 - Once primary lesions are identified, along with distribution, arrangement, color, and secondary changes, observations should be captured in 1 or 2 sentences to assist in differential diagnosis.

Elevated lesions in neonates

- Papules
 - Common
 - Erythematous
 - Erythema toxicum
 - Miliaria rubra
 - Acne (see Figure 80 on page F27)
 - Candidiasis
 - Scabies
 - White
 - Milia
 - Yellow
 - Sebaceous gland hypertrophy
 - Skin colored
 - Epidermal nevus
 - Skin tags
 - Uncommon
 - Yellow
 - Mastocytosis
 - Juvenile xanthogranuloma
- Nodules
 - Common
 - Erythematous
 - Hemangioma

- Uncommon
 - Skin colored
 - Condylomata accuminata
 - Dermoid cyst
 - Yellow
 - Mastocytosis
 - Plaques
 - Common
 - Skin colored or yellow
 - Nevus sebaceous
 - Skin colored
 - Epidermal nevus
 - Vesicles or bullae (see Figure 81 on page F27)
 - Common
 - Erythema toxicum
 - Miliaria crystallina
 - Sucking blisters
 - Bullous impetigo
 - Herpes simplex virus infection
 - Uncommon
 - Incontinentia pigmenti
 - Aplasia cutis congenita
 - Varicella (see Figure 82 on page F27)
 - Epidermolysis bullosa
 - Bullous ichthyosiform erythroderma
 - Pustules
 - Common
 - Erythema toxicum
 - Transient neonatal pustular melanosis
 - Miliaria pustulosa
 - Herpes simplex virus infection
 - Folliculitis (see Figure 83 on page F27)
 - Acne
 - Candidiasis
 - Scabies
 - Uncommon
 - Acropustulosis of infancy
- Flat lesions in neonates**
- Macules
 - Common
 - Hypopigmented
 - Prehemangioma
 - Postinflammatory hypopigmentation
 - Hyperpigmented
 - Transient neonatal pustular melanosis
 - Café-au-lait macule
 - Postinflammatory hyperpigmentation
 - Congenital melanocytic nevus
 - Uncommon
 - Hypopigmented
 - Ash-leaf macule
 - Patches
 - Common
 - Erythematous
 - Salmon patch (nevus simplex)
 - Hemangioma (early)
 - Port wine stain (see Figure 84 on page F28)
 - Atopic dermatitis
 - Seborrheic dermatitis
 - Diaper dermatitis (irritant or seborrheic)
 - Hyperpigmented
 - Mongolian spot
 - Lentigo
 - Uncommon
 - Erythematous
 - Acrodermatitis enteropathica (see Figure 85 on page F28)
 - Hyperpigmented
 - Linear and whorled hypermelanosis
 - Hypopigmented
 - Hypomelanosis of Ito
 - Nevus depigmentosus
- Depressed lesions in neonates**
- Erosions
 - Common
 - Bullous impetigo
 - Neonatal herpes simplex virus infection
 - Staphylococcal scalded-skin syndrome
 - Uncommon
 - Aplasia cutis congenital
 - Acrodermatitis enteropathica
 - Epidermolysis bullosa
 - Bullous ichthyosiform erythroderma

Elevated lesions in older infants, children, and adolescents

■ Papules without scaling

- Common
 - Erythematous
 - Viral exanthems (many exanthems have a papular as well as macular component)
 - Scarlet fever
 - Insect bites
 - Scabies
 - Urticaria (see Figure 86 on page F28)
 - Papular urticaria
 - Acne
 - Early lesions of guttate psoriasis
 - Erythema multiforme
 - Skin colored
 - Keratosis pilaris
 - Molluscum contagiosum
 - Flat warts
 - Hyperpigmented
 - Nevus (intra-dermal)
- Uncommon
 - Yellow
 - Mastocytosis

■ Plaques without scaling

- Common
 - Skin colored
 - Nevus sebaceous
 - Epidermal nevus
 - Hyperpigmented
 - Congenital melanocytic nevus

■ Papules or plaques with scaling (papulosquamous disease)

- Common
 - Tinea corporis
 - Pityriasis rosea
 - Chronic atopic or contact dermatitis
 - Psoriasis
- Uncommon
 - Dermatomyositis
 - Lupus erythematosus
 - Lichen planus

■ Nodules

- Common
 - Erythematous
 - Pyogenic granuloma

- Skin colored
 - Wart
 - Callus
 - Corn
 - Epidermal cyst
 - Granuloma annulare
- Uncommon
 - Erythematous
 - Angiofibroma
 - Skin colored
 - Neurofibroma (see Figure 87 on page F28)
 - Yellow
 - Mastocytosis

■ Vesicles or bullae

- Common
 - Contact dermatitis
 - Bullous impetigo
 - Varicella
 - Herpes simplex virus infection
 - Hand, foot, and mouth disease
 - Erythema multiforme
- Uncommon
 - Polymorphous light eruption
 - Linear immunoglobulin A dermatosis

■ Pustules

- Common
 - Folliculitis
 - Scabies
 - Acne
 - Perioral dermatitis
- Uncommon
 - Associated with systemic bacterial infection (eg, disseminated gonococcal infection)

Flat lesions in older infants, children, and adolescents

■ Macules

- Common
 - Erythematous
 - Viral exanthems
 - Drug eruptions
 - Hypopigmented
 - Pityriasis alba (postinflammatory hypopigmentation)
 - Tinea versicolor
 - Vitiligo
 - Halo nevus

- Hyperpigmented
 - Freckles
 - Postinflammatory hyperpigmentation
 - Tinea versicolor
 - Café-au-lait macules
 - Melanocytic nevus
- Uncommon
 - Hypopigmented
 - Lichen sclerosus et atrophicus
 - Scleroderma
 - Ash-leaf macule
 - Piebaldism
- Patches
 - Common
 - Erythematous
 - Salmon patch (nevus simplex)
 - Port wine stain
 - Atopic dermatitis
 - Hyperpigmented
 - Mongolian spot
 - Becker nevus
 - Lentigo
 - Uncommon
 - Erythematous
 - Toxic shock syndrome (diffuse macular erythema)
 - Hyperpigmented
 - Linear and whorled hypermelanosis
 - Incontinentia pigmenti

Depressed lesions in older infants, children, and adolescents

- Erosions
 - Common
 - Bullous impetigo
 - Herpes simplex virus infection
 - Staphylococcal scalded-skin syndrome
 - Uncommon
 - Epidermolysis bullosa

Hair loss in older infants, children, and adolescents

- Congenital
 - Localized
 - Nevus sebaceous
 - Epidermal nevus
 - Aplasia cutis congenita
 - Diffuse
 - Hair shaft abnormalities
 - Hypothyroidism
- Acquired
 - Localized
 - Friction alopecia
 - Tinea capitis
 - Traction alopecia
 - Trichotillomania
 - Alopecia areata
 - Psoriasis
 - Secondary syphilis
 - Scleroderma
 - Diffuse
 - Telogen effluvium
 - Chemotherapy
 - Hypothyroidism
 - Acrodermatitis enteropathica

Recurrent Infections

DEFINITION

- Normal pattern of infections in childhood
 - Healthy children experience 6–8 upper respiratory tract infections per year in the first few years of life.
 - Up to 15 infections per year can still be within the normal range.
 - The high frequency of infections results from immunologic immaturity and frequent exposure to respiratory pathogens.
 - Attendance in child care and exposure to secondhand smoke may increase the number of infections.
- Recurrent infections may be a sign of an underlying, possibly immunologic, disorder.
 - This is much less common than “normal” childhood infections.
 - Early identification of these children is critical.
 - Prompt intervention can decrease morbidity and mortality.

EPIDEMIOLOGY

- In the normal host, infections are:
 - Self-limited
 - Occur more frequently in the winter
 - Associated with periods of wellness between infection
 - The average duration of a viral illness is 7–10 days.
 - A toddler may be sick for up to 100 days or almost one third of the year.
- Primary immunodeficiencies
 - Prevalence (excluding selective immunoglobulin A [IgA] deficiency)
 - 1 in 10,000 cases
 - Sex
 - Boys are affected more commonly than girls because many of these syndromes are X-linked.

MECHANISM

- Defects in anatomic, physiologic, and inflammatory host defense barriers can lead to recurrent infections.
 - Increased susceptibility of young children to otitis media results from an age-related dysfunction of the eustachian tubes, rarely associated with underlying immunodeficiency.
 - Recurrent meningitis may occur as the result of an occult cerebral spinal fluid leak.
 - Recurrent pneumonia may result from foreign body aspiration, tracheoesophageal fistula, gastroesophageal reflux, impaired function of mucociliary transport (eg, cystic fibrosis), and immotile cilia syndromes.
 - Reactive airway disease can produce recurrent respiratory symptoms in association with pulmonary infiltrates.
 - Recurrent infections can occur as a result of alteration in the normal microbial flora associated with antibiotic use and circulatory disorders.

- Secondary immunodeficiencies
 - More common than primary
 - Acquired or a consequence of a nonimmunologic process, including:
 - Infection
 - Cancer
 - Medication (cytotoxic, immunosuppressive)
 - Malnutrition
 - Splenic dysfunction
 - Metabolic disorders
 - Organ transplants
 - Rheumatologic diseases
 - New therapies, such as anticytokines or implantation of foreign materials (eg, heart valves, catheters)
- Primary immunodeficiencies
 - Far less common than secondary
 - Caused by intrinsic defects in the immune system that are genetically determined
 - Classified by the component of the immune system that is affected: humoral, cellular, complement, or phagocytic

HISTORY

- A complete history should be obtained for all children being evaluated for recurrent infections.
- Document characteristics of previous infections
 - Types of pathogens and infections
 - Duration of illnesses
 - Need for hospitalization
- Detailed family history is important.
 - Many of the primary immunodeficiencies are hereditary.
- History of risk factors for HIV infection
 - Personal for adolescents
 - Parental when congenital transmission is a possibility
 - Drug use
 - Prostitution
 - Blood-product transfusion
 - Multiple sexual partners
 - History of sexually transmitted infection
 - Homosexual behavior
- Obtain a complete review of systems.
 - Pay attention to known associated features of immunodeficiency syndromes.
 - Failure to thrive
 - Intractable diarrhea and malabsorption
 - Rheumatologic conditions
 - Hepatosplenomegaly
 - Lymphadenopathy

- Absence of lymph tissue
- Thrombocytopenia
- Eczema
- Oculocutaneous albinism
- Immunization history
 - Failure to make protective antibodies in response to immunizations can be indicative of immunodeficiency.
- Infections associated with an underlying immune disorder may present in various ways.
 - Increased frequency of common infections
 - Repeated serious bacterial infections
- Immunodeficiency may cause a common infection to:
 - Have increased severity
 - Have prolonged duration
 - Fail to respond to appropriate treatment
- Immunodeficiency may cause a common infection to present at an uncommon age.
 - Thrush or candidal diaper dermatitis in children >1 year suggests a defect in T-cell immunity.
- Immunodeficiency may produce an infection with an opportunistic pathogen.
 - *Pneumocystis carinii*
 - *Cryptococcus neoformans*
- Immunodeficiency may become apparent as an infection after the administration of a live virus vaccine (rare).

PHYSICAL EXAM

- A complete physical examination should be performed.
- Children with immunodeficiency appear chronically ill.
- Growth parameters should be obtained to determine the presence of failure to thrive.
 - Height
 - Weight
 - Head circumference
- Physical signs that may indicate underlying immunodeficiency
 - Absence of tonsils
 - Presence of generalized lymphadenopathy and hepatosplenomegaly
 - Skin lesions
 - Eczema
 - Abscesses
 - Seborrhea
 - Mucous membrane involvement
 - Telangiectasias
 - Mucositis
- Look for signs of recurrent infection.
 - Dull, retracted tympanic membranes
- Look for evidence of ongoing infection.
 - Thrush
- Note any specific or abnormal signs that may be associated with a particular immunodeficiency syndrome.
 - Oculocutaneous albinism in Chédiak-Higashi syndrome
- Signs associated with primary immunodeficiencies
 - Intractable diarrhea and malabsorption
 - Severe combined immunodeficiency (SCID), X-linked agammaglobulinemia (XLA), common variable immunodeficiency
 - Rheumatologic conditions
 - Common variable immunodeficiency, IgA deficiency, XLA
 - Hepatosplenomegaly, lymphadenopathy
 - Hyper-IgM syndrome
 - Absence of lymph tissue
 - XLA
 - Thrombocytopenia
 - Wiskott-Aldrich syndrome
 - Eczema
 - Wiskott-Aldrich syndrome, chronic granulomatous disease, hyper-IgE syndrome (Job syndrome)
 - Oculocutaneous albinism
 - Chédiak-Higashi syndrome

DIFFERENTIAL DIAGNOSIS

Secondary immunodeficiency

- Infection
 - HIV
 - Congenital rubella
- Cancer
 - Leukemia
 - Lymphoma
- Medication
 - Cytotoxic
 - Immunosuppressive
 - Corticosteroids
- Malnutrition
- Splenic dysfunction
 - Splenectomy
 - Sickle cell disease
 - Congenital asplenia
- Metabolic disorders
 - Uremia
 - Malnutrition
 - Protein-losing enteropathy

- Diabetes
- Galactosemia
- Chromosomal
 - Down syndrome
 - Bloom syndrome
- Improvements in medical care
 - Organ transplants
 - Rheumatologic diseases
 - Cancer
 - Anticytokine therapies
 - Anti-tumor necrosis factor- α for rheumatoid diseases and Crohn disease have been associated with an increased susceptibility to tuberculosis and histoplasmosis.
 - Implants
 - Heart valves
 - Catheters

Primary immunodeficiency

- Evaluation of the child for a primary immunodeficiency should be considered after nonimmunologic and secondary immunodeficiency syndromes have been ruled out.
- Most children are symptomatic within the first few years of life, except in:
 - Common variable immunodeficiency
 - Deficiencies of the terminal complement components
- Primary immunodeficiency is classified by the component of the immune system that is affected:
 - Humoral (see table Humoral Immunodeficiencies)
 - The antibody-mediated arm of the immune system
 - Comprises 50–70% of symptomatic primary immunodeficiencies
 - Children are susceptible to recurrent sinopulmonary infections with encapsulated bacteria.
 - *Streptococcus pneumoniae*
 - *Haemophilus influenzae*
 - Combined defects in cellular and humoral immunity (see table Combined Immunodeficiencies)
 - The second largest group of primary immunodeficiencies
 - In addition to bacterial infections, affected children are characteristically more susceptible to fungal, mycobacterial, and viral infections.
 - May experience recurrent or persistent candidiasis
 - Thrush
 - Diaper candidiasis
 - Common viral infections of childhood may cause severe or recurrent disease in affected children.
 - Varicella, for example
 - Complement
 - Least common among the primary immunodeficiencies

- Occurs in older children and in adolescents
 - May experience recurrent meningococcal infection: meningitis or meningococemia
 - Children may also have gonococcal arthritis.
- Phagocytic
 - Absence of a particular cell type
 - Congenital neutropenia
 - Cyclical neutropenia
 - Defects in chemotaxis
 - Leukocyte adhesion disorder
 - Defects in effector function
 - Chronic granulomatous disease
 - Children typically experience:
 - Recurrent skin infections
 - Abscesses
 - Sinopulmonary infections
 - Poor wound healing
 - Delayed umbilical cord separation
 - Gingivitis
 - Eczema

LABORATORY EVALUATION

- Laboratory evaluation should be guided by the type of infections the child is experiencing.
- Initial screening tests usually include:
 - Complete blood count and differential
 - Serum Ig levels (IgG, IgA, and IgM)
 - HIV serology, as indicated by the history and physical findings
- Tests of humoral immunity
 - B-cell count
 - IgG subclass determinations
 - Antibody titers against protein (diphtheria, tetanus toxoid) and polysaccharide (*Pneumococcus*, *Haemophilus*) antigens
 - Antibody levels must be interpreted with respect to age-appropriate values.
 - High or low levels can be significant.
- Tests of cellular immunity
 - Delayed-type hypersensitivity skin test (skin testing may not be reliable <1 year of age)
 - Lymphocyte count
 - Total lymphocyte count is obtained by multiplying the total leukocyte count by the percentage of lymphocytes.
 - A value <1500 cells/ μ L is considered lymphopenia.
- Phagocytic (macrophage or neutrophil)
 - Complete blood count
 - Neutrophil count may be abnormal.

Humoral Immunodeficiencies

Syndrome	Clinical Features	Associated Features
X-linked agammaglobulinemia	Susceptibility to encapsulated bacterial pathogens	Asymmetric arthritis, dermatomyositis, malabsorption, absence of tonsils, adenoids, and lymph nodes
	Sinopulmonary and gastrointestinal infections, sepsis, meningitis	
	Enhanced susceptibility to enterovirus and rotavirus	
	Symptomatic polio infection following live polio vaccination	
Transient hypogammaglobulinemia of infancy	Recurrent sinopulmonary infections; generally improves by 3–4 yr of age	May develop IgA deficiency
Hyper-IgM syndrome	X-linked	Low levels of IgG, IgA, and IgE
	Recurrent bacterial infections including encapsulated pathogens	Neutropenia, thrombocytopenia, T-cell defects
	Infections associated with T-cell defects (eg, <i>Pneumocystis [carinii] jiroveci</i>) also seen	
Common variable immunodeficiency	Sinopulmonary infections	Most common in second and third decade
	Bronchiectasis	Noncaseating granulomas, malabsorption, autoimmune disease
	Giardiasis	
IgA deficiency	Very common (1 in 400 individuals) but usually asymptomatic	Systemic lupus erythematosus, rheumatoid arthritis, chronic diarrhea
	Recurrent pulmonary infections leading to bronchiectasis	Allergic reactions to γ -globulin preparations
		IgG subclass deficiency in some
Specific antibody deficiency with normal immunoglobulins	Recurrent bacterial infections of the respiratory tract	
IgG-subclass deficiency	Normal immunoglobulin levels but with impaired antibody responses to polysaccharide antigens	
	Clinical significance not well delineated	

- IgE level
 - Elevated in hyper-IgE syndrome (Job syndrome)
- Nitroblue tetrazolium test
- Flow cytometric respiratory burst assay
- Complement
 - CH₅₀ assay
 - Screening assay for components of classic complement pathway

IMAGING

- Radiologic studies are used primarily in the diagnosis or management of associated infections.
 - The absence of a thymic shadow can be indicative of DiGeorge syndrome or SCID.

TREATMENT APPROACH

- Pending a complete immunologic evaluation, children who are thought to have immunodeficiency syndromes should not receive live attenuated vaccines, such as varicella, rotavirus, and measles/mumps/rubella, to avoid the possibility of vaccine-associated infection.
 - Vaccine recommendations for specific immunodeficiencies can be found in *Red Book: Report of the Committee on Infectious Diseases*.
- Treatment of primary immunodeficiency is condition specific.

SPECIFIC TREATMENT

Intravenous immunoglobulin (IVIG)

- Patients with humoral and combined immunodeficiencies may benefit from IVIG as replacement therapy.

Combined Immunodeficiencies

Syndrome	Clinical Features	Associated Features
DiGeorge syndrome	Clinically variable Increased incidence of viral and fungal infections	Hypocalcemia, hypoparathyroidism, congenital heart disease, abnormal facies
Severe combined immunodeficiency (SCID)	Both B-cell and T-cell deficiencies present Includes a variety of disorders that have multiple modes of inheritance Presents early in life (within first 3 mo of age) with recurrent or severe infections with all types of pathogens	Failure to thrive, diarrhea Most common (50%) form is X-linked Thymic hypoplasia Cartilage-hair hypoplasia with certain forms of SCID At increased risk for graft-versus-host disease with red blood cell transfusions
Ataxia telangiectasia	Recurrent sinopulmonary infections	Truncal ataxia, mental retardation, thymic hypoplasia, telangiectasia of skin and conjunctiva, glucose intolerance, increased risk for malignancy
Wiskott-Aldrich syndrome	Recurrent sinopulmonary infections	Eczema, thrombocytopenia, increased risk for malignancy

- Initial regimen is 300–400 mg/kg every 3–4 weeks.
- Should be adjusted on the basis of the patient's response
- The trough concentration of antibody should be ≥ 500 mg/dL.
- Replacement IVIG is not indicated for all types of humoral deficiency.
 - Patients with IgA deficiency may develop anaphylaxis to certain brands of IVIG that contain small amounts of IgA.

Other therapies

- Bone marrow transplantation
 - SCID
 - Wiskott-Aldrich syndrome
 - DiGeorge syndrome
- Enzyme replacement
 - Certain forms of SCID (adenosine deaminase deficiency)
- Cytokine therapy
 - Interleukin-2 deficiency
- Interferon- γ treatment
 - Decreases the number of infections in patients with chronic granulomatous disease
- Blood transfusion
 - When needed, should be with cytomegalovirus-negative, irradiated cells to prevent graft-versus-host disease

WHEN TO REFER

- Referral to an immunologist or infectious disease specialist should be considered in the following cases.
 - Recurrent serious bacterial infections
 - Sepsis

- Pneumonia
- Meningitis
- Serious bacterial infection in the context of failure to thrive
- Infection with an opportunistic pathogen
 - *Pneumocystis*
 - *Cryptococcus*
- Vaccine-associated infection
- Unusual age for infection
 - Zoster
 - Thrush
- Unusual severity or chronicity for a given infection
- Family history of immunodeficiency

WHEN TO ADMIT

- All patients with severe infections, infections with an unusual organism, or infections requiring intravenous antibiotics
- Patients suspected of having severe immunodeficiencies, such as SCID or Wiskott-Aldrich syndrome

PROGNOSIS

- Prognosis depends on the type of immunodeficiency and promptness of diagnosis and management of these conditions.

PREVENTION

- The genetic basis for many of the primary immunodeficiencies is now known, and prenatal screening is increasingly available.

Red Eye/Pink Eye

DEFINITION

- Red eye, pink eye, or conjunctivitis
 - A nonspecific finding that indicates conjunctival inflammation
 - A variety of disease processes can cause conjunctival inflammation.
 - In most children, it is a benign, self-limiting condition.

MECHANISM

- Neonatal infections can be acquired from:
 - Vaginal microorganisms during birth
 - Vaginal delivery
 - Cesarean delivery, if amniotic membranes rupture before delivery
 - Hand-to-eye contamination from hospital workers.
 - Infectious causes of neonatal conjunctivitis usually develop at least 48 hours after birth (see table Causes of Neonatal Conjunctivitis).
 - *Chlamydia trachomatis*
 - *Neisseria gonorrhoeae*
 - Group B *Streptococcus*
 - *Staphylococcus aureus*
 - *Escherichia coli*

- *Haemophilus influenzae*
- Herpes simplex virus (HSV) type 2
- Before the use of topical prophylaxis, ophthalmia neonatorum was a devastating disease associated with high morbidity.
 - Routine topical prophylaxis with silver nitrate, tetracycline ointment, or erythromycin ointment has dramatically reduced its incidence.
- Nasolacrimal duct (NLD) obstruction
 - At birth, tear production by the lacrimal gland is minimal.
 - Normal tearing develops several days to 2 weeks after birth.
 - Normally, the process of nasolacrimal canalization is completed by the end of the 9th month of gestation.
 - When canalization is incomplete, failure most often occurs at the distal end of the NLD at the Hasner valve.
 - Outflow obstruction at the Hasner valve is the most common cause of NLD obstruction.
 - Other, less common anatomic variations within the nasolacrimal system can cause obstruction of tear outflow.
 - Agenesis of the canaliculus
 - Crowding of the NLD opening by the inferior turbinate
- The most common bacteria causing conjunctivitis in children include:
 - *H influenzae*
 - *Streptococcus pneumoniae*

Causes of Neonatal Conjunctivitis

Cause	Time of Onset	Presentation	Conjunctival Scraping	Treatment
Silver nitrate toxicity	Within 24 hr	Watery discharge	Negative gram-negative Giemsa; few PMN	None needed
<i>Neisseria gonorrhoea</i>	2–4 days	Lid swelling, purulent discharge; corneal involvement can lead to corneal ulcer and perforation	Gram-negative intracellular diplococci and culture	Topical erythromycin and IV cefotaxime; treat even if asymptomatic
Other bacteria (staphylococci, streptococci)	4–7 days	Purulent discharge, with or without lid swelling	Gram-positive for specific bacteria and culture	Topical erythromycin or trimethoprim–polymyxin B eyedrops, or moxifloxacin
<i>Chlamydia</i>	4–10 days	Variable severity of lid swelling and serous or purulent discharge	Giemsa stain, basophilic, cytoplasmic inclusion bodies, positive direct immunofluorescent assay and culture	Initial IV erythromycin, then 50 mg/kg/day by mouth for 14 days; treat even if asymptomatic
<i>Haemophilus</i>	5–10 days	Serous or serosanguineous discharge, hemorrhagic conjunctivitis common; lid swelling with petechiae and bluish lid skin indicate preseptal cellulitis	Gram-negative <i>Coccobacillus</i> and culture	Topical trimethoprim–polymyxin B eyedrops and IV cefotaxime
Herpes simplex virus type 2	6 days to 2 wks	Usually unilateral, serous discharge with keratitis, positive corneal staining	Gram stain, multinucleated giant cells, Papanicolaou-stained intranuclear inclusion bodies, and herpes culture	Topical trifluorothymidine (Viroptic®) and IV acyclovir

Abbreviations: IV, intravenous; PMN, polymorphonucleocytes.

- *Moraxella catarrhalis*
- *Staphylococcus*

HISTORY

- A history of friends or family members with conjunctivitis usually indicates a contagious origin.
 - Viral conjunctivitis is usually caused by an adenovirus and is extremely contagious.
- Ask about itching.
 - Hallmark sign of allergic conjunctivitis
- Eye discharge
 - 1 or both eyes
- Watery
 - Allergic or viral conjunctivitis
- Purulent
 - Bacterial infections
- Infectious conjunctivitis usually begins in one eye, then spreads to the second eye after a few days.
- If only 1 eye is affected, consider:
 - Foreign body
 - Corneal ulcer
 - Herpes simplex keratitis

PHYSICAL EXAM

- The pediatric patient should receive an ocular examination using the mnemonic I-ARM.
 - Inspection
 - Acuity
 - Red reflex
 - The red reflex test should also be performed on older children with conjunctivitis because an abnormal red reflex may indicate a serious disease process.
 - Benign pediatric conjunctivitis almost never interferes with vision.
 - Motility

- Note whether conjunctivitis is unilateral or bilateral.
 - Unilateral conjunctivitis may be caused by
 - Foreign body
 - Corneal ulcer
 - Herpes simplex keratitis
- Note whether there is any discharge.
 - Minimal
 - Blepharitis
 - Watery
 - Allergic reaction
 - Viral conjunctivitis
 - Purulent
 - Bacterial conjunctivitis
- Note presence of preauricular lymph adenopathy.
 - Indicative of viral conjunctivitis
- Distinguishing features of conjunctivitis in children (see table Distinguishing Features of Conjunctivitis in Children)
 - Blepharitis
 - Minimal discharge
 - Minimal itching (real irritation, not itching)
 - *Staphylococcus* on culture common
 - Allergic reaction
 - Watery discharge
 - Marked itching
 - Eosinophils on conjunctival scraping
 - Bacterial
 - Purulent discharge
 - Minimal itching
 - Children with a bacterial conjunctivitis often complain that their eyelids stick together in the morning.
 - Most often, one eye is initially involved, with subsequent involvement of the other.

Distinguishing Features of Conjunctivitis in Children

Feature	Blepharitis	Allergic Reaction	Bacterial	Viral
Discharge	Minimal	Watery	Purulent	Watery
Itching	Minimal (real irritation, not itching)	Marked	Minimal	Minimal
Preauricular lymph adenopathy	Absent	Absent	Absent	Common
Laboratory test results	Staphylococcus on culture common	Eosinophils on conjunctival scraping	Bacteria on Gram stain; PMN response	Lymphocytes and monocytes

Abbreviation: PMN, polymorphonuclear neutrophil.

- The bulbar conjunctiva is diffusely injected, and a mucopurulent exudate is present in the inferior conjunctival fornix.
- Viral
 - Watery discharge
 - Minimal itching
 - Commonly preauricular lymph adenopathy
 - Patients often begin with infection in one eye that then spreads to the other.
 - Eyelids may be swollen, and they may produce reactive ptosis, severe conjunctival hyperemia, and hemorrhagic conjunctivitis.
 - The cornea may be involved; such patients are sensitive to light.
 - Tearing, redness, and the sensation of having a foreign body lodged in the eye are the extreme (termed *catarrhal conjunctivitis*).
- Neonatal conjunctivitis
 - As for all newborns, the ophthalmic examination should start with the red reflex test.
 - The red reflex should be normal, if the abnormality is isolated to the conjunctiva and does not involve the cornea or intraocular structures.
 - Conditions that have an abnormal red reflex test finding and require immediate consultation with an ophthalmologist
 - Endophthalmitis
 - Congenital glaucoma
 - Corneal infections
 - An urgent consultation is indicated if the neonatal patient has marked lid swelling or unilateral conjunctivitis that does not improve over 1 or 2 days.
 - This condition may be HSV-2 keratitis.

DIFFERENTIAL DIAGNOSIS

Conjunctivitis

Neonatal conjunctivitis

- Other causes of a red, teary eye in a newborn include:
 - Congenital herpes keratitis
 - Congenital glaucoma, characterized by clear tears, large cornea, hazy cornea due to corneal edema
 - Dacryocystitis, an infection of the nasolacrimal sac that causes swelling in medial canthal area of lower lid

Gonococcal conjunctivitis

- Occurs approximately 48 hours after birth
- It may appear even earlier if rupture of the amniotic membranes occurs several hours before delivery.

- Typically bilateral, purulent conjunctivitis with copious discharge and lid edema
 - *N gonorrhoeae* is one of the few bacteria that can penetrate intact corneal epithelium, causing corneal ulceration and even corneal perforation.
 - Diagnosis is usually made by identifying gram-negative intracellular diplococci on conjunctival scrapings and verifying by culture.

Chlamydial conjunctivitis

- Typically bilateral and mild to moderate in severity
- Approximately 4–10 days after birth
- Eyelid swelling and a tarsal conjunctival pseudomembrane may be present.
 - A conjunctival pseudomembrane is an accumulation of debris, not a true vascular tissue.
- The diagnosis is confirmed by conjunctival scrapings identifying cytoplasmic inclusion bodies in corneal epithelial cells (Giemsa stain) or by indirect immunofluorescence assay or culture.

Viral conjunctivitis

- Pharyngoconjunctival fever consists of an upper respiratory infection (pharyngitis and fever) with bilateral conjunctivitis.
 - Most commonly associated with adenovirus type 3 and type 7
 - Pharyngoconjunctival fever produces:
 - A severe, watery conjunctival discharge
 - Hyperemic conjunctivitis
 - Chemosis (conjunctival edema)
 - Preauricular lymph adenopathy
 - Quite often, a foreign-body sensation that results from corneal involvement
 - Disease is highly contagious and lasts approximately 2–3 weeks.
- Epidemic keratoconjunctivitis (EKC)
 - EKC is caused by adenovirus types 8, 19, and 37.
 - It occurs most often in older children and adolescents.
 - In contrast to pharyngoconjunctival fever, EKC is isolated to the eyes.
 - The virus causes a severe bilateral conjunctivitis with:
 - Conjunctival hyperemia
 - Watery discharge
 - Eyelid swelling
 - A reactive ptosis
 - Petechial conjunctival hemorrhages are common.
 - Pseudomembrane may be found along the conjunctiva.
 - Preauricular adenopathy may be present.
 - In many instances, one eye is involved first, and the second eye becomes affected several days later.

- Approximately one-third of patients develop corneal inflammation (keratitis) with subepithelial infiltrates 7–10 days after onset of the conjunctivitis.
- Keratitis is a hypersensitive reaction to the virus, not a true viral infection.
- Corneal infiltrates cause severe photophobia and irritation.

Hemorrhagic conjunctivitis (conjunctivitis with subconjunctival hemorrhage)

- Common causes include:
 - Infection with *H influenzae*, adenovirus, or picornavirus
 - *H influenzae* hemorrhagic conjunctivitis is associated with a purplish discoloration of the eyelids, caused by multiple tiny subcutaneous hemorrhages.
 - Spontaneous subconjunctival hemorrhage is a painless rupture of a small conjunctival vessel.
 - Usually no known reason
 - Conjunctiva surrounding the hemorrhage will be normal.
 - No tearing or exudate is present.
 - Hemorrhage resolves without treatment.
 - A systemic workup is not usually necessary unless:
 - Hemorrhage becomes recurrent.
 - History of prior bleeding or bruising exists.

Phlyctenular conjunctivitis

- A delayed hypersensitivity reaction to bacterial protein usually associated with staphylococcal blepharitis
- Creamy white or yellowish elevated nodules with a surrounding erythematous base
- Usually located at 3 and 9 o'clock around the limbus
- When tuberculosis was prevalent, it was a major cause of phlyctenulosis.

Seasonal allergic conjunctivitis

- Seasonal allergic (hay fever) conjunctivitis is common and affects approximately 10% of the general population.
 - The hallmark is itching and tearing.
 - Seasonal allergic rhinitis often accompanies seasonal allergic conjunctivitis, which is a type-1 hypersensitivity reaction.
 - Conjunctival scrapings or biopsy samples reveal mast cells and eosinophils.
 - Serum quantitative immunoglobulin E levels are usually high.
 - Skin tests may be positive for environmental allergens.
 - Allergic conjunctivitis is most common in the spring, when pollen levels are high.
 - Many cases occur during the winter, when forced-air heating is turned on and filters have not been cleaned or replaced.

- Diagnosis usually can be made through clinical signs and symptoms.
 - A family history of allergies, atopic disease, or asthma may be found.

Vernal conjunctivitis

- Severe allergic condition characterized by:
 - Severe itching
 - Tearing
 - Mucus production
 - Giant papillae of the upper tarsal conjunctiva
 - Most commonly affects young boys from the Mediterranean basin and from Central and South America
 - Patients often have reactive ptosis and squint in bright light.
 - The result of secondary keratitis caused by the giant papillae scraping the cornea
 - Papillae may be found around the limbus (junction of the sclera and cornea) with characteristic white centers (Horner-Trantas dots representing an accumulation of inflammatory cells, predominantly eosinophils).
 - Conjunctival scrapings of the papillae show many eosinophils.
- Full-blown vernal conjunctivitis is a vision-threatening disease; however, with the advent of topical mast cell stabilizers and antihistamines, this outcome is now rare.

Giant papillary conjunctivitis

- Large papillae develop underneath the superior tarsal conjunctiva as a result of wearing soft contact lenses.
 - Similar to vernal conjunctivitis
 - Reaction results from sensitization of the conjunctiva to allergic materials present on the surface of the contact lens or in contact lens solutions.

Atopic conjunctivitis

- Atopic conjunctivitis is a form of allergic conjunctivitis associated with eczema.
- Serum immunoglobulin E concentrations are often high in these patients.
- Patients with atopic dermatitis often have associated conjunctivitis, with itching, burning, and mucus discharge.

Conjunctivitis associated with systemic disease

- Stevens-Johnson syndrome (erythema multiforme major)
 - Most likely a type-III hypersensitivity reaction associated with mycoplasmal and HSV infections and with many drugs, especially antibiotics and anticonvulsants
 - Patients have fever, malaise, headache, loss of appetite, and nausea.
 - Generalized erythematous papular rash
 - The skin is friable, and traction on it can produce tears.
 - Mucous membranes are most severely affected, including nose, mouth, vagina, anus, and conjunctiva.

- Eye involvement consists of conjunctival injection and the formation of bullae that can rupture and lead to scarring.
- Conjunctival scarring can distort eyelids and turn lashes toward the cornea, causing corneal damage.

Herpes infections

■ HSV-2

- Usually associated with keratitis
- Herpes keratoconjunctivitis may be associated with systemic disease and encephalitis, although it can occur as an isolated eye infection.
- Onset is usually between 1 and 2 weeks after birth.
- Serous discharge with moderate conjunctival injection
- Almost always occurs in only 1 eye
- Breakdown of the normal epithelial barrier can result in a secondary bacterial corneal ulcer.
- Early stages of keratitis are detected by corneal fluorescein staining with a geographic or dendritic pattern.
- Diagnosis is confirmed by viral cultures.
 - May take up to 7–10 days to become positive

■ Recurrent ocular HSV

- After initial cutaneous facial infection or infection of mucus membranes, HSV gains access to the sensory nerve endings and travels up the axons to the trigeminal ganglion.
- The virus remains sequestered and protected within the ganglion.
- Recurrent ocular herpes infections occurs when virus from the ganglion travels down the sensory nerve and infects the cornea or eyelids.
- Cutaneous eyelid disease consists of a vesicular reaction similar to primary herpes simplex.
- Corneal disease from recurrent HSV affects the corneal surface epithelium.
 - Active virus replication causes punctate, dendritic, or geographic epithelial defects.
- The dendritic pattern is a classic sign of herpes keratitis (corneal infection).
- Recurrent herpes keratitis is almost always unilateral.
- Cornea becomes anesthetized as a result of sensory nerve damage.
- With recurrent herpes, the cornea can scar, and a secondary inflammatory reaction can occur in response to the viral antigen.

■ Herpes zoster and varicella-zoster virus

- Chickenpox, or varicella-zoster virus, rarely affects the eye, even when vesicular lesions occur on the eyelid or eyelid margin.
- Some physicians administer topical trifluorothymidine if the conjunctiva becomes involved.

- In immunocompromised patients, herpes zoster can present a high risk.
 - These patients especially should be treated with antiviral therapy.
- Secondary, or recurrent, herpes zoster ophthalmicus affects patients >50 years or immunocompromised patients.
 - This severe ocular inflammation can affect all layers of the eye.

NLD obstruction and aminotocele

■ NLD obstruction

- A watery eye and an increased tear lake
- Eyelash matting
- Mucus in the medial canthal area
- Congenital NLD obstruction is common and occurs in 1–5% of the population.
 - Approximately a third are bilateral.
- If left untreated, NLD blockage spontaneously opens by 6 months of age in almost one-half of cases.
 - The incidence of spontaneous resolution after 13 months of age decreases to only 15%.

■ Amniotocele (dacryocystocele)

- Swelling of the nasal lacrimal sac from an accumulation of fluid within the sac as a result of punctal and NLD obstruction
- A few days after birth, a bluish swelling appears in the medial canthal area, representing fluid that is sequestered within a distended nasolacrimal sac.

Congenital glaucoma

- *Primary congenital glaucoma* refers to increased intraocular pressure occurring at birth or shortly thereafter.
 - Normal intraocular pressure in infants is approximately 10–15 mm Hg.
 - Intraocular pressure in infants with congenital glaucoma is often >30 mm Hg.
- Congenital glaucoma differs from adult glaucoma by causing enlargement of the eye in addition to damaging the optic nerve.
 - The eye enlarges because, in infants, the eye wall is elastic and stretches.
 - Normal corneas at birth are approximately 10.5 mm in diameter.
 - Corneal diameters >12 mm are considered abnormally large (megalocornea).
 - As the cornea enlarges, breaks of the basement membrane of the corneal endothelium (Haab striae) occur, resulting in corneal edema that reduces vision and can lead to amblyopia.
 - After 3 years of age, the eye wall becomes fairly rigid, and ocular enlargement resulting from glaucoma does not occur.

- Features of congenital glaucoma include:
 - Tearing
 - Photophobia
 - Blepharospasm
 - Large cornea
 - Corneal clouding
 - Edema
 - Bilateral in approximately 70% of cases
- The classic findings of congenital glaucoma are not always present.
 - Signs of ocular enlargement and corneal edema may be subtle.
- In cases with tearing, diagnosis of congenital glaucoma may be misdiagnosed as NLD obstruction.
 - In contrast to NLD obstruction, however, the tearing associated with congenital glaucoma is caused by corneal edema.
 - Can be seen as a dull red reflex with an ophthalmoscope
- Primary ocular HSV-1
 - Most adults have been exposed to HSV-1, and unless immunocompromised, have circulating antibodies to the virus.
 - Only 1% of the population will exhibit clinical HSV-1 infection.
 - Most infections are asymptomatic.
 - Primary ocular herpes represents the first exposure to HSV-1.
 - Occurs initially as a skin eruption with multiple vesicular lesions
 - Virus can be cultured from vesicle fluid.

Blepharitis

- Blepharitis, or eyelid inflammation, is one of the most common causes of pink eye in children.
- The 2 most common types of blepharitis are staphylococcal blepharitis and meibomian gland dysfunction.
 - Both types of blepharitis are treated with lid hygiene (lid scrubs with baby shampoo) and topical antibiotics.
- Complaints of itching and burning
- Children often awake with eyelids stuck together with crusting.
- The eyes are irritated, but true itching is not present.
- Crusting and scales at the base of the eyelashes
- The eyelid margins are thickened and hyperemic.
- Vascularization of the eyelid margin
- Lashes may become misdirected, broken, or absent (madarosis).
- Sties, or external hordeolums, are common.
 - An external hordeolum is an abscess of the gland of Zeis on the anterior eyelid margin.

- In contrast to a chalazion, which is deeper and an inflammation of the meibomian gland that results from breakdown of the fatty secretions

- Blepharitis may be associated with corneal changes that cause severe photophobia.

Meibomian gland dysfunction

- Meibomian glands are sebaceous glands with orifices at the eyelid margins.
- Secretions consist of sterol esters and waxes that provide a covering to the tear film, thereby preventing evaporation
- Dysfunction or blockage of the meibomian gland orifice by desquamated epithelial cells results in stagnation of the lipids and causes a secondary local inflammation.
- Microbial lipases from *Propionibacterium acnes* and other bacteria contribute to producing irritating fatty acids that increase the inflammatory response.
- Obstruction of the meibomian gland orifices may result in a chalazion or sty.
 - Chalazion appears as a lump near the upper or lower eyelid margin.
 - Swelling can occur externally as a lump on the skin or internally as a lump underneath the conjunctiva.
 - Chalazion is not an infection, but a granulomatous inflammation that results from the irritating lipids within the meibomian gland.

Molluscum contagiosum

- Molluscum contagiosum is a viral disease of the skin caused by a DNA virus of the poxvirus group often occurring on the eyelids.
- Lesions are small, round, discrete bumps with a central pit.
- Presumed to be contagious and are transmitted by direct touch
- When present on the eyelid margin, they can cause a conjunctival reaction and a follicular conjunctivitis.

Kawasaki disease

- Kawasaki disease is a systemic vasculitis occurring in children usually <8 years.
- Onset of fever, present for >5 days, along with 4 of the following 5 criteria:
 - Nonpurulent conjunctivitis
 - Oral mucus membrane injection or swelling (or both)
 - Erythema and edema of the hands and feet
 - Polymorphous rash
 - Cervical lymphadenopathy
- Vasculitis may involve coronary arteries and cause a coronary aneurysm or a thrombosis that may lead to sudden death.
- The cause of Kawasaki disease is unknown.

Graft-versus-host disease

- Approximately 40% of patients who receive a bone marrow transplant will have graft-versus-host disease.
 - Donor T lymphocytes attack the recipient cells, primarily affecting the skin, liver, intestine, oral mucosa, conjunctiva, lacrimal gland, vaginal mucosa, and esophageal mucosa.
 - Ocular effects of graft-versus-host disease consist of conjunctivitis, dry eye, corneal epithelial erosions, and corneal ulcerations.

Conjunctival nevi

- Congenital or acquired lesions of the conjunctiva are usually located near the corneal limbus.
- They appear as pink or inflamed conjunctiva.
- Nevi come from melanocytes, but they have varying amounts of pigmentation.
- 30% of patients have minimal pigmentation.
- The most common types include junctional, compound, and subepithelial nevi.
- All types have low malignant potential and usually become noticeable in the 1st decade of life through puberty.

LABORATORY EVALUATION

- The initial work-up for presumed infectious neonatal conjunctivitis includes conjunctival cultures on:
 - Chocolate agar
 - Thayer-Martin agar
 - Blood agar
- Conjunctival scrapings should be obtained and examined.
 - Gram stain
 - Giemsa stain
 - Indirect immunofluorescent antibody assay for *Chlamydia*
- If herpes keratitis is suspected (unilateral conjunctivitis with corneal fluorescein staining) then a corneal scraping for herpes culture should be obtained.
- A serologic test for concurrent congenital syphilis infection is advised for venereal-transmitted neonatal conjunctivitis.
- Fluorescein staining of the corneal epithelium is indicated if a corneal abrasion is the suspected cause of the pink eye.
 - Fluorescein staining indicates a defect of the corneal epithelium most commonly caused by a traumatic abrasion, less frequently, an infectious process.
 - Bacterial corneal ulcer
 - Herpes simplex keratitis
- Blepharitis
 - *Staphylococcus* is common on culture.
- Allergic reaction
 - Eosinophils likely on conjunctival scraping

■ Bacterial conjunctivitis

- Polymorphonuclear neutrophils are present.
- Bacteria on Gram stain

■ Viral conjunctivitis

- Lymphocytes and monocytes are present.

TREATMENT APPROACH

■ Neonatal conjunctivitis

- Treatment of presumed infectious neonatal conjunctivitis before receiving laboratory results includes the use of topical erythromycin ointment and intravenous (IV) cephalosporin, such as cefotaxime.
 - Ceftriaxone is usually avoided in neonates because it may result in hyperbilirubinemia.
- Antibiotic treatment should be provided immediately after samples are taken for culture.
- Topical trifluorothymidine (Viroptic) and IV acyclovir should be provided if herpes is suspected.
- Once laboratory results are known, therapy is tailored to treat the identified organism.

■ NLD obstruction

- Optimal timing for initial NLD probing is controversial.
- Some experts advocate probing even when the patient is only a few months of age.
- Most pediatric ophthalmologists suggest waiting until the child is ≥ 6 months of age.
 - Almost one-half the cases will have spontaneously resolved by then.
- Other experts suggest waiting until the child is 1 or 2 years of age for probing.
 - Evidence indicates that delaying probing until 1.5–2 years of age means that a single probing will be less successful.
- Performing initial probing when the patient is between 6 months and 1 year of age allows time for most cases to resolve spontaneously, but it also offers the highest opportunity for success.
- Probing should be performed on an urgent basis in the case of amniotocele.
- Probing should be performed in the office without anesthesia.
- Medical management during the observational period is a combination of nasolacrimal sac massage and intermittent topical antibiotics.
 - Initial massage is directed inferiorly to push the tears in the normal direction, out the NLD.
 - Subsequent massage is directed superiorly so that any tears that did not exit are cleared from the punctum.
 - Occasionally, inferior pressure itself will open a mild NLD obstruction.

- Topical antibiotic eyedrops or ointments may be provided if signs of infection are present, eg, mucopurulent discharge.
 - For example, moxifloxacin (Vigamox) or trimethoprim-polymyxin B
 - Drops should be prescribed only when evidence of a true infection exists.
- Congenital glaucoma
 - Treatment is based on decreasing the intraocular pressure.
 - Prevent optic nerve damage
 - Prevent progressive expansion of the eye
 - Reduce corneal edema
 - Medications used to lower intraocular pressures include:
 - β -Adrenergic inhibitors, such as timolol
 - Carbonic-anhydrase inhibitors, such as acetazolamide can be administered topically or systemically.
 - Adrenergic agonists, such as apraclonidine
 - Medical treatment is not effective in most cases of congenital glaucoma, which is almost always treated with surgery directed at opening the outflow channels at the trabecular meshwork.
- Bacterial conjunctivitis
 - In general, cultures and Gram stain are not routinely performed for mild to moderate conjunctivitis.
 - Patients are treated with antibiotic eyedrops, including the quinolones.
 - Moxifloxacin
 - Levofloxacin
 - Gatifloxacin
 - Ofloxacin
 - Other antibiotic eyedrops include:
 - Sulfacetamide
 - Trimethoprim sulfate
 - Trimethoprim-polymyxin B (Polytrim)
 - Gentamicin
 - Tobramycin
 - Erythromycin ointment may also be applied.
 - An ophthalmology referral should be considered for severe conjunctivitis or chronic conjunctivitis that does not improve after 7 days of treatment.

SPECIFIC TREATMENT

Gonococcal conjunctivitis

- Treatment for gonococcal conjunctivitis is topical erythromycin ointment and IV cefotaxime.
- Parents may also need to be evaluated for possible treatment.

Chlamydial conjunctivitis

- The first-line treatment is topical erythromycin ointment.
- Along with oral erythromycin to remove Chlamydia organisms from the nasopharynx at 1–3 months of age
 - To decrease the risk of subsequent Chlamydia pneumonia
 - Because pneumonitis can occur after neonatal conjunctivitis, parents should be warned of this possibility.
 - Parents harbor the infection and should be treated with oral erythromycin or tetracycline even if they do not have any symptoms.

HSV-2

- If herpes neonatal conjunctivitis is suspected, the treatment of choice is topical trifluorothymidine (trifluridine) combined with IV acyclovir.
- Topical antibiotics should be used to prevent a secondary bacterial infection.

NLD obstruction

- NLD probing is a simple but delicate procedure.
- A small steel wire is passed through the nasolacrimal system, through the Hasner valve, and into the nose.
 - In some cases, the inferior turbinate is fractured to relieve crowding.
- The success rate for NLD probing is >90% when performed before 1.5 years of age.
- In cases in which NLD probing fails, intubation with silicone tubes is indicated to establish a patent system.
 - In general, tubes are used only when the probing procedure fails.
- Amniotocele
- Treatment for a noninfected amniotocele is local massage.
- If decompression does not occur within a few days, then infection (ie, dacryocystitis) is almost certain.
- Because of this likelihood, probing the NLD to open the obstruction may be performed.
- An infected amniotocele is red, warm, and large, approximately 1 cm in diameter.
- Treatment of the infection consists of IV antibiotics (cephalosporin).
- Urgent NLD probing should be performed to relieve the obstruction and drain the abscess.
- Although a cutaneous incision into the sac to decompress the abscess may be performed, this procedure leaves a scar and may produce an external fistula.
- NLD probing does not leave a scar and avoids fistulae.
- Probing has the advantage of directly addressing the primary cause of the abscess by opening the NLD obstruction.
- If the abscess is not drained, then an infected amniotocele can result in cellulitis and even sepsis.

Congenital glaucoma

- The 2 most frequently used procedures are goniotomy and trabeculotomy ab externum.
 - Goniotomy
 - A microscopic knife is used to lyse the abnormal trabecular meshwork to open up the angle.
 - Trabeculotomy ab externum
 - A microscopic probe is placed in the Schlemm canal and then swept through the trabecular meshwork and into the anterior chamber to open up the angle.
 - The success rate of these procedures for congenital glaucoma is approximately 60–70%.
 - If the first procedure fails, a second one may be performed.
 - When these procedures are not successful, a trabeculectomy is usually performed.
 - Trabeculectomy is a filtering procedure in which aqueous fluid is filtered through a small hole in the eye to the subconjunctival space.
- If all these procedures fail, congenital glaucoma can sometimes be managed by ciliary body destructive procedures, such as cryotherapy and laser surgery.
 - Eliminate the ciliary body epithelium that produces aqueous fluid
 - These end-stage procedures have a high failure rate.
- The prognosis for congenital glaucoma is fair, with approximately 70% of patients maintaining good, long-term visual acuity.
 - Unfortunately, patients with unfavorable outcomes often become blind.
 - The most important cause of visual loss is attributed to optic nerve damage, which is not reversible.
 - Other causes include chronic corneal edema with corneal scarring, refractive errors, and, importantly, dense irreversible amblyopia.
- Juvenile glaucoma is more amenable to medical treatment.
 - In many cases, however, juvenile glaucoma must also be treated with surgical techniques.

EKC

- EKC is caused by adenovirus types 8, 19, and 37; the treatment of adenovirus conjunctivitis is prevention of further transmission.
- The clinician must thoroughly wash everything before seeing another patient, if a patient seems to have adenoviral conjunctivitis.
- A patient with this disease will be contagious for up to 2 weeks and should observe isolation precautions during this time.
- Patients with adenoviral conjunctivitis should be referred to an ophthalmologist because of the possibility of corneal involvement.

- No effective antiviral treatment for EKC exists.
 - Cold compresses and topical nonsteroidal antiinflammatory drugs may reduce symptoms.
- A scraping for viral antigen quick preparation is indicated.
- Because of the contagious nature of the adenoviral conjunctivitis, if results are positive, then patients should not return to school for 1–2 weeks.
- Corticosteroids are discouraged except for the treatment of keratitis and should be administered only by an ophthalmologist.

Primary ocular HSV-1

- The use of antiviral medications is controversial.
- Oral acyclovir may be used for severe skin involvement.
- Systemic or topical acyclovir may speed recovery if provided within 1 or 2 days of onset.
- Topical antibiotics applied to the skin may be useful for preventing secondary bacterial infection.
- Over several days to 2 weeks, the skin lesions heal, with or without treatment, usually without much scarring.
- The cornea is involved in 30% of patients with primary ocular HSV-1 infection.
- Topical ophthalmic antiviral medications, such as trifluorothymidine, may be provided to prevent secondary corneal involvement.
- Primary ocular HSV rarely causes intraocular inflammation or uveitis.

Recurrent ocular HSV

- The treatment for acute recurrent herpes keratitis is topical antiviral therapy.
 - Usually with trifluorothymidine (trifluridine).
- Systemic treatment with oral acyclovir has proven to be effective, especially in cases of multiple recurrences or in immunocompromised children.
 - Treatment must sometimes last 6 months to 1 year to prevent recurrence.
 - Topical corticosteroids are not indicated for active herpes keratitis because they will decrease the body's immune response.
 - The clinician needs to be careful about unilateral pink eye because some of these cases may be herpes keratitis.
 - Topical corticosteroids in conjunction with antiviral therapy may be used by ophthalmologists to reduce corneal scarring.

Blepharitis

- Treatment of staphylococcal blepharitis includes eyelid hygiene and topical antibiotic ointment, usually erythromycin.
- In severe cases, systemic erythromycin may be indicated.
- Eyelid cultures are not routinely performed because most eyelids normally are colonized with *Staphylococcus* organisms.

- Eyelid hygiene includes lid scrubs with baby shampoo once or twice a day.

- Prevention of recurrent blepharitis consists of ongoing lid hygiene.

Phlyctenular conjunctivitis

- Treatment consists of treating the blepharitis (lid scrubs and topical antibiotics) and the use of topical corticosteroids.
 - If topical corticosteroids are to be administered, then treatment should be monitored by an ophthalmologist.
- When tuberculosis was prevalent, it was a major cause of phlyctenulosis.
 - Patients with phlyctenular conjunctivitis who are at risk should be evaluated for tuberculosis.

Meibomian gland dysfunction

- Chalazia may resolve without treatment.
- Applying hot soaks several times a day helps the drainage of lipid material.
- If the chalazion does not resolve over several weeks of treatment, then incision and drainage may be necessary.
- An external hordeolum is an acute infection of an accessory gland, which can be treated with:
 - Erythromycin ointment
 - Hot soaks
 - Eyewashes with baby shampoo
- Chalazia may be prevented by eyelid hygiene with eye wipes or a baby shampoo eyewash each day.

Molluscum contagiosum

- Lesions can be treated by excising the central core.
- Rarely, through the use of cryotherapy or application of chemical caustics, such as trichloroacetic acid or aqueous phenol

Seasonal allergic conjunctivitis

- Treatment has greatly improved with the advent of combination mast cell stabilizer–antihistamine eyedrops, such as olopatadine.
 - Mast cell stabilizers require 2–3 days of continued use to reduce symptoms
 - Because they do not inhibit activity of already-circulating histamines, combination mast cell stabilizer–antihistamine eyedrops have a double effect.
 - They provide immediate relief because they directly block histamine receptors and prevent the release of histamine by mast cells.
 - Patients with chronic allergic conjunctivitis can use the eye-drops every day, year round.
 - Side effects are rare.
- In cases of severe allergic conjunctivitis, an oral antihistamine may be added to the eyedrops.

- Topical corticosteroids are reserved for severe allergic conjunctivitis not responsive to other treatment.

- They are only used for a few days.
- If corticosteroids are used, then an ophthalmologist should monitor the patient for potential side effects of glaucoma and cataracts.
- Fluorometholone, a mild topical corticosteroid, is a good choice because it does not penetrate the cornea, thus reducing the likelihood of glaucoma and cataracts.

Vernal conjunctivitis

- Treatment is based on avoiding allergens and using combination mast cell stabilizer–antihistamine eyedrops, such as olopatadine.
 - Patients need to use the eyedrops daily during the allergy season.
 - In temperate climates, patients with vernal conjunctivitis may need treatment year round.
- An oral antihistamine can be added to the use of the eye drops if necessary.
- In some instances, severe episodes of inflammation can be controlled only with intermittent short courses of topical corticosteroids.
 - They should be administered and supervised by an ophthalmologist.

Giant papillary conjunctivitis

- Treatment consists of:
 - Using mast cell stabilizers
 - Discontinuing contact lens wear
 - Changing to a regimen of frequent contact lens replacement
- Prognosis is good.

Atopic conjunctivitis

- Treatment of eye symptoms includes:
 - Use of cold compresses
 - Topical vasoconstrictors
 - Topical antihistamines
 - Topical mast cell stabilizers
 - Topical corticosteroids should be used only for short periods while being monitored by an ophthalmologist.

Stevens-Johnson syndrome

- Therapy remains controversial.
- Topical corticosteroids may be administered early, before advanced disease leads to conjunctival scarring.
 - Their use may prevent severe ocular sequelae.
 - Once conjunctival scarring occurs, however, no effective treatment exists.
 - Patients with Stevens-Johnson syndrome should be referred immediately to an ophthalmologist for consultation.

Graft-versus-host disease

- Treatment with topical artificial tears, short courses of topical corticosteroids, and, in severe cases, cyclosporine may improve symptoms.
 - These patients should be referred to an ophthalmologist for careful follow-up.

Conjunctival nevi

- Treatment is controversial, but growth or change in pigmentation of the nevus may be an indication for surgical removal.
- Malignant melanoma is rare in children.

WHEN TO REFER

- Severe neonatal conjunctivitis
- Conjunctivitis with poor red reflex
- Conjunctivitis not improving after 1 week of treatment
- Recurrent conjunctivitis, unilateral or bilateral
- Conjunctivitis with positive corneal fluorescein staining
- Conjunctivitis with decreased visual acuity (20/50 or worse)
- Unilateral conjunctivitis in a contact lens user
- Neonatal swollen nasolacrimal sac (amniotocele)
- Tearing with a poor red reflex
- Tearing with large eye (buphthalmos)
- Patients with conjunctivitis associated with contact lens use should be immediately referred to an ophthalmologist.

WHEN TO ADMIT

- Patients with suspected Stevens-Johnson syndrome
- Neonates with gonococcal conjunctivitis

FOLLOW-UP

- Patients with corneal involvement need to be closely followed for development of corneal scars.
- Patients with congenital glaucoma need to be monitored for pressure changes, as well as visual acuity, by the pediatric ophthalmologist.

COMPLICATIONS

- Corneal scarring due to keratitis
- Loss of vision in patients with congenital glaucoma

PREVENTION

- The best agent to use to prevent neonatal conjunctivitis is controversial.
 - The efficacies of erythromycin ointment, tetracycline ointment, and silver nitrate are approximately the same.
 - The use of povidone iodine as prophylaxis has also been advocated.
 - Effective coverage of a broad spectrum of bacteria
 - Coverage for such viruses as HSV and HIV
 - Little chemical irritation reaction

Renal Failure, Acute

DEFINITION

- Acute renal failure is a syndrome of sudden diminution or cessation of kidney function.
- Definitions vary according to specific patient populations and the outcome measure.
 - For example, increase in creatinine level versus need for renal replacement therapy
 - Given that most acute renal failure definitions are based on a serum creatinine increase:
 - Lack of a uniform definition may result in lack of recognition of significant kidney injury and delay in treatment.
 - Creatinine-based acute renal failure definitions are problematic for infants and small children.
 - Normal serum creatinine level is 0.2–0.4 mg/dL.
 - A serum creatinine change of 0.1 mg/dL represents a 25–50% change for small children.
- A graded acute renal failure classification system is needed to assess best the state of kidney injury in patients with a renal insult.
 - Identifies patients at risk for significant kidney insult and metabolic disturbance
 - One system uses the RIFLE criteria to classify degree of kidney insult by changes in serum creatinine and duration of decreased urine output.
 - **R**isk
 - **I**njury
 - **F**ailure
 - **L**oss
 - **E**nd-stage renal disease
 - The change in terminology from *acute renal failure* to *acute kidney injury* (AKI) focuses attention on early recognition of kidney insult and interventions to prevent or mitigate effects of significant renal failure.
- Clinicians still rely on historical definitions based on urine output to characterize degree of acute renal failure.
 - Until RIFLE or other AKI classification systems undergo systematic validation
 - The following definitions are used here for decreased urine output.
 - *Anuria*: <100 mL/m² daily
 - *Oliguria*: <300 mL/m² daily
 - *Nonoliguric state*: sufficient urine volume to allow administration of necessary fluids, nutrition, blood products, and medication without resulting volume overload
 - *Oligoanuric state*: insufficient urine volume to allow administration of necessary fluids, nutrition, blood products, and medication without resulting volume overload

ETIOLOGY

- The causes of AKI in children have changed from primary kidney diseases to secondary effects of other systemic illnesses or their treatment.
- In studies of acutely ill hospitalized patients, the most common causes of AKI in children are:
 - Congenital heart disease
 - Sepsis
 - Nephrotoxic medicines
- Classification of AKI should focus on determining the cause and site of kidney insult.
 - Factors leading to diminished kidney function are often grouped as:
 - Prerenal
 - Causes that diminish kidney perfusion without producing actual parenchymal injury
 - Renal (parenchymal)
 - Postrenal *or*
 - A combination of these mechanisms
 - In children, hypovolemia is the most common clinical situation in which diminished kidney function occurs.
 - Usually results from dehydration associated with acute gastrointestinal losses
 - Hypovolemia may also occur in shock as the result of:
 - Hemorrhage
 - Burns
 - Sepsis
 - Trauma
 - Less common causes of prerenal AKI are those that diminish renal blood flow in the absence of hypovolemia, such as:
 - Congestive heart failure
 - Kidney vascular obstruction from thrombosis or embolism
 - Liver failure
 - Increased kidney vascular resistance, occasionally after anesthesia or surgery
 - Although oliguria or AKI (or both) occur in prerenal syndrome, normal compensatory kidney tubular function usually persists.
 - Characterized by high urinary osmolality and low urinary sodium concentrations as the result of kidney water and sodium conservation.
- AKI from glomerular injury results most commonly from any of the glomerulonephritides or microangiopathy of hemolytic-uremic syndrome.
 - Tubular injury is frequently the result of prolonged ischemia or exposure to a variety of nephrotoxins.

- Renal ischemia may be seen in:
 - Hypotensive episodes
 - Severe dehydration
 - Sudden hemorrhage
 - Sepsis
- Tubular toxins may be endogenous (eg, hemoglobin, myoglobin) or exogenous (eg, such medications as aminoglycoside antibiotics).
 - Various chemicals (eg, carbon tetrachloride, diethylene glycol, heavy metals) may cause acute parenchymal kidney failure.
 - Drugs can produce acute kidney failure by inducing a hypersensitivity reaction (drug-induced interstitial nephritis).
- Diffuse pyelonephritis may result in AKI, particularly in infants.
- Kidney cortical necrosis associated with infection, hemorrhage, or dehydration can produce significant irreversible injury to both glomeruli and tubules.
- AKI from intrinsic parenchymal injury may result from:
 - Glomerular disorders
 - Tubular disorders
 - Interstitial disorders

SIGNS AND SYMPTOMS

- Many children with AKI have markedly diminished urine output.
- Complete anuria is unusual and leads to consideration of a catastrophic renovascular event or urinary obstruction.
- In the child with anuria or oliguria, fluid retention can produce:
 - Edema
 - Water intoxication
 - Vascular overload with congestive heart failure
 - Pulmonary edema
 - Hypertension
 - Or any combination
- In many instances, fluid overload is iatrogenic.
 - Results from attempts to increase urinary output by increasing fluid intake
- Early detection of fluid retention is determined best by short-term weight gain on serial measurements and carefully recorded intakes and outputs.
- In contrast, nonoliguric AKI may be clinically covert.
 - Usually suspected only after laboratory tests reveal an elevation in serum creatinine level or an electrolyte imbalance

DIFFERENTIAL DIAGNOSIS

- The processes contributing to kidney functional impairment can frequently be identified from the patient's history.
- Reduction in urine production is not included in the definition of AKI.
 - Kidney failure occurs not only in anuric states but also in patients with oliguric or nonoliguric states.
 - Some kidney insults are frequently associated with oligoanuric AKI.
 - Various glomerulonephritides
 - Hemolytic-uremic syndrome
 - Others will more often cause nonoliguric kidney failure.
 - Aminoglycoside toxicity
 - Determining the type of insult provides clinician with insights into:
 - Possible manifestations of kidney failure
 - Probable duration of AKI
 - Overall prognosis
 - History often helps distinguish between an episode of AKI in an otherwise healthy child and acute deterioration of kidney function in a child with preexisting undiagnosed chronic kidney disease.
 - A history of the following would lead the practitioner to suspect undiagnosed kidney disease.
 - Urinary abnormalities
 - Fatigue
 - Pallor
 - Slowed linear growth
 - Poor school performance
 - Anorexia extending over a period
- AKI may be heralded by seizures precipitated by:
 - Hypocalcemia
 - Hypertensive encephalopathy
 - Uremia
 - Water intoxication
 - It is not unusual for a child to first have a sudden onset of seizures and other signs of central nervous system dysfunction, only to be found to have AKI.

LABORATORY FINDINGS

- Abbreviations used in this section: *U*, urine; *Na*, sodium; *Cr*, creatinine; *S*, serum.
- Clinical tests to differentiate functional from parenchymal oliguric AKI
 - Sodium conservation
 - Urine sodium concentration (U_{Na})
 - Functional AKI: <20 mEq/L
 - Parenchymal AKI: >40 mEq/L
 - Discrimination: poor

- Fractional excretion of sodium (FE_{Na}):
 $FE_{Na} = (U_{Na} \times S_{Cr}) / (S_{Na} \times U_{Cr}) \times 100$
 - Functional AKI: <1
 - Parenchymal AKI: >1
 - Discrimination: good
 - Children with nonoliguric acute tubular necrosis can have $FE_{Na} < 1\%$.
 - The FE_{Na} test is only helpful for oliguric acute tubular necrosis.
 - The threshold for FE_{Na} in neonates is 3% and not 1%.
- Water conservation
 - Urine osmolality (Uosm)
 - Functional AKI: >500 mOsm/L
 - Parenchymal AKI: >350 mOsm/L
 - Discrimination: Poor
 - Urine/serum osmolality ratio (Uosm/Sosm)
 - Functional AKI: >2
 - Parenchymal AKI: <1.1
 - Discrimination: fair
 - Response to diagnostic challenge with intravenous mannitol and furosemide
 - Functional AKI: urine flow increase
 - Parenchymal AKI: no change
 - Discrimination: good
- Biochemical disturbances that contribute to clinical findings in AKI are complex and interrelated.
 - Inherent to diagnosis of acute renal failure is accumulation of nitrogenous waste products characterized by increases in blood urea nitrogen and creatinine levels.
 - If hypotonic fluids have been used in excess to hydrate the patient, dilutional hyponatremia and anemia may affect central nervous system and cardiac function adversely.
 - Hyperkalemia is often the result of injudicious potassium administration or inadequate renal potassium excretion.
 - In AKI, metabolic acidosis develops as result of the kidney's failure to excrete hydrogen ions and reabsorb bicarbonate.
 - Any state associated with increased catabolism may accentuate degree of acidosis as a result of increased production of organic and inorganic acid radicals.
 - Shock
 - Fever
 - Poor caloric intake
 - Extensive tissue damage
 - Acidosis promotes further hyperkalemia resulting from:
 - Movement of intracellular potassium into extracellular space as the body attempts to accommodate the higher hydrogen ion concentration

- Respiratory compensation for an underlying metabolic acidosis may cause low carbon dioxide pressure resulting from tachypnea or Kussmaul breathing.
- Failure of phosphate excretion can lead to hyperphosphatemia.
 - The hypocalcemia associated with hyperphosphatemia may exhibit clinically as:
 - Tremors
 - Tetany
 - Seizures

TREATMENT APPROACH

- Acute kidney injury management should begin before consulting with a nephrologist and before initiating renal replacement therapy.
 - Maintenance of adequate urine volumes and prevention and treatment of metabolic derangements are the goals of therapy in children with acute renal failure.
 - The essential first measure to maintain urine output in critically ill patients is:
 - Preservation or restoration of renal perfusion with appropriate fluid resuscitation and inotropic agents

SPECIFIC TREATMENTS

Goal-directed fluid therapy

- Represents use of physiologic end points to guide initiation and termination of fluid resuscitation of patients in shock
 - Heart rate
 - Central venous pressure
 - Mean arterial pressure
- Goal-directed fluid therapy leads to better survival in adults with shock.
- Adult patients who receive early goal-directed fluid therapy in the emergency center:
 - Received more fluid in emergency center but received less fluid and have better survival in the intensive care unit compared with patients who receive standard therapy
- The concept that worsening fluid overload is associated with worse outcomes in critically ill pediatric patients who require renal replacement therapy was the focus of a recent pediatric study.
 - The Prospective Pediatric Continuous Renal Replacement Therapy Registry Group demonstrated that worsening fluid overload is an independent risk factor for mortality.
 - Earlier initiation at lesser fluid overload degrees may:
 - Allow more expeditious optimal nutrition and blood product provision without further fluid or waste product accumulation
 - Prevent worsening volume overload and, in particular, pulmonary edema

Medication dosing

- Most pediatric drug dosing is based on intensive care unit admission weight.
 - Worsening fluid overload might increase volume of distribution of inotropes, antimicrobials, and chemotherapeutic agents, resulting in underdosing.
- Medication dosing should be altered for specific drugs that are primarily eliminated by the kidneys.
 - Drug dose or interval (or both) may need to be altered on the basis of the level of kidney dysfunction.
 - Drug concentrations can be wholly or partially reduced by dialysis in patients who receive intermittent or continuous renal replacement therapy.
 - Factors associated with enhanced dialytic elimination include low volume of distribution and low protein binding.

Treatment in hyperkalemia in pediatric patients

- Calcium gluconate (10%)
 - Dose: 0.5 mL/kg IV over 2–4 min
 - Effect: rapid but transient
 - Monitor the electrocardiogram for bradycardia during injection; may be repeated but is not likely to be effective.
- Sodium bicarbonate (7.5%)
 - Dose: 2.5 mEq/kg (approximately 3 mL/kg) IV by slow push
 - Effect: rapid but transient
 - Repetition is not recommended.
- Glucose (50%)
 - Dose: 1 mL/kg IV by slow push
 - Effect: Within 1–2 hr
 - Attempt to increase blood glucose level to 250 mg/dL; may be maintained by infusion of 30% glucose at rate equal to insensible fluid loss.
- Insulin (regular)
 - Dose: 0.1 U/kg IV
 - Effect: rapid
 - Give only with hypertonic glucose infusion (30%).
- Sodium polystyrene sulfonate (Kayexalate)
 - Dose: 1 g/kg PO or PR
 - Effect: 3–6 hr
 - Side effects: gastric irritation (nausea and vomiting), diarrhea, or fecal impaction
 - Oral administration is more effective than rectal administration.
 - Enemas should be retained >60 minutes and removed by a cleansing enema.
 - May cause hypokalemia: use cautiously in patients who tolerate sodium loads poorly
 - Chelates Ca⁺ and Mg⁺

WHEN TO ADMIT

- When AKI is unexplained, rapidly progressive, or oliguric or anuric
- In the presence of severe or potentially dangerous fluid or metabolic abnormalities (eg, hyperkalemia, hypocalcemia, acidosis, clinical fluid overload, dehydration)
- For renal biopsy

WHEN TO REFER

- For guidance on diagnostic evaluation
- Management of complex fluid, mineral, electrolyte, and blood pressure abnormalities
- Evaluation of dialysis options and preparation for and implementation of dialysis or continuous renal replacement therapy (CRRT)
- Disease-specific management

COMPLICATIONS

- Hyperkalemia is a potentially life-threatening complication of AKI.
 - Can be especially severe in disease states associated with cellular damage and the consequent release of intracellular potassium
 - Hemolysis
 - Burns
 - Trauma
 - Infections
- Hyperkalemia produces a state of increased neuromuscular excitability, including a vulnerability to cardiac arrhythmias.
- Unfortunately, hyperkalemia produces no consistent physical signs.
 - Diagnosis depends on measurement of serum potassium *and*
 - If indicated, assessment of electrocardiogram for evidence of altered cardiac electrical activity

PROGNOSIS

- In the past decade, survival rates stratified by the renal replacement therapy modality have been stable.
 - Survival rates for patients receiving hemodialysis are higher than those receiving peritoneal dialysis or CRRT.
 - Hemodialysis: 73–89%
 - Peritoneal dialysis: 49–64%
 - CRRT: 34–42%
 - Better survival in patients who receive hemodialysis likely results from improved hemodynamic stability.
 - No prospective pediatric study that controls for patients illness severity has compared survival across modalities.

- Improvements in pediatric specific technology and CRRT techniques have led to:
 - Preferential use of CRRT in pediatric patients with AKI
 - Decreased morbidity in patients who require CRRT
- The 3- to 5-year patient survival of an AKI episode is 57%.
 - Approximately 60% of patients demonstrate evidence of chronic kidney injury.

PREVENTION

- Routine evaluation of all pediatric AKI survivors may help prevent the long-term sequelae of AKI.
 - Chronic kidney disease
 - Hypertension
 - Microalbuminuria

Renal Tubular Acidosis

DEFINITION

- Renal tubular acidosis (RTA) is impaired capacity of the kidney to excrete the usual daily load of acid arising from metabolism.
 - Renal excretory function, as estimated by creatinine clearance, is relatively intact.
 - Metabolic acidosis results from a defect affecting tubular mechanisms for acid excretion, with intact glomerular filtration.
 - Not caused by underexcretion of acid due to kidney failure or increase in acid production (eg, in diabetic ketoacidosis, lactic acidosis, or total parenteral nutrition)
- Consequence of mismatch between the usual rate of acid production and renal acid excretion
- Principal cause of hyperchloremic metabolic acidosis in an infant or child ingesting a typical diet who does not have gastroenteritis or chronic kidney disease

ETIOLOGY

- Possible explanation for impaired growth in children with RTA
 - Metabolic acidosis suppresses pulse amplitude of growth hormone secretion in rats.
 - The principal mediator on target organs of growth hormone is insulinlike growth factor 1 (IGF-1), which is also suppressed by acidosis.
 - Consequent antianabolic effect results in decreased net protein synthesis.
 - Expression of IGF-1 receptor in epiphyseal growth plate of long bones and of hepatic growth hormone receptor is suppressed by acidosis.
 - Metabolic acidosis impairs conversion of 25-hydroxy vitamin D₃ to its biologically active form, 1,25-dihydroxy vitamin D₃.
 - Increase in 1,25-dihydroxy vitamin D₃ by dietary phosphorous restriction may be reversed by metabolic acidosis.
 - Impaired phosphate reabsorption of the Fanconi syndrome contributes to rickets and short stature.
 - Buffering of hydrogen ions (H⁺) by bone causes release of calcium (Ca²⁺) and consequent hypercalciuria, which may contribute to osteopenia and short stature in certain forms of RTA.
 - Metabolic acidosis inhibits osteoblasts and bone turnover.
 - Growth impairment is multifactorial, and some children with Fanconi syndrome continue to lag in growth despite correction of metabolic acidosis.
- Mechanisms of acid excretion
 - The role of the kidneys in maintaining pH homeostasis principally involves 2 discrete processes in handling of bicarbonate (HCO₃⁻).

- Reclamation
 - Absorb filtered HCO₃⁻ in proximal segments of nephron
- Regeneration of HCO₃⁻
 - Excrete H⁺ in form of ammonium (NH₄⁺) and dihydrogenphosphate (H₂PO₄⁻) in collecting duct and, in the process, generate new HCO₃⁻
- These processes are the basis for the physiologic classification of RTA into 2 main types.
 - Reclamation type
 - Traditionally referred to as proximal RTA or type 2 RTA
 - Regeneration type
- Mechanisms of ammonium excretion
 - All forms of RTA are due to inability of the kidneys to maintain the plasma HCO₃⁻ concentration at a physiologic level in the face of the usual rate of acid production.
 - A common feature is a low rate of NH₄⁺ excretion.
 - NH₄⁺ excretion involves the proximal and distal segments of nephrons.
 - 4 steps are involved, each of which is implicated in the pathogenesis of forms of RTA.
 - Ammoniogenesis occurs in the proximal tubule.
 - Impaired by hyperkalemia occurring in mineralocorticoid deficiency or unresponsive states
 - Absorption in the thick ascending limb of the loop of Henle by occupying the K⁺ site on the apical Na⁺-K⁺-2Cl⁻ cotransporter
 - Also impaired by hyperkalemia because K⁺ more effectively competes with NH₄⁺ for same binding site on transporter
 - Interstitial accumulation of NH₃; depends on an intact countercurrent system for concentration of solute in renal medulla
 - Impaired transport of NH₄⁺ affects this step, as does inflammation and scarring of inner medulla (distorts the architecture of countercurrent multiplier system responsible for increasing concentration of solutes and NH₃).
 - The countercurrent system is also affected by nephrocalcinosis, which occurs in regeneration-type RTA and is typically accompanied by a low rate of citrate excretion.
 - Diffusion of NH₃, which has accumulated to relatively high concentration in the medullary interstitium, into the lumen of the collecting duct
 - Consequence of 2 different defects affecting ion-trapping of NH₄⁺—either H⁺ secretory defect or voltage defect

SIGNS AND SYMPTOMS

- Rarely presents as isolated idiopathic hypercalciuria or passage of a kidney stone in a child with incomplete RTA, which may be accompanied by a family history of nephrolithiasis in association with hypocitraturia
- For some children in at-risk families, hypocitraturia may be the only indication of so-called incomplete RTA.
- Family history should be explored with questions about other affected family members in preceding generations or affected siblings of the individual with suspected RTA.
- With apparent de novo RTA, consanguinity may play role.
- Apparent isolated nephrolithiasis in other family members may be significant.
- A history of sudden unexplained death in a neonate suggests the possibility of a salt-losing condition that may be associated with RTA.
- Failure to thrive during infancy is often a presenting feature of RTA.

DIFFERENTIAL DIAGNOSIS

- The clinician is more likely to encounter secondary forms of RTA that result from drugs, toxins, or acquired medullary tubulointerstitial disease.
- Other instances of RTA are associated with:
 - Another hereditary disorder, such as cystinosis, *or*
 - Other causes of Fanconi syndrome
- The transient form of RTA may occur in young infants with delayed maturity of renal tubular function.
- RTA, in association with hyponatremia and hyperkalemia, can also present as acute life-threatening event in some infants with profound salt-losing condition and hypovolemia.
 - Pseudohypoaldosteronism type 1
 - Congenital adrenal hyperplasia with insufficient mineralocorticoid production
- Reclamation-type RTA may be an isolated defect and, in some infants, simply a transient immaturity of function that eventually resolves.
- Hereditary RTA syndromes in children are due to mutations of genes encoding ion transporters or channels that play a key role in the kidney's contribution to acid-base balance.
 - Rare primary monogenic disorders that have classical Mendelian patterns of inheritance
 - Pseudohypoaldosteronism type 1
 - Congenital adrenal hyperplasia with insufficient mineralocorticoid production

DIAGNOSTIC APPROACH

- RTA should be considered in any infant or young child with any of the following conditions.
 - Failure to thrive
 - Recurrent vomiting

- Short stature
- Rickets
- Nephrocalcinosis
- Hypotonia
- Muscle weakness
- Sensorineural hearing loss
- Recurrent episodes of dehydration
- Kidney stones
- Gastroenteritis with incomplete recovery from metabolic acidosis

LABORATORY FINDINGS

- In the absence of blood gas analysis confirming acidemia, consider RTA if:
 - Venous blood carbon dioxide (CO_2) content is <20 mEq/L in an infant or young child.
 - The child has hyperchloremia.
 - The anion gap is normal.
 - Urine pH is not <5.5 .
- Once a renal cause for hyperchloremic metabolic acidosis is established, estimate urinary NH_4^+ by measuring Na^+ , K^+ , and Cl^- in a random urine specimen and calculating the urinary anion gap (UAG).
 - On a typical diet, Cl^- is the main anion accompanying urinary NH_4^+ , and the concentration of Cl^- exceeds the sum of Na^+ and K^+ .
 - Because urinary NH_4^+ is not directly measured, the UAG is negative or close to zero.
 - With regeneration-type RTA, the rates of NH_4^+ excretion and Cl^- excretion are low; its concentration is usually less than the sum of $[\text{Na}^+] + [\text{K}^+]$; and in this instance, UAG is positive.
 - This estimate is less reliable if urine pH is relatively alkaline, exceeding 6.7, at which HCO_3^- becomes significant component of unmeasured anions.
 - The UAG is normal in reclamation-type RTA during the acidemia that ensues after stopping alkali treatment.
 - The UAG estimate in such patients is not reliable during alkali treatment because of massive HCO_3^- wasting.
- Urine osmolal gap (UOG): another surrogate measure for urinary NH_4^+
 - Actual NH_4^+ is approximately half the UOG because concentrations of NH_4^+ and Cl^- are approximately equal.
- Use a pH meter to determine urine pH.
- Provocative test of capacity to acidify urine: administer furosemide and, later, measure urine pH.
 - Administer fludrocortisone (Florinef) about 1 hour before infusion of furosemide.
 - Failure to acidify urine to $\text{pH} <5.5$ suggests defect of H^+ secretion.

- Traditional way to assess rate of H⁺ secretion in collecting duct: measure urine-to-blood PCO₂ gradient by intravenous administration of NaHCO₃ load in a clinical research center.
 - In the ambulatory setting, achieve a similar effect by aggressive treatment of regeneration-type RTA with bicarbonate precursor (eg, oral sodium or potassium citrate).
 - If the urine-to-blood PCO₂ gradient is <20 mm Hg, then an H⁺ secretory defect is likely.
 - Promptly aspirate the voided urine specimen into a syringe, eliminating dead space, to minimize loss of CO₂.
 - Administering a single dose of acetazolamide also loads distal H⁺ secretory sites with HCO₃⁻.
 - The renal HCO₃⁻ threshold in a child suspected of having reclamation-type RTA may be estimated over several days after beginning treatment with alkali.
 - Monitor urine pH and blood HCO₃⁻.
 - The threshold is a level of blood HCO₃⁻ at which urine pH increases markedly, indicating bicarbonaturia, approaching 10–15% of filtered load.
 - If the serum K⁺ concentration is low or normal, diagnostic possibilities include reclamation-type or nonhyperkalemic regeneration-type RTA.
 - If urine glucose is positive, further testing is done to establish Fanconi syndrome in association with reclamation defect.
 - Empiric treatment with citrate solution may confirm the diagnosis of reclamation defect if the dose required to correct the serum HCO₃⁻ approaches 10–15 mEq/kg/day, well above the endogenous rate of acid production.
 - An increased dose may be required in some infants with regeneration-type RTA as a transient phenomenon during the first few years of life.
 - In young infants, obtaining reliable 24-hour urine collection to estimate calcium excretion is impossible without an indwelling catheter.
 - Collect multiple random specimens throughout the day.
 - Age range and calcium-to-creatinine ratio (mol/mol, mg/mg), 95th percentiles
 - 1 month–1 year: 2.2, 0.81
 - 1–2 years: 1.5, 0.56
 - 2–3 years: 1.4, 0.50
 - 3–5 years: 1.1, 0.41
 - 5–7 years: 0.8, 0.30
 - 7–10 years: 0.7, 0.25
 - If the serum K⁺ concentration is high, suggesting hyperkalemic regeneration-type RTA, an impaired capacity to secrete K⁺ may be confirmed by:
 - Measurement of K⁺ and osmolality in plasma
 - Random urine specimen
 - Calculation of the transtubular potassium gradient (TTKG)
 - In the setting of hyperkalemia, TTKG should be ≥8 if the distal tubule responds to mineralocorticoid.
 - A value <8 suggests insufficient production of aldosterone or lack of responsiveness of the mineralocorticoid receptor aldosterone.
 - Pseudohypoaldosteronism type 1 is suggested by increased level of plasma aldosterone and renin.
 - If aldosterone and renin are suppressed and blood pressure is increased, the rare familial hyperkalemic hypertension syndrome (pseudohypoaldosteronism type 2) is possible.
 - If blood pressure is normal or low and aldosterone is low in clinical setting of salt-wasting, consider congenital adrenal hyperplasia.
 - If aldosterone is high, consider the severe, potentially fatal neonatal presentation of pseudohypoaldosteronism type 1.
- ### IMAGING
- Ultrasonography
 - Medullary nephrocalcinosis confirms nonhyperkalemic regeneration-type RTA because this type is also associated with hypercalciuria and hypocitraturia.
- ### CLASSIFICATION
- Conventional classification
 - Type 1: classic distal RTA
 - Type 2: proximal RTA
 - Type 3: hybrid of 1 and 2
 - Type 4: distal defect that results in high levels of potassium in the blood
 - Physiologic classification: now in use because it is physiologically accurate
 - 2 basic processes of HCO₃⁻ absorption are the basis.
 - Reclamation type
 - Type 2 proximal (conventional classification)
 - Most reclamation-type disorders are accompanied by other defects localized to the proximal tubule, such as Fanconi syndrome (impaired absorption of amino acids, glucose, and phosphate).
 - May be a transient isolated defect in infancy that resolves in time
 - Regeneration type, including classic distal type 1 RTA—there are 2 types:
 - Nonhyperkalemic
 - Hyperkalemic (acidification intact: pseudohypoaldosteronism Ia, Ib, II; acidification impaired: medullary tubulointerstitial disease)
 - Hybrid of reclamation and regeneration: old type 3
- ### TREATMENT APPROACH
- Aims of treatment
 - Correct metabolic acidosis
 - Correct growth impairment

- Mitigate osteopenia
- Prevent chronic kidney failure caused by progression of nephrocalcinosis (in the instance of a primary H^+ secretory defect)
- Appropriate treatment with alkali restores growth to the expected trajectory, but the requirement to sustain growth was 2- to 5-fold greater than the expected rate of endogenous acid production.

SPECIFIC TREATMENTS

Citrate solution

- Mainstay of treatment in most children
- Hypokalemia and K^+ depletion are characteristic of non-hyperkalemic regeneration-type RTA; thus, potassium citrate preparation is optimal (eg, Polycitra-K).
- The solution contains:
 - 2 mEq/mL of K^+ and 2 mEq/mL of HCO_3^- precursor as citrate
 - Citric acid (to make it taste better)
 - pH of approximately 5 before further dilution
 - Solution is hyperosmolar; must first be diluted 4- or 5-fold with water or formula before oral administration.
- Potassium citrate is available as a capsule (Urocit-K) in 2 dose forms, providing 5 mEq or 10 mEq of K^+ .
 - Slowly released from wax matrix; the capsule must be swallowed whole and not opened or crushed.
- Monitor serum potassium, especially if the glomerular filtration rate is reduced or the patient is receiving angiotensin-converting enzyme inhibitor or angiotensin-receptor blocker.
- Polycitra (not Polycitra-K) provides 1 mEq of K^+ /mL and 1 mEq of Na^+ /mL and requires dilution before administration.
 - Avoid K^+ -containing solutions in hyperkalemic forms of RTA.
- Sodium-containing solutions (eg, Bicitra)
 - May be used for buffer repletion in hyperkalemic regeneration-type RTA
 - Provide 1 mEq of Na^+ /mL and thus has lower osmolality than Polycitra K or Polycitra
 - Requires dilution to lower strength for safety and palatability
 - Total daily dose should be divided into 3 or 4 doses to minimize amplitude of fluctuations of serum HCO_3^- level that may occur with less frequent administration.
 - Metabolic acidosis inhibits growth hormone secretion, so administer a somewhat larger dose of citrate solution at bedtime to coincide with the nocturnal peak of growth hormone release.

- $NaHCO_3$ may be used, but rapid buildup of CO_2 in the stomach after ingestion may cause gastric distention.
 - This approach may be a preferable means of buffer repletion in infants who refuse citrate solutions.
 - 1-quarter teaspoon of baking soda powder ($NaHCO_3$) provides 13 mEq each of Na^+ and HCO_3^- and should be diluted in water or infant formula.
 - Tablets of $NaHCO_3$ are available, which may be crushed.
- Adequate treatment of nonhyperkalemic RTA with citrate should lessen hypercalciuria.
 - Nephrocalcinosis, once established, is not reversible.
 - The aim of treatment is to prevent its further progression to end-stage kidney disease.
- Given the risk of hypokalemia, severe K^+ depletion, muscle weakness, and even paralysis, treating hypercalciuria with thiazide should be done only with frequent monitoring of serum K^+ and provision of an adequate dose of potassium citrate.
- Adequate treatment with potassium citrate should correct metabolic acidosis, reduce urinary calcium excretion, and obviate the need for a thiazide.
- Correction of acidosis does not ameliorate hearing impairment of autosomal-recessive forms of proton-pump defects of type A intercalated cells.
- Monitor growth and serum electrolytes periodically.
- Maintain serum HCO_3^- near the upper limit of range between 25 and 29 mEq/L.
- Draw blood just before the next dose of alkali.

WHEN TO ADMIT

- Hypovolemia (often caused by diarrhea or vomiting illness)
- Hypokalemia with serum $K^+ < 2.5$ mEq/L accompanied by muscle weakness
- If adherence with the medication regimen or intercurrent illness interferes with taking medication, hospitalization may be needed for parenteral administration of HCO_3^- to treat severe metabolic acidosis.
- Kidney stone

WHEN TO REFER

- Comprehensive evaluation of suspected RTA entails studies in a kidney function laboratory; referral to a nephrologist is appropriate.
- The role of primary care physician is to:
 - Be aware of the possibility of RTA
 - Take some initial steps in patient's workup, such as calculation of UAG or UOG
- More detailed studies and explanations to the parents are best accomplished by a pediatric kidney disease specialist.

- Genetic counseling is needed for parents with a child who has monogenic RTA disorder, in anticipation of possible future pregnancies.
- Because commercially available gene testing is not yet available, the consultant nephrologist may have access to a research laboratory capable of sequencing DNA.

FOLLOW-UP

- Once a child is established on an effective treatment regimen and is clinically stable, periodic follow-up by the primary care physician may be done in collaboration with a nephrologist.

COMPLICATIONS

- RTA associated with episodic hypokalemia may be accompanied by profound muscle weakness and, in some instances, recurrent paralysis.
- Most children with RTA (especially those with nephrocalcinosis) have impairment of urinary concentrating mechanism and consequent obligatory polyuria.
- Superimposed dehydrating illness (eg, diarrhea or protracted vomiting) can culminate in profound hypovolemia.
 - This susceptibility warrants prompt hospitalization and fluid administration before signs of severe dehydration emerge.

- Susceptibility to hypokalemia in children with regeneration-type RTA calls for regular monitoring of serum K^+ .
 - If low, increase the dose of potassium-containing citrate solution.
 - If profound hypokalemia exists with a serum K^+ concentration <2.5 mEq/L accompanied by muscle weakness, prompt hospitalization is needed.
- Newborns with a salt-losing tendency should be monitored closely.
 - If the disorder was not recognized before discharge from nursery, the following signs call for urgent readmission and vigorous volume repletion.
 - Emergence of vomiting
 - Feeding difficulty
 - Listlessness
 - Hypotonia
 - Hyperventilation
 - Pallor
 - Signs of dehydration
- In the absence of virilization, congenital adrenal hyperplasia in a male infant may not be recognized at birth.
 - Infant may be discharged from nursery only to develop profound salt wasting and hypovolemic shock 1–2 weeks later.

Rheumatic Fever

DEFINITION

- Acute rheumatic fever is a systemic connective tissue disorder.

EPIDEMIOLOGY

■ Incidence

- Annual incidence is low, even at large teaching medical centers.
- During 3 years of pediatric training, a resident physician may not see many children with acute rheumatic fever.

■ Prevalence

- ~2–3% in epidemics of streptococcal pharyngitis
- ~0.2–0.3% after sporadic streptococcal upper respiratory tract infection
- In patients who have already had ≥ 1 attacks of rheumatic fever.
 - Recurrence rate of carditis increases to ~15% after subsequent streptococcal infection.

■ Age

- Most first cases occur between 5 and 15 years of age.
- Uncommon in patients <5 years
- Extremely rare in patients <3 years
- In infancy, acute rheumatic fever is usually associated with:
 - Severe carditis
 - Congestive heart failure
- In preschool-age children
 - Polyarthritis caused by rheumatic fever is unusual.
 - Rheumatoid arthritis and other inflammatory diseases of the joint are more likely.
- In early childhood chorea is uncommon
 - Most of the cases occur in patients >8 years.

■ Socioeconomic distribution

- Most studies have noted a strong association with poverty.
- Major social risk factors that predispose patients to rheumatic fever
 - Crowding
 - Increases likelihood of transmission of group A β -hemolytic *Streptococcus*
 - Lack of medical attention
 - Precludes timely treatment of streptococcal pharyngitis
 - Late attention to signs and symptoms of acute rheumatic fever

■ Sex

- No sex predisposition in the incidence of arthritis or carditis in childhood
- Sex differences exist in the type of valvular lesions that develop with carditis.
 - Boys have a higher incidence of aortic regurgitation.

- In young adults, mitral stenosis is more common in women.

- Chorea is more common in girls.

■ Geographic distribution

- In the US and Europe, acute rheumatic fever has declined in the past 5 decades.
- In underdeveloped countries, rheumatic fever remains a common childhood illness.
- Apparent resurgence of acute rheumatic fever in certain areas of the US both urban and suburban, was reported between:
 - 1984–1988
 - 1997–1998
 - No evidence indicates that this trend has continued.
- Contribution to prevalence of the disease in the US includes immigration from:
 - Caribbean Islands
 - South America
 - Southeast Asia

ETIOLOGY

- Immunologic reaction to group A β -hemolytic streptococci infection is the established cause of rheumatic fever.

RISK FACTORS

- Tendency for rheumatic fever to occur in >1 family member has long been recognized.
 - The observation is noted when family members are not concurrently living in the same household.
 - No genetic factors have been clearly established.

SIGNS AND SYMPTOMS

Major clinical manifestations

- The sequence of manifestations of rheumatic fever is noteworthy.
 - Polyarthritis, when it occurs, is usually present before onset of carditis.
 - Carditis may be present without preceding joint symptoms.
 - Most often, apical systolic murmur of mitral valvulitis occurs within 2 weeks of onset of arthritis.
 - Diastolic murmur of isolated aortic valvulitis takes longer to appear.
 - May not be heard for 6–8 weeks after the joint signs and symptoms appear
 - Chorea may develop during the convalescent phase of carditis.
 - A longer latent period usually occurs.
 - Classically, chorea appears as an independent manifestation of rheumatic fever long after initial streptococcal infection.

- Majority of cases begin 2 months after streptococcal infection, with episodes occurring up to 6 months afterward.
- Chorea and carditis may coexist.
- Chorea and polyarthritides rarely appear concurrently, presumably because of the difference in latent periods

Polyarthritides

- Most common manifestation at the onset of rheumatic fever
 - Usually involves large joints of lower extremities, particularly ankles or knees
- May result in joint pain while walking
 - Often initially considered to be secondary to trauma
- Other large joints become involved in a migratory fashion, eg, wrists and elbows.
- The affected joint characteristically is:
 - Warm
 - Reddened
 - Minimally swollen
- Involved joints are:
 - Exquisitely sensitive to touch
 - Painful on motion
- Suggestive of but not specific for rheumatic fever
 - Arthralgias, or aching in joints without objective signs of inflammation
- Fever is almost always present.
 - Temperatures are usually <102°F (38.8°C).

Carditis

- Inflammation of cardiac tissue is characteristically expressed as valvulitis.
 - Pancarditis involving myocardium and pericardium may be present in severe cases.
- Murmurs audible in rheumatic carditis are the result of mitral or aortic valvulitis, or both.
 - Mitral involvement is by far the most common.
- Auscultatory diagnosis of valvulitis often includes presence of an apical mid-diastolic murmur.
- Pericarditis
 - Typically silent
 - Occasionally, friction rub or distant heart sounds are noted.
 - Isolated pericarditis without associated auscultatory findings of mitral or aortic involvement is not consistent with diagnosis of acute rheumatic fever.
- Viral inflammation of the heart by coxsackievirus type B or Kawasaki disease may be associated with myocarditis and pericarditis.
 - These entities do not cause valvulitis.

- Auscultation of heart and evaluation of murmurs are influenced by fever and tachycardia.
 - The patient should be reexamined frequently after:
 - Diagnosis of acute rheumatic fever
 - Normalization of temperature with aspirin therapy
 - A changing functional murmur in an anxious or febrile child does not indicate the presence of carditis.
- Carditis is clinically diagnosed by the presence of valvulitis with characteristic murmurs.
 - May be arbitrarily designated as mild, moderate, or severe
 - Such categorization is useful in:
 - Approach to management
 - Establishing prognosis for development of rheumatic heart disease
- Mild carditis
 - Characteristically defined by the presence of prominent, high-pitched, apical systolic murmur typical of mitral insufficiency
 - Heart murmur of mild carditis is usually of grade 2 or 3 intensity (on a scale of 1–6).
 - Occupies all or most of systole
 - Mid-diastolic rumble at the apex is not present.
- Moderate carditis
 - Defined as:
 - Long systolic and prominent mid-diastolic apical murmurs, reflecting greater severity of mitral valvulitis
 - Basilar diastolic murmur of aortic valvulitis
 - Combination of mitral and aortic valvulitis
 - Aortic diastolic murmur
 - High pitched, decrescendo in character
 - Heard best during end expiration with diaphragm of stethoscope placed firmly at the third left intercostal space
- Severe carditis
 - Defined by the presence of:
 - Pericarditis
 - Congestive heart failure
 - Mitral or aortic valvulitis
 - Quality of heart sounds may be poor because of:
 - Pericardial effusion
 - Low cardiac output
 - Murmurs may become more intense as cardiac compensation improves.

Chorea

- The clinical picture of Sydenham chorea includes poor neuromuscular coordination.
 - Sometimes first detected by a change or sloppiness in handwriting

- A wide variety of jerky, involuntary movements may occur for 6–8 weeks when most cases of chorea are active.
- Neurologic examination may give evidence of specific deficiencies, particularly in the trunk and upper extremity control of movements.
- When chorea occurs as an isolated manifestation, the patient is usually afebrile.
 - The sedimentation rate is normal.
 - Long interval after the initiating streptococcal infection
 - Antistreptolysin O titer is typically normal or only mildly elevated.
 - Murmur of mild mitral insufficiency may be noted.

Erythema marginatum

- Transient pink rash with irregular, deeper-colored serpiginous borders
 - Seen on the smooth, hairless surfaces of the inner aspect of the upper arms and thighs or trunk
- Infrequently encountered in recent decades

Subcutaneous nodules

- Characteristically pea-sized
- Usually located on the extensor surfaces of:
 - Fingers
 - Toes
 - Elbows
 - Other joints
 - Occiput (less frequently)
- Usually reflect longstanding or smoldering illness after severe carditis
- Nodules may persist for weeks or months.
- Subcutaneous nodules are rarely found in children with rheumatic fever in present era.

Minor clinical manifestations

- Nonspecific fever
- Nonspecific arthralgia
 - Defined as joint discomfort without objective signs of joint inflammation
- Elevated acute-phase reactant, such as erythrocyte sedimentation rate (ESR), ranges from 60–120 mm/hour initially.
- In chorea, the sedimentation rate is normal due to long interval beyond the antecedent streptococcal infection.
- C-reactive protein is elevated in a variety of other diseases.
 - Helpful in diagnosing cases with borderline findings
- Streptococcal pharyngitis presumptively precedes an attack of rheumatic fever.
 - Some patients fail to report such a history.

- Scarlet fever will occasionally be followed by signs of polyarthritides or carditis.
 - Suppurative streptococcal disease, such as skin infection, is not a precursor of rheumatic fever.
- Polyarthritides and carditis usually occur 3–5 weeks after infection.
- Streptococcal antibody titer peaks before onset of clinical symptoms, then decreases gradually.
- Occasionally, children have abdominal pain after streptococcal infection for which medical or surgical evaluation is sought.
 - This symptom may occasionally precede signs of joint or cardiac involvement.

DIFFERENTIAL DIAGNOSIS

- Throat cultures may be misleading in the evaluation of patients suspected of having rheumatic fever.
 - Streptococcal infection antedates the common manifestations of polyarthritides and carditis by periods varying from 3–8 weeks.
 - ≤50% of patients with rheumatic fever continue to harbor streptococci during the course of their illness.

DIAGNOSTIC APPROACH

- No pathognomonic clinical findings and specific laboratory tests are available to confirm diagnosis of rheumatic fever.
 - The diagnosis must be somewhat arbitrary and empirical.
 - The tendency to label any low-grade febrile illness with arthralgia for which no obvious cause can be found as rheumatic fever should be avoided.
- A list of major and minor criteria for the evaluation and diagnosis of rheumatic fever and rheumatic heart disease was published >50 years ago by Dr T. Duckett Jones.
 - These guidelines have been accepted as diagnostic criteria throughout the world.
 - The most recent review of the Jones criteria by the American Heart Association was designated in a 1992 update and was reviewed in 2002.
- Jones criteria for the diagnosis of an initial episode of rheumatic fever
 - Evidence of antecedent group A streptococcal infections, 2 major manifestations, or 1 major and 2 minor manifestations indicates high probability of acute rheumatic fever.
 - The 5 major manifestations, in descending order of frequency, are:
 - Polyarthritides
 - Carditis
 - Chorea
 - Erythema marginatum
 - Subcutaneous nodules

- Minor manifestations are:
 - Clinical findings
 - Arthralgia
 - Fever
 - Laboratory findings
 - Elevated acute-phase reactants: ESR, C-reactive protein level
 - Prolonged PR interval
- Supporting evidence of antecedent group A streptococcal infections
 - Positive throat culture or rapid streptococcal antigen test
 - Elevated or rising streptococcal antibody titer
- 2 major manifestations involving skin, especially nodules that were most often seen only after multiple attacks of rheumatic fever, have been extremely uncommon during the late 1900s in the US.
- Minor manifestations include 2 laboratory findings.
 - Elevated acute-phase reactants: ESR and C-reactive protein level
 - Electrocardiographic (ECG) evidence of prolongation of the PR interval
- Fever may be present early in the course of polyarthritis or carditis.
 - Usually temperature <math><102^{\circ}\text{F}</math> (38.8°C)
- Arthralgia
 - Another minor manifestation
 - Nonspecific
 - May affect any joint without objective signs of inflammation
 - Should not be considered a minor manifestation if arthritis is counted as a major manifestation
- The Jones criteria should be viewed as a guide to a probable diagnosis of rheumatic fever.
 - Final diagnosis must remain a clinical judgment.
- Institution of prophylactic regimens requires prolonged administration of antistreptococcal agents, an important responsibility on the physician who diagnoses rheumatic fever.

LABORATORY FINDINGS

- Under current guidelines, laboratory confirmation of recent streptococcal infection should be part of the diagnostic evaluation.
 - Absence of evidence of streptococcal infection should make the clinician suspicious of the diagnosis of rheumatic fever.
 - Exception: cases in which indolent carditis or chorea are the major manifestations

- Minor clinical manifestations
 - Elevated acute-phase reactant is an invaluable though non-specific laboratory sign of inflammation.
 - ESR
- Most reliable evidence of a preceding streptococcal infection
 - Obtained by demonstration of antibody response to ≥ 1 of the streptococcal antigens
 - ASLO titer
 - Most common
 - Reaches maximal levels 3–5 weeks after infection
 - Gradually declines to preinfection levels 6–12 months later
 - Elevated in ~85% of patients with rheumatic fever
 - Titers are never extremely low.
 - Serologic evidence of an antecedent streptococcal infection increases to 95% if other streptococcal antibody tests are performed.
 - Antihyaluronidase
 - Antideoxyribonuclease B
 - Antistreptokinase

IMAGING

- Ultrasonography
 - 2-dimensional echocardiography for documentation and quantification of pericardial effusion
 - Interpretation of valvular regurgitation by Doppler ultrasonography should not constitute the basis of a diagnosis of carditis without auscultatory evidence of significant mitral or aortic involvement.
 - Doppler studies in healthy individuals frequently show a small degree of regurgitation across the mitral valve.
 - Trivial aortic valve regurgitation may be noted occasionally.
- Radiographic studies
 - In mild carditis, heart size on chest radiography is usually normal.
 - In moderate carditis, may show mild cardiac enlargement
 - In severe carditis, shows obvious cardiomegaly
 - May reveal pulmonary vascular congestion compatible with left-sided heart failure and pulmonary edema
 - Appearance may be consistent with rheumatic pneumonia.

DIAGNOSTIC PROCEDURES

- ECG of minor clinical manifestations
 - Prolongation of the PR interval (first-degree heart block) on ECG is considered to be a vagal effect and supports the diagnosis of rheumatic fever.
 - Most commonly noted when polyarthritis is apparent
 - Not necessarily associated with carditis

- ECG is almost always otherwise normal regardless of cardiac involvement.
- PR interval prolongation is the common manifestation.
 - Occasionally, second- or third-degree heart block occurs.
 - Indicates further heightening of vagal tone
 - Perhaps more pronounced in the rheumatic state than in other acute illnesses
- First- or second-degree heart block is not a:
 - Major criterion for carditis
 - Harbinger of potential rheumatic heart disease
 - Threat to progress to complete heart block
 - Cause of symptoms

TREATMENT APPROACH

- Therapeutic management of acute rheumatic fever includes the use of:
 - Antistreptococcal antibiotics
 - Antiinflammatory agents

SPECIFIC TREATMENTS

Chorea

- A protective environment is recommended while the process is active.
- Occasionally, mild sedation is indicated.
- Agents that may help in the treatment of more severe movement disorders
 - Clonazepam (Klonopin)
 - Haloperidol (Haldol)

Antistreptococcal therapy

- Eradication of group A β -hemolytic streptococcal infection by antibiotic treatment is the foremost principle in management of acute rheumatic fever.
 - Prescribed even in the absence of a positive throat culture
- Antibiotic treatment must always be immediately followed by institution of a prophylactic program to prevent reinfection.
- Penicillin is the drug of choice, prescribed initially at a dose and duration to maintain therapeutic blood levels for 10 days.
- Several treatment schedules are outlined by the American Heart Association.
 - Intramuscular administration of long-acting repository benzathine penicillin G (Bicillin) is preferred.
 - Ensures therapeutic levels for a sufficient length of time
 - A single injection of 1.2 million U for children 5–15 years of age is recommended.
 - Follow by prophylactic injections of 1.2 million U every 3–4 weeks.

- Alternative methods
 - Oral penicillin, 200,000 or 250,000 units (penicillin G or penicillin V), given 3 or 4 times a day for a full 10 days, followed by same dose twice daily thereafter, *or*
 - Combination of oral and intramuscular penicillin
- For patients sensitive to penicillin, erythromycin may be used for antistreptococcal therapy.
- Sulfonamide drugs are not effective for streptococcal eradication.
 - Bacteriostatic rather than bactericidal
 - Can be used in rheumatic prophylaxis programs to prevent reinfection
 - Rarely used in the present era

Antiinflammatory therapy

- Salicylates are indicated in the presence of acute, painful arthritis during the febrile phase of acute rheumatic fever.
 - Duration of therapy usually ranges from 4–8 weeks.
 - Average initial dose should be ~50–75 mg/kg/day, given in 4 divided doses.
 - Extremely high doses are not required.
- Aspirin is used for symptomatic relief only and is usually associated with:
 - Rapid and significant improvement in objective arthritis signs and symptoms
 - Almost immediate defervescence
- Specific blood levels do not need to be reached or maintained if clinical signs have disappeared.
- No evidence exists that salicylate administration affects the clinical course or later manifestations of cardiac involvement.
- Administration of steroid hormones is indicated for severe cardiac involvement characterized by pancarditis with congestive heart failure.
 - Most commonly prednisone
- When myocarditis appears to be fulminant, steroid therapy has been shown to significantly improve survival.
 - No evidence of long-term palliative effects on chronic rheumatic valvular disease is available.
- Duration of steroid treatment may be extended to 1–3 months in severe cases.
 - Varying schedules of tapering dose
 - Possible addition of salicylate therapy
- Specific therapeutic measures to control congestive heart failure may be useful.
 - Diuretics
 - Digitalis
- Furosemide (Lasix) is used for the management of pulmonary congestion with left-ventricular failure.

- Digitalis (digoxin) should be administered cautiously.
 - The threshold for toxicity may be reduced in the presence of inflammatory myocarditis.
 - Withholding digitalis for 1 or 2 days until steroid therapy has begun to suppress the myocarditis may be prudent.
 - Serum potassium levels should be monitored because steroids and furosemide both decrease body potassium.
 - Predispose patient to digitalis intoxication
- Enalapril is sometimes used in patients with mitral valve insufficiency.

Limitation of activity

- The role of bed rest in the treatment of rheumatic fever has been deemphasized in recent years.
- For children with arthritis
 - Ambulation can be permitted when pain and joint tenderness improve.
- Patients with stable, mild cardiac involvement can be allowed to ambulate when they feel well enough.
- Patients with more severe carditis
 - Length of restricted activity is individualized according to the severity of cardiac involvement.

WHEN TO ADMIT

- All children with acute rheumatic fever should be hospitalized.
- Hospitalizing a youngster who has arthritis or carditis may be advisable for:
 - Observation
 - Appropriate documentation of poststreptococcal illness
 - Initiation of treatment
- Hospitalization emphasizes to the parents:
 - Seriousness of the disease
 - Importance of prophylaxis to prevent recurrence
- Specific association of Sydenham chorea with rheumatic fever
 - Hospitalizing a child with this manifestation should not be mandatory if:
 - Abnormal neuromuscular activity is mild.
 - Unlikely to cause self-inflicted injury

WHEN TO REFER

- All children with acute rheumatic fever should be referred to a cardiologist for evaluation and management.

FOLLOW-UP

- An issue that arises is the amount of physical activity permitted.
 - Children with mild mitral regurgitation with normal heart size should be allowed to engage in all athletic activities, except for the most strenuous, competitive sports.

- Children with more severe mitral regurgitation or aortic insufficiency with cardiomegaly should have:
 - Some restriction of their activities
 - Continuing appropriate regimen
- If symptoms of fatigue or exercise intolerance persist despite medical management, a full diagnostic evaluation should be performed.
 - Surgical intervention with valvuloplasty or valve replacement should be considered.

COMPLICATIONS

- The major long-term consequence is the potential for inflammatory cardiac valvar involvement, leading to chronic heart disease.
- Ultimate development of rheumatic heart disease after a first attack of rheumatic fever can be correlated with severity of acute carditis.
 - A 10-year follow-up study of treatments begun in 1951 showed that patients developed chronic rheumatic heart disease (mitral insufficiency or stenosis or aortic regurgitation, or any combination).
 - ~30% of patients who had mild carditis
 - 50% of those who had moderate carditis
 - 75% with severe carditis
- Most children who develop rheumatic heart disease after a single attack of rheumatic fever have mitral regurgitation.
- Others either have both mitral and aortic regurgitation or aortic regurgitation alone.
- Mitral stenosis evolves slowly.
 - Usually after repeated episodes of acute rheumatic fever
 - Sometimes evolves unexpectedly
 - Many years after initial mild mitral valvulitis
 - Perhaps previously undiagnosed
 - Isolated mitral stenosis is:
 - Unusual before early adulthood
 - Rare in developed nations
- Contraception and pregnancy
 - Patients who have severe rheumatic heart disease are at high risk of cardiac complications during pregnancy and delivery.
 - Mitral stenosis has an especially high-risk profile.
 - Mild rheumatic heart disease is well tolerated during pregnancy.
 - Adolescent girls with rheumatic heart disease should be counseled with regard to contraceptive methods.
 - Oral medication with a low level of estrogen can be prescribed.
 - Give instructions on use of the diaphragm.
 - An intrauterine device should be avoided, because of risk of bacteremia.

- Added cardiovascular burden during pregnancy
 - Thorough obstetrical care should be provided from the first trimester through delivery.
 - Prophylaxis against streptococcal infection should be continued.
 - Psychosocial support may be needed.
 - Especially for pregnant teenagers with significant rheumatic heart disease who face medical complications during pregnancy
 - If early termination is sought, therapeutic abortion should be performed in the hospital.

PROGNOSIS

- In the months and years following an attack:
 - Auscultatory findings frequently change from those heard during the acute episode.
 - Apical systolic murmurs heard initially may diminish or completely disappear.
 - Aortic diastolic murmur will almost always persist during the follow-up period.
- An initial diagnosis of carditis does not necessarily imply progression to permanent heart damage.
- In children labeled as having history of acute rheumatic fever:
 - An additional appellation of rheumatic heart disease must be reevaluated continually.
- Even patients with severe carditis in the acute phase will show improvement in weeks and months after the recuperative period.
 - >50% of murmurs of mild or moderate mitral insufficiency will disappear completely.
- Other manifestations are self-limiting with no late sequelae.
- Arthritis clears without joint dysfunction or deformity.
- Chorea leaves no neuromuscular impediment.
- Recurrence of rheumatic fever
 - Striking tendency to recur
 - Before the introduction of preventive measures, most patients who had initial attack of rheumatic fever had ≥ 1 recurrences.
 - Recurrence rate is highest during first 3 years after initial attack.
 - Diminishes with time after the original episode
 - Recurrence is rare in adulthood.

PREVENTION

Rheumatic fever

- The incidence of first attack can be reduced by adequate penicillin treatment in all cases of streptococcal pharyngitis.

- Numerous community primary prevention programs have demonstrated the efficacy of identifying streptococcal infection by:
 - Performing throat cultures on susceptible children
 - Early treatment
- Application of secondary prevention in the form of antistreptococcal prophylaxis after the first attack has significantly reduced:
 - Recurrence rate
 - Additive effects of repeated bouts of carditis

Recurrence

- Preventing recurrent attacks that carry risk of recrudescing heart involvement and further cardiac damage is the most important concern.
- Continuous antimicrobial prophylaxis should be given in all children who have a history of rheumatic fever, including those who present with chorea.
- Prophylaxis may be discontinued if:
 - The patient is 18 years of age
 - A patient who initially had cardiac involvement has no auscultatory evidence of heart disease
- Prophylaxis should be maintained into adulthood if there is:
 - Chronic mitral valve disease
 - Aortic valvular disease
- Prophylaxis can be discontinued after 5 years:
 - In children who had no cardiac involvement during the initial attack
- The rationale for antibiotic prophylaxis in a patient with known rheumatic fever is protection against recurrence of rheumatic fever through prevention of group A streptococcal infection.
- The most effective method for reducing streptococcal infections and rheumatic fever recurrence
 - Intramuscular injections of long-acting penicillin (benzathine penicillin G, 1.2 million U)
- Preventive regimen most effective when given every 3–4 weeks.
 - In residual cardiac involvement, this approach is recommended
 - Every 3 week regimen is recommended for the first 6–12 months.
 - Continue every 3–4 weeks for at least a 1- or 2-year period
 - Followed by oral prophylaxis
- Parenteral therapy is most effective method of prophylaxis.
 - Strict adherence to a program of daily oral medication is especially difficult for children and adolescents.

- Transient discomfort at the injection site (anterior thigh or buttock) may be relieved by:
 - Hot bath
 - Aspirin on the evening of injection
- Alternative methods of prophylaxis include
 - Oral administration of penicillin G
 - 200,000 or 250,000 U, twice a day
 - Sulfisoxazole
 - Gantrisin, 0.5 g twice a day
- For the patient sensitive to both penicillin and sulfisoxazole:
 - Consider daily prophylaxis with another agent.
 - Successful oral prophylaxis is hard to maintain.
 - If used, its value and need for compliance should be reinforced constantly.
 - Rheumatic fever recurrence is less likely after 2–5 years.
- Patients with chronic rheumatic heart disease
 - Oral regimen can be substituted for intramuscular penicillin.
 - Oral prophylaxis can be instituted immediately for patients who did not have carditis during the acute attack.
 - Under these circumstances, recurrences with carditis are extremely rare.

Bacterial endocarditis

- Individuals who have a history of rheumatic fever without evidence of significant murmurs on follow-up examination:
 - Are not susceptible to bacterial endocarditis.
 - Do not have damaged heart valves
- Recent guidelines from the American Heart Association report that patients with heart disease
 - More likely to get infective endocarditis from frequent exposure to random bacteremic events associated with daily activities
 - Less likely to get infective endocarditis from bacteremia following dental or surgical procedures
- Latest guidelines for prevention of infective endocarditis recommend antibiotic prophylaxis for patients with:
 - Prosthetic cardiac valves
 - Previous infective endocarditis
 - Certain types of repaired and unrepaired congenital heart diseases
- Antibiotic prophylaxis before dental or surgical procedures is no longer recommended for patients with mitral or aortic valve disease following rheumatic fever.
- Recommendations for prevention of recurrent episodes of rheumatic fever have not changed.

Rocky Mountain Spotted Fever

DEFINITION

- Rocky Mountain spotted fever (RMSF) is an acute infectious disease.

EPIDEMIOLOGY

■ Incidence

- Increased slightly during the past several years
 - >500 cases per year in the 1990s
 - >1000 cases per year since 2000

■ Geographic distribution

- First reported in patients from the Rocky Mountain region
- Incidence is now greatest east of the Mississippi River, with most cases reported from southeastern and south-central US.
- From 1994–2003, 54% of the cases of RMSF reported in the US were in:
 - North Carolina
 - Tennessee
 - Oklahoma
 - South Carolina
 - Arkansas
- Disease occurs predominantly in the US but has been reported in other areas in the Western Hemisphere, specifically:
 - Canada
 - Central America
 - South America

■ Age

- Two-thirds of cases occur in children <15 years.
- Peak ages of infection from 5–9 years
- 15% of deaths occur in children <10 years.

■ Sex

- Occurs more frequently in boys than girls

■ Race

- Higher incidence in white people than people of other races

■ Seasonality

- Can occur at any time of the year
- 90% of cases occur from April to September.

ETIOLOGY

- Caused by *Rickettsia* that multiply in endothelial cells

- May produce cellular injury by various mechanisms, including:

- Cell wall penetration
- Disturbance of intracellular metabolism
- Production of toxic metabolites
- Use of metabolites required by the host cell

- Perivascular mononuclear cell infiltration caused by the reproducing organism results in:

- Necrosis of endothelial cell walls
- Increase in vascular permeability
- Fibrin extravasation
- Thrombosis of small blood vessels

- Resulting cell damage in multiple locations is responsible for the clinical picture.

- The major pathologic lesion in RMSF, vasculitis, makes RMSF a multisystem disease.

- Skeletal muscle
- Brain
- Lungs
- Kidneys
- Testes
- Adrenal glands
- Liver
- Heart

- Ticks serve as a vector for the infectious agent *Rickettsia rickettsii*.

- Transmission to humans occurs when:

- The tick takes a blood meal.
- Abraded skin is contaminated by tick feces or a crushed tick and may occur when ticks are removed.

- Usually, tick attachment lasting 12–24 hours is needed to transfer disease.

- 2 specific ticks serve as major carriers.

- Wood tick, *Dermacentor andersoni*: more important vector in the western US
- Dog tick, *Dermacentor variabilis*: usual vector in the eastern US

- Ticks acquire the rickettsiae by feeding on infected wild mammals, such as:

- Squirrels
- Opossums
- Rabbits
- Dogs
- Mice

- Dog ticks infected with *R. rickettsii* have been found in urban areas.

- Suggests this tick's ubiquitous nature
- Places individuals at risk without travel to endemic areas

- The brown dog tick, *Rhipicephalus sanguineus*, is implicated in causing outbreak of *R. rickettsii* infection in Arizona.

- Exposure to a tick is not elicited in every case.

- Only 60% of patients with RMSF can recall a specific tick exposure or encounter.

- Tick bite is painless.

- Leaves no local lesion or regional lymphadenopathy

RISK FACTORS

- In adults, occupational or recreational exposure to ticks increases the risk of infection.
- The clinician should question the patient specifically about prior activities that increase risk of exposure.
 - Removal of a tick from a pet
 - Camping or picnicking in high-risk area
- Overall risk to patients, even when in high-risk areas, is low.
 - Approximately only 1–3% of the tick population carries *Rickettsia* at any given time.

SIGNS AND SYMPTOMS

- Characterized by:
 - Fever
 - Headache
 - Myalgia
 - Distinctive exanthem
- After inoculation with rickettsiae
 - Incubation period ranges from 2–12 days.
 - The usual period is 5–7 days.
 - Shorter incubation periods are associated with more serious disease.
- The prodromal period lasts 2–3 days, predominated by:
 - Low-grade fever
 - Chills
 - Muscle aches
- Muscle pain is most common in the calf region in younger patients.
- Headache is an early symptom.
 - Infants and toddlers may express pain from headache or myalgias as crying or fussiness.
- Other frequent symptoms include:
 - Malaise
 - Anorexia
 - Vomiting
 - Photophobia
- The prodrome is followed by accentuation of symptoms.
 - Especially fever
 - Temperatures often as high as $\geq 104^{\circ}\text{F}$ (40°C)
 - The lowest temperatures, although still elevated, are recorded in the mornings.
 - Lethargy and mental obtundation become prominent.
 - Symptoms seen at this stage are not diagnostic.
- Rash is the most distinctive sign.
 - Usually appears 3–5 days after onset of fever
 - Begins peripherally on:
 - Wrists
 - Ankle
 - Hands
 - Feet
 - Initially, the lesions are:
 - Macular
 - Discrete
 - Erythematous
 - Blanch on pressure
 - Rash rapidly spreads centrally, involving:
 - Arms
 - Legs
 - Axillae
 - Buttocks
 - Trunk
 - Neck
 - Face
 - Lesions deepen in color, becoming:
 - Dusky red
 - Maculopapular
 - Petechial
 - True petechiae may not form until day 6 of illness.
 - 35–60% of patients never develop petechiae.
 - Petechial lesions may coalesce and form large ecchymotic areas.
 - In severe cases and when treatment is delayed, these ecchymotic areas may ulcerate.
 - Distal regions (eg, fingers and toes) may become gangrenous in as many as 4% of cases.
 - As many as 15% of patients do not develop rash, or develop a fine rash that may be difficult to appreciate in patients with darker skin tones.
 - Rash does not occur until day 4 of the illness.
 - Petechiae may be a much later finding.
 - Some patients never develop a discernible exanthem.
- Tachycardia and an elevated pulse rate are noted early and are proportional to the degree of hyperpyrexia.
- A sudden increase in pulse rate or a decrease in blood pressure may indicate:
 - Peripheral circulatory collapse
 - Severe bleeding
 - Myocardial failure
- Photophobia is associated with conjunctival ecchymosis involving both bulbar and palpebral conjunctivae.
- Other manifestations include:
 - Abdominal pain
 - Retinal hemorrhages
 - Vomiting
 - Hepatomegaly

- Splenomegaly with generalized abdominal tenderness
 - Lethargy
 - Obtunded state of consciousness
 - Jaundice is not usually seen except in the most critically ill patients, with disseminated intravascular coagulation (DIC).
- Diminished urinary output caused by:
- Fever
 - Poor fluid intake from nausea
 - Vomiting
 - Mild azotemia caused by fluid losses should respond to rehydration.
- The patient may exhibit nuchal rigidity, resulting from vasculitic reaction in the meninges.
- Neurologic manifestations include:
- Disorientation
 - Confusion
 - Seizures
 - Coma
 - Central deafness
 - Cortical blindness
 - Sixth nerve palsies
- Causes of neurologic effects include:
- Vasculitis
 - Hemorrhage from coagulopathies
 - Secondary metabolic changes caused by circulatory collapse
- ### DIFFERENTIAL DIAGNOSIS
- Neurologic and abdominal symptoms early in RMSF may mask its diagnosis.
- Illnesses to be considered and differentiated from RMSF, especially after the rash appears, include:
- Rubeola (measles)
 - Meningococemia
 - Henoch-Schönlein purpura
 - Kawasaki disease
 - Immune thrombocytopenic purpura
 - Leukemia
 - Typhus
 - Ehrlichiosis
 - Infectious mononucleosis
- Meningococemia
- Petechial rash of meningococemia differs from that of RMSF in:
 - Distribution
 - Rapid extension
 - Coalescence of lesions into larger hemorrhagic, purpuric areas
 - Prostration develops rapidly if the patient remains untreated.
 - Often apparent on admission to the hospital
 - Helpful points in differentiating meningococemia from RMSF
 - Absence of myalgia
 - Extremely abrupt onset
 - Leukocyte count may be elevated in meningococemia.
 - The sickest patients are frequently leukopenic.
 - Other presentations include:
 - Meningitis with pleocytosis
 - Low glucose levels
 - Organisms in the cerebrospinal fluid (CSF)
 - Distinguishing between these entities clinically is not often possible.
 - Treatment for both diseases in an ill patient is warranted.
- Ehrlichiosis
- Rickettsial disease with clinical similarity to RMSF
 - Rash occurs with less frequency.
 - >60% of children with ehrlichiosis have been noted to have rash.
 - Variable in location and appearance
 - May be petechial
 - Can be confused with rickettsial exanthems
 - Early diagnosis and treatment of with doxycycline reduces morbidity.
- Rubeola (measles)
- Characterized by a macular rash
 - Infrequently becoming hemorrhagic
 - Begins on the face and neck
 - Preceded by:
 - An enanthem
 - Koplik spots on the buccal mucosa
 - Coryza and cough in the prodromal stage of illness are not consistent with RMSF.
 - A history of adequate immunization with rubeola vaccine greatly diminishes this possibility.
- Henoch-Schönlein purpura
- May produce a petechial or purpuric rash, frequently concentrated on lower extremities and buttocks
 - Cutaneous lesions may be multiform.
 - May occur on other parts of the body
 - Arthralgia with periarticular swelling and accompanying signs and symptoms of upper respiratory tract inflammation, intense abdominal pain, or nephritis
- Kawasaki disease
- Fever
 - Puffy hands and feet

- Rash
 - Typically does not begin peripherally and spread centrally or become petechial in 1–2 days
- Conjunctival injection
- Usually, Kawasaki disease is not seriously considered until the following occur.
 - 5 days of fever
 - Enlarged cervical node
 - Pharyngeal hyperemia
 - Dry cracked lips
 - Strawberry tongue
 - Marked irritability
- Leukocyte and erythrocyte sedimentation rates are usually elevated significantly.
- Kawasaki disease usually occurs in the winter and spring months
- Children with Kawasaki disease do not give a history of tick exposures.
- Elevated platelet count begins during the second week of illness.
- Other illnesses that produce petechiae and lack distinctive distribution of rash
 - Immune thrombocytopenic purpura
 - Seen as a petechial rash in an otherwise healthy patient
 - Patients with leukemia who initially have fever and petechiae would be expected to:
 - Be anemic
 - Have lymphadenopathy
 - Have hepatosplenomegaly
 - Patients with infectious mononucleosis with petechial eruption usually have:
 - Lymphadenopathy
 - Hepatosplenomegaly
 - Gradual onset
 - Typhus is a rickettsial infection to be excluded.
 - Murine typhus produces a milder disease.
 - Rash is macular, not petechial.
 - Epidemic typhus may produce a petechial rash that typically begins proximally and extends peripherally.
 - Does not usually involve the palms or soles
 - History of tick bite is absent.

DIAGNOSTIC APPROACH

- The diagnosis is made clinically.
- Clinical diagnosis and treatment are typically required before laboratory confirmation.
- The disease still has a significant risk of morbidity and mortality when treatment is delayed.

LABORATORY FINDINGS

- Available laboratory tests to confirm the presence of *R. rickettsii* include:
 - Increase in antibody titer detected by immunofluorescence or latex agglutination
 - Polymerase chain reaction testing
 - Immunofluorescence of skin biopsy
 - Isolation of organism from clinical specimen
- Immunofluorescent staining of the skin biopsy specimen
 - May identify *R. rickettsii*
 - May provide early proof of RMSF
 - Not readily available to most clinicians
 - Appropriate antibiotic therapy started 3 days before biopsy has resulted in negative immunofluorescence.
 - When appropriate treatment has been initiated before biopsy, clinical criteria justify a full course of antibiotic therapy.
- Polymerase chain reaction testing provides a specific diagnostic tool for early diagnosis.
 - Expensive
 - Not commonly available
- Complement fixation and immunofluorescent antibody studies in serum will identify patients with RMSF.
 - Test results do not become positive until 7–10 days after the onset of illness, or later if antibiotic therapy has begun early.
 - Titers should be performed during the acute illness.
 - Repeat 3 weeks later.
 - 4-fold increase in titer in the convalescent sera is diagnostic for infection.
- Weil-Felix reaction is at best a nonspecific test for RMSF.
 - Agglutination of *Proteus vulgaris* by the patient's serum
 - Acute and convalescent sera must be compared.
 - Proteus agglutinins may appear by the end of the first week of illness.
 - Availability of more specific and sensitive tests makes this test obsolete.
- Rickettsiae can be isolated from body fluid or tissue specimens when grown in laboratory animals or chick embryos.
 - The high rate of disease transmission to laboratory technicians makes such techniques feasible only in laboratories engaged in *Rickettsia*-related research in which all workers are immunized.
 - Culture identification of rickettsiae is not available in most clinical settings.
- Blood leukocyte counts and differential counts are usually within normal limits, but neutrophils often predominate.
 - Neutrophil predominance may help distinguish RMSF from ehrlichiosis.

- Most patients with ehrlichiosis have lymphopenic leukopenia.
- Thrombocytopenia is a complication seen in the later stages of the disease.
 - May be the result of platelet adherence to damaged endothelium
- Up to 20% of patients may have hyponatremia.
 - Possibly caused by increased vascular permeability of the kidney to sodium
 - Nonspecific finding; does not exclude other diagnoses, such as ehrlichiosis
 - The remainder of electrolyte profile is usually normal.
 - Hypochloremia is seen in some.
 - Up to 25% of patients will display increased blood urea nitrogen levels and increased liver enzymes.
 - With the development of DIC, abnormalities can occur.
 - Prothrombin time
 - Partial thromboplastin time
 - Fibrinogen
 - Fibrin split products
- Patients with neurologic manifestations may have normal CSF cell counts.
 - Most have normal CSF glucose and protein levels.
 - CSF analysis might reveal:
 - Neutrophilic or lymphocytic pleocytosis
 - Elevated protein
 - Nonspecific findings; may not help distinguish RMSF from meningococcal disease or ehrlichiosis
- Long-term morbidity from neurologic complications, though rare, are still significant.
 - Hematuria and anemia may occur.
 - Transfusion or renal dialysis is rarely required.

DIAGNOSTIC PROCEDURES

- Skin biopsy

TREATMENT APPROACH

- Treatment should never be withheld or delayed due to:
 - Absence of rash
 - Lack of exposure to ticks
 - Desire to await confirmatory laboratory study results
 - Patient location where RMSF is uncommon
 - Pediatrician discomfort using doxycycline in a child <8 years
- Treatment for RMSF mandated until the diagnosis can be excluded if:
 - Triad of fever, headache, and myalgia
 - Combined with a history of tick bite or removal within the previous 2 weeks

- If a pediatrician strongly suspects RMSF because of patient's clinical history and physical findings, therapy should be initiated immediately.
 - Can be administered concurrently with treatment for meningococemia

SPECIFIC TREATMENTS

Pharmacotherapy

- Doxycycline
 - Drug of choice for all ages
 - Given and continued for ≥ 3 days after clinical improvement and defervescence
 - Usual length of therapy is 7–10 days.
 - Intravenous therapy should be given to all ill patients.
 - Transition to oral therapy when the patient's condition has improved.
 - Effective against ehrlichiosis, which may mimic RMSF
 - Has a broad therapeutic index
 - Levels do not need to be monitored as required with other RMSF medications, such as chloramphenicol.
- Tetracycline
 - Shown to be effective against RMSF
 - Can lead to increased dental staining compared with doxycycline in children <9 years
 - No more effective than doxycycline
 - Tetracycline is less commonly used in children.
- Chloramphenicol
 - No longer the drug of choice for RMSF
 - Data have shown it may be more effective than doxycycline.
 - The toxic effects of this drug (aplastic anemia) make it an undesirable treatment option.
 - May be given to patients who cannot tolerate doxycycline or tetracycline
- Combination therapy
 - Initiating treatment for meningococcal disease, as well as RMSF and ehrlichiosis, in an ill patient may be necessary.
 - When this situation arises, doxycycline will treat both ehrlichiosis and RMSF.
 - Can be used in conjunction with a third-generation cephalosporin to treat meningococcal infection
- Hospitalization
 - Desirable initially for most patients, both to:
 - Confirm diagnosis
 - Observe effect of therapy
 - Therapy should be continued until the patient has improved and has been afebrile for 72 hours.
 - Generally occurs after 7–10 days of therapy

- Supportive therapy
 - Includes maintenance of hydration and nutrition with appropriate intravenous fluids and oral feedings (if tolerated).
 - Management of DIC may include therapeutic maneuvers, such as administering:
 - Fresh-frozen plasma
 - Fresh platelets
 - Packed red blood cells
 - Vitamin K
 - Seizures may require the use of anticonvulsant medications.

WHEN TO ADMIT

- Most patients need to be admitted and kept hospitalized until they show clinical improvement.
- Hemodynamic instability
- Dehydration
- Requires intensive monitoring
- RMSF with its complications

WHEN TO REFER

- Uncertain diagnosis
- Clinical suspicion of disease

COMPLICATIONS

- Vascular necrosis and thrombosis may result in local gangrene and loss of tissue.
- DIC may develop (uncommon).
 - Patients with this complication have the greatest risk of dying.
- Myocardial failure may result from myocarditis and arrhythmias.
- Edema may be generalized as a result of:
 - Increase in capillary permeability caused by the vasculitis
 - Heart failure
 - Iatrogenic fluid overload
 - Any combination
- Long-term morbidity from neurologic complications is rare but still significant.
- Hematuria and anemia may occur.
 - Transfusions or renal dialysis are rarely required.

PROGNOSIS

- Mortality of approximately 2–4% in recognized cases
 - Patients who escaped clinical detection have been identified by serologic evidence.
 - Disease may occur in a mild or subclinical form.

- Rocky Mountain spotless fever has also been described.
 - Suggestion that patients who have spotless or almost spotless fever have a significantly higher mortality as a result of delayed diagnosis and treatment
- RMSF can be considered a potentially fatal illness.
 - Younger patients are likely to be less severely affected than older patients.
- Early diagnosis and prompt therapy lessen disease severity.
 - Under such circumstances, death would be extremely unusual.
 - In most patients, early clinical diagnosis and adequate therapy shorten the duration of illness appreciably.
- Recovery from the illness is accompanied by immunity to *Rickettsia*.

PREVENTION

- Repellents have been shown to be effective against ticks.
 - *N,N*-Diethyl-meta-toluamide (DEET) skin repellents
 - Permethrin-containing repellents used on clothes
- Systemic reactions to DEET are possible when the repellents contain a high concentration of the chemical.
- The best preventive measure is avoidance of tick exposure.
- When exposure is likely, daily searches for ticks should be performed.
 - In tick-infested areas, twice-daily searches are advised.
 - Careful inspection at bath time is an excellent way to discover ticks.
- Ticks may be removed by gentle traction with forceps or tweezers.
 - Care must be taken not to crush them.
 - Skin should be disinfected both before and after tick exposure to remove feces that may carry *Rickettsia*.
 - The tick should never be covered in:
 - Petroleum jelly
 - Nail polish remover
 - Alcohol
 - No one should attempt to burn the tick to coax it to detach itself.
 - These attempts may lead the tick to defecate or aerosolize infected body fluids.
- Antimicrobial prophylaxis is not indicated after a tick bite.
 - The chance of a tick carrying the disease, even in an endemic area, are low.
 - No demonstrable benefit of prophylaxis has been found.

Screening for Anemia

BACKGROUND

- Anemia may be defined by laboratory values (low hemoglobin) or physiologic consequences (inadequate oxygen-carrying capacity).
 - Both are equally important.
- Prevalence of iron-deficiency anemia
 - Varies, but may be as high as 2.9%
 - Has decreased over the past several decades, primarily because of:
 - Improved dietary recommendations
 - Use of iron-fortified formulas
- Sickle cell anemia
 - Affects approximately 1 of every 600 African-American children
 - Early detection with rapid institution of penicillin prophylaxis has dramatically reduced incidence of fatal pneumococcal sepsis in newborns and young children.
 - Screening is now required for all 50 states and District of Columbia.
 - Many states also report variant hemoglobins identified incidentally during the screening process.

GOALS

- Screening programs are directed primarily at detecting disease in otherwise asymptomatic children.
- Adequate iron stores are critical for normal neurocognitive development, and inadequate levels should be detected and treated as early as possible.
 - Iron deficiency is the major impetus behind public health recommendations for anemia-screening programs.
 - Screening for anemia is the most reliable and cost-effective method for detecting occult iron deficiency.

GENERAL APPROACH

- Screening for anemia in infants and young children begins shortly after birth via newborn hemoglobinopathy screening programs.
 - Many of the variant hemoglobins are benign, particularly when patients are heterozygous.
 - Newborn screening improves sensitivity of detection for α -thalassemia.
 - Some forms of β -thalassemia may not be detectable until after hemoglobin switching from fetal forms has been completed at 6–12 months of age.
- The AAP recommends next screening at 9–12 months.
- The AAP recommends additional screening between 15 months and 5 years for children at risk.
 - Preterm or low-birth-weight infants
 - Infants receiving unfortified formula
 - Infants receiving cow's milk before age 12 months

- Breastfed infants not getting iron supplementation after age 6 months
- Children consuming >24 ounces of cow's milk per day
- Children with special health care needs
- The AAP recommends screening at least once during adolescence for males.
- The AAP recommends annual screening for menstruating females.
- Further information about the morphologic characteristics of the patient's erythrocytes should also be obtained.
- Important information that is relevant to the anemic patient
 - A history of:
 - Neonatal jaundice
 - Ethnicity
 - Dietary intake
 - Family history of:
 - Splenectomy
 - Cholecystectomy
 - Iron therapy
 - Blood transfusions

SPECIFIC INTERVENTIONS

Anemia screening

- Screening is accomplished by determining the whole-blood hemoglobin concentration using blood obtained by skin puncture of the finger or heel.
 - The sample may be analyzed using a small portable spectrophotometer or a bench-top particle counter.
 - Either method is quick and reliable, with minimal quality control and maintenance required.
 - Hemoglobin concentration is compared with reference values for age-matched normal children.
 - Levels that are less than the lower reference limit (2 standard deviations below the mean) are defined as anemic.
- Positive screening tests for anemia must be confirmed and correlated with the clinical presentation.
 - Confirmation is usually performed by submitting a venous blood sample anticoagulated with ethylenediamine tetraacetic acid to the hematology laboratory for:
 - Complete blood count
 - Microscopic examination of a Wright-stained peripheral blood smear.
- Other studies that may be helpful in determining iron status:
 - Serum ferritin (most reliable indicator of iron status/stores in the absence of an underlying inflammatory illness)
 - Serum iron

- Iron-binding capacity
 - Best obtained in the fasting state, since findings may be misleading if the patient has recently eaten an iron-rich meal
- Lead level
 - Younger children may be more prone to lead intoxication secondary to pica associated with iron deficiency.

Differential diagnoses

- Iron-deficiency anemia will generally have microcytic-hypochromic indices:
 - Low mean corpuscular volume
 - Low mean corpuscular hemoglobin concentration
 - High red-cell distribution width
 - May be associated with thrombocytosis
 - Thrombocytopenia may be observed in severe iron deficiency.
- Types of anemia that should be included in the differential diagnosis of microcytic anemia:
 - Thalassemia
 - Sickle-thalassemia syndromes
 - Some hemoglobinopathies (C and E)
 - Severe lead intoxication
 - Anemia of chronic disease
 - Hereditary spherocytosis

- For additional information on differential diagnoses, see Anemia and Pallor.

Management

- Mild microcytic anemia (ie, hemoglobin level 8–10 g/dL)
 - Empiric treatment with iron supplementation (3–4 mg elemental iron/kg daily) is appropriate.
 - Reticulocyte count should increase within 1 week of beginning iron therapy.
 - The hemoglobin level should increase by at least 1 g/dL within a month.
 - Treatment should continue for an additional 2 months in patients who respond.
 - Appropriate dietary counseling is important to prevent recurrence.
 - For patients who fail to respond:
 - Additional laboratory evaluation is indicated.
 - Referral to a hematologist should be considered.
 - An evaluation should be undertaken to identify sources of occult blood loss.
 - Particularly in older children who are not consuming significant amounts of cow's milk.
- If anemia is more severe, then confirmatory laboratory evaluation should be done when empiric iron therapy is begun.

Screening for Drugs

BACKGROUND

General

- Adolescent substance abuse is a major public health problem that contributes to potentially preventable morbidity and mortality.
- Up to 1 in 10 adolescents should receive a full diagnostic evaluation for substance abuse.
 - At least half are likely to require treatment.
- Earlier identification can prevent many adverse consequences.
- Very high-risk children (who abuse nicotine, alcohol, marijuana, and other substances) are very likely to suffer from:
 - School failure
 - Sexually transmitted infections, such as HIV infection
 - Teenage pregnancy
 - Delinquency
 - Suicide
 - Homicide

Drug use

- Cigarettes
 - 8th graders
 - 10% report having smoked in the previous 30 days.
 - 5% smoked daily.
 - 12th graders
 - 26.7% report smoking in the previous 30 days
 - >16.9% smoked daily.
 - 75% of adolescents who smoke will become lifetime smokers and face longer exposure to nicotine toxicity.
 - Nicotine alone accounts for more substance-related deaths than all other drugs (including alcohol) together.
 - Adolescents who abuse nicotine and alcohol are more likely to abuse marijuana and other illicit substances.
- Alcohol
 - 8th graders—in the previous 30 days:
 - 19.5% used alcohol.
 - 6.7% had been drunk.
 - 12th graders—in the previous 30 days
 - Nearly 50% used alcohol.
 - 30.3% had been drunk.
 - 3.9% of high school seniors report being drunk daily.
 - In youth 15–24 years of age, half of all motor vehicle accidents are alcohol related.
- Marijuana
 - 21.3% of high school seniors have smoked marijuana in the previous 30 days.
 - 6% smoked marijuana daily.
- Other illicit drugs
 - 11.3% of high school seniors report using some type of other illicit drug.

- Isolated use of drugs other than marijuana and alcohol is uncommon.

Drug abuse

- Excluding nicotine, 7% of 12- to 17-year-olds have a substance use disorder.
- The highest age-specific prevalence occurs during adolescence.
- Rates of current dependence on alcohol and other drugs peak between 16 and 19 years of age.
- Alcohol and marijuana are most commonly abused substances among adolescents.
- Of adolescents with substance use disorders:
 - 41% have alcohol use disorder.
 - 11% have alcohol or marijuana use disorder.
 - 5% have alcohol use disorder with another substance use disorder (other than marijuana).
 - 3% have marijuana use disorder with another substance use disorder (other than alcohol).

Gateway hypothesis

- Progression of substance use from cigarettes and alcohol to marijuana or from marijuana to cocaine and possibly heroin
- Only 12.8% of persons who have smoked marijuana once or twice have tried cocaine.
 - Of those who have smoked >300 times, over 71% have tried cocaine.
- The extent to which nicotine use predisposes to marijuana use or marijuana use predisposes to cocaine use is unclear, but compelling associations exist.
- Age of onset of substance use is also associated with transition between stages.
 - Heroin users typically report first smoking cigarettes at 12.6 years.
 - Cocaine users report beginning cigarettes at 14 years.
 - Marijuana users report beginning cigarettes at 14.6 years.
 - Alcohol-only users report beginning at 15.8 years.
- Early-onset substance abuse disorders
 - The earlier the age of onset, the more likely substance use is to develop into a lifetime disorder.
- Early-onset (adolescent) substance use disorders differ from disorders developing later.
 - Increased degree of disruptive behaviors or delinquency
 - Increased degree of novelty or sensation seeking
 - Decreased dependence on external incentives (eg, doing well in school, performing a job well)
- Late-onset substance abuse disorders
 - Tend to be associated with decreased antisocial behavior and increased reward dependence compared with early-onset disorders

Risk factors

- Behavioral impulsivity, conduct problems, and difficulties in functioning that arise before first use of the substance
- Aggression
 - Sometimes accompanies behavioral impulsivity and develops during the preschool or early school-age period
 - More highly associated with oppositional defiant disorder, which, in turn, is highly associated with early-onset conduct disorder
- Disruptive behavior disorders, such as conduct disorder, strongly predict transition from substance use to abuse.
- Untreated attention-deficit/hyperactivity disorder
 - Increases risk of substance use by about 2 times the general risk
 - If comorbid with conduct disorder, increases risk for substance use disorder by up to 4 times the general risk
- Low levels of parental monitoring
- Parental substance abuse
- Peers who also use substances
- Poverty and neglect

Substance abuse versus substance dependence

- Abuse
 - Maladaptive pattern of substance use leading to clinically significant impairment or distress
 - Symptoms
 - Recurrent substance use resulting in failure to fulfill major role obligations at work, school, or home
 - Recurrent substance use in situations in which it is physically hazardous
 - Recurrent substance-related legal problems
 - Continued substance use despite persistent or recurrent social or interpersonal problems caused or exacerbated by the substance
- Dependence
 - Symptoms indicating tolerance or withdrawal or loss of function due to substance use
 - Tolerance: need for increased amounts of substance to achieve intoxication or desired effect *and* markedly diminished effect with continued use of the same amount of substance
 - Withdrawal: characteristic withdrawal syndrome for the substance *and* use of the same (or a closely related) substance to relieve or avoid withdrawal symptoms
 - Use of substance in larger amounts or for a longer period than expected
 - Persistent desire or unsuccessful effort to reduce or control substance use
 - Much time spent in activities necessary to obtain or use the substance or recover from its effects

- Surrender of or decrease in important social, occupational, or recreational activities due to substance use
- Continued use of substance despite knowledge of persistent or recurrent physical or psychological problems probably caused or exacerbated by the substance

GOALS

- After suspecting or detecting substance use, determine whether substance use disorder is present.
 - Substance use alone does not imply substance use disorder.
 - Infrequent substance use may be a normative part of adolescent development.
- Patterns of use in adolescents differ from those in adults (eg, availability, freedom, supervision).
- Some youth can meet 1 or 2 criteria of substance dependence but no criteria for abuse.
 - These diagnostic orphans appear similar to youth with substance abuse diagnoses and make up about one-third of youth who use alcohol regularly.
 - Because of the high prevalence of these diagnostic orphans, ask youth about symptoms of both substance abuse and dependence.
 - Allow the diagnosis to depend largely on the maladaptive significance of substance use.

GENERAL APPROACH

- To identify substance use disorder, pay attention to surrounding behaviors.
 - Disruptive or defiant behavior
 - School failure or truancy
 - Depression or suicidal thoughts
 - Early-onset sexual behavior
 - Sexually transmitted infection
 - Pregnancy
 - Legal problems
- Encourage parents to remain involved in their adolescents' lives so that they may identify and seek help for these problem behaviors.
- Increased parental monitoring and involvement help protect against development of substance abuse.
- The adolescent's self-report of substance-related problems is key to accurate diagnosis and treatment.
 - Create an environment in which the adolescent can talk about alcohol or drug use by defining adolescent confidentiality.
 - Confidentiality involves a safety exclusion: only information that indicates adolescent is a danger to self or others will be revealed to the parent or guardian.
 - By including substance use in this exclusion to confidentiality, any talk of drug use will be muted because of fear of parental knowledge.

- Thus do not readily divulge normative substance experimentation to caretakers.
- Decide each case on the basis of the particular risks involved.
- Helping an adolescent self-identify his or her own substance problems is usually the best-case scenario.
 - Family intervention is usually required for effective treatment.
- Assess the adolescent's functioning through several viewpoints.
 - Parents
 - Other health care providers
 - Adolescent's school, if possible

SPECIFIC INTERVENTIONS

Screening

- Standardized instruments
 - The screening instruments that are most sensitive ask about substance use and substance-related problems.
 - The following self-report instruments concentrate on substance-related problems (adaptive significance of substance use symptoms).
 - Substance Abuse Subtle Screening Inventory
 - Personal Experience Inventory
 - Problem Oriented Screening Instrument for Teenagers
 - Rutgers Alcohol Problem Index
 - Structured interviews
 - Assess both symptoms and relationship between substance use and other domains of functioning.
 - Examples
 - Comprehensive Addiction Severity Index
 - Global Appraisal of Individual Needs
 - Both give diagnoses of substance abuse according to the *Diagnostic and Statistical Manual of Mental Disorders*.
 - Both assess:
 - Substance use
 - Substance-related problems
 - Family relationships
 - Peer relationships
 - Legal status
 - Psychiatric problems
 - Leisure activities
 - CRAFFT screening tool
 - Validated for adolescents
 - Consists of 6 items to identify adolescents with problematic substance use
 - Positive answers to ≥ 2 items suggest that intervention is necessary.
- Urine drug screens
 - Sequence of urine drug screens and clinical interviewing of parents and youth are usually necessary to diagnose adolescent substance abuse.
 - The meaning of a positive urine drug screen varies greatly according to the context in which it is obtained.
 - Hospitalization for medical problem
 - A urine drug screen positive for marijuana more likely indicates use rather than abuse, but use or abuse can be determined only after clinical interview with the adolescent, parent, or teacher or other representative from school.
 - Random positive finding from a urine drug screen for cocaine or heroin
 - Increases suspicion of substance use disorder
 - High index of suspicion of substance abuse
 - Youth who has been truant, verbally aggressive toward parents, not fulfilling obligations at home, staying out late
 - The presence of any substance suggests that the youth has substance use disorder.
 - Youths who refuse to give urine samples or claim they cannot urinate often fear the consequences and are likely to be hiding substance use.
 - To determine severity of use, warn adolescent before urine drug screen.
 - If substance use is infrequent, the adolescent should be able to produce clean urine.
 - A positive drug screen after advance warning indicates a more severe problem.
 - The gold standard is supervised urine collection, but this method can be complicated and overly invasive.
 - Less invasive method: plastic thermometer, which indicates the urine's temperature
 - Test urine for creatinine level.
 - Youth may hydrate themselves or use diuretic substances to reduce drug concentration in urine.
 - Low urine creatinine suggests significant substance use.
 - Urine drugs screens vary in sensitivity.
 - Marijuana: may last 7 to 28 days in urine
 - Duration depends on frequency of marijuana use.
 - Alcohol: lasts only 12 hours in urine
 - Difficult to detect or monitor with this method
 - Alcohol breathalyzers are generally more sensitive than urine tests and can be used readily.
 - Cocaine: lasts up to 48
 - Heroin: lasts up to 72 hours
 - Tests for substances not included on regular drug panels can be costly.
 - Methylenedioxymethamphetamine (MDMA or ecstasy)

- Lysergic acid diethylamide (LSD or acid)
- Ketamine (special K)
- Phencyclidine (PCP or angel dust)

Management

■ Referral

- When substance use disorder is diagnosed or suspected, make an appropriate referral.
- Referral depends on the severity of the problem.
 - Arrest for driving under the influence: substance abuse treatment center
 - Unclear extent of abuse: private mental health practitioner
- Adherence to referral varies by the adolescent's relationship with the referring clinician and the clinician's relationship with the adolescent's parents or guardian.
- Likelihood of a successful referral is lower without development of some understanding with the adolescent and family.
- Indications for referral
 - Ongoing substance use despite monitoring
 - Prior parent or authority attempts to get the patient to abstain from or control substance use
 - Progression of substance use to substances of greater risk (eg, alcohol to cocaine)
 - Meeting criteria for substance abuse or dependence (by parent, adolescent, or teacher or other authority figure's report)
 - High index of suspicion due to unexplained adaptive impairment or unexplained decline in adaptive function
 - Patient substance use and high index of suspicion due to substance use disorder in parent, sibling, or peer
 - Patient substance use and high index of suspicion due to patient psychiatric comorbidity or delinquent behaviors
 - Dangerous behavior by patient with substance use (eg, self-mutilation, suicidal thoughts, driving under the influence)

■ Motivational interviewing in primary care

- Increases awareness of substance-related problems
- Emphasizes supporting personal-change goals with a non-judgmental attitude toward the adolescent's substance use
- Develops the clinician's empathy with the adolescent and forges an alliance that is less confrontational than most other approaches
- Effects change by encouraging the adolescent to contemplate discrepancy between personal goals and actions (ie, substance use)
- Holds great promise in adolescents because of emphasis on personal choice and support of adolescent's developing autonomy

■ Outpatient specialty treatments

- Family therapy
 - Family therapies that include the adolescent have the most empirical support.
 - Seeks to reduce familial contributions to development or maintenance of adolescent substance abuse behaviors
 - Experienced family therapists can help families find the right kind of professional guidance for the problem.
 - Empirically validated family therapies include:
 - Functional family therapy (positive relabeling, consistently clear communication, and development of supportive recovery environment)
 - Family system therapy
- Behavioral therapy
 - Role playing, response rehearsal, homework assignments, diary keeping
 - Reduces substance use (measured by urine drug screen, adolescent self-reports, and collateral reports) compared with supportive therapy
- Cognitive-behavioral therapy
 - Short- and long-term benefits for adolescents with substance use disorder
- 12-step facilitation therapies
 - Most common available treatments in most areas
 - Least empirical support compared with other methods
 - May integrate aspects of evidence-based treatments

■ Inpatient or residential treatments

- Can stop the vicious cycle of substance abuse, particularly when negative reinforcement (eg, withdrawal from opiates or alcohol or, to a lesser extent, marijuana) maintains dependence
- Can range from a few weeks to ≥ 1 year
- Can help establish alternative reinforcers to substance use that may generalize to the outside world
- Associated with long-term benefits in behavior
 - Reductions in substance use and criminal recidivism
 - Increased adaptive functioning
- Associated with high levels of attrition (30–40% within the first month; up to 80% within the first year)
- Direct relationship between length of treatment and outcome
- Substance abuse treatment can be effective even when mandated.
 - Mandated community support groups reduce criminal recidivism among incarcerated delinquents with drug-related crimes.
 - Voluntary treatment is associated with the best outcomes.

Screening for Lead Poisoning

BACKGROUND

- Lead adversely affects:
 - Attention
 - Vigilance
 - Language development
 - Transfer of information from short-term to long-term memory
 - Aggression
 - Antisocial or delinquent behaviors
- Negative effects are seen at levels >10 mcg/dL, but lower levels may also produce negative effects.
- An estimated 310,000 children in the US between 1 and 5 years of age have elevated blood lead levels.
 - Levels peak between 1 and 3 years of age.
 - Levels vary inversely with family income.
 - An impoverished home and Medicaid enrollment are closely linked to increased exposure.
 - All children in Medicaid are required by federal regulation to be tested for blood lead levels at 1 and 2 years of age.
- Lead-contaminated interior or exterior household paint that is peeling or chipping is the most common, concentrated source of exposure.
 - The older a house, the more likely it is to contain lead-based paint.
 - The less affluent the family, the more likely the paint is to be in disrepair.
 - Housing built before 1950 poses the greatest danger.
 - 50% of these houses are in California, Illinois, Massachusetts, Missouri, New York, Ohio, and Pennsylvania.
- Other sources of lead exposure
 - Water
 - Food
 - Soil
 - Toys
 - Ceramics
 - Parents whose clothing becomes contaminated with lead at work
 - Battery production or repair
 - Making pottery
 - Smelting
 - Printing
 - Paint contracting
 - Working on a firing range
 - Brass foundry
 - Work on the demolition or renovation of outdoor structures

- Hobbies
 - Making lead fishing sinkers or bullets
 - Collecting lead figurines
 - Spending time at indoor firing ranges
 - Making pottery
- Home remedies (in certain Latin American and Southeast Asian cultures): azarcon or greta
- Cosmetics (kohl)
- Lead plumbing, especially in areas with older water supplies

GOALS

- Prevention of severe toxicity and deaths, eg, due to accidental ingestion of lead-containing necklaces and metallic charms
- Reduction of low-level effects through community abatement and clinical screening
 - Screening serves to detect lead levels.
 - Each 10-mcg/dL increase in blood lead results in a loss of 2–3 points in IQ.

GENERAL APPROACH

- Centers for Disease Control and Prevention (CDC) Guidance defines national standards for screening programs.
 - The CDC recommends use of venous or capillary blood lead level as the examination of choice.
 - Capillary specimens collected by finger-stick are acceptable, but values ≥ 10 mcg/dL must be confirmed with a venous sample.
 - Uses 10 mcg/dL as the cutoff point for defining an elevated lead level
 - Allowable error (per Clinical Laboratory Improvement Amendments) is ± 4 mcg/dL or 10% of the value, whichever is greater.
 - At low levels, the allowable laboratory error can result in misclassification that might affect management.
- The CDC advises state health officials to develop screening programs based on risk characteristics of their local communities.
- The CDC advises that professionals use blood lead tests to screen:
 - 1- and 2-year-olds (and 3- to 6-year-olds who have not been screened previously) who meet ≥ 1 of these criteria:
 - The child lives in a ZIP code where $\geq 27\%$ of housing stock built before 1950 or $\geq 12\%$ of children have blood lead levels ≥ 10 mcg/dL.
 - The child receives services from public assistance programs, eg, Medicaid or the Special Supplemental Nutrition Program for Women, Infants, and Children (WIC).
 - If at the 2-year screen the blood lead level is again < 10 mcg/dL and the child's potential exposures have not increased, further screening is not necessary.

- In communities where universal screening is recommended, children whose blood lead screening test result at age 1 year is <10 mcg/dL should be rescreened at age 2 years.
 - Screening by questionnaire to evaluate risk
 - Part of the CDC guidelines, but limited by variable sensitivity and specificity
 - Still used by some states and localities as part of an overall lead-screening strategy, often with modifications in the specific questions used based on locale
 - In addition to state- or local-level guidelines, health care professionals should watch for children who should be screened because of exposure to less usual sources of lead from parental occupations or hobbies.
 - If parents or health care professionals suspect lead exposure, promptly test for blood lead, regardless of:
 - Patient age
 - General health department recommendations
 - Responses to screening questionnaires
 - Health care providers must participate in and comply with the recommended program.
 - Compliance needs to be improved, especially for at-risk children.
 - The CDC Web site has the latest, most accurate screening questions by region.
- If levels are between 15 and 19 mcg/dL: retest every 2 months.
 - Lead values >10 mcg/dL may prompt a home inspection.
- Blood lead values 20–44 mcg/dL require both medical and environmental intervention.
 - Medical evaluation: detailed medical, nutritional, developmental, and environmental history, and complete physical examination
 - Evaluation should focus on identifying signs and symptoms of lead poisoning (although very unusual at these levels).
 - Assess development to determine the need for early intervention services (although risk of demonstrable delays is unlikely).
 - Concerns about inattention and hyperactivity should prompt referral for early intervention services.
 - Nutritional assessment
 - To identify patterns that result in increased absorption of lead from the gastrointestinal tract, eg, iron deficiency, low calcium intake, or infrequent meals
 - Many children are eligible for support from WIC and should be referred.
 - If the child is iron deficient, then iron supplements should be prescribed.
 - Increasing calcium intake is not proven but generally recommended, especially when calcium intake is low.
 - Increasing meal frequency may decrease lead absorption, but should be done in the context of a diet not excessive in calories.
 - Laboratory evaluation of iron status, including:
 - Hematocrit
 - Mean corpuscular volume
 - Either a ferritin level or iron and iron binding capacity levels
 - Environmental inspection and, when indicated, environmental intervention to diminish or curtail further exposure to lead
 - Case management can ensure that needed counseling and medical, nutritional, and environmental interventions are provided quickly and effectively.
 - Home inspections, usually performed by local public health departments, are often a lengthy process, but abatement of hazards and subsequent dust control are cornerstones of treatment.

SPECIFIC INTERVENTIONS

CDC recommended test schedule for follow-up of positive screens

- Follow-up testing based on initial screening result (using confirmatory venous sample)
 - 10–19 mcg/dL: confirmation test at 3 months
 - 20–44 mcg/dL: confirmation test at 1 week to 1 month
 - 45–59 mcg/dL: confirmation test at 48 hours
 - 60–69 mcg/dL: confirmation test at 24 hours
 - >70 mcg/dL: confirmation test immediately/emergency

Management by blood level results

- Blood lead values 10–19 mcg/dL (confirmed)
 - Parents should be counseled on ways to diminish ongoing exposure.
 - Lead-based paint abatement performed by a properly licensed contractor and, if possible, supervision of the local health department
 - Relocate children and pregnant women to another site while abatement is being performed.
 - Have thorough cleanup of dust before allowing children to reinhabit the home.
 - If levels are between 10 and 14 mcg/dL: retest every 3 months.

- Blood lead values ≥ 45 mcg/dL
 - Remove from sources of lead.
 - Initiate chelation therapy.

How to avoid lead hazards in the home

- Cover leaded paint that is chipping or peeling.
- Move cribs, playpens, furniture, and play areas away from chipping or peeling paint.
- Wet-mop floors and wet-clean windowsills and window wells with a high-phosphate detergent.
- Avoid dry dusting or sweeping.
- Wash children's hands, toys, and pacifiers regularly.
- Use cold water for cooking; run tap water for 2–3 minutes every morning before using.
- Repair deteriorated windowpanes in house and on porches.
- Replace old windows.
- Remove paint in old homes (only by trained contractors).
- Postabatement cleanup, preferably by professional house-cleaners, is essential.
- Relocate the family to lead-safe housing.

Scrotal Swelling and Pain

DEFINITION

■ Scrotal swelling is usually classified as:

- Painful versus painless
- Acute versus chronic
- *Testicular torsion* is the twisting of the spermatic cord, with resulting compromise of the blood supply to the testis.
 - The appendix testis is a vestige of the müllerian duct system that hangs from the upper pole of the testis and is susceptible to torsion.
- *Epididymitis* is inflammation of the epididymis.
- *Orchitis* is inflammation of the testis.
- *Inguinal hernias* and *hydroceles* fall along a continuum, both caused by persistent patency of the processus vaginalis.
- *Varicoceles* are dilatations of the spermatic veins or pampiniform plexus
- *Spermatoceles* and *epididymal* cysts are sperm-filled cystic lesions attached to the upper pole of the testis

EPIDEMIOLOGY

■ Prevalence

- Inguinal hernias and hydroceles are the most common causes of scrotal swelling.
- Testicular torsion occurs in 1:4000 boys.
- Varicoceles are present in 15% of male adolescents and adults.

■ Age

- Hernias can occur at any age but are more common in premature infants.
- Testicular torsion most commonly occurs between the ages of 12 and 18 years.
- Idiopathic scrotal edema affects children <14 years.
- Acute inflammation of the epididymis or testis, including mumps orchitis, can occur at any age but is uncommon before adolescence.
- Varicoceles are usually asymptomatic and are usually detected between 10 and 15 years of age.

MECHANISM

■ Acute scrotal swelling with pain

- Torsion of the testicle
 - Twisting of the spermatic cord, with resulting compromise of the blood supply to the testis
- Torsion of the appendix testis
 - When the appendix testis torses, inflammation and swelling of the testis and epididymis ensue, causing testicular pain and scrotal erythema.
- Acute epididymitis-orchitis
 - Results from an anomaly of the urinary tract, either congenital or acquired

- Renal duplications and posterior urethral valves are among the more common anomalies.
- With intermittent catheterization, the condition can occur from retrograde passage of bacteria back from ejaculatory ducts at the level of the prostate to the testis and epididymis.
- Henocho-Schönlein purpura
 - Systemic vasculitis that can cause abdominal and joint pain
 - May involve the scrotal wall in a minority of cases
- Trauma
 - Zipper entrapment of scrotal skin
 - Severe blunt or straddle trauma affecting the scrotal contents
- Scrotal skin disease
 - Insect bites, folliculitis, and allergic dermatitis may cause erythema and edema of the scrotal wall.
- Scrotal swelling without pain
 - Hernias and hydroceles
 - Most are caused by persistent patency of the processus vaginalis (peritoneal out-pouching that accompanies the testis during its abdominal-scrotal descent).
 - Layers of the processus vaginalis condense late in gestation or early postnatally.
 - Obliteration of the processus vaginalis only around the testis leads to an indirect inguinal hernia with protrusion of fluid (or other contents) through the internal ring to the end of the pouch and potentially to the scrotum.
 - Communicating hydrocele occurs when fluid travels through a processus vaginalis into the tunica vaginalis around the testis.
 - Scrotal hydrocele occurs after complete obliteration proximally with patency distally.
 - Hydroceles of the cord occur when the processus vaginalis obliterates proximally and distally, leaving a patent area in the midportion with retained fluid.
 - Varicoceles
 - A predilection for the left side exists, reflecting anatomy of the left gonadal vein entering the left renal vein at a right angle.
 - The right gonadal vein enters the vena cava directly at an angle, precluding reflux of venous blood.

HISTORY

■ Take the history from both child (when possible) and parent.

History

■ Determine the following.

- Whether swelling or pain is recurrent and acute or chronic
- Exact timing of the onset of symptoms, particularly in the presence of acute pain and swelling

- Nature of the pain
 - Sharp
 - Dull
 - Constant
 - Intermittent
 - Constant, with intermittent increases in intensity
 - Associated with nausea or vomiting
- Location of pain
 - Scrotum, specifically the testis
 - Radiation into abdomen or from abdomen into the scrotum
- Laterality of swelling and pain
- Activity or positions that alleviate or aggravate pain and swelling
- Nature of swelling
 - Changes in size during a single day *or*
 - Is constant *or*
 - Increases or decreases with time
- Recent trauma, sexual activity, use of medications, presence of rashes, and weight loss
 - In more severe cases, the process may involve the testis and epididymis, mimicking testicular torsion.

- Focal fat necrosis
 - Can exhibit with scrotal pain and swelling, usually after trauma in an obese boy
- Trauma
 - History (eg, injury from zipper entrapment of scrotal skin) can be definitive.
- Mumps orchitis
 - Rarely occurs in isolation; pain and swelling usually occur within a week after parotitis.
- Scrotal skin disease
 - History may be of limited utility.

■ Scrotal swelling without pain

- Inguinal hernias and hydroceles
 - Hernia
 - Swelling expands with increases in intraabdominal pressure (eg, crying, bowel movements, coughing).
 - The parent or child often reports the swelling to be smallest in the morning and largest late in the day.
 - Hydrocele
 - Whether the hydrocele is acute or whether the scrotum has been chronically enlarged is often unclear.
 - The patient may have a history of trauma to the scrotum that stimulates production of serous fluid.
 - When the scrotum changes size during the day, suspect a communicating hydrocele.
- Tumors
 - Usually present as a hard, painless mass (or vague heavy feeling) in the testicle detected by the child, parent, or examining physician
- Varicoceles
 - Dilated veins are usually asymptomatic and are detected by the patient or the physician during routine physical examination.
 - Some patients report heaviness or a dragging feeling.
- Spermatoceles and epididymal cysts
 - Painless and round, they usually remain stable in size but can sometimes enlarge.

Specific conditions

■ Acute scrotal swelling with pain

- Torsion of the testicle
 - Acute onset of constant, severe scrotal pain aggravated by physical activity
 - If periods of respite from pain occur, then intermittent torsion and detorsion should be considered.
 - Nausea and vomiting may occur.
 - Possible history of incidental antecedent scrotal trauma, but pain usually occurs during rest or sleep
 - Neonatal testicular torsion
 - Can exhibit at delivery as a nontender hard scrotal mass
- Torsion of the appendix testis
 - Onset of pain and swelling is commonly acute but can be progressive, usually occurring during rest.
 - Pain can be severe, but nausea and vomiting are less common than with testicular torsion.
- Acute epididymitis-orchitis
 - History can reveal acute or more protracted onset of pain.
 - The patient may have fever or dysuria.
 - Epididymal inflammation may arise after scrotal trauma.
 - In the adolescent patient, a history of sexual activity or urethral discharge helps guide antibiotic treatment.
- Henoch-Schönlein purpura
 - Onset may be insidious or acute, producing a variable degree of erythema and edema.

PHYSICAL EXAM

- Palpate the abdomen and groin to determine whether an intraabdominal process extends into the scrotum.
- Inspect the scrotum to look for laterality of the process and scrotal erythema.
- Palpate the scrotum to determine the presence of:
 - Cremasteric reflexes
 - Testicular position
 - Tenderness

- Localization of the swelling to the scrotum
- Presence of proximal extension into the cord
- Acute scrotal swelling with pain
 - Torsion of the testicle
 - Scrotal erythema
 - Swelling of the involved hemiscrotum
 - Higher-than-normal position of the testis within the scrotum
 - Palpation may show a horizontal rather than normal vertical orientation of the testicle.
 - Evaluation of the cremasteric reflex should begin on the contralateral side; palpate the apparently unaffected testis to confirm normal size and position.
 - Unilateral loss of the cremasteric reflex on the side of the swelling and pain highly correlates with the presence of torsion.
 - The testis should then be palpated.
 - Despite the pain this maneuver may cause, it helps differentiate torsion from epididymitis.
 - With torsion, exquisite pain is elicited on palpation from the testis, as well as from the epididymis and distal spermatic cord.
 - Actual point of torsion of the spermatic cord can sometimes be palpated.
 - Associated hydrocele may be palpated and confirmed by transillumination.
 - Tense or large hydrocele often makes examination difficult.
 - Torsion of the appendix testis
 - May demonstrate hemiscrotal erythema and swelling
 - A blue-dot sign, the necrotic appendage visible through the scrotal skin, can help make the diagnosis.
 - A normal cremasteric reflex is present bilaterally, and the testis is normally positioned within the scrotum.
 - Testicular discomfort, if present, is typically mild, but point tenderness may be elicited from uppermost pole of the testis near the head of the epididymis—the location of the appendages.
 - On palpation, examiner may feel a 3- to 5-mm tender indurated mass on the upper pole.
 - Acute epididymitis-orchitis
 - Scrotal erythema and swelling are present, along with an intact cremasteric reflex.
 - Palpation during early phase of the inflammatory process demonstrates tenderness limited to the epididymis.
 - In the later phase, tenderness and inflammation include both epididymis and testis, and the distinction between the 2 structures may be difficult to appreciate.
 - The Prehn sign (relief of pain with testicular elevation) may be positive.
 - Focal fat necrosis
 - Examination shows pain and swelling limited to the scrotum and not the testis.
 - Examination can be limited by discomfort and degree of obesity.
 - Trauma
 - Examination must include both hemiscrotums and surrounding structures (penis, perineum), assessing for swelling, ecchymosis, and bleeding.
 - Palpation may be limited by the degree of swelling or blood in the scrotum.
 - Tenderness may be limited to testis or epididymis, depending on extent of trauma.
 - Mumps orchitis
 - Tender testis
 - Scrotal skin disease
 - Redness and edema limited to scrotum, with normal testicle and spermatic cord
- Scrotal swelling without pain
 - Inguinal hernias and hydroceles
 - Feel for the testis first and keep it in mind during the rest of the examination.
 - Avoid confusing testis with contents of an incarcerated hernia.
 - Hernia
 - A bulge in the inguinal region with fluid that can be gently reduced back into the abdomen is diagnostic of an inguinal hernia.
 - In the cooperative child who can increase his intra-abdominal pressure, this procedure may be repeatedly shown, particularly with the child standing.
 - Presence of thickened spermatic cord or silk-stocking sign (the feel of the layers of the processus vaginalis being rubbed against each other) suggests patency of the processus vaginalis or a hernia.
 - Hydrocele
 - When fluid is limited to the testis and spermatic cord can be palpated above the fluid, a hydrocele is present.
 - Hydrocele of the spermatic cord feels distinct from the testis and is round or ovoid, possibly mimicking the presence of an additional testis.
 - Hydroceles (communicating, scrotal, or of the cord) are rarely associated with tenderness on palpation
 - Tumors
 - On palpation, mass is harder than the substance of the testis, but this distinction may be difficult to discern.
 - Mass may bulge from surface of the testis.
 - Varicoceles
 - Perform physical examination with the patient in the supine and standing positions.

- Varicocele is usually decompressed in the supine position and present in the standing position.
- Inspection may reveal dilated veins (grade 3 of 3).
- Increased blood pooling in veins can sometimes be prompted by a Valsalva maneuver (grade 2 of 3).
- Spermatoceles and epididymal cysts
 - Separate from the testis and can be transilluminated

DIFFERENTIAL DIAGNOSIS

Acute scrotal swelling with pain

- Torsion of spermatic cord
- Torsion of appendix testis
- Acute epididymitis-orchitis
- Mumps orchitis
- Henoch-Schönlein purpura
- Trauma
- Insect bite
- Thrombosis of spermatic vein
- Fat necrosis
- Hernia
- Folliculitis
- Dermatitis, acute

Scrotal swelling without pain

- Tumor
- Idiopathic scrotal edema
- Hydrocele
- Henoch-Schönlein purpura
- Hernia

Chronic scrotal swelling

- Hydrocele
- Hernia
- Varicocele
- Spermatocele
- Sebaceous cyst
- Tumor

LABORATORY EVALUATION

- Laboratory tests are of limited value.
- The leukocyte count may be elevated in the setting of infection.
- Urinalysis may help distinguish orchitis from torsion of the spermatic cord or testicular appendage when leukocytes or nitrites are present.
- Acute scrotal swelling with pain
 - Torsion of the testicle
 - Urinalysis is unremarkable.
 - Although the leukocytes count may be mildly elevated, it is not discriminating.

- Acute epididymitis-orchitis
 - Urinalysis may prove positive for leukocytes and nitrite but is often unremarkable among adolescents.
 - The leukocyte count is usually elevated.

■ Scrotal swelling without pain

- Inguinal hernias and hydroceles
 - Laboratory tests are useful only for incarcerated inguinal hernias, with an elevated leukocyte count and possible acidosis.
- Tumors
 - Preoperative tumor markers (α -fetoprotein, β -human chorionic gonadotropin) should be measured and used for postoperative monitoring.

IMAGING

■ Ultrasonography can determine whether the scrotal swelling:

- Is fluid filled or solid
- Arises from abdomen and extends into groin
- Is limited to the scrotum
- Arises from the testis or spermatic cord structures

■ Ultrasonography with Doppler can assess the flow of blood into the testis, helping to differentiate torsion of the testis from an inflammatory process.

- Benefits
 - Does not use ionizing radiation
 - Takes less time to perform than nuclear scanning
- Drawbacks
 - Limited by user variability
 - Requires placing a probe over a sensitive area
- Nuclear scintigraphy using ^{99m}Tc -pertechnetate evaluates blood flow to the testis.
 - Absence of flow results in a cold spot and suggests torsion.
 - Inflammation results in increased flow to the same area.
 - Benefits
 - Not limited by user variability associated with ultrasonography
 - Does not require placing a probe over a tender area
 - Drawbacks
 - Uses ionizing radiation
 - Takes longer to perform than ultrasonography, thus limiting utility when time is of the essence
 - Sensitivity and specificity of the 2 modalities are similar.

■ Acute scrotal swelling with pain

- Torsion of the testicle
 - Imaging by Doppler ultrasonography or nuclear scintigraphy should be done if the diagnosis of testicular torsion is in question.

- Perform imaging only when it will not delay surgical exploration if torsion exists, adding to the risk of testicular loss.
- Torsion of the appendix testis
 - If an inflammatory process resulting from torsion of the appendage makes differentiation from true spermatic cord torsion impossible, imaging may be helpful.
 - Scrotal Doppler ultrasonography or nuclear scintigraphy will show normal or increased flow to ipsilateral testis.
- Acute epididymitis-orchitis
 - Ultrasonography and nuclear scintigraphy show normal symmetric blood flow or increased blood flow to an enlarged epididymis or testis.
 - Voiding cystourethrography has been a routine part of the evaluation, but its yield is low with a normal ultrasound and a sterile urine.
- Henoch-Schönlein purpura
 - Concurrent Henoch-Schönlein purpura and testicular torsion has been reported; therefore, if torsion is a consideration, imaging with Doppler ultrasonography or nuclear scintigraphy is indicated to evaluate testicular blood flow.
- Trauma
 - Scrotal ultrasonography can document the integrity of the testis and of the tunica albuginea and the adequacy of blood flow.
- Scrotal swelling without pain
 - Inguinal hernias and hydroceles
 - Ultrasonography can delineate scrotal contents, especially when a large or tense hydrocele limits physical examination.
 - Ultrasonography can determine cystic or solid nature of a tense scrotal mass (eg, hydrocele, tumor) or spermatic cord mass (eg, hydrocele of the cord, paratesticular tumor).
 - Tumors
 - Scrotal ultrasonography is used to delineate the mass.
 - Varicoceles
 - Testicular size, most accurately assessed by ultrasonography, should be measured; significant loss of testicular volume is an indication for surgery.
- The likelihood of salvaging the testis is highest when surgery is done shortly after onset of pain.
 - The chance of a successful outcome dissipates rapidly with time.
- With surgery, first explore the affected testis, and, when torsion is present, detorse the cord.
- Explore the contralateral testis (will have the same defect in anatomy) and fix it in place to avert a future torsion.
- Reinspect the affected gonad and determine the possibility of salvage.
- If the testis can be saved, fix it in the scrotum.
- Neonatal testicular torsion
 - At exploration, anchor contralateral testis and remove nonviable testis.
- Torsion of appendix testis
 - Management is nonsurgical.
 - The patient should rest and use nonsteroidal pain relievers and cold compresses for several days to reduce inflammation, swelling, and pain.
 - Surgical intervention is indicated only when acute testicular torsion cannot be excluded.
 - In these cases, the infarcted appendage is removed at surgical exploration.
- Acute epididymitis-orchitis
 - Treat with antibiotics based on the results of the urine culture and sensitivities.
 - In sexually active adolescents, antibiotic coverage must include gonococcal and nongonococcal sexually transmitted infections.
 - Antiinflammatory agents, scrotal elevation, and rest should be prescribed.
- Focal fat necrosis
 - Treat with rest and antiinflammatory agents.
- Trauma
 - Testicular or spermatic cord contusions: Manage symptomatically.
 - Testicular rupture requires surgical exploration, evacuation of the hematoma, debridement, and repair (when possible).
- Mumps orchitis
 - Treatment is symptomatic.

TREATMENT APPROACH

- Surgical intervention is indicated not only when testicular torsion is strongly suspected, but also in equivocal cases in which torsion cannot be convincingly excluded.

SPECIFIC TREATMENT

Acute scrotal swelling with pain

- Torsion of the testicle
 - Surgical intervention is indicated not only when testicular torsion is strongly suspected, but also in equivocal cases when torsion cannot be convincingly excluded.

Scrotal swelling without pain

- Inguinal hernias and hydroceles
 - Repair on diagnosis to prevent incarceration.
 - The risk of incarceration increases with time and is more likely in the young child or infant.
 - Repair communicating hydroceles on diagnosis to avert progression.

- Perform surgery inguinally; isolate the sac from the cord structures and ligate it at the level of the internal ring.
- Inspect the contralateral ring using diagnostic laparoscopy through the isolated ipsilateral sac.
 - If the internal ring is open, proceed with contralateral surgical correction.
- If the hydrocele is painful, then surgery should proceed sooner.
- Tumors
 - Perform radical orchiectomy through an inguinal approach.
 - If the mass is not suspicious for cancer, a possible approach is to enucleate the mass and proceed with orchiectomy only if the frozen section is positive.
- Varicoceles
 - Indications for surgery
 - Significant loss of testicular volume
 - Abnormal semen analysis (older adolescent patients)
 - Pain
 - Corrective measures (all aimed at occluding direct venous return through the internal spermatic vein to improve the likelihood of normal fertility)
 - Open surgery
 - Laparoscopic surgery
 - Radiologic ablative techniques
- Spermatoceles and epididymal cysts
 - Management typically is observation.
 - Surgery may be indicated when pain or significant enlargement is present.

WHEN TO REFER

- Acute painful scrotal swelling
- Acute hydrocele
- Hernia
- Scrotal trauma
- Cellulitis of scrotum
- Varicocele
- Testicular mass
- Paratesticular mass

WHEN TO ADMIT

- Acute painful scrotal swelling with suspected testicular torsion
- Acute hydrocele
- Scrotal trauma with suspected ruptured testicle
- Testicular mass

COMPLICATIONS

- Torsion of the testicles
 - Subsequent atrophy may still result after surgery because of vascular insult.
 - Fertility may be compromised.
- Spermatoceles and epididymal cysts
 - Postoperative scarring can obstruct the epididymal ductal system and lead to infertility.

PROGNOSIS

- Acute scrotal swelling with pain
 - Torsion of the testicle
 - Spermatogenesis may be compromised after 4–6 hours of ischemia.
 - Testicular salvage is time dependent, with universal loss of the testis after 24 hours of torsion.
 - Neonatal testicular torsion
 - Neonatal testicular torsion can exhibit at delivery as a nontender hard scrotal mass.
 - Salvage in these cases is rare.
 - Torsion may occur after delivery and then is more typical of torsion in the older patient, with greater potential for salvage if intervention is rapid.
 - Mumps orchitis
 - Infertility may occur when the condition results in atrophy of both testicles.
- Scrotal swelling without pain
 - Inguinal hernias and hydroceles
 - Most hydroceles resolve spontaneously by 1 year and should be repaired if they persist beyond this age.
 - Varicoceles
 - After corrective measures, most testes increase in size to equal that of the contralateral testis.

Seborrheic Dermatitis

DEFINITION

- Seborrheic dermatitis (SD) is a common, usually asymptomatic, dermatosis of unknown cause seen primarily in infants but also in adolescents and adults.
- Psoriasiform SD, also known as sebopsoriasis or seborrhiasis, produces features of both SD and psoriasis and may represent a bridge between the 2 conditions.

EPIDEMIOLOGY

- Incidence
 - 2–5% of the general population
- Age
 - In 50% of affected infants, symptoms begin before 5 weeks of age.
- SD is occasionally seen in infants who are infected with HIV.
 - Increased incidence in this group has not been documented.

ETIOLOGY

- The cause of SD remains unknown.
- Different pathogenic mechanisms have been proposed.
 - Early evidence that *Pitysporum ovale* may play a role in the evolution of SD
 - Recent data supports a causal link between *Malassezia* yeast and SD.
 - Demonstrated clinical improvement of SD when interventions reduce *Malassezia* counts on the body
 - Separate research has shown that antifungal agents effectively treat SD.
 - No difference has been found in *Malassezia* carriage rates in patients with and without SD.
 - Immunomodulatory factors of the host may influence manifestation of SD, not actual colonization counts.
 - *Malassezia* may serve as the primary trigger in an inflammatory reaction, ultimately resulting in SD.
 - Studies have revealed an increase in both:
 - Lymphocyte transformation response
 - Leukocyte migration inhibition
 - This differing immunogenic host theory may explain the increase prevalence of SD in patients with AIDS.
 - Other research postulates that lesions of SD are induced by:
 - Toxin production
 - Lipase activity of *Malassezia*
 - SD lesions tend to occur on locations corresponding with the highest sebaceous gland concentration.
 - Scalp
 - Face
 - Eyebrows
 - Nasolabial folds

- Axillary folds
- Inguinal folds
- Experts have proposed that the following may result in SD.
 - Abnormality in the sebaceous gland
 - Increased sensitivity to circulating maternal or endogenous hormones
- Patients with SD have normal sebaceous secretion and hormonal levels.

RISK FACTORS

- No evidence suggests genetic predisposition.

SIGNS AND SYMPTOMS

- Most commonly characterized as greasy, scaly dermatitis
- Less often characterized as psoriasiform SD
- Rarely characterized as erythrodermic SD
- SD in infancy is characterized by:
 - Diffuse, red, crusted, and yellow scaling plaques on the vertex of the scalp (see Figure 88 on page F29)
 - Similar lesions also may be found in:
 - Retroauricular creases
 - Eyebrows
 - Nasolabial folds (see Figure 89 on page F29)
 - Lesions appear as shiny red patches with foul-smelling scale in the folds in:
 - Axillary and inguinal folds
 - Neck
 - Diaper area
- Posterior lymphadenopathy has been shown to be significantly associated with SD in patients with a negative fungal culture.
 - Asymptomatic
 - Distributed symmetrically
 - Similar in adolescents
 - Patients may note a greasy, scaling, pruritic eruption on the scalp.
 - Except for lack of inguinal area involvement, distribution of the lesions is the same as that for infants.
 - HIV-positive children age 2–5 years may exhibit SD with lesions similar to those seen in adolescents and adults.
 - Distinctly unusual in immunocompetent children
 - Appears to be a manifestation of HIV infection
- Psoriasiform SD
 - Psoriasiform plaques
 - Annular, red-brown plaques having a silvery scale
 - May be present among classic greasy, yellow, scaling lesions of SD
 - Patients may or may not have pitted nails as seen with classic psoriasis.

- Erythrodermic SD is rare and causes widespread exfoliative erythroderma.
 - Diffuse desquamation usually begins in the flexures and then spreads.
- Patients may have signs and symptoms of systemic involvement.
- Fever
 - Chills
 - Lymphadenopathy
 - Peripheral edema
 - Dehydration
- Involvement may be the presentation of Leiner disease.

DIFFERENTIAL DIAGNOSIS

■ Atopic dermatitis

- Usually distinguished by the presence of:
 - Extreme pruritus
 - Extensoral distribution in infancy
 - Flexural distribution in older children (tending to spare the scalp and to involve hands and feet)
 - Family history in 70% of affected persons
- SD may occur concomitantly with atopic dermatitis.

■ Psoriasis

- Common inherited papulosquamous skin disorder
- Characterized by well-demarcated, annular, thick, red-brown, scaling plaques usually present on:
 - Trunk
 - Extensor areas on the arms
 - Knees
 - Elbows
 - Diaper area
 - Scalp
- Characterized by nail pitting
- Usually lacks specific distribution and the greasy component of SD
- Some cases of SD may overlap with psoriasis.
- Extensive cases of SD become persistent.
- When the family history of psoriasis is positive, patients should be referred to a dermatologist for:
 - Biopsy
 - Long-term follow-up care

■ Dermatophyte infection of the scalp (tinea capitis)

- Symptoms may include:
 - Scaling
 - Pruritus
 - Redness of the scalp
- Usually results in alopecia

- Performing a fungal culture by swabbing the affected area vigorously will yield a positive result.
- Tinea corporis appears as annular, red, scaly plaques with central clearing.
- Cultures from the skin may be obtained in a similar fashion to the scalp.
- Potassium hydroxide preparation of scales from body lesions will demonstrate septate hyphae.

■ Diaper dermatitis, or irritant diaper rash

- Characterized by:
 - Involvement primarily of the convex surfaces by red, scaling plaques
 - Inguinal folds are spared (see Figure 90 on page F29).
- In candidal diaper dermatitis, similar red, scaling plaques involve the skin folds.
 - Satellite pustules in areas not covered by the diaper may be found (see Figure 91 on page F29).
- SD in the diaper area involves the skin folds.
 - No satellite lesions

■ Histiocytosis X

- Refers to a group of Langerhans cell histiocytoses
 - Letterer-Siwe disease (diffuse disseminated histiocytosis)
 - Hand-Schüller-Christian disease
 - Eosinophilic granuloma (chronic multifocal or focal histiocytosis)
- Letterer-Siwe disease may be confused with SD.
 - The pattern of distribution is similar.
- Letterer-Siwe disease is also characterized by:
 - Axillary, inguinal, and oral mucosal erosions
 - Purpura
 - Petechiae
 - Hepatosplenomegaly
- Skin biopsy will distinguish these disorders easily.
 - Recommended in cases of SD unresponsive to treatment

■ Leiner disease

- Sometimes referred to as *erythrodermic SD*
- Inherited immunologic disorder
- Characterized by:
 - Generalized SD
 - Persistent diarrhea
 - Failure to thrive
 - Recurrent gram-negative infections
- Diagnosis is made by demonstrating deficient yeast opsonic activity in the patient's serum.

- Other immunodeficiencies and metabolic disorders may occur in an erythrodermic SD pattern.

TREATMENT APPROACH

- Effective treatment for SD may involve:
 - A wide range of keratolytic agents
 - Low-potency corticosteroids
 - Antifungal therapies

SPECIFIC TREATMENTS

- The choice of medication is tailored to the age of the patient.

Infants

- A more conservative approach is suggested when treating infantile SD (cradle cap).
 - Apply mineral oil or white petrolatum to the scalp.
 - Follow with a nonmedicated shampoo.
- If unresponsive, second-line agents include
 - 1–2% salicylic acid in liquid or petrolatum form
 - Follow with a keratolytic shampoo.
 - Sebulex
 - Neutrogena
 - T/Sal P & S
 - Salicylic acid solution or petrolatum should be applied for only 10 minutes, then shampooed out carefully.
 - Avoid the face and particularly eyes because severe contact irritation may occur.
 - Follow with a topical low-potency corticosteroid.
 - 1–2.5% hydrocortisone, Synalar solution
 - Derma-Smoothe
 - Corticosteroid solution should be applied sparingly and left on for several hours.
 - This regimen may be repeated up to twice daily as needed and then tapered.
 - Dramatic improvement occurs usually within 1 week.
- Topical antifungals, specifically the azoles, are effective.
- More recently, use of topical macrolactam immunomodulators has been successful.
- Tacrolimus has antifungal properties that contribute to its therapeutic effectiveness.
- Low-potency topical corticosteroid cream (1% hydrocortisone cream) can be used twice a day to treat lesions occurring on the:
 - Face
 - Intertriginous areas
 - Diaper area
- A midpotency corticosteroid, such as 0.1% Kenalog cream, may be used on the body twice a day.
- A mid-potency or strong halogenated corticosteroid should not be used on the:
 - Face
 - Intertriginous areas
 - Diaper area

- Topical ketoconazole (Nizoral)
 - Has been used to treat adult SD
 - Has been found to be beneficial in treating infantile SD
- Lesions in the diaper and intertriginous areas may become superinfected with *Candida* species.
 - Requires topical antifungal creams twice a day in addition to a topical corticosteroid

Children and adolescents

- Topical corticosteroids
- Keratolytic shampoos applied to the scalp
- Topical and oral ketoconazole may be used in severe cases.
- Psoriasiform SD of the scalp is treated as described for cradle cap.
- Psoriasiform lesions on the face and trunk respond to:
 - Topical corticosteroid ointments
 - Emollients
- If lesions persist into childhood, use:
 - Modified Goeckerman regimen consisting of application of a tar preparation
 - Followed by outdoor exposure to sunlight and topical corticosteroids
- Generalized erythrodermic SD may require:
 - Systemic corticosteroids
 - Antibiotics to control superinfection
- Hospitalization for intravenous antibiotic administration may be required.

WHEN TO ADMIT

- Generalized erythrodermic SD may require systemic corticosteroids and antibiotics to control superinfection.
- Hospitalization for intravenous antibiotic administration may be required.

WHEN TO REFER

- Patients who do not respond to standard accepted therapy
- To rule out such conditions as psoriasis and histiocytosis

COMPLICATIONS

- Infants with SD may be:
 - At increased risk of atopic dermatitis
 - At risk of psoriasis (less often)

PROGNOSIS

- Usually excellent
- Most cases resolve within the first 6 months of life.
- Adolescent-onset and HIV-related SD may be more persistent.
 - Usually responds readily to topical therapy

Seizure Disorders

DEFINITION

- Seizures are caused by abnormal discharges of neurons.
- A seizure should be considered a symptom of systemic or central nervous system dysfunction.
- Types of seizures
 - Generalized seizures
 - Absence seizures
 - Myoclonic seizures
 - Atonic seizures (also known as *astatic seizures* or *drop attacks*)
 - Generalized tonic-clonic seizures (also known as *grand mal seizures*)
 - Infantile spasms (also known as *West syndrome*)
 - Lennox-Gastaut syndrome
 - Juvenile myoclonic epilepsy
 - Partial seizures
 - Simple partial seizures
 - Complex partial seizures
 - Benign partial epilepsy of childhood (also known as *rolandic epilepsy*, *sylvian seizures*, and *centrotemporal epilepsy*)
 - Epilepsia partialis continua
 - Unclassified seizures
 - Neonatal seizures
 - Febrile seizures
 - Pseudoseizures

EPIDEMIOLOGY

- Prevalence
 - Seizures occur in approximately 1% of all children up to the age of 14 years.
 - Greatest in first year of life (~120 cases per 100,000 population)
 - Thereafter, 40–50 cases per 100,000 population until puberty
 - ~10 cases per 100,000 population in the early and mid teens
 - ~15% of children who have epilepsy have intractable seizures.
 - ~50% of these may be appropriate candidates for epilepsy surgery.
- Absence seizures
 - Age of onset: 3–8 years
 - Rarely occur before 2 years or after 15 years of age
 - Girls are affected more commonly than boys.
 - 15–44% of first-degree relatives have a history of absence seizures, paroxysmal electroencephalography (EEG) abnormalities, or both.
- Infantile spasms
 - Peak age of onset: 3–7 months
 - Estimated 0.24–0.60 per 1000 infants

- Boys are more likely to be affected than girls.
- Children with tuberous sclerosis account for up to 25% of patients who have symptomatic infantile spasms.
- Infants in whom no etiologic factor is found tend to be older at onset than symptomatic infants.
- Lennox-Gastaut syndrome
 - Age of onset: 3–5 years
 - Boys are affected slightly more frequently than girls.
- Juvenile myoclonic epilepsy
 - Age of onset: 12–18 years
 - Represents 7% of all epilepsy cases
- Benign partial epilepsy of childhood
 - Age of onset: 5–8 years
 - Boys are more often affected than girls.
- Febrile seizures
 - Age of onset: 3 months to 5 years
 - Median age of occurrence: 18–22 months
 - ~2–5% of children will experience a febrile convulsion.
 - Boys are more susceptible than girls.
- Pseudoseizures
 - Can occur in early childhood but are more frequent in adolescence, especially girls

ETIOLOGY

Neonatal seizures

- Hypoxia-ischemia
 - Most common cause of seizures in both premature and full-term infants
 - These seizures usually begin within the first 24 hours of life and may be difficult to control for several days.
- Intracranial hemorrhage
 - Seen mainly in premature infants within the first 3 days of life
 - Generalized tonic seizures may be associated with severe hemorrhage involving the brain parenchyma.
- Metabolic disturbances
 - Hypoglycemia
 - Hypocalcemia
 - Hyponatremia
 - Hypernatremia
 - Local anesthetic intoxication
 - Pyridoxine dependence
 - Variety of inborn errors of metabolism
- Bacterial and viral intracranial infections
 - Most common bacterial causes are group B streptococci and *Escherichia coli*.
 - Prenatal nonbacterial causes include toxoplasmosis and infections with rubella, herpes simplex virus, coxsackievirus type B, and cytomegalovirus.

- Malformations of the brain
 - Cortical dysgenesis, such as lissencephaly, pachygyria, and polymicrogyria

Childhood seizures

- A cause is identifiable in <20% of children with seizures.
- If a child has no abnormalities by history or examination at the time of seizure onset, then a cause is rarely identified.
- The more abnormal the child's neurodevelopmental status, the more likely a cause will be identified or may already have been determined before seizure onset. These include:
 - Brain malformations
 - Genetic disorders
 - Disorders of metabolism
 - Traumatic or previous infectious injury of the brain
 - Neoplasm
- Children with infantile spasms and Lennox-Gastaut syndrome are more likely to have an identifiable cause.
- Idiopathic generalized epilepsies (eg, childhood absence epilepsy and juvenile myoclonic epilepsy) are more likely to be related to genetic factors.

Cause, by type of seizure

- Infantile spasms
 - Divided into symptomatic and cryptogenic groups based on the presence of a predisposing etiologic factor
 - Symptomatic spasms occur in infants with abnormal neurologic development before onset of spasms.
 - Causes of symptomatic spasms include:
 - Structural abnormalities of the brain
 - Hypoxic-ischemic insults
 - Central nervous system (CNS) infections or hemorrhages
 - Inborn errors of metabolism
- Simple partial seizures
 - Caused by focal epileptiform discharges, but a focal structural lesion may not be found in most patients
 - Identifiable causes include:
 - Prenatal and perinatal insults
 - CNS malformations and tumors
 - Inborn errors of metabolism (rare)
- Complex partial seizure
 - Causes include:
 - Perinatal insults
 - Head trauma
 - Encephalitis
 - Status epilepticus (possibly)
 - Indolent tumors (eg, hamartomas and low-grade gliomas)

- Specific types of neonatal seizure
 - Subtle seizure
 - Abnormal movements may arise from regions of brain from which abnormal electrical activity cannot be detected with surface electrodes.
 - Subtle seizures usually occur in infants with severe CNS insults.
 - Clonic seizure
 - Can result from focal CNS lesions, such as cerebral infarction
 - Can also occur with metabolic disturbances
 - Tonic seizure
 - May be a brain stem phenomenon rather than seizures
 - Myoclonic seizure
 - Infants with myoclonic seizures tend to have severely abnormal dysgenetic brains or metabolic defects.
- Febrile seizures
 - Triggered by any illness that causes fever (eg, otitis media and upper respiratory tract infections)
 - The rate of febrile seizures with shigellosis, salmonellosis, and roseola is high, possibly because of a direct effect of causative organism on the CNS or to a neurotoxin they produce.

RISK FACTORS

- Genetic risk factors
 - The fact that some genetic syndromes (eg, Angelman syndrome and Rett syndrome) predispose a child to seizures raises interest in the role of different genes in the susceptibility to seizures.
 - The following types of seizure have a potentially genetic component.
 - Juvenile myoclonic seizures (a locus on the short arm of chromosome 6 has been identified)
 - Complex partial seizure (secondary etiologic role)
 - Benign partial epilepsy of childhood
 - Febrile seizures
 - Familial clustering of febrile seizures occurs.
 - Mutations of the *SCN1A* gene have been found in some families.
- Other risk factors
 - Lennox-Gastaut syndrome
 - Many patients have neurologic deficits before onset (intellectual disability and cerebral palsy).
 - Neurologic deficits may be related to hypoxic or other insults to the brain or abnormal brain development.
 - Patients may have a history of infantile spasms.
 - Juvenile myoclonic epilepsy may be precipitated by:
 - Sleep deprivation
 - Stress

- Alcohol
- Hormonal changes
- Epilepsia partialis continua
- Focal encephalitis and tumor
- Risk factors for neonatal seizures
 - Hypoglycemic seizures
 - Infants small for gestational age
 - Postterm infants
 - Infants of diabetic mothers
 - Hypocalcemic seizures (which occur when calcium levels decrease to <7 mg/dL during the first 2–3 days of life)
 - Low-birth-weight infants
 - Infants of diabetic mothers
 - History of hypoxia
 - Hypocalcemic seizures that occur later are usually related to a low-calcium and high-phosphate intake.

SIGNS AND SYMPTOMS

Absence seizures

- Generalized, nonconvulsive seizures characterized by interruption of activity, staring, and unresponsiveness
- Usually last 5–15 seconds
- Start without warning and end abruptly with resumption of the child's preictal activity
- The child may be unaware that the episode occurred.
- Unresponsiveness is sometimes accompanied by:
 - Eyelid fluttering
 - Upward rotation of the eyes
 - Mild clonic movements or automatisms (eg, lip smacking, grimacing, or swallowing)

Myoclonic seizures

- Brief, sudden muscle contractions that may involve only part of the body or may be generalized
- May occur in clusters, especially when child is falling asleep or shortly after awakening
- Usually, no alteration in consciousness is associated with jerks.

Atonic seizures

- Sudden decrease in muscle tone that may cause head nodding or mild flexing of the legs
 - More significant decreases in muscle tone may cause the patient to slump to the floor.
- Usually, no alteration in consciousness is detectable with these seizures.

Generalized tonic-clonic seizures

- Tonic phase
 - Sustained contraction of muscles that causes patient

to fall to the ground, usually in opisthotonus

- Extensor posturing usually occurs with tonic contraction of the diaphragm and intercostal muscles
 - Halts respirations and, in turn, produces cyanosis
- Lasts <1 minute and is followed by the clonic phase
- Clonic phase
 - Consists of bilateral rhythmic jerking
 - Jerks may be accompanied by expiratory grunts produced by diaphragmatic contractions against a closed glottis.
 - Frequency of jerks decreases as the seizure progresses, although intensity may increase.
 - The tongue may be bitten, and bowel and bladder incontinence may occur.
 - Usually stops within several minutes
 - May be followed by vomiting, confusion, and lethargy, with gradual recovery of consciousness during minutes to hours

Infantile spasms

- Sudden contraction of neck, trunk, and extremity muscles
- Spasms may be flexor, extensor, or mixed flexor-extensor.
- Spasms last only a few seconds each but often occur in clusters of up to 100 individual spasms.
- A typical episode involves dropping of the head along with abduction of the shoulders and flexion of the lower extremities.
- The infant may cry during or after the spasm.
- Pallor, flushing, grimacing, laughter, and nystagmus sometimes occur.
- Episodes are common on awakening from sleep, during drowsiness, and with feedings but are rare during sleep.

Lennox-Gastaut syndrome

- Severe epileptic encephalopathy characterized by a variety of generalized seizures
 - Tonic seizures cause sudden, sustained contraction of the muscle groups.
 - Atypical absence seizures consist of a brief period of staring and immobility.
 - Onset and recovery of atypical absence seizures are less abrupt than in typical absence.
 - Episodes may be associated with mild tonic motor manifestations, automatisms, or loss of postural tone.
 - Atonic seizures occur and may be preceded by myoclonic jerks.
 - Tonic-clonic seizures and partial seizures may occur.

Juvenile myoclonic epilepsy

- Primary generalized epilepsy characterized by myoclonic jerks that affect mainly the upper extremities and less commonly the lower extremities.
 - Jerks usually occur shortly after awakening.

- Patients may report clumsiness or difficulty holding objects early in the morning.
- Myoclonic jerks almost always precede the onset of generalized tonic-clonic seizures by months to years.

Complex partial seizures

- Result in impaired consciousness
- May begin as a simple partial seizure that progresses to impairment of consciousness
- Initial portion of a seizure that occurs before consciousness is lost is called the aura.
- Aura may consist of:
 - Auditory, olfactory, or visual illusions or hallucinations
 - Affective symptoms, such as fear or other unpleasant feelings
- Anger and rage are very rare as seizure manifestations but may occur during postictal confusion if the patient is restrained.

Simple partial seizures

- Seizure activity with focal or limited manifestations and preserved consciousness
- Symptoms may be motor, sensory, or cognitive.
- Motor seizures may be restricted to a body part (eg, face or a limb) or may involve the entire side.
- If seizure discharge spreads to structures involved in consciousness, the seizure will become a complex partial seizure.
- Seizure activity may spread to opposite side of the brain, causing a generalized seizure.
- Partial or secondary generalized seizure may be followed by Todd paralysis, weakness of the limbs most involved in seizure.
- Partial sensory seizures are most often displayed by paresthesias lasting <1–2 minutes.
- Seizure discharges from 1 occipital lobe may cause scintillating colored spots or scotomata in the visual field contralateral to the discharge.
- Seizures with more complex visual hallucinations often progress to complex partial seizures with diminished consciousness.
- Auditory seizures are manifested by hearing noises and, less commonly, by having elaborate but usually nonverbal auditory hallucinations (eg, hearing music).
- Common auras include:
 - Déjà vu (feeling that an experience has occurred before)
 - Jamais vu (feeling that a previously experienced sensation is unfamiliar and strange)
 - Rising epigastric sensation
- Staring and automatisms occur when consciousness is clouded.

- Automatisms include:
 - Chewing, lip smacking, swallowing, and hissing
 - Picking at clothes, searching, or ambulating
- Automatisms are usually followed by postictal amnesia; the child may become tired and go to sleep.

Benign partial epilepsy of childhood

- Seizures typically occur during sleep.
 - Occasionally occur during wakefulness
- The child awakens with 1 side of the face twitching.
- Oropharyngeal muscles are also often involved, causing the child to make unintelligible gurgling sounds.
- The ipsilateral upper extremity may be involved, but the lower extremity involved only rarely.
- The seizure episode rarely becomes generalized.
- Consciousness is often retained during seizure, although the child may not be able to speak.
- Most seizure episodes last <2 minutes.

Epilepsia partialis continua

- Twitching is continuous and limited to 1 side of the body.
- Twitching frequently involves only a few muscles and occurs most often in hand or foot.
- Consciousness is preserved, but seizure activity might weaken the extremity involved.
- Seizure activity may persist for hours to months.

Febrile seizures

- Occur in children with fever but no evidence of intracranial infection or acute neurologic illness
- Simple febrile seizures are generalized tonic-clonic convulsions that last <15 minutes and do not recur within 24 hours.
- Complex febrile seizures are less common and are focal or prolonged beyond 15 minutes or recur within 24 hours.

Pseudoseizures

- Uncommon
- Movements are usually not clonic but may be quivering or random thrashing.
- Episodes may be dramatic, with screaming and shouting.
- Episodes may vary greatly in same patient.
- Usually, no postictal period occurs.

DIFFERENTIAL DIAGNOSIS

- Seizures must be differentiated from other paroxysmal disorders in childhood.
 - Syncope
 - Breath-holding spells
 - Staring related to inattention
 - Paroxysmal vertigo
 - Cardiac arrhythmias
 - Stereotypic behaviors

■ Complex partial seizures

- Differentiate from absence seizures, which are also characterized by staring and unresponsiveness.
 - Absence seizures have abrupt onset and termination compared with complex partial seizures, which have a more gradual onset and termination.
 - Absence seizures last <30 seconds and are not associated with postictal confusion.
 - Automatisms can occur if absence episodes are prolonged, but are often just a continuation of motor activity present before onset of seizure.

■ Neonatal seizures

- Clonic seizures
 - Differentiate from benign neonatal sleep myoclonus, which consists of small-amplitude clonic activity that may wax and wane in various parts of the body.
- Myoclonic seizures
 - Differentiate from benign myoclonic jerks that occur during sleep in neonates
- Febrile seizure
 - If child is <1 year of age or has not rapidly returned to normal, lumbar puncture should be strongly considered to evaluate for meningitis.

■ Pseudoseizures

- Differentiate from epileptic seizures.
 - Movements are usually not clonic but may be quivering or random thrashing movements.
 - Usually not associated with incontinence, injury, or tongue biting

DIAGNOSTIC APPROACH

■ Neonatal seizures

- Because electrical seizures may not have clinical correlates, EEG should be done for all infants at risk for seizures to identify these clinically silent electrical seizures.

■ Pseudoseizures

- Detailed history and observation of an episode may be all that is needed to diagnose pseudoseizures.

LABORATORY FINDINGS

■ Laboratory tests usually performed at the time of the initial seizure include measurement of:

- Serum electrolytes
- Calcium
- Magnesium
- Blood glucose

■ In some cases, history or examination may indicate that more extensive laboratory evaluation is required.

IMAGING

■ Plain radiography

- Radiographs of the skull can detect calcifications that may be seen in some syndromes, but they rarely help in evaluating children who have epilepsy.

■ Computed tomography (CT) and magnetic resonance imaging (MRI)

- Have replaced skull radiography in evaluation of seizures
- Detect structural abnormalities
- MRI is more sensitive than CT in detecting:
 - Low-grade tumors
 - Changes in myelination
 - Heterotopic gray matter
- MRI is not warranted in every child who has epilepsy; however, it should be done in children with focal neurologic abnormalities on examination or intractable epilepsy.

■ Positron emission tomography and single-photon emission CT

- Useful in localizing metabolic alterations with seizure activity and seizure foci
- Clinically relevant only in individuals with intractable epilepsy being evaluated for epilepsy surgery

DIAGNOSTIC PROCEDURES

■ EEG

- Measures physiologic function of the brain
- Important in evaluating a child with seizures because it helps define the seizure type
- Epileptiform EEG may support diagnosis, but a normal tracing does not exclude epilepsy.
- Other abnormalities, such as slowing and background disorganization, are much less specific.
- Repeat tracings increase the likelihood of detecting epileptiform discharges in patients who have seizures.
- Such procedures as hyperventilation, photic stimulation, and sleep should be used when obtaining EEG recordings.
- Nasopharyngeal and sphenoidal electrodes may be used to detect mesial temporal discharges, but they rarely add to information obtained by special scalp electrode placements.
- Video EEG monitoring helps correlate clinical symptoms with electrical seizure activity and may be useful when clinical manifestations are atypical or pseudoseizures are in question.
- EEG abnormalities must be interpreted in view of the clinical symptoms.

■ EEG findings, by seizure type

- Absence seizures
 - Classic EEG finding: bilaterally synchronous 3-Hz spike-and-wave discharges
 - Hyperventilation may be used to precipitate electrical discharge and clinical seizure.

- Photic stimulation during EEG induces seizure discharge in some patients.
- Generalized tonic-clonic seizures
 - Associated with bilaterally synchronous electrical discharges on EEG
 - EEG may demonstrate focal discharge that may spread to both hemispheres or may show only bilateral synchronous discharges.
- Infantile spasms
 - The EEG pattern is hypsarrhythmia, characterized by high-voltage slow waves with irregularly interspersed multifocal spike-and-sharp waves.
 - Hypsarrhythmia may precede the onset of clinical manifestations, or it may occur later or not at all.
 - Over time, hypsarrhythmia usually evolves into other focal or generalized abnormalities; in some cases, the EEG may normalize.
- Lennox-Gastaut syndrome
 - EEG typically shows an irregular, high-voltage, slow (2.5 Hz or slower) spike-wave pattern.
 - Discharges are bilaterally synchronous.
- Juvenile myoclonic seizures
 - Ictal EEG typically shows generalized, symmetrical polyspike and waves at 4–6 Hz.
 - Photic stimulation precipitates the electrical discharges in some patients.
- Benign partial epilepsy of childhood
 - Typical EEG findings are midtemporal or centrotemporal spike discharges occurring unilaterally or independently bilaterally, often frequent in light sleep and sometimes induced by hyperventilation.
 - Neuroradiologic studies show no abnormalities to correlate with the EEG focus.
- Neonatal seizures
 - Subtle seizures: EEG recordings do not always show correlation of electrical seizure discharges with the clinical seizure activity.
 - Clonic seizures: EEG shows multifocal independent areas of electrical discharge.
 - Tonic seizures: often have no electrographic correlate and are usually associated with severe EEG background abnormalities
 - Myoclonic seizures: EEG usually abnormal; may show a burst suppression pattern but might not change during the myoclonic event
- Febrile seizures
 - EEG is generally not helpful in evaluating children who have febrile seizures.
 - EEG within 1 week of the seizure often shows posterior slowing.
- Paroxysmal activity is seen in EEGs of 35–45% of patients who are followed up for several years.
- EEG abnormalities do not predict recurrence of febrile seizures or development of epilepsy.
- Pseudoseizures
 - Capturing pseudoseizures during video EEG monitoring establishes the diagnosis in patients in whom the distinction cannot be made clinically.

TREATMENT APPROACH

- Seizures in neonates
 - Electrographic seizures may continue after clinical seizures are controlled.
 - If frequent or prolonged, may merit further anticonvulsant therapy
 - Seizures related to acute injuries (eg, asphyxia, stroke, or acute CNS infections other than herpes) are self-limited and stop after several days.
 - Continuing treatment past neonatal period will not change the chance of recurrence.
 - Such seizures are usually treated short term.
 - Infants are often not sent home on anticonvulsants or receive continued anticonvulsant therapy for only a few weeks.
 - Seizures related to brain malformations or inborn errors of metabolism may be much more persistent.
 - Duration of treatment depends on the infant's clinical course.
- Seizures in children beyond the neonatal period
 - Diagnosing the seizure type correctly is the critical first step in treatment, because some seizure disorders respond to certain medications.
 - Select the drug with the fewest adverse effects.
 - Give medication at a dose that will result in a low therapeutic blood level; increase the dose until seizures are controlled or adverse effects become unacceptable.
 - Add a second medication if the initial medication is not fully effective.
 - Consider discontinuing the first medication if seizures are fully controlled with the second medication.
 - Strive for monotherapy if possible—polytherapy often does not improve seizure control but may significantly increase toxicity.
 - Closely monitor for potential cognitive and behavioral adverse effects of antiepileptic medications.
 - To devise the optimal dosing regimen, consider pharmacokinetics of various antiepileptic medications.
 - Determine dosing frequency according to half-life (time in which the serum level decreases to 50% of initial value).
 - The dosing interval should be no longer than half-life of the medication.

- Most antiepileptic agents may be administered twice a day, some only once daily.
- Evaluate the efficacy of an antiepileptic medication only after 5 half-lives have elapsed because this period is required for medication to reach a steady state.
- In antiepileptic medications that induce hepatic enzymes (eg, phenobarbital, phenytoin, carbamazepine), half-life decreases during first weeks of treatment.
- If breakthrough seizures occur at times of low (trough) serum drug levels, or if toxic effects occur at times of peak serum drug levels, increase frequency of dosing.
- Patients requiring higher antiepileptic medication levels usually need more frequent dosing to avoid toxic effects.
- Serum drug levels can guide adjustment of doses of antiepileptic medications.
 - Obtain a baseline level:
 - When the patient has been taking an appropriate dose long enough to have stable levels
 - To verify adherence, breakthrough seizures, and toxic effect
 - When other medications have been added or deleted from patient's regimen
 - The timing of the sample relative to the last dose received is important in interpretation of levels, especially in drugs with short half-lives.

SPECIFIC TREATMENTS

Treatment, by type of seizure

■ Absence seizure

- Monotherapy with ethosuximide, valproate, or lamotrigine usually controls absence seizures effectively.
- Valproate and lamotrigine are the drugs of choice if the patient also has tonic-clonic seizures.
- Any 2 of these medications may be used together when absence seizures are not completely controlled with 1.
- Benzodiazepines are effective, but adverse effects on behavior make them second-line agents.
- Phenytoin, phenobarbital, and carbamazepine are usually ineffective for treating absence seizures and may exacerbate them.

■ Generalized tonic-clonic seizure

- Valproate, lamotrigine, phenobarbital, topiramate, and zonisamide
- Secondary generalized seizures may be effectively treated with these, as well as with carbamazepine, oxcarbazepine, and phenytoin.
- One of the newest anticonvulsants, levetiracetam, may be effective in both types of generalized seizures.

■ Infantile spasm

- Resistant to treatment with most anticonvulsants

• Cryptogenic group

- The treatment used most often in cryptogenic group is adrenocorticotrophic hormone (ACTH).
- ACTH in a long-acting form is administered as a single daily intramuscular dose of 20–40 IU.
- Adverse effects of ACTH and steroids are significant and include Cushing syndrome, hypertension, susceptibility to infections, hyperglycemia, gastrointestinal bleeding, and electrolyte disturbance.

• Symptomatic group

- Alternative anticonvulsants may be tried before ACTH.

• Benzodiazepines are effective.

• Nitrazepam seems to be more effective than clonazepam or diazepam.

• Both valproic acid and topiramate are effective therapy in some infants.

• Zonisamide can be effective against infantile spasms.

■ Lennox-Gastaut syndrome

- The goal of treatment is to achieve reasonable seizure control with as few medications as possible to minimize adverse effects.
- Valproate is the drug of choice.
- Lamotrigine, topiramate, and felbamate significantly reduce the frequency of atonic and generalized tonic-clonic seizures.

• Benzodiazepines control atonic, myoclonic, and atypical absence seizures.

- With increasing doses, the frequency of adverse effects also increases.

- Development of tolerance is a problem.

• Ethosuximide can help control atypical absence episodes.

• Phenytoin can be used for tonic seizures.

• A ketogenic diet has been beneficial in seizure control.

- Adherence may be a problem because of the nature of the diet.

■ Juvenile myoclonic seizures

• Valproate will control myoclonic jerks, absence seizures, and generalized tonic-clonic seizures in >80% of patients but is often avoided in females of childbearing age.

• Lamotrigine is effective in most patients.

• Topiramate, zonisamide, and levetiracetam may be effective.

• Phenytoin is not effective.

• Carbamazepine may exacerbate seizures.

■ Simple partial seizures

- Most anticonvulsants are equally effective, but these seizures are sometimes hard to control.

■ Complex partial seizures

- Carbamazepine, oxcarbazepine, and valproate are preferred over phenytoin, phenobarbital, and primidone.

- Carbamazepine is the drug of choice in children because of its efficacy and relatively mild adverse effects.
 - If seizures are not controlled with carbamazepine, adding acetazolamide may improve seizure control.
 - For some, oxcarbazepine is less sedating.
 - In infants and very young children, phenobarbital may be tried first.
- **Benign partial epilepsy of childhood**
- For infrequent episodes, no treatment may be needed.
 - If episodes frighten the child and treatment is initiated, carbamazepine has been the drug of choice.
 - Most anticonvulsants are effective.
 - Some children are prone to absence seizures, and carbamazepine may exacerbate absences.
- **Epilepsia partialis continua**
- Most anticonvulsants have some efficacy, but medical control of epilepsia partialis continua is generally difficult to achieve.
- **Neonatal seizures**
- Ensure adequate ventilation and perfusion.
 - Obtain blood for glucose, calcium, magnesium, and electrolyte studies; check a Dextrostix for an immediate determination of glucose.
 - Correct any associated metabolic abnormality.
 - Hypoglycemia: If glucose level is low (<40 mg/dL), immediately give 10% dextrose intravenously in a dose of 2 mL/kg.
 - Maintain blood glucose levels above 40 mg/dL by continuous intravenous infusion.
 - Monitor the levels in both full-term and premature infants.
 - Hypocalcemia: Correct by administering 5% calcium gluconate solution, 4 mL/kg, intravenously at a rate of 1 mL/min to maintain serum calcium levels above 7 mg/dL while monitoring cardiac rate and rhythm.
 - Hypomagnesemia: Correct serum magnesium levels to 1 mmol/L with 50% magnesium sulfate solution, 0.2 mL/kg intramuscularly.
 - For continued seizure activity, administer anticonvulsants.
 - Give phenobarbital in a loading dose of 20 mg/kg intravenously over 10 minutes
 - Additional doses of 5 or 10 mg/kg can be given, up to a total of 40 mg/kg.
 - Give phenytoin or fosphenytoin in a loading dose of 20 mg/kg intravenously while monitoring cardiac rhythm.
 - Give lorazepam in doses of 0.1 mg/kg intravenously for persistent seizures.
 - Respiratory status should be monitored.
- **Febrile seizures**
- Usually, seizure activity has stopped by the time the child is evaluated.
 - If the seizure continues, administer lorazepam or diazepam.
 - Bring down temperature by using rectal antipyretics, removing blankets and clothing, and sponging.
 - Educate the family about the benign nature of seizures, use of antipyretics, and first aid for seizures.
- **Pseudoseizures**
- Treatment is directed toward the psychosocial issues involved.
- **Specific antiepileptic medications**
- **Phenobarbital**
- With its long half-life, it requires dosing only once or twice a day.
 - Relatively safe in terms of serious toxic effects, so monitoring of parameters other than serum levels is not necessary
 - Major disadvantage: effect on behavior and cognitive function
 - Maintaining serum levels at the minimum for seizure control may help decrease these adverse effects.
 - Phenobarbital administration will decrease serum levels of carbamazepine and valproate.
 - Administration of valproate will increase phenobarbital levels.
 - Phenobarbital doses should be decreased by 25–50% to prevent toxic effects when prescribed concomitantly with valproate.
 - Properties
 - Indications: neonatal, febrile, partial, secondary generalized, primary generalized, akinetic seizures
 - Half-life: 36–120 hours
 - Usual daily dose: 3–5 mg/kg (weight <25 kg), 2–3 mg/kg (weight 25–50 kg), 1–2 mg/kg (weight >50 kg)
 - Therapeutic levels: 10–40 µg/mL
 - Adverse effects: sedation, inattention, hyperactivity, irritability, cognitive impairment, rare hypersensitivity reactions
- **Phenytoin**
- Now used infrequently for long-term therapy because alternatives with fewer adverse effects and more steady pharmacokinetics are available.
 - Changes in dose should be monitored via serum levels.
 - Only small dose changes should be made when serum levels are close to or within the therapeutic range.
 - Valproic acid may decrease the total serum phenytoin levels, but the free phenytoin level transiently increases and then returns to original level; thus, no adjustment in dose is necessary.
 - Phenytoin may decrease carbamazepine levels and increase phenobarbital levels.
 - Properties
 - Indications: partial, secondary generalized seizures

- Half-life: 7–42 hours (nonlinear kinetics)
 - Usual daily dose: 5–7 mg/kg
 - Therapeutic levels: 10–20 µg/mL (occasionally lower)
 - Adverse effects: rashes, hirsutism, gingival hyperplasia, coarse features, psychomotor slowing, neuropathy, folate deficiency, myelosuppression, drug-induced lupus
- Carbamazepine
- Widely used because it has relatively few effects on cognitive function
 - May positively affect behavior
 - Complete blood cell count should be obtained before carbamazepine therapy is initiated and should be repeated after 2–3 weeks.
 - The dose may need to be changed during treatment because this drug tends to induce its own metabolic breakdown.
 - Phenobarbital, phenytoin, primidone, and clonazepam decrease carbamazepine serum levels.
 - Properties
 - Indications: partial, secondary generalized seizures
 - Half-life: 18–55 hours initially; 3–23 hours on chronic therapy
 - Usual daily dose: 2–5 mg/kg initially; 5–25 mg/kg
 - Therapeutic levels: 4–12 µg/mL
 - Adverse effects: allergic rashes, nausea, diplopia, blurry vision, dizziness, hypersensitivity, hepatitis, aplastic anemia
- Valproic acid
- Broad spectrum of efficacy and only minimal cognitive adverse effects
 - Rarely, has been associated with fatal hepatotoxicity
 - Most cases occur during the first 3 months of treatment.
 - Patients at greatest risk for hepatotoxicity are children <2 years who receive valproic acid as part of antiepileptic polytherapy.
 - Valproic acid should be administered cautiously to patients with preexisting hepatic dysfunction.
 - Liver function should be monitored in patients taking valproic acid, especially those in the high-risk group.
 - Valproic acid increases the level of phenobarbital; therefore, the phenobarbital dose must be decreased by 25–50% if valproic acid is added.
 - Carbamazepine, phenobarbital, and phenytoin decrease valproic acid serum levels.
 - Properties
 - Indications: primary generalized, absence, myoclonic, akinetic, and febrile seizures; infantile spasms; Lennox-Gastaut syndrome; partial seizures
 - Half-life: 6–16 hours
 - Usual daily dose: 10–30 mg/kg on monotherapy; may need more in polytherapy
- Therapeutic levels: 50–100 µg/mL (150 µg/mL if tolerated)
 - Adverse effects: nausea, tremor, weight gain, hair loss, thrombocytopenia, hepatic failure, pancreatitis
- Ethosuximide
- Limited spectrum of efficacy
 - Because pancytopenia has been associated with long-term administration, periodic blood cell counts may be necessary.
 - Does not interact significantly with other antiepileptic medications
 - Properties
 - Indications: absence, myoclonic, akinetic seizures
 - Half-life: 15–68 hours
 - Usual daily dose: 15–40 mg/kg
 - Therapeutic levels: 40–100 µg/mL
 - Adverse effects: nausea, abdominal discomfort, hiccups, drowsiness, behavioral problems, dystonias, myelosuppression, drug-induced lupus
- Primidone
- Not a commonly used antiepileptic agent because it has no specific advantage over other agents and tends to be more sedating
 - Because one third of primidone is metabolized to phenobarbital, phenobarbital levels should be monitored.
 - Phenobarbital levels may be 1.3–2 times higher than primidone levels.
 - Valproate increases primidone serum levels.
 - Phenytoin and carbamazepine increase the phenobarbital/primidone ratio.
 - Properties
 - Indications: partial, secondary generalized, primary generalized seizures
 - Half-life: 3–20 hours
 - Usual daily dose: 1–2 mg/kg initially; 5–10 mg/kg
 - Therapeutic levels: 5–12 µg/mL
 - Adverse effects: sedation, irritability, psychomotor slowing, rare hematologic and hypersensitivity reactions
- Clonazepam
- A benzodiazepine
 - Not a first-line antiepileptic medication because of adverse effects
 - Causes increased secretions, which may be a problem in children with reactive airways or cerebral palsy and associated compromised swallowing mechanisms
 - May lead to swallowing dysfunction in higher levels
 - Because withdrawal of drug may cause irritability, myoclonus, and increased seizures, it should be withdrawn slowly.
 - Usually reserved for myoclonic seizures that are refractory to ethosuximide and valproic acid

- Properties
 - Indications: absence and primary generalized seizures, infantile spasms
 - Half-life: 20–36 hours
 - Usual daily dose: 0.01–0.2 mg/kg
 - Therapeutic levels: 0.01–0.07 µg/mL
 - Adverse effects: sedation, hyperactivity, inattention, aggressiveness, tolerance, ataxia, withdrawal seizures
- Other benzodiazepines
 - Clorazepate
 - Least sedating of the benzodiazepines
 - Sometimes used adjunctively for resistant seizures
 - Diazepam and lorazepam may be used.
 - All benzodiazepines are associated with tachyphylaxis and some sedation and withdrawal seizures.
 - Rotating from one to another may help retain the efficacy of these medications.
 - Their most significant role in epilepsy is in intermittent use, as in status epilepticus, for which intravenous lorazepam is the drug of choice.
 - Rectal preparation of diazepam may be administered safely during prolonged seizure outside a hospital setting.
 - These drugs may be used:
 - To stop flurries of seizures in patients predisposed to them
 - Sometimes for nocturnal seizures
- Acetazolamide
 - Effective adjunctive therapy
 - Antiepileptic properties are not well understood.
 - Can be used in combination with valproic acid for treatment of absence, myoclonic, and akinetic seizures
 - Adding acetazolamide to carbamazepine may improve control of partial seizures.
 - Acetazolamide metabolism is not affected significantly by other medications.
 - Properties
 - Indications: absence, myoclonic, akinetic, partial seizures
 - Half-life: 10–12 hours
 - Usual daily dose: 10–20 mg/kg
 - Therapeutic levels: 10–14 µg/mL
 - Adverse effects: diuresis, paresthesias, sedation, carbon dioxide retention, rashes
- Felbamate
 - 1 year after felbamate was approved and widely used because of its lack of associated sedation, >20 cases of aplastic anemia among persons taking it were reported.
 - Incidence of and predisposing factors to this problem have not been fully determined.
 - Use decreased significantly after these reports and associated warning.
 - Only 1 additional case has been reported in the past 12 years, and no cases have been reported in children <13 years of age.
 - Should be used only in patients whose epilepsy is so severe that benefits from use outweigh risk of aplastic anemia
 - Interacts with phenytoin, carbamazepine, and valproate ; therefore, these medications must be reduced by 25–50% when felbamate is added
 - Felbamate levels are lowered by medications that induce liver enzymes; consequently, felbamate doses may need to be increased.
 - Properties
 - Indications: partial seizures (in patients >12 years), Lennox-Gastaut syndrome
 - Half-life: 20 hours (in monotherapy)
 - Usual daily dose: 15–45 mg/kg (maximum of 3600 mg)
 - Adverse effects: anorexia, weight loss, nausea, insomnia, headache, fatigue, aplastic anemia
- Gabapentin
 - Approved for adjunctive therapy in patients ≥3 years
 - Gabapentin significantly reduces seizure frequency in patients refractory to conventional anticonvulsants but is not as effective an anticonvulsant as most other agents.
 - Currently used more for neuritic pain than for seizure control
 - Does not interact with other drugs and is 100% excreted renally, offering an advantage to patients with liver failure
 - Properties
 - Indications: partial seizures, with or without secondary generalized seizures in patients >12 years
 - Half-life: 5–7 hours
 - Usual daily dose: total daily dose 900–1800 mg
 - Adverse effects: somnolence, dizziness, ataxia, fatigue
- Lamotrigine
 - Approved for treating partial seizures in patients >16 years and as add-on therapy in patients ≥3 years with Lennox-Gastaut syndrome
 - Reduces frequency of both partial and generalized seizures
 - Has no effect on metabolism of other antiepileptic drugs; however, phenobarbital, phenytoin, and carbamazepine decrease the half-life of lamotrigine
 - Valproic acid increases the half-life of lamotrigine by 2- or 3-fold; therefore, doses of lamotrigine should be lower when given with valproic acid.
 - The range of therapeutic plasma concentrations is wide (1 to ≥12 µg/mL), making monitoring of serum levels less useful.
 - Properties
 - Indications: partial, primary generalized, absence, atypical absence, atonic, myoclonic seizures

- Half-life: 7–45 hours
- Usual daily dose: total 5–15 mg/kg without valproic acid, 1–5 mg/kg with valproic acid ;muststart at very low doses and titrate slowly over 2–3 months
- Therapeutic levels: 0.01–0.07 µg/mL
- Adverse effects: rash, including Stevens-Johnson syndrome; vomiting

■ Topiramate

- Approved for
 - Initial monotherapy for partial seizures and primary generalized tonic-clonic seizures in patients ≥ 10 years
 - Adjunctive therapy in patients ≥ 2 years for partial and primary generalized tonic-clonic seizures and for Lennox-Gastaut syndrome
- Minimal effect on metabolism of other antiepileptic drugs
 - However, concomitant therapy with phenytoin or carbamazepine will decrease topiramate levels.
- Properties
 - Indications: partial, primary generalized, tonic, atonic, and atypical absence seizures; infantile spasms
 - Half-life: 20–30 hours
 - Usual daily dose: 1–9 mg/kg
 - Adverse effects: somnolence, anorexia, fatigue, difficulty with concentration, nervousness, kidney stones, oligohidrosis

■ Tiagabine

- Adjunctive therapy of partial seizures in adults
- Effective as adjunctive or monotherapy for partial seizures in some children
- Enzyme inducers (eg, carbamazepine, phenytoin, and phenobarbital) decrease tiagabine levels.
- Therapeutic plasma concentrations for tiagabine have not been established.
- Used only infrequently for seizure control in children because other anticonvulsants are more effective
- Properties
 - Indications: partial seizures
 - Half-life: 3–9 hours
 - Usual daily dose: 0.25–1.5 mg/kg (maximum of 56 mg)
 - Adverse effects: dizziness, somnolence, headache, depression

■ Levetiracetam

- Approved for adjunctive therapy for partial seizures in patients ≥ 4 years
- May be effective in treating primary generalized seizures
- Lack of significant adverse effects and significant drug interactions is leading to increasing use.
- Half-life of 6–8 hours means that it must be given ≥ 2 times a day.

• Properties

- Indications: partial, secondary generalized seizures
- Half-life: 6–8 hours
- Usual daily dose: start at 10–20 mg/kg/day, increase every 2 weeks; top dose 60 mg/kg or 3000 mg
- Adverse effects: somnolence, irritability, hostility

■ Oxcarbazepine

- Approved for initial monotherapy and adjunctive therapy for partial seizures in patients ≥ 4 years
- Rapidly becoming a drug of first choice for partial seizures
- Well tolerated in infants and young children
- Properties
 - Indications: partial, secondary generalized seizures
 - Half-life: 4–9 hours
 - Usual daily dose: 10–50 mg/kg; start at 10 mg/kg up to 600 mg divided into 2 daily doses
 - Adverse effects: somnolence, nausea, dizziness, rash, hyponatremia

■ Zonisamide

- Approved as adjunctive therapy in adults with partial seizures
- Few studies have evaluated its use in children in the US.
- In Japan, where it has been available longer, zonisamide is used widely in children with both partial and primary generalized epilepsy and infantile spasms.
- Half-life of 24–60 hours allows once-a-day dosing.
- Properties
 - Indications: partial, primary generalized seizures; infantile spasms
 - Half-life: 24–60 hours
 - Usual daily dose: start at 1–2 mg/kg and may work up to 10 mg/kg; top adult dose is 600 mg
 - Adverse effects: somnolence, dizziness, kidney stones, oligohidrosis

Other treatments

■ Ketogenic diet

- Effective alternative treatment for some children
- Half of patients with intractable epilepsy showed decrease in seizure frequency of 50%; some were seizure free at 1 year.
- To achieve ketosis, the patient is given a high-fat, low-protein, and low-carbohydrate diet, sometimes with calorie restriction.
 - The patient is usually admitted to hospital for initiation of the diet, which allows monitoring for hypoglycemia and other complications.
 - During hospitalization, a dietitian teaches the parents about the diet, giving them sample menus and explaining how to measure foods.

- Initial use of 24 hours of fasting to initiate the diet is no longer adhered to.
- Strict adherence to diet is required for success.
- Complications of diet include constipation, renal stones, fatigue, and metabolic acidosis.
- Vagal nerve stimulation
 - A vagal nerve stimulation device is surgically implanted subcutaneously in the anterior chest wall to stimulate the left vagus nerve.
 - Most studies report approximately 50% improvement of seizure frequency in one half of children, with a few becoming seizure free.
 - Stimulation is associated with alertness, a benefit to many children with intractable epilepsy who have often been experiencing sedation from their anticonvulsant therapy.
 - Adverse effects: generally uncommon and mild
 - Infection
 - Hoarseness
 - Neck pain
 - Insomnia
 - Emergence of behavioral abnormalities (which may be related to increasing alertness)
- Addressing psychosocial issues
 - Parents and patients may have many fears and need reassurance.
 - Explain the terms *epilepsy* and *seizure* disorder.
 - Help parents understand that diagnosis of epilepsy does not mean that the child has intellectual disability or a psychiatric disorder.
 - Give guidelines on what to do when child has a seizure, including positioning on the side and putting nothing in the mouth.
 - Emphasize to parents that death from a seizure is rare.
 - Discuss activities of patients with seizures.
 - Activities should be restricted as little as possible.
 - A child with a seizure disorder should not swim alone or go bike riding without a helmet (as for all children).
 - Contact sports are permissible when epilepsy is controlled.
 - The decision about climbing up to certain heights should be based on how well the child's seizures are controlled.
 - Older children who are not supervised when bathing should be encouraged to take showers rather than baths to minimize risk of drowning if a seizure occurs.

WHEN TO ADMIT

- Seizures are uncontrolled or prolonged
- Video EEG monitoring is needed
- Rapidly changing anticonvulsant medication is needed
- Ketogenic diet is initiated

WHEN TO REFER

- Type of seizure is unclear
- Seizures are refractory to medication
- Patients with medically intractable partial seizures should be evaluated at a comprehensive epilepsy center to determine candidacy for surgical intervention, which results in complete seizure control in up to 90% of patients.

FOLLOW-UP

- Discontinuation of antiepileptic therapy
 - After seizures have been controlled for 2 years, discontinuing antiepileptic medications should be considered.
 - ~75% of children seizure free for >2 years remained seizure free after antiepileptic medications were discontinued.
 - In children with idiopathic epilepsy and normal EEG, the prognosis for remaining seizure free after discontinuation of medications is good, except in juvenile myoclonic epilepsy.
 - If EEG shows slowing, risk of seizure recurrence is higher.
 - Risk of recurrence is not increased if medication is tapered over ≥ 6 weeks.
 - 50% of recurrences occur within 6 months and 60–80% within 2 years.
- Intractable seizures
 - When seizures continue despite anticonvulsant therapy, 3 possibilities should be considered before deciding that seizures are intractable to anticonvulsant therapy.
 - Seizures may be occurring when the child has lower blood levels of medication because of incomplete adherence or because dosing intervals are too long.
 - Medication may not be appropriate to the seizure type.
 - Primary generalized seizures will often not respond and may even worsen if treated with medications indicated for partial or secondary generalized seizures (eg, carbamazepine, phenytoin).
 - Repeated events may represent a nonepileptiform paroxysmal disorder rather than electrical seizure.
 - Pseudoseizures can be especially difficult to differentiate from seizures because they tend to occur in persons with epilepsy.
 - If the child is having electrographic seizures that continue despite appropriate amounts of correct medications, then the child has intractable seizures.

COMPLICATIONS

- Learning and behavioral problems
 - Children with epilepsy and without intellectual disability tend to have more learning problems, especially reading and attention deficit, than children without epilepsy.

- Behavioral problems may be identified in $\leq 50\%$ of children with epilepsy, and this number may increase with added adverse effects of medication and burden of a chronic disorder.
- The risk of subsequent epilepsy in children with febrile seizures is $< 5\%$.
- Factors associated with subsequent afebrile partial seizures include:
 - Focal seizures
 - Prolonged seizures
 - Repeated episodes of seizures with the same febrile illness
- Factors associated with development of afebrile, generalized seizures include:
 - > 3 febrile seizures
 - Family history of afebrile seizures
 - Age > 3 years at the time of the first febrile seizure

PROGNOSIS

- Risk of seizure recurrence is important when deciding whether to initiate antiepileptic therapy.
- Some types of seizures (eg, absence, myoclonic, and akinetic seizures and infantile spasms) have a recurrence rate of almost 100%.
 - Seizures have usually recurred by the time the child is seen by a primary care physician.
 - These seizures require treatment.
 - Children with generalized tonic-clonic or partial seizures have a recurrence risk of $\sim 40\%$.
 - Factors that increase risk of recurrence include:
 - Partial complex seizure
 - Abnormal neurologic examination
 - Focal epileptiform abnormalities on EEG
- The best prognosis is in children with a generalized seizure, normal neurologic examination, and a nonepileptiform EEG.
- $> 50\%$ of recurrences occur within 6 months, up to 69% within 1 year, and 88% within 2 years.
- If epilepsy surgery is performed soon after intractability of seizures has been established, some of the secondary physiologic and psychosocial effects of growing up with epilepsy may be prevented, and children are more likely to be able to live up to their potential in adult life.
- Infantile spasms
 - Prognosis remains grave.
 - Average mortality is $\sim 20\%$.
 - Aspiration pneumonia related to severe developmental abnormalities is a common cause of death.
 - $\sim 80\%$ of survivors are intellectually disabled.

- Spasms usually remit by a few years of age, but 55–60% of patients subsequently develop other forms of seizures.
- Prognosis is more favorable for infants whose neurologic development was normal before onset of spasms.
- Lennox-Gastaut syndrome
 - Otherwise healthy preschool-age children with normal background and fast polyspike-and-wave changes on EEG have a much better prognosis for seizure control and cognitive development.
- Juvenile myoclonic seizures
 - The rate of seizure recurrence among patients who discontinue therapy is high.
 - Lifelong condition that requires continuous treatment
- Benign partial epilepsy of childhood
 - Remits when child is ~ 9 –12 years of age (no later than 17 years of age)
 - Remission is long lasting.
 - No associated developmental or neurologic impairment, other than some increased incidence of attention deficit
- Febrile seizure
 - One third of children who have a febrile seizure will have another one with another febrile illness.
 - The younger the child is at the time of the first episode, the greater the risk of recurrence.
 - Approximately 50% of recurrences occur within 6 months of the initial seizure; 75% occur within 1 year.

PREVENTION

- Febrile seizures
 - Oral diazepam (0.33 mg/kg of body weight administered every 8 hours during febrile illness) reduces the risk of recurrent febrile seizures.
 - Administering phenobarbital at onset of a febrile illness does not prevent seizure activity because therapeutic blood levels are not achieved soon enough.
 - Prophylactic treatment with anticonvulsant agents should be considered if:
 - Neurologic development is abnormal.
 - Seizure is complex febrile.
 - The child is < 1 year of age.
 - Administering phenobarbital in doses that achieve blood levels of 15 $\mu\text{g}/\text{mL}$ reduces recurrence of febrile seizures.
 - Valproate appears to be effective in prophylaxis.
 - Phenytoin and carbamazepine do not prevent recurrences.
 - Adverse effects of anticonvulsant therapy must be weighed against possible benefits.

Self-Stimulating Behaviors

DEFINITION

- Self-stimulating behaviors include:
 - Head banging and rocking
 - Rhythmic movements of the head and sometimes the entire body against a solid object
 - Thumb sucking and nail biting
 - Masturbation
 - Hair pulling and twisting
 - Trichotillomania (pulling out the hair)

EPIDEMIOLOGY

- Prevalence
 - Most common behaviors described in preschool children
 - Masturbation: almost universal
 - Thumb/finger sucking: 25–40%
 - Nail biting: 23%
 - Head banging and rocking: 3–20%
 - Hair pulling and twisting: uncommon
- Age
 - Self-stimulating behaviors typically appear before 12 months of age and peak at age 2.5 years.
 - Subsequently, the behaviors decline rapidly.
 - Thumb sucking
 - Continues in 10–20% of American children beyond 6 years of age
 - Nail biting
 - As many as 40% of all children >6 years bite their nails at some time.
 - 20% of college students continue to bite their nails.
 - Masturbation
 - Typically begins at around 2 months of age
 - Peaks at 4 years of age and again in adolescence
 - Hair pulling and twisting
 - A hairball (trichobezoar) in the stomach has been reported in preschoolers, school-age children, adolescents, and adults.
- Sex
 - Head banging and rocking
 - Male-to-female ratio of approximately 3:1
 - Hair pulling and twisting
 - Trichobezoar is more common in girls than in boys.

MECHANISM

- Research has suggested that commonalities exist among such behaviors.
 - Sometimes classified as *stereotypies*

- An interaction of the stage of neuromotor development with environmental influences (eg, restrictive car seats and cribs)
- Homeostatic mechanism that serves to regulate stimulation from the environment
- Head banging and rocking
 - Appear to be linked to maturational patterns
 - They correlate closely with teething and other transitions of growth and development.
 - Possibly a mechanism for increasing or reducing arousal and maintaining homeostasis
 - Rocking is thought to be a soothing, pleasurable experience.
 - Every infant encounters rocking in utero.
 - Most infants encounter it from the neonatal period onward.
 - Pleasure from movement is repeated throughout life.
- Thumb sucking
 - Pleasurable sensations are associated with the double tactile experience of sucking and being sucked.
 - The feelings of security and comfort that these experiences evoke tend to reinforce this type of behavior.
- Nail biting
 - An extension or permutation of the habit of thumb sucking
 - Some experts consider this behavior a form of more overt self-aggression.
 - Others define nail biting simply as a variation of thumb sucking because this behavior is also seen typically during times of stress.
- Masturbation
 - Generally initiated as a response to the learned pleasure associated with touching of the genitalia first experienced in infancy during normal body exploration
 - May vary from direct manual genital stimulation to movement of the thighs against each other
 - Rhythmic swaying or thrusting motions of the child while straddling a hobby horse, pillow, stuffed animal, or other objects are common methods of masturbation.
 - Infants and children are capable of a physiologic orgasmic response similar to that experienced by the adult except for the absence of ejaculation in the male child.
 - Occasionally, orgasmic response has been incorrectly thought to represent a convulsive disorder in the pre-school child.

HISTORY

- Head banging and rocking
 - Most common at bedtime or at times of fatigue or stress
 - May vary in duration from several minutes to hours
 - Often continues even when the child is asleep

- Occasionally, a family history of such behavior can be found.
 - Only 20% of siblings of children who rock exhibit similar or other rhythmic pattern disturbances.
- Individual constitutional patterns in childhood account for wide variability in the amount of stimulation any particular child requires.
- Marked rhythmic movements are commonly found in children with:
 - Hearing or sight impairment
 - Emotional disturbance
 - Severe intellectual disability
- Movements may represent a compensatory reaction for lack of stimuli or the inability to integrate stimuli.
- A child who has no disability but who is inactive because of physical illness generally shows a need for motor release.
 - Often characterized by bed rocking or other rhythmic body movements
 - Generally disappears once normal mobility is restored
- Studies indicate no connection between rocking behavior and parental divorce or separation.
 - However, the question of inadequate stimulation should be raised.
 - The presence of family turmoil and stress should be investigated.
- Thumb sucking and nail biting
 - Family history appears to exist in most cases.
 - This habit is so common that an apparent association may be of no significance.
 - No apparent correlation has been found with:
 - Number of children in the family
 - Birth order
 - Type of feeding or feeding schedule
 - Age or race of the parents
 - A significant association exists with the time of weaning.
 - The later the weaning takes place, the less likely the chance of thumb sucking.
 - Underlying causes of tension should also be investigated.
 - Many families substitute artificial pacifiers as a more socially acceptable means of oral pleasure.
 - Children often spontaneously suck a security blanket, doll, or stuffed animal.
 - Thumb sucking usually occurs:
 - With stress or boredom or at bedtime, when young children use it to help them fall asleep
- Hair pulling and twisting
 - Often indicates the presence of psychological stress

PHYSICAL EXAM

- Head banging and rocking
 - Most children will be predominantly within normal limits on physical and neurologic examination.
 - Psychosocial growth and development are apparently not disturbed.
- Thumb sucking and nail biting
 - Increased probability of dental malocclusion
 - Increased incidence of digital cutaneous infections
- Hair pulling and twisting (trichotillomania)
 - The scalp is the most common area affected.
 - The eyebrows and eyelashes are the next most likely sites.
 - Trichobezoar in the stomach if the child ingests the hair
 - Serious problem that often results in hospitalization for surgical removal of the accumulated matted hair
 - Trichotillomania is classified by the *Diagnostic and Statistical Manual of Mental Disorders* as a disorder of impulse control.
 - May best be grouped with the obsessive-compulsive disorder spectrum because of the common pathological compulsion of excessive grooming
 - Focused type
 - The activity is associated with tension before and relief after the hair is pulled.
 - Time is set aside to pull the hair.
 - Sedentary type
 - The patient is generally unaware of the behavior during the hair pulling or twisting itself.
 - The patient recognizes the action as senseless and undesirable.
 - Local irritation from a dermatologic condition
 - Rarely the cause of this disorder, but the possibility should be investigated

DIFFERENTIAL DIAGNOSIS

- Masturbation
 - Exclude:
 - Local genital irritation
 - *Candida* infection
 - Pinworms
- Obsessive-compulsive disorder
 - The clinician should investigate and refer appropriately if the patient engages in excessive:
 - Thumb sucking
 - Nail biting
 - Cuticle picking or biting
 - Hair pulling

- Infantile autism or childhood schizophrenia
 - Body twirling or spinning
 - Hand or arm flapping
- Special problems in severely intellectually disabled or emotionally disturbed children
 - Excessive rocking behavior
 - Severe self-mutilating behaviors (Lesch-Nyhan syndrome, Cornelia de Lange syndrome)
 - Compulsive self-biting
 - Severe head banging
 - Skin gouging
 - Prader-Willi syndrome
 - Severe skin picking
 - These behaviors are part of a symptom complex in a severe disorder, in contrast to generally isolated behavior in normal children.
 - The cause is generally linked to the basic disorder and may also reflect the lack, or disordered integration, of sensory stimuli.

DIAGNOSTIC PROCEDURES

- Electroencephalography
 - Not indicated in head banging and rocking because the findings are generally not helpful

TREATMENT APPROACH

- Most of these behaviors are self-limited to the preschool period and are usually viewed as normal, common, and expected behaviors.
- These habits generally do not signify psychological maladjustment.
- They often require little intervention other than reassuring parents and suggesting adequate stimulation of their child.

SPECIFIC TREATMENT

Head banging and rocking

- Treatment is generally directed toward assuring the parents that:
 - Head banging cannot cause brain injury.
 - The child will show no adverse neurologic effects in later life.
 - Children who engage in head-banging behavior usually grow up as completely normal, coordinated children.
- Padding the crib and securing the bed to prevent rolling may help during the limited rocking behavior.
- Sedation in the form of diphenhydramine may prove effective.
- Psychotropic medication is generally unnecessary and is thus discouraged.

- Rarely, if ever, do fractures of the skull or cerebral hemorrhages result from head banging.
 - Soft-tissue swelling and scalp contusions have been reported.
 - A protective helmet may be advised in severe cases.

Thumb sucking and nail biting

- Parents
 - Clarify with them the nature of these habits.
 - Advise parents to avoid punishment, shaming the child, threats, or anger.
 - Encouragement instead of restrictions helps engage children in their own program to decrease or eliminate the behavior.
- Simple behavioral therapy (based on positive reinforcement) is often sufficient to alleviate the habit.
 - The choice of reinforcement reward should be the child's.
- Bitter-tasting commercial preparations
 - May be applied to the fingers as a reminder
 - These preparations are generally inadequate unless supplemented by consistent positive reinforcement.
 - A combination of aversive taste treatment and a reward system appears to be effective in treating chronic thumb sucking.
- Hypnosis is often successful and poses no danger.
- Psychotropic medications are of little value.

Masturbation

- Counsel parents about masturbatory practices and emphasize that masturbation is:
 - Normal
 - Harmless
 - Almost universal in children
 - A healthy practice that helps the child to derive pleasure from his/her own body
- Dispel persistent myths concerning the belief that masturbation may cause:
 - Intellectual disability
 - Physical deformity
 - Blindness
 - Poor physical and mental health
 - Facial pimples
 - Hair on the palms of the hand
 - Homosexuality
 - Sexual perversions
- Encourage parents to avoid punishing or shaming their child for a normal behavior.

- If parents observe masturbatory activity in their child:
 - They may want to suggest to the child the inappropriateness of manipulating their genitalia in public places or in front of others.
 - Parents can inform the child that certain practices, such as using the toilet and masturbating, are best carried out in private.
- Counseling and advice given by the practitioner may be met with covert or overt resistance by parents or school authorities.
 - The pediatrician should be well prepared to educate persons responsible for the growth and development of children.

Hair pulling and twisting

- Treatment is usually indicated.
- Dynamic therapy with little evidence of effectiveness
- Behavioral therapy
- Psychopharmacologic measures in patients unresponsive to nonmedication treatment
 - Clomipramine
 - Selective serotonin reuptake inhibitors
- Hypnosis or psychotherapy

Special problems in disturbed children

- All stimulatory behaviors require treatment for the underlying disorder.
- Special behavioral treatment is needed beyond the scope and expertise of the primary care physician.
- When severe, institutionalization is often required, and methods of treatment include:
 - Aversive behavior modification techniques
 - Use of arm and neck restraints
 - Head helmets
 - Psychotropic medications
 - Psychotherapeutic behavioral programs

WHEN TO REFER

- Persistence of head banging or rocking beyond the age of 3 years
- Preoccupation with self-stimulating behavior to the point that it interferes with healthy social and emotional interaction
- Presence of accompanying symptoms, such as decreased socialization or other behavioral problems
- Presence of tissue damage

FOLLOW-UP

- Weekly visits to the physician for the first month of treatment are important to reinforce the change in behavior.

PROGNOSIS

- Thumb sucking and nail biting
 - Only 4% develop motor stereotypies.
 - The probability of malocclusion in children who suck their thumbs appears to be directly related to the age at which the habit is discontinued.
 - Children who cease the habit when they are >6 years of age generally exhibit some degree of malocclusion when examined at 12 years of age.
 - Thumb sucking that persists into school age can bring on teasing from peers and criticism from teachers and family, leaving the child with decreased self-esteem and increased psychological distress.
- Masturbation
 - Masturbation will continue as a lifelong pleasurable experience unless suppressed by parents or other adults.
- Hair pulling and twistinga
 - Obvious cosmetic damage often results in ridicule by peers and shame for the child.

Septic Arthritis

DEFINITION

- Pyogenic, or septic, arthritis refers to a bacterial infection of the joint space.
- Can lead to permanent deformity and disability, particularly in the young child
- Complications can be minimized by prompt diagnosis and aggressive treatment.

EPIDEMIOLOGY

- Age
 - Most commonly affects young children and infants
 - Can occur at any age

ETIOLOGY

- Hematogenous seeding of the synovial membrane is the most common cause in children.
- Infection also can occur by:
 - Direct inoculation of bacteria into the joint after:
 - Penetrating wound
 - Intraarticular injection
 - Joint surgery
 - Contiguous spread from an adjoining osteomyelitis
 - Occurs most often in infancy
 - Transphyseal blood vessels allow early spread of bacteria from the metaphysis of the bone across the growth plate to the epiphysis and into the joint cavity.
- Potential organisms include:
 - *Staphylococcus aureus*
 - Organism most commonly responsible for septic arthritis across all age groups
 - Group A *Streptococcus*
 - After *S aureus*, the next most common cause of septic arthritis in children >5 years
 - *Neisseria gonorrhoeae*
 - Monoarticular gonococcal arthritis can occur after genital infection.
 - Consider it in the sexually active teenager.
 - Gonococcal septic arthritis is a result of hematogenous seeding of the joint.
 - Can follow the bacteremia of untreated disseminated gonococcal disease
 - *Kingella kingae*
 - First described in Israel, has been identified with increasing frequency in the US.
 - More common in children <5 years
- In neonates, septic arthritis can also be caused by:
 - Gram-negative organisms
 - Coagulase-negative staphylococci
 - *Streptococcus agalactiae* (group B)

- In older infants and young children, *Haemophilus influenzae* type b was once common.
 - Vaccination against *H influenzae* has made it extremely rare as a cause of bacterial infection in children in the US.

SIGNS AND SYMPTOMS

- Joints of the lower extremities are the most common sites of septic arthritis.
 - The knee is the most affected joint.
 - Rarely, and usually with prolonged bacteremia, ≥1 joint can become infected.
- Common signs
 - Pain with joint motion or refusal to move an infected joint (most characteristic finding)
 - Swelling
 - Erythema
 - Tenderness
 - Redness of the skin over the joint
 - Can be difficult to detect in a deep joint, such as the hip
 - Limp or refusal to bear weight when a lower-extremity joint is involved
 - Limited range of motion when an upper-extremity joint is involved
 - May result in concerns about a neurologic problem, a pseudoparalysis
- Older children and teenagers can usually localize the pain.
 - Pain can be referred to an unaffected joint.
- Signs of acute illness most often accompany the onset of septic arthritis.
 - Fever
 - Malaise
 - Poor appetite
 - Irritability
- In the neonate, systemic signs may be less apparent.
 - Localized signs are usually prominent.
 - Failure to move an infected joint
 - Severe pain associated with passive movement of the affected extremity
 - Significant pain on manipulation of the hip joint during diaper changes

DIFFERENTIAL DIAGNOSIS

- Rheumatologic
 - Typically involves multiple joints
 - Presentation is often subacute and chronic.
 - Includes juvenile idiopathic arthritis (JIA)
 - Formerly called *juvenile rheumatoid arthritis*
 - A diagnosis of exclusion

- When children with JIA have high fever and single joint involvement, the diagnosis can be more confusing.
- In many instances, the diagnosis is made only over time, when:
 - Fevers persist.
 - Other joints become involved.
 - The single joint fails to have a pathogen isolated and fails to respond to therapy for a pyogenic infection.
- The diagnosis of JIA can remain unclear for weeks to months until the course clarifies the chronicity of the disease.
- Reactive or postinfectious arthritis
 - An immunologically induced inflammatory response to a distant infection
 - Often follows a prior obvious infection
 - Children can be very ill from an associated bacteremia.
 - In adolescents and older children, can be associated with uveitis and conjunctivitis
- Leukemia
 - Children with leukemia can have:
 - Fever
 - Bone pain
 - Examining the bone marrow is often required to confirm the diagnosis.
- Isolated neuropathy
 - Can cause decreased movement of a joint, but will not be associated with pain or fever
- *Mycobacterium tuberculosis*
 - A history of exposure can direct the diagnosis.
 - Culturing of the joint fluid must be done on special media.
 - If suspected, place a tuberculin skin test and order a chest radiograph.
- Lyme disease
 - The child with *Borrelia burgdorferi* will often have a history of erythema migrans.
 - Serologic testing can help confirm the diagnosis.
 - Knowing the frequency of this pathogen in the pediatrician's area of practice is important.

DIAGNOSTIC APPROACH

- Characteristic signs help suggest the diagnosis.
 - The child holds the infected joint very still to decrease pain.
 - The joint is held immobile by muscle spasm in a position that:
 - Maximizes capsular volume
 - Minimizes intraarticular pressure
 - Preferred positions
 - For the hip, a combination of moderate flexion, abduction, and external rotation

- For the knee, gentle flexion
- For the shoulder, adduction against the trunk
- The child may appear entirely well and in no distress as long as the affected joint is allowed to remain undisturbed.
- If the child holds a joint still and has a fever, a septic joint is assumed.

LABORATORY FINDINGS

- Erythrocyte sedimentation rate is typically elevated.
 - May be normal early in the course of infection
- C-reactive protein level is increased.
 - A more sensitive test during initial illness because it increases earlier than the sedimentation rate
- Blood cultures should always be obtained.
 - Blood cultures are positive in $\geq 40\%$ of children with septic arthritis.
- Examination of joint fluid in pyogenic arthritis
 - Appearance
 - Generally cloudy or purulent
 - Cell count
 - Leukocyte count $> 50,000$ cells/mcL
 - There is a predominance of polymorphonuclear cells.
 - Gram stain/fluid culture
 - Cultures are positive in 50–60% of cases caused by bacterial infection.
 - Attention to culture technique and special media is required to isolate *N gonorrhoeae* and *M tuberculosis*.
- Examination of joint fluid in JIA
 - Can also contain many neutrophils
 - In general, levels are lower than with bacterial infection.
- A joint effusion with a low leukocyte count and normal glucose suggests that:
 - The arthritis may be caused by a sympathetic effusion from:
 - An adjacent osteomyelitis or
 - An aseptic arthritis caused by a reactive arthritis, JIA, or other rheumatologic disease
- Serologic testing can help to confirm a diagnosis of Lyme disease.

IMAGING

- Plain films should be obtained to look for early changes and to exclude other bone abnormalities.
 - Early changes include:
 - Swelling of the soft tissue
 - Edematous infiltration into the fatty tissue planes

- Ultrasonography can:
 - Define the presence of a joint effusion
 - Detect the capsular distention that accompanies septic arthritis of the hip
 - Assist the operator in accurate needle placement during diagnostic aspiration
- Magnetic resonance imaging may be helpful in defining adjacent bony involvement and soft-tissue abscesses, especially in areas of complex anatomy, such as:
 - Hip
 - Sacroiliac joint
 - Pelvic bones

DIAGNOSTIC PROCEDURES

- Joint aspiration with a large-bore needle is the most important diagnostic maneuver.
 - Should be performed by an orthopaedic surgeon skilled in care of pediatric patients
 - Fluoroscopy, or possibly ultrasonography, may be used to confirm entrance into the relatively inaccessible hip and shoulder joints.
 - Failure to obtain pus from a joint that appears clinically to be infected can be caused by the thickness of pus in the joint.
- Open drainage of the joint may be necessary to confirm diagnosis and treat infection.

TREATMENT APPROACH

- Septic arthritis is an urgent situation and requires consultation among the:
 - Primary physician
 - Orthopaedic surgeon
 - Radiologist
 - Infectious diseases specialist
- Empirical therapy with antimicrobial agents that are appropriate for the likely pathogen should be started urgently after aspiration of the joint.
- Length of treatment is a minimum of 3–4 weeks.
 - Treatment should continue until the clinical response is complete.
 - Treatment will be longer if:
 - Concurrent osteomyelitis is present.
 - Most of the course is oral therapy.

SPECIFIC TREATMENTS

Parenteral antibiotic therapy

- Most infections are caused by *S aureus*.
 - An effective antistaphylococcal antimicrobial is almost always part of initial treatment.

- The following is usually sufficient initially.
 - Penicillinase-resistant penicillin (ie, nafcillin or oxacillin) *or*
 - First-generation cephalosporin
- Broader coverage in which vancomycin should be considered as initial therapy instead of a β -lactam is appropriate
 - For a child with signs of bacteremia and sepsis
 - For a child who lives in an area with a high incidence of methicillin-resistant *S aureus*

- Once a pathogen is identified, therapy should be narrowed to treat the specific organism.
- In a severely ill or immunocompromised child or an adolescent who is thought to be abusing an intravenous drug as the cause of a bacteremia
 - Antibiotics selected empirically should be effective against:
 - *S aureus*
 - Enteric Gram-negative bacilli
 - *Pseudomonas*
 - Broad-spectrum penicillin, such as ceftazidime, and an aminoglycoside with vancomycin might be empirical therapy, pending final joint and blood cultures.
- Adolescent with possible gonococcal joint infection
 - Should be treated for staphylococci and gonococci until diagnosis is clarified
 - Cefuroxime or ceftriaxone, perhaps with vancomycin, might be selected, depending on the specifics of the case.
- Neonate
 - A first-generation cephalosporin should *not* be used in a neonate as empirical therapy because of:
 - Poor cerebrospinal fluid penetration
 - The concern for a bacteremia seeding the central nervous system
 - A safer approach would be to:
 - Start empirical therapy with high doses of a penicillin that is effective for treating *S aureus*
 - *Example:* oxacillin
 - Combine with an antibiotic to treat gram-negative enterics
 - Ceftazidime
 - An aminoglycoside
- Parenteral antibiotic therapy is continued:
 - At least until child is doing well *and*
 - Signs of acute infection have resolved

Oral antibiotic therapy

- Oral therapy can sometimes be used to finish treatment when an organism:
 - Has been identified by blood or joint fluid culture *and*
 - An effective oral agent is available

- Oral antibiotics can be used only if:
 - The organism is susceptible to the oral antibiotic.
 - The child's social situation guarantees reliably that the antibiotics will be given as directed.
 - The antibiotic does not cause a gastrointestinal disturbance that might interfere with absorption or compliance.
- The antibiotic must achieve therapeutic levels in bone and joint.
- Laboratory tests (eg, erythrocyte sedimentation rate and C-reactive protein level) should be normalized before switching to an oral agent.

Surgical treatment

- Surgical referral may be required to:
 - Aspirate the joint
 - Reach diagnosis at times
 - Treat the infection
- All children with septic arthritis of the hip should be seen emergently by an orthopaedic surgeon.
 - They require immediate drainage of the joint.
 - Delay in draining a major joint, such as the hip joint, is associated with worse outcomes.
 - Open debridement may be required.
- Other infected joints less often require open debridement but should also be evaluated for surgical treatment.
- Repeated aspirations of a joint may be necessary if fluid reaccumulates.

WHEN TO ADMIT

- All children thought to have bacterial infection of a major joint should be hospitalized.

WHEN TO REFER

- Children being evaluated for bone or joint infection should be evaluated by an:
 - Orthopaedic surgeon *and/or*
 - Infectious disease specialist

COMPLICATIONS

- Pyogenic arthritis constitutes a clinical emergency.
 - Complications of untreated infection include:
 - Dissolution of articular cartilage
 - Necrosis of the underlying epiphysis
 - Destruction of the adjacent growth plate
 - Dislocation of the joint itself
- Possible neuropathies
 - Septic arthritis of the shoulder: brachial plexus neuropathy
 - Septic arthritis of the hip: neuropathies of femoral and sciatic nerves
 - These neuropathies occurring without infection should not be associated with pain or fever.
- Complications can be minimized by:
 - Prompt diagnosis
 - Aggressive treatment

PROGNOSIS

- Consequences of bacterial arthritis can be severe.
 - Direct destructive effect of infection
 - The host's inflammatory response can add to the damage.
 - By increasing intraarticular pressure, intracapsular infection can obstruct blood flow.
 - May lead to necrosis of the epiphysis and underlying growth plate
 - Untreated joint infection can result in joint instability through destruction of the ligamentous fibers of the capsule.
 - These factors are of special concern for the hip joint in children.

Sexually Transmitted Infections

DEFINITION

■ Sexually transmitted organisms

- *Campylobacter* species
- *Chlamydia trachomatis*
- Cytomegalovirus
- *Entamoeba histolytica*
- *Giardia lamblia*
- Hepatitis A and B virus
- Herpes simplex virus types 1 and 2 (HSV-1 and HSV-2)
- Human immunodeficiency virus (HIV)
- Human papillomavirus (HPV)
- Molluscum contagiosum (papovavirus)
- *Mycoplasma genitalium*
- *Mycoplasma hominis*
- *Neisseria gonorrhoeae*
- *Phthirus pubis* (pubic lice)
- *Salmonella* species
- *Sarcoptes scabiei* (mites)
- *Shigella* species
- *Treponema pallidum*
- *Trichomonas vaginalis*
- *Ureaplasma urealyticum*

EPIDEMIOLOGY

■ Prevalence

- 15- to 24-year-olds represent only one-quarter of sexually active individuals in the US, but almost one-half of all sexually transmitted infections (STIs) occur in this age group.

■ Specific agents

- *C trachomatis*
 - Appears to cause 35–50% of symptomatic nongonococcal urethritis among heterosexual men
- *N gonorrhoeae*
 - Overall prevalence, 0.4% (range, up to 2.4%); >95% of patients are asymptomatic.
 - Among young adult women: overall rate of infection, 0.4% (range, up to 1.9%); almost 87% of patients are asymptomatic.
- HPV
 - Most prevalent STI in the US.
 - Infection rates in adolescents and young adults are high.
 - Prevalence of cervical HPV infection among adolescents age 12–21 years is approximately 51–64%.
 - Approximately 45–55% of adolescent girls may become infected over 3 years of observation.
- HSV
 - Infection with HSV-1 has accounted for an increasing proportion of genital herpes infections.

- Prevalence of HSV-2 infection in young people has decreased dramatically in the past decade (with a smaller decline for HSV-1).

■ STIs/syndromes associated with STIs

- Syphilis
 - Rates of primary and secondary syphilis decreased by 90% from 1990–2000, then increased (in men only) from 2000–2004.
 - For the first time in a decade, rate of syphilis among women did not continue to decrease from 2003 to 2004.
 - Syphilis remains a significant problem in the southern US and in some urban areas.
 - Rates have increased since 2000 among men who have sex with men.
- Enteric infections
 - Proctitis and proctocolitis are limited mostly to adolescent boys who practice anal receptive intercourse.

ETIOLOGY

■ Causes of syndromes associated with STI

- Pelvic inflammatory disease (PID)
 - Often results from undetected or inadequately treated STIs of the lower genital tract (endocervix)
 - Sexually transmitted organisms, especially *N gonorrhoeae* and *C trachomatis*, are implicated in many cases.
 - Microorganisms that comprise vaginal flora (eg, anaerobes, *Gardnerella vaginalis*, *Haemophilus influenzae*, enteric gram-negative rods, *Streptococcus agalactiae*) have also been associated with PID.
 - Cytomegalovirus, *Mycoplasma hominis*, *Ureaplasma urealyticum*, and *Mycoplasma genitalium* might be associated with some cases of PID.
- Perihepatitis (Fitz-Hugh–Curtis syndrome)
 - *C trachomatis* infections can cause a picture similar to this condition.
- Epididymitis
 - Among sexually active adolescents, acute epididymitis is most frequently caused by *N gonorrhoeae* or *C trachomatis*.
 - Sexually transmitted enteric organisms (eg, *Escherichia coli*) may be the causative agent in male adolescents who practice anal insertive intercourse.
- Enteric infections
 - A variety of organisms can cause enteritis in HIV-infected patients.
 - Proctitis
 - *N gonorrhoeae*, *C trachomatis* (including lymphogranuloma venereum [LGV] serovars), *T pallidum*, and HSV are the most common sexually transmitted pathogens involved.

- Proctolitis
 - Pathogenic organisms include *Campylobacter* species; *Shigella* species; *E histolytica*; and, rarely, LGV serovars of *C trachomatis*.
- Enteritis
 - In otherwise healthy patients, *G lamblia* is most frequently implicated.
- Vaginitis
 - *T vaginalis* is an important cause of vaginitis among sexually active adolescents.
- Cervicitis
 - Causes include:
 - *C trachomatis* and *N gonorrhoeae*
 - *Trichomonas* species and HSV, especially HSV-2
 - *M genitalium*
 - Bacterial vaginosis
 - Douching
 - In most cases of cervicitis, no etiologic agent is identified.
- Genital HSV infection
 - Most cases of recurrent genital herpes are caused by HSV-2.
 - HSV-1 might become more common as a cause of first-episode genital herpes.
- The major risk factor for PID is a prior episode; adolescent girls who experience illness early in their reproductive life cycle are at great risk for having further significant problems.
- When eliciting history from a patient who has lower abdominal pain, keep in mind factors that place an individual at risk for infection.
 - Failure to use barrier methods of contraception
 - Douching
 - Presence of an intrauterine device
 - Multiple partners
 - Recent change in partner
 - History of other STIs or PID
- Latent syphilis
 - Sex partner documented to have primary, secondary, or early latent syphilis
- Enteric infections
 - Proctitis and proctocolitis are limited mostly to adolescent boys who practice anal receptive intercourse.
 - Enteritis occurs among persons whose sexual practices include oral-anal contact.
- Vaginitis
 - Bacterial vaginosis is associated with:
 - Multiple sex partners
 - New sex partner
 - Douching
 - Male sex partners of women who have bacterial vaginosis more often have *G vaginalis* recovered from urethra than do controls.
 - Nongonococcal, nonchlamydial pathogens associated with PID are recovered more often from endometrium of women who have bacterial vaginosis than from those who do not.

RISK FACTORS

- Why adolescents are at risk for sexually transmitted infections
 - Sense of invulnerability (“It can’t happen to me.”)
 - Lack of information (“If I don’t feel sick, I can’t be sick.”)
 - Inconsistent and improper use of condoms
 - Poor communication skills with partners and physicians
 - Barriers to care (legal obstacles, concerns about confidentiality)
 - Inability to adhere to treatment regimens
 - Sexual networks with high prevalence of infection
 - Physiologic changes associated with puberty
- STIs/syndromes associated with STIs
 - *Chlamydia*
 - Oral contraceptives, a popular method of contraception among adolescents, may increase the risk for chlamydial infection
 - Injections of contraceptive depot medroxyprogesterone acetate (Depo-Provera) may increase the risk for chlamydia.
 - PID
 - Oral contraceptives may protect against development of symptomatic PID.
 - Among all sexually active girls and women, those <19 years of age are at greatest risk for PID.
 - Risk is 1:8 for sexually active 15-year-olds and 1:16 for 16-year-olds, but only 1:80 for 24-year-olds.

SIGNS AND SYMPTOMS

Signs and symptoms, by sex

- Boys
 - Dysuria, discharge, urethral itching (urethritis)
 - Scrotal pain, swelling (epididymitis)
 - Rectal discharge, tenesmus, anorectal pain (proctitis, proctocolitis, colitis)
- Girls
 - Mucopurulent cervicitis
 - Vaginitis (vaginal discharge)
 - Dysuria, urgency, frequency
 - Right upper quadrant abdominal pain
 - PID (low abdominal pain)
 - Bleeding between periods (cervicitis) or a heavier, more prolonged period (PID)

- Both sexes

- Dermatitis
- Genital ulcers (single or multiple)
- Genital warts
- Hepatitis A virus or hepatitis B virus infection
- Lymphadenopathy, especially inguinal or generalized (associated with HIV)
- Persistent pharyngitis
- Septic arthritis

Specific agents

- *C trachomatis*

- Symptoms generally develop 1–3 weeks after infection.
- Male adolescents may report:
 - Only mild dysuria or itching at terminal urethra
 - May have scanty, mucoid discharge that is easily ignored and may disappear without treatment
- Dysuria can be the primary manifestation of infection.
- Female patients may report spotting between periods as a result of cervicitis.
- If infection has spread to the upper genital tract, female patients may report low abdominal pain or right upper quadrant pain (Fitz-Hugh–Curtis syndrome).
- Infections in teenage girls and teenage boys are often asymptomatic.
- At pelvic examination, clues to infection are:
 - Presence of mucopurulent discharge from the cervical os (known as mucopus)
 - Cervical erythema
 - Friability

- *N gonorrhoeae*

- Produces symptoms similar to those of *C trachomatis*
- Symptomatic men tend to have more pronounced symptoms.
 - More severe dysuria
 - Greater amount of and more purulent discharge
- Pharyngitis and proctitis
- The organism may become blood borne and can lead to the so-called arthritis-dermatitis syndrome, disseminated gonococcal infection (DGI).
 - Strains of *N gonorrhoeae* that lead to DGI characteristically tend to cause few genital symptoms.
 - Patients develop fever (although not always) and may have anorexia, malaise, or both.
 - Skin lesions then appear, generally distributed on extremities (arms more often than legs).
 - Lesions appear as erythematous macules <5 mm in diameter; they become pustular and occasionally hemorrhagic or necrotic.

- Lesions are most often noticed near the small joints of the hands and feet.
- Tenosynovitis tends to occur over extensor and flexor tendons of the hands and feet.
- Once tenosynovitis and dermatitis clear, patients develop polyarthralgia but usually seek care only when an oligoarthritis develops.
 - The knee is the joint most commonly infected.
 - Followed by the elbow, ankle, and small joints of the hands and feet

- HPV

- Visible warts usually develop within 6 weeks to 8 months after infection, but the incubation period may be longer.
- Typical pedunculated warts with keratotic and irregular surfaces are easy to recognize.
 - Warts may also be flat and more difficult to detect.
 - Use of a handheld magnifying glass or colposcope is extremely helpful.
- Among male adolescents, warts are usually seen on the penile shaft, prepuce, frenulum, corona, and glans but may also be present on the skin of the scrotum and anus.
- Among female adolescents, the posterior vaginal introitus, labia minora, and vestibule are most common sites of infection, but warts can be seen anywhere on the external or internal genitalia.
- Perianal warts can be seen even in women who have not had anal intercourse.
- Subclinical disease is most likely to occur on the cervix; this relatively large transformation zone of the maturing adolescent cervix affords a hospitable site of infection.

- HSV

- In primary infection, symptoms usually occur 2–20 days after sexual exposure.
- Because primary infection represents the first episode of infection with a particular virus type, systemic symptoms, such as fever, malaise, and headache are common.
- ~50% of patients have tender inguinal lymphadenopathy.
- Burning or itching occurs at the site of inoculation, followed by erythema and development of discrete vesicles.
- Vesicles first contain clear fluid but rapidly form pustules with an erythematous base.
- Patients typically may have 15–30 vesicles, each full of infectious viral particles.
- Female adolescents: Lesions are located on the vulva, cervix, clitoris, or perineum.
- Male adolescents: Lesions may occur on the penile shaft, glans, or prepuce.
- Infection can involve the urethra, leading to dysuria or urinary retention.

- Vesicles can be seen on the thighs, buttocks, groin, or perianal region as a result of autoinoculation or anal receptive perianal region.
- After 2–4 days, pustules break open and coalesce to form wet ulcers (usually prompting patients to seek health care).
- New lesions still may be developing at this point (with a peak at 7–11 days), but within 20 days, all lesions have crusted over, and pain and other symptoms have disappeared.

STIs/syndromes associated with STIs

■ PID

- Suggestive of PID:
 - Presence of a new vaginal discharge (or a change in odor, color, or amount)
 - Abnormal menstrual bleeding (increased or prolonged; occurring at the wrong time in the cycle)
 - Dyspareunia
- Other symptoms include:
 - Dysuria
 - Dysmenorrhea (usually more severe than normal)
 - Nausea
 - Vomiting
 - Diarrhea
 - Fever (<50% of patients)
 - Malaise
- If infection involves capsule of the liver, right upper quadrant tenderness may be elicited.
- With extensive infection, signs of peritonitis, particularly rebound tenderness, are present.
- Palpation of an adnexal mass suggests a coexisting tuboovarian abscess.
- Mucopus visible in the cervical os strongly suggests infection, but its absence does not rule out diagnosis.

■ Syphilis

- The typical chancre of syphilis develops at the site of intimate sexual contact approximately 2–3 weeks after exposure
- The lesion varies in size from a few millimeters to a few centimeters; is clean based and painless; and has sharply demarcated, indurated borders.
- Multiple ulcers may be present.
- Lymphadenopathy is usually present, often bilaterally.
- Because the ulcer is painless, its appearance in the vagina or rectum or even in the mouth is likely to go unnoticed.
- While the ulcer is present, the exudate overlying it is highly infectious.
- Secondary syphilis
 - The rash of secondary syphilis appears 4–10 weeks after chancre appears in an untreated patient.

- Rash and chancre may coexist.
- Constitutional symptoms, such as fever, malaise, sore throat, and generalized lymphadenopathy, may be present.
- Rash is typically papulosquamous but can be macular or pustular.
- Initially, rash involves trunk and flexor surfaces of arms but then spreads to the entire body, including palms, soles, and mucous membranes.
- Annular papules can appear on the face, and rash can resemble impetigo or eczema.
- In some cases, moist, fissured papules or raised, thickened papules (condyloma lata) are seen; both are highly infectious.
- Loss of scalp or eyebrow hair can be associated with secondary syphilis.
- Rash disappears spontaneously 3–12 weeks after appearance; at this point, the patient is classified as having latent syphilis.

■ Perihepatitis (Fitz-Hugh–Curtis syndrome)

- Violin-string adhesions between liver and anterior abdominal wall, localized peritonitis of liver's anterior surface, upper abdominal pain and tenderness
- Onset of upper abdominal pain usually follows the onset of lower abdominal pain, but can precede it.
- Pain generally occurs on the patient's right side and can radiate to the shoulder.

■ Epididymitis

- Acute or subacute onset of unilateral scrotal pain
- Adolescent boys may report testicular pain.
- Preceding symptoms may include urethral discharge and dysuria, but these symptoms may be so mild that they are easily ignored.
- Fever may be present.
- At physical examination, tenderness may occur on palpation of the epididymis, but the testicle may also be slightly tender.
- Hydrocele may be present, and the spermatic cord may be swollen and tender.

■ Enteric infections

- Symptoms of proctitis and proctocolitis include anorectal pain, tenesmus, constipation, and anal discharge.
- Patients with proctocolitis or enteritis have diarrhea.
- Enteritis: Symptoms are usually limited to abdominal pain and diarrhea; other symptoms of proctitis and proctocolitis are absent.

■ Cervicitis

- Characterized by purulent or mucopurulent discharge from endocervical os or by significant endocervical bleeding (or both) that is induced when a swab is introduced into the os

DIFFERENTIAL DIAGNOSIS

Anatomic area

■ Urinary tract

- Cystitis
- Pyelonephritis
- Urethritis
- Other

■ Gastrointestinal tract

- Appendicitis
- Constipation
- Diverticulitis
- Gastroenteritis
- Inflammatory bowel disease
- Irritable bowel syndrome
- Other

■ Reproductive tract

- Acute PID
- Cervicitis
- Dysmenorrhea (primary or secondary)
- Ectopic pregnancy
- Endometriosis
- Endometritis
- Mittelschmerz
- Ovarian cyst (torsion, rupture)
- Pregnancy (intrauterine, ectopic)
- Ruptured follicle
- Septic abortion
- Threatened abortion
- Torsion of adnexa
- Tuboovarian abscess

Specific agents

■ *C trachomatis*

- Profuse, purulent discharge should raise the possibility of *N gonorrhoeae* co-infection or of this being the single causative agent.
- Unless a thorough history is obtained, combination of dysuria and right upper quadrant or right flank pain might lead to the erroneous diagnosis of pyelonephritis.
- Lower abdominal pain suggests the possibility of PID.
- Vaginal discharge is more likely to indicate presence of another infection.

STIs/syndromes associated with STIs

■ PID

- Most symptoms of PID occur in patients with diseases of the urinary tract (eg, pyelonephritis) or gastrointestinal tract (eg, appendicitis).

- Clinical diagnosis of PID has a positive predictive value for salpingitis of 65–90%.
 - Positive predictive value is higher for adolescents and in clinical settings with high prevalence of such STIs as chlamydia or gonorrhea.
- Signs and symptoms can be nonspecific, and the only sure method of diagnosis, laparoscopy, is not routinely performed for diagnostic purposes in the US.
- To avoid misdiagnosis, primary care physicians must:
 - Maintain a high index of suspicion
 - Obtain an extensive history
 - Perform a thorough physical examination
- More elaborate diagnostic evaluation is often needed because incorrect diagnosis and management might cause unnecessary morbidity.
- Additional criteria to enhance specificity of minimal criteria and support a diagnosis of PID include:
 - Oral temperature >101°F (38.3°C)
 - Abnormal cervical or vaginal mucopurulent discharge
 - Abundant leukocytes on saline microscopy of vaginal secretions
 - Increased erythrocyte sedimentation rate
 - Increased C-reactive protein level
 - Laboratory documentation of cervical infection with *N gonorrhoeae* or *C trachomatis*
- Other diagnoses to consider include:
 - Cervicitis
 - Dysmenorrhea (primary or secondary)
 - Ectopic pregnancy
 - Endometriosis
 - Endometritis
 - Mittelschmerz
 - Ovarian cyst (torsion, rupture)
 - Pregnancy (intrauterine, ectopic)
 - Ruptured follicle
 - Septic abortion
 - Threatened abortion
 - Torsion of adnexa
 - Tuboovarian abscess
- Latent syphilis
 - Early latent syphilis cannot be reliably distinguished from late latent syphilis solely on the basis of nontreponemal titers.
 - All patients with latent syphilis should have thorough examination of all accessible mucosal surfaces to evaluate for internal mucosal lesions.
 - Oral cavity
 - Perineum in women

- Perianal area
- Underneath foreskin in uncircumcised men
- Epididymitis
 - In adolescents, rule out testicular torsion.
- Cervicitis
 - Women with cervicitis should be carefully evaluated for:
 - PID
 - Presence of trichomonas and bacterial vaginosis
 - Chlamydia
 - Gonorrhoea

DIAGNOSTIC APPROACH

- When an adolescent seeks care for symptoms and clinical findings that might be caused by an STI, the physician must proceed with appropriate diagnostic tests or therapy, even though the history may appear to exclude such a cause.
- Most sexually active teenagers will be truthful when:
 - Questioned respectfully without parent or guardian present
 - Given appropriate guarantees about confidentiality
- Increasingly widespread availability and use of nucleic acid amplification tests (NAAT) to diagnose *C trachomatis* and *N gonorrhoeae* infections represent major advances.
 - Benefits of these tests
 - More sensitive than culture and previous generations of nonculture tests
 - Do not require recovery of viable organisms
 - Can be performed on urine specimens
 - By eliminating or reducing need for invasive testing, NAAT may expand number of at-risk youth who are screened.
 - Self-collection of vaginal specimens will also enhance detection efforts.

LABORATORY FINDINGS

Specific agents

- *C trachomatis*
 - Gram stain of cervical tissue will reveal presence of 10–30 polymorphonuclear white blood cells (WBCs) per oil-immersion field.
 - Culture of urethral or cervical samples was previously the gold standard for detecting infection.
 - NAAT are considerably more sensitive than culture or older nonculture techniques.
 - Sensitivity of culture for chlamydia is 54–85% from endocervical specimens, versus 88–100% by using various NAAT.
 - Older nonculture tests, such as DNA probes or enzyme-linked immunoabsorbent assays, are only 54–84% sensitive.

- Chlamydia culture remains the only diagnostic test for chlamydia infection admissible in a court of law (eg, in cases of child sexual abuse).

- *N gonorrhoeae*
 - Organism can be grown from:
 - Urethral or cervical discharge
 - Swabs of the vagina, cervix, urethra, pharynx, or rectum
 - Urine sediment (in many cases)
 - In the past, diagnosis rested on culture or classic findings of WBCs and gram-negative intracellular diplococci in Gram stains of discharge or material obtained from a urethral swab.
 - Even under ideal conditions, the organism can be difficult to grow, and physicians relying on culture should be familiar with yield from the laboratory they use.
 - In men, typical Gram stain from a urethral discharge is diagnostic.
 - For samples taken from women, sorting out gram-negative organisms that truly are intracellular versus those that may be overlying or near cells is more difficult.
 - When ≥ 8 pairs of such diplococci are seen in ≥ 2 polymorphonuclear leukocytes, culture will be positive 96% of the time.
 - *N gonorrhoeae* infections can now be diagnosed by NAAT.
 - At least as sensitive as culture results
 - Eliminate pelvic examination or swabbing urethral meatus to obtain specimens
 - Allow use of a urine specimen or vaginal swab
- HSV
 - Cultures of intact vesicles are generally positive, as are cultures of the cervix.
 - Recurrence rates for genital HSV-1 and HSV-2 differ significantly; culture should be obtained whenever a patient presents with new-onset genital herpes.

STIs/syndromes associated with STIs

- PID
 - Acute-phase reactants lack the necessary sensitivity and specificity to help diagnose PID.
 - Although 60–80% of patients have an increased WBC count, sedimentation rate, or C-reactive protein level, so do 20–50% of patients with abdominal pain without PID.
- Syphilis
 - When chancre is present, dark-field examination of nonbloody exudate should be performed by expert in dark-field microscopy.
 - If test is done on 3 successive days, the likelihood of obtaining a positive result from an infected individual is extremely high.
 - If results of all 3 tests are negative, reconsider diagnosis of primary syphilis.

- If dark-field examination is unavailable, obtain serologic test for syphilis.
- If the examiner is relatively certain that chancre is one of primary syphilis, request a fluorescent treponemal antibody absorption test.
 - The sensitivities of the VDRL (Venereal Disease Research Laboratory) flocculation test, rapid plasma reagin (RPR) test, and microhemagglutination assay for antibody to *T pallidum* at this point in the disease process are relatively low.
- Perihepatitis (Fitz-Hugh–Curtis syndrome)
 - <50% of patients have mildly increased liver enzyme levels.
- Epididymitis
 - Supportive laboratory evidence includes:
 - Positive leukocyte esterase test on first-catch urine specimen (the first 20 mL of urine voided) or presence of >10 WBCs per high-power field if first-catch urine specimen is spun down and sediment examined *or*
 - Gram stain of urethral secretions showing >5 WBCs per oil-immersion field
 - If Gram stain also shows WBCs containing intracellular gram-negative diplococci, *N gonorrhoeae* should be considered the causative agent.
- Enteric infections
 - Proctolitis: Fecal leukocytes may be detected on stool examination, depending on the pathogen.

DIAGNOSTIC PROCEDURES

- Patients with proctitis (the distal 10–12 cm of the rectum) should be examined with anoscopy and evaluated for *C trachomatis* (including LGV serovars), *N gonorrhoeae*, herpes simplex virus, and *T pallidum* infection.
- Patients with anal warts and warts on the rectal mucosa can benefit from inspection of the rectal mucosa by digital examination or anoscopy.
- Primary and secondary syphilis
 - After the newborn period (≥ 1 month), examine the cerebrospinal fluid (CSF) of children with syphilis to detect asymptomatic neurosyphilis.
 - Review birth and maternal medical records to assess whether the child has congenital or acquired syphilis.
- Latent syphilis
 - After the newborn period, examine the CSF of children with syphilis to exclude neurosyphilis.
 - Review birth and maternal records to assess whether the child has congenital or acquired syphilis.

TREATMENT APPROACH

- Empiric treatment of PID should be initiated in sexually active young women and others at risk for STIs if:
 - They are experiencing pelvic or lower abdominal pain.
 - No cause for illness other than PID can be identified.

- ≥ 1 of the following minimal criteria are present on pelvic examination.
 - Cervical motion tenderness *or*
 - Uterine tenderness *or*
 - Adnexal tenderness
- Requiring that all 3 of the minimal criteria listed previously be present before initiating antibiotic treatment might result in insufficient sensitivity for diagnosing PID.

SPECIFIC TREATMENTS

C trachomatis

- Co-infection with *C trachomatis* often occurs among patients who have gonococcal infection; therefore, presumptive treatment of such patients for chlamydia is appropriate.
- The following recommended treatment regimens and alternative regimens cure infection and usually relieve symptoms.
- Recommended regimens
 - Azithromycin 1 g orally in a single dose *or*
 - Doxycycline 100 mg orally twice a day for 7 days
- Alternative regimens
 - Erythromycin base 500 mg orally 4 times a day for 7 days *or*
 - Erythromycin ethylsuccinate 800 mg orally 4 times a day for 7 days *or*
 - Ofloxacin 300 mg orally twice a day for 7 days *or*
 - Levofloxacin 500 mg orally once daily for 7 days
- Other considerations
 - Azithromycin
 - Used to treat patients with questionable adherence to multiday dosing
 - In populations with erratic health-care-seeking behavior, poor compliance with treatment, or unpredictable follow-up, may be more cost effective because it offers single-dose, directly observed therapy
 - Doxycycline
 - Costs less than azithromycin
 - No greater risk of adverse events
 - Erythromycin
 - Might be less efficacious than both azithromycin and doxycycline, mainly because gastrointestinal side effects frequently discourage patients from compliance
 - Ofloxacin and levofloxacin
 - Effective but more expensive
 - No advantage with regard to dose regimen
 - Other quinolones
 - Not reliably effective against chlamydial infection *or*
 - Have not been adequately evaluated

- To maximize adherence to recommended therapies, dispense medications for chlamydial infections on site; the first dose should be directly observed.

N gonorrhoeae

Dual therapy for gonococcal and chlamydial infection

- Patients infected with *N gonorrhoeae* often are co-infected with *C trachomatis*.
- Patients treated for gonococcal infection should be treated routinely with regimen effective against uncomplicated genital *C trachomatis* infection.
- Most gonococci in the US are susceptible to doxycycline and azithromycin; thus, routine co-treatment might hinder development of antimicrobial-resistant *N gonorrhoeae*.

Quinolone-resistant *N gonorrhoeae*

- Prevalence of fluoroquinolone resistance among *N gonorrhoeae* isolates in the US has increased and become widespread.
- The Centers for Disease Control and Prevention (CDC) “no longer recommends the use of fluoroquinolones for the treatment of gonococcal infections and associated conditions such as pelvic inflammatory disease.”

Uncomplicated gonococcal infections of the cervix, urethra, and rectum

- Recommended regimens
 - Ceftriaxone 125 mg IM in a single dose *or*
 - Cefixime 400 mg orally in a single dose *plus*
 - Treatment for chlamydia if *C trachomatis* infection is not ruled out
 - Ceftriaxone is safe and effective for treating uncomplicated gonorrhea at all anatomic sites.
 - Cefixime offers the advantage of oral administration.
 - May not be available in many areas; the CDC or state health departments can provide updates on its availability.
- Alternative regimens
 - Spectinomycin 2 g IM in a single dose *or*
 - Single-dose cephalosporin regimens
 - Spectinomycin is expensive and must be injected but is effective.
 - Useful for treating patients who cannot tolerate cephalosporins and quinolones
 - Single-dose cephalosporin regimens that are safe and highly effective against uncomplicated urogenital and anorectal gonococcal infections include:
 - Cefprozime 500 mg IM
 - Cefoxitin 2 g IM with probenecid 1 g orally
 - Cefotaxime 500 mg IM
 - None of the injectable cephalosporins offer any advantage over ceftriaxone.

Uncomplicated gonococcal infections of the pharynx

- More difficult to eradicate than infections at urogenital and anorectal sites
- Few antimicrobial regimens can reliably cure such infections >90% of the time.
- Although chlamydial co-infection of pharynx is unusual, co-infection at genital sites sometimes occurs.
- Therefore, treatment for both gonorrhea and chlamydia is suggested.
- Recommended regimens
 - Ceftriaxone 125 mg IM in a single dose *plus*
 - Treatment for chlamydia if *C trachomatis* infection is not ruled out

DGI

- Hospitalization is recommended for initial therapy in:
 - Patients who cannot be relied on to adhere to treatment
 - Patients in whom the diagnosis is uncertain
 - Patients with purulent synovial effusions or other complications
- Examine patients for clinical evidence of endocarditis and meningitis.
- For patients who are receiving therapy for DGI, presumptively treat for concurrent *C trachomatis* infection unless appropriate testing excludes this infection.
- Recommended regimen
 - Ceftriaxone 1 g IM or IV every 24 hour
- Alternative regimens
 - Cefotaxime 1 g IV every 8 hours *or*
 - Cefprozime 1 g IV every 8 hours *or*
 - Spectinomycin 2 g IM every 12 hours
- Continue all regimens for 24–48 hours after improvement begins, at which time therapy may be switched to 1 of the following regimens to complete at least 1 week of antimicrobial therapy
 - Cefixime 400 mg orally twice a day *or*
 - Cefixime suspension 400 mg twice daily orally (200 mg/5mL) *or*
 - Cefpodoxime 400 mg orally twice daily
- Fluoroquinolones may be an alternative treatment option if antimicrobial susceptibility can be documented by culture.

HPV (genital warts)

- Treatment is primarily directed toward symptomatic warts.
- Clinicians who treat genital warts should determine which technique is most suitable to their practice and become familiar with that technique.
- Clinicians should be knowledgeable about ≥1 physician-applied and 1 patient-applied regimen.
- The primary goal of treating visible genital warts is wart removal.

- In most patients, treatment can induce wart-free periods.
- Factors that might influence selection of treatment include:
 - Wart size
 - Wart number
 - Anatomic site of wart
 - Wart morphology
 - Patient preference
 - Cost of treatment
 - Convenience
 - Adverse effects
 - Provider experience
- Warts located on moist surfaces and in intertriginous areas tend to respond better to topical treatment than do warts on drier surfaces.

Recommended regimens for external genital warts

- Patient-applied options
 - Podofilox 0.5% solution or gel
 - Patients should apply podofilox solution with a cotton swab, or podofilox gel with a finger, to visible genital warts twice a day for 3 days, followed by 4 days of no therapy.
 - Repeat cycle as necessary for a total of 4 cycles.
 - The total wart area treated should not exceed 10 cm, and the total volume of podofilox should not exceed 0.5 mL per day.
 - If possible, the primary care physician should apply initial treatment to show proper technique and identify which warts should be treated.
 - The safety of podofilox during pregnancy has not been established.
 - Imiquimod 5% cream
 - Patients should apply imiquimod cream once daily at bedtime, 3 times a week for up to 16 weeks.
 - Wash the treatment area with mild soap and water 6–10 hours after the application.
 - The safety of imiquimod during pregnancy has not been established.
- Physician-administered options
 - Cryotherapy with liquid nitrogen or cryoprobe
 - Repeat applications every 1–2 weeks.
 - Podophyllin resin 10–25% in compound tincture of benzoin
 - Apply a small amount to each wart; allow to air dry.
 - Repeat treatment weekly if necessary.
 - Trichloroacetic acid (TCA) or bichloroacetic acid (BCA) 80–90%
 - Apply a small amount only to warts and allow to dry, at which time a white frosting develops.
 - Powder with talc, sodium bicarbonate (ie, baking soda), or liquid soap to remove unreacted acid if an excess amount is applied.
 - Repeat weekly if necessary.
 - Surgical removal by tangential scissor excision, tangential shave excision, curettage, or electrocautery
- Alternative treatments
 - Intralesional interferon *or*
 - Laser surgery
- Other considerations
 - Podofilox 0.5% solution or gel
 - Relatively inexpensive
 - Easy to use
 - Safe
 - Self-applied by patients
 - Most patients experience mild or moderate pain or local irritation after treatment.
 - Imiquimod
 - Local inflammatory reactions (redness and irritation) are common and usually mild to moderate.
 - Cryotherapy
 - Clinicians must be trained in proper use because over treatment or under treatment can result in complications or low efficacy.
 - Pain after application of the liquid nitrogen, followed by necrosis and sometimes blistering, is not unusual.
 - Local anesthesia (topical or injected) might facilitate treatment if warts are present in many areas or if the area of warts is large.
 - Podophyllin resin
 - Over application or failure to air dry can result in local irritation caused by spread of the compound to adjacent areas.
 - TCA and BCA can spread rapidly if applied excessively, damaging adjacent normal tissue.
 - If pain is intense, then acid can be neutralized with soap or sodium bicarbonate (ie, baking soda).
 - Because of shortcomings of available treatments, some clinics use combination therapy (≥ 2 modalities on the same wart at the same time).
 - No data support use of >1 therapy at a time to improve the efficacy of treatment.
 - Combining modalities may increase complications.

Recommended regimens for cervical warts

- For exophytic cervical warts, high-grade squamous intra-epithelial lesions must be excluded before treatment is begun.
- Management of exophytic cervical warts should include consultation with an expert.

Recommended regimens for vaginal warts

- Cryotherapy with liquid nitrogen
 - Use of a cryoprobe in the vagina is not recommended because of risk for vaginal perforation and fistula formation.
- TCA or BCA 80–90% applied to warts
 - Apply a small amount only to warts and allow to dry, at which time a white frosting develops.
 - Powder with talc or baking soda or liquid soap preparations to remove unreacted acid if an excess amount is applied.
 - Repeat weekly if necessary.

Recommended regimens for urethral meatus warts

- Cryotherapy with liquid nitrogen
- Podophyllin 10–25% in compound tincture of benzoin
 - The treatment area must be dry before contact with normal mucosa.
 - Can be applied weekly if necessary
 - The safety of podophyllin during pregnancy has not been established.
- Although data on podofilox and imiquimod for treating distal meatal warts are limited, some specialists recommend their use in some patients.

Recommended regimen for anal warts

- Cryotherapy with liquid nitrogen
- TCA or BCA 80–90% applied to warts
 - Apply a small amount only to warts and allow to dry, at which time a white frosting develops.
 - Powder with talc or baking soda or with liquid soap preparations to remove unreacted acid if an excess amount is applied.
 - Repeat weekly if necessary.
- Surgical removal
- Manage warts on the rectal mucosa in consultation with a specialist.

HSV

- Genital HSV infection
 - Recommended regimens
 - Acyclovir 400 mg orally 3 times a day for 7–10 days *or*
 - Acyclovir 200 mg orally 5 times a day for 7–10 days *or*
 - Famciclovir 250 mg orally 3 times a day for 7–10 days *or*
 - Valacyclovir 1 g orally twice a day for 7–10 days
 - Treatment may be extended if healing is incomplete after 10 days of therapy.
- Established HSV-2 infection
 - Antiviral therapy for recurrent disease can be administered:
 - Continuously as suppressive therapy to reduce the frequency of recurrences *or*

- Episodically to ameliorate or shorten the duration of lesions
- Suppressive therapy (valacyclovir 500 mg daily) decreases HSV-2 transmission in disease-discordant heterosexual couples in which the source partner has a history of genital HSV-2 infection.
- Suppressive therapy probably reduces transmission in persons with multiple partners (including men who have sex with men) and those who are HSV-2 seropositive without history of genital herpes.
- Recommended regimens for daily suppressive treatment
 - Acyclovir 400 mg orally twice a day *or*
 - Famciclovir 250 mg orally twice a day *or*
 - Valacyclovir 500 mg orally once a day *or*
 - Valacyclovir 1.0 g orally once a day
- Valacyclovir 500 mg once a day may be less effective than other valacyclovir or acyclovir regimens in patients with very frequent recurrences (≥ 10 episodes per year).

■ Episodic therapy for recurrent genital herpes

- Initiate within 1 day of lesion onset or during the prodrome that precedes some outbreaks.
- Provide the patient with a supply of drug or prescription for medication with instructions to initiate treatment as soon as symptoms begin.
- Recommended regimens
 - Acyclovir 400 mg orally 3 times a day for 5 days *or*
 - Acyclovir 800 mg orally twice a day for 5 days *or*
 - Acyclovir 800 mg orally 3 times a day for 2 days *or*
 - Famciclovir 125 mg orally twice a day for 5 days *or*
 - Famciclovir 1.0 g orally twice daily for 1 day *or*
 - Valacyclovir 500 mg orally twice a day for 3 days *or*
 - Valacyclovir 1.0 g once a day for 5 days

M genitalium

- Treatment is more effective with azithromycin than with tetracyclines.

PID

- When selecting a treatment regimen, consider availability, cost, patient acceptance, and antimicrobial susceptibility.
- Parenteral treatment
 - For mild to moderate PID, parenteral therapy and oral therapy appear to have similar clinical efficacy.
 - Clinical experience should guide decisions on transition to oral therapy, which usually can begin within 24 hours of clinical improvement.
 - Recommended parenteral regimen A
 - Cefotetan 2 g IV every 12 hours *or*
 - Cefoxitin 2 g IV every 6 hours *plus*
 - Doxycycline 100 mg orally or IV every 12 hours

- Other considerations
 - Doxycycline should be administered orally when possible, even when the patient is hospitalized.
 - Discontinue parenteral therapy 24 hours after the patient improves clinically.
 - Oral therapy with doxycycline (100 mg twice a day) should continue for a total of 14 days.
 - For tuboovarian abscess, many primary care physicians use clindamycin or metronidazole with doxycycline for continued therapy, rather than doxycycline alone, because they provide more effective anaerobic coverage.
 - Other second- or third-generation cephalosporins (eg, ceftizoxime, cefotaxime, ceftriaxone) might be effective therapy for PID and might replace cefotetan or cefoxitin; however, they are less active than cefotetan or cefoxitin against anaerobic bacteria.
- Recommended parenteral regimen B
 - Clindamycin 900 mg IV every 8 hours *plus*
 - Gentamicin loading dose IV or IM (2 mg/kg of body weight) followed by a maintenance dose (1.5 mg/kg) every 8 hours; single daily dosing may be substituted.
 - Other considerations
 - Although a single daily dose of gentamicin has not been evaluated for treatment of PID, it is efficacious in analogous situations.
 - Discontinue parenteral therapy 24 hours after the patient improves clinically.
 - Continuing oral therapy should consist of doxycycline 100 mg orally twice a day or clindamycin 450 mg orally 4 times a day to complete a total of 14 days of therapy.
 - For tuboovarian abscess, many primary care physicians use clindamycin for continued therapy rather than doxycycline because clindamycin provides more effective anaerobic coverage.
- Alternative parenteral regimens
 - Ampicillin/sulbactam 3 g IV every 6 hours *plus*
 - Doxycycline 100 mg orally or IV every 12 hours
- Oral treatment
 - Recommended oral regimen
 - Ceftriaxone 250 mg IM in a single dose *plus*
 - Doxycycline 100 mg orally twice a day for 14 days, *with or without*
 - Metronidazole 500 mg orally twice a day for 14 days *or*
 - Cefoxitin 2 g IM in a single dose and probenecid, 1 g orally administered concurrently *plus*
 - Doxycycline 100 mg orally twice a day for 14 days, *with or without*
 - Metronidazole 500 mg orally twice a day for 14 days *or*
 - Other parenteral third-generation cephalosporin (eg, ceftizoxime or cefotaxime) *plus*
 - Doxycycline 100 mg orally twice a day for 14 days, *with or without*
 - Metronidazole 500 mg orally twice a day for 14 days
 - Other considerations
 - The optimal choice of cephalosporin is unclear.
 - Cefoxitin has better anaerobic coverage; ceftriaxone has better coverage against *N gonorrhoeae*.
 - Metronidazole will effectively treat bacterial vaginosis, which is frequently associated with PID.
 - No data have been published on use of oral cephalosporins for treating PID.
 - Limited data suggest that oral metronidazole plus doxycycline after primary parenteral therapy is safe and effective.
- Alternative regimens
 - If parenteral cephalosporin therapy is not feasible, consider:
 - Fluoroquinolones (levofloxacin 500 mg orally once daily *or*
 - Ofloxacin 400 mg orally twice daily for 14 days), *with or without*
 - Metronidazole (500 mg orally twice daily for 14 days) if the community prevalence and individual risk of gonorrhea are low
 - Perform tests for gonorrhea before instituting therapy.
 - Manage the patient as follows if the test is positive.
 - If NAAT are positive, a parenteral cephalosporin is recommended.
 - If culture for gonorrhea is positive, base treatment on results of antimicrobial susceptibility.
 - If the isolate is quinolone-resistant *N gonorrhoeae* or antimicrobial susceptibility cannot be assessed, a parenteral cephalosporin is recommended.
 - Although data are limited, amoxicillin/clavulanic acid and doxycycline or azithromycin with metronidazole has shown short-term clinical cure.

Syphilis

■ Primary and secondary syphilis

- Parenteral penicillin G is the preferred drug for treating all stages of syphilis.
- Preparation or preparations used (ie, benzathine, aqueous procaine, aqueous crystalline), dose, and length of treatment all depend on stage and clinical manifestations of disease.
- Recommended regimen for children
 - Evaluate children with acquired primary or secondary syphilis (including consultation with child-protection services) and treat them by using the following pediatric regimen.
 - Benzathine penicillin G 50,000 units/kg IM, up to adult dose of 2.4 million units in a single dose.

- A child or adolescent weighing ≥ 48 kg would receive the adult dose.
- Latent syphilis
 - Treatment usually does not affect transmission and is intended to prevent late complications.
 - Although clinical experience supports the effectiveness of penicillin in achieving this goal, limited evidence is available for guidance in choosing specific regimens.
 - Recommended regimen for adults (nonallergic patients who have normal CSF examination, if performed)
 - Early latent syphilis
 - Benzathine penicillin G 2.4 million units IM in a single dose
 - Late latent syphilis or latent syphilis of unknown duration
 - Benzathine penicillin G 7.2 million units total, administered as 3 doses of 2.4 million units IM each at 1-week intervals
 - Recommended regimens for children
 - Treat older children with acquired latent syphilis using the following pediatric regimens.
 - These regimens are for penicillin-nonallergic children with acquired syphilis who have normal CSF examination results.
 - Early latent syphilis
 - Benzathine penicillin G 50,000 units/kg IM, up to adult dose of 2.4 million units, in a single dose (a child or adolescent who weighs ≥ 48 kg would receive the adult dose)
 - Late latent syphilis or latent syphilis of unknown duration:
 - Benzathine penicillin G 50,000 units/kg IM, up to adult dose of 2.4 million units, administered as 3 doses at 1-week intervals (total 150,000 units/kg up to the adult dose of 7.2 million units)

Perihepatitis (Fitz-Hugh–Curtis syndrome)

- Treatment for PID eliminates perihepatitis.

Epididymitis

- All patients should receive ceftriaxone plus doxycycline for initial treatment.
- Additional therapy may include a quinolone if:
 - Acute epididymitis is not caused by gonorrhea (results from culture or NAAT are negative) *or*
 - Infection is most likely caused by enteric organisms.
- Recommended regimens
 - For acute epididymitis most likely caused by gonococcal or chlamydial infection:
 - Ceftriaxone 250 mg IM in single dose *plus*
 - Doxycycline 100 mg orally twice a day for 10 days

- For acute epididymitis most likely caused by enteric organisms, or with negative culture or NAAT, or for patients allergic to cephalosporins or tetracyclines or both:
 - Ofloxacin 300 mg orally twice a day for 10 days *or*
 - Levofloxacin 500 mg orally once daily for 10 days

Enteric infections

- If anorectal exudate is found on examination, or if polymorphonuclear leukocytes are found on Gram-stained smear of anorectal secretions, the following may be prescribed pending results of additional laboratory tests.
- Recommended regimen
 - Ceftriaxone 125 mg IM (or another agent effective against rectal and genital gonorrhea) *plus*
 - Doxycycline 100 mg orally twice a day for 7 days
- Patients with suspected or documented herpes proctitis should be managed as for genital herpes.
- If painful perianal ulcers are present or mucosal ulcers are detected on anoscopy, then presumptive therapy should include a regimen for treating genital herpes.
- If LGV proctitis and proctocolitis are present, administer doxycycline (100 mg orally twice daily for 3 weeks).

Vaginitis

- Treatment of symptomatic women who have bacterial vaginosis is warranted.
- Asymptomatic women who are scheduled to undergo abortion or hysterectomy should also be treated.

Cervicitis

- Adolescents with cervicitis should be presumptively treated for C trachomatis, especially if follow-up is uncertain or if the clinician does not have access to NAAT.
- Appropriate therapy for gonorrhea should be provided if the prevalence of infection in patient population is $>5\%$.

WHEN TO ADMIT

- PID
 - In the past, some experts suggested that all patients with PID be hospitalized so that bed rest and supervised treatment with parenteral antibiotics might be initiated.
 - However, in women with mild or moderate PID, outpatient therapy can provide short- and long-term clinical outcomes similar to inpatient therapy.
 - Limited data support use of outpatient therapy in women with more severe disease.
 - The decision to hospitalize should be based on the discretion of primary care physician.
 - The following criteria for hospitalization are suggested.
 - Surgical emergencies, such as appendicitis, cannot be excluded.
 - The patient is pregnant.

- The patient does not respond clinically to oral antimicrobial therapy.
- The patient cannot follow or tolerate an outpatient oral regimen.
- The patient has severe illness, nausea and vomiting, or high fever.
- The patient has a tuboovarian abscess.
- Many practitioners have preferred to hospitalize adolescents with suspected acute PID, but no evidence supports this approach.
 - Adolescents with mild to moderate acute PID have similar outcomes with outpatient or inpatient therapy.
 - Clinical response to outpatient therapy is similar among adolescents and older women.
 - The decision to hospitalize an adolescent should be based on the same criteria as for older women.
- Most clinicians favor at least 24 hours of direct inpatient observation for patients who have tuboovarian abscesses.
- Epididymitis
 - Consider hospitalization if:
 - Pain is particularly severe.
 - The patient is febrile.
 - Nonadherence is of concern.

WHEN TO REFER

- If the clinician is inexperienced in the diagnosis or management of:
 - PID
 - DGI
 - Syphilis (or positive VDRL or RPR test)
 - Anogenital warts
 - Genital herpes
 - Abnormal Papanicolaou (Pap) smears

FOLLOW-UP

Specific agents

- *C trachomatis*
 - Except for pregnant women, patients do not need to be retested for chlamydia after completing treatment unless:
 - Adherence is in question.
 - Symptoms persist.
 - Reinfection is suspected.
 - False-negative results might occur because of small numbers of chlamydial organisms.
 - NAAT done <3 weeks after completion of therapy for patients treated successfully might yield false-positive results because of continued presence of dead organisms.
 - Rates of infection are high among women retested several months after treatment (presumably because of reinfection by an untreated sex partner).
 - Infection from a new partner with chlamydia is also possible.
 - Repeat infections confer increased risk for PID and other complications compared with initial infection.
 - Consider advising all women with chlamydial infection to be retested approximately 3 months after treatment.
 - Retest all women treated for *C trachomatis* whenever they next seek medical care in the next 3–12 months, regardless of whether the woman believes her sex partner or partners were treated.
- *N gonorrhoeae*
 - Test of cure is not indicated for patients with uncomplicated gonorrhea treated with any of the recommended or alternative regimens.
 - Patients with symptoms that persist after treatment should be evaluated with culture for *N gonorrhoeae*, and any gonococci isolated should be tested for antimicrobial susceptibility.
 - Persistent urethritis, cervicitis, or proctitis also might be caused by *C trachomatis* or other organisms.
- HPV
 - Careful follow-up is essential to monitor results and prevent regrowth between too-widely-spaced treatment intervals.
 - Because identifying external warts may be difficult, follow-up evaluation 3 months after treatment may be useful for patients.
 - Earlier follow-up visits also may be useful to:
 - Document wart-free status
 - Monitor for or treat complications of therapy
 - Provide opportunity for patient education and counseling
 - Traditionally, follow-up visits are not usually recommended for patients using self-administered treatments, but they may be useful several weeks into therapy to:
 - Determine whether treatment is being applied correctly
 - Measure response to treatment
 - The benefit of treating subclinical HPV infection in absence of cervical dysplasia is unclear.
 - Examination and treatment of sex partners is of uncertain benefit.
 - The treatment modality should be changed if the patient has not improved substantially.
 - Most genital warts respond within 3 months of therapy.
 - Response to treatment and side effects should be evaluated throughout therapy.
 - After visible genital warts have cleared, follow-up evaluation may be helpful.

- Caution patients to watch for recurrences, which occur most frequently during the first 3 months.
- Counsel women about the need for regular Pap screening as recommended for women without genital warts.

■ HSV

- Lesions generally heal without scarring.
- Safety and efficacy have been documented among patients receiving daily therapy with:
 - Acyclovir for as long as 6 years
 - Valacyclovir or famciclovir for 1 year
- The frequency of recurrences diminishes over time in many patients, and the patient's psychological adjustment to disease might change.
- Periodically (eg, once a year), clinicians should discuss the need to continue suppressive therapy with the patient.

STIs/syndromes associated with STIs

■ PID

- If outpatient therapy is attempted, ensure careful follow-up at 48 hours and establish mechanism for hospitalizing the patient before that time if symptoms worsen.

■ Syphilis

- Follow-up with repeat clinical evaluation and serologic testing should occur at 6 and 12 months.
- More frequent evaluation is warranted if findings at follow-up are uncertain.
- Criteria for reevaluation or retreatment include:
 - Persistence or recurrence of clinical signs and symptoms
 - Sustained ≥ 4 -fold increase in titers
 - Failure of nontreponemal tests to decrease 4-fold within 6 months after treatment for primary or secondary syphilis
- All patients with syphilis should be screened for HIV infection.

■ Primary and secondary syphilis

- Treatment failure can occur with any regimen.
- Assessing response to treatment is often difficult; no definitive criteria for cure or failure have been established.
- Nontreponemal test titers may decline more slowly for patients who previously had syphilis.
- Patients should be reexamined clinically and serologically 6 and 12 months after treatment; more frequent evaluation may be prudent if follow-up is uncertain.
- Patients probably have treatment failure or were reinfected and should be retreated and reevaluated for HIV infection if:
 - They have signs or symptoms that persist or recur.
 - They have a sustained 4-fold increase in nontreponemal test titer (ie, compared with the maximum or baseline titer at time of treatment).

- Treatment failure usually cannot be reliably distinguished from reinfection with *T pallidum*; lumbar puncture should be performed.
- Failure of nontreponemal test titers to decline 4-fold within 6 months after therapy for primary or secondary syphilis might indicate probable treatment failure.
- Persons whose titers remain serofast should be reevaluated for HIV infection.
 - Optimal management of such patients is unclear.
 - At a minimum, they should have additional clinical and serologic follow-up.
 - HIV-infected patients should be evaluated more frequently (ie, at 3-month intervals instead of 6-month intervals).
- If additional follow-up cannot be ensured, retreatment is recommended.
- Because treatment failure might be the result of unrecognized central nervous system infection, many specialists recommend CSF examination in such situations.
- When patients are retreated, most experts recommend:
 - Weekly injections of benzathine penicillin G 2.4 million units IM for 3 weeks *unless*
 - CSF examination indicates that neurosyphilis is present.

■ Latent syphilis

- Patients who are seroreactive but do not have any physical findings of infection are classified as having latent syphilis.
- Patients who are known to have seroconverted within the previous 12 months are classified as having early latent syphilis, as are those who, within the previous year:
 - Have had unequivocal symptoms of primary or secondary syphilis
 - Have had a sex partner documented to have primary, secondary, or early latent syphilis
 - Have reactive treponemal and nontreponemal tests with the only possible exposure occurring within the previous year
- Repeat quantitative nontreponemal serologic tests at 6, 12, and 24 months.
- Patients with normal CSF examination should be retreated for latent syphilis if:
 - Titers increase 4-fold.
 - An initially high titer ($\geq 1:32$) fails to decrease ≥ 4 -fold (ie, 2 dilutions) within 12–24 months.
 - Signs or symptoms attributable to syphilis develop.

■ Epididymitis

- Adolescents treated as outpatients should be followed up within 48–72 hours of initiating treatment.
- Failure to improve should prompt reevaluation of the diagnosis and the treatment.

- Sex partners of adolescents with epididymitis suspected of being or confirmed to be caused by chlamydia or gonorrhoea should be evaluated and treated if their contact with index patient occurred <60 days before onset of the patient's symptoms.

COMPLICATIONS

■ Long-term sequelae of STIs

- Cervical cancer
- Infertility
- Ectopic pregnancy
- Chronic pelvic pain
- AIDS

■ Ample evidence exists that STIs increase an individual's risk for acquiring HIV infection.

■ Specific agents

- *C trachomatis*
 - Infection with chlamydia is not an independent risk factor for development of cervical dysplasia, but it may play some role.
 - An untreated infected woman can pass the organism to her infant through colonization during birth.
- *N gonorrhoeae*
 - Gonorrhoea may produce epididymitis and PID.
 - In addition and in contrast to chlamydia, the gonococcal organism can become blood borne and can lead to so-called arthritis-dermatitis syndrome, or DGI.
- HPV
 - HPV infection has been associated with >90% of cervical dysplasia worldwide.
 - Complications rarely occur if treatments for warts are used properly.
 - Persistent hypo- or hyperpigmentation is common with ablative modalities.
 - Depressed or hypertrophic scars are rare but can occur, especially if the patient has had insufficient time to heal between treatments.
 - Treatment can result rarely in disabling chronic pain syndromes (eg, vulvodynia or analdynia, hyperesthesia of the treatment site) or, in the case of rectal warts, painful defecation or fistulas.
 - A limited number of case reports of severe systemic effects from podophyllin resin and interferon have been documented.
 - To prevent the possibility of complications associated with systemic absorption and toxicity, 2 important guidelines should be followed.
 - Application should be limited to <0.5 mL of podophyllin or an area <10 cm of warts per session.
 - No open lesions or wounds should exist in the area to which the treatment is to be applied.

• HSV

- HSV infections of the male and female genital tract are particularly distressing to patients because of the potential for recurrence after initial episode, especially if caused by infection with HSV-2.
- After the infection resolves, the virus remains latent in the sacral ganglia and may reactivate at any time.
- Vesicles usually occur near the initial infection site but tend to be fewer in number.
- Just before recurrence, the patient may experience burning or itching at the site of infection.
- Healing takes place within 1–2 weeks.
- Recurrences may occur in association with stress, local trauma, fever, or menstruation and tend to be shorter and less symptomatic.
- In the year after a first documented episode of genital HSV-2 infection, 90% of individuals will have ≥ 1 recurrence, about one-third will have ≥ 6 , and one-fifth will have ≥ 10 .
- The risk of recurrence depends on many factors.
 - Male adolescents are somewhat more likely to have recurrent disease, as are those whose infection was caused by HSV-2.
 - Once a second episode occurs, the patient is likely to have multiple recurrences.
- Some patients with recurrent disease may benefit from therapy if it begins during the prodrome or within 1 day lesion onset.
- Those with ≥ 6 recurrences per year have a 75% reduction in recurrences with daily suppressive therapy.
- Patient-initiated administration of a single-day course of famciclovir also shortens the duration of recurrences.
- Valacyclovir reduces asymptomatic virus shedding and reduces the risk of infection in couples who are serodiscordant for HSV-2.
- Most cases of recurrent genital herpes are caused by HSV-2, although HSV-1 might become more common as a cause of first episode genital herpes.
- Most patients with symptomatic, first-episode genital HSV-2 infection will have recurrent episodes of genital lesions; recurrences are less frequent after initial genital HSV-1 infection.
- Intermittent asymptomatic shedding occurs in persons with genital HSV-2 infection, even in those with long-standing or clinically silent infection.

■ STIs/syndromes associated with STIs

- PID
 - In the short term, PID can lead to such problems as tuboovarian abscess.
 - In the long run, the following are attributable to PID, even when an acute episode has been managed appropriately.

- Tubal factor infertility
 - Chronic pelvic pain
 - Increased risk for ectopic pregnancy
 - Failure to see improvement should raise concerns about the accuracy of diagnosis or presence of complications.
 - Repeat pelvic examination to look for a tuboovarian abscess if one has not already been detected.
 - Approximately 10–20% of patients with PID develop tuboovarian abscess; 3–15% of these abscesses rupture.
 - Risk for infertility and ectopic pregnancy increases with the number of episodes of PID and with the severity of infection.
 - Women >25 years at time of diagnosis are less likely to develop either complication.
 - Syphilis
 - Evaluate all patients with latent syphilis for evidence of tertiary disease (eg, aortitis, gumma) and syphilitic ocular disease (eg, iritis, uveitis).
 - Patients with syphilis who demonstrate any of the following should have a prompt CSF examination.
 - Neurologic or ophthalmic signs or symptoms
 - Evidence of active tertiary syphilis (eg, aortitis, gumma)
 - Treatment failure
 - HIV infection with late latent syphilis or syphilis of unknown duration
 - Some specialists recommend examining CSF in all patients who have latent syphilis and a nontreponemal serologic test of at least 1:32 or if the patient is HIV infected with a CD4 count ≤ 350 cells/mm³.
 - The likelihood of neurosyphilis in this circumstance is unknown.
 - If CSF examination demonstrates abnormalities consistent with neurosyphilis, then the patient should be treated.
- PREVENTION**
- Specific agents
 - *C trachomatis*
 - Screening programs reduce the incidence of PID.
 - Treatment of infected patients prevents transmission to sex partners.
 - For infected pregnant women, treatment usually prevents transmission of *C trachomatis* to infants during birth.
 - Treatment of sex partners helps prevent reinfection of the index patient and infection of other partners.
 - To minimize further transmission of infection, instruct patients treated for chlamydia to abstain from sexual intercourse for 7 days after single-dose therapy or until completion of a 7-day regimen.
 - Instruct patients to abstain from sexual intercourse until all sex partners are treated to minimize the risk for reinfection.
 - HPV
 - Pap screening
 - Evidence links HPV with the development of dysplastic and malignant changes in the cervix.
 - Routine Pap smear screening to detect precancerous lesions is extremely important.
 - Because most HPV infections among adolescents resolve spontaneously, Pap smear screening in adolescents may lead to additional diagnostic testing that can be psychologically upsetting, unnecessary, and expensive.
 - American Cancer Society recommends that Pap smear screening begin within 3 years of initiation of voluntary sexual intercourse or age 21, whichever comes first.
 - Some experts suggest initiating earlier screening for adolescents who:
 - Have many sexual partners
 - Are immunosuppressed
 - Are at risk for nonadherence to follow-up advice
 - These experts recommend initial screening of teenagers who have been sexually abused (with penetration) whenever feasible by someone skilled in examining this population.
 - Immunosuppressed women should be screened every 6 months in the first year and then yearly as long as the result is normal.
 - Use of HPV DNA typing has become an important adjunct to the management of abnormal Pap smear screening findings in adult women.
 - Use may be limited in teenagers because HPV infection is so common among sexually active adolescents yet tends to be self-limited (ie, rarely progresses to cervical cancer).
 - Current guidelines from the American Society for Colposcopy and Cervical Pathology do not include the use of HPV DNA typing for the management of adolescents (age ≤ 20 years) with atypical squamous cells of undetermined significance or low-grade squamous intraepithelial cells on Pap smear screening.
 - HPV vaccine
 - The US Food and Drug Administration recently approved a 3-dose (0, 2, and 6 months) quadrivalent HPV vaccine containing virus-like particles of types 6, 11, 16, and 18.

- The Advisory Committee on Immunization Practices recommends:
 - Administration to girls age 11 and 12 as a priority
 - Vaccine can be offered to girls as young as 9 years of age.
 - Recommended for those age 13–26 years who have not been vaccinated or have not received all 3 doses
- Protective effect appears to last for 2.5–3.5 years; whether a booster dose will be needed is unknown at this time.
- Sex partners
 - Examination of sex partners is not necessary for management of genital warts because no data indicate that reinfection plays a role in recurrences.
 - Providing treatment solely to prevent future transmission cannot be recommended because the value of treatment in reducing infectivity is unknown.
 - Sex partners of patients with genital warts might benefit from counseling and examination to assess the presence of genital warts and other sexually transmitted infections.
- Female sex partners of patients with genital warts should be reminded that cytologic screening for cervical cancer is recommended for all sexually active women.
- Herpes genitalis
 - Glycoprotein vaccine to prevent HSV-2 infection has a protective effect at 5 months but not at 1 year for persons receiving the vaccine.
- STIs/syndromes associated with STIs
 - Syphilis
 - Because all syphilis symptoms may not be present in everyone infected, most adolescents with syphilis will be identified only through routine serologic screening.
 - Testing at-risk youth is important.
 - Clinicians should strongly consider screening any sexually active adolescent with a generalized eruption (eg, that seen with pityriasis rosea) for syphilis.

Shock

DEFINITION

- Shock can be considered a progressive process of compensated, decompensated, and irreversible states.
- Shock, especially septic shock and hypovolemic shock caused by diarrhea or blood loss, is a common cause of pediatric morbidity and mortality.
- Refractory shock
 - Persists despite aggressive fluid management, use of pressors, and maintenance of normal glucose and calcium levels, and thyroid and adrenal status
- Septic shock
 - Classified by perfusion status
 - Shock can be defined by:
 - Clinical signs and symptoms
 - Hemodynamic variables
 - Parameters of oxygen delivery

EPIDEMIOLOGY

- Prevalence
 - Severe sepsis is one of the most common causes of death in infants and children in the world.
 - In 1995 sepsis was the 4th leading cause of death in infants and the 2nd leading cause of death in children ages 1 to 14 years.
 - Diarrhea leading to dehydration severe enough to produce shock is no longer a common cause of death in the US.
 - Remains a world health problem
 - Septic shock is the most common and best-studied cause of cardiovascular collapse.
 - Causes of bacterial septic shock have changed since vaccination against *Haemophilus influenzae* type b was instituted in 1988.
 - Meningococci and streptococci are the most frequently encountered causes of sepsis.
 - Presence of shock increases morbidity and mortality when it complicates other childhood diseases.
 - Investigators at the University of Pittsburgh evaluated 1766 children with respiratory disease who required transport to a tertiary facility.
 - Shock complicated the respiratory failure presentation in 25% (440) of the children, and this group had a mortality rate of 38%.
 - In the group of children transferred for respiratory failure only, without shock present, the mortality rate was only 3%.
- Incidence
 - Meningitis and sepsis
 - 1.3:100,000 in the US
 - 15:100,000 in Ireland

■ Cost

- In an analysis of data from 1997 hospitalizations, children with severe sepsis had an average hospital stay of 31 days, at a cost of \$40,600 per case.
- In a 2005 report, the national annual cost of caring for children with severe sepsis alone is estimated at \$2.3 billion.

ETIOLOGY

- In all shock states, oxygen delivery and blood flow to vital organs is decreased or cellular oxygen needs are increased, and metabolic demands are not met, resulting in multiple organ failure.
- Shock is the result of inadequate perfusion of oxygen and nutrients (eg, glucose) to vital organs.
 - Perfusion is a clinical representation of the combined effects of cardiac output and systemic vascular resistance.
 - Delivery of oxygen to tissue is the product of content of oxygen in blood and cardiac output.
- In young children, the pulse rate is a reasonable proxy of cardiac output, and capillary refill rate is a reliable indicator of perfusion.
 - Cardiac output is the product of heart rate and stroke volume, which is expressed in liters of blood flow per minute.
 - Hypotension (loss of peripheral vascular tone) is sensed by baroreceptors, which act through mediators to increase both heart rate and stroke volume.
- In older children and adults, stroke volume depends on contractility (inotropy) and preload (venous return to the right heart).
 - Contractility of the myocardium is depressed by acidosis, hypoglycemia, and hypocalcemia.
 - Epinephrine and other catecholamines act as inotropic agents, increasing contractility.
- Preload is the vascular volume presented to the heart during diastole, which stretches cardiac muscle, to enable optimal contraction during systole.
 - Clinically, the central venous pressure or a pulmonary capillary wedge pressure and left atrial pressure represent preload to right and left ventricles, respectively.
 - A patient with hypovolemia is said to have a low preload.
 - If blood volume is restored, preload increases and stroke volume is increased (see “point a” in Figure 92 on page F30).
- Hypovolemic shock
 - Shock from loss of blood volume caused by trauma, diarrhea, burns, and third-spacing (as in peritonitis)
 - Most common form of shock in children
 - Loss of fluid leads to low intravascular volume.
 - Preload to the heart is decreased.

- In hypovolemic shock caused by trauma or diarrhea:
 - Pulses would be thready, heart rate would be high, and the capillary refill rate is >2 seconds.
 - Physiologically, patient has a low vascular volume, heart rate is high in an effort to restore blood flow, and systemic vascular resistance is elevated; thus, the skin is cool and poorly perfused.
 - **Cardiogenic shock**
 - Can be caused by mechanical obstruction or muscle (pump) failure
 - In obstructive cardiogenic shock, air and fluid in the pericardium or pleural spaces (rarely) can:
 - Impede venous return to the heart
 - Decrease systolic ejection
 - Massive pulmonary embolus
 - Rare in children
 - Can obstruct flow from the right to the left side of the heart
 - Cardiac output is also compromised in:
 - Coarctation of the aorta
 - Hypoplastic left heart syndrome
 - Left ventricular outflow tract stenosis
 - High volumes may stretch the heart muscle, and diastolic or systolic function (or both) may be altered.
 - Preload is high, but contractility (inotropy) is greatly diminished (see “point b” in Figure 92 on page F30).
 - **Septic shock**
 - The most frequently encountered bacterial causes of sepsis (except in the immunocompromised) are:
 - Meningococci
 - Streptococci
 - Children with sepsis may exhibit symptoms of hyperdynamic, vasodilated shock (see “point c” in Figure 92 on page F30).
 - Physiologically, cardiac output is high, peripheral vasculature is vasodilated, venous return (preload) to the heart is diminished, and systemic vascular resistance is low.
 - Symptoms result not from low cardiac output, but rather from maldistribution of blood flow.
 - **Distributive shock**
 - Global disorder in vasomotor control is present.
 - Causes maldistribution of blood flow and oxygen to tissue
 - The 2 types most likely to be encountered in primary care are:
 - Anaphylaxis
 - Spinal cord injury
 - Cardiac output may be normal or increased.
 - Patients lose sympathetic control of the vascular system, which reduces peripheral vascular tone, resulting in pooling of blood in the periphery.
 - This leads to decreased venous return to the heart.
- RISK FACTORS**
- Infants and children at risk of severe septic shock include:
 - Those with septic shock and purpura
 - Those with known or suggested adrenal abnormalities
 - Those who have received a therapeutic course of steroids within 6 months
 - **Shock in infants**
 - Cardiac
 - Hypoplastic left heart syndrome
 - Coarctation of the aorta
 - Myocarditis
 - Arrhythmia
 - Infectious
 - Family history
 - In a study of Danish families, risk of death was increased 5-fold in children whose parent had died of a severe infection before the age of 50 years.
 - Bacterial meningitis
 - Urinary tract sepsis
 - Herpes (meningitis and sepsis)
 - Streptococcal sepsis
 - Metabolic
 - Hypoglycemia
 - Inborn errors of metabolism
 - Traumatic
 - Child abuse
 - Occult central nervous system hemorrhage
 - Surgical
 - Bowel obstruction
 - Occult blood loss
 - **Causes of hypovolemic shock**
 - Gastrointestinal losses
 - Excess urine output, diuretic administration
 - Mannitol administration
 - Hypoalbuminemia
 - Burns
 - Third-space fluid losses
 - Peritonitis
 - Edema
 - Traumatic blood loss
 - **Causes of obstructive cardiogenic shock**
 - Tamponade (air, blood, or effusion)

- Coarctation of the aorta
- Aortic valve stenosis or atresia
- Pump failure
 - Arrhythmia
 - Hypoplastic left heart syndrome
 - Decreased contractility acquired in sepsis syndrome or shock of any cause
 - Myocardiopathy
 - Myocarditis
 - Anomalous coronary artery
 - Cardiac contusion
 - Glycogen storage disease

SIGNS AND SYMPTOMS

- Hyperthermia or hypothermia
- Altered mental status
 - Lethargy
 - Confusion
 - Coma (implies significant brain hypoperfusion)
- Oliguria
 - Defined as urine output <0.5 mL/kg/h
 - Caveats
 - Many children have multiple caretakers during a typical day.
 - Frequency and volume of urination may not be accurately recounted.
- Patients with high obligatory urine losses:
 - Those with high-output renal failure
 - Those with hyperglycemia (diabetes mellitus)
 - Those receiving diuretics
 - Those who have received mannitol
- Altered perfusion diagnosed by capillary refill (>2 seconds) before the onset of hypotension
 - Brisk in warm shock (vasodilated)
 - Delayed in cold shock (vasoconstricted)
- Cold shock
 - Patient is cold to the touch, with capillary refill rate >2 seconds.
 - Patient has increased peripheral vascular resistance.
- Warm shock
 - Patient is warm to the touch.
 - Patient has a rapid blush of capillary refill.
 - Patient has a vasodilated, low peripheral resistance shock.
- Fluid refractory dopamine-resistant shock
 - Persistence of symptoms with >60 mL/kg in the first hour of fluid therapy and dopamine infusion of 10 mcg/kg min

- Catecholamine-resistant shock
 - Shock persists despite addition of epinephrine or norepinephrine, or both.
 - Hypovolemic shock
 - Increased thirst
 - Increased heart rate
 - Retention of fluid by concentrating urine
 - Large volumes of fluid loss result in:
 - Diminished mental status
 - Tachycardia
 - Poorly perfused skin with prolonged capillary refill; oliguria; and, eventually, hypotension
 - Mild dehydration: 5%
 - Dry skin, mild tachycardia, concentrated urine
 - Moderate dehydration: 10%
 - Lethargy, poor perfusion
 - Severe dehydration: 15%
 - Obtundation, tachycardia, hypotension, very poor perfusion to skin
 - Hemorrhagic shock
 - Physical findings correlate to the volume of blood loss.
 - 15% loss: minimal tachycardia, normal respiratory rate, blood pressure, and capillary refill
 - 15–30% loss: tachycardia, tachypnea, decreased pulse pressure, normal systolic pressure, prolonged capillary refill, anxiety
 - 30–40% loss: hypotension, decreased urine output, mental status changes
 - $>40\%$ loss: hypotension, loss of consciousness
 - Cardiogenic shock
 - Low cardiac output resulting in the clinical signs of:
 - Altered mental status
 - Tachycardia
 - Decreased capillary refill rate
 - Evidence of venous congestion (hepatomegaly, rales)
 - Children with pericardial effusion may have muffled heart sounds.
 - Decompensated phase of shock
 - Tachycardia
 - Hypotension occurs as the child's compensatory mechanisms are exhausted.
 - Vital signs and leukocyte count by age group are shown in the table Vital Signs and White Blood Counts by Age.
- ### Differential Diagnosis
- Infants
 - A broader differential diagnosis should be considered for infants <6 weeks.

Vital Signs and White Blood Counts by Age^a

Age Group	Heart Rate— Tachycardia	Heart Rate— Bradycardia	Respiratory Rate	Systolic Blood Pressure	Leukocyte count × 10/mm
0 days to 1 wk	>180	<100	>50	<65	>34
1 wk to 1 mo	>180	<100	>40	<75	>19.5 or <5
1 mo to 1 yr	>180	<90	>34	<100	>17.5 or <5
2–5 yr	>140	NA	>22	<94	>15.5 or <6
6–12 yr	>130	NA	>18	<105	>13.5 or <4.5
13–<18 yr	>110	NA	>14	<117	>11 or <4.5

^a From: Goldstein B, Giroir B, Randolph A. International pediatric sepsis consensus conference: definitions for sepsis and organ dysfunction in pediatrics. *Pediatr Crit Care Med.* 2005;6(1):2–8.

- Early discharge of newborns shortly after birth requires attention to both acquired and congenital or inherited conditions.
- **Toddlers**
 - Shock in toddlers usually has a determinable, apparent cause.
 - Clinician should be aware of the propensities that are unique to this age group, especially:
 - Poisoning
 - Ingestion of medications
 - Inhaling and swallowing of foreign bodies
 - Trauma resulting from falls
 - Playground and household accidents
 - Child abuse
- **Adolescents**
 - May not be forthright in volunteering an accurate history
 - Risk-taking behavior of the teen years should be taken into consideration.
 - Poisoning after attempted suicide or experimentation with drugs and alcohol may not be reported.
 - Antipsychotic medications can cause cardiovascular collapse and arrhythmias.
 - Ingestion of antihypertensive agents and opiates in the home should be considered.
- In all age groups, note:
 - History of travel
 - Possibility of *Salmonella* infection
 - Recent exposure to pets
 - Exposure to organophosphates
 - Indicated by weakness at presentation
- Hemolytic-uremic syndrome is implicated by:
 - Recent ingestion of meat
 - Early onset of central nervous system symptoms with bloody diarrhea
- **Hypovolemic shock**
 - Shock from loss of blood volume caused by trauma, diarrhea, burns, and third-spacing (as in peritonitis)
 - Most common form of shock in children
 - Loss of fluid leads to low intravascular volume.
 - Preload to the heart is decreased.
 - In hypovolemic shock caused by trauma or diarrhea:
 - Pulse is thready, heart rate is high, and the capillary refill rate is >2 seconds.
 - Physiologically, the patient has a low vascular volume, heart rate is high in an effort to restore blood flow, and systemic vascular resistance is elevated; thus, the skin is cool and poorly perfused.
- **Cardiogenic shock**
 - Can be caused by mechanical obstruction or muscle (pump) failure
 - In obstructive cardiogenic shock, air and fluid in the pericardium or pleural spaces (rarely) can:
 - Impede venous return to the heart
 - Decrease systolic ejection
 - Massive pulmonary embolus
 - Rare in children
 - Can obstruct flow from the right to the left side of the heart
 - Cardiac output is also compromised in:
 - Coarctation of the aorta
 - Hypoplastic left heart syndrome
 - Left ventricular outflow tract stenosis
 - High volumes may stretch the heart muscle, and either or both diastolic and systolic function may be altered.
 - Preload is high, but contractility (inotropy) is greatly diminished (see “point b” in Figure 92 on page F30).

■ Septic shock

- The most frequently encountered bacterial causes of sepsis (except in the immunocompromised) are:
 - Meningococci
 - Streptococci
- Children with sepsis may exhibit symptoms of hyperdynamic, vasodilated shock (see “point c” in Figure 92 on page F30).
- Physiologically, cardiac output is high, peripheral vasculature is vasodilated, venous return (preload) to the heart is diminished, and systemic vascular resistance is low.
- Symptoms result not from low cardiac output, but rather from maldistribution of blood flow.
- Children and adults have developmental differences in hemodynamic response.
 - In adults, death is caused by a pressor- and volume-resistant state characterized as vasomotor paralysis.
 - Myocardial dysfunction is common in adults.
 - Cardiac output is maintained by tachycardia and ventricular dilatation.
 - In pediatric septic shock, low cardiac output, not vasodilatation, is associated with mortality.
 - In children, oxygen delivery is the major determinant of oxygen consumption.
 - In adults, oxygen used by tissues (oxygen extraction) is more important.
- Survival correlates to the restoration of:
 - Cardiac output
 - Oxygen delivery

■ Distributive shock

- Global disorder in vasomotor control is present.
- Causes maldistribution of blood flow and oxygen to tissue
- The 2 types most likely to be encountered in primary care are:
 - Anaphylaxis
 - Spinal cord injury
- Cardiac output may be normal or increased.
- Patients lose sympathetic control of the vascular system, which reduces peripheral vascular tone, resulting in pooling of blood in the periphery.
- This leads to decreased venous return to the heart.

DIAGNOSTIC APPROACH

- In the primary care setting, the diagnosis is based on clinical signs and symptoms.
- Shock in the pediatric setting is a relatively common emergency.
- Early stages of shock are easy to recognize.
- The primary care physician can dramatically reduce morbidity and mortality by:

- Recognizing and treating shock early in the community setting
- Following consensus guidelines and algorithms

■ Infants in shock present unique diagnostic challenges.

- Algorithmic approaches to shock diagnosis developed for children and adults may not be appropriate.

■ Shock can be diagnosed in the early compensated state by easily detectable clinical signs:

- Altered mental status
- Tachycardia
- Decreased capillary refill rate
- Changes in blood pressure and urine output
- Intervention in this state has the highest likelihood of success.

■ Children with sepsis may exhibit symptoms of hyperdynamic, vasodilated shock (see “point c” in Figure 92 on page F30).

- Cardiac output is high.
- Peripheral vasculature is vasodilated.
- Venous return (preload) to the heart is diminished.
- Systemic vascular resistance is low.
- Symptoms result not from low cardiac output, but rather from maldistribution of blood flow.
- On physical examination, the patient:
 - Has brisk capillary refill
 - Is warm to the touch
 - Has bounding pulses, tachycardia, and a hyperdynamic precordium

■ Heart rate

- Infants cannot increase stroke volume as readily as adults.
 - Increase in heart rate is a compensatory mechanism to increase blood flow to vital organs.
 - An infant in shock whose heart rate is 2 standard deviations above normal is attempting to increase cardiac output.
- The return of pulse rate and blood pressure to normal values is a valuable indicator of therapeutic success.
- After the patient is stabilized, an accurate history may help selection of appropriate treatments and guide referral.

LABORATORY FINDINGS

■ In a patient with cardiovascular symptoms, confirm inadequate perfusion:

- Unexplained metabolic acidosis (base deficit >3.0 mEq/L)
- Increased arterial lactate level (2 times upper limit of normal)

TREATMENT APPROACH

- Early treatment with fluids and pressor therapy for shock remains the same regardless of the cause.

- The clinician should be confident in treating the hemodynamic abnormalities first and establishing the cause later.
- Early treatment does not require:
 - Sophisticated monitors
 - Central venous catheters
 - Invasive monitoring
- The 3 basic principles that should guide therapy are:
 - Prompt recognition of a patient in shock
 - Rapid restoration of systemic and regional perfusion to prevent ongoing shock and cellular injury
 - Prevention of the development of end-organ failure
- Treatment of shock, especially in primary care settings, is based on:
 - Restoring adequate circulating blood volume
 - Achieving adequate delivery of glucose and oxygen to all tissues
 - Monitoring and documenting the patient's response to each intervention is essential.
 - Early volume resuscitation and vasopressor therapy are always indicated in the treatment of shock.
 - A common error is to give too little fluid too slowly.
 - Gauge the patient's response to fluid administration.
- Patients are critically ill and in catecholamine-resistant shock if they:
 - Remain tachycardic
 - Have poor capillary refill
 - Have inadequate urine output (<0.5 mL/kg/h) after 60 mL/kg of fluid and the addition of 2 vasopressors
 - Placement of a central venous catheter is recommended at this point.
 - Patients in this decompensated state will require referral to a tertiary pediatric intensive care unit for further diagnosis and treatment.
- Hypotension and tachycardia are indicative of severe shock in a decompensating patient.
- Restoration of blood pressure and reduction of heart rate indicate therapeutic success.
- Severe septic shock
 - Some patients may develop a hypoadrenal response characterized by refractory shock.
 - By definition, these patients are unresponsive to:
 - Volume resuscitation
 - Addition of 2 catecholamine drugs
 - Normalization of:
 - Acid-base status
 - Glucose level
 - Calcium homeostasis

SPECIFIC TREATMENTS

Guidelines for treatment of shock

- Guidelines for diagnosis, care, and treatment of infants and children are simple to understand and follow (see Figure 93 on page F31).
 - Timely recognition and treatment are critical.
- American College of Critical Care Medicine Clinical Practice Parameters for Hemodynamic Support of Pediatric and Neonatal Shock
 - 5 minutes:
 - First, secure airway and ventilation.
 - Children have low lung volumes and are at risk for hypoxemia.
 - Establish venous access within 5 minutes of recognition of shock.
 - An intraosseous device or peripheral intravenous device suffices for this purpose; central access is not part of the first response.
 - Begin monitoring the child.
 - 15 minutes:
 - Administer intravenous fluids.
 - Fluid needs can exceed 60 mL/kg of body weight.
 - The volume of each fluid bolus should be 20 mL/kg.
 - 30 minutes (15 minutes after fluid therapy begins):
 - For children who do not immediately respond to fluid administration (15 minutes from beginning of fluid therapy), begin infusion of dopamine, a first-line catecholamine, at a dose of 5–20 mcg/kg/min.
 - Infants <6 months may not respond as well to dopamine.
 - Children who do not respond to dopamine infusion up to 20 mcg/kg/min and fluid resuscitation have dopamine-fluid refractory shock.
 - Institute epinephrine (for cold shock) or norepinephrine (for warm shock) infusions.
 - Monitor and restore the following to normal levels:
 - Glucose
 - Serum hemoglobin or hematocrit
 - Acid-base homeostasis
 - Ionized calcium
 - 60 minutes:
 - Children who do not respond to fluid and an infusion of 2 catecholamine agents within 60 minutes have catecholamine-resistant shock.
 - Adrenal insufficiency should be considered.
 - Refer to a tertiary care pediatric intensive care unit if children do not respond to:
 - Fluid administration
 - Dopamine and epinephrine or norepinephrine infusions

- These children require diagnostic evaluation for cardiac function and will require:
 - Central venous access
 - Echocardiography
 - Mixed venous oxygen saturation monitoring

Management of shock

■ Fluid replacement

- No conclusive data are found in the literature proving superiority of one fluid.

- Commonly used solutions are:
 - Normal saline (20–80 mL/kg)
 - Lactated Ringer solution
 - 5% albumin (20–80 mL/kg)

■ Glucose replacement

- Children consume glucose at a faster rate than adolescents and adults.
- In infants and toddlers, glucose levels should be considered a vital sign.
- Blood glucose needs to be added to maintain adequate blood glucose levels.
- Glucose replacement is crucial, especially in very young patients.
- Glucose level should be maintained at >60 mg/dL.

■ Oxygen

- All patients in shock should immediately be given 100% oxygen.
- Oxygenation should be monitored continuously with a pulse oximeter.
 - Values should be documented in the patient's record.
 - Normal oxygen saturation on a pulse oximeter does not imply adequate tissue delivery.
- Maintain hemoglobin (the carrying vehicle for oxygen) at a normal level.
- In septic shock, adequate oxygen delivery is associated with improved survival.
- Blood transfusions may be necessary to ensure adequate oxygen delivery.
 - Despite concerns over the adverse effect of transfusion, hemoglobin or hematocrit must be monitored.
 - Maintaining the hemoglobin at least 10-g percentage is reasonable.
- If circulation is compromised and cardiac output decreases, oxygen delivery to tissues will be compromised.
 - Oxygen delivery is the product of oxygen content and cardiac output.
- Oxygen content = $1.36 \times$ the percentage of saturation \times hemoglobin (in grams), expressed as milliliters of oxygen per 100 mL of blood.

- In healthy children, oxygen consumption is 25% of oxygen delivery.
- In shock states, oxygen consumption may increase simultaneously with inadequate cardiac output, leading to inadequate tissue oxygenation.
- In lung disease or hypoventilation:
 - Hemoglobin is desaturated.
 - Oxygen delivery is compromised further.

- Arterial lactic acidosis (normal level is <2 mmol/L) or an increasing base deficit (>3 mEq) document inadequate perfusion.

- The effects of restoring the pH to >7.25 are important.

- Myocardial contractility is enhanced.
- Sensitivity to catecholamines is improved.
- Potassium is returned to the intracellular space.

- Sodium bicarbonate may be required to:

- Improve blood pH to >7.25
- Bring serum bicarbonate levels to >15 mEq/dL

- Any remaining base deficit may be corrected by using the following guide:

- $0.3 \times$ body weight in kilograms \times base deficit = milliequivalents of sodium bicarbonate

- Hypocalcemia is common.

- Total calcium measurements do not correlate with measurements of the biologically important ionized calcium.
- Restoring ionized calcium to normal levels improves myocardial contractility.

- Platelet counts

- Unless bleeding is evident, platelet counts of 20,000 to 50,000 cells/mm³ are tolerated well.
- Prothrombin time and partial thromboplastin time should be maintained at approximately 1.3 times normal values.
- Fresh frozen plasma, administered at 10 mL/kg, is a reasonable method of:
 - Repairing volume deficit
 - Replenishing coagulation factors
- Rapid infusion of fresh frozen plasma can contribute to hypotension resulting from the presence of vasoactive kinins.

- Therapeutic end points are:

- Capillary refill rate <2 seconds
- Normal peripheral pulses
- Warm limbs
- Urine output >1 mL/kg/hr
- A decreasing lactic acid level or improved base deficit
- Normalization of mental status

Anaphylactic shock

- The inciting agent should be removed if possible.
- These patients uniformly respond well to:
 - Volume administration
 - Epinephrine infusion
 - Antihistamines that include an H₂-receptor blocker
 - Steroid therapy

Catecholamine-resistant shock

- In patients whose shock state is refractory to volume restoration, dopamine or dobutamine, and addition of epinephrine or norepinephrine
 - Empirically initiating stress-dose steroids (hydrocortisone at stress doses of 50–100 mg/m²/day would be reasonable).
- If time and condition allow:
 - A baseline serum cortisol level
 - A 250 microgram dose of corticotropin
 - Repeat cortisol level measurement at 30 minutes.
 - The response (or absence of) will determine the presence of a hypoadrenal state and the need for continued steroid administration.
 - A baseline serum cortisol <18 mcg/dL and a poststimulation increment <9 mcg/dL indicate a hypoadrenal state.
 - If a stimulation test cannot be done, continuation of steroid therapy for 3–5 days should be based on clinical response.

Vasopressor drugs

- Drugs of choice in the early treatment of shock are:
 - Dopamine (5–20 mcg/kg/min)
 - In the majority of cases of shock, dopamine with adequate fluid replacement saves the patient.
 - Norepinephrine (0.01–0.2 mcg/kg/min)
 - Epinephrine (0.01–0.2 mcg/kg/min)
 - Dobutamine (5–20 mcg/kg/min)
- A vasoactive drug should be infused continuously with a calibrated infusion pump.
- Continuous heart rate and blood pressure monitoring is required.
- Catecholamines do not replace adequate, aggressive, and early fluid administration as the initial treatment of shock.
- Catecholamines are classified by their relative effects on the α - or β -receptor.
 - The α -receptor produces vasoconstriction, which accounts for its salutary effect in raising blood pressure.
 - β -Agonists have 2 receptor sites.
 - β_1 -Agonist receptors stimulate heart rate and cardiac muscle contractility.
 - Toxicity is reflected in cardiac tachyarrhythmias and ischemia.

- β_2 -Agonist receptors are present in bronchial and arteriole smooth muscles.
 - These muscles relax when stimulated.
- These agents stimulate adenylyl cyclase activity.
- One of the effects is increased entry of potassium into cells.

Dopamine

- The drug of choice
- Administered at 5–20 mcg/kg/min, titrated to effect
- The α -adrenergic effects predominate with:
 - Vasoconstriction
 - Reduced peripheral perfusion
- Patients who do not respond to fluid resuscitation of 60 mL/kg and dopamine at 20 mcg/kg/min:
 - Are in a state called *dopamine fluid resistant shock*
 - Require addition of epinephrine (cold shock) or norepinephrine (warm shock)
- Infants <6 months may not respond well to dopamine; epinephrine (0.01–0.2 mcg/kg/min) may be more effective.
- In some circumstances, especially shock after hypoxic-ischemic injury, epinephrine or dobutamine may be preferred because dopamine may:
 - Precipitate tachyarrhythmias
 - Increase myocardial oxygen consumption

Dobutamine (5–20 mcg/kg/min)

- Children who are thought to have low cardiac output may benefit from dobutamine.
- Dobutamine differs from dopamine because of:
 - Enhanced inotropic effect
 - Less chronotropic effect
 - Less effect on systemic vascular resistance

Hydrocortisone (2 mg/kg/dose)

- Indicated in limited circumstances
- Stress-dose steroids at 1–2 mg/kg hydrocortisone are indicated in:
 - Children with anaphylaxis
 - Those with known or suggested adrenal abnormalities
 - Children who have received a therapeutic course of steroids for chronic illness in the previous 6 months
- Children in refractory septic shock may respond to hydrocortisone.

Other vasodilator drugs, such as nitroprusside, milrinone (0.3–0.7 mcg/kg/min), and nitroglycerine, may be beneficial in reducing afterload when the patient has high peripheral vascular resistance and low cardiac output.

- Should only be used in selected situations and in tertiary care settings
- Optimizes myocardial contractility
- Improves cardiac output

- Requires sophisticated monitoring, including:
 - Pulmonary arterial oximetry
 - Cardiac output measurement
 - Pulmonary vascular pressure catheters

Experimental therapies

- Trials of activated protein C and granulocyte-macrophage colony stimulating factor have been unsuccessful or have not affected outcomes for pediatric patients.
- Extracorporeal membrane oxygenation has not been explored adequately in children in shock and should be performed only at the few centers capable of supporting this technology.
- Survival in cases of septic shock has not been improved in trials of:
 - Ibuprofen
 - Antibody to endotoxin
 - Antibody to tumor necrosis factor- α

FOLLOW-UP

- Monitoring the child in shock includes:
 - Measurement of the capillary refill rate
 - Documentation of mental status
 - Pulse oximetry
 - Continuous electrocardiography
 - Blood pressure (measured with a cuff)
 - Temperature measurement
 - Urine output measurement
 - Glucose and ionized calcium level
 - Serum hemoglobin level or hematocrit
- Hepatomegaly is a reliable indicator of volume overload and cardiac compromise.
- Successful resuscitation is recognized by:
 - Return of pulse rate to normal
 - Improvement in mental status
 - Return of capillary refill
 - Improvement in acid-base status

COMPLICATIONS

Organ failure in septic shock

- Cardiovascular dysfunction despite administration of isotonic intravenous fluid bolus ≥ 40 mL/kg in 1 h
 - Decrease in blood pressure (hypotension): < 5 th percentile for age or systolic blood pressure > 2 standard deviations below normal for age or
 - Need for vasoactive drug to maintain blood pressure in normal range (dopamine > 5 mcg/kg/min or dobutamine, epinephrine, or norepinephrine at any dose) *or*
 - 2 of the following:
 - Unexplained metabolic acidosis: base deficit > 5.0 mEq/L

- Increased arterial lactate: > 2 times upper limit of normal
- Oliguria: Urine output < 0.5 mL/kg/h
- Prolonged capillary refill: > 5 seconds
- Core to peripheral temperature gap: $> 3^{\circ}\text{C}$

■ Respiratory

- PaO₂/FiO₂ ratio: < 300 in absence of cyanotic heart disease or preexisting lung disease *or*
- PaCO₂: > 65 torr or 20 mm Hg over baseline PaCO₂ *or*
- Proven need or $> 50\%$ FiO₂ to maintain saturation $\geq 92\%$ *or*
- Need for nonelective invasive or noninvasive mechanical ventilation

■ Neurologic

- Glasgow Coma Score ≤ 11 *or*
- Acute change in mental status with a decrease in Glasgow Coma Score ≥ 3 points from abnormal baseline

■ Hematologic

- Platelet count: $< 80,000$ cells/mm³ or a decrease of 50% in platelet count from highest value recorded over the past 3 days (for patients with chronic hematologic disease or cancer) *or*
- International normalized ratio: > 2

■ Renal

- Serum creatinine: ≥ 2 times upper limit of normal for age *or*
- 2-fold increase in baseline creatinine level

■ Hepatic

- Total bilirubin level: ≥ 4 mg/dL (not applicable for newborn) *or*
- Alanine aminotransferase levels: 2 times upper limit of normal for age

Acute respiratory distress syndrome (ARDS)

- A common form of hypoxemic respiratory failure that occurs 24–48 hours after presentation in shock
- The child becomes dyspneic and hypoxemic.
 - PaO₂/FiO₂ ratio: < 200
- Physical examination reveals rales and tachypnea.
- Chest radiography reveals diffuse infiltrates.
- These changes may be delayed for ≥ 24 hours.
- Interstitial edema that appears to be caused by a capillary leak syndrome
- ARDS is life threatening, and patients should be referred to a tertiary intensive care unit.
 - The following may be required.
 - Mechanical ventilation
 - Positive end-expiratory pressure
 - Right heart catheters
 - High-frequency oscillatory ventilation
 - Extracorporeal membrane support

Myocardial depression

- Commonly encountered in septic shock
- Inadequate perfusion, increased work, and distension in the presence of inflammatory mediators affect contractility.
- May lead to a decrease in cardiac output

Renal failure

- Renal failure, especially acute tubular necrosis, is a common complication.
- Suggested when the urine output is <0.5 mL/kg/hr, despite adequate restoration of blood volume.
- A serum creatinine level more than twice normal for age is diagnostic.
- Aggressive use of dialysis and hemofiltration has minimized morbidity resulting from this complication.
- Unrecognized renal failure will increase mortality resulting from shock.
- Serum levels of drugs in the blood become uncertain.
- Doses of antibiotics, sedatives, and analgesics must be monitored carefully, following blood levels in serum whenever possible.
- Fluid therapy must be titrated carefully to insensible fluid loss replacement; otherwise, congestive heart failure will result.
- Anuria or oliguria complicating shock requires referral or consultation with a nephrologist or intensivist.
- Diuretics may increase mortality in acute renal failure.

Hypoxemia and ischemia

- The central nervous system is most susceptible.
- A child may suffer significant neurologic impairment, although other organs are spared.
- Early central nervous system signs of shock include:
 - Delirium
 - Irritability
 - Confusion
 - Coma
- Signs of increased intracranial pressure are usually delayed 24–72 hours after a hypoxemic-ischemic insult.
- Presence of increased intracranial pressure accompanying the acute presentation of shock implies a traumatic or metabolic etiology.
- A Glasgow Coma Score <11 or a decrease of 3 points from baseline is diagnostic of central nervous system compromise.

Impaired liver function

- May become impaired as a result of inadequate perfusion
- Bilirubin levels >4 mg/dL and alanine aminotransferase levels greater than twice normal are diagnostic of hepatic failure.
- Clotting factors may be diminished.
- In septic shock, liver perfusion may be adequate, but bacteria or toxins may damage hepatic cells.
- Liver failure is usually transient.

PROGNOSIS

- The most important predictor of outcome is appropriate resuscitation and reversal of shock within 75 minutes of recognition.
- Mortality rates
 - Higher in patients with infection caused by:
 - *Staphylococcus aureus*
 - *Pseudomonas aeruginosa*
 - *Candida* species
 - *Streptococcus pyogenes*
 - Lower in patients with infection caused by:
 - Coagulase-negative *Staphylococcus*
 - *Acinetobacter* species
 - Invasive meningococcal disease
 - Mortality remains high despite modern advances in critical care.
 - Most common in children <4 years
 - Characteristics of cases rapidly progressing to death include:
 - Young age
 - Absence of meningitis
 - Thrombocytopenia
 - Leukopenia
 - Multiorgan failure
 - Severity of petechiae
- If organ failure develops, the child can enter a phase of refractory shock, with increased morbidity and mortality.
- A study of children who were treated following the American College of Critical Care Medicine *Pediatric Advanced Life Support* (ACCM-PALS) practice parameters for hemodynamic support:
 - Demonstrated increased survival and decreased morbidity in infants and children in shock treated by community physicians compared with a group where these algorithms were not followed.
- In a 9-year study, community physicians successfully achieved shock reversal within 75 minutes of recognition in 24 of 91 children.
 - Survival increased to 96%.
 - >9 -fold increase in the odds of survival
 - Each additional hour of persistent shock was associated with >2 -fold increase in the odds of death.
 - Shock resuscitation was consistent with ACCM-PALS guidelines in 30% of patients.
 - When practice was consistent with these guidelines, mortality was only 8% compared with 38% in the children treated without following the guidelines.
 - These data parallel and corroborate findings in adults.

Short Stature

DEFINITION

- The accepted medical definition of when a child is too short may be at variance with when parents worry about their child's height.
- The normal range for height encompasses 2 standard deviations above and below the mean (between the 97th and the 3rd percentiles).
 - The 3rd percentile may be difficult to appreciate, since the lowest curve on many growth charts is the 5th percentile.
- A single point on a growth chart often does not define a worrisome growth pattern.
 - Previous growth data should be plotted whenever available.
 - Any suggestion of growth deceleration should be reviewed.
- Standard growth charts do not incorporate pubertal stage.
 - Short children who start puberty relatively late may appear to fall further behind even though they are growing at a normal rate.

MECHANISM

- Constitutional growth delay (CGD)
 - Children grow below but parallel to the 3rd percentile line.
 - Birth weight is normal, but between 6 and 24 months, linear growth and weight track downward to the 3rd percentile or below.
 - After age 3 years, children follow their own curve parallel to the low end of the growth chart.
 - Children with CGD typically have a delayed onset of puberty/growth spurt.
- Familial short stature (FSS)
 - The child is growing at a normal rate below the 3rd percentile.
 - ≥ 1 parents are quite short.
 - Tend to have puberty at a normal age and to achieve an adult height within 2–3 inches of their adult target height
- Other causes of short stature
 - Certain syndromes
 - Being born small for gestational age (SGA)
 - Chronic illness
 - Nutritional disorders
 - Medications
 - Endocrine disorders
 - Idiopathic short stature (ISS): no known cause

HISTORY

- The growth curve is most helpful for evaluation.
 - If the growth rate has been normal for the previous ≥ 2 years, the child most likely has CGD or FSS and is unlikely to have a defined, treatable cause.

- A single point that falls off the established curve is often a measurement error and should be rechecked.
- A history of stimulant medications or glucocorticoid use might be key information.
- Decreased energy level and poor appetite
 - Could indicate a chronic, growth-limiting illness
 - Many short, healthy children are picky eaters.
- Abnormal stool history could indicate:
 - Malabsorption
 - Celiac disease
 - Inflammatory bowel disease
- Family history
 - May suggest FSS in a healthy child who is short but growing at normal rate
 - Height of parents and grandparents
 - Growth percentiles of siblings
 - Two-thirds of children with CGD have a family history of a parent who was a late maturer.
 - Mother's menarche after age 14 years
 - Father who continued to grow after high school

PHYSICAL EXAM

- Usually, there are no physical findings that point to a specific diagnosis.
- In children with decreased subcutaneous fat stores, weight is more affected than height.
 - May not be getting enough calories
 - May have bowel disease or another chronic illness
- A short child who is relatively pudgy (particularly if excess rippled fat is present over the trunk) may have growth hormone (GH) deficiency.
- Dysmorphic features may suggest a syndrome associated with short stature.
 - In girls, look for Turner syndrome.
 - High-arched palate
 - Cubitus valgus
 - Fingernails that bend upward
- An enlarged thyroid may be the only clue to hypothyroidism.
- Pubertal staging should be done on any short child ≥ 10 years of age.
 - A short, healthy 14-year-old boy (and less often, a short, healthy 13-year-old girl) who is still prepubertal is most likely to have CGD.
 - A child with a flattened growth curve at 13–16 years and who is in the late stages of puberty has completed or has nearly completed growing (nothing can increase the individual's adult height).

DIFFERENTIAL DIAGNOSIS

■ Most common causes of short stature

- CGD
- FSS

■ Syndromes with short stature

- Often associated with being born SGA
- Turner syndrome
 - Should be considered in any girl with height well below the 3rd percentile
 - Common features
 - Lymphedema as a newborn
 - Frequent ear infections beyond 2 years of age
 - Narrow, high-arched palate
 - Cubitus valgus
 - Upturned fingernails
 - Webbed neck present in only about 40%
 - Congenital heart disease in about 15%
 - Coarctation of the aorta and bicuspid aortic valve are the most common.
- Russell-Silver syndrome
 - SGA
 - Triangular face with down-turned mouth
- Noonan syndrome
 - Typical facial features
 - Flat nasal bridge
 - Hypertelorism
 - Ptosis
 - Webbed neck
 - Cryptorchidism
 - Pulmonic stenosis
- Other syndromes with short stature
 - De Lange
 - Rubinstein-Taybi
 - Seckel

■ Chronic illnesses and nutritional disorders

- Should be considered in short children whose weight is further below the curve than their height, or whose BMI is <10% for age
- Inadequate caloric intake
 - Not commonly the result of poverty in the US, because high-calorie foods are cheap
 - Overly restricted diet to avoid gaining weight or to lower cholesterol
 - Anorexia nervosa is the extreme example.

- Inflammatory bowel disease
 - Growth attenuation may start before gastrointestinal (GI) symptoms are apparent.
- Celiac disease
 - May have few, if any, GI symptoms
- Renal disease
 - Renal tubular acidosis
 - Chronic renal failure
- Liver disease

■ Medication-related poor growth

- Long-term oral glucocorticoid therapy
 - Much less impact from inhaled corticosteroids for asthma
- Stimulant medications

■ Endocrine disorders

- Height is often more affected than weight.
- GH deficiency
 - Not a common cause of short stature
 - Should be suspected in children below the 3rd percentile who are falling further behind over time
 - A suggestive physical finding is an increase in truncal subcutaneous fat.
 - Most cases are congenital, with fall-off in growth starting late in the first or in the second year of life.
 - Acquired GH deficiency is less common and raises the possibility of a pituitary tumor.
 - Partial GH deficiency is difficult to distinguish from CGD and FSS.
- Hypothyroidism
 - Acquired hypothyroidism needs to be excluded in any child with growth deceleration, even if height is above the 3rd percentile.
- Cushing syndrome
 - Endogenous Cushing syndrome is extremely rare.
 - Iatrogenic Cushing syndrome is more common.
 - Key findings include:
 - Rapid truncal, rather than generalized, weight gain
 - Slowing of linear growth
 - Moon facies
 - Abdominal striae
 - Increased skin pigmentation

■ ISS

- Moderately to severely short children who do not meet the criteria for CGD and FSS, often with subnormal rate of growth
- After extensive testing, no cause for poor growth is found.

LABORATORY EVALUATION

- Resist the temptation to order multiple laboratory tests for a child who is only mildly short (at or above the 3rd percentile) and whose growth rate appears to be normal.
 - Clinically significant abnormal test results are rarely found to explain short stature.
- Screening tests before a visit with a specialist might be appropriate if:
 - Height is well below 3rd percentile.
 - There is growth deceleration that cannot be explained by medication is well documented.
- A specialist can order any needed test at first consultation.
- Insulinlike growth factor-1 (IGF-1) is the best screening test if GH deficiency is suspected.
 - However, many children with CGD have borderline low IGF-1 levels for their age.
 - A random GH level is of no value because of the pulsatile nature of GH secretion.
- Thyroid testing
 - Limit to free thyroxine (T_4) and thyroid-stimulating hormone (TSH).
 - Will pick up both primary and secondary hypothyroidism
 - Borderline TSH (5.5- to 10-mcU/mL range) with normal free T_4 is usually a normal variation and will not explain poor growth.
- Complete blood count and erythrocyte sedimentation rate are mainly useful in the occasional child in whom inflammatory bowel disease is suspected.
- Microcytic anemia may be a clue to occult GI blood loss.
- Tests to screen for celiac disease
 - Tissue transglutaminase immunoglobulin A (IgA) antibody or antiendomysial antibody
 - Antigliadin IgG and IgA are much less specific and not worth the extra cost.
- A comprehensive metabolic profile will rule out rare causes of short stature
 - Electrolyte disturbances
 - Kidney disease
 - Liver disease

IMAGING

- A bone age film is the only radiographic examination that should be considered.
 - Not very useful as a diagnostic test, since most children who are short (aside from genetic short stature) have a bone age delay of ≥ 1 year
 - A consultant may order bone age film in a child >7 years of age to make a height prediction if either CGD or FSS is suspected.

TREATMENT APPROACH

- In healthy children at or above the 3rd percentile and growing at normal rate, the chances of finding a treatable cause for shortness are small.
 - The child should have growth carefully measured and plotted at each visit to make sure it is not dropping below the 3rd percentile.
 - If the parents insist on seeing a specialist, they should be told that their child will not likely need or be eligible for coverage of GH therapy.
- A child who is in the normal range but crossing percentiles
 - Between 6 and 24 months, such shifts are common, especially in CGD.
 - If the child crosses 1 percentile channel (eg, from the 25th to the 10th percentile) over ≥ 3 years, and history and examination are normal, a cause will not likely be found.
 - Children who cross >1 percentile channel in <3 years have a greater chance of having a definable cause for short stature.
 - The most common cause is the use of stimulant medication for attention-deficit/hyperactivity disorder.
- Parents of children short enough to be referred can be told that screening tests and a period of observation are needed before a decision can be made regarding the need for GH therapy.
- Such children are best referred between the ages of 3 and 6 years.
 - Children who are pubertal or on the verge of puberty do not usually benefit from GH therapy.

SPECIFIC TREATMENT

Human GH

- Children with a history of intrauterine growth retardation (born SGA) who have not caught up to the normal range by age ≥ 2 years:
 - The US Food and Drug Administration has approved use of GH without the need for GH testing.
- GH treatment
 - Children within normal range in height with a drop-off in linear growth >1 percentile channel over ≤ 3 years or who have shown documented growth arrest for 1 year
 - Children with short stature who have not started puberty by age 14 years (occurs mostly in boys with CGD)
 - When the boy is anxious to start his growth spurt sooner rather than later, treatment with a brief course of testosterone injections is appropriate.
 - The US Food and Drug Administration has approved GH for children at or below the 1st percentile with an anticipated adult height (based on bone age) below the normal range.
- Some insurance companies refuse to cover GH to treat ISS, arguing that no medical condition exists.

WHEN TO REFER

- Children below the 3rd percentile, particularly if height is falling further below the normal range over time
- Children who were born SGA (intrauterine growth restriction) who have not caught up to the normal range by ≥ 2 years
- Children within the normal range for height who have dropped off >1 percentile channel over the past ≤ 3 years or who have documented growth arrest for 1 year.
- Children with short stature who have not started puberty by age 14 years
- Dysmorphic children with short stature should be referred to a geneticist for a specific diagnosis.
- For children reporting poor self-esteem because they are short, referral to a psychologist may be more helpful than to an endocrinologist.
- If weight gain is persistently poor, referral to a GI or nutrition specialist should be considered.

FOLLOW-UP

- Follow-up of patients with short stature is important before the diagnosis, to establish the growth velocity, and after the therapy, to monitor its success.

COMPLICATIONS

- Some children with short stature develop significant psychosocial problems, such as poor self-esteem.

PROGNOSIS

- Children with CGD usually end up with heights in the lower half of the normal range.
- Children with FSS tend to achieve adult height within 2–3 inches of their adult target height.
 - Target height is calculated by averaging the heights of the parents and adding 2.5 inches for boys and subtracting 2.5 inches for girls.
- Children with ISS respond variably to GH, with a modest average improvement in adult height.

PREVENTION

- Measuring length and height at each clinic visit, and plotting them on growth curves, can lead to earlier identification of children with short stature.
- Appropriate evaluation and therapy can be instituted sooner for better outcomes.

Sinusitis

DEFINITION

- Sinusitis is infection of the paranasal sinuses.

EPIDEMIOLOGY

- Prevalence
 - Infection of the paranasal sinuses in children occurs frequently.
 - 5–13% of viral upper respiratory tract infections in children are complicated by acute bacterial sinusitis.
- Incidence
 - On average, children develop 5–10 upper respiratory tract infections yearly.

ETIOLOGY

- Respiratory viruses that contribute to the development of sinusitis
 - Adenoviruses
 - Influenza viruses
 - Parainfluenza viruses
 - Rhinoviruses
- The most common bacterial pathogens associated with acute sinusitis are:
 - *Streptococcus pneumoniae*
 - *Haemophilus influenzae*
 - *Moraxella catarrhalis*
 - *Staphylococcus aureus* and anaerobes are prevalent in chronic sinusitis
 - *Streptococcus pyogenes* (group A *Streptococcus*) may be associated with both acute and chronic disease.
- Inflammation and edema of the respiratory mucosa lead to obstruction of the ostium.
 - Pressure changes in the sinus that result from occlusion or from blowing and sniffing through the nose allow bacteria to invade the normally sterile sinus cavity.
- The ostia of the maxillary sinuses are located in the upper part of the chamber, where cilia must battle gravity to clear secretions.
 - This circumstance probably contributes to the high frequency of infection in these sinuses.

RISK FACTORS

- Sinusitis occurs most frequently after a viral upper respiratory tract infection or nasal allergy.
- Conditions that can predispose the sinuses to infection
 - Occlusion of the ostia
 - Impairment of ciliary motility
 - Alterations in the consistency of mucus secretions
 - Alone or in combination

- Several anatomic and physiologic conditions can predispose a child to paranasal sinusitis.
 - Anatomic
 - Nasal malformations
 - Nasal trauma
 - Tumors and polyps
 - Cleft palate
 - Foreign bodies
 - Dental infection
 - Cyanotic congenital heart disease
 - Physiologic barotrauma
 - Abnormalities of local defense mechanisms
 - Allergy
 - Cystic fibrosis
 - Immotile-cilia syndrome and Kartagener syndrome
 - Abnormalities of systemic defense mechanisms
 - Immunodeficiency
 - Primary or secondary

SIGNS AND SYMPTOMS

- Cough and nasal discharge are the most common clinical manifestations of acute sinusitis.
 - The cough occurs during the day but may be worse at night when the child is supine.
 - Nasal discharge may be clear or purulent.
- Parents of young children may report fetid breath.
- Headache and facial pain are uncommon symptoms in children with acute sinusitis.
- Painless swelling of the periorbital tissues without erythema is an occasional symptom.
 - May be confused with periorbital cellulitis in its early stage
- A less common presentation of acute sinusitis is an unusually severe upper respiratory tract infection.
 - Most uncomplicated upper respiratory tract infections improve after 5–7 days.
 - Symptoms that persist without improvement for >10 but <30 days suggest bacterial superinfection.
 - In most cases of viral upper respiratory infection, fever precedes the onset of watery nasal discharge and is associated with constitutional symptoms.
 - Thickening of nasal secretions occurs later in the course, before resolution.
 - A high fever and purulent discharge that coexist for ≥3 days suggests acute sinusitis.
- Cough and nasal discharge persisting for >30 days occurs with both subacute or chronic sinusitis.

- During physical examination, carefully inspect the nasal mucosa.
 - It will usually be erythematous and swollen.
 - It may be pale and boggy.
- Mucopurulent material can sometimes be seen in the nose or draining into the nasopharynx.
- Palpation or percussion of the sinuses may elicit tenderness.

DIFFERENTIAL DIAGNOSIS

- The presence of a foreign body in the nose must be ruled out.

DIAGNOSTIC APPROACH

- The distinction between viral infections and acute bacterial sinusitis is based on the persistence and severity of upper respiratory symptoms.

LABORATORY FINDINGS

- Nasopharyngeal culture results correlate poorly with sinus culture results.

IMAGING

- Sinus radiographs can help confirm the diagnosis of sinusitis.
 - Routine use to confirm the diagnosis of uncomplicated sinusitis is not recommended in young children.
 - Sinus radiographs are more specific and therefore more helpful in children >6 years of age.
- Cysts and polyps also may be seen on sinus radiographs.
- Computed tomography (CT) of the sinuses should be reserved for patients with:
 - Frequent recurrences or persistent symptoms that are not improving
 - Complicated sinusitis accompanied by orbital or intracranial complications
 - Need for consideration of sinus surgery

DIAGNOSTIC PROCEDURES

- Transnasal aspiration of the maxillary sinuses can be performed by an otolaryngologist for diagnostic purposes in specific situations.
- Bacteria are present in a sinus aspirate 75% of the time when:
 - Clinical signs and symptoms suggest acute sinusitis.
 - Maxillary sinus radiographs show:
 - Air-fluid levels
 - Complete opacification
 - Mucosal thickening of at least 4–5 mm
- Sinus aspiration and lavage are indicated only in children who:
 - Fail to respond to conventional antibiotic therapy
 - Are immunosuppressed
 - Have an illness that is severe or life threatening

TREATMENT APPROACH

- Treatment of sinusitis in children involves:
 - Antibiotic therapy
 - Symptomatic relief measures
 - Drainage, if necessary
 - The following are recommended to help drain the sinuses:
 - Decongestants
 - Antihistamines
 - Saline nose drops
 - No proof of the efficacy of these agents exists.
 - The AAP does not recommend the use of antihistamines and decongestants in children <6 years of age because of possible side effects and occasional adverse effects due to accidental overdosing.
- Amoxicillin is an appropriate initial choice for treating uncomplicated sinusitis.
 - It is most appropriate in geographic areas where the prevalence of β -lactamase-producing strains of *H influenzae* and *M catarrhalis* is low.
- Intranasal steroids may provide some benefit, particularly in the second week of therapy.
 - Further research is necessary to define their role in management.

SPECIFIC TREATMENTS

Amoxicillin

- Amoxicillin is the drug of choice for treatment of uncomplicated sinusitis.
- For children who do not respond to amoxicillin, broader coverage should be considered with amoxicillin plus:
 - A clavulanate *or*
 - A carbacephem *or*
 - A macrolide *or*
 - A 3rd-generation cephalosporin
- These alternatives should also be considered for the child who has:
 - Recently been treated with amoxicillin
 - Frontal or sphenoid sinusitis
 - Complicated ethmoid sinusitis
 - Very protracted symptoms
- Patients who are allergic to amoxicillin may be treated with:
 - A carbacephem *or*
 - A macrolide *or*
 - A 3rd-generation cephalosporin

WHEN TO ADMIT

- In unusually severe cases, hospitalization and parenteral antibiotics may be required.

WHEN TO REFER

- Otolaryngologic consultation is appropriate in cases where hospitalization is needed.
- Surgery may be required in cases of medically recalcitrant severe chronic sinusitis in children.
- Patients with recurrent sinusitis or chronic sinusitis associated with immunodeficiencies should be referred to otolaryngologists and/or infectious disease consultants.

FOLLOW-UP

- For the child who has recurrent sinusitis and no underlying disorder:
 - Some experts have recommended antibiotic prophylaxis.
 - No scientific studies support this practice.
 - May lead to the rapid development of antibiotic resistance

COMPLICATIONS

- Complications of sinusitis are most often due to local extension of the disease.
 - Orbital cellulitis is the most common serious complication of sinusitis.
 - In many cases, it lacks the common symptoms of sinusitis.
 - The eyelids appear intensely red and swollen.
 - Fever, malaise, and an increased leukocyte count are present.
 - To distinguish this condition from preseptal (periorbital) cellulitis, evaluate the child for:
 - Orbital pain
 - Proptosis
 - Limitation of eye movement (ophthalmoplegia)
 - Diminished visual acuity
 - CT may be needed to differentiate the 2 conditions.
 - This complication has been reported most frequently in male adolescents.
- Intracranial infection is the second most common complication of sinusitis.
 - Subdural empyema (most common)
 - Low-grade fever
 - Malaise
 - Frontal headache

- Then, as the disease progresses:
 - Vomiting
 - Decreased level of consciousness
- Infection can occur by direct extension through necrotic bone or by bacterial spread through the venous system.
- Peak age of incidence of this complication is between 10 and 20 years, but it can develop in younger children.

- If a patient is thought to have an intracranial abscess:
 - Head CT with contrast should be obtained.
 - Lumbar puncture should be avoided until intracranial mass effect has been ruled out.
 - Treatment with high-dose parenteral antibiotics should be started immediately.
 - To drain the abscess and to debride necrotic bone:
 - Neurosurgery should be consulted.
 - Steroids and hypertonic agents (mannitol or glycerol) may be necessary to control intracranial hypertension.
- Other, less common complications of sinusitis in children include:
 - Meningitis
 - Osteomyelitis of the frontal bone (Pott puffy tumor)
 - Epidural abscess
 - Cavernous sinus thrombosis

PROGNOSIS

- Clinical improvement should be expected within 48 hours after treatment is initiated.
- A minimum of 10 days of antibiotic therapy usually is adequate.
 - If symptoms fail to resolve completely within 10 days, patients should be treated for an additional 7 days beyond the resolution of symptoms.

PREVENTION

- If the patient is known to have allergic rhinitis, environmental controls, anti-allergic medications, and/or referral to an allergist may help prevent recurrent sinusitis.
- Chronic prophylactic antibiotic use did not prove to be successful in preventing recurrent sinusitis.

Spina Bifida

DEFINITION

■ *Neural tube defects* are congenital defects of the head and spine. They include:

- Head
 - Anencephaly
 - Cranial meningocele
 - Encephalocele
- Spine
 - Spina bifida occulta
 - Occult spinal dysraphism (OSD)
 - Meningocele
 - Meningomyelocele

■ *Spina bifida* refers to defects in the caudal region of the spine.

EPIDEMIOLOGY

■ Prevalence

- Neural tube defects: 1–2 cases per 1,000 live births in the US
 - Second most common major congenital defect
- Meningomyelocele (or myelomeningocele): 0.4–0.8 cases per 1000
- Greater among:
 - Girls
 - Children of lower socioeconomic status
 - Families of English, Irish, or Welsh extraction
- Has been declining for the last several decades due to:
 - Improved nutrition
 - Fortification of food with folic acid
 - Establishment of prenatal diagnosis with elective termination

ETIOLOGY

■ The cause of neural tube defects is unknown.

- The primary mechanism seems to be faulty closure of the neural groove by day 28 of gestation.
- Most recent etiologic hypothesis
 - Neural tube defects result from the interaction of many genes (polygenic expression).
 - Can be modified by factors in the embryonic (maternal) environment

■ Meningomyelocele may be associated with certain chromosomal aberrations, including:

- Trisomy 13
- Trisomy 18
- Cri du chat syndrome

■ 4 major malformations account for findings of meningomyelocele.

- Soft-tissue malformation
- Brain malformation

- Vertebral body malformation
- Spinal cord malformation

■ Soft-tissue malformation

- Failure of skin and other soft tissues to close leaves the spinal cord open to infection.
- Lipomas that occasionally accompany the defect may grow larger, possibly:
 - Compressing the spinal cord
 - Causing progressive neurologic symptoms

■ Brain malformation

- Chiari type II deformity
 - Pons and medulla are distorted and elongated.
 - Cerebellar vermis is displaced inferiorly into the spinal canal.

■ Most neural tube defects are isolated findings, but some may be associated with other malformations:

- Tracheoesophageal fistula
- Diaphragmatic hernia
- Imperforate anus
- Cryptorchism
- Inguinal hernias
- Renal anomalies
- Cleft palate
- Ventricular septal defect

RISK FACTORS

■ Increased risk for neural tube defects

- Maternal exposure to:
 - Hyperthermia
 - Valproic acid (Depakene, Depakote)
 - Carbamazepine (Tegretol)
 - Isotretinoin (Accutane)
 - Ethanol
- Mothers who have:
 - Diabetes
 - Obesity
 - Maternal malnutrition
 - Folic acid deficiency
- Family member with the disease
 - Assuming overall incidence of 1 per 1000
 - For a second affected child, from the same parent incidence is 2–3 per 100.
 - For a third affected child, the incidence is 10 per 100.
 - Adult with meningomyelocele
 - 2–3% chance of having a child with a neural tube defect

SIGNS AND SYMPTOMS

History

- Affected newborns may have a family history of neural tube defects or spontaneous abortions (miscarriages).
- Historical facts worth noting in the newborn period include:
 - Length of gestation
 - Type of delivery
 - Complications with and length of labor
 - Maternal nutrition
 - Environmental exposures
 - Current family functioning, including social support and stress
 - Parental expectations and understanding of malformation
- For older children, obtain information about current and past therapies for:
 - Neurologic conditions
 - Orthopedic conditions
 - Urologic conditions
 - Ophthalmologic conditions
 - Dermatologic conditions
 - Gastrointestinal conditions
- Educational and social functioning
- Child's knowledge of condition
- Sexual function
- Understanding of sexuality
- Assess the child's:
 - Growth
 - Development
 - Mobility
 - Independence in activities of daily living
 - Personal hygiene
 - Ability to self-feed
 - Self-help skills
- Determine any onset of new neurologic symptoms, such as:
 - Pain
 - Fatigue
 - Weakness
 - Changes in bowel and bladder function
 - Tripping
 - Clumsiness
- These symptoms usually indicate treatable conditions, such as:
 - Tethered spinal cord
 - Diastematomyelia
 - Syringomyelia
 - Ventricular shunt malfunction

- Up to 50% of children who have meningocele have allergies to latex.
- Seek history of reactions to products made of latex, such as:
 - Balloons
 - Bandages
 - Balls
- Contact with latex-containing products should be restricted from the first day of life.
- All operative procedures should be performed in a latex-free environment.

Findings

- Spina bifida occulta
 - Common, benign condition
 - Spinal cord and soft tissues are normal.
 - Vertebral arches are incomplete.
- OSD
 - The underlying spinal cord is at risk for deterioration.
 - The infant is born with a visible abnormality on the lower back, which may be:
 - Birthmark (eg, hemangioma)
 - Tuft of hair
 - Dermal sinus
 - Lipoma
 - Atypical dimple
 - Many healthy infants are born with a small, midline sacral dimple.
 - Dimples associated with OSD are:
 - Not in the middle
 - Above the sacral region
 - Large
 - Without visible base
 - Spinal cord may be connected to the surface through a sinus that increases the risk for meningitis.
 - The cord itself may be:
 - Tethered to surrounding tissue
 - Split (diastematomyelia or diplomyelia)
- Meningocele
 - Meninges protrude through abnormal vertebral arches and soft tissue.
 - The spinal cord is normal.
 - On rare occasions, may appear as an anterior mass in:
 - Pelvis
 - Abdomen
 - Thorax
- Meningocele
 - The malformed spinal cord and nerve roots protrude through abnormal vertebral arches and soft tissue.

Physical examination

- Backs of all children should be examined for signs that may indicate OSD.
 - Pigmented spots
 - Hairy patches
 - Sinuses that extend into spine
- These children are at high risk for:
 - Meningitis
 - Neurologic deterioration secondary to:
 - Diastematomyelia
 - Lipoma
 - Tethering of spinal cord
- Children with meningocele should have a complete physical examination that emphasizes:
 - Neurologic function
 - Orthopedic function
 - Gastrointestinal function
- Neurologic examination should include determination of:
 - Motor function
 - Sensory functional levels
- Assisting in the evaluation of lesions at S2–S4
 - Rectal examination
 - Assessment of the anal wink
- Assess upper extremity:
 - Strength
 - Function
- Aids to evaluation of shunt function
 - Palpation of the anterior fontanelle
 - Ophthalmoscopic visualization of the eyegrounds
 - Assessment of the cranial nerves, especially extraocular movements
 - Palpation of shunt valve and tubing
- Orthopedic examination should include assessment of:
 - Posture
 - Scoliosis
 - Lordosis
 - Kyphosis
 - Joint mobility
 - Stability
- Erythema and swelling of joint or bone in an area that lacks sensation means fracture until proved otherwise.
- Skin should be examined for evidence of:
 - Erythema
 - Ulcers in insensate areas
- Formal and informal developmental assessment
 - Verbal
 - Performance
 - Sensory integration
 - Educational measures
 - Fine-motor
 - Gross-motor
 - Language
 - Social-adaptive skills
- Determine the child's learning profile before school entry.
 - Helps the school provide appropriate interventions that will optimize the child's learning
 - Formal psychoeducational testing is a critical part of the evaluation.
 - Identify academic strengths and weaknesses.
 - Test before an individualized education plan is developed.

LABORATORY FINDINGS

- Serum blood urea nitrogen and creatinine levels should be obtained as a baseline assessment of renal function.
- As the child grows, urinalysis and urine cultures should be performed as indicated.

IMAGING

- Infants with abnormal findings on the back should have evaluation of underlying soft tissue and spinal cord using:
 - Ultrasonography
 - Magnetic resonance imaging (MRI)
 - Ultrasonography or computed tomography (CT), or both, of the head
- Monitor kidneys with:
 - Routine renal ultrasonography
 - Voiding cystourethrography
 - Renal scans
 - Urodynamics
- Periodic CT of the head to detect asymptomatic ventricular enlargement
- Condition of the spine and joints should be monitored by plain radiography.
- Special studies that may be indicated include:
 - MRI of the spine and posterior fossa, including evaluation of cerebrospinal flow in the posterior fossa
 - ^{99m}Tc dimercaptosuccinic acid renal scan to evaluate kidney structure and function, including damage from recurrent infections

- A child with signs and symptoms of ventricular shunt malfunction or other neurologic deterioration should undergo:
 - CT of the head
 - Shunt series (to evaluate the integrity of the tubing)

TREATMENT APPROACH

- 2 overriding goals
 - Prevent dysfunctions (eg, neurologic defects) from becoming disabilities (eg, cannot walk).
 - Prevent disabilities from becoming handicaps.
- Achieving these goals requires:
 - Comprehensive, coordinated care
 - Routine care, such as:
 - Immunizations
 - Anticipatory guidance
- The newborn and family should be evaluated by a team, consisting of:
 - Pediatrician
 - Nurse
 - Social worker
 - Neurosurgeon
 - Orthopedist
 - Physical therapist
 - Urologist
- Long-term management goals
 - Optimize the child's activities and participation in society.
- To optimize health and well being, all of these children should have:
 - Healthy diets
 - Regular physical activities
- Should have access to:
 - Appropriate recreation
 - Leisure activities

SPECIFIC TREATMENTS

Initial actions

- Once the neonate has received supportive care, central nervous system infection must be prevented.
- For infants with an open lesion:
 - As soon as possible, give parenteral antibiotics that provide coverage against:
 - Gram-negative bacilli
 - *Staphylococcus aureus*
- Surgery to close the open defect, typically within the first 72 hours of life

- Ventriculoperitoneal shunt placement to reduce hydrocephalus, guided by ultrasonography or CT
 - No universally accepted criteria exist to determine the need or the timing of shunt placement.
- Daily measurement of head circumference
- Genetic counseling and social support should be provided to the family.

Orthopedic treatment

- Goals include:
 - Optimal alignment
 - Maximal range of motion
 - Stability of spine and extremities
 - Maximal function and comfort, while protecting the skin
- Deformities, such as clubfoot and joint contractures, should be managed with
 - Range-of-motion exercises
 - Splinting
 - Casting
- May include surgery for:
 - Joint contractures
 - Scoliosis
 - Kyphosis
- 1 or both hips may become dislocated.
 - Surgical treatment may not be indicated if:
 - Dislocation is bilateral.
 - The child has complete paraplegia.
- Prevention of contractures and dislocations may require:
 - Regular passive range-of-motion exercises
 - Splints
 - Body jackets
 - Casts
- Various exercises and orthoses (braces) may be used to enhance locomotion.
 - Between 18 and 24 months, start using:
 - Parapodium—a standing brace that allows the child to be in an upright position with hands unencumbered
 - Reciprocal gait orthosis
 - Crutches or walkers in conjunction with more standard bracing may be used.
 - Early use of wheeled mobility is encouraged, especially for children with quadriceps paralysis.
 - Adaptive equipment, such as carts and hand-pedaled tricycles, can enhance function and self-esteem.

Urologic treatment

- Goals include:
 - Protecting the kidneys and ureters by:
 - Emptying the bladder
 - Lowering intravesicular pressure
 - Preventing urinary tract infections
 - Treating reflux
 - Achieving continence
- Urologic system should be evaluated by:
 - Urine culture
 - Renal ultrasonography
- Clean intermittent catheterization
 - Safer than urinary diversion via ileal loops
 - More acceptable
 - Results in better renal function
- Vesicostomy may be indicated in the infant with:
 - Vesicoureteral reflux
 - Hydronephrosis
- Most families can perform clean intermittent catheterization when the child is 4–5 years of age.
 - Many children this age can perform the procedure themselves.
 - Clean intermittent catheterization has been used in children <3 years of age to manage:
 - Vesicoureteral reflux with or without hydronephrosis
 - Frequent urinary tract infections
- Drugs that relax the detrusor muscle or increase sphincter tone can enhance continence.
 - Imipramine hydrochloride
 - Oxybutynin chloride
 - Pseudoephedrine
- In older children in whom catheterization does not provide continence:
 - Use a surgical procedure, such as bladder augmentation.
 - Create a continent stoma with clean intermittent catheterization.
- Prevent renal damage by:
 - Obtaining regular urine cultures to detect urinary tract infection
 - Administering prophylactic antibiotics in children who have frequent infections
- Prophylaxis—use the following in less than the therapeutic dose:
 - Trimethoprim-sulfamethoxazole
 - Sulfisoxazole
 - Nitrofurantoin
 - Cephalexin

Neurosurgery

- Goals include monitoring for signs and symptoms of:
 - Ventricular shunt dysfunction
 - Occurrence of spinal cord problems, such as tethering
 - Assessment of functioning
 - Decrease in school performance may indicate chronic shunt malfunction.
- Occasionally, cranial imaging (ultrasonography in infants and CT in older children) is performed.
 - The optimal frequency of these studies has not been determined.
- Surgical treatment to correct OSD should be performed early.
 - Even in asymptomatic infants
 - Prevents progressive neurologic damage

Reproductive issues

- Impotence in the male patient may be managed:
 - Surgically
 - Penile implants
 - Vacuum pumps
 - Injection or insertion of prostaglandin
 - With such medications as sildenafil (Viagra)
- Women have normal fertility.
 - Should use precautions to prevent pregnancy and sexually transmitted infections
 - Precocious puberty is common in young women who have meningomyelocele with hydrocephalus, because of disorder of the hypothalamus.
 - Precocious puberty can be treated with leuprolide (Lupron).
 - Pregnant women may need to have cesarean delivery because of hip contractures.
 - Frequent neurologic evaluations throughout pregnancy are recommended.
 - Intervertebral disks may become herniated, with neurologic sequelae.

Fecal continence

- Often difficult to achieve:
 - Bowel continence after 4 years of age
 - Avoidance of severe constipation
- Use the following singly or in combination to attain this goal.
 - High-fiber diet
 - Stool softeners
 - Regular toileting
 - Regular stimulants
 - Biofeedback in children who have rectal sensation

- Regular enemas, using 20 mL/kg of normal saline
- Suppositories
- Small-volume enemas (Enemeez)
- Several surgical procedures (antegrade colonic enema) have been developed to help children achieve fecal continence.
 - Show promise for a select group for whom more conventional constipation-relieving techniques have failed
 - Original surgical procedure (Malone)
 - Removes appendix
 - Opens its distal end
 - Uses it to create a channel between the colon and the abdominal wall
 - In a related procedure (cecostomy)
 - An opening is made in the cecum, either surgically or in the radiology suite.
 - A gastrostomy button is placed into the cecum.
 - In a newer antegrade colonic enema procedure
 - An opening is placed into the descending colon.
 - After all of these procedures, irrigation fluids are flushed into the colon, washing out stool.
 - These procedures are used on a regular basis.

Psychosocial support

- A child with a disability has the same psychosocial needs as a healthy child.
- The clinician should help the family achieve shift to independent function.
- If a child has a learning disability, the school should provide:
 - Remediation
 - Additional instructional time
 - Different instructional approaches
 - Fixing an area of weakness
 - Building strength in a particular area to facilitate potential learning
 - Compensation
 - Alternative approaches (eg, assistive technology) to offset, or counterbalance, a learning disability
- Children, especially teens are at increased risk for:
 - Depression
 - Anxiety
 - Both
- These conditions should be considered causes of:
 - Changes in physical functioning
 - Problems at school

Alternative medicine

- Alternative therapies include:
 - Cutaneous electrical field stimulation
 - Therapeutic electrical stimulation

- Transrectal electrostimulation
- Bladder stimulation
- Biofeedback
- Acupuncture
- These methods have been tried with varying success.
- Little evidence-based research exists to support their use.
- Families often turn to alternative therapies, including herbal medications, because:
 - Many conventional therapies are ineffective in treating the symptoms of spina bifida.
 - No cure exists.
- Inquire about the use of these treatments.
 - Be aware of their nature, possible interactions with medications, and potential for harm.

WHEN TO ADMIT

- When the child is acutely ill and cannot be managed at home
- When the child requires surgical intervention

WHEN TO REFER

- Infants born with meningocele should be referred to a tertiary medical center that specializes in the care of these children.
 - Ideally before delivery
- All infants born with meningocele should be monitored during childhood by a multidisciplinary team that includes experts in:
 - Child development
 - Neurosurgery
 - Orthopedics
 - Urology
 - Orthotics
 - Social work
 - Nursing
 - Physical and occupational therapies
 - Plastic surgery
- Early on, refer to:
 - Ophthalmologist
 - At least 1 visit by an ophthalmologist during infancy because of risk of strabismus leading to amblyopia
 - Geneticist
 - Early intervention program

FOLLOW-UP

- Head circumference, height, and weight should be monitored.
- Some clinicians recommend substituting arm span for height because growth below the waist is disproportionately slow.

- As the child grows, the primary care physician should:
 - Coordinate the child's care
 - Be the child's advocate
- In most instances, children may benefit from services.
 - Services are mandated under the Individuals with Disabilities Education Act. They include:
 - Formal early-intervention programs
 - Special education services
 - Physical and occupational therapies
- Opportunities for interactions with people and objects (toys) should be provided.
- The child should be encouraged to develop the best social interaction and self-help skills possible, including development of independence in hygiene and eating.

COMPLICATIONS

Hydrocephalus

- Abnormality is often associated with progressive hydrocephalus, which may lead to:
 - Laryngeal nerve palsy
 - Difficulty in swallowing
 - Hypoventilation
 - Apnea
 - Sudden death
- Central precocious puberty develops in many girls with hydrocephalus.
- 25–60% develop evidence of hydrocephalus within the first year of life.
- The higher (ie, the more cephalad) the spinal lesion is, the greater the likelihood of developing hydrocephalus.
- Subtle abnormalities of cranial nerve nuclei occur in many affected children.
- Seizures occur in 15–20% of children and adolescents.
 - ~25% have seizures at birth.

Shunt malfunction

- Sudden shunt malfunction may produce life-threatening elevations of intracranial pressure, requiring emergency intervention.
 - Signs and symptoms of acute shunt malfunction include:
 - Headache
 - Lethargy
 - Irritability
 - Paralysis of upward gaze
 - Sixth cranial nerve palsy
 - Bulging fontanelle (in infants)
 - Vomiting

- Progression may rapidly ensue to:
 - Loss of consciousness
 - Abnormal pupillary reflexes
 - Papilledema
 - Deterioration of vital signs
 - Death

Intellectual development

- Most children have normal overall IQ scores.
- Most have selective cognitive disabilities, including:
 - Nonverbal learning disabilities
 - Impairment of executive functions
- Even children with very low performance scores may have surprising verbal fluency, sometimes referred to as *cocktail party syndrome*.
- Specific cognitive testing often reveals deficiencies of:
 - Selective visual attention
 - Visual-spatial perception
 - Tactile perception
 - Auditory concentration
 - Higher-order functioning (eg, organizational skills)
- Children with hydrocephalus and higher spinal lesions are more likely to have these deficits.
- Manifestations seen in school include:
 - Short attention span
 - Distractibility
 - Perseveration
 - Poor comprehension
 - Poor handwriting
 - Disorganization
 - Poor memory
 - Faulty problem-solving and decision-making skills
 - Reduced social skills
 - Emotional instability
 - Impulsivity
 - Irritability
 - Difficulty with subjects requiring visual-motor integration and visual-perceptual integration, eg, arithmetic

Surgical complications

- Surgery to cover the cord may:
 - Result in loss of neurologic function
 - Lead to scar tissue that tethers the cord and results in further neurologic deterioration as the child grows

- ≤50% may have allergies to latex, including anaphylaxis, during surgery.
 - Contact with products made from latex should be avoided.
 - All surgical procedures should occur in latex-free settings.
 - Catheterization should be performed with nonlatex catheters.
 - Gloves worn during care should be of nonlatex material.
 - Toys that contain significant amounts of latex should be avoided.
 - Products that contact the skin, such as adhesive or Ace bandages, should be latex-free.

Complications of vertebral malformations

- Caused by abnormal segmentation or formation, including:
 - Absent vertebrae
 - Fused vertebrae
 - Hemivertebrae
 - Butterfly vertebrae
 - Bony or ligamentous spurs that lead to diastematomyelia (occasionally)
- Of children who have thoracic lesions:
 - 10% are born with kyphosis.
 - Rate increases to 33% by adolescence
- Children with lumbar lesions have a 5% occurrence of kyphosis by adolescence.
- In addition to cosmetic deformity, severe kyphosis can lead to:
 - Back pain
 - Pulmonary and cardiac dysfunction
 - Recurrent skin ulceration
 - Interference with walking
- Occurrence of scoliosis is related to the level of the lesion.
- Curves ≥30 degrees appear in:
 - 81% of adolescents with thoracic lesions
 - 23% of those with lower lumbar lesions
- Consequences of scoliosis are similar to those of kyphosis.
- Lordosis is much less common.

Complications of spinal cord malformation

- Results in:
 - Loss of sensation, making child vulnerable to burns, abrasions
 - Loss of motor function
- Decubitus ulcers, especially among adolescents and adults who spend extensive time in wheelchairs
 - Skin lesions may become infected, leading to osteomyelitis.

- Loss of motor function leads to decreased movement in utero.
 - May lead to deformities seen at birth, such as clubfoot (talipes equinovarus), dislocated hips
- Loss of efferent nerve stimuli to urinary bladder and sphincter results in neurogenic voiding dysfunction in virtually all patients.
 - Bladder dysfunction may be classified as:
 - Failure to store urine
 - Hypotonic urinary outlet
 - Spastic, hypertonic bladder
 - Failure to empty completely
 - Spastic urinary sphincter
 - Hypotonic bladder
 - The combination of spastic outlet and hypertonic bladder is especially serious.
 - Reflux and hydronephrosis occur frequently with this combination.
 - Urinary tract infections lead to:
 - Fibrosis of the bladder
 - Chronic renal damage, a significant source of morbidity and mortality
 - Repeated urinary infections in the presence of reflux lead to renal failure.
- Altered sexual function, especially in men
 - ~25% of men with meningocele cannot have erections.
 - Of those who can, most have retrograde ejaculation and decreased fertility.
- Women have:
 - Decreased sensation
 - Decreased lubrication in response to sexual stimulation
 - Most can experience orgasm and have normal fertility.
- Children usually have neurogenic bowel.
 - Most children have intact internal rectal sphincter function.
 - Many have intact rectal sensation.
 - Abnormal migration of neural cells in utero can lead to diminished peristalsis.
 - Constipation or obstipation with overflow soiling are caused by:
 - Abnormal rectal function
 - Poor peristalsis
 - Limited mobility
 - Ingestion of a low-fiber diet because of difficulty swallowing or fear of incontinence

- Loss of motor function in the lower extremities leads to loss of mobility.
 - Degree of mobility is related closely to the level of the lesion.
 - Children with intact quadriceps (L2–L4) are much more likely to be ambulatory through adolescence than are those with higher-level lesions.
 - Joint contractures develop in children who have:
 - Imbalance of forces around a joint
 - No function
 - A child with a thoracic-level lesion who has no hip function is at risk for hip flexion contractures from sitting all day in a wheelchair.
 - Loss of mobility and innervation increases risk for:
 - Osteoporosis
 - Pathologic fractures in the lower extremities
 - Unnoticed fractures

Psychosocial complications

- The birth of a child with meningocele is potentially devastating.
- Most parents go through the phases characteristic of people undergoing a loss.
- Some families may go through part of the grief process several times during the child's life, particularly at significant milestones.
- Parents must share in:
 - Grieving
 - Difficult medical decisions
- Parents will require support from medical professionals.
- Most children with meningocele have multiple medical problems.
 - Require money, time, patience, understanding
 - Such demands stress parents and can lead to isolation of one parent from the other.
 - Stresses may affect siblings, who can develop behavioral problems.
- Children may have difficulty at home if parents cannot:
 - Provide affection
 - Set consistent limits
- These children may have difficulty:
 - With peers who see them as “cripples” rather than as children with disabilities
 - Performing academically
- They may:
 - Lose interest in school because of frequent negative reinforcement
 - Have no adult role models
 - Lose self-esteem

PREVENTION

- Periconceptual folate supplementation has been shown to decrease:
 - Primary occurrence of neural tube defects
 - Recurrence of these defects in families
- The AAP and Centers for Disease Control and Prevention recommend that all women of child-bearing age receive 0.4 mg of folic acid daily.
 - Women who have a first-degree relative with a neural tube defect should receive 4.0 mg of folic acid daily.
- Open neural tube defects may be diagnosed prenatally.
 - Measurement of α -fetoprotein levels in maternal serum between 14 and 16 weeks of gestation *and*
 - Confirmation of diagnosis via high-resolution ultrasonography
 - Amniocentesis is recommended for women with elevated serum α -fetoprotein levels to confirm diagnosis.
- Prenatal detection of a neural tube defect allows the family to:
 - Consider termination
 - Plan peri- and postnatal care, including the decision to deliver by cesarean section
- Prenatal surgery to cover the open lesion on the back during the second trimester may decrease the severity of:
 - Hydrocephalus
 - Chiari malformation
 - Major risks of this procedure include premature delivery and maternal complications (bleeding and infection).
 - A multicenter controlled clinical trial is underway in the US to evaluate the effects of prenatal surgery (www.spinabifidamoms.com).

Spinal Deformities

DEFINITION

- Scoliosis is a side-to-side curve of the spine.
 - Most cases are idiopathic scoliosis.
 - Less common types include:
 - Congenital: absent or fused spinal segments
 - Metabolic: juvenile osteoporosis
 - Neuromuscular: poliomyelitis, cerebral palsy
- Larsen syndrome is an autosomal-dominant osteochondrodysplasia.
- Dysraphism is failure of closure of the primary neural tube.
- Kyphosis is an acquired dorsal hump.
- Spondylolysis is a defect in the continuity of the pars interarticularis of the posterior portion of L4 or L5.
- Spondylolisthesis is a forward slippage of one vertebra on the vertebra below.

EPIDEMIOLOGY

Congenital malformations

- Congenital scoliosis
 - The overall incidence of congenital anomalies of the spine is unknown.
 - One estimate of thoracic spine congenital deformity is 0.5 per 1000 persons.
- Goldenhar syndrome: ocular-auricular-vertebral spectrum (OAVS)
 - Rare; prevalence is estimated to be ~1 in 45,000 live births.
 - Male infants are affected more often than females.
 - The right side of the face or body (or both) is generally more commonly and severely affected than the left.
- VACTERL complex (see description in Etiology)
 - Estimated incidence: 1 in 25,000 live births with ≥ 3 components of the spectrum

Acquired abnormalities

- Scoliosis
 - Most cases are idiopathic; ~75% of all cases
 - Idiopathic scoliosis can appear at any age.
 - The majority of cases begin in adolescence.
 - More prevalent in girls
 - Right thoracic or right thoracolumbar pattern is prevalent
- Adolescent idiopathic scoliosis
 - 2% of adolescents have a scoliosis (>10 degrees).
- Spondylolysis and spondylolisthesis
 - Gymnasts and other athletes who repeatedly hyperextend the spine have a higher incidence of spondylolysis than the general population.
 - In adolescence and adulthood, incidence is estimated at 5%.
- Infections of the spine
 - Exceedingly rare

ETIOLOGY

Spinal cord and vertebral embryonic development

- Factors that adversely affect normal differentiation of the musculoskeletal system during the embryonic period are:
 - Genetic abnormalities
 - Teratogen exposure
- Errors in the embryologic sequence of the spine cause several congenital defects of spinal column and cord.
 - Range in severity
 - From isolated hemivertebrae to:
 - More complex errors of vertebral formation and segmentation associated with defects of the neural tube or spinal cord
 - Structural spinal curves, such as congenital scoliosis or kyphosis, develop when errors:
 - Result in asymmetric vertebral formation
 - Produce asymmetric vertebral growth potential
- In patients with high thoracic and cervical curves, frequent occurrences include malformations of:
 - Head and neck, especially internal and external auditory apparatuses
 - Maxillae
 - Mandibles

Congenital malformations

- Congenital scoliosis
 - Due to:
 - Failure of formation
 - Failure of segmentation
 - Produced by deformities in the coronal plane
- Congenital kyphosis
 - Due to:
 - Lack of segmentation of vertebral bodies anteriorly
 - Lack of formation of a vertebral body
 - Produced by deformities in the sagittal plane
- Larsen syndrome
 - Recently shown to be caused by missense mutations or small in-frame deletions in the *FLNB* gene
- Morquio syndrome (mucopolysaccharidosis [MPS] type IV)–odontoid dysplasia with atlantoaxial subluxation
 - MPS IV-A results from mutations in the gene-encoding galactosamine-6-sulfatase, located at *16q24.3*.
 - MPS IV-B (a milder variant) is due to β -galactosidase deficiency.
 - Clinical features result from accumulation of keratan sulfate and chondroitin-6-sulfate.

- Klippel-Feil syndrome—association of:
 - Short neck
 - Low posterior hairline
 - Restriction in neck motion caused by the congenital fusion of cervical vertebrae
 - Common associated anomalies include:
 - Renal anomalies
 - Congenital elevation of the scapulae (ie, Sprengel deformity)
 - Impaired hearing
 - Congenital heart disease
- VATER syndrome
 - Vertebral defects
 - Imperforate anus
 - Tracheoesophageal fistula
 - Radial and renal dysplasia
- VACTERL complex—VATER syndrome with:
 - Congenital cardiac lesions
 - Rib and limb lesions

Acquired abnormalities

- Scoliosis
 - Nonstructural scoliosis results from:
 - Posture habit
 - Splinting because of pain
 - Muscle spasm
 - Hysteria
- Kyphosis
 - Can be secondary to:
 - Spinal tumor
 - Radiation
 - Infection
 - Surgery
 - Most common cause of acquired kyphosis
 - Osteochondrosis known as *Scheuermann disease*
 - Occurs in 5% of the population
 - Glucocorticoid-induced osteoporosis
 - Caused by:
 - Supraphysiologic levels of endogenous glucocorticoids (Cushing disease)
 - Exogenously administered glucocorticoids
 - Can provoke kyphosis
 - Excess glucocorticoids often act to suppress bone formation and increase bone resorption, leading to:
 - Trabecular bone loss
 - Vertebral body collapse

- Pathologic fractures
- Increased propensity toward kyphotic spinal malalignment

- Spondylolysis
 - Often due to stress fracture/trauma in a genetically susceptible host
- Spondylolisthesis
 - Spondylolysis may lead to forward slippage of the vertebral body.

RISK FACTORS

- Scoliosis
 - Increased risk when there is an affected family member
- Adolescent idiopathic scoliosis
 - Key risk factors for curve progression are combinations of:
 - Remaining spinal growth (skeletal immaturity)
 - Curve magnitude at a given time
- Spondylolysis and spondylolisthesis
 - Spondylolysis is fairly common in young athletes with low back pain.
 - The propensity for spondylolysis to become spondylolisthesis with forward slippage is increased during growth spurts.

SIGNS AND SYMPTOMS

Postural

- Back pain in children is often a sign of an underlying disorder.
- Postural abnormalities may or may not indicate an underlying spine disorder.
- The challenge to the physician is to determine whether the child's posture is caused by:
 - Underlying skeletal deformity
 - A habit that has altered—exaggerates, increases, or decreases—normal spinal curves
- Abnormal curvatures and protrusions merit careful investigation.
- Thoracic spine normally has some kyphosis.
- Lumbar spine normally has slight lordosis.
- If either condition is excessive, progressive, or painful, then concern is appropriate.
- Scoliosis is always abnormal.

Congenital malformations

- When the newborn is held prone in the examiner's palm, the infant's back falls into slight flexion, allowing detection of:
 - Meningomyelocele
 - Scoliosis
 - Kyphosis
 - Dorsolumbar hyperflexion

■ Lumbar spinal deformity may be indicated by:

- Hair tuft
- Dimple
- Discoloration
- Palpable spina bifida lamina defect

Congenital scoliosis

- Vertebral anomalies are present at birth.
- Clinical deformity develops with spinal growth.
 - May not become apparent until later childhood
 - Sometimes related to cardiac or urologic abnormalities

Congenital kyphosis

- More severe deformities are usually recognized in neonate.
 - Rapidly progress thereafter
- Less obvious deformities may not appear until several years later.

Spina bifida

- Spina bifida can be mild and of no clinical significance (occulta).
- Can be severe (vera), with meningeal protrusion (meningocele) or protrusion of both meninges and neural elements (myelomeningocele) posteriorly
 - When the protrusion includes bony elements, it may transfix the spinal cord.
 - Transfixing spur is called *diastematomyelia*.
 - Most of the lesions occur in the lower lumbar and upper sacral areas.
 - Few spinal defects are at a higher level.

Larsen syndrome

- Characteristic pattern of spinal deformity consisting of:
 - Vertebral anomalies
 - Spondylolysis
 - Scoliosis
- Cervical spine is the most severely involved.
- Most consistent patterns of deformity represented by:
 - Dysraphism
 - Hypoplasia
- Scoliosis is the most common deformity seen in the thoracic spine.
- Dysraphism, scoliosis, and spondylolysis are common in the lumbar spine.
- Dysraphism is the most common anomaly in the sacrum.
- Joint, facial and palate abnormalities occur in some patients.
 - Tracheomalacia is also seen.

Goldenhar syndrome: OAVS

- Abnormalities include
 - Ocular
 - Auricular
 - Vertebral
- The terms *Goldenhar syndrome* and *OAVS* are used interchangeably to describe this myriad of congenital anomalies.
- Wide phenotypic variation
- Multiple malformations have been seen in small numbers of patients with OAVS, including congenital diseases of heart, brain, and kidneys.

Morquio syndrome (MPS type IV)—odontoid dysplasia with atlantoaxial subluxation

- The disorder consists of 2 forms with similar clinical findings and autosomal recessive inheritance.
 - MPS IV-A
 - MPS IV-B
- In both forms, mental symptoms are absent or only mildly present.
- Neurologic symptoms may result from compression of spinal cord or medulla.
- Skeletal changes include:
 - Joint laxity
 - Short stature
 - Pectus carinatum
 - Shortened vertebrae
 - Genu valgum
 - Pes planus
 - Enlarged joints
- Corneal clouding is present in 50% of cases.
- The neck is short.

VACTERL complex

- The categorical breakdown of anomalies in a large series was as follows.
 - Vertebral (25%)
 - Anal, esophageal (or other gastrointestinal) atresia (15%)
 - Cardiac (33%)
 - Tracheoesophageal fistula (95%)
 - Urinary (renal dysplasia, urethral valves) (17%)
 - Skeletal (16%)

Acquired abnormalities

Adolescent idiopathic scoliosis

- Usually painless and is discovered on routine physical examinations or at school scoliosis screening programs
 - Incidence of pain in children with idiopathic scoliosis is no different than in the general population.
 - ~30% report back pain at some time.

- Pain:
 - Many arise during a phase of rapid progression of scoliosis
 - Might be related to underlying neurologic disorder
- The physician should be concerned about pain that arouses the child from sleep.
 - Unlike usually benign pain that delays falling asleep
- Constant pain is reason for concern.

Kyphosis

- The most common site is the lower thoracic vertebrae.
 - Can occur in any site in the vertebral column
- The initial event is bulging of intervertebral disks in direction of contiguous vertebral bodies.
 - Exerts pressure against cartilage plates
 - Causes thinning of plates
- Interferes with endochondral bone formation on the growth surface of plates
 - Causes gaps that are basis for herniation of disk into the bodies
 - Isolates apophyseal ossification center from vertebral body
- Disk space narrows, more so anteriorly
 - Causes increased pressure on anterior portions of contiguous vertebral bodies
 - Impedes their longitudinal growth anteriorly
 - Results in attendant kyphosis
- An aching pain aggravated by physical exertion is present in the affected part of the vertebral column.
 - The affected area is tender to palpation.
 - Having the patient assume a stooping position often causes pain to increase.
 - Once backache has been present for 1 year or so, kyphosis is easily apparent as a round-back deformity.
- In many instances, pain is so minor that the patient first complains to the physician about pain caused by poor posture; then kyphosis is noted.

Spondylolisthesis

- Horizontal slippage usually involves the L5 vertebral body moving anteriorly in relationship to S1.
 - Can occur anywhere in the vertebral column
- Spondylolysis often causes back pain before spondylolisthesis develops.
 - Flattening of normal lumbar lordosis with posterior tilting of pelvis is noted in spondylolysis.
 - Defect in the arch dissociates vertebra from its inferior facet and posterior ligamentous restraints.
 - Separation may allow slow forward slippage of vertebra on the vertebra below.
- Low back pain is the most common symptom.

- Some cases are diagnosed because the patient has:
 - Abnormal gait
 - Postural deformity
- Only 10–15% of patients ever develop symptoms.

Infections of the spine

- Bone destruction, initially in the anterior portion of the vertebrae, leads to collapse caused by:
 - Acute pyogenic osteomyelitis
 - Tuberculosis (Pott disease)
- Disk space inflammation, or diskitis, can appear as:
 - Fever of unknown origin accompanied by a limp
 - Low back pain
 - Refusal to walk
- The majority of younger patients do not have evidence of bacterial infection.
- Children >8 years of age occasionally have staphylococcal infections of the spine.

DIFFERENTIAL DIAGNOSIS

Classification of spinal deformity

- Idiopathic
 - Infantile
 - Juvenile
 - Adolescent
- Neuromuscular
 - Neuropathic
 - Upper motor neuron lesions
 - Cerebral palsy
 - Spinocerebellar degenerations
 - Syringomyelia
 - Spinal cord tumor
 - Spinal cord trauma
 - Lower motor neuron lesion
 - Poliomyelitis
 - Other viral myelitis
 - Trauma
 - Spinal muscular atrophy
 - Meningocele (paralytic)
 - Dysautonomia (Riley-Day syndrome)
- Myopathic
 - Arthrogryposis
 - Muscular dystrophy
 - Fiber-type disproportion
 - Congenital hypotonia
 - Myotonia dystrophica

■ Congenital

- Congenital scoliosis
 - Failure of formation
 - Wedge
 - Hemivertebra
 - Failure of segmentation
 - Unilateral bar
 - Bilateral bar
- Congenital kyphosis
 - Failure of formation
 - Failure of segmentation
 - Mixed
- Congenital lordosis
- Associated with neural tissue defect
 - Meningomyelocele
 - Meningocele
 - Spinal dysraphism (diastematomyelia)

■ Neurofibromatosis

■ Mesenchymal

- Marfan syndrome
- Ehlers-Danlos syndrome

■ Traumatic

- Fracture or dislocation
- After irradiation
- After laminectomy

■ Soft-tissue contractures

- After thoracoplasty
- Burns

■ Osteochondrodystrophies

- Achondroplasias
- Spondyloepiphyseal dysplasia
- Diastrophic dwarfism
- MPS

■ Scheuermann disease

■ Infection

■ Tumor

■ Rheumatoid disease

■ Metabolic

- Rickets
- Juvenile osteoporosis
- Osteogenesis imperfecta

■ Lumbosacral anomalies

■ Hysterical

■ Functional

- Postural
- Secondary to short limb
- Secondary to pain

DIAGNOSTIC APPROACH

Congenital malformations

Goldenhar syndrome: OAVS

- No clear standard for diagnosis
- Authorities generally agree that the spectrum includes ≥ 2 of the following abnormalities.
 - Ear malformations
 - Including microtia and accessory tragi
 - Low-set ears, hemifacial microsomia
 - Including micrognathia
 - Coloboma
 - Vertebral anomalies
 - Fused or cervical hemivertebrae
- Multiple accessory tragi in a preauricular-mandibular distribution
 - 1 of the more constant findings
 - Important diagnostic clue to recognizing the syndrome

Acquired abnormalities

Adolescent idiopathic scoliosis

- Discovered at:
 - Routine physical examinations
 - School scoliosis screening programs
- Perform an Adams forward-bend test to screen for scoliosis.
 - Child bends forward until:
 - Spine is horizontal with the neck relaxed.
 - Knees fully extended
 - Feet together
 - Upper limbs dependent
 - Palms opposed
- When the patient bends forward, the site and direction of the scoliosis are indicated by prominence of:
 - 1 scapula
 - 1 side of the rib cage
 - Lumbar paraspinous muscles
- Truncal rotation (prominence) may be quantified with inclinometer or scoliometer.
 - Center over the apical spinous process (at the maximal degree of rotation and prominence).
- Seven degrees of rotation corresponds with 20 of coronal deviation.

LABORATORY FINDINGS

- Infections of the spine
 - Blood cultures are indicated in all cases.

IMAGING

- Infantile idiopathic scoliosis
 - Rib vertebral angle difference is defined as the difference in angulation of the left and right ribs on the apical vertebra as measured on an anteroposterior radiograph.
- Kyphosis
 - Radiography
 - Reveal narrowing of anterior disk space and defects on surfaces of adjacent vertebrae at sites where disk tissue has penetrated vertebral bodies
 - Schmorl nodule: prolapsed disk tissue that, in time, becomes walled off by osseous tissue and forms a bulbous mass of extruded tissue appearing as area of lucency in the affected body
- Spondylolysis and spondylolisthesis
 - Single-photon emission computed tomography is an important aid in diagnosis.
 - Oblique radiography reveals the pars intervertebralis defect.
 - Standing lateral radiography demonstrates spondylolisthesis.
- Infections of the spine
 - Narrowing of disk space is the usual radiographic finding.
 - Bone scanning with ^{99m}technetium is helpful in assessing and localizing inflammatory spine lesions.

TREATMENT APPROACH

- Several groups have reported exciting advances in spinal surgery techniques to correct acquired and congenital deformities.
- Growing rods
 - Revived technique
 - Research is showing it a viable option for preserving near-normal growth of the spine.
- New techniques have been described recently, including:
 - Vertebral stapling that produces asymmetric and corrective growth of the concavity of a deformity
 - Vertical expandable prosthetic titanium rib instrumentation
 - Indirectly corrects spine deformity
 - Protects spine growth remaining to treat an associated thoracic insufficiency syndrome

SPECIFIC TREATMENTS

Congenital malformations

Congenital scoliosis

- Management requires frequent clinical and radiographic follow-up to detect progression.
- When located near the middle of the spine:
 - Segments of spine above and below compensate by curving in opposite directions.
 - The result is a balanced spine and a straight back.
 - Treatment is unnecessary.
- When asymmetrical vertebra is at the base of the spine (lumbar, sacral, or lumbosacral):
 - The compensatory curve that develops above is insufficient.
 - Curvature progresses as the patient grows.
 - Requires surgical correction before adolescence
- When deformity occurs in the cervical spine:
 - *Wryneck* deformity results.
 - Thoracolumbar compensatory curvature severely distorts posture.
 - Unilateral surgical fusions are required to minimize deformity.

Congenital kyphosis

- When necessary, the treatment is fusion.

Spina bifida

- Severe forms require prompt neurosurgical correction.
- Exercises to maintain the neck's functional range of motion are indicated.
- Surgery is contraindicated in mild cases.
 - Danger of injuring the cervical spinal cord

Morquio syndrome (MPS type IV)—odontoid dysplasia with atlantoaxial subluxation

- Surgery to stabilize upper cervical spine
 - Perform before development of cervical myelopathy.
 - Use posterior spinal fusion
 - Can be lifesaving

Acquired abnormalities

Juvenile idiopathic scoliosis

- If the scoliosis is in the thoracic region, surgery is required in >95% of cases.

Adolescent idiopathic scoliosis

- Treatment is undertaken to prevent sequelae of untreated severe scoliosis.
 - Pulmonary restriction
 - Significant back pain
 - Cosmetic deformity

- Exercises are of no benefit in retarding or reversing progress of scoliosis.
- Curvature
 - $>40^\circ$: requires surgical fusion regardless of the patient's age.
 - $20\text{--}40^\circ$: should not require treatment if skeletal maturation is complete; bracing is often recommended in the growing child
 - $<20^\circ$: should be observed for possible progression; does not require treatment

Kyphosis

- Treatment is aimed at preventing further deformity by casting or bracing.
- In rare instances of rapid progression or very severe pain, spinal fusion is necessary.
- The majority of youngsters require careful observation, with intervention only if progression of deformity occurs.

Spondylolysis and spondylolisthesis

- In the absence of symptoms, requires no treatment or activity restriction
- Treatment is typically aimed at alleviation of back pain.
 - Can usually be accomplished with activity restrictions or a period of bracing
 - Activities that hyperextend the lumbar spine should be avoided.
 - Exercises to reduce lumbar lordosis relieve the pain of spondylolysis.
- Once slippage occurs, surgical spinal fusion is necessary.

Infections of the spine

- Bone destruction
 - Vigorous antibiotic therapy and immobilization are indicated.
- The majority of younger patients require only immobilization.
- Indications for using antibiotics include:
 - Positive blood culture results
 - Recurrences of back pain accompanied by systemic signs, such as:
 - Fever
 - Leukocytosis with a left shift in the leukocyte count
 - Elevated erythrocyte sedimentation rate
 - Bone erosion
 - Clinical advancement of disease despite immobilization

WHEN TO REFER

- Adolescent idiopathic scoliosis
 - Refer to a pediatric orthopedist when 7 of rotation corresponds with 20 of coronal deviation.

COMPLICATIONS

Congenital malformations

- Congenital kyphosis
 - Progressive deformity in the thoracic spine can result in paraplegia.
 - Associated with failure of the formation of the vertebral body
- Morquio syndrome (MPS type IV)—odontoid dysplasia with atlantoaxial subluxation
 - Odontoid process in the cervical region is often dysplastic and fails to ossify, leading to:
 - Atlantoaxial instability
 - C1–C2 subluxation
 - Insidious onset of cervical cord compression, beginning with fatigue and progressing to weakness, can occur.
 - Acute cord compression and respiratory arrest may occur after minor falls.

Acquired abnormalities

- Infantile idiopathic scoliosis
 - The vast majority of these curves are self-limiting.
 - Those that progress can be difficult to manage.
 - Usually double structural curves
 - In cases in which the rib vertebral angle difference is $>20^\circ$, progression is likely.

PROGNOSIS

Congenital malformations

- Congenital scoliosis
 - Curve progression is strongly related to the type of vertebral abnormality.
 - The poorest prognosis is for unilateral unsegmented bars with contralateral hemivertebrae.
 - Up to 10° /year progression
 - Less severe progression in cases of hemivertebrae (seen in 40% of cases) or double hemivertebrae
 - $1\text{--}2.5^\circ$ /year and $2\text{--}5^\circ$ /year, respectively
 - Least severe progression in patients with block and wedge vertebrae
- Congenital kyphosis
 - After progression begins, it does not cease until end of growth.
- Spina bifida
 - The physician should assess defect level accurately because it affects prognosis.
 - All thoracic lesions are associated with paraparesis.
 - Lesions below L4 are associated with normal ambulation.
 - Prognosis with lesions between L1 and L4 is mixed.

■ Juvenile idiopathic scoliosis

- Often progressive
 - Estimated at ~70%
- Potential for trunk deformity with cardiac and pulmonary compromise exists.
 - Especially in scoliosis with onset before 5 years of age
- Curves $>30^\circ$ are almost always progressive.
 - Rate of $1\text{--}3^\circ/\text{year}$ before 10 years of age
 - Rate of $4.5\text{--}11^\circ/\text{year}$ after 10 years of age

Acquired abnormalities**■ Adolescent idiopathic scoliosis**

- 5% of those with disease have a progression of the curve to $>30^\circ$.
 - Progression of scoliosis is dependent on:
 - Growth velocity
 - Magnitude of the curve at first visit
 - Progression is most notable with a growth velocity of $>2\text{ cm/year}$.
 - Between 9 and 13 years
 - At bone ages between 9 and 14 years
 - Between 0.5 and 2 years before menarche

- Main progression occurs at the time of most rapid skeletal growth.

- 11–13 years for girls

- 13–15 years for boys

- Primary thoracic curve scoliosis progresses more than primary lumbar curve scoliosis.

■ Kyphosis

- In some children, the condition can progress to cause severe deformity and dysfunction.
- In others, it stabilizes and the deformity may disappear.

■ Spondylolysis and spondylolisthesis

- Progression is estimated to occur in 5–7% of patients with spondylolisthesis.
 - Most likely to occur during the adolescent growth spurt

Splenomegaly

DEFINITION

- Splenomegaly is enlargement of the spleen resulting from abnormalities of the lymphoid, reticuloendothelial, or vascular components of the spleen.

EPIDEMIOLOGY

- Prevalence
 - A soft spleen is normally palpable in 15–30% of neonates.
 - By 1 year of age, 10% of healthy children have a palpable spleen.
 - After 10 years of age, 1% of children have palpable spleens.
- Sex
 - No sex-based differences in spleen size have been found.

MECHANISM

- The spleen has many functions:
 - Hematopoietic
 - The spleen is a major hematopoietic organ during fetal life and can resume extramedullary hematopoiesis in children and adults with bone marrow failure.
 - Phagocytic
 - Immunologic
 - The spleen is a major lymphoreticular organ that acts as a filter for infectious organisms in the blood.
 - Removes senescent and abnormal erythrocytes
 - Removes particulate material
 - Acts as a site of immunoglobulin M and properdin production
 - Reservoir for blood-borne elements, including:
 - Platelets, reticulocytes, and plasma proteins (in particular, factor VIII)
- Splenomegaly may be caused by:
 - Systemic infections
 - In infectious processes, splenomegaly results from hypertrophy of lymphatic and reticuloendothelial elements.
 - An increase in the normal splenic process, eg, hemolytic anemia
 - Infiltration from storage diseases or cancer
 - Congestion from splenic or portal vein obstruction
 - Inflammatory diseases
- Splenomegaly associated with hemolytic states results from:
 - Engorgement of the splenic sinusoids by abnormal erythrocytes
 - Increased phagocytic activity (work hypertrophy) of the reticuloendothelial elements.

HISTORY

- In most cases, the cause of splenomegaly can be determined by history and physical examination.
- Family history may be relevant.

- In infants, ask about birth history and the early neonatal period.
 - A history of umbilical vein catheterization or omphalitis in the neonatal period may suggest a diagnosis of portal vein thrombosis.
- In a newborn with unexplained jaundice, consider congenital hemolytic anemia, especially if there is a family history of:
 - Anemia
 - Jaundice
 - Splenomegaly
 - Splenectomy
- A viral cause (Epstein-Barr virus, cytomegalovirus) should be considered in a child with a history of:
 - Fever
 - Pharyngitis
 - Malaise
- Malaria or histoplasmosis may be the cause if the patient has recently traveled to areas endemic for these diseases.
- An underlying inflammatory, infectious, or malignant process should be suspected in the patient with:
 - Fever
 - Night sweats
 - Malaise
 - Weight loss
 - Rash
 - Arthralgia
 - Bone pain

PHYSICAL EXAM

- Spleen length is correlated with age, height, weight, and body surface area in a nonlinear fashion, similar to the liver.
- Wide interobserver variability exists in the ability to detect an enlarged spleen on examination.
 - Not generally associated with clinical experience
- The spleen:
 - Moves downward with inspiration
 - Enlarges diagonally across the midline toward the right ileac fossa.
- An enlarged spleen may extend into the pelvis.
- Palpation and percussion are important techniques in the physical examination of the child with suspected splenomegaly.
- Palpation
 - Begin in the right lower quadrant.
 - Move across the abdomen toward the left upper quadrant.
 - The normal palpable spleen is:
 - Soft
 - Smooth

- Nontender
 - <1–2 cm below the left costal margin
 - A pathologically enlarged spleen:
 - Is usually firm
 - Has an abnormal surface
 - Is often associated with signs and symptoms of an underlying disease
 - Spleen may be tender if it has enlarged quickly.
 - Splenic sequestration
 - Splenic trauma with subcapsular hemorrhage
 - When portal hypertension causes splenomegaly, dilatation of the superficial abdominal veins can be seen.
 - Consider an autoimmune disorder when the following are present:
 - Rash
 - Arthritis
 - Mucosal ulcerations
 - Splenomegaly
 - A palpable spleen may be normal.
 - However, the concomitant finding of hepatomegaly is usually pathologic, and further investigation is warranted.
 - A palpable spleen may be encountered as a result of thin abdominal musculature.
- **Percussion**
- Percussion cannot confirm splenic enlargement but can raise suspicion.
 - Percuss the left lower anterior chest wall between lung resonance above and the costal margin below.
 - This is known as the *Traube space*.
 - An enlarged spleen replaces the tympany of the stomach and colon with the dullness of a solid organ.
 - If tympany is prominent, especially laterally, then splenomegaly is not likely.
 - A change from tympany to dullness on inspiration when percussing at the lower interspace in the left anterior axillary line suggests splenic enlargement.
- **Bacterial infection**
- Acute bacterial infections
 - Subacute bacterial endocarditis
 - Congenital syphilis
 - Tuberculosis
 - Other chronic bacterial infections
 - Septicemia from meningococcus or pneumococcus may also be associated with splenomegaly.
- **Parasitic infection**
- Toxoplasmosis
 - Malaria
 - Leishmaniasis
- **Fungal infection**
- Candidiasis
 - Histoplasmosis
 - Progressive disseminated histoplasmosis can occur in healthy children <2 years.
 - Results from exposure to the fungus in endemic areas of the US (Mississippi, Ohio, and Missouri River valleys)
 - Early symptoms are fever, failure to thrive, and hepatosplenomegaly.
 - Coccidioidomycosis
- **Hematologic disorders**
- Splenic enlargement as a result of extramedullary hematopoiesis
- Occurs in diseases associated with increased demand on the bone marrow for cell production, eg, thalassemia major
- Acute splenic sequestration crisis is a medical emergency that requires prompt recognition and treatment.
- It is a leading cause of death in children with sickle cell anemia.
 - A rapidly enlarging spleen with:
 - Falling hematocrit
 - Pallor
 - Dyspnea
 - Weakness
 - Left-sided abdominal pain
- **Hemolytic anemias—congenital and acquired**
- Red cell membrane defects
 - Hereditary spherocytosis
 - Hereditary elliptocytosis
 - Red cell hemoglobin defects
 - Sickle cell disease and related syndromes
 - Thalassemia
- **DIFFERENTIAL DIAGNOSIS**
- Infection**
- **Viral infection**
- The most common cause of splenomegaly in children
 - Splenic enlargement is usually transient and mild to moderate in severity.
 - Common viral infections include:
 - Epstein-Barr virus (infectious mononucleosis)
 - Splenomegaly occurs in 50–75% of cases of infectious mononucleosis.

- Red cell enzyme defects
 - Pyruvate kinase deficiency
 - Glucose-6-phosphate dehydrogenase deficiency
 - Others

- Autoimmune hemolytic anemia

■ Extramedullary hematopoiesis

- Occurs in diseases associated with increased demand on the bone marrow for cell production.
 - Thalassemia major
 - Osteopetrosis
 - Myelofibrosis

Infiltrative disorders

- In malignant infiltration, the spleen is firm, massively enlarged, and crosses the midline of the body.
- The spleen is commonly infiltrated in:
 - Leukemias and lymphomas
 - Lipidoses
 - Mucopolysaccharidosis
 - Phagocytic reticuloendothelial elements of the spleen accumulate large amounts of lipid and mucopolysaccharide, respectively.
 - Langerhans cell histiocytosis
 - Metastatic neoplasia of the spleen is rare and is usually caused by neuroblastoma.

Congestive splenomegaly (Banti syndrome)

- Splenomegaly may occur from obstruction of the hepatic, portal, or splenic veins.
- Common causes include:
 - Portal vein thrombosis
 - Cirrhosis
 - Congestive heart failure
 - Umbilical vein catheterization or septic omphalitis in neonates may also result in obliteration of the portal, hepatic, or splenic veins.
- Congestive splenomegaly is the most common cause of hypersplenism (splenomegaly), peripheral blood cytopenias from excessive splenic function, and increased bone marrow production of the affected blood cells.

Inflammatory diseases

- Splenomegaly is the result of increased numbers of reticuloendothelial cells that remove antibody-coated cells and proteins in inflammatory diseases, such as:
 - Systemic lupus erythematosus
 - Rheumatoid arthritis (Still disease)
 - Serum sickness
 - Sarcoidosis
 - Immune thrombocytopenias and neutropenias

- Lymphoid hyperplasia may occur as a result of accelerated antibody production in the spleen.

Primary splenic disorders

■ Splenoptosis (wandering spleen)

- Splenoptosis, or wandering spleen, is a congenital fusion anomaly of dorsal mesogastrium.
- Results in a spleen of normal size that moves freely within the peritoneal cavity
- A patient with splenoptosis usually has an asymptomatic abdominal mass.

■ Cysts

- Splenic cysts may mimic splenomegaly.
- 2 types of splenic cysts have been identified:
 - Congenital (epidermoid)
 - Acquired (pseudocyst) from trauma or infarction
- Cysts are generally asymptomatic, and their presence is usually confirmed by radiologic studies.

■ Hemangiomas and lymphangiomas

■ Subcapsular hemorrhage

- Abdominal trauma may cause subcapsular hemorrhage of the spleen.
- Abdominal pain

■ Accessory spleen may also mimic splenomegaly.

- Found in 10–15% of individuals

LABORATORY EVALUATION

- The initial laboratory testing of a child with splenomegaly should include:
 - Complete blood count
 - Leukocyte differential
 - Reticulocyte count
 - Examination of the peripheral blood smear
- Further laboratory investigations should be directed at the suspected diagnosis, based on findings from:
 - History
 - Physical examination
 - Initial laboratory tests

IMAGING

- Imaging of the spleen can be an important adjunct to the physical examination in defining pathologic changes in this organ.
- Radiologic confirmation of a mass in the left upper quadrant should be performed if any question exists about the nature of the mass.
 - Retroperitoneal tumors may be mistaken for an enlarged spleen, eg, neuroblastoma or Wilms tumor.

- Ultrasonography
 - Used to quantify splenic enlargement
 - Differentiates the spleen from other left upper-quadrant abdominal masses
 - Contrast-enhanced sonography is a novel technique that allows real-time assessment.
- Radioactive (technetium-99m) sulfur colloid scintigraphy
 - Used to assess splenic function
- Computed tomography
 - Used to evaluate splenic trauma and focal splenic pathology
- Magnetic resonance imaging
 - Can further clarify abnormalities in size and shape
 - Can define parenchymal disease

TREATMENT APPROACH

- Treatment of splenomegaly should be aimed at the underlying disease entity.
 - Patients who have bacterial infections should receive appropriate antibiotic therapy.
 - Viral causes of splenomegaly require supportive care.

SPECIFIC TREATMENT

Infectious mononucleosis

- Patients should refrain from contact or collision sports until illness has completely resolved clinically and the spleen has returned to a normal size.
 - Generally, this is at least 4 weeks from the onset of illness.
 - Sonographic evaluation of spleen size may be necessary to determine when the patient can resume full athletic activity.

Splenectomy

- May be indicated to help control or stage some diseases that cause splenomegaly
 - Hereditary spherocytosis
 - Autoimmune thrombocytopenia or hemolysis
 - Lymphoma, Hodgkin disease
- Splenectomy may also be indicated to treat chronic, severe hypersplenism.

- Laparoscopic splenectomy is being performed more commonly in children.
 - The procedure is safe and hospital stay is shorter compared with open splenectomy.

WHEN TO REFER

- Splenomegaly with concomitant hepatomegaly
- Palpation of a hard spleen
- Suspicion of cancer or other infiltrative disorders
- Evidence of hemolytic anemias

WHEN TO ADMIT

- Admission may be required when there is:
 - Splenic sequestration in sickle cell disease
 - Injury to the spleen from abdominal trauma
 - Possible cancer

FOLLOW-UP

- All children without spleens:
 - Are at risk for fulminant bacteremia, particularly from:
 - *Streptococcus pneumoniae*
 - *Haemophilus influenzae*
 - *Neisseria meningitides*
 - Should receive appropriate immunizations
 - Daily antimicrobial prophylaxis against pneumococcal infections (in addition to immunization) is recommended:
 - In children <5 years of age and
 - For ≥1 year after splenectomy

Complications

- Rupture of the enlarged and friable spleen is possible if the child participates in contact sports.
- Hypersplenism can cause cytopenias and severe anemia.

Prognosis

- Prognosis depends on underlying cause.
 - Splenomegaly caused by Epstein-Barr virus or cytomegalovirus infection usually resolves by 4 weeks.

Sports Injuries

DEFINITION

■ Sports medicine is a discipline in itself; an introduction to some of the more common problems is presented here.

■ Types of sports injuries include:

- Heat injury
 - Heat cramps
 - Heat exhaustion
 - Heatstroke
- Drug use in athletes
- Injuries to bone and soft tissue
 - Overuse syndromes
 - Stress fracture
 - Metaphyseal and diaphyseal stress injuries
 - Osgood-Schlatter disease
 - Sinding-Larsen-Johansson disease
 - Calcaneal apophysitis
 - Little League shoulder
 - Physeal widening of the distal radius
 - Panner disease
 - Osteochondritis dissecans of the capitellum
 - Tendonoses
 - Rotator cuff tendonitis
- Acute trauma
 - Ankle sprains
 - Collateral ligament injuries of the knee
 - Meniscal tears
 - Quadriceps contusion
 - Avulsion fracture of the pelvis
 - Muscle strain
 - Patellar dislocation
 - Shoulder dislocation
 - Chondromalacia patella
 - Patellofemoral pain syndrome
 - Winter sports injury

EPIDEMIOLOGY

Drug use in athletes

■ Anabolic steroid use has been reported to be as high as 5–11% among high school boys and 2.5% among high school girls.

Injuries to bone and soft tissue

- Metaphyseal and diaphyseal stress injuries
 - Most occur in later adolescence (age 16–19 years); some occur at younger ages.
 - Distribution of male and female patients is typically equal.
- Osgood-Schlatter disease
 - Patients are typically 10–15 years of age at onset.

- Boys are more commonly affected than girls; however, female gymnasts are particularly prone to this problem.

■ Sinding-Larsen-Johansson disease

- Affected youngsters are typically 10–13 years of age.

■ Calcaneal apophysitis

- The patient is typically 9–14 years of age, with a substantial peak occurring at 10 and 11 years of age.
- Most (60–80%) cases are bilateral.

■ Tendonoses

- The most common tendonitis in young athletes is that of the Achilles tendon.

Acute trauma

■ Ankle sprains

- The most common musculoskeletal injury in sports
- Approximately 97% involve the lateral ankle ligaments.

■ Anterior cruciate ligament (ACL) injuries

- As adolescents become skeletally mature, the incidence of ACL injuries increases rapidly.
- The incidence of injuries to young female athletes, particularly in soccer, basketball, and gymnastics, is increasing rapidly.

■ Meniscal tears

- For patients >10 years of age, the incidence of tearing of normal menisci rises.

■ Muscle strain

- Muscle strains are not as common in young athletes as they are in older ones.

■ Patellofemoral pain syndrome

- The typical patient is a teenage girl >12 years of age.

■ Winter sports injury

- Children are more likely to experience upper-extremity injuries.
- Lower-extremity injuries are more frequent in adolescents and adults.
- Children <10 years incur more fractures and catastrophic injuries (head injuries) with individual recreational activities than they do with organized sports.

ETIOLOGY

■ Organized sports account for only about one-third of sports injuries.

■ The remainder occur in physical education classes and in recreational sports.

Heat injury

■ Heat exhaustion is probably caused by ineffective cardiovascular and autonomic responses to heat.

Injuries to bone and soft tissue

- Overuse syndromes
 - Characterized by injury to bone, cartilage, or soft tissue caused by repetitive submaximal physical stress
 - In contrast to acute injury, tissue breakdown in overuse injuries occurs gradually, and the body continually remodels these tissues so that they recuperate fully.
 - When imbalance occurs between rate of breakdown of connective tissues and the body's ability to remodel them, stress injuries occur.
 - Stress fracture
 - Repetitive loading of relatively rigid musculoskeletal tissue leads to work hardening.
 - Unless remodeling occurs, the bone becomes brittle and eventually breaks.
 - Metaphyseal and diaphyseal stress injuries
 - Metaphyseal and diaphyseal stress fractures in young athletes most commonly involve the fibula, metatarsals, tibia, femur, and ulna, but virtually any bone can be affected.
 - Osgood-Schlatter disease
 - The tubercle of the proximal tibia is the insertion site of the patellar tendon.
 - The quadriceps is the strongest muscle group, and tensions it generates through the patellar tendon are enormous.
 - Stresses applied at interface between tendon and apophysis disrupt normal transition from ossified and unossified tubercle into the tendon.
 - Sinding-Larsen-Johansson disease
 - Due to chronic repetitive stress to the inferior pole of the patella
 - In response, the patellar periosteum creates a bony reaction.
 - Calcaneal apophysitis
 - Occurs at the apophyseal insertion of the Achilles tendon into the calcaneus
 - Little League shoulder
 - Actually, physiolysis of the proximal humerus
 - Due to a widening of the proximal humeral physeal plate
 - Physeal widening of the distal radius
 - Physeal stress injury of the distal radius
 - Osteochondritis dissecans of the capitellum
 - The disorder is a repetitive stress phenomenon, not due to an inflammatory process.
 - As the ball is released during the pitching motion, a valgus movement occurs at the elbow.
 - Tension occurs on the medial side of the elbow, and compressive forces are created across the radial capitellar articulation.
 - The capitellum has an end arterial blood supply, which may be responsible for its susceptibility to developing avascular necrosis.
 - Tendonoses
 - Due to overuse injury to a tendon
 - In adults, divided into 3 stages
 - Inflammation of the paratenon
 - Inflammation of the tendon itself
 - Degenerative change of the tendon that ultimately results in rupture
 - In children, typically only the earliest stage of inflammation is seen.
 - Rotator cuff tendonitis
 - The rotator cuff is a convergence of the tendons of the subscapularis, supraspinatus, infraspinatus, and teres minor muscles.
 - Due to stress to the shoulder, especially when the arm extends overhead
 - The inherent laxity of the glenohumeral capsule is likely to be a significant factor in younger athletes.
- ## Acute trauma
- Ankle sprains
 - Inversion and external rotation of the foot results in sequential tearing of the anterior talofibular ligament, calcaneal fibular ligament, and finally the posterior talofibular ligament.
 - Other areas are sometimes involved: the anterior talofibular ligament, syndesmosis complex, and deltoid ligament.
 - ACL injuries
 - The ACL is a key stabilizer of the knee joint, particularly to rotational movements, and is frequently injured in sports that involve cutting and twisting.
 - Alternatively, the knee may be struck from the lateral side, injuring the medial collateral ligament and then the ACL.
 - Meniscal tears
 - In youths ≤ 10 years of age, most meniscal tears are related to the discoid menisci.
 - For patients >10 years, tearing occurs in association with significant ligament injury, such as a tear of the ACL.
 - Tear without a substantial injury is rare in teens.
 - Patellar dislocation
 - Often result of a trivial injury
 - History of injury can vary from a minor twisting episode to a significant direct blow to the knee.
 - Shoulder dislocation
 - Dislocations of glenohumeral joint can occur.
 - From relatively minor trauma in predisposed individuals
 - As a result of major trauma in the average person

- Chondromalacia patella
 - Softening of the articular surface of the patella, which can occur in mild to severe grades, ranging from edema of the cartilage to complete ulceration of the articular surface
- Patellofemoral pain syndrome
 - Although the cause of this problem is not clear, abnormality of patellar tracking may be responsible.
 - Abnormal stresses in the patellofemoral articulation or surrounding soft tissues are probably responsible.

RISK FACTORS

In general

- Wrestling and football have the highest significant injury rates per participant in high school, followed by softball, gymnastics, track and field, and soccer.
- Tennis and swimming produce the fewest injuries.
- Frequency of injury is not always the best measure of a sport's risk.
 - Trampoline accounts for a disproportionately large number of injuries that cause paralysis.
- Risk of injury is much greater among senior high school students than among junior high and younger participants.
- Inexperienced coaches with high expectations of young athletes and poor understanding of training may contribute to injury.

Heat injury

- Heat cramps, heat exhaustion, and heatstroke are increasingly common in athletes who:
 - Do not drink adequate fluids
 - Are not acclimatized to local heat and humidity
 - Are poorly conditioned
- Heatstroke
 - Most often seen in long-distance runners
 - Second-most common cause of death in football players
 - Most common when temperature >95°F (35°C) and humidity >50%

Drug use in athletes

- Anabolic steroid use is most common among football players and track participants.

Injuries to bone and soft tissue

- Overuse syndromes
 - Training errors
 - Increased recreational time
 - Increased intensity and duration of competition
 - Increasing standards of competition
 - Inadequate preseason conditioning
 - Suboptimal facilities and equipment

- Overly enthusiastic coaches and parents
- Participation in multiple sports
- Lengthy seasons
- Stress fracture
 - Commonly occurs with long-distance running
- Little League shoulder
 - Almost exclusive to Little League baseball players
 - Typically affects pitchers, but sometimes occurs in players who do a lot of throwing from other positions
- Physeal widening of the distal radius
 - Almost exclusively in young female gymnasts
- Osteochondritis dissecans of the capitellum
 - Most common in baseball pitchers
 - Any pitching style that releases the ball lateral to the body's midsagittal plane accentuates valgus moment at the elbow.
 - Side-arm pitches, many curve-ball techniques, and others can increase compression loads across the lateral side of the elbow.
- Rotator cuff tendonitis
 - In young athletes, inherent laxity of the glenohumeral capsule (ligament complex) is likely to be a significant factor.
 - Sporting activities that stress the shoulder joint with the arm extended overhead are particularly prone to precipitate symptoms.
 - Overhead throwing in baseball
 - Swimming
 - Tennis serves
 - Gymnastics

Acute trauma

- ACL injuries
 - Girls: soccer, basketball, and gymnastics
 - Boys: football, soccer, and basketball
- Quadriceps contusion
 - Common in contact sports, such as football, soccer, and lacrosse
- Patellar dislocation
 - Predisposition to dislocation of the patella as a result of genetic variability in knee extensor mechanism
 - Variations leading to easy dislocation include:
 - Shallow sulcus in the distal femur
 - Lateral translation of the insertion of the patellar tendon into the tibia
 - Relative underdevelopment of the vastus medialis muscle
 - Tightness of the lateral retinaculum

- Patellofemoral pain syndrome
 - May result from training errors
 - Sudden increase in mileage
 - Running on hard surfaces
 - Poor preseason conditioning
 - Inadequate footwear
- Winter sports injury
 - Downhill snow skiing: knee contusions, ACL sprains, spiral fracture of tibia
 - Cross-country snow skiing: medial collateral ligament sprain, acute ankle inversion strain, acromioclavicular joint separation, skier's toe, hypothermia
 - Snowboarding: wrist, ankle, and knee injuries
 - Snowmobiling: multisystem trauma with head injury
 - Sledding: head and face, extremity, abdominal injuries
 - Water skiing: lower-extremity and trunk injuries
 - Wakeboarding: head and face injuries

SIGNS AND SYMPTOMS

Heat injury

- Heat cramps
 - Usually involve the arms, abdomen, or legs
 - Affected individuals usually have been sweating profusely.
- Heat exhaustion
 - Patients feel weak, faint, dizzy, and nauseous.
 - They may vomit and appear pale.
 - Syncope sometimes occurs.
 - Patients may sweat profusely, or if severely dehydrated, the skin may feel warm and dry.
 - Body temperature is often normal.
- Heatstroke
 - High rectal temperature
 - Hot and dry skin
 - Signs of central nervous system dysfunction, such as irritability, combativeness, and disorientation, which may progress to obtundation
 - Tachycardia and hypotension are often present.

Drug use in athletes

- Anabolic steroid use
 - Clues to excessive use include:
 - Jaundice
 - Increased acne
 - Behavioral changes (aggressiveness, irritability, marked mood swings)
 - Gynecomastia

- Testicular atrophy
- Hirsutism and deepening of the voice (in women)

■ Anabolic steroid withdrawal

- Mood changes
- Irritability
- Hot flashes
- Nausea
- Myalgia
- Malaise
- Tachycardia
- Hypertension

Injuries to bone and soft tissue

- Stress fracture
 - Progressive discomfort with activities
- Metaphyseal and diaphyseal stress injuries
 - Gradual onset of symptoms
 - Eventually, pain may preclude running.
- Osgood-Schlatter disease
 - Pain is well localized to the tibial tubercle; it typically increases with activity.
 - Significant pain, tenderness, and swelling of the tubercle on the presenting side and, usually, some degree of findings on the contralateral side
 - Many patients have a history of heel pain compatible with Sever disease (calcaneal apophysitis).
 - No signs or symptoms of intraarticular problems of the knee joint itself
- Sinding-Larsen-Johansson disease
 - Well-localized pain at the inferior pole of the patella
 - No signs or symptoms of internal derangement of the knee joint itself
 - On physical examination, point tenderness at the inferior edge of the patella and typically no other abnormal findings
- Calcaneal apophysitis
 - Complain of heel, ankle, or foot pain
 - On physical examination, discomfort is typically well localized at the region of the calcaneal apophysis.
 - Pain is typically medial or posterior, although occasionally may be on the lateral side.
 - Tenderness rarely occurs distal near the origin of the plantar fascia.
 - No swelling, warmth, or limitation of motion
 - Occasionally, because of concurrent tendonitis, some tenderness can occur along the course of the Achilles tendon itself.

■ Little League shoulder

- Pain in the shoulder related to overhead throwing
- Many of the signs and symptoms are the same as for rotator cuff tendonitis, but the patient with Little League shoulder typically has more pain in the deltoid region as opposed to the subacromial region.

■ Physeal widening of the distal radius

- Progressive pain in the wrists
- Most often the pain is bilateral, but it may be more prominent on one side.
- On physical examination, point tenderness is often present, and a prominence may be noted on the dorsum of the distal radial physis.

■ Osteochondritis dissecans of the capitellum

- Aching pain in the lateral side of the elbow
- With time, patients can lose range of motion.
- Osteochondral fragments can displace acutely, resulting in a loose body sensation, a locked elbow, significant synovitis and pain, or any combination.

■ Tendonoses (specifically Achilles tendonitis, the most common tendonoses in children)

- Symptoms are typically located 2–6 cm above the insertion of the Achilles tendon into the calcaneus.
- Lack of flexibility in the gastrocnemius muscle group may be found on physical examination.

■ Rotator cuff tendonitis

- Pain with overhead activities
- In many instances, the athlete will report the arm becoming heavy or tired, or feeling dead.

Acute trauma

■ Ankle sprains

- Persistent anterolateral ankle pain can occur after even mild ankle sprains.

■ ACL injuries

- Patients report an acute “pop” and moderate to severe pain, causing them to fall to the ground.
- The knee may not swell immediately, but typically it does swell within the first few hours because of the development of hemarthrosis.
- Tenderness is sometimes not marked, and athletes will attempt to return to their sporting competition, only to discover that the knee is not stable, which may worsen the injury.

■ Quadriceps contusion

- Minor hematomas do not limit knee movement.
- Large ones limit knee movement.

■ Avulsion fracture of the pelvis

- Acute onset of pain following a sudden athletic movement, such as:
 - An explosive start for a sprint
 - An extreme pike maneuver (hips flexed and knees extended) in gymnastics
 - A combination twisting movement and direct blow to the iliac crest
- Focal tenderness to palpation over the affected apophysis
- Pain with resisted strength testing of the corresponding muscle insertion or origin

■ Muscle strain

- Slipped capital femoral epiphysis is the most common disorder of the hip in adolescents.
 - Although classically exhibiting with hip pain, discomfort may be referred to the thigh or knee joint.
- Hamstring strain causes pain at the musculotendinous junction, which is at the junction of the middle and distal thirds of the posterior thigh.

■ Patellar dislocation

- The patellae typically dislocates to the lateral side.

■ Patellofemoral pain syndrome

- Typical onset is insidious and without a specific history of trauma.
- No history of erythema, warmth, induration, or true effusion
- Slightly puffy knee in some patients
- No mechanical complaints of catching or locking
- Popping may be present, but the popping is usually painful.
- On physical examination:
 - Tenderness along the medial and lateral sides of the patellofemoral articulation
 - Mild discomfort over the anterior portion of the joint line, but typically no tenderness over the middle or posterior portion of the tibial femoral articulation
 - The joint has full range of motion with no crepitation.
 - Stable knee

DIFFERENTIAL DIAGNOSIS

Injuries to bone and soft tissue

■ Osgood-Schlatter disease

- Tumor or infection can mimic Osgood-Schlatter disease.

■ Sinding-Larsen-Johansson disease

- Irregular ossification at the inferior pole of the patella may be mistaken for a fracture.

■ Calcaneal apophysitis

- Significant irregularity of the ossifying calcaneal apophysis is a normal finding in children and should not be confused with evidence of a fracture.

- Need to rule out other osseous processes, such as tumor or infection.
- Little League shoulder
 - Rotator cuff tendonitis: Many of the signs and symptoms are the same.
 - Impending pathologic fracture from a simple bone cyst in the upper humerus
- Physeal widening of the distal radius should be distinguished from:
 - Carpal laxity with dorsal wrist capsular impingement
 - Posterior interosseous neuroma
 - Avascular necrosis of the lunate
- Rotator cuff tendonitis
 - Need to rule out other bony abnormalities

Acute trauma

- Collateral ligament injuries of the knee
 - Consider concurrent injury to the cruciate ligaments, menisci, and articular surfaces.
 - Lateral knee and ligament injuries are uncommon in young athletes; they should raise suspicion of another explanation for the patient's signs and symptoms, and referral is wise.
- ACL injuries
 - A high index of suspicion should be maintained for ACL injury, and it must be ruled out before a young athlete who has a knee injury returns to practice or competition.
- Quadriceps contusion
 - Differentiating a large quadriceps hematoma from a malignant tumor (eg, Ewing sarcoma and osteosarcoma) becomes challenging, since those tumors have a propensity to occur in teenagers and may bleed internally.
- Muscle strain
 - Muscle strains are not as common in young athletes as they are in older ones.
 - An unknown musculoskeletal malady is often misdiagnosed as strain.
 - Particularly around the hip and thigh area, the examiner should be careful not to miss a slipped capital femoral epiphysis, an avulsion fracture, an infection, or a tumor as causes of pain.
 - More proximal hamstring tenderness should raise suspicion of an occult injury to the ischial apophysis.
- Patellar dislocation
 - Should not be labeled as knee dislocation, which denotes displacement of the articulation between the tibia and femur.
 - The latter is a high-energy injury and has high associated morbidity, including, occasionally, loss of limb.

- Shoulder dislocation
 - Pathologic collagen disorders, such as Marfan syndrome, need to be considered.
 - Physical findings consistent with Marfan syndrome include tall, thin body habitus; arachnodactyly; pectus excavation; heart murmur; dislocated lens; and myopia.

Anterior knee pain

- Can arise from many disorders, including:
 - Osgood-Schlatter disease
 - Sinding-Larsen-Johansson disease
 - Patellar tendonitis
 - Patellar instability
 - Chondromalacia patella
 - Patellofemoral pain syndrome
- Less common disorders
 - Quadriceps tendonitis
 - Bipartite patella
 - Osteochondritis dissecans of the femur or patella
 - Iliotibial band tendonitis
 - Popliteus tendonitis
 - Inflamed plica
 - Prepatellar bursitis
 - Synovial flat pin impingement syndrome
 - Osteomyelitis
 - Septic arthritis
 - Inflammatory arthritis
 - Tumors

IMAGING

Injuries to bone and soft tissue

- Metaphyseal and diaphyseal stress injuries
 - Magnetic resonance imaging (MRI) may be the most sensitive study for stress fractures.
 - Only about 10% of radiographs are abnormal at symptom onset.
 - Bone scan may detect an early stress fracture of the metaphysis or diaphysis.
 - Bone scan findings must be correlated to clinical symptoms.
 - Up to 50% of adolescents with stress fractures will show multiple areas of stress response on bone scan, many of which do not correlate to areas of symptoms.
- Osgood-Schlatter disease
 - A lateral radiograph of the knee can show irregularity of the tibial tubercle.

- Sinding-Larsen-Johansson disease
 - Lateral radiograph of the knee may show irregular ossification at the inferior pole of the patella.
- Calcaneal apophysitis
 - Because of concurrent tendonitis, some tenderness can occur along the course of the Achilles tendon itself; no classic radiographic change of calcaneal apophysitis.
 - In bilateral cases, radiographs are necessary only if some atypical component of the history and physical examination raises concern about some other diagnosis.
- Physeal widening of the distal radius
 - Anteroposterior and lateral radiographs show physeal widening.
 - Comparison films of the other side are almost always obtained, although both sides may be involved.
 - Typically, some asymmetry is noted.
- Osteochondritis dissecans of the capitellum
 - Plain-film radiographs often show a lesion of the capitellum.
 - Sclerotic region or simply radiolucency may be present.
 - Tangential views may be necessary to see the lesion.
 - Computed tomography (CT) and/or MRI are sometimes helpful.
- Tendonoses
 - Radiography and MRI are rarely indicated.
- Rotator cuff tendonitis
 - Plain-film radiographs are not diagnostic of rotator cuff tendonitis but are often obtained to rule out other bony abnormalities.
 - MRI can be diagnostic for rotator cuff tendonitis but is often not necessary.

Acute trauma

- Ankle sprains
 - The decision to obtain radiographs is based on several factors.
 - Patient age
 - History of injury
 - Physical findings
 - Ability to bear weight
 - Progress since injury
 - A typical fracture of the distal fibular physis has a Salter-Harris type I fracture pattern without displacement, which results in a normal radiograph of bone, showing only soft-tissue swelling.
 - Diagnosis is made clinically; radiography excludes displacement of fracture or presence of other fractures.
- Collateral ligament injuries of the knee
 - Plain-film radiographs may not be diagnostic.
 - Stress radiography or MRI is occasionally needed to make this diagnosis.
- Meniscal tears
 - If a meniscal tear is suspected, referral or MRI is appropriate.
 - Arthrograms are obtained much less commonly than before.
- Avulsion fracture of the pelvis
 - Diagnosis can often be confirmed with plain-film radiographs.
 - Special oblique views and, occasionally, CT or MRI are helpful.
- Patellar dislocation
 - Unless patellar dislocation or subluxation is a trivial event that incites little joint pain, radiographs should be obtained to assess for osteochondral fragments.
- Shoulder dislocation
 - Unless the episode is minor, radiographs confirm reduction and rule out an associated fracture.
- Anterior knee pain
 - Diagnostic imaging, including MRI, often does not reveal source of pain.
 - These studies are sometimes indicated to rule out other definable abnormalities.
- Patellofemoral pain syndrome
 - Plain-film radiographs are usually negative; further diagnostic evaluation is not indicated.

DIAGNOSTIC PROCEDURES

Overuse syndromes

- Rotator cuff tendonitis
 - Positive impingement test: pain when bringing the shoulder fully overhead
 - Examination should include:
 - A thorough examination of the neck and shoulder
 - Range-of-motion limitation, muscle atrophy, and focal tenderness in the subacromion region, both anteriorly and laterally
 - Tenderness along the biceps tendon
 - Supraspinatus strength
 - Glenohumeral laxity

Acute trauma

- ACL injuries
 - Lachman examination
 - Performing this examination competently requires experience.
 - The patient lies supine and the knee is gently flexed to approximately 30 degrees.

- The patient must relax quadriceps and hamstrings enough to allow the examiner to attempt to slide the proximal tibia anteriorly.
- Although the amount of tibial movement is important, the key factor is the end point.
 - If the test is negative (ie, ligament is intact), a distinct end point or cessation of forward movement should be felt.
 - The end point should feel similar to holding 2 ends of a short piece of rope and quickly pulling the ends apart until movement suddenly stops.
- Comparison with the uninjured knee can be helpful.
- Success depends on:
 - Size of patient's leg
 - Ability of patient to relax
 - Size of examiner's hands
- If doubt exists, the knee should be reevaluated later or the patient referred to an orthopedist.
- If the affected athlete cannot tolerate oral fluids, consider administering intravenous fluids.

■ Heatstroke

- Apply ice water–soaked towels or wet sheets with fans (if ice is not available).
- The patient should be taken to the emergency department immediately.

Injuries to bone and soft tissue

■ Overuse syndromes

- Metaphyseal and diaphyseal stress injuries
 - Managed by rest
 - Crutches often necessary
 - Casts and immobilization sometimes needed
 - Surgical intervention required occasionally
 - Suspected stress fracture of proximal femur is probably best managed by an orthopedic surgeon.
 - Screw stabilization for slipped epiphysis or stress fracture may be needed.
 - Stress fractures of the fifth metatarsal tend to be recurrent and are often best managed with an intramedullary screw.

■ Osgood-Schlatter disease

- Symptoms are often relieved with:
 - Application of an ice pack
 - Intermittent use of oral nonsteroidal antiinflammatory drugs (NSAIDs)
 - Application of compression band
 - Activity modifications as indicated by symptoms
 - Hamstring stretching
- Casts are not routinely used because immobilization may weaken ligament insertions
- Brief periods of rigid immobilization may be necessary for acute exacerbations.

■ Sinding-Larsen-Johansson disease

- Treatment with ice, NSAIDs, and activity modification
- Immobilization and surgery are rarely necessary.

■ Calcaneal apophysitis

- Ice, NSAIDs, and activity modification are dictated by symptoms.
- Shoe inserts that provide padding beneath the heel can be helpful; a three-eighths–inch silicone or felt pad works best.
- Casts or Cam walkers (a removable rigid walking splint) are occasionally necessary for severe cases.
- Surgery is not indicated.

■ Little League shoulder

- Managed by rest of the shoulder

CLASSIFICATION

Acute trauma

■ Severity grading of sprains

- Grade I (mild)
 - Stretching of the ligament with minimal microscopic injury
 - Clinical presentation: mild swelling, limp
 - Typical recuperation time: 0–2 weeks
- Grade II (minor)
 - Partial disruption of the ligament
 - Clinical presentation: modest swelling, diffuse tenderness, difficulty in weight bearing
 - Typical recuperation time: 1–4 weeks
- Grade III (severe)
 - Complete disruption of the ligament
 - Clinical presentation: extensive swelling and bleeding, instability, and disability
 - Typical recuperation time: 4–12 weeks

SPECIFIC TREATMENTS

Heat injury

■ Heat cramps

- Rest in a cool environment
- Stretching
- Fluids

■ Heat exhaustion

- Provide cool fluids and place the athlete in a cool environment.
- Cool compresses and fanning

- Physeal widening of the distal radius
 - The treatment goal is resolution of symptoms and normalization of radiographs.
- Panner disease
 - Treatment simply involves rest.
- Osteochondritis dissecans of the capitellum
 - May heal with prolonged rest, but surgery is often necessary to remove an unstable or displaced bone fragment
- Tendonoses
 - In young athletes, treatment is entirely nonoperative.
 - If analysis of lower-extremity mechanics during gait suggests hyperpronation, custom foot orthoses can be helpful.
 - Ice, stretching, and NSAIDs
 - Training modifications and heel lifts
 - Immobilization rarely is necessary.

Acute trauma

- The fundamental principles of treatment for many musculoskeletal injuries go by the acronym RICE (**r**est, **i**ce, **c**ompression, and **e**levation).
 - Rest
 - Especially important for the first 24–72 hours after significant injury
 - For lower-extremity injuries, crutches should be used to avoid weight bearing.
 - Ice
 - May be applied for 20 minutes every 2–4 waking hours
 - Use a wet cloth between ice and skin to decrease chance of cold injury.
 - Continue using ice until swelling disappears completely.
 - Compression
 - Applied with an elastic bandage
 - Elevation
 - Place the injured extremity above the level of the heart to aid in reducing edema.
- Ankle sprains
 - Treatment options are complicated and are chosen on the basis of:
 - Severity of injury (see Classification)
 - Demands of the athlete
 - Experience of the health care team
 - Minor sprains
 - Apply RICE principles and periodically reevaluate.
 - At reevaluation, if pain is minimal, test the ankle for stability.
 - Observe athlete in functional tasks (eg, running, cutting, and twisting).

- If tasks are performed well without significant pain, the individual may return to competition.
- Ideally, tape or splint the ankle to lessen risk of reinjury, and consider a preventive physical therapy program.
- Moderate sprains
 - For the less serious athlete, use an expectant approach.
 - Crutches
 - Elastic bandage wrap
 - Gradual progression of weight bearing
 - Cast or Cam walker
 - Return to sports only after symptoms resolve
 - For the serious athlete, referral to a physical therapist is often helpful.
- Severe sprains
 - Should be managed by someone with advanced skills in dealing with musculoskeletal problems (eg, an experienced primary care physician or orthopedic surgeon)
 - A period of immobilization to reduce bleeding and swelling is often helpful.
 - Myriad rehabilitation protocols can be used successfully.
 - Assessment for chronic laxity and tarsal coalitions should be made.
- Persistent anterolateral ankle pain can occur after even mild ankle sprains; initial treatment includes:
 - NSAIDs
 - Ankle supports
 - Physical therapy modalities
 - Steroid injection
- Collateral ligament injuries of the knee
 - First, use RICE principles.
 - Depending on the severity of the injury, mobilize knee as the swelling and tenderness diminish.
 - Assess strength as range of motion returns.
 - For moderate and severe sprains, consider using a dual, upright, hinged, functional knee orthosis.
- ACL injuries
 - Most reconstructive techniques involve drilling holes through the proximal tibia and distal femur to insert grafts along the anatomic course of the ACL.
 - For the skeletally immature individual, this procedure raises some concerns about potential injury to the physis.
- Meniscal tears
 - Symptomatic discoid lateral menisci require surgical intervention.
 - Preserves as much of a normal functioning rim of meniscal cartilage as possible
 - Alleviates the mechanical snapping that ultimately leads to degenerative changes of the articular surfaces

- If a normal meniscus is torn, general principles of surgical treatment are preservation of meniscal tissue and reconstruction of the unstable joint.
- Quadriceps contusion
 - Initial treatment of quadriceps hematoma involves RICE and crutches.
 - As pain and swelling diminish, begin active knee flexion exercises.
- Avulsion fracture of the pelvis
 - Crutches and rest for the first few weeks
 - Stretching may inhibit healing and should be avoided until it is pain free.
- Muscle strain
 - For hamstring strain, RICE and crutches
- Patellar dislocation
 - Manipulative reduction can often be achieved.
 - Place the patient in a prone position, which facilitates hip extension and relaxes the hamstrings.
 - Gently extend the knee; as the knee extends, the patella should reduce without forced manipulation.
 - Significant patellar dislocation
 - Immobilize the knee.
 - Use RICE principles.
- Shoulder dislocation
 - Traditional treatment: 3 weeks of immobilization, followed by a rigorous physical therapy program
- Chondromalacia patella
 - In mild cases, pain from chondromalacia patella will abate with:
 - Intermittent NSAID use
 - Quadriceps-strengthening program
 - Judicious activity modification
- Patellofemoral pain syndrome
 - Education, reassurance, and symptom management are the cornerstones of treatment.
 - Stretching and strengthening quadriceps muscles often reduce anterior knee pain.
 - Principles are to strengthen the vastus medialis and improve patellar tracking.
 - Taping or supportive knee sleeves sometimes provide relief.
 - Intermittent and judicious use of NSAIDs may help.
 - In some cases, adjustment of expectations and activities is necessary.
 - In refractory cases, referral to a musculoskeletal specialist may become appropriate.
 - Surgery is occasionally performed, although the exact indications and preferred techniques are controversial.

WHEN TO ADMIT

- Fractures requiring open reduction
- Internal organ injuries
- Possible or definite traumatic brain injury

WHEN TO REFER

- When the diagnosis of the musculoskeletal injury is uncertain
- When the patient is not responding to initial treatment
- When injuries involve the growth plate in which future growth may be compromised
- When uncertainty exists in the safety of the young athlete to return to a competitive sports environment

FOLLOW-UP

Injuries to bone and soft tissue

- Metaphyseal and diaphyseal stress injuries
 - A well-designed plan of alternative training, gradual resumption of participation in sports, and monitoring for recurrent symptoms is necessary.
- Physeal widening of the distal radius
 - Once the athlete returns to gymnastics, clinical and radiographic monitoring are required.

Acute trauma

- Ankle sprains
 - For moderate strains in a serious athlete, a variety of physical therapy modalities can help reduce the swelling.
 - Range of motion is begun early, and strengthening is emphasized.
 - As the ankle becomes comfortable, the proprioception training phase of rehabilitation begins.
 - Lace-up and Velcro ankle supports may be used.
 - For some, taping may be an option.
 - In all cases, functional criteria for return to sports, prevention of reinjury, and reassessment of progress are key components.
- Collateral ligament injuries of the knee
 - A physical therapist or athletic trainer can help design an adequate rehabilitation program.
- Quadriceps contusion
 - Monitoring for reinjury is essential.
- Avulsion fracture of the pelvis
 - The athlete should be gradually returned to activity and monitored for recurrence of symptoms.
- Muscle strain
 - Once the patient is comfortable, a gradual stretching and strengthening program is initiated.
 - The athlete is returned to activities as tolerated and monitored for recurrent symptoms.

■ Patellar dislocation

- As pain and swelling subside, a rehabilitation program is initiated that emphasizes strengthening of the quadriceps muscles, particularly the vastus medialis.
 - Hamstrings are stretched.
 - A lower-extremity rehabilitation program is undertaken.
- A patellar-stabilizing knee sleeve is used during the initial phases of return to activity.

■ Shoulder dislocation

- After 3 weeks of immobilization, a rigorous physical therapy program begins.
 - Directed at strengthening the rotator cuff muscles
 - The principle is to strengthen these dynamic stabilizers of the joint to help compensate for laxity of the shoulder joint capsule (ligaments).
 - The patient's program is advanced, and an experienced therapist monitors progress.
 - Recurrent instability despite a therapy program is generally an indication for surgical stabilization.
 - Support is growing for earlier surgical intervention, particularly with less invasive arthroscopic techniques.

■ Chondromalacia patella

- Although a therapy program can be helpful, the patient must have a clear understanding that the goal is to reduce symptoms.
- Completely eliminating symptoms may not be possible.
- Surgical intervention to alter the patella's articular surface is sometimes indicated.

PROGNOSIS

Injuries to bone and soft tissue

■ Metaphyseal and diaphyseal stress injuries

- Healing time ranges from 4–12 weeks.

■ Osgood-Schlatter disease

- In most patients, will run its course with time
- Symptoms can last 1–4 years.
- In about 3% of patients, a persistent ossicle will form that can remain symptomatic and may ultimately require surgical excision.
- Fracture of the tibial tubercle has been reported in patients with Osgood-Schlatter disease.
 - Incidence is not known, but it appears to be low.
 - Remaining active in sports is not absolutely contraindicated.

■ Sinding-Larsen-Johansson disease

- This entity is self-limited and typically lasts 3–12 months.
- In general, athletes may participate in sports as tolerated.

■ Calcaneal apophysitis

- Almost always resolves with time
- Complications are extremely rare.

■ Little League shoulder

- If symptoms are minimal, the patient can often be allowed to bat and play in an infield position that involves minimal throwing.
- Clinical and radiographic resolution can take up to 6 months.
- Carefully planned resumption of pitching can then begin, but monitoring for recurrence of symptoms is necessary.

■ Physeal widening of the distal radius

- Goal of treatment is resolution of symptoms and normalization of radiographs, which usually takes ≥ 3 months.

■ Osteochondritis dissecans of the capitellum

- Can result in permanent arthrosis of the elbow joint

■ Tendonoses

- Gradual reintroduction of sporting activities

Acute trauma

■ Collateral ligament injuries of the knee

- Most medial collateral ligament injuries heal satisfactorily.

■ ACL injuries

- In contrast to collateral ligaments of the knee, healing potential of the ACL is limited because of its susceptible vascular supply.
- As a result, most ACL injuries do not heal well, and primary surgical repairs (as opposed to reconstructive surgery) are not effective.
- Left without ACL stability, most knees in young, active patients eventually become symptomatically unstable, and reinjury will occur.
- In older and less active individuals, nonoperative management of these injuries plays a role; however, most ACL injuries in young athletes should be reconstructed.
- Leaving the knee unstable makes it vulnerable to injury to the joint capsule, other ligaments, and menisci.

■ Meniscal tears

- Young patients have the potential to heal.
- Pattern and location of tear determine whether meniscus may heal on its own or will require arthroscopic partial removal or repair.

■ Quadriceps contusion

- Full return of motion is the minimal requirement for return to contact sports, at which time a padded guard should be used.

■ Avulsion fracture of the pelvis

- Most do not displace significantly; almost all heal with time and rest.

- Muscle strain
 - Mild injuries heal fairly rapidly, whereas severe strains can lead to large areas of scar tissue that are prone to reinjury.
 - Reduction of tenderness can take days to weeks, depending on the initial severity of the injury.
 - Reinjury is a problem with hamstring strains.
 - Patellar dislocation
 - Recurrent patellar instability, particularly in those with a familial history, may require reconstruction.
- PREVENTION**
- 4 basic principles of injury-prevention measures
 - Passive strategies are more effective than those requiring repeated actions.
 - Specific advice is more effective than generalized information.
 - Injury control must also include postinjury care and rehabilitation.
 - Attention should focus on common problems for which effective interventions are available.
 - Although many sports injuries are random events, nearly two-thirds of all injuries might be reduced by improvements in:
 - Conditioning
 - Equipment
 - Compliance with rules
 - Coaching and supervision
 - Rehabilitation of existing injuries
 - Efforts to prevent reinjury
 - Many schools now use certified athletic trainers for prevention of and rehabilitation from sports injuries.
 - Heat injury
 - Most authorities suggest that adult-sized athletes drink 0.5 L of fluids per hour during persistent activity.
 - Water is usually adequate.
 - Thirst is not a reliable indicator of fluid requirements during vigorous exercise.
 - Salt tablets should not be provided because most athletes receive abundant salt in their diets.
 - Injuries to bone and soft tissue
 - Overuse syndromes
 - Prevention involves the education of young athletes, parents, coaches, and the entire health care team, from trainers to physicians.
 - Understanding these principles is crucial to returning an athlete to sports successfully after experiencing overuse conditions.
 - Failure to change underlying problems leads to reinjury.
 - Osteochondritis dissecans of the capitellum
 - The most important lesson about this condition is the opportunity for prevention.
 - Junior baseball programs typically have rules limiting duration of pitching.
 - Typically, the limit is 3 innings per game and up to 6 innings per week.
 - Young athletes, parents, and coaches need to be educated about this condition so that excessive pitching does not occur at other times.

Staphylococcal Toxic Shock Syndrome

DEFINITION

- Staphylococcal toxic shock syndrome (TSS) is a distinct clinical entity characterized by:
 - Fever
 - Diffuse, nonexudative mucous membrane inflammation
 - Vomiting and profuse diarrhea
 - Generalized myalgia
 - Scarletiform erythroderma
 - Hypotension
 - Shock associated with multiple organ failure—renal, myocardial, pulmonary, hepatic, hematologic, and central nervous system

EPIDEMIOLOGY

- Incidence
 - 0.53 cases per 100,000 population; rate varies by geographic region
- Prevalence
 - >90% of adults, but fewer children, have antibodies against TSS toxin type 1
 - Occurs in 3 per 100,000 population following all types of surgery
 - Occurs in 16.5 per 100,000 following ear, nose, and throat surgery
- Association with menstruation
 - TSS was first described in association with menstruation and tampon use, but a public health information campaign resulted in a shift to predominantly nonmenstrual cases.
 - Incidence of nonmenstrual cases now exceeds that of menstrual cases.
- Nonmenstrual cases
 - 18.3% were reported after surgical procedures.
 - 11.5% were postpartum or postabortion.
 - 23% were associated with nonsurgical cutaneous lesions.

ETIOLOGY

- Patients who develop staphylococcal TSS are colonized or infected with specific strains of *Staphylococcus aureus*.
- The syndrome is thought to be a superantigen-mediated disease.
 - Superantigens are proteins that can activate the immune system by bypassing steps in the usual antigen-mediated immune response sequence and thus cause an amplified immune response.

RISK FACTORS

- The following superantigens are the major toxins associated with staphylococcal TSS.
 - TSS toxin type 1, a staphylococcal exotoxin
 - Staphylococcal exotoxins A, B, C, D, E, and H

- Absence of antibodies to these superantigens appears to be a major risk factor for staphylococcal TSS
- Their absence explains in part why not all patients exposed to virulent strains develop TSS.

SIGNS AND SYMPTOMS

- Patients are usually healthy before the onset of symptoms.
- Prodrome
 - Occasionally a prodrome may occur in the week before acute illness.
 - Low-grade fever
 - Malaise
 - Myalgia
 - Vomiting
- Acute onset
 - Spiking fever (temperature, 102.2°F–105.8°F [39 C–41°C])
 - Chills
 - Severe gastrointestinal symptoms (abdominal cramps; nausea; vomiting; and profuse, watery, nonbloody diarrhea)
 - Headache
 - Myalgia
 - Sore throat
- 24–72 hours
 - Diffuse, blanching, macular erythroderma (sunburn-like) or scarlatiniform rash that:
 - May be faint or evanescent
 - Is not pruritic but is occasionally petechial
 - Bilateral conjunctival hyperemia without discharge
 - Photophobia
 - Oropharyngeal inflammation, sometimes with an associated strawberry tongue or buccal ulcerations
 - Vaginal erythema with minimal clear watery discharge (in cases associated with menstruation)
 - Orthostatic dizziness or syncope or both (due to orthostatic hypotension)
 - Hypotension: systolic blood pressure 90 mm Hg for adults or <5th percentile by age for children <16 years of age, orthostatic drop in diastolic blood pressure 15 mm Hg from lying to sitting, or orthostatic syncope
- Illness peak (day 2 or 3) (multisystem involvement: ≥3 of the following systems)
 - Central nervous system dysfunction
 - Headache
 - Confusion
 - Disorientation
 - Hallucinations
 - Paresthesias of the hands and feet
 - Stiff, tender neck

- Musculoskeletal
 - Exquisite muscle tenderness
 - Severe myalgias
 - Arthralgias
 - Joint effusions
 - Nonpitting edema over the wrists and ankles
 - Synovitis of the small joints of the hands and feet
 - Abdominal
 - Abdominal musculature tenderness
 - Absent or hypoactive bowel sounds
 - Renal
 - Azotemia and diminished creatinine clearance (indicating renal involvement)
 - Oliguria
 - Pulmonary
 - Shock lung or adult-type respiratory distress syndrome
 - Hematologic
 - Progressive normochromic normocytic anemia
 - Thrombocytopenia
 - Leukocytosis
 - Cardiac
 - Arrhythmias or prolonged shock, possibly leading to eventual myocardial failure
 - Stevens-Johnson syndrome
 - No hypotension
 - Erythema multiforme
 - Bleeding, fissured lips
 - Bullous enanthem of the oral cavity
 - Purulent conjunctivitis
 - Involvement of hands and feet
 - Desquamation involves only individual lesions
 - Respiratory and gastrointestinal tract involvement
 - Clinical: skin biopsy
 - Kawasaki disease
 - No hypotension
 - Polymorphous rash
 - Red, fissured lips
 - Erythematous, strawberry tongue
 - Nonpurulent conjunctivitis
 - Erythematous, edematous hands and feet
 - Desquamation of fingertips
 - Coronary aneurysms, generalized vasculitis
 - Clinical: no diagnostic test
 - Streptococcal scarlet fever
 - No hypotension
 - Diffuse erythroderma, circumoral pallor, Pastia lines
 - Strawberry tongue
 - Hands and feet relatively spared
 - Fine, flaky desquamation
 - Rheumatic fever, glomerulonephritis
 - Clinical: culture of group A streptococci from pharynx, serology
 - Measles
 - No hypotension
 - Morbilliform rash
 - Koplik spots
 - Conjunctivitis
 - Involvement of hands and feet
 - Fine desquamation
 - Respiratory tract involvement
 - Clinical: serology
 - Leptospirosis
 - Hypotension, sometimes
 - Erythematous, macular, petechial, purpuric
 - Pharyngitis
 - Conjunctivitis
 - Hands and feet relatively spared
 - Central nervous system, renal, hepatic involvement
 - Clinical: serology
- DIFFERENTIAL DIAGNOSIS**
- Staphylococcal TSS must be distinguished from other serious or potentially life-threatening disease.
 - Staphylococcal TSS
 - Hypotension
 - Diffuse erythroderma, Nikolsky sign
 - Red lips
 - Erythematous oral cavity
 - Nonpurulent conjunctivitis
 - Erythematous, edematous hands and feet
 - Desquamation of hands and feet; can be generalized
 - Diarrhea, renal, hepatic, central nervous system, hematologic abnormalities
 - Clinical: culture of *S aureus* from nasopharynx, vagina, or wound
 - Staphylococcal scalded-skin syndrome
 - No hypotension
 - Erythroderma, bullae, Nikolsky sign
 - Purulent conjunctivitis
 - Hands and feet relatively spared or grossly involved
 - Gross desquamation
 - Clinical: culture of *S aureus* from nasopharynx or wound, skin biopsy

- Drug-related toxic epidermal necrolysis
 - Hypotension, sometimes
 - Painful erythroderma, bullae, Nikolsky sign
 - Conjunctivitis
 - Involvement of hands and feet
 - Gross desquamation
 - Clinical: serology
- Streptococcal TSS
 - Hypotension
 - Diffuse erythroderma, maculopapular rash
 - Cracked lips
 - Erythematous oral cavity
 - Injected eyes
 - Confusion, abdominal pain and vomiting, hyperesthesia
 - Clinical: culture of group A streptococci

DIAGNOSTIC APPROACH

- Although no laboratory test is available to confirm the diagnosis of staphylococcal TSS, obtain the following cultures.
 - Blood
 - Throat
 - Vagina
 - Nares
 - Rectum
 - Other appropriate sites

LABORATORY FINDINGS

- Initial laboratory findings
 - Leukocytosis, with a striking increase in the percentage of immature neutrophils
 - Progressive anemia
 - Thrombocytopenia, accompanied by:
 - Prolongation of prothrombin time
 - Prolongation of partial thromboplastin time
 - Appearance of increased fibrin split products
 - Hypoproteinemia and hypoalbuminemia
 - Metabolic acidosis, possibly complicated by hyponatremia and hypokalemia as a result of accompanying persistent vomiting and diarrhea
 - Dangerously low serum concentrations of calcium (tetany is rare)
 - Elevated blood urea nitrogen and creatinine levels (at least twice the upper limit of normal [early in the illness])
 - Urinary sediment with pyuria (>5 leukocytes/high-power field) in the absence of urinary tract infection
 - Peak abnormal values occur after 5–7 days and then usually return rapidly to normal.
 - Hypophosphatemia (first days of illness)

- Elevated creatine phosphokinase level (at least twice the upper limit of normal) with occasional myoglobinemia
- Total bilirubin, serum aspartate aminotransferase, or serum alanine aminotransferase levels at least twice the upper limit of normal
- Platelet count <100,000 cels/mm³

TREATMENT APPROACH

- Initial steps in management
 - Consider other possible diagnoses.
 - Remove potentially infected foreign bodies (eg, tampons).
 - Drain and irrigate infected sites.
 - Give an intravenous antistaphylococcal β -lactamase-resistant antimicrobial agent at maximal dose for weight and age.
 - Consider methylprednisolone for severe cases.
 - Treat aggressively and monitor for the following.
 - Hypovolemia and inadequate tissue perfusion
 - Adult-type respiratory distress syndrome
 - Myocardial dysfunction
 - Acute renal failure
 - Cerebral edema
 - Hypocalcemia, hypophosphatemia
 - Metabolic acidosis
 - Disseminated intravascular coagulation
 - Fluid and electrolyte abnormalities
- The first and major resuscitative goal is:
 - Administer large volumes (2–4 times normal daily maintenance) of crystalloid (lactated Ringer solution) or colloid (fresh-frozen plasma or albumin) solutions to restore normal intravascular volume and correct hypotension.
 - Treatment of hypotension may require vasopressor therapy (eg, dopamine or dobutamine).
 - Much of the administered fluid is sequestered outside the intravascular space, sometimes leading to marked edema.
 - Have a central venous pressure line or a Swan-Ganz catheter in place to monitor left-ventricular end-diastolic pressure (prevent congestive heart failure due to overly vigorous fluid resuscitation).
- Patients who develop adult-type respiratory distress syndrome or shock lung require endotracheal intubation and ventilatory assistance with positive end-expiratory pressure and high oxygen flow rates. The following can occur in such patients:
 - Renal failure
 - Severe electrolyte and acid-base abnormalities
 - Ventricular ectopy
 - Refractory ventricular arrhythmias
 - Disseminated intravascular coagulation

SPECIFIC TREATMENTS

Antibiotics

- High-dose β -lactamase-resistant antistaphylococcal antibiotics are recommended to eradicate the organism and prevent recurrences.
- Nafcillin, oxacillin, and first-generation cephalosporins are the first-line agents for *S aureus*.
- Vancomycin should not be used routinely as initial empirical therapy.
 - Methicillin-resistant *S aureus* causes <1% of cases of staphylococcal TSS.
 - Methicillin-resistant *S aureus* recently emerged as a community pathogen and thus raised an important issue of initial empirical antibiotic therapy in these patients.
 - Clindamycin plus a β -lactamase-resistant antistaphylococcal agent may help by decreasing the synthesis of TSS toxin type 1.
 - Duration of antimicrobial therapy:
 - ≥ 10 –14 days, to eradicate the organism and prevent recurrences
 - Total duration is based on the usual duration established for the underlying focus of infection.

Intravenous immunoglobulin

- May be an effective adjunctive therapy for diseases associated with superantigens
 - Usual dose: 400 mg/kg over 4–8 hours as a single dose
 - A higher dose may be required for staphylococcal TSS to achieve protective titers and clinical efficacy.

High-dose corticosteroids

- May be of possible benefit for shock syndromes, but should not be administered routinely to patients with TSS because they:
 - May result in a shorter time to defervescence and clinical stability
 - Make no difference in overall risk for death

Nonsteroidal anti-inflammatory drugs

- Contraindicated because they may increase progression to TSS by enhancing production of tumor necrosis factor

WHEN TO ADMIT

- Nearly all patients with staphylococcal TSS should be hospitalized.
- For significant hypotension (and probable coexistence of multiple organ system failure), pursue the steps outlined in Management while arranging transport to a tertiary care facility.
 - There, continued management largely will be supportive and dictated by the degree of organ dysfunction.

WHEN TO REFER

- All patients must be managed in consultation with infectious disease and critical care specialists.
 - The pediatrician plays a key role in coordinating the care.

COMPLICATIONS

- Adult-type respiratory distress syndrome
- Multi-organ failure
- Death

PROGNOSIS

- Most patients with staphylococcal TSS recover within 7–10 days.
- Fatigue and weakness for as long as 3 months may occur in the recovery phase.
- The case fatality rate is 2–5%.
- Convalescence is characterized by a desquamation of the palms and soles within 1–2 weeks after the onset of illness.
- Some patients also experience hair and nail loss.
- Although most patients with TSS do not experience pulmonary compromise, mortality is increased if early or prolonged adult-type respiratory distress syndrome becomes apparent.
- Nongenital TSS seems to carry a worse prognosis than vaginal disease, probably because of delayed diagnosis and the more serious nature of the primary infection.
- Refractory hypotension is associated with mortality rates of up to 50%.

PREVENTION

- The incidence of recurrent staphylococcal TSS may be as high as 28% if the patient does not receive antistaphylococcal antibiotics and does not produce antibody to toxin.
- The criteria for recurrent disease are less stringent than those required for defining an initial episode.
- Recurrent vaginal TSS occurs, but much less frequently than genital vaginal disease.
- Persistent neuropsychological symptoms, such as fatigue, depression, and memory loss, have been described in up to 50% of patients who recover from nonvaginal TSS.

Stomatitis

DEFINITION

- Inflammation of the oral mucosa, characterized by multiple ulcerations inside the mouth
 - Frequently painful
 - May lead to decreased oral intake and dehydration

EPIDEMIOLOGY

- Recurrent aphthous stomatitis (RAS) is the most common form of painful oral ulcers.
 - Prevalence
 - 37% of surveyed school-age children reported a history of RAS.
 - Age
 - Peak age of onset is the second decade of life.
 - Bouts may recur throughout adulthood.
- Viral infection is the most common infectious cause of stomatitis.
 - In 1 study, 33% of 5- to 17-year-old participants reported a history of recurrent herpes labialis.
 - Herpangina (acute febrile illness associated with the development of lesions in the posterior oropharynx) and hand-foot-mouth disease (HFMD) are quite frequent in young children.
 - Outbreaks of acute stomatitis caused by herpangina are most likely to occur in the summer and early fall.
 - HFMD is most likely to occur in the spring and summer.
- Stomatitis as the only presenting feature of a systemic disorder does occur, but it is rare.
 - Approximately 15% of patients with aphthous ulcers and other symptoms have a systemic disorder.
- Periodic fever accompanied by aphthous stomatitis, pharyngitis, and (cervical) adenopathy (PFAPA) syndrome is a relatively new entity.
 - Multiple case series have been reported in the medical literature.

ETIOLOGY

- Stomatitis can be a disease entity unto itself, such as RAS, or it may be a symptom of an underlying condition.
- RAS is a benign condition characterized by painful oral ulcers that recur at irregular intervals.
 - In otherwise healthy individuals, most cases are idiopathic.
 - Exact cause of RAS is not known.
- Medical interventions may lead to stomatitis.
 - Chemotherapy agents and radiation disrupt the mucosal barrier of the mouth, allowing ulceration, desquamation, and secondary infection by both acquired and endogenous flora.

- Medications that can lead to oral dryness and the development of aphthous stomatitis
 - Cyclooxygenase-2 inhibitors
 - Nonsteroidal anti-inflammatory drugs
 - Sertraline

RISK FACTORS

- Suggested triggers include:
 - Stress
 - Genetics
 - Hormonal and immunologic influences
 - Trauma
 - Smoking
- Viruses
 - Herpes simplex
 - Varicella-zoster
 - Various subtypes of coxsackie
 - Herpangina
 - Coxsackie A16 is the most common cause of HFMD, but other enteroviral subtypes have been implicated as causative agents.
 - Rubeola
 - Epstein-Barr virus
 - HIV
- Trauma
 - Secondary to biting one's own mucosa
 - Friction from dental appliances
 - Riga-Fede syndrome (rare)
 - Formation of ulcerative lesions of the lower lip, lingual frenulum, and ventral tongue secondary to repeated rubbing of the teeth against these mucosal surfaces
 - Age of onset: 6–8 months
 - Coincides with the age of primary tooth eruption
- Irritant exposure
 - Excessive heat
 - Cold
 - Acidic or basic substances
 - Smokeless tobacco
 - Leads to oral lesions in older school-age children
 - Misuse of commercial mouthwash with high alcohol content
- Allergic contact stomatitis
 - Incites an allergic delayed-type hypersensitivity reaction
 - Preservatives and oral flavorings (eg, cinnamon, menthol, peppermint) may cause a reaction.

- Metals (eg, nickel found in dental instruments) may elicit an oral allergic reaction.
 - Systemic disorders
 - Bacteria
 - *Borrelia vincentii* and *Fusobacterium dentium* are bacterial causes of oral inflammation known as *necrotizing ulcerative gingivitis*.
 - Syphilis
 - Gonorrhea
 - Tuberculosis
 - Fungi
 - Infrequently cause stomatitis in otherwise healthy children
 - *Candida albicans*
 - Infection is common in the newborn.
 - Histoplasmosis
 - Can develop in otherwise healthy children and produce mucosal ulceration along with other systemic manifestations
- ## SIGNS AND SYMPTOMS
- RAS
 - Oral lesions are the only physical examination finding.
 - Assess for ≥ 1 painful ulcers on the buccal, labial, and lingual surfaces, as well as on the floor of the mouth.
 - 3 clinically distinct types of RAS
 - Minor variety
 - Small, round craters, < 5 mm in diameter and surrounded by an erythematous halo
 - Heal in 1–2 weeks
 - Major variety
 - Lesions > 5 mm that often scar
 - May last 6 weeks
 - Herpetiform variety
 - Herpes-like appearance of multiple, small clusters of pinpoint lesions
 - Resolve in 7–10 days
 - Not caused by the herpes virus
 - Children with RAS are otherwise healthy.
 - Herpes simplex virus type 1
 - Fever, malaise, sore throat, and cervical adenopathy are present.
 - Vesicles can develop anywhere on the oral mucosa, most typically in the anterior oropharynx on the lips, tongue, and buccal mucosa
 - Gingiva may be swollen and erythematous.
 - The perioral area may also display vesicles and small ulcers that coalesce and continue to appear for the next week.
 - Oral pain is present.
 - May result in anorexia and dehydration
 - Spontaneous resolution in 7–10 days
 - Coxsackievirus
 - Herpangina
 - Ulcers surrounded by erythematous halos located in the posterior oropharynx
 - Spontaneous resolution in 3–5 days
 - HFMD
 - Along with lesions of the posterior oropharynx, blanching red macules or vesicles appear on the palms, soles, and buttocks.
 - Erythematous halos may surround the macules.
 - Resolve spontaneously within a week
 - Fever, malaise, dysphagia, and anorexia accompany coxsackie infections and can lead to dehydration in children.
 - Necrotizing ulcerative gingivitis
 - Painful, erythematous, and friable gingiva
 - Necrotic tissue accumulates as a pseudomembrane over the gingival surface.
 - Foul breath
 - Fever, malaise, anorexia, and dehydration may be present.
 - Candidal mucositis
 - White, curdlike patches on many of the surfaces of the oral mucosa
 - If white patch is scraped and removed, an ulceration will be present at the base.
 - Diaper dermatitis may also be present.
 - Contact stomatitis
 - Can present in 4 general ways
 - Red lesions with general mouth erythema
 - White lesions and leukoplakia
 - Erosions and ulcerations
 - No obvious lesions accompanied by mouth pain and burning
 - The manifestation of stomatitis in the multitude of potential underlying multisystem diseases will vary depending on the diagnosis.
 - Immunocompromised patients may:
 - Experience more frequent and severe episodes of oral ulceration
 - Take longer for episodes to resolve
 - Appearance of individual aphthae in stomatitis secondary to a benign or self-limiting condition may be indistinguishable from that associated with a serious underlying systemic disease.

- Important to identify other symptoms and use physical examination findings to determine the appropriate etiology

■ PFAPA syndrome

- Recurrent fevers every 4–6 weeks with onset in the first 6 years of life
- General malaise, anorexia, headache, abdominal pain, and arthralgias are present.
- Symptoms typically resolve within 1 week.
- The child has complete resolution of symptoms between recurrences.

DIFFERENTIAL DIAGNOSIS

■ RAS infection

- Viruses
 - Herpes simplex type 1
 - Varicella-zoster, coxsackie
 - Other enteroviruses
 - Rubeola
 - Epstein-Barr virus
 - HIV
- Bacteria
 - *B vincentii*
 - *F dentium*
 - Syphilis
 - Gonorrhea
 - Tuberculosis
- Fungi
 - *Candida*
 - Histoplasmosis

■ Irritant contact stomatitis

■ Allergic contact stomatitis

■ Iatrogenically induced stomatitis

■ Systemic disorders

- Behçet syndrome
- Inflammatory bowel disease
- Celiac disease
- Diabetes mellitus
- Systemic lupus erythematosus
- Scleroderma
- Dermatomyositis
- Wegener granulomatosis
- PFAPA syndrome
- Cyclic neutropenia
- Nutritional deficiencies
- Dermatologic disorders

LABORATORY FINDINGS

- In most cases, laboratory evaluation is not helpful in diagnosis or management.
- Measure serum electrolytes in patients with severe dehydration during the rehydration process.
- If frequently recurring or persistent oral aphthae are present, along with genital lesions or other systemic findings, an evaluation for the underlying cause may include:
 - Complete blood count
 - Erythrocyte sedimentation rate
 - Serum levels of:
 - Iron
 - Folate
 - Vitamin B₁₂
 - Zinc
 - Depending on the history, screening for the following may be necessary:
 - Antinuclear antibodies
 - HIV
 - Celiac disease

TREATMENT APPROACH

■ Goals of treatment

- Relieving pain
- Preventing dehydration

- By maximizing pain relief, the child will be able to remain hydrated and consume a soft diet.

SPECIFIC TREATMENTS

Pain relief

■ Systemic ibuprofen, acetaminophen, or opiates

■ Application of topical substances

- Swish and then spit *or*
- Paint the substance on the sores with a cotton-tip swab.
- Topical agents that have been studied minimally for safety and efficacy include:
 - Saline rinses
 - Diphenhydramine–aluminum hydroxide with magnesium hydroxide–viscous lidocaine compounded in various combinations
 - Benzocaine
 - Kaolin
 - Pectin
- Most of these agents, if used too aggressively, can lead to overdose and adverse side effects.

- Topical anesthetic preparations in particular must be used cautiously.
 - Risk of aspiration, loss of protective airway reflexes, and systemic toxicity caused by absorption through inflamed oral mucosa
- In the immunocompromised child or child with stomatitis secondary to cancer treatment:
 - Use topical and systemic analgesics for pain relief.
 - Topical sucralfate and capsaicin have been found to relieve pain of chemotherapy- or radiation-induced mucositis.
 - These agents are not routinely used for children with benign, self-limiting conditions.
 - Monitor for secondary infection.

Antimicrobial treatment

- Antimicrobials are of limited value.
 - In patients with necrotizing ulcerative gingivitis, the following may be required:
 - Chlorhexidine mouth rinses
 - Systemic antibiotics, such as penicillin
- Oral acyclovir is of limited therapeutic benefit in the otherwise healthy child with herpes stomatitis.
 - Topical acyclovir is ineffective.

PFAPA syndrome

- Typically responds well to short course of oral steroids (1–2 mg/kg per day for 5 days) if prescribed at the onset of symptoms

WHEN TO ADMIT

- Hospitalization may be required for intravenous rehydration therapy in a child who cannot eat and drink because of severe pain from mouth lesions.

WHEN TO REFER

- Referral to an oral surgeon or otolaryngologist should be considered when:
 - Underlying cause of the stomatitis is uncertain *or*
 - If oral lesions persist for >2 weeks
 - Biopsy of the lesion may be necessary.
 - Especially for a child who uses smokeless tobacco
- Children with stomatitis plus multiple symptoms and abnormal physical examination findings may require specialty expertise to establish the definitive diagnosis and administer appropriate treatment.
 - Allergist-immunologist
 - Rheumatologist
 - Dermatologist
 - Gastroenterologist
 - Ophthalmologist

PREVENTION

- Most causes of stomatitis cannot be prevented.
- In general, promote:
 - Avoidance of tobacco products and any possible irritants
 - Good oral hygiene to reduce the risk of dental caries and gingivitis
- Minimize exposure to the proposed triggers for RAS.
- On the basis of studies in adults, continuous oral acyclovir is a therapeutic option for preventing recurrences in a child with frequent herpetic flares.
- Children with cancer may benefit from a preventive protocol that includes:
 - Frequent plaque biofilm removal and teeth brushing
 - Chlorhexidine or saline rinses
 - Nystatin

Strabismus

DEFINITION

- *Strabismus* is the condition of ocular misalignment.
 - Esotropia: eye turned in
 - Exotropia: eye turned out
 - Vertical strabismus: eye turned up or down
 - Hypertropia: deviation upward
 - Hypotropia: deviation downward
- Comitant strabismus: deviation the same in all fields of gaze
- Incomitant strabismus: limited eye movement and different deviation in different fields of gaze
- A *phoria* is a tendency for the eyes to drift apart, but alignment is maintained by binocular fusion.
- A *tropia* is a manifest deviation of the eyes, without binocular fusion.
- Infantile (congenital) esotropia: a large esotropia with onset before 6 months of age
- Pseudoesotropia: The eyes are straight, but a wide nasal bridge and epicanthal folds give the appearance of esotropia.
- Accommodative esotropia: an acquired deviation (most often at 1–5 years) usually associated with farsightedness
- Sensory esotropia: an esodeviation caused by unilateral blindness
- Convergence insufficiency: an exotropia at near fixation, but straight eyes with distance fixation

MECHANISM

- Comitant strabismus
 - Not usually associated with neurologic disease
- Incomitant strabismus involves limited eye movement from:
 - Restriction
 - Periocular scarring
 - Tight extraocular muscles
 - Neuromuscular paresis
 - Cranial nerve palsies: third, fourth, sixth

PHYSICAL EXAM

Infantile estropia

- The patient may show a strong fixation preference for one eye, indicating amblyopia.
- The patient may alternate fixation.
- Amblyopia occurs in approximately 50% of children with infantile esotropia.
- Some limitation of abduction often is found in voluntary version testing.
 - However, the doll's head maneuver reveals normal abduction and normal lateral rectus function.
- Associated motor anomalies are often related to infantile esotropia.
 - Develop late, at age 1 or 2 years, often several months after the esotropia has been surgically corrected

- Vertical strabismus (inferior oblique overaction in 70% and dissociated vertical deviation in 75%)
- Nystagmus
 - Unusual in children with congenital esotropia
 - Latent nystagmus is found in approximately 50% of cases.
 - Becomes evident during standard vision testing when one eye is covered.
 - The best visual potential in children with latent nystagmus is obtained by testing with both eyes open (binocular vision) to avoid inducing nystagmus.

Pseudoesotropia

- Pseudoesotropia is common and should be distinguished from infantile esotropia.
 - The infant has a wide nasal bridge and wide, prominent epicanthal folds, giving the appearance of esotropia.
 - However, the eyes actually are orthotropic.
 - Hirschberg corneal light reflex test can document proper eye alignment.
 - Follow-up is important in patients with pseudoesotropia, because a small percentage will develop true esotropia.

Accommodative esotropia

- Esotropia is seen mostly at near fixation or when the child is tired.
 - The child may squint or close 1 eye.
 - The deviation initially is small and intermittent.
- Over time—sometimes only a few weeks—the deviation may increase to become constant, and amblyopia may develop.

Intermittent exotropia

- Initially, an exotropia may be present only when the patient is fatigued or ill.
- Covering 1 eye will produce the exotropia; thus, this form of strabismus is best detected by the cover test.
- Symptoms include:
 - Blurred vision
 - Asthenopia (vague visual discomfort, such as eyestrain or brow ache)
 - Visual fatigue
 - Photophobia with squinting is thought to be a mechanism for eliminating diplopia or confusion.
- The natural history is variable.
 - Approximately 70% of patients show increasing frequency of exotropia and progressive loss of fusion.
 - 20% stay the same.
 - A small percentage improve over time.
 - During the exophoric phase, patients have bifoveal fusion with excellent stereo acuity.
 - When exotropia (developed strabismus) is present, most patients demonstrate suppression.

- Patients with late-onset intermittent exotropia (after 5 or 6 years of age) sometimes experience diplopia.
- Significant amblyopia is rare in patients with intermittent exotropia.

Convergence insufficiency

- A type of intermittent exotropia characterized by an exotropia at near fixation but straight eyes with distance fixation
- Appropriate near convergence is insufficient.

Fourth nerve palsy

- A superior oblique palsy (fourth nerve palsy) is the most common cause of a vertical deviation.
- The superior oblique muscle is a depressor and intortor (twists the eye nasally).
- A weak superior oblique muscle will cause:
 - Strabismus consisting of hypertropia (vertical strabismus)
 - Extorsion (temporal twisting of the eye)
- The hypertropia is worse when the patient's head tilts to the side of the weak superior oblique muscle.
- The hypertropia diminishes with head tilt to the side opposite the palsy.
- Patients with a superior oblique paresis usually exhibit a compensatory head tilt to the opposite side of the paresis to help keep their eyes aligned.
- A family photo album should be examined to estimate onset of the head tilt.
- Patients with congenital superior oblique paresis typically have good stereopsis and exhibit the hyper-deviation intermittently when fatigued.
- Most have the ability to suppress so as not to experience diplopia when the deviation is apparent.
- Facial asymmetry
 - A subtle finding in most children with a congenital superior oblique palsy
 - The dependent side of the face is more shallow and atrophied, possibly as the result of the effects of gravity on facial development.
- Even though the paresis present at birth, symptoms may develop in late childhood or even adulthood.
- Over time, the fusional control weakens and results in a deviation that becomes apparent later in life.

Sixth nerve palsy

- Results in limited abduction and an esotropia that is worse on the side of the palsy
- Neonates can have a transient sixth nerve palsy, often associated with a facial palsy.
 - Resolves spontaneously by 4–8 weeks
- Approximately one half of sixth nerve palsies resolve over a 6-month observational period.

Third nerve palsy

- Involves all extraocular muscles (ie, medial rectus, superior rectus, inferior rectus, inferior oblique muscles) except the lateral rectus (sixth cranial nerve) and the superior oblique (fourth cranial nerve)
 - Because both major vertical muscles are weak, the eye does not move up or down and is exotropic because of the weak medial rectus muscle.
 - The levator muscle of the upper eyelid is also innervated by the third cranial nerve, and ptosis is usually present.
 - The pupil is large and nonreactive in complete third nerve palsy.

Brown syndrome

- Clinical findings include:
 - Limited elevation in adduction
 - An exodeviation in attempted upgaze
 - An ipsilateral hypotropia that increases in upgaze
- Most patients with Brown syndrome have good binocular vision with a compensatory chin elevation and slight face turn away from the affected eye.

Double elevator palsy

- Congenital limitation of elevation of 1 eye
- The term *double elevator* implies paresis of the superior rectus muscle and inferior oblique muscle.
 - However, in 70% of cases, the deficient elevation results from a tight inferior rectus muscle.
- May be mistaken for Brown syndrome
 - The limited elevation in Brown syndrome is worse in adduction than in abduction.

DIFFERENTIAL DIAGNOSIS

Differential diagnosis of infantile esotropia

- Duane syndrome
 - Caused by a congenital hypoplasia of the sixth nerve nucleus with misdirection of the medial rectus nerve, innervating both the medial rectus and the lateral rectus muscles
 - Because both the medial and the lateral rectus muscles are innervated by the nerve to the medial rectus muscle, both muscles fire and contract simultaneously on attempted adduction.
 - This co-contraction of the medial and lateral rectus muscles causes globe retraction and lid fissure narrowing on attempted adduction.
 - Most children with Duane syndrome adopt a compensatory face turn to keep their eyes straight.
- Congenital fibrosis syndrome of extraocular muscles
 - Rare
 - Congenital fibrosis of the extraocular muscles usually is inherited as an autosomal-dominant trait.

- Cause unknown
- Associated with fibrotic replacement of extraocular muscle tissue
- Clinical features may be classified into 5 groups.
 - Generalized fibrosis syndrome
 - Fibrosis of inferior rectus with blepharophimosis
 - Strabismus fixus
 - Vertical retraction syndrome
 - Unilateral fibrosis blepharoptosis and enophthalmos
- Because of the tight fibrotic muscles, ductions are limited.
- The medial rectus muscle is affected most commonly, producing an esotropia.
- The fibrosis can be generalized and can affect virtually all of the rectus muscles.
- Congenital sixth nerve palsy
- Möbius syndrome associated with sixth nerve paresis
 - Rare
 - Characterized by:
 - Facial palsy
 - Sixth nerve palsy, often with a partial third nerve palsy
 - Distal limb abnormalities such as syndactyly or even amputation defects
 - Craniofacial anomalies can occur.
 - Micrognathia
 - Tongue abnormalities
 - Facial or oral clefts
 - Ocular motility abnormalities include:
 - Failure of the eyes to abduct
 - Presence of lid retraction on adduction (also typical in some patients with Duane syndrome)
 - The facial palsy usually spares the lower face, although orbicularis function is weak.
 - Skeletal abnormalities also include pectoralis muscle deficits.
 - Inheritance pattern is variable and may be familial, but most cases are sporadic.
- Infantile myasthenia gravis
- These disorders all have limited abduction, and they can therefore be differentiated from infantile esotropia, in which the ductions should be full.
- Esotropia in an infant may also be an important sign of vision loss.
 - Disorders, such as congenital cataracts and retinoblastoma, often first exhibit as infantile esotropia.

Differential diagnosis of acquired esotropia

- Includes any neurologic cause of a sixth nerve palsy, including:
 - Intracranial tumors
 - Meningitis

- Mastoiditis (Gradenigo syndrome)
- Hydrocephalus
- Arnold-Chiari malformation
- Myasthenia gravis
- Viral illness

Differential diagnosis of an incomitant strabismus

- Fourth nerve palsy
 - Congenital superior oblique palsy
 - The most common cause of vertical strabismus
 - The child has a compensatory head tilt, often misdiagnosed as torticollis.
 - Acquired superior oblique paresis
 - Trauma—tends to be bilateral
 - Vascular disease
 - Multiple sclerosis
 - Intracranial neoplasm
 - Herpes zoster ophthalmicus
 - Diabetes with mononeuropathy
- Sixth nerve palsy (see above)
- Duane syndrome (see above)
- Möbius syndrome (see above)
- Third nerve palsy
 - Congenital
 - Trauma
 - Intracranial tumor
 - Viral illness
 - Posterior communicating aneurysm
- Brown syndrome
 - Inability to elevate eye in adduction
 - Acquired Brown syndrome
 - Inflammation around the superior oblique tendon, often from chronic sinusitis
 - Congenital Brown syndrome
 - Congenitally tight superior oblique tendon complex
 - Clinical findings include:
 - Limited elevation in adduction
 - Exodeviation with attempted upward gaze
 - Ipsilateral hypotropia that increases with upward gaze
 - Most patients with Brown syndrome have good binocular vision with a compensatory chin elevation and slight face turn away from the affected eye.
- Double elevator palsy
 - May be mistaken for Brown syndrome, but limited elevation in Brown syndrome is worse in adduction than abduction
- Congenital fibrosis syndrome (see above)

IMAGING

- If no specific cause of an acquired superior oblique paresis can be found, then a neurologic workup, including neuroimaging, should be performed.

SPECIFIC TREATMENT

Infantile esotropia

- Best treated with early surgery
 - Surgery usually is performed when the patient is between 6 months and 2 years of age.
 - Peripheral fusion can be achieved if the eyes are aligned before 2 years of age.
 - Surgery should be considered as early as 3 months of age if the following criteria are met.
 - Large-angle esotropia (≥ 40 prism diopters)
 - Constant or increasing deviation documented by 2 visits 1 month apart
 - Infant able to tolerate anesthesia
- Approximately half of children with congenital esotropia will require multiple surgeries.
- Excellent fusion with high-grade stereopsis and good alignment can be obtained when surgery is performed before the child is 6 months old.

Acquired esotropia

- Immediate referral is important.
 - To provide early treatment to establish binocular vision
 - To rule out ocular or neurologic disease

Accommodative esotropia

- Unlike children with congenital esotropia, patients with acquired accommodative esotropia have had straight eyes during early visual development; thus, they retain relatively good fusion potential.
 - The earlier the eyes are straightened, the better the chances will be for recovering fusion.
- Accommodative esotropia is usually associated with farsightedness.
- The first line of treatment is to prescribe spectacles.
 - If spectacles do not correct the esotropia, then surgery will be needed.
- Patients who are corrected to proper alignment with glasses for distance viewing, but whose eyes still cross at near viewing, can be prescribed bifocal glasses.
 - In most cases, these children will need spectacles after surgery to maintain good alignment.
- Early treatment is critical to achieving best results.

Sensory esotropia

- An esodeviation caused by unilateral blindness
- Loss of vision may cause an eye to drift.
 - If the visual loss occurs before 2 years of age, then patients develop esotropia.
 - If the vision loss occurs after 2 years of age, then patients develop exotropia.
- Requires urgent intervention
- Treatment
 - Recession-resection procedure of the blind eye
 - Surgery is not performed on the eye with good vision.

Intermittent exotropia

- Treatment is elective.
 - Eye muscle surgery is the treatment of choice for most forms of intermittent exotropia.
 - Usually requires strabismus surgery if the deviation is poorly controlled
- Indications for surgery include:
 - Increasing exotropia
 - Exotropia is present $>50\%$ of the time.
 - Poor fusion control of the exotropia
- Nonsurgical treatments include:
 - Part-time occlusion of the dominant eye
 - Correction for myopia
 - Eye exercises
- Nonsurgical interventions act as temporary treatments at best, except in patients with a special type of exotropia known as convergence insufficiency.
 - The one form of strabismus that is best treated with eye exercises instead of surgery

Duane syndrome

- Strabismus surgery
 - Effective for correcting the compensatory face turn
 - Improves abduction slightly, but does not result in full abduction capabilities

Brown syndrome

- The management of true congenital Brown syndrome is conservative unless the vertical deviation in primary position is significant.
- In most cases, waiting until the child's vision is mature before performing surgery is advised because an induced strabismus after surgery is not uncommon and can lead to the loss of binocular vision.

■ Acquired Brown syndrome

- Usual treatment is treating sinusitis, if present, and providing oral nonsteroidal antiinflammatory drugs
- Surgery usually is not usually indicated for acquired inflammatory Brown syndrome.

Congenital fibrosis syndrome

- Treatment is surgical recession of the fibrotic muscle.
- These cases can be technically difficult because exposure of the muscle is limited, especially in cases with a fibrotic medial rectus muscle.

WHEN TO REFER

- Acquired strabismus
- Diplopia
- Limited eye movements (incomitant strabismus)
- Ptosis or other neurologic signs
- Poor vision or abnormal red reflex

Strange Behavior

DEFINITION

- Pervasive developmental disorder (PDD) is a neuropsychiatric disorder that is usually identified in the first 5 years of life.
- In separation anxiety disorder (SAD), the child experiences excessive anxiety of a magnitude that leads to disruptions in social or academic function when separated from home or from those to whom the child is attached.
- Posttraumatic stress disorder (PTSD) requires exposure to an extreme traumatic stressor involving direct personal experience of an event that included actual or threatened death or serious injury to make the diagnosis.
- Pica is the persistent eating of nonnutritive substances.
- Rumination disorder is characterized by repeated regurgitation and rechewing of food.
- Feeding disorder of infancy or early childhood involves persistent failure to eat adequately.
- Gender identity is the child's sense of being male or female.
- A transitional object is the first possession used by the child as a defense against anxiety, which arises in the course of separation and individuation from the mother or primary caretaker.
- Oppositional defiant disorder (ODD) is characterized by recurrent, severe pattern of negativistic, defiant, disobedient, and hostile behaviors toward authority figures lasting >6 months.
- Conduct disorder is characterized by repetitive and persistent pattern of behavior in which basic rights of others and social rules and norms are violated.
- Pathological dissociation is defined as disruption of integrated functions of consciousness, memory, identity, or perception of environment.
- Depersonalization is a subjective sense of being unreal, strange, or unfamiliar to oneself.
- Major depressive disorder is the presence of a single major depressive episode, with ≥ 5 or more symptoms lasting for ≥ 2 weeks and occurring daily.
- Manic episode is a distinct period of abnormally and persistently elevated, expansive, or irritable mood lasting for at least 1 week.
- Psychosis currently implies serious disturbance in an individual's reality testing, as evidenced by hallucinations, delusions, and disturbances in the form of thinking.

EPIDEMIOLOGY

- Transitional objects and imaginary companions
 - Existence of transitional objects and imaginary companions is common in early childhood.
 - In 1 study:
 - 65% of children between 3 and 5 of age years had imaginary playmates.
 - 75% of children had transitional objects.

- Attention-deficit/hyperactivity disorder (ADHD)
 - Most prevalent and important psychiatric disorder of middle childhood years
 - Current prevalence estimates in the school-age population are between 3% and 5%.
- ODD
 - Occurs frequently in children with ADHD
- Dissociative disorders
 - Prevalence in children and adolescents is unknown.
 - 85–100% of adults who have dissociative identity disorder have documented histories of severe childhood abuse.
- Psychotic disorders
 - Very uncommon in prepubertal children
- Schizophrenia
 - In adolescence, frequency increases dramatically.
- Eating disorders
 - Anorexia nervosa and bulimia nervosa are common psychiatric disorders of childhood.
 - Commonly occur in adolescence
 - Prevalence has increased markedly over the last 50 years.
 - Much more common in girls, with onset typically in later adolescence
 - Most typically girls are white and upper middle-class
 - Seen mostly in Western industrialized nations

MECHANISM

- Pathological dissociation
 - Major risk factors
 - Childhood trauma
 - Early sexual abuse
 - Dissociation is a defensive coping mechanism that functions to protect the child against extreme pain and vulnerability in severe childhood abuse.
- Eating disorders
 - In puberty, the need for the young girl to integrate realities of menstruation, breast development, and the broadening of hips can result in:
 - Transient perturbations of body image
 - Abnormal eating behaviors

HISTORY

Infancy and early childhood (birth to 5 years)

PDD

- Specific deviance noted in the domains of:
 - Language
 - Communication
 - Personal-social domains

- Includes related abnormalities in stereotypic and repetitive behaviors
- Communication impairments seen in children with PDD include:
 - Abnormalities in verbal and nonverbal communication
 - Delay in spoken and gestural language
 - Use of echolalia
- About two-thirds of children with PDD are mentally retarded.
- Cognitive delay is not intrinsic to the diagnosis.
- Social abnormalities seen in PDD are present in the first year of life.
- Children who have PDD have little interest in
 - Human faces
 - Interactions with others
- Deficit in social interaction can be identified in the 1st year of life by astute and experienced observer.
- Frequent signs include bizarre, restricted, and repetitive stereotypic behaviors, such as:
 - Flapping
 - Spinning
 - Head banging
- Asperger disorder
 - Subcategory of PDD
 - Differs from classical presentation of PDD
 - Language and cognitive functioning are preserved.
 - Social abnormalities and stereotypic behaviors are present.

Reactive attachment disorder of infancy or early childhood

- Abnormalities of social relatedness are the hallmark.
- Abnormalities are rooted in grossly pathological care of the child in the earliest years of life.
- Children can display inhibited type of reactive attachment disorder in which they appear:
 - Withdrawn
 - Hypervigilant
 - Resistant to all attempts to establish relatedness or comfort
- In the disinhibited type, children show:
 - Indiscriminate sociability
 - Excessive sociability
 - Superficial sociability
- In both cases, failure to develop age-appropriate attachment behaviors is obvious.
- In extreme cases, children may fail to thrive with:
 - Severe growth and cognitive delays
 - Developmental deviances are related to failure of caretaking and attachment.

SAD

- The child often refuses to go to school.
- Unwilling to travel independently
- Unwilling to be separated from the parent for brief, developmentally appropriate activities, such as:
 - Play dates
 - Sleepovers
 - Camping
- Child with SAD will often:
 - Shadow the parent
 - Refuse to be on a different floor of the house
 - Refuse to sleep alone
- Common traits are excessive worries, including:
 - Generating frightening fantasies about misfortune occurring to the parent

PTSD

- Well established in adults, adolescents, and children
- Formidable challenge to diagnose in children <5 years
- *Diagnostic and Statistical Manual of Mental Disorders, 4th edition (DSM-IV)* criteria require:
 - Verbal descriptions of thoughts and experiences, which are difficult to obtain from children whose language skills are limited
- Clinical observations of the posttraumatic symptoms of early childhood
 - Strongly visualized or repetitively perceived memories of the traumatic event can either take form of the well-known flashback or be less intrusive.
 - Posttraumatic play
 - Compulsive
 - Repetitive
 - Grim
 - Incorporates a portion of the trauma, known as play reenactment
 - Much less imaginative and more rigid than normal play
 - Does not relieve anxiety or trauma-specific fears
 - Does not change attitudes about people and life; characterized by excessive pessimism and hopelessness about the future
- Preliminary investigation to explore whether *DSM-IV* PTSD criteria accurately describe the symptoms of young, traumatized children found that it did not.
 - Authors suggest more objective, behaviorally anchored, and developmentally sensitive criteria, including assessment of:
 - Posttraumatic play
 - Sleep disturbances
 - Emergence of new aggressive and separation anxiety symptoms

Feeding and eating disorders of infancy and early childhood

- The *DSM-IV* recognizes 3 feeding disorders in early childhood.
 - Pica
 - Rumination disorder
 - Feeding disorder of infancy or early childhood
- Pica is frequently seen in association with:
 - Mental retardation
 - Developmental disorders
- Rumination disorder
 - Frequently seen in mentally retarded infants and children
- Failure to thrive
 - Failure to gain weight or significant weight loss over ≥ 1 month
 - Must not result from a medical condition
 - Often associated with:
 - Parental psychopathological abnormality
 - Child neglect
 - Abuse

Cross-gender behavior and gender identity disorder (GID)

- Emerges in early childhood
- Usually consolidated by age 3–4 years
- Children with clinically significant GID exhibit a persistent, pervasive desire to be of the opposite sex.
- In the *DSM-IV*, GID is defined as having 2 important components.
 - Strong, persistent cross-gender identification and persistent discomfort with child's own sex
 - Sense of inappropriateness in assigned gender role
- Boys with GID will assert that:
 - Their genitalia are disgusting.
 - They wish them to disappear.
- Rejection of stereotypical toys, games, and activities is common.

Transitional objects and imaginary companions

- Soft object or stuffed animal
- Emerges at age 4–12 months
- Persists well into early childhood

Middle childhood years (5 years to puberty)**ADHD**

- According to the *DSM-IV*, core symptoms require onset of inattention and hyperactivity-impulsivity by age 7 years, occurring in ≥ 2 settings.
- Symptoms must be more severe and frequent than those seen in a normal child at a comparable development level.
- Tend to emerge once the child enters school because of taxing of limited attention and impulse control available

- Highly structured setting
- Significant demands
- Lack of one-to-one adult-to-child supervision

ODD

- Symptoms are seen invariably in the home.
- Frequently focused on one particular authority figure
- Behaviors must be particularly frequent, severe, and persistent to prevent inappropriate labeling of children exhibiting developmentally normal oppositionalism as having ODD.

Conduct disorder

- Mild antisocial behaviors can be developmentally normal in certain settings, such as:
 - A preschooler who cannot play by the rules in structured games
- In the school-age child and adolescent, conduct disorder symptoms are grossly developmentally deviant and include:
 - Aggressivity
 - Deceitfulness
 - Theft
 - Serious rule violations
 - Property destruction
- Children and adolescents who have conduct disorder are at high risk for developing antisocial personality disorder in adulthood.

Dissociative disorders

- *DSM-IV* includes 4 diagnoses within the category of dissociative disorders.
 - The most familiar is dissociative identity disorder, also known as multiple personality disorder.
- Core of these disorders is the presence of pathological dissociation.
 - Can be transient or chronic
 - Onset can be acute or gradual.
 - Capacity for dissociation develops in childhood and is a normal process used in imaginative play.
 - This normal process declines markedly by late adolescence.
 - The key differences between the normal dissociation of a daydreaming child or a child in the throes of fantasy play and the pathological dissociation seen in the dissociative disorders are:
 - Amnesia for complex behaviors
 - Extreme forms of depersonalization
 - These symptoms rarely occur in healthy children or in children who have psychiatric disorders other than dissociative disorders.

Adolescence**Major depressive disorder and bipolar disorder**

- Signs and symptoms

- Depressed mood for most of the day
- Markedly diminished interest or pleasure in almost all activities
- Significant weight loss or gain caused by a decrease or increase in appetite
- Insomnia or hypersomnia
- Psychomotor agitation or retardation
- Fatigue or loss of energy
- Feelings of excessive worthlessness or guilt
- Diminished ability to concentrate
- Recurrent thoughts of death or suicide
- Adolescents with bipolar disorder characteristically have occurrence of a major depressive episode before a first manic episode.
 - Characteristics of a manic episode
 - Grandiosity
 - Decreased sleep requirement
 - Pressured speech
 - Racing thoughts
 - Agitation
 - High-risk behaviors
 - Spending sprees
 - Sexual promiscuity
 - Gambling
- Both major depressive disorder and bipolar disorder typically occur in adolescence.
- Milder forms of depressive and manic disorders exist and can be seen in adolescence.
- Prepubertal manic and depressive disorders
 - Have been diagnosed more frequently in recent years
 - Are associated with a more severe course

Schizophrenia and other psychotic disorders

- Before 1980, all serious forms of childhood psychiatric disturbance were labeled schizophrenia.
- The label of psychosis has been significantly narrowed in a climate of growing understanding that perception of reality differs in:
 - Various developmental phases
 - Diverse cultural contexts
- In adolescents, schizophrenic symptoms closely parallel those seen in adult-onset schizophrenia.
- The *DSM-IV* identifies characteristic symptoms of schizophrenia as:
 - Delusions
 - Hallucinations
 - Disorganized speech
 - Grossly disorganized behavior

- So-called negative symptoms
 - Avolition
 - Alogia
 - Affective flattening

- These symptoms are accompanied by significant occupational and social dysfunction.

Eating disorders

- 2 classic eating disorders: anorexia nervosa and bulimia nervosa
- Signs and symptoms are typically seen by pediatrician before any mental health intervention is sought.
- In the eating disorders, both thinking and behavior are disturbed.
- Anorexia nervosa produces:
 - Intense fear of gaining weight or becoming fat, even when patient is underweight
 - Disturbance in the way in which body weight is experienced
- The patient refuses to maintain body weight above a minimally normal level.
 - Specified in *DSM-IV* as 85% of expected body weight
- 2 forms of behavior are used by patients with anorexia nervosa to inhibit weight gain.
 - Restricting food intake
 - Cycle of binge eating followed by purging
- Methods of purging may include:
 - Self-induced vomiting
 - Excessive use of laxatives
 - Excessive exercise
 - Use of diuretic medications and enemas
- Patients with bulimia nervosa:
 - Are typically within a normal weight range
 - Often have had a prior period of anorexia nervosa
- Bulimia nervosa is characterized by recurrent episodes of binge eating.
 - During a discrete period, an excessive amount of food intake occurs, accompanied by a feeling of total lack of control.
 - The binge is then followed by purging behavior.

DIFFERENTIAL DIAGNOSIS

- SAD
 - Must be distinguished from the developmentally appropriate anxiety of early childhood during the rapprochement phase.
 - In the second year of life, the child shows normal separation and stranger anxiety.

- Cultural variations on acceptable child-from-parent separation must always be considered.
 - Traditional cultures place great emphasis on family interdependence.
- Pica
 - The clinician should recognize that this practice is sanctioned in certain cultures.
 - In this context, it would not be appropriately viewed as a pathological behavior.
- Feeding and eating disorders of infancy and early childhood
 - Developmental disorders and extreme difficulties in temperament
 - May lead to feeding difficulties
 - Must be distinguished from feeding disorders for proper management
- Cross-gender behavior and GID
 - Must be distinguished from developmentally normal failure to conform to stereotypical gender role behavior, such as:
 - Tomboyism of some latency age girls
 - Cultural variants such as effeminate style of the bohemian artist or dandy
 - Normal variants are usually distinguished easily from true GID by:
 - Lack of severe disgust with the individual's anatomy and assigned gender role
 - Absence of a strong identification with the other sex
- Transitional objects and imaginary companions
 - Normal developmental element of early childhood should be distinguished from the transitional phenomena and imaginary companions of the severely disturbed child.
 - These experiences are not always easy to distinguish in early childhood.
 - Children with a history of severe physical or sexual abuse may develop symptoms of
 - Pathological dissociation
 - Psychosis, including auditory hallucinations or imaginary companions
 - Unlike the benign imaginary companions of a normal child, the hallucinatory experiences of the dissociative or psychotic child are:
 - Threatening
 - Frightening
 - Aggressive toward others
 - The child feels little control over the experience.
 - The child often cannot distinguish between reality and this frightening product of the imagination.
 - Assessment by an experienced child psychiatrist is required if doubt exists.
- ADHD
 - Normal exuberance of early childhood is most commonly confused with ADHD.
- ODD
 - To prevent inappropriate labeling of developmentally normal oppositionalism as ODD, behaviors must be particularly:
 - Frequent
 - Severe
 - Persistent
- Conduct disorder
 - Mild antisocial behaviors can be developmentally normal in certain settings, such as:
 - A preschooler who cannot play by the rules in structured games
- Dissociative disorders
 - Aspects of normal adolescent development in the psychological and cognitive area can gain clinical attention and can be mistaken for an abnormality.
 - Tendency toward egocentric, grandiose thinking and abstract theorizing is pronounced during adolescence.
 - Obsessive, ruminative focus on the body or on the person's own thinking process can be mistaken for:
 - Anxiety disorders
 - A hypomanic episode
 - Oppositional behavior
- Schizophrenia
 - Severe symptoms can be contrasted with disturbances in reality testing seen in various phases of normal development.
 - Transient hallucinatory experiences, often tactile or visual in nature, are commonly seen in:
 - Early childhood
 - In older children during times of stress
 - Magical, animistic thinking is common and developmentally normal in preschool and early school-age children.
 - Imaginary companions and transitional objects imbued with lifelike qualities by the child are normal in early childhood.
 - All such normal phenomena should gradually disappear by the end of middle childhood.
- Eating disorders
 - Distinguishing factors that identify eating disorders from the transient, developmentally normal process
 - Severity of weight loss
 - Persistence of a disturbed body image
 - Loss of menses in anorexia nervosa is necessary to make the diagnosis.

TREATMENT APPROACH

- The first 2 decades of life comprise the most complex and dynamic links among
 - Mind
 - Body
 - Development
- Behaviors and thoughts that at one phase are entirely normal can be a harbinger of a serious pathology when they emerge in a different stage of development and with subtle differences in presentation.
- Organic illness during childhood or adolescence may:
 - Cause regressions or deviances in thinking and behavior
 - Blur the clinician's understanding of the patient
- Nuances of different cultural and belief systems can be interpreted as pathological thinking and behavior to the culturally naive observer.
- Successful collaboration between child psychiatry and pediatrics is crucial in diagnosis and treatment of children.

Infancy and early childhood (birth to 5 years)

- Psychiatric assessment of children is unique and most challenging in the first 5 years of life.
 - Accurate evaluation of a psychopathological abnormality requires a firm grasp of normal development.
 - To identify abnormalities, combine:
 - Keen observation
 - Skilled and informed probing
 - In assessment of infants and preschoolers, break down observations into 4 categories (Gesell).
 - Motor skills
 - Language abilities
 - Personal-social abilities
 - Adaptive functioning
 - Manipulation of objects
 - Alertness
 - Hand-eye coordination
 - The Bayley scale breaks down infant assessment into useful subdivisions focusing on:
 - Social communication
 - Object constancy
 - Capacity for discrimination
 - Abnormalities in any can direct more serious consideration of major types of psychopathological abnormality.

Middle childhood years (5 years to puberty)

- Phase of middle childhood begins:
 - Elementary school
 - Formal learning and participation in a structured peer group
 - Interaction in the world beyond the family

- Period during which disruptive behavior disorders emerge and gain clinical attention
- Industriousness is called for in acquisition of:
 - Academic skills
 - Social competence with peers
 - Successful relationships with authority figures outside the family
- One-to-one supervision by an adult gives way to:
 - Structured classroom setting
 - Formal rules of behavior within a distracting group of peers
- Several psychiatric disorders emerge or are more readily identifiable in this developmental stage and social setting.
- Accurate understanding of symptoms gathered from a combination of:
 - Skilled interview
 - Supporting information from parents, teachers, and other relevant reporters

Adolescence

- Adolescence is a developmental phase unique to human beings.
- Hormonal and neurologic changes develop slowly over many years, culminating during puberty.
- With biological changes come psychological and social changes, including:
 - Preoccupation with the body
 - Development of sexuality
 - Social anxiety
 - Increased importance of the peer group over parents and other adult figures
 - Development of more abstract cognitive abilities
- These developments result in unfamiliar changes in thinking and behavior.
 - May at times be mistaken for psychopathology
- Several major psychiatric disorders occur typically in adolescence.

Special considerations

Extreme temperament in childhood

- 9 categories have been identified that define temperament.
 - Activity level
 - Rhythmicity or regularity
 - Approach or withdrawal behavior
 - Adaptability to new situations
 - Threshold of responsiveness
 - Intensity of reaction
 - Quality of mood
 - Distractibility
 - Attention span

- 3 distinct temperamental styles.
 - Easy temperament
 - Regular, easily adaptable child
 - Displays a predominantly positive mood and only mild intensity
 - Difficult temperament
 - Behaviorally opposite of easy temperament
 - Characterized by biological irregularity, withdrawal in reaction to novel stimuli, slow adaptability to change, predominantly negative mood, high intensity
 - Slow-to-warm-up temperament, also known as shy
 - Slow adapters
 - Significant withdrawal responses, low intensity, and frequent negative mood
- The difficult child and the slow-to-warm-up child are developmentally and psychologically normal.
 - Because of their difficulty to manage, may be labeled as behaviorally disordered by caretakers and brought to pediatric attention.
 - Extremely negative temperamental features have not been found to be equivalent to psychiatric disorders in childhood.
 - Can predict poor psychiatric functioning in adolescence
 - Particularly in the context of poor caretaker-child interaction and dysfunctional behavioral control among adult family members
- In cognitive-developmental theory, a systematic and predictable sequence exists by which concepts of illness are acquired.
- Children who are ill often exhibit strange behavior that can be understood by:
 - Appreciation of child's cognitive level
 - The fact that children often regress to an earlier level of cognitive functioning under stress
- Symptoms that existed previously and were overcome by the child may recur and persist during the course of the illness, such as:
 - Enuresis
 - Soiling
 - Sleep difficulties
 - Separation anxiety
- Elements specific to the plight of the child with a medical illness may predispose the child to unusual thinking and behavior.
- The experience of being nursed and change in parental emotional climate can cause great anxiety and may even be traumatic.
- Being forced into a passive role and being treated by the parent and medical staff as a much younger child can be upsetting to the child who has acquired independent functioning and detachment from parents.
- The resulting anxiety can create a difficult, even intractable, patient.

Medically ill child

- The pediatrician is a primary observer of the child in the role of patient.
- The pediatrician needs to understand emotional and developmental reactions to pain and illness exhibited by children.
- Cognitive-developmental theory define a predictable sequence of stages by which cognitive concepts are acquired throughout childhood.
 - Sensorimotor stage, infancy to 2 years
 - Things exist only insofar as the child can act on them.
 - The ultimate cognitive outcome is the achievement of object permanence.
 - Preoperational stage, age 2–7 years
 - Symbolic thought and representations, including language, develop.
 - Thinking is not logical.
 - Egocentric and animistic
 - Concrete operational stage, ages 7–puberty
 - Logical thinking takes hold
 - The formal operational stage begins at puberty.
 - Formal abstract thinking is the predominant mode of thought.
 - Not all individuals reach the formal operational stage, even in adulthood.
- **WHEN TO REFER**
 - When a high index of suspicion exists for a psychiatric disorder:
 - Refer to a child and adolescent psychiatrist for a full diagnostic assessment
 - Clinical situations in which immediate referral should be made
 - Suicidal ideation or intent
 - Violence or serious recent history of violence
 - Thought disorder and other psychotic symptoms
 - Suspicion of serious substance abuse
 - Pediatric depression
 - Assessment for initiation or continuation of treatment with psychotropic medication
- **WHEN TO ADMIT**
 - Suicidal ideation
 - Violent behavior
- **PROGNOSIS**
 - Psychotic disorders
 - When present in prepubertal children, harbingers of a poor prognosis

Streptococcal Toxic Shock Syndrome

DEFINITION

- Streptococcal toxic shock syndrome (STSS)
 - A syndrome caused by group A streptococci (GAS) that involves severe invasive diseases, including:
 - Necrotizing fasciitis
 - Necrotizing myositis
 - Bacteremia
 - Sepsis with vascular collapse, hypotension, and multiorgan failure

EPIDEMIOLOGY

- Incidence
 - Severe invasive GAS infections: 1.5–7.0 cases per 100,000 population annually
- Patients with STSS have epidemiologic features that distinguish them from patients with other invasive GAS infections:
 - Younger age
 - Alcohol abuse
 - Fewer underlying illnesses
- Outbreaks of severe invasive GAS infections have occurred in some closed environments:
 - Military bases
 - Nursing homes
 - Hospitals
- Overall fatality rate of invasive GAS diseases
 - Children: 5–10%
 - Adults: 30–80%
- Case fatality rate associated with STSS remains high in both pediatric and adult populations.

ETIOLOGY

- Most cases of STSS are caused by GAS strains that produce bacterial superantigens known as the *streptococcal pyrogenic exotoxins*.

RISK FACTORS

- Clinical risk factors
 - History of soft-tissue injury
 - Animal or insect bite
 - Blunt or penetrating trauma
 - Surgical wounds
 - Subcutaneous injections of insulin or illicit drugs
 - Varicella infection (15–30% of invasive GAS diseases are associated with varicella)
 - Invasive GAS infections
 - Pneumonia
 - Meningitis
 - Peritonitis

- Osteomyelitis
- Bacteremia
- Septic arthritis
- Inconsequential scratch or abrasion
- STSS occurs without readily identifiable focus of infection in 21% of cases.
- Relative risks of invasive GAS infections among household contacts of patients with invasive GAS infections are 19–200 times the baseline risk in general population

■ Biochemical risk factor

- Major human host defense against invasive GAS infection is phagocytosis and killing by polymorphonuclear leucocytes.
- Thus, a critical somatic GAS virulence factor is an antiphagocytic surface constituent known as M protein.
- Strains of GAS isolated from patients with STSS are not of a single M type, but M1 and M3 infections are associated with invasive diseases and STSS.

SIGNS AND SYMPTOMS

- Sudden severe pain
 - Most common initial symptom of STSS
 - Usually involves an extremity
- Fever
 - Hypothermia may be present in patients with shock.
- Rapid-onset hypotension
 - Systolic blood pressure ≤ 90 mm Hg in adults or below 5th percentile for age in children
 - Nearly one-half of patients with STSS may have normal blood pressure at admission but soon develop hypotension.
 - Hypotension is significant risk factor for death.
- Rapidly accelerated renal failure
- Acute respiratory distress syndrome
- Necrotizing fasciitis in up to 70% of patients
 - Life-threatening soft tissue infection primarily involving the superficial fascia with relative sparing of skin and muscles, both of which may be infected secondarily
 - Ominous signs of necrotizing fasciitis
 - Progression of soft tissue swelling to the formation of violaceous or hemorrhagic vesicles, then bullae
 - Line of demarcation becomes sharply defined.
 - Dead skin begins to separate at margins or breaks in center, revealing extensive necrosis of subcutaneous tissue.
 - Crepitus on physical examination, which is pathognomonic for necrotizing soft-tissue infections, is seen in only one-third of cases.

- Myositis: up to 70% of patients
 - Early signs
 - Severe pain
 - Swelling
 - Erythema
 - Fever
 - Pain often out of proportion to clinical findings, possibly related to muscle compartment syndrome
- Pharyngitis and local soft tissue infection (eg, cellulitis, abscess)
- Soft tissue swelling and erythema: 80% of patients
- Confusion: 55% of patients
- Preceding influenza-like syndrome (20% of patients), characterized by:
 - Fever
 - Chills
 - Myalgia
 - Nausea
 - Vomiting
 - Diarrhea
- Diffuse scarlatina-like erythema: 10% of patients
- Coma or combativeness
- Erythematous, tender, swollen area that resembles cellulitis, with disproportionately severe pain at the site of involvement

DIFFERENTIAL DIAGNOSIS

- Pain of STSS usually involves an extremity but also may mimic the following:
 - Peritonitis
 - Pelvic inflammatory disease
 - Acute chest syndrome
- Necrotizing fasciitis and myositis are difficult to diagnose.
 - Some patients with STSS may have both.
 - Emergent surgical exploration should be done to establish and distinguish GAS infection from other soft tissue infections.

LABORATORY FINDINGS

- Case definition includes the following laboratory findings:
 - Isolation of group A β -hemolytic streptococci
 - From normally sterile site (eg, blood, cerebrospinal fluid, peritoneal fluid, tissue biopsy specimen)
 - From nonsterile site (eg, throat, sputum, vagina)
 - Clinical signs of severity, ≥ 2 of the following signs:
 - Renal impairment (creatinine ≥ 2 mg/dL for adults or twice the upper limit or more of normal for age)
 - Coagulopathy (platelets $\leq 100,000/\mu\text{L}$ or disseminated intravascular coagulation)

- Hepatic involvement (alanine aminotransferase, aspartate aminotransferase, or total bilirubin levels twice the upper limit of normal or more for age)
- Other possible laboratory findings include:
 - Hypoalbuminemia
 - Hypocalcemia
 - Lactic acidosis
 - Hyperglycemia
 - Thrombocytopenia
- When serum creatinine kinase level is increased, a good correlation exists with necrotizing fasciitis or myositis.
- Mild leucocytosis may be seen initially, but the mean percentage of immature neutrophils can reach 40–50%.
- Culture
 - Blood cultures are positive for GAS in 60% of cases.
- Gram stain
 - Subcutaneous fluid may be aspirated from the affected limb for Gram stain and culture.
 - Subject all tissues from initial surgical debridement to Gram staining and culturing for aerobic and anaerobic microorganisms
- Rapid antigen detection tests for GAS
 - Approved only for pharyngeal swab specimens
 - May be able to identify GAS from necrotic tissue
 - In necrotizing soft-tissue infections in children, GAS is identified as a single organism in only 25% of cases; the remaining cases are polymicrobial.

IMAGING

- Imaging studies are only adjuncts in evaluations of STSS and necrotizing soft tissue infections and should not be relied on to exclude the diagnosis.
- Diagnosis of invasive GAS infection, including STSS, is still primarily clinical.
- Radiography
 - May depict soft tissue air at affected area (50% of cases)
- Computed tomography and magnetic resonance imaging
 - Help diagnose necrotizing fasciitis and myositis and delineate extent of infection
 - Features of necrotizing fasciitis
 - Deep fascial thickening
 - Enhancement
 - Presence of fluid and gas in the fascial planes
 - Features of myositis
 - General homogenous enlargement of the muscle
 - Low attenuation values
 - Edema or presence of intramuscular gas

SPECIFIC TREATMENTS

Severe invasive GAS infection

- Hemodynamic stabilization
- Specific antibiotic therapy
- Prompt and aggressive surgical exploration
- Fasciotomy
- Debridement of suspected deep-seated infection
- Surgical exploration and incisional biopsy, to provide both definitive diagnosis and treatment

Suspected STSS

- Empiric broad-spectrum antibiotic therapy with drugs that cover gram-positive, gram-negative, and anaerobic organisms
 - Combination of ampicillin, penicillin, aminoglycosides, and clindamycin
 - Combination of expanded-spectrum penicillin or cephalosporins, clindamycin, and aminoglycosides
- Patients allergic to penicillin may receive vancomycin in place of ampicillin or penicillin.
- Antibiotic regimen can be changed once the causative organism is identified.

Treatments

- Penicillin
 - Less efficacious in overwhelming GAS infections when large numbers of organisms are present (so-called Eagle effect).
 - Fails to halt GAS infection because of physiologic state of organism
 - Less efficacious against slowly growing organisms
- Clindamycin
 - Administering clindamycin in addition to penicillin seems advisable in patients with overwhelming invasive GAS infection.
 - Should not be used alone, because strains of GAS with clindamycin resistance have been reported
- Intravenous immunoglobulin
 - May be provided as adjunctive therapy for patients with STSS, because it:
 - Decreases mortality rates
 - Is associated with significant improvement of organ dysfunction after therapy
 - Leads to significant increase in plasma-neutralizing activity against superantigens
- Hyperbaric oxygen
 - Patient is enclosed in a chamber and breathes 100% oxygen at pressure >1 atmosphere absolute.
 - Results of clinical studies of necrotizing fasciitis have been inconsistent.
 - May improve patient survival and decrease the number of debridements required to achieve wound control.

WHEN TO ADMIT

- All patients with STSS need to be admitted.

WHEN TO REFER

- All patients with STSS should be managed in consultation with infectious diseases specialists.

COMPLICATIONS

- Renal dysfunction
 - May occur before or after hypotension
 - Progresses or persists in all patients for 48–72 hours despite treatment
 - Many patients require dialysis.
 - In survivors, serum creatinine values return to normal within 4–6 weeks.

PROGNOSIS

- High fatality rate is associated with invasive GAS infections:
 - Necrotizing fasciitis: 22%
 - STSS: 45%
 - Case-fatality rate among patients with neither STSS nor necrotizing fasciitis: 10%
- Survival is possible with:
 - Early surgical debridement
 - Reexploration at 24–36 hours
 - Intensive supportive care
 - Extent of debridement is determined by radiographic findings and physical findings at surgery.
- Recurrent STSS episodes have not been reported.

PREVENTION

- Protective humoral immunity
 - Immunity to cell-associated and soluble GAS virulence factors is important in preventing invasive disease.
 - Patients with invasive GAS disease have significantly lower serum levels of protective antibodies against M protein and superantigens compared with serum samples from noninvasive cases.
 - Lack of immunity against GAS virulence factors contributes to susceptibility to invasive infection.
- Opportunities for preventing STSS are few.
 - Varicella vaccination
 - Because of association between invasive GAS infections, including STSS and varicella infection, in healthy children, routine childhood immunization against varicella is suggested.
 - Children who receive varicella vaccine are less likely to be hospitalized for varicella-related invasive GAS infections.

- Nonsteroidal antiinflammatory drugs (NSAIDs)
 - Relationship between NSAID use and necrotizing fasciitis has been reported.
 - NSAIDs can impair granulocytic function and enhance production of cytokines.
 - A causal relationship between NSAID use and severe invasive GAS infections has not been established.
- Infection-control practices
 - To prevent nosocomial GAS infections, improve infection-control practices for:
 - Surgical and obstetric procedures
 - Placement and care of intravascular devices
- Household spread
 - GAS can easily spread through household.
 - Family members, usually children, are identified with pharyngitis or with carriage of same strain of GAS that caused invasive disease.
 - Secondary cases of invasive GAS infections, including STSS within same household, have been reported.
 - Although risk of subsequent invasive GAS disease among household contacts is higher than in general population, such infections are rare.
 - No studies on effectiveness of chemoprophylaxis in preventing invasive GAS disease among household contacts of patients with invasive GAS infections
 - Routine chemoprophylaxis and routine use of cultures among household contacts is not warranted.
 - Health care providers should:
 - Inform members of the household about clinical manifestations of pharyngeal and invasive GAS infections.
 - Emphasize importance of seeking immediate medical attention if they develop such symptoms, particularly within 30 days after index case is diagnosed.
- Chemoprophylaxis among household members
 - Those age ≥ 65 years
 - Those with:
 - HIV infection
 - Concurrent varicella infection
 - Diabetes mellitus
 - Cancer
 - Chronic cardiac or pulmonary diseases
 - Injection drug use
 - Alcoholism
 - Known immunodeficiency disorder
 - Corticosteroid use
- Because the source of GAS in households may not be the person with invasive infection, prescribe chemoprophylaxis for both the elderly or high-risk household member *and* all members in household.
- If available, use antibiotic susceptibility data to select most appropriate chemoprophylactic agent.
- Everyone receiving chemoprophylaxis should watch for sign and symptoms of invasive GAS disease for 30 days after diagnosis of invasive disease in index case.
- Chemoprophylactic regimens:
 - Single dose of benzathine penicillin G (600,000 units intramuscularly for persons weighing < 27 kg or 1,200,000 units intramuscularly for persons weighing ≥ 27 kg) *and* oral rifampin 20 mg/kg/day (maximum daily dose, 600 mg) in 2 divided doses for 4 days
 - Clindamycin 20 mg/kg/day (maximum daily dose, 900 mg) in 3 divided doses for 10 days
 - Azithromycin 12 mg/kg/day (maximum daily dose, 500 mg) once a day for 5 days
- Other agents
 - Limited evidence that first- and second-generation cephalosporins eradicate pharyngeal colonization of GAS
 - Consider these agents for patients allergic to penicillin whose allergic reactions are not anaphylactic.
 - Rifampin is not recommended for pregnant women because of its teratogenic effect.
- Postpartum or postsurgical invasive GAS infections
 - Implement enhanced surveillance by infection control personnel.
 - Store all GAS isolates from suspected cases and compare them by serotyping or molecular techniques.
 - Suspect that health care worker may be source of cluster if ≥ 2 cases of invasive GAS infection by same GAS type occur within 6 months.
 - Screen health care workers who are epidemiologically linked to case patients by obtaining cultures from throat, anus, vagina, and skin lesions.
 - Prescribe one of the three regimens above to health care workers who are colonized with GAS.
 - Perform follow-up culture 7–10 days after completion of therapy.

Stridor

DEFINITION

- Stridor is a high-pitched, monophonic noise caused by turbulent airflow through a partially obstructed extrathoracic airway, heard predominately on inspiration.

MECHANISM

- During the normal respiratory cycle, rhythmic expansion and contraction of the thorax leads to dynamic changes in thoracic pressures.
 - Result: Air flows into and out of the lungs.
- During expiration, the volume of the thoracic cavity decreases.
 - Result: Positive pressures within the thorax are created.
- Airways located within the thorax are directly subjected to these positive pressures.
 - Result: These airways are more prone to obstruction during expiration, leading to turbulent airflow and wheezing.
- On inspiration, the thoracic cavity expands.
 - Result: Negative intrathoracic pressures occur and patency of intrathoracic airways improves.
- This portion of the airway is susceptible to obstruction, and thus stridor, during inspiration because:
 - Intraluminal airway pressure decreases to allow inflow of air.
 - Extrathoracic airways (nose, nasopharynx, oropharynx, and larynx) may collapse from transmitted negative intrathoracic pressures.

HISTORY

- Age at initial presentation and a description of the events surrounding symptom onset can provide important clues to the underlying diagnosis.
- Viral croup
 - Stridor preceded by fever, upper respiratory symptoms, and a barking or seal-like cough
 - No stridor between episodes
 - The patient may have history of similar episodes in the past.
 - Stridor caused by viral croup improves within days.
- Laryngomalacia
 - Suspected if stridor begins in the first few weeks of life and presents only during specific phases of alertness, such as eating, sleeping, or excitement
 - Laryngomalacia is the most common cause of congenital stridor in infancy.
 - Stridor caused by laryngomalacia is typically intermittent and worsens over the first several months of life.
 - With age, episodes become less severe and less frequent; symptoms usually completely resolve by the first birthday.

- Subglottic stenosis or granulation tissue
 - Stridor that develops shortly after a prolonged intubation
 - May be continuous
 - Often seen in premature infants who required mechanical ventilation during the neonatal period
- Retropharyngeal abscess
 - Fever
 - Difficulty swallowing
- Hemangioma
 - Worsening stridor
 - History of cutaneous hemangiomas
- Bilateral vocal cord paralysis
 - History of injury to both recurrent laryngeal nerves
 - Arnold-Chiari malformation or increased intracranial pressure
- Foreign body
 - Sudden onset
 - History of choking or placing small objects in the mouth
- Vocal cord cyst
 - Hoarse voice
 - Chronic irritation to vocal cords or airway instrumentation
- Recurrent respiratory papillomatosis
 - Usually associated with stridor or hoarseness 2–3 years after birth
 - Infection is acquired through vertical transmission in the birth canal from maternal cervical human papillomavirus infection.
- Laryngeal web
 - Develops shortly after birth (congenital)
 - Develops after airway instrumentation (acquired)
- Onset of stridor in an older child or adolescent with no previous history should prompt a more thorough evaluation.

PHYSICAL EXAM

- Assess position.
 - Extension of the neck is often seen with serious infection, such as epiglottitis or retropharyngeal abscess.
- Look for drooling.
 - Suggests a mass effect or edema in the posterior pharynx, causing dysphagia in addition to stridor
- Keep the patient calm and maintain the airway.
- Examine the oropharynx to detect:
 - Retropharyngeal bulge
 - Lateral displacement of the uvula and swelling of a tonsillar pillar from an underlying infection

- Externally examine the neck for:
 - Presence of suprasternal retractions when obstruction is severe
 - Displacement of the larynx, a mass obstructing the airway, or signs of trauma
- Note the quality of the voice.
 - Hoarseness, aphonia, or a weak cry suggest vocal cord disease.
- Physical examination findings
 - Laryngomalacia
 - Predominately inspiratory
 - May be positional
 - Viral croup
 - Predominately inspiratory
 - No change with position
 - Subglottic stenosis
 - Predominately inspiratory, but often biphasic
 - Foreign body
 - Predominately inspiratory if obstruction is extrathoracic
 - Retropharyngeal abscess
 - Often present with stertor
 - Presence of drooling
 - Hemangioma
 - Cutaneous hemangiomas may be present.

DIFFERENTIAL DIAGNOSIS

- Causes of stridor
 - Laryngomalacia
 - Viral croup
 - Subglottic stenosis
 - Foreign body
 - Retropharyngeal abscess
 - Hemangioma
 - Bilateral vocal cord paralysis
 - Vocal cord cyst
 - Laryngeal papillomatosis
 - Laryngeal web
- Because the extrathoracic airways extend from the nose to the proximal trachea, high-pitched laryngeal stridor must be differentiated from other abnormal inspiratory noises.
 - Stertor
 - Noisy, rumbling-type noise similar to snoring
 - Heard with partial airway obstruction in the oropharynx or nasopharynx

- For stridor that worsens or persists, coexisting or alternate diagnoses should be considered.
 - Laryngopharyngeal acid reflux may aggravate the underlying condition.
 - Mild stridor caused by a subglottic hemangioma may initially be attributed to a more common problem (eg, laryngomalacia).
 - Similar to laryngomalacia, obstruction from a hemangioma tends to worsen after initial presentation as the lesion enlarges.
 - Unlike with laryngomalacia, natural resolution of the hemangioma, and thus the stridor, may take several years rather than months.
- History of a hoarse voice or cry suggests glottic disease and might result from chronic irritation of the vocal cords.
- Other clues that suggest more ominous conditions include:
 - Constant stridor
 - Failure to thrive
 - Difficulty swallowing
 - Severe and sudden onset of symptoms

LABORATORY EVALUATION

- Although laboratory testing has limited value for stridor, *Bordetella pertussis* infection can sometimes cause stridor and can be diagnosed by:
 - Polymerase chain reaction
 - Culture of pharyngeal secretions

IMAGING

- Radiographic findings
 - A simple radiograph of the neck can identify obstructive lesions in the retropharynx, glottis, and subglottic area.
 - Viral croup
 - Steeple sign on neck radiograph
 - Subglottic stenosis
 - Subglottic narrowing on neck radiograph
 - Foreign body
 - May be visualized on radiograph if radio-opaque
 - Retropharyngeal abscess
 - Retropharyngeal mass on lateral neck radiograph
 - Hemangioma
 - Subglottic obstruction on neck radiograph

DIAGNOSTIC PROCEDURES

- Pulmonary function testing
 - Not often necessary, but can confirm suspicion of an extrathoracic obstruction

- Flexible laryngoscopy
 - Direct visualization of the airway (including the posterior pharynx and glottis) by flexible laryngoscopy often provides definitive information.
 - Usually well tolerated, and most often with topical anesthesia alone
 - For laryngomalacia:
 - Laryngoscopy merely confirms presence of laryngomalacia while excluding other causes of airway obstruction.
 - For severe laryngomalacia, laryngoscopy can also identify specific structural obstruction that might be amenable to surgical correction.
 - Severe laryngomalacia might obscure the view of the subglottic area such that a more distal lesion would not be visible.
 - Direct visualization of the subglottic region and proximal trachea may be indicated to exclude a second lesion.
 - Direct laryngoscopy and bronchoscopy under sedation or general anesthesia can help diagnose and quantify the severity of subglottic stenosis or identify other subglottic lesions that cause obstruction.
- Findings on diagnostic tests
 - Laryngomalacia
 - Obstruction of glottic space by collapsing supraglottic structures on laryngoscopy
 - Subglottic stenosis
 - Flat inspiratory and expiratory loop on spirometry
 - Subglottic narrowing on direct laryngoscopy
 - Hemangioma
 - Seen on direct laryngoscopy
 - Bilateral vocal cord paralysis
 - No movement of vocal cords during laryngoscopy
 - Vocal cord cyst
 - Visible on laryngoscopy
 - Laryngeal papillomatosis
 - Visible on laryngoscopy
 - Laryngeal web
 - Visible on laryngoscopy

TREATMENT APPROACH

- Ensure airway patency before reaching a differential diagnosis.
 - Stridor reflects obstruction of a large centralized airway.
 - Stridor can range in severity from mild to life threatening.
- For most cases of stridor:
 - Obtain a succinct, focused history.
 - Perform physical examination.
 - Perform directed diagnostic tests.

- For the child with signs of severe respiratory compromise—distressed appearance, severe retractions, nasal flaring, pallor or cyanosis, altered mental status—initially focus on:
 - Maintaining the airway
 - If possible, relieving the obstruction
 - Intubation
 - Attempted only by personnel skilled at airway management
 - Performed in as controlled a setting as possible
 - If potentially difficult, surgical support should be present in case tracheostomy is required.

SPECIFIC TREATMENT

Laryngomalacia

- Most cases can be managed with observation alone, with particular attention to adequate caloric intake and weight gain.

Viral croup

- Most cases of croup can be managed with close observation alone.

More severe obstruction (nasal flaring, retractions)

- Racemic epinephrine may temporarily relieve symptoms of obstruction.
- Dexamethasone may temporarily alleviate inflammation.

WHEN TO REFER

- Progressive or continuous stridor
- Poor weight gain or growth associated with persistent stridor
- Repeated hospitalization
- Presence of cutaneous hemangiomas in association with persistent stridor
- Severe episodes of stridor causing hypoxemia or cyanosis
- Laryngomalacia requiring surgical management to relieve the obstruction caused by redundant epiglottic folds or arytenoid tissue

WHEN TO ADMIT

- Respiratory distress or hypoxemia
- Inability to eat or drink
- Altered mental status or signs of fatigue
- Stridor associated with signs of increased intracranial pressure

Stuttering

DEFINITION

- Speech disorder marked by involuntary interruptions or breaks in speech fluency
- Breaks/disfluencies include:
 - Part-word repetitions (eg, “pi-pi-picture,” “mo-mother”)
 - Single-syllable or single-word repetition (eg, “but-but,” “he-he-he”)
 - Prolongations of speech sounds (eg, “winnnter,” “annnnd”)
 - Blocks or abnormal pauses (eg, “be...because”)
- Developmental stuttering causes the following reactions.
 - Fear and avoidance of speech
 - Chronic and worsening stuttering
- Acquired stuttering
 - Appears suddenly
 - Appears long after speech and language skills have been developed

EPIDEMIOLOGY

- Prevalence
 - 4–5% of children demonstrate persistent or chronic stuttering at some point.
 - Lifetime prevalence: approximately 5% of general population
 - Point prevalence estimate is 1%.
- Age
 - Typically emerges in early preschool years (2–5 years of age)
 - Onset rarely observed after puberty
- Sex
 - More prevalent in boys
 - First-grade children: 3:1 male/female ratio
 - Fifth-grade children: 5:1 male/female ratio

ETIOLOGY

- Developmental stuttering
 - Specific causes are still unknown.
 - Some evidence of a genetic component
 - Genes on chromosomes 1, 13, 16, and 18 are associated with stuttering.
 - Relation to child’s efforts to learn to talk
 - Physical, cognitive, emotional, or motor effort
 - Early stuttering begins between the ages of 2 and 5 years, when the child is rapidly mastering speech and language skills.
 - Demands and capacities model
 - Internal or external demands for fluency exceed the child’s capacity for speech at that point.
 - Environmental demands include parental pressures and self-imposed pressures.

- Acquired stuttering is neurogenic or psychogenic in origin.
 - Neurogenic stuttering
 - Due to brain damage; however, no consistent pattern in type of damage has been found

RISK FACTORS

- Family history of stuttering
- Presence of other speech or language disorders
- Male sex
- Child’s temperament

SIGNS AND SYMPTOMS

- Age 2–6 years
 - Sound and syllable repetitions, produced with some tension and effort
 - Some reactions to the stuttering; mild tension may be observed
 - Child’s initial reactions are surprise and frustration.
 - Reactions when stuttering continues include:
 - Fear of being stuck
 - Children as young as 2 years may hide or twist their faces or show other signs of struggle.
 - Stuttering is considered severe when all of the criteria below are seen.
 - Stuttering is very frequent ($\geq 10\%$ of the syllables spoken).
 - Repetitions are rapid and uneven.
 - Sound prolongation or blocking lasts ≥ 1 second.
 - The child appears to struggle in an attempt to say a word.
 - Fear or avoidance of speaking is evident.
- Age 6–10 years
 - Syllable repetitions
 - More tension and struggles at point of stutter
 - Tongue protrusions
 - Jaw tremors
 - Grimaces and other involuntary behaviors may become habituated.
 - Blocks appear.
 - Child pushes to get unstuck.
- Early teens and adolescents
 - Blocks (eg, getting stuck)
 - Sound prolongations (“...mmmmouse pad”)
 - Frequent use of escape/avoidance behaviors to hide the stuttering
 - Some fear of or avoidance of specific words, speaking situations, or both
 - Feelings of shame and embarrassment are evident, and that individual may begin to have a significant negative self-concept.

DIFFERENTIAL DIAGNOSIS

- All children exhibit some disfluency
- Disfluencies often increase when the child is excited or tired.
- Normally disfluent speech
 - Repetitions are usually brief (typically ≤ 1 second).
 - Repetitions occur infrequently (≤ 1 in 10 syllables).
 - No signs of struggle in speaking
 - Repetitions of a word or phrase are normal and often associated with searching for a word.
- Early stuttering
 - Occurs on initial sound or syllable of an utterance
 - Repetitions are common but produced with more tension and effort.

DIAGNOSTIC APPROACH

- At onset, stuttering is variable and often difficult to diagnose.
 - Many young children are hesitant to talk with unfamiliar people, particularly in a medical setting.
 - Physician may not hear a sample of speech.
 - All speakers are disfluent sometimes, and young children are even more likely to be so.
- Obtaining information about disfluent speech by questioning the parents or caregivers may be necessary.
- Critical clinical questions to ask
 - Which of these children will naturally recover?
 - Which will require intervention services from speech-language pathologists?

TREATMENT APPROACH

- Speech pathologists commonly practice early intervention with young children.
- Many therapy approaches are based on play and use parental participation to facilitate the transfer of treatment effect to the child's daily speaking.

SPECIFIC TREATMENTS

- Parents should be advised to reduce communication time pressure by:
 - Pausing briefly before speaking
 - Avoiding bringing attention to disfluencies
 - Giving the child their full attention
 - Allowing the child plenty of time to say what he or she wants to say
- Physician can assist teenagers who stutter by:
 - Showing an understanding for the difficulties they encounter
 - Urging them not to let the stuttering prevent them from engaging in activities they would otherwise attempt
- The Lidcombe Program (developed in Australia, used in the US and elsewhere) is a highly systematic direct intervention approach.

- Efficacy has been well documented.

WHEN TO REFER

- Mild stuttering: refer to a speech-language pathologist if:
 - The child has stuttered for ≥ 3 months.
 - Stuttering continues after the parents have tried to follow suggestions for patient listening.
- Severe stuttering: refer to a speech-language pathologist as soon as possible.
 - Treatment may last ≥ 1 year.
- The speech-language pathologist should have:
 - A certificate of clinical competence from the American Speech-Language-Hearing Association
 - License by state board of examiners in speech-language abnormalities
 - Experience working with childhood stuttering (preferred)

COMPLICATIONS

- As a child who stutters enters school, stuttering can make reading aloud difficult and interfere with academic performance or learning.
 - Many stuttering children will not ask or answer questions of a teacher.
- Psychosocial impact
 - Teasing
 - Embarrassment (usually increases in adolescence)
 - Teens may avoid speaking or participating in specific speaking and social situations.
 - Adults who formerly stuttered often report feeling embarrassed and guilty about their use of tactics to avoid or conceal the problem.

PROGNOSIS

- 80% experience recovery from stuttering.
- Developmental stuttering
 - When treated appropriately, especially in beginning stages, the prognosis is generally good.
 - The key to success is early identification and intervention.
 - Behaviors seen in advanced stuttering (severe struggling and fear of talking) can usually be prevented.
 - If therapy starts when stuttering consists primarily of easy, effortless repetitions, chances for success are much better than when the stuttering has become complicated by struggle and avoidance behaviors.
 - Even adults who have stuttered for years can learn to decrease severity of stuttering and improve attitudes about speaking.
- Acquired stuttering
 - Prognosis is uncertain because of variability in type of neurologic damage or trauma.

Sudden Infant Death Syndrome

DEFINITION

■ The National Institute of Child Health and Human Development defines sudden infant death syndrome (SIDS) as sudden death of an infant <1 year of age, which remains unexplained after a thorough case investigation, including:

- Performance of a complete autopsy
- Examination of the death scene
- Review of the clinical history

EPIDEMIOLOGY

■ Prevalence

- Leading cause of death of infants between 1 month and 1 year of age in the US

■ Incidence

- Accounts for ~200 deaths per year in the US

■ Racial disparity

- 2.5-fold higher rate in black infants than in white infants in 2001
- This disparity may be partially attributed to the increased prevalence of prone positioning in black infants.

■ Age distribution

- Rare in the first month of life
- Peaks between 2 and 3 months of age
- Decreases thereafter
- ~90% of SIDS deaths occur in the first 6 months of life.

ETIOLOGY

■ The leading hypothesis is that certain infants, for reasons yet unknown, have a maldevelopment or delay in maturation of the brainstem neural network responsible for arousal and the physiologic responses to life-threatening challenges during sleep.

- When the physiologic stability of such infants becomes compromised during sleep, they may not arouse sufficiently to avoid fatal noxious insult or condition.

■ Possible theories

- Rebreathing and associated hypoxia and hypercarbia provide a noxious stimulus.
- Hyperthermia, perhaps in combination with asphyxia, is the stimulus.

RISK FACTORS

■ Prone or side sleep position

- The prone position increases risk for SIDS, particularly if the infant is unaccustomed to it.
 - Secondary caregivers (grandparents, babysitters, child care providers, relatives) are more likely to place infants prone.

- Now that a large number of infants are placed to sleep on their backs, contribution of the side sleep position to SIDS risk has increased.

- The side sleep position is unstable.
- A large proportion of infants placed on the side will roll to prone.

■ Sleeping on a soft surface, such as pillows, quilts, comforters, sheepskins, and porous mattresses

- A strong association has been found between prone sleep position and soft bedding surface, indicating that these 2 factors together are very hazardous.
- Soft surfaces have been implicated in infant deaths occurring on adult beds.

■ Maternal smoking during pregnancy

- Postnatal exposure to tobacco smoke has emerged as a separate risk factor, although separating this variable from maternal smoking prenatally is difficult.

■ Overheating

- Increased risk of SIDS has been associated with increased layers of clothing or blankets on infant and warmer room temperatures.
- The increased risk of overheating is particularly evident when infants sleep prone but is less clear when they sleep supine.
- It is unclear whether overheating is an independent factor or merely a reflection of use of more clothing, quilts, and other potentially asphyxiating materials in the sleeping environment during cold weather.

■ Late or no prenatal care

■ Young maternal age

■ Preterm birth or low birth weight (or both)

- Risk increases with decreasing gestational age or birth weight.
- Increased risk cannot be explained by greater likelihood of apnea of prematurity among preterm SIDS victims while they are in hospital after birth.
- Whether other complications of prematurity can explain increased risk is unclear.
- The association of sleep position and SIDS is the same for infants born preterm as for those born at term.
- Strategies designed to reduce risk in full-term infants should be applied to infants born preterm after they are no longer in an intensive care setting.

■ Male sex

■ Race

- SIDS rates are consistently 2–3 times the national average in African-American and Native American infants.

■ Bed sharing

- Risk of sudden unexpected death with bed sharing seems to be particularly high when:
 - Multiple people share the bed.
 - The infant is <11 weeks of age.
 - Bed sharing occurs on a couch.
 - Bed sharing occurs for the whole night.
- Likelihood of bed sharing may be increased when the bed sharer has consumed alcohol or is overtired.
- Bed sharing is particularly hazardous with mothers who smoke, but bed sharing with nonsmoking mothers is a risk factor among infants <11 weeks.
- Breastfeeding in bed has not been shown to carry a risk if the baby is returned to the crib after feeding.
 - Because breastfeeding has many benefits, parents should be encouraged to bring infant into bed for breastfeeding and for bonding.

- A family in which an infant has previously died of SIDS has a 2–6% risk of a second SIDS death.

DIFFERENTIAL DIAGNOSIS

- Illnesses that should be considered in the differential diagnosis include:

- Sepsis
- Pneumonia
- Myocarditis
- Cardiomyopathy
- Congenital heart defect
- Arrhythmia
- Prolonged QT syndrome
- Trauma (accidental or nonaccidental)
- Suffocation
- Adrenal hypoplasia
- Inherited metabolic disorders, such as fatty acid oxidation disorders

- The large majority of SIDS cases have no evidence suggesting parental psychiatric disease or neglect of the infant.

- The proportion of SIDS deaths attributable to homicide probably is <10%.

- Suffocation, either accidental or nonaccidental, is difficult to distinguish on autopsy from SIDS.

- Since 1999, some deaths that would previously have been classified as SIDS are now being classified as suffocation.

DIAGNOSTIC APPROACH

- SIDS is a diagnosis of exclusion.

- Other conditions must be ruled out by autopsy, death scene investigation, and review of the clinical history.

TREATMENT APPROACH

- SIDS risk reduction has centered on eliminating risk factors that have been shown epidemiologically to be associated with SIDS.

SPECIFIC TREATMENTS

- The AAP has made the following recommendations for SIDS risk reduction.

- Infants should be placed in a supine position for every sleep.
 - Side sleeping is not advised.
- A firm sleep surface should be used.
- Firm crib mattress
- Well-fitted sheet
- Soft materials or objects, such as pillows, quilts, comforters, sheepskins, and stuffed toys, should be kept out of the infant's sleeping environment.
- Loose bedding, such as blankets and sheets, should be avoided.
- Smoking during pregnancy or in the infant's environment is strongly discouraged.
- A separate but proximate sleeping environment is recommended; the infant should sleep in the same room, in a crib or bassinet, next to the parent's bed.

- Offering a pacifier at nap time and bedtime should be considered.

- It does not need to be reinserted once the infant falls asleep and should not be forced if the infant refuses it.
- Introduction of the pacifier should be delayed in breastfeeding infants until 1 month of age to ensure that breastfeeding is fully established.

- Overheating should be avoided.

- Commercial devices marketed to reduce risk of SIDS should be avoided.

- Home monitors should not be used as a strategy to reduce risk of SIDS.

FOLLOW-UP

- Loss of an infant to SIDS is devastating for the family, friends, and health care providers.

- Uncertainty as to how the infant died adds an additional and difficult element to the grief process.

- Physician can play an active role by:

- Ensuring that an autopsy is performed in all cases of sudden unexpected death
- Discussing results of the autopsy with parents
- Providing emotional support to the entire family, including age-appropriate support for surviving siblings

- The family should be directed to local counseling and support groups.

COMPLICATIONS

- With the increased rate of supine sleeping, the incidence of plagiocephaly without synostosis has increased.
 - Infants with plagiocephaly are:
 - More likely not to have had head position altered when put down to sleep
 - More likely to have spent little awake time in the prone position (“tummy time”)
 - Less likely to have been held in the upright position while awake
- Development of positional plagiocephaly can be avoided by:
 - Altering supine head position during sleep
 - Encouraging upright cuddle time
 - Avoiding excessive time in car seats, infant carriers, and bouncers, all of which place pressure on the occiput
 - Encouraging tummy time when the infant is awake and observed
 - Awake tummy time will also enhance upper body motor development.
- A perception exists that sleeping supine may increase the risk of:
 - Gastroesophageal reflux
 - Choking
 - Aspiration

- However, evidence indicates that infants who vomit are at greater risk of choking when they are prone.
- The incidence of aspiration or vomiting has not increased with increased supine sleeping.

PREVENTION

- Sleeping in a non-prone position
 - The rate of prone sleeping decreased from 70% in 1992 to 13% in 2004.
 - The rate of SIDS decreased from 1.2 deaths per 1000 live births to 0.57 deaths per 1000 live births in 2002.
 - Similar decreases in SIDS have been experienced in other countries that have initiated similar educational campaigns.
- Use of pacifiers
 - By a yet unidentified mechanism, pacifiers appear to reduce the risk of SIDS when used at sleep time.
 - 2 recent meta-analyses demonstrate a strong protective effect.
 - Several studies have shown a negative correlation between pacifier use and breastfeeding duration.
 - Early pacifier use may interfere with establishment of good breastfeeding practices.
 - Thus, in breastfed infants, pacifiers should not be offered for the first month of life until breastfeeding has been well established and incidence of SIDS is low.

Syncope

DEFINITION

- Syncope: a transient sudden loss of consciousness and postural tone
- Presyncope: the presence of sensory and postural impairment without actual loss of consciousness

EPIDEMIOLOGY

- Prevalence
 - Syncope affects 3.5% of the general adult population.
 - Almost one-third of these adults will have recurrent syncope.
 - Corresponding numbers for children are not known, but recurrence appears to be less common in childhood.
- Age
 - Both neurocardiogenic syncope and orthostatic hypotension affect adolescents more commonly than adults or children of any other age.
 - Also common from 6 months to 3 years, when breath-holding spells are prevalent
 - Children with the pallid type of breath-holding spell have an increased risk of neurally mediated syncope (NMS) as adults.

MECHANISM

- Two causes account for almost 80% of all cases of benign syncope.
 - Neurocardiogenic (vasovagal) syncope
 - Orthostatic hypotension
- Neurocardiogenic or vasovagal syncope
 - The most common cause of benign syncope
 - Also known as *common faint*, *church faint*, *reflex syncope*, and *NMS*
 - Classified into 3 types
 - Postural syncope
 - The most common type of NMS
 - Associated with the upright position
 - Typically develops while the person is standing or walking
 - Central syncope
 - Occurs in response to strong emotional stimuli, such as pain, anticipated pain, or the sight of blood
 - In susceptible individuals, emotional stimulation activates ill-defined areas in the central nervous system that trigger sympathetic inhibition and parasympathetic activation.
 - Situational syncope
 - Occurs after specific stimulation of sensory or visceral afferents, resulting in hypotension and then syncope
 - Syncope evoked by the hypersensitivity of carotid baroreceptors

- Micturition syncope
- Defecation syncope
- Hair-grooming syncope
- Swallow syncope
- Cough syncope
- Weight-lifter's syncope
 - Much less common in teenagers than in adults

- Orthostatic hypotension is the decrease in blood pressure after assuming the upright position.
 - The autonomic nervous system provides the principal responses to changes in position.
 - If mechanisms that balance cardiac output and cerebral perfusion cannot maintain the blood pressure on standing, then the decrease in the pressure in the carotid sinus leads to reduced afferent traffic in the carotid sinus and thus to an increase in the heart rate.
 - The compensatory increase in heart rate is inadequate in patients with orthostatic hypotension.
 - Symptoms of weakness and light-headedness develop, typically within seconds of standing.
 - Sinus tachycardia of orthostatic hypotension sets this type of syncope apart from NMS, during which bradycardia is a prominent sign.
- The origin of syncope that is not benign can be:
 - Cardiac
 - Structural lesions
 - Dysrhythmias
 - Bradyrhythmias
 - Tachyrhythmias
 - Neurologic
 - Metabolic
 - Psychiatric

HISTORY

- Detailed inquiry into exact circumstances surrounding the event
 - Time of day
 - Presence of upper respiratory infection
 - Time since last meal
 - Posture during syncope and time spent in this posture before syncope
 - Presence of prodromal symptoms
 - Duration of loss of consciousness
 - Consciousness usually is regained quickly in the case of vasovagal syncope (a few seconds to 1 or 2 minutes).
 - A seizure may last longer, and the postictal state may be characterized by prolonged confusion and fatigue.

- Bystander testimony
 - In orthostatic hypotension, symptoms occur within seconds of standing; in NMS, symptoms characteristically appear after being upright for at least a few minutes.
- Any headache or prolonged disorientation after syncope
- Circumstances precipitating the event
 - The prodrome of a seizure may consist of an aura; a cardiac event often occurs without warning or is induced by exercise.
 - NMS is most often brought about by pain or prolonged standing, especially in warm environments.
- Degree of unconsciousness
 - Was the child completely unconscious?
 - Was some degree of responsiveness present, suggesting hysteria or malingering?
 - A truly unconscious person will not respond if the eyelashes are lightly brushed.
 - A hysterical person will respond, albeit often with just a mild flickering of the lids.
 - In NMS of childhood, loss of consciousness typically is preceded by:
 - Light-headedness, nausea, yawning, feeling of being hot, sounds seeming distant
- The presence of seizure-like movements
 - However, generalized tonic-clonic movements may be seen in any form of syncope.
- Significant diseases in the medical history include:
 - Congenital heart disease
 - Seizure disorder
 - Endocrine abnormality, such as diabetes
- Migraine
 - The primary care physician should always ask about migraine when a syncopal episode that does not fit the typical pattern of NMS, particularly if dizziness occurs in the sitting position and no other provoking factors can be elicited.
 - History of flashing lights, severe headache preceding syncope, and family history of migraines usually help clinch the diagnosis of migraine.
- Recurrent syncopal episodes are unusual and may require more extensive testing.
- The family history
 - Seizure disorders and cardiac disease leading to syncope may be inherited in an autosomal-dominant fashion.
 - Marfan syndrome
 - Hypertrophic cardiomyopathy
 - Prolonged QT syndrome
 - Breath-holding spells also can have a familial pattern.
- Occasionally, a cause is not identifiable.

PHYSICAL EXAM

- Level of consciousness
 - A child who is not alert and oriented:
 - Has not had a benign syncopal episode
 - Needs immediate evaluation for potentially life-threatening causes
 - In most children who are fully alert after a syncopal episode, physical examination is normal.
- Heart
 - Cardiac murmur may point to an obstructive lesion, such as aortic or pulmonic stenosis.
 - Listening to the heart in both the supine and upright positions is important.
 - A mild obstructive gradient in hypertrophic cardiomyopathy may become audible only when the patient is upright.
 - Heart rate and blood pressure
 - Obtain in both the supine and upright positions to ascertain the presence of orthostatic intolerance.

DIFFERENTIAL DIAGNOSIS

Behavioral or psychiatric causes

- Breath-holding spells
 - Two types of breath-holding spells typically occur in children between 6 months and 3 years.
 - Cyanotic
 - Cyanosis and apnea are precipitated after a child is upset and begins to cry.
 - Stiffening of the body and loss of consciousness may soon follow.
 - The pathophysiologic basis is unclear, but crying during expiration may cause increased intrathoracic pressure, which leads to low cardiac output.
 - Hypoxia combined with decreased cerebral blood flow leads to loss of consciousness.
 - The event is brief, and afterward, the child becomes fully conscious.
 - Pallid
 - Pallid breath-holding spells (pallid infantile syncope) are less common and usually begin with sudden pain.
 - The child suddenly becomes pale and limp and loses consciousness.
 - The pathophysiologic basis is increased vagal tone causing apparent asystole.
 - Ordinarily lasts only seconds to minutes, and the child awakens to full consciousness
- Hyperventilation
 - Benign
 - Frequent among adolescents, especially in the presence of anxiety

- It results in the washing out of carbon dioxide, and hypocapnia causes reduced cerebral blood flow, dizziness, and syncope.
 - Classically, hyperventilation is associated with numbness and parasthesias of the hands and feet.
- **Psychiatric syncope**
- The child is likely to be unusually calm.
 - No autonomic effects, such as change in heart rate or blood pressure, are noted during episodes.
 - Episodes tend to be recurrent and frequent and to occur in front of an audience.
 - Recovery of consciousness often is prolonged, and usually no injury is sustained.
- **Cardiac causes**
- Syncope can result from low cardiac output secondary to either a dysrhythmia or a structural problem.
- The abnormal rhythm underlying the syncope may be either too slow or too fast.
- **Bradycythmias**
- Sick sinus syndrome is extremely rare in a child with a normal heart.
 - Usually seen after extensive surgery in the atria with the Senning and Mustard operations for transposition of the great arteries
 - Patients who have undergone the Fontan procedure for a single ventricle may be at risk secondary to atriectomies and dilated atria.
 - Atrioventricular (AV) block
 - Very slow heart rates from AV block can lead to syncopal episodes termed *Stokes-Adams attacks*.
 - Congenital AV block in the presence of a structurally normal heart is most commonly associated with a mother who has a history of systemic lupus erythematosus.
 - Structural heart disease most commonly associated with congenital AV block or risk of acquired AV block is corrected transposition of the great arteries.
 - AV block is also occasionally acquired after cardiac surgery or Lyme disease.
- **Tachyrhythmias**
- Supraventricular tachycardia
 - Majority of children with supraventricular tachycardia have a structurally normal heart
 - In those children, palpitations and dizziness are more common symptoms of supraventricular tachycardia than syncope.
 - With a structural abnormality resulting in reduced hemodynamic reserve (eg, a single ventricle), syncope may be a presenting feature.
 - In patients with congenital heart defects, Wolff-Parkinson-White syndrome is seen most often in children with disorders of the AV fibrous valve annuli, such as Ebstein disease and corrected transposition of the great arteries.
- Ventricular tachycardia (VT)
- Rare in children, but can cause sudden death
 - Early identification of underlying conditions that predispose to VT can be life saving.
 - Prolonged QT syndrome
 - Patients are at risk of sudden death secondary to a polymorphic VT termed *torsades de pointes*.
 - Prolongation of the QT interval may be part of a congenital syndrome.
 - Two syndromes that result in prolonged QT interval are caused by mutations in genes encoding cardiac ion channels
 - Romano-Ward syndrome: autosomal dominant
 - Jervell and Lange-Nielsen syndrome: autosomal recessive, associated with congenital neural deafness
 - May be caused by an electrolyte imbalance, such as
 - Hypokalemia
 - Hypocalcemia
 - May be caused by a variety of drugs, including:
 - Tricyclic antidepressants
 - Certain macrolide antibiotics
 - Antiarrhythmic medications
 - VT also can occur in children as a complication of myocarditis or in adolescents with Tetralogy of Fallot who have undergone surgical repair in infancy.
- **Pacemaker malfunction**
- Syncope in a child with a pacemaker should prompt immediate interrogation of the device for either a malfunction or inappropriate programming.
- **Structural heart disease**
- Acute reduction in cardiac output can result in reduced cerebral perfusion and syncope.
 - With certain heart conditions, patients may be able to maintain adequate cardiac output at rest but experience syncopal episodes with exercise.
 - Aortic stenosis
 - Mechanisms that may contribute to syncope in children with severe aortic stenosis include:
 - Impediment to the forward flow of blood from marked left ventricular hypertrophy
 - Stimulation of the ventricular mechanoreceptors, resulting in systemic vasodilatation
 - Subendocardial ischemia causing a ventricular arrhythmia

- Hypertrophic cardiomyopathy
 - Syncope with exercise may be an important presenting sign.
 - Most affected patients have no left ventricular obstruction at rest.
 - With exercise, they can develop a dynamic gradient with an acute reduction in cardiac output.
 - These patients also may develop VT from subendocardial ischemia.
 - The electrocardiogram often is abnormal.
 - The echocardiogram is diagnostic.
- Tetralogy of Fallot
 - Children with unrepaired tetralogy of Fallot may have syncopal episodes in association with hypercyanotic tet spells.
 - Syncope is often precipitated by crying, straining with a bowel movement, or awakening from sleep.
- Pulmonary hypertension
 - With exertion, children with pulmonary hypertension may experience syncope from an inability to maintain transpulmonary flow.
- Marfan syndrome
- Coronary artery abnormalities
 - A patient with syncope who is demonstrated to have a coronary artery aberrant either in its origin or course should be presumed at risk for sudden death.
 - Typically, syncope occurs with exercise.
 - Acquired abnormalities of the coronary arteries include:
 - Coronary artery aneurysms
 - Stenosis caused by Kawasaki disease in early childhood.
 - Cocaine
 - Can cause acute coronary vasoconstriction and ventricular arrhythmias, with consequent syncope

Postural orthostasis tachycardia syndrome

- Diagnosis requires either
 - Orthostatic heart rate acceleration >120 bpm
 - Absolute increase ≥ 30 bpm in the absence of significant orthostatic hypotension
- Two forms have been identified, both more common in young women.
 - Peripheral variety (more common)
 - Persistent tachycardia, associated with fatigue, exercise intolerance, and palpitations, is present while the patient is upright.
 - Onset may occur after a viral illness, trauma, or surgery.
 - β -Hypersensitivity (or central) form
 - Often associated with migraines, tremor, and excessive sweating

Neurologic causes

- Seizures
 - Typically, generalized seizures are preceded by a prodrome that includes tonic-clonic activity with loss of consciousness and a period of confusion and lethargy after recovery.
 - Atypical seizures can be difficult to differentiate from the benign forms of syncope.
 - Loss of consciousness in the recumbent position is more likely to occur from seizure, especially if the heart is normal.
 - Pallor is seen more often in benign syncope, and flushing is more common with seizures.
 - Bowel incontinence points toward a seizure disorder.
- Migraine
 - Migraine should be considered in a child who has a syncopal episode that does not fit the pattern of typical NMS.
 - A history of flashing lights, severe headache preceding the episode of syncope, and a family history of migraines usually help clinch the diagnosis.
- Head trauma
 - Brief loss of consciousness with head trauma is not uncommon and is termed *concussion*.
- Narcolepsy

Metabolic causes

- Hypoglycemia can cause syncope, most commonly in a child who has diabetes and is on medication.
 - Presyncopal symptoms may be present: weakness, hunger, confusion
 - This syncope typically is not brief.
- Dehydration
- Severe anemia
- Pregnancy should always be considered when a woman of childbearing age faints.
 - Pregnancy-associated fainting results from increased estrogen and progesterone levels that cause decreased peripheral vascular resistance and hypotension.

Drug-induced syncope

- Diuretics
- Vasodilators

LABORATORY EVALUATION

- The complete blood count should be checked if anemia is suspected as the cause for syncope.
- Serum glucose should be checked if hypoglycemia is considered to be a cause of syncope.

IMAGING

■ Echocardiography

- When suspicion exists based either on history (eg, syncope with exercise) or on examination of a structural cardiac lesion
- Usually can demonstrate the origin and course of the coronary arteries adequately

DIAGNOSTIC PROCEDURES

■ Electrocardiography

- The only test indicated in most patients with a history typical of benign syncope
- May reveal the presence of AV block or dysrhythmia
- Abnormally large left ventricular forces, especially with left ventricular strain, may be the only evidence of hypertrophic cardiomyopathy in a patient with normal findings on physical examination.
- Corrected QT interval should be measured in all children with syncope or seizures to ensure that prolonged QT syndrome is not missed.

■ Monitors

- Holter monitor
 - 24-hour electrocardiographic monitoring test
 - Used if a cardiac dysrhythmia is strongly suspected because of:
 - Prominent palpitations that occurred before the episode
 - History of cardiac surgery that may predispose a child to abnormal rhythms
- Event monitor
 - Patients can keep the monitor for 1 month and use it when symptoms are occurring.

■ Electrophysiologic testing and cardiac catheterization

- Must be considered for any patient who has had syncope during active exercise and no abnormality on physical examination, electrocardiogram, and echocardiogram.

■ Tilt-table testing

- Creates an orthostatic stress
- Can provoke symptoms in patients with NMS and orthostatic hypotension
- A means of provoking vasodepressor syncope in susceptible individuals after other more serious causes have been ruled out
- Procedure
 - The patient is placed supine on a table that has a footboard.
 - The table is then tilted up 60–80 degrees for 30–60 minutes.
 - Patients are monitored closely for a syncopal episode.

- Sensitivity and specificity
 - Sensitivity ranges from 30–80%, depending on the laboratory.
 - Some centers use low-dose intravenous isoproterenol infusions to increase sensitivity.
 - The specificity of a negative test without isoproterenol ranges from 80–100%.
- The utility of head-upright tilt-table testing in children is still controversial.
- Indications for the use of this test include:
 - ≥ 3 syncopal episodes during a 12-month period with no evidence of heart disease
 - Syncope during exertion in which heart disease has been ruled out after an exhaustive workup
 - Recurrent syncopal episodes thought to be hysterical in nature

TREATMENT APPROACH

- The management of cardiac, neurologic, metabolic, and behavioral/psychiatric syncope depends on the cause.
- For most patients with NMS or orthostatic hypotension:
 - Reassurance
 - Education regarding the cause of the syncope and how to avoid aggravating factors, such as extreme heat or standing still for long periods
 - Patients should be instructed to sit down or lie down at the onset of any prodromal symptoms to avoid injury.

SPECIFIC TREATMENT

Isometric exercises

- In a small randomized trial of adults, intense gripping of hands and tensing of the arms for 2 minutes at the onset of tilt-induced symptoms increased systolic blood pressure.
 - Syncope occurred in 37% of these patients, compared with 89% in those who did not perform the maneuver.
- “Tilt training”
 - Controversial, but may be helpful to some patients
 - Patients are instructed to stand with their backs against a wall, initially for short periods, and slowly increasing the duration to approximately 30 minutes per day.

Volume expansion

- A reduced frequency of syncope in adolescents with neurocardiogenic syncope was reported after they drank 2 liters of water in the morning.
- Fludrocortisone is a synthetic mineralocorticoid that causes salt retention and expansion of the central blood volume.
 - One randomized trial in adolescents showed similar results to atenolol, but no placebo was studied.

β-Blockers

- Have been used for many years as therapy for neurocardiogenic syncope
- Studies of their effectiveness have been at best equivocal.

Investigational agents

- Mitodrine
 - A direct α_1 -receptor agonist that has been shown to reduce episodes in adults with severely symptomatic neurocardiogenic syncope
- Selective serotonin reuptake inhibitors
 - Serotonin may have a role in regulating the sympathetic nervous system activity.
 - Selective serotonin reuptake inhibitors have been considered for treatment of NMS.
- Paroxetine
 - In a trial in adults, has been shown to be superior to placebo
- Cardiac pacing
 - Currently has a very limited role in the management of syncope
 - Has been used for children in whom asystole is the prominent symptom in recurrent syncope caused by vagal hypertonia, including some patients with deglutition syncope

WHEN TO REFER

- Patient history of cardiac disease
- Family history of sudden death, cardiac disease, or deafness
- Recurrent episodes
- Recumbent episode
- Exertional syncope
- Prolonged loss of consciousness
- Associated chest pain or palpitations
- On medications that can alter cardiac conduction

FOLLOW-UP

- All patients with syncope need a close follow-up to monitor the frequency of syncopal episodes and also to monitor the response to therapy.

COMPLICATIONS

- Injury due to fall

PREVENTION

- Prognosis for syncope depends on its cause.

Tics

DEFINITION

- Tics are recurring, nonrhythmic, sudden, rapid, stereotyped, involuntary movements or vocalizations.
- Tics may be classified as motor or vocal and as simple or complex.
 - The most common *simple motor tics* are:
 - Eye blinking
 - Neck twisting
 - Shoulder shrugging
 - Grimacing
 - The most common *simple vocal tics* are:
 - Coughing
 - Throat clearing
 - Sniffing
 - Grunting
 - *Complex motor tics* include more sustained, orchestrated, or seemingly purposeful gestures.
 - Touching, stomping on, or sniffing objects
 - Jumping
 - Sustained dystonic movements
 - Copropraxia (obscene gestures)
 - Echokinesis (automatic imitation of another person's movements)
 - *Complex vocal tics* include:
 - Sudden changes in volume or prosody
 - Syllables, words, or stock phrases spoken out of context
 - Palilalia (repeating one's own words)
 - Echolalia (repeating the words of others)
 - Coprolalia (uttering obscenities)

EPIDEMIOLOGY

- Tic disorders exist on a clinical spectrum ranging from:
 - Transient, isolated, inconsequential tics to
 - More persistent multiple motor and vocal tics that interfere with daily functioning
- Isolated and transitory tics are common.
 - Occur in as many as 24% of first- and second-graders
- The childhood prevalence of Tourette syndrome (TS) is thought to be 2 to 185 per 10,000 persons.
 - Much higher than previously believed
 - Many milder, uncomplicated cases do not come to clinical attention.
 - Boys are affected more than girls by TS.
 - A ratio as high as 9:1 to 14:1
- The most common age at onset for tics is 6 or 7 years.

MECHANISM

- Tics are a neurobiological disorder.
 - They are not caused, but only worsened, by psychological factors.
- The cause of tics is unknown.
 - Areas of research include:
 - Basal ganglia
 - Cortico-striatal-thalmo-cortical circuitry
 - Genetics
 - Immunology
 - Current research is considering a multifactorial cause for TS.
 - Genetic vulnerability
 - Environmental and perinatal risk factors
 - Disturbances in the prefrontal cortex and basal ganglia
- Developmental basis
 - Tics are common in middle childhood.
 - Usually begin to disappear by early adolescence, pointing to maturation in the neuromuscular apparatus
- Sex
 - Boys are more affected than girls.
 - This supports the motor developmental view.
 - Boys are more active in terms of motor movement than girls at all ages, especially in middle childhood.
 - Androgens are implicated for the following reasons.
 - Postnatal exposure to androgens may elicit TS.
 - Antiandrogen therapy may improve tics.
 - Androgen-dependent alterations in prenatal brain development may be associated with TS.

HISTORY

- Obtain history on potential prenatal and perinatal risk factors.
 - Maternal smoking
 - Vomiting and stress during pregnancy
 - Drugs
 - Fetal nutrition
 - Low birth weight
 - Exposure to androgens

PHYSICAL EXAM

- Assess tics, considering how to distinguish them from other neurologic disorders.
 - Evaluate for:
 - Stereotyped nature
 - Variability over time
 - Transient suppressibility
 - Accompanying premonitory urges
 - Lack of other neurologic symptoms

- The usual initial motor tics are blinking or facial grimacing, followed by rostral-caudal involvement.
 - The most common initial vocal tics are:
 - Sniffing
 - Coughing
 - Throat clearing
 - Symptoms are often initially mistaken for allergies or otolaryngologic or respiratory symptoms.
 - With tics, other characteristics of such disorders are absent.
 - Tics wax and wane in intensity and frequency.
 - One tic disappears, and a new one takes its place.
 - Stress or excitement often exacerbates tics.
 - Children are generally unaware of their tics.
 - Premonitory urges are often reported in more severe cases or in older children.
 - Tics are often transiently suppressible with effort.
 - This usually results in an increased urge to perform the tic.
 - Many patients describe their tics as neither fully voluntary nor involuntary.
 - Some consider the effort to suppress tics in social situations as burdensome as the tic.
- ### DIFFERENTIAL DIAGNOSIS
- Anxiety, stress, and excitement make existing tics worse and may even precipitate them.
 - Children with anxiety disorders are overrepresented in clinical samples.
 - Little is known about the psychological status of most children in the general population who have tics because they are rarely seen in clinics.
 - However, evidence exists for increased autonomic lability in individuals with TS.
 - Psychiatric disorders should be distinguished from psychological or stress factors because of severity.
 - Studies point to a relationship between tics and:
 - Attention-deficit/hyperactivity disorder (ADHD)
 - Obsessive-compulsive disorder (OCD) with symptoms
 - Premonitory urges
 - Intrusive thoughts
 - Compulsive actions
 - Many cases of tics are genetic in origin.
 - Drugs that may produce or exacerbate tics include:
 - Amphetamines and other dopaminergic drugs
 - Cocaine and other stimulants
 - Sympathomimetics
 - Caffeine
 - Serotonin uptake inhibitors and other antidepressants
 - Anabolic steroids
 - Neuroleptics
 - Distinguish tics from chorea.
 - Centripetal location
 - Repetitive form
 - Normal muscle tone
 - Lack of postural imperistence
 - Distinguish true tics from stereotypies or self-stimulating behaviors, such as rocking, head banging, flapping, or spinning.
 - Tics are characterized by:
 - Later onset
 - Lower complexity
 - Fluctuating intensity and locus
 - Intrusive, bothersome, disruptive, and involuntary nature
 - In contrast, stereotypies are bothersome to parents but not to the child.
 - The child finds them pleasurable and resists adult attempts to interrupt them.
 - Self-stimulating movements
 - Mostly occur at times of boredom or excitement
 - Rarely disrupt coordinated movements
 - Persist without much change in form or location
 - The *Diagnostic and Statistical Manual of Mental Disorder*, fourth edition, distinguishes 4 arbitrary subtypes of tic disorder.
 - Transient
 - Duration >4 weeks but <1 year
 - Chronic
 - ≥1 year
 - Tourette disorder (also known as TS)
 - ≥1 year in duration with any remission, lasting <3 months
 - Tic disorder not otherwise specified
 - Minimum duration of 4 weeks *or*
 - Frequency of many times a day *and*
 - Present most every day
 - Whether these 4 classifications reflect varying severity of the same disorder is unknown.
 - Most recent research has been restricted to TS and suggests that these subtypes are probably related.
- ### TREATMENT APPROACH
- Most tics in children are mild and short lived and do not require treatment.

- The possible role of any medications the child is receiving should be considered because their removal or reduction may be the required treatment.
 - Stimulants
 - Sympathomimetics
 - Selective serotonin uptake inhibitors (SSRIs) and other antidepressants
 - Neuroleptics
 - Androgenic steroids
 - Any drug that interferes with dopamine
- Once a tic has persisted for several months, treatment may be considered, if the tic is:
 - Conspicuous
 - Disabling
 - Distressing to the child
- No treatment for tics can be said to be simple, entirely effective, or free of side effects.
- Pharmacotherapy
 - Only physicians thoroughly familiar and experienced with the drugs indicated in children with tics should undertake pharmacotherapy.
 - The first consideration is deciding which symptom to target.
 - Tics
 - Comorbid conditions, such as OCD or ADHD, are often a greater source of impairment.
 - Because of frequent side effects (especially sedation), medication should be administered only when the tics are seriously disruptive, stigmatizing, or painful.
 - Start with a low dose.
 - Titrate the dose upward gradually.
 - Avoid sedation and cognitive blunting.
 - Set realistic goals in terms of reducing tics to tolerable levels.
 - Attempts to suppress tics completely often result in overmedication.
 - Discontinuing anti-tic medications should be done gradually.
 - Abrupt discontinuation may produce bothersome acute rebound or withdrawal-related exacerbation of tics that may persist for several weeks.

SPECIFIC TREATMENT

Behavioral interventions

- A variety of behavioral techniques (eg, relaxation, massed practice, avoidance learning) have been tried for tic disorders.
- Habit-reversal therapy has empirical support.
 - It is best carried out by a psychologist who is experienced in the technique and used to working with children.

- Anxiety reducing and supportive interventions
 - Relaxation training and biofeedback are not of proven value in treating tics.
 - Psychotherapy (specifically focused on stressful interpersonal difficulties), work with parents, and other means of addressing environmental stresses may be helpful.
 - Stress and high expressed emotion can exacerbate tics.
 - These procedures should not be considered specific; they are ancillary and holistic in meeting therapeutic objectives.
- Acceptance interventions
 - Explain to parents, teachers, and peers that the tics are a physical disability and the child cannot help them.
 - Acceptance of both the child and tics is the kindest, safest, and simplest way to deal with them.
 - Criticizing and belittling the child are likely to make tics worse and prolong their course.
 - Peer problems can be a major difficulty for children with tics and TS.
 - Collaboration with school staff to reduce peer teasing and stigmatization is a major therapeutic task.

Pharmacotherapy for tics

- Various medications are effective in partially suppressing tics but are not curative.
- First choice: α -adrenergic agonists
 - Clonidine
 - Guanfacine
 - Preferred first-choice agents because they are longer acting, less sedating, and more effective for attentional problems
 - These agents are relatively benign; their principal dose-related side effects are sedation and hypotension.
- Next line of agents: dopamine-blocking neuroleptics (antipsychotic drugs)
 - They appear to be effective because tics are executed through the basal ganglia.
 - There is apparent relative overactivity in the dopaminergic nigrostriatal systems that inhibits cholinergic basal ganglia systems.
 - Haloperidol, pimozide, or fluphenazine are preferred.
 - Even at relatively low doses, neuroleptics may produce:
 - Acute dystonic reactions
 - Sedation
 - Cognitive blunting
 - Medication-induced separation anxiety
 - Parkinsonism
 - Akathisia (restless legs)
 - If moderate doses are not effective, then higher doses, which increase the risk of side effects, are not likely to be either.

- Higher doses make weaning the patient from the drug difficult without rebound exacerbation.
- In many patients, typical antipsychotics are now being replaced by atypical antipsychotics, such as:
 - Risperidone, olanzapine, and ziprasidone
 - However, atypical neuroleptics have the same other adverse effects as typical neuroleptics.
 - Acute dystonic or extrapyramidal reactions
 - Hyperphagia and weight gain, with potentially serious metabolic consequences (risperidone and olanzapine)
- When neither a-adrenergic agents nor neuroleptics are effective, a variety of second-line drugs or augmentation strategies may be tried with caution.
 - Clonazepam should only be used in unusual instances.
 - Side effects: cognitive blunting, sedation, irritability, disinhibition
 - Can lead to dependence and withdrawal symptoms

Pharmacotherapy for comorbid conditions

- These conditions include ADHD, OCD, anxiety, or depression.
- Stimulants may increase tics or precipitate new tics.
- ADHD is often more disabling than the child's tics.
 - A cautious trial of a stimulant may be necessary, beginning with very low doses and increasing gradually.
 - Alternatives to the stimulants are:
 - α -Adrenergic agents (clonidine or guanfacine)
 - Atomoxetine (may also increase tics)
 - Second-line drugs are older tricyclic antidepressants.
 - Initiate electrocardiographic monitoring.
 - Most children with tics and ADHD can tolerate methylphenidate.
 - The combination of methylphenidate and clonidine is better than either agent alone.
- SSRIs are effective in children with OCD and tics.
 - Evidence suggests that monotherapy with SSRIs is less effective in the presence of tics.
 - Augmentation with a low dose of a neuroleptic often boosts the treatment response.
 - In rare cases, SSRIs can exacerbate or even precipitate tics, akathisia, or other movement abnormalities, or can increase suicidal thinking.

WHEN TO REFER

- Criteria for referring children who have tics to a mental health specialist
 - Presence of tics associated with additional evidence of a psychiatric disorder, such as ADHD, generalized anxiety, or OCD

- Presence of chronic or recurrent tics that seem to have a clear relationship to stress, particularly if there is reason to believe that psychosocial interventions may be helpful
- Presence of chronic, disabling, or discomforting tics for which differential diagnosis or treatment is needed
- When the primary physician knows little about tics and wants an expert opinion
- When psychoactive drugs, such as antipsychotics (neuroleptics) or clonidine, may be indicated
 - Psychiatrists routinely use these medications and are well informed about risks, side effects, dose levels, and newer drugs.
- Referral may be only for consultation, not necessarily for continued management.
- The preferred mental health specialist is a well-trained child or adolescent psychiatrist.
 - Broad biopsychosocial perspective
 - Knowledge of neuropsychiatry and pharmacotherapy
 - Capacity to work closely with behavioral psychologists
 - The child psychiatrist should also be alert to the possibilities of rare neurologically induced tics.
 - Will order any appropriate neuroimaging studies and neurologic consultations
- Referral should be made to a child psychologist experienced in behavioral types of treatment when:
 - The tic is disabling and no further diagnostic workup is required
 - Pharmacotherapy is not an option or is already in place, but further relief is necessary

WHEN TO ADMIT

- Never in the first instance (for tics alone)
- Occasionally, for complex assessments to initiate treatments or to taper a child from high doses of multiple medications

COMPLICATIONS

- Children with tics and especially TS can experience related problems of self-image when adult criticism and peer rejection result.
- Persistent tics are associated with an increased risk of comorbid ADHD.
 - Predates the tics or any accompanying OCD
 - Children with combined ADHD and tics have the greatest social and academic difficulties.
 - ADHD severity is a better predictor of poor adjustment than tic severity.
 - Chronic tics are often associated with learning impairment independent of ADHD.

- Individuals with TS are also at risk for:
 - Other anxiety disorders
 - Depression
 - Fine-motor difficulties
 - Uneven cognitive profile
 - Performance IQ scores are lower than verbal IQ scores.
 - ADHD is common and is seen in 50% of patients with TS.
 - OCD is found in up to 50% of patients with TS.
 - Most common compulsions and obsessions are around:
 - Symmetry
 - Evening up
 - Sex
 - Aggression
- OCD may develop during adolescence or late in TS.
- OCD can be a persistent source of distress despite the improvement in tic severity with age.
- Occasionally, severe complex motor tics result in injury or self-mutilation.

PROGNOSIS

- Most tics last only a few weeks.
 - Tics may flit from one muscle group to another.
 - Tics change their form at irregular intervals.
- Even the chronic tics of TS are likely to disappear in later adolescence.
 - Tic severity peaks at age 10 to 12 years.
 - Although most tics improve by late adolescence, OCD or ADHD symptoms may persist.
- Prevalence of tics drops sharply after age 13 years.
 - Tics that persist into later adolescence are more likely to become chronic.
- Tic severity in adulthood is inversely proportional to:
 - Caudate volume in childhood.
 - Childhood performance on a dominant hand fine-motor skill test

BACKGROUND

- Tonsillectomy is surgical removal of the tonsils.
- Adenoidectomy is surgical removal of the adenoids.
- Tonsillectomy and adenoidectomy are 2 of the most common surgical procedures performed on children worldwide.
- A consensus is just beginning to emerge regarding the proper indications for these procedures.
- Obstructive sleep apnea syndrome (OSAS)
 - Prolonged partial upper airway obstruction and/or intermittent complete obstruction (obstructive apnea) disrupts normal ventilation and sleep patterns.
 - Poor-quality sleep leads to:
 - Emotional problems
 - Increased school difficulties, including deficits in memory, vocabulary, and learning
 - Severe and untreated airway obstruction may contribute to:
 - Growth failure
 - Development of cor pulmonale
 - Enlargement of adenoids and tonsils is a common cause of OSAS.
 - OSAS can also be found in children with:
 - Obesity
 - Genetic syndromes
 - Neuromuscular disorders
 - Abnormalities of the oropharynx
 - Signs include:
 - Nighttime snoring
 - Respiratory pauses
 - Snorts
 - Gasps
 - ~10% of the population has benign primary snoring; only ~2% of children have true obstructive sleep apnea.
 - Additional diagnostic testing is needed in the habitually snoring child before proceeding with surgical intervention.
- Tonsillitis
 - Many children with recurrent tonsillitis are referred for tonsillectomy.
 - The criteria for recommending surgery are controversial.
 - The Cochrane Database of Systematic Reviews states:
 - Effectiveness of tonsillectomy has not been formally evaluated.
 - Further trials addressing relevant outcome measures are required.
 - The American Academy of Otolaryngology supports surgery in patients with ≥ 3 infections of tonsils or adenoids per year.

- Pittsburgh criteria: selection of patients with recurrent tonsillitis for tonsillectomy with or without adenoidectomy (document ≥ 1 of the following):
 - Tonsillar exudate
 - Positive cultures
 - Tender cervical lymphadenopathy (>2 cm)
 - Temperature $>38.3^{\circ}\text{C}$ (101°F)
 - *Plus* antibiotics for proven or possible streptococcal infection

GOALS

- Elimination of OSAS
 - Almost all patients with OSAS will have clinical resolution of symptoms and normalization of polysomnography after adenotonsillectomy.
 - Patients with the following conditions are less likely to have complete resolution of sleep abnormalities after an adenotonsillectomy and warrant restudy postoperatively.
 - Obesity
 - Neuromuscular weakness
 - Craniofacial anomalies
 - Severe OSAS
 - Some patients have significant improvement after adenotonsillectomy despite negative polysomnograms.
 - May respond to treatment with montelukast or nasal steroids
 - More controlled trials are needed to delineate adequate criteria for recommending surgery in patients with negative polysomnograms.
- Reduction of throat infections and elimination of tonsillitis
 - However, most experts recommend surgery only for patients with recurrent pharyngitis who meet stringent Pittsburgh criteria because of costs and complications of surgery.
 - In 1 study, children who had tonsillectomy consistently had fewer throat infections, particularly in episodes rated moderate or severe.
 - Despite better outcomes in the surgical group, rates of infection in the control group in subsequent years were relatively low, favoring observation over surgical intervention.
 - A complication rate of 14% occurred in the surgical group: all were self-limited and readily managed.
 - More recent research analyzed the adenotonsillectomy for patients with less severe criteria.
 - Differences between the surgical group and controls were statistically but not clinically significant.
 - Moderate inclusion criteria did not justify the risks of surgery, including morbidity (7.9% complication rate) and cost.

- In another study in which a wait-and-see approach was proposed for patients who do not meet stringent Pittsburgh criteria:
 - 4% complication rate
 - 1% required surgery for hemorrhage.
 - 2.6% had severe nausea or dehydration.
 - Did not justify minimal reductions in the frequency of tonsillitis
 - Adenoidectomy
 - Adenoidectomy (but not tonsillectomy) appears to be effective in decreasing the rate of pressure-equalization tube reinsertion.
 - Has a limited role in treatment of chronic otitis media with effusion for children >4 years, particularly with those with:
 - Nasal obstruction
 - Recurrent sinusitis
 - Chronic sinusitis
 - Does not reduce the incidence of recurrent acute otitis media when performed in conjunction with insertion of pressure-equalization tubes for children <4 years.
 - Improved quality of life
 - Polysomnography and parental questionnaires show significant resolution of the following symptoms after adenotonsillectomy.
 - Sleep disturbance
 - Growth
 - Breathing problems
 - Emotional problems
 - Hyperactivity
 - Aggression
 - Swallowing disorders
 - Speech problems
 - Parental anxiety or concerns
 - Activity limitations
 - Somatization behaviors
- GENERAL APPROACH**
- Clear indications for tonsillectomy; these conditions are uncommon:
 - Recurrent peritonsillar abscess
 - Infectious mononucleosis with immunodeficiency
 - Cancer: suspect in cases of
 - Lymphadenopathy >3 cm
 - Splenomegaly with asymmetric tonsillar hypertrophy
 - Hemorrhagic tonsillitis
 - Indications for adenoidectomy are not well studied.
 - Chronic otitis media with effusion if pressure-equalization tubes have to be reinserted
 - Significant nasal obstruction
 - Recurrent sinusitis
 - Chronic adenoiditis
 - Speech or orthognathic issues
 - Referring all children who have snoring as the only symptom of OSAS for further testing is impractical.
 - ~40% of children with a combination of snoring and other symptoms (mouth breathing, adenoid facies, hyponasal speech, tonsillar enlargement) have OSAS and should be referred for further testing.
 - High-risk patients are those with:
 - Cardiac disease
 - Peritonsillar abscess
 - Craniofacial anomalies
 - Trisomy 21 syndrome
 - Cerebral palsy
 - Neuromuscular disease
 - Chronic lung disease
 - Sickle cell disease
 - Central hypoventilation syndromes
 - Genetic, metabolic, or storage diseases
 - Strong consideration of further testing is recommended in snoring children who are struggling academically or being evaluated for hyperactivity.
 - The gold-standard test used to diagnose OSAS accurately is the nocturnal polysomnogram.
 - Polysomnography is useful to identify those at risk for adverse outcomes who require surgery, those for whom surgery is unnecessary, and those at risk from complications.
 - Overnight pulse oximetry, unsupervised home study, and nap studies are diagnostic but not sensitive enough to rule out OSAS.
 - Thus, when these test results are negative, the patient should be referred for polysomnography.
 - If positive, the patient should be referred for surgery.
 - Nonsurgical treatment options for OSAS
 - Continuous positive airway pressure
 - Weight loss if patient is obese
 - Referral to sleep specialist
 - Contraindications for tonsillectomy and adenoidectomy include:
 - Cleft palate or submucous cleft palate
 - Risk for velopharyngeal insufficiency
 - Evaluate for the presence of a bifid uvula or a notched hard palate as clues to making this diagnosis preoperatively.
 - Severe bleeding disorders should be given special consideration.

SPECIFIC INTERVENTIONS

Tonsillectomy and adenoidectomy

- Techniques for adenoidectomy
 - Blunt curettage with a ring curette
 - Vaporization using an electrocautery device
- Various techniques for tonsillectomy have evolved over the last several years.
 - Objectives
 - A surgical approach that can be performed with fewer complications in an ambulatory surgery setting
 - Less postoperative pain
- Dissection and snare tonsillectomy
 - Traditional technique
 - Blunt dissection of the tonsillar capsule from the adherent pharyngeal constrictor muscle
 - From the superior to the inferior pole of the tonsil
 - Causes stretching and avulsion of the small tonsillar arteries, leading to arterial spasm and subsequent hemostasis
 - Proven to be safe, but abandoned because of the relatively large amount of intraoperative blood loss
- Electrocautery
 - Currently the most common technique for tonsillectomy
 - Dissection is conducted in a manner similar to the dissection and snare technique.
 - Minimal additional safety precautions are required.
 - Equipment is relatively inexpensive and widely available.
 - Technique is safe and rapid, with little or no blood loss.
 - Disadvantages
 - Increased postoperative pain from thermal injury to underlying constrictor muscle
 - Delayed return to normal diet
- Surgical lasers
 - Used in tonsillectomy for the past 2 decades
 - The oropharynx and tonsils are easily accessible with laser handpieces used in either:
 - Illumination mode (thermocoagulation)
 - Contact mode (vaporization)
 - Advantages include:
 - Less superior pharyngeal constrictor muscle injury
 - Better hemostasis
 - Less pain than with the more popular electrocautery technique
 - Disadvantage
 - Requires special and extensive precautions to avoid injury to the patient or operating room staff by reflected or misdirected laser light

- Extracapsular tonsillectomy
 - Uses traditional or powered instrumentation (frequently a microdebrider) to remove 90–95% of the tonsil tissue medial to the tonsillar capsule
 - Decreased injury to the pharyngeal constrictor muscle yielding decreased postoperative pain
- Harmonic scalpel tonsillectomy
 - Uses ultrasonography to disrupt and coagulate tissues
 - Operates at a lower temperature than laser or electrocautery
- Radiofrequency tonsillectomy
 - Radiofrequency energy is applied directly to tissues to generate heat and vaporize tonsillar tissue
 - Compared with electrocautery or dissection tonsillectomy
 - Less postoperative pain
 - Faster return to normal diet

COMPLICATIONS

- Life-threatening situations are rare (see table Posttonsillectomy and Adenoidectomy Complications) and generally result from catastrophic hemorrhagic and respiratory complications.
- Mortality rates after tonsillectomy are difficult to estimate because death is such a rare outcome.
 - Death usually results from aspiration of blood into the lungs, not from exsanguination.
 - If the patient can be intubated and the airway protected during an acute and catastrophic bleeding event, risk of mortality is decreased.
 - Recent improvements in outcomes are probably attributed to advances in anesthesia, monitoring equipment, medications, and preparation for hemorrhagic consequences.
- Patients at high risk for postoperative complications who require special attention to maintaining airway include:
 - Infants
 - Those with:
 - Craniofacial disorders
 - Trisomy 21 syndrome
 - Cerebral palsy
 - Neuromuscular disorders
 - Chronic lung disease
 - Sickle cell disease
 - Central hypoventilation syndromes
 - Obesity
 - Genetic or metabolic storage diseases

Posttonsillectomy and Adenoidectomy Complications

Complication	Onset	Presentation	Treatment
Immediate hemorrhage	<24 hr	Oral bleeding Hemoptysis Hematemesis	Exploration and ligation of blood vessel
Delayed hemorrhage	5–14 days	Oral bleeding Hemoptysis Hematemesis	Ice pack to neck and iced liquids Elevation of head and neck AgNO ₃ cautery Blood vessel ligation Coagulopathy workup
Immediate airway compromise	Extubation—2 hr	Cyanosis Stridor	Rule out pulmonary edema Rule out aspiration Rule out laryngospasm
Delayed airway compromise	2–24 hr	Shortness of breath Stridor	Intravenous or oral steroid Nasopharyngeal airway
Dehydration	1–6 days	Lethargy Tachycardia Anuria	Intravenous rehydration Pain control Parent education

Abbreviation: AgNO₃, silver nitrate.

Torticollis

DEFINITION

- The word *torticollis* originates from 2 Latin words: *tortus*, which means *twisted*, and *collum*, meaning *neck*.
- The classic clinical picture of torticollis is of the head tilted to one side and rotated in such a way that the chin and face point to the contralateral side.
- Torticollis can be broadly classified as 1 of 2 types.
 - Congenital
 - Acquired
- Facial asymmetry is often observed in congenital torticollis but not in acquired torticollis.
 - This finding can be useful in clinically distinguishing between the 2 forms.

MECHANISM

Congenital torticollis

- Muscular torticollis is the most common form of congenital torticollis.
- Occurs clinically in the first 8 weeks of life
 - Not obvious at birth, but begins to become apparent at approximately 2 weeks of age
- Several theories have been proposed to explain the cause of this disorder.
 - Difficult delivery may result in stretching of the neck, with rupture and hemorrhage within the sternocleidomastoid muscle (SCM).
 - Subsequent muscle ischemia results from increased pressure from blood trapped within the fascial compartment, producing progressive muscle fibrosis and contracture, with eventual clinical torticollis.
 - This theory is supported by the fact that approximately 40% of patients with congenital torticollis have had a difficult birth, including forceps delivery and breech presentation.
 - Against the theory are the facts that:
 - Congenital torticollis has also been reported in children after uncomplicated births.
 - Specimens of SCM in patients with torticollis sometimes show no evidence of trauma or hemorrhage.
 - Torticollis may result from an intrauterine position that occludes venous drainage from the SCM, leading to vascular congestion, ischemia, muscle damage, and fibrosis.
 - This theory is supported in that 75% of congenital muscular torticollis cases are right sided because of intrauterine, left occiput–anterior positioning.
 - Approximately 20% of patients who have congenital torticollis also have other musculoskeletal anomalies.
 - Congenital hip dysplasias
 - Talipes equinovarus
 - Metatarsus adductus

- Possible variations in congenital torticollis
 - A sternomastoid tumor or pseudotumor is palpable as a characteristically nontender, soft, and mobile mass in or next to the inferior aspect of the SCM.
 - The mass enlarges in the first few weeks of life, reaching its maximal size at 1 month of age.
 - Then, it begins to shrink until it disappears by 4–6 months.
 - The mass is replaced by a fibrous band, leading to contracture.
 - Normal growth and range of motion of the neck are prevented.
 - Facial asymmetry results from uneven growth forces.
 - A second form of congenital torticollis involves thickening and tightness of the SCM itself.
- Congenital postural torticollis occurs without the presence of a palpable mass or tightness of the SCM.

Acquired torticollis

- Most cases of torticollis in older children are primarily muscular in origin.
 - Cervical muscle or ligament injury arising from trauma can cause a head tilt and unilateral neck tenderness.
 - The condition can also occur on awakening as a result of awkward positioning of the neck during sleep.
- Benign paroxysmal torticollis
 - Disease of infancy with an unknown cause
 - A familial pattern has been described.
 - Manifestations of the condition begin in the first year of life.
 - Recurrent episodes of head tilt are associated with:
 - Emesis
 - Pallor
 - Agitation
 - Ataxia
 - Malaise
 - Behavioral changes
 - Attacks may last from several hours to several days.
 - Spontaneous and complete remission usually occurs by 5 years of age.
 - Some patients develop migraines or benign paroxysmal vertigo.

HISTORY

- Obtain a thorough and detailed history.
- Particular attention should be given to:
 - Duration of symptoms
 - Previous trauma
 - Presence of fever
 - Other systemic manifestations
- In younger patients, the birth history is essential.

PHYSICAL EXAM

- Physical examination should not be limited to the head and neck.
 - Include all organ systems.
- Such findings as craniofacial asymmetry suggest a congenital torticollis of long duration.
- Webs or cysts in the neck should raise the suspicion of pterygium colli or remnant cysts.
- Patients with acquired torticollis as a result of trauma often have a tender SCM.
- Point tenderness over the cervical spine may suggest an underlying fracture or subluxation.
- Cervical vertebral osteomyelitis should be suspected in patients who have point tenderness in association with unexplained fever.

DIFFERENTIAL DIAGNOSIS**Congenital**

- Muscular torticollis
- Postural torticollis
- Cervical spine anomalies
- Hemivertebra
- Atlantooccipital fusion
- Klippel-Feil syndrome
- Sprengel deformity
- Pterygium colli
- Sternocleidomastoid cysts
- Cystic hygroma
- Bronchial cleft cyst
- Unilateral absence of sternocleidomastoid
- Occipital condylar dysplasia

Acquired

- Muscular
 - Cervical muscle injury
 - Psychogenic torticollis
 - Benign paroxysmal torticollis
 - Vertebral
 - Atlantoaxial subluxation
 - Laxity of the transverse cervical ligaments results in atlantoaxial instability in up to 15% of patients with Down syndrome.
- Atlantooccipital subluxation
- C2–C3 subluxation
- Rotary subluxation
- Cervical fractures
- Cervical vertebral osteomyelitis
- Rheumatoid arthritis

- Inflammatory reactions around the spine produce hyperemia and edema, which lead to laxity of the supporting ligaments and a predisposition to spontaneous subluxations and torticollis.

- Acute cervical disk calcification caused by trauma or respiratory infection
- Eosinophilic granuloma

Infectious

- Infections of the head and neck (Grisel syndrome)
- Upper respiratory infection
- Retropharyngeal abscess
- Cervical lymphadenitis
- Cervical vertebral osteomyelitis
- Dental infections

Neurologic

- Ocular torticollis caused by:
 - Paralysis of the extraocular muscles
 - Strabismus
 - Nystagmus
 - Refractive errors
- Spasmus nutans, including acquired nystagmus, head nodding, torticollis
 - No known cause
 - Signs and symptoms usually develop within the first 2 years of life.
 - May persist for months to years, but the clinical course often is benign and self-limited
- Dystonic torticollis may follow administration of phenothiazines, carbamazepine, or phenytoin.
 - The presence of other extrapyramidal signs can often be used to distinguish patients who have dystonic reactions.
- Wilson disease
- Syringomyelia
- Labyrinthine torticollis
- Accessory nerve palsy
- Brachial plexus palsy
- Arnold-Chiari malformation
- Neoplasms, including cervical cord tumors, cerebellar tumors
 - Ataxia is often a cardinal feature.
- Soft-tissue tumor
- Histiocytosis X (Langerhans cell histiocytosis)
- Infantile desmoid fibromatosis

Other

- Sandifer syndrome is an abnormal posturing that includes torticollis and opisthotonos.
 - Believed to be a protective mechanism adopted by some patients with one of several conditions, including gastroesophageal reflux, esophagitis, or hiatal hernia

- Dermatogenic torticollis is a painful, stiff neck that results from extensive local skin lesions.
- Spurious torticollis is stiffness of the neck resulting from dental malformations and caries.

LABORATORY EVALUATION

- Helpful adjuncts to diagnose torticollis caused by infection or inflammation
 - Peripheral leukocytosis
 - Increased sedimentation rate

IMAGING

- Imaging of the cervical spine should be obtained:
 - In all neonates with torticollis
 - In older children with findings that suggest vertebral involvement
 - In older children with persistent torticollis
- Ultrasonography is the imaging modality of choice for initial evaluation.
- Patients with neurologic deficits should undergo prompt computed tomography or magnetic resonance imaging of the head and neck.
- Several congenital cervical spine anomalies can occur in conjunction with torticollis.
 - Most of these anomalies can be diagnosed by radiographic studies of the cervical spine.
 - Pterygium colli, a congenital web of the skin of the neck extending from the acromial process to the mastoid, can be restrictive and result in torticollis.
 - Congenital remnant cysts within the body of the SCM are a less common cause of torticollis.
 - Unilateral absence of 1 SCM results in unopposed action of the other muscle and produces a contralateral torticollis.

TREATMENT APPROACH

- Congenital muscular torticollis responds well to prompt conservative treatment during the first year of life.
- The treatment of acquired torticollis arising from other specific diseases should be directed at the cause.
- Any child with severe neck pain or tenderness over the vertebra requires immediate cervical immobilization until radiography can be performed to exclude the possibility of vertebral fracture or subluxation.

SPECIFIC TREATMENT

Congenital torticollis

- Medical management includes passive and active stretching of the neck.
 - Gentle (passive) stretching can be performed daily by parents or a physical therapist.
 - Active stretching

- Manipulate the infant's environment in such a way that objects of interest are located on the side of the room opposite to the torticollis to induce the infant to turn the neck in the desired direction.

- Surgical correction is essential if:
 - Deformity persists beyond the first year of life.
 - Range of motion is restricted >30%.
 - Residual craniofacial deformity exists.
- Craniofacial asymmetry is best reversed early, when the child's growth potential is at its maximum.
- The surgical procedure that has the best results involves:
 - Bipolar tenotomy of the affected SCM
 - Followed by casting or bracing to maintain the corrected posture

Acquired torticollis

- Acquired muscular or ligamentous torticollis should be managed with:
 - Local heat
 - Massage
 - Analgesics
 - Muscle relaxants
 - Soft cervical collar
- Symptoms usually resolve in 7–10 days.
- Patients with acquired muscular or ligamentous torticollis experience only mild discomfort.
- For drug-induced dystonic reaction:
 - Discontinue the offending drug.
 - Administer intravenous diphenhydramine.

WHEN TO REFER

- Presence of craniofacial asymmetry
- Radiographic evidence of cervical spine abnormality
- >30% restriction in range of motion
- Persistence beyond the first year of life

WHEN TO ADMIT

- Presence of neurologic deficits
- Severe neck pain
- Point tenderness over the vertebrae

FOLLOW-UP

- Congenital torticollis should be followed carefully for development or worsening of craniofacial deformities.

COMPLICATIONS

- If not treated appropriately, patients with congenital torticollis may develop craniofacial deformities or worsen existing craniofacial deformities.

Tuberculosis

DEFINITION

- Tuberculosis (TB)
 - Serious disease caused by *Mycobacterium tuberculosis*
 - Distinguished from latent TB infection (LTBI)
 - Common clinical presentations
 - Pneumonia
 - Intrathoracic or peripheral lymphadenopathy
 - Meningitis
 - Disseminated TB
 - Bone and joint disease
- Latent TB infection
 - Occurs when the organism is in a metabolically dormant state and replicating slowly within granulomata in the lung and other tissues
- Tuberculosis exposure
 - A person is defined as exposed to TB if he or she has spent time in close proximity to a potentially contagious patient with TB disease.
 - The exposed individual may or may not be infected.

EPIDEMIOLOGY

- Prevalence
 - TB disproportionately affects young children because of:
 - Increased risk of progression to disease once infected by *M tuberculosis*
 - Increased likelihood of disseminated disease
 - Case rates of TB per 100,000 US children (2006 report)
 - Children age 0–14 years: 1.3
 - Children age <5 years: 2.4
 - Foreign-born: 21.9
 - US-born: 2.1
 - Hispanic or Latino: 5.5
 - Asian: 5.2
 - Black or African American: 4.5
 - White: 0.2
 - Among US children with TB in 2006
 - 485 were <5 yrs of age; 322 were ages 5–14.
 - 48% were Hispanic (most from Mexico).
 - 31% were black.
 - 25% of TB cases in children occurred in the foreign-born group.
 - 15% were <5 years of age
 - 40% were 5–14 yrs of age.
 - 36% of cases were reported from California, Texas, and New York.
 - 73% had pulmonary TB (with or without extrapulmonary TB).

- Because LTBI is not a reportable condition in most states, the number of children who have LTBI is unknown.

ETIOLOGY

- TB is caused by a member of the *M tuberculosis* complex, which includes *M tuberculosis* and *Mycobacterium bovis*.

RISK FACTORS

- Children at highest risk for TB
 - Children of color
 - Children born in countries with a high prevalence of TB or into families from these countries
 - Children who live with or in contact with adults who are at risk for TB
 - Children <4 years
- If several family members have positive tuberculin skin test results, then likelihood that patient's disease is TB increases.
- Ingestion of foreign unpasteurized milk and milk products, such as Mexican-style soft cheeses (queso fresco), raises possibility of infection with *M bovis*.
- Patients infected with HIV or who have another immunocompromising conditions are more likely than others to have:
 - TB *or*
 - Atypical or extrapulmonary presentation of TB

SIGNS AND SYMPTOMS

- US children diagnosed with TB disease
 - Often are asymptomatic, *but*
 - Have radiographic evidence of disease, eg, infiltrate or intrathoracic adenopathy
- Common symptoms of TB
 - Weight loss or failure to gain weight
 - Anorexia
 - Fever
 - Cough
 - Decreased energy, playfulness, or activity
- Symptoms of extrapulmonary TB
 - Lymph node enlargement
 - Headache
 - Personality changes
 - Focal neurologic changes
 - Musculoskeletal pain
- TB can produce fulminant or indolent symptoms, but symptoms typically are more chronic when caused by TB than when caused by bacterial or viral infections.
 - Cough often is noted for weeks rather than days.
 - Lymph node swelling develops over weeks, with gradual and modest changes in the overlying skin.

- Occasionally, symptoms such as cough and fever actually have begun to improve by the time of diagnosis.

DIFFERENTIAL DIAGNOSIS

Forms of Tuberculosis

- Pulmonary infiltrate
 - Community-acquired pneumonia (eg, bacterial pneumonia, including lung abscess and necrotizing pneumonia; viral pneumonia)
 - Atelectasis caused by reactive airways disease or other processes
 - Other granulomatous diseases (eg, coccidiomycosis, histoplasmosis)
- Intrathoracic lymphadenopathy
 - Infections caused by fungus, virus, or bacteria
 - Nontuberculous mycobacterial infections
 - Malignancies
 - Round pneumonia
 - Other granulomatous diseases (eg, coccidiomycosis, histoplasmosis)
- Subacute peripheral adenopathy
 - Scrofula caused by nontuberculous mycobacteria
 - Cat-scratch disease
 - Toxoplasmosis
 - Partially treated pyogenic infection
- Viral, bacterial, fungal, and chemical meningitis
- Differential diagnosis for tuberculin skin test (TST) results
 - Truly positive
 - Caused by infection with *M tuberculosis* complex
 - Falsely positive
 - Cross-reaction with nontuberculous mycobacteria (eg, *Mycobacterium avium* complex and *Mycobacterium scrofulaceum*); often, but not always, smaller than reactions caused by *M tuberculosis*
 - Cross-reaction with recent or multiple vaccinations with bacille Calmette-Guérin (BCG) (see below)
 - Allergic-type reactions—peak within 24 hours of TST placement and should be gone within 48–72 hours
 - Induration that peaks >24 hours after TST placement is due to a delayed-type hypersensitivity, the mechanism of a true-positive TST reaction.
 - Irritation from a circular Band-Aid or tape
 - Injection with a substance other than purified protein derivative (PPD)
 - Falsely negative
 - Recent infection with *M tuberculosis* (delayed-type hypersensitivity reaction takes 2–8 weeks after infection to develop)
 - Infancy

- Improper storage of the PPD skin test material (eg, not refrigerated, prolonged storage in syringe)
- Improper placement (eg, subcutaneous placement, pressure by gauze or a Band-Aid leading to the absorption of PPD solution)
- Vaccination with a live virus vaccine within the previous 6 weeks
- Generalized or specific anergy associated with extensive or disseminated TB or as seen in immunocompromised patients, especially those infected with HIV

Prior BCG vaccination

- Sometimes causes a small, transient TST reaction as a result of cross-reactivity among antigens
- Clinicians are advised to discount history of BCG vaccination when interpreting TST.
- The following factors decrease the likelihood that the skin test reaction is caused by BCG:
 - TST reaction (induration) >10 mm
 - Previous receipt of a single rather than multiple BCG vaccines
 - BCG given in the first month of life
 - A long period since the BCG dose
 - Receipt of no other recent TST
- New blood tests may further clarify the impact of BCG on TST reactions and allow for more accurate TST cutoff points in individuals who have received BCG.

DIAGNOSTIC APPROACH

- TB diagnosis in a child usually is a clinical diagnosis, influenced by:
 - Probability of exposure to a person with infectious TB
 - TST results
 - Clinical symptoms and signs
 - Results of imaging tests
- All of these factors are weighed, along with the risk to the child of not treating TB, when considering whether to begin treatment.
- Universal skin testing for TB is not recommended.
- Annual assessment for TB risk factors and testing of children with defined risk factors are the standard of care.
- Testing asymptomatic children without known risk factors for TB is no longer performed.
- Use the TST to diagnose LTBI and support the diagnosis of TB disease.
- Because of the poor sensitivity and specificity of the TST in low-incidence populations, administer it only to the following children:
 - Those who have clinical disease that raises concern for TB
 - Those at high risk for progression to TB disease

- Those who have new risk factors for TB exposure since their last TST
- Most children with US-born parents never require a TST.
- If a child has a positive TST result, the evaluation includes:
 - Chest radiograph
 - A 2-view chest radiograph (frontal and lateral views) is particularly helpful in differentiating intrathoracic lymphadenopathy from other hilar structures.
 - National guidelines suggest obtaining 2-view radiographs on all children when resources permit.
 - If resources are limited, children >6 years of age should be screened with 1-view chest radiographs.
 - Focused history
 - Physical examination
- Pertinent medical history
 - Previous TB skin test results
 - Previous TB treatment
 - Results of any previous chest radiographs
 - Factors that would complicate TB therapy, including underlying liver disease and use of potentially hepatotoxic drugs
- If the family does not know anyone with TB disease, ask family members if they:
 - Have close contact with an adolescent or adult with chronic cough, fever, or unexplained weight loss
 - Have household contact with an individual with a positive TST result (especially a newly positive result)
- Because >50% of adult patients with TB disease are born outside the US (primarily in Latin America, Asia, Africa, and Eastern Europe), contacts from these areas should be solicited.
- Ask family members:
 - Where children were born
 - Where they have traveled
 - How long they stayed
 - With whom they stayed when traveling in TB-endemic areas
- Immediately perform a TST on any family member who has not recently had such a test (and has never had a positive result in the past).
- To prevent possible continued transmission of TB, obtain chest radiographs of adults with a previous or newly positive TST result or suspicious TB-like symptoms.
- Physical exam
 - Assess vital signs
 - Assess growth parameters
 - Examine conjunctiva
 - Check neck flexion
 - Palpate lymph nodes

- Auscultate heart and lungs
- Palpate abdomen and flank
- Palpate spine and bone
- Briefly examine skin
- Conduct neurologic exam (depending on concerns for TB of the central nervous system).
- Limitations of physical exam
 - LTBI: no examination abnormalities that suggest TB disease
 - Even children with pulmonary TB may have no findings at physical exam.
 - Findings on chest radiograph often are more useful than those found by physical exam or history.

LABORATORY FINDINGS

- Routine testing for children suspected of having TB includes:
 - HIV serologic testing
 - Mycobacterial cultures
- Sputum specimens are challenging to collect from young children, but they can be collected by 3 methods:
 - Gastric aspiration (procedure is described below)
 - Aspirates typically are collected on 3 consecutive mornings after an overnight fast.
 - Yields of 30–50%; highest in the youngest infants and from the initial sample collected
 - If the patient is not otherwise ill enough to require inpatient management, then gastric aspirates can be collected in the outpatient setting.
 - Sputum induction
 - In older children, attempt sputum induction with hypertonic saline.
 - Inducing sputum in infants is difficult.
 - Bronchoalveolar lavage
 - Used primarily when diagnoses other than TB are being strongly considered
 - Yield in children: 10–21%
 - Yields are lower than for gastric lavage in children.
- Other tests
 - Cerebrospinal fluid (CSF): 50–75% yield in diagnosis of TB meningitis
 - Acid-fast bacillus (AFB) smear: even lower yield, but can be improved by centrifugation of large volumes of CSF
 - Polymerase chain reaction: disappointing, but may play a role as an adjunct diagnostic method
 - AFB smear and culture of other tissues, as indicated for:
 - Lymph node tissue
 - Abscess drainage
 - Bone or synovial fluid
 - Urine

- Blood
- Bone marrow
- Other tissue
- Submit specimens for AFB smear and culture in a sterile cup (rather than on a swab) and without formalin preservative.
- Regardless of the culture method or specimen, culture for *M tuberculosis* in children has suboptimal yields.
- Families should understand that:
 - AFB smears usually are not positive from specimens from children.
 - Cultures must be incubated for several weeks before results are available.
 - Yield from cultures is <50% in most situations.
- Consider other laboratory evaluations based on individual circumstances.
- Measure liver transaminase levels in patients with:
 - TB-HIV coinfection
 - Severe TB disease
 - Symptoms or signs of hepatitis
 - Known underlying liver disease
- The QuantiFERON-TB Gold test
 - In vitro diagnostic test for detecting interferon gamma (IFN- γ) when a patient's whole blood is incubated with specific TB proteins and controls.
 - Detection of IFN- γ indicates a T-cell response by the patient's lymphocytes and probable infection with *M tuberculosis*
 - Few data support its applicability to children, although studies are underway.
- Gastric aspirate procedure for culture of *M tuberculosis*
 - Health care workers present during gastric aspirate procedures of a patient with suspected or confirmed infectious TB disease should wear at least N-95 disposable respirators.
 - Collect all supplies and have everything ready:
 - N-95 respirators
 - Papoose board or sheet
 - No. 10-French or larger nasogastric or suction tube
 - 30-mL syringe with appropriate connector for tube
 - Pen
 - Sterile water
 - Specimen cup or laboratory-prepared tube containing bicarbonate for bedside neutralization
 - Requisition and label
 - Helper
 - Child should not take anything by mouth for at least 6 hours before the procedure.
 - Immobilize the child with a sheet, with or without a papoose board.
 - Measure the distance from the nose to the stomach.
 - Insert a No. 10-French nasogastric tube through the nose into the stomach.
 - Puff in the child's face as the tube enters the throat to elicit a swallow reflex.
 - Gently aspirate the tube with an appropriately fitted 30- to 60-mL syringe.
 - If no significant yield, then advance and withdraw the tube slightly while aspirating.
 - If yield is still <5–10 mL, then place any collected mucus into a container.
 - Check tube position by auscultating the stomach while pushing air from the syringe into tube.
 - Instill 20 mL of sterile water into the stomach and quickly aspirate again.
 - If yield is <5–10 mL, roll the child on the side and advance the tube, aspirating continuously to find the pool of mucus in the stomach.
 - As tube is withdrawn, continuously aspirate the syringe.
 - Place any yield, including any spontaneously vomited emesis, in the specimen container.
 - Label the specimen and order AFB smear and culture.
 - Promptly transport the specimen to the laboratory for processing (tell the laboratory if the specimen has already been neutralized).

IMAGING

■ Radiography

- Perform in children with:
 - Positive TST result
 - Suspicion of pulmonary or extrapulmonary TB
- For the best-quality radiograph, the child should be in full inspiration and should not be rotated.
- Guidelines suggest obtaining 2-view radiographs on all children when resources permit. If resources are limited, children >6 years can be screened with 1-view chest radiographs.
 - Lateral view helps distinguish other central shadows from intrathoracic lymph nodes, which are spherical and often can be seen on both views.
- Films should be interpreted by a clinician or radiologist experienced in pediatric TB.
- Findings on chest radiographs
 - Enlarged intrathoracic lymph nodes and infiltrate are the most common abnormalities.
 - Intrathoracic adenopathy: present in up to 85% of children <3 years of age

- Hilar, mediastinal, paratracheal, and subcarinal nodes may be seen, most often on the right side.
- Isolated adenopathy should be treated as TB disease.
- An infiltrate may be seen in any lung field and is seen in multiple lobes in one-quarter of children.
- Older children, especially adolescents, may have radiographic findings that are consistent with adult reactivation (postprimary) TB, including:
 - Upper lobe disease with fibronodular infiltrates
 - Volume loss
 - Hilar retraction
 - Cavities
- Segmental lesion (infection spread to other parenchymal locations) when the material is limited to one bronchus
- Diffuse bronchopneumonia (when the organism spreads throughout the lung)
- Disseminated disease (distribution of *M tuberculosis* via hematogenous dissemination that causes disease to the lung and other organs) causes lesions with small, round, millet-like radiographic appearance.
 - These disseminated processes do not always appear radiographically in the classic disseminated pattern.
- Larger, patchy, reticulonodular lesions may be present and are difficult to distinguish from other diffuse lung infections.
- Pleural effusion and empyema are less common in children with TB compared with adults.
- Signs of healed *M tuberculosis*
 - Isolated, dense nodules with calcification
 - Nonenlarged calcified lymph nodes
 - Isolated pleural thickening
- Peribronchial cuffing or thickening is commonly associated with reactive airway disease and viral infection and, in isolation, is not consistent with TB.
- Computed tomography
 - Not indicated in evaluation of an asymptomatic child with a normal chest radiograph and a positive TST result
 - Can be helpful when the radiograph is equivocal and it is necessary to look for other causes of lung disease

DIAGNOSTIC PROCEDURES

- Tuberculin skin testing
 - The only recommended TST is intradermal instillation of 5 TU (0.1 mL) PPD by the Mantoux method.
 - The skin test should be placed and interpreted by a trained health care professional.
 - The definition of a positive TST result depends on risk factors for infection and the likelihood of TB disease.

- TST results are considered positive under the following circumstances:
 - ≥ 5 -mm induration
 - Child is immunosuppressed (receiving immunosuppressive therapy) or immunocompromised, including HIV infection.
 - Child is a recent contact of a person with TB or suspected TB disease.
 - Radiograph or clinical evidence suggests TB disease.
 - Fibrotic changes on chest radiograph are consistent with prior TB infection.
 - ≥ 10 mm induration
 - Child is < 4 years of age.
 - Child has preexisting medical conditions (eg, lymphoma, Hodgkin disease, diabetes mellitus, chronic renal failure, malnutrition).
 - Child or parent was born in a country with a high prevalence of TB.
 - Child has frequent exposure to high-risk adults (HIV infected, homeless, residents of nursing homes, institutionalized, incarcerated, users of illicit drugs, migrant farm workers).
 - Child has traveled to a high-prevalence country.
 - Child is a resident of California.
 - ≥ 15 -mm induration
 - Child is ≥ 4 years of age and has no risk factors.

TREATMENT APPROACH

- Asymptomatic presentations of TB disease are treated with multidrug therapy because they will progress in most children if not treated.
- Providers are legally mandated to report persons suspected of having or confirmed to have TB to the local health department.
- Manage children with TB disease in a dedicated TB clinic or by the most experienced pediatric TB clinician available.
- In areas where this treatment is not feasible, seek close and ongoing consultation with an experienced clinician.

SPECIFIC TREATMENTS

Tuberculosis

- Four-drug empiric regimen
 - Isoniazid (INH), rifampin, pyrazinamide, and ethambutol
 - Recommended for individuals who
 - Are at higher risk for having INH-resistant TB, including exposure to an individual from an area of high prevalence of drug-resistant TB
 - Have known drug-resistant TB
 - Previously received treatment for TB

■ Directly observed therapy (DOT) by a health care professional (not parents) is recommended for treatment of TB in children and adolescents.

■ Corticosteroids

- Beneficial in central nervous system disease, particularly stage 2 and 3 (altered mental status)
- Sometimes used for any child with symptomatic TB meningitis
- Frequently used for TB pericarditis
- Two reports support the use of corticosteroids in children with symptomatic airways compression caused by lymphatic disease.

■ Prednisone

- Generally used at a dose of 1–2 mg/kg/day given for 4–8 weeks, then tapered over several weeks

■ Treatment regimens for TB in children

• Pulmonary TB

- Minimal duration of therapy: 6 months
- Initial regimen: Isoniazid, rifampin, pyrazinamide, and ethambutol daily for 2 weeks to 2 months (3-drug therapy only if no risk of resistance)
- 4-drug initial therapy is provided if any risk exists of drug resistance.
- If a cavitary lesion was present on the chest radiograph and sputum culture is positive after 2 months of treatment, extend total treatment duration to 9 months rather than 6 months.

• Extrapulmonary (meningitis, bone or joint, disseminated)

- Minimal duration of therapy: 9–12 months
- Initial regimen: Isoniazid, rifampin, pyrazinamide, and ethambutol daily for 2 weeks to 2 months (3-drug therapy only if no risk of resistance)
- Some clinicians use an injectable drug (eg, amikacin, kanamycin) for initial treatment of disseminated or meningeal disease.
- Strongly consider corticosteroid therapy for some types of extrapulmonary disease (eg, meningitis, pericarditis).

• Other extrapulmonary (cervical adenopathy)

- Minimal duration of therapy: 6 months
- Initial regimen: isoniazid, rifampin, pyrazinamide, and ethambutol daily for 2 weeks to 2 months (3-drug therapy only if no risk of resistance)
- 4-drug initial therapy is provided if any risk exists of drug resistance.
- If a cavitary lesion was present on the chest radiograph and sputum culture is positive after 2 months of treatment, extend total treatment duration to 9 months rather than 6 months.

Latent tuberculosis infection

■ INH

- Patients should receive INH monotherapy daily for 9 months unless they have a medical contraindication (including infection with a known INH-resistant strain).
- Dosing is 270 daily doses (or twice a week administered by DOT) within a 12-month period.
- Available as 100-mg and 300-mg scored tablets and as a liquid suspended in sorbitol. The tablet can be crushed and mixed with or layered into a strong-flavored semisoft food in a spoon.
- Doses by weight (10–15 mg/kg per day; maximal dose, 300 mg)
 - Daily dose for weight 3–5 kg (6.6–11 lbs)
 - 50 mg
 - 100-mg tablets: ½
 - Daily dose for weight 5–7.5 kg (11–16.4 lbs)
 - 75 mg
 - 100-mg tablets: ¾
 - 300-mg tablets: ¼
 - Daily dose for weight 7.5–10 kg (16.5–22 lbs)
 - 100 mg
 - 100-mg tablets: 1
 - Daily dose for weight 10–15 kg (22–33 lbs)
 - 150 mg
 - 300-mg tablets: ½
 - Daily dose for weight 15–20 kg (33–44 lbs)
 - 200 mg
 - 100-mg tablets: 2
 - Daily dose for weight >20 kg (>44 lbs)
 - 300 mg
 - 100-mg tablets: 3 or
 - 300-mg tablets: 1
- When a prolonged break occurs after a short initial treatment period, restart therapy.
- Short lapses are tolerated, especially if the regimen is well underway.
- If therapy is interrupted for >2 months, reevaluate child for possible TB disease before restarting INH.
- Vitamin-B₆ (pyridoxine) supplementation is indicated only for
 - Exclusively breastfed infants
 - Children and adolescents on milk- and meat-deficient diets
 - Children who experience paresthesias while receiving INH therapy
 - Children with HIV infection

- Examine children monthly and question them about symptoms of toxicity.
 - Most side effects of INH can be overcome with adjustments of timing or symptomatic management.
 - Patients receiving antiepileptic drugs (particularly phenytoin and carbamazepine) should have these drug levels monitored.
- **Rifampin**
- Occasionally used as an alternative for a patient who is intolerant to INH or is known to be infected by an INH-resistant TB strain
 - Given for 180 daily doses
 - May accelerate the metabolism or have other interactions with several important classes of drugs:
 - Anticonvulsants
 - Antiarrhythmics
 - Antifungals
 - Barbiturates
 - β -Blockers
 - Calcium channel blockers
 - Antibiotics
 - Corticosteroids
 - Oral contraceptives
 - Oral hypoglycemics
 - Drugs used to treat HIV infection

WHEN TO ADMIT

- For culture collection if local resources are not available for outpatient culture collection
- Patients with increased work of breathing, meningitis, or complicating simultaneous conditions
- Patients who require diagnostic evaluation
- Few children require admission to the hospital based on clinical severity of TB disease.

WHEN TO REFER

- All patients suspected of having active TB should be reported to the local health department according to state statute (eg, within 1 working day).
- In many jurisdictions, young children with LTBI should be reported to the local health department, according to local regulations.
- Ideally, an experienced pediatric TB clinician should manage children with TB disease. If local resources are not available, then close and ongoing consultation with a pediatric TB expert should be established.

FOLLOW-UP

- Monitor patients monthly during therapy.
- For children from whom sputum can be obtained, follow-up sputum to document culture conversion
- Twice-weekly dosing by DOT can be used after induction phase of daily treatment if child is tolerating the regimen well and has shown considerable clinical improvement.
 - Number of doses actually observed should be counted when considering whether a patient has completed therapy.
 - Patients receiving daily doses for the first 2 months typically will receive 40 observed doses
 - Monday through Friday for ~8 weeks
 - Followed by 36 twice-weekly doses in the following 18 weeks
- Routine laboratory evaluation is not necessary, unless:
 - Patient has symptoms of toxicity or underlying liver disease.
 - Patient is taking other medications that might interfere with the TB drugs or cause similar toxicities.
- Obtain end-of-therapy chest radiograph.
 - Most children do not have a normal radiograph at the end of therapy, but significant improvement is expected.
- Follow-up regimen for pulmonary TB
 - Stop ethambutol as soon as the patient or reliable source case isolate is found to be drug susceptible.
 - Document a follow-up chest radiograph 2 months into therapy.
 - If isolate is sensitive and patient is clinically well and radiographically improving or stable, then change to isoniazid and rifampin at 2 months to complete a 6-month course; twice-weekly therapy can be provided by directly observed therapy.
 - Document chest radiograph at end of treatment—frequently not quite normal.
- Follow-up regimen for extrapulmonary TB (meningitis, bone or joint, disseminated)
 - 7–10 months of isoniazid and rifampin, either daily or twice a week by directly observed therapy
- Follow-up regimen for other extrapulmonary TB (cervical adenopathy)
 - Same as for pulmonary TB disease, except no need to follow chest radiographs if initially normal
- Unless an alternative diagnosis is established, most often, once TB therapy is begun, course should be completed.

COMPLICATIONS

■ INH

- The liquid formulation causes cramping and diarrhea in more than one-half of children because of its osmotic load.
- INH-related transient increase of transaminases has been noted in children, with effects increasing with increasing age.
 - INH rarely causes clinical hepatotoxicity in children.
- Routine monitoring of liver transaminases is not indicated for asymptomatic children who do not have underlying liver disease and who are not receiving other hepatotoxic drugs.
- Thoroughly educate families about recognizing symptoms of hepatotoxicity (eg, anorexia, malaise, abdominal pain, vomiting) and instruct them to stop therapy and return to clinic if these symptoms arise.
- Lack of association with other viral symptoms and lack of improvement after a few days should suggest possibility of hepatotoxicity rather than an intercurrent illness.

PREVENTION

■ Identify children at risk for exposure to TB

- Aggressively evaluate and treat children exposed to potentially contagious adolescents and adults with TB (young children usually are not contagious)
- Treat LTBI
- Promptly treat contagious TB patients

■ Targeted testing

- Skin testing only for children who are at high risk of contracting TB infection or developing TB disease if infected
 - Results in fewer unnecessary skin tests
 - Avoids evaluation and treatment of children with false-positive TST results
- At each well-child visit, screen child with a risk-factor questionnaire (modify based on local risks).
- Conduct skin testing only if a new risk factor has been identified since the last TST.

■ Tuberculosis exposure

- Contagious TB requires prompt and thorough evaluation to determine whether the child already has evidence of LTBI or TB disease.
- Children <5 years and all immunocompromised individuals with significant exposure should receive window prophylaxis after TB disease has been ruled out by a normal chest radiograph and negative physical examination.
 - Window prophylaxis: treatment with INH until a repeat TST (given 8–10 weeks after their last exposure) is performed and is negative.

Umbilical Anomalies

DEFINITION

- Aberrations in configuration, formation, or position of the umbilical cord, including minor anomalies, can offer helpful clues to underlying disease in the young child.

EPIDEMIOLOGY

- Prevalence
 - Meckel diverticulum
 - Present in 2.5% of newborns in the US
 - Vascular abnormalities
 - Variations in the pattern of 2 arteries and 1 vein occur in 0.7% of all births.
 - The most common variation is the presence of only 1 artery (single umbilical artery) and 1 vein.
 - In 25–50% of cases, it is associated with various anomalies, including malformations of central nervous system, genitourinary tract, spine, and extremities.
 - Absence of the left umbilical artery is more commonly associated with fetal anomalies.
 - Associated aneuploidies include trisomy 13, trisomy 18, and triploidy.
 - A persistent right umbilical vein has been reported to occur in 1 in 400 births; this is a benign finding.
 - Umbilical hernia
 - Extremely common; could be considered a variation of normal
 - Varies with race and age
 - More common in African-American infants (32%) than in white infants (4%)
 - Decreases to 12% and 2%, respectively, at 1 year
 - More common in low-birth-weight babies
 - Boys and girls are equally affected.

ETIOLOGY

- The umbilical cord appears within the first 6 weeks of gestation.
- It is derived from the fusion of 3 separate embryonic structures.
 - The primitive or primary yolk sac, which contains:
 - Allantois and a portion of the vitelline duct, transient structures that ultimately form the central portion of the embryonic gut
 - Urinary bladder
 - Umbilical blood vessels
 - The secondary yolk sac
 - Remainder of the vitelline duct
 - The mesenchyme of the connecting body stalk of the embryo
 - Tissue that produces Wharton jelly, which is the packing substance that holds the cord together

- Many of the structures that form the umbilical cord are present for only brief periods during embryogenesis.
- After fusion is complete, these unified structures become covered by amnion and ultimately are surrounded by amniotic fluid.
- Anomalies may result when these structures fail to undergo normal regression and persist into postnatal life.

SIGNS AND SYMPTOMS

Failure of closure and regression of the vitelline duct

- Failure of closure and total regression by the 7th week of gestation may lead to:
 - Meckel diverticulum
 - Outpouching of gut without attachment to anterior abdominal wall
 - Well-known cause of clandestine lower intestinal bleeding from the presence of ectopic gastric mucosa within the diverticulum
 - Can occur anywhere from the ileocecal valve to a point ≥ 3 feet proximal to the valve
 - Resembles supernumerary vermiform appendix
 - Presence may be signaled by symptoms and signs of acute appendicitis.
 - Vitelline cyst or enterocystoma
 - A connection between the midgut and umbilicus without communication with either structure
 - Enteric or vitelline fistula
 - Formed from a communicating connection between the midgut and the umbilicus
 - Urachal sinus, cyst, or fistula
 - Results from a connection between the bladder and the urachus
- Presence of these anomalies may be indicated by:
 - Signs of infection and lower midline abdominal mass caused by infection of a vitelline cyst
 - Discharge of feces and urine can lead to erosive dermatitis (from enteric and urachal fistulas)
 - Urinary tract infections resulting from urachal fistulas
- Persistence of a fibrous band of tissue attached to the gut results from incomplete involution.
 - May serve as the lead point for a volvulus or the cause of intestinal obstruction

Vascular abnormalities of the umbilical cord

- Blood vessels are the most important structures in the umbilical cord.
 - The pattern of anomalies in infants with aberrant cord vessels often depends on which vessels are present and which are missing.
 - 3 patterns have been described.

- Single umbilical artery of allantoic origin, associated with growth restriction, anomalies of central nervous system, such as anencephaly and spina bifida, and abnormalities of the lower genitourinary tract
- Single artery of vitelline origin, associated with sirenomelia, sacral agenesis, reduction defects of lower extremities, anal atresia (features of VACTERL [vertebral, anal atresia, cardiac, trachea, esophageal, renal, and limb defects]), and trisomy 18
- 3 vessels, including a single umbilical artery (of either allantoic or vitelline origin); a left umbilical vein; and a persistent and aberrant right umbilical vein, described in some children with Noonan syndrome and 47,XXY karyotype

Umbilical hernia

- Usually no associated medical sequelae
 - Incarceration, strangulation, rupture, or skin breakdown occurred in <5% of 590 children in 1 study.
 - Other studies have revealed even lower rates of complication.
- Most close spontaneously without medical intervention.
 - The major indication for surgical treatment is cosmetic, and surgery should only be considered in carefully selected individuals.
- Although most umbilical hernias occur as isolated findings in otherwise healthy children, they can be associated with a variety of known conditions, many of which feature increased abdominal girth or hypotonia.
 - Common autosomal trisomies
 - Mucopolysaccharidoses
 - Inborn errors of metabolism associated with organomegaly
 - Dysmorphic syndromes, such as Beckwith-Wiedemann syndrome

Umbilical granulomas

- At birth, the normal umbilical cord contains only umbilical vessels surrounded by protective Wharton jelly.
- Within the first 2 weeks after birth, the umbilical stump normally dries and separates from the abdomen; the umbilicus is completely covered by skin in 3 to 4 weeks.
- Delayed healing with accumulation of excessive amounts of granulation tissue produces an umbilical granuloma, a small, reddened mass.
- The lesion may be associated with infection at its base or with a foreign body, such as talcum, but recedes rapidly after repeated topical applications of silver nitrate.
- Persistence of embryonic remnants may be suggested by:
 - Persistence of a granulomatous-appearing lesion after treatment
 - Presence of erosive dermatitis at the site
 - Egress of gas, feces, or urine from the site

Umbilical polyps

- External remnants of the umbilical cord may superficially resemble umbilical granulomas
- May be sinuses of the vitelline duct or urachus
- Differ from granulomas
 - Larger
 - Bright red
 - Not responsive to treatment with silver nitrate

DIFFERENTIAL DIAGNOSIS

- Variations may be linked to specific dysmorphic syndromes.
 - Aarskog-Scott syndrome: prominent, protruding, pouting
 - Achondroplasia: low placement
 - Bladder exstrophy: low placement
 - Cloacal exstrophy: low placement
 - Cornelia de Lange syndrome: hypoplasia
 - Rieger syndrome: prominent, broad, redundant periumbilical skin
 - Robinow syndrome: high placement, broad, scar is poorly epithelialized
- Conditions associated with umbilical hernias
 - Chromosomal anomalies
 - Trisomy 21
 - Trisomy 18
 - Deletion 9p
 - Duplication 3q
 - Metabolic disorders
 - Hypothyroidism
 - Mucopolipidosis III (pseudo-Hurler syndrome)
 - Mucopolysaccharidoses
 - Type 1 (Hurler syndrome)
 - Type 2 (Hunter syndrome)
 - Type 4 (Morquio syndrome)
 - Type 6 (Maroteaux-Lamy syndrome)
 - Dysmorphic syndromes
 - Aarskog syndrome
 - Beckwith-Wiedemann syndrome
 - Fetal hydantoin syndrome
 - Marfan syndrome
 - Opitz syndrome
 - Weaver syndrome

LABORATORY FINDINGS

- Presence of urachal fistula can be documented by the presence of methylene blue dye in urine after dye has been instilled at the umbilicus.
- Diagnosis of umbilical polyps depends on histologic examination.

IMAGING

- Gastrointestinal radionuclide scans using 99m technetium pertechnetate
 - To detect embryonic umbilical remnants lined with gastric mucosa

- Sonography or computed tomography
 - Helpful in delineating vitelline cysts that exhibit as abdominal masses after onset of infection

TREATMENT APPROACH

- Treatment of all symptomatic internal umbilical cord remnants is surgical excision and repair.

Urinalysis and Urine Culture

BACKGROUND

- Examination of the urine is a simple and efficient office procedure that may detect or evaluate for renal, urinary tract, and systemic disorders.
 - A first-morning, midstream, clean-catch specimen is most reliable.
 - Usually only needed in symptomatic children to aid in diagnosis
 - Important in evaluating the child with renal symptoms
 - Should be considered in patients with vague signs and symptoms, because some renal disorders may exhibit in such nonspecific ways
 - Less useful as a screening procedure in asymptomatic patients than in patients with symptoms

GOALS

- Several principles need to be considered in screening for abnormalities in the urine.
 - A screening test should be reliable and accurate.
 - Screening should be done for conditions that can be diagnosed with certainty and benefit from early diagnosis and treatment.
 - A screening test should be cost effective for the individual and the general population.
- Early discovery of a symptom-free child who has renal disease may prove to be beneficial.
 - The cost-effectiveness to society of mass screening in young children remains unproven.
- Current data do not support the current practice of routine screening urinalysis.
 - High degree of sensitivity
 - Lack of specificity (ability to minimize false-positive results)
 - The low prevalence of end-stage renal disease in children limits the positive predictive value of screening for hematuria or proteinuria.

GENERAL APPROACH

- Recommendations for urine screening have evolved over time.
 - The majority of pediatricians conduct screening urinalyses frequently.
 - The AAP and Bright Futures practice guidelines recommend:
 - Complete urinalysis at 5 years of age
 - Annual urinalysis for sexually active adolescents
 - Bright Futures also recommends that complete urinalysis be performed at least once during adolescence even if the individual is not sexually active.
 - This policy is currently under review by the AAP and may be changed in the near future.

- Findings that can help diagnose and manage a pathologic condition
 - Presence of heavy proteinuria
 - Nephrotic syndrome or other significant renal disease
 - Hematuria
 - Glomerulonephritis
 - Glucosuria
 - Diabetes mellitus
 - Leukocyte esterase or nitrites
 - Urinary tract infection (UTI)
- When to refer
 - Persistent proteinuria (first morning void)
 - Gross hematuria of unknown cause
 - Persistent hematuria associated with proteinuria or hypertension
 - Hematuria suggested to be of lower urinary tract origin, accompanied by elevated serum glucose level
 - Physician discomfort with diagnosis and management
 - Family reassurance

SPECIFIC INTERVENTIONS

Proteinuria

- Detected most easily by the dipstick method
- The presence of protein causes a change in indicator color from yellow to blue-green.
 - Proportional to the amount of protein present
 - Albumin causes the color to change more readily than do other proteins.
 - Does not usually detect the small quantity of protein that healthy persons normally excrete.
- Sensitivity of detecting proteinuria with a urine dipstick ranges from 83.9–95.1%.
- Specificity ranges from 93.8–95.5%.
- False-positive findings can occur in:
 - Alkaline urine
 - pH >6.5
 - Urine contaminated by skin antiseptics, including chlorhexidine or benzalkonium chloride
- Urine concentration also affects dipstick results and should be taken into consideration.
- Results are considered to be persistent if:
 - Dipstick is positive ($\geq 1+$) for ≥ 2 of 3 random urine specimens collected ≥ 1 week apart
 - Quantifying proteinuria using the protein-to-creatinine ratio on a random urine sample is recommended.
 - A ratio ≥ 0.2 mg protein per mg creatinine is considered abnormal for children ≥ 2 years.

- This method is suggested because accurately obtaining a 24-hour urine collection in children can be difficult.
 - The prevalence rate in the symptom-free pediatric population depends on the definition of proteinuria used.
 - Prevalence increases with age and is greater in girls than it is in boys.
 - The prevalence of proteinuria can range from <1% in 6-year-old boys to as high as 6% in adolescent girls using less stringent criteria.
 - If more strict criteria are used (2+ on each dipstick with ≥ 2 performed), prevalence decreases considerably.
 - 0.2–0.45% in boys
 - 1–1.6% in girls
 - More than 50–75% of symptom-free patients found to have protein in a single urinalysis will have normal urine on repeat testing.
 - Of those having several positive random urinalysis results, $\geq 60\%$ will have orthostatic proteinuria.
 - Not considered to be a harbinger of clinically significant renal disease
 - Regular follow-up is important.
 - Changes in the pattern of protein excretion
 - Appearance of hematuria
 - Follow-up care
 - Spontaneous resolution occurs in $>40\%$ of cases within 4 years.
 - Identifiable renal disease is present in 1 per 1000 children screened.
 - Asymptomatic children who have proteinuria without hematuria are not likely to have overt renal disease.
 - Patients with hematuria and proteinuria have high rates of significant parenchymal renal disease.
 - Isolated cases of significant renal disease can sometimes exhibit solely with proteinuria in the asymptomatic child.
 - Significant glomerular changes which progress with time to chronic renal impairment
 - Focal segmental glomerulosclerosis
 - Immunoglobulin A (IgA) nephropathy
 - Mesangial proliferative glomerulonephritis
 - Membranous glomerulonephritis
 - Pyelonephritic scarring
 - Most children with significant renal disease will have other signs and symptoms.
 - These symptoms cause them to seek medical care and thus can be identified even in the absence of urine screening.
 - High sensitivity and low specificity of screening for proteinuria in asymptomatic children can produce undue anxiety in patients and parents.
 - Can direct the practitioner to perform more invasive testing
 - Often provides no new information
 - May detract from the overall well-being of the population
 - May be costly
 - Currently, less enthusiasm is found for mass screening for proteinuria in symptom-free children.
 - Satisfactory compromise for the health of children is to screen a first morning urine at 5 years of age.
 - First morning urine avoids the identification of children with orthostatic proteinuria.
 - In the case of persistent proteinuria:
 - Meticulous examination of fresh urinary sediment should precede any additional laboratory evaluation.
- ### Hematuria
- Not all discolored urine indicates hematuria.
 - Urine can be discolored by many substances.
 - The presence of blood should be confirmed by dipstick for symptoms of gross hematuria.
 - Dipstick is highly sensitive.
 - Reacts to hemoglobin levels as low as 0.015–0.062 mg/dL
 - Sensitivity of the dipstick for blood is 85–100%.
 - Specificity is 86.3–99.3%.
 - False-positive tests for blood in the urine may result from:
 - Presence of oxidizing cleansing agents
 - Povidone-iodine or hypochlorite
 - Microbial peroxidases
 - False-negative tests may be caused by the presence of large amounts of a reducing agent.
 - A positive dipstick result for blood:
 - Does not discriminate between hemoglobin and myoglobin from muscle
 - Differentiation requires spectrophotometric analysis.
 - Does not differentiate hemoglobinuria from hematuria or whether the blood originates from the upper or lower urinary tract
 - Microscopic examination of the centrifuged urine sediment
 - Dipstick-positive, red, or cola-colored urine without red blood cells (RBCs) on microscopic examination is diagnostic of free hemoglobin or myoglobin in the urine.

- In presence of RBC casts, proteinuria, brown or tea-colored urine, and dysmorphic RBCs, glomerular bleeding (upper tract) is suggested.
- Red or pink urine or clots usually indicate lower urinary tract bleeding.
- The prevalence of microscopic hematuria in an ambulatory setting
 - 2–6% when a single urinalysis is abnormal
 - Approximately 1% when >1 urinalysis is positive
 - Persists >6 months in <0.5% of these cases
 - The annual incidence of new cases is 0.4%.
 - Defined as at least 5 RBCs/high-power field
 - No consistent trends exist for age, sex, and race dependence of hematuria.
- Few children whose hematuria was detected in screening programs are found to have significant renal or urologic disease.
- Hematuria persisting for >6 months is more likely to be associated with renal disease if patient has:
 - ≥1 episode of gross hematuria or proteinuria
 - Family history of hematuria in a first-degree relative
 - The most likely diagnoses in these cases are:
 - IgA nephropathy thin basement membrane disease
 - Alport syndrome (hereditary nephritis)
- In a review of studies of screened, symptomless microhematuria
 - IgA nephropathy was found in 2–21% of biopsies.
 - Other glomerular lesions were much less frequent.
 - The most common nonglomerular finding was asymptomatic UTI (4.8–6.0%).
 - Less common were ureteropelvic junction obstruction and reflux nephropathy.
- In more recent follow-up studies of children referred for isolated hematuria, the most common underlying diagnosis (11–16%) was hypercalciuria.
- Screening for hematuria is limited by low specificity.
 - Potential value exists in identifying patients at risk for renal disease in patients with:
 - Symptoms
 - Gross hematuria, especially if recurrent
 - Proteinuria
 - A positive family history
- Persistent isolated microscopic hematuria
 - A careful examination of fresh urinary sediment and microscopic analysis should precede any additional laboratory evaluation for asymptomatic children.
 - The great majority of these children will not have clinically significant disease.
 - Continued observation without work-up is appropriate.

Glucosuria

- Can be detected by glucose oxidase-impregnated dipsticks
 - Glucose is not detectable in the urine when the plasma glucose level is <180 mg/dL.
 - Seen most commonly when the filtered load of glucose is increased as a result of hyperglycemia in diabetes mellitus
 - Less often, a defect can be found in proximal tubular reabsorption that may be selective, or may be part of a more generalized proximal tubular dysfunction.
 - Measurement of blood glucose will help differentiate among these conditions.
 - Observed in the latter stages of tubular destruction seen in a variety of chronic kidney diseases
 - Urinalysis usually also shows proteinuria, and the urinary sediment may contain renal tubular cells and casts.
- Urine screening reveals a prevalence of glycosuria that is <0.1%.
 - Up to 10–50 previously undetected cases of diabetes mellitus per 100,000 children could be identified.
 - New-onset diabetes mellitus is much more likely to produce classic symptoms of polyuria and polydipsia. (See Diabetes Mellitus.)
 - Rarely cases of renal glucosuria, Fanconi syndrome, and other tubular dysfunction may be identified.
 - The cost-effectiveness of screening asymptomatic patients for glucosuria is low.
 - Not recommended for routine visits

Bacteriuria

- Defined as growth of >100,000 colony-forming units/mL in ≥2 consecutive urine specimens in a child who has no other symptoms of infection at a regular checkup
- Prevalence of asymptomatic bacteriuria in school-age children is:
 - 1–2% in girls
 - 0–0.1% in boys
- In a child with symptoms consistent with a UTI, the presence of leukocyte esterase or nitrites generated by gram-negative organisms from nitrates will increase suspicion for bacteriuria.
- Nitrites are extremely specific to bacteriuria.
 - Specificity of 98%
 - Sensitivity of 50%
- Leukocyte esterase is much more sensitive.
 - Specificity of only 78%
 - Sensitivity of 84%
- When either leukocyte esterase or nitrite is positive:
 - Sensitivity is 88%.
 - Specificity is 93%.

- When both leukocyte esterase and nitrites are positive:
 - Sensitivity is 72%.
 - Specificity is 96%.
- Dipstick detection of leukocyte esterase or nitrites is variable depending on the method of collection and the age of patient.
 - In 1 study:
 - The sensitivity of bag-collected urine was 85%.
 - Catheter-collected urine samples had a sensitivity of 71% in non-toilet-trained children.
 - The specificity of bag-collected urine was 62%.
 - The specificity of catheter-collected urine was 97%.
 - The sensitivities of the 2 methods are decreased by approximately 20% in infants <90 days.
- When investigating a possible UTI with urinalysis:
 - The AAP has provided guidelines on the use of bagged urine specimens for analysis.
 - A negative result can be trusted, and no further invasive collection of urine is needed.
 - The following bagged urine sample results require that another urine sample be obtained via more invasive measures for urine culture before starting antibiotic therapy.
 - Positive leukocyte esterase or nitrites
 - A positive Gram stain
 - >5 leukocytes per high-power field
- Asymptomatic or covert bacteriuria in school-age girls
 - Nontreatment does not influence episodes of:
 - Symptomatic UTI
 - Renal growth
 - Renal function in normal or scarred kidneys
 - Treatment of asymptomatic bacteriuria may be associated with:
 - A greater risk for pyelonephritis because of development of more pathogenic and resistant organisms
 - Antibiotic treatment does not prevent further renal scarring once it has occurred or restore poor renal growth.
- Child with signs and symptoms consistent with UTI
 - Physician should have a low threshold for obtaining a diagnostic urinalysis.
 - Positive results should be confirmed by urine culture and treated.
- Screening of asymptomatic patients for asymptomatic bacteriuria is not recommended.
 - If asymptomatic bacteriuria is discovered, it should not be treated.
- Persistent bacteriuria should be more thoroughly evaluated.
 - Obtain a careful history for renal and urinary tract symptoms.
 - Assess growth and blood pressure.
 - Consider obtaining renal ultrasonography.

Urinary Tract Infections

DEFINITION

- Urinary tract infection (UTI) is a common childhood infectious disease.

EPIDEMIOLOGY

- Incidence
 - ~2–8% of children experience at least 1 UTI episode by 10 years of age.
- Age
 - Highest incidence in children <1 year of age
 - ~30% of children <12 months of age are affected by recurrent infections.
 - 85% of recurrences occur within 6 months after the primary episode.
 - Febrile UTI (pyelonephritis) is more common in children <12 months.
 - Cystitis mostly occurs in older children.
- Sex
 - Boys constitute the majority of infants ≤6 months of age.
 - Girls more commonly have UTIs beyond 6 months of age.
 - In school-age children, symptomatic UTI is 5 times more common in girls than boys.
 - Recurrence rates do not differ significantly between boys and girls.

ETIOLOGY

Community-acquired infections

- *Escherichia coli*
 - Occurs naturally in feces
 - Responsible for >75% cases of community-acquired UTI
- *Enterococcus*
- *Klebsiella*
- Coagulase-negative *Staphylococcus*
- *Proteus*
- Other commonly occurring pathogens
 - Each accounts for ~3–5% of cases.
- Genotypic analysis of pathogens causing second-time UTIs
 - 65% of recurrences caused by same pathogen as the first episode of UTI
 - Anatomic abnormalities of urinary tract significantly more frequently among patients with:
 - Non-*E coli* UTI
 - Infections caused by nonvirulent *E coli* strains

Non-community-acquired and unusual infections

- Non-*E coli* organisms should be considered possible causes of UTI in sexually active adolescents.
 - *Neisseria gonorrhoeae*
 - *Chlamydia trachomatis*

- Common pathogens causing nosocomial infections
 - Multidrug-resistant *E coli* strains
 - Non-*E coli* pathogens, eg, *Candida*
- The majority of nosocomial infections are associated with:
 - Urinary tract instrumentation
 - Catheterization
- Thus critically ill children are especially prone to UTI.
- Fungal infections are significant in:
 - Immunocompromised patients
 - Diabetic patients
- Fungal overgrowth may complicate antibiotic treatment of immunologically normal children with:
 - Abnormal urinary tract emptying
 - Indwelling urinary catheters
- Viral uropathogens are relatively uncommon, except for adenovirus infections in patients with acute hemorrhagic cystitis.
- Adenovirus, polyomavirus, cytomegalovirus
 - Can cause UTI and hemorrhagic cystitis in immunocompromised patients
 - Especially those undergoing solid organ or bone marrow transplantation
- Protozoan infections of the urinary tract are important in many parts of the world.
 - Uncommon in the United States
- Urinary infections with *Mycobacterium tuberculosis* occur rarely in secondary tuberculosis.
 - Should be considered when sterile pyuria is found in a suspect clinical setting
 - Prevalence of tuberculosis is increasing in the US.

Bacterial virulence factors

- Uropathogenicity of the bacteria depends on:
 - Presence of virulence genes, which determines their adhesive capacity
 - Resistance to host defense mechanisms
 - Ability to cause tissue damage by toxin production
- These factors influence:
 - Severity of symptoms, such as fever and dysuria
 - Long-term effects of UTI, such as renal cell damage and scarring

RISK FACTORS

- Constipation
- Encopresis
- Not circumcised
- Bladder dysfunction (detrusor instability)

SIGNS AND SYMPTOMS

History

- Clinical presentation of UTI depends on:
 - Age of the child
 - Virulence of underlying pathogen
 - Inflammatory response of the host
- Symptoms most often associated with UTI
 - Dysuria
 - Frequency
 - Urgency
 - Lower back pain
- Symptoms of UTI are variable and nonspecific in young children, especially infants.
- Bacteremic UTI can be clinically indistinguishable from other types of infection in very young children.
- Small children usually cannot:
 - Localize pain
 - Report precise symptoms
- By 4 years, their capability improves to report more specific symptoms.
 - Abdominal pain
 - Pain at micturition
- Fever is the most prominent and often the only clearly recognized sign of UTI in children.
- With some caveats, fever can be used as a rough estimate of the level of UTI.
 - Body temperature $<38^{\circ}\text{C}$ suggests cystitis.
 - Temperature $\geq 38.5^{\circ}\text{C}$ is most often associated with upper UTI.

Physical examination

- Findings of UTI vary depending on severity of the infection.
- In infants, findings are nonspecific and rarely suggestive of a definitive diagnosis.
- In addition to fever, other findings suggestive of septicemia can be seen in young infants, including:
 - Irritability
 - Abnormal crying
 - Peripheral cyanosis
 - Hypothermia
 - Long capillary filling time
- Tenderness on palpation of the abdomen in the suprapubic region can be found with cystitis.
- Costovertebral angle tenderness is elicited with pyelonephritis in older children.
- An absence of typical findings does not rule out the possibility of UTI.

- Examination of the urethral meatus should be included in the examination of every child with suspected UTI.
- In some cases, dysuria can be caused by local inflammation or irritation of external genitalia.
 - External genitalia in girls should be examined carefully.
 - Labial adhesions are often associated with UTI.

DIFFERENTIAL DIAGNOSIS

- UTI should be included in the sepsis workup of seriously ill infants and younger children.
- UTI should always be considered as a possible cause of unexplained fever.
- Fever can be an inconsistent finding.
 - In newborn infants, normal body temperature does not exclude the possibility of upper UTI.
 - Fever exists in only ~10–40% of UTI cases in children <2 years of age.
 - In these cases, other symptoms should be considered as indications for urine screening, such as:
 - Vomiting
 - Irritability
 - Abnormal crying
 - Lethargy
 - Failure to thrive
 - Feeding problems

DIAGNOSTIC APPROACH

- UTI should be suspected in infants and young children with unexplained fever.
- Thoroughly assess:
 - Degree of toxicity
 - Dehydration
 - Ability to retain oral intake
- If child is critically ill, a urine specimen should be obtained by:
 - Catheterization
 - Suprapubic percutaneous aspiration
- If the urinalysis suggests UTI, repeat urine collection by:
 - Catheterization
 - Suprapubic aspiration
- Correct diagnosis is crucial for successful treatment and follow-up of childhood UTI.
 - Incorrect diagnosis of UTI may lead to:
 - Missing a potentially harmful urinary tract abnormality
 - Unnecessary studies, costs, and stress
- UTI must be always confirmed by adequate urine collection and culture.

LABORATORY FINDINGS

Urine collection

- Adequate urine collection is essential for correct diagnosis.
 - To prevent contamination, all samples should be carefully collected, stored, and analyzed.
 - Sample collection at home is discouraged because of the high risk of contamination.
 - Urine samples should be kept at 4°C until cultured.
- Toilet-trained children and adolescents
 - A midstream urine sample is preferred for culture.
 - Before micturation, the periurethral area and surrounding skin should be washed and dried properly.
- Incontinent children
 - A urine bag or absorbent pad may be suitable for urine collection.
 - Urine contamination rates are similar for bag and pad (75% of positive cultures).
 - Contamination is significantly higher than for clean-catch urine, catheterization, or suprapubic aspiration.
 - A negative culture result from urine collected by bag or pad excludes UTI.
 - A positive culture result from a urine bag or urine pad sample should always be verified by:
 - Catheterization
 - Suprapubic aspiration
- Guidelines for suprapubic percutaneous aspiration
 - Indications
 - Verification of UTI in newborns and infants
 - Sepsis workup in critically ill children
 - Equipment
 - 21- to 25-gauge needle
 - 5- to 10-mL syringe
 - EMLA cream
 - Sterile gloves
 - Portable ultrasonography equipment
 - Technique
 - Put a small amount of EMLA cream on a circle area (~3 cm) ~2–3 cm above symphysis midline.
 - Wait about 30 minutes.
 - Set the child in a supine position.
 - Clean the patient's skin with antiseptic solution.
 - Insert the needle percutaneously at ~1 fingerbreadth above the symphysis pubis.
 - Advance slowly with continuous suction.
 - Usually urine is obtained at a depth of 2–3 cm.

- Complications
 - Generally safe and reliable
 - Occasionally transient hematuria (2–3%)
 - Intestinal puncture not harmful

Urine culture

- Diagnosis is confirmed by the growth of a single pathogen on urinary culture.
- The bacteria level considered significant depends on the method used for urine collection.
 - For voided samples (clean-catch urine, urine bag, and absorbent pad)
 - Bacterial count $\geq 100,000$ colony-forming units (CFU)/mL is considered significant.
 - Contamination risk for catheterization and suprapubic aspirate is considerably lower.
 - Any bacterial growth in suprapubic aspirate or a bacterial count $\geq 50,000$ CFU/mL in a catheter sample is indicative of UTI.
- If signs and symptoms strongly suggest UTI:
 - Lower bacteria counts ($\geq 10,000$ CFU/mL), particularly in the presence of pyuria, may be considered diagnostic.
- Urine cultures showing growth of ≥ 1 pathogen should be considered contaminated; a repeat sample is required before starting any treatment.

Urinalysis

- Urinalysis by itself is not sufficient to diagnose UTI.
 - Normal urinalysis does not rule out UTI.
 - If UTI is suspected, urine culture should always be sent despite normal urinalysis.
- Results of urine culture are not generally available on the same day the sample is collected.
- Urinalysis showing leukocyturia can support the diagnosis of UTI.
 - Leukocytes may be present in urine (pyuria) for several reasons besides UTI.
 - Pyuria is defined as ≥ 10 leukocytes/mcL in an uncentrifuged urinary specimen.
 - A count < 10 leukocytes/mcL is almost invariably associated with a sterile urine culture.
 - A count ≥ 10 leukocytes/mcL is found in 90% of patients with bacterial growth $\geq 50,000$ CFU/mL.
 - The dipstick leukocyte esterase test can be used for detecting urinary leukocytes.
 - This method has a low sensitivity in detecting:
 - ≥ 10 leukocytes/mcL (~53%)
 - ≥ 20 leukocytes/mcL (~67%)
- UTI can be an important cause of microscopic hematuria.
 - The presence of erythrocytes in urine does not have diagnostic or prognostic value.

- The combination of cell count and Gram stain can be:
 - More sensitive (87.7%)
 - More specific (99.2%)
- The combination of leukocyte esterase test and nitrite can improve:
 - Sensitivity (78.7%)
 - Specificity (98.3%)
- The nitrite test is usually positive if bacterial counts are high enough (>10 CFU/mL).
 - A positive nitrite test result usually requires bladder time ≥ 4 hours.

Determining location of UTI

- Reliable differentiation of upper UTI from lower UTI can be difficult.
- Pyelonephritis is suggested by:
 - Temperature $\geq 38.5^{\circ}\text{C}$
 - Increased C-reactive protein level (≥ 40 mg/L)
 - Leukocytosis
 - Infants may have afebrile bacteremic UTI.
- Several biomarkers are currently being evaluated as possible indicators of upper UTI.
 - Procalcitonin
 - Recently proposed as a possible indicator of pyelonephritis
 - Increased serum procalcitonin levels correlate significantly with renal parenchymal involvement in children with febrile UTI.
 - This method is not currently routinely available.
 - No correlation between level of UTI and serum electrolyte, creatinine, and blood urea nitrogen concentrations has been reported.
 - These parameters should be measured to assess level of hydration or other attendant complications in:
 - Children <12 months of age
 - Patients with febrile UTI
 - Patients with associated symptoms, such as vomiting or diarrhea

IMAGING

General

- Imaging studies of the urinary tract are recommended for children with first-time UTI to exclude:
 - Obstructive disorders
 - Vesicoureteral reflux (VUR)
 - Severe loss of renal parenchyma
 - Significant bladder abnormalities

- Imaging studies used in UTI include:
 - Renal ultrasonography (RUS)
 - Voiding cystourethrography (VCUG)
 - $^{99\text{m}}\text{Tc}$ mercaptosuccinic acid (DMSA) scan

Indications for imaging studies in children

- Ultrasonography
 - First-time UTI: age <2 years
 - Febrile UTI: all ages
 - Non-*E coli* UTI: all ages
 - Second episode of afebrile cystitis: age >2 years
- VCUG
 - First-time UTI: age <2 years
 - If ultrasonogram or DMSA scan (or both) is abnormal and suggestive of VUR: all ages
 - Consider if family history of VUR
 - Consider if recurrent pyelonephritis
- DMSA scan
 - Abnormal ultrasonogram (parenchymal thinning, suggestive of renal dysplasia or hypoplasia)
 - High-grade VUR
 - Consider before VCUG if febrile UTI and age >2 years
 - Consider if recurrent UTIs
- The AAP recommends that children <2 years with first-time UTI should be studied by:
 - Ultrasonography in the acute phase
 - Cystography or renal cortical scan thereafter as soon as possible
- Infants and children who do not demonstrate the expected clinical response within 2 days of antimicrobial therapy should promptly undergo:
 - Ultrasonography
- At the earliest convenient time, perform either:
 - VCUG *or*
 - Radionuclide scan
- Infants and young children who have the expected response to antimicrobials should have:
 - Ultrasonography
 - At the earliest convenient time, either:
 - VCUG *or*
 - Radionuclide scan
- The optimal time for VCUG is ~2–6 weeks after the infection.
- Recommendations about imaging studies after UTI in older children are:
 - More variable
 - Dependent on clinical presentation

- The probability of factors predisposing patient to renal damage is relatively low in children >2 years.
 - Imaging studies are recommended in this age group in the following scenarios.
 - Recurrent UTI
 - Non-*E coli* infection
 - Positive family history

RUS

- Least invasive, most widely available imaging modality
- Can be performed during the acute phase of UTI
- Can detect:
 - Dilated collecting system
 - Thinning of kidney parenchyma
 - Size of kidneys
 - Thickness and size of urinary bladder
- May not be able to detect:
 - VUR
 - Smaller renal scars
- Reliability is highly dependent on the experience of the ultrasonographer.
- Recent studies have suggested that results may have little or no influence on treatment, because of routine prenatal ultrasonography.
 - The need for ultrasonography after UTI has been questioned.
 - Widespread use of maternal-fetal ultrasonography in industrialized countries has possibly lessened the need for ultrasonography later in childhood.
 - Several studies have shown that a significant kidney or urinary tract abnormality may be missed despite prenatal RUS in 5–6% of children with first-time febrile UTI.

VCUG

- Traditionally used to diagnose VUR because VUR:
 - Predisposes patients to pyelonephritis and recurrent infections
 - May be associated with renal scarring
 - The incidence of VUR is highest in children <2 years of age.
- VCUG can be performed using:
 - Radiocontrast medium
 - Radiolabeled nuclides
- Contrast VCUG is usually preferred in boys.
 - More reliable than other methods in detecting urethral valves
 - Recommended as a baseline study in all children with first-time UTI
 - Allows more exact grading of reflux
- Isotope VCUG is recommended for follow-up studies.

- Cystography requires catheterization.
 - Relatively invasive and stressful, especially in older children
- Spontaneous resolution of VUR occurs in a high proportion of children.
 - Isotope VCUG is recommended every 1–3 years until resolution of VUR is documented.
- Some authors have suggested that VCUG be performed only on selected patients with abnormalities on DMSA scan.
 - This approach would reduce the number of VCUGs performed by ~50% without adding any major risk for the patient.
- VCUG should be performed only if:
 - Positive family history of VUR exists.
 - Urinary tract dilation is detected prenatally.
 - History is found of recurrent pyelonephritis.

DMSA scan

- One of the most reliable methods to differentiate pyelonephritis from lower UTI
- Radionuclide is taken up by renal tubular cells and provides information on:
 - Functional anatomy
 - Scarring of renal parenchyma
- More often abnormal in patients with documented reflux than in children without VUR
- Only 55–85% of children with febrile UTI have changes on radionuclide studies, such as DMSA scan.
 - Suggested as a gold standard for diagnosing pyelonephritis

CLASSIFICATION

- International classification of VUR
 - Grade I: involves only ureters
 - Grade II: involves ureters and intrarenal collecting systems
 - Grade III: mild ureteral and pelvic dilatation; no or slight obliteration of caliceal fornices
 - Grade IV: moderate ureteral and pelvic dilatation; clear obliteration of caliceal fornices
 - Grade V: gross dilatation of ureters and renal pelvis and calyces

TREATMENT APPROACH

- Initial antibiotics should be administered parenterally if the child with suspected UTI is:
 - Septic
 - Dehydrated
 - Unable to retain oral intake
- Antibiotic therapy should be initiated parenterally or orally in a child who:
 - May not appear ill
 - Has a urine culture confirming the presence of UTI

- Reevaluate infants and children who do not demonstrate expected clinical response within 2 days of antimicrobial therapy.
- Infants and young children should complete a 7- to 14-day antimicrobial course.
- After antimicrobial therapy and sterilization of urine:
 - Infants and young children should receive prophylactic antimicrobial doses until the imaging studies are completed.

SPECIFIC TREATMENTS

General

- Successful treatment includes:
 - Early recognition
 - Early, appropriate treatment
- Before initiating treatment, adequate samples of urine should be collected for:
 - Culture
 - Antibiotic sensitivities of organisms
- If the patient is septic or dehydrated:
 - Adequate rehydration should coincide with antibiotic therapy.
- Route of antibiotic administration (oral or parenteral) depends on:
 - Age
 - Clinical condition of patient

Pyelonephritis

- Infants <1 year are:
 - Hospitalized
 - Treated with parenteral antibiotics for ≥ 3 days
 - Followed by oral antibiotic therapy for 11 days (total of 14 days)
- Research has shown that oral antibiotics are as effective as parenteral antibiotics, even in young children with febrile UTI.
 - If the child does not appear septic and can tolerate oral medications:
 - Initial treatment with oral antibiotic might be appropriate.
 - Follow-up is essential to ensure complete recovery.

Cystitis

- Oral therapy alone is usually adequate to treat cystitis.
- First-line therapy for outpatient treatment of UTI
 - Trimethoprim-sulfamethoxazole (TMP-SMX)
 - Amoxicillin
- Other choices include:
 - Amoxicillin-clavulanate
 - First-generation cephalosporins, such as cephalexin
- 5 days of treatment with appropriate antibiotics is adequate.

Asymptomatic bacteriuria (ABU)

- Studies on infants and school-age girls have shown that untreated ABU does not increase the risk for:
 - Pyelonephritis
 - Renal damage
- Children treated with antibiotics for ABU can have a higher incidence of pyelonephritis than untreated children.
- Researchers have suggested that pathogens causing ABU have low virulence and may protect against overgrowth of uropathogenic bacteria.
- Current recommendations
 - Should not be treated with antibiotics in:
 - Children who use intermittent catheterization
 - Children with neurologic bladder dysfunction
 - These children frequently have ABU.
 - Asymptomatic
 - Often do not have leukocyturia

Antibiotic dosing

- Parenteral therapy
 - Ampicillin
 - 100 mg/kg/day divided every 6 hr
 - Amikacin
 - 15–22.5 mg/kg/day divided every 8 hr
 - Ampicillin-sulbactam
 - 100–200 mg/kg/day ampicillin divided every 6 hr
 - Cefepime
 - 100–150 mg/kg/day divided every 8 hr
 - Cefotaxime
 - 100–150 mg/kg/day divided every 8 hr
 - Ceftazidime
 - 100–150 mg/kg/day divided every 8 hr
 - Gentamicin
 - 5–7.5 mg/kg/day divided every 8 hr
 - TMP-SMX
 - 6–12 mg/kg/day TMP with 30–60 mg/kg/day SMX divided every 12 hr
- Enteral therapy
 - Amoxicillin
 - 30–40 mg/kg/day divided every 12 hr
 - Amoxicillin-clavulanate
 - 30 mg/kg/day divided every 12 hr
 - Cefixime
 - 8–16 mg/kg/day once daily or divided every 12 hr
 - Cephalexin
 - 40–50 mg/kg/day divided every 6–8 hr

- Cefpodoxime
 - 10 mg/kg/day divided every 12 hr
- Methenamine mandelate
 - 40–50 mg/kg/day divided every 8–12 hr
- Nitrofurantoin
 - 5–7 mg/kg/day divided every 6 hr
- Sulfisoxazole
 - 150 mg/kg/day divided every 6 hr
- TMP-SMX
 - 6–12 mg/kg/day TMP with 30–60 mg/kg SMX divided every 8–12 hr

WHEN TO ADMIT

- Suspected urosepsis
- Infant <3 months of age with UTI
- Suspected UTI in a dehydrated patient or a patient who cannot retain oral fluids.
- Patients whose symptoms worsen or do not improve despite oral treatment

WHEN TO REFER

- Abnormal findings on imaging
- Frequently relapsing UTI
- Suspicion of voiding dysfunction

FOLLOW-UP

- After the first UTI, prophylactic antibiotics are started and continued until imaging studies are performed.
- Patients with VUR need to be continued on prophylactic antibiotics and should have regular follow-up and repeat VCUG to determine the status of VUR.

COMPLICATIONS

- Association of anatomic abnormalities in the kidneys or in the urinary tract is increased in children with UTI.
 - Risk is higher in children with non-*E coli* UTI versus those with *E coli*-associated UTI.
- Renal scarring
 - Isotope uptake studies (DMSA scans) have shown that the renal parenchyma is affected in ~55–75% of children with febrile UTI.
 - ~20–40% of these children will develop permanent renal parenchymal damage (renal scarring).
 - In some cases, renal disease may be congenital rather than acquired and not dependent on UTI.
 - In an analysis of 1221 children with first-time UTI, the incidence of permanent renal damage was:
 - 86% in boys
 - 30% in girls

- The mean age of boys at the time of UTI was significantly lower compared with girls.
- VUR was present in:
 - 67% of boys (higher incidence of congenital renal disease and damage to the kidney parenchyma)
 - 19% of girls (renal damage is acquired and results from UTI)
- Infants (mean age 4 months) with high-grade VUR without UTI have fewer scars than patients with VUR with a history of UTI.
- It may be difficult to determine the exact cause of renal dysfunction in children with high-grade VUR, UTI, and renal damage.
- Contributing factors include congenital factors, reflux, and infection.
- Risk factors for renal parenchymal damage include:
 - Gross VUR
 - Young age at the time of first infection
 - Delayed initiation of treatment
 - Recurrent infections
- Incidence of complications after UTI can be dramatically reduced by:
 - Thorough radiologic investigation of young children with UTI
 - Appropriate treatment
 - Follow-up
- Long-term effects of UTI
 - Risk of permanent renal damage
 - May increase risk of hypertension
 - May ultimately cause varying degrees of renal failure
 - Increased risk of preeclampsia during pregnancy
 - Risk for end-stage kidney disease is relatively small in children with UTI.
 - According to the North American Pediatric Renal Trials and Collaborative Studies:
 - Pyelonephritis or interstitial nephritis accounts for renal failure in only 1.8% of all patients who require renal transplantation.
 - Obstructive uropathy accounts for renal failure in 16.1%.
 - Renal hypoplasia or dysplasia accounts for renal failure in 16%.
 - Reflux nephropathy accounts for renal failure in 5.2%.
 - Anatomic abnormality with or without UTI is a more important threat for kidney function than UTI itself.
 - Hypertension has been shown to be a significant long-term complication of childhood febrile UTI associated with renal scarring.
 - Exact risk ranges from 6–23%.

- Lower incidences of hypertension may be the result of increased awareness of risk factors related to childhood UTI.
- Remains an important long-term complication of childhood UTI
- Incidence may be decreased by careful attention to risk factors and early treatment.
- Bacteriuria and symptomatic UTI are significantly more frequent in pregnant women with history of childhood UTI.
- UTI may contribute to increased risk to preeclampsia (hypertension and proteinuria).
 - May be harmful to the fetus
 - Can cause premature labor

PREVENTION

Prophylaxis

- Recommended for all children after their first UTI until imaging studies are performed
- Thereafter, prophylaxis should be considered for children with an increased risk of UTI.
 - Children with higher grades of VUR (higher than grade II)
 - Children with obstructive uropathy and a history of UTI
 - Children with recurrent UTIs (>2 per year)
- The most common prophylactic regimen is:
 - Co-trimoxazole (TMP-SMX [2 mg/kg TMP with 10 mg/kg/day SMX once every night])
 - Nitrofurantoin (1–2 mg/kg/day) as a single daily bedtime dose
- Duration of prophylaxis depends on indication.
- In children with VUR, prophylaxis is usually continued until:
 - Reflux has resolved spontaneously.
 - Reflux has been surgically corrected.
 - The child has been free of symptoms and bacteriuria for ≥ 1 year.

Dosing

- Amoxicillin
 - 10–15 mg/kg once daily at bedtime
- Amoxicillin-clavulanate
 - 25 mg/kg once daily at bedtime
- Cephalexin
 - 12–15 mg/kg once daily at bedtime
- Nitrofurantoin
 - 1–2 mg/kg once daily at bedtime
- Sulfisoxazole
 - 50 mg/kg once daily at bedtime
- TMP-SMX
 - 2 mg/kg TMP with 10 mg/kg/day SMX once every night

Supplemental therapy

- Constipation and encopresis are known to be risk factors for UTI.
 - Anticipated in children with recurrent UTI
- Treatment of these problems is important to prevent recurrent UTI by:
 - Dietary modification
 - Medication
- The role of circumcision in preventing UTI has been studied.
 - Relative risk of UTI in uncircumcised male infants compared with circumcised male infants is increased from 4-fold to as much as 10-fold during the first year of life.
 - Absolute risk of UTI in an uncircumcised male infant is low (at most, ~1%).
 - Currently, data are not sufficient to recommend routine neonatal circumcision.

Vaginal Bleeding

DEFINITION

- Assessing vaginal bleeding depends largely on the pubertal status of the patient.

MECHANISM

- In prepubertal girls, vaginal bleeding probably reflects a localized problem in the vagina or uterus.
- In pubertal girls and young women, bleeding can be caused by:
 - Disorders affecting the hypothalamic-pituitary-ovarian axis
 - Complications of pregnancy
 - Local causes

HISTORY

- Most causes of vaginal bleeding or abnormal uterine bleeding can be ruled out by history and physical examination.
- Maternal support during the initial history taking can be useful.
 - Many mothers track the menstrual periods of their daughters in the early years and are acutely aware of:
 - Quantity of bleeding based on the amount of feminine products purchased and stained laundry
 - Evidence of fatigue
 - General activity level and behavior
 - Mothers can also provide detailed family medical histories for:
 - First-degree female relatives
 - Their daughters
- Key aspects of the history may be difficult to obtain, ie, sexual intercourse or sexual abuse.
- The patient should be interviewed alone regarding:
 - Sexual activity
 - Occasionally, a small amount of bleeding or spotting may follow sexual intercourse.
 - Sexually transmitted infections and associated symptoms, such as:
 - Cramping
 - Vaginal discharge
 - Dyspareunia
 - Abuse
 - Stress
 - Weight changes and eating habits
 - Participation in sports and other activities
 - Chronic illnesses
 - Other bleeding problems
 - Medication use (particularly contraceptives)
 - Substance use

- Menstrual pattern
 - Is there bleeding between normal periods?
 - Have previously regular menses become more frequent or heavier?
 - A teenager whose prior menses have been regular might begin to have infrequent but heavy menstrual bleeding.
 - Likelihood of a coagulopathy or another pathologic condition is increased by:
 - Heavy bleeding at menarche
 - Significant anemia
 - Need for hospitalization to control the bleeding
- In general, normal periods in adult women are:
 - 28 days apart (measured from the first day of one period to the first day of the next)
 - Range of 21–45 days
 - Flow of 3–7 days
 - Flow >1 week is considered excessive.
 - A similar cycle pattern is observed in adolescent girls.
 - Cycle length is more variable especially in the first few years after menarche.
 - Some women will have spotting around the time of ovulation.
- Normal blood loss during menses
 - 30–40 mL
 - Upper limit of 80 mL
 - Quantity of blood loss is difficult to assess by history unless bleeding is scant.
 - The patient should describe the number of pads or tampons used.
- Changes related to hormonal contraceptive use
 - Bleeding between periods is common during the first 2 or 3 cycles of oral contraceptive use.
 - Teenagers who forget to take 1 or 2 oral contraceptive pills may experience bleeding.
 - Depot medroxyprogesterone acetate (Depo-Provera) injections
 - Associated with frequent and irregular periods of excess bleeding, particularly in the first months after beginning use
- Complete family history
 - Important to determine whether other family members have any kind of bleeding problem
 - Family history is a better predictor of coagulopathy than menstrual history.

PHYSICAL EXAM

- Make sure that the bleeding is vaginal in origin.
 - A prolapsed urethra can mimic vaginal bleeding.

Prepubertal girls

- Any suggestion of sexual abuse
 - Careful, nonthreatening questioning of the child or care-taker may reveal necessity for a referral to child protective services for a forensic interview and examination.
 - Bruises
 - Hymenal tears
 - Other signs of trauma
- Nighttime pruritus
 - May indicate a pinworm infestation
 - The Scotch tape slide test to look for pinworm eggs can help establish *Enterobius vermicularis* infestation.
- Petechiae or numerous bruises
 - Possible coagulopathy
- Foreign body in the vagina
 - Should always be considered, even if no history of such exists
- Excoriation, erythema, or a rash in the perineal area
 - Vaginitis is a distinct possibility.
 - Microscopic examination of vaginal discharge demonstrates large numbers of leukocytes.
 - Diarrhea in the weeks preceding onset of the bleeding suggests vaginitis caused by *Shigella* organisms.
 - Group A β -hemolytic streptococcus can also cause vaginitis.

Pubertal girls

- Normal findings help rule out many causes of vaginal bleeding or abnormal uterine bleeding.
 - Height
 - Weight
 - Blood pressure
 - Thorough palpation of the thyroid gland
 - Pelvic examination
 - Fundoscopic and visual fields examinations to exclude prolactinoma
- Endocrine disorders are indicated by:
 - Increased facial hair
 - Polycystic ovaries
 - Adrenal tumor
 - Cold intolerance
 - Hypothyroidism
 - Polyuria
 - Pituitary tumor
 - Nipple discharge
 - Hyperprolactinemia
 - Headache
 - Pituitary tumor

- Acne
 - Polycystic ovaries
 - Adrenal tumor
- Striae
 - Cushing disease
- Enlarged clitoris
 - Androgen-secreting tumor
 - Late-onset 21-hydroxylase deficiency
- Vulvar or vaginal bruising or lacerations
 - Probable sexual abuse
- Lack of adnexal or cervical motion tenderness
 - Excludes pelvic inflammatory disease
- Ovaries of normal size
 - Ovarian tumors or cysts are unlikely
- Uterus size
 - Minimal enlargement consistent with early pregnancy may not be noted by an inexperienced examiner.
 - Endometrial polyps or submucosal leiomyomas (unusual in women <20 years) cannot be palpated by the examiner on the usual pelvic examination.
- Crampy lower abdominal pain
 - Possible ectopic pregnancy
 - Incomplete or spontaneous abortion
 - History of 1 or 2 missed periods
 - Prior menstrual period lighter than normal
 - Tissue present in the vaginal canal or history of passing tissue
 - Other symptoms of pregnancy (breast tenderness or nausea)
- Foul-smelling and bloody discharge
 - Foreign body or retained tampon is likely.
 - Necrotic tumors can result in similar bleeding patterns
- Pruritus or dysuria
 - Vaginitis (*Trichomonas vaginalis*)
 - Cervicitis (*Neisseria gonorrhoeae* or *Chlamydia trachomatis* infection)

DIFFERENTIAL DIAGNOSIS

- Pubertal girls and young women
 - Most teenagers who seek evaluation for genital bleeding in the first few years after menarche will have dysfunctional uterine bleeding (DUB).
 - DUB is abnormal bleeding not resulting from uterine disease, medications, systemic illness, or pregnancy.
 - DUB is considered a diagnosis of exclusion.
 - Disorders affecting the hypothalamic-pituitary-ovarian axis can mimic DUB.

- Systemic disease
 - Renal failure
 - Hepatic failure
 - Cancer
 - Sexually transmitted infection
 - Conditions of the reproductive tract
 - Vagina
 - Vaginitis
 - Trauma
 - Foreign body
 - Congenital anomaly (septum)
 - Neoplasia
 - Cervix
 - Cervicitis, erosion
 - Cervical polyp
 - Neoplasia
 - Uterus
 - Endometritis
 - Endometrial polyp
 - Submucosal leiomyoma
 - Arteriovenous malformation
 - Congenital anomaly
 - Neoplasia
 - Pelvis
 - Endometriosis
 - Pelvic inflammatory disease
 - Pregnancy complications
 - Spontaneous abortion
 - Ectopic pregnancy
 - Retained gestational products
 - Trophoblastic disease
 - Endocrine disorders
 - Hypothalamus, pituitary
 - Immature hypothalamic-pituitary-ovarian axis
 - Hyperprolactinemia
 - Anorexia nervosa, malnutrition
 - Excessive exercise
 - Emotional stress
 - Chronic illness
 - Adrenal
 - Congenital adrenal hyperplasia
 - Cushing disease
 - Adrenal insufficiency
 - Neoplasm
 - Thyroid
 - Hypothyroidism
 - Hyperthyroidism
 - Ovary
 - Polycystic ovary syndrome
 - Luteal phase abnormality
 - Premature ovarian failure
 - Neoplasia (hormone secreting)
 - Coagulation disorders
 - von Willebrand disease
 - Immune thrombocytopenia
 - Other causes
 - Disorders of platelet function (Glanzmann thrombasthenia, Bernard-Soulier syndrome)
 - Leukemia
 - Iatrogenic
 - Hormonal medications
 - Anticoagulants
 - Neuroleptics
 - Intrauterine contraceptive device
- ### LABORATORY EVALUATION
- For most cases of vaginal bleeding, relatively few laboratory tests are needed.
 - Complete blood count with indices
 - Provides an objective measurement of the amount and duration of bleeding
 - Determines whether significant blood loss resulting in anemia has occurred
 - Guides the treatment approach for patients with an otherwise negative evaluation
 - Urinalysis
 - Urine pregnancy test
 - Quantitative serum pregnancy test also should be obtained if ectopic pregnancy is suspected.
 - Cultures in sexually active patients or where there is concern for sexual abuse
 - *N gonorrhoeae*
 - *C trachomatis*
 - *Trichomonas*
 - Bacterial vaginosis
 - Coagulation tests (prothrombin time, partial thromboplastin time, von Willebrand panel) if the patient has:
 - Profuse hemorrhage
 - Menorrhagia at menarche
 - Family history of bleeding disorders
 - Unexplained heavy vaginal bleeding

- If hormonal therapy is contemplated:
 - Thyroid-stimulating hormone function tests
 - Prolactin
 - Luteinizing hormone and follicle-stimulating hormone
 - Coagulation tests
- Patients with any evidence of hyperandrogenism:
 - Free and total testosterone
 - Dehydroepiandrosterone sulfate

IMAGING

- Pelvic sonography when:
 - Ectopic pregnancy is suspected.
 - The patient has a pelvic mass on bimanual examination.
 - Pelvic examination is difficult.

DIAGNOSTIC PROCEDURES

- Endometrial biopsy: rarely indicated
- Dilation and curettage: rarely indicated
- Transvaginal ultrasonography: pelvic mass on bimanual examination

TREATMENT APPROACH

- Most cases of vaginal bleeding in adolescent girls are caused by DUB.
 - In other instances, the clinician must manage the bleeding without knowing the cause.
 - Treatment decisions can be guided using:
 - The patient's clinical symptoms
 - Results of basic laboratory testing
- If treatment of the presumed cause does not end the bleeding, referral for a more thorough examination is indicated.

SPECIFIC TREATMENT

Infants

- After birth, estrogen levels in the infant decrease.
 - The result is a physiologic vaginal discharge that can be blood tinged or frankly bloody.
 - No treatment, except reassurance, is necessary.
 - The discharge usually disappears within 10 days.

Foreign bodies or vulvitis

- Removal of the foreign body
 - Foreign bodies can often be washed out with a soft, flexible catheter.
 - Sharp objects should be removed carefully, under direct visualization.
 - Referral to a gynecologist may be required if the patient is uncooperative.

- After removing a foreign body, bleeding should subside within 10 days.
 - If not, referral to a gynecologist is indicated.
 - The entire foreign body may not have been removed.
 - A tumor, not readily visualized by the primary care physician, may be the actual cause of the bleeding.
- Proper perineal hygiene
 - Occasionally, systemic antibiotics may be necessary.

Sexually transmitted infections

- Usually treated with antibiotics

Complications of pregnancy

- Threatened or spontaneous abortion can be managed in the outpatient setting.
 - A clinician experienced in the management of early pregnancy should be consulted.
 - For patients with bleeding disorders, consultation with a hematologist may be required.

DUB: hormonal therapy

- Indicated in:
 - Teenagers who have moderate bleeding (enough to cause a decrease in hematocrit level to <34%)
 - Girls who have menses every 1–3 weeks
 - The primary care physician may prefer the guidance of a more experienced clinician.
- Combined oral contraceptives (COCs) or progestin alone
 - COCs are easier to use (1 pill is taken daily every day of the month).
 - If the patient has a condition in which COCs are contraindicated or this method is rejected by the patient or her parents:
 - Medroxyprogesterone, 10 mg orally, can be given daily for 10–14 days.
 - Begin treatment on the first day of each month (calendar method) or on the 14th day of the menstrual cycle (day 1 being the first day of bleeding).
 - Assure the parents that:
 - COCs are, in this instance, being used as treatment.
 - COCs are the most convenient way to package and deliver hormonal treatment.
 - Short-term use of COCs for 3–6 months is anticipated.
 - Close follow-up will be given during the treatment period.
 - Such an approach will often:
 - Alleviate concerns about hormonal treatment
 - Prevent rejection of these methods by the family

DUB: mild bleeding

- No anemia
 - Does not greatly upset the patient and her parents
 - Can be managed expectantly with no immediate, specific therapy
- Mild anemia
 - Hemoglobin value 11–12 g/dL
 - Treated with iron supplementation
- Some problems will resolve in 3 or 4 cycles.
 - If the patient is sexually active, COCs can be prescribed to treat the bleeding, as well as to provide contraception.
- Nonsteroidal antiinflammatory drugs
 - Can also be used for their demonstrated antiprostaglandin effects
 - Ibuprofen
 - Naproxen

DUB: severe prolonged heavy bleeding

- Severe prolonged heavy bleeding accompanied by a decrease in hemoglobin to ≤ 10 g/dL must be treated more aggressively.
 - An adolescent medicine or gynecologic consult should be sought.
 - Clotting studies should be obtained.
 - Hospitalization should be strongly considered.
- COCs (1 tablet taken twice daily for 3–4 days) will generally stop the bleeding.
 - LoOvral every 4 hours may be necessary initially until the bleeding stops.
 - Then every 6 hours for 24 hours
 - Then every 8 hours for 4 days
 - Then twice daily to complete 3 weeks of hormonal therapy
 - Some clinicians prefer to use conjugated estrogens (25 mg IV every 4 hours).
 - Antiemetic medications may be required to counteract the side effects of the high levels of estrogen contained in this regimen.
 - Withdrawal bleeding will occur 2–4 days after completion of this initial course of therapy.
 - Patients with significant bleeding should avoid the placebo pills contained in the COC pill packs and continue continuous COCs until hemoglobin and hematocrit levels begin to normalize.
- Iron and folic acid supplementation
 - Should be included as a part of the therapeutic plan

- Blood transfusion
 - Need depends on the hemodynamic stability of the patient.
- Endometrial biopsy
 - Rarely indicated
- Dilation and curettage
 - Rarely indicated

WHEN TO REFER

- The patient is experiencing severe bleeding or initial attempts to control the bleeding by the primary care physician have failed.
- Vaginal bleeding appears to be secondary to a chronic illness that the primary care physician cannot manage.
- The primary care physician feels uncomfortable performing a pelvic examination.
- Long-term hormonal therapy is required.
- Evidence exists for:
 - Anatomical abnormality
 - Complicated endocrine disorder
 - Coagulopathy, especially if causing severe bleeding
 - Cancer
 - Sexual abuse

WHEN TO ADMIT

- Severe prolonged heavy bleeding accompanied by a decrease in hemoglobin to ≤ 10 g/dL
- Hemodynamic instability

FOLLOW-UP

- All patients with abnormal vaginal bleeding should be instructed to maintain a menstrual calendar to facilitate follow-up management.
- Patients with mild bleeding should be reevaluated in 6–8 weeks.
- Patients with severe bleeding require long-term, close follow-up.
- Even when measures succeed in controlling the vaginal bleeding, an appreciable number of patients will continue to have menstrual abnormalities.

COMPLICATIONS

- Anemia

Vaginal Discharge

DEFINITION

- Vaginal discharge is fluid produced by glands in the vaginal wall and cervix that drains from the opening of the vagina.

MECHANISM

- Newborns
 - In utero, the vaginal epithelium is stimulated by maternal hormones that cross the placenta into the fetal circulation.
 - After delivery, these hormone levels decrease rapidly, and there may be a thick, grayish-white, mucoid discharge from the neonate's vagina.
 - In many instances, the discharge is blood-tinged or even grossly bloody.
- Prepubertal girls
- The genital area of prepubertal girls is susceptible to infection.
 - Labial folds are smaller and lack pubic hair.
 - Distance between the vagina and the anus is relatively short.
 - Low levels of circulating estrogen render the vaginal mucosa relatively thin and susceptible to irritation or infection.
 - Alkaline pH (approximately 7.0) of the vaginal secretions is hospitable to bacteria and allows fecal flora to establish themselves.
- Nonspecific vaginitis
 - No clear causative agent for the discharge can be established.
 - Accounts for 25–75% of cases of vulvovaginitis
- Sexually transmitted organisms
 - *Neisseria gonorrhoeae*, *Chlamydia trachomatis*, or *Trichomonas vaginalis* cause vaginal infections in prepubertal girls.
 - *N gonorrhoeae* clearly causes vaginal discharge; evidence that *C trachomatis* alone does so is limited.
- Foreign body
 - Typically, the child has placed an object, such as toilet paper, a coin, or a small toy, in her vagina.
 - Accounts for <5% of cases of vaginal discharge
- Pubertal and postpubertal adolescents
 - With the onset of puberty, circulating estrogen and progesterone levels increase, stimulating vaginal mucus production and an increase in the turnover of vaginal epithelial cells.
 - Bartholin and sebaceous glands are also stimulated.
 - Generally, the clear mucoid discharge that results will not cause problems.
 - Amount of secretion can increase midway through a normal menstrual cycle or with sexual excitement.
 - Discharge is particularly prominent at the onset of puberty (physiological leukorrhoea).

- Sexually transmitted organisms
 - *N gonorrhoeae*, *C trachomatis*, and *T vaginalis* are all known to cause vaginal infections in sexually active adolescents.
 - Herpesvirus infections of the vulvovaginal area or cervix (or both) are associated with vaginal discharge.
- Bacterial vaginosis
 - Associated with multiple sex partners, douching, smoking, and the presence of sexually transmitted infections
 - Vaginosis is not considered a sexually transmitted infection.

HISTORY

- Prepubertal girls
- Inquire about hygiene.
 - Wiping from the anus toward the vagina brings intestinal flora to the vaginal introitus.
 - Use of chemicals, such as bubble baths, deodorants, or strong laundry detergents, can irritate the vulva and vagina.
- Parents should be asked about recent or concomitant illness.
 - *Streptococcus pyogenes* infection (with or without scarlet fever)
 - *Shigella flexneri* infection, occurring coincident with or after an episode of diarrhea
 - Systemic illnesses, such as varicella
 - Rectal infestations with *Enterobius vermicularis* (pinworms) can lead to vaginitis if the eggs are deposited around or in the vagina.
 - *Candida vulvovaginitis* is an uncommon cause of vaginal discharge in prepubertal girls unless the child:
 - Has recently taken antibiotics
 - Has diabetes mellitus
 - Is immunocompromised
- Pubertal and postpubertal adolescents
 - In addition to the above, inquire about sexual activity.
 - Many teenagers fear admitting to sexual intercourse.
 - Negative response to queries about sexual activity should not rule out consideration of a sexually transmitted organism as the cause.
 - Sexual abuse should be considered.
 - Presence of a foreign body (eg, a retained tampon or condom)
 - Use of spermicides or douching can cause vaginitis.

PHYSICAL EXAM

- Prepubertal girls
 - Physical examination should include:
 - Entire genital and anal area
 - Vulva, urethral meatus, and vaginal introitus

- Infections in prepubertal girls usually involve the vulva as opposed to only the vagina.
- Presence of bruises, lacerations, or scrapes in the genital area is suggestive of sexual abuse.
- Excoriations around anus or vagina suggest itching caused by pinworms.
- A rash that spares skin folds is consistent with an irritative cause.
- A rash that is predominantly within the skin folds suggests candidiasis.
- Positioning options for examination
 - Sitting on the mother's lap with legs spread so that they dangle outside mother's legs
 - Lying supine in the frog-leg position
 - Lying face down in the knee-chest position
- If a foreign body is thought to be present but not visualized
 - Irrigating the vagina with a soft, flexible catheter and tepid saline solution will often flush out bits of toilet paper or small objects.

DIFFERENTIAL DIAGNOSIS

■ Causes of vaginal discharge in prepubertal girls

- Nonspecific vaginitis (the most common cause)
- Irritative agents (bubble baths, sand); the vulva is often involved as well. Nonabsorbent occlusive clothing (nylon undergarments, tights, bathing suits) also irritate the vulva, leading to skin breakdown and infection.
- Poor perineal hygiene
- Foreign body
- Associated systemic illness (group A streptococci, varicella)
- Other respiratory pathogens (eg, *Haemophilus influenzae*)
- Enteric infections
- *Escherichia coli* with foreign body
- *Shigella* organisms
- *Yersinia* organisms
- *E vermicularis* (pinworm)
- Sexually transmitted infections (strong presumption of sexual abuse in prepubertal girls)
 - *N gonorrhoeae*
 - *T vaginalis*
 - *C trachomatis* (whether this organism alone can cause discharge is unclear. *C trachomatis* is often isolated in conjunction with *N gonorrhoeae*.)
 - Primary vulvar skin disease
 - Tumor, polyps (rare)

■ Major causes of vaginal discharge in pubertal girls

- *Candida albicans*
 - Discharge: thick, white, curdlike, cheesy
 - Odor: none usually
 - pH: 4.5 (obtained from midvagina with nitrazine paper)
 - Dysuria: frequent
 - Pruritus: 4+
 - Other clues: Vulva affected; associated with use of some oral contraceptives and, in some women, with antibiotic use
- *T vaginalis*
 - Discharge: frothy; yellow green or gray
 - Odor: foul-smelling
 - pH: 5.2–5.5
 - Dysuria: frequent
 - Pruritus: yes
 - Other clues: Low abdominal pain; “strawberry” cervix; punctate vaginal hemorrhages
- Bacterial vaginosis
 - Discharge: homogeneous, thin, white discharge that smoothly coats the vaginal walls
 - Odor: a fishy odor of vaginal discharge before or after addition of 10% KOH (ie, the whiff test)
 - pH: >4.5
 - Dysuria: no
 - Pruritus: slight
 - Other clues: Occurs in association with anaerobes and *Gardnerella vaginalis*
- Herpesvirus (occasionally associated with vaginal discharge)
 - Pain or a burning sensation is felt in the genital area
 - Vulva is reddened.
 - Groups of small vesicles are noted on the vulva, in the vagina, or on the cervix
 - If the vesicles have ruptured, only small ulcerations may be present.
 - Inguinal adenopathy, fever, and malaise are usually present if this attack is the first one.

LABORATORY EVALUATION

■ Slide preparation

- If sufficient vaginal discharge is present, several drops of the secretion should be placed on 2 glass slides.
- If discharge is scant, a saline-moistened cotton swab can be introduced into the vagina to obtain samples.
- First slide
 - Add several drops of normal saline solution.

- Second slide
 - Add several drops of 10% potassium hydroxide and gently heat to dissolve epithelial cells, allowing visualization of hyphae.
- If indicated, culture for *N gonorrhoeae* and *C trachomatis*.
- Cellophane tape with its sticky side applied to the perianal area and then onto a glass slide may reveal the typical eggs of *E vermicularis*.
- Typical findings
 - *C albicans*
 - Hyphae on potassium hydroxide examination
 - *T vaginalis*
 - Motile trichomonads on wet preparation; avoid drying specimen
 - Bacterial vaginosis
 - Clue cells on wet preparation (bacteria-coated epithelial cells)

TREATMENT APPROACH

- In the newborn, no treatment is needed, and the discharge usually resolves by 10 days of age.
- Prepubertal girls
 - If the history or physical examination suggests an irritative origin:
 - Discontinue the offending agent.
 - Have the child wear cotton underpants.
 - Sitz baths will provide temporary relief until natural healing takes place.
 - Removal of a foreign body will result in rapid improvement and cessation of the discharge.
 - Pinworm infestations should be treated in the usual manner (mebendazole, pyrantel pamoate, or albendazole).
 - Infections caused by poor personal hygiene will respond to general measures, coupled with instructions about proper perineal hygiene.
 - If discharge is associated with another infection (such as *S pyogenes* or *Shigella* organisms), treat the underlying infection.
 - When the organism causing the vaginal discharge is found to be sexually transmitted, more comprehensive evaluation and treatment are required.
 - A report to Child Protective Services should be made.
- Pubertal and postpubertal adolescents
 - Persistent discharge unresponsive to therapy may indicate:
 - Noncompliance with treatment
 - Reinfected by an untreated sexual partner
 - In the absence of *N gonorrhoeae*, *C trachomatis*, and *T vaginalis* or causes described above, recommend:
 - Trial of sitz baths
 - Use of cotton as opposed to nylon underwear
 - Careful attention to perineal hygiene
- Candidal infections can be especially difficult to treat and may recur.
 - Predisposing factors include:
 - Oral contraceptive use
 - Broad-spectrum antibiotic use
 - Diabetes mellitus

SPECIFIC TREATMENT

Prepubertal girls

- Nonspecific vaginitis
 - Usually responds to thorough perineal hygiene, sitz baths, and mild soaps
 - Patients should:
 - Wear white cotton underpants and loose-fitting pants or skirts
 - Avoid nylon tights and tight pants
 - Avoid sitting for long periods in nylon bathing suits
 - Wipe only from front to back
 - For persistent cases, treat in standard childhood doses for 10–14 days with:
 - Amoxicillin
 - Amoxicillin-clavulanate
 - Cephalosporin
 - Clindamycin
 - Alternatively, a 1- to 2-month daily low-dose antibiotic may be helpful.
 - If unsuccessful, then antibiotic or estrogen creams may be used.
 - Mupirocin
 - Gentamicin
 - Metronidazole
 - Clindamycin

Pubertal and postpubertal adolescents

- Vulvovaginal candidiasis (*C albicans*)
 - Topical therapy for 7–14 days or
 - Oral fluconazole, 150 mg repeated 72 hours after the first dose
 - If more intensive treatment is warranted
 - Oral fluconazole, 150 mg once weekly for 6 months after initial treatment of 1 dose every 3 days for 3 doses
 - A variety of month-long antifungal treatments have been successful; however, intravaginal treatment over a long period is inconvenient.

- Long-term ketoconazole has been used to suppress recurrent infection, but hepatotoxicity is a concern.
- Male sexual partners should be treated if they have any signs or symptoms of penile candidal involvement.
- *T vaginalis*
 - Metronidazole 2 g orally in a single dose
 - Alternatively, this medication can be given as 500 mg twice daily for 7 days.
 - Some strains of *T vaginalis* have decreased susceptibility to metronidazole.
 - Repeated failures should be treated with 2 g once daily for 3–5 days.
 - The patient should be told to avoid alcohol until 24 hours after completion of therapy.
 - Sexual partners must be treated.
- Bacterial vaginosis
 - Metronidazole 500 mg orally twice daily for 7 days or
 - Metronidazole gel 0.75% one full applicator (5 g) intravaginally once daily for 5 days or
 - Clindamycin cream 2%, one full applicator (5 g) intravaginally every night at bedtime for 7 days or
 - Alternative regimens that include:
 - Metronidazole 2 g orally in a single dose
 - Clindamycin 300 mg orally twice daily for 7 days
 - Clindamycin ovules 100 g intravaginally every night at bedtime for 3 days

WHEN TO REFER

- If the clinician is uncomfortable with evaluating genital symptoms in prepubertal girls
- If the clinician lacks experience in performing pelvic examinations
- If the evaluation yields evidence of sexual abuse
- If discharge persists despite seemingly appropriate therapy

PREVENTION

- Proper perineal hygiene
 - Keeping the area clean
 - Wiping from front to back
- Patients should be advised:
 - To wear white cotton underpants and loose-fitting pants or skirts
 - To avoid nylon tights and tight pants
 - To avoid sitting for long periods in nylon bathing suits

Verrucae (Warts)

DEFINITION

- Verrucae (warts) are virally induced tumors of the skin.

EPIDEMIOLOGY

- Cutaneous warts
 - Affect up to 10% of children between 2 and 12 years of age
 - Rank among the top 3 dermatoses in this age group
 - No sex predilection
- Genital warts
 - Uncommon in children before puberty
 - One of the most common sexually transmitted infections in adolescents and adults

ETIOLOGY

- Warts are caused by human papillomavirus (HPV).
 - Infects epidermal cells
 - Causes focal epidermal proliferation
 - Expressed clinically as a verrucous papule
- >100 types of HPV have been characterized.
- Specific types have been associated with specific warts.
 - HPV types 1, 2, and 4: plantar warts
 - HPV-2 and HPV-7: common warts
 - HPV-3 and HPV-10: flat warts
 - HPV types 1, 6, and 11: benign genital warts
 - HPV types 6, 7, 11, 16, and 32: laryngeal papillomas
 - HPV types 16, 18, 31, 33, 35, 39, 45, 51, 52, 56, 58, 59, and 68: genital warts with malignant potential
- HPV typing holds promise in helping identify:
 - Premalignant warts
 - Sources of transmission
- HPV types 6, 11, 16, and 18 cause:
 - 70% of cervical cancers
 - 90% of genital warts
- Presumably inoculated into the skin from an external source
 - Neither source nor event of inoculation is elicitable.
- Asking about and searching for warts on other areas of the body is reasonable.
 - Patients who have warts on their lips often have them on their fingers.
 - Warts are transmissible.
 - Other family members may have them.
- Genital warts in children can raise the question of sexual abuse.
 - A complete social history and thorough physical examination is indicated.

- On the basis of HPV typing, anogenital and laryngeal HPV infection in most infants appears to be acquired by:
 - Nonsexual transmission from the mother's vaginal tract during delivery
 - Evidence exists pointing to possibility of in utero transmission of HPV.
- A study demonstrating a high incidence of HPV-2 in anogenital warts in prepubertal children suggested that common means of acquisition may be innocent auto- or heteroinoculation from cutaneous warts.

RISK FACTORS

- Patients with systemic defects in cell-mediated immunity are more susceptible to warts.
 - Often recalcitrant to treatment
- Cellular immune responses in the skin are impaired with atopic dermatitis.
 - These patients have more difficulty with warts and other viral infections of the skin.

SIGNS AND SYMPTOMS

- Clinical appearance of warts varies, depending on the type and location.
- Common wart, or verruca vulgaris
 - Easily recognized as a superficial, light-colored papule
 - Coarse, roughened surface
- Warts are often studded with black specks.
 - Actually small, superficial dermal capillaries
- Warts are sometimes found in a linear array, presumably as a result of autoinoculation through scratching.
- Not all warts appear as verrucous papules.
 - Variants include:
 - Flat (planar) warts
 - Plantar warts
 - Periungual warts
 - Anogenital warts

DIFFERENTIAL DIAGNOSIS

- The distinctive clinical appearance of the common wart usually presents no problem in diagnosis.
- Epidermal nevi
 - Hamartomas that may be confused with warts
 - They are:
 - Softer
 - More pigmented
 - More persistent
 - Much less common

- Flat (planar) warts appear as small, flesh-colored papules (see Figure 94 on page F32).
 - Flat warts have sharp borders and a finely verrucous surface.
 - When located on the face, warts may be confused with the closed comedones (whiteheads) seen in acne.
 - Closed comedones are smooth, dome-shaped lesions.
- Plantar warts
 - Named for their appearance on the plantar surface of the foot (see Figure 95 on page F32)
 - Often confused with calluses and corns
 - Corns are much less common in children.
 - Large plantar warts are often composed of confluent smaller warts.
 - Form a mosaic wart surrounded by satellite lesions
 - Differ from corns by having a verrucous surface that interrupts skin markings and often punctuated with black specks
 - In some cases, the 2 entities can only be distinguished by paring down the surface.
 - Wart tissue still has a roughened texture and remains the same size as it is pared.
 - Corn tissue is smooth, and it becomes smaller in diameter as it is pared.
- Periungual warts
 - Occur around the nail fold and should not pose diagnostic difficulty
 - Warts under free edge of the nail
 - Can cause nail plate to separate from nail bed
 - May be confused with fungal infection
 - On close inspection, the verrucous nature of the wart usually can be appreciated.
- Anogenital warts (condylomata acuminata)
 - Sometimes, but not always, acquired by sexual contact
 - Can usually be identified as verrucous papules (see Figure 96 on page F32)
 - Sometimes small or flat and more difficult to see
 - May be confused with the less common condylomata lata found in secondary syphilis
 - Condylomata acuminata is drier and more verrucous.
 - Condylomata lata are flat and moist.
 - If doubt exists, a serologic test for syphilis should settle the issue.

DIAGNOSTIC APPROACH

- Warts are almost always diagnosed clinically.
- If doubt exists, skin biopsy can provide histologic confirmation.

DIAGNOSTIC PROCEDURES

- Anogenital warts: Acetowhitening technique can aid in the diagnosis.
 - A compress containing 5% acetic acid is applied for several minutes to the suspected area.
 - Reexamine, ideally under magnification.
 - With this technique, warty tissue turns white and is visualized more easily.

TREATMENT APPROACH

- Among schoolchildren:
 - Warts are often a focus for teasing and insensitive remarks.
 - Children usually ask that their warts be treated because of social pressure.
 - Successful therapy gives patients the opportunity to feel better about themselves and their appearance.
- Warts commonly regress spontaneously.
 - Time required varies considerably.
 - In some patients, therapy may only serve to appease the patient while nature takes its course.
- In some patients, the destructive techniques may:
 - Initiate an inflammatory reaction
 - Expose the viral antigen to the body's immune system, which rejects the wart
- Whenever warts are treated, the physician must guard against doing harm by being overzealous.
 - Surgical excision is usually discouraged.
 - Radiotherapy is contraindicated.
- The goal of therapy is to shorten the time required for the wart to disappear.

SPECIFIC TREATMENTS

Cryotherapy

- Tissue is frozen by applying liquid nitrogen (-195°C).
 - Swab
 - Canister delivery system
- Freezing should extend beyond wart to include a 1- to 2-mm rim of normal skin.
- To destroy affected tissue more effectively, the wart may be refrozen after initial thaw.
- Patients must be advised:
 - The frozen area will be sore for several days.
 - A blister may form.
 - Several weeks are usually needed for the wart to turn dark and drop off.
- Cryotherapy is a favorite office therapy for common warts.
- For small warts, a single treatment is often successful.
- Large warts frequently need to be refrozen about every 3 weeks.

- Scars may result, but are uncommon.
- Skin may become hypopigmented.
- In freezing warts on the fingers:
 - Care must be taken to avoid freezing too deeply.
 - Underlying structures, such as digital nerves, can be damaged.
- Over-the-counter freezing treatments
 - May not be as effective as liquid nitrogen

Keratolytic (acid) therapy

- Slower and involves more patient participation than freezing
 - Less immediately painful
 - Least likely to cause scarring
- Variety of acids are available for treating warts.
- Convenient outpatient medication incorporates 17% salicylic acid in a polyacrylic or flexible collodion vehicle (Occlusal-HP, Duofilm).
 - Dries rapidly to prevent spread of acid onto surrounding skin
 - Patients are instructed to:
 - Apply medication at bedtime
 - Cover area with thick tape
 - Superficial necrotic tissue should be pared daily using a pumice stone.
- Thick palmar or plantar warts often require stronger acid, such as a 40% salicylic acid plaster.
 - These products can be bought over the counter (Mediplast and Duofilm patches).
 - Patients need instruction in application.
 - A plaster is cut to match size of the wart.
 - The adhesive, medicated side is applied to the wart and held in place with tape.
 - The plaster is changed every 24 hours and the macerated wart pared daily using a callus grater.
- Flat warts are often treated successfully with:
 - Nightly applications to the affected area with:
 - Topical adapalene (Differin)
 - Tretinoin (Retin-A)
 - Imiquimod (Aldara)
 - Products act as peeling agents.
 - Painful irritation may necessitate less frequent use.
- Home acid therapies usually require ≥ 1 month of continuous use to be effective.
 - If no progress has been made after several months, other treatments should be considered.
 - For deeply seeded warts, paring after a combination of acid and cryotherapy usually provides successful treatment.

- Caustic acids, such as trichloroacetic acid at concentrations of 30–100%, are reserved for office treatment of palmar or plantar warts.
 - Must be carefully applied
 - Can cause destruction of normal tissue
- Cantharidin is a protein phosphatase inhibitor produced by the Spanish fly, *Lytta vesicatoria*.
 - Penetrates the epidermis
 - Causes acantholysis
 - Results in vesiculation
 - Destroys infected keratinocytes
 - Can be used for almost all nongenital warts
 - Reapplication may be required at 1- to 3-week intervals.
 - Painless when initially applied
 - Causes little risk of scarring
 - Occasionally, a ring wart will develop at the edge of the treated site.
- All of these treatments are nonspecific.
- In some instances, different modalities are used in sequence.

Imiquimod

- Imiquimod (Aldara) 5% cream
 - Immunomodulator that augments cellular immunity by inducing a variety of cytokines
 - Can be self-administered daily or every other day
 - Should be left on overnight
 - Controlled, multicenter trials have evaluated its role in treating genital warts; trials will soon be under way for common warts.
 - Smaller studies and case reports are suggesting its potential as an alternative treatment.
 - Used alone or in combination with other modalities, such as cryotherapy and salicylic acid
- Mechanism of action may make it especially useful in treating nongenital warts in immunosuppressed patients.

Electrodesiccation and laser therapy

- Electrodesiccation can be preceded or followed by curettage.
 - The advantage is the patient leaves the office without visible evidence of the wart.
 - Cure rate is probably no higher than with cryotherapy.
 - Disadvantages are:
 - The procedure requires local anesthesia.
 - Scarring is more likely.
- Carbon dioxide laser can be used to destroy large or refractory warts.
 - Risk of scarring is significant.
- Pulsed dye laser destroys vascular component of the wart.
 - May become another alternative
 - Less risk of scarring

■ Used for some recalcitrant warts, particularly:

- Palmar
- Plantar
- Periungual
- Anogenital

Other treatments

- A recent study showed that duct tape occlusion therapy was significantly more effective than cryotherapy in treating non-genital warts.
- Efficacy of oral cimetidine in the treatment of warts is still controversial.
 - May be useful in the treatment of flat warts
 - Use in other types of warts is under investigation.
- Immunotherapy
 - Involves sensitization to antigens, such as:
 - *Candida*
 - Mumps
 - *Trichophyton*
 - Used by dermatologists when topical therapies fail
 - Studies have demonstrated response rates ranging from:
 - 54–74% in treated warts
 - 34–78% in untreated, distant warts

Genital warts

- Condylomata in children are usually asymptomatic.
 - May be treated to:
 - Curtail spread
 - Allay parental concerns
 - Some forms of therapy may be painful.
 - Recurrence rates may be as high as 50%.
 - Weighing the risks versus benefits is wise before treating genital warts in children.
- 2 therapeutic options for condyloma have been approved by the US Food and Drug Administration in adults; case reports with children have shown promise.
 - Imiquimod
 - Podophyllotoxin
- Podophyllin
 - Available in 10–25% solutions in alcohol or benzoin
 - Exclusively for office use
 - Painless when applied
 - Can be toxic if used over large areas
 - Must be washed off within 6 to 8 hours of application
 - Marketed as purified 0.5% podophyllotoxin (Condylox) solution or gel
 - Can be very irritating for some patients

■ Other options include:

- Cryotherapy
- Lasers
- Caustic acids
- Cimetidine

WHEN TO REFER

- Patients with persistent warts may benefit from an evaluation by a dermatologist.

COMPLICATIONS

- Major complications are those caused by overzealous therapy, resulting in:
 - Short-term discomfort
 - Scarring
- The annoyance of a wart (usually temporary) must be balanced against the inconvenience of a scar.
 - Lifelong
 - May be unsightly
 - Sometimes tender, particularly if present on a pressure-bearing surface

PROGNOSIS

- Most warts eventually involute spontaneously.
 - Probably through immunologic rejection
- The time required for involution varies greatly.
 - Predicting when it might occur for an individual patient is impossible.
- The therapies discussed in Specific Treatments result in clearing in most cases.

PREVENTION

- Gardasil
 - Vaccine for HPV types 6, 11, 16, and 18
 - Approved by the US Food and Drug Administration in June 2006
 - For use in female patients 9–26 years
 - Administered 3 times over a 6-month period
 - Whether it should be mandatory or remain voluntary is being addressed at the state level.

SUGGESTED RESOURCES

- What is a Pediatric Dermatologist? (fact sheet), AAP (www.aap.org/family/PedDermatologistfacts.pdf).

Violence Prevention

BACKGROUND

■ Most peer violence in the US results from conflicts among:

- Friends
- Acquaintances
- Intimate partners

■ Stranger violence ranges from 6–40% among all instances of personal violence.

■ Primary prevention

- Preventing a child from becoming a victim
- Helping the child learn nonviolent problem-solving skills and attitudes
 - Developing these skills and attitudes begins in infancy.
- Effective, nonviolent discipline is key to developing resilient children who can resist being drawn into violence.

■ Violence is learned.

- Parents can help reduce the risk of serious violence through attention to the child's environment.
 - Decreased exposure to media violence
 - Decreased exposure to domestic violence
 - Decreased access to firearms
 - All of these measures effectively reduce serious violence.
- Parents can encourage a nonviolent attitude by:
 - Resisting toys that promote violence (eg, toy guns, violent video games, and toys that encourage racial or ethnic stereotypes)
- Although many factors place children at high risk for violence, countervailing resilience factors help reduce the risk.

■ Witnessing violence

- Domestic violence
 - One of the greatest risks of violence for infants and toddlers comes from the family through domestic violence and child abuse.
- Television (TV) violence
 - US children spend more time watching TV than any other activity except sleep.
 - Violence is pervasive on TV: the average child will see >10,000 TV deaths before completing high school.
 - Violence on TV is generally viewed as socially acceptable behavior.
 - The American Psychological Association has concluded that exposure to TV violence is a major risk factor for children.
 - Children who view TV violence are more likely to experience violence as victims or aggressors and are much less likely to intervene in tense situations, as bystanders, to reduce the likelihood of violence.
- Violence in urban minority communities
 - A pattern of violence that has been observed is known as the *code of the streets* or the *sucker phenomenon*.

- Individuals who cannot defend themselves are likely prey to multiple and repeated attacks.
- Parents may adopt protective strategies that keep their children out of harm's way in the first place, often by enrolling them in supervised after-school programs or keeping them safely in the house, watching TV.

■ Bullying

- Repeated infliction of harm on younger, smaller, or less powerful peers
- A nearly universal problem for school-age children
- Bullies are usually larger and stronger (among boys) or more socially powerful (among girls) than are their victims.
- Targets of bullies are physically and emotionally weaker and cannot strike back, either physically or verbally.
- Negative behaviors often happen outside of school supervision: before school, after school, or at recess.
 - Classroom teachers are often unaware of the problem.
 - Usually cannot solve it without significant support from their administrators
- Bullying has severe adverse consequences for both bully and victim.
 - Victim outcomes—a bullied child may be:
 - Physically hurt
 - Unable to concentrate on his/her studies
 - Lacking in self-esteem
 - Several perpetrators in school shootings in the US were victims of bullies, and their lethal outbursts may have resulted from the effects of being bullied.

GOALS

- Overall goal: reduce death and disability for children in the US resulting from violence
- Primary prevention: anticipatory guidance for young children
 - During infancy and early childhood, patterns of behavior and family interactions are established.
 - Discuss with the parents:
 - Reduction in exposure to violence, including:
 - Domestic violence
 - TV violence
 - Teach appropriate, nonviolent methods of discipline.
 - Alternatives to corporal punishment
 - Awareness of the effects of TV violence during early childhood
 - Such interventions are effective.
- Secondary prevention: older children and adolescents
 - Identification, counseling, and referral of high-risk patients should be a standard of care.
- Advocacy
 - Advocate for school policies and state and federal legislation to reduce the risk of violence for children.

GENERAL APPROACH

Young children

- The overall goal is to ameliorate risk factors and reinforce factors that protect the child from harm.
- Anticipatory guidance for parents should include:
 - Reduction in exposure to violence, including both domestic violence and television violence.
 - Teaching appropriate, nonviolent methods of discipline (violence-free parenting).
- Because patients and families see their physicians often during this period, opportunities for brief, focused interventions are numerous.

School-age children

- As children get older, the external influences of their behavior become more important.
 - TV has an enormous effect.
 - Children begin to deal with playground fights and bullying.
 - Bullying has also been identified as an important precursor to other forms of violence.
 - “Stop Bullying Now” is a comprehensive set of resources for parents, schools, and communities, developed by the federal government.
- Despite a general reduction in traumatic injury and death, child and adolescent deaths caused by firearms continue to increase.
 - Individual families can be counseled that the safest home for children is one without handguns.
 - Any guns present in the home should be locked and unloaded.

Adolescents

- The overall goal is to reduce the risk of violence.
 - Screen all adolescents to identify those at high risk.
 - Prevent reinjury to injured adolescents.
 - Refer high-risk or traumatized adolescents for appropriate treatment.
- Identify and reinforce teen resilience factors.
 - Attachment to school, family, community, and pro-social peer groups all exert strong protective effects.
 - Programs that provide opportunities to belong to a pro-social group and develop mastery protect young adults from health-risk behaviors, including fighting.

SPECIFIC INTERVENTIONS

Infants and young children

- Violence-free parenting: effective parenting without corporal punishment
 - Describe and endorse specific effective behavioral techniques to help discipline children.
 - Toddlers gain power over their world by being able to understand what is happening and predict what will happen next.

- Maintaining a schedule, eg, bedtimes, naptimes, meal-times, bath time, and playtime, provides a feeling of mastery for the child.
- Pay attention to the child.
 - The best attention is parental praise for good behavior.
 - In the absence of this positive reinforcement, toddlers may feel ignored and misbehave simply to grab parental attention.
 - A misperception is that children who are praised will become self-centered; this is not true.
 - Parents can be told very simply to tell their child, “I love it when you...”
- There will be times when a child’s misbehavior necessitates negative consequences.
 - An effective, simple negative reinforcement technique is the time out.
 - Time-out periods should be used:
 - Judiciously in the background of positive reinforcement
 - Consistently whenever the child has behavior patterns that need to be stopped
 - Children should be placed in time-out for approximately 1 minute per year of age.
 - Parents should explain clearly why the time-out was deserved and ignore the child during the time-out.
 - Longer explanations and discussions should be deferred until things have calmed down.

School-age children

- Interventions to deal with bullying
 - Antibullying programs have been shown to be effective in Scandinavia and the US.
 - Identify where and when bullying usually occurs.
 - Control bullying on 3 levels.
 - In the school building and grounds:
 - Ensure a safe physical environment.
 - Coordinate classroom activities.
 - In the classroom
 - Teacher-led discussions on roles of bullies, victims, and bystanders
 - Establish that bullying behavior will not be tolerated.
 - With individual students
 - Help to generate rules to prevent bullying.
 - Report bullying behavior.
 - Encourage resistance of attempts by bullies to ostracize their victims.
 - When bullies are identified:
 - The child should receive a stern message from the principal.
 - The principal should speak with the child’s parents.

- A social worker or guidance counselor is assigned to work with the child on setting appropriate and enforceable behavioral limits at home.

Adolescents

- Screening for violence: general screen to identify adolescents at risk
 - Ask about drug use and fighting.
 - Ask, “How many fights have you been in the past 12 months?”
 - Teens who are in school and report neither drug use nor fighting are at low risk of violence-related injuries.
 - Teens at low risk deserve acknowledgment of their success at avoiding this problem.
 - Note that courage is often needed to walk away from a fight.
 - Teens who are in school and are passing courses but report either fighting or drug use are at medium risk.
 - Risk is approximately 3 times that of low-risk students.
 - These teens need to hear that risks are real and individual: “You are strong and healthy. However, I am worried about your telling me that you have been in several fights this year.”
 - Basic information concerning techniques for defusing tense situations should be discussed.
 - Teens who are failing school, already dropped out of school, or report both fighting and drug use are at high-risk.
 - Risk is approximately 7-fold increase for future violence-related injury.
 - Refer to appropriate community-based intervention services.
 - Emphasize the importance of follow-up to both the teen and parents.
 - Obtain a violence history, particularly from teens you suspect are at risk, using the acronym FISTS:
 - **F: Fighting**
 - When was your last pushing or shoving fight? How many fights have you been in the last month? In the last year?
 - Teens who have been in ≥ 1 physical fight in the preceding 12 months are at increased risk of violence-related injury.
 - **I: Injuries**
 - Have you ever been injured in a fight? Has anyone you know been injured in a fight? Has anyone you know been injured or killed?
 - Multiple or serious previous injuries may indicate an increased risk of future injury.
 - **S: Sexual violence**
 - What happens when you and your boyfriend or girlfriend have an argument? Have you ever been forced to have sex against your will?
 - Teen dating violence is both a serious problem in itself and a harbinger of future domestic violence.

- **T: Threats**
 - Have you ever been threatened with a knife? With a gun?
 - Previous threats with a weapon indicate that the patient is at future risk of weapons-related injury.
- **S: Self-defense**
 - How do you avoid getting in fights? Do you carry a weapon for self-defense?
 - Young people who have learned to de-escalate situations of conflict (or to avoid them altogether) deserve praise and encouragement.
 - Teens who arm themselves in self-defense are at extremely high risk.
- After a fight: secondary prevention
 - Patients who have been hurt in a fight are at high risk for further violence, either as the victim of another violence-related injury or by attempting to exact revenge on the assailants.
 - The immediate need is for crisis intervention. Ask:
 - “Is the fight over? Do you feel safe leaving here? If the fight is ongoing, is there someone who can mediate?”
 - If the situation is volatile, the patient and family should be referred to social services or, occasionally, the police.
 - Police intervention is warranted whenever the patient is in danger or reveals specific plans to harm another person.
 - Parents and patients should be advised of the risk of serious injury and that successful injury prevention involves learning how to de-escalate conflicts.
 - After a serious injury, the following steps have been advocated:
 - Have the child tell you about the problem, allowing narrative to flow freely, avoiding judgments.
 - This approach allows feelings of revenge to be expressed and offers an opportunity to learn patient’s perspective before offering advice.
 - Evaluate the youth’s other risks: Does he or she carry a weapon? Does he or she use alcohol or other drugs? Is the youth involved in a gang?
 - Discuss the known risk factors for violence, including the fact that most violent injuries occur between friends or acquaintances and often involve alcohol or drugs.
 - Develop a plan to stay safe after leaving the hospital or clinic. Does he or she have a relative with whom to stay who lives out of the neighborhood? Do the police need to be involved?
 - Discuss conflict-avoidance strategies. This discussion can start with the particular incident involved and may need to be continued on subsequent visits.
 - Refer to others, including a psychologist or social worker. Referral may involve reaching out to church members, recreation departments, or mentoring programs.

Vision Screening

BACKGROUND

- Amblyopia is permanent uncorrectable vision loss caused by long-standing visual image disturbance.
 - Major threat to vision
 - Preventable when detected early
- During development, the visual cortex must receive focused images from both eyes to learn how to see.
 - Conditions that interfere with the normal visual image during this time can lead to amblyopia if not identified and corrected.
 - Strabismus
 - Certain refractive errors
 - Cataracts
- Prevalence
 - Approximately 5% of preschool-age children have amblyopia.
 - Up to 10% have other vision problems, such as refractive error.
 - The prevalence of refractive error increases with age.
 - Refractive error affects over 20% of high school-age children.

GOALS

- Goals of vision screening
 - To identify deficits in vision or conditions that might threaten vision or impair function
 - To detect amblyogenic conditions before 5 years of age
 - The likelihood of successfully treating amblyopia decreases with age.
 - Amblyopia can be prevented with early identification and treatment.
 - To ensure that appropriate diagnostic and therapeutic referrals are made so that conditions threatening vision are ameliorated
- Few data are available about the accuracy of vision screening in the primary care setting.
 - A proportion of children will fail vision screening but have a normal ophthalmologic evaluation.
 - False-positive results are a feature of all screening programs and should not discourage practitioners from screening.
 - Vision screening examinations will detect the overwhelming proportion of children who have treatable vision problems.
 - Once identified, these cases must be detected and treated properly.
- Screening for vision problems is justified.
 - Vision problems are common.
 - Vision problems pose a threat to a child's well-being.
 - Vision problems are likely to go undetected without screening.

- Screening tests can identify children who have or are at risk for vision problems.
- Efficacious treatments for vision problems are available.
- Early diagnosis and treatment can have positive outcomes for many vision problems, including:
 - Congenital cataracts
 - Strabismus
 - Amblyopia

GENERAL APPROACH

- Appropriate vision screening techniques and procedures vary by age.
 - Infants and toddlers (<3 years)
 - Preschool children (3–5 years)
 - School-age children and adolescents
- Performing vision screening
 - Some elements of vision screening can be done during the physical examination.
 - This is particularly true with infants and toddlers.
 - In older children, vision can be tested by ancillary personnel.
 - Nonprofessional personnel can be trained to conduct vision screens.
 - Children who have developmental disabilities are often at increased risk for vision problems.
 - May require special expertise for assessment
- Equipment and location for vision screening
 - The necessary equipment for vision screening (ie, Snellen chart) is readily available.
 - Vision testing requires a well-lit environment and ≥ 10 feet of available space for nonmachine testing.
 - Vision testing machines require less space but are expensive.
 - Vision screening in the practice setting is appropriate.
 - Continuity of care is more likely in this setting.
- Children should be screened during well-child visits.
 - Record and communicate the results of the screening to parents.
 - Make sure that follow-up and referral appointments are made and kept.
 - Rates of screening follow-up are suboptimal.
 - Many children whose visual testing is abnormal never receive evaluation by an eye care specialist.

SPECIFIC INTERVENTIONS

Infants and toddlers

- Physical examination
 - Eye examination is part of the newborn assessment.
 - Eyes should be assessed at every visit.

- Inspect the eyes for structural abnormalities.
 - Evaluate the red reflex with an ophthalmoscope for:
 - Absence
 - Asymmetrical appearance
 - After an infant can fixate on an object (usually by 3 months), corneal light reflections should be tested with the Hirschberg test.
 - Use a penlight held in midline 12 inches in front of the eye.
 - Asymmetry of the light's reflection on the 2 corneas suggests strabismus.
 - Assess ocular motility by having the child follow a brightly colored object.
 - Perform a cover-uncover test to observe movement of each eye when the other is covered and then uncovered.
 - If movement is present, it can suggest:
 - Unilateral visual defect
 - Ocular muscle weakness in the eye that moves
 - Formal screening
 - New technology is available for screening young children.
 - Photorefractive screening (photoscreening)
 - Autorefraction
 - The validity and reliability of these devices in the primary care setting are unknown.
 - Special circumstances
 - The following infants should be evaluated by an ophthalmologist.
 - Preterm infants at risk for retinopathy of prematurity
 - Infants with a family history of congenital eye problems
 - Infants with problems that place their eyes at risk
 - Genetic (eg, trisomy 21)
 - Acquired (eg, cerebral palsy)
 - Parents may report a history of asymmetry that cannot be demonstrated at the visit.
 - Some problems of muscle imbalance occur only when the child is fatigued.
 - Pay attention to such history and refer to a specialist if symptoms persist.
 - Positive family history of the following should prompt consideration of referral.
 - Amblyopia
 - Lazy eye
 - Crossed eyes
- Preschool children**
- Physical examination at every visit:
 - Inspection
 - Bilateral red reflex
 - Corneal light reflection
 - Ocular motility
 - Formal screening
 - Testing for visual acuity should be attempted beginning at 3 years.
 - An interpretable result should be achieved by 4 years.
 - A child who is uncooperative or inconsistent in responses should return for a repeat test.
 - Repeated failure to achieve an interpretable test result may indicate a visual problem.
 - At this age, simpler tests of acuity that do not rely on knowledge of letters are the most acceptable.
 - The Lea chart requires the child to identify 4 symbols.
 - Tests are available for testing from a distance of 10 and 20 feet.
 - At 10 feet, children are less likely to become distracted by other activities in the immediate environment.
 - Testing for binocular vision (stereoacuity) is not a substitute for assessing visual acuity but is a useful adjunct.
 - Will sometimes identify a child whose vision problems have been missed on physical examination and acuity testing
 - Acceptable tests for this age group
 - The Random Dot E Test
 - The Stereo Fly Test
 - Special circumstances
 - Children at high risk for poor vision should be referred if satisfactory results cannot be obtained on screening.
- School-age children and adolescents**
- Physical examination
 - At every visit
 - Inspection
 - Bilateral red reflex
 - Corneal light reflex
 - Ocular motility tests
 - Formal screening
 - The Snellen letters on a wall chart are appropriate for visual acuity screening.
 - A child will usually accept testing on a vision testing machine that combines acuity testing with tests of binocular vision.
 - Special circumstances
 - School difficulties may be a presenting symptom of visual problems.
 - The prevention of amblyopia becomes less of a concern with increasing age.
 - Children should continue to be tested at well-child visits.

Referral

- The child should be referred to an eye care specialist if the following are suspected or found:
 - Strabismus
 - Amblyopia
 - Structural abnormality of the eye or its movements
 - Asymmetry or abnormality of the red reflex
 - Asymmetry of the corneal reflection
 - Aversion to the occlusion of one eye
 - Any movement of the eyes on the cover-uncover test
- Refer preschool children who:
 - Fail a visual acuity test in either or both eyes at the 20/40 level
 - Have a 2-line discrepancy between the eyes, eg, 20/20 and 20/40
- Refer any child who cannot be tested successfully by age 4 years after repeated attempts.
- School-age children and adolescents who fail to pass at the 20/30 level in either or both eyes
- Children with developmental disabilities who cannot be tested successfully
- Children of any age who fail a test of binocular vision

Vomiting

DEFINITION

- Vomiting is a common symptom of acute and chronic illness in childhood.
- Vomiting is a coordinated, active process, usually preceded by nausea in association with increased salivation, gastric atony, and reflux of duodenal contents into the stomach that results from nonperistaltic contractions of the small bowel.
- Vomiting should be distinguished from regurgitation, a passive reflux of gastric contents into the esophagus and mouth through a relaxed lower esophageal sphincter.
 - In infancy, regurgitation, or spitting up, is very common.
 - Most often a developmental event
 - Has no sequelae and gradually resolves
 - Pathologic gastroesophageal reflux is defined by the association of regurgitation with severe complications, including:
 - Esophagitis with or without anemia secondary to blood loss or stricture
 - Recurrent apnea
 - Aspiration pneumonia
 - Failure to thrive

MECHANISM

- Retching immediately precedes actual vomiting.
 - Coordinated contraction of abdominal and intercostal muscles, as well as the diaphragm and simultaneous closure of the glottis
- Increased intragastric pressure from contraction of the abdominal wall musculature, lowering of the diaphragm, and pyloric contraction are associated with elevation and relaxation of the cardia, and vomiting occurs.
- The process of vomiting is coordinated in the medullary vomiting center, which may be influenced:
 - Directly by visceral afferent stimuli
 - Indirectly through the chemoreceptor trigger zone
- The chemoreceptor trigger zone is the site of action of many of drugs that cause nausea and vomiting, including apomorphine and digitalis.
- Stimulation of the vestibular system (as with motion sickness) can activate the vomiting center and perhaps the chemoreceptor trigger zone.
- Higher central nervous system centers may also influence the medullary vomiting center.
- Understanding the role of neurotransmitters as mediators of the initiation of vomiting has led to a range of new antiemetics.
- The area postrema, which is a major lower brainstem center for coordination of drug-induced vomiting, is rich in enkephalins, 5-hydroxytryptamine (HT) receptors, and dopamine receptors.
- Enkephalins and 5-HT both stimulate release of dopamine.

- Dopamine and 5-HT antagonists have been successful in the treatment of chemotherapy-induced nausea and vomiting.
- Antihistamines and anticholinergics prevent motion sickness by acting at histamine (H_1) and muscarinic cholinergic receptors in the nucleus ambiguus in the lower brainstem and in the lateral vestibular nucleus in the midpons.

HISTORY

- Bilious vomiting usually occurs only with ileus or intestinal tract obstruction below the ampulla of Vater in the second portion of the duodenum.
 - Especially when associated with the first vomitus
 - In newborns, bilious vomiting can be associated with necrotizing enterocolitis, especially when there is blood in the stool.
 - In older children who vomit persistently, reflux of bile from the duodenum into the stomach may lead to bilious vomiting without gastrointestinal tract obstruction.
 - When a previously well newborn develops sudden-onset of bilious vomiting, especially within the first few days of life:
 - Consider a malrotation with secondary midgut volvulus, a surgical emergency requiring early diagnosis and surgical intervention.
- Projectile vomiting commonly occurs with pyloric stenosis.
 - When this condition persists, however, gastric atony may eliminate the projectile character.
 - A succussion splash may be present, as in other causes of gastric outlet obstruction.
 - The splashing sound present when a patient who has fluid in a hollow organ is shaken on physical examination
 - Vomiting associated with increased intracranial pressure may be projectile and may take place in the absence of nausea or retching.
- Persistent vomiting in a newborn or young infant who has no evidence of infection usually suggests:
 - Congenital gastrointestinal anomaly
 - Inborn error of metabolism
 - Central nervous system abnormality, eg, hydrocephalus or subdural effusion
 - If history and physical examination do not suggest a cause, then evaluating all 3 possibilities simultaneously is best.
 - Beyond the first week of life but within the first 2 months, pyloric stenosis is the most common cause of persistent vomiting.
 - Persistent or recurrent vomiting without other symptoms may be the major manifestation of an emotional disorder.
 - A complete psychosocial history is an important part of the evaluation.
- With a history of acute vomiting and somnolence, the clinician should always consider:
 - Drug overdose, especially aspirin toxicity

- Meningoencephalitis
 - Inborn errors of mitochondrial fatty acid oxidation
 - Reye syndrome
 - Cyclic vomiting is characterized by repeated episodes of vomiting.
 - Sometimes associated with abdominal pain
 - Uncontrollable vomiting and retching are typical of an attack.
 - Patients are well between episodes.
 - Approximately 10% of these children have an identifiable disorder as the probable cause.
 - Gastrointestinal
 - Extraintestinal (renal, metabolic, neurologic)
 - Abdominal migraine is a common cause of cyclic vomiting.
 - Paroxysmal onset of repetitious attacks is often relieved with sleep.
 - Strong family history of migraine
 - May be accompanied by typical migraine headache
 - Abdominal epilepsy is a much less common cause of cyclic vomiting.
- PHYSICAL EXAM**
- Physical examination should begin with measurement of weight, length/height, heart rate, blood pressure and orthostatic changes in blood pressure.
 - Determine the hydration status of the child.
 - Observe the shape of the abdomen
 - Distention may be associated with ascites, paralytic ileus, and abdominal masses.
 - Visible peristalsis and gastric splash are associated with gastric outlet obstruction in infants.
 - Acute abdominal signs, such as generalized tenderness and rigidity, suggest surgical abdomen.
- DIFFERENTIAL DIAGNOSIS**
- Causes of emesis, by usual age of earliest occurrence**
- Infancy/early childhood
 - Gastrointestinal
 - Congenital
 - Regurgitation—gastroesophageal reflux (developmental or pathologic)
 - Atresia—stenosis (tracheoesophageal fistula, antral web, intestinal atresia, annular pancreas)
 - Duplication
 - Volvulus (secondary to an error in rotation and fixation or to Meckel diverticulum)
 - Congenital bands
 - Meconium ileus (cystic fibrosis), meconium plug
 - Acquired
 - Hirschsprung disease
 - Nongastrointestinal
 - Infectious—otitis, urinary tract infection, pneumonia, upper respiratory tract infection, sepsis, meningitis
 - Metabolic—aminoaciduria and organic aciduria, galactosemia, fructosemia, adrenogenital syndrome, renal tubular acidosis, hyperammonemia, disorders of fatty acid oxidation (eg, medium-chain acyl-coenzyme A dehydrogenase deficiency), mitochondrial disease, Reye syndrome
 - Central nervous system—trauma, tumor, infection, diencephalic syndrome, rumination, autonomic responses (pain, shock)
 - Medications— anticholinergics, aspirin, alcohol, idiosyncratic reaction (eg, codeine)
- Childhood/adolescence—most of the above remain considerations, with additional possible causes.
 - Gastrointestinal
 - Appendicitis
 - Food poisoning (staphylococcal, clostridial)
 - Peptic disease—ulcer, gastritis, duodenitis
 - Trauma—duodenal hematoma, traumatic pancreatitis, perforated bowel
 - Pancreatitis—mumps, trauma, cystic fibrosis, hyperparathyroidism, hyperlipidemia, organic acidemias
 - Gallbladder—cholelithiasis, choledochal cyst
 - Crohn disease
 - Adhesions—congenital or secondary to abdominal surgery
 - Idiopathic intestinal pseudoobstruction
 - Superior mesenteric artery syndrome

- Nongastrointestinal
 - Central nervous system—cyclic vomiting, migraine, anorexia nervosa, bulimia
 - Motion sickness
 - Metabolic—diabetic ketoacidosis, acute intermittent porphyria
 - Pregnancy—must always be considered in the differential diagnosis of vomiting in a postpubertal girl

LABORATORY EVALUATION

- With persistent vomiting, the clinician should expect to see a metabolic alkalosis.
- Metabolic acidosis raises concerns about underlying metabolic disorder or drug intoxication.

IMAGING

- Evaluation of the gastrointestinal tract usually includes an upper gastrointestinal contrast roentgenographic study.
- In an infant between 2 and 12 weeks of age, the first study is often ultrasonography of the abdomen for pyloric stenosis.
- Magnetic resonance imaging is more sensitive than computed tomography of the head if brain tumor is a consideration in an infant.
 - Further workup for metabolic or neurologic disease should be considered, as appropriate.
- If a midgut malrotation is suspected:
 - Plain-film radiography of the abdomen may show a paucity of gas distal to the upper small intestine.
 - If a midgut volvulus is suspected, an upper gastrointestinal roentgenographic series should be done at once.
 - Should be performed with controlled introduction of barium through a nasogastric tube after gastric aspiration
 - A barium enema investigation of cecal position is less reliable when evaluating a patient for malrotation.
 - Lack of complete correlation of developmental rotation of the cecum with that of the duodenum

DIAGNOSTIC PROCEDURES

- The following tests are all useful in establishing a diagnosis of gastroesophageal reflux.
 - Esophageal pH monitoring
 - Esophageal biopsies
 - Gastroesophageal scintiscan
- Endoscopy is feasible in all children, even newborns, and when indicated should be performed by an experienced examiner using a pediatric instrument.

TREATMENT APPROACH

- Acute intercurrent vomiting without serious underlying disease or significant dehydration should be treated by administering clear liquids by mouth, eg, in acute gastroenteritis or otitis media.

- Begin with frequent small quantities of clear liquids.
 - 1 teaspoonful every few minutes for infants
 - Gradually increase volume and extension of the intervening period
- If vomiting is associated with diarrhea and dehydration, oral rehydration solution is indicated.
 - Carbonated beverages may increase vomiting.
 - Fluids that tend to slow gastric emptying and should be avoided:
 - High osmolality
 - Long-chain triglycerides
 - Anticholinergic drugs
- Antiemetic drugs
 - Should be avoided in infants, but may at times be useful in older children
 - Do not appear to have a role in the management of acute viral gastroenteritis
- For persistent vomiting, a nasoduodenal infusion may be useful.
- Patients should be monitored for signs of dehydration.
- Mild to moderate degree of dehydration may be corrected by oral hydration, even in the presence of ongoing vomiting.
- Significant vomiting that requires intravenous fluid therapy is usually associated with hypochloremic alkalosis with secondary hypokalemia.

SPECIFIC TREATMENT

Antiemetics

- Antiemetic drugs used most commonly for acute symptoms are ondansetron and promethazine.
- Trimethobenzamide may be less effective but is also used.
- Rectal suppositories are preferable to oral drugs.
 - Nausea is associated with gastric atony and unpredictable absorption.
- Dopamine-receptor antagonists are effective for chemotherapy-induced vomiting.
 - Metoclopramide
 - 5-HT₃-receptor antagonists (ondansetron) appear to have even greater efficacy and are without the risks of dystonic reactions associated with metoclopramide.
- Low-dose erythromycin has been used successfully to treat some children who have idiopathic cyclic vomiting.

Motion sickness

- H₁-receptor antagonists prevent motion sickness.
 - Diphenhydramine
 - Dimenhydrinate
 - Meclizine
 - Promethazine

- As do muscarinic cholinergic receptor antagonists

- Scopolamine

Gastroesophageal reflux

- Management of gastroesophageal reflux must be individualized.
- The extent of treatment depends on the volume of emesis and the presence of any of the complications of reflux.
 - Esophagitis with or without esophageal stricture or intractable anemia
 - Failure to thrive
 - Respiratory manifestations
- Medical management includes thickening of feeds with cereal.
 - Standard concentration is 1 tablespoonful of cereal for each 1–2 ounces of formula.
- For a sleeping infant, the left lateral decubitus position may be helpful for reflux.
 - An infant in the first months of life should never sleep prone.
- Elevating the head of the bed remains standard therapy for older children and adults.
- Older children should also avoid snacks or liquids after dinner and agents that exacerbate esophagitis, eg, alcohol, caffeine, smoking.
- Medications can be used in an attempt to improve lower esophageal function and gastric emptying.
 - Metoclopramide
 - Low-dose erythromycin
- Medications also can be used to decrease exposure of the esophageal mucosa to acid.
 - Antacids
 - H₁-receptor blockers
 - Proton pump inhibitors
- A slurry of sucralfate is used occasionally as cytoprotective.
- Medical management may be unsatisfactory.
 - In this case, antireflux surgery, fundoplication, should be considered.
 - In these children, results of surgery are generally good when performed by an experienced surgeon and benefits can be long lasting.
 - In children who have psychomotor retardation and gastroesophageal reflux, antireflux surgery may not eliminate respiratory symptoms.
 - Other factors, such as swallowing dysfunction, may contribute to these findings.
 - Among all children undergoing a Nissen fundoplication, risk of a postoperative complication requiring further surgery may be as high as 10%.
 - Underscores the need for careful patient selection for this operation

Abdominal migraine

- The following are highly effective as prophylactic treatment for abdominal migraine.
 - Cyproheptadine
 - Amitriptyline
 - Topiramate
 - Propranolol
- Treatment success helps confirm the diagnosis.

WHEN TO REFER

- Persistent vomiting
- Recurrent episodes of vomiting
- Vomiting associated with a significant underlying process (eg, surgical abdomen, neurologic problem)

WHEN TO ADMIT

- Intractable vomiting with dehydration
- Vomiting associated with severe dehydration
- Vomiting in association with symptoms or signs of an acute abdominal process (eg, acute appendicitis, pancreatitis, cholecystitis)
- Vomiting associated with metabolic derangement
- Vomiting associated with a central nervous system abnormality, such as meningoencephalitis and tumors.

FOLLOW-UP

- All patients with vomiting should be followed carefully and monitored for weight changes, signs of dehydration, and electrolyte abnormalities.

COMPLICATIONS

- The most significant complications of vomiting include:
 - Dehydration and electrolyte imbalance, especially when the vomiting is persistent
 - Aspiration pneumonia
 - Hemorrhage from prolapse gastropathy
 - A hemorrhagic area on the posterior wall of the proximal stomach
 - Less commonly, Mallory-Weiss syndrome, a tear at the gastroesophageal junction, may occur.
 - Rupture of the esophagus, which is very uncommon in children
 - Feeding refusal may follow persistent vomiting, especially in infants.
 - Persistent vomiting may lead to failure to thrive.

PROGNOSIS

- Prognosis for vomiting depends on the cause of the vomiting.

Weight Loss

DEFINITION

- Clinically significant weight loss is dependent on age.
 - Newborns may lose 5–10% of birth weight in the first few days of life; losses >12% are concerning.
 - In children, weight loss >5–10% from baseline may be concerning.
 - In adolescents, in addition to weight relative to baseline, consider absolute weight in relation to ideal body weight.

EPIDEMIOLOGY

- In adolescents, planned dieting must be distinguished from an eating disorder, such as anorexia nervosa or bulimia nervosa.
 - 0.5% of female adolescents have anorexia nervosa.
 - 1–5% meet criteria for bulimia.
 - 5–10% of all cases of eating disorders occur in boys.
- As many as one-half of adolescents with eating disorders do not meet the *Diagnostic and Statistical Manual of Mental Disorders* criteria.
 - These individuals remain at risk for both physical and psychological complications from their altered eating habits.

MECHANISM

- In general, weight loss occurs when caloric intake does not meet caloric expenditure.
 - In breastfed infants, actual intake may be difficult to ascertain, given dependencies on both maternal milk production and effective feeding.
 - In children, even if enteral intake appears sufficient, there may be issues with absorption and ability to metabolize the nutrition.
- Weight loss may result from fluid losses.

HISTORY

- In all patients, records of previous body weights, allowing for differences in weighing technique, can be helpful.
- Obtain a complete history, including:
 - Diet and consumption history of child and family, with caloric assessment
 - Assess parental expectations.
 - Take a careful birth, family, past medical, and medication history.
 - Assess sick contacts/exposure to illness, and immediate past history of febrile or other illness.
 - Determine the number of urinations and bowel movements per day.
 - Review gastrointestinal/malabsorption symptoms, such as emesis, constipation, and diarrhea, and amount, frequency, and character of stools.
 - Assess other indications of feeding intolerance, including rashes.
 - Compare caloric intake with estimated caloric needs.

- For infants:
 - In general, an infant should gain 25–30 g each day in the first 3 months of life.
 - Assess feeding effort and coordination.
 - If formula-feeding:
 - Discuss the proportions in which formula is constituted.
 - Estimate total caloric intake from the volume of formula and caloric density of formula (standard is 20 kcal/oz).
 - The formula-fed newborn rarely loses >5% of birth weight in the first few days.
 - Weight less than birth weight at the age of 10 days is unusual for a formula-fed infant and indicates need for thorough evaluation.
 - If breastfeeding, assess:
 - Perceived adequacy of maternal milk production
 - Ability of infant to breastfeed
 - Typically, birth weight is regained in 10 days; consider interventions if it is unlikely to be regained in the first 2 weeks, especially with new parents.
- For children and adolescents:
 - Discuss whether eating leads to symptoms, such as pain, emesis, diarrhea, or fatigue.
 - Discuss quantity and type of stools.
 - Assess body image, social context (including family function, patient's emotional well being), and stressors.
 - Consider HEADDSSS examination and substance abuse.
 - Does the patient participate in sports where weight loss is a goal?
 - Wrestling, gymnastics, ice skating, running, swimming, diving, dancing
 - If yes, obtain a thorough dietary and supplement history.
 - For girls, obtain a menstruation history.

PHYSICAL EXAM

- The definition of significant weight loss varies by the child's age and includes acute and chronic causes.
- Subjective impressions of weight loss should be verified objectively before an evaluation is undertaken.
 - True weight loss may sometimes be difficult to differentiate from factitious weight loss.
 - Errors occur in 5–20% of all children weighed because of faulty equipment or poor technique.
- Vital signs
 - Assess temperature; consider heart rate, blood pressure, and orthostatic vital signs.

- Weigh the individual and plot on growth chart; consider serial weights for computation of growth velocities.
- With breastfed infants, consider weighing the infant before and after feedings.
- Obtain length/height.
 - In children ≥ 2 years, compute body mass index, body mass index percentile, and weight for length/height.
- Physical examination
 - Assess mental status.
 - Assess volume status and for anemia (eg, pale conjunctiva).
 - Examine oral mucosa for thrush and ulcerations.
 - Oral aphthous ulcers may be related to Crohn disease.
 - Discoloration of teeth may be related to purging behaviors.
 - Assess cardiorespiratory status.
 - Assess abdomen and for presence of organomegaly.
 - Look for signs of malnutrition or vitamin deficiencies (eg, lanugo).
 - Assess for toxidromes in adolescents.
- In breastfed infants, where weight loss is suspected because of inadequacy of feeding, observe the mother nursing the baby.
 - The infant should be observed to latch on to the breast correctly.
 - Note whether there is loud swallowing or occasional choking at the start of feeding.

DIFFERENTIAL DIAGNOSIS

- The differential diagnosis for weight loss is broad and varies somewhat with age.
- Of note, poverty is the greatest single risk factor for failure to thrive in the US.
 - Psychosocial factors (poor parent-child interaction, depression, rumination) often underlie poor growth and development.
 - Actual weight loss is much less common in this setting than slowdown or cessation of weight gain and linear growth.
 - Psychosocial dysfunction that results in a child's weight loss requires a prompt and thorough evaluation.
 - Eating disorders have been described in prepubertal children as young as 7 years.

Newborns and young infants

- Difficulties in establishing breastfeeding
- Inappropriate dilution or choice of formula
- Inadequate intake
 - In breastfed infants, inadequate intake at the breast is the most common reason for weight loss.

- In formula-fed infants, consider unsuccessful feeding related to parental inexperience; if this is not the case:
 - Search for an organic problem.
 - Evaluate family dynamics, support mechanisms, and adjustment to the newborn.

- Infection
- Metabolic abnormality
- Craniofacial abnormalities
- Central nervous system dysfunction
- Somnolence from maternal medications/substance abuse
- Congenital heart disease
- Maternal depression, inexperience, lack of knowledge
- Excessive losses secondary to vomiting or diarrhea
- Vomiting because of gastrointestinal malformations (eg, duodenal atresia)
- Polyuria (diabetes insipidus, renal disease)
- Diarrhea

Older infants, preschoolers, and school-age children

- Pyloric stenosis
- Gastroesophageal reflux
- Central nervous system tumors
- Vomiting
- Diarrhea
- Fever and infection
- Diabetes mellitus
- Excessive activity
- Inadequate intake
- Tuberculosis
- Surgery
- Medication effect (loss of appetite)
- Cancer
- Congenital heart disease
- Poor utilization
- Malabsorption syndromes
- Inflammatory bowel disease
- Immunodeficiency disorders, especially HIV infection
- Psychosocial dysfunction
- Neglect; nonorganic failure to thrive
- Parental depression
- Childhood depression
- Rumination
- Childhood eating disorder

Adolescents

- Dieting behavior
- Adolescent eating disorders

■ Anorexia nervosa

- Suspect when the adolescent is unwilling or unable to maintain body weight over a minimally normal weight for age and height.
- Attitudes and behaviors about eating or body image are distorted; amenorrhea, emaciation, and overactivity may be described.
- Concurrently, may have hypothyroidism, bradycardia, hypothermia, growth of lanugo-like hair on body and extremities

■ Bulimia nervosa

- Binge eating, followed by self-induced vomiting, self-starvation, overactivity, and use of cathartics or diuretics to reduce weight
 - These behaviors are practiced in secret, and the adolescent often denies them.

■ Other eating disorders

■ Psychiatric affective disorders, especially depression

■ Cancer

■ Inflammatory bowel disease

■ Diabetes mellitus

■ Hyperthyroidism

■ Tuberculosis

■ Sports-related weight loss

- Adolescents may engage in unhealthy weight-control practices to seek advantage in their athletic activities.
 - These may include food restriction, vomiting, overexercise, diet pills, stimulants, insulin, nicotine, and voluntary dehydration.

LABORATORY EVALUATION

- Evaluation is guided by clinical suspicion.
- In infants, ensure that newborn screening has been performed.
- Studies may include:
 - Blood chemistries, kidney function tests
 - Complete blood cell count, smear
 - Erythrocyte sedimentation rate
 - Serum protein and albumin levels; serum carotene; specific tests of malabsorption
 - Tuberculosis skin test
 - Stool guaiac
 - Kidney-related tests; urinalysis, including specific gravity; urine culture
- Please also refer to the Laboratory Evaluation section of Loss of Appetite (on anorexia).

IMAGING

- Imaging is guided by clinical suspicion.

DIAGNOSTIC PROCEDURES

- Diagnostic procedures may be performed as guided by clinical suspicion.
 - Upper endoscopy with biopsy
 - Colonoscopy
 - Sweat chloride testing
 - Esophageal motility testing
 - pH probes

TREATMENT APPROACH

- In addition to diagnostic testing, serial evaluations of weight and intake are the cornerstones of assessing weight issues.

SPECIFIC TREATMENT

- See Loss of Appetite (anorexia), Anorexia Nervosa, and Bulimia Nervosa.

Infants

- In breastfed infants with inadequate weight gain, support and education are appropriate interventions.
- Appropriate weight gain in the following few days provides evidence that the infant is well and confirms the diagnosis of initial underfeeding.
- Prematurely recommending discontinuation of breastfeeding is inappropriate.
 - The mother's motivation to breastfeed and her positive or negative feelings about the experience should be discussed.
 - Encouragement and support should be given for continuation of nursing.
 - Do not reinforce parental perceptions that the mother's milk supply is insufficient or less nutritious than formula.
 - Lactation consultants or community organizations (eg, La Leche League) may be helpful in supporting lactation efforts.
 - Infants who fail to thrive while breastfeeding require more intensive nutritional rehabilitation while still preserving breastfeeding.

WHEN TO REFER

- Refer when there is evidence or suspicion of:
 - Cancer
 - Endocrinopathy (thyroid, adrenal, pituitary)
 - Gastrointestinal disorder (eg, gastroesophageal reflux; malabsorption, including cystic fibrosis; inflammatory bowel disease)
 - Pancreatitis
 - Heart disease
 - Renal disease
 - Pulmonary disease
 - Rheumatologic condition

- Central nervous system abnormality
- Metabolic disorder
- Surgical abdominal problem (eg, pyloric stenosis, Hirschsprung disease, volvulus)
- Immunodeficiency
- Unusual infection
- Psychiatric diagnosis in child or caretaker
- Anorexia nervosa or bulimia nervosa in the child or adolescent
- New-onset of diabetes mellitus (usually)
- Evidence of severe febrile illness (eg, pneumonia, pyelonephritis, osteomyelitis, meningitis, septic arthritis)
- Evidence of dehydration
- Physiological instability
- Severe bradycardia
- Hypotension
- Hypothermia
- Orthostatic changes
- Electrolyte abnormalities (eg, hypernatremia, hypokalemia)
- Evidence of significant psychosocial dysfunction

WHEN TO ADMIT

■ A newborn, when:

- Weight loss cannot be managed as an outpatient
- Weight loss is >12–15% of birth weight
- Excessive fluid loss (vomiting, diarrhea, polyuria)
- Evidence of clinically significant dehydration or inability to maintain adequate hydration status
- Suspicion of infection, metabolic abnormality, congenital heart disease, other conditions requiring evaluation
- Extreme passivity of the infant, which may require tube feeding
- Need for intensive maternal education and support

■ At any age, when:

- Weight loss is excessive (>5–10% of previous weight).
- Excessive fluid loss from vomiting or diarrhea

■ An adolescent, when:

- Eating disorder cannot be managed as an outpatient
- Severe malnutrition, with weight <75% of ideal body weight
- Evidence of dehydration or electrolyte abnormalities
- Physiologic instability
- Acute food refusal
- Uncontrollable binge eating and purging
- Acute medical complication of malnutrition (syncope, seizures, cardiac failure, pancreatitis)
- Suicidal intent or ideation, or psychosis

Wheezing

DEFINITION

- Wheezing is a continuous, musical sound that represents turbulent, intrathoracic airflow.
- It may be present in both inspiration and expiration but is usually more prominent during expiration.

MECHANISM

- During the normal respiratory cycle, rhythmic expansion and contraction of the thorax leads to dynamic changes in thoracic pressures, allowing air to flow into and out of the lungs.
- On inspiration, the thoracic cavity expands, resulting in negative intrathoracic and airway pressures and allowing air to flow into the lungs.
 - Extrathoracic airway obstruction, signaled by stridor, is most likely to cause turbulent airflow during this phase.
- Expiration is accomplished by contracting the volume of the thoracic cavity, creating positive pressure in the thorax, which is transmitted to the intrathoracic airways.
 - The intrathoracic airways are more prone to obstruction leading to turbulent airflow during expiration.
- Wheezing is most commonly associated with distal airway obstruction.
- External compression of large airways may be caused by:
 - Vascular abnormalities (rings and slings)
 - Mediastinal masses
 - Infectious agents, such as lymphobronchial tuberculosis
- Intrinsic airway abnormalities may be caused by:
 - Complete tracheal rings and webs
 - Acquired obstructions, such as tracheal stenosis or granulation tissue
- Asthma exacerbations can be initiated by:
 - Vigorous activity
 - Changes in weather
 - Upper respiratory infection
 - Exposure to a triggering allergen/irritant

HISTORY

- A detailed and focused history can often provide clues to an accurate diagnosis.
- History includes:
 - Onset and frequency of wheezing
 - Recent illnesses and surgeries

PHYSICAL EXAM

- Through auscultation, determine if wheezing is bilateral or unilateral.
- Unilateral wheezing
 - Most often associated with aspiration of a foreign body

- Can accompany unilateral bronchial compression or stenosis
- Make a detailed assessment of the auditory characteristics of the wheeze.
 - Can help determine whether the obstruction is central or peripheral
 - Wheezing that varies in pitch and can be heard throughout the chest (musical, heterophonous) typically represents small airway obstruction.
 - Wheezing that is more even in pitch (monophonic, homophonous) is typically central airway obstruction and can often be heard best in central locations, such as the sternal notch.
 - Large airway obstruction is more likely to be heard throughout the entire expiratory phase.
- Positional characteristics should be evaluated.
 - Wheezing caused by a dynamic lesion (eg, tracheomalacia) is often worse when a patient is supine.
 - Mediastinal structures, such as the heart and the great vessels:
 - Tend to fall posteriorly in the supine position and can be obstructive
 - Fall anteriorly when the patient is prone, relieving pressure on the airway and improving the wheeze
 - Wheezing caused by small airway obstruction or fixed compression of a large airway does not typically change with position.

DIFFERENTIAL DIAGNOSIS

- Any process that can cause obstruction of intrathoracic airways should be considered in the differential diagnosis.
- Viral bronchiolitis and asthma account for most wheezing.
- Pulmonary hemosiderosis can cause recurrent wheezing because blood irritates the peripheral airways.
- Wheezing after a recent surgical procedure or intubation suggests acquired obstruction.
- Asthma
 - Worse with exercise or respiratory infections
 - Responds to bronchodilators and steroids
 - Reversible obstruction on pulmonary function testing
 - Heterophonous wheeze
 - Positive broncho-provocation
- Tracheomalacia
 - Worse with activity or agitation
 - Poor response to bronchodilators and steroids
 - Homophonous wheeze
 - Airway collapse on fluoroscopy
 - Collapsible trachea on bronchoscopy

- Bronchomalacia
 - Worse with activity or agitation
 - Poor response to bronchodilators and steroids
 - Homophonous wheeze
 - Airway collapse on fluoroscopy
 - Collapsible bronchus on bronchoscopy
 - Foreign body
 - Sudden onset
 - May have a history of choking
 - Differential breath sounds
 - Differential hyperinflation or collapse on radiography
 - Heart failure or pulmonary edema
 - Poor response to albuterol
 - Poor growth
 - Hepatomegaly
 - Radiography showing increased fluid
 - Responds to diuresis
 - Bronchiolitis
 - Infant: upper respiratory infection symptoms
 - Positive viral studies
 - Wheezing caused by viral bronchiolitis:
 - Is usually preceded by upper respiratory symptoms and fever
 - Worsens within the first few days of onset
 - Tends to improve slowly thereafter
 - Vocal cord dysfunction
 - Poor response to all therapies
 - Severe distress reported
 - Pulmonary function tests: normal or with abnormal inspiratory loop
 - Laryngoscopy: vocal cord adduction during inspiration
 - Cystic fibrosis
 - Poor growth, gastrointestinal (GI) symptoms
 - Recurrent pneumonias
 - Positive sweat test
 - Gastroesophageal reflux and aspiration
 - Variable response to bronchodilators
 - Often worse after meals
 - Poor growth, GI symptoms
 - Recurrent pneumonias
 - Positive reflux evaluation (upper GI, nuclear scan or pH probe)
 - Vascular compression
 - Central wheeze
 - No bronchodilator response
 - Indentation on esophagram
 - Anatomy demonstrated on thoracic magnetic resonance imaging
 - Large airway abnormality (stenosis, complete rings, compression)
 - No response to therapy
 - Worse with activity
 - Stridor noted at times
 - Flattened or square flow–volume loop
 - Obstruction visible on imaging or bronchoscopy
 - Wheezing that appears at birth or soon afterward should prompt an evaluation for congenital airway abnormalities, such as:
 - Tracheomalacia
 - Complete rings
 - Vascular abnormalities or compression
- LABORATORY EVALUATION**
- Laboratory testing may be indicated to diagnose specific clinical entities.
 - Sweat test for cystic fibrosis
 - Viral studies can identify respiratory syncytial virus or influenza.
- IMAGING**
- Chest radiography can be used to detect:
 - Thoracic masses that cause obstruction of airways
 - Foreign body aspiration
 - Airway fluoroscopy
 - Can confirm diagnosis and help quantify the severity of tracheobronchomalacia
 - Esophagraphy or upper GI series
 - Useful if a vascular abnormality is suspected
 - Computed tomography or magnetic resonance imaging
 - Confirmation of vascular abnormality
- DIAGNOSTIC PROCEDURES**
- Pulmonary function testing
 - Can help characterize a wheeze objectively
 - Direct visualization of the airway via flexible bronchoscopy
 - To characterize dynamic lesions (ie, tracheobronchomalacia)
 - Rigid bronchoscopy
 - Can be useful in diagnosis and treatment of tracheal stenosis

TREATMENT APPROACH

- In general, when evaluating and managing the wheezing child:
 - Be aware of the various clinical entities that can produce wheezing.
 - Be able to recognize by history or physical examination patients who require further workup.
 - Initiate simple diagnostic tests.

SPECIFIC TREATMENT**Asthma and viral bronchiolitis**

- See Asthma.
 - Responds to bronchodilators
 - Responds to steroids
- See Viral Bronchiolitis.
 - No evidence supports the regular use of β -agonist therapy in viral bronchiolitis.
- Some children require hospitalization for severe respiratory distress, hypoxemia, poor feeding, or dehydration.
- Wheezing associated with failure to thrive in an infant may be a sign of significant underlying disease.

WHEN TO REFER

- Refer to appropriate subspecialty physicians children with unusual presentations or poor response to conventional therapies.
 - Persistent or recurrent wheezing in an infant <1 year
 - Apparent paradoxical response to bronchodilators
 - Poor weight gain or growth associated with chronic or recurrent wheezing
 - Repeated hospitalization or multiple courses of oral corticosteroids

WHEN TO ADMIT

- Respiratory distress unresponsive to therapy
- Hypoxemia
- Tachypnea interfering with ability to eat or drink
- Altered mental status or signs of fatigue

Conversion Formulas

Height (length)	
1 millimeter (mm) = 0.04 inch 1 centimeter = 0.4 inch	1 inch = 2.54 centimeter 1 meter = 39.37 inches
Weight	
60 milligrams (mg) = 1 grain 28.35 grams (g) = 1 ounce 453.6 grams = 1 pound 1000 grams (1 kilogram [kg]) = 2.2046 pounds	1 liter (L) = 1.06 quarts 1 fluid ounce (oz) = 29.57 mL 1 tablespoon = 15 mL 1 teaspoon = 5 mL
Milligram–milliequivalent conversions	
mEq/L = mg/L × valence/atomic weight Equivalent weight = atomic weight/valence	mg/L = mEq/L × atomic weight/valence
Milligram-millimole conversions	
Millimoles/L (mmol/L) = mg/L ÷ molecular weight	
Milliosmols	
The milliequivalent (mEq) is roughly equivalent to the milliosmol (mOsm), the unit of measure of osmotic pressure or tonicity. One osmole is the amount of a substance that dissociates in solution to form one mole of osmotically active particles.

Blood Pressure Nomograms for Healthy Term Infants During the First 12 Hours of Life

A. Linear regressions (broken lines) and 95% confidence limits (solid lines) of systolic (top) and diastolic (bottom) aortic blood pressures on birth weight in 61 healthy newborn infants during the first 12 hours after birth. For systolic pressure, $y = 7.13x + 40.45$; $r = .79$. For diastolic pressure, $y = 4.81x + 22.18$; $r = .71$. For both, $n = 413$ and $p < .001$. **B.** Linear regressions (broken lines) and 95% confidence limits (solid lines) of mean pressure (top) and pulse pressure (systolic-diastolic pressure amplitude) (bottom) on birth weight in 61 healthy newborn infants during the first 12 hours after birth. For mean pressure, $y = 5.16x + 29.80$; $n = 443$; $r = .80$. For pulse pressure, $y = 2.31x + 18.27$; $n = 413$; $r = .45$. For both, $p < .001$.

From: Versmold HT, Kitterman JA, Phibbs RH, et al. Aortic blood pressure during the first 12 hours of life in infants with birth weight 610 to 4,220 grams. *Pediatrics*. 1981;67(5):607.

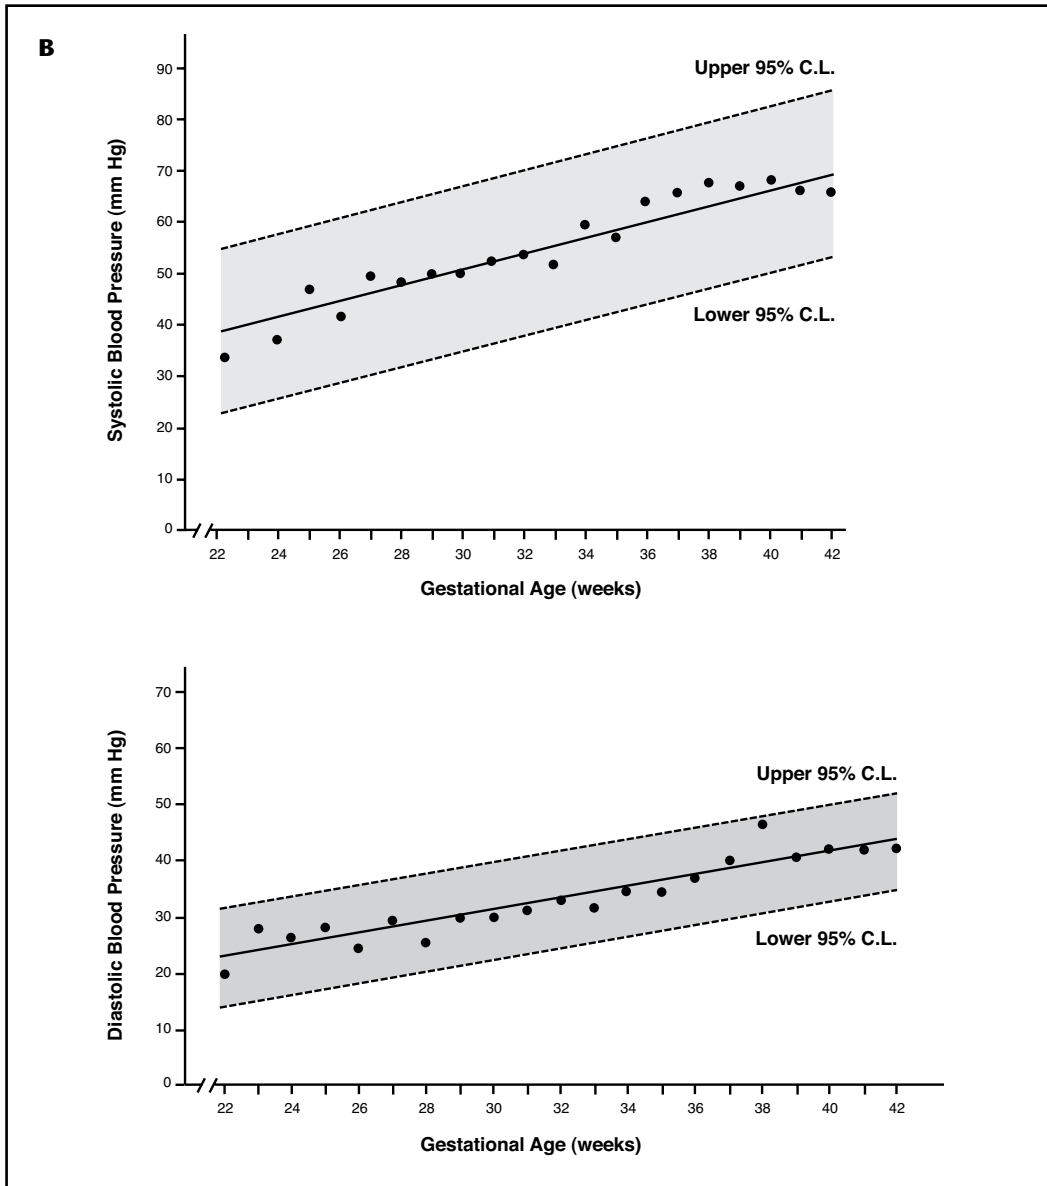

Blood Pressure Nomograms for Preterm and Full-term Neonates During the First Day of Life (According to Birth Weight)

A. Linear regression of mean systolic and diastolic blood pressures by birth weight on day 1 of life, with 95% confidence limits (*upper and lower dashed lines*).

From: Zubrow AB, Hulman S, Kushner H, et al. Determinants of blood pressure in infants admitted to neonatal intensive care units: a prospective multicenter study. *J Perinatol.* 1995;15(6):470–479. Reprinted by permission from Macmillan Publishers Ltd: *Journal of Perinatology*.

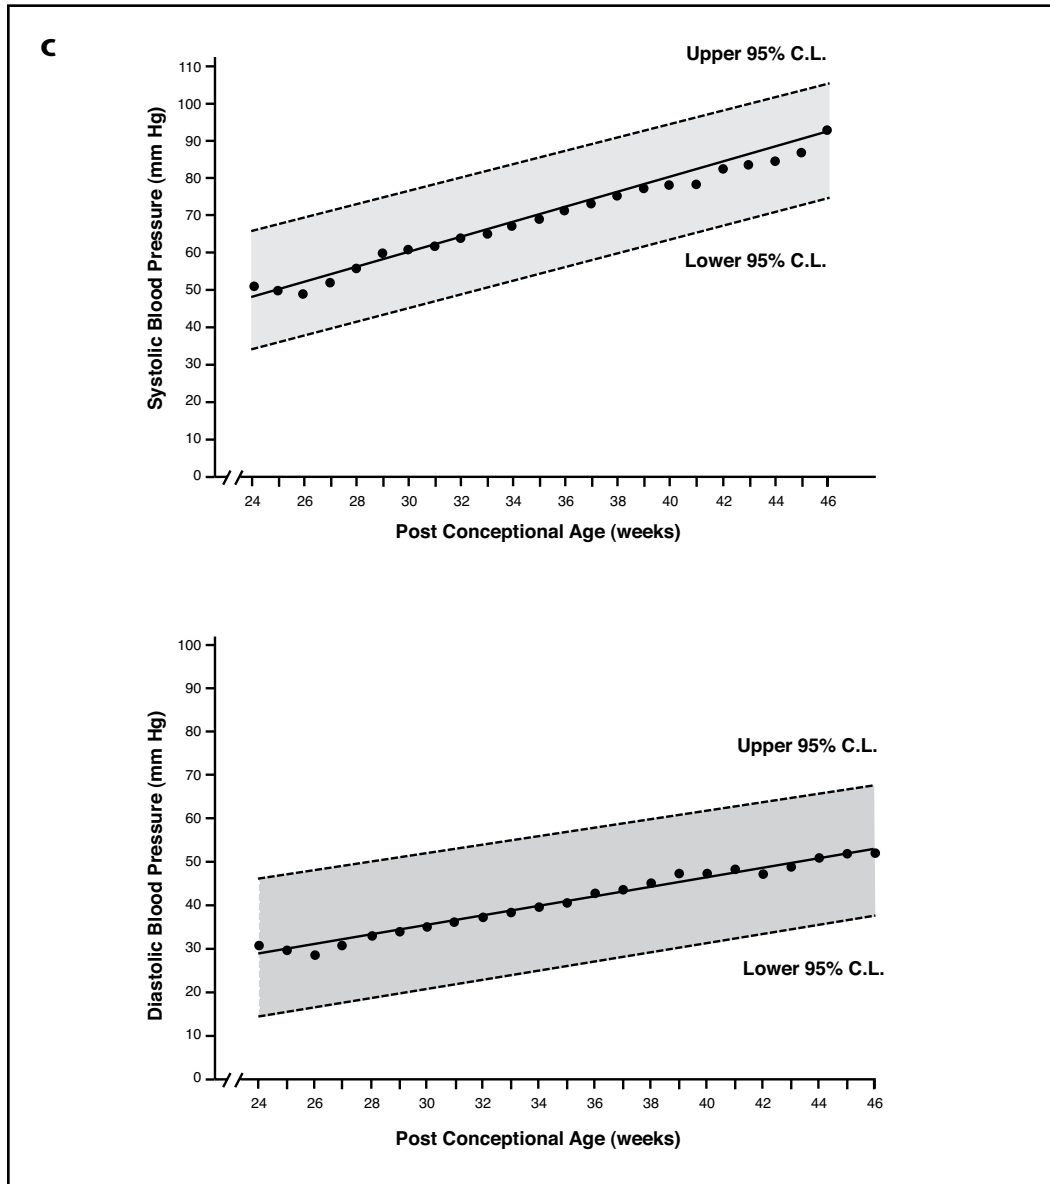

Blood Pressure Nomograms for Preterm and Full-term Neonates During the First Day of Life (According to Gestational Age)

B. Linear regression of mean systolic and diastolic blood pressures by gestational age on day 1 of life, with 95% confidence limits (*upper and lower dashed lines*).

From: Zubrow AB, Hulman S, Kushner H, et al. Determinants of blood pressure in infants admitted to neonatal intensive care units: a prospective multicenter study. *J Perinatol.* 1995;15(6):470–479. Reprinted by permission from Macmillan Publishers Ltd: *Journal of Perinatology*.

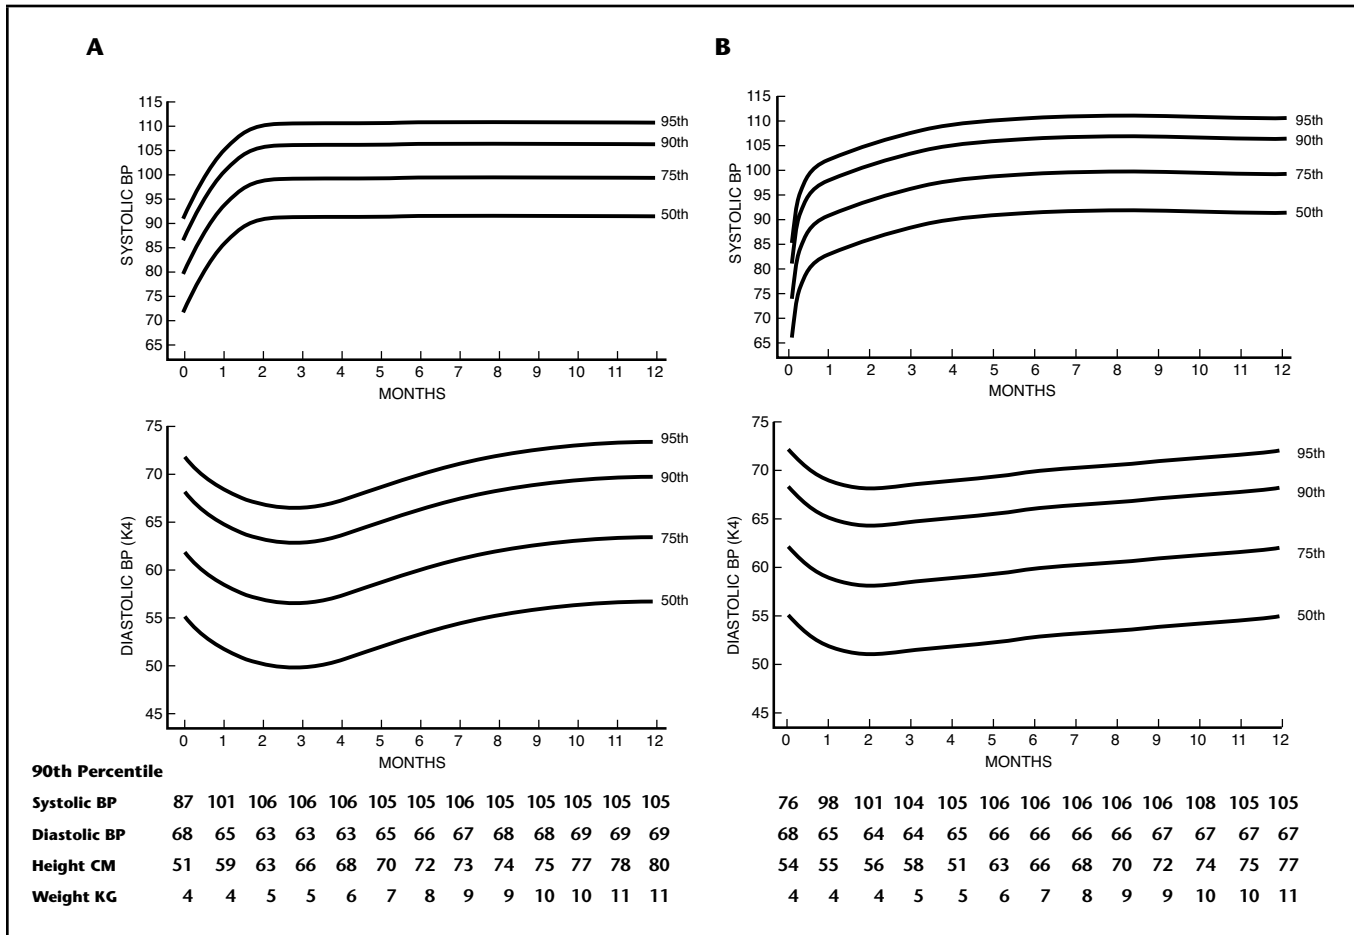

Blood Pressure Nomograms for Preterm and Full-term Neonates During the First Few Weeks of Life

C. Linear regression of mean systolic and diastolic blood pressures by postconceptional age in weeks, with 95% confidence limits (*upper and lower dashed lines*).

From: Zubrow AB, Hulman S, Kushner H, et al. Determinants of blood pressure in infants admitted to neonatal intensive care units: a prospective multicenter study. *J Perinatol.* 1995;15(6):470–479. Reprinted by permission from Macmillan Publishers Ltd: *Journal of Perinatology*.

Blood Pressure Nomograms for Children Younger Than 1 Year

A. Age-specific percentiles of BP measurements in boys—birth to 12 months of age; Korotkoff phase IV (K4) used for diastolic BP. **B.** Age-specific percentiles of BP measurements in girls—birth to 12 months of age; Korotkoff phase IV (K4) used for diastolic BP.

From: American Academy of Pediatrics. Report of the Second Task Force on Blood Pressure Control in Children—1987. Task Force on Blood Pressure Control in Children. National Heart, Lung, and Blood Institute, Bethesda, Maryland. *Pediatrics*. 1987;79(1):1.

Elk Grove Village, IL: American Academy of Pediatrics; 2009.

Determining Body Surface Area

Based on the nomogram shown in Figure C-4, a straight line joining the patient's height and weight will intersect the center column at the calculated body surface area (BSA). For children

of normal height and weight, the child's weight in pounds is used, then the examiner reads across to the corresponding BSA in meters². Alternatively, Mosteller's formula can be used.

Nomogram and equation to determine body surface area.

Bone Age

Sontag Method

The Sontag method is used to evaluate the skeletal development of children between 1 and 60 months of age:

1. Radiographs are taken of all epiphyseal centers on the left side of the body: shoulder, elbow, wrist and hand, hip, knee (anteroposterior [AP] views before 24 months of age, lateral views after 24 months), and ankle and foot (AP views before 48 months of age, lateral views after 48 months).
2. All ossification centers in the left half of the body are counted. A center is counted as soon as it casts any shadow on the roentgenogram.
3. The number of ossification centers is compared with normal values for the patient's age (Table C 1).

Grulich and Pyle Method

The Grulich and Pyle method is used to evaluate the skeletal development of girls from 5 to 18 years of age and of boys from 5 to 19 years:

1. A radiograph is taken of the left hand and wrist.
2. Calculation of the skeletal development is based on the order of appearance and maturation of the epiphyseal centers. (For normal values, see Grulich and Pyle's *Radiographic Atlas of Skeletal Development of the Hand and Wrist*.)

Mean Total Number of Centers on the Left Side of Body Ossified at Given Age Levels

Age (mos)	Boys		Girls	
	Mean	SD	Mean	SD
1	4.11	1.41	4.58	1.76
3	6.63	1.86	7.78	2.16
6	9.61	1.95	11.44	2.53
9	11.88	2.66	15.36	4.92
12	13.96	3.96	22.40	6.93
18	19.27	6.61	34.10	8.44
24	29.21	8.10	43.44	6.65
30	37.59	7.40	48.91	6.50
36	43.42	5.34	52.73	5.48
42	47.06	5.26	56.61	3.98
48	51.24	4.59	57.94	3.91
54	53.94	4.35	58.89	3.36
60	56.24	4.07	61.52	2.69

SD, standard deviation.

Acid Base Response in Respiratory Acidosis and Alkalosis

The nomogram shows confidence bands for the normal adjustment in carbon dioxide content and pH made to accommodate acute and chronic changes in arterial P_{CO_2} .

1. The pH is determined on the nomogram from the plotted (P_{CO_2}) and carbon dioxide content obtained from blood gas measurements.
2. If the pH value is not within confidence bands, the change in carbon dioxide content and pH is different from that expected from a pure respiratory condition; thus a metabolic abnormality is also present.

3. To estimate the effect of acute and chronic changes in P_{CO_2} and bicarbonate HCO_3^- on pH, the following formulas are used:

Acute change in P_{CO_2} : (ΔP_{CO_2}) (0.008) = Δ pH
Chronic change in P_{CO_2} : (ΔP_{CO_2}) (0.003) = Δ pH
Change in HCO_3^- : (ΔHCO_3^-) (0.015) = Δ pH

Anion Gap: The gap caused by anions (other than HCO_3^- and chloride $[Cl^-]$) that balance the positive charge of sodium (Na^+).

Anion Gap = $Na^+ - (Cl^- + HCO_3^-)$; normal = 12 mEq/L \pm 2 mEq/L

CSF, cerebral spinal fluid

Calculating the ratio of red blood cells (RBCs) to white blood cells (WBCs) in CSF.^a

General rule: for every 500 RBCs in CSF, acceptable to have 1 WBC.

Normal ratio of RBCs to WBCs in peripheral blood: 1000 RBCs: 1–2 WBCs × 10⁶/L.

$$\text{Number of WBCs introduced into the CSF per L} = \frac{(\text{WBC}_{[\text{peripheral}]} \times \text{RBC}_{[\text{CSF}]})}{\text{RBC}_{(\text{peripheral})}} \times 10^6/\text{L}$$

Compare this number with the actual number of WBCs in the CSF.

1000 × 10⁶/L RBCs in CSF raises CSF protein by approximately 0.015 g/L.

	pH	Pao ₂ (mmHg)	Paco ₂ (mmHg)	Hco ₃ ⁻ (MEq/L)
Blood Gas, Arterial (Breathing Room Air)				
Newborn (birth)	7.26–7.29	60	55	19
Newborn (>4 hr)	7.37	70	33	20
Infant (1–24 mo)	7.40	90	34	20
Child (7–19 yr)	7.39	96	37	22
Adult (>9 yr)	7.35–7.45	90–110	35–45	22–26

Note: Venous blood gases can be used to assess acid-base status, not oxygenation. Pco₂ averages 6–8 mmHg higher than Paco₂, and pH is slightly lower. Peripheral venous samples are strongly affected by the local circulatory and metabolic environment. Capillary blood gases correlate best with arterial pH and moderately well with Paco₂.

Newborn	100–250 mcg/dL		17.9–44.8 mcmol/L
Infant	40–100 mcg/dL		7.2–17.9 mcmol/L
Child	50–120 mcg/dL		9.0–21.5 mcmol/L
Male adult	65–175mc/dL		11.6–31.3 mcmol/L
Female adult	50–170 mcg/dL		9.0–30.4 mcmol/L
Ketones (Serum)			
Quantitative	0.5–3.0 mg/dL		5–30 mg/L
Lactate capillary blood			
Newborn	<27 mg/dL		0.0–3.0 mmol/L
Child	5–20 mg/dL		0.56–2.25 mmol/L
Venous	5–20 mg/dL		0.5–2.2 mmol/L
Arterial	5–14 mg/dL		0.5–1.6 mmol/L
Lactate dehydrogenase (at 37° C)			
0–4 days	290–775 U/L		290–775 U/L
4–10 days	545–2000 U/L		545–2000 U/L
10 days–24 mos	180–430 U/L		180–430 U/L
24 mos–12 yrs	110–295 U/L		110–295 U/L
>12 yrs	100–190 U/L		100–190 U/L
Lead			
Child	<10 µg/dL		<0.48 µmol/L
Lipase			
0–90 days	10–85 U/L		
3–12 mos	9–128 U/L		
1–11 yrs	10–150 U/L		
>11 yrs	10–220 U/L		
Lipids			
Cholesterol (mg/dL)	Desirable	Borderline	High
Child/adolescent	<170	170–199	>200
Adult	<200	200–239	>240
Low-density lipoprotein (mg/dL)			
Child/adolescent	<110	110–129	>130
Adult	<100	100–159	>160
High-density lipoprotein (mg/dL)			
Child/adolescent	45		
Adult	45		
Magnesium	1.3–2.0 mEq/L	0.5	0.65–1.0 mmol/L
Methemoglobin	<1.5% total Hgb		

Determination	Standard Units	X Conversion Factor	SI Units
Osmolality	275–295 mOsm/kg	1	275–295 mmol/kg
Phenylalanine			
Preterm	2.0–7.5 mg/dL		121–454 mcmol/L
Newborn	1.2–3.4 mg/dL		73–206 mcmol/L
Adult	0.8–1.8 mg/dL		45–109 mcmol/L
Phosphorus		0.3229	
Newborn	4.5–9.0 mg/dL		1.45–2.9 mmol/L
10 days–24 mos	4.5–6.7 mg/dL		1.45–2.16 mmol/L
24 mos–12 yrs	4.5–5.5 mg/dL		1.45–1.78 mmol/L
>12 yrs	2.7–4.5 mg/dL		0.87–1.45 mmol/L
Potassium		1	
Newborn	3.7–5.9 mEq/L		3.7–5.9 mmol/L
Infant	4.1–5.3 mEq/L		4.1–5.3 mmol/L
Child	3.4–4.7 mEq/L		3.4–4.7 mmol/L
Adult	3.5–5.1 mEq/L		3.5–5.1 mmol/L
Prealbumin			
Newborn	7–39 mg/dL		
1–6 mos	8–34 mg/dL		
6 mos–4 yrs	2–36 mg/dL		
4–6 yrs	12–30 mg/dL		
6–19 yrs	12–42 mg/dL

Plasminogen (CTA, U/mL)	1.95 ± 0.35 (44)	2.17 ± 0.38 (60)	1.98 ± 0.36 (52)	2.48 ± 0.37 (44)	3.01 ± 0.40 (47)	3.36 ± 0.44 (29)

NOTE: All factors except fibrinogen and plasminogen are expressed as units per milliliter where pooled plasma contains 1.0 U/mL. Plasminogen units are those recommended by the Committee on Thrombolytic Agents (CTA). All values are expressed as mean ± 1 standard deviation. aPTT, activated partial thromboplastin time; HMWK, high molecular-weight kininogen; PK, prekallikrein; PT, prothrombin time; TCT, thrombin clotting time; vWF, von Willebrand factor.

*Values that do not differ statistically from the adult values.

† These measurements are skewed because of a disproportionate number of high values. The lower limit that excludes the lower 2.5th percentile of the population has been given in the respective figures. The lower limit for factor VIII was 0.50 U/mL at all time points for the infant.

Formulas

Preparation of Infant Formulas for Standard and Soy Formulas*

Formula Type	Caloric Concentration (kcal/oz)	Amount of Formula	Water (oz)
Liquid concentrates (40 kcal/oz)	20	13 oz	13
	24	13 oz	8.5
	27	13 oz	6.3
	30	13 oz	4.3
Powder (44 kcal/scoop)	20	1 scoop	2
	24	3 scoops	5
	27	3 scoops	4.25
	30	3 scoops	4

* Does not apply to Enfacare LIPIL, Neocate Infant, Neosure Advance, EleCare; Enfamil AR should not be concentrated greater than 24 kcal/oz. Use a packed measure for Nutramigen LIPIL and Pregestimil LIPIL; all others unpacked powder.

Modified from: Custer J, Rau R, eds. *The Harriet Lane Handbook*. 18th ed. St Louis, MO: Mosby; 2009. Copyright © Elsevier 2009.

Common Caloric Supplements*

Component		Calories
Protein	Casec	3.7 kcal/g (0.9 g protein)
		17 kcal/tbsp (4 g protein)
	Beneprotein	25 kcal/scoop (6 g protein)
	Complete Amino Acid Mix	3.28 kcal/g (0.82 g protein)
Carbohydrate	Polycose	Powder: 3.8 kcal/g, 8 kcal/tsp
		Liquid: 2.0 kcal/mL, 10 kcal/tsp
Fat	MCT oil†	7.7 kcal/mL
	Vegetable oil	8.3 kcal/mL
	Microlipid	4.5 kcal/mL
Fat and Carbohydrate	Duocal	42 kcal/tbsp (59% carbohydrates, 41% fat; 35% fat as MCT oil)

* Use these caloric supplements when you want to increase protein or when you have reached the maximum concentration tolerated and wish to further increase caloric density.

† MCT oil is unnecessary unless there is fat malabsorption.

Development

Primary Teeth Eruption Chart

Primary Teeth

The diagram illustrates the eruption and shedding timelines for primary teeth. It features two rows of teeth: the upper row (maxillary) and the lower row (mandibular). Each tooth is labeled with its name, eruption period (in months), and shedding period (in years). The eruption periods are listed in the 'Erupt' column, and the shedding periods are listed in the 'Shed' column. The teeth are arranged in a semi-circle, with lines connecting them to their respective labels in the adjacent columns.

Upper Teeth		Erupt	Shed
Central incisor	8-12 months	6-7 years	
Lateral incisor	9-13 months	7-8 years	
Canine (cuspid)	16-22 months	10-12 years	
First molar	13-19 months	9-11 years	
Second molar	23-33 months	10-12 years	
Lower Teeth		Erupt	Shed
Second molar	23-31 months	10-12 years	
First molar	14-18 months	9-11 years	
Canine (cuspid)	17-23 months	9-12 years	
Lateral incisor	10-16 months	7-8 years	
Central incisor	6-10 months	6-7 years	

From: American Dental Association. Tooth eruption: the primary teeth. *J Am Dent Assoc.* 2005;136(11):1619.

Developmental Milestones by Age and Ethnicity, Months

Task	Anglo	Puerto Rican	Filipino
Eat solid food	8.2	10.	16.7
Use training cup	12.0	17.1	21.9
Use utensils	17.7	26.5	32.4
Eat finger foods	8.9	9.4	9.5
Wean	16.8	18.2	36.2
Sleep by self	13.8	14.6	38.8
Sleep all night	11.4	14.5	32.4
Choose clothes	31.1	44.2	33.1
Dress self	38.2	44.2	39.2
Play alone	25.0	24.8	12.3
Toilet trained (day)	31.6	29.0	20.4
Toilet trained (night)	33.2	31.8	34.2

Developmental Milestones at a Glance—Infancy

Age	Gross Motor	Fine Motor	Cognitive, Linguistic, and Communication	Social-Emotional
2 Months	Head up 45° Lift head	Follow past midline Follow to midline	Laugh Vocalize	Smile spontaneously Smile responsively
4 Months	Roll over Sit—head steady	Follow to 180° Grasp rattle	Turn to rattling sound Laugh	Regard own hand
6 Months	Sit—no support Roll over	Look for dropped yarn Reach	Turn to voice Turn to rattling sound	Feed self Work for toy (out of reach)
9 Months	Pull to stand Stand holding on	Take 2 cubes Pass cube (transfer)	Dada/Mama, nonspecific Single syllables	Wave bye-bye Feed self

KEY

Black Color: 50% to 90% of children pass this item.

Blue Color: More than 90% of children pass this item.

Domains of Adolescent Development

	Early Adolescence (11 to 14 Years)	Middle Adolescence (15 to 17 Years)	Late Adolescence (18 to 21 Years)
Physiological	Onset of puberty, growth spurt, menarche (females)	Ovulation (females), growth spurt (males)	Growth completed
Psychological	Concrete thought, preoccupation with rapid body changes, sexual identity, questioning independence, parental controls remain strong	Competence in abstract and future thought, idealism, sense of invincibility or narcissism, sexual identity, beginning of cognitive capacity to provide legal consent	Future orientation, emotional independence, unmasking of psychiatric disorders, capacity for empathy, intimacy, and reciprocity in interpersonal relationships, self-identity, recognized as legally capable of providing consent, ⁶⁴ attainment of legal age for some issues (eg, voting) but not all issues (eg, drinking alcohol)
Social	Search for same-sex peer affiliation, good parental relationships, other adults as role models; transition to middle school, involvement in extracurricular activities; sensitivity to differences between home culture and culture of others	Beginning emotional emancipation, increased power of peer group, conflicts over parental control, interest in sexual relationships, initiation of driving, risk-taking behavior, transition to high school, reduced involvement in extracurricular activities, possible cultural conflict as adolescent navigates between family's values and values of broader culture and peer culture	Individual over peer relationships; transition in parent-child relationship, transition out of home; may begin preparation for further education, career, marriage, and parenting
Potential Problems	Delayed puberty; acne; orthopedic problems; school problems; psychosomatic concerns; depression; unintended pregnancy; initiation of tobacco, alcohol, or other drug use	Experimentation with health risk behaviors (eg, sex, drinking, drug use, smoking), auto crashes, menstrual disorders, unintended pregnancy, acne, short stature (males), conflicts with parents, overweight, physical inactivity, poor eating behaviors, eating disorders (eg, purging, binge eating, and anorexia nervosa)	Eating disorders, depression, suicide, auto crashes, unintended pregnancy, acne, smoking, alcohol or drug dependence

Feeding and Nutrition

Degree of Dehydration

PARAMETER	DEGREE OF DEHYDRATION		
	MILD	MODERATE	SEVERE
Weight loss (%)—infants	5	10	15
Weight loss (%)—children	3	6	>9
Skin color	Pale	Gray	Mottled
Skin turgor	May be normal	Decreased	Tenting
Mucous membranes	Slightly dry	Dry	Dry, parched, collapse of sublingual veins
Eyes	Normal	Decreased tears	Sunken, absence of tears
Central nervous system	Alert but thirsty	Irritable	Lethargic, grunting, coma
Pulse	Normal and strong	Rapid and slightly weak	Significantly tachycardic and very weak to not palpable
Capillary refill	Normal (< 2 sec)	2-4 sec	> 4 sec
Blood pressure	No change	Orthostatic decrease	Shock
Urine	Normal to mildly reduced	Significantly reduced	Anuria
Volume of deficit—infants	50 mL/kg	60 mL/kg	150 mL/kg
Volume of deficit—children	30 mL/kg	100 mL/kg	> 90 mL/kg

From: McInerney TK, Adam HM, Campbell DE, Kamat DM, Kelleher KJ. *American Academy of Pediatrics Textbook of Pediatric Care*. Elk Grove Village, IL: American Academy of Pediatrics; 2008.

Composition of Fluids Frequently Used in Oral Rehydration

Solution	Glucose/CHO, g/L	Sodium, mEq/L	HCO ₃ ⁻ , mEq/L	Potassium, mEq/L	Osmolality, mmol/L	CHO/Sodium
Pedialyte (Abbott Laboratories, Columbus, OH)	25	45	30	20	250	3.1
Pediatric Electrolyte (PendoPharm, Montreal, Quebec)	25	45	20	30	250	3.1
Kaoelectrolyte (Pfizer, New York, NY)	20	48	28	20	240	2.4
Rehydralyte (Abbott Laboratories, Columbus, OH)	25	75	30	20	310	1.9
WHO ORS, 2002 (reduced osmolarity)	75	75	10 [†]	30	224	1.0
WHO ORS, 1975, (original formulation)	111	90	10 [†]	20	311	1.2
Cola*	126	2	13	0.1	750	1944
Apple juice*	125	3	0	32	730	1278
Gatorade* (Gatorade, Chicago, IL)	45	20	3	3	330	62.5

CHO indicates carbohydrate; HCO₃⁻, bicarbonate; WHO, World Health Organization.

* Cola, juice, and Gatorade are shown for comparison only; they are not recommended for use.

Mainly for maintenance therapy; may be used for rehydration therapy in mildly dehydrated patients.

[†] Citrate.

From: Kleinman RE, ed. *Pediatric Nutrition Handbook*. Elk Grove Village, IL: American Academy of Pediatrics; 2009.

Fluid Therapy Chart

Degree of Dehydration	Signs	Fluids	Feeding
Mild*	Slightly dry mucous membranes, increased thirst	ORS, 50–60 mL/kg [†]	Breastfeeding, undiluted lactose-free formula, full-strength cow milk, or lactose-containing formula
Moderate	Sunken eyes, sunken fontanelle, loss of skin turgor, dry mucous membranes	ORS, 80–100 mL/kg [†]	Same as above
Severe	Signs of moderate dehydration plus one or more of the following: rapid thready pulse, cyanosis, rapid breathing, delayed capillary refill time, lethargy, coma	Intravenous or intraosseous isotonic Fluids (0.9% saline or Ringer lactate), 40 mL/kg per hour until pulse and state of consciousness return to normal, then 50–100 mL/kg of ORS based on remaining degree of dehydration [‡]	Begin after clinically improved and ORS has begun

* If no signs of dehydration are present, rehydration phase may be omitted. Proceed with maintenance therapy and replacement of ongoing losses.

[†] First 4 hours, repeat until no signs of dehydration remain. Replace ongoing stool losses and vomitus with ORS, 10 mL/kg for each diarrheal stool and 5 mL/kg for each episode of vomiting.

[‡] Although parenteral access is being sought, nasogastric infusion of ORS may be begun at 30 mL/kg per hour, provided airway protective reflexes remain intact.

From: Kleinman RE, ed. *Pediatric Nutrition Handbook*. Elk Grove Village, IL: American Academy of Pediatrics; 2008.

Selected Bioactive Factors in Human Milk

Secretory IgA	Specific antigen-targeted anti-infective action
Lactoferrin	Immunomodulation, iron chelation, antimicrobial action, anti-adhesive, trophic for intestinal growth
Lysozyme	Bacterial lysis, immunomodulation
κ-casein	Anti-adhesive, bacterial flora
Oligosaccharides	Bacterial attachment
Cytokines	Anti-inflammatory, epithelial barrier function
Growth factors Epidermal growth factor Transforming growth factor (TGF) Nerve growth factor	Luminal surveillance, repair of intestine Promotes epithelial cell growth (TGF-α) Suppresses lymphocyte function (TGF-β) Growth
Enzymes Platelet-activating factor-acetylhydrolase Glutathione peroxidase	Blocks action of platelet activating factor Prevents lipid oxidation
Nucleotides	Enhance antibody responses, bacterial flora
Vitamins A, E, C	Antioxidants
Amino acids Glutamine	Intestinal cell fuel, immune responses
Lipids	Anti-infective properties

IgA indicates immunoglobulin A.

Adapted from: American Academy of Pediatrics and American College of Obstetricians and Gynecologists. The importance of breastfeeding for infants, mothers, and society. In: *Breastfeeding Handbook for Physicians*. Elk Grove Village, IL: American Academy of Pediatrics; 2006:19–36.

Increasing the Caloric Density of Infant Formula

Caloric Density	Water	Concentrated Liquid	Approximate Yield
20 kcal/fl oz	13 fl oz	13 fl oz (1 can)	26 fl oz
22 kcal/fl oz	11 fl oz	13 fl oz (1 can)	24 fl oz
24 kcal/fl oz	9 fl oz	13 fl oz (1 can)	22 fl oz
27 kcal/fl oz	6 fl oz	13 fl oz (1 can)	19 fl oz
30 kcal/fl oz	4.5 fl oz	13 fl oz (1 can)	17.5 fl oz

Using Powder

Because of the variability of scoop sizes for different formulas from different manufacturers and the variability of household measures, no single set of recipes can be provided that is safe for all products. Some manufacturers provide recipes for their specific products on their Web sites. In the absence of such information, contact the manufacturer directly.

Increasing Caloric Density Using Other Additives

- Medium-chain triglyceride oil provides 7.7 kcal/mL; 1 teaspoon provides 38 kcal.
- Vegetable oils provide 40 kcal/teaspoon.
- Polycose powder (Abbott Nutrition, Columbus, OH) contains 8 kcal/teaspoon.

Note that increasing caloric density using fat and/or carbohydrate should be done with caution, because the additional energy (kcal) effectively decreases the density (amount per 100 kcal) of all other nutrients.

From: Kleinman RE, ed. *Pediatric Nutrition Handbook*. Elk Grove Village, IL: American Academy of Pediatrics; 2009.

Estimated Energy Requirements

Age	Estimated Energy Requirements*
0–3 mo	$(89 \times \text{weight [kg]} - 100) + 175 \text{ kcal}$
4–6 mo	$(89 \times \text{weight [kg]} - 100) + 56 \text{ kcal}$
7–12 mo	$(89 \times \text{weight [kg]} - 100) + 22 \text{ kcal}$
13–36 mo	$(89 \times \text{weight [kg]} - 100) + 20 \text{ kcal}$
Boys 3 through 8 y	$88.5 - (61.9 \times \text{age [y]}) + \text{PA} \times (26.7 \times \text{weight [kg]} + 903 \times \text{height [m]}) + 20 \text{ kcal}$
Girls 3 through 8 y	$135.3 - (30.8 \times \text{age [y]}) + \text{PA} \times (10.0 \times \text{weight [kg]} + 934 \times \text{height [m]}) + 20 \text{ kcal}$
Boys 9 through 18 y	$88.5 - (61.9 \times \text{age [y]}) + \text{PA} \times (26.7 \times \text{weight [kg]} + 903 \times \text{height [m]}) + 25 \text{ kcal}$
Girls 9 through 18 y	$135.3 - (30.8 \times \text{age [y]}) + \text{PA} \times (10.0 \times \text{weight [kg]} + 934 \times \text{height [m]}) + 25 \text{ kcal}$

*Total energy expenditure + energy deposition.

PA indicates the physical activity coefficient:

For boys 3 through 18 years of age:

- PA = 1.00 (sedentary, estimated physical activity level 1.0–1.4)
- PA = 1.13 (low active, estimated physical activity level 1.4–1.6)
- PA = 1.26 (active, estimated physical activity level 1.6–1.9)
- PA = 1.42 (very active, estimated physical activity level 1.9–2.5)

For girls 3 through 18 years of age:

- PA = 1.00 (sedentary, estimated physical activity level 1.0–1.4)
- PA = 1.16 (low active, estimated physical activity level 1.4–1.6)
- PA = 1.31 (active, estimated physical activity level 1.6–1.9)
- PA = 1.56 (very active, estimated physical activity level 1.9–2.5)

American Academy of Pediatrics Recommendations Relevant to the Initiation of Complementary Foods

Nutrient/Food	Subgroups	AAP Recommendations
Human milk	Most infants	Exclusive breastfeeding for minimum of 4 but preferably 6 mo.
	Infants with unique needs or feeding patterns	Individual infants may require complementary foods as early as 4 mo of age or may be unable to accept them until about 8 mo of age. ⁷
Calcium	Term infants	Recommended intakes, human milk or infant formulas: First 6 mo: 210 mg/day 7–12 mo: 270 mg/day No benefit from increasing calcium content of infant formulas above these amounts.
	Preterm infants	Have higher calcium requirements than term infants. Can meet requirements using human milk plus commercial fortifiers or preterm infant formulas enriched with calcium and vitamin D. Optimal calcium concentrations and duration of use unknown. ⁸
Cholesterol	Infants younger than 2 y	No restriction of fat or cholesterol; rapid growth requires high energy intake. ⁹
Fluoride	Infants 6 mo and older	Supplement with 0.25 mg/day in areas with <0.3 ppm fluoride concentration in community drinking supplies (see Chapter 48).
Iron	Breastfed infants 6–12 mo	Iron from complementary foods at 6 mo of age (see Chapters 2 and 18).
	Nonbreastfed infants younger than 12 mo	Ingest iron-fortified formula (10–12 mg/L) until weaning at 12 mo of age.
	Breastfed preterm or low birth weight infant	Oral iron supplement drops at 2 mg/kg per day, 1–12 mo of age (see Chapter 4).
	Formula-fed preterm infants	May benefit from an additional iron supplement (drops) of 1 mg/kg per day.
Lactose	Children from populations with high rates of lactose malabsorption	Unwise to discourage use of milk unless children have severe diarrhea or clear intolerance; clinical problems usually manifest at 5–7 y of age. ¹⁰
Vitamin D	All breastfed infants and nonbreastfed infants	Should have a supplement of 400 IU/day of vitamin D beginning during first 2 mo of life through childhood and adolescence unless ingesting at least 500 mL/day of vitamin D-fortified formula or milk. ¹¹

American Academy of Pediatrics Recommendations Relevant to the Initiation of Complementary Foods, *continued*

Nutrient/Food	Subgroups	AAP Recommendations
Fruit juice	Infants up to 1 y of age	Should not be introduced before 6 mo of age.
		Should not be given juice in containers that allow them to consume juice easily throughout the day.
		Should not be given at bedtime.
		Should not consume unpasteurized juices. ¹²
Soy protein-based formulas	Term infants whose nutritional needs are not met by human or cow milk	Isolated soy protein-based formula is a safe, effective alternative.
	Infants with documented lactose intolerance	Use is appropriate.
	Most infants with documented immunoglobulin E-mediated allergy to cow milk	Use may be appropriate.
	Preterm infants who weigh <1800 g	Use is not recommended. ¹³
Water*	All infants up to 1 y of age	No data basis for minimum or maximum usual water intake recommendations; water intoxication not a discernable public health problem.
	Formula-fed infants	<i>During hot weather:</i> No recommendations.
	Infants up to 1 y of age, exclusively breastfed or partial breastfeeding eating complementary foods	Monitor for dark or decreased urine output. When present, offer solute-free water up to maximum of 225 mL/kg per day.

* AAP Committee on Nutrition advice, based on literature search pertaining to water intoxication, current recommendations from AAP materials, and opinions of pediatric nutrition experts.

From: Kleinman RE, ed. *Pediatric Nutrition Handbook*. Elk Grove Village, IL: American Academy of Pediatrics; 2009.

Dietary Reference Intakes: Recommended Intakes for Individuals, Food and Nutrition Board, Institute of Medicine, *continued*

This table (taken from the DRI reports; see <http://www.iom.edu/CMS/3788/21370.aspx>) presents Recommended Dietary Allowances (RDAs) in bold type, and Adequate Intakes (AIs) are in ordinary type followed by the symbol (*). ND indicates not determined.

- * RDAs and AIs may both be used as goals for individual intake. RDAs are set to meet the needs of almost all (97%–98%) individuals in a group. For healthy breastfed infants, the AI is the mean intake. The AI for other life stage and gender groups is believed to cover needs of all individuals in the group, but lack of data or uncertainty in the data prevent being able to specify with confidence the percentage of individuals covered by this intake.
- † As retinol activity equivalents (RAEs). 1 RAE = 1 µg retinol, 12 µg β-carotene, 24 µg α-carotene, or 24 µg β-cryptoxanthin in foods. The RAE for dietary provitamin A carotenoids is twofold greater than retinol equivalents (RE), whereas the RAE for preformed vitamin A is the same as RE.
- ‡ As cholecalciferol. 1 µg cholecalciferol = 40 IU vitamin D.
- § In the absence of adequate exposure to sunlight.
- || As α-tocopherol. α-Tocopherol includes RRR-α-tocopherol, the only form of α-tocopherol that occurs naturally in foods, and the 2R-stereoisomeric forms of α-tocopherol (RRR-, RSR-, RRS-, and RSS-α-tocopherol) that occur in fortified foods and supplements. It does not include the 2S-stereoisomeric forms of α-tocopherol (SRR-, SSR-, SRS-, and SSS-α-tocopherol), also found in fortified foods and supplements.
- ¶ As niacin equivalents (NEs). 1 mg of niacin = 60 mg of tryptophan; 0–6 mo = preformed niacin (not NEs).
- # As dietary folate equivalents (DFEs). 1 DFE = 1 µg food folate = 0.6 µg of folic acid from fortified food or as a supplement consumed with food = 0.5 µg of a supplement taken on an empty stomach.
- ** In view of evidence linking folate intake with neural tube defects in the fetus, it is recommended that all women capable of becoming pregnant consume 400 µg from supplements or fortified foods in addition to intake of food folate from the diet.
- †† It is assumed that women will continue consuming 400 µg from supplements or fortified food until their pregnancy is confirmed and they enter prenatal care, which ordinarily occurs after the end of the periconceptual period—the critical time for formation of the neural tube.
- ‡‡ Although AIs have been set for choline, there are few data to assess whether a dietary supply of choline is needed at all stages of the life cycle, and it may be that the choline requirement can be met by endogenous synthesis at some of these stages.

From: Kleinman RE, ed. *Pediatric Nutrition Handbook*. Elk Grove Village, IL: American Academy of Pediatrics; 2009.

Feeding Guide for Children

Food Group	Age, y						Comments
	2–3		4–8		9–12		
	Portion Size	Daily Amounts*	Portion Size	Daily Amounts*	Portion Size	Daily Amounts*	
Milk, yogurt, and cheese	1/2 cup (4 oz)	2 cups	1/2–3/4 cup (4–6 oz)	2 cups	1/2–1 cup (4–8 oz)	3 cups	Make most choices fat free or low fat. The following may be substituted for 1/2 cup fluid milk: 1/2–3/4 oz cheese, 1/2 cup low-fat yogurt, or 2 1/2 tsp nonfat dry milk.
Meat, fish, poultry, dry beans, eggs, and nuts	1–2 oz	2 oz	1–2 oz	3 oz	2 oz	5 oz	Make most choices lean or low fat. The following may be substituted for 1 oz meat, fish, or poultry: 1 egg, 2 tbsp peanut butter, or 4 tbsp cooked dry beans or peas.
Vegetables Cooked Raw*	2–3 tbsp Few pieces	1 cup	3–4 tbsp Few Pieces	1 1/2 cups	1/4–1/2 cup Several pieces	2 cups	Include dark green and orange vegetables, such as carrots, spinach, broccoli, winter squash, or greens. Limit starchy vegetables (potatoes) to 2 1/2 cups weekly (1 1/2 cups for 2- to 3-year-olds).
Fruit Raw Canned Juice	1/2–1 small 2–4 tbsp 3–4 oz	1 cup	1/2–1 small 4–6 tbsp 4 oz	1 cup	1 medium 1/4–1/2 cup 4 oz	1 1/2 cups	Make less than half of total fruit choices juice.
Grains (bread, cereal, rice, and pasta)		3 oz eq.		4 oz eq		5 oz eq	One oz eq equals a 1-oz slice of bread. The following may be substituted for 1 slice of bread: 1/2 cup spaghetti, macaroni, noodles, or rice; 5 saltine crackers; 1/2 English muffin or bagel; 1 tortilla; corn grits; or posole. Make at least 1/2 of grain intake whole grain.
Whole-grain or enriched bread	1/2–1 slice		1 slice		1 slice		
Cooked cereal	1/4–1/2 cup		1/2 cup		1/2–1 cup		
Dry cereal	1/2–1 cup		1 cup		1 cup		

* Daily amounts are from MyPyramid Plans to meet needs for sedentary children of average size at the younger end of each age range. Amounts shown are from 1000-kcal (2- to 3-year-olds), 1200-kcal (4- to 8-year-olds), and 1600-kcal MyPyramid Plans. Active, older, and larger children would need more energy and foods from each group. A specific MyPyramid Plan for a child of a specified age, gender, and activity level can be found at <http://www.mypyramid.gov/>. For children 9 years and older, height and weight can also be specified in selecting a MyPyramid Plan.

† Do not give to young children until they can chew well.

From: Kleinman RE, ed. *Pediatric Nutrition Handbook*. Elk Grove Village, IL: American Academy of Pediatrics; 2009.

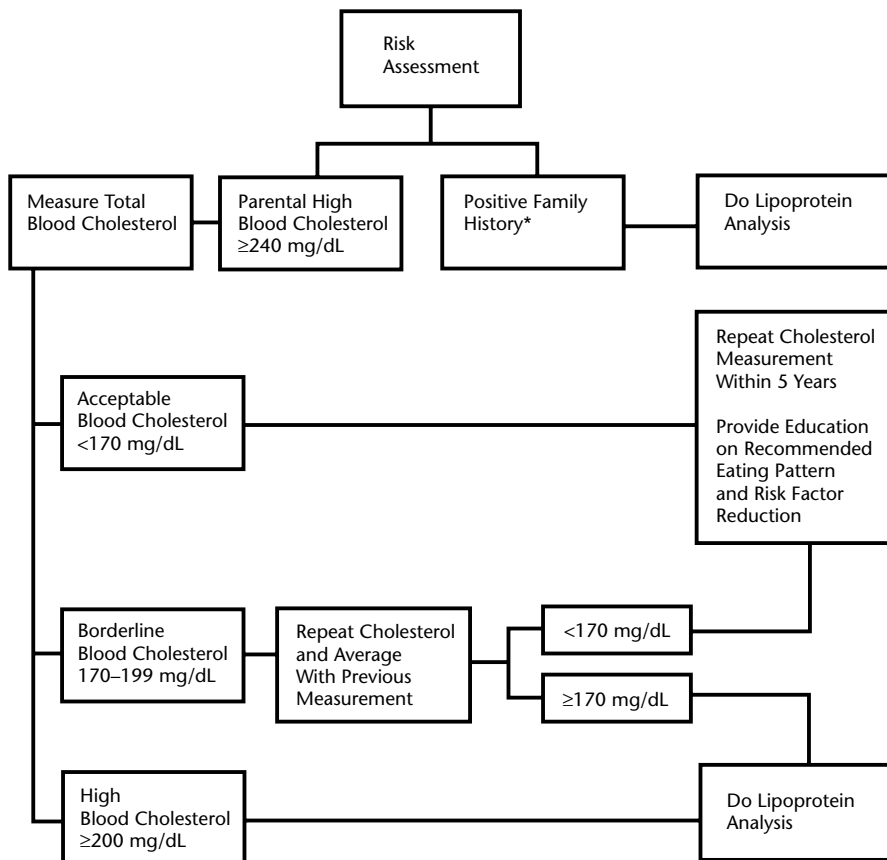

Interpretation of Cholesterol Concentrations for Children and Adolescents

Term	Total Cholesterol, mg/dL	LDL, mg/dL
Acceptable	<170	<110
Borderline	170–199	110–129
High	≥200	>130

From: National Cholesterol Education Program (NCEP): highlights of the report of the Expert Panel on Blood Cholesterol Levels in Children and Adolescents. *Pediatrics*. 1992;89(3):495–501.

Classification, Education, and Follow-up Based on LDL Concentration (from the NCEP)

To convert mg/dL to mmol/l, multiply by 0.02586.

From: National Cholesterol Education Program (NCEP): highlights of the report of the Expert Panel on Blood Cholesterol Levels in Children and Adolescents. *Pediatrics*. 1992;89(3):495–501.

Immunization

Vaccines Licensed for Immunization and Distributed in the United States and Their Routes of Administration^a

Vaccine	Type	Route
BCG	Live bacteria	ID (preferred) or SC
Diphtheria-tetanus (DT, Td)	Toxoids	IM
DTaP	Toxoids and inactivated bacterial components	IM
DTaP, hepatitis B, and IPV	Toxoids and inactivated bacterial components, recombinant viral antigen, inactivated virus	IM
DTaP/Hib conjugate (PRP-T ^b reconstituted with DTaP)	Toxoids and inactivated bacterial components with polysaccharide-protein conjugate	IM
DTaP-IPV	Toxoids and inactivated bacterial components, inactivated virus	IM
DTaP-IPV/Hib (PRP-T reconstituted with DTaP-IPV)	Toxoids and inactivated bacterial components, polysaccharide-protein conjugate, inactivated virus	IM
Hepatitis A	Inactivated viral antigen	IM
Hepatitis B	Recombinant viral antigen	IM
Hepatitis A-hepatitis B	Inactivated and recombinant viral antigens	IM
Hib conjugates ^b	Polysaccharide-protein conjugate	IM
Hib conjugate (PRP-OMP ^b)-hepatitis B	Polysaccharide-protein conjugate with recombinant viral antigen	IM
Human papillomavirus (HPV)	Recombinant viral antigens	IM
Influenza	Inactivated viral components	IM
Influenza	Live-attenuated viruses	Intranasal
Japanese encephalitis	Inactivated virus	SC
Meningococcal	Polysaccharide	SC
Meningococcal conjugate	Polysaccharide-protein conjugate	IM
MMR	Live-attenuated viruses	SC
MMRV	Live-attenuated viruses	SC
Pneumococcal	Polysaccharide	IM or SC
Pneumococcal conjugate	Polysaccharide-protein conjugate	IM
Poliovirus (IPV)	Inactivated viruses	SC or IM
Rabies	Inactivated virus	IM
Rotavirus	Live-attenuated virus	Oral
Tdap	Toxoids and inactivated bacterial component	IM
Tetanus	Toxoid	IM
Typhoid	Capsular polysaccharide	IM
Typhoid	Live-attenuated bacteria	Oral
Varicella	Live-attenuated virus	SC
Zoster	Live-attenuated virus	SC
Yellow fever	Live-attenuated virus	SC

BCG indicates bacille Calmette-Guérin; ID, intradermal; SC, subcutaneous; DT, diphtheria and tetanus toxoids (for children younger than 7 years of age); Td, diphtheria and tetanus toxoids (for children 7 years of age or older and adults); IM, intramuscular; DTaP, diphtheria and tetanus toxoids and acellular pertussis, adsorbed; IPV, inactivated poliovirus; Hib, *Haemophilus influenzae* type b; PRP-T, polyribosylribitol phosphate-tetanus toxoid; PRP-OMP, polyribosylribitol phosphate-meningococcal outer membrane protein; MMR, live measles-mumps-rubella; MMRV, live measles-mumps-rubella-varicella (monovalent measles, mumps, and rubella components are not being produced in the United States); Tdap, tetanus toxoid, reduced diphtheria toxoid, and acellular pertussis.

^aOther vaccines licensed in the United States but not distributed include anthrax, smallpox, oral poliovirus (OPV), and H5N1 influenza vaccines. The FDA maintains a Web site listing currently licensed vaccines in the United States (www.fda.gov/cber/vaccine/licvacc.htm). The AAP maintains a Web site (www.aapredbook.org/news/vaccstatus.dtl) showing status of licensure and recommendations for new vaccines.

Site and Needle Length by Age for Intramuscular Immunization

Age Group	Needle Length, inches (mm) ^a	Suggested Injection Site
Newborns (preterm and term) and infants <2 mo of age	$\frac{5}{8}$ (16)	Anterolateral thigh muscle
Term infants, 2–12 mo of age	1 (25)	Anterolateral thigh muscle
Toddlers and children	$\frac{5}{8}$ (16)	Deltoid muscle of the arm
	1–1 $\frac{1}{4}$ (25–32)	Anterolateral thigh muscle
Adolescents and young adults		
Female and male, weight <60 kg	$\frac{5}{8}$ (16)	Deltoid muscle of the arm
Female, weight 60–90 kg	1 (25)	Deltoid muscle of the arm
Female, weight >90 kg	1 $\frac{1}{2}$ (38)	Deltoid muscle of the arm
Male, weight 60–118 kg	1 (25)	Deltoid muscle of the arm
Male, weight >118 kg	1 $\frac{1}{2}$ (38)	Deltoid muscle of the arm

^aAssumes that needle is inserted fully.

From: American Academy of Pediatrics. Active immunization. In: Pickering LK, Baker CJ, Kimberlin DW, Long SS, eds. *Red Book: 2009 Report of the Committee on Infectious Diseases*. 28th ed. Elk Grove Village, IL: American Academy of Pediatrics; 2009:19.

Guidelines for Spacing of Live and Inactivated Antigens

Antigen Combination	Recommended Minimum Interval Between Doses
2 or more inactivated ^a	None; can be administered simultaneously or at any interval between doses
Inactivated and live	None; can be administered simultaneously or at any interval between doses
2 or more live ^b	28-day minimum interval if not administered at the same visit

^aIf simultaneous administration of tetanus toxoid, reduced diphtheria toxoid, and acellular pertussis (Tdap) vaccine and meningococcal conjugate vaccine (MCV4) is not feasible (ie, one of the vaccines is not available), the American Academy of Pediatrics recommends that administration be separated by at least 28 days.

^bSome live oral vaccines (eg, Ty21a typhoid vaccine, oral poliovirus vaccine, rotavirus vaccine) can be administered simultaneously or at any interval before or after inactivated or live parenteral vaccines.

From: American Academy of Pediatrics. Active immunization. In: Pickering LK, Baker CJ, Kimberlin DW, Long SS, eds. *Red Book: 2009 Report of the Committee on Infectious Diseases*. 28th ed. Elk Grove Village, IL: American Academy of Pediatrics; 2009:22.

Recommended Immunization Schedule for Persons Aged 0 Through 6 Years—United States • 2010

For those who fall behind or start late, see the catch-up schedule

Vaccine ▼	Age ►	Birth	1 month	2 months	4 months	6 months	12 months	15 months	18 months	19–23 months	2–3 years	4–6 years
Hepatitis B ¹	HepB	HepB	HepB			HepB						
Rotavirus ²				RV	RV	RV ²						
Diphtheria, Tetanus, Pertussis ³				DTaP	DTaP	DTaP	<i>see footnote³</i>	DTaP				DTaP
<i>Haemophilus influenzae</i> type b ⁴				Hib	Hib	Hib ⁴		Hib				
Pneumococcal ⁵				PCV	PCV	PCV		PCV			PPSV	
Inactivated Poliovirus ⁶				IPV	IPV			IPV				IPV
Influenza ⁷							Influenza (Yearly)					
Measles, Mumps, Rubella ⁸							MMR			<i>see footnote⁸</i>		MMR
Varicella ⁹							Varicella			<i>see footnote⁹</i>		Varicella
Hepatitis A ¹⁰							HepA (2 doses)				HepA Series	
Meningococcal ¹¹											MCV	

Range of recommended ages for all children except certain high-risk groups

Range of recommended ages for certain high-risk groups

This schedule includes recommendations in effect as of December 15, 2009. Any dose not administered at the recommended age should be administered at a subsequent visit, when indicated and feasible. The use of a combination vaccine generally is preferred over separate injections of its equivalent component vaccines. Considerations should include provider assessment, patient preference, and the potential for adverse

events. Providers should consult the relevant Advisory Committee on Immunization Practices statement for detailed recommendations: <http://www.cdc.gov/vaccines/pubs/acip-list.htm>. Clinically significant adverse events that follow immunization should be reported to the Vaccine Adverse Event Reporting System (VAERS) at <http://www.vaers.hhs.gov> or by telephone, 800-822-7967.

1. Hepatitis B vaccine (HepB). (Minimum age: birth)

At birth:

- Administer monovalent HepB to all newborns before hospital discharge.
- If mother is hepatitis B surface antigen (HBsAg)-positive, administer HepB and 0.5 mL of hepatitis B immune globulin (HBIG) within 12 hours of birth.
- If mother's HBsAg status is unknown, administer HepB within 12 hours of birth. Determine mother's HBsAg status as soon as possible and, if HBsAg-positive, administer HBIG (no later than age 1 week).

After the birth dose:

- The HepB series should be completed with either monovalent HepB or a combination vaccine containing HepB. The second dose should be administered at age 1 or 2 months. Monovalent HepB vaccine should be used for doses administered before age 6 weeks. The final dose should be administered no earlier than age 24 weeks.
- Infants born to HBsAg-positive mothers should be tested for HBsAg and antibody to HBsAg 1 to 2 months after completion of at least 3 doses of the HepB series, at age 9 through 18 months (generally at the next well-child visit).
- Administration of 4 doses of HepB to infants is permissible when a combination vaccine containing HepB is administered after the birth dose. The fourth dose should be administered no earlier than age 24 weeks.

2. Rotavirus vaccine (RV). (Minimum age: 6 weeks)

- Administer the first dose at age 6 through 14 weeks (maximum age: 14 weeks 6 days). Vaccination should not be initiated for infants aged 15 weeks 0 days or older.
- The maximum age for the final dose in the series is 8 months 0 days
- If Rotarix is administered at ages 2 and 4 months, a dose at 6 months is not indicated.

3. Diphtheria and tetanus toxoids and acellular pertussis vaccine (DTaP).

- (Minimum age: 6 weeks)
- The fourth dose may be administered as early as age 12 months, provided at least 6 months have elapsed since the third dose.
- Administer the final dose in the series at age 4 through 6 years.

4. *Haemophilus influenzae* type b conjugate vaccine (Hib).

- (Minimum age: 6 weeks)
- If PRP-OMP (PedvaxHIB or Comvax [HepB-Hib]) is administered at ages 2 and 4 months, a dose at age 6 months is not indicated.
- TriHibit (DTaP/Hib) and Hiberix (PRP-T) should not be used for doses at ages 2, 4, or 6 months for the primary series but can be used as the final dose in children aged 12 months through 4 years. See *MMWR* 1997;46(No. RR-8).

5. Pneumococcal vaccine. (Minimum age: 6 weeks for pneumococcal conjugate vaccine [PCV]; 2 years for pneumococcal polysaccharide vaccine [PPSV])

- PCV is recommended for all children aged younger than 5 years. Administer 1 dose of PCV to all healthy children aged 24 through 59 months who are not completely vaccinated for their age.
- Administer PPSV 2 or more months after last dose of PCV to children aged 2 years or older with certain underlying medical conditions, including a cochlear implant.

6. Inactivated poliovirus vaccine (IPV) (Minimum age: 6 weeks)

- The final dose in the series should be administered on or after the fourth birthday and at least 6 months following the previous dose.
- If 4 doses are administered prior to age 4 years a fifth dose should be administered at age 4 through 6 years. See *MMWR* 2009;58(30):829–30.

7. Influenza vaccine (seasonal). (Minimum age: 6 months for trivalent inactivated influenza vaccine [TIV]; 2 years for live, attenuated influenza vaccine [LAIV])

- Administer annually to children aged 6 months through 18 years.
- For healthy children aged 2 through 6 years (i.e., those who do not have underlying medical conditions that predispose them to influenza complications), either LAIV or TIV may be used, except LAIV should not be given to children aged 2 through 4 years who have had wheezing in the past 12 months.
- Children receiving TIV should receive 0.25 mL if aged 6 through 35 months or 0.5 mL if aged 3 years or older.
- Administer 2 doses (separated by at least 4 weeks) to children aged younger than 9 years who are receiving influenza vaccine for the first time or who were vaccinated for the first time during the previous influenza season but only received 1 dose.
- For recommendations for use of influenza A (H1N1) 2009 monovalent vaccine see *MMWR* 2009;58(No. RR-10).

8. Measles, mumps, and rubella vaccine (MMR). (Minimum age: 12 months)

- Administer the second dose routinely at age 4 through 6 years. However, the second dose may be administered before age 4, provided at least 28 days have elapsed since the first dose.

9. Varicella vaccine. (Minimum age: 12 months)

- Administer the second dose routinely at age 4 through 6 years. However, the second dose may be administered before age 4, provided at least 3 months have elapsed since the first dose.
- For children aged 12 months through 12 years the minimum interval between doses is 3 months. However, if the second dose was administered at least 28 days after the first dose, it can be accepted as valid.

10. Hepatitis A vaccine (HepA). (Minimum age: 12 months)

- Administer to all children aged 1 year (i.e., aged 12 through 23 months). Administer 2 doses at least 6 months apart.
- Children not fully vaccinated by age 2 years can be vaccinated at subsequent visits
- HepA also is recommended for older children who live in areas where vaccination programs target older children, who are at increased risk for infection, or for whom immunity against hepatitis A is desired.

11. Meningococcal vaccine. (Minimum age: 2 years for meningococcal conjugate vaccine [MCV4] and for meningococcal polysaccharide vaccine [MPSV4])

- Administer MCV4 to children aged 2 through 10 years with persistent complement component deficiency, anatomic or functional asplenia, and certain other conditions placing them at high risk.
- Administer MCV4 to children previously vaccinated with MCV4 or MPSV4 after 3 years if first dose administered at age 2 through 6 years. See *MMWR* 2009; 58:1042–3.

Recommended Immunization Schedule for Persons Aged 7 Through 18 Years—United States • 2010

For those who fall behind or start late, see the schedule below and the catch-up schedule

Vaccine ▼	Age ►	7–10 years	11–12 years	13–18 years
Tetanus, Diphtheria, Pertussis ¹			Tdap	Tdap
Human Papillomavirus ²		see footnote 2	HPV (3 doses)	HPV series
Meningococcal ³		MCV	MCV	MCV
Influenza ⁴		Influenza (Yearly)		
Pneumococcal ⁵		PPSV		
Hepatitis A ⁶		HepA Series		
Hepatitis B ⁷		Hep B Series		
Inactivated Poliovirus ⁸		IPV Series		
Measles, Mumps, Rubella ⁹		MMR Series		
Varicella ¹⁰		Varicella Series		

Range of recommended ages for all children except certain high-risk groups

Range of recommended ages for catch-up immunization

Range of recommended ages for certain high-risk groups

This schedule includes recommendations in effect as of December 15, 2009. Any dose not administered at the recommended age should be administered at a subsequent visit, when indicated and feasible. The use of a combination vaccine generally is preferred over separate injections of its equivalent component vaccines. Considerations should include provider assessment, patient preference, and the potential for adverse

events. Providers should consult the relevant Advisory Committee on Immunization Practices statement for detailed recommendations: <http://www.cdc.gov/vaccines/pubs/acip-list.htm>. Clinically significant adverse events that follow immunization should be reported to the Vaccine Adverse Event Reporting System (VAERS) at <http://www.vaers.hhs.gov> or by telephone, 800-822-7967.

1. Tetanus and diphtheria toxoids and acellular pertussis vaccine (Tdap).

- (Minimum age: 10 years for Boostrix and 11 years for Adacel)
- Administer at age 11 or 12 years for those who have completed the recommended childhood DTP/DaP vaccination series and have not received a tetanus and diphtheria toxoid (Td) booster dose.
- Persons aged 13 through 18 years who have not received Tdap should receive a dose.
- A 5-year interval from the last Td dose is encouraged when Tdap is used as a booster dose; however, a shorter interval may be used if pertussis immunity is needed.

2. Human papillomavirus vaccine (HPV). (Minimum age: 9 years)

- Two HPV vaccines are licensed: a quadrivalent vaccine (HPV4) for the prevention of cervical, vaginal and vulvar cancers (in females) and genital warts (in females and males), and a bivalent vaccine (HPV2) for the prevention of cervical cancers in females.
- HPV vaccines are most effective for both males and females when given before exposure to HPV through sexual contact.
- HPV4 or HPV2 is recommended for the prevention of cervical precancers and cancers in females.
- HPV4 is recommended for the prevention of cervical, vaginal and vulvar precancers and cancers and genital warts in females.
- Administer the first dose to females at age 11 or 12 years.
- Administer the second dose 1 to 2 months after the first dose and the third dose 6 months after the first dose (at least 24 weeks after the first dose).
- Administer the series to females at age 13 through 18 years if not previously vaccinated.
- HPV4 may be administered in a 3-dose series to males aged 9 through 18 years to reduce their likelihood of acquiring genital warts.

3. Meningococcal conjugate vaccine (MCV4).

- Administer at age 11 or 12 years, or at age 13 through 18 years if not previously vaccinated.
- Administer to previously unvaccinated college freshmen living in a dormitory.
- Administer MCV4 to children aged 2 through 10 years with persistent complement component deficiency, anatomic or functional asplenia, or certain other conditions placing them at high risk.
- Administer to children previously vaccinated with MCV4 or MPSV4 who remain at increased risk after 3 years (if first dose administered at age 2 through 6 years) or after 5 years (if first dose administered at age 7 years or older). Persons whose only risk factor is living in on-campus housing are not recommended to receive an additional dose. See *MMWR* 2009;58:1042–3.

4. Influenza vaccine (seasonal).

- Administer annually to children aged 6 months through 18 years.
- For healthy nonpregnant persons aged 7 through 18 years (i.e., those who do not have underlying medical conditions that predispose them to influenza complications), either LAIV or TIV may be used.
- Administer 2 doses (separated by at least 4 weeks) to children aged younger than 9 years who are receiving influenza vaccine for the first time or who were vaccinated for the first time during the previous influenza season but only received 1 dose.
- For recommendations for use of influenza A (H1N1) 2009 monovalent vaccine. See *MMWR* 2009;58(No. RR-10)

5. Pneumococcal polysaccharide vaccine (PPSV).

- Administer to children with certain underlying medical conditions, including a cochlear implant. A single revaccination should be administered after 5 years to children with functional or anatomic asplenia or an immunocompromising condition. See *MMWR* 1997;46(No. RR-8).

6. Hepatitis A vaccine (HepA).

- Administer 2 doses at least 6 months apart.
- HepA is recommended for children older than 23 months of age who live in areas where vaccination programs target older children or who are at increased risk for infection or for whom immunity against hepatitis A is desired.

7. Hepatitis B vaccine (HepB).

- Administer the 3-dose series to those not previously vaccinated.
- A 2-dose series (separated by at least 4 months) of adult formulation Recombivax HB is licensed for children aged 11 through 15 years.

8. Inactivated poliovirus vaccine (IPV).

- The final dose in the series should be administered on or after the fourth birthday and at least 6 months following the previous dose.
- If both OPV and IPV were administered as part of a series, a total of 4 doses should be administered, regardless of the child's current age.

9. Measles, mumps, and rubella vaccine (MMR).

- If not previously vaccinated, administer 2 doses or the second dose for those who have received only 1 dose, with at least 28 days between doses.

10. Varicella vaccine.

- For persons aged 7 through 18 years without evidence of immunity (see *MMWR* 2007;56[No. RR-4]), administer 2 doses if not previously vaccinated or the second dose if only 1 dose has been administered.
- For persons aged 7 through 12 years, the minimum interval between doses is 3 months. However, if the second dose was administered at least 28 days after the first dose, it can be accepted as valid.
- For persons aged 13 years and older, the minimum interval between doses is 28 days.

Catch-up Immunization Schedule for Persons Aged 4 Months Through 18 Years Who Start Late or Who Are More Than 1 Month Behind—United States • 2010

The table below provides catch-up schedules and minimum intervals between doses for children whose vaccinations have been delayed. A vaccine series does not need to be restarted, regardless of the time that has elapsed between doses. Use the section appropriate for the child's age.

PERSONS AGED 4 MONTHS THROUGH 6 YEARS					
Vaccine	Minimum Age for Dose 1	Minimum Interval Between Doses			
		Dose 1 to Dose 2	Dose 2 to Dose 3	Dose 3 to Dose 4	Dose 4 to Dose 5
Hepatitis B ¹	Birth	4 weeks	8 weeks (and at least 16 weeks after first dose)		
Rotavirus ²	6 wks	4 weeks	4 weeks ²		
Diphtheria, Tetanus, Pertussis ³	6 wks	4 weeks	4 weeks	6 months	6 months ³
<i>Haemophilus influenzae</i> type b ⁴	6 wks	4 weeks if first dose administered at younger than age 12 months 8 weeks (as final dose) if first dose administered at age 12–14 months No further doses needed if first dose administered at age 15 months or older	4 weeks ⁴ 8 weeks (as final dose) ⁴ if current age is 12 months or older and first dose administered at younger than age 12 months and second dose administered at younger than 15 months No further doses needed if previous dose administered at age 15 months or older	8 weeks (as final dose) This dose only necessary for children aged 12 months through 59 months who received 3 doses before age 12 months	
Pneumococcal ⁵	6 wks	4 weeks if first dose administered at younger than age 12 months 8 weeks (as final dose for healthy children) if first dose administered at age 12 months or older or current age 24 through 59 months No further doses needed for healthy children if first dose administered at age 24 months or older	4 weeks if current age is younger than 12 months 8 weeks (as final dose for healthy children) if current age is 12 months or older No further doses needed for healthy children if previous dose administered at age 24 months or older	8 weeks (as final dose) This dose only necessary for children aged 12 months through 59 months who received 3 doses before age 12 months or for high-risk children who received 3 doses at any age	
Inactivated Poliovirus ⁶	6 wks	4 weeks	4 weeks	6 months	
Measles, Mumps, Rubella ⁷	12 mos	4 weeks			
Varicella ⁸	12 mos	3 months			
Hepatitis A ⁹	12 mos	6 months			
PERSONS AGED 7 THROUGH 18 YEARS					
Tetanus, Diphtheria/ Tetanus, Diphtheria, Pertussis ¹⁰	7 yrs ¹⁰	4 weeks	4 weeks if first dose administered at younger than age 12 months 6 months if first dose administered at 12 months or older	6 months if first dose administered at younger than age 12 months	
Human Papillomavirus ¹¹	9 yrs	Routine dosing intervals are recommended ¹¹			
Hepatitis A ⁹	12 mos	6 months			
Hepatitis B ¹	Birth	4 weeks	8 weeks (and at least 16 weeks after first dose)		
Inactivated Poliovirus ⁶	6 wks	4 weeks	4 weeks	6 months	
Measles, Mumps, Rubella ⁷	12 mos	4 weeks			
Varicella ⁸	12 mos	3 months if person is younger than age 13 years 4 weeks if person is aged 13 years or older			

1. Hepatitis B vaccine (HepB).

- Administer the 3-dose series to those not previously vaccinated.
- A 2-dose series (separated by at least 4 months) of adult formulation Recombivax HB is licensed for children aged 11 through 15 years.

2. Rotavirus vaccine (RV).

- The maximum age for the first dose is 14 weeks 6 days. Vaccination should not be initiated for infants aged 15 weeks 0 days or older.
- The maximum age for the final dose in the series is 8 months 0 days.
- If Rotarix was administered for the first and second doses, a third dose is not indicated.

3. Diphtheria and tetanus toxoids and acellular pertussis vaccine (DTaP).

- The fifth dose is not necessary if the fourth dose was administered at age 4 years or older.

4. Haemophilus influenzae type b conjugate vaccine (Hib).

- Hib vaccine is not generally recommended for persons aged 5 years or older. No efficacy data are available on which to base a recommendation concerning use of Hib vaccine for older children and adults. However, studies suggest good immunogenicity in persons who have sickle cell disease, leukemia, or HIV infection, or who have had a splenectomy; administering 1 dose of Hib vaccine to these persons who have not previously received Hib vaccine is not contraindicated.
- If the first 2 doses were PRP-OMP (PedvaxHIB or Comvax), and administered at age 11 months or younger, the third (and final) dose should be administered at age 12 through 15 months and at least 8 weeks after the second dose.
- If the first dose was administered at age 7 through 11 months, administer the second dose at least 4 weeks later and a final dose at age 12 through 15 months.

5. Pneumococcal vaccine.

- Administer 1 dose of pneumococcal conjugate vaccine (PCV) to all healthy children aged 24 through 59 months who have not received at least 1 dose of PCV on or after age 12 months.
- For children aged 24 through 59 months with underlying medical conditions, administer 1 dose of PCV if 3 doses were received previously or administer 2 doses of PCV at least 8 weeks apart if fewer than 3 doses were received previously.
- Administer pneumococcal polysaccharide vaccine (PPSV) to children aged 2 years or older with certain underlying medical conditions, including a cochlear implant, at least 8 weeks after the last dose of PCV.

6. Inactivated poliovirus vaccine (IPV).

- The final dose in the series should be administered on or after the fourth birthday and at least 6 months following the previous dose.

- A fourth dose is not necessary if the third dose was administered at age 4 years or older and at least 6 months following the previous dose.

- In the first 6 months of life, minimum age and minimum intervals are only recommended if the person is at risk for imminent exposure to circulating poliovirus (i.e., travel to a polio-endemic region or during an outbreak).

7. Measles, mumps, and rubella vaccine (MMR).

- Administer the second dose routinely at age 4 through 6 years. However, the second dose may be administered before age 4, provided at least 28 days have elapsed since the first dose.
- If not previously vaccinated, administer 2 doses with at least 28 days between doses.

8. Varicella vaccine.

- Administer the second dose routinely at age 4 through 6 years. However, the second dose may be administered before age 4, provided at least 3 months have elapsed since the first dose.
- For persons aged 12 months through 12 years, the minimum interval between doses is 3 months. However, if the second dose was administered at least 28 days after the first dose, it can be accepted as valid.
- For persons aged 13 years and older, the minimum interval between doses is 28 days.

9. Hepatitis A vaccine (HepA).

- HepA is recommended for children older than 23 months who live in areas where vaccination programs target older children, who are at increased risk for infection, or for whom immunity against hepatitis A is desired.

10. Tetanus and diphtheria toxoids vaccine (Td) and tetanus and diphtheria toxoids and acellular pertussis vaccine (Tdap).

- Doses of DTaP are counted as part of the Td/Tdap series
- Tdap should be substituted for a single dose of Td in the catch-up series or as a booster for children aged 10 through 18 years; use Td for other doses.

11. Human papillomavirus vaccine (HPV).

- Administer the series to females at age 13 through 18 years if not previously vaccinated.
- Use recommended routine dosing intervals for series catch-up (i.e., the second and third doses should be administered at 1 to 2 and 6 months after the first dose). The minimum interval between the first and second doses is 4 weeks. The minimum interval between the second and third doses is 12 weeks, and the third dose should be administered at least 24 weeks after the first dose.

Information about reporting reactions after immunization is available online at <http://www.vaers.hhs.gov> or by telephone, 800-822-7967. Suspected cases of vaccine-preventable diseases should be reported to the state or local health department. Additional information, including precautions and contraindications for immunization, is available from the National Center for Immunization and Respiratory Diseases at <http://www.cdc.gov/vaccines> or telephone, 800-CDC-INFO (800-232-4636).

Recommended and Minimum Ages and Intervals Between Vaccine Doses, *continued*

Vaccine and Dose No.	Recommended Age for This Dose	Minimum Age for This Dose	Recommended Interval to Next Dose	Minimum Interval to Next Dose
RV-3 [†]	6 mo	14 wk
Herpes zoster [‡]	60 y	60 y

DTaP indicates diphtheria and tetanus toxoids and acellular pertussis vaccine; MMR, measles-mumps-rubella; TIV, trivalent (inactivated) influenza vaccine; LAIV, live-attenuated (intranasal) influenza vaccine; Td, tetanus and reduced diphtheria toxoids; Tdap, tetanus toxoid, reduced diphtheria toxoid, and reduced acellular pertussis vaccine.

[‡]Combination vaccines are available and may be used to reduce the number of injections. When administering combination vaccines, the minimum age for administration is the oldest age for any of the individual components; the minimum interval between doses is equal to the greatest interval of any of the individual components.

[†]For travel vaccines, including typhoid, Japanese encephalitis, and yellow fever, see www.cdc.gov/travel.

[‡]Combination vaccines containing the hepatitis B component are available (HepB-Hib, DTaP-HepB-IPV, and HepA-HepB). These vaccines should not be administered to infants younger than 6 weeks of age because of the other components (ie, Hib, DTaP, HepA, and IPV).

[†]HepB-3 should be administered at least 8 weeks after HepB-2 and at least 16 weeks after HepB-1 and should not be administered before 24 weeks of age.

[‡]Calendar months.

[†]The minimum recommended interval between DTaP-3 and DTaP-4 is 6 months. However, DTaP-4 need not be repeated if administered at least 4 months after DTaP-3.

[‡]For Hib and PCV, children receiving the first dose of vaccine at 7 months of age or older require fewer doses to complete the series (see Fig 1.1–1.3, p 24–28).

[†]If PRP-OMP (Pedvax-Hib) was administered at 2 and 4 months of age, a dose at 6 months of age is not required.

[‡]Combination measles-mumps-rubella-varicella (MMRV) vaccine can be used for children 12 months through 12 years of age.

[†]The minimum interval from VAR-1 to VAR-2 for people beginning the series at 13 years of age or older is 4 weeks.

[‡]One dose of influenza vaccine per season is recommended for most people. Children younger than 9 years of age who are receiving influenza for the first time or received only 1 dose the previous season (if it was their first immunization season) should receive 2 doses this season.

[†]The minimum age for inactivated influenza vaccine varies by vaccine manufacturer (see Influenza, p 400).

[‡]Some experts recommend a second dose of MPSV 3 years after the first dose for people at increased risk of meningococcal disease (see Meningococcal Infections, p 455).

[†]A second dose of meningococcal vaccine is recommended for people previously immunized with MPSV who remain at high risk of meningococcal disease. MCV is preferred when reimmunizing people 2 through 55 years of age, but a second dose of MPSV is acceptable.

[‡]Only one dose of Tdap is recommended. Subsequent doses should be given as Td. If immunization to prevent tetanus and/or diphtheria disease is required for children 7 through 9 years of age, Td should be administered (minimum age for Td is 7 years). For one brand of Tdap, the minimum age is 11 years. The preferred interval between Tdap and a previous dose of Td is 5 years.

[†]In people who have received a primary series of tetanus-toxoid containing vaccine, for management of a tetanus-prone wound, the minimum interval after a previous dose of any tetanus-containing vaccine is 5 years.

[‡]A second dose of PPV is recommended for people at highest risk of serious pneumococcal infection and those who are likely to have a rapid decline in pneumococcal antibody concentration (see Pneumococcal Infections, p 524).

[†]HPV is approved only for females 9 through 26 years of age.

[‡]HPV-3 should be administered at least 12 weeks after HPV-2 and at least 24 weeks after HPV-1.

[†]The first dose of RV should be administered at 6 through 14 weeks of age. The vaccine series should not be started at 15 weeks of age or older. RV should not be administered to children older than 8 calendar months of age regardless of the number of doses received between 6 weeks and 8 calendar months of age.

[‡]If Rotarix is administered as age appropriate, a third dose is not necessary.

[†]Herpes zoster vaccine is approved as a single dose for people 60 years of age and older.

From: American Academy of Pediatrics. Active immunization. In: Pickering LK, Baker CJ, Kimberlin DW, Long SS, eds. *Red Book: 2009 Report of the Committee on Infectious Diseases*. 28th ed. Elk Grove Village, IL: American Academy of Pediatrics; 2009:29–31.

Combination Vaccines Licensed by the US Food and Drug Administration (FDA)

Vaccine ^b	Trade Name (Year Licensed)	FDA Licensure	
		Age Group	Recommendations
Hib-HepB	Comvax (1996)	6 wk through 71 mo	Three-dose schedule given at 2, 4, and 12 through 15 mo of age.
DTaP/Hib	TriHIBit (1996)	Fourth dose of Hib and DTaP series	15 through 18 mo of age.
Hep A-HepB	Twinrix (2001)	≥18 y	Three doses on a 0-, 1-, and 6-mo schedule.
DTaP-HepB-IPV	Pediarix (2002)	6 wk through 6 y	Three-dose series at 2, 4, and 6 mo of age.
MMRV	ProQuad (2005)	12 mo through 12 y	Two doses 28 days apart on or after first birthday.
DTaP-IPV	Kinrix (2008)	4 through 6 y	Booster for fifth dose of DTaP and fourth dose of IPV.
DTaP-IPV/Hib	Pentacel (2008)	6 wk through 4 y	Four-dose series at 2, 4, 6, and 15 through 18 mo of age.

Hib indicates *Haemophilus influenzae* type b vaccine; HepB, hepatitis B vaccine; DTaP indicates diphtheria and tetanus toxoids and acellular pertussis vaccine; HepA, hepatitis A vaccine; IPV/Hib trivalent inactivated polio vaccine and *Haemophilus influenzae* type b vaccine; MMRV, measles-mumps-rubella-varicella vaccine.

^a Excludes measles-mumps-rubella (MMR), DTaP, Tdap, and IPV vaccines, for which individual components are not available.

^b Dash (-) indicates products are supplied in their final form by the manufacturer and do not require mixing or reconstitution by user; slash (/) indicates products are mixed or reconstituted by user.

From: American Academy of Pediatrics. Active immunization. In: Pickering LK, Baker CJ, Kimberlin DW, Long SS, eds. *Red Book: 2009 Report of the Committee on Infectious Diseases*. 28th ed. Elk Grove Village, IL: American Academy of Pediatrics; 2009:35.

Uses of Immune Globulin Intravenous (IGIV) for Which There is Approval by the US Food and Drug Administration

Primary immunodeficiency states

Kawasaki disease

Immune-mediated thrombocytopenia

Pediatric human immunodeficiency virus infection

Secondary immunodeficiency in chronic lymphocytic leukemia

Prevention of graft-versus-host disease and infection in hematopoietic cell transplantation in adults

^aTherapeutic differences among IGIV products from different manufacturers are likely to exist.

From: American Academy of Pediatrics. Passive immunization. In: Pickering LK, Baker CJ, Kimberlin DW, Long SS, eds. *Red Book: 2009 Report of the Committee on Infectious Diseases*. 28th ed. Elk Grove Village, IL: American Academy of Pediatrics; 2009:59.

Immunization of Children and Adolescents With Primary and Secondary Immune Deficiencies

Category	Example of Specific Immunodeficiency	Vaccine Contraindications	Effectiveness and Comments
Primary^a			
B lymphocyte (humoral)	Severe antibody deficiencies (eg, X-linked agammaglobulinemia and common variable immunodeficiency)	OPV, ^b smallpox, LAIV, yellow fever, and live-bacteria vaccines ^c ; consider measles vaccine; no data for varicella or rotavirus vaccines	Effectiveness of any vaccine dependent only on humoral response is doubtful; IGIV therapy interferes with measles and possibly varicella immune response.
	Less severe antibody deficiencies (eg, selective IgA deficiency and IgG subclass deficiencies)	OPV ^b ; other live vaccines ^d appear to be safe, but caution is urged	All vaccines probably effective. Immune response may be attenuated.
T lymphocyte (cell-mediated and humoral)	Complete defects (eg, severe combined immunodeficiency, complete DiGeorge syndrome)	All live vaccines ^{c,d}	All vaccines ineffective.
	Partial defects (eg, most patients with DiGeorge syndrome, Wiskott-Aldrich syndrome, ataxia telangiectasia)	All live vaccines ^{c,d}	Effectiveness of any vaccine depends on degree of immune suppression. Recommend inactivated vaccines.
Complement	Deficiency of early components (C1, C4, C2, C3)	None	All routine vaccines probably effective. Pneumococcal and meningococcal vaccines are recommended.
	Deficiency of late components (C5–C9), properdin, factor B	None	All routine vaccines probably effective. Meningococcal and pneumococcal vaccines are recommended.
Phagocytic function	Chronic granulomatous disease, leukocyte adhesion defects, myeloperoxidase deficiency	Live-bacteria vaccines ^c	All inactivated vaccines safe and probably effective. Live-virus vaccines probably safe and effective.
Secondary^a			
	HIV/AIDS	OPV, ^b smallpox, BCG, LAIV ^d ; withhold MMR and varicella in severely immunocompromised children	MMR, varicella, rotavirus, and all inactivated vaccines, including inactivated influenza, may be effective. ^e
	Malignant neoplasm, transplantation, autoimmune disease, immunosuppressive or radiation therapy	Live-virus and -bacteria, depending on immune status ^{c,d}	Effectiveness of any vaccine depends on degree of immune suppression.

OPV indicates oral poliovirus; LAIV, live-attenuated influenza vaccine; IGIV, Immune Globulin Intravenous; Ig, immunoglobulin; HIV, human immunodeficiency virus; AIDS, acquired immunodeficiency syndrome; BCG, bacille Calmette-Guérin; MMR, measles-mumps-rubella.

^aAll children and adolescents should receive an annual age-appropriate inactivated influenza vaccine. LAIV is indicated only for healthy people 5 to 49 years of age.

^bOPV vaccine no longer is recommended for routine use in the United States.

^cLive-bacteria vaccines: BCG and Ty21a *Salmonella typhi* vaccine.

^dLive-virus vaccines: LAIV, MMR, measles-mumps-rubella-varicella (MMRV), herpes zoster (ZOS), OPV, varicella, yellow fever, vaccinia (smallpox), and rotavirus.

^eHIV-infected children should receive Immune Globulin after exposure to measles (see Measles, p 444) and may receive varicella vaccine if CD4+ lymphocyte count $\geq 15\%$ of expected for age (see Varicella-Zoster Infections, p 714).

From: American Academy of Pediatrics. Immunization in special clinical circumstances. In: Pickering LK, Baker CJ, Kimberlin DW, Long SS, eds. *Red Book: 2009 Report of the Committee on Infectious Diseases*. 28th ed. Elk Grove Village, IL: American Academy of Pediatrics; 2009:74–75.

Schedule for Trivalent Inactivated Influenza Vaccine (TIV) Dosage by Age

Age	Dose, mL ^b	No. of Doses	Route ^c
6 through 35 mo	0.25	1–2 ^d	Intramuscular
3 through 8 y	0.5	1–2 ^d	Intramuscular
9 y or older	0.5	1	Intramuscular

^aManufacturers include sanofi pasteur (Fluzone, split-virus vaccine licensed for people 6 months of age or older), Novartis Vaccine (Fluvirin, purified surface antigen, licensed for people 4 years of age or older), CSL Biotherapies (Afluria, split-virus vaccine licensed for people 18 years of age or older), and GlaxoSmithKline Biologicals (Fluarix and FluLaval, split-virus vaccines licensed for people 18 years of age or older).

^bDosages are those recommended in recent years. Physicians should refer to the product circular each year to ensure that the appropriate dosage is given.

^cFor adults and older children, the recommended site of immunization is the deltoid muscle. For infants and young children, the preferred site is the anterolateral aspect of the thigh.

^dTwo doses administered at least 4 weeks apart are recommended for children younger than 9 years of age who are receiving inactivated trivalent influenza vaccine for the first time. If possible, the second dose should be administered before December.

From: American Academy of Pediatrics. Influenza. In: Pickering LK, Baker CJ, Kimberlin DW, Long SS, eds. *Red Book: 2009 Report of the Committee on Infectious Diseases*. 28th ed. Elk Grove Village, IL: American Academy of Pediatrics; 2009:406.

Schedule for Live-Attenuated Influenza Vaccine (LAIV)

Age	Dose, mL ^b	No. of Doses	Route
2 through 8 y	0.2	1–2 ^c	Intranasal
9 y or older	0.2	1	Intranasal

^aManufacturer: MedImmune Vaccines, Inc (FluMist).

^bDosage is the one recommended in recent years. Physicians should refer to the product circular each year to ensure that the appropriate dosage is given.

^cTwo doses administered at least 4 weeks apart are recommended for children younger than 9 years of age who are receiving LAIV for the first time. If possible, the second dose should be administered before December.

From: American Academy of Pediatrics. Influenza. In: Pickering LK, Baker CJ, Kimberlin DW, Long SS, eds. *Red Book: 2009 Report of the Committee on Infectious Diseases*. 28th ed. Elk Grove Village, IL: American Academy of Pediatrics; 2009:407.

Suggested Intervals Between Immune Globulin Administration and Measles Immunization (MMR, MMRV, or Monovalent Measles Vaccine)

Indications or Product	Route	Dose		Interval, mo ^a
		U or mL	mg IgG/kg	
Tetanus prophylaxis (as TIG)	IM	250 U	10	3
Hepatitis A prophylaxis (as IG)				
Contact prophylaxis	IM	0.02 mL/kg	3.3	3
International travel	IM	0.06 mL/kg	10	3
Hepatitis B prophylaxis (as HBIG)	IM	0.06 mL/kg	10	3
Rabies prophylaxis (as RIG)	IM	20 IU/kg	22	4
Varicella prophylaxis (as VariZIG)	IM	125 U/10 kg (maximum 625 U)	20–40	5
Measles prophylaxis (as IG)				
Standard	IM	0.25 mL/kg	40	5
Immunocompromised host	IM	0.50 mL/kg	80	6
RSV prophylaxis (palivizumab monoclonal antibody) ^b	IM	...	15 mg/kg (monoclonal)	None
Cytomegalovirus Immune Globulin	IV	3 mL/kg	150	6
Blood transfusion				
Washed RBCs	IV	10 mL/kg	Negligible	0
RBCs, adenine-saline added	IV	10 mL/kg	10	3
Packed RBCs	IV	10 mL/kg	20–60	5
Whole blood	IV	10 mL/kg	80–100	6
Plasma or platelet products	IV	10 mL/kg	160	7
Replacement (or therapy) of im- mune deficiencies (as IGIV)	IV	...	300–400	8
ITP (as IGIV)	IV	...	400	8
ITP	IV	...	1000	10
ITP for Kawasaki disease	IV	...	1600–2000	11

MMR indicates measles-mumps-rubella; MMRV, measles-mumps-rubella-varicella; IgG, immunoglobulin G; TIG, Tetanus Immune Globulin; IG, Immune Globulin; IM, intramuscular; HBIG, Hepatitis B IG; RIG, Rabies IG; VariZIG, Varicella-Zoster Immune Globulin; RSV, respiratory syncytial virus; IV, intravenous; RBCs, Red Blood Cells; IGIV, IG intravenous; ITP, immune (formerly termed “idiopathic”) thrombocytopenic purpura.

^aThese intervals should provide sufficient time for decreases in passive antibodies in all children to allow for an adequate response to measles vaccine. Physicians should not assume that children are fully protected against measles during these intervals. Additional doses of IG or measles vaccine may be indicated after exposure to measles (see text).

^bMonoclonal antibodies, such as palivizumab, and tumor necrosis factor (TNF) inhibitors do not interfere with response to vaccines.

From: American Academy of Pediatrics. Measles. In: Pickering LK, Baker CJ, Kimberlin DW, Long SS, eds. *Red Book: 2009 Report of the Committee on Infectious Diseases*. 28th ed. Elk Grove Village, IL: American Academy of Pediatrics; 2009:448.

Infectious Disease

General Recommendations for Exclusion of Children in Out-of-Home Child Care

Symptom(s)	Management
Illness preventing participation in activities, as determined by child care staff	Exclusion until illness resolves and able to participate in activities
Illness that requires a need for care that is greater than staff can provide without compromising health and safety of others	Exclusion or placement in care environment where appropriate care can be provided, without compromising care of others
Severe illness suggested by fever with behavior changes, lethargy, irritability, persistent crying, difficulty breathing, progressive rash	Medical evaluation and exclusion until symptoms have resolved
Rash with fever or behavioral change	Medical evaluation and exclusion until illness is determined not to be communicable
Persistent abdominal pain (2 hours or more) or intermittent abdominal pain associated with fever, dehydration, or other systemic signs and symptoms	Medical evaluation and exclusion until symptoms have resolved
Vomiting 2 or more times in preceding 24 hours	Exclusion until symptoms have resolved, unless vomiting is determined to be caused by a noncommunicable condition and child is able to remain hydrated and participate in activities
Diarrhea or stools containing blood or mucus	Medical evaluation and exclusion until symptoms have resolved
Oral lesions	Exclusion until child or staff member is considered to be noninfectious (lesions crusted and dry)

From: American Academy of Pediatrics. Children in out-of-home child care. In: Pickering LK, Baker CJ, Kimberlin DW, Long SS, eds. *Red Book: 2009 Report of the Committee on Infectious Diseases*. 28th ed. Elk Grove Village, IL: American Academy of Pediatrics; 2009:128.

Disease- or Condition-Specific Recommendations for Exclusion of Children in Out-of-Home Child Care

Condition	Management of Case	Management of Contacts
Hepatitis A virus (HAV) infection	Serologic testing to confirm HAV infection in suspected cases. Exclusion until 1 week after onset of jaundice.	If ≥ 1 case confirmed in child or staff attendees or ≥ 2 cases in households of staff or attendees, HAV vaccine or Immune Globulin (IG) should be administered within 14 days of exposure to unimmunized staff and attendees. In centers without diapered children, HAV vaccine or IG should be given to unimmunized classroom contacts of index case. Asymptomatic IG recipients may return after receipt of IG (see Hepatitis A, p 329).
Impetigo	Exclusion until 24 hours after treatment has been initiated. Lesions on exposed skin covered with watertight dressing.	No intervention unless additional lesions develop.
Measles	Exclusion until 4 days after beginning of rash and when the child is able to participate.	Immunize exposed children without evidence of immunity within 72 hours of exposure. Children who do not receive vaccine within 72 hours or who remain unimmunized after exposure should be excluded until at least 2 weeks after onset of rash in the last case of measles. For use of IG, see Measles (p 444).
Mumps	Exclusion until 5 days after onset of parotid gland swelling.	In outbreak setting, people without documentation of immunity should be immunized or excluded. Immediate readmission may occur following immunization. Unimmunized people should be excluded for ≥ 26 days following onset of parotitis in last case.
<i>Pediculosis capitis</i> (head lice)	Treatment at end of program day and readmission on completion of first treatment.	Household and close contacts should be examined and treated if infested. No exclusion necessary.
Pertussis	Exclusion until 5 days of appropriate antimicrobial therapy course have been completed (see Pertussis, p 504).	Immunization and chemoprophylaxis should be administered as recommended for household contacts. Symptomatic children and staff should be excluded until completion of 5 days of antimicrobial therapy course. Untreated adults should be excluded until 21 days after onset of cough (see Pertussis Infections, p 504).
Rubella	Exclusion until 6 days after onset of rash for postnatal infection.	Pregnant contacts should be evaluated (see Rubella, p 579).
<i>Salmonella</i> serotype Typhi infection	Exclusion until diarrhea resolves. Three negative stool culture results required before readmission.	Stool cultures should be performed for attendees and staff; infected people should be excluded on the basis of age (see <i>Salmonella</i> Infections, p 584).
Non-serotype Typhi <i>Salmonella</i> infection	Exclusion until diarrhea resolves. Negative stool culture results not required for non-serotype Typhi <i>Salmonella</i> species.	Symptomatic contacts should be excluded until symptoms resolve. Stool cultures are not required for asymptomatic contacts. Antimicrobial therapy is not recommended for asymptomatic infection or uncomplicated diarrhea or for contacts.
Scabies	Exclusion until after treatment given.	Close contacts with prolonged skin-to-skin contact should have prophylactic therapy. Bedding and clothing in contact with skin of infected people should be laundered (see Scabies, p 589).
Shiga toxin-producing <i>Escherichia coli</i> (STEC), including <i>E coli</i> O157:H7, or <i>Shigella</i> infection	Exclusion until diarrhea resolves and results of 2 stool cultures are negative for these organisms, depending on state regulations.	Meticulous hand hygiene; stool cultures should be performed for contacts. Center(s) with cases should be closed to new admissions during <i>E coli</i> O157:H7 outbreak (see <i>Escherichia coli</i> diarrhea, p 294, and <i>Shigella</i> infections, p 593).
<i>Staphylococcus aureus</i> skin infections	Exclusion only if skin lesions are draining and cannot be covered with a watertight dressing.	Meticulous hand hygiene; cultures of contacts are not recommended.
Streptococcal pharyngitis	Exclusion until 24 hours after treatment has been initiated and the child is able to participate in activities.	Symptomatic contacts of documented cases of group A streptococcal infection should be tested and treated if test results are positive.
Tuberculosis	For active disease, exclusion until determined to be non-infectious by physician or health department authority. May return to activities after therapy is instituted, symptoms have diminished, and adherence to therapy is documented. No exclusion for latent tuberculosis infection (LTBI).	Local health department personnel should be informed for contact investigation (see Tuberculosis, p 680).
Varicella (see Varicella-Zoster Infections, p 714)	Exclusion until all lesions have dried and crusted (usually 6 days after onset of rash in immunocompetent people; may be longer in immunocompromised people).	Varicella vaccine should be administered by 3 to 5 days after exposure, and Varicella-Zoster Immune Globulin should be administered up to 96 hours after exposure when indicated.

Antiviral Drugs for Influenza

Drug (Trade Name)	Virus	Administration	Treatment Indications ^a	Prophylaxis Indications ^a	Adverse Effects
Oseltamivir ^b (Tamiflu)	A and B	Oral	1 y of age or older	1 y of age or older	Nausea, vomiting
Zanamivir (Relenza)	A and B	Inhalation	7 y of age or older	5 y of age or older	Bronchospasm
Amantadine ^c (Symmetrel)	A	Oral	1 y of age or older	1 y of age or older	Central nervous system, anxiety, gastrointestinal
Rimantadine ^c (Flumadine)	A	Oral	13 y of age or older	1 y of age or older	Central nervous system, anxiety, gastrointestinal

^aUS Food and Drug Administration (FDA)-approved ages.

^bHigh prevalence of resistance among H1N1 influenza strains.

^cHigh prevalence of adamantane resistance among H3N2 and B influenza strains.

See www.cdc.gov/flu/professionals/antivirals/index.htm or www.aapredbook.org/flu for current information for use of antiviral drugs for treatment or chemoprophylaxis against influenza.

From: American Academy of Pediatrics. Influenza. In: Pickering LK, Baker CJ, Kimberlin DW, Long SS, eds. *Red Book: 2009 Report of the Committee on Infectious Diseases*. 28th ed. Elk Grove Village, IL: American Academy of Pediatrics; 2009:404.

Definitions of Positive Tuberculin Skin Test (TST) Results in Infants, Children, and Adolescents

Induration 5 mm or greater

Children in close contact with known or suspected contagious people with tuberculosis disease

Children suspected to have tuberculosis disease:

- Findings on chest radiograph consistent with active or previous tuberculosis disease
- Clinical evidence of tuberculosis disease^b

Children receiving immunosuppressive therapy^c or with immunosuppressive conditions, including human immunodeficiency (HIV) infection

Induration 10 mm or greater

Children at increased risk of disseminated tuberculosis disease:

- Children younger than 4 years of age
- Children with other medical conditions, including Hodgkin disease, lymphoma, diabetes mellitus, chronic renal failure, or malnutrition (see Table 3.80, p 684)

Children with likelihood of increased exposure to tuberculosis disease:

- Children born in high-prevalence regions of the world
- Children frequently exposed to adults who are HIV infected, homeless, users of illicit drugs, residents of nursing homes, incarcerated or institutionalized, or migrant farm workers
- Children who travel to high-prevalence regions of the world

Induration 15 mm or greater

Children 4 years of age or older without any risk factors

^aThese definitions apply regardless of previous bacille Calmette-Guérin (BCG) immunization (see also Interpretation of TST Results in Previous Recipients of BCG Vaccine, p 685); erythema alone at TST site does not indicate a positive test result. Tests should be read at 48 to 72 hours after placement.

^bEvidence by physical examination or laboratory assessment that would include tuberculosis in the working differential diagnosis (eg, meningitis).

^cIncluding immunosuppressive doses of corticosteroids (see Corticosteroids, p 694).

From: American Academy of Pediatrics. Tuberculosis. In: Pickering LK, Baker CJ, Kimberlin DW, Long SS, eds. *Red Book: 2009 Report of the Committee on Infectious Diseases*. 28th ed. Elk Grove Village, IL: American Academy of Pediatrics; 2009:681.

Tuberculin Skin Test (TST) Recommendations for Infants, Children, and Adolescents^a

Children for whom immediate TST or IGRA is indicated^b:

- Contacts of people with confirmed or suspected contagious tuberculosis (contact investigation)
- Children with radiographic or clinical findings suggesting tuberculosis disease
- Children immigrating from countries with endemic infection (eg, Asia, Middle East, Africa, Latin America, countries of the former Soviet Union), including international adoptees
- Children with travel histories to countries with endemic infection and substantial contact with indigenous people from such countries^c

Children who should have annual TST or IGRA:

- Children infected with HIV infection (TST only)
- Incarcerated adolescents

Children at increased risk of progression of LTBI to tuberculosis disease: Children with other medical conditions, including diabetes mellitus, chronic renal failure, malnutrition, and congenital or acquired immunodeficiencies deserve special consideration. Without recent exposure, these people are not at increased risk of acquiring tuberculosis infection. Underlying immune deficiencies associated with these conditions theoretically would enhance the possibility for progression to severe disease. Initial histories of potential exposure to tuberculosis should be included for all of these patients. If these histories or local epidemiologic factors suggest a possibility of exposure, immediate and periodic TST or IGRA should be considered. **An initial TST or IGRA should be performed before initiation of immunosuppressive therapy, including prolonged steroid administration, use of tumor necrosis factor-alpha antagonists, or other immunosuppressive therapy in any child requiring these treatments.**

IGRA indicates interferon-gamma release assay; HIV, human immunodeficiency virus; LTBI, latent tuberculosis infection.

^aBacille Calmette-Guérin immunization is not a contraindication to a TST.

^bBeginning as early as 3 months of age.

^cIf the child is well, the TST or IGRA should be delayed for up to 10 weeks after return.

From: American Academy of Pediatrics. Tuberculosis. In: Pickering LK, Baker CJ, Kimberlin DW, Long SS, eds. *Red Book: 2009 Report of the Committee on Infectious Diseases*. 28th ed. Elk Grove Village, IL: American Academy of Pediatrics; 2009:684.

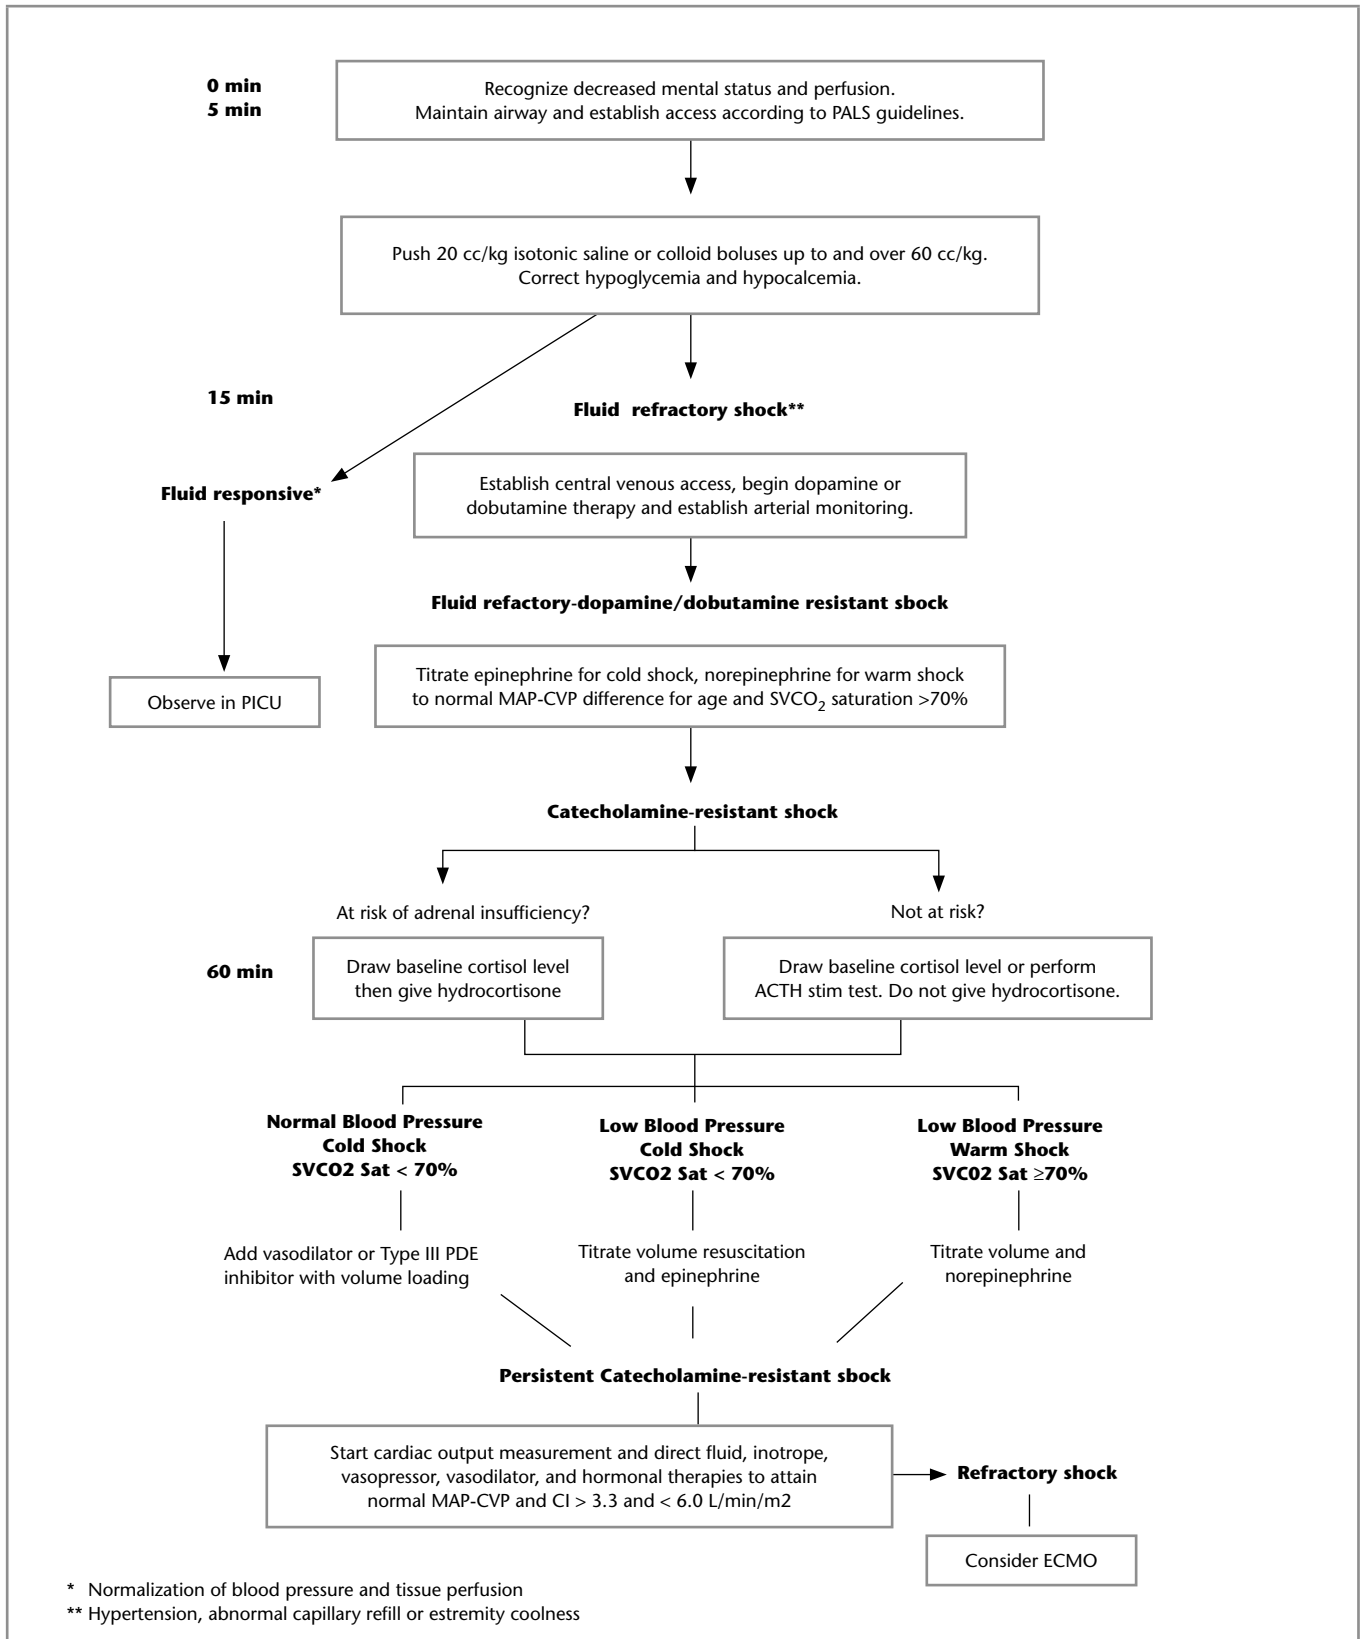

Validated Questions for Determining Risk of LTBI in Children in the United States

- Has a family member or contact had tuberculosis disease?
- Has a family member had a positive tuberculin skin test result?
- Was your child born in a high-risk country (countries other than the United States, Canada, Australia, New Zealand, or Western European countries)?
- Has your child traveled (had contact with resident populations) to a high-risk country for more than 1 week?

LTBI indicates latent tuberculosis infection.

From: American Academy of Pediatrics. Tuberculosis. In: Pickering LK, Baker CJ, Kimberlin DW, Long SS, eds. *Red Book: 2009 Report of the Committee on Infectious Diseases*. 28th ed. Elk Grove Village, IL: American Academy of Pediatrics; 2009:685.

Management of Septic Shock Algorithm

Medications

Drugs for Which Absorption Is Increased by Food

Atovaquone (administer with a high-fat meal)
Cefpodoxime
Cefuroxime
Erythromycin
Griseofulvin (administer with a high-fat meal)
Morphine sulfate (oral solution)
Nitrofurantoin
Theophylline sustained release (food may induce sudden release of sustained-release preparation)

From: Kleinman RE, ed. *Pediatric Nutrition Handbook*. Elk Grove Village, IL: American Academy of Pediatrics; 2009.

Drugs for Which Absorption May Be Delayed by Food or Milk

Medication Name	Comments
Acetaminophen	Rate may decreased by high carbohydrate load
Amitriptyline	Increased fiber may decrease effect
Ampicillin	Food decreases rate and extent of absorption
Cefaclor	Delays and decreases peak concentration
Cephalexin	Food may delay absorption
Cimetidine	Limit xanthine-containing food and beverages
Ciprofloxacin	Dairy products/minerals decrease concentration
Digoxin	Increased fiber or pectin may decrease absorption
Diltiazem	Food may increase absorption from sustained-release product
Fluoxetine	Food may delay absorption
Furosemide	Avoid acidic solutions
Glipizide	Rate of absorption, not extent, delayed by food
Lansoprazole	Food decreases bioavailability by 40%
Metronidazole	
Omeprazole	Administering with food decreases level by 50%
Penicillin	
Trazodone	Rate of absorption, not extent, delayed by food
Valproic acid	Rate of absorption, not extent, delayed by food
Zafirlukast	Food decreases absorption by 40%
Zalcitabine	

(Drugs in this category should either be administered on an empty stomach or taken consistently with regard to food.)

From: Kleinman RE, ed. *Pediatric Nutrition Handbook*. Elk Grove Village, IL: American Academy of Pediatrics; 2009.

Drugs That Should Be Administered on an Empty Stomach

Medication Name	Comments
Ampicillin	
Amprenavir	Avoid antacids and high-fat meals
Captopril	
Ceftibuten	
Cloxacillin	
Dicloxacillin	
Didanosine	
Diltiazem	
Efavirenz	
Erythromycin base	
Indinavir	
Iron	Avoid milk and antacids
Isoniazid	
Itraconazole oral solution	
Ketoconazole	Administer 2 h before antacids; may administer with food to decrease gastrointestinal distress
Lansoprazole	
Levofloxacin oral solution	
Loracarbef	
Mycophenolate	
Nifedipine	
Omeprazole	
Rifampin	May administer with food to decrease gastrointestinal distress
Tacrolimus	Separate antacids by at least 2 hours
Tetracycline	
Zafirlukast	

From: Kleinman RE, ed. *Pediatric Nutrition Handbook*. Elk Grove Village, IL: American Academy of Pediatrics; 2009.

Neurologic

Classification of Concussion

GRADE	DEFINITION	MANAGEMENT
1	Transient confusion No loss of consciousness, mental status abnormalities for < 15 min	Return to sports activities same day only if all symptoms resolve within 15 min. If a second grade-1 concussion occurs, no sports activity until asymptomatic for 1 week.
2	Transient confusion No loss of consciousness, mental status abnormalities for > 15 min	No sports activity until asymptomatic for 1 week. If a grade-2 concussion occurs on the same day as a previous grade-1 concussion, no sports activity for 2 weeks.
3	Concussion involving any loss of consciousness	No sports activity until asymptomatic for 1 week if loss of consciousness was brief (seconds). No sports activity until asymptomatic for 2 weeks if loss of consciousness was prolonged (minutes or longer). Second grade-3 concussion. No sports activity until asymptomatic for 1 month. Any abnormality on CT or MRI. No sports activity for remainder of season. Patient should be discouraged from any future return to contact sports.

*Concussion symptoms: early (minutes and hours)—headache, dizziness or vertigo, lack of awareness of surroundings, nausea or vomiting. Late (days to weeks)—persistent low-grade headache, light-headedness, poor attention and concentration, memory dysfunction, easy fatigability, irritability and low frustration tolerance, intolerance to bright lights or difficulty focusing vision, intolerance of loud noises, sometimes ringing in the ears, anxiety or depressed mood, sleep disturbance. *CT*, Computed tomography; *MRI*, magnetic resonance imaging.

From: Quality Standards Committee, American Academy of Neurology. Practice parameter: the management of concussion in sports (summary statement). *Neurology*. 1997;48(3):581–585.

Glasgow Coma Scale

EYE-OPENING RESPONSE

SCORE	> 1 YEAR	< 1 YEAR
4	Spontaneous	Spontaneous
3	To verbal command	To shout
2	To pain	To pain
1	None	None

MOTOR RESPONSE

SCORE	> 1 YEAR	< 1 YEAR
6	Obeys commands	Spontaneous response
5	Localizes pain	Localizes pain
4	Withdraws from pain	Withdraws from pain
3	Displays abnormal flexion to pain (decorticate rigidity)	Displays abnormal flexion to pain (decorticate rigidity)
2	Displays abnormal extension to pain (decerebrate rigidity)	Displays abnormal extension to pain (decerebrate rigidity)
1	None	None

VERBAL RESPONSE

SCORE	> 5 YEARS	2 TO 5 YEARS	0-23 MONTHS
5	Is oriented and converses	Uses appropriate words and phrases	Babbles, coos appropriately
4	Conversation is confused	Use inappropriate words	Cries but is consolable
3	Words are inappropriate	Cries or screams persistently to pain	Cries or screams persistently to pain
2	Sounds are incomprehensible	Grunts or moans to pain	Grunts or moans to pain
1	None	None	None

*The Glasgow Coma Scale score is the sum of best eye-opening, motor, and verbal responses. Scores range from 3 to 15. Severe indicates a score of <9; moderate, 9-12; and mild, 13-15.

Modified from: Teasdale G, Jennett B. Assessment of coma and impaired consciousness: a practical scale. *Lancet*. 1974;304(7872):81-84. Copyright © Elsevier 1974.

Obesity

**Body Mass Index for Age Percentiles:
Girls, 2 to 20 Years**

**Body Mass Index for Age Percentiles:
Boys, 2 to 20 Years**

Developed by the National Center for Health Statistics in collaboration with the National Center for Chronic Disease Prevention and Health Promotion (2000).

Interpreting BMI

Growth Indicator	Anthropometric Indices	Percentile Cutoff
Underweight	Low BMI for age and gender	<5th percentile
Normal	Normal BMI for age and gender	≥5th percentile but <85th percentile
Overweight	High BMI for age and gender	≥85th percentile but <95th percentile
Obese	High BMI for age and gender	≥95th percentile

From: Hagan JF, Shaw JS, Duncan PM, eds. *Bright Futures: Guidelines for Health Supervision of Infants, Children, and Adolescents*. 3rd ed. Elk Grove Village, IL: American Academy of Pediatrics; 2008.

Percentiles for Assessing Overweight and Obesity

Percentile	Status
<85th	Normal, or healthy, weight
≥85th but <95th	Overweight
≥95th	Obese

From: Hagan JF, Shaw JS, Duncan PM, eds. *Bright Futures: Guidelines for Health Supervision of Infants, Children, and Adolescents*. 3rd ed. Elk Grove Village, IL: American Academy of Pediatrics; 2008.

Oral Health

American Academy of Pediatrics Dentistry Caries-Risk Assessment Tool (CAT)

Risk Factors to Consider	Risk Indicators		
	High	Moderate	Low
(For each item below, circle the most accurate response found to the right under "Risk Indicators")			
Part 1 – History (determined by interviewing the parent/primary caregiver)			
Child has special health care needs, especially any that impact motor coordination or cooperation ^A	Yes		No
Child has condition that impairs saliva (dry mouth) ^B	Yes		No
Child's use of dental home (frequency of routine dental visits)	None	Irregular	Regular
Child has decay	Yes		No
Time lapsed since child's last cavity	<12 months	12 to 24 months	>24 months
Child wears braces or orthodontic/oral appliances ^C	Yes		No
Child's parent and/or sibling(s) have decay	Yes		No
Socioeconomic status of child's parents ^D	Low	Mid-level	High
Daily between-meal exposures to sugars/cavity producing foods (includes on demand use of bottle/sippy cup containing liquid other than water; consumption of juice, carbonated beverages, or sports drinks; use of sweetened medications) ^E	>3	1 to 2	Mealtime only
Child's exposure to fluoride ^{F,G}	Does not use fluoridated toothpaste; drinking water is not fluoridated and is not taking fluoride supplements	Uses fluoridated toothpaste; usually does not drink fluoridated water and does not take fluoride supplements	Uses fluoridated toothpaste; drinks fluoridated water or takes fluoride supplements
Times per day that child's teeth/gums are brushed	<1	1	2-3
Part 2 – Clinical evaluation (determined by examining the child's mouth)			
Visible plaque (white, sticky buildup)	Present		Absent
Gingivitis (red, puffy gums) ^H	Present		Absent
Areas of enamel demineralization (chalky white-spots on teeth)	More than 1	1	None
Enamel defects, deep pits/fissures ^I	Present		Absent
Part 3 – Supplemental professional assessment (Optional) ^J			
Radiographic enamel caries	Present		Absent
Levels of mutans streptococci or lactobacilli	High	Moderate	Low

Each child's overall assessed risk for developing decay is based on the highest level of risk indicator circled above (ie, single risk indicator in any area of the "high risk" category classifies a child as being "high risk").

continued

American Academy of Pediatrics Dentistry Caries-Risk Assessment Tool (CAT), continued

- A Children with special health care needs are those who have a physical, developmental, mental, sensory, behavioral, cognitive, or emotional impairment or limiting condition that requires medical management, health care intervention, and/or use of specialized services. The condition may be developmental or acquired and may cause limitations in performing daily self-maintenance activities or substantial limitations in a major life activity. Health care for special needs patients is beyond that considered routine and requires specialized knowledge, increased awareness and attention, and accommodation.
- B Alteration in salivary flow can be the result of congenital or acquired conditions, surgery, radiation, medication, or age-related changes in salivary function. Any condition, treatment, or process known or reported to alter saliva flow should be considered an indication of risk unless proven otherwise.
- C Orthodontic appliances include both fixed and removable appliances, space maintainers, and other devices that remain in the mouth continuously or for prolonged time intervals and which may trap food and plaque, prevent oral hygiene, compromise access of tooth surfaces to fluoride, or otherwise create an environment supporting caries initiation.
- D National surveys have demonstrated that children in low-income and moderate-income households are more likely to have caries and more decayed or filled primary teeth than children from more affluent households. Also, within income levels, minority children are more likely to have caries. Thus, socioeconomic status should be viewed as an initial indicator of risk that may be offset by the absence of other risk indicators.
- E Examples of sources of simple sugars include carbonated beverages, cookies, cake, candy, cereal, potato chips, French fries, corn chips, pretzels, breads, juices, and fruits. Clinicians using caries-risk assessment should investigate individual exposures to sugars known to be involved in caries initiation.
- F Optimal systemic and topical fluoride exposure is based on use of a fluoride dentifrice and American Dental Association/American Academy of Pediatrics guidelines for exposure from fluoride drinking water and/or supplementation.
- G Unsupervised use of toothpaste and at-home topical fluoride products are not recommended for children unable to expectorate predictably.
- H Although microbial organisms responsible for gingivitis may be different than those primarily implicated in caries, the presence of gingivitis is an indicator of poor or infrequent oral hygiene practices and has been associated with caries progression.
- I Tooth anatomy and hypoplastic defects (eg, poorly formed enamel, developmental pits) may predispose a child to develop caries.
- J Advanced technologies such as radiographic assessment and microbiologic testing are not essential for using this tool.

From: Hagan JF, Shaw JS, Duncan PM, eds. *Bright Futures: Guidelines for Health Supervision of Infants, Children, and Adolescents*. 3rd ed. Elk Grove Village, IL: American Academy of Pediatrics; 2008.

Dietary Fluoride Supplementation Schedule

Age	<0.3 ppm F	0.3-0.6 ppm F	>0.6 ppm F
Birth-6 months	0	0	0
6 mo-3 years	0.25 mg	0	0
3-6 years	0.50 mg	0.25 mg	0
6 y up to at least 16 years	1.00 mg	0.50 mg	0

American Academy of Pediatrics

Quick Reference Guide to Pediatric Care

Directed by a distinguished editorial team

Editor in Chief: Deepak M. Kamat, MD, PhD, FAAP

Coeditors: Henry M. Adam, MD, FAAP; Kathleen K. Cain, MD, FAAP; Deborah E. Campbell, MD, FAAP; Alexander M. Holston, MD; Kelly J. Kelleher, MD, MPH, FAAP; Michael G. Leu, MD, MS, MHS, FAAP; Thomas K. McInerney, MD, FAAP; Lamia M. Soghier, MD, FAAP; Mark L. Wolraich, MD, FAAP; Beverly P. Wood, MD, MEd, PhD, FAAP

For nearly 80 years, the American Academy of Pediatrics has been the nation's leading and most trusted child health expert. The all-new *AAP Quick Reference Guide to Pediatric Care* continues this tradition by providing a wealth of expert guidance spanning every aspect of current clinical practice.

Custom built for the busy practitioner, this all-new guidebook delivers the practical, action-oriented clinical solutions you need “right now.” It's the perfect resource to use during or between patient encounters. Authoritative AAP content is presented in a concise outline format that makes it easy to zero in on what you're looking for.

If you see it in your practice, you're likely to see it here.

Coverage spans more than 230 areas of current pediatric care—everything from abdominal pain and ADHD to herpes and HIV to umbilical anomalies and UTIs.

Regardless of the patient presentation you're confronted with, you'll have quick access to the help you need to

- Efficiently evaluate signs and symptoms.
- Order the right screening/diagnostic tests.
- Implement approved therapeutic strategies.
- Prescribe safe and effective medications.
- Recommend proven prevention measures.
- Confidently respond to parent questions.

Valuable “extras” help you find solutions even faster.

A 32-page insert with 100 full-color images complements the text.

Plus, special sections include laboratory values and detailed data tables from popular AAP resources such as the *Red Book* infectious disease problem-solver...Bright Futures health supervision guidelines...*Pediatric Nutrition Handbook*...and the best-selling *AAP Textbook of Pediatric Care: Tools for Practice*.

Combine with the *AAP Textbook of Pediatric Care* and *Pediatric Care Online*[™] for powerful problem-solving.

Quickly look up key information and recommendations on

- Prevention
- Screening
- Signs and symptoms
- Treatment
- Emotional and behavioral problems
- Specific clinical problems
- Critical situations
