lb)

1 milliliter (mL) = 16.23 minims (m)

1 minim (m) = 0.06 milliliter (mL)

1 fluid ounce (fl oz) = 29.57 milliliters (mL)

1 pint (pt) = 473.2 milliliters (mL)

1 US gallon = 3.78 liters (L)

1 Canadian gallon = 4.55 liters (L)

0.1 milligram = 1/600 grain

0.12 milligram = 1/500 grain

0.15 milligram = 1/400 grain

0.2 milligram = 1/300 grain

0.3 milligram = 1/200 grain

0.4 milligram = 1/150 grain

0.5 milligram = 1/120 grain

0.6 milligram = 1/100 grain

0.8 milligram = 1/80 grain

1 milligram = 1/65 grain

► Metric Length Conversion Equivalents

2.54 cm = 1 inch

30.48 cm = 1 foot

1 m = 3.28 feet

1.6 km = 1 mile

ANTHROPOMETRICS

Creatinine Clearance Formulas

► Formulas for Estimating Creatinine Clearance in Patients with Stable Renal Function

Cockcroft-Gault Formula

Adults (age 18 years and older)¹:

$$\text{CrCl (men)} = \frac{(140 - \text{age}) \text{ weight}}{\text{SCr} \cdot 72}$$

$$\text{CrCl (women)} = 0.85 \times \text{above value}^*$$

where CrCl is creatinine clearance (in mL/min), SCr is serum creatinine (in mg/dL [or $\mu\text{mol/L}$ divided by 88.4]), age is in years, and weight is in kilograms.

* Some studies suggest that the predictive accuracy of this formula for women is better *without* the correction factor of 0.85.

Traub-Johnson Formula

Children (age 1–18 years)²:

$$\text{CrCl} = \frac{0.48 \text{ height BSA}}{\text{SCr } 1.73}$$

where BSA is body surface area (in m^2), CrCl is creatinine clearance (in mL/minute), SCr is serum creatinine (in mg/dL [or $\mu\text{mol/L}$ divided by 88.4]), and height is in centimeters.

► Formula for Estimating Creatinine Clearance From a Measured Urine Collection

$$\text{CrCl (mL/minute)} = \frac{U}{P} \frac{V}{T}$$

where U is the concentration of creatinine in a urine specimen in mg/dL, V is the volume of urine in mL, P is the concentration of creatinine in serum at the midpoint of the urine collection period in mg/dL, and T is the time of the urine collection period in minutes (e.g., 6 hours = 360 minutes; 24 hours = 1,440 minutes). Procedures for obtaining urine specimens should stress the importance of complete urine collection during the collection time period.

► MDRD Formula for Estimating Glomerular Filtration Rate (From the Modification of Diet in Renal Disease Study)³

Conventional calibration MDRD equation (used only with those creatinine methods that have *not* been recalibrated to be traceable to isotope dilution mass spectrometry [IDMS])
For creatinine in mg/dL:

$$X = 186 \text{ creatinine}^{-1.154} \times \text{age}^{-0.203} \times \text{constant}$$

For creatinine in $\mu\text{mol/L}$:

$$X = 32,788 \times \text{creatinine}^{-1.154} \times \text{age}^{-0.203} \times \text{constant}$$

where X is the glomerular filtration rate (GFR), constant for white men is 1 and for women is 0.742, and constant for African Americans is 1.21. Creatinine levels in $\mu\text{mol/L}$ can be converted to mg/dL by dividing by 88.4.

► IDMS-Traceable MDRD Equation (Used Only With Creatinine Methods That Have Been Recalibrated to Be Traceable to IDMS)

For creatinine in mg/dL:

$$X = 175 \times \text{creatinine}^{-1.154} \times \text{age}^{-0.203} \times \text{constant}$$

For creatinine in $\mu\text{mol/L}$:

$$X = 175 \times (\text{creatinine}/88.4)^{-1.154} \times \text{age}^{-0.203} \times \text{constant}$$

where X is the GFR, constant for white men is 1 and for women is 0.742, and constant for African Americans is 1.21.

Ideal Body Weight

IBW is the weight expected for a nonobese person of a given height. The IBW formulas below and various life insurance tables can be used to estimate IBW. Dosing methods described in the literature may use IBW as a method in dosing obese patients.

Adults (age 18 years and older)⁴:

$$\text{IBW (men)} = 50 + (2.3 \times \text{height in inches over 5 ft})$$

$$\text{IBW (women)} = 45.5 + (2.3 \times \text{height in inches over 5 ft})$$

where IBW is in kilograms.

Children (age 1–18 years)² under 5 feet tall:

$$\text{IBW} = \frac{\text{height}^2 \cdot 1.65}{1,000}$$

where IBW is in kilograms and height is in centimeters.

Children (age 1–18 years) 5 feet or taller:

$$\text{IBW (males)} = 39 + (2.27 \times \text{height in inches over 5 ft})$$

$$\text{IBW (females)} = 42.2 + (2.27 \times \text{height in inches over 5 ft})$$

where IBW is in kilograms.

Appendix B: Common Laboratory Tests

The following table is an alphabetical listing of some common laboratory tests and their reference ranges for adults as measured in plasma or serum (unless otherwise indicated). Reference values differ among laboratories, so readers should refer to the published reference ranges used in each institution. For some tests, both the *Système International Units* and Conventional Units are reported.

Laboratory Test	Conventional Units	Conversion Factor	<i>Système International Units</i>
Acid phosphatase			
Male	2–12 U/L	16.7	33–200 nkat/L
Female	0.3–9.2 U/L	16.7	5–154 nkat/L
Activated partial thromboplastin time (aPTT)	25–40 sec		
Adrenocorticotrophic hormone (ACTH)	15–80 pg/mL or ng/L	0.2202	3.3–17.6 pmol/L
Alanine aminotransferase (ALT, SGPT)	7–53 U/L	0.01667	0.12–0.88 μ kat/L
Albumin	3.5–5.0 g/dL	10	35–50 g/L
Albumin:creatinine ratio (urine)		0.113	
Normal	Less than 30 mg/g creatinine		Less than 3.4 mg/mmol creatinine
Microalbuminuria	30–300 mg/g creatinine		3.4–34 mg/mmol creatinine
Proteinuria	Greater than 300 mg/g creatinine		Greater than 34 mg/mmol creatinine
or	or		
Normal			
Male	Less than 18 mg/g creatinine	0.113	Less than 2.0 mg/mmol creatinine
Female	Less than 25 mg/g creatinine	0.113	Less than 2.8 mg/mmol creatinine
Microalbuminuria			
Male	18–180 mg/g creatinine	0.113	2.0–20 mg/mmol creatinine
Female	25–250 mg/g creatinine	0.113	2.8–28 mg/mmol creatinine
Proteinuria			
Male	Greater than 180 mg/g creatinine	0.113	Greater than 20 mg/mmol creatinine
Female	Greater than 250 mg/mmol creatinine	0.113	Greater than 28 mg/mmol creatinine
Alcohol			
See under Ethanol			
Aldosterone			
Supine	Less than 16 ng/dL	27.7	Less than 444 pmol/L
Upright	Less than 31 ng/dL	27.7	Less than 860 pmol/L
Alkaline phosphatase			
10–15 years	130–550 IU/L	0.01667	2.17–9.17 μ kat/L
16–20 years	70–260 IU/L	0.01667	1.17–4.33 μ kat/L
Greater than 20 years	38–126 IU/L	0.01667	0.63–2.10 μ kat/L
α -Fetoprotein (AFP)	Less than 15 ng/mL	1	Less than 15 mcg/L
α -1-Antitrypsin	80–200 mg/dL	0.01	0.8–2.0 g/L
Amikacin, therapeutic			
Peak	15–30 mg/L	1.71	25.6–51.3 μ mol/L
Trough	Less than or equal to 8 mg/L	1.71	Less than or equal to 13.7 μ mol/L
Amitriptyline	80–200 ng/mL or mcg/L	3.605	288–721 nmol/L
Ammonia (plasma)	15–56 mcg NH ₃ /dL	0.5872	9–33 μ mol NH ₃ /L
Amylase	25–115 U/L	0.01667	0.42–1.92 μ kat/L
Androstenedione	50–250 ng/dL	0.0349	1.7–8.7 nmol/L
Angiotensin-converting enzyme	15–70 units/L	16.67	250–1167 nkat/L
Anion gap	7–16 mEq/L	1	7–16 mmol/L
Anti-double-stranded DNA (anti-ds DNA)	Negative		
Anti-HAV	Negative		

(Continued)

Laboratory Test	Conventional Units	Conversion Factor	Système International Units
Anti-HBc	Negative		
Anti-HBs	Negative		
Anti-HCV	Negative		
Anti-Sm antibody	Negative		
Antinuclear antibody (ANA)	Negative		
Apolipoprotein A-1			
Male	95–175 mg/dL	0.01	0.95–1.75 g/L
Female	100–200 mg/dL	0.01	1.0–2.0 g/L
Apolipoprotein B			
Male	50–110 mg/dL	0.01	0.5–1.10 g/L
Female	50–105 mg/dL	0.01	0.5–1.05 g/L
Aspartate aminotransferase (AST, SGOT)	11–47 IU/L	0.01667	0.18–0.78 μ kat/L
β_2 -Microglobulin	Less than 0.2 mg/dL	10	Less than 2 mg/L
Bicarbonate	22–26 mEq/L	1	22–26 mmol/L
Bilirubin			
Total	0.3–1.1 mg/dL	17.1	5.1–18.8 μ mol/L
Direct	0–0.3 mg/dL	17.1	0–5.1 μ mol/L
Indirect	0.1–1.0 mg/dL	17.1	1.7–17.1 μ mol/L
Bleeding time	3–7 minutes	60	180–420 seconds
Blood gases (arterial)			
pH	7.35–7.45	1	7.35–7.45
Po ₂	80–105 mm Hg	0.133	10.6–14.0 kPa
Pco ₂	35–45 mm Hg	0.133	4.7–6.0 kPa
HCO ₃	22–26 mEq/L	1	22–26 mmol/L
O ₂ saturation	Greater than or equal to 95%	0.01	Greater than or equal to 0.95
Blood urea nitrogen (BUN)	8–25 mg/dL	0.357	2.9–8.9 mmol/L
B-type natriuretic peptide (BNP)	0–99 pg/mL	1	0–99 ng/L
		0.289	0–29 pmol/L
BUN-to-creatinine ratio	10:1–20:1		
C-peptide	0.51–2.70 ng/mL	331	170–894 pmol/L
		0.331	0.17–0.89 nmol/L
C-reactive protein	Less than 0.8 mg/dL	10	Less than 8 mg/L
CA-125	Less than 35 units/mL	1	Less than 35 kU/L
CA 15–3	Less than 30 units/mL	1	Less than 30 kU/L
CA 19–9	Less than 37 units/mL	1	Less than 37 kU/L
CA 27.29	Less than 38 units/mL	1	Less than 38 kU/L
Calcium			
Total	8.6–10.3 mg/dL	0.25	2.15–2.58 mmol/L
	4.3–5.16 mEq/L	0.50	2.15–2.58 mmol/L
Ionized	4.5–5.1 mg/dL	0.25	1.13–1.28 mmol/L
	2.26–2.56 mEq/L	0.50	1.13–1.28 mmol/L
Carbamazepine, therapeutic	4–12 mg/L	4.23	17–51 μ mol/L
Carboxyhemoglobin (nonsmoker)	Less than 2%	0.01	Less than 0.02
Carcinoembryonic antigen (CEA)			
Nonsmokers	Less than 2.5 ng/mL	1	Less than 2.5 mcg/L
Smokers	Less than 5 ng/mL	1	Less than 5 mcg/L
CD4 lymphocyte count	31–61% of total lymphocytes	0.01	0.31–0.61 of total lymphocytes
CD8 lymphocyte count	18–39% of total lymphocytes	0.01	0.18–0.39 of total lymphocytes
Cerebrospinal fluid (CSF)			
Pressure	75–175 mm H ₂ O		
Glucose	40–70 mg/dL	0.0555	2.2–3.9 mmol/L
Protein	15–45 mg/dL	0.01	0.15–0.45 g/L
White blood cell (WBC) count	Less than 10/mm ³	1	Less than 10 10 ⁶ /L
Ceruloplasmin	18–45 mg/dL	10	180–450 mg/L
Chloride	97–110 mEq/L	1	97–110 mmol/L
Cholesterol			
Desirable	Less than 200 mg/dL	0.0259	Less than 5.18 mmol/L
Borderline high	200–239 mg/dL	0.0259	5.18–6.19 mmol/L
High	Greater than or equal to 240 mg/dL	0.0259	Greater than or equal to 6.2 mmol/L
Chorionic gonadotropin (β -hCG)	Less than 5 mIU/mL	1	Less than 5 IU/L
Clozapine, minimum trough	300–350 ng/mL or mcg/L	3.06	918–1,071 nmol/L
		0.00306	0.92–1.07 μ mol/L
CO ₂ content	22–30 mEq/L	1	22–30 mmol/L
Complement component 3 (C3)	70–160 mg/dL	0.01	0.70–1.60 g/L
Complement component 4 (C4)	20–40 mg/dL	0.01	0.20–0.40 g/L
Copper	70–150 mcg/dL	0.157	11–24 μ mol/L
Cortisol (fasting, morning)	5–25 mcg/dL	27.6	138–690 nmol/L

(Continued)

Laboratory Test	Conventional Units	Conversion Factor	Système International Units
Cortisol (free, urinary)	10–100 mcg/d	2.76	28–276 nmol/day
Creatine kinase			
Male	30–200 IU/L	0.01667	0.50–3.33 µkat/L
Female	20–170 IU/L	0.01667	0.33–2.83 µkat/L
MB fraction	0–7 IU/L	0.01667	0.0–0.12 µkat/L
Creatinine clearance (CrCl) (urine)	85–135 mL/min/1.73 m ²	0.00963	0.82–1.30 mL/s/m ²
Creatinine			
Male 4–20 years	0.2–1.0 mg/dL	88.4	18–88 µmol/L
Female 4–20 years	0.2–1.0 mg/dL	88.4	18–88 µmol/L
Male (adults)	0.7–1.3 mg/dL	88.4	62–115 µmol/L
Female (adults)	0.6–1.1 mg/dL	88.4	53–97 µmol/L
Cyclosporine			
Renal, cardiac, liver, or pancreatic transplant	100–400 ng/mL or mcg/L	0.832	83–333 nmol/L
Cryptococcal antigen	Negative		
D-dimers	Less than 250 ng/mL	1	Less than 250 mcg/L
Desipramine	75–300 ng/mL or mcg/L	3.75	281–1125 nmol/L
Dexamethasone suppression test (DST) (overnight), 8:00 am cortisol	Less than 5 mcg/dL	27.6	Less than 138 nmol/L
DHEAS (dehydroepiandrosterone sulfate)			
Male	170–670 mcg/dL	0.0272	4.6–18.2 µmol/L
Female			
Premenopausal	50–540 mcg/dL	0.0272	1.4–14.7 µmol/L
Postmenopausal	30–260 mcg/dL	0.0272	0.8–7.1 µmol/L
Digoxin, therapeutic (heart failure)	0.5–0.8 ng/mL or mcg/L	1.28	0.6–1.0 nmol/L
Therapeutic (atrial fibrillation)	0.8–2.0 ng/mL or mcg/L	1.28	1.0–2.6 nmol/L
Erythrocyte count (blood)			
See under red blood cell (RBC) count			
Erythrocyte sedimentation rate (ESR)			
Westergren			
Male	0–20 mm/h		
Female	0–30 mm/h		
Wintrobe			
Male	0–9 mm/h		
Female	0–15 mm/h		
Erythropoietin	2–25 mIU/mL	1	2–25 IU/L
Estradiol			
Male	10–36 pg/mL	3.67	37–132 pmol/L
Female	34–170 pg/mL	3.67	125–624 pmol/L
Ethanol, legal intoxication (depends on location)	Greater than or equal to 50–100 mg/dL	0.217	Greater than or equal to 10.9–21.7 mmol/L
	Greater than or equal to 0.05–0.1%	217	Greater than or equal to 10.9–21.7 mmol/L
Ethosuccimide, therapeutic	40–100 mg/L or mcg/mL	7.08	283–708 µmol/L
Factor VIII or factor IX			
Severe hemophilia	Less than 1 IU/dL	0.01	Less than 0.01 IU/mL
Moderate hemophilia	1–5 IU/dL	0.01	0.01–0.05 IU/mL
Mild hemophilia	Greater than 5 IU/dL	0.01	Greater than 0.05 IU/mL
Usual adult levels	60 to 140 IU/dL	0.01	0.60–1.40 IU/mL
Ferritin			
Male	20–250 ng/mL	1	20–250 mcg/L
Female	10–150 ng/mL	1	10–150 mcg/L
Fibrin degradation products (FDP)	2–10 mg/L		
Fibrinogen	200–400 mg/dL	0.01	2.0–4.0 g/L
Folate (plasma)	3.1–12.4 ng/mL	2.266	7.0–28.1 nmol/L
Folate (RBC)	125–600 ng/mL	2.266	283–1,360 nmol/L
Follicle-stimulating hormone (FSH)			
Male	1–7 mIU/mL	1	1–7 IU/L
Female			
Follicular phase	1–9 mIU/mL	1	1–9 IU/L
Midcycle	6–26 mIU/mL	1	6–26 IU/L
Luteal phase	1–9 mIU/mL	1	1–9 IU/L
Postmenopausal	30–118 mIU/mL	1	30–118 IU/L
Free thyroxine index (FT ₄ I)	6.5–12.5		
Gamma glutamyltransferase (GGT)	0–30 IU/L	0.01667	0–0.50 µkat/L
Gastrin (fasting)	0–130 pg/mL	1	0–130 ng/L
Gentamicin, therapeutic (traditional dosing)			
Peak	4–10 mg/L	2.09	8.4–21 µmol/L
Trough	Less than or equal to 2 mg/L	2.09	Less than or equal to 4.2 µmol/L

(Continued)

Laboratory Test	Conventional Units	Conversion Factor	Système International Units
Globulin	2.3–3.5 g/dL	10	23–35 g/L
Glucose (fasting, plasma)	65–109 mg/dL	0.0555	3.6–6.0 mmol/L
Glucose, 2-hour postprandial blood (PPBG)	Less than 140 mg/dL	0.0555	Less than 7.8 mmol/L
Granulocyte count	1.8–6.6 × 10 ³ /mm ³	10 ⁶	1.8–6.6 × 10 ⁹ /L
Growth hormone (fasting)			
Male	Less than 5 ng/mL	1	Less than 5 mcg/L
Female	Less than 10 ng/mL	1	Less than 10 mcg/L
Haptoglobin	60–270 mg/dL	0.01	0.6–2.7 g/L
Hepatitis B surface antigen, extracellular form (HBeAg)	Negative		
Hepatitis B surface antigen (HbsAg)	Negative		
Hepatitis B virus (HBV) DNA	Negative		
Hematocrit			
Male	40.7–50.3%	0.01	0.407–0.503
Female	36.1–44.3%	0.01	0.361–0.443
Hemoglobin (blood)			
Male	13.8–17.2 g/dL	10	138–172 g/L
		0.621	8.56–10.68 mmol/L
Female	12.1–15.1 g/dL	10	121–151 g/L
		0.621	7.51–9.36 mmol/L
Hemoglobin A1c	4.0–6.0%	0.01	0.04–0.06
		^a	20–42 mmol/mol hemoglobin
Heparin			
Via protamine titration method	0.2–0.4 units/mL		
Via antifactor Xa assay	0.3–0.7 units/mL		
High-density lipoprotein (HDL) cholesterol	Greater than 35 mg/dL	0.0259	Greater than 0.91 mmol/L
Homocysteine	3.3–10.4 μmol/L		
Ibuprofen			
Therapeutic	10–50 mcg/mL	4.85	49–243 μmol/L
Toxic	Greater than or equal to 100 mcg/mL	4.85	Greater than or equal to 485 μmol/L
Imipramine, therapeutic	100–300 ng/mL or mcg/L	3.57	357–1,071 nmol/L
Immunoglobulin A (IgA)	85–385 mg/dL	0.01	0.85–3.85 g/L
Immunoglobulin G (IgG)	565–1,765 mg/dL	0.01	5.65–17.65 g/L
Immunoglobulin M (IgM)	53–375 mg/dL	0.01	0.53–3.75 g/L
Insulin (fasting)	2–20 μU/mL or mU/L	7.175	14.35–143.5 pmol/L
International normalized ratio (INR), therapeutic	2.0–3.0 (2.5–3.5 for some indications)		
Iron			
Male	45–160 mcg/dL	0.179	8.1–28.6 μmol/L
Female	30–160 mcg/dL	0.179	5.4–28.6 μmol/L
Iron-binding capacity (total)	220–420 mcg/dL	0.179	39.4–75.2 μmol/L
Iron saturation	15–50%	0.01	0.15–0.50
Itraconazole			
Trough, therapeutic	0.5–1 mcg/mL	1	0.5–1 mg/L
Lactate (plasma)	0.7–2.1 mEq/L	1	0.7–2.1 mmol/L
	6.3–18.9 mg/dL	0.111	0.7–2.1 mmol/L
Lactate dehydrogenase (LDH)	100–250 IU/L	0.01667	1.67–4.17 μkat/L
Lead	Less than 25 mcg/dL	0.0483	Less than 1.21 μmol/L
Leukocyte count	3.8–9.8 × 10 ³ /mm ³	10 ⁶	3.8–9.8 × 10 ⁹ /L
Lidocaine, therapeutic	1.5–6.0 mcg/mL or mg/L	4.27	6.4–25.6 μmol/L
Lipase	Less than 100 IU/L	0.01667	1.67 μkat/L
Lithium, therapeutic	0.5–1.25 mEq/L	1	0.5–1.25 mmol/L
Low-density lipoprotein (LDL) cholesterol			
Target for very high-risk patients	Less than 70 mg/dL	0.0259	Less than 1.81 mmol/L
Target for high-risk patients (optimal)	Less than 100 mg/dL	0.0259	Less than 2.59 mmol/L
Desirable	Less than 130 mg/dL	0.0259	Less than 3.36 mmol/L
Borderline high risk	130–159 mg/dL	0.0259	3.36–4.11 mmol/L
High risk	Greater than or equal to 160 mg/dL	0.0259	Greater than or equal to 4.14 mmol/L
Luteinizing hormone (LH)			
Male	1–8 mIU/mL	1	1–8 IU/L
Female			
Follicular phase	1–12 mIU/mL	1	1–12 IU/L
Midcycle	16–104 mIU/mL	1	16–104 IU/L
Luteal phase	1–12 mIU/mL	1	1–12 IU/L
Postmenopausal	16–66 mIU/mL	1	16–66 IU/L
Lymphocyte count	1.2–3.3 × 10 ³ /mm ³	10 ⁶	1.2–3.3 × 10 ⁹ /L
Magnesium	1.3–2.2 mEq/L	0.5	0.65–1.10 mmol/L
	1.58–2.68 mg/dL	0.411	0.65–1.10 mmol/L
Mean corpuscular volume (MCV)	80.0–97.6 μm ³	1	80.0–97.6 fL
Mononuclear cell count	0.2–0.7 × 10 ³ /mm ³	10 ⁶	0.2–0.7 × 10 ⁹ /L

(Continued)

Laboratory Test	Conventional Units	Conversion Factor	Système International Units
Nortriptyline, therapeutic	50–150 ng/mL or mcg/L	3.797	190–570 nmol/L
Osmolality (serum)	275–300 mOsm/kg	1	275–300 mmol/kg
Osmolality (urine)	250–900 mOsm/kg	1	250–900 mmol/kg
Parathyroid hormone (PTH), intact	10–60 pg/mL or ng/L	0.107	1.1–6.4 pmol/L
PTH, N-terminal	8–24 pg/mL or ng/L		
PTH, C-terminal	50–330 pg/mL or ng/L		
Phenobarbital, therapeutic	15–40 mcg/mL or mg/L	4.31	65–172 µmol/L
Phenytoin, therapeutic	10–20 mcg/mL or mg/L	3.96	40–79 µmol/L
Phosphate	2.5–4.5 mg/dL	0.323	0.81–1.45 mmol/L
Platelet count	140–440 × 10 ³ /mm ³	10 ⁶	140–440 × 10 ⁹ /L
Potassium (plasma)	3.3–4.9 mEq/L	1	3.3–4.9 mmol/L
Prealbumin (adult)	19.5–35.8 mg/dL	10	195–358 mg/L
Primidone, therapeutic	5–12 mcg/mL or mg/L	4.58	23–55 µmol/L
Procainamide, therapeutic	4–10 mcg/mL or mg/L	4.25	17–42 µmol/L
Progesterone			
Male	13–97 ng/dL	0.0318	0.4–3.1 nmol/L
Female			
Follicular phase	15–70 ng/dL	0.0318	0.5–2.2 nmol/L
Luteal phase	200–2,500 ng/dL	0.0318	6.4–79.5 nmol/L
Prolactin	Less than 20 ng/mL	1	Less than 20 mcg/L
Prostate-specific antigen (PSA)	Less than 4 ng/mL	1	Less than 4 mcg/L
Protein, total	6.0–8.0 g/dL	10	60–80 g/L
Prothrombin time (PT)	10–12 second		
Quinidine, therapeutic	2–5 mcg/mL or mg/L	3.08	6.2–15.4 µmol/L
Radioactive iodine uptake (RAIU)	Less than 6% in 2 hours		
Red blood cell (RBC) count (blood)			
Male	4–6.2 × 10 ⁶ /mm ³	10 ⁶	4–6.2 × 10 ¹² /L
Female	4–6.2 × 10 ⁶ /mm ³	10 ⁶	4–6.2 × 10 ¹² /L
Pregnant			
Trimester 1	4–5 × 10 ⁶ /mm ³	10 ⁶	4–5 × 10 ¹² /L
Trimester 2	3.2–4.5 × 10 ⁶ /mm ³	10 ⁶	3.2–4.5 × 10 ¹² /L
Trimester 3	3–4.9 × 10 ⁶ /mm ³	10 ⁶	3–4.9 × 10 ¹² /L
Postpartum	3.2–5 × 10 ⁶ /mm ³	10 ⁶	3.2–5 × 10 ¹² /L
Red blood cell distribution width (RDW)	11.5–14.5%	0.01	0.115–0.145
Reticulocyte count			
Male	0.5–1.5% of total RBC count	0.01	0.005–0.015
Female	0.5–2.5% of total RBC count	0.01	0.005–0.025
Retinol-binding protein (RBP)	2.7–7.6 mg/dL	10	27–76 mg/L
Rheumatoid factor (RF) titer	Negative		
Salicylate, therapeutic	150–300 mcg/mL or mg/L	0.00724	1.09–2.17 mmol/L
	15–30 mg/dL	0.0724	1.09–2.17 mmol/L
Sirolimus (renal transplant)	4–20 ng/mL	1	4–20 mcg/L
		1.094	4–22 nmol/L
Sodium	135–145 mEq/L	1	135–145 mmol/L
Tacrolimus			
Renal, cardiac, liver, or pancreatic transplant	5–20 ng/mL	1	5–20 mcg/L
		1.24	6.2–24.8 nmol/L
Testosterone (total)			
Men	300–950 ng/dL	0.0347	10.4–33.0 nmol/L
Women	20–80 ng/dL	0.0347	0.7–2.8 nmol/L
Testosterone (free)			
Men	9–30 ng/dL	0.0347	0.31–1.04 nmol/L
Women	0.3–1.9 ng/dL	0.0347	0.01–0.07 nmol/L
Theophylline			
Therapeutic	5–15 mcg/mL or mg/L	5.55	28–83 µmol/L
Toxic	20 mcg/mL or mg/L or more	5.55	111 µmol/L or more
Thiocyanate	Toxic level unclear; units are mcg/mL or mg/L	17.2	µmol/L
Thrombin time	20–24 second		
Thyroglobulin	Less than 42 ng/mL	1	Less than 42 mcg/L
Thyroglobulin antibodies	Negative		
Thyroxine-binding globulin (TBG)	1.2–2.5 mg/dL	10	12–25 mcg/L
Thyroid-stimulating hormone (TSH)	0.35–6.20 µIU/mL	1	0.35–6.20 mIU/L
TSH receptor antibodies (TSHRab)	0–1 units/mL		
Thyroxine (T ₄)			
Total	4.5–12.0 mcg/dL	12.87	58–154 nmol/L
Free	0.7–1.9 ng/dL	12.87	9.0–24.5 pmol/L
Thyroxine index, free (FT ₄ I)	6.5–12.5		
TIBC—see Iron binding capacity (total)			

(Continued)

Laboratory Test	Conventional Units	Conversion Factor	Système International Units
Tobramycin, therapeutic			
Peak	4–10 mcg/mL or mg/L	2.14	8.6–21.4 µmol/L
Trough	Less than or equal to 2 mcg/mL or mg/L	2.14	Less than or equal to 4.3 µmol/L
Transferrin	200–430 mg/dL	0.01	2.0–4.3 g/L
Transferrin saturation	30–50%	0.01	0.30–0.50
Triglycerides (fasting)	Less than 160 mg/dL	0.0113	Less than 1.81 mmol/L
Triiodothyronine (T ₃)	45–132 ng/dL	0.0154	0.069–2.03 nmol/L
Triiodothyronine (T ₃) resin uptake	25–35%		
Uric acid	3–8 mg/dL	59.48	178–476 µmol/L
Urinalysis (urine)			
pH	4.8–8.0		4.8–8.0
Specific gravity	1.005–1.030		
Protein	Negative		
Glucose	Negative		
Ketones	Negative		
RBC	1–2 per low-power field		
WBC	Less than 5 per low-power field		
Valproic acid, therapeutic	50–100 mcg/mL or mg/L	6.93	346–693 µmol/L
Vancomycin, therapeutic			
Peak	20–40 mcg/mL or mg/L	0.690	14–28 µmol/L
Trough	10–20 mcg/mL or mg/L	0.690	7–14 µmol/L
Trough for central nervous system infections	15–20 mcg/mL or mg/L	0.690	10–14 µmol/L
Vitamin A (retinol)	30–95 mcg/dL	0.0349	1.05–3.32 µmol/L
Vitamin B ₁₂	180–1,000 pg/mL	0.738	133–738 pmol/L
Vitamin D ₃ , 125-dihydroxy	20–76 pg/mL	2.4	48–182 pmol/L
Vitamin D ₃ , 25-hydroxy	10–50 ng/mL	2.496	25–125 nmol/L
Vitamin E (<i>α</i> -tocopherol)	0.5–2.0 mg/dL	23.22	12–46 µmol/L
WBC count	4–10 × 10 ³ /mm ³	10 ⁶	4–10 × 10 ⁹ /L
WBC differential (peripheral blood)			
Polymorphonuclear neutrophils (PMNs)	50–65%	0.01	0.50–0.65
Bands	0–5%	0.01	0–0.05
Eosinophils	0–3%	0.01	0–0.03
Basophils	1–3%	0.01	0.01–0.03
Lymphocytes	25–35%	0.01	0.25–0.35
Monocytes	2–6%	0.01	0.02–0.06
WBC differential (bone marrow)			
PMNs	3–11%	0.01	0.03–0.11
Bands	9–15%	0.01	0.09–0.15
Metamyelocytes	9–25%	0.01	0.09–0.25
Myelocytes	8–16%	0.01	0.08–0.16
Promyelocytes	1–8%	0.01	0.01–0.08
Myeloblasts	0–5%	0.01	0–0.05
Eosinophils	1–5%	0.01	0.01–0.05
Basophils	0–1%	0.01	0–0.01
Lymphocytes	11–23%	0.01	0.11–0.23
Monocytes	0–1%	0.01	0–0.01
Zinc	60–150 mcg/dL	0.153	9.2–23.0 µmol/L

^aHemoglobin A1c (mmol/mol hemoglobin) = (Hemoglobin A1c (%) – 2.15) 10.929.

This table is a modification of the Medical Algorithms Project (Chapter 40), unit conversions of the following Excel worksheets: Conversion of Conventional to SI units: Blood Chemistries; Conversion of Conventional to SI units: Urine Chemistries; Conversion of Conventional to SI units: Hematology and Coagulation; and Conversion of Conventional to SI units: Therapeutic Drug Monitoring.

Appendix C: Common Medical Abbreviations

These are the abbreviations used commonly in medical practice both in verbal communication and in the medical record.

A&O	alert and oriented	AFEB	afebrile
A&O×3	awake (or alert) and oriented to person, place, and time	AI	aortic insufficiency
A&O×4	awake (or alert) and oriented to person, place, time, and situation	AIDS	acquired immune deficiency syndrome
A&P	active and present; anterior and posterior; assessment and plans; auscultation and percussion	AKA	above-knee amputation; alcoholic ketoacidosis; all known allergies; also known as
A&W	alive and well	AKI	acute kidney injury
A1c	hemoglobin A1c	ALFT	abnormal liver function test
AA	aplastic anemia; alcoholics anonymous	ALL	acute lymphoblastic leukemia; acute lymphocytic leukemia
AAA	abdominal aortic aneurysm	ALP	alkaline phosphatase
AAO	awake, alert, and oriented	ALS	amyotrophic lateral sclerosis
AAO×3	awake and orientated to time, place, and person	ALT	alanine transaminase (SGPT); alanine aminotransferase
ABC	absolute band counts; absolute basophil count; apnea, bradycardia, and cytology; aspiration, biopsy, and cytology; artificial beta cells	AMA	against medical advice; American Medical Association; antimitochondrial antibody
Abd	abdomen	AMI	acute myocardial infarction
ABG	arterial blood gases	AML	acute myelogenous leukemia
ABO	blood group system (A, AB, B, and O)	Amp	ampule
ABP	arterial blood pressure	ANA	antinuclear antibody
ABW	actual body weight	ANC	absolute neutrophil count
ABx	antibiotics	ANLL	acute nonlymphocytic leukemia
AC	before meals (<i>ante cibos</i>)	AODM	adult-onset diabetes mellitus
ACE	angiotensin-converting enzyme	AOM	acute otitis media
ACE-I	angiotensin-converting enzyme inhibitor	AP	anteroposterior
ACLS	advanced cardiac life support	APAP	acetaminophen (acetyl- <i>p</i> -aminophenol)
ACS	acute coronary syndromes	aPTT	activated partial thromboplastin time
ACTH	adrenocorticotrophic hormone	ARB	angiotensin receptor blocker
AD	Alzheimer's disease; right ear (<i>auris dextra</i>)	ARC	AIDS-related complex
ADA	American Diabetes Association; adenosine deaminase	ARD	acute respiratory disease; adult respiratory disease; antibiotic removal device; aphakic retinal detachment
ADE	adverse drug effect (or event)	ARDS	adult respiratory distress syndrome
ADH	antidiuretic hormone	ARF	acute renal failure; acute respiratory failure; acute rheumatic fever
ADHD	attention-deficit hyperactivity disorder	AROM	active range of motion
ADL	activities of daily living	AS	left ear (<i>auris sinistra</i>)
ADR	adverse drug reaction	ASA	aspirin (acetylsalicylic acid)
AF	atrial fibrillation	ASCVD	arteriosclerotic cardiovascular disease
AFB	Acid-fast bacillus; aortofemoral bypass; aspirated foreign body	ASD	atrial septal defect
		ASH	asymmetric septal hypertrophy
		ASHD	arteriosclerotic heart disease

AST	aspartate transaminase (SGOT); aspartate aminotransferase	CIWA	Clinical Institute Withdrawal Assessment
ATG	antithymocyte globulin	CK	creatinine kinase
ATN	acute tubular necrosis	CKD	chronic kidney disease
AU	each ear (<i>auris uterque</i>)	CLL	chronic lymphocytic leukemia
AV	arteriovenous; atrioventricular; auditory visual	CM	costal margin
AVR	aortic valve replacement	CMG	cystometrogram
BBB	bundle branch block; blood-brain barrier	CML	chronic myelogenous leukemia
BC	blood culture	CMV	cytomegalovirus
BCOP	Board Certified Oncology Pharmacist	CN	cranial nerve
BCP	birth control pill	CNS	central nervous system
BCPP	Board Certified Psychiatric Pharmacist	C/O	complains of
BCPS	Board Certified Pharmacotherapy Specialist	CO	cardiac output; carbon monoxide
BE	barium enema	COLD	chronic obstructive lung disease
BG	blood glucose	COPD	chronic obstructive pulmonary disease
bid	twice daily (<i>bis in die</i>)	CP	chest pain; cerebral palsy
BKA	below-knee amputation	CPAP	continuous positive airway pressure
BM	bone marrow; bowel movement; an isoenzyme of creatine phosphokinase	CPK	creatinine phosphokinase (BB, MB, and MM are isoenzymes)
BMC	bone marrow cells	CPP	cerebral perfusion pressure
BMD	bone mineral density	CPR	cardiopulmonary resuscitation
BMI	body mass index	CrCl	creatinine clearance
BMP	basic metabolic panel	CRF	chronic renal failure; corticotropin-releasing factor
BMR	basal metabolic rate	CRH	corticotropin-releasing hormone
BMT	bone marrow transplantation	CRI	chronic renal insufficiency; catheter-related infection
BP	blood pressure	CRNA	Certified Registered Nurse Anesthetist
BPD	bronchopulmonary dysplasia	CRNP	Certified Registered Nurse Practitioner
BPH	benign prostatic hyperplasia	CRP	C-reactive protein
bpm	beats per minute	CRTT	Certified Respiratory Therapy Technician
BR	bed rest	CSF	cerebrospinal fluid; colony-stimulating factor
BS	bowel sounds; breath sounds; blood sugar	CT	computed tomography; chest tube
BSA	body surface area	cTnI	cardiac troponin I
BUN	blood urea nitrogen	CTZ	chemoreceptor trigger zone
Bx	biopsy	CV	cardiovascular
C&S	culture and sensitivity	CVA	cerebrovascular accident
CA	cancer; calcium	CVC	central venous catheter
CABG	coronary artery bypass grafting	CVP	central venous pressure
CAD	coronary artery disease	Cx	culture; cervix
CAH	chronic active hepatitis	CXR	chest x-ray
CAM	complementary and alternative medicine	CYP	cytochrome P450
CAPD	continuous ambulatory peritoneal dialysis	D&C	dilatation and curettage
CBC	complete blood count	D ₅ W	5% dextrose in water
CBD	common bile duct	DBP	diastolic blood pressure
CBG	capillary blood gas; corticosteroid-binding globulin	D/C	discontinue; discharge
CC	chief complaint	DCC	direct-current cardioversion
CCA	calcium channel antagonist	DI	diabetes insipidus
CCB	calcium channel blocker	DIC	disseminated intravascular coagulation
CCE	clubbing, cyanosis, edema	Diff	differential
CCK	cholecystokinin	DJD	degenerative joint disease
CCU	coronary care unit	DKA	diabetic ketoacidosis
CF	cystic fibrosis	dL	deciliter
CFS	chronic fatigue syndrome	DM	diabetes mellitus
CFU	colony-forming unit	DNA	deoxyribonucleic acid
CHD	coronary heart disease	DNR	do not resuscitate
CHF	congestive heart failure; chronic heart failure	DO	Doctor of osteopathy
CHO	carbohydrate	DOA	dead on arrival; date of admission; duration of action
CI	Cardiac index		

DOB	date of birth	g	gram
DOE	dyspnea on exertion	G-CSF	granulocyte colony-stimulating factor
DOT	directly observed therapy	G6PD	glucose-6-phosphate dehydrogenase
DPGN	diffuse proliferative glomerulonephritis	GB	gallbladder
DPI	dry powder inhaler	GBS	group B <i>Streptococcus</i> ; Guillain-Barré syndrome
DRE	digital rectal examination	GC	gonococcus
DRG	diagnosis-related group	GDM	gestational diabetes mellitus
DS	double strength	GE	gastroesophageal; gastroenterology
d/t	due to	GERD	gastroesophageal reflux disease
DTP	diphtheria–tetanus–pertussis	GFR	glomerular filtration rate
DTR	deep tendon reflex	GGT	γ -glutamyl transferase
DVT	deep vein thrombosis	GGTP	γ -glutamyl transpeptidase
Dx	diagnosis	GI	gastrointestinal
EBV	Epstein-Barr virus	GM-CSF	granulocyte-macrophage colony-stimulating factor
EC	enteric coated	GN	glomerulonephritis; graduate nurse
ECF	extracellular fluid	gr	grain
ECG	electrocardiogram	GT	gastrostomy tube
ECHO	echocardiogram	gtt	drops (<i>guttae</i>)
ECT	electroconvulsive therapy	GTT	glucose tolerance test
ED	emergency department	GU	genitourinary
EEG	electroencephalogram	GVHD	graft-versus-host disease
EENT	eyes, ears, nose, throat	GVL	graft-versus-leukemia
EF	ejection fraction	Gyn	gynecology
EGD	esophagogastroduodenoscopy	H&H, H/H	hemoglobin and hematocrit
EIA	enzyme immunoassay	H&P	history and physical examination
ECG	electrocardiogram	HA	headache
EMG	electromyogram	HAART	highly active antiretroviral therapy
EMT	Emergency Medical Technician	HAMD	Hamilton Rating Scale for Depression
Endo	endotracheal, endoscopy	HAV	Hepatitis A virus
EOMI	extraocular movements (or muscles) intact	Hb, hgb	hemoglobin
EPO	erythropoietin	HbAlc	glycosylated hemoglobin (hemoglobin Alc)
EPS	extrapyramidal symptoms	HBIG	hepatitis B immune globulin
ER	emergency room	HBP	high blood pressure
ERCP	endoscopic retrograde cholangiopancreatography	HBsAg	hepatitis B surface antigen
ERT	estrogen replacement therapy	HBV	hepatitis B virus
ESKD	end-stage kidney disease	HC	hydrocortisone, home care
ESLD	end-stage liver disease	HCG	human chorionic gonadotropin
ESR	erythrocyte sedimentation rate	HCO ₃	bicarbonate
ESRD	end-stage renal disease	Hct	hematocrit
ET	endotracheal	HCTZ	hydrochlorothiazide
EtOH	ethanol	HCV	hepatitis C virus
FB	finger breadth; foreign body	HD	Hodgkin's disease; hemodialysis
FBS	fasting blood sugar	HDL	high-density lipoprotein
FDA	Food and Drug Administration	HEENT	head, eyes, ears, nose, and throat
FEF	forced expiratory flow rate	HF	heart failure
FEV ₁	forced expiratory volume in 1 second	HFA	hydrofluoroalkane
FFP	fresh-frozen plasma	H flu	<i>Hemophilus influenzae</i>
FH	family history	HGH	human growth hormone
FiO ₂	fraction of inspired oxygen	HH	hiatal hernia
FOBT	fecal occult blood test	Hib	<i>Hemophilus influenzae</i> type b
FPG	fasting plasma glucose	HIT	heparin-induced thrombocytopenia
FPIA	fluorescence polarization immunoassay	HIV	human immunodeficiency virus
FSH	follicle-stimulating hormone	HJR	hepatojugular reflux
FTA	fluorescent treponemal antibody	HLA	human leukocyte antigen; human lymphocyte antigen
FT ₄	free thyroxine	HMG-CoA	hydroxy-methylglutaryl coenzyme A
F/U	follow-up		
FUO	fever of unknown origin		
Fx	fracture		

H/O	history of	kcal	kilocalorie
HOB	head of bed	KCl	potassium chloride
HPA	hypothalamic–pituitary axis	KOH	potassium hydroxide
hpf	high-power field	KUB	kidney, ureter, and bladder
HPI	history of present illness	KVO	keep vein open
HR	heart rate	L	liter
H ₂ RA	H ₂ receptor antagonist	LABA	long-acting beta agonist
HRSD	Hamilton Rating Scale for Depression	LAD	left anterior descending; left axis deviation
HRT	hormone-replacement therapy	LAO	left anterior oblique
HS	at bedtime (<i>hora somni</i>)	LBBB	left bundle branch block
HSV	herpes simplex virus	LBP	low-back pain
HTN	hypertension	LDH	lactate dehydrogenase
Hx	history	LDL	low-density lipoprotein
I&D	incision and drainage	LE	lower extremity
I&O, I/O	intake and output	LES	lower esophageal sphincter
IBD	inflammatory bowel disease	LFT	liver function test
IBW	ideal body weight	LHRH	luteinizing hormone-releasing hormone
ICD	implantable cardioverter defibrillator	LLE	left lower extremity
ICP	intracranial pressure	LLL	left lower lobe
ICS	intercostal space; inhaled corticosteroid	LLQ	left lower quadrant (abdomen)
ICU	intensive care unit	LMD	local medical doctor
ID	identification; infectious disease	LMP	last menstrual period
IDDM	insulin-dependent diabetes mellitus	LMWH	low-molecular-weight heparin
IFN	interferon	LOS	length of stay
Ig	immunoglobulin	LP	lumbar puncture
IgA	immunoglobulin A	LPN	Licensed Practical Nurse
IgD	immunoglobulin D	LPT	Licensed Physical Therapist
IHD	ischemic heart disease	LR	Lactated Ringer's
IJ	internal jugular	LS	lumbosacral
IM	intramuscular; infectious mononucleosis	LT ₄	levothyroxine
INH	isoniazid	LUE	left upper extremity
INR	international normalized ratio	LUL	left upper lobe
IOP	intraocular pressure	LUQ	left upper quadrant
IP	intraoperative	LUTS	lower urinary tract symptoms
IPG	impedance plethysmography	LVH	left ventricular hypertrophy
IPN	interstitial pneumonia	MAP	mean arterial pressure
IRB	institutional review board	MAR	medication administration record
ISA	intrinsic sympathomimetic activity	MB-CK	a creatine kinase isoenzyme
ISH	isolated systolic hypertension	mcg	microgram
IT	intrathecal	MCH	mean corpuscular hemoglobin
ITP	idiopathic thrombocytopenic purpura	MCHC	mean corpuscular hemoglobin concentration
IU	international units (this can be dangerous abbreviation because it may be read as “IV” for “intravenous”)	MCV	mean corpuscular volume
IUD	intrauterine device	MD	Medical Doctor
IV	intravenous; Roman numeral four; symbol for class 4 controlled substances	MDI	metered-dose inhaler
IVC	inferior vena cava; intravenous cholangiogram	MDRD	modification of diet in renal disease
IVDA	intravenous drug abuse	MEFR	maximum expiratory flow rate
IVDU	injection drug use; intravenous drug use	mEq	milliequivalent
IVF	intravenous fluids	mg	milligram
IVIG	intravenous immunoglobulin	MHC	major histocompatibility complex
IVP	intravenous pyelogram; intravenous push	MI	myocardial infarction; mitral insufficiency
JODM	juvenile-onset diabetes mellitus	MIC	minimum inhibitory concentration
JRA	juvenile rheumatoid arthritis	mL	milliliter
JVD	jugular venous distension	MM	multiple myeloma; an isoenzyme of creatine phosphokinase
JVP	jugular venous pressure	MMR	measles–mumps–rubella; midline malignant reticulosis
K	potassium	MOM	milk of magnesia
		MPV	mean platelet volume

m/r/g	murmur/rub/gallop	P	pulse; plan; percussion; pressure
MRI	magnetic resonance imaging	P&A	percussion and auscultation
MRSA	methicillin-resistant <i>Staphylococcus aureus</i>	P&T	peak and trough
MRSE	methicillin-resistant <i>Staphylococcus epidermitis</i>	PA	physician assistant; posteroanterior; pulmonary artery
MS	mental status; mitral stenosis; musculoskeletal; multiple sclerosis; morphine sulfate	PAC	premature atrial contraction
MSE	mental status exam	Paco ₂	arterial carbon dioxide tension
MSW	Master of Social Work	Pao ₂	arterial oxygen tension
MTD	maximum tolerated dose	PAOP	pulmonary artery occlusion pressure
MTX	methotrexate	PC	after meals (<i>post cibum</i>)
MVA	motor vehicle accident	PCA	patient-controlled analgesia
MVI	multivitamin	PCI	percutaneous coronary intervention
MVR	mitral valve replacement; mitral valve regurgitation	PCKD	polycystic kidney disease
MVS	mitral valve stenosis; motor, vascular, and sensory	PCN	penicillin
N&V	nausea and vomiting	PCP	<i>Pneumocystis carinii</i> pneumonia (also known as <i>Pneumocystis jirovecii</i> pneumonia); pneumocystis pneumonia; primary care physician; phenacyclidine
NAD	no acute (or apparent) distress	PCWP	pulmonary capillary wedge pressure
N/C	noncontributory; nasal cannula	PDE	paroxysmal dyspnea on exertion
NG	nasogastric	PE	physical examination; pulmonary embolism
NGT	nasogastric tube; normal glucose tolerance	PEEP	positive end-expiratory pressure
NIDDM	non-insulin-dependent diabetes mellitus	PEFR	peak expiratory flow rate
NIH	National Institutes of Health	PEG	percutaneous endoscopic gastrostomy; polyethylene glycol
NKA	no known allergies	Peg-IFN	pegylated interferon
NKDA	no known drug allergies	PERL	pupils equal, react to light
NHDA	nonketotic hyperosmolar acidosis	PERRLA	pupils equal, round, and reactive to light and accommodation
NL	normal	PERRRLA	pupils equal, round, regular, and react to light and accommodation
NOS	not otherwise specified	PET	positron emission tomography
NPN	nonprotein nitrogen	PFT	pulmonary function test
NPO	nothing by mouth (<i>nil per os</i>)	pH	hydrogen ion concentration
NS	normal saline solution (0.9% sodium chloride solution); neurosurgery	PH	past history; personal history; pinhole; poor health; pubic hair; public health
NSAID	nonsteroidal antiinflammatory drug	PHx	past history
NSR	normal sinus rhythm	PharmD	Doctor of Pharmacy
NSS	normal saline solution	PID	pelvic inflammatory disease
NTG	nitroglycerin	PJD	<i>Pneumocystis jirovecii</i> pneumonia (also known as <i>Pneumocystis carinii</i> pneumonia)
NT/ND	nontender, nondistended	PKU	phenylketonuria
NVD	nausea/vomiting/diarrhea; neck vein distension; neovascularization of the disk; neurovesicle dysfunction; nonvalvular disease	PMH	past medical history
N&V	nausea and vomiting	PMI	past medical illness; point of maximal impulse
NYHA	New York Heart Association	PMN	polymorphonuclear leukocyte
O&P	ova and parasites	PMS	premenstrual syndrome
OA	osteoarthritis	PND	paroxysmal nocturnal dyspnea
OB	obstetrics	Po	by mouth (<i>per os</i>)
OCD	obsessive-compulsive disorder	Po ₂	partial pressure of oxygen
OD	right eye (<i>oculus dexter</i>)	POAG	primary open-angle glaucoma
OGTT	oral glucose tolerance test	POD	postoperative day
OPV	Oral poliovirus vaccine	PPBG	postprandial blood glucose
OR	operating room	ppd	packs per day
OR×1	oriented to time	PPI	proton pump inhibitor
OR×2	oriented to time and place	PPN	peripheral parenteral nutrition
OR×3	oriented to time, place, and person	PR	per rectum
OS	left eye (<i>oculus sinister</i>)	PRBC	packed red blood cell
OSA	obstructive sleep apnea		
OT	occupational therapy		
OTC	over the counter		
OU	each eye (<i>oculus uterque</i>)		

PRERLA	pupils round, equal, react to light and accommodation	RSV	respiratory syncytial virus
PRN	when necessary, as needed (<i>pro re nata</i>)	RT	radiation therapy
PSA	prostate-specific antigen	RUE	right upper extremity
PSH	past surgical history	RUL	right upper lobe
PST	paroxysmal supraventricular tachycardia	RUQ	right upper quadrant
PSVT	paroxysmal supraventricular tachycardia	RVH	right ventricular hypertrophy
PT	prothrombin time; physical therapy; patient	S ₁	first heart sound
PTA	prior to admission; percutaneous transluminal angioplasty	S ₂	second heart sound
PTCA	percutaneous transluminal coronary angioplasty	S ₃	third heart sound (ventricular gallop)
PTE	pulmonary thromboembolism	S ₄	fourth heart sound (atrial gallop)
PTH	parathyroid hormone	SA	sinoatrial
PTSD	posttraumatic stress disorder	SABA	short-acting beta agonist
PTT	partial thromboplastin time	SAD	seasonal affective disorder
PUD	peptic ulcer disease	SAH	subarachnoid hemorrhage
PVC	premature ventricular contraction	SaO ₂	arterial oxygen percent saturation
PVD	peripheral vascular disease	SBE	subacute bacterial endocarditis
PVR	peripheral vascular resistance	SBFT	small bowel follow-through
PVT	paroxysmal ventricular tachycardia	SBGM	self-blood glucose monitoring
q	every (<i>quaque</i>)	SBO	small bowel obstruction
QA	quality assurance	SBP	systolic blood pressure
qday	every day (<i>quaque die</i>)	SC	subcutaneous; subclavian
QI	quality improvement	SCr	serum creatinine
qid	four times daily (<i>quater in die</i>)	SEM	systolic ejection murmur
QNS	quantity not sufficient	SG	specific gravity
qod	every other day	SGOT (AST)	serum glutamic oxaloacetic transaminase (aspartate transaminase)
QOL	quality of life	SGPT (ALT)	serum glutamic pyruvic transaminase (alanine transaminase)
QS	quantity sufficient	SH	social history
QTc	corrected QT interval	SIADH	syndrome of inappropriate antidiuretic hormone secretion
R&M	routine and microscopic	SIDS	sudden infant death syndrome
R&R	rate and rhythm	SJS	Stevens-Johnson syndrome
RA	rheumatoid arthritis; right atrium	SL	sublingual
RAAS	renin-angiotensin-aldosterone system	SLE	systemic lupus erythematosus
RBC	red blood cell	SMA-6	sequential multiple analyzer for sodium, potassium, CO ₂ , chloride, glucose, and BUN
RCA	right coronary artery	SMA-7	sequential multiple analyzer for sodium, potassium, CO ₂ , chloride, glucose, BUN, and creatinine
RCM	right costal margin	SMA-12	sequential multiple analyzer for glucose, BUN, uric acid, calcium, phosphorous, total protein, albumin, cholesterol, total bilirubin, alkaline phosphatase, SGOT, and LDH
RDA	Recommended Daily Allowance	SMA-23	includes the entire SMA-12 plus sodium, potassium, CO ₂ , chloride, direct bilirubin, triglyceride, SGPT, indirect bilirubin, R fraction, and BUN/creatinine ratio
RDS	respiratory distress syndrome	SMBG	self-monitoring of blood glucose
RDW	red blood cell distribution width	SNF	skilled nursing facility
REM	rapid eye movement; recent event memory	SNS	sympathetic nervous system
RES	reticuloendothelial system	SOB	shortness of breath; see order book; side of bed
RF	rheumatoid factor; renal failure; rheumatic fever	S/P	status post
Rh	rhesus factor in blood	SPF	sun protection factor
RHD	rheumatic heart disease	SQ	subcutaneous
RLE	right lower extremity		
RLL	right lower lobe		
RLQ	right lower quadrant		
RML	right middle lobe		
RN	Registered Nurse		
RNA	ribonucleic acid		
R/O	rule out		
ROM	range of motion		
ROS	review of systems		
RPh	Registered Pharmacist		
RR	respiratory rate; recovery room		
RRR	regular rate and rhythm		
RRT	Registered Respiratory Therapist		

SSKI	saturated solution of potassium iodide	TOD	target organ damage
SSRI	selective serotonin reuptake inhibitor	TPN	total parenteral nutrition
STAT	immediately; at once	TPR	temperature, pulse, respiration
STEMI	ST-segment elevated myocardial infarction	T PROT	total protein
STD	sexually transmitted disease	TSH	thyroid-stimulating hormone
SV	stroke volume	TURP	transurethral resection of the prostate
SVC	superior vena cava	Tx	treat, treatment
SVRI	systemic vascular resistance index	UA	urinalysis, uric acid
SVR	supraventricular rhythm; systemic vascular resistance	UC	ulcerative colitis
		UE	upper extremity
SVT	supraventricular tachycardia	UFH	unfractionated heparin
SW	social worker	UGI	upper gastrointestinal
Sx	signs	UOQ	upper outer quadrant
T	temperature	UPT	urine pregnancy test
T ₃	triiodothyroxine	URI	upper respiratory infection
T ₄	thyroxine	USP	United States Pharmacopeia
T&A	tonsillectomy and adenoidectomy	UTI	urinary tract infection
T&C	type and crossmatch	UV	ultraviolet
TB	tuberculosis	VF	ventricular fibrillation
TBG	thyroid-binding globulin	VLDL	very low-density lipoprotein
TBI	total-body irradiation; traumatic brain injury	VO	verbal order
TBW	total body weight	VOD	veno-occlusive disease
T bili	total bilirubin	V _A /Q	ventilation-perfusion
TCA	tricyclic antidepressant	VRE	vancomycin-resistant <i>Enterococcus</i>
TCN	tetracycline	VS	vital signs
Tdap	tetanus, diphtheria, acellular pertussis vaccine	VSS	vital signs stable
		VT	ventricular tachycardia
TEE	transesophageal echocardiogram	VTE	venous thromboembolism
TFT	thyroid function test	WA	while awake
TG	triglyceride	WBC	white blood cell (count)
TIA	transient ischemic attack	W/C	wheelchair
TIBC	total iron-binding capacity	WDWN	well-developed, well-nourished
tid	three times daily (<i>ter in die</i>)	WHO	World Health Organization
TLC	therapeutic lifestyle changes	WNL	within normal limits
TMJ	Temporomandibular joint	W/U	workup
TMP-SMX	trimethoprim-sulfamethoxazole	yo	year old
TNTC	too numerous to count	y	year

This page intentionally left blank

Appendix D: Glossary

- Acanthosis nigricans:** Increased thickness and hyperpigmentation of the outer cell layers of the skin; typically observed at areas of flexure.
- Acaricide:** A chemical that kills mites and ticks.
- Acetaldehyde:** Metabolic by-product of alcohol; hepatotoxic.
- Acetylcholine:** Neurotransmitter responsible for transmitting messages between certain nerve cells in the brain.
- Achalasia:** Disorder in which the esophageal sphincter is impaired, preventing normal swallowing and often causing reflux of contents and a feeling that something is caught in the throat.
- Achlorhydria:** Absence of free hydrochloric acid in the stomach.
- Acidemia:** An increase in the hydrogen ion concentration of the blood or a fall below normal in pH.
- Acidosis:** Any pathologic state that leads to acidemia.
- Acinar cells:** Exocrine glands of the pancreas that secrete digestive enzymes.
- Acromegaly:** A pathologic condition characterized by excessive production of growth hormone during adulthood after epiphyseal (long bone) fusions have completed.
- Action potential:** A rapid change in the polarity of the voltage of a cell membrane from negative to positive and back to negative; a wave of electrical discharge that travels across a cell membrane.
- Acute coronary syndromes:** Ischemic chest discomfort at rest most often accompanied by ST-segment elevation, ST-segment depression, or T-wave inversion on the 12-lead electrocardiogram; further, it is caused by plaque rupture and partial or complete occlusion of the coronary artery by thrombus. Acute coronary syndromes include myocardial infarction and unstable angina. Former terms used to describe types of acute coronary syndromes include Q-wave myocardial infarction, non-Q-wave myocardial infarction, and unstable angina.
- Acute disorder:** An acid-base disturbance that has been present for minutes to hours.
- Acute kidney injury:** Spectrum of acute changes in kidney function ranging from minor changes to those requiring renal replacement therapy.
- Acute otitis media:** Inflammation of the middle ear accompanied by fluid in the middle ear space and signs or symptoms of an acute ear infection.
- Acute tubular necrosis:** Form of acute kidney injury that results from toxic or ischemic injury to the cells in the proximal tubule of the kidney.
- Adenoma:** A nonmalignant tumor of the epithelial tissue that is characterized by glandular structures.
- Adenomatous polyposis coli gene:** A tumor suppressor gene (see definition) that is one of the first genes mutated in the development of colon cancer. Patients with familial adenomatous polyposis are born with this gene mutated.
- Adjuvant chemotherapy:** Treatment given after the primary treatment that is designed to eliminate any remaining cancer cells that are undetectable with the goal of improving survival. Adjuvant therapy for cancer usually refers to surgery followed by chemotherapy or radiation.
- Adjuvant therapy:** Treatment which follows the primary modality with the intent of reducing the risk of disease relapse and prolonging survival. The ultimate goal is to cure patients who would not otherwise be cured by the primary modality alone.
- Adnexal:** Adjacent or appending as the fallopian tubes and ovaries are to the uterus.
- Adrenalectomy:** Surgical removal of an adrenal gland.
- Adrenocorticotrophic hormone:** A hormone secreted by the anterior pituitary that controls secretion of cortisol from the adrenal glands. Also referred to as corticotropin.
- Adverse drug reaction:** Any unexpected, unintended, undesired, or excessive response to a medication that may require discontinuing the medication, changing the medication, or modifying the dose (except for minor dosage adjustments); necessitates admission to the hospital; prolongs stay in a healthcare facility; necessitates supportive treatment; significantly complicates diagnosis; negatively affects prognosis; or results in temporary or permanent harm, disability, or death.
- Aeroallergen:** An airborne substance that causes an allergic response.
- Afterload:** The force against which a ventricle contracts that is contributed to by the vascular resistance, especially of the arteries, and by the physical characteristics (mass and viscosity) of the blood.
- Ageism:** Discrimination against aged persons.

- Air embolus:** An obstruction in a small blood vessel caused by air that is introduced into a blood vessel and is carried through the circulation until it lodges in a smaller vessel.
- Aldosterone:** A hormone produced in and secreted by the zona glomerulosa of the adrenal cortex. Aldosterone acts on the kidneys to reabsorb sodium and excrete potassium. It is also a part of the renin-angiotensin-aldosterone system that regulates blood pressure and blood volume.
- Alkalemia:** A decrease in the hydrogen ion concentration of the blood or a rise above normal in pH.
- Alkalosis:** Any pathologic state that leads to alkalemia.
- Allogeneic:** A transplant taking cells from one person and donating them to another.
- Allogeneic HSCT:** In the setting of stem cell transplantation, the scenario in which the donor is genetically similar but not identical to the recipient. The donor is usually a sibling or a matched related donor.
- Allograft:** Tissue or organ transplanted from a donor of the same species but different genetic makeup; recipient's immune system must be suppressed to prevent rejection of the graft.
- Allograft survival:** After the transplant procedure, when the transplanted organ continues to have some degree of function, from excellent to poor.
- Alloreognition:** Recognition of the foreign antigens present on the transplant organ or the donor's antigen presenting cells.
- Alopecia:** Hair loss.
- Amenorrhea:** Abnormal cessation or absence of menses.
- Ampulla of Vater:** Dilation of the duodenal wall at the opening of the fused pancreatic and common bile ducts.
- Amyloid:** Any of a group of chemically diverse proteins which are composed of linear nonbranching aggregated fibrils.
- Anaphylactic/anaphylaxis:** Immediate, severe, potentially fatal hypersensitivity reaction induced by an antigen.
- Anaphylactoid:** An anaphylactic-like reaction, similar in signs and symptoms but not mediated by IgE. The drug causing this reaction produces direct release of inflammatory mediators by a pharmacologic effect.
- Anastomosis:** The connection of two hollow organs to restore continuity after resection.
- Androgen:** A steroid hormone, such as testosterone or androsterone, that controls the development and maintenance of masculine characteristics.
- Anemia:** A reduction below normal in the concentration of hemoglobin in the body that results in a reduction of the oxygen-carrying capacity of the blood.
- Anemia of chronic kidney disease:** A decline in red blood cell production caused by a decrease in erythropoietin production by the progenitor cells of the kidney. As kidney function declines in chronic kidney disease, erythropoietin production also declines, resulting in decreased red blood cell production. Other contributing factors include iron deficiency and decreased red blood cell life span caused by uremia.
- Energy:** A reduction or lack of an immune response to a specific antigen.
- Angina:** Discomfort in the chest or adjacent areas caused by decreased blood and oxygen supply to the myocardium (myocardial ischemia).
- Angina pectoris:** Severe constricting pain in the chest, often radiating from the precordium to a shoulder (usually left) and down the arm, due to ischemia of the heart muscle usually caused by a coronary disease.
- Angioedema:** Swelling similar to urticaria (hives), but the swelling occurs beneath the skin instead of on the surface. Angioedema is characterized by deep swelling around the eyes and lips and sometimes of the hands and feet. If it proceeds rapidly, it can lead to airway obstruction and suffocation, and it should therefore be treated as a medical emergency.
- Angiogenesis:** The formation of new blood vessels; tumors require angiogenesis to grow and spread. Antiangiogenesis drugs attempt to block this process, thereby preventing tumor growth.
- Angiography:** Examination of the blood vessels using x-rays after injection of a radiopaque substance.
- Anorexia:** The loss of appetite, especially as a result of disease.
- Antiangiogenic:** Preventing or inhibiting the formation and differentiation of blood vessels.
- Anticoagulant:** Any substance that inhibits, suppresses, or delays the formation of blood clots. These substances occur naturally and regulate the clotting cascade. Several anticoagulants have been identified in a variety of animal tissues and have been commercially developed for medicinal use.
- Antimicrobial prophylaxis:** Use of an antimicrobial to prevent an infection.
- Antiproteinase:** A substance that inhibits the enzymatic activity of a proteinase.
- Anuria:** Urine output of less than 50 mL over 24 hours.
- Apoptosis:** Programmed cell death as signaled by the nuclei in normally functioning cells when age or state of cell health and condition dictates.
- Arcuate scotoma:** An arc-shaped area of blindness in the field of vision.
- Arthrocentesis:** Puncture and aspiration of a joint. Certain drugs can be injected into the joint space for a local effect.
- Arthus reaction:** Local inflammatory response due to deposition of immune complexes in tissues.
- Articular:** Related to a joint or joints.
- Ascites:** Accumulation of fluid within the peritoneal cavity.
- Asterixis:** A flapping tremor of the arms and hands that is seen in patients with end-stage liver disease.
- Astringent:** A substance that causes tissues to constrict, resulting in a drying effect of the skin.
- Atelectasis:** Decreased or absent air in a partial or entire lung, with resulting loss of lung volume.
- Atherosclerosis:** Accumulation of lipids, inflammatory cells, and cellular debris in the subendothelial space of the arterial wall.
- Atopy:** A genetic predisposition to develop type I hypersensitivity reactions against common environmental antigens. Commonly seen in patients with allergic rhinitis, asthma, and atopic dermatitis.

- Atresia:** Congenital absence of a normal opening or normally patent lumen.
- Attenuate:** Render less virulent.
- Auto-induction:** The process of a drug increasing or inducing its own metabolism.
- Autologous:** A transplant using one's own stem cells.
- Autologous HSCT:** In the setting of stem cell transplantation, the scenario in which the donor and recipient are the same person.
- Automaticity:** Ability of a cardiac fiber or tissue to spontaneously initiate depolarizations.
- Azoospermic:** Having no living spermatozoa in the semen, or failure of spermatogenesis.
- B2 microglobulin:** A low-molecular-weight protein that may be elevated in multiple myeloma.
- Bacille Calmette-Guérin:** A tuberculosis vaccine prepared from an attenuated strain of the closely related species *Mycobacterium bovis*, used for immunization against tuberculosis in many countries, but not in the United States.
- Bacteriuria:** Presence of bacteria in urine.
- Barium enema:** A diagnostic test using an x-ray examination to view the lower gastrointestinal tract (colon and rectum) after rectal administration of barium sulfate, a chalky liquid contrast medium.
- Barrett's esophagus:** Disorder in which the cells of the lower esophagus are damaged, most often a result of long-standing reflux.
- Bence-Jones proteins:** Free light chains of immunoglobulins found in the urine.
- Bilateral salpingo-oophorectomy:** Surgical excision (removal) of both ovaries.
- Bile acids:** The organic acids in bile. Bile is the yellowish-brown or green fluid secreted by the liver and discharged into the duodenum where it aids in the emulsification of fats, increases peristalsis, and retards putrefaction; contains sodium glycocholate and sodium taurocholate, cholesterol, biliverdin and bilirubin, mucus, fat, lecithin, and cells and cellular debris.
- Biliary sludge:** A deposit of tiny stones or crystals made up of cholesterol, calcium bilirubinate, and other calcium salts. The cholesterol and calcium bilirubinate crystals in biliary sludge can lead to gallstone formation.
- Biopsy:** A procedure that involves obtaining a tissue specimen for microscopic analysis to establish a precise diagnosis.
- Bladder hypotonicity:** Inability of the detrusor muscle of the bladder to contract when the bladder is full.
- Blast:** An immature cell.
- Blastopore:** A fungal spore produced by budding.
- Blood dyscrasias:** Any abnormality in the blood or bone marrow's cellular components such as low white or red blood cell count or low platelets.
- Blood urea nitrogen (BUN):** A waste product in the blood produced from the breakdown of dietary proteins. The kidneys filter blood to remove urea and maintain homeostasis; a decline in kidney function results in an increase in BUN.
- Body mass index:** A calculation utilized to correct weight changes for height and is a direct calculation regardless of gender. It is the result of the weight in kilograms divided by the height in meters squared. If nonmetric measurements are used, it is the result of the weight in pounds multiplied by 703 and then that quantity divided by the product of height in inches squared.
- Bone remodeling:** The constant process of bone turnover involving bone resorption followed by bone formation.
- Bouchard's nodes:** Hard, bony enlargement of the proximal interphalangeal (middle) joint of a finger or toe.
- Brachial plexus:** Collection of nerves that arises from the spine at the base of the neck from nerves that supply parts of the shoulder, arm, forearm, and hand.
- Brachytherapy:** A procedure in which radioactive material sealed in needles, seeds, wires, or catheters is placed directly into or near a tumor. Also called internal radiation, implant radiation, or interstitial radiation therapy.
- Bronchiectasis:** Chronic condition of one or more bronchi or bronchioles marked by irreversible dilatation and destruction of the bronchial walls.
- Bronchoalveolar lavage:** Diagnostic procedure in which a scope is passed through the nose or mouth into the lungs and fluid is squirted into an area of lung, then recollected for examination.
- Bullectomy:** Surgical removal of one or more bullae (air spaces in the lung measuring more than 1 cm in diameter in the distended state).
- Bursitis:** An inflammation of the bursa, the fluid-filled sac near the joint where tendons and muscles pass over bone.
- Cachexia:** Weight loss, wasting of muscle, loss of appetite, and general debility that can occur with cancer. Anorexia may or may not be present.
- Capillary leak:** Loss of intravascular volume into the interstitial space within the body.
- Carcinoembryonic antigen:** A protein normally seen during fetal development. When elevated in adults, it suggests the presence of colorectal and other cancers. Normal level range is less than 2.5 ng/mL (less than 2.5 mcg/L) in nonsmokers but can be elevated in smokers and other nonmalignant conditions such as pancreatitis.
- Carcinogenesis:** Production or origin of cancer.
- Carcinoma:** A malignant growth that arises from epithelium, found in skin or the lining of body organs. Carcinomas tend to infiltrate into adjacent tissue and spread to distant organs.
- Carcinomatosis:** Condition of having widespread dissemination of carcinoma (cancer) in the body.
- Cardiac cachexia:** Physical wasting with loss of weight and muscle mass caused by cardiac disease; a wasting syndrome that causes weakness and a loss of weight, fat, and muscle.
- Cardiac index:** Cardiac output normalized for body surface area (cardiac index = cardiac output/body surface area).
- Cardiac output:** The volume of blood ejected from the left side of the heart per unit of time [cardiac output (L/min) = stroke volume × heart rate].
- Cardiac remodeling:** Genome expression resulting in molecular, cellular, and interstitial changes and manifested

- clinically as changes in size, shape, and function of the heart resulting from cardiac load or injury.
- Carotid:** The two main arteries in the neck.
- Carotid bruit:** Abnormal sound heard when auscultating a carotid artery caused by turbulent blood flow usually due to the presence of atherosclerotic plaques.
- Carotid intima-media thickness:** A measurement of the surface between the intima and media. This is a well-validated measure of the progression of atherosclerosis. Increasing measurements over time correlate with increasing atherosclerosis, whereas a decrease in the measurement is indicative of atherosclerotic regression.
- Caseating granulomas:** A central soft, dry, crumbly cheeselike necrotic mass bordered by giant multinucleated cells, and surrounded by epithelioid cell aggregates, lymphocytes, and fibroblasts.
- Cavitary lesions:** A spherical, air-containing lesion found on radiograph or computer tomography. The lesion usually has a thick wall and can be found within an area of a surrounding infiltrate or mass.
- CCR5 inhibitor:** A drug that prevents the binding of HIV to the coreceptor CCR5 on the host cell surface, thereby inhibiting viral entry into the cell.
- Cephalic:** Of or relating to the head.
- Cervicitis:** Inflammation of the cervix.
- Chemoprevention:** The use of drugs, vitamins, or other agents to reduce the risk of, or delay the development or recurrence of, cancer.
- Chemoreceptor trigger zone:** Located in the area postrema of the fourth ventricle of the brain, it is exposed to cerebrospinal fluid and blood and is easily stimulated by circulating toxins to induce nausea and vomiting.
- Chemosis:** Edema of the bulbar conjunctiva.
- Cheyne-Stokes respiration:** Pattern of breathing with gradual increase in depth (and sometimes in rate) to a maximum, followed by a decrease resulting in apnea; the cycles ordinarily are 30 seconds to 2 minutes in duration, with 5 to 30 seconds of apnea.
- Chimeric:** Composed of parts from different origins.
- Chloasma:** Melasma characterized by irregularly shaped brown patches on the face and other areas of the skin, often seen during pregnancy or associated with the use of oral contraceptives.
- Cholecystitis:** Inflammation of the gallbladder.
- Cholelithiasis:** Formation of stones in the gallbladder.
- Cholestasis:** Reduced or lack of flow of bile, or obstruction of bile flow.
- Cholesteatoma:** A mass of keratinized epithelial cells and cholesterol resembling a tumor that forms in the middle ear or mastoid region.
- Cholinesterase inhibitors:** A class of medications used in the treatment of Alzheimer's disease which prevent the breakdown of acetylcholine.
- Chronic disorder:** An acid-base disturbance that has been present for hours to days.
- Chronic kidney disease:** A progressive, irreversible decline in kidney function that occurs over a period of several months to years.
- Chronic stable angina:** Manifestation of ischemic heart disease that typically results when an atherosclerotic plaque progresses to occlude at least 70% of a major coronary artery. Patients typically present with a sensation of chest pressure or heaviness that is provoked by exertion and relieved with rest or sublingual nitroglycerin.
- Chronotropic:** Pertaining to the heart rate.
- Chvostek's sign:** A tap on the patient's facial nerve adjacent to the ear produces a brief contraction of the upper lip, nose, or side of the face.
- Chylothorax:** The presence of lymphatic fluid (chyle) in the pleural cavity.
- Circulatory shock:** A condition wherein the circulatory system is inadequately supplying oxygen and vital metabolic substrates to cells throughout the body.
- Cirrhosis:** Progressive scarring of the liver resulting in nonfunctional hepatocytes.
- Clinical cure:** Resolution of signs and symptoms of a disease.
- Clonal expansion:** An immunologic response in which lymphocytes stimulated by antigen proliferate and amplify the population of relevant cells.
- Closed comedo:** A plugged follicle of sebum, keratinocytes, and bacteria that remains beneath the surface of the skin. Also referred to as a "whitehead."
- Clotting cascade:** A series of enzymatic reactions by clotting factors leading to the formation of a blood clot. The clotting cascade is initiated by several thrombogenic substances. Each reaction in the cascade is triggered by the preceding one and the effect is amplified by positive feedback loops.
- Clotting factor:** Plasma proteins found in the blood that are essential to the formation of blood clots. Clotting factors circulate in inactive forms but are activated by their predecessor in the clotting cascade or a thrombogenic substance. Each clotting factor is designated by a Roman numeral (e.g., Factor VII) and by the letter "a" when activated (e.g., Factor VIIa).
- Clubbing:** Proliferation of soft tissues, especially in the nail bed, which results in thickening and widening of finger and toe extremities.
- Coalescence:** Fusion of smaller lipid emulsion particles forming larger particles, resulting in destabilization of the emulsion.
- Coitus:** Sexual intercourse.
- Collateral damage:** Use of an antimicrobial agent that leads to an increase in colonization and infections with multidrug-resistant organisms in a population setting.
- Colloids:** Intravenous fluids composed of water and large-molecular-weight molecules used to increase volume in patients with hypovolemic shock via increased intravascular oncotic pressure.
- Colon cancer:** A disease in which cells in the lining of the colon become malignant and proliferate without control. Often referred to as colorectal cancer to include cancer cells found in the rectum.
- Colonoscopy:** A visual examination of the colon using a lighted, lens-equipped, flexible tube (colonoscope) inserted into the rectum.

- Colony-forming units:** The number of microorganisms that form colonies when cultured and is indicative of the number of viable microorganisms in a sample.
- Combined modality:** Use of two or more different treatment strategies such as systemic chemotherapy (i.e., cyclophosphamide plus doxorubicin; recently, non-anthracycline-containing regimens have also been shown to be effective) plus radiation to “consolidate” local-regional control of the tumor, and surgery such as modified radical mastectomy (breast conserving surgery has been performed with good results but established guidelines are limited by small numbers, lack of randomized trials, and absence of long-term follow-up).
- Comedolytic:** An agent that is able to break up or destroy a comedo.
- Comorbidities:** Multiple disease states occurring concurrently in one patient.
- Compartment syndrome:** The compression of nerves and blood vessels within an enclosed space.
- Complete remission:** Disappearance of all previously identifiable disease.
- Complete response:** In cancer, disappearance of all targeted lesions.
- Complex regimen:** Taking medications 3 or more times per day, or 12 or more doses per day.
- Complicated disorder:** The presence of two or more distinct acid-base disorders.
- Congenital adrenal hyperplasia:** A rare inherited condition resulting from a deficiency in cortisol and aldosterone synthesis with resulting excess androgen production. The clinical presentation depends on the variant of the condition but typically manifests as abnormalities in sexual development and/or adrenal insufficiency.
- Conjunctivitis:** Inflammation of the conjunctiva.
- Conjunctivitis medicamentosa:** A drug-induced form of allergic conjunctivitis resulting from overuse of topical ocular vasoconstrictors.
- Consolidation:** A type of high-dose chemotherapy given as the second phase (after induction) of a treatment regimen for leukemia.
- Contiguous:** Describes two structures that are in close contact, or located next to each other.
- Convection:** The movement of dissolved solutes across a semipermeable membrane by applying a pressure gradient to the fluid transport.
- Convulsion:** Uncontrolled muscle movement that may or may not result from abnormal electrical activity in the brain.
- Cor pulmonale:** Right-sided heart failure caused by lung disease.
- Corneal arcus:** Accumulation of lipid on the cornea.
- Coronary artery bypass graft:** Surgical intervention to improve coronary blood flow by removing a vein from the leg and attaching one end to the aorta and the other end to the coronary artery distal to the atherosclerotic plaque. Alternatively, an artery from the inside of the chest wall may be used to bypass the coronary occlusion.
- Coronary artery disease:** Narrowing of one or more of the major coronary arteries, most commonly by atherosclerotic plaques. May be referred to as coronary heart disease.
- Coronary heart disease:** Narrowing of one or more of the major coronary arteries, most commonly by atherosclerotic plaques. May be referred to as coronary artery disease.
- Corpus luteum:** The small yellow endocrine structure that develops within a ruptured ovarian follicle and secretes progesterone and estrogen.
- Corticotropin-releasing hormone:** A hormone released by the hypothalamus that stimulates release of adrenocorticotropic hormone by the anterior pituitary gland.
- Cortisol:** An adrenal gland hormone responsible for maintaining homeostasis of carbohydrate, protein, and fat metabolism.
- Cosyntropin:** A synthetic version of adrenocorticotropic hormone.
- Counterirritant:** A substance that elicits a superficial inflammatory response with the objective of reducing inflammation in deeper, adjacent structures.
- Creaming:** Aggregation of lipid emulsion particles that then migrate to the surface of the emulsion; can be reversed with mild agitation.
- Creatine kinase, creatine kinase myocardial band:** Creatine kinase (CK) enzymes are found in many isoforms, with varying concentrations depending on the type of tissue. Creatine kinase is a general term used to describe the nonspecific total release of all types of CK, including that found in skeletal muscle (MM), brain (BB), and heart (MB). Creatine kinase MB is released into the blood from necrotic myocytes in response to infarction and is a useful laboratory test for diagnosing myocardial infarction. If the total CK is elevated, then the relative index (RI), or fraction of the total that is composed of CK-MB, is calculated as follows:
- $$RI = (CK-MB/CK \text{ total}) \times 100$$
- A RI greater than 2 is typically diagnostic of infarction.
- Creatinine:** A waste product in the blood produced from the breakdown of protein by-products generated by muscle in the body or ingested in the diet. The kidneys filter blood to remove creatinine and maintain homeostasis; a decline in kidney function results in an increase in creatinine.
- Creatinine clearance:** Rate at which creatinine is filtered across the glomerulus; estimate of glomerular filtration rate.
- Crepitus:** A grating sound or sensation typically produced by friction between bone-on-cartilage or bone-on-bone contact.
- Cross-allergenicity:** Sensitivity to one drug and then reacting to a different drug with a similar chemical structure.
- Crypt abscess:** Neutrophilic infiltration of the intestinal glands (Crypts of Lieberkuhn); a characteristic finding in patients with ulcerative colitis.
- Crystalloids:** Intravenous fluids composed of water and electrolytes (e.g., sodium chloride, etc.) used as intravascular volume expanders for patients with hypovolemic shock.

- Culture-negative IE:** Implies acute endocardial damage with negative blood cultures. It is common in patients treated with antibiotics before blood cultures are obtained.
- Cure:** Disease-free period, which may vary by tumor type or disease state, exceeding an arbitrary duration of time. For breast cancer, this period exceeds 15 years from the end of treatment; for acute leukemia, the period is 5 years. [Note: By this definition, dormant viable tumor cells may still be present even in patients who are deemed cured.]
- Cutis laxa:** Hyporeflexivity of the skin with loss of elasticity.
- Cyanosis:** Bluish discoloration of the skin and mucous membranes due to lack of oxygenation.
- Cyclic citrullinated peptide:** A circular peptide (a ring of amino acids) containing the amino acid citrulline. Auto-antibodies directed against cyclic citrullinated peptide provide the basis for a test of importance in rheumatoid arthritis.
- Cyclooxygenase:** An enzyme that catalyzes the conversion of arachidonic acid to prostaglandins and consists of two isoforms, generally abbreviated COX-1 and COX-2.
- Cystitis:** Inflammation of urinary bladder.
- Cystocele:** Hernial protrusion of the bladder, usually through the vaginal wall.
- Cytokines:** Regulatory proteins, such as interleukins and lymphokines, that are released by cells of the immune system and act as intercellular mediators in the generation of an immune response. Soluble glycoproteins released by the immune system which act through specific receptors to regulate immune responses.
- Cytomegalovirus (CMV) disease:** This is the term used when patients who are already infected with CMV present with the classic associated symptoms that resemble a viral infection and may include fever, malaise, arthralgias and others.
- Cytomegalovirus (CMV) infection:** This is the term used when a patient has anti-CMV antibodies in the blood, when CMV antigens are detected in infected cells, or when the virus is isolated from a culture.
- Deep vein thrombosis:** A disorder of thrombus formation causing obstruction of a deep vein in the leg, pelvis, or abdomen.
- Delirium:** Transient brain syndrome presenting as disordered attention, cognition, psychomotor behavior, and perception.
- Dementia:** Loss of brain function that occurs with certain diseases. It affects memory, thinking, judgment, and behavior.
- Dennie-Morgan line:** A line or fold below the lower eyelids; associated with atopy.
- Dermatophytes:** Any microscopic fungus that grows on the skin, scalp, nails, or mucosa but does not invade deeper tissues.
- Desensitization:** A method to reduce or eliminate an individual's negative reaction to a substance or stimulus.
- Desquamation:** Peeling or shedding of the epidermis (superficial layer of the skin) in scales or flakes.
- Detumescence:** The return of the penis to a flaccid state.
- Dialysate:** The physiologic solution used during dialysis to remove excess fluids and waste products from the blood.
- Dialysis:** The process of removing fluid and waste products from the blood across a semipermeable membrane to maintain fluid, electrolyte, and acid-base balance in patients with kidney failure.
- Diaphoresis:** Perspiration.
- Diarthrodial joint:** A freely moveable joint (e.g., knee, shoulder). Contrast with amphiarthrodial joint (a slightly movable joint; e.g., vertebral joint) and synarthrodial joint (an unmovable joint; e.g., fibrous joint).
- Diastolic dysfunction:** Abnormal filling of the ventricles during diastole.
- Diffusion:** The movement of a solute across the dialyzer membrane from an area of higher concentration (usually the blood) to a lower concentration (usually the dialysate).
- 2,3-Diphosphoglycerate:** A compound in red blood cells that affects oxygen binding to and release from hemoglobin.
- Direct current cardioversion:** The process of administering a synchronized electrical shock to the chest, the purpose of which is to simultaneously depolarize all of the myocardial cells, resulting in restoration of normal sinus rhythm.
- Directly observed therapy:** Directly observing patients while taking their anti-tuberculosis medication to ensure compliance.
- Disease-free survival:** Length of time after treatment during which no disease is found.
- Disease progression:** In cancer, at least a 20% increase in the sum of the longest diameter of target lesions from baseline, including new lesions discovered during treatment.
- Disseminated idiopathic skeletal hyperostosis:** Excessive bone formation at skeletal sites subject to stress, generally where tendons and ligaments attach to bone.
- DNA mismatch repair genes:** Genes that identify and correct errors in DNA base pairs during DNA replication. Mutations in the genes can lead to cancer by allowing abnormal cells to continue to grow.
- Down-regulation:** The process of reducing or suppressing a response to a stimulus.
- Drusen:** Tiny yellow or white deposits of extracellular material in the eye.
- Ductus arteriosus:** Shunt connecting the pulmonary artery to the aortic arch that allows most of the blood from the right ventricle to bypass fetal lungs.
- Duodenal:** The first of three parts of the small intestine.
- Dysarthria:** Speech disorder due to weakness or incoordination of speech muscles; speech is slow, weak, and imprecise.
- Dyslipidemia:** Elevation of the total cholesterol, low-density lipoprotein cholesterol, or triglyceride concentrations or a decrease in high-density lipoprotein cholesterol concentration in the blood.
- Dysmenorrhea:** Crampy pelvic pain occurring with or just prior to menses. "Primary" dysmenorrhea implies pain in the setting of normal pelvic anatomy, while "secondary" dysmenorrhea is secondary to underlying pelvic pathology.
- Dyspareunia:** Pain during or after sexual intercourse.
- Dysphagia:** Difficulty in swallowing.

- Dysphonia:** Impairment of the voice or difficulty speaking.
- Dysphoria:** An unhappy or depressed feeling.
- Dyspnea:** Shortness of breath or difficulty breathing.
- Dyssynergic defecation:** A lack of coordination between the pelvic floor muscles and the anal sphincter.
- Dysuria:** Difficulty or pain in urination.
- Ebstein's anomaly:** Congenital heart defect in which the opening of the tricuspid valve is displaced toward the apex of the right ventricle of the heart.
- Eburnation:** A condition in which bone or cartilage becomes hardened and denser.
- Ecchymosis:** Passage of blood from ruptured blood vessels into subcutaneous tissue causing purple discoloration of the skin.
- Ectopic pregnancy:** Presence of a fertilized ovum outside of the uterine cavity.
- Effector cells:** Cells that become active in response to initiation of the immune response.
- Ejection fraction:** The fraction of the volume present at the end of diastole that is pushed into the aorta during systole.
- Electrocardiogram:** A noninvasive recording of the electrical activity of the heart.
- Electroencephalogram:** A test that measures and records electrical activity in the brain.
- Embolectomy:** Surgical removal of a clot or embolism.
- Embolism:** The sudden blockage of a vessel caused by a blood clot or foreign material which has been brought to the site by the flow of blood.
- Embolization:** The process by which a blood clot or foreign material dislodges from its site of origin, flows in the blood, and blocks a distant vessel.
- Emesis:** See vomiting.
- Enderterectomy:** Removal of a thrombus from the carotid artery.
- Endometritis:** Inflammation of the endometrium.
- Endoscopic evaluation:** General term used to describe the visual inspection of the inside of hollow organs with an endoscope; used mainly for diagnostic purposes; refers to procedures such as gastroscopy, duodenoscopy, colonoscopy, sigmoidoscopy, and others.
- Endoscopy:** A diagnostic tool used to examine the inside of the body using a lighted, flexible instrument called an endoscope.
- Endothelial cell:** A single layer of cells surrounding the lumen of arteries.
- End-stage liver disease:** Liver failure that is usually accompanied by complications such as ascites or hepatic encephalopathy.
- Engraftment:** The process by which transplanted stem cells begin to grow and reproduce in the recipient to produce functioning leukocytes, erythrocytes, and platelets.
- Enteral nutrition:** Delivery of nutrients via the gastrointestinal tract, either by mouth or by feeding tube.
- Enterobacteriaceae:** A family of enteric gram-negative bacilli, e.g., *Escherichia coli* or *Klebsiella pneumoniae*.
- Enterocytes:** Cells lining the small intestine.
- Entesitis:** Inflammation of the sites where tendons, ligaments, or fascia attach to bone.
- Enuresis:** Incontinence at night.
- Enzyme-linked immunosorbent assay:** A solid phase in the form of a microtiter plate or bead to which HIV antigen is attached. The antigen may be either a preparation of lysed whole virus or a combination of recombinant viral antigens.
- Epilepsy:** The propensity for a patient to have repeated, unprovoked seizures.
- Epistaxis:** A nosebleed.
- Erectile dysfunction:** Condition defined as the inability to achieve or maintain an erection sufficient for sexual intercourse.
- Erythema multiforme:** A rash characterized by papular (small raised bump) or vesicular lesions (blisters), and reddening or discoloration of the skin often in concentric zones about the lesion.
- Erythematous:** Flushing of the skin caused by dilation of capillaries. Erythema is often a sign of inflammation and infection.
- Erythropoiesis stimulating agents:** Agents developed by recombinant DNA technology that have the same biologic activity as endogenous erythropoietin to stimulate erythropoiesis (red blood cell production) in the bone marrow. The currently available agents in the United States are epoetin alfa and darbepoetin alfa.
- Erythropoietin:** A hormone primarily produced by the progenitor cells of the kidney that stimulates red blood cell production in the bone marrow. Lack of this hormone leads to anemia.
- Esophageal varices:** Dilated blood vessels in the esophagus.
- Essential fatty acid deficiency:** Deficiency of linoleic acid, linolenic acid, and/or arachidonic acid, characterized by hair loss, thinning of skin, and skin desquamation. Long-chain fatty acids include trienes (containing 3 double-bonds [e.g., 5,8,11-eicosatrienoic acid {or Mead acid}, trienoic acids]) and tetraenes (containing 4 double-bonds [e.g., arachidonic acid]). Biochemical evidence of essential fatty acid deficiency includes a triene-to-tetraene ratio greater than 0.2 and low linoleic or arachidonic acid plasma concentrations.
- Euphoria:** A feeling of happiness and excitement.
- Event-free survival:** This term refers to the length of time after treatment that a person remains free of certain negative events.
- Evoked potential testing:** A procedure in which sensory nerve pathways are stimulated, and the time lapse to electrical response in the corresponding area of the brain is measured.
- Exanthem:** Eruption of the skin.
- Exfoliative dermatitis:** Severe inflammation of the entire skin surface due to a reaction to certain drugs.
- Exploratory laparotomy:** Surgical incision into the abdominal cavity, performed to examine the abdominal organs and cavity in search of an abnormality and diagnosis.
- External beam radiotherapy:** Treatment by radiation emitted from a source located at a distance from the body. Also called beam therapy and external beam therapy.
- Extra-abdominal:** Outside of the abdominal cavity.

Extraction ratio: Fraction of the drug entering the liver in the blood which is irreversibly removed.

Extrapyramidal symptoms: Adverse drug effects of medications such as phenothiazines; includes dystonia (involuntary muscle contractions), tardive dyskinesia (repetitive, involuntary movements), and akathisia (motor restlessness or anxiety).

Facultative: Biologic term meaning “optional.” A facultative intracellular pathogen can optionally survive intracellularly even if it is typically an extracellular pathogen.

Facultative anaerobe: An organism that makes adenosine triphosphate by aerobic respiration if oxygen is present, but switches to fermentation under anaerobic conditions.

Felty’s syndrome: An extraarticular manifestation of rheumatoid arthritis associated with splenomegaly and neutropenia.

Fibrin: An insoluble protein that is one of the principal ingredients of a blood clot. Fibrin strands bind to one another to form a fibrin mesh. The fibrin mesh often traps platelets and other blood cells.

Fibrinolysis: A normal ongoing process that dissolves fibrin and results in removal of small blood clots; hydrolysis of fibrin.

Fibroadenoma: A benign neoplasm which commonly occurs in breast tissue and is derived from glandular epithelium.

Fibrosis: Formation of tissue containing connective tissues formed by fibroblasts as part of tissue repair or as a reactive process.

Fistula: Abnormal connection between two internal organs (e.g., arteriovenous fistula is a connection between an artery and a vein), or between an internal organ and the exterior or skin (e.g., enterocutaneous fistula is a connection between the intestine and the skin).

Floppy iris syndrome: Alpha-adrenergic antagonists cause relaxation of the iris and papillary constriction. This complicates cataract surgery. Also known as the small pupil syndrome.

Flow cytometry: A technology used to study characteristics of individual cells in a suspension.

Fluorescence in situ hybridization: A laboratory technique used to look at genes or chromosomes in cells and tissues. Pieces of DNA that contain a fluorescent dye are made in the laboratory and added to cells or tissues on a glass slide. When these pieces of DNA bind to specific genes or areas of chromosomes on the slide, they light up when viewed under a microscope with a special light.

Foam cell: Lipid-laden white blood cell.

Forced expiratory volume in 1 second: The volume of air that a patient can blow out in the first second of forced exhalation after taking a maximal breath.

Forced vital capacity: The maximum volume of air that can be forcibly exhaled after taking a maximal breath.

Fragility fracture: A fracture resulting from a fall from standing height or less amount of trauma.

Frailty: Excess demand imposed on reduced capacity; a common biologic syndrome in the elderly.

Frank-Starling mechanism: One of the mechanisms by which the heart can increase cardiac output.

Fremitus: A palpable vibration, as felt by the hand placed on the chest during coughing or speaking.

Friable: Easily crumbled, pulverized, or reduced to powder.

Friction: Risk factor for pressure ulcers that is created when a patient is dragged across a surface, which can lead to superficial skin damage.

Fructooligosaccharides: Polymers of fructose that reach the colon undigested and are broken down there to short-chain fatty acids by bacterial enzymes.

Functional gastrointestinal disorder: A term used to describe symptoms occurring in the gastrointestinal tract in the absence of a demonstrated pathologic condition; the clinical product of psychosocial factors and altered intestinal physiology involving the brain–gut interrelationship.

Gadolinium: An intravenous contrast agent used with magnetic resonance imaging.

Gallstone (cholelithiasis): A solid formation in the gallbladder or bile duct composed of cholesterol and bile salts.

Gastrectomy: Surgical excision of part or all of the stomach.

Gastric bypass: A surgical procedure for weight loss that elicits its effectiveness through malabsorption and volume limitation. The procedure involves full partitioning of the proximal gastric segment into a jejunal loop.

Gastritis: Chronic or acute inflammation of the lining of the stomach.

Gastroenteritis: Inflammation of the gastrointestinal tract causing nausea, vomiting, diarrhea, and fever; sometimes referred to as the stomach flu although not related to influenza.

Gastroplasty: A surgical procedure for weight loss that elicits its effectiveness through gastric volume limitation. The procedure involves partial partitioning at the proximal gastric segment with the placement of a gastric outlet stoma of fixed diameter.

Gastroschisis: Inherited congenital abdominal wall defect in which the intestines and sometimes other organs develop outside the fetal abdomen through an opening in the abdominal wall.

Gastrostomy: Operative placement of a new opening into the stomach, usually associated with feeding tube placement.

Geniculate nucleus: The portion of the brain that processes visual information from the optic nerve and relays it to the cerebral cortex.

Genotype: The genetic constitution of an individual.

Geriatric syndrome: Age-specific presentations or differential diagnoses, including visual and hearing impairment, malnutrition and weight loss, urinary incontinence, gait impairment and falls, osteoporosis, dementia, delirium, sleep problems, and pressure ulcers; commonly seen conditions in elder patients.

Gigantism: A condition of abnormal size or overgrowth of the entire body or of any of its parts.

Glasgow Coma Scale: A scale for evaluating level of consciousness after central nervous system injury (evaluates eye opening and verbal and motor responsiveness).

- Glomerular filtration rate:** The volume of plasma that is filtered by the glomerulus per unit time, usually expressed as mL/min or mL/min/1.73 m², which adjusts the value for body surface area. This is the primary index used to describe overall renal function.
- Glomerulonephritis:** Glomerular lesions that are characterized by inflammation of the capillary loops of the glomerulus. These lesions are generally caused by immunologic, vascular or other idiopathic diseases. Leads to high blood pressure and possible loss of kidney function.
- Glutamate:** Primary excitatory neurotransmitter in the central nervous system involved in memory, learning, and neuronal plasticity.
- Gonioscopy:** Examination of the anterior chamber angle. A gonioscope or Goldman lens are used to perform gonioscopic evaluation.
- Graft versus host disease:** A complication of stem cell transplantation where the donor's cells attack the host's tissue.
- Graft versus tumor effect:** The phenomenon by which transplanted donor cells recognize host malignant cells as foreign and thus eradicate the malignant cells through immunologic mechanisms.
- Granulomas:** Unique inflammatory response composed of macrophages, giant cells and other cells of the immune response to wall off infectious pathogens perceived as foreign but cannot be eliminated.
- Gummatous:** A tumor of rubbery consistency that is characteristic of the tertiary stage of syphilis.
- Gut-associated lymphoid tissue:** Lymphoid tissue, including Peyer's patches, found in the gut that are important for providing localized immunity to pathogens.
- Haptation:** The process where a drug, usually of low molecular weight, is bound to a carrier protein or cell and becomes immunogenic.
- Health literacy:** Degree to which individuals have the capacity to obtain, process, and understand basic health information and services needed to make appropriate health decisions.
- Heberden's nodes:** Hard, bony enlargement of the distal interphalangeal (terminal) joint of a finger or toe.
- Hemarthrosis:** Blood in the joint space.
- Hematemesis:** The vomiting of blood.
- Hematochezia:** Bright red blood per rectum.
- Hematogenous:** Spread through the blood.
- Hematuria:** Presence of blood or red blood cells in urine.
- Hemiparesis:** Weakness on one side of the body.
- Hemisensory deficit:** Loss of sensation on one side of the body.
- Hemithorax:** A single side of the trunk between the neck and the abdomen in which the heart and lungs are situated.
- Hemoptysis:** The expectoration of blood or blood-tinged sputum from the larynx, trachea, bronchi, or lungs.
- Hemorrhagic conversion:** Conversion of an ischemic stroke into a hemorrhagic stroke.
- Hemostasis:** Cessation of bleeding through natural (clot formation or constriction of blood vessels), artificial (compression or ligation), or surgical means.
- Heparin-induced thrombocytopenia:** A clinical syndrome of IgG antibody production against the heparin-platelet factor 4 complex occurring in approximately 1% to 5% of patients exposed to either heparin or low-molecular-weight heparin. Heparin-induced thrombocytopenia results in excess production of thrombin, platelet aggregation, and thrombocytopenia (due to platelet clumping), often leading to venous and arterial thrombosis, amputation of extremities, and death.
- Hepatic encephalopathy:** Confusion and disorientation experienced by patients with advanced liver disease due to accumulation of ammonia in the bloodstream.
- Hepatic steatosis:** Accumulation of fat in the liver.
- Hepatocellular carcinoma:** Cancer of the liver.
- Hepatojugular reflex:** Distention of the jugular vein induced by pressure over the liver; it suggests insufficiency of the right heart.
- Hepatorenal syndrome:** Acute kidney injury resulting from decreased perfusion in cirrhosis.
- Hepatosplenomegaly:** An enlarged liver and spleen secondary to leukemic infiltration.
- Hepatotoxicity:** Toxicity to the liver causing damage to liver cells.
- Herniation:** Protrusion of the brain through the cranial wall.
- Heterotopic:** Placing a transplanted organ into an abnormal anatomic location.
- Heterozygous:** Having different alleles at a gene locus.
- Hirschsprung's disease:** A congenital abnormality where the ganglia in sections of the large intestine do not develop, resulting in chronic constipation and possibly obstruction; the severity of the condition can range from mild to severe.
- Hirsutism:** Excessive body and facial hair, especially in the female.
- Histocompatibility:** The examination of human leukocyte antigen differences between a donor and a recipient in order to determine if the recipient is more likely to accept, rather than reject, a graft from that particular donor.
- HIV genotype:** A type of resistance testing for HIV where a patient's blood sample is obtained, their HIV RNA is sequenced, and mutations that have developed which may confer resistance to antiretrovirals are reported.
- HIV phenotype:** A type of resistance testing for HIV where a patient's blood sample is obtained, and the patient's HIV genes that encode for reverse transcriptase and protease are removed and placed in an HIV viral vector. This viral vector is replicated in a cell culture system with varying concentrations of antiretrovirals. A drug concentration-viral inhibition curve is developed and the concentration needed to inhibit 50% of the patient's virus is reported. This is used to predict resistance versus susceptibility.
- HIV virtual phenotype:** A database of matching HIV genotypes and phenotypes is developed. When an HIV genotype for a patient is obtained, the database is used to predict the patient's phenotype based on their actual genotype using matches that occur in the database.
- Homeostenosis:** Impaired capability to withstand stressors and decreased ability to maintain physiologic and

- psychosocial homeostasis; a state commonly found in the elderly.
- Homozygous:** Having identical alleles at a gene locus.
- Hormone-receptor positive breast cancer:** Tumors that appear to grow in the presence of estrogens; likewise, anti-estrogen therapy or estrogen deprivation strategies lead to tumor regression.
- Hospice:** The provision of palliative care during the last 6 months of life as defined by federal guidelines.
- Hot flashes:** A feeling of warmth that is commonly accompanied by skin flushing and mild to severe perspiration.
- Human leukocyte antigens (HLA):** Groups of genes found on the major histocompatibility complex which contain cell-surface antigen presenting proteins. The body uses HLA to distinguish between self cells and nonself cells.
- Humoral:** Products secreted into the blood or body fluids.
- Hydramnios:** Increased amniotic fluid.
- Hyperalgesia:** An exaggerated intensity of pain sensation.
- Hypercalcemia:** Excessive amount of calcium in the blood.
- Hypercalciuria:** Excessive amount of calcium in the urine.
- Hypercapnia:** Abnormally high concentration of carbon dioxide in the blood.
- Hypercoagulable state:** A disorder or state of excessive or frequent thrombus formation; also known as thrombophilia.
- Hyperemesis gravidarum:** A rare disorder of severe and persistent nausea and vomiting during pregnancy that can result in dehydration, malnutrition, weight loss, and hospitalization.
- Hyperglycemic hyperosmolar nonketotic syndrome:** Severe increase in serum glucose concentration without the production of ketones, leading to an increase in serum osmolality and symptoms such as increased thirst, increased urination, weakness, fatigue, confusion, and in severe cases, convulsions and/or coma.
- Hyperopia:** Farsightedness.
- Hyperpigmentation:** A common darkening of the skin which occurs when an excess of melanin forms deposits in the skin.
- Hyperplasia:** An abnormal or unusual increase in the cells of a body part.
- Hyperprolactinemia:** A medical condition of elevated serum prolactin characterized by prolactin serum concentrations greater than 20 ng/mL (20 mcg/L) in men or 25 ng/mL (25 mcg/L) in women.
- Hypertrichosis:** Excessive growth of hair.
- Hypertrophy:** An increase in the size of the cells in a tissue or organ.
- Hypogammaglobinemia:** Reduced levels of antibodies.
- Hypogonadism:** A medical condition resulting from or characterized by abnormally decreased functional activity of the gonads, with retardation of growth and sexual development. Associated with testosterone deficiency resulting from either testicular or pituitary/hypothalamic diseases. Presenting symptoms differ according to the timing of disease onset in relation to puberty.
- Hypopituitarism:** A clinical disorder characterized by complete or partial deficiency in pituitary hormone production.
- Hypovolemic shock:** Circulatory shock caused by severe loss of blood volume and/or body water.
- Hypoxemia:** Deficiency of oxygen in the blood.
- Hysterectomy:** Excision of the uterus.
- Immune reconstitution inflammatory syndrome:** A condition in AIDS patients or other types of immunosuppression where paradoxical worsening of the infection is observed as the immune system begins to recover due to increasing inflammation at the site of infection.
- Immunogenicity:** The property that gives a particular substance the ability to provoke an immune response.
- Immunoglobulin G index:** The ratio of immunoglobulin G to protein in the serum or cerebrospinal fluid.
- Immunophenotype:** The process of identification and quantitation of cellular antigens through flourochrome-labeled monoclonal antibodies.
- Immunotherapy:** Treatment of a disease by stimulating the body's own immune system.
- Impedance pH monitoring:** Detects gastroesophageal reflux based on changes in resistance to electrical current flow between two electrodes when a liquid and/or gas bolus moves between them. It can detect both acid and nonacid reflux.
- Implantable cardioverter-defibrillator:** A device implanted into the heart transvenously with a generator implanted subcutaneously in the pectoral area that provides internal electrical cardioversion of ventricular tachycardia or defibrillation of ventricular fibrillation.
- Index patient:** The patient originally diagnosed with a disease.
- Indirect immunofluorescence assay:** HIV-infected T-lymphocytes are fixed onto a microscope slide, covered with the blood sample to be tested, incubated under heat, and washed. If antibodies to HIV are bound to the fixed viral antigens, they will remain on the slide. FITC-conjugated anti-human globulin is then added, incubated, and washed. If the sample contains antibodies to HIV, the cells will show a bright, fluorescent membrane under the microscope.
- Induction:** Treatment designed to be used as the first step in eliminating the leukemic burden.
- Infarction:** The formation of an infarct, an area of tissue death due to a local lack of oxygen.
- Initiation:** It occurs in cancer when a carcinogenic substance encounters a normal cell to produce genetic damage, and results in a mutated cell.
- Inotropic:** Relating to or influencing the force of muscular contractions.
- Insulin-like growth factor-I:** An anabolic peptide that acts as a direct stimulator of cell proliferation and growth in all body cells.
- Integrase strand transfer inhibitor:** A drug that prevents the enzyme integrase from allowing the HIV RNA to incorporate into the host cell genome.
- International normalized ratio (INR):** The ratio of the patient's clotting time to the clinical laboratory's mean

- reference value; normalized by raising it to the international sensitivity index (ISI) power to account for differences in thromboplastin reagents. Therefore: $INR = (\text{Patient's prothrombin time} / \text{laboratory's mean normal prothrombin time})^{ISI}$.
- Intima:** The inner layer of the wall of an artery or vein.
- Intraarticular:** Administered to or occurring in the space within joints.
- Intraabdominal:** Within the abdominal cavity.
- Intraperitoneal:** Within the peritoneal cavity.
- Intrathecal:** Within the meninges of the spinal cord.
- Intravenous pyelogram:** After intravenous administration of radiocontrast media, an x-ray of kidneys, ureters, bladder, and urethra is performed, which provides information on anatomic aspects (size, shape, location, axis) and function of these organs.
- Intravesicular:** Administration directly into the bladder through the urethra.
- Intussusception:** The prolapse of one part of the intestine into the lumen of an immediately adjoining part.
- Iontophoresis:** Introduction of a medication into tissue through use of an electric current.
- Ipsilateral:** Occurring on the same side.
- Ischemic heart disease:** Imbalance between myocardial oxygen supply and oxygen demand.
- Jejunal:** A section of the small intestine connecting the duodenum to the ileum.
- Jejunostomy:** Operative placement of a new opening into the jejunum, usually associated with feeding tube placement.
- Kegel exercises:** Specific exercises that strengthen the pelvic floor muscles and help to prevent and treat stress incontinence.
- Keratinization:** The sloughing of epithelial cells in the hair follicle.
- Keratinocyte:** The epidermal cell that synthesizes keratin; makes up 95% of all epidermal cells; commonly called “skin cells.”
- Keratitis:** Infection of the cornea.
- Keratoconjunctivitis sicca:** Ocular surface disease caused by dysfunctional tear film; also known as Sjogren’s syndrome or dry eye syndrome.
- Kindling:** A process of inducing epilepsy in a laboratory animal by repeated, low-level electrical stimulation of specific areas of the brain.
- Koebner phenomenon:** The occurrence of psoriatic lesions due to skin trauma.
- Korotkoff sounds:** The noise heard over an artery by auscultation when pressure over the artery is reduced below the systolic arterial pressure.
- KRAS:** Protein involved in normal cell signaling processes (product of KRAS gene).
- Kyphosis:** Abnormal curvature of the spine resulting in protrusion of the upper back; hunchback.
- β -Lactam allergy:** Allergy to the β -lactam family, namely penicillins and cephalosporins, but may also include carbapenems.
- Lactose intolerance:** An inability to digest milk and some dairy products, resulting in abnormal bloating, cramping, and diarrhea; caused by enzymatic lactase deficiency.
- Lag-ophthalmos:** Poor closure of the upper eyelid.
- Lamina cribrosa:** A series of perforated sheets of connective tissue that the optic nerve passes through as it exits the eye.
- Laminectomy:** Excision of the posterior arch of a vertebra to relieve pressure on the spinal cord.
- Laparoscopic:** Abdominal exploration or surgery employing a type of endoscope called laparoscope.
- Laparotomy:** Surgical opening of the abdominal cavity.
- Latent tuberculosis (TB) infection:** Infection with *Mycobacterium tuberculosis* has occurred but the disease is not active. Patients with latent tuberculosis are not infectious, and it is not possible to get TB from someone with latent tuberculosis.
- Lentigines:** Plural of lentigo—a small, flat, tan to dark brown or black, macular melanosis on the skin which looks like a freckle but is histologically distinct. Lentigines do not darken on exposure to sunlight, freckles do.
- Leukocytoclastic:** The breaking up of white blood cells.
- Leukopenia:** A condition where the number of circulating white blood cells are abnormally low due to decreased production of new cells, possibly in conjunction with medication toxicities.
- Leukostasis:** An abnormal intravascular leukocyte aggregation and clumping seen in leukemia patients. The brain and the lungs are the two most frequent organs involved.
- Lhermitte’s sign:** Tingling or shock-like sensation passing down the arms or trunk when the neck is flexed.
- Libido:** Conscious or unconscious sexual desire.
- Ligament of Treitz:** Landmark in the proximal portion of the jejunum beyond which it is preferred that postpyloric feedings be delivered for minimization of aspiration.
- Light chain assay:** A highly sensitive assay that determines the ratio of serum free light chain kappa to lambda.
- Linea nigra:** Dark vertical line that appears on the abdomen during pregnancy.
- Lipoprotein lipase:** Enzyme located in the capillary endothelium involved in the breakdown of intravenous lipid emulsion particles.
- Liver biopsy:** A procedure whereby tissue is removed from the liver and used to determine the severity of liver damage.
- Luteolysis:** Death of the corpus luteum.
- Lymphadenectomy:** Surgical excision of lymph nodes.
- Lymphangitis:** Inflammation of lymphatic channels.
- Lymphatic:** The network of vessels carrying tissue fluids.
- Lymphoproliferative:** Of or related to the growth of lymphoid tissue.
- Maceration:** The softening or breaking down of a solid by leaving it immersed in a liquid.
- Macrophages:** Large scavenger cell.
- Macula:** The central portion of the retina.
- Maculopapular:** A rash that contains both macules and papules. A macule is a flat discolored area of the skin, and a

- papule is a small raised bump. A maculopapular rash is usually a large area that is red, and has small, confluent bumps.
- Major malformation:** A defect that has either cosmetic or functional significance to the child.
- Mastalgia:** Tenderness of the breast.
- Matrix metalloproteinases:** Any of a group of enzymes, normally located in the extracellular space of tissue, that function to break down proteins (e.g., collagen), and require zinc or calcium atoms as cofactors for enzymatic activity.
- Meatal stenosis:** Abnormal narrowing or closing of the urethral opening, which slows urination or causes a change in the direction of the urinary stream.
- Meconium:** The first intestinal discharge or "stool" of a newborn infant, usually green in color and consisting of epithelial cells, mucus, and bile.
- Media:** The middle layer of the wall of an artery or vein.
- Melanosis:** Excessive pigmentation of the skin due to a disturbance in melanin pigmentation; also called melanism.
- Melasma:** Dark skin discoloration.
- Melena:** Abnormally dark black, tarry feces containing blood (usually from gastrointestinal bleeding).
- Menarche:** The onset of cyclic menstrual periods in a woman.
- Meninges:** Covering of the brain consisting of three layers.
- Menopause:** Permanent cessation of menses following the loss of ovarian follicular activity.
- Menorrhagia:** Menstrual blood loss of greater than 80 mL per cycle or menstrual cycles lasting greater than 7 days.
- Mesothelioma:** A benign or malignant tumor affecting the lining of the chest or abdomen. Commonly caused by exposure to asbestos fibers.
- Metabolic acidosis:** A condition in the blood and tissues that is a consequence of an accumulation of lactic acid resulting from tissue hypoxia and anaerobic metabolism.
- Metabolic alkalosis:** Alkalosis that is caused by an increase in the concentration of alkaline compounds (typically bicarbonate).
- Metabolic syndrome:** Constellation of cardiovascular risk factors related to hypertension, abdominal obesity, dyslipidemia, and insulin resistance diagnosed by the presence of at least three of the following criteria: increased waist circumference, elevated triglyceride concentrations, decreased high-density lipoprotein (HDL) cholesterol or active treatment to raise HDL cholesterol, elevated blood pressure or active treatment with antihypertensive therapy, or elevated fasting glucose or active treatment for diabetes.
- Metastasis:** Plural is metastases. Cancer that has spread from the original site of the tumor.
- Micelles:** A microscopic particle of digested fat and cholesterol.
- Microalbuminuria:** Urinary excretion of small but abnormal amounts of albumin. Confirmed spot urine albumin to creatinine ratio of 30 to 300 mg/g (3.4 to 34 mg/mmol creatinine) is consistent with microalbuminuria. Considered an early sign of chronic kidney disease.
- Micrognathia:** Abnormal smallness of the jaws.
- Micrometastasis:** Deposits of tumor cells in distant organs that cannot be detected by any imaging techniques available.
- Microsatellite instability:** Unstable sequences of repeating DNA caused by deficiencies in the normal DNA repair process.
- Microvascular pulmonary emboli:** An obstruction in the small blood vessels in the lung caused by material (e.g., blood clot, fat, air, foreign body) that is carried through the circulation until it lodges in another small vessel.
- Minimal residual disease:** A quantitative assessment of subclinical remnant of leukemic burden remaining at the end of the initial phase of treatment (induction) when a patient may appear to be in a complete morphologic remission.
- Minimum inhibitory concentration:** The lowest concentration of an antimicrobial agent that inhibits visible bacterial growth after approximately 24 hours.
- Minor malformation:** A defect that has neither cosmetic nor functional significance to the child.
- Mixed disorder:** See Complicated disorder.
- Miosis:** Pupil constriction.
- Mobilization:** The release of stem cells into the peripheral blood from the bone marrow compartment for the purposes of collecting these stem cells (in anticipation of stem cell transplantation).
- Mobitz type I:** A type of second-degree AV nodal blockade.
- Mobitz type II:** A type of second-degree AV nodal blockade.
- Moebius syndrome:** Extremely rare congenital neurologic disorder which is characterized by facial paralysis and affects eye movement.
- Monocytes:** A variety of white blood cells.
- Monoparesis:** Slight or incomplete paralysis affecting a single extremity or part of one.
- Monosodium urate:** A crystallized form of uric acid that can deposit in joints leading to an inflammatory reaction and the symptoms of gout.
- Morphology:** The science of structure and form of cells without regard to function.
- Mucosa-associated lymphoid tissue:** Lymphoid tissue in the gut that samples luminal antigens and delivers them to the systemic lymph system.
- Mucositis:** Inflammation of mucous membranes, typically within the oral and esophageal mucosa. Usually associated with certain chemotherapy agents and radiation therapy involving mucosal area.
- Mucous colitis:** A condition of the mucous membrane of the colon characterized by pain, constipation, or diarrhea (sometimes alternating), and passage of mucus or mucous shreds.
- Muscularis mucosa:** The thin layer of smooth muscle found in most parts of the gastrointestinal tract.
- Mydriasis:** Pupil dilation.
- Myelin:** A protein and phospholipid sheath that surrounds the axons of certain neurons. Myelinated nerves conduct impulses more rapidly than nonmyelinated nerves.
- Myeloablative preparative regimen:** Radiation and/or chemotherapy that destroys bone marrow activity in preparation

- for a stem cell transplant. Patients will not likely recover bone marrow function without an infusion of “rescue” autologous or allogeneic stem cells.
- Myelodysplastic syndrome:** A disease in which the bone marrow does not function properly.
- Myelosuppression:** Reduction in white blood cells, red blood cells, and platelets caused by bone marrow suppression.
- Myocarditis:** Inflammation of the muscular wall of the heart.
- Myoglobinuria:** The presence of myoglobin in urine.
- Myonecrosis:** Necrotic damage to muscle tissue.
- Myopathy:** Any disease of the muscle causing weakness, pain, and tenderness.
- Myringotomy:** A surgical incision in the tympanic membrane to relieve pressure and drain fluid from the middle ear.
- Nasal scotoma:** An area of blindness in the nasal portion of peripheral vision.
- Nascent:** Immature.
- Nasolacrimal occlusion:** The closing of the tear duct to decrease systemic absorption of a drug.
- Nausea:** The subjective feeling of a need to vomit.
- Necrosectomy:** Surgical excision of necrotic tissue; debridement.
- Necrotizing enterocolitis:** Medical condition primarily seen in premature infants, where portions of the bowel undergo necrosis.
- Nelson syndrome:** A condition characterized by the aggressive growth of a pituitary tumor and hyperpigmentation of the skin.
- Neoadjuvant chemotherapy:** Chemotherapy or radiation therapy given prior to primary surgical treatment. In cancer, it is often used to downstage the tumor to a resectable stage.
- Neoadjuvant therapy:** Therapeutic strategy that precedes primary treatment modality (usually surgery). The goals are to “down-stage” tumors so that the surgical field is smaller or to transform a patient from a nonsurgical candidate to one that is. Neoadjuvant therapy may improve overall survival. Strategies usually involve the use of systemic therapy with or without radiation.
- Neovascular maculopathy:** Proliferation of blood vessels in the macula.
- Nephrolithiasis:** A condition marked by the presence of renal calculi (stones) in the kidney or urinary system.
- Nephron:** The working unit of the kidney that filters blood to remove fluid, toxins, and drugs. Each kidney contains approximately 1 million nephrons.
- Nephrostomy:** Insertion of a catheter through the skin into the renal pelvis to bypass ureteral obstruction and facilitate urine drainage.
- Neuralgia:** Pain which extends along the course of one or more nerves.
- Neuritis:** Inflammation of a nerve.
- Neutralizing antibodies:** Antibodies that develop in response to a therapeutic agent that decrease the efficacy of the agent.
- Nidus:** A central point or focus consisting of a fibrin matrix (in the case of infective endocarditis), where bacteria are able to accumulate and multiply, allowing for formation of an infected vegetation.
- Nitric oxide:** An endogenous vasodilator.
- NMDA-receptor antagonist:** A medication used in the treatment of Alzheimer’s disease. It blocks the *N*-methyl-D-aspartate receptors and protects cells against excess glutamate.
- Nociceptors:** Receptors for pain caused by injury from physical stimuli (mechanical, electrical, or thermal) or chemical stimuli (toxins); located in the skin, muscles, or in the walls of the viscera.
- Nocturia:** Excessive urination at night.
- Nodules:** When seen with rheumatoid arthritis, nodules are subcutaneous knobs over bony prominences or extensor surfaces.
- Nonbacterial thrombotic endocarditis:** Endocarditis caused by noninfectious vegetations.
- Nonmyeloablative preparative regimen:** Radiation and/or chemotherapy that does not completely eradicate host bone marrow activity; host bone marrow activity is suppressed but may recover after approximately 4 weeks, even in the absence of “rescue” allogeneic stem cells.
- Nonnucleoside reverse transcriptase inhibitor (NNRTI):** A noncompetitive inhibitor of the viral reverse transcriptase enzyme by binding to the active site of the enzyme itself, rather than by terminating the enzymatic product. NNRTIs are only active against HIV-1.
- Nonpolypoid:** Absence of polyps.
- Nonprotein kilocalorie-to-nitrogen ratio:** Numerical value derived from dividing kilocalories from carbohydrate plus fat by the number of grams of nitrogen in the diet.
- Non-ST-segment elevation:** A type of myocardial infarction (MI) that is limited to the subendocardial myocardium and is smaller and less extensive than an ST-segment MI, and usually there is no pathologic Q wave on the electrocardiogram.
- Normochromic:** Being normal in color; referring especially to red blood cells.
- Normocytic:** Normal size especially referring to red blood cells.
- Nuchal rigidity:** Neck stiffness.
- Nuclear factor kappa B (Nf-kappa-B):** Regulates cytokine production.
- Nucleoside reverse transcriptase inhibitor (NRTI)/nucleotide reverse transcriptase inhibitor (NtRI):** A modified version of a naturally occurring nucleoside or nucleotide that prevents HIV replication by interfering with the function of the viral reverse transcriptase enzyme. The nucleoside/nucleotide analog causes early termination of the proviral DNA chain. For activity, an NRTI requires three phosphorylation steps once inside the cell, whereas a NtRI has a phosphate group attached and needs only two phosphorylation steps inside the cell for activity.
- Nulliparity:** Condition of not having given birth to a child.
- Nystagmus:** Rapid involuntary eye movement.
- Obliterative bronchiolitis:** Inflammation of the bronchioles (the small elements of the tracheobronchial tree) characterized by obliteration and/or permanent narrowing of the airways.
- Off-label use:** Use of a medication outside the scope of its approved, labeled use.

- Oiling out:** Continued coalescence of lipid emulsion particles, resulting in irreversible separation of the emulsion (also called “breaking” or “cracking” of the emulsion).
- Oligoanovulation:** The condition of having few to no ovulatory menstrual cycles.
- Oligoclonal bands:** Small discrete bands in the γ -globulin region of fluid electrophoresis.
- Oligohydramnios:** Decreased amniotic fluid.
- Oligomenorrhea:** Abnormally light or infrequent menstruation.
- Oliguria:** Reduced urine output; usually defined as less than 400 mL in 24 hours or less than 0.5 mL/kg/h.
- Omentectomy:** Excision of the double fold of peritoneum attached to the stomach and connecting it with abdominal viscera (omentum).
- Oncogene:** Genes that cause transformation of normal cells into cancer cells by promoting uncontrolled cell growth and multiplication leading to tumor formation.
- Open comedo:** A plugged follicle of sebum, keratinocytes, and bacteria that protrudes from the surface of the skin and appears black or brown in color. Also referred to as a “blackhead.”
- Opsonization:** The process by which an antigen is altered so as to become more readily and more efficiently engulfed by phagocytes.
- Optic neuritis:** Usually monocular central visual acuity loss and ocular/periorbital pain caused by demyelination of the optic nerve.
- Oral rehydration solution:** A liquid preparation, commercially prepared or made at home using common ingredients according to a formula developed by the World Health Organization, designed to replace fluid loss in persons with diarrhea.
- Orchiectomy:** The surgical removal of the testicles.
- Orthopnea:** Difficulty in breathing that occurs when lying down and is relieved upon changing to an upright position.
- Orthostasis:** Characterized by a drop in blood pressure when standing up from sitting or lying down, often causing lightheadedness and dizziness.
- Orthotopic:** Placing a transplanted organ into the normal anatomic location.
- Osmolality:** A measure of the number of osmotically active particles per unit solution, independent of the weight or nature of the particle.
- Osmolar gap:** The difference between the measured serum osmolality and the calculated serum osmolality.
- Osteoblasts:** Cells involved in bone formation; “builders of bone.”
- Osteoclasts:** Cells involved in bone resorption; “creators of cavities.”
- Osteomalacia:** Softening of the bones.
- Osteonecrosis:** Death of bone tissue.
- Osteopenia:** Reduced bone density or mass, which can lead to osteoporosis.
- Osteophytes:** Bony outgrowths (also called bone spurs) into the joint space.
- Osteoporosis:** Disease of the bones characterized by a loss of bone tissue, resulting in brittle, weak bones that are susceptible to fracture (porous bones).
- Ostomy:** Surgical operation where part of the abdominal wall is opened and part of the intestine is connected to the opening for intestinal draining (e.g., colostomy, ileostomy)
- Otitis media with effusion:** Fluid in the middle ear space with no signs or symptoms of an acute infection.
- Ovulation:** Periodic ripening and rupture of mature follicle and the discharge of ovum from the cortex of the ovary.
- Pacemaker:** A mass of fibers that possess actual or potential automaticity which initiates and determines the rate of spontaneous depolarizations.
- Palliative care:** The active, total care of patients whose disease is not responsive to curative treatment.
- Palliative chemotherapy:** Treatment given to control the symptoms of an incurable cancer.
- Pancolitis:** Inflammation that involves the majority of the colon in patients with inflammatory bowel disease.
- Pancreatic pseudocysts:** A cyst-like space not lined by epithelium and contained within the pancreas.
- Pancreatitis:** Inflammation of the pancreas.
- Panhypopituitarism:** A state in which the secretion of all anterior pituitary hormones is inadequate or absent.
- Pannus:** Inflamed synovial tissue that invades and destroys articular structures.
- Paracentesis:** Removal of (ascitic) fluid from the peritoneal space.
- Paracentral scotoma:** Blind spots near the center of the visual field.
- Parenchyma:** Specific cells or tissue of an organ.
- Parenteral nutrition:** Delivery of nutrients via the intravenous route.
- Paroxysmal:** Intermittent occurrence, initiating suddenly and spontaneously, lasting minutes to hours, and terminating suddenly and spontaneously.
- Partial response:** In cancer, at least a 30% decrease in the sum of the longest diameter of target lesions from baseline.
- Patient survival:** After the transplant procedure, the survival of the transplant recipient, without regard to the function or survival of the allograft.
- Peak expiratory flow:** The maximum flow rate of air leaving the lungs upon forced exhalation.
- Pelvic inflammatory disease:** Inflammation of the endometrium, uterine tubes, and pelvic peritoneum; often due to a sexually transmitted infection.
- Percutaneous coronary intervention:** A minimally invasive procedure whereby access to the coronary arteries is obtained through the femoral artery up the aorta to the coronary os. Contrast media is used to visualize the coronary artery stenosis using a coronary angiogram. A guidewire is used to cross the stenosis and a small balloon is inflated and/or stent is deployed to break up atherosclerotic plaque and restore coronary artery blood flow. The stent is left in place to prevent acute closure and restenosis of the coronary artery. Newer stents are coated with antiproliferative drugs, such as paclitaxel and sirolimus, which further reduce the risk of restenosis of the coronary artery.

- Percutaneous endoscopic gastrostomy:** Gastric feeding tube placed via endoscopic technique.
- Percutaneous endoscopic jejunostomy:** Jejunal feeding tube placed via endoscopic technique.
- Performance status:** An attempt to quantify the ability of a cancer patient to perform daily activities. This is used to determine if and how much chemotherapy they can receive. Patients with good performance status can tolerate more aggressive chemotherapy.
- Perihilar:** The area surrounding the depression in the medial surface of a lung that forms the opening through which the bronchus, blood vessels, and nerves pass.
- Perimenopause:** Also known as the climacteric, it is the period of time prior to menopause when hormonal and biologic changes and physical symptoms begin to occur and usually last for 1 year after the last menstrual period. The perimenopausal period may last for an average of 3 to 5 years.
- Perimetry:** Measurement of the field of vision.
- Peripheral artery disease:** Atherosclerosis of the peripheral arteries.
- Peripheral resistance:** The sum of resistance to blood flow offered by systemic blood vessels.
- Peritonitis:** An acute inflammatory reaction of the peritoneal lining to microorganisms or chemical irritation.
- Petechiae:** Tiny localized hemorrhages from the small blood vessels just beneath the surface of the skin.
- PET scan:** A scan that produces images of the body after the injection of a radioactive form of glucose. The scan is often used to detect cancer since tumors use more sugar than normal cells. PET scans may also be used to see how well the tumor is responding to treatment.
- Phagocytic cell:** A cell that absorbs waste material, harmful microorganisms, or other foreign bodies in the bloodstream and tissues.
- Phagocytosis:** The process of engulfing and ingesting an antigen by phagocytes.
- Pharmacogenomic:** The influence of genetic variation on drug response in patients and is used to correlate gene expression with a drug's efficacy or toxicity.
- Pharyngitis:** Inflammation and/or infection of the pharynx that causes throat pain.
- Pheochromocytoma:** A tumor arising from chromaffin cells, most commonly found in the adrenal medulla. The tumor causes the adrenal medulla to hypersecrete epinephrine and norepinephrine resulting in hypertension and other signs and symptoms of excessive sympathetic nervous system activity. The tumor is usually benign but may occasionally be cancerous.
- Phenotype:** The visible properties of an organism that are produced by the interaction of the genotype and the environment.
- Phlebitis:** Inflammation of a blood vessel (e.g., vein).
- Photochemotherapy:** The use of phototherapy together with topical or systemic drugs in the treatment of psoriasis.
- Photodynamic therapy:** Cancer treatment that uses interaction between laser light and a substance that makes the cells more sensitive to light. When light is applied to cells that have been treated with this substance, a chemical reaction occurs and destroys cancer cells.
- Photophobia:** Intolerance to bright light.
- Phototherapy:** The use of ultraviolet light applied to the skin, for example in treating psoriasis or neonatal hyperbilirubinemia.
- Pilosebaceous unit:** A hair follicle and the surrounding sebaceous glands.
- Plaques:** Extracellular protein deposits of fibrils and amorphous aggregates of b-amyloid protein.
- Plasma cell:** Antibody producing cells.
- Plasmapheresis:** A process of separating cells out from the plasma. This process is used to remove the monoclonal antibodies from the blood.
- Pleocytosis:** A transient increase in the number of leukocytes in a body fluid.
- Pleuritis:** Inflammation of the lining around the lungs.
- Pneumatic otoscopy:** A diagnostic technique involving visualization of the tympanic membrane for transparency, position, and color, and its response to positive and negative air pressure to assess mobility.
- Pneumothorax:** The presence of air in the pleural cavity, often causing part of the lung to collapse.
- Podocyte:** The epithelial cells that surround the capillaries in the Bowman's capsule and are responsible for filtering blood in the glomerulus of the nephron.
- Polycythemia:** An abnormal increase in the number of erythrocytes in the blood.
- Polypharmacy:** Taking multiple medications concurrently.
- Polyps:** A growth from a mucous membrane commonly found in organs such as the colon, rectum, and the nose. Usually not malignant, these can develop into cancer and require removal once found.
- Polyuria:** Excessive excretion of urine resulting in profuse micturition.
- Portal hypertension:** Increased pressure in vessel leading to liver; usually a result of cirrhosis.
- Postpyloric feeding:** Delivery of nutrients via a tube placed with its tip past the pyloric sphincter separating the stomach from the duodenum.
- Prader-Willi syndrome:** A genetic disorder characterized by short stature, mental retardation, low muscle tone, abnormally small hands and feet, hypogonadism, and excessive eating leading to extreme obesity.
- Predictive factors:** Any measurements associated with response to therapy (e.g., over-expression of HER2 increases the likelihood of response to agents targeting the receptor; the same is true for ER).
- Preload:** The stretched condition of the heart muscle at the end of diastole just before contraction; volume in the left ventricle at the end of diastole estimated by the pulmonary artery occlusion pressure (also known as the pulmonary artery wedge pressure or pulmonary capillary wedge pressure).
- Preparative regimen (conditioning regimen):** Radiation and/or chemotherapy given to stem cell transplant patients in order to kill malignant cells, create space

- in the bone marrow compartment, and suppress the immune system of the host in order to prevent graft rejection.
- Priapism:** A prolonged, painful erection lasting more than 4 hours. Considered a medical emergency.
- Primary amenorrhea:** Absence of menses by age 15 in the presence of normal secondary sexual development or absence of menses within 5 years of breast development (if occurring prior to age 10).
- Primary prevention:** The removal or reduction of risk factors before the development of disease.
- Prinzmetal's angina:** Vasospasm or contraction of the coronary arteries in the absence of significant atherosclerosis. Also referred to as variant angina.
- Probiotics:** Dietary supplements containing potentially beneficial bacteria that promote health by stimulating optimal mucosal immune responses.
- Proctitis:** Inflammation confined to the rectum in patients with inflammatory bowel disease.
- Progenitor:** A primitive cell.
- Prognostic factors:** Biologic or clinical indicators associated with survival independent of therapy (e.g., over-expression of HER2 is associated with increased risk of relapse and shorter survival).
- Progression:** In cancer, cell proliferation takes over and the tumor spreads or develops metastases.
- Progression-free survival:** Length of time that a disease remains stable following treatment.
- Progressive primary disease:** Tuberculosis infection in which the immune response fails to control multiplication of the tubercle bacilli. The primary focus in the lung enlarges rapidly and spreads. This occurs in less than 10% of normal adults, but it is more common in children younger than 5 years, and in patients with suppressed immunity.
- Prolapse:** Protrusion of an organ or part of an organ through an opening, e.g., uterine prolapse occurs when the uterus is displaced downward such that the cervix is within the vaginal opening (first degree), the cervix is outside the opening (second degree), or the entire uterus is outside the opening (third degree).
- Promotion:** Reversible process in cancer, the environment is altered by carcinogens or other factors to favor the growth of the mutated cell over the normal cell.
- Prostaglandin:** Any of a large group of biologically active, carbon-20, unsaturated fatty acids that are produced by the metabolism of arachidonic acid through the cyclooxygenase pathway.
- Prostatectomy:** Surgical removal of the prostate.
- Prostatic hyperplasia:** Enlargement of the prostate.
- Prosthetic-valve endocarditis:** Endocarditis that occurs in patients with bioprosthetic or synthetic implanted heart valves.
- Protease inhibitor:** A drug that acts by inhibiting the viral protease enzyme, which prevents long strands of protein from being cleaved into the smaller proteins that the virus requires for assembly.
- Protectant:** An agent that forms an occlusive barrier between the skin and surrounding moisture.
- Protected specimen brush:** Used in bronchoscopy, a brush in the lumen of a tube inside the bronchoscope. The brush is extended into the lung to obtain a sample, then retracted back into the tube for removal from the lung.
- Proteinase:** Any of numerous enzymes that catalyze the breakdown of proteins (also called protease).
- Proteinuria:** The presence of measurable amounts of protein (greater than 150 mg/day) in the urine, which is often indicative of glomerular or tubular damage in the kidney.
- Proteoglycans:** Glycosaminoglycans (mucopolysaccharides) bound to protein chains in covalent complexes. Proteoglycans are present in the extracellular matrix of connective tissue.
- Proteolysis:** The degradation of proteins in damaged tissue.
- Proteasome:** An enzyme complex that degrades intracellular proteins.
- Prothrombin:** A clotting factor that is converted to thrombin; also known as Factor II.
- Prothrombin time:** A measure of coagulation representing the amount of time required to form a blood clot after the addition of thromboplastin to the blood sample; also known as Quick's test.
- Prothrombotic state:** A state of high coagulation of the blood.
- Protooncogenes:** Normal genes that are present in all normal cells and regulate cell function and replication, and through some genetic alteration caused by carcinogens, change into oncogenes.
- Pseudohyphae:** Elongated forms created by replicating yeast that form buds but do not detach from one another.
- Pseudophakic:** Presence of an artificial lens placed after cataract extraction.
- Pseudopolyps:** An area of hypertrophied gastrointestinal mucosa that resembles a polyp and contains nonmalignant cells.
- Pulmonary artery catheter:** An invasive device used to measure hemodynamic parameters directly, including cardiac output and pulmonary artery occlusion pressure; calculated parameters include stroke volume and systemic vascular resistance.
- Pulmonary artery occlusion pressure:** A hemodynamic measurement obtained via a catheter placed into the pulmonary artery used to evaluate patient volume status within the left ventricle.
- Pulmonary embolism:** A disorder of thrombus formation causing obstruction of a pulmonary artery or one of its branches and resulting in pulmonary infarction.
- Pulsus paradoxus:** A large fall in systolic blood pressure and pulse volume during inspiration or an abnormal variation in pulse volume during respiration in which the pulse becomes weaker with inspiration and stronger with expiration.
- Purkinje fiber:** Specialized myocardial fibers that conduct impulses from the atrioventricular node to the ventricles.
- Purified protein derivative:** A mixture of antigens obtained from the culture of *M. tuberculosis* that can be injected intracutaneously to stimulate the immune system to produce a measurable response.

- Purpura:** A small hemorrhage of the skin, mucous membrane, or serosal surface.
- Purulent:** Containing, consisting of, or being pus.
- Pyelonephritis:** Inflammation of a kidney.
- Pyuria:** Presence of pus in urine when voided.
- Quality indicators:** A list of indicator used by long-term care facility administrators and government overseers to identify potential problems in patient care.
- Quality of life:** Perceived physical and mental health over time.
- Radiofrequency catheter ablation:** Procedure during which radiofrequency energy is delivered through a catheter positioned at the atrioventricular node for the purpose of destroying one pathway of a reentrant circuit.
- Receptor editing:** The process by which cells proofread, alter, and reexpress modified receptors to become non-autoreactive.
- Recombinant activated factor VII:** A clotting factor manufactured via recombinant technology used off-label (non-Food and Drug Administration approved) to foster clotting in hemorrhagic shock patients with massive hemorrhage refractory to conventional therapies such as fresh frozen plasma.
- Rectal prolapse:** Sinking of the rectum through the anal sphincter so that it is visible externally.
- Reentry:** Circular movement of electrical impulses, a mechanism of many arrhythmias.
- Refractory period:** The period of time after an impulse is initiated and conducted during which cells cannot be depolarized again.
- Regurgitation:** A passive process without involvement of the abdominal wall and the diaphragm wherein gastric or esophageal contents move into the mouth.
- Remission:** An inability to detect the presence of disease.
- Renal osteodystrophy (ROD):** Altered bone turnover that results from sustained metabolic conditions that occur in chronic kidney disease, including secondary hyperparathyroidism, hyperphosphatemia, hypocalcemia, and vitamin D deficiency. The disease can be characterized by high bone turnover, low bone turnover, or adynamic disease, or may be a mixed disorder.
- Renin-angiotensin-aldosterone system:** The hormonal system controlled mainly by the kidneys and adrenal glands that regulates blood pressure, blood volume, and electrolyte balance.
- Replication capacity:** This term is often used interchangeably with the term “viral fitness” and refers to how quickly HIV reproduces or replicates. The slower HIV replicates, the less likely a patient is to have disease progression. A replication capacity may be reported on a resistance test. It is reported as a percentage of the median replication rate for drug-sensitive (wild-type) HIV strains.
- Resorption:** The process of bone breakdown by osteoclasts.
- Respiratory acidosis:** Acidosis that is caused by an accumulation of carbon dioxide.
- Respiratory alkalosis:** Alkalosis that is caused by a loss of carbon dioxide.
- Restenosis:** Renarrowing of the coronary artery after a percutaneous intervention to improve coronary blood flow.
- Retching:** A process that follows nausea and consists of diaphragm, abdominal wall, and chest wall contractions and spasmodic breathing against a closed glottis.
- Reticulocytes:** Immature blood cells that mature into erythrocytes.
- Reticuloendothelial system:** Phagocytic cells excluding granulocytes; widely distributed throughout the body.
- Retrograde ejaculation:** Flow of ejaculate into the bladder instead of antegrade out of the urethra.
- Rhabdomyolysis:** Destruction of skeletal muscle.
- Rheumatic fever:** An acute inflammatory disease involving the joints, heart, skin, brain, and other tissues caused by an immune response to streptococcal infection in genetically susceptible people, particularly in children.
- Rheumatoid factors:** Antibodies reactive with the Fc region of IgG.
- Rhinosinusitis:** Inflammation of the mucous membranes in the nose and sinuses.
- Rhonchi:** Abnormal, rumbling sounds heard on auscultation of an obstructed airway. They are more prominent during expiration and may clear somewhat on coughing.
- Rouleaux formation:** The stacking of red blood cells on a peripheral smear when diluted.
- Rubefacients:** A substance that produces redness of the skin.
- Salicylism:** A toxic syndrome caused by excessive doses of acetylsalicylic acid (aspirin), salicylic acid, or any other salicylate product. Signs and symptoms may include severe headache, nausea, vomiting, tinnitus (ringing in the ears), confusion, increased pulse, and increased respiratory rate.
- Scarlatiniform rash:** Bright, scarlet-colored skin eruption that occurs in patches over the entire body with eventual peeling as a result of streptococcal infection.
- Scleritis:** Inflammation of the outer layer of the eyeball.
- Scoliosis:** A congenital lateral curvature of the spine.
- Secondary amenorrhea:** Absence of menses for 3 cycles or 6 months in a previously menstruating woman.
- Secondary hyperparathyroidism:** Increased secretion of parathyroid hormone from the parathyroid glands caused by hyperphosphatemia, hypocalcemia, and vitamin D deficiency that results from decreased kidney function. Secondary hyperparathyroidism can lead to bone disease (renal osteodystrophy).
- Secondary transmission:** Transferring a disease from the primary source to another person.
- Seizure:** A sudden electrical disturbance in the brain that results from a population of neurons rapidly and repetitively firing in a rhythmic and synchronous pattern for seconds to minutes.
- Semiology:** The clinical symptoms and presentation of a seizure.
- Sentinel lymph node:** Refers to the first (axillary) node that picks up dye injected into the tumor.
- Sera:** Pertaining to human serum.
- Seropositive:** Showing a positive reaction to a test on blood serum for a disease.

- Serum sickness:** A group of symptoms caused by a delayed immune response to certain medications. Arthralgias, fever, malaise, and urticaria may develop usually 7 to 14 days after exposure to the causative antigen.
- Shear stress:** Risk factor for pressure ulcers that is generated when the head of a patient's bed is elevated and can cause deeper blood vessels to crimp, leading to ischemia.
- Sick sinus syndrome:** Idiopathic sinus node dysfunction leading to symptomatic sinus bradycardia.
- Sigmoidoscopy:** A visual inspection of the sigmoid colon and rectum with a flexible tube called a sigmoidoscope.
- Simple disorder:** The presence of a single acid-base disorder, with or without compensation.
- Sjögren's syndrome:** A chronic autoimmune disease characterized by dry eyes and dry mouth.
- Sleep apnea:** The temporary stopping of breathing during sleep; can be caused by narrowing of the airways resulting from swelling of soft tissue.
- Slit-lamp biomicroscope:** An instrument that allows for the microscopic examination of the cornea, anterior chamber lens, and posterior chamber.
- Somatic hypermutation:** The occurrence of multiple point mutations.
- Somatotrope:** Growth hormone producing cells in the anterior pituitary
- Spastic colon:** A synonym for irritable bowel syndrome.
- Spasticity:** A motor disorder characterized by an increase in muscle tone with exaggerated tendon jerks, resulting from hyperexcitability of the stretch reflex.
- Spectrum of activity:** A qualitative term that describes the number of different bacterial species that are susceptible to an antimicrobial regimen. Generally, broad-spectrum activity refers to regimens that possess activity against many bacterial species, whereas narrow-spectrum therapy refers to activity against a few bacterial species.
- Sphincter of Oddi:** Structure through which the common bile duct empties bile and pancreatic secretions into the duodenum.
- Spirometry:** Measurement by means of a spirometer of the air entering and leaving the lungs.
- Splenomegaly:** An enlarged spleen secondary to leukemic infiltration.
- Sprain:** An overstretching of supporting ligaments that results in a partial or complete tear of the ligament.
- Sputum culture:** A sputum sample obtained from the lower respiratory tract is placed into a container that contains substances to promote, in this case, mycobacterial growth. Positive results indicate live mycobacteria, which can be tested for susceptibility to drugs.
- Sputum smear:** A sputum sample obtained from the lower respiratory tract, spread on a glass slide, and stained for examination under a microscope. Used to identify the presence of microorganisms.
- Stable disease:** In cancer, neither sufficient shrinkage to qualify for partial response nor sufficient increase to qualify for progressive disease.
- Staging:** Analysis that provides a semiquantitative estimate of tumor burden, which is not only of prognostic importance, but also has important implications regarding appropriate treatment options.
- Steatohepatitis:** A severe form of liver disease caused by fat deposition in the liver, characterized by hepatic inflammation that may rapidly progress to liver fibrosis and cirrhosis.
- Steatorrhea:** Excessive loss of fat in stool.
- Steatosis:** Excessive fat accumulation. Fat deposition in liver.
- Stenosis:** Blockage of an artery.
- Stenting:** Placement of a stent to allow blood flow through an artery.
- Stereotactic radiosurgery:** Radiation technique that uses a large number of narrow, precisely aimed, highly focused beams of ionizing radiation. The beams are aimed from many directions circling the head and meet at a specific point.
- Stevens-Johnson syndrome:** A severe expression of erythema multiforme (also known as erythema multiforme major). It typically involves the skin and the mucous membranes with the potential for severe morbidity and even death.
- Stomatitis:** Inflammation of mucous membranes in the mouth.
- Strain:** Damage to the muscle fibers or tendon without tearing of the ligament.
- Striae:** Linear, atrophic, pinkish or purplish, scarlike lesions that later become white (striae albicantes, lineae albicantes), which may occur on the abdomen, breasts, buttocks, and thighs. They are due to weakening of the elastic tissues; commonly called stretch marks.
- Stricture:** An area of narrowing or constriction in the gastrointestinal tract due to buildup of fibrotic tissue; often a result of long-standing inflammation.
- Stroke volume:** The amount of blood ejected from the heart during systole.
- ST-segment elevation:** A type of myocardial infarction that typically results in an injury that transects the thickness of the myocardial wall. Following an ST-elevation myocardial infarction, pathologic Q waves are frequently seen on the electrocardiogram, indicating transmural myocardial infarction.
- Subchondral:** Situated beneath and supporting cartilage.
- Subtrochanteric:** Below the trochanter (the bony protrusion at the end of the femur where the hip and thigh muscles attach).
- Surgical site infection:** Infections occurring at or near the surgical incision within 30 days of the operation; up to 1 year if a prosthesis is implanted.
- Suspending agent:** An additive used in the compounding of oral liquid medications to suspend drug particles throughout a liquid and enables resuspension of particles by agitation (e.g., shaking well).
- Synechia:** Adhesions or the abnormal attachment of the iris to another structure. Peripheral anterior synechia refers to occurrence of synechia with the trabecular meshwork.
- Synovitis:** Inflammation of the synovial membrane, often in combination with pain and swelling of the affected joint.
- Synovium:** The membrane lining the internal surfaces of the joint.

- Systolic dysfunction:** An abnormal contraction of the ventricles during systole.
- Tachycardia:** Abnormally fast heart rate.
- Tachyphylaxis:** Rapid decreasing response to a drug or other physiologically active agent after a few doses.
- Tachypnea:** Abnormally fast respiratory rate.
- Tangles:** Twisted fibers of a protein, tau, that build up inside cells.
- Telangiectasia:** Permanent dilation of preexisting small blood vessels (capillaries, arterioles, venules), usually in the skin or mucous membranes which presents as a coarse or fine red line.
- Tendonitis:** Inflammation of the tendon.
- Tenesmus:** Difficulty with bowel evacuation despite the urgency to defecate.
- Tenosynovitis:** Inflammation of the tendon sheath.
- Teratogenic potential:** The ability of an agent to cause harm or malformations to a fetus or embryo. Medications are assigned pregnancy categories based on their teratogenic potential.
- Terminal secretions:** The noise produced by the oscillatory movements of secretions in the upper airways in association with the inspiratory and expiratory phases of respiration. It is also known as “death rattle.”
- Thelarche:** The onset of breast development in women.
- Third spacing:** Fluid accumulation in the interstitial space disproportionate to the intracellular and extracellular fluid spaces.
- Thoracentesis:** Removal of fluid that is present in the pleural space. Common procedure to determine what caused the fluid accumulation.
- Thrombin:** An enzyme formed from prothrombin which converts fibrinogen to fibrin. It is the principal driving force in the clotting cascade.
- Thrombocytopenia:** A condition where the number of circulating platelets are abnormally low due to decreased production of new cells, possibly secondary to medication toxicities.
- Thrombocytosis:** Increased number of platelets in the blood.
- Thrombogenesis:** The process of forming a blood clot.
- Thrombolysis:** The process of enzymatically dissolving or breaking apart a blood clot.
- Thrombolytic:** An enzyme that dissolves or breaks apart blood clots.
- Thrombophlebitis:** Inflammation of a blood vessel (e.g., vein) associated with the stimulations of clotting and formation of a thrombus (or blood clot).
- Thromboplastin:** A substance that triggers the coagulation cascade. Tissue factor is a naturally occurring thromboplastin and is used in the prothrombin time test.
- Thrombosis:** A condition in which blood changes from a liquid to a solid state and produces a blood clot.
- Thrombotic thrombocytopenic purpura:** Condition characterized by formation of small clots within the circulation resulting in the consumption of platelets and a low platelet count.
- Thrombus:** Blood clot attached to the vessel wall and consisting of platelets, fibrin, and clotting factors. A thrombus may partially or completely occlude the lumen of a blood vessel compromising blood flow and oxygen delivery to distal tissue.
- Thyroiditis:** Inflammation of the thyroid gland.
- Tocolytic:** Medication used to suppress premature labor.
- Tonometry:** A method by which the cornea is indented or flattened by an instrument. The pressure required to achieve corneal indentation or flattening is a measure of intraocular pressure.
- Topoisomerase:** Enzymes that temporarily alter supercoiled DNA by cutting the DNA, causing the DNA to relax the supercoil during DNA replication. Topoisomerase inhibitors prevent the DNA from sealing the cut which causes DNA strand breakage.
- Torsade de pointes:** Very rapid ventricular tachycardia characterized by a gradually changing QRS complex in the ECG; may change into ventricular fibrillation.
- Toxic epidermal necrolysis:** A life-threatening skin disorder characterized by blistering and peeling of the top layer of skin.
- Toxoid:** A modified bacterial exotoxin that has lost toxicity.
- Tracheal aspirate:** Suctioning of secretions from the trachea.
- Transesophageal echocardiogram:** Procedure used to generate an image of the heart via sound waves, via a probe introduced into the esophagus (rather than the traditional transthoracic view) in order to obtain a better image of the left atrium.
- Transformation (conversion):** Mutated cell becomes malignant.
- Transient ischemic attack:** Focal neurologic deficit lasting less than 24 hours where symptoms resolve completely.
- Translocation:** Movement of bacteria and endotoxin from the intestinal lumen through the gut mucosa and into the lymphatic and systemic circulation.
- Transmural:** Across the wall of an organ or structure; in the case of Crohn’s disease, inflammation may extend through all four layers of the intestinal wall.
- Tubal ligation:** Surgical process of tying up the fallopian tubes to prevent passage of ova from the ovaries to the uterus.
- Tumor suppressor genes:** Genes that normally restrain cell growth but, when missing or inactivated by mutation, allow cells to grow uncontrolled and tumors to form.
- Tuberoeruptive xanthomas:** Small yellow-red raised papules usually presenting on the elbows, knees, back, and buttocks.
- Tubulointerstitial:** Involving the tubules or interstitial tissue of the kidneys.
- Tumor lysis syndrome:** A syndrome resulting from cytotoxic therapy, occurring generally in aggressive, rapidly proliferating lymphoproliferative disorders. It is characterized by combinations of hyperuricemia, lactic acidosis, hyperkalemia, hyperphosphatemia, and hypocalcemia.
- T2-weighted magnetic resonance imaging:** A setting of the magnetic resonance imaging machine that shows water as a bright signal.

Tympanocentesis: Puncture of the tympanic membrane with a needle to aspirate middle ear fluid.

Tympanostomy tube: Small plastic or metal tube inserted in the eardrum to keep the middle ear aerated and improve hearing in patients with chronic middle ear effusion.

Uhthoff's phenomenon: Acute worsening of multiple sclerosis symptoms on exposure to heat because high body temperatures may exceed the capacitance of the demyelinated nerve and conduction may fail.

Ultrafiltration: The movement of plasma water across a semi-permeable membrane.

Uncomplicated disorder: See Simple disorder.

Uremia: A condition that results from accumulation of metabolic waste products and endogenous toxins in the body resulting from impaired kidney function. Symptoms of uremia include nausea, vomiting, weakness, loss of appetite, and mental confusion.

Urethral stricture: Narrowing of the urethral lumen by scar tissue. This could result from trauma, inflammation, infection, or instrumentation.

Uricosuric: Pertaining to, characterized by, or promoting renal excretion of uric acid.

Urosepsis: Sepsis resulting from a urinary source.

Urticaria: Itchy, raised, swollen areas on the skin. Also known as hives.

Uveitis: An inflammation of the uvea. Uveal structures include the iris, the ciliary body, and the choroids.

Vagal maneuvers: Stimulate the activity of the parasympathetic nervous system, which inhibits atrioventricular nodal conduction. Examples of vagal maneuvers include cough, carotid sinus massage, and Valsalva.

Vagotomy: A surgical procedure that blocks vagal (cholinergic) stimulation to the stomach.

Valsalva maneuver: Vagal maneuver; patient bears down against a closed glottis, as if they were having a bowel movement.

Variceal bleeding: Varices are weak collateral blood vessels that are friable and rupture easily; often observed in the esophagus or stomach.

Vasculitis: Inflammation of the walls of blood vessels.

Vasomotor symptoms: Menopausal symptoms that include both hot flashes and night sweats.

Vasopressors: Medications that cause constriction of blood vessels, increase in vascular resistance, and increase in blood pressure.

Vasospasm: Narrowing (constriction) of a blood vessel causing a reduction in blood flow.

Ventilation/perfusion ratio (V_A/Q): A comparison of the proportion of lung tissue being ventilated by inhaled air to the rate of oxygenation of pulmonary blood.

Ventricular depolarization: Change in the membrane potential of a ventricular myocyte, resulting in loss of polarization. Under normal conditions, depolarization of ventricular myocytes is followed by ventricular contraction.

Vertigo: Sensation of spinning or feeling out of balance.

Vesicants: A chemical or agent that causes significant tissue damage if extravasation occurs during IV administration.

Virilization: Production or acquisition of virilism, which is masculine characteristics.

Volvulus: Twisting of the intestine causing obstruction and possible necrosis.

Vomiting: A reflexive rapid and forceful oral expulsion of upper gastrointestinal contents due to powerful and sustained contractions in the abdominal and thoracic musculature.

Waist circumference: A practical tool to measure the abdominal fat in patients with a BMI of less than 35.

Western blot analysis: The "gold standard" for HIV diagnostic testing. Disrupted virus is purified, gel-electrophoresed to separate by molecular weight to form bands corresponding to the nine HIV antigens, and blotted onto a membrane support. HIV serum antibodies from the patient are allowed to bind to proteins in the membrane support. If HIV antibodies from the patient are bound, the bands will change color. The test is considered reactive if 2 of the 3 major bands (p24, gp41, and/or gp120/160) change color. The test is nonreactive if no viral bands are visible.

White coat hypertension: A persistently elevated average office blood pressure of greater than 140/90 mm Hg and an average awake ambulatory reading of less than 135/85 mm Hg.

Wilson's disease: A disorder of copper metabolism, characterized by cirrhosis of the liver and neurologic manifestations.

Xanthoma: Firm raised nodules composed of lipid-containing histocytes.

Xerostomia: Dry mouth resulting from decreased salivary secretion.

ZAP-70 expression: An intracellular tyrosine kinase found in CLL B-cells.

Zymogen: An inactive protein precursor of an enzyme that is converted into an active form.

Appendix E: Prescription Writing Principles

Julie Haase, Kim Hawkins, Jill Isaacs, Emily Knezevich, and Jon Knezevich

According to the International Monetary Systems (IMS) Health Report, 3.9 billion prescriptions were written and dispensed in the United States in 2009. This demonstrated an increase of 5.1% from 2008 and reflects a need for prescribers and dispensers to fully understand prescriptive privileges and rational prescribing.¹ The following outlines principles of pharmacotherapy, including obtaining prescriptive privileges, rational prescribing of medications, electronic prescribing, safe prescribing practices, adverse event reporting, and medication education.

It is essential that the prescriber and dispenser familiarize themselves with the professional guidelines, state laws, and federal laws. In addition, they must also understand the components of rational prescribing. [Table E-1](#) below provides key elements a prescriber should understand as well as useful resources.

TYPES OF PRESCRIPTION ORDERS

Prescription orders can be provided in a variety of ways by authorized prescribers. Outpatient prescriptions may be written, verbally authorized by phone, faxed, or provided via electronic means. All outpatient prescriptions are subject to federal regulations and contain the same basic components. Laws and regulations for outpatient prescription requirements can vary from state to state, so prescribers should be knowledgeable of all applicable laws. The basic components of a prescription are listed below as well as numbered in [Figure E-1](#).²

1. Prescriber information: name, address, and phone number
2. Prescriber's signature and prescriptive authority number or Drug Enforcement Administration (DEA) number (if applicable)
3. Patient information: full name and address, and weight and age if appropriate
4. Date the prescription was written
5. Superscription (Rx symbol), meaning "you take" or "recipe"
6. Inscription: medication being prescribed (name of medication, strength, and dose)

7. Signa, sig, or signature: directions to the patient (e.g., take one tablet daily)
8. Subscription: dispensing instructions to the pharmacist (number, quantity, or volume to dispense)
9. Number of refills allowed
10. Generic substitution requirement: "DAW (dispense as written)" or "no substitution" if brand name medication only is desired

Further regulations are in place for prescriptions written for controlled substances. In addition to the above elements, prescriptions for controlled substances must also include the patient's full name and address as well as the full name, address, and DEA number of the prescriber. Stricter regulations exist for Schedule II controlled substances compared with Schedule III-V. Schedule II prescriptions must be written and can only be provided orally in an emergency situation. Refills are prohibited with Schedule II prescriptions.³

Chart orders, orders written for hospital inpatients, are not considered prescriptions and are not subject to the same requirements. Typically chart orders include:

- Patient identifiers including name, account number
- Physician name
- Medication name, dose, route, and frequency of administration
- Date and time of order
- Physician signature
- If the order was given verbally, the person reducing the order to writing must sign the order and the ordering physician countersign

Electronic prescribing has become common practice because of government incentives aimed at moving health records to electronic databases.⁴ Principles discussed previously in regard to requirements of a prescription hold true for electronic orders; however, additional considerations must be taken to ensure safe prescribing habits occur. A brief list of potential risks and benefits is summarized in [Table E-2](#).

Electronic prescribing is no longer a projection of the future but instead is becoming the norm amongst prescribers and clinical staff. Careful thought should be placed into the

Table E-1

Pharmacotherapy Principles

Pharmacotherapy Principle	Description	Online Resources
Prescriptive privileges	Dictated by federal and state law Scope of practice and formularies vary by profession. Physicians, nurse practitioners, physician assistants, and dentists all have varying scopes of practice, which may include formularies or supervising prescribers. Each provider must become familiar with his or her profession's scope of practice. Pharmacology courses in program of study and Continuing Education required Prescribing legend drugs requires board examination and National Provider Identifier (NPI)	https://nppes.cms.hhs.gov/NPPES/Welcome.do
Rational prescribing	Prescribing controlled substances requires DEA registration number Ensure necessity of medication Obtain pertinent history <ul style="list-style-type: none"> • Health history: comorbidities or contraindications (i.e. pregnancy, hepatic failure, or renal failure) • Medication history: prior and current prescription, OTC, or herbal use; drug allergies or sensitivities; compliance issues • Family and social history Select correct medication <ul style="list-style-type: none"> • It is important to know the following components of each medication when prescribing or dispensing: <ul style="list-style-type: none"> • Pharmacokinetics • Pharmacodynamics • Drug interactions • Drug-disease interactions • Interdisciplinary collaboration when necessary 	http://www.justice.gov/dea/ http://www.jointcommission.org/

DEA, Drug Enforcement Administration; OTC, over the counter.

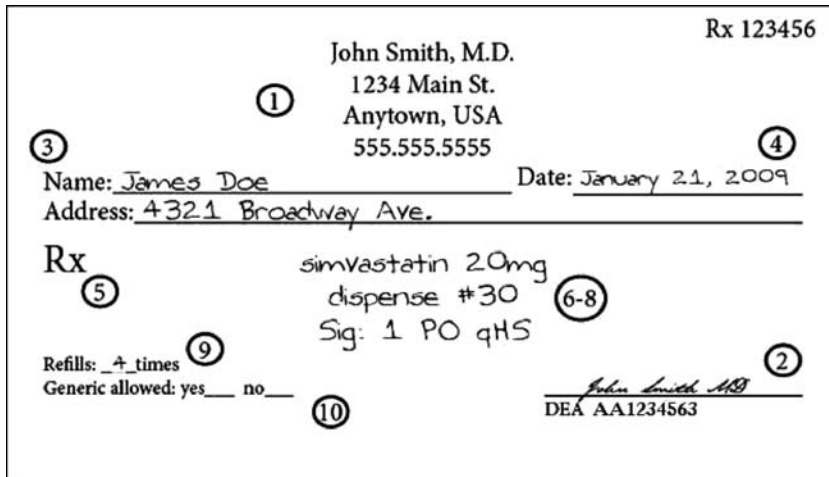

FIGURE E-1. Example of a prescription.

Table E-2

Electronic Prescribing⁴⁻⁶

Benefits	Risks
<ul style="list-style-type: none"> Reduce medication errors Reduce adverse drug events Improves efficiency Improved recognition of drug–drug and drug–disease interactions Improved recognition of medication allergy cross-sensitivity Enhanced prescriber knowledge of patient adherence Enhanced prescriber knowledge of insurance coverage for medications 	<ul style="list-style-type: none"> Cost of software programs Lack of financial benefit seen immediately Lack of software standardization Indirect costs: training personnel, reduced patient visits during training period Clinician resistance: worry of worsening relationship with patient, negative impact on workflow, and fears of restrictions on prescribing habits

implementation process to ensure that patient care is not compromised. With appropriate use of this technology, patients are provided ultimately with safer and more efficient care.

Omission of any of the above-discussed elements on a prescription order can be considered erroneous and poses a danger to patient care. Responsibility lies with the prescriber as well as the pharmacist dispensing the medication to ensure the prescriptions are not only accurate but also appropriate for the given patient.

SAFE PRESCRIBING PRACTICES

Safe prescribing should be a priority of all healthcare providers. To avoid inappropriate use of medications in patients, prescribers should take careful consideration in writing clear and descriptive prescriptions. This ensures appropriate communication among all interdisciplinary healthcare providers.

A thorough understanding of the medication prescribed, including its expected risks and benefits, should be realized by the prescriber ensuring appropriate drug selection. Providers should be aware of common errors related to prescription writing. These errors include: sound-alike/look-alike medications and inappropriate use of shorthand

Table E-3

Sound-Alike/Look-alike Medications^{7,a}

Medication Name	Misinterpreted Medication Name
acetoHEXAMIDE	acetaZOLAMIDE
chlordiazePOXIDE	chlproMAZINE
CISplatin	CARBOplatin
ePHEDrine	EPINEPHrine
hydrALAZINE	hydroXYzine
LORazepam	ALPRAZolam
NIFEdipine	niCARDipine
RABEprazole	ARIPiprazole
risperiDONE	rOPINIrole
sulfADIAZINE	sulfaSALAZine
valACYclovir	valGANciclovir
Zantac	Xanax

^aFor additional information, please see <http://www.ismp.org/tools/confuseddrugnames.pdf>.

language and abbreviations. The Joint Commission, as well as the Institute for Safe Medication Practices (ISMP), has collected common examples of these errors seen during the ordering process. Common examples are described in **Tables E-3** and **E-4**.

Table E-4

Error-Prone Abbreviations^{8,a}

Abbreviation	Anticipated Meaning	Misinterpretation	Correction
µg	Microgram	Mistaken as "mg"	Use "mcg"
IJ	Injection	Mistaken as "IV" or "intrajugular"	Use "injection"
q.d. or QD	Every day	Mistaken as q.i.d., especially if the period after the "q" or the tail of the "q" is misunderstood as an "i"	Use "daily"
Dose Designation	Anticipated Meaning	Misinterpretation	Correction
Trailing zero after decimal point (e.g., 4.0 mg)	4 mg	Mistaken as 40 mg if the decimal point is not seen	Do not use trailing zeros for doses expressed in whole numbers
No leading zero before a decimal point (e.g., .8 mg)	0.8 mg	Mistaken as 8 mg if the decimal point is NOT seen	Use zero before a decimal point when the dose is less than a whole unit
Large doses without properly placed commas (e.g., 100000 units; 1000000 units)	100,000 units 1,000,000 units	100000 has been mistaken as 10,000 or 1,000,000; 1000000 has been mistaken as 100,000	Use commas for dosing units at or above 1,000 or use words such as 100 "thousand" or 1 "million" to improve readability
Drug Name Abbreviation	Anticipated Meaning	Misinterpretation	Correction
AZT	Zidovudine (Retrovir)	Mistaken as azathioprine or aztreonam	Use complete drug name
MS, MSO ₄	Morphine sulfate	Mistaken as magnesium sulfate	Use complete drug name
PCA	Procainamide	Mistaken as patient-controlled analgesia	Use complete drug name
T3	Tylenol with codeine No. 3	Mistaken as liothyronine	Use complete drug name
Stemmed Drug Names	Anticipated Meaning	Misinterpretation	Correction
"Nitro" drip	Nitroglycerin infusion	Mistaken as sodium nitroprusside infusion	Use complete drug name
"IV Vanc"	Intravenous vancomycin	Mistaken as Invanz	Use complete drug name
Symbol	Anticipated Meaning	Misinterpretation	Correction
x3d	For three days	Mistaken as 3 doses	Use "for three days"
&	And	Mistaken as "2"	Use "and"
°	Hour	Mistaken as a zero (e.g., q2° seen as q 20)	Use "hr," "h," or "hour"

^aFor additional information, please see ISMP/Joint Commission List of Error Prone Abbreviations.

Table E-5

Frequently Used Abbreviations²

Abbreviation or Shorthand	Meaning	Abbreviation or Shorthand	Meaning
QD	Daily	PO	By mouth
BID	Twice daily	PR, rect	Per rectum
TID	Three times daily	gtt	Drop
QID	Four times daily	subQ	Subcutaneously
HS	At bedtime	V, PV	Vaginally
PRN	As needed	supp	Suppository
WM	With meals	SL	Sublingual
q4h, q6h, etc.	Every 4 hours, every 6 hours, etc.	ou	Each eye
qAM	Every morning	od	Right eye
qPM	Every evening	os	Left eye
QS	Quantity sufficient	pc	After a meal
au	Each ear	ac	Before a meal
ad	Right ear	HCTZ	Hydrochlorothiazide
as, al	Left ear		

Other abbreviations are commonly used in prescription writing. Examples are included in [Table E-5](#).

Adverse Event Reporting

If adverse events related to medication use are determined, the healthcare provider who discovers the event is responsible for reporting it. The Food and Drug Administration's reporting system for such adverse events is MedWatch <http://www.fda.gov/Safety/MedWatch/default.htm>.⁹ This online database archives medication-related adverse events, and providers are able to report errors seen in clinical practice through this same system.

Medication Education

After a prescription has been written, counseling patients on newly prescribed therapies is an essential responsibility of the prescriber as well as the pharmacist dispensing the medication. The patient should be made aware of the rationale for drug use, the dose, route, and frequency at which they should administer the medication and expectations of the prescribed drug. Expectations should include risks and benefits to avoid patient confusion about side effects or efficacy measures. Thorough discussion of medication therapy selected with the patient may identify contraindications previously unknown or a patient history of failure or success with the selected agent in the past.

CONCLUSION

Multiple principles must be exercised for appropriate drug delivery from the bedside to the patient. As a healthcare provider, understanding these processes helps to ensure safe medication prescribing, as outlined in this appendix.

adverse effects of, 1060
in antihyperuricemic treatment, 1060
dosage of, 1058*t*, 1060
in gout, 1058*t*
- FEC regimen, in breast cancer, 1550*t*
- Fecal impaction, 395, 956*t*
urinary incontinence in, 946
- Fecal occult blood tests, screening for colorectal cancer, 1585, 1586*t*
- Feeding tube, 1777–1792. *See also* Enteral nutrition; *specific types of tubes*
flushing of, 1790
medication administered through, 1790–1791
placement of, 1781*t*
- Felbamate
adverse effects of, 568*t*, 573, 574*t*
drug interactions of, 879*t*
- Felodipine
anxiety with, 720*t*
drug interactions of, 994*t*
in heart failure, 96
in ischemic heart disease, 125
- Felty's syndrome, in rheumatoid arthritis, 1028
- Fenfluramine, 1801
- Fenofibrate
adverse effects of, 259*t*
in antihyperuricemic treatment, 1061
dosage of, 259*t*
drug interactions of, 219*t*
in dyslipidemia, 257*t*, 259*t*
in hyperlipidemia, 263
- Fenoldopam, in acute renal failure, 459
- Fenopropfen
dosage of, 1058*t*
in gout, 1058*t*
- Fentanyl
dosage of, 613*t*
for epidural analgesia, 614
in pain, 613, 613*t*
in sickle cell anemia/disease, 1203
in pancreatitis, 426
in PCA pumps, 614
transdermal, in osteoarthritis, 1050
- Fenugreek, 220*t*
- Ferric gluconate, 1762
in anemia of chronic kidney disease, 481*t*
iron content of, 1165*t*
in iron-deficiency anemia, 1164, 1165*t*
- Ferrous fumarate
iron content of, 1165*t*
in iron-deficiency anemia, 1165*t*
- Ferrous gluconate
iron content of, 1165*t*
in iron-deficiency anemia, 1165*t*
- Ferrous sulfate
drug interactions of, 338
iron content of, 1165*t*
in iron-deficiency anemia, 1165*t*
- Fertile window, 881
- Fertility awareness-based methods, 872*t*, 881
- Fertilization, 870
- Ferumoxylol, in anemia of chronic kidney disease, 481*t*
- Festination, in Parkinson's disease, 593
- Fetal hemoglobin, 1192, 1193
- Fetal hemoglobin inducers, in sickle cell anemia/disease, 1195*t*, 1196, 1198
- Fever
in infection, 1210
in sickle cell anemia/disease, 1199–1200
vaccine-related, 1477–1478
- Feverfew, 127, 616
- Fexofenadine, 1116, 1117*t*
in nausea and vomiting, 378
- Fiber, dietary, in constipation, 391, 856
- Fibrates
adverse effects of, 263
drug interactions of, 260, 263
in dyslipidemia, 257*t*, 259*t*
in hyperlipidemia, 263, 999
mechanism of action of, 263
- Fibrin, 200, 1172, 1172*f*
- Fibrinolysis, 200, 1171, 1180
- Fibrinolysis inhibitors, in von Willebrand's disease, 1178
- Fibrinolytic therapy. *See also* Thrombolytic therapy; *specific drugs*
in acute coronary syndromes, 138–142, 145*t*, 149–150, 150*t*, 156, 161*t*
adverse effects of, 161*t*
contraindications to, 145*t*, 150*t*
- Fibroadenoma, of breast, 874
- Fibrocystic breast disease, 1542
- Fibromyalgia, 606
- Fidaxomicin, in *Clostridium difficile* infection, 1337–1338
- FIGO staging system, in ovarian cancer, 1643, 1644*a*
- Filgrastim
adverse effects of, 1739*t*
dosage of, 1706, 1739*t*
in mobilization of peripheral blood progenitor cells, 1706, 1711
in neutropenia, 1579
prophylactic, in neutropenic cancer patients, 1729, 1739*t*
- Finasteride
in benign prostatic hyperplasia, 929, 933, 938, 938*t*, 1605
dosage of, 1605
mechanism of action of, 929, 938
pharmacologic properties of, 938*t*
in prevention of prostate cancer, 1605
in prostate cancer, 1604*t*
- Fine-needle aspiration biopsy, in lung cancer, 1569*t*
- Fingolimod
administration of, 552
adverse effects of, 549*t*, 552
dosage of, 549*t*, 552
mechanism of action of, 551–552
in multiple sclerosis, 549*t*, 550*t*, 551–552
pharmacology of, 551–552
- Fish oils
in hyperlipidemia, 263
in pain, 616
- Fixed drug eruption, 970
- Flank pain, in urinary tract infections, 1377
- Flecainide
adverse effects of, 86*t*, 181*t*
arrhythmia with, 174*f*, 175*t*, 176*t*, 189*t*, 192*t*
in atrial fibrillation, 183*a*, 183*t*, 184*t*
dosage of, 183*t*
drug interactions of, 183*t*
mechanism of action of, 175*t*
in ventricular premature depolarizations, 188
- Flight of ideas, in cyclothymic disorder, 699
- Floppy baby syndrome, 712
- Floppy iris syndrome, 936
- Flow cytometry, immunophenotyping by, 1655–1656

- Fluconazole
arrhythmia with, 192t
in aspergillosis, 1455–1456
in cryptococcosis, 1449t, 1453
dosage of, 861t, 1427, 1428t, 1432, 1447–1448, 1449t, 1450–1451, 1453, 1716
drug interactions of, 219t, 994t, 1444–1445
in endemic mycosis, 1444–1445
in esophageal candidiasis, 1432, 1451
in fungal infections, 996, 996t
in infective endocarditis, 1308
in invasive candidiasis, 1447–1448, 1449t, 1451
in oropharyngeal candidiasis, 1432, 1451
in pancreatitis, 427
in peritonitis, 496
in prevention of cryptococcosis, 1453
in prevention of endemic mycosis, 1446
in prevention of fungal infections, 1716
in prevention of invasive candidiasis, 1451
in sepsis, 1420
teratogenic effects of, 851t
in tinea infections, 1436t
in vulvovaginal candidiasis, 862, 1427, 1428t
- Fluconazole resistance, 1432
- Flucytosine
in cryptococcosis, 1449t, 1453
dosage of, 1449t
in endemic mycosis, 1445t
in invasive candidiasis, 1449t
in meningitis, 1239
in peritonitis, 496
in vulvovaginal candidiasis, 1429
- Fludarabine, 1521–1522
adverse effects of, 1522, 1677–1678, 1678t
in cancer therapy, 1521–1522
in chronic lymphocytic leukemia, 1677–1679, 1678t
dosage of, 1677, 1678t, 1696t, 1708t
mechanism of action of, 1520a, 1521–1522
in non-Hodgkin's lymphoma, 1696, 1696t
pharmacokinetics of, 1521–1522
in preparation for hematopoietic cell transplant, 1708t, 1709
- Fludrocortisone
in adrenal insufficiency, 810, 812t
in hyperkalemia, 477
- Fluid balance, 501–515, 502t
case study of, 502, 503, 507, 508, 509, 515
in diarrhea, 395
enteral nutrition and, 1789
maintenance by body weight, 26t
parenteral nutrition and, 1759
- Fluid and electrolyte homeostatic mechanism, in elderly patients, 12
- Fluid loss
insensible, 502
sensible, 502
- Fluid management
in constipation, 391
in diarrhea, 395, 397
in hypovolemic shock, 275–277
indications for, 506
in intra-abdominal infections, 1349
monitoring of, 506
in pancreatitis, 425–426
in prevention of contrast-induced nephropathy, 461
in sepsis, 1416
therapeutic fluids, 503–515, 504t
colloids, 505
crystalloids, 503–505
electrolytes, 506–515
sodium, 507–509
- Fluid requirement, 503
calculation of, 503t
in pediatric patients, 26
- Fluid restriction
in chronic kidney disease, 475–476
in heart failure, 89
- Fluid retention, in heart failure, 84
- Flukes, 1361
- Flumazenil, in hepatic encephalopathy, 419
- Flumethasone pivalate
in contact dermatitis, 1153t
dosage and potency of, 1153t
- Flunisolide
in allergic rhinitis, 1114, 1115t
in asthma, 292t
dosage of, 292t
- Fluocinolone acetonide
in contact dermatitis, 1153t
dosage and potency of, 1153t
- Fluocinonide
in contact dermatitis, 1153t
dosage and potency of, 1153t
in psoriasis, 1133
- Fluorescence in situ hybridization (FISH), 1589
- Fluoroquinolone(s). *See also specific drugs*
administration through feeding tube, 1792

adverse effects of, 1088
dosage of, 1084*t*
in glaucoma, 1084*t*, 1088
mechanism of action of, 1084*t*
- Methimazole**
adverse effects of, 800
agranulocytosis with, 800
dosage of, 800
in hyperthyroidism, 799–802
mechanism of action of, 800
- Methocarbamol, in musculoskeletal disorders**, 1073
- Methotrexate**, 1522
in acute lymphocytic leukemia, 1660, 1661*t*, 1663*t*, 1664*t*
in acute myelogenous leukemia, 1666
adverse effects of, 462, 1030*t*, 1034–1035, 1136, 1522, 1552*t*, 1664*t*, 1668
in breast cancer, 1548, 1550*t*
in cancer therapy, 1536*t*
dosage of, 365*t*, 369*t*, 1030*t*, 1136, 1522, 1661*t*, 1663*t*, 1713
drug interactions of, 640*t*, 1522, 1664*t*, 1717
emetogenicity of, 383*t*
hepatotoxicity of, 1136
in inflammatory bowel disease, 365–366, 365*t*, 369*t*, 370
intrathecal, 1522, 1663*t*
mechanism of action of, 1034, 1520*a*, 1522, 1664*t*
monitoring treatment with, 1030*t*
in non-Hodgkin's lymphoma, 1697–1698
osteoporosis with, 1011*t*
pharmacokinetics of, 1522
in prevention of GVHD, 1713
in psoriasis, 1134, 1136
in rheumatoid arthritis, 1030*t*, 1034–1035
teratogenicity of, 1037
- Methoxamine, growth hormone deficiency with**, 835
- Methyl aminolevulinate, in skin cancer**, 1635, 1635*t*
- Methylcellulose**
in constipation, 391, 392*t*
in diarrhea, 398
dosage of, 392*t*, 403*t*
in irritable bowel syndrome, 398, 403*t*
- Methyldopa**
adverse effects of, 64*t*
allergic drug reactions, 967*t*
dosage of, 64*t*
drug interactions of, 684*t*
erectile dysfunction with, 917*t*
in hypertension, 64*t*
pancreatitis with, 424*t*

- Methylaltraxone bromide
adverse effects of, 393
dosage of, 393
- Methyl nicotinate
adverse effects of, 1073
in musculoskeletal disorders, 1072*t*, 1073
in osteoarthritis, 1051
- Methylphenidate
in ADHD, 749, 751*t*, 752*t*, 754*t*
adverse effects of, 752*t*
anxiety with, 720*t*
augmentation of antidepressant therapy with, 689
dosage of, 553*t*, 751*t*
drug interactions of, 685
in fatigue, 553*t*
growth hormone deficiency with, 835
in insomnia, 740
in pain, 615
respiratory alkalosis with, 526*t*

- Tobramycin
 clinical parameters for, 1417
 in conjunctivitis, 1096, 1096*t*, 1097*t*
 in cystic fibrosis, 327, 327*t*, 328, 328*t*
 dosage of, 327*t*, 328*t*, 1096*t*, 1097*t*, 1253*t*, 1351*t*, 1732*t*
 drug interactions of, 993
 in infections in cancer patients, 1732*t*
 in infective endocarditis, 1308
 inhaled, 327, 328
 in intra-abdominal infections, 1351*t*
 in keratitis, 1101*t*
 in meningitis, 1238
 nephrotoxicity of, 460
 in pneumonia, 1253, 1253*t*
 in urinary tract infections, 1375*t*
- Tocainide, in arrhythmias, 174*f*
- Tocilizumab, 1031*t*, 1036
 dosage of, 1031*t*
 monitoring treatment with, 1031*t*
 in rheumatoid arthritis, 1031*t*
- Tocolytics, 863
- Today sponge, 881
- Tofacitinib, in rheumatoid arthritis, 1036
- Toilet mapping, 934
- Tolbutamide
 in diabetes mellitus, 769
 dosage of, 769
 drug interactions of, 684*t*
- Tolcapone
 dosage of, 596*t*
 mechanism of action of, 596*t*
 in Parkinson's disease, 596*t*, 600
- Tolmetin
 dosage of, 1058*t*
 in gout, 1058*t*
- Tolnaftate, in tinea infections, 1436*t*
- Tolterodine
 adverse effects of, 950, 951*t*
 in benign prostatic hyperplasia, 939
 dosage of, 951*t*
 pharmacokinetics of, 951*t*
 in urinary incontinence, 553, 601, 950, 951*t*, 952
- Tolvaptan, in heart failure, 105
- Tonometry, 1082
- Topical analgesics, in osteoarthritis, 1046*t*, 1051
- Topiramate
 adverse effects of, 565*t*–566*t*
 dosage of, 565*t*–566*t*, 586
 drug interactions of, 574*t*, 879*t*
 in epilepsy, 565*t*–566*t*, 571*t*, 573, 574*t*
 mechanism of action of, 565*t*–566*t*
 metabolic acidosis with, 522*t*
 pharmacokinetics of, 565*t*–566*t*
 in prevention of migraine, 628, 628*t*
 in status epilepticus, 586
- Topoisomerase inhibitors, 1524–1525
 in colorectal cancer, 1596
 secondary malignancies and, 1667–1668
- Topotecan, 1524–1525
 adverse effects of, 1524–1525, 1649*t*
 in cancer therapy, 1524–1525
 dosage of, 1573*t*–1574*t*, 1649*t*
 in renal dysfunction, 1573*t*–1574*t*
 extravasation of, 1750*t*
 in lung cancer, 1573*t*–1574*t*, 1574, 1576
 mechanism of action of, 1524
 in ovarian cancer, 1649*t*
 pharmacokinetics of, 1525
- Toremifene, 1535
 adverse effects of, 1535, 1554*t*
 in breast cancer, 1554*t*, 1556
 in cancer therapy, 1535
 dosage of, 1554*t*, 1556
 mechanism of action of, 1535
 pharmacokinetics of, 1535
- Torsades de pointes, 11, 191–193
 clinical presentation in, 193
 diagnosis of, 193
 drug-related, 192, 192*t*
 epidemiology of, 191–192

- etiology of, 191–192
 outcome evaluation in, 193
 pathophysiology of, 192
 prevention of, 193
 treatment of, 192–193
- Torsemide
 in acute renal failure, 456–457
 adverse effects of, 456
 dosage of, 90*t*, 101*t*, 457
 in heart failure, 90, 90*t*, 101, 101*t*
 in hypertension, 65
- Tositumomab, 1532
 adverse effects of, 1532
 in cancer therapy, 1532
 mechanism of action of, 1532
- Total-body irradiation, in preparation for
 hematopoietic cell transplant, 1708, 1718
- Total body water, 501–502
 estimation of, 506–507
- Total iron-binding capacity, 1162, 1164*t*
- Total parenteral nutrition. *See* Parenteral nutrition

 in aspergillosis, 1448, 1449*t*–1450*t*, 1456–1457
 dosage of, 1448, 1449*t*–1450*t*, 1732*t*
 drug interactions of, 994*t*, 1448
 in endemic mycosis, 1445*t*
 in esophageal candidiasis, 1432, 1451
 in fusariosis, 1449*t*–1450*t*
 in infections in cancer patients, 1732*t*
 in infective endocarditis, 1308
 in invasive candidiasis, 1447–1448, 1449*t*–1450*t*,
 1450–1451
 in peritonitis, 496
 in sepsis, 1420
- Vorinostat
 adverse effects of, 1529
 in cancer therapy, 1529
 pharmacokinetics of, 1529
- Vulvovaginal atrophy, in menopause, 903, 908
- Vulvovaginal candidiasis, 1426–1429
 case study of, 1427
 clinical presentation in, 1426
 complicated, 1426
 diagnosis of, 1426
 epidemiology of, 1426
 etiology of, 1426
 nonalbicans, 1426, 1429
 outcome evaluation in, 1430
 pathophysiology of, 1426
 patient care and monitoring in, 1429
 in pregnancy, 855, 858*t*, 862, 1429
 recurrent, 1426, 1428–1429
 risk factors for, 1426, 1427*t*
 treatment of
 antifungal therapy, 1428, 1428*t*
 cultural awareness, 1429
 nonpharmacologic, 1427
 uncomplicated, 1426–1428, 1428*t*
- Vytorin, 263
- W**
- Waist circumference, 1795–1797, 1806
 determination of, 1797
 high-risk, 1797, 1797*t*
- Waldenström's macroglobulinemia, 1684
- Warfarin, 10
 administration through feeding tube, 1791
 adverse effects of, 184–185, 211*t*, 215–216
 in atrial fibrillation, 182, 184–185
 dosage of, 205*t*, 216–217
 drug interactions of, 219, 219*t*, 220*t*, 262, 263,
 340, 402, 612, 684*t*, 994*t*, 1048, 1057,
 1060, 1217, 1428, 1444, 1520, 1801
 food interactions of, 219, 220*t*
 in heart failure, 96
 initiation of therapy with, 216–217, 216*a*
 laboratory monitoring of therapy with,
 217–218
 mechanism of action of, 215, 215*f*

- Warfarin (*Cont.*):
 metabolism of, 215–216, 215*f*, 219
 in pregnancy, 219
 in prevention of deep vein thrombosis, 1683
 in prevention of stroke, 239, 239*t*
 in prevention of venous thromboembolism, 206–207, 211*t*
 teratogenic effects of, 851*t*
 in venous thromboembolism, 207, 207*a*, 211*t*, 215–219, 223*t*
- Warts, genital. *See* Genital warts
- Water balance, impaired
 in chronic kidney disease, 474–476
 clinical presentation in, 475
 diagnosis of, 475
 in heart failure, 83
 outcome evaluation in, 476
 pathophysiology of, 474–475
 treatment of, 475–476
 nonpharmacologic, 475–476
 pharmacologic, 476
- Water intoxication, 960
- Weight gain
 drugs contributing to, 1798*t*
 with oral contraceptives, 877
- Weight loss, 1797–1804
 in hypertension, 60, 61*t*
 in ischemic heart disease, 118–119
 in pancreatitis, chronic, 428
- Wernicke's encephalopathy, 639, 643
- Western blot, for HIV, 1484, 1484*t*
- West Nile virus, in CNS infections, 1238
- West syndrome, 560*t*
- Wheezing, in asthma, 284
- Whipple's disease, 395
- White blood cell count
 in CSF, 1227*t*
 in infections, 1211, 1211*t*
- White blood cell count differential, in infections, 1211, 1211*t*
- White coat hypertension, 60
- White petrolatum, for diaper dermatitis, 1156
- WHO classification, 1692*t*
 of acute myelogenous leukemia, 1656*t*
 of Hodgkin's lymphoma, 1689, 1689*t*
 of lymphoid neoplasms, 1689*t*
 of non-Hodgkin's lymphoma, 1691
- Whole blood, in hypovolemic shock, 277
- Whole-brain radiotherapy, in melanoma with brain metastasis, 1626
- WHO oral rehydration solution, 397
- Wild yam, 911*t*
- Willow bark, 220*t*
- Wilms' tumor, kidney transplantation in, 979
- Wilson's disease, 880
 liver disease in, 412
 liver transplantation in, 979
 osteoarthritis in, 1043*t*

 dosage of, 919*t*
 in erectile dysfunction, 919*t*, 923
 mechanism of action of, 923
- Z**
- Zafirlukast
 adverse effects of, 294
 in asthma, 291*t*, 293–294
 dosage of, 291*t*
 drug interactions of, 219*t*, 294, 994*t*
- Zaleplon
 adverse effects of, 741*t*
 dosage of, 739*t*, 741*t*
 in insomnia, 739*t*
 pharmacokinetics of, 741*t*
 in restless-legs syndrome, 741, 741*t*
- Zanamivir, in pneumonia, 1251, 1252
- ZAP-70 expression, in chronic lymphocytic leukemia, 1676
- Zenpep products, 329*t*
- Zidovudine
 adverse effects of, 1487, 1491*t*, 1501*t*–1505*t*
 anemia due to, 1167*t*, 1168
 dosage of, 1491*t*
 drug interactions of, 1428, 1491*t*
 in HIV infection, 1487, 1491*t*, 1498
 mania with, 641*t*
 mechanism of action of, 1483*f*
- Zileuton
 adverse effects of, 294
 in asthma, 291*t*, 293–294
 dosage of, 291*t*
- Zinc oxide
 in diaper dermatitis, 1156
 in macular degeneration, 1104
- Zinc supplementation
 drug interactions of, 1217
 for parenteral nutrition, 1761, 1761*t*
- Ziprasidone
 adverse effects of, 661*t*, 662, 711
 in Alzheimer's disease, 537*t*
 in bipolar disorder, 704*t*, 711
 dosage of, 537*t*, 661*t*, 662, 704*t*
 in geriatric patients, 669*t*
 in hepatic, 669*t*
 in pediatric patients, 669*t*
 in renal impairment, 669*t*
 drug interactions of, 671*t*, 672
 mechanism of action of, 662
 metabolism of, 671*t*, 672
 in schizophrenia, 660, 661*t*, 662, 670
- Zoledronic acid
 adverse effects of, 1018, 1021, 1022, 1745
 arrhythmia with, 178*t*
 dosage of, 513*t*, 1613, 1744*t*
 in hypercalcemia, 512, 513*t*, 1744*t*
 in osteoporosis, 1016
 in prostate cancer, 1613
- Zollinger–Ellison syndrome
 treatment of, 347
- Zolmitriptan
 dosage of, 626*t*
 drug interactions of, 626*t*
 in migraine, 626*t*
- Zolpidem
 adverse effects of, 741*t*
 dosage of, 739*t*, 741*t*
 drug interactions of, 994*t*
 in insomnia, 739*t*
 pharmacokinetics of, 739*t*
 in restless-legs syndrome, 741, 741*t*
- Zona fasciculata, 808, 809*a*
- Zona glomerulosa, 808, 809*a*
- Zona reticularis, 808, 809*a*
- Zonisamide
 adverse effects of, 565*t*
 dosage of, 566
 drug interactions of, 522*t*
 in epilepsy, 565*t*, 566, 572*t*, 573, 574*t*
 mechanism of action of, 565*t*
 metabolic acidosis with, 522*t*
 pharmacokinetics of, 565*t*
- Zoster vaccine, 1472*t*, 1476–1477
- Zotarolimus, drug-eluting vascular stents, 119
- Z-score, 1012
- Zymogens, 423–424
