Simple numerical Solution of the GVF equation

Fitsume T.
Direct–step Method

• In the Direct Step method, the location where the specified depth, \( y_d \) occurs is determined, given the location for the occurrence of depth, \( y_u \). Consider the channel shown in figure below.

• In this channel, say depth \( y_u \) occurs at a distance \( x_u \) from the reference point. Discharge, \( Q \), channel bottom slope, \( S_0 \), the roughness coefficient, \( n \) and cross-sectional shape parameters (which relate \( A \), \( P \) and \( R \) to \( y \)) are also known.

• The problem now is to determine the location \( x_d \).
Direct–step Method
Direct–step Method

\[ z_u + y_u + \frac{\alpha_u V_u^2}{2g} = z_d + y_d + \frac{\alpha_d V_d^2}{2g} + S_f (x_d - x_u) \]

\[ S_f = \frac{n^2 Q^2}{A^2 R^{4/3}} \]

• $S_f$ varies between sections $u$ and $d$ since the flow depth, and consequently $A$ and $R$ vary between these two sections.

• $S_f$ may also due to variation in the roughness between the two sections. Following equations may be used to determine $S_f$. 

Direct–step Method

Arithmetic mean

\[ \overline{S_f} = \frac{1}{2} \left( S_{f_u} + S_{f_d} \right) \]

Geometric mean

\[ \overline{S_f} = \sqrt{\left( S_{f_u} \times S_{f_d} \right)} \]

Harmonic mean

\[ \overline{S_f} = \frac{2S_{f_u} S_{f_d}}{S_{f_u} + S_{f_d}} \]
Direct–step Method

• Experience has indicated that the arithmetic mean gives the lowest maximum error, although it is not always the smallest error. Also, it is the simplest of the three approximations. Therefore, its use is generally recommended.

• Noting that the bed elevations $Z_u$ and $Z_d$ are related through the bed slope, $S_0$ and the distance between the sections, $(x_d - x_u)$, can be written as
Direct–step Method

where $E_u$ and $E_d$ are specific energies at section $u$ and $d$, respectively.
Disadvantages of Direct step method

• Interpolations become necessary if the flow depths are required at specified locations.
• It is inconvenient to apply this method to non-prismatic channels because the cross-sectional shape at the unknown location should be known a priori.
Standard Step Method

- In the standard step method, flow depth at a specified location, $y_d$, is determined, given the flow depth, $Y_u$, at another specified location. Consider the channel shown in Figure below. In this channel, say $Y_u$ occurs at a distance $X_u$ from the reference point.

- Discharge, $Q$, Channel bottom slope, $S_0$, the roughness coefficient, $n$ and cross-sectional shape parameters (which relate $A$, $P$ and $R$ to $y$) are also known.

- The problem now is to determine the flow depth, $Y_d$ at the specified location $X_d$. 
Standard Step Method

Flow

$y_u \text{ (known)}$

$y_d \text{ (unknown)}$

$X_u \text{ (known)}$

$Z_u$

$Z_d$

Datum

Water surface

Channel Bed

$X_d \text{ (known)}$
Standard Step Method

- Can be written as

\[
-\left( y_d + \alpha_d \frac{V_d^2}{2g} \right) + \left( y_u + \alpha_u \frac{V_u^2}{2g} \right) = \bar{S}_f (x_d - x_u) - S_0 (x_d - x_u)
\]

- the flow rate \( (Q) \), the roughness coefficient \( (n) \), distances \( X_d \) and \( X_u \), the channel slope \( (S_0) \), the flow conditions at section \( u \left( y_u, \alpha_u \text{ and } A_u \right) \) are known.

- Therefore the right hand side of Eq. Above can be determined. On the left hand side, the area, \( A_d \) and the friction slope, \( S_{f_d} \) are functions of the flow depth \( Y_d \). Thus we have one equation in one unknown \( Y_d \). Therefore, \( Y_d \) can be determined by solving the a non-linear equation.
Standard Step Method

• Either trial and error or numerical techniques such as bisection, Newton –Raphson techniques etc. can be used for solving

\[ y_d + \frac{\alpha_d Q^2}{2gA_d} + \frac{S_{f_d} (x_d - x_u)}{2.0} = y_u + \frac{\alpha_u Q^2}{2gA_u} - \frac{S_{f_u}}{2} (x_d - x_u) + S_0 (x_d - x_u) \]

• For example, for a wide rectangular channel (assuming \( \alpha_u = \alpha_d = 1.0 \))

\[ y_d + \frac{q^2}{2gy_d} + \frac{n^2 q^2 (x_d - x_u)}{2y_d^{10/3}} = y_u + \frac{q^2}{2gy_u} - \frac{n^2 q^2}{2y_u^{10/3}} (x_d - x_u) + S_0 (x_d - x_u) \]
Example

- A grouted-riprap, trapezoidal channel (n= 0.0025) with a bottom width of 4 meters and side slopes of m = 1 carries a discharge 12.5 m³/sec on a 0.001 slope. Compute the backwater curve (upstream water surface profile) created by a low dam that backs water up to a depth of 2 m immediately behind the dam. Specifically, water depths are required at critical diversion points that are located at distances of 188 m, 423 m, 748 m, and 1,675 m upstream of the dam.
Solution:

1. Calculate normal depth,

\[ S_o = S_0 \] for uniform flow conditions

\[ \frac{Q}{A} = \frac{1}{n} \cdot R_h^{2/3} \cdot S_o^{1/2} \]

<table>
<thead>
<tr>
<th>Section Type</th>
<th>Area (A)</th>
<th>Wetted perimeter (P)</th>
<th>Hydraulic Radius (R_h)</th>
<th>Top Width (T)</th>
<th>Hydraulic Depth (D)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Trapezoidal</td>
<td>((b + my)y)</td>
<td>(b + 2y\sqrt{1 + m^2})</td>
<td>(\frac{(b + my)y}{b + 2y\sqrt{1 + m^2}})</td>
<td>(b + 2my)</td>
<td>(\frac{(b + my)y}{b + 2my})</td>
</tr>
</tbody>
</table>

\[
\frac{12.5}{(b+m.y).y} = \frac{1}{0.025} \cdot \left(\frac{(b+m.y).y}{b+2.y\sqrt{1+m^2}}\right)^{2/3} \cdot (0.001)^{1/2}
\]

\[
\frac{12.5}{(1.y+4.m).y} = \frac{1}{0.025} \cdot \left(\frac{(4+y).y}{4+2.y\sqrt{1+1}}\right)^{2/3} \cdot (0.001)^{1/2}
\]

By trial and error; \(y_n = 1.66 \text{ m}\)
2. Calculate critical depth

\[
\frac{Q\cdot m^{3/2}}{g^{1/2}\cdot b^{5/2}} = \frac{(12.5)\cdot(1)^{3/2}}{(9.81)^{1/2}\cdot(4)^{5/2}} = 0.125
\]

\[
\frac{m\cdot y_c}{b} = 0.230
\]

\[
y_c = \frac{(0.23)\cdot(4 \text{ m})}{1}
\]

\[
y_c = 0.92 \text{ m}
\]
Known water depth; $y = 2 \text{ m}$

Normal depth; $y_n = 1.66 \text{ m}$

Critical depth; $y_c = 0.92 \text{ m}$

The depth $(y = 2 \text{ m})$ just upstream from the dam is the control section designated as section 1. Energy balance computations begin here and progress upstream (backwater) because the flow is subcritical ($y_c < y_n$).

Since the profile has an M-1 classification, the flow depth will approach normal depth asymptotically as the computations progress upstream.

Since $y/y_c > 1$ and $y/y_n > 1$; the value $dy/dx$ is positive, indicating that water depth increases in the direction of flow.

</tr>
</tbody>
</table>

*Note:* The trial depth of 1.82 m is correct. Now balance energy between sections 3 and 4.

---

**Column (1)** Section numbers are arbitrarily designated from downstream to upstream.

**Column (2)** Sections are designated as either downstream (D) or upstream (U) to assist in the energy balance.

**Column (3)** Depth of flow (meters) is known at section 1 and assumed at section 2. Once the energies balance, the depth is now known at section 2, and the depth at section 3 is assumed until the energies at sections 2 and 3 balance.

**Column (4)** The channel bottom elevation (meters) above some datum (e.g., mean sea level) is given. In this case, the datum is taken as the channel bottom at section 1. The bottom slope and distance interval are used to determine subsequent bottom elevations.

**Column (5)** Water cross-sectional area (square meters) corresponds to the depth in the trapezoidal cross section.

**Column (6)** Mean velocity (meters per second) is obtained by dividing the discharge by the area in column 5.
### Standard Step Method

| Column (7) | Velocity head (meters). |
| Column (8) | Wetted perimeter (meters) of the trapezoidal cross section based on the depth of flow. |
| Column (9) | Hydraulic radius (meters) equal to the area in column 5 divided by the wetted perimeter in column 8. |
| Column (10) | Energy slope obtained from Manning equation (Equation 6.27a). |
| Column (11) | Average energy grade line slope of the two sections being balanced. |
| Column (12) | Energy loss (meters) from friction between the two sections found using $h_L = S_{e(\text{avg})}(\Delta L)$ from Equation 6.26b. |
| Column (13) | Total energy (meters) must balance in adjacent sections (Equation 6.26b). Energy losses are always added to the downstream section. Also, the energy balance must be very close before proceeding to the next pair of adjacent sections or errors will accumulate in succeeding computations. Thus, even though depths were only required to the nearest 0.01 m, energy heads were calculated to the nearest 0.001 m. |
