The guideline primarily addresses the generation of photostability information for submission in Registration Applications for new molecular entities and associated drug products. The guideline does not cover the photostability of drugs after administration (i.e., under conditions of use) and those applications not covered by the Parent Guideline. Alternative approaches may be used if they are scientifically sound and justification is provided.

A systematic approach to photostability testing is recommended, covering, as appropriate, studies such as

i. Tests on the drug substance
ii. Tests on the exposed drug product outside the immediate pack, and if necessary,
iii. Tests on the drug product in the immediate pack, and if necessary,
iv. Tests on the drug product in the marketing pack

The extent of drug product testing should be established by assessing whether or not acceptable change has occurred at the end of the light exposure testing as described in the decision flow chart for photostability testing of drug products (Figure 9.1). Acceptable change is change within limits justified by the applicant. The formal labeling requirements for photolabile drug substances and drug products are established by national/regional requirements.

B. Light Sources

The light sources described in this section may be used for photostability testing. The applicant should either maintain an appropriate control of temperature to minimize the effect of localized temperature changes or include a dark control in the same environment unless otherwise justified. For both options 1 and 2, a pharmaceutical manufacturer/applicant may rely on the spectral distribution specification of the light source manufacturer.

Option 1

Any light source that is designed to produce an output similar to the D65/ID65 emission standard, such as an artificial daylight fluorescent lamp combining visible and ultraviolet (UV) outputs, xenon, or metal halide lamp. D65 is the internationally recognized standard for outdoor daylight as defined in ISO 10977 (1993). ID65 is the equivalent indoor indirect daylight standard. For a light source emitting significant radiation below 320 nm, an appropriate filter(s) may be fitted to eliminate such radiation.

Option 2

For option 2, the same sample should be exposed to both the cool white fluorescent and the near UV lamp.

1. A cool white fluorescent lamp designed to produce an output similar to that specified in ISO 10977(1993), and
2. A near UV fluorescent lamp having a spectral distribution from 320 nm to 400 nm with a maximum energy emission between 350 nm and 370 nm; a significant proportion of UV should be in both bands of 320 to 360 nm and 360 to 400 nm.

C. Procedure

For confirmatory studies, samples should be exposed to light providing an overall illumination of not less than 1.2 million lux hours and an integrated near UV energy of not less than 200 Wh/m^2 to allow direct comparisons to be made between the drug substance and the drug product.

Samples may be exposed side-by-side with a validated chemical actinometric system to ensure the specified light exposure is obtained, or for the appropriate duration of time when conditions have been monitored using calibrated radiometers/lux meters. An example of an actinometric procedure is provided in the Annex.

If protected samples (e.g., wrapped in aluminum foil) are used as dark controls to evaluate the contribution of thermally induced change to the total observed change, these should be placed alongside the authentic sample.

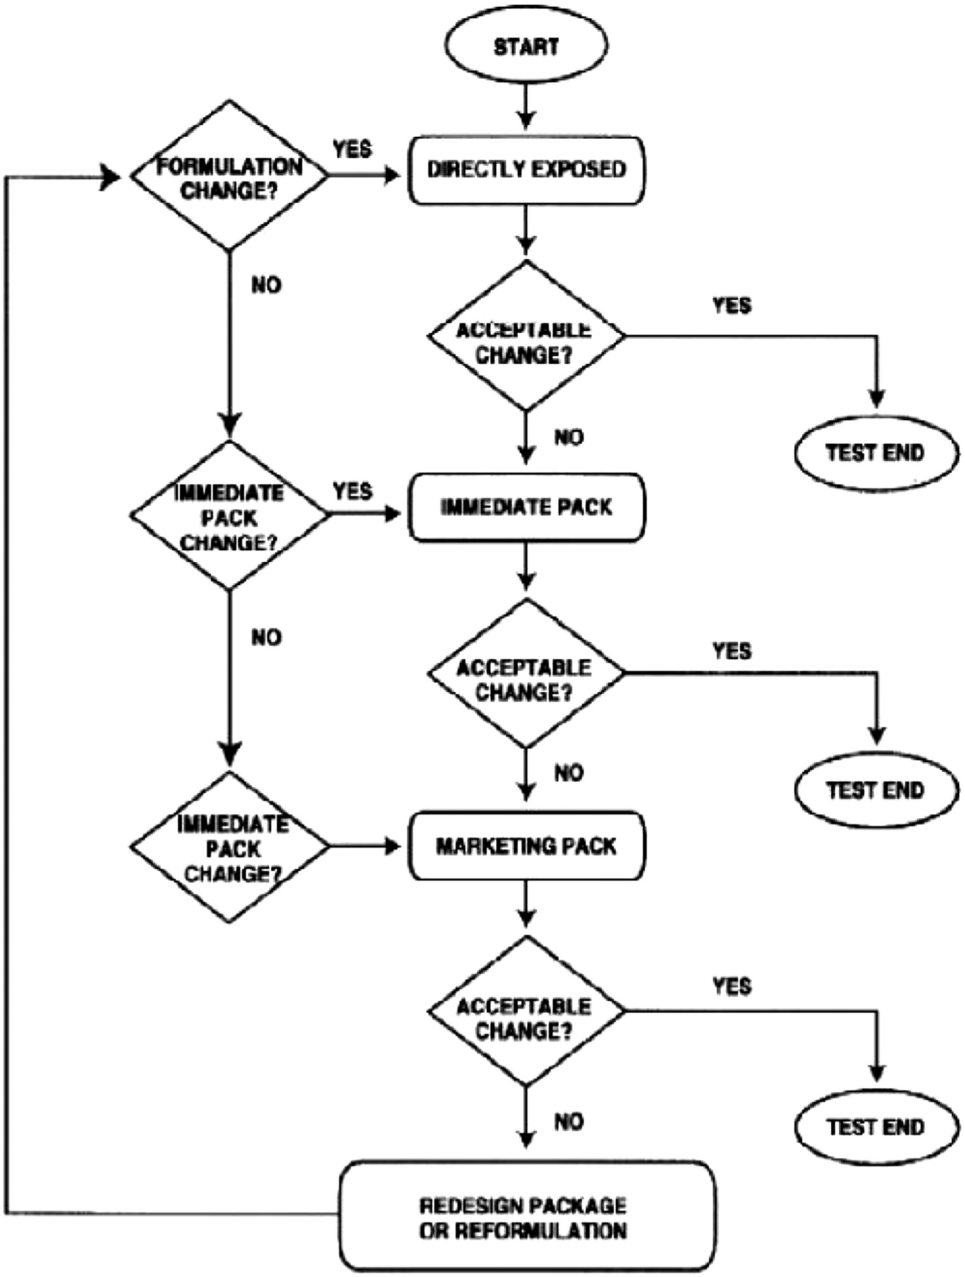

FIGURE 9.1 Decision flow chart for photostability testing of drug products.

II. DRUG SUBSTANCE

For drug substances, photostability testing should consist of two parts: forced degradation testing and confirmatory testing.

The purpose of forced degradation testing studies is to evaluate the overall photosensitivity of the material for method development purposes and/or degradation pathway elucidation. This testing may involve the drug substance alone and/or in simple solutions/suspensions to validate the analytical procedures. In these studies, the samples should be in chemically inert and transparent containers. In these forced degradation studies, a variety of exposure conditions may be used, depending on the photosensitivity of the drug substance involved and the intensity of the light sources used. For development and validation purposes, it is appropriate to limit exposure and end the studies if extensive decomposition occurs. For photostable materials, studies may be terminated after an appropriate exposure level has been used. The design of these experiments is left to the applicant's discretion, although the exposure levels used should be justified.

Under forcing conditions, decomposition products may be observed that are unlikely to be formed under the conditions used for confirmatory studies. This information may be useful in developing and validating suitable analytical methods. If in practice it has been demonstrated that they are not formed in

the confirmatory studies, these degradation products need not be further examined.

Confirmatory studies should then be undertaken to provide the information necessary for handling, packaging, and labeling (see Sections I.C., Procedure, and II.A., Presentation, for information on the design of these studies).

Normally, only one batch of drug substance is tested during the development phase, and then, the photostability characteristics should be confirmed on a single batch selected as described in the Parent Guideline if the drug is clearly photostable or photolabile. If the results of the confirmatory study are equivocal, testing of up to two additional batches should be conducted. Samples should be selected as described in the Parent Guideline.

A. Presentation of Samples

Care should be taken to ensure that the physical characteristics of the samples under test are taken into account, and efforts should be made, such as cooling and/or placing the samples in sealed containers, to ensure that the effects of changes in physical state, such as sublimation, evaporation, or melting, are minimized. All such precautions should be chosen to provide minimal interference with the exposure of samples under test. Possible interactions between the samples and any material used for containers or for general protection of the sample should also be considered and eliminated wherever not relevant to the test being carried out.

As a direct challenge for samples of solid drug substances, an appropriate amount of sample should be taken and placed in a suitable glass or plastic dish and protected with a suitable transparent cover if considered necessary. Solid drug substances should be spread across the container to give a thickness of typically not more than 3 mL. Drug substances that are liquids should be exposed in chemically inert and transparent containers.

B. Analysis of Samples

At the end of the exposure period, the samples should be examined for any changes in physical properties (e.g., appearance, clarity, or color of solution) and for assay and degradants by a method suitably validated for products likely to arise from photochemical degradation processes.

Where solid drug substance samples are involved, sampling should ensure that a representative portion is used in individual tests. Similar sampling considerations, such as homogenization of the entire sample, apply to other materials that may not be homogeneous after exposure. The analysis of the exposed sample should be performed concomitantly with that of any protected samples used as dark controls, if these are used in the test.

C. Judgement of Results

The forced degradation studies should be designed to provide suitable information to develop and validate test methods for the confirmatory studies. These test methods should be capable of resolving and detecting photolytic degradants that appear during the confirmatory studies. When evaluating the results of these studies, it is important to recognize that they form part of the stress testing and are not therefore designed to establish qualitative or quantitative limits for change.

The confirmatory studies should identify precautionary measures needed in manufacturing or in formulation of the drug product, and whether light-resistant packaging is needed. When evaluating the results of confirmatory studies to determine whether change due to exposure to light is acceptable, it is important to consider the results from other formal stability studies in order to ensure that the drug will be within justified limits at the time of use (see the relevant ICH Stability and Impurity Guidelines).

III. DRUG PRODUCT

Normally, the studies on drug products should be carried out in a sequential manner, starting with testing the fully exposed product, then progressing as necessary to the product in the immediate pack, and then in the marketing pack. Testing should progress until the results demonstrate that the drug product is adequately protected from exposure to light. The drug product should be exposed to the light conditions described under the procedure in Section I.C.

Normally, only one batch of drug product is tested during the development phase, and then, the photostability characteristics should be confirmed on a single batch selected as described in the Parent Guideline if the product is clearly photostable or photolabile. If the results of the confirmatory study are equivocal, testing of up to two additional batches should be conducted.

For some products, where it has been demonstrated that the immediate pack is completely impenetrable to light, such as aluminum tubes or cans, testing should normally only be conducted on directly exposed drug product.

It may be appropriate to test certain products such as infusion liquids, dermal creams, etc., to support their photostability in use. The extent of this testing should depend on and relate to the directions for use and is left to the applicant's discretion.

The analytical procedures used should be suitably validated.

A. Presentation of Samples

Care should be taken to ensure that the physical characteristics of the samples under test are taken into account, and efforts, such as cooling and/or placing the samples in sealed containers, should be made to ensure that the effects of changes in physical states, such as sublimation, evaporation, or melting, are minimized. All such precautions should be chosen to provide minimal interference with the irradiation of samples under test. Possible interactions between the samples and any material used for containers or for general protection of the sample should also be considered and eliminated wherever not relevant to the test being carried out.

Where practicable, when testing samples of the drug product outside the primary pack, these should be presented in

a way similar to the conditions mentioned for the drug substance. The samples should be positioned to provide the maximum area of exposure to the light source. For example, tablets, capsules, etc., should be spread in a single layer.

If direct exposure is not practical (e.g., due to oxidation of a product), the sample should be placed in a suitable protective inert transparent container (e.g., quartz).

If testing of the drug product in the immediate container or as marketed is needed, the samples should be placed horizontally or transversely with respect to the light source, whichever provides for the most uniform exposure of the samples. Some adjustment of testing conditions may have to be made when testing large-volume containers (e.g., dispensing packs).

B. Analysis of Samples

At the end of the exposure period, the samples should be examined for any changes in physical properties (e.g., appearance, clarity or color of solution, dissolution/disintegration for dosage forms such as capsules, etc.) and for assay and degradants by a method suitably validated for products likely to arise from photochemical degradation processes.

When powder samples are involved, sampling should ensure that a representative portion is used in individual tests. For solid oral–dosage form products, testing should be conducted on an appropriately sized composite of, for example, 20 tablets or capsules. Similar sampling considerations, such as homogenization or solubilization of the entire sample, apply to other materials that may not be homogeneous after exposure (e.g., creams, ointments, suspensions, etc.). The analysis of the exposed sample should be performed concomitantly with that of any protected samples used as dark controls if these are used in the test.

C. Judgement of Results

Depending on the extent of change, special labeling or packaging may be needed to mitigate exposure to light. When evaluating the results of photostability studies to determine whether change due to exposure to light is acceptable, it is important to consider the results obtained from other formal stability studies in order to ensure that the product will be within proposed specifications during the shelf life (see the relevant ICH Stability and Impurity Guidelines).

IV. ANNEX

A. Quinine Chemical Actinometry

The following provides details of an actinometric procedure for monitoring exposure to a near UV fluorescent lamp (based on a Food and Drug Administration [FDA]/National Institute of Standards and Technology study). For other light sources/actinometric systems, the same approach may be used, but each actinometric system should be calibrated for the light source used.

Prepare a sufficient quantity of a 2% weight/volume aqueous solution of quinine monohydrochloride dihydrate (if necessary, dissolve by heating).

Option 1

Put 10 mL of the solution into a 20 mL colorless ampoule, seal it hermetically, and use this as the sample. Separately, put 10 mL of the solution into a 20 mL colorless ampoule (see note 1), seal it hermetically, wrap in aluminum foil to protect completely from light, and use this as the control. Expose the sample and control to the light source for an appropriate number of hours. After exposure, determine the absorbances of the sample (AT) and the control (Ao) at 400 nm using a 1 cm path length. Calculate the change in absorbance, $\Delta A = AT - Ao$. The length of exposure should be sufficient to ensure a change in absorbance of at least 0.9.

Option 2

Fill a 1 cm quartz cell and use this as the sample. Separately fill a 1 cm quartz cell, wrap in aluminum foil to protect completely from light, and use this as the control. Expose the sample and control to the light source for an appropriate number of hours. After exposure, determine the absorbances of the sample (AT) and the control (Ao) at 400 nm. Calculate the change in absorbance, $\Delta A = AT - Ao$. The length of exposure should be sufficient to ensure a change in absorbance of at least 0.5.

Alternative packaging configurations may be used if appropriately validated. Alternative validated chemical actinometers may be used.

Note 1: Shape and dimensions (see Japanese Industry Standard [JIS] R3512 [1974] for ampoule specifications [Figure 9.2]).

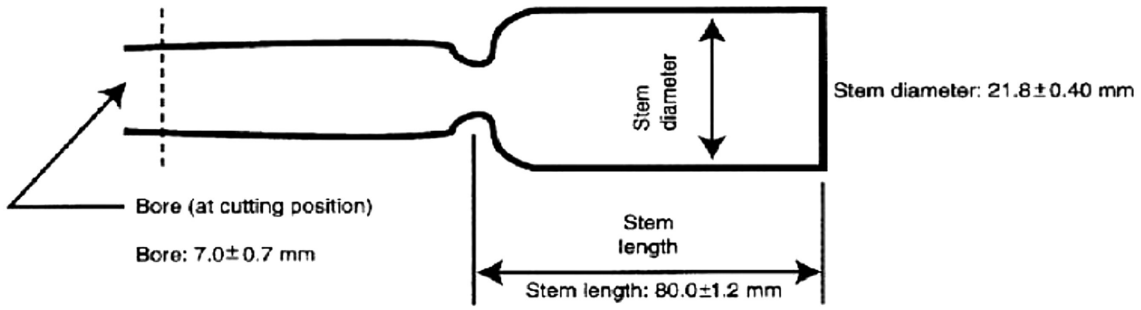

FIGURE 9.2 Shape and dimension specifications for ampoules.

10 Bracketing and Matrixing Designs for Stability Testing of New Drug Substances and Products

I. INTRODUCTION

A. Objectives of the Guideline

This guideline is intended to address recommendations on the application of bracketing and matrixing to stability studies conducted in accordance with principles outlined in the International Conference on Harmonisation (ICH) Q1A(R) Harmonised Tripartite guideline on Stability Testing of New Drug Substances and Products (hereafter referred to as the parent guideline).

B. Background

The parent guideline notes that the use of matrixing and bracketing can be applied, if justified, to the testing of new drug substances and products, but provides no further guidance on the subject.

C. Scope of the Guideline

This document provides guidance on bracketing and matrixing study designs. Specific principles are defined in this guideline for situations in which bracketing or matrixing can be applied. Sample designs are provided for illustrative purposes and should not be considered the only, or the most appropriate, designs in all cases.

II. GUIDELINES

A. General

A full study design is one in which samples for every combination of all design factors are tested at all time points. A reduced design is one in which samples for every factor combination are not all tested at all time points. A reduced design can be a suitable alternative to a full design when multiple design factors are involved. Any reduced design should have the ability to adequately predict the retest period or shelf life. Before a reduced design is considered, certain assumptions should be assessed and justified. The potential risk should be considered of establishing a shorter retest period or shelf life than could be derived from a full design due to the reduced amount of data collected.

During the course of a reduced design study, a change to full testing or to a less reduced design can be considered if a justification is provided and the principles of full designs and reduced designs are followed. However, proper adjustments should be made to the statistical analysis, where applicable, to account for the increase in sample size as a result of the change. Once the design is changed, full testing or less reduced testing should be carried out through the remaining time points of the stability study.

B. Applicability of Reduced Designs

Reduced designs can be applied to the formal stability study of most types of drug products, although additional justification should be provided for certain complex drug delivery systems where there are a large number of potential drug–device interactions. For the study of drug substances, matrixing is of limited utility, and bracketing is generally not applicable.

Whether bracketing or matrixing can be applied depends on the circumstances, as discussed in detail in the following. The use of any reduced design should be justified. In certain cases, the condition described in this guideline is sufficient justification for use, while in other cases, additional justification should be provided. The type and level of justification in each of these cases will depend on the available supporting data. Data variability and product stability, as shown by supporting data, should be considered when a matrixing design is applied.

Bracketing and matrixing are reduced designs based on different principles. Therefore, careful consideration and scientific justification should precede the use of bracketing and matrixing together in one design.

C. Bracketing

As defined in the glossary to the parent guideline, bracketing is the design of a stability schedule such that only samples on the extremes of certain design factors (e.g., strength, container size, and/or fill) are tested at all time points as in a full design. The design assumes that the stability of any intermediate levels is represented by the stability of the extremes tested.

The use of a bracketing design would not be considered appropriate if it cannot be demonstrated that the strengths or container sizes and/or fills selected for testing are indeed the extremes.

1. Design Factors

Design factors are variables (e.g., strength, container size, and/or fill) to be evaluated in a study design for their effect on product stability.

a. Strength

Bracketing can be applied to studies with multiple strengths of identical or closely related formulations. Examples include but are not limited to (1) capsules of different strengths made with different fill plug sizes from the same powder blend, (2) tablets of different strengths manufactured by compressing varying amounts of the same granulation, and (3) oral solutions of different strengths with formulations that differ only in minor excipients (e.g., colorants or flavorings).

With justification, bracketing can be applied to studies with multiple strengths where the relative amounts of drug substance and excipients change in a formulation. Such justification can include a demonstration of comparable stability profiles among the different strengths of clinical or development batches.

In cases where different excipients are used among strengths, bracketing generally should not be applied.

b. Container Closure Sizes and/or Fills

Bracketing can be applied to studies of the same container closure system where either container size or fill varies while the other remains constant. However, if a bracketing design is considered where both container size and fill vary, it should not be assumed that the largest and smallest containers represent the extremes of all packaging configurations. Care should be taken to select the extremes by comparing the various characteristics of the container closure system that may affect product stability. These characteristics include container wall thickness, closure geometry, surface area to volume ratio, headspace to volume ratio, water vapor permeation rate or oxygen permeation rate per dosage unit, or unit fill volume, as appropriate.

With justification, bracketing can be applied to studies for the same container when the closure varies. Justification could include a discussion of the relative permeation rates of the bracketed container closure systems.

2. Design Considerations and Potential Risks

If, after starting the studies, one of the extremes is no longer expected to be marketed, the study design can be maintained to support the bracketed intermediates. A commitment should be provided to carry out stability studies on the marketed extremes post approval.

Before a bracketing design is applied, its effect on the retest period or shelf life estimation should be assessed. If the stability of the extremes is shown to be different, the intermediates should be considered no more stable than the least stable extreme (i.e., the shelf life for the intermediates should not exceed that for the least stable extreme).

3. Design Example

An example of a bracketing design is given in Table 10.1. This example is based on a product available in three strengths and three container sizes. In this example, it should be demonstrated that the 15 and 500 mL high-density polyethylene container sizes truly represent the extremes. The batches for each selected combination should be tested at each time point as in a full design.

TABLE 10.1
Example of a Bracketing Design

Batch		50 mg			75 mg			100 mg		
		1	2	3	1	2	3	1	2	3
Container size	15 mL	T	T	T				T	T	T
	100 mL									
	500 mL	T	T	T				T	T	T

Key: T = Sample tested.

D. Matrixing

As defined in the glossary of the parent guideline, matrixing is the design of a stability schedule such that a selected subset of the total number of possible samples for all factor combinations would be tested at a specified time point. At a subsequent time point, another subset of samples for all factor combinations would be tested. The design assumes that the stability of each subset of samples tested represents the stability of all samples at a given time point. The differences in the samples for the same drug product should be identified as, for example, covering different batches, different strengths, different sizes of the same container closure system, and possibly, in some cases, different container closure systems.

When a secondary packaging system contributes to the stability of the drug product, matrixing can be performed across the packaging systems.

Each storage condition should be treated separately under its own matrixing design. Matrixing should not be performed across test attributes. However, alternative matrixing designs for different test attributes can be applied if justified.

1. Design Factors

Matrixing designs can be applied to strengths with identical or closely related formulations. Examples include but are not limited to (1) capsules of different strengths made with different fill plug sizes from the same powder blend, (2) tablets of different strengths manufactured by compressing varying amounts of the same granulation, and (3) oral solutions of different strengths with formulations that differ only in minor excipients (e.g., colorants or flavorings).

Other examples of design factors that can be matrixed include batches made by using the same process and equipment, and container sizes and/or fills in the same container closure system.

With justification, matrixing designs can be applied, for example, to different strengths where the relative amounts of drug substance and excipients change, or where different excipients are used, or to different container closure systems. Justification should generally be based on supporting data. For example, to matrix across two different closures or container closure systems, supporting data could be supplied showing relative moisture vapor transmission rates or similar

protection against light. Alternatively, supporting data could be supplied to show that the drug product is not affected by oxygen, moisture, or light.

2. Design Considerations

A matrixing design should be balanced as far as possible so that each combination of factors is tested to the same extent over the intended duration of the study and through the last time point prior to submission. However, due to the recommended full testing at certain time points, as discussed in the following, it may be difficult to achieve a complete balance in a design where time points are matrixed.

In a design where time points are matrixed, all selected factor combinations should be tested at the initial and final time points, while only certain fractions of the designated combinations should be tested at each intermediate time point. If full long-term data for the proposed shelf life will not be available for review before approval, all selected combinations of batch, strength, container size, and fill, among other things, should also be tested at 12 months or at the last time point prior to submission. In addition, data from at least three time points, including initial, should be available for each selected combination through the first 12 months of the study. For matrixing at an accelerated or intermediate storage condition, care should be taken to ensure that testing occurs at a minimum of three time points, including initial and final, for each selected combination of factors.

When a matrix on design factors is applied, if one strength or container size and/or fill is no longer intended for marketing, stability testing of that strength or container size and/or fill can be continued to support the other strengths or container sizes and/or fills in the design.

3. Design Examples

Examples of matrixing designs on time points for a product in two strengths (S1 and S2) are shown in Table 10.2. The terms *one-half reduction* and *one-third reduction* refer to the reduction strategy initially applied to the full study design. For example, a one-half reduction initially eliminates one in every two time points from the full study design, and a one-third reduction initially removes one in every three. In the examples shown in Table 10.2, the reductions are less than one-half and one-third due to the inclusion of full testing of all factor combinations at some time points. These examples include full testing at the initial, final, and 12 month time points. The ultimate reduction is therefore less than one-half (24/48) or one-third (16/48); it is actually 15/48 or 10/48, respectively.

Additional examples of matrixing designs for a product with three strengths and three container sizes are given in Table 10.3. Table 10.3(A) shows a design with matrixing on time points only, and Table 10.3(B) depicts a design with matrixing on time points and factors. In Table 10.3(A), all combinations of batch, strength, and container size are tested, while in Table 10.3(B), certain combinations of batch, strength, and container size are not tested.

TABLE 10.2
Examples of Matrixing Designs on Time Points for a Product with Two Strengths

Time Point (Months)			0	3	6	9	12	18	24	36
One-half reduction										
Strength	S1	Batch 1	T	T		T	T		T	T
		Batch 2	T	T		T	T	T		T
		Batch 3	T		T		T	T		T
	S2	Batch 1	T		T		T		T	T
		Batch 2	T	T		T	T	T		T
		Batch 3	T		T		T		T	T
One-third reduction										
Strength	S1	Batch 1	T	T		T	T		T	T
		Batch 2	T	T	T		T	T		T
		Batch 3	T		T	T	T	T	T	T
	S2	Batch 1	T		T	T	T	T	T	T
		Batch 2	T	T		T	T		T	T
		Batch 3	T	T	T		T	T		T

Key: T = Sample tested.

TABLE 10.3
Examples of Matrixing Designs for a Product with Three Strengths and Three Container Sizes

Strength	S1			S2			S3		
A. Matrixing on time points									
Container size	A	B	C	A	B	C	A	B	C
Batch 1	T1	T2	T3	T2	T3	T1	T3	T1	T2
Batch 2	T2	T3	T1	T3	T1	T2	T1	T2	T3
Batch 3	T3	T1	T2	T1	T2	T3	T2	T3	T1
B. Matrixing on time points and factors									
Container size	A	B	C	A	B	C	A	B	C
Batch 1	T1	T2		T2		T1		T1	T2
Batch 2		T3	T1	T3	T1		T1		T3
Batch 3	T3		T2		T2	T3	T2	T3	
Time point (months)	0	3	6	9	12	18	24	36	
T1	T		T	T	T	T	T	T	
T2	T	T		T	T		T	T	
T3	T	T	T		T	T		T	

S1, S2, and S3 are different strengths. A, B, and C are different container sizes. *Key*: T = Sample tested.

4. Applicability and Degree of Reduction

The following, although not an exhaustive list, should be considered when a matrixing design is contemplated:

- Knowledge of data variability
- Expected stability of the product

- Availability of supporting data
- Stability differences in the product within a factor or among factors and/or
- Number of factor combinations in the study

In general, a matrixing design is applicable if the supporting data indicate predictable product stability. Matrixing is appropriate when the supporting data exhibit only small variability. However, where the supporting data exhibit moderate variability, a matrixing design should be statistically justified. If the supportive data show large variability, a matrixing design should not be applied.

A statistical justification could be based on an evaluation of the proposed matrixing design with respect to its power to detect differences among factors in the degradation rates or its precision in shelf-life estimation.

If a matrixing design is considered applicable, the degree of reduction that can be made from a full design depends on the number of factor combinations being evaluated. The more factors associated with a product, and the more levels in each factor, the larger the degree of reduction that can be considered. However, any reduced design should have the ability to adequately predict the product shelf life.

5. Potential Risk

Because of the reduced amount of data collected, a matrixing design on factors other than time points generally has less precision in shelf-life estimation and yields a shorter shelf life than the corresponding full design. In addition, such a matrixing design may have insufficient power to detect certain main or interaction effects, thus leading to incorrect pooling of data from different design factors during shelf-life estimation. If there is an excessive reduction in the number of factor combinations tested, and data from the tested factor combinations cannot be pooled to establish a single shelf life, it may be impossible to estimate the shelf lives for the missing factor combinations.

A study design that matrixes on time points only would often have similar ability to that of a full design to detect differences in rates of change among factors and to establish a reliable shelf life. This feature exists because linearity is assumed and because full testing of all factor combinations would still be performed at both the initial time point and the last time point prior to submission.

E. Data Evaluation

Stability data from studies in a reduced design should be treated in the same manner as data from full design studies.

11 Evaluation of Stability Data

I. INTRODUCTION

A. Objectives of the Guideline

This guideline is intended to provide recommendations on how to use stability data generated in accordance with the principles detailed in the International Conference on Harmonisation (ICH) guideline "Q1A(R) Stability Testing of New Drug Substances and Products" (hereafter referred to as the parent guideline) to propose a retest period or shelf life in a registration application. This guideline describes when and how extrapolation can be considered when proposing a retest period for a drug substance or a shelf life for a drug product that extends beyond the period covered by "available data from the stability study under the long-term storage condition" (hereafter referred to as *long-term data*).

B. Background

The guidance on the evaluation and statistical analysis of stability data provided in the parent guideline is brief in nature and limited in scope. The parent guideline states that regression analysis is an appropriate approach to analyzing quantitative stability data for retest period or shelf-life estimation and recommends that a statistical test for batch poolability be performed using a level of significance of 0.25. However, the parent guideline includes few details and does not cover situations where multiple factors are involved in a full- or reduced-design study.

This guideline is an expansion of the guidance presented in the Evaluation sections of the parent guideline.

C. Scope of the Guideline

This guideline addresses the evaluation of stability data that should be submitted in registration applications for new molecular entities and associated drug products. The guideline provides recommendations on establishing retest periods and shelf lives for drug substances and drug products intended for storage at or below "room temperature."* It covers stability studies using single- or multifactor designs and full or reduced designs.

ICH Q6A and Q6B should be consulted for recommendations on the setting and justification of acceptance criteria, and ICH Q1D should be referenced for recommendations on the use of full- versus reduced-design studies.

* *Note*: The term *room temperature* refers to the general customary environment and should not be inferred to be the storage statement for labeling.

II. GUIDELINES

A. General Principles

The design and execution of formal stability studies should follow the principles outlined in the parent guideline. The purpose of a stability study is to establish, based on testing a minimum of three batches of the drug substance or product, a retest period or shelf life and label storage instructions applicable to all future batches manufactured and packaged under similar circumstances. The degree of variability of individual batches affects the confidence that a future production batch will remain within acceptance criteria throughout its retest period or shelf life.

Although normal manufacturing and analytical variations are to be expected, it is important that the drug product be formulated with the intent to provide 100% of the labeled amount of the drug substance at the time of batch release. If the assay values of the batches used to support the registration application are higher than 100% of label claim at the time of batch release, after taking into account manufacturing and analytical variations, the shelf life proposed in the application can be overestimated. On the other hand, if the assay value of a batch is lower than 100% of label claim at the time of batch release, it might fall below the lower acceptance criterion before the end of the proposed shelf life.

A systematic approach should be adopted in the presentation and evaluation of the stability information. The stability information should include, as appropriate, results from the physical, chemical, biological, and microbiological tests, including those related to particular attributes of the dosage form (e.g., dissolution rate for solid oral dosage forms). The adequacy of the mass balance should be assessed. Factors that can cause an apparent lack of mass balance should be considered, including, for example, the mechanisms of degradation and the stability-indicating capability and inherent variability of the analytical procedures.

The basic concepts of stability data evaluation are the same for single- versus multifactor studies and for full- versus reduced-design studies. Data from formal stability studies and, as appropriate, supporting data should be evaluated to determine the critical quality attributes likely to influence the quality and performance of the drug substance or product. Each attribute should be assessed separately, and an overall assessment should be made of the findings for the purpose of proposing a retest period or shelf life. The retest period or shelf life proposed should not exceed that predicted for any single attribute.

The decision tree in Appendix A outlines a stepwise approach to stability data evaluation and when and how much extrapolation can be considered for a proposed retest period

or shelf life. Appendix B provides (1) information on how to analyze long-term data for appropriate quantitative test attributes from a study with a multifactor, full, or reduced design; (2) information on how to use regression analysis for retest period or shelf-life estimation; and (3) examples of statistical procedures to determine poolability of data from different batches or other factors. Additional guidance can be found in the references listed; however, the examples and references do not cover all applicable statistical approaches.

In general, certain quantitative chemical attributes (e.g., assay, degradation products, and preservative content) for a drug substance or product can be assumed to follow zero-order kinetics during long-term storage (Carstensen, 1977). Data for these attributes are therefore amenable to the type of statistical analysis described in Appendix B, including linear regression and poolability testing. Although the kinetics of other quantitative attributes (e.g., pH and dissolution) is generally not known, the same statistical analysis can be applied if appropriate. Qualitative attributes and microbiological attributes are not amenable to this kind of statistical analysis.

The recommendations on statistical approaches in this guideline are not intended to imply that the use of statistical evaluation is preferred when it can be justified to be unnecessary. However, statistical analysis can be useful in supporting the extrapolation of retest periods or shelf lives in certain situations and can be called for to verify the proposed retest periods or shelf lives in other cases.

B. Data Presentation

Data for all attributes should be presented in an appropriate format (e.g., tabular, graphical, or narrative), and an evaluation of such data should be included in the application. The values of quantitative attributes at all time points should be reported as measured (e.g., assay as percent of label claim). If a statistical analysis is performed, the procedure used and the assumptions underlying the model should be stated and justified. A tabulated summary of the outcome of statistical analysis and/or graphical presentation of the long-term data should be included.

C. Extrapolation

Extrapolation is the practice of using a known dataset to infer information about future data. Extrapolation to extend the retest period or shelf life beyond the period covered by long-term data can be proposed in the application, particularly if no significant change is observed at the accelerated condition. Whether extrapolation of stability data is appropriate depends on the extent of knowledge about the change pattern, the goodness of fit of any mathematical model, and the existence of relevant supporting data. Any extrapolation should be performed such that the extended retest period or shelf life will be valid for a future batch released with test results close to the release acceptance criteria.

An extrapolation of stability data assumes that the same change pattern will continue to apply beyond the period covered by long-term data. The correctness of the assumed change pattern is critical when extrapolation is considered. When estimating a regression line or curve to fit the long-term data, the data themselves provide a check on the correctness of the assumed change pattern, and statistical methods can be applied to test the goodness of fit of the data to the assumed line or curve. No such internal check is possible beyond the period covered by long-term data. Thus, a retest period or shelf life granted on the basis of extrapolation should always be verified by additional long-term stability data as soon as these data become available. Care should be taken to include in the protocol for commitment batches a time point that corresponds to the end of the extrapolated retest period or shelf life.

D. Data Evaluation for Retest Period or Shelf-Life Estimation for Drug Substances or Products Intended for Room-Temperature Storage

A systematic evaluation of the data from formal stability studies should be performed as illustrated in this section. Stability data for each attribute should be assessed sequentially. For drug substances or products intended for storage at room temperature, the assessment should begin with any significant change at the accelerated condition and if appropriate, at the intermediate condition and progress through the trends and variability of the long-term data. The circumstances are delineated under which extrapolation of the retest period or shelf life beyond the period covered by long-term data can be appropriate. A decision tree is provided in Appendix A as an aid.

1. No Significant Change at Accelerated Condition

Where no significant change occurs at the accelerated condition, the retest period or shelf life would depend on the nature of the long-term and accelerated data.

a. Long-Term and Accelerated Data Showing Little or No Change over Time and Little or No Variability

Where the long-term data and accelerated data for an attribute show little or no change over time and little or no variability, it might be apparent that the drug substance or product will remain well within the acceptance criteria for that attribute during the proposed retest period or shelf life. In these circumstances, a statistical analysis is normally considered unnecessary, but justification for the omission should be provided. Justification can include a discussion of the change pattern or lack of change, relevance of the accelerated data, mass balance, and/or other supporting data as described in the parent guideline. Extrapolation of the retest period or shelf life beyond the period covered by long-term data can be proposed. The proposed retest period or shelf life can be up to twice, but should not be more than 12 months beyond, the period covered by long-term data.

b. Long-Term or Accelerated Data Showing Change over Time and/or Variability

If the long-term or accelerated data for an attribute show change over time and/or variability within a factor or among factors, statistical analysis of the long-term data can be useful in establishing a retest period or shelf life. Where there are differences in stability observed among batches or among other factors (e.g., strength, container size, and/or fill) or factor combinations (e.g., strength-by-container size and/or fill) that preclude the combining of data, the proposed retest period or shelf life should not exceed the shortest period supported by any batch, other factor, or factor combination. Alternatively, where the differences are readily attributed to a particular factor (e.g., strength), different shelf lives can be assigned to different levels within the factor (e.g., different strengths). A discussion should be provided to address the cause for the differences and the overall significance of such differences on the product. Extrapolation beyond the period covered by long-term data can be proposed; however, the extent of extrapolation would depend on whether long-term data for the attribute are amenable to statistical analysis.

- *Data not amenable to statistical analysis:* Where long-term data are not amenable to statistical analysis, but relevant supporting data are provided, the proposed retest period or shelf life can be up to one-and-a-half times, but should not be more than 6 months beyond, the period covered by long-term data. Relevant supporting data include satisfactory long-term data from development batches that are (1) made with a closely related formulation to, (2) manufactured on a smaller scale than, or (3) packaged in a container closure system similar to, that of the primary stability batches.
- *Data amenable to statistical analysis:* If long-term data are amenable to statistical analysis, but no analysis is performed, the extent of extrapolation should be the same as when data are not amenable to statistical analysis. However, if a statistical analysis is performed, it can be appropriate to propose a retest period or shelf life of up to twice, but not more than 12 months beyond, the period covered by long-term data, when the proposal is backed by the result of the analysis and relevant supporting data.

2. Significant Change at Accelerated Condition

Where significant change* occurs at the accelerated condition, the retest period or shelf life would depend on the outcome of stability testing at the intermediate condition as well as at the long-term condition.

However, if phase separation of a semisolid dosage form occurs at the accelerated condition, testing at the intermediate condition should be performed. Potential interaction effects should also be considered in establishing that there is no other significant change.

a. No Significant Change at Intermediate Condition

If there is no significant change at the intermediate condition, extrapolation beyond the period covered by long-term data can be proposed; however, the extent of extrapolation would depend on whether long-term data for the attribute are amenable to statistical analysis.

- *Data not amenable to statistical analysis:* When the long-term data for an attribute are not amenable to statistical analysis, the proposed retest period or shelf life can be up to 3 months beyond the period covered by long-term data if backed by relevant supporting data.
- *Data amenable to statistical analysis:* When the long-term data for an attribute are amenable to statistical analysis, but no analysis is performed, the extent of extrapolation should be the same as when data are not amenable to statistical analysis. However, if a statistical analysis is performed, the proposed retest period or shelf life can be up to one-and-a-half times, but should not be more than 6 months beyond, the period covered by long-term data when backed by statistical analysis and relevant supporting data.

b. Significant Change at Intermediate Condition

Where significant change occurs at the intermediate condition, the proposed retest period or shelf life should not exceed the period covered by long-term data. In addition, a retest period or shelf life shorter than the period covered by long-term data could be called for.

E. Data Evaluation for Retest Period or Shelf-Life Estimation for Drug Substances or Products Intended for Storage below Room Temperature

1. Drug Substances or Products Intended for Storage in a Refrigerator

Data from drug substances or products intended to be stored in a refrigerator should be assessed according to the same principles as described in Section D for drug substances or products intended for room-temperature storage except where explicitly noted in the following section. The decision tree in Appendix A can be used as an aid.

a. No Significant Change at Accelerated Condition

Where no significant change occurs at the accelerated condition, extrapolation of the retest period or shelf life beyond the

* *Note*: The following physical changes can be expected to occur at the accelerated condition and would not be considered significant change that calls for intermediate testing if there is no other significant change:

- Softening of a suppository that is designed to melt at 37 °C, if the melting point is clearly demonstrated
- Failure to meet acceptance criteria for dissolution for 12 units of a gelatin capsule or gel-coated tablet if the failure can be unequivocally attributed to cross-linking

period covered by long-term data can be proposed based on the principles outlined in subsection 1 of Section D, except that the extent of extrapolation should be more limited.

If the long-term and accelerated data show little change over time and little variability, the proposed retest period or shelf life can be up to one-and-a-half times, but should not be more than 6 months beyond, the period covered by long-term data normally without the support of statistical analysis.

Where the long-term or accelerated data show change over time and/or variability, the proposed retest period or shelf life can be up to 3 months beyond the period covered by long-term data if (1) the long-term data are amenable to statistical analysis, but a statistical analysis is not performed, or (2) the long-term data are not amenable to statistical analysis, but relevant supporting data are provided.

Where the long-term or accelerated data show change over time and/or variability, the proposed retest period or shelf life can be up to one-and-a-half times, but should not be more than 6 months beyond, the period covered by long-term data if (1) the long-term data are amenable to statistical analysis, and a statistical analysis is performed, and (2) the proposal is backed by the result of the analysis and relevant supporting data.

b. Significant Change at Accelerated Condition

If significant change occurs between 3 and 6 months' testing at the accelerated storage condition, the proposed retest period or shelf life should be based on the long-term data. Extrapolation is not considered appropriate. In addition, a retest period or shelf life shorter than the period covered by long-term data could be called for. If the long-term data show variability, verification of the proposed retest period or shelf life by statistical analysis can be appropriate.

If significant change occurs within the first 3 months' testing at the accelerated storage condition, the proposed retest period or shelf life should be based on long-term data. Extrapolation is not considered appropriate. A retest period or shelf life shorter than the period covered by long-term data could be called for. If the long-term data show variability, verification of the proposed retest period or shelf life by statistical analysis can be appropriate. In addition, a discussion should be provided to address the effect of short-term excursions outside the label storage condition (e.g., during shipping or handling). This discussion can be supported, if appropriate, by further testing on a single batch of the drug substance or product at the accelerated condition for a period shorter than 3 months.

2. Drug Substances or Products Intended for Storage in a Freezer

For drug substances or products intended for storage in a freezer, the retest period or shelf life should be based on long-term data. In the absence of an accelerated storage condition for drug substances or products intended to be stored in a freezer, testing on a single batch at an elevated temperature (e.g., 5°C ± 3°C or 25°C ± 2°C) for an appropriate time period should be conducted to address the effect of short-term excursions outside the proposed label storage condition (e.g., during shipping or handling).

3. Drug Substances or Products Intended for Storage below –20°C

For drug substances or products intended for storage below –20°C, the retest period or shelf life should be based on long-term data and should be assessed on a case-by-case basis.

F. General Statistical Approaches

Where applicable, an appropriate statistical method should be employed to analyze the long-term primary stability data in an original application. The purpose of this analysis is to establish, with a high degree of confidence, a retest period or shelf life during which a quantitative attribute will remain within acceptance criteria for all future batches manufactured, packaged, and stored under similar circumstances.

In cases where a statistical analysis was employed to evaluate long-term data due to a change over time and/or variability, the same statistical method should also be used to analyze data from commitment batches to verify or extend the originally approved retest period or shelf life.

Regression analysis is considered an appropriate approach to evaluating the stability data for a quantitative attribute and establishing a retest period or shelf life. The nature of the relationship between an attribute and time will determine whether data should be transformed for linear regression analysis. The relationship can be represented by a linear or nonlinear function on an arithmetic or logarithmic scale. In some cases, a nonlinear regression can better reflect the true relationship.

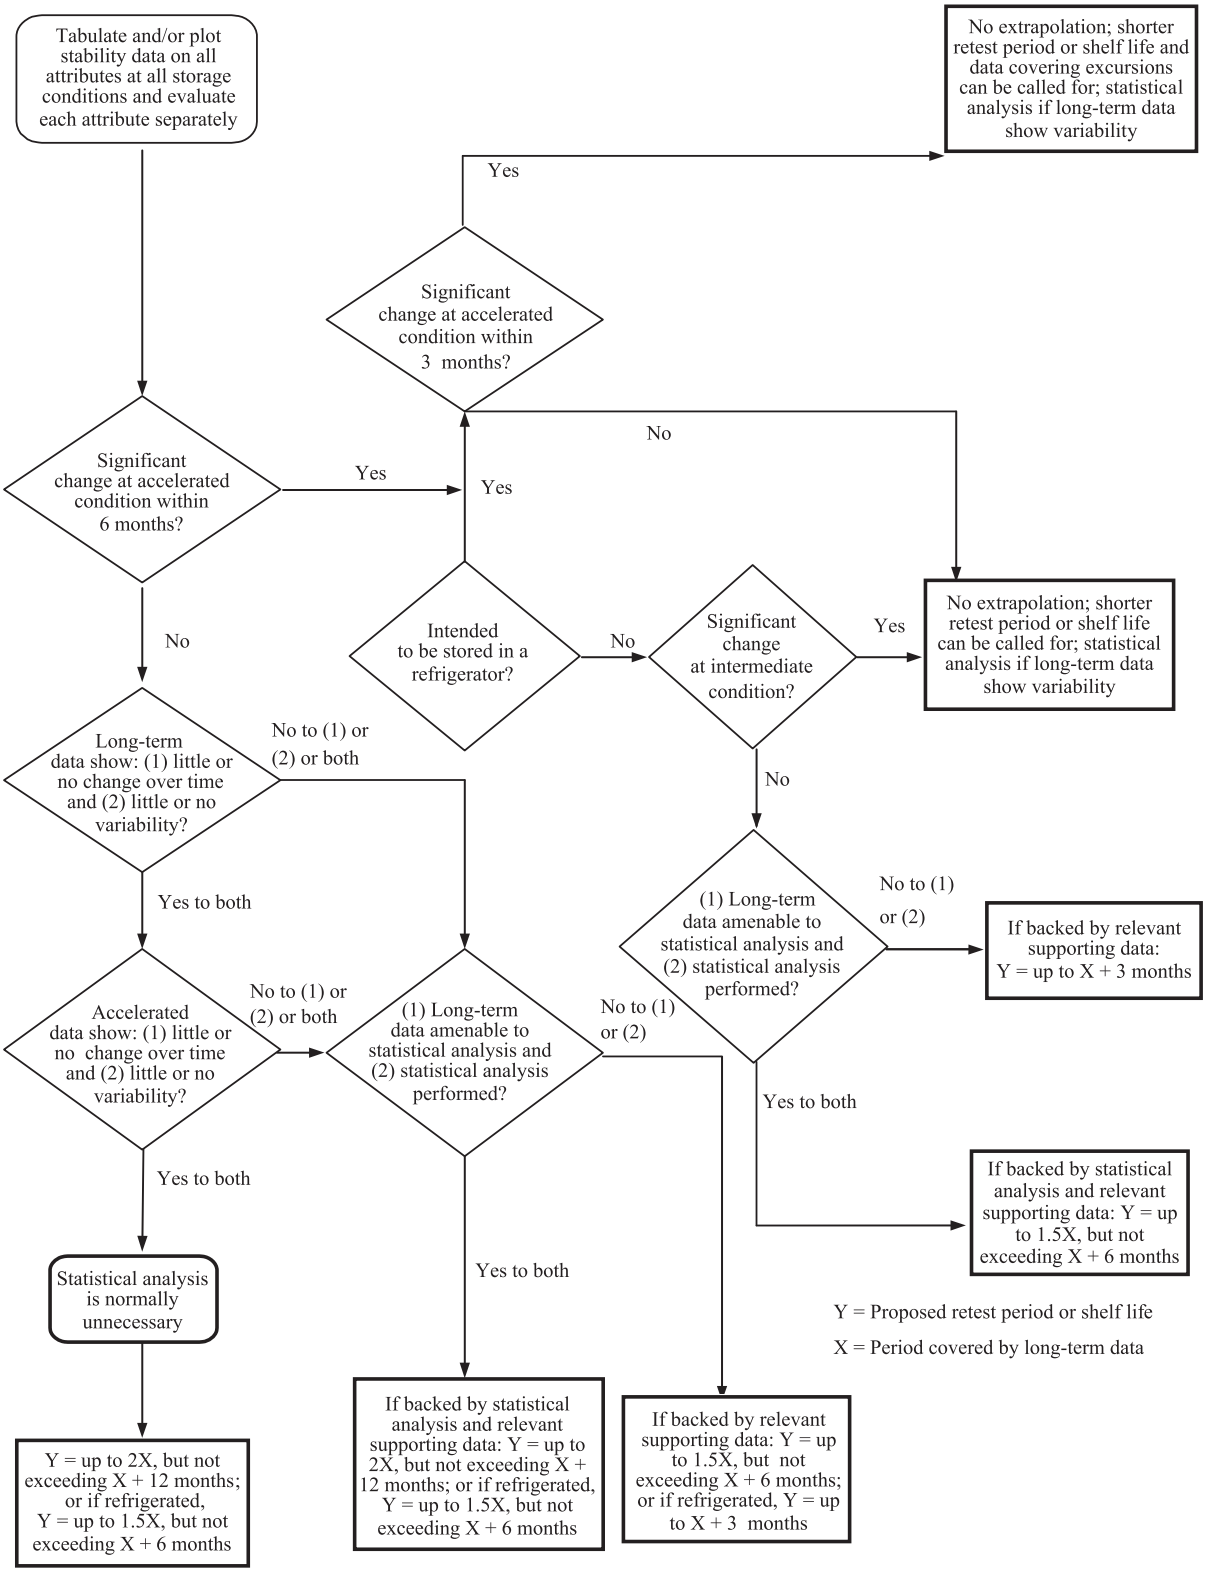
An appropriate approach to retest period or shelf-life estimation is to analyze a quantitative attribute (e.g., assay or degradation products) by determining the earliest time at which the 95% confidence limit for the mean intersects the proposed acceptance criterion.

For an attribute known to decrease with time, the lower one-sided 95% confidence limit should be compared with the acceptance criterion. For an attribute known to increase with time, the upper one-sided 95% confidence limit should be compared with the acceptance criterion. For an attribute that can either increase or decrease, or whose direction of change is not known, two-sided 95% confidence limits should be calculated and compared with the upper and lower acceptance criteria.

The statistical method used for data analysis should take into account the stability study design to provide a valid statistical inference for the estimated retest period or shelf life. The approach described can be used to estimate the retest period or shelf life for a single batch or for multiple batches when the data are combined after an appropriate statistical test. Examples of statistical approaches to the analysis of stability data from single- or multifactor, full- or reduced-design studies are included in Appendix B. References to current literature sources can be found in Appendix B.6.

APPENDICES

Appendix A: Decision Tree for Data Evaluation for Retest Period or Shelf-Life Estimation for Drug Substances or Products (Excluding Frozen Products)



Appendix B: Examples of Statistical Approaches to Stability Data Analysis

Linear regression, poolability tests, and statistical modeling, described in the following, are examples of statistical methods and procedures that can be used in the analysis of stability data that are amenable to statistical analysis for a quantitative attribute for which there is a proposed acceptance criterion.

B.1. Data Analysis for a Single Batch

In general, the relationship between certain quantitative attributes and time is assumed to be linear (Carstensen, 1977). Figure 11.1 shows the regression line for assay of a drug product with upper and lower acceptance criteria of 105% and 95% of label claim, respectively, with 12 months of long-term data and a proposed shelf life of 24 months. In this example, two-sided 95% confidence limits for the mean are applied, because it is not known ahead of time whether the assay will increase or decrease with time (e.g., in the case of an aqueous-based product packaged in a semipermeable container). The lower confidence limit intersects the lower acceptance criterion at 30 months, while the upper confidence limit does not intersect with the upper acceptance criterion until later. Therefore, the proposed shelf life of 24 months can be supported by the statistical analysis of the assay, provided the recommendations in Sections D and E are followed.

When data for an attribute with only an upper or a lower acceptance criterion are analyzed, the corresponding one-sided 95% confidence limit for the mean is recommended. Figure 11.2 shows the regression line for a degradation product in a drug product with 12 months of long-term data and a proposed shelf life of 24 months, where the acceptance criterion is not more than 1.4%. The upper one-sided 95% confidence limit for the mean intersects the acceptance criterion at 31 months. Therefore, the proposed shelf life of 24 months can be supported by statistical analysis of the degradation product data, provided the recommendations in Sections D and E are followed.

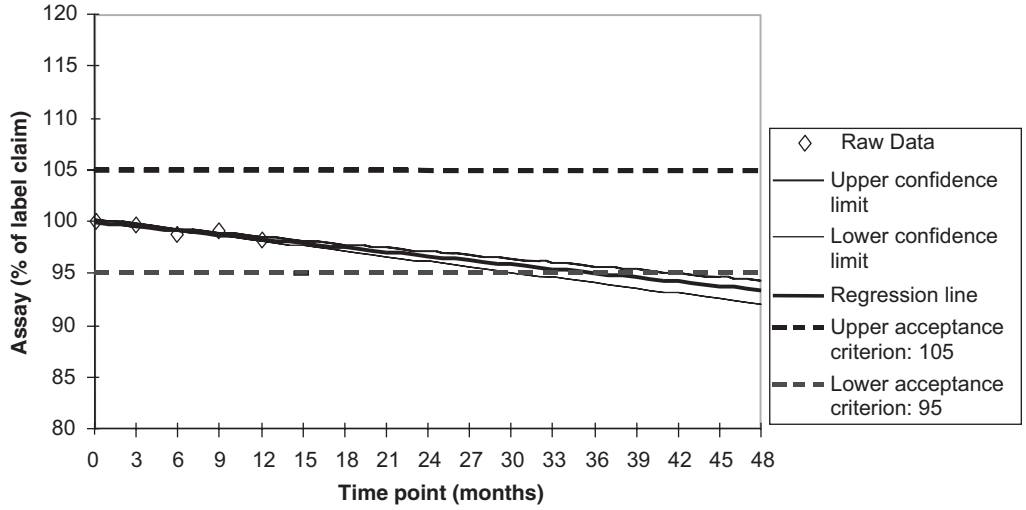


FIGURE 11.1 Shelf-life estimation with upper and lower acceptance criteria based on assay at 25°C/60% RH.

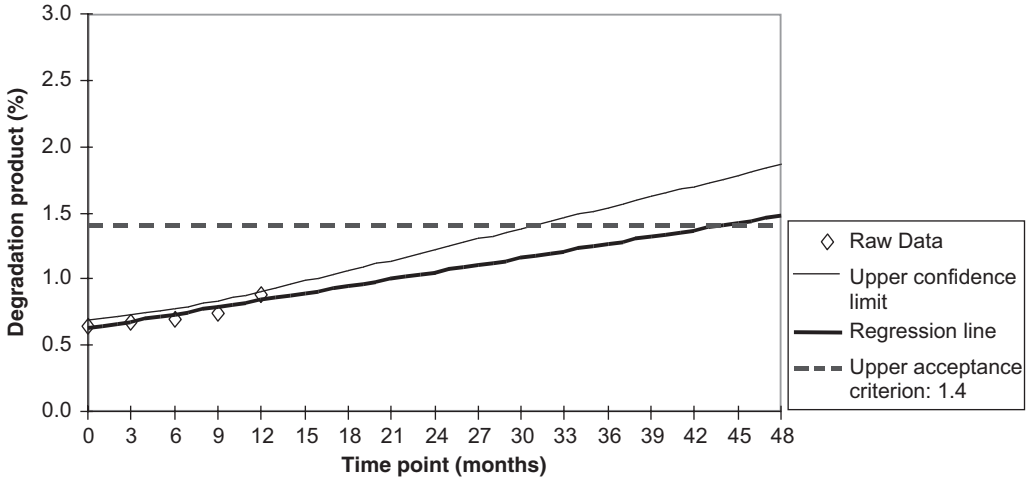

FIGURE 11.2 Shelf-life estimation with upper acceptance criterion based on a degradation product at 25°C/60% RH.

If this approach is used, the mean value of the quantitative attribute (e.g., assay or degradation products) can be expected to remain within the acceptance criteria through the end of the retest period or shelf life at a confidence level of 95%.

The approach described can be used to estimate the retest period or shelf life for a single batch, individual batches, or multiple batches when combined after appropriate statistical tests described in Sections B.2 through B.5.

B.2. Data Analysis for One-Factor, Full-Design Studies

For a drug substance or for a drug product available in a single strength and a single container size and/or fill, the retest period or shelf life is generally estimated based on the stability data from a minimum of three batches. When analyzing data from such one-factor, batch-only, full-design studies, two statistical approaches can be considered:

- The objective of the first approach is to determine whether the data from all batches support the proposed retest period or shelf life.
- The objective of the second approach, testing for poolability, is to determine whether the data from different batches can be combined for an overall estimate of a single retest period or shelf life.

B.2.1. Evaluating Whether All Batches Support the Proposed Retest Period or Shelf Life

The objective of this approach is to evaluate whether the estimated retest periods or shelf lives from all batches are longer than the one proposed. Retest periods or shelf lives for individual batches should first be estimated using the procedure described in Section B.1 with individual intercepts, individual slopes, and the pooled mean square error calculated from all batches. If each batch has an estimated retest period or shelf life longer than that proposed, the proposed retest period or shelf life will generally be considered appropriate, as long as the guidance for extrapolation in Sections D and E is followed. There is generally no need to perform poolability tests or identify the most reduced model. If, however, one or more of the estimated retest periods or shelf lives are shorter than that proposed, poolability tests can be performed to determine whether the batches can be combined to estimate a longer retest period or shelf life.

Alternatively, this approach can be taken during the pooling process described in Section B.2.2. If the regression lines for the batches are found to have a common slope, and the estimated retest periods or shelf lives based on the common slope and individual intercepts are all longer than the proposed retest period or shelf life, there is generally no need to continue to test the intercepts for poolability.

B.2.2. Testing for Poolability of Batches

B.2.2.1. Analysis of Covariance Before pooling the data from several batches to estimate a retest period or shelf life, a preliminary statistical test should be performed to determine whether the regression lines from different batches have a common slope and a common time-zero intercept. Analysis of covariance (ANCOVA) can be employed, where time is considered the covariate, to test the differences in slopes and intercepts of the regression lines among batches. Each of these tests should be conducted using a significance level of 0.25 to compensate for the expected low power of the design due to the relatively limited sample size in a typical formal stability study.

If the test rejects the hypothesis of equality of slopes (i.e., if there is a significant difference in slopes among batches), it is not considered appropriate to combine the data from all batches. The retest periods or shelf lives for individual batches in the stability study can be estimated by applying the approach described in Section B.1 using individual intercepts and individual slopes and the pooled mean square error calculated from all batches. The shortest estimate among the batches should be chosen as the retest period or shelf life for all batches.

If the test rejects the hypothesis of equality of intercepts but fails to reject that the slopes are equal (i.e., if there is a significant difference in intercepts but no significant difference in slopes among the batches), the data can be combined for the purpose of estimating the common slope. The retest periods or shelf lives for individual batches in the stability study should be estimated by applying the approach described in Section B.1 using the common slope and individual intercepts. The shortest estimate among the batches should be chosen as the retest period or shelf life for all batches.

If the tests for equality of slopes and equality of intercepts do not result in rejection at a level of significance of 0.25 (i.e., if there is no significant difference in slope and intercepts among the batches), the data from all batches can be combined. A single retest period or shelf life can be estimated from the combined data by using the approach described in Section B.1 and applied to all batches. The estimated retest period or shelf life from the combined data is usually longer than that from individual batches, because the width of the confidence limit(s) for the mean will become narrower as the amount of data increases when batches are combined.

The pooling tests described earlier should be performed in a proper order such that the slope terms are tested before the intercept terms. The most reduced model (i.e., individual slopes, common slope with individual intercepts, or common slope with common intercept, as appropriate) can be selected for retest period or shelf-life estimation.

B.2.2.2. Other Methods Statistical procedures other than those described earlier can be used in retest period or shelf-life estimation (Murphy and Weisman, 1990; Ruberg and Stegeman, 1991; Ruberg and Hsu, 1992; Shao and Chow, 1994; Yoshioka et al., 1997). For example, if it is possible to decide in advance the acceptable difference in slope or in mean retest period or shelf life among batches, an appropriate procedure for assessing the equivalence in slope or in mean retest period or shelf life can be used to determine the data poolability. However, such a procedure should be prospectively defined, evaluated, and justified and where appropriate, discussed with the regulatory authority. A simulation study

can be useful, if applicable, to demonstrate that the statistical properties of the alternative procedure selected are appropriate (Chen et al., 1997).

B.3. Data Analysis for Multifactor, Full-Design Studies

The stability of the drug product could differ to a certain degree among different factor combinations in a multifactor, full-design study. Two approaches can be considered when analyzing such data.

- The objective of the first approach is to determine whether the data from all factor combinations support the proposed shelf life.
- The objective of the second approach, testing for poolability, is to determine whether the data from different factor combinations can be combined for an overall estimate of a single shelf life.

B.3.1. Evaluating Whether All Factor Combinations Support the Proposed Shelf Life

The objective of this approach is to evaluate whether the estimated shelf lives from all factor combinations are longer than the one proposed. A statistical model that includes all appropriate factors and factor combinations should be constructed as described in Section B.3.2.2.1, and the shelf life should be estimated for each level of each factor and factor combination.

If all shelf lives estimated by the original model are longer than the proposed shelf life, further model building is considered unnecessary, and the proposed shelf life will generally be appropriate as long as the guidance in Sections D and E is followed. If one or more of the estimated shelf lives fall short of the proposed shelf life, model building as described in Section B.3.2.2.1 can be employed. However, it is considered unnecessary to identify the final model before evaluating whether the data support the proposed shelf life. Shelf lives can be estimated at each stage of the model-building process, and if all shelf lives at any stage are longer than the one proposed, further attempts to reduce the model are considered unnecessary.

This approach can simplify the data analysis of a complicated multifactor stability study compared with the data analysis described in Section B.3.2.2.1.

B.3.2. Testing for Poolability

The stability data from different combinations of factors should not be combined unless supported by statistical tests for poolability.

B.3.2.1. Testing for Poolability of Batch Factor Only If each factor combination is considered separately, the stability data can be tested for poolability of batches only, and the shelf life for each nonbatch factor combination can be estimated separately by applying the procedure described in Section B.2. For example, for a drug product available in two strengths and four container sizes, eight sets of data from the 2×4 strength–size combinations can be analyzed, and eight separate shelf lives should be estimated accordingly. If a single shelf life is desired, the shortest estimated shelf life among all factor combinations should become the shelf life for the product. However, this approach does not take advantage of the available data from all factor combinations, thus generally resulting in shorter shelf lives than does the approach in Section B.3.2.2.

B.3.2.2. Testing for Poolability of All Factors and Factor Combinations If the stability data are tested for poolability of all factors and factor combinations, and the results show that the data can be combined, a single shelf life longer than that estimated based on individual factor combinations is generally obtainable. The shelf life is longer because the width of the confidence limit(s) for the mean will become narrower as the amount of data increases when batches, strengths, container sizes and/or fills, and so forth are combined.

B.3.2.2.1. Analysis of Covariance Analysis of covariance can be employed to test the difference in slopes and intercepts of the regression lines among factors and factor combinations (Chen et al., 1997; Fairweather et al., 1995). The purpose of the procedure is to determine whether data from multiple factor combinations can be combined for the estimation of a single shelf life.

The full statistical model should include the intercept and slope terms of all main effects and interaction effects and a term reflecting the random error of measurement. If it can be justified that the higher-order interactions are very small, there is generally no need to include these terms in the model. In cases where the analytical results at the initial time point are obtained from the finished dosage form prior to its packaging, the container intercept term can be excluded from the full model, because the results are common among the different container sizes and/or fills.

The tests for poolability should be specified to determine whether there are statistically significant differences among factors and factor combinations. Generally, the pooling tests should be performed in a proper order, such that the slope terms are tested before the intercept terms, and the interaction effects are tested before the main effects. For example, the tests can start with the slope and then the intercept terms of the highest-order interaction, and proceed to the slope and then the intercept terms of the simple main effects. The most reduced model, obtained when all remaining terms are found to be statistically significant, can be used to estimate the shelf lives.

All tests should be conducted using appropriate levels of significance. It is recommended that a significance level of 0.25 be used for batch-related terms and a significance level of 0.05 be used for non-batch-related terms. If the tests for poolability show that the data from different factor combinations can be combined, the shelf life can be estimated according to the procedure described in Section B.1 using the combined data.

If the tests for poolability show that the data from certain factors or factor combinations should not be combined, either of two alternatives can be applied: (1) a separate shelf life can

be estimated for each level of the factors and of the factor combinations remaining in the model; or (2) a single shelf life can be estimated based on the shortest estimated shelf life among all levels of factors and factor combinations remaining in the model.

B.3.2.2.2. Other Methods Alternative statistical procedures to those described earlier can be applied (Murphy and Weisman, 1990; Ruberg and Stegeman, 1991; Ruberg and Hsu, 1992; Shao and Chow, 1994; Yoshioka et al., 1997). For example, an appropriate procedure for assessing the equivalence in slope or in mean shelf life can be used to determine the data poolability. However, such a procedure should be prospectively defined, evaluated, properly justified, and where appropriate, discussed with the regulatory authority. A simulation study can be useful, if applicable, to demonstrate that the statistical properties of the alternative procedure selected are appropriate (Chen et al., 1997).

B.4. Data Analysis for Bracketing Design Studies

The statistical procedures described in Section B.3 can be applied to the analysis of stability data obtained from a bracketing design study. For example, for a drug product available in three strengths (S1, S2, and S3) and three container sizes (P1, P2, and P3) and studied according to a bracketing design where only the two extremes of the container sizes (P1 and P3) are tested, six sets of data from the 3×2 strength–size combinations will be obtained. The data can be analyzed separately for each of the six combinations for shelf-life estimation according to section B.3.2.1 or tested for poolability prior to shelf-life estimation according to section B.3.2.2.

The bracketing design assumes that the stability of the intermediate strengths or sizes is represented by the stability at the extremes. If the statistical analysis indicates that the stability of the extreme strengths or sizes is different, the intermediate strengths or sizes should be considered no more stable than the least stable extreme. For example, if P1 from the bracketing design in the previous paragraph is found to be less stable than P3, the shelf life for P2 should not exceed that for P1. No interpolation between P1 and P3 should be considered.

B.5. Data Analysis for Matrixing Design Studies

A matrixing design has only a fraction of the total number of samples tested at any specified time point. Therefore, it is important to ascertain that all factors and factor combinations that can have an impact on shelf-life estimation have been appropriately tested. For a meaningful interpretation of the study results and shelf-life estimation, certain assumptions should be made and justified. For instance, the assumption that the stability of the samples tested represents the stability of all samples should be valid. In addition, if the design is not balanced, some factors or factor interactions might not be estimable. Furthermore, for different levels of factor combinations to be poolable, it might have to be assumed that the higher-order factor interactions are negligible. Because it is usually impossible to statistically test the assumption that the higher-order terms are negligible, a matrixing design should be used only when it is reasonable to assume that these interactions are indeed very small, based on supporting data.

The statistical procedure described in Section B.3 can be applied to the analysis of stability data obtained from a matrixing design study. The statistical analysis should clearly identify the procedure and assumptions used. For instance, the assumptions underlying the model in which interaction terms are negligible should be stated. If a preliminary test is performed for the purpose of eliminating factor interactions from the model, the procedure used should be provided and justified. The final model on which the estimation of shelf life will be based should be stated. The estimation of shelf life should be performed for each of the terms remaining in the model. The use of a matrixing design can result in an estimated shelf life shorter than that resulting from a full design.

Where bracketing and matrixing are combined in one design, the statistical procedure described in Section B.3 can be applied.

12 Stability Data Package for Registration Applications in Climatic Zones III and IV

I. INTRODUCTION

A. Objectives of the Guideline

This guideline describes an approach to broader use of the International Conference on Harmonisation (ICH) guideline "Q1A(R) Stability Testing of New Drug Substances and Products" (hereafter referred to as the parent guideline) and outlines the stability data package for a new drug substance or drug product that is considered sufficient for a registration application in territories in Climatic Zones III and IV (Schumacher, 1974; Grimm, 1985).

B. Background

The parent guideline describes the stability data package for the ICH tripartite regions (the EU, Japan, and the United States), which are in Climatic Zones I and II. The parent guideline can be followed to generate stability data packages for registration applications in other countries or regions in Zones I and II. For territories in Climatic Zones III and IV, the data package as described in the parent guideline can be considered applicable except for certain storage conditions. An approach for the classification of countries according to Climatic Zones I, II, III, and IV can be found in the literature (Dietz et al., 1993; Grimm, 1998).

The World Health Organization (WHO) has published a guideline "Stability testing of pharmaceutical products containing well-established drug substances in conventional dosage forms" (WHO Technical Report Series, No. 863, Annex 5), updated in the Report of the thirty-seventh meeting of the WHO Expert Committee on Specifications for Pharmaceutical Preparations, Geneva, October 22–26, 2001. The WHO guideline describes stability testing recommendations, including storage conditions for all four climatic zones.

The stability testing recommendations in this guideline are based on the parent guideline and the WHO guideline. To harmonize with the long-term storage conditions for Zones III and IV, the intermediate storage condition in the General Case for Zones I and II in the parent guideline is changed to 30°C ± 2°C/65% RH ± 5% RH. This condition of 30°C ± 2°C/65% RH ± 5% RH can also be a suitable alternative to 25°C ± 2°C/60% RH ± 5% RH as the long-term storage condition for Zones I and II.

C. Scope of the Guideline

This document is an annex to the parent guideline and recommends the long-term storage condition for stability testing of a new drug substance or drug product for a registration application in territories in Climatic Zones III and IV.

II. GUIDELINES

A. Continuity with the Parent Guideline

This guideline should be used in conjunction with the parent guideline and subsequently published annexes (Q1B, Q1C, Q1D, Q1E, and Q5C). The recommendations in the parent guideline and annexes should be followed unless specific alternatives are described within this guideline. The following sections of the parent guideline can be considered common to any territory in the world and are not reproduced here.

- Stress testing
- Selection of batches
- Container closure system
- Specification
- Testing frequency
- Storage conditions for drug substance or product in a refrigerator
- Storage conditions for drug substance or product in a freezer
- Stability commitment
- Evaluation
- Statements/labeling

B. Storage Conditions

1. General Case

For the "General case" (as described in the parent guideline), the recommended long-term and accelerated storage conditions for Climatic Zones III and IV are shown as follows:

Study	Storage Condition	Minimum Time Period Covered by Data at Submission
Long-term	30°C ± 2°C/65% RH ± 5% RH	12 months
Accelerated	40°C ± 2°C/75% RH ± 5% RH	6 months

No intermediate storage condition for stability studies is recommended for Climatic Zones III and IV. Therefore, the intermediate storage condition is not relevant when the principles of retest period or shelf life extrapolation described in Q1E are applied.

2. Aqueous-Based Drug Products Packaged in Semipermeable Containers

For aqueous-based drug products packaged in semipermeable containers (as described in the parent guideline), the recommended long-term and accelerated storage conditions for Climatic Zones III and IV are shown as follows:

Study	Storage Condition	Minimum Time Period Covered by Data at Submission
Long-term	30°C ± 2°C/35% RH ± 5% RH	12 months
Accelerated	40°C ± 2°C/not more than 25% RH ± 5% RH	6 months

As described in the parent guideline, an appropriate approach for deriving the water loss rate at the reference relative humidity is to multiply the water loss rate measured at an alternative relative humidity at the same temperature by a water loss rate ratio (see the following table for examples).

The ratio of water loss rates at a given temperature is calculated by the general formula (100 – reference% RH)/(100 – alternative% RH).

Alternative Relative Humidity	Reference Relative Humidity	Ratio of Water Loss Rates at a Given Temperature
65% RH	35% RH	1.9
75% RH	25% RH	3.0

Valid water loss rate ratios at relative humidity conditions other than those shown in the table can be used. A linear water loss rate at the alternative relative humidity over the storage period should be demonstrated.

3. Tests at Elevated Temperature and/or Extremes of Humidity

Special transportation and climatic conditions outside the storage conditions recommended in this guideline should be supported by additional data. For example, these data can be obtained from studies on one batch of drug product conducted for up to 3 months at 50°C/ambient humidity to cover extremely hot and dry conditions and at 25°C/80% RH to cover extremely high humidity conditions (Grimm, 1985).

Stability testing at a high humidity condition, for example, 25°C/80% RH, is recommended for solid dosage forms in water vapor–permeable packaging, such as tablets in PVC/aluminum blisters, intended to be marketed in territories with extremely high humidity conditions in Zone IV. However, for solid dosage forms in primary containers designed to provide a barrier to water vapor, for example, aluminum/aluminum blisters, stability testing at a storage condition of extremely high humidity is not considered necessary.

C. Additional Considerations

If it cannot be demonstrated that the drug substance or drug product will remain within its acceptance criteria when stored at 30°C ± 2°C/65% RH ± 5% RH for the duration of the proposed retest period or shelf life, the following options should be considered: (1) a reduced retest period or shelf life, (2) a more protective container closure system, or (3) additional cautionary statements in the labeling.

13 EU Guidelines to Good Manufacturing Practice Medicinal Products for Human and Veterinary Use

I. INTRODUCTION

The pharmaceutical industry of the European Union maintains high standards of quality assurance in the development, manufacture, and control of medicinal products. A system of Marketing Authorizations ensures that all medicinal products are assessed by a competent authority to ensure compliance with contemporary requirements of safety, quality, and efficacy. A system of manufacturing authorizations ensures that all products authorized on the European market are manufactured only by authorized manufacturers, whose activities are regularly inspected by the competent authorities. Manufacturing authorizations are required by all pharmaceutical manufacturers in the European Community whether the products are sold within or outside the Community.

Two directives laying down principles and guidelines of good manufacturing practice (GMP) for medicinal products were adopted by the Commission. Directive 2003/94/EC applies to medicinal products for human use and Directive 91/412/EEC for veterinary use. Detailed guidelines in accordance with those principles are published in the *Guide to Good Manufacturing Practice*, which will be used in assessing applications for manufacturing authorizations and as a basis for inspection of manufacturers of medicinal products.

The principles of GMP and the detailed guidelines are applicable to all operations that require the authorization referred to in Article 40 of Directive 2001/83/EC and in Article 44 of Directive 2001/82/EC, as amended by Directives 2004/27/EC and 2004/28/EC, respectively. They are also relevant for all other large-scale pharmaceutical manufacturing processes, such as that undertaken in hospitals, and for the preparation of products for use in clinical trials.

All member states and the industry agreed that the GMP requirements applicable to the manufacture of veterinary medicinal products are the same as those applicable to the manufacture of medicinal products for human use. Certain detailed adjustments to the GMP guidelines are set out in two annexes specific to veterinary medicinal products and to immunological veterinary medicinal products.

The guide is presented in two parts: basic requirements and specific annexes. Part I covers GMP principles for the manufacture of medicinal products. Part II covers GMP for active substances used as starting materials.

Chapters of Part I on "basic requirements" are headed by principles as defined in Directives 2003/94/EC and 91/412/EEC. Chapter 1 on Quality Management outlines the fundamental concept of quality assurance as applied to the manufacture of medicinal products. Thereafter, each chapter has a principle outlining the quality assurance objectives of that chapter and a text that provides sufficient detail for manufacturers to be made aware of the essential matters to be considered when implementing the principle.

Part II was newly established on the basis of a guideline developed at the level of the International Conference on Harmonisation (ICH) and published as ICH Q7a on "active pharmaceutical ingredients," which was implemented as GMP Annex 18 for voluntary application in 2001. According to the revised Article 47 and Article 51, respectively, of the Directive 2001/83/EC and Directive 2001/82/EC, as amended, detailed guidelines on the principles of GMP for active substances used as starting materials shall be adopted and published by the Commission. The former Annex 18 has been replaced by the new Part II of the GMP guide, which has an extended application for both the human and the veterinary sector.

In addition to the general matters of GMP outlined in Parts I and II, a series of annexes providing detail about specific areas of activity is included. For some manufacturing processes, different annexes will apply simultaneously (e.g., annex on sterile preparations and on radiopharmaceuticals and/or on biological medicinal products).

GMP Part I, Chapter 1 on Quality Management has been revised to include aspects of quality risk management within the quality system framework. In future revisions of the guide, the opportunity will be taken to introduce quality risk management elements when appropriate.

The new GMP Annex 20, which corresponds to the ICH Q9 guideline, provides guidance on a systematic approach to quality risk management leading to compliance with GMP and other quality requirements. It includes principles to be used and options for processes, methods, and tools, which may be used when applying a formal quality risk management approach. While the GMP guide is primarily addressed to manufacturers, the ICH Q9 guideline has relevance for other quality guidelines and includes specific sections for regulatory agencies. However, for reasons of coherence and completeness, the ICH Q9 guideline has been transferred completely into GMP Annex 20.

A glossary of some terms used in the guide has been incorporated after the annexes.

The guide is not intended to cover security aspects for the personnel engaged in manufacture. This may be particularly important in the manufacture of certain medicinal products,

such as highly active, biological and radioactive medicinal products. However, those aspects are governed by other provisions of Community or national law.

Throughout the guide, it is assumed that the requirements of the Marketing Authorization relating to the safety, quality, and efficacy of the products are systematically incorporated into all the manufacturing, control, and release for sale arrangements of the holder of the manufacturing authorization.

The manufacture of medicinal products has for many years taken place in accordance with guidelines for GMP, and the manufacture of medicinal products is not governed by European Committee for Standardization (CEN)/International Organization for Standardization (ISO) standards. Harmonized standards as adopted by the European standardization organizations CEN/ISO may be used at industry's discretion as a tool for implementing a quality system in the pharmaceutical sector. The CEN/ISO standards have been considered, but the terminology of these standards has not been implemented in this edition. It is recognized that there are acceptable methods, other than those described in the guide, which are capable of achieving the principles of quality assurance. The guide is not intended to place any restraint upon the development of any new concepts or new technologies that have been validated and that provide a level of quality assurance at least equivalent to those set out in this guide. With its principles, methods, and tools, Annex 20 provides a systematic approach, which may be used to demonstrate such equivalence.

The GMP guide will be regularly revised. Revisions will be made publicly available on the Web site of the European Commission (http://ec.europa.eu/enterprise/pharmaceuticals/eudralex/homev4.htm).

Part I: Chapter 1: Quality Management

Principle

The holder of a manufacturing authorization must manufacture medicinal products so as to ensure that they are fit for their intended use, comply with the requirements of the Marketing Authorization, and do not place patients at risk due to inadequate safety, quality, or efficacy. The attainment of this quality objective is the responsibility of senior management and requires the participation and commitment of staff in many different departments and at all levels within the company, of the company's suppliers, and of the distributors. To achieve the quality objective reliably, there must be a comprehensively designed and correctly implemented system of Quality Assurance incorporating Good Manufacturing Practice, Quality Control, and Quality Risk Management. It should be fully documented and its effectiveness monitored. All parts of the Quality Assurance system should be adequately resourced with competent personnel and suitable and sufficient premises, equipment, and facilities. There are additional legal responsibilities for the holder of the manufacturing authorization and for the Qualified Person(s).

The basic concepts of Quality Assurance, Good Manufacturing Practice, Quality Control, and Quality Risk Management are interrelated. They are described here in order to emphasize their relationships and their fundamental importance to the production and control of medicinal products.

Quality Assurance

1.1 Quality Assurance is a wide-ranging concept, which covers all matters that individually or collectively influence the quality of a product. It is the sum total of the organized arrangements made with the objective of ensuring that medicinal products are of the quality required for their intended use. Quality Assurance therefore incorporates Good Manufacturing Practice plus other factors outside the scope of this guide.

The system of Quality Assurance appropriate for the manufacture of medicinal products should ensure that

(i) Medicinal products are designed and developed in a way that takes account of the requirements of GMP.
(ii) Production and control operations are clearly specified and GMP adopted.
(iii) Managerial responsibilities are clearly specified.
(iv) Arrangements are made for the manufacture, supply, and use of the correct starting and packaging materials.
(v) All necessary controls on intermediate products, and any other in-process controls and validations, are carried out.
(vi) The finished product is correctly processed and checked according to the defined procedures.
(vii) Medicinal products are not sold or supplied before a Qualified Person has certified that each production batch has been produced and controlled in accordance with the requirements of the Marketing Authorization and any other regulations relevant to the production, control, and release of medicinal products.
(viii) Satisfactory arrangements exist to ensure, as far as possible, that the medicinal products are stored, distributed, and subsequently, handled so that quality is maintained throughout their shelf life.
(ix) There is a procedure for Self-Inspection and/or quality audit, which regularly appraises the effectiveness and applicability of the Quality Assurance system.

Good Manufacturing Practice for Medicinal Products (GMP)

1.2 Good Manufacturing Practice is that part of Quality Assurance which ensures that products are consistently produced and controlled to the quality standards appropriate to their intended use and as required by the Marketing Authorization or product specification.

Good Manufacturing Practice is concerned with both production and Quality Control. The basic requirements of GMP are as follows:

(i) All manufacturing processes are clearly defined, systematically reviewed in the light of experience, and shown to be capable of consistently manufacturing

medicinal products of the required quality and complying with their specifications.

(ii) Critical steps of manufacturing processes and significant changes to the process are validated.

(iii) All necessary facilities for GMP are provided, including

Appropriately qualified and trained personnel
Adequate premises and space
Suitable equipment and services
Correct materials, containers, and labels
Approved procedures and instructions; and suitable storage and transport

(iv) Instructions and procedures are written in an instructional form in clear and unambiguous language, specifically applicable to the facilities provided.

(v) Operators are trained to carry out procedures correctly.

(vi) Records are made, manually and/or by recording instruments, during manufacture, which demonstrate that all the steps required by the defined procedures and instructions were in fact taken and that the quantity and quality of the product were as expected. Any significant deviations are fully recorded and investigated.

(vii) Records of manufacture, including distribution, which enable the complete history of a batch to be traced, are retained in a comprehensible and accessible form.

(viii) The distribution (wholesaling) of the products minimizes any risk to their quality.

(ix) A system is available to recall any batch of product from sale or supply.

(x) Complaints about marketed products are examined, the causes of quality defects investigated, and appropriate measures taken in respect of the defective products and to prevent reoccurrence.

Quality Control

1.3 Quality Control is that part of Good Manufacturing Practice which is concerned with sampling, specifications, and testing, and with the organization, documentation, and release procedures that ensure that the necessary and relevant tests are actually carried out and that materials are not released for use, or products released for sale or supply, until their quality has been judged to be satisfactory.

The basic requirements of Quality Control are as follows:

(i) Adequate facilities, trained personnel, and approved procedures are available for sampling, inspecting, and testing starting materials, packaging materials, intermediate, bulk, and finished products, and where appropriate, monitoring environmental conditions for GMP purposes.

(ii) Samples of starting materials, packaging materials, intermediate products, bulk products, and finished products are taken by personnel and by methods approved by Quality Control.

(iii) Test methods are validated.

(iv) Records are made, manually and/or by recording instruments, that demonstrate that all the required sampling, inspecting, and testing procedures were actually carried out. Any deviations are fully recorded and investigated.

(v) The finished products contain active ingredients complying with the qualitative and quantitative composition of the Marketing Authorization, are of the purity required, and are enclosed within their proper containers and correctly labeled.

(vi) Records are made of the results of inspection and that the testing of materials, intermediate, bulk, and finished products is formally assessed against specification. Product assessment includes a review and evaluation of relevant production documentation and an assessment of deviations from specified procedures.

(vii) No batch of product is released for sale or supply prior to certification by a Qualified Person that it is in accordance with the requirements of the relevant authorizations.

(viii) Sufficient reference samples of starting materials and products are retained to permit future examination of the product if necessary, and the product is retained in its final pack unless exceptionally large packs are produced.

Product Quality Review

1.4 Regular periodic or rolling quality reviews of all licensed medicinal products, including export-only products, should be conducted with the objective of verifying the consistency of the existing process, the appropriateness of current specifications for both starting materials and finished product to highlight any trends, and to identify product and process improvements. Such reviews should normally be conducted and documented annually, taking into account previous reviews, and should include at least

(i) A review of starting materials including packaging materials used in the product, especially those from new sources

(ii) A review of critical in-process controls and finished product results

(iii) A review of all batches that failed to meet established specification(s) and their investigation

(iv) A review of all significant deviations or nonconformances, their related investigations, and the effectiveness of resultant corrective and preventative actions taken

(v) A review of all changes carried out to the processes or analytical methods

(vi) A review of Marketing Authorization variations submitted/granted/refused, including those for third country (export-only) dossiers

(vii) A review of the results of the stability monitoring program and any adverse trends

(viii) A review of all quality-related returns, complaints, and recalls and the investigations performed at the time
(ix) A review of the adequacy of any other previous product, process, or equipment corrective actions
(x) For new Marketing Authorizations and variations to Marketing Authorizations, a review of postmarketing commitments
(xi) The qualification status of relevant equipment and utilities; for example, heating, ventilation, and air-conditioning (HVAC), water, and compressed gases
(xii) A review of any contractual arrangements to ensure that they are up to date

The manufacturer and Marketing Authorization holder should evaluate the results of this review, where different, and an assessment should be made of whether corrective and preventative action or any revalidation should be undertaken. The reasons for such corrective actions should be documented. Agreed corrective and preventative actions should be completed in a timely and effective manner. There should be management procedures for the ongoing management and review of these actions, and the effectiveness of these procedures should be verified during self-inspection. Quality reviews may be grouped by product type, for example, solid dosage forms, liquid dosage forms, and sterile products, where scientifically justified.

Where the Marketing Authorization holder is not the manufacturer, there should be a technical agreement in place between the various parties that defines their respective responsibilities in producing the quality review. The Qualified Person responsible for final batch certification together with the Marketing Authorization holder should ensure that the quality review is performed in a timely manner and is accurate.

Quality Risk Management

1.5 Quality Risk Management is a systematic process for the assessment, control, communication, and review of risks to the quality of the medicinal product. It can be applied both proactively and retrospectively.

1.6 The Quality Risk Management system should ensure that

- The evaluation of the risk to quality is based on scientific knowledge and experience with the process and ultimately, links to the protection of the patient.
- The level of effort, formality, and documentation of the Quality Risk Management process is commensurate with the level of risk.

Chapter 2: Personnel

Principle

The establishment and maintenance of a satisfactory system of Quality Assurance and the correct manufacture of medicinal products relies upon people. For this reason, there must be sufficient qualified personnel to carry out all the tasks that are the responsibility of the manufacturer. Individual responsibilities should be clearly understood by the individuals and recorded. All personnel should be aware of the principles of Good Manufacturing Practice that affect them and receive initial and continuing training, including hygiene instructions, relevant to their needs.

General

2.1 The manufacturer should have an adequate number of personnel with the necessary qualifications and practical experience. The responsibilities placed on any one individual should not be so extensive as to present any risk to quality.

2.2 The manufacturer must have an organization chart. People in responsible positions should have specific duties recorded in written job descriptions and adequate authority to carry out their responsibilities. Their duties may be delegated to designated deputies of a satisfactory qualification level. There should be no gaps or unexplained overlaps in the responsibilities of those personnel concerned with the application of Good Manufacturing Practice.

Key Personnel

2.3 Key Personnel include the head of Production, the head of Quality Control, and if at least one of these persons is not responsible for the duties described in Article 51 of Directive 2001/83/EC1, the Qualified Person(s) designated for the purpose. Normally, key posts should be occupied by full-time personnel. The heads of Production and Quality Control must be independent of each other. In large organizations, it may be necessary to delegate some of the functions listed in 2.5, 2.6, and 2.7.

2.4 The duties of the Qualified Person(s) are fully described in Article 51 of Directive 2001/83/EC and can be summarized as follows:

- For medicinal products manufactured within the European Community, a Qualified Person must ensure that each batch has been produced and tested/checked in accordance with the directives and the Marketing Authorization.
- For medicinal products manufactured outside the European Community, a Qualified Person must ensure that each imported batch has undergone, in the importing country, the testing specified in paragraph 1 (b) of Article 51; Article 55 of Directive 2001/82/EC (2). According to Directive 75/319/EEC (now codified Directive 2001/83/EC) and the Ruling (Case 247/81) of the Court of Justice of the European Communities, medicinal products that have been properly controlled in the EU by a Qualified Person do not have to be recontrolled or rechecked in any other member state of the Community.
- A Qualified Person must certify in a register or equivalent document, as operations are carried out and before any release, that each production batch satisfies the provisions of Article 51. The persons responsible for these duties must meet the qualification requirements laid down in Article 493 of the

same Directive, and they shall be permanently and continuously at the disposal of the holder of the manufacturing authorization to carry out their responsibilities. Their responsibilities may be delegated, but only to other Qualified Person(s).

2.5 The head of the Production Department generally has the following responsibilities:

(i) To ensure that products are produced and stored according to the appropriate documentation in order to obtain the required quality
(ii) To approve the instructions relating to production operations and to ensure their strict implementation
(iii) To ensure that the production records are evaluated and signed by an authorized person before they are sent to the Quality Control Department
(iv) To check the maintenance of his or her department, premises, and equipment
(v) To ensure that the appropriate validations are done
(vi) To ensure that the required initial and continuing training of his or her department personnel is carried out and adapted according to need

2.6 The head of the Quality Control Department generally has the following responsibilities:

(i) To approve or reject, as he or she sees fit, starting materials, packaging materials, and intermediate, bulk and finished products
(ii) To evaluate batch records
(iii) To ensure that all necessary testing is carried out
(iv) To approve specifications, sampling instructions, test methods, and other Quality Control procedures
(v) To approve and monitor any contract analysts
(vi) To check the maintenance of his or her department, premises, and equipment
(vii) To ensure that the appropriate validations are done
(viii) To ensure that the required initial and continuing training of his or her department personnel is carried out and adapted according to need

Other duties of the Quality Control Department are summarized in Chapter 6.

2.7 The heads of Production and Quality Control generally have some shared, or jointly exercised, responsibilities relating to quality. These may include, subject to any national regulations,

The authorization of written procedures and other documents, including amendments
The monitoring and control of the manufacturing environment
Plant hygiene
Process validation
Training
The approval and monitoring of suppliers of materials
The approval and monitoring of contract manufacturers
The designation and monitoring of storage conditions for materials and products
The retention of records
The monitoring of compliance with the requirements of Good Manufacturing Practice
The inspection, investigation, and taking of samples in order to monitor factors that may affect product quality

Training

2.8 The manufacturer should provide training for all the personnel whose duties take them into production areas or into control laboratories (including the technical, maintenance, and cleaning personnel) and for other personnel whose activities could affect the quality of the product.

2.9 Besides the basic training on the theory and practice of Good Manufacturing Practice, newly recruited personnel should receive training appropriate to the duties assigned to them. Continuing training should also be given, and its practical effectiveness should be periodically assessed. Training programs should be available, approved by either the head of Production or the head of Quality Control, as appropriate. Training records should be kept.

2.10 Personnel working in areas where contamination is a hazard, for example, clean areas or areas where highly active, toxic, infectious, or sensitizing materials are handled, should be given specific training.

2.11 Visitors or untrained personnel should, preferably, not be taken into the production and Quality Control areas. If this is unavoidable, they should be given information in advance, particularly about personal hygiene and the prescribed protective clothing. They should be closely supervised.

2.12 The concept of Quality Assurance and all the measures capable of improving its understanding and implementation should be fully discussed during the training sessions.

Personnel Hygiene

2.13 Detailed hygiene programs should be established and adapted to the different needs within the factory. They should include procedures relating to the health, hygiene practices, and clothing of personnel. These procedures should be understood and followed in a very strict way by every person whose duties take him or her into the production and control areas. Hygiene programs should be promoted by management and widely discussed during training sessions.

2.14 All personnel should receive medical examination upon recruitment. It must be the manufacturer's responsibility that there are instructions ensuring that health conditions that can be of relevance to the quality of products come to the manufacturer's knowledge. After the first medical examination, examinations should be carried out when necessary for the work and personal health.

2.15 Steps should be taken to ensure as far as is practicable that no person affected by an infectious disease or having open lesions on the exposed surface of the body is engaged in the manufacture of medicinal products.

2.16 Every person entering the manufacturing areas should wear protective garments appropriate to the operations to be carried out.

2.17 Eating, drinking, chewing, or smoking, or the storage of food, drink, smoking materials, or personal medication, in the production and storage areas should be prohibited. In general, any unhygienic practice within the manufacturing areas or in any other area where the product might be adversely affected should be forbidden.

2.18 Direct contact should be avoided between the operator's hands and the exposed product as well as with any part of the equipment that comes into contact with the products.

2.19 Personnel should be instructed to use the hand-washing facilities.

2.20 Any specific requirements for the manufacture of special groups of products, for example, sterile preparations, are covered in the annexes.

Chapter 3: Premises and Equipment

Principle

Premises and equipment must be located, designed, constructed, adapted, and maintained to suit the operations to be carried out. Their layout and design must aim to minimize the risk of errors and permit effective cleaning and maintenance in order to avoid cross-contamination, the build-up of dust or dirt, and in general, any adverse effect on the quality of products.

Premises

General

3.1 Premises should be situated in an environment that, when considered together with measures to protect the manufacture, presents minimal risk of causing contamination of materials or products.

3.2 Premises should be carefully maintained, ensuring that repair and maintenance operations do not present any hazard to the quality of products. They should be cleaned and where applicable, disinfected according to detailed written procedures.

3.3 Lighting, temperature, humidity, and ventilation should be appropriate and such that they do not adversely affect, directly or indirectly, either the medicinal products during their manufacture and storage or the accurate functioning of equipment.

3.4 Premises should be designed and equipped so as to afford maximum protection against the entry of insects or other animals.

3.5 Steps should be taken in order to prevent the entry of unauthorized people. Production, storage, and Quality Control areas should not be used as a right of way by personnel who do not work in them.

Production Area

3.6 In order to minimize the risk of a serious medical hazard due to cross-contamination, dedicated and self-contained facilities must be available for the production of particular medicinal products, such as highly sensitizing materials (e.g., penicillins) or biological preparations (e.g., from live microorganisms). The production of certain additional products, such as certain antibiotics, certain hormones, certain cytotoxics, and certain highly active drugs and nonmedicinal products, should not be conducted in the same facilities. For those products, in exceptional cases, the principle of campaign working in the same facilities can be accepted provided that specific precautions are taken and the necessary validations are made. The manufacture of technical poisons, such as pesticides and herbicides, should not be allowed in premises used for the manufacture of medicinal products.

3.7 Premises should preferably be laid out in such a way as to allow the production to take place in areas connected in a logical order corresponding to the sequence of the operations and to the requisite cleanliness levels.

3.8 The adequacy of the working and in-process storage space should permit the orderly and logical positioning of equipment and materials so as to minimize the risk of confusion between different medicinal products or their components, to avoid cross-contamination, and to minimize the risk of omission or wrong application of any of the manufacturing or control steps.

3.9 Where starting and primary packaging materials and intermediate or bulk products are exposed to the environment, interior surfaces (walls, floors, and ceilings) should be smooth and free from cracks and open joints, should not shed particulate matter, and should permit easy and effective cleaning and if necessary, disinfection.

3.10 Pipework, light fittings, ventilation points, and other services should be designed and sited to avoid the creation of recesses that are difficult to clean. As far as possible, for maintenance purposes, they should be accessible from outside the manufacturing areas.

3.11 Drains should be of adequate size and have trapped gullies. Open channels should be avoided where possible, but if necessary, they should be shallow to facilitate cleaning and disinfection.

3.12 Production areas should be effectively ventilated, with air-control facilities (including temperature and where necessary, humidity and filtration) appropriate to the products handled, to the operations undertaken within them, and to the external environment.

3.13 Weighing of starting materials usually should be carried out in a separate weighing room designed for that use.

3.14 In cases where dust is generated (e.g., during sampling, weighing, mixing and processing operations or in the packaging of dry products), specific provisions should be taken to avoid cross-contamination and facilitate cleaning.

3.15 Premises for the packaging of medicinal products should be specifically designed and laid out so as to avoid mix-ups or cross-contamination.

3.16 Production areas should be well lit, particularly where visual controls are carried out.

3.17 In-process controls may be carried out within the production area provided they do not carry any risk to the production.

Storage Areas

3.18 Storage areas should be of sufficient capacity to allow orderly storage of the various categories of materials and products: starting and packaging materials, intermediate, bulk and finished products, and products in quarantine, released, rejected, returned, or recalled.

3.19 Storage areas should be designed or adapted to ensure good storage conditions. In particular, they should be clean and dry and maintained within acceptable temperature limits. Where special storage conditions are required (e.g., temperature or humidity), these should be provided, checked, and monitored.

3.20 Receiving and dispatch bays should protect materials and products from the weather. Reception areas should be designed and equipped to allow containers of incoming materials to be cleaned where necessary before storage.

3.21 Where quarantine status is ensured by storage in separate areas, these areas must be clearly marked and their access restricted to authorized personnel. Any system replacing the physical quarantine should give equivalent security.

3.22 There should normally be a separate sampling area for starting materials. If sampling is performed in the storage area, it should be conducted in such a way as to prevent contamination or cross-contamination.

3.23 Segregated areas should be provided for the storage of rejected, recalled, or returned materials or products.

3.24 Highly active materials or products should be stored in safe and secure areas.

3.25 Printed packaging materials are considered critical to the conformity of the medicinal product, and special attention should be paid to the safe and secure storage of these materials.

Quality Control Areas

3.26 Normally, Quality Control laboratories should be separated from production areas. This is particularly important for laboratories for the control of biologicals, microbiologicals, and radioisotopes, which should also be separated from each other.

3.27 Control laboratories should be designed to suit the operations to be carried out in them. Sufficient space should be given to avoid mix-ups and cross-contamination. There should be adequate suitable storage space for samples and records.

3.28 Separate rooms may be necessary to protect sensitive instruments from vibration, electrical interference, humidity, and so forth.

3.29 Special requirements are needed in laboratories handling particular substances, such as biological or radioactive samples.

Ancillary Areas

3.30 Rest and refreshment rooms should be separate from other areas.

3.31 Facilities for changing clothes, washing, and toilet purposes should be easily accessible and appropriate for the number of users. Toilets should not directly communicate with production or storage areas.

3.32 Maintenance workshops should as far as possible be separated from production areas. Whenever parts and tools are stored in the production area, they should be kept in rooms or lockers reserved for that use.

3.33 Animal houses should be well isolated from other areas, with separate entrance (animal access) and air-handling facilities.

Equipment

3.34 Manufacturing equipment should be designed, located, and maintained to suit its intended purpose.

3.35 Repair and maintenance operations should not present any hazard to the quality of the products.

3.36 Manufacturing equipment should be designed so that it can be easily and thoroughly cleaned. It should be cleaned according to detailed and written procedures and stored only in a clean and dry condition.

3.37 Washing and cleaning equipment should be chosen and used in such a way as not to be a source of contamination.

3.38 Equipment should be installed in such a way as to prevent any risk of error or of contamination.

3.39 Production equipment should not present any hazard to the products. The parts of the production equipment that come into contact with the product must not be reactive, additive, or absorptive to such an extent that they will affect the quality of the product and thus, present any hazard.

3.40 Balances and measuring equipment of an appropriate range and precision should be available for production and control operations.

3.41 Measuring, weighing, recording, and control equipment should be calibrated and checked at defined intervals by appropriate methods. Adequate records of such tests should be maintained.

3.42 Fixed pipework should be clearly labeled to indicate the contents and where applicable, the direction of flow.

3.43 Distilled, deionized, and where appropriate, other water pipes should be sanitized according to written procedures that detail the action limits for microbiological contamination and the measures to be taken.

3.44 Defective equipment should, if possible, be removed from production and Quality Control areas, or at least be clearly labeled as defective.

Chapter 4: Documentation

Principle

Good documentation constitutes an essential part of the Quality Assurance system. Clearly written documentation prevents errors from spoken communication and permits tracing of batch history. Specifications, Manufacturing Formulae and instructions, procedures, and records must be free from errors and available in writing. The legibility of documents is of paramount importance.

General

4.1 *Specifications* describe in detail the requirements to which the products or materials used or obtained during manufacture have to conform. They serve as a basis for quality evaluation.

Manufacturing Formulae, Processing, and Packaging Instructions state all the starting materials used and lay down all processing and packaging operations.

Procedures give directions for performing certain operations: for example, cleaning, clothing, environmental control, sampling, testing, and equipment operation.

Records provide a history of each batch of product, including its distribution, and also of all other relevant circumstances pertinent to the quality of the final product.

4.2 Documents should be designed, prepared, reviewed, and distributed with care. They should comply with the relevant parts of the manufacturing and Marketing Authorization dossiers.

4.3 Documents should be approved, signed, and dated by appropriate and authorized persons.

4.4 Documents should have unambiguous contents; the title, nature, and purpose should be clearly stated. They should be laid out in an orderly fashion and be easy to check. Reproduced documents should be clear and legible. The reproduction of working documents from master documents must not allow any error to be introduced through the reproduction process.

4.5 Documents should be regularly reviewed and kept up to date. When a document has been revised, systems should be operated to prevent inadvertent use of superseded documents.

4.6 Documents should not be handwritten, although where documents require the entry of data, these entries may be made in clear, legible, and indelible handwriting. Sufficient space should be provided for such entries.

4.7 Any alteration made to the entry on a document should be signed and dated; the alteration should permit the reading of the original information. Where appropriate, the reason for the alteration should be recorded.

4.8 The records should be made or completed at the time each action is taken and in such a way that all significant activities concerning the manufacture of medicinal products are traceable. They should be retained for at least 1 year after the expiry date of the finished product.

4.9 Data may be recorded by electronic data processing systems or photographic or other reliable means, but detailed procedures relating to the system in use should be available, and the accuracy of the records should be checked. If documentation is handled by electronic data processing methods, only authorized persons should be able to enter or modify data in the computer, and there should be a record of changes and deletions; access should be restricted by passwords or other means, and the result of entry of critical data should be independently checked. Batch records electronically stored should be protected by backup transfer on magnetic tape, microfilm, paper, or other means. It is particularly important that the data are readily available throughout the period of retention.

4.10 There should be appropriately authorized and dated specifications for starting and packaging materials, and finished products; where appropriate, they should be also available for intermediate or bulk products.

Specifications for Starting and Packaging Materials

4.11 Specifications for starting and primary or printed packaging materials should include, if applicable,

- A description of the materials, including
- The designated name and the internal code reference
- The reference, if any, to a pharmacopoeial monograph
- The approved suppliers and if possible, the original producer of the products
- (a) Specimens of printed materials, (b) directions for sampling and testing or reference to procedures, (c) qualitative and quantitative requirements with acceptance limits, and (d) storage conditions and precautions
- The maximum period of storage before reexamination

Specifications for Intermediate and Bulk Products

4.12 Specifications for intermediate and bulk products should be available if these are purchased or dispatched, or if data obtained from intermediate products are used for the evaluation of the finished product. The specifications should be similar to specifications for starting materials or for finished products, as appropriate.

Specifications for Finished Products

4.13 Specifications for finished products should include (a) the designated name of the product and the code reference where applicable; (b) the formula or a reference to it; (c) a description of the pharmaceutical form and package details; (d) directions for sampling and testing or a reference to procedures; e) the qualitative and quantitative requirements, with the acceptance limits; (f) the storage conditions and any special handling precautions, where applicable; and (g) the shelf life.

Manufacturing Formula and Processing Instructions

Formally authorized Manufacturing Formula and Processing Instructions should exist for each product and batch size to be manufactured. They are often combined in one document.

4.14 The Manufacturing Formula should include (a) the name of the product, with a product reference code relating to its specification; (b) a description of the pharmaceutical form, strength of the product, and batch size; (c) a list of all starting materials to be used, with the amount of each, described using the designated name and a reference that is unique to that material; mention should be made of any substance that may disappear in the course of processing; and (d) a statement of the expected final yield, with the acceptable limits, and of relevant intermediate yields, where applicable.

4.15 The Processing Instructions should include (a) a statement of the processing location and the principal equipment to be used; (b) the methods, or reference to the methods, to be used for preparing the critical equipment (e.g., cleaning, assembling, calibrating, and sterilizing); (c) detailed stepwise processing instructions (e.g., checks on materials, pretreatments, sequence for adding materials, mixing times, and temperatures); (d) the instructions for any in-process controls with their limits; (e) where necessary, the requirements for bulk storage of the products, including the container, labeling, and special storage conditions where applicable; and (f) any special precautions to be observed.

Packaging Instructions

4.16 There should be formally authorized Packaging Instructions for each product, pack size, and type. These should normally include, or have a reference to, the following:

(a) Name of the product
(b) Description of its pharmaceutical form, and strength where applicable
(c) The pack size expressed in terms of the number, weight, or volume of the product in the final container
(d) A complete list of all the packaging materials required for a standard batch size, including quantities, sizes, and types, with the code or reference number relating to the specifications of each packaging material
(e) Where appropriate, an example or reproduction of the relevant printed packaging materials, and specimens indicating where to apply batch number references and shelf life of the product
(f) Special precautions to be observed, including a careful examination of the area and equipment in order to ascertain the line clearance before operations begin
(g) A description of the packaging operation, including any significant subsidiary operations, and equipment to be used
(h) Details of in-process controls with instructions for sampling and acceptance limits

Batch Processing Records

4.17 A Batch Processing Record should be kept for each batch processed. It should be based on the relevant parts of the currently approved Manufacturing Formula and Processing Instructions. The method of preparation of such records should be designed to avoid transcription errors. The record should carry the number of the batch being manufactured.

Before any processing begins, there should be recorded checks that the equipment and work station are clear of previous products, documents, or materials not required for the planned process, and that equipment is clean and suitable for use.

During processing, the following information should be recorded at the time each action is taken, and after completion, the record should be dated and signed in agreement by the person responsible for the processing operations:

(a) The name of the product
(b) Dates and times of commencement, of significant intermediate stages, and of completion of production
(c) Name of the person responsible for each stage of production
(d) Initials of the operator of different significant steps of production and where appropriate, of the person who checked each of these operations (e.g., weighing)
(e) The batch number and/or analytical control number as well as the quantities of each starting material actually weighed (including the batch number and amount of any recovered or reprocessed material added)
(f) Any relevant processing operation or event and major equipment used
(g) A record of the in-process controls, the initials of the person(s) carrying them out, and the results obtained
(h) The product yield obtained at different and pertinent stages of manufacture
(i) Notes on special problems, including details, with signed authorization for any deviation from the Manufacturing Formula and Processing Instructions

Batch Packaging Records

4.18 A Batch Packaging Record should be kept for each batch or part batch processed. It should be based on the relevant parts of the Packaging Instructions, and the method of preparation of such records should be designed to avoid transcription errors. The record should carry the batch number and the quantity of bulk product to be packed, as well as the batch number and the planned quantity of finished product that will be obtained.

Before any packaging operation begins, there should be recorded checks that the equipment and work station are clear of previous products, documents, or materials not required for the planned packaging operations, and that equipment is clean and suitable for use.

The following information should be entered at the time each action is taken, and after completion, the record should be dated and signed in agreement by the person(s) responsible for the packaging operations:

(a) The name of the product
(b) The date(s) and times of the packaging operations
(c) The name of the responsible person carrying out the packaging operation
(d) The initials of the operators of the different significant steps
(e) Records of checks for identity and conformity with the packaging instructions, including the results of in-process controls
(f) Details of the packaging operations carried out, including references to equipment and the packaging lines used
(g) Whenever possible, samples of printed packaging materials used, including specimens of the batch coding, expiry dating, and any additional overprinting
(h) Notes on any special problems or unusual events, including details, with signed authorization for any deviation from the Manufacturing Formula and Processing Instructions
(i) The quantities and reference number or identification of all printed packaging materials and bulk product issued, used, destroyed, or returned to stock, and the quantities of obtained product, in order to provide for an adequate reconciliation

Procedures and Records

Receipt

4.19 There should be written procedures and records for the receipt of each delivery of each starting and primary and printed packaging material.

4.20 The records of the receipts should include (a) the name of the material on the delivery note and the containers; (b) the "in-house" name and/or code of material (if different from a); (c) date of receipt; (d) supplier's name and if possible, manufacturer's name; (e) manufacturer's batch or reference number; (f) total quantity and number of containers received; (g) the batch number assigned after receipt; and (h) any relevant comment (e.g., state of the containers).

4.21 There should be written procedures for the internal labeling, quarantine, and storage of starting materials, packaging materials, and other materials, as appropriate.

Sampling

4.22 There should be written procedures for sampling, which include the person(s) authorized to take samples, the methods and equipment to be used, the amounts to be taken, and any precautions to be observed to avoid contamination of the material or any deterioration in its quality (see Chapter 6, item 13).

Testing

4.23 There should be written procedures for testing materials and products at different stages of manufacture, describing the methods and equipment to be used. The tests performed should be recorded (see Chapter 6, item 17).

Other

4.24 Written release and rejection procedures should be available for materials and products, and in particular, for the release for sale of the finished product by the Qualified Person(s) in accordance with the requirements of Article 51 of Directive 2001/83/EC

4.25 Records should be maintained of the distribution of each batch of a product in order to facilitate the recall of the batch if necessary.

4.26 There should be written procedures and the associated records of actions taken or conclusions reached, where appropriate, for

- Validation
- Equipment assembly and calibration
- Maintenance, cleaning, and sanitation
- Personnel matters, including training, clothing, and hygiene
- Environmental monitoring
- Pest control
- Complaints
- Recalls
- Returns

4.27 Clear operating procedures should be available for major items of manufacturing and test equipment.

4.28 Logbooks should be kept for major or critical equipment, recording, as appropriate, any validations, calibrations, maintenance, cleaning, or repair operations, including the dates and identity of people who carried these operations out.

4.29 Logbooks should also record in chronological order the use of major or critical equipment and the areas where the products have been processed.

Chapter 5: Production

Principle

Production operations must follow clearly defined procedures; they must comply with the principles of Good Manufacturing Practice in order to obtain products of the requisite quality and be in accordance with the relevant manufacturing and Marketing Authorizations.

General

5.1 Production should be performed and supervised by competent people.

5.2 All handling of materials and products, such as receipt and quarantine, sampling, storage, labeling, dispensing, processing, packaging, and distribution, should be done in accordance with written procedures or instructions and where necessary, recorded.

5.3 All incoming materials should be checked to ensure that the consignment corresponds to the order. Containers should be cleaned where necessary and labeled with the prescribed data.

5.4 Damage to containers and any other problem that might adversely affect the quality of a material should be investigated, recorded, and reported to the Quality Control Department.

5.5 Incoming materials and finished products should be physically or administratively quarantined immediately after receipt or processing until they have been released for use or distribution.

5.6 Intermediate and bulk products purchased as such should be handled on receipt as though they were starting materials.

5.7 All materials and products should be stored under the appropriate conditions established by the manufacturer and in an orderly fashion to permit batch segregation and stock rotation.

5.8 Checks on yields, and reconciliation of quantities, should be carried out as necessary to ensure that there are no discrepancies outside acceptable limits.

5.9 Operations on different products should not be carried out simultaneously or consecutively in the same room unless there is no risk of mix-up or cross-contamination.

5.10 At every stage of processing, products and materials should be protected from microbial and other contamination.

5.11 When working with dry materials and products, special precautions should be taken to prevent the generation and dissemination of dust. This applies particularly to the handling of highly active or sensitizing materials.

5.12 At all times during processing, all materials, bulk containers, major items of equipment, and where appropriate, rooms used should be labeled or otherwise identified with an indication of the product or material being processed, its strength (where applicable), and the batch number. Where

applicable, this indication should also mention the stage of production and batch number.

5.13 Labels applied to containers, equipment, or premises should be clear, unambiguous, and in the company's agreed format. It is often helpful, in addition to the wording on the labels, to use colors to indicate status (e.g., quarantined, accepted, rejected, clean, under processing, etc.).

5.14 Checks should be carried out to ensure that pipelines and other pieces of equipment used for the transportation of products from one area to another are connected in a correct manner.

5.15 Any deviation from instructions or procedures should be avoided as far as possible. If a deviation occurs, it should be approved in writing by a competent person, with the involvement of the Quality Control Department when appropriate.

5.16 Access to production premises should be restricted to authorized personnel.

5.17 Normally, the production of nonmedicinal products should be avoided in areas and with equipment destined for the production of medicinal products.

Prevention of Cross-Contamination in Production

5.18 Contamination of a starting material or of a product by another material or product must be avoided. This risk of accidental cross-contamination arises from the uncontrolled release of dust, gases, vapors, sprays, or organisms from materials and products in process, from residues on equipment, and from operators' clothing. The significance of this risk varies with the type of contaminant and of product being contaminated. Among the most hazardous contaminants are highly sensitizing materials, biological preparations containing living organisms, certain hormones, cytotoxics, and other highly active materials. Products in which contamination is likely to be most significant are those administered by injection and those given in large doses and/or over a long time.

5.19 Cross-contamination should be avoided by appropriate technical or organizational measures: for example, (a) production in segregated areas (required for products such as penicillins, live vaccines, live bacterial preparations, and some other biologicals) or by campaign (separation in time) followed by appropriate cleaning; (b) providing appropriate air locks and air extraction; (c) minimizing the risk of contamination caused by recirculation or reentry of untreated or insufficiently treated air; (d) keeping protective clothing inside areas where products with special risk of cross-contamination are processed; (e) using cleaning and decontamination procedures of known effectiveness, as ineffective cleaning of equipment is a common source of cross-contamination; (f) using "closed systems" of production; and (g) testing for residues and use of cleaning status labels on equipment.

5.20 Measures to prevent cross-contamination and their effectiveness should be checked periodically according to set procedures.

Validation

5.21 Validation studies should reinforce Good Manufacturing Practice and be conducted in accordance with defined procedures. Results and conclusions should be recorded.

5.22 When any new manufacturing formula or method of preparation is adopted, steps should be taken to demonstrate its suitability for routine processing. The defined process, using the materials and equipment specified, should be shown to yield a product consistently of the required quality.

5.23 Significant amendments to the manufacturing process, including any change in equipment or materials, that may affect product quality and/or the reproducibility of the process should be validated.

5.24 Processes and procedures should undergo periodic critical revalidation to ensure that they remain capable of achieving the intended results.

Starting Materials

5.25 The purchase of starting materials is an important operation, which should involve staff who have a particular and thorough knowledge of the suppliers.

5.26 Starting materials should only be purchased from approved suppliers named in the relevant specification and where possible, directly from the producer. It is recommended that the specifications established by the manufacturer for the starting materials be discussed with the suppliers. It is of benefit that all aspects of the production and control of the starting material in question, including handling, labeling, and packaging requirements, as well as complaints and rejection procedures, are discussed with the manufacturer and the supplier.

5.27 For each delivery, the containers should be checked for integrity of package and seal and for correspondence between the delivery note and the supplier's labels.

5.28 If one material delivery is made up of different batches, each batch must be considered as separate for sampling, testing, and release.

5.29 Starting materials in the storage area should be appropriately labeled (see Chapter 5, item 13). Labels should bear at least the following information:

- The designated name of the product and the internal code reference where applicable
- A batch number given at receipt
- Where appropriate, the status of the contents (e.g., in quarantine, on test, released, or rejected)
- Where appropriate, an expiry date or a date beyond which retesting is necessary

When fully computerized storage systems are used, not all the above information need necessarily be in a legible form on the label.

5.30 There should be appropriate procedures or measures to ensure the identity of the contents of each container of starting material. Bulk containers from which samples have been drawn should be identified (see Chapter 6, item 13).

5.31 Only starting materials that have been released by the Quality Control Department and are within their shelf life should be used.

5.32 Starting materials should only be dispensed by designated persons, following a written procedure, to ensure that

the correct materials are accurately weighed or measured into clean and properly labeled containers.

5.33 Each dispensed material and its weight or volume should be independently checked and the check recorded.

5.34 Materials dispensed for each batch should be kept together and conspicuously labeled as such.

Processing Operations: Intermediate and Bulk Products

5.35 Before any processing operation is started, steps should be taken to ensure that the work area and equipment are clean and free from any starting materials, products, product residues, or documents not required for the current operation.

5.36 Intermediate and bulk products should be kept under appropriate conditions.

5.37 Critical processes should be validated (see "Validation" in this chapter).

5.38 Any necessary in-process controls and environmental controls should be carried out and recorded.

5.39 Any significant deviation from the expected yield should be recorded and investigated.

Packaging Materials

5.40 The purchase, handling, and control of primary and printed packaging materials shall be accorded attention similar to that given to starting materials.

5.41 Particular attention should be paid to printed materials. They should be stored in adequately secure conditions to exclude unauthorized access. Cut labels and other loose printed materials should be stored and transported in separate closed containers so as to avoid mix-ups. Packaging materials should be issued for use only by authorized personnel following an approved and documented procedure.

5.42 Each delivery or batch of printed or primary packaging material should be given a specific reference number or identification mark.

5.43 Outdated or obsolete primary packaging material or printed packaging material should be destroyed and this disposal recorded.

Packaging Operations

5.44 When a program for the packaging operations is being set up, particular attention should be given to minimizing the risk of cross-contamination, mix-ups, or substitutions. Different products should not be packaged in close proximity unless there is physical segregation.

5.45 Before packaging operations are begun, steps should be taken to ensure that the work area, packaging lines, printing machines, and other equipment are clean and free from any products, materials, or documents previously used, if these are not required for the current operation. The line clearance should be performed according to an appropriate checklist.

5.46 The name and batch number of the product being handled should be displayed at each packaging station or line.

5.47 All products and packaging materials to be used should be checked on delivery to the packaging department for quantity, identity, and conformity with the Packaging Instructions.

5.48 Containers for filling should be clean before filling. Attention should be given to avoiding and removing any contaminants such as glass fragments and metal particles.

5.49 Normally, filling and sealing should be followed as quickly as possible by labeling. If this is not the case, appropriate procedures should be applied to ensure that no mix-ups or mislabeling can occur.

5.50 The correct performance of any printing operation (e.g., code numbers or expiry dates) to be done separately or in the course of the packaging should be checked and recorded. Attention should be paid to printing by hand, which should be rechecked at regular intervals.

5.51 Special care should be taken when using cut labels and when overprinting is carried out off-line. Rollfeed labels are normally preferable to cut labels in helping to avoid mix-ups.

5.52 Checks should be made to ensure that any electronic code readers, label counters, or similar devices are operating correctly.

5.53 Printed and embossed information on packaging materials should be distinct and resistant to fading or erasing.

5.54 Online control of the product during packaging should include at least checking the following:

(a) General appearance of the packages
(b) Whether the packages are complete
(c) Whether the correct products and packaging materials are used
(d) Whether any overprinting is correct
(e) Correct functioning of line monitors

Samples taken away from the packaging line should not be returned.

5.55 Products that have been involved in an unusual event should only be reintroduced into the process after special inspection, investigation, and approval by authorized personnel. A detailed record should be kept of this operation.

5.56 Any significant or unusual discrepancy observed during reconciliation of the amount of bulk product and printed packaging materials and the number of units produced should be investigated and satisfactorily accounted for before release.

5.57 Upon completion of a packaging operation, any unused batch-coded packaging materials should be destroyed and the destruction recorded. A documented procedure should be followed if uncoded printed materials are returned to stock.

Finished Products

5.58 Finished products should be held in quarantine until their final release under conditions established by the manufacturer.

5.59 The evaluation of finished products and documentation that is necessary before the release of product for sale is described in Chapter 6 (Quality Control).

5.60 After release, finished products should be stored as usable stock under conditions established by the manufacturer.

Rejected, Recovered, and Returned Materials

5.61 Rejected materials and products should be clearly marked as such and stored separately in restricted areas. They

should either be returned to the suppliers or where appropriate, reprocessed or destroyed. Whatever action is taken should be approved and recorded by authorized personnel.

5.62 The reprocessing of rejected products should be exceptional. It is only permitted if the quality of the final product is not affected, if the specifications are met, and if it is done in accordance with a defined and authorized procedure after evaluation of the risks involved. A record should be kept of the reprocessing.

5.63 The recovery of all or part of earlier batches that conform to the required quality by incorporation into a batch of the same product at a defined stage of manufacture should be authorized beforehand. This recovery should be carried out in accordance with a defined procedure after evaluation of the risks involved, including any possible effect on shelf life. The recovery should be recorded.

5.64 The need for additional testing of any finished product that has been reprocessed, or into which a recovered product has been incorporated, should be considered by the Quality Control Department.

5.65 Products returned from the market and that have left the control of the manufacturer should be destroyed unless without doubt their quality is satisfactory; they may be considered for resale, relabeling, or recovery in a subsequent batch only after they have been critically assessed by the Quality Control Department in accordance with a written procedure. The nature of the product, any special storage conditions it requires, its condition and history, and the time elapsed since it was issued should all be taken into account in this assessment. Where any doubt arises over the quality of the product, it should not be considered suitable for reissue or reuse, although basic chemical reprocessing to recover active ingredient may be possible. Any action taken should be appropriately recorded.

Chapter 6: Quality Control

Principle

Quality Control is concerned with sampling, specifications, and testing as well as the organization, documentation, and release procedures that ensure that the necessary and relevant tests are carried out and that materials are not released for use, or products released for sale or supply, until their quality has been judged satisfactory. Quality Control is not confined to laboratory operations but must be involved in all decisions that may concern the quality of the product. The independence of Quality Control from Production is considered fundamental to the satisfactory operation of Quality Control (see also Chapter 1).

General

6.1 Each holder of a manufacturing authorization should have a Quality Control Department. This department should be independent of other departments and under the authority of a person with appropriate qualifications and experience, who has one or several control laboratories at his or her disposal. Adequate resources must be available to ensure that all the Quality Control arrangements are effectively and reliably carried out.

6.2 The principal duties of the head of Quality Control are summarized in Chapter 2. The Quality Control Department as a whole will also have other duties, such as to establish, validate, and implement all Quality Control procedures, keep the reference samples of materials and products, ensure the correct labeling of containers of materials and products, ensure the monitoring of the stability of the products, participate in the investigation of complaints related to the quality of the product, and so forth. All these operations should be carried out in accordance with written procedures and where necessary, recorded.

6.3 Finished product assessment should embrace all relevant factors, including production conditions, results of in-process testing, a review of manufacturing (including packaging) documentation, compliance with Finished Product Specification, and examination of the final finished pack.

6.4 Quality Control personnel should have access to production areas for sampling and investigation as appropriate.

Good Quality Control Laboratory Practice

6.5 Control laboratory premises and equipment should meet the general and specific requirements for Quality Control areas given in Chapter 3.

6.6 The personnel, premises, and equipment in the laboratories should be appropriate to the tasks imposed by the nature and the scale of the manufacturing operations. The use of outside laboratories, in conformity with the principles detailed in Chapter 7, Contract Analysis, can be accepted for particular reasons, but this should be stated in the Quality Control records.

Documentation

6.7 Laboratory documentation should follow the principles given in Chapter 4. An important part of this documentation deals with Quality Control, and the following details should be readily available to the Quality Control Department:

- Specifications
- Sampling procedures
- testing procedures and records (including analytical worksheets and/or laboratory notebooks)
- Analytical reports and/or certificates
- Data from environmental monitoring, where required
- Validation records of test methods, where applicable
- Procedures for and records of the calibration of instruments and maintenance of equipment

6.8 Any Quality Control documentation relating to a batch record should be retained for 1 year after the expiry date of the batch and at least 5 years after the certification referred to in Article 51(3) of Directive 2001/83/EC.

6.9 For some kinds of data (e.g., analytical test results, yields, and environmental controls), it is recommended that records are kept in a manner permitting trend evaluation.

6.10 In addition to the information that is part of the batch record, other original data such as laboratory notebooks and/or records should be retained and readily available.

Sampling

6.11 The sample taking should be done in accordance with approved written procedures that describe

- The method of sampling
- The equipment to be used
- The amount of the sample to be taken
- Instructions for any required subdivision of the sample
- The type and condition of the sample container to be used
- The identification of containers sampled
- Any special precautions to be observed, especially with regard to the sampling of sterile or noxious materials
- The storage conditions
- Instructions for the cleaning and storage of sampling equipment

6.12 Reference samples should be representative of the batch of materials or products from which they are taken. Other samples may also be taken to monitor the most stressed part of a process (e.g., the beginning or end of a process).

6.13 Sample containers should bear a label indicating the contents, with the batch number, the date of sampling, and the containers from which samples have been drawn.

6.14 Further guidance on reference and retention samples is given in Annex 19.

Testing

6.15 Analytical methods should be validated. All testing operations described in the Marketing Authorization should be carried out according to the approved methods.

6.16 The results obtained should be recorded and checked to make sure that they are consistent with each other. Any calculations should be critically examined.

6.17 The tests performed should be recorded, and the records should include at least the following data: (a) name of the material or product and where applicable, dosage form; (b) batch number and where appropriate, the manufacturer and/or supplier; (c) references to the relevant specifications and testing procedures; (d) test results, including observations and calculations, and reference to any certificates of analysis; (e) dates of testing; (f) initials of the persons who performed the testing; (g) initials of the persons who verified the testing and the calculations, where appropriate; and (h) a clear statement of release or rejection (or other status decision) and the dated signature of the designated responsible person.

6.18 All the in-process controls, including those made in the production area by production personnel, should be performed according to methods approved by Quality Control and the results recorded.

6.19 Special attention should be given to the quality of laboratory reagents, volumetric glassware and solutions, reference standards, and culture media. They should be prepared in accordance with written procedures.

6.20 Laboratory reagents intended for prolonged use should be marked with the preparation date and the signature of the person who prepared them. The expiry date of unstable reagents and culture media should be indicated on the label, together with specific storage conditions. In addition, for volumetric solutions, the last date of standardization and the last current factor should be indicated.

6.21 Where necessary, the date of receipt of any substance used for testing operations (e.g., reagents and reference standards) should be indicated on the container. Instructions for use and storage should be followed. In certain cases, it may be necessary to carry out an identification test and/or other testing of reagent materials upon receipt or before use.

6.22 Animals used for testing components, materials or products should, where appropriate, be quarantined before use. They should be maintained and controlled in a manner that ensures their suitability for the intended use. They should be identified, and adequate records should be maintained, showing the history of their use.

Ongoing Stability Program

6.23 After marketing, the stability of the medicinal product should be monitored according to a continuous appropriate program that will permit the detection of any stability issue (e.g., changes in levels of impurities or dissolution profile) associated with the formulation in the marketed package.

6.24 The purpose of the ongoing stability program is to monitor the product over its shelf life and to determine that the product remains, and can be expected to remain, within specifications under the labeled storage conditions.

6.25 This mainly applies to the medicinal product in the package in which it is sold, but consideration should also be given to the inclusion in the program of bulk product. For example, when the bulk product is stored for a long period before being packaged and/or shipped from a manufacturing site to a packaging site, the impact on the stability of the packaged product should be evaluated and studied under ambient conditions. In addition, consideration should be given to intermediates that are stored and used over prolonged periods. Stability studies on reconstituted product are performed during product development and need not be monitored on an ongoing basis. However, when relevant, the stability of reconstituted product can also be monitored.

6.26 The ongoing stability program should be described in a written protocol following the general rules of Chapter 4, and the results should be formalized as a report. The equipment used for the ongoing stability program (stability chambers, among others) should be qualified and maintained following the general rules of Chapter 3 and Annex 15.

6.27 The protocol for an ongoing stability program should extend to the end of the shelf-life period and should include, but not be limited to, the following parameters:

- Number of batch(es) per strength and different batch sizes, if applicable
- Relevant physical, chemical, microbiological, and biological test methods

- Acceptance criteria
- Reference to test methods
- Description of the container closure system(s)
- Testing intervals (time points)
- Description of the conditions of storage (standardized ICH conditions for long-term testing, consistent with the product labeling, should be used)
- Other applicable parameters specific to the medicinal product

6.28 The protocol for the ongoing stability program can be different from that of the initial long-term stability study as submitted in the Marketing Authorization dossier provided that this is justified and documented in the protocol (e.g., the frequency of testing, or when updating to ICH recommendations).

6.29 The number of batches and frequency of testing should provide a sufficient amount of data to allow for trend analysis. Unless otherwise justified, at least one batch per year of product manufactured in every strength and every primary packaging type, if relevant, should be included in the stability program (unless none are produced during that year). For products where ongoing stability monitoring would normally require testing using animals, and no appropriate alternative, validated techniques are available, the frequency of testing may take account of a risk–benefit approach. The principle of bracketing and matrixing designs may be applied if scientifically justified in the protocol.

6.30 In certain situations, additional batches should be included in the ongoing stability program. For example, an ongoing stability study should be conducted after any significant change or significant deviation to the process or package. Any reworking, reprocessing, or recovery operation should also be considered for inclusion.

6.31 The results of ongoing stability studies should be made available to key personnel and in particular, to the Qualified Person(s). Where ongoing stability studies are carried out at a site other than the site of manufacture of the bulk or finished product, there should be a written agreement between the parties concerned. The results of ongoing stability studies should be available at the site of manufacture for review by the competent authority.

6.32 Out of specification or significant atypical trends should be investigated. Any confirmed out of specification result, or significant negative trend, should be reported to the relevant competent authorities. The possible impact on batches on the market should be considered in accordance with Chapter 8 of the GMP guide and in consultation with the relevant competent authorities.

6.33. A summary of all the data generated, including any interim conclusions on the program, should be written and maintained. This summary should be subjected to periodic review.

Chapter 7: Contract Manufacture and Analysis

Principle

Contract manufacture and analysis must be correctly defined, agreed, and controlled in order to avoid misunderstandings, which could result in a product or work of unsatisfactory quality. There must be a written contract between the Contract Giver and the Contract Acceptor, which clearly establishes the duties of each party. The contract must clearly state the way in which the Qualified Person releasing each batch of product for sale exercises his or her full responsibility.

Note: This chapter deals with the responsibilities of manufacturers toward the competent authorities of the member states with respect to the granting of marketing and manufacturing authorizations. It is not intended in any way to affect the respective liability of Contract Acceptors and Contract Givers to consumers; this is governed by other provisions of Community and national law.

General

7.1 There should be a written contract covering the manufacture and/or analysis arranged under contract and any technical arrangements made in connection with it.

7.2 All arrangements for contract manufacture and analysis, including any proposed changes in technical or other arrangements, should be in accordance with the Marketing Authorization for the product concerned.

The Contract Giver

7.3 The Contract Giver is responsible for assessing the competence of the Contract Acceptor to carry out successfully the work required and for ensuring by means of the contract that the principles and guidelines of GMP as interpreted in this guide are followed.

7.4 The Contract Giver should provide the Contract Acceptor with all the information necessary to carry out the contracted operations correctly in accordance with the Marketing Authorization and any other legal requirements. The Contract Giver should ensure that the Contract Acceptor is fully aware of any problems associated with the product or the work that might pose a hazard to his or her premises, equipment, personnel, other materials, or other products.

7.5 The Contract Giver should ensure that all processed products and materials delivered to him or her by the Contract Acceptor comply with their specifications or that the products have been released by a Qualified Person.

The Contract Acceptor

7.6 The Contract Acceptor must have adequate premises and equipment, knowledge and experience, and competent personnel to carry out satisfactorily the work ordered by the Contract Giver. Contract manufacture may be undertaken only by a manufacturer who is the holder of a manufacturing authorization.

7.7 The Contract Acceptor should ensure that all products or materials delivered to him or her are suitable for their intended purpose.

7.8 The Contract Acceptor should not pass to a third party any of the work entrusted to him or her under the contract without the Contract Giver's prior evaluation and approval of the arrangements. Arrangements made between the Contract Acceptor and any third party should ensure that the manufacturing and analytical information is made available in the same way as between the original Contract Giver and Contract Acceptor.

7.9 The Contract Acceptor should refrain from any activity that may adversely affect the quality of the product manufactured and/or analyzed for the Contract Giver.

The Contract

7.10 A contract should be drawn up between the Contract Giver and the Contract Acceptor, which specifies their respective responsibilities relating to the manufacture and control of the product. Technical aspects of the contract should be drawn up by competent persons suitably knowledgeable in pharmaceutical technology, analysis, and Good Manufacturing Practice. All arrangements for manufacture and analysis must be in accordance with the Marketing Authorization and agreed by both parties.

7.11 The contract should specify the way in which the Qualified Person releasing the batch for sale ensures that each batch has been manufactured and checked for compliance with the requirements of Marketing Authorization.

7.12 The contract should describe clearly who is responsible for purchasing materials, testing and releasing materials, undertaking production and Quality Controls, including in-process controls, and who has responsibility for sampling and analysis. In the case of contract analysis, the contract should state whether or not the Contract Acceptor should take samples at the premises of the manufacturer.

7.13 Manufacturing, analytical, and distribution records and reference samples should be kept by, or be available to, the Contract Giver. Any records relevant to assessing the quality of a product in the event of complaints or a suspected defect must be accessible and specified in the defect/recall procedures of the Contract Giver.

7.14 The contract should permit the Contract Giver to visit the facilities of the Contract Acceptor.

7.15 In the case of contract analysis, the Contract Acceptor should understand that he or she is subject to inspection by the competent authorities.

Chapter 8: Complaints and Product Recall

Principle

All complaints and other information concerning potentially defective products must be reviewed carefully according to written procedures. In order to provide for all contingencies, and in accordance with Article 117 of Directive 2001/83/EC and Article 84 of Directive 2001/82/EC, a system should be designed to recall, if necessary, promptly and effectively products known or suspected to be defective from the market.

Complaints

8.1 A person should be designated responsible for handling the complaints and deciding the measures to be taken, together with sufficient supporting staff to assist him or her. If this person is not the Qualified Person, the latter should be made aware of any complaint, investigation, or recall.

8.2 There should be written procedures describing the action to be taken, including the need to consider a recall, in the case of a complaint concerning a possible product defect.

8.3 Any complaint concerning a product defect should be recorded with all the original details and thoroughly investigated. The person responsible for Quality Control should normally be involved in the study of such problems.

8.4 If a product defect is discovered or suspected in a batch, consideration should be given to checking other batches in order to determine whether they are also affected. In particular, other batches that may contain reworks of the defective batch should be investigated.

8.5 All the decisions and measures taken as a result of a complaint should be recorded and referenced to the corresponding batch records.

8.6 Complaints records should be reviewed regularly for any indication of specific or recurring problems requiring attention and possibly the recall of marketed products.

8.7 Special attention should be given to establishing whether a complaint was caused because of counterfeiting.

8.8 The competent authorities should be informed if a manufacturer is considering action following possibly faulty manufacture, product deterioration, detection of counterfeiting, or any other serious quality problems with a product.

Recalls

8.9 A person should be designated as responsible for the execution and coordination of recalls and should be supported by sufficient staff to handle all the aspects of the recalls with the appropriate degree of urgency. This responsible person should normally be independent of the sales and marketing organization. If this person is not the Qualified Person, the latter should be made aware of any recall operation.

8.10 There should be established written procedures, regularly checked and updated when necessary, in order to organize any recall activity.

8.11 Recall operations should be capable of being initiated promptly and at any time.

8.12 All competent authorities of all countries to which products may have been distributed should be informed promptly if products are intended to be recalled because they are, or are suspected of being, defective.

8.13 The distribution records should be readily available to the person(s) responsible for recalls and should contain sufficient information on wholesalers and directly supplied customers (with addresses, phone and/or fax numbers inside and outside working hours, batches, and amounts delivered), including those for exported products and medical samples.

8.14 Recalled products should be identified and stored separately in a secure area while awaiting a decision on their fate.

8.15 The progress of the recall process should be recorded and a final report issued, including a reconciliation between the delivered and recovered quantities of the products.

8.16 The effectiveness of the arrangements for recalls should be evaluated regularly.

14 Impurities: Guideline for Residual Solvents

I. INTRODUCTION

The objective of this guideline is to recommend acceptable amounts for residual solvents in pharmaceuticals for the safety of the patient. The guideline recommends the use of less toxic solvents and describes levels considered to be toxicologically acceptable for some residual solvents.

Residual solvents in pharmaceuticals are defined here as organic volatile chemicals that are used or produced in the manufacture of drug substances or excipients, or in the preparation of drug products. The solvents are not completely removed by practical manufacturing techniques. Appropriate selection of the solvent for the synthesis of a drug substance may enhance the yield or determine characteristics such as crystal form, purity, and solubility. Therefore, the solvent may sometimes be a critical parameter in the synthetic process. This guideline does not address solvents deliberately used as excipients, nor does it address solvates. However, the content of solvents in such products should be evaluated and justified.

Since there is no therapeutic benefit from residual solvents, all residual solvents should be removed to the greatest extent possible to meet product specifications, good manufacturing practices, or other quality-based requirements. Drug products should contain no higher levels of residual solvents than can be supported by safety data. Some solvents that are known to cause unacceptable toxicity (Class 1, Table 14.1) should be avoided in the production of drug substances, excipients, or drug products unless their use can be strongly justified in a risk–benefit assessment. Some solvents associated with less severe toxicity (Class 2, Table 14.2) should be limited in order to protect patients from potential adverse effects. Ideally, less toxic solvents (Class 3, Table 14.3) should be used where practical. The complete list of solvents included in this guideline is given in Appendix 1.
The lists are not exhaustive, and other solvents can be used and later added to the lists. Recommended limits of Class 1 and 2 solvents or classification of solvents may change as new safety data become available. Supporting safety data in a marketing application for a new drug product containing a new solvent may be based on concepts in this guideline or the concept of qualification of impurities as expressed in the guideline for drug substance (Q3A, *Impurities in New Drug Substances*) or drug product (Q3B, *Impurities in New Drug Products*) or all three guidelines.

II. SCOPE OF THE GUIDELINE

Residual solvents in drug substances, excipients, and drug products are within the scope of this guideline. Therefore, testing should be performed for residual solvents when production or purification processes are known to result in the presence of such solvents. It is only necessary to test for solvents that are used or produced in the manufacture or purification of drug substances, excipients, or drug product. Although manufacturers may choose to test the drug product, a cumulative method may be used to calculate the residual solvent levels in the drug product from the levels in the ingredients used to produce the drug product. If the calculation results in a level equal to or below that recommended in this guideline, no testing of the drug product for residual solvents need be considered. If, however, the calculated level is above the recommended level, the drug product should be tested to ascertain whether the formulation process has reduced the relevant solvent to an acceptable level. Drug product should also be tested if a solvent is used during its manufacture.

This guideline does not apply to potential new drug substances, excipients, or drug products used during the clinical research stages of development, nor does it apply to existing marketed drug products.

The guideline applies to all dosage forms and routes of administration. Higher levels of residual solvents may be acceptable in certain cases, such as short term (30 days or less) or topical application. Justification for these levels should be made on a case-by-case basis.

See Appendix 2 for additional background information related to residual solvents.

III. GENERAL PRINCIPLES

A. Classification of Residual Solvents by Risk Assessment

The term *tolerable daily intake* (TDI) is used by the International Programme on Chemical Safety (IPCS) to describe exposure limits of toxic chemicals, and *acceptable daily intake* (ADI) is used by the World Health Organization (WHO) and other national and international health authorities and institutes. The new term *permitted daily exposure* (PDE) is defined in the present guideline as a pharmaceutically acceptable intake of residual solvents to avoid confusion due to differing values for ADIs of the same substance.

Residual solvents assessed in this guideline are listed in Appendix 1 by common names and structures. They were

TABLE 14.1
Class 1 Solvents in Pharmaceutical Products (Solvents That Should Be Avoided)

Solvent	Concentration limit (ppm)	Concern
Benzene	2	Carcinogen
Carbon tetrachloride	4	Toxic and environmental hazard
1,2-Dichloroethane	5	Toxic
1,1-Dichloroethene	8	Toxic
1,1,1-Trichloroethane	1500	Environmental hazard

TABLE 14.2
Class 2 Solvents in Pharmaceutical Products

Solvent	PDE (mg/day)	Concentration limit (ppm)
Acetonitrile	4.1	410
Chlorobenzene	3.6	360
Chloroform	0.6	60
Cyclohexane	38.8	3880
1,2-Dichloroethene	18.7	1870
Dichloromethane	6.0	600
1,2-Dimethoxyethane	1.0	100
N,*N*-Dimethylacetamide	10.9	1090
N,*N*-Dimethylformamide	8.8	880
1,4-Dioxane	3.8	380
2-Ethoxyethanol	1.6	160
Ethyleneglycol	6.2	620
Formamide	2.2	220
Hexane	2.9	290
Methanol	30.0	3000
2-Methoxyethanol	0.5	50
Methylbutyl ketone	0.5	50
Methylcyclohexane	11.8	1180
N-Methylpyrrolidone	48.4	4840
Nitromethane	0.5	50
Pyridine	2.0	200
Sulfolane	1.6	160
Tetralin	1.0	100
Toluene	8.9	890
1,1,2-Trichloroethene	0.8	80
Xylene[a]	21.7	2170

[a] Usually 60% *m*-xylene, 14% *p*-xylene, and 9% *o*-xylene with 17% ethyl benzene.

TABLE 14.3
Class 3 Solvents That Should Be Limited by GMP or Other Quality-Based Requirements

Acetic acid	**Heptane**
Acetone	Isobutyl acetate
Anisole	Isopropyl acetate
1-Butanol	Methyl acetate
2-Butanol	3-Methyl-1-butanol
Butyl acetate	Methylethyl ketone
tert-Butylmethyl ether	Methylisobutyl ketone
Cumene	2-Methyl-1-propanol
Dimethyl sulfoxide	Pentane
Ethanol	1-Pentanol
Ethyl acetate	1-Propanol
Ethyl ether	2-Propanol
Ethyl formate	Propyl acetate
Formic acid	Tetrahydrofuran

evaluated for their possible risk to human health and placed into one of three classes as follows:

Class 1 solvents: solvents to be avoided: Known human carcinogens, strongly suspected human carcinogens, and environmental hazards.

Class 2 solvents: solvents to be limited: Nongenotoxic animal carcinogens or possible causative agents of other irreversible toxicity such as neurotoxicity or teratogenicity. Solvents suspected of other significant but reversible toxicity.

Class 3 solvents: solvents with low toxic potential: Solvents with low toxic potential to humans; no health-based exposure limit is needed. Class 3 solvents have PDEs of 50 mg or more per day.

B. Methods for Establishing Exposure Limits

The method used to establish permitted daily exposures for residual solvents is presented in Appendix 3. Summaries of the toxicity data that were used to establish limits are published in *Pharmeuropa*, Vol. 9, No. 1, Supplement, April 1997.

C. Options for Describing Limits of Class 2 Solvents

Two options are available when setting limits for Class 2 solvents.

Option 1: The concentration limits in parts per million stated in Table 14.2 can be used. They were calculated using Equation 14.1 by assuming a product mass of 10 g administered daily.

$$\text{Concentration (ppm)} = \frac{1000 \times \text{PDE}}{\text{dose}} \qquad (14.1)$$

Here, PDE is given in terms of milligrams per day, and dose is given in grams per day.

These limits are considered acceptable for all substances, excipients, or products. Therefore, this option may be applied if the daily dose is not known or fixed. If all excipients and drug substances in a formulation meet the limits given in Option 1, then these components may be used in any proportion. No

further calculation is necessary provided the daily dose does not exceed 10 g. Products that are administered in doses greater than 10 g/day should be considered under Option 2.

Option 2: It is not considered necessary for each component of the drug product to comply with the limits given in Option 1. The PDE in terms of milligrams per day as stated in Table 14.2 can be used with the known maximum daily dose and Equation 14.1 to determine the concentration of residual solvent allowed in the drug product. Such limits are considered acceptable provided that it has been demonstrated that the residual solvent has been reduced to the practical minimum. The limits should be realistic in relation to analytical precision, manufacturing capability, and reasonable variation in the manufacturing process, and the limits should reflect contemporary manufacturing standards.

Option 2 may be applied by adding the amounts of a residual solvent present in each of the components of the drug product. The sum of the amounts of solvent per day should be less than that given by the PDE.

Consider an example of the use of Option 1 and Option 2 applied to acetonitrile in a drug product. The permitted daily exposure to acetonitrile is 4.1 mg/day; thus, the Option 1 limit is 410 ppm. The maximum administered daily mass of a drug product is 5.0 g, and the drug product contains two excipients. The composition of the drug product and the calculated maximum content of residual acetonitrile are given in the following table.

Component	Amount in formulation (g)	Acetonitrile content (ppm)	Daily exposure (mg)
Drug substance	0.3	800	0.24
Excipient 1	0.9	400	0.36
Excipient 2	3.8	800	3.04
Drug product	5.0	728	3.64

Excipient 1 meets the Option 1 limit, but the drug substance, excipient 2, and drug product do not meet the Option 1 limit. Nevertheless, the product meets the Option 2 limit of 4.1 mg/day and thus conforms to the recommendations in this guideline.

Consider another example using acetonitrile as residual solvent. The maximum administered daily mass of a drug product is 5.0 g, and the drug product contains two excipients. The composition of the drug product and the calculated maximum content of residual acetonitrile are given in the following table.

Component	Amount in formulation (g)	Acetonitrile content (ppm)	Daily exposure (mg)
Drug substance	0.3	800	0.24
Excipient 1	0.9	2000	1.80
Excipient 2	3.8	800	3.04
Drug Product	5.0	1016	5.08

In this example, the product meets neither the Option 1 nor the Option 2 limit according to this summation. The manufacturer could test the drug product to determine whether the formulation process reduced the level of acetonitrile. If the level of acetonitrile was not reduced during formulation to the allowed limit, then the manufacturer of the drug product should take other steps to reduce the amount of acetonitrile in the drug product. If all these steps fail to reduce the level of residual solvent, in exceptional cases, the manufacturer could provide a summary of efforts made to reduce the solvent level to meet the guideline value and provide a risk–benefit analysis to support allowing the product to be used with residual solvent at a higher level.

D. Analytical Procedures

Residual solvents are typically determined using chromatographic techniques such as gas chromatography. Any harmonized procedures for determining levels of residual solvents as described in the pharmacopoeias should be used if feasible. Otherwise, manufacturers would be free to select the most appropriate validated analytical procedure for a particular application. If only Class 3 solvents are present, a nonspecific method such as loss on drying may be used.

Validation of methods for residual solvents should conform to International Conference on Harmonisation (ICH) guidelines, *Text on Validation of Analytical Procedures* and *Extension of the ICH Text on Validation of Analytical Procedures.*

E. Reporting Levels of Residual Solvents

Manufacturers of pharmaceutical products need certain information about the content of residual solvents in excipients or drug substances in order to meet the criteria of this guideline. The following statements are given as acceptable examples of the information that could be provided from a supplier of excipients or drug substances to a pharmaceutical manufacturer. The supplier might choose one of the following as appropriate:

- Only Class 3 solvents are likely to be present. Loss on drying is less than 0.5%.
- Only Class 2 solvents X, Y, … are likely to be present. All are below the Option 1 limit. (Here, the supplier would name the Class 2 solvents represented by X, Y, ….)
- Only Class 2 solvents X, Y, … and Class 3 solvents are likely to be present. Residual Class 2 solvents are below the Option 1 limit, and residual Class 3 solvents are below 0.5%.

If Class 1 solvents are likely to be present, they should be identified and quantified.

"Likely to be present" refers to the solvent used in the final manufacturing step and to solvents that are used in earlier

TABLE 14.4
Solvents for Which No Adequate Toxicological Data Were Found

1,1-Diethoxypropane	Methylisopropyl ketone
1,1-Dimethoxymethane	Methyltetrahydrofuran
2,2-Dimethoxypropane	Petroleum ether
Isooctane	Trichloroacetic acid
Isopropyl ether	Trifluoroacetic acid

manufacturing steps and not removed consistently by a validated process.

If solvents of Class 2 or Class 3 are present at greater than their Option 1 limits or 0.5%, respectively, they should be identified and quantified (Table 14.4).

IV. LIMITS OF RESIDUAL SOLVENTS

A. Solvents to Be Avoided

Solvents in Class 1 should not be employed in the manufacture of drug substances, excipients, and drug products because of their unacceptable toxicity or their deleterious environmental effect. However, if their use is unavoidable in order to produce a drug product with a significant therapeutic advance, then their levels should be restricted as shown in Table 14.1 unless otherwise justified. 1,1,1-Trichloroethane is included in Table 14.1 because it is an environmental hazard. The stated limit of 1500 ppm is based on a review of the safety data.

B. Solvents to Be Limited

Solvents in Table 14.2 should be limited in pharmaceutical products because of their inherent toxicity. PDEs are given to the nearest 0.1 mg/day, and concentrations are given to the nearest 10 ppm. The stated values do not reflect the necessary analytical precision of determination. Precision should be determined as part of the validation of the method.

C. Solvents with Low Toxic Potential

Solvents in Class 3 (shown in Table 14.3) may be regarded as less toxic and of lower risk to human health. Class 3 includes no solvent known as a human health hazard at levels normally accepted in pharmaceuticals. However, there are no long-term toxicity or carcinogenicity studies for many of the solvents in Class 3. Available data indicate that they are less toxic in acute or short-term studies and negative in genotoxicity studies. It is considered that amounts of these residual solvents of 50 mg/day or less (corresponding to 5000 ppm or 0.5% under Option 1) would be acceptable without justification. Higher amounts may also be acceptable provided they are realistic in relation to manufacturing capability and good manufacturing practice.

D. Solvents for Which No Adequate Toxicological Data Were Found

The solvents shown in Table 14.4 may also be of interest to manufacturers of excipients, drug substances, or drug products. However, no adequate toxicological data on which to base a PDE was found. Manufacturers should supply justification for residual levels of these solvents in pharmaceutical products.

GLOSSARY

Genotoxic Carcinogens: Carcinogens that produce cancer by affecting genes or chromosomes.

LOEL: Abbreviation for lowest-observed effect level.

Lowest-Observed Effect Level: The lowest dose of substance in a study or group of studies that produces biologically significant increases in frequency or severity of any effects in the exposed humans or animals.

Modifying Factor: A factor determined by professional judgment of a toxicologist and applied to bioassay data to relate that data safely to humans.

Neurotoxicity: The ability of a substance to cause adverse effects on the nervous system.

NOEL: Abbreviation for no-observed-effect level.

No-Observed-Effect Level: The highest dose of a substance at which there are no biologically significant increases in frequency or severity of any effects in the exposed humans or animals.

PDE: Abbreviation for permitted daily exposure.

Permitted Daily Exposure: The maximum acceptable intake per day of residual solvent in pharmaceutical products.

Reversible Toxicity: The occurrence of harmful effects that are caused by a substance and which disappear after exposure to the substance ends.

Strongly Suspected Human Carcinogen: A substance for which there is no epidemiological evidence of carcinogenesis, but there are positive genotoxicity data and clear evidence of carcinogenesis in rodents.

Teratogenicity: The occurrence of structural malformations in a developing fetus when a substance is administered during pregnancy.

APPENDIX 1 LIST OF SOLVENTS INCLUDED IN THE GUIDELINE

Solvent	Other names	Structure	Class
Acetic acid	Ethanoic acid	CH_3COOH	Class 3
Acetone	2-Propanone Propan-2-one	CH_3COCH_3	Class 3
Acetonitrile		CH_3CN	Class 2
Anisole	Methoxybenzene		Class 3
Benzene	Benzol		Class 1
1-Butanol	*n*-Butyl alcohol Butan-1-ol	$CH_3(CH_2)_3OH$	Class 3
2-Butanol	*sec*-Butyl alcohol Butan-2-ol	$CH_3CH_2CH(OH)CH_3$	Class 3
Butyl acetate	Acetic acid butyl ester	$CH_3COO(CH_2)_3CH_3$	Class 3
tert-Butylmethyl ether	2-Methoxy-2-methyl-propane	$(CH_3)_3COCH_3$	Class 3
Carbon tetrachloride	Tetrachloromethane	CCl_4	Class 1
Chlorobenzene			Class 2
Chloroform	Trichloromethane	$CHCl_3$	Class 2
Cumene	Isopropylbenzene (1-Methyl) ethylbenzene		Class 3
Cyclohexane	Hexamethylene		Class 2
1,2-Dichloroethane	*sym*-Dichloroethane Ethylene dichloride Ethylene chloride	CH_2ClCH_2Cl	Class 1
1,1-Dichloroethene	1,1-Dichloroethylene Vinylidene chloride	$H_2C=CCl_2$	Class 1
1,2-Dichloroethene	1,2-Dichloroethylene Acetylene dichloride	$ClHC=CHCl$	Class 2
Dichloromethane	Methylene chloride	CH_2Cl_2	Class 2
1,2-Dimethoxyethane	Ethyleneglycol dimethyl ether Monoglyme Dimethyl Cellosolve	$H3COCH_2CH_2OCH_3$	Class 2
N,*N*-Dimethylacetamide	DMA	$CH_3CON(CH_3)_2$	Class 2
N,*N*-Dimethylformamide	DMF	$HCON(CH_3)_2$	Class 2
Dimethyl sulfoxide	Methylsulfinylmethane Methyl sulfoxide DMSO	$(CH_3)_2SO$	Class 3
1,4-Dioxane	*p*-Dioxane [1,4]Dioxane		Class 2
Ethanol	Ethyl alcohol	CH_3CH_2OH	Class 3
2-Ethoxyethanol	Cellosolve	$CH_3CH_2OCH_2CH_2OH$	Class 2
Ethyl acetate	Acetic acid ethyl ester	$CH_3COOCH_2CH_3$	Class 3
Ethyleneglycol	1,2-Dihydroxyethane 1,2-Ethanediol	$HOCH_2CH_2OH$	Class 2
Ethyl ether	Diethyl ether Ethoxyethane 1,1′-Oxybisethane	$CH_3CH_2OCH_2CH_3$	Class 3
Ethyl formate	Formic acid ethyl ester	$HCOOCH_2CH_3$	Class 3
Formamide	Methanamide	$HCONH_2$	Class 2
Formic acid		$HCOOH$	Class 3

(*Continued*)

Solvent	Other names	Structure	Class
Heptane	*n*-Heptane	$CH_3(CH_2)_5CH_3$	Class 3
Hexane	*n*-Hexane	$CH_3(CH_2)_4CH_3$	Class 2
Isobutyl acetate	Acetic acid isobutyl ester	$CH_3COOCH_2CH(CH_3)_2$	Class 3
Isopropyl acetate	Acetic acid isopropyl ester	$CH_3COOCH(CH_3)_2$	Class 3
Methanol	Methyl alcohol	CH_3OH	Class 2
2-Methoxyethanol	Methyl Cellosolve	$CH_3OCH_2CH_2OH$	Class 2
Methyl acetate	Acetic acid methyl ester	CH_3COOCH_3	Class 3
3-Methyl-1-butanol	Isoamyl alcohol Isopentyl alcohol 3-Methylbutan-1-ol	$(CH_3)_2CHCH_2CH_2OH$	Class 3
Methylbutyl ketone	2-Hexanone Hexan-2-one	$CH_3(CH_2)_3COCH_3$	Class 2
Methylcyclohexane	Cyclohexylmethane		Class 2
Methylethyl ketone	2-Butanone MEK Butan-2-one	$CH_3CH_2COCH_3$	Class 3
Methylisobutyl ketone	4-Methylpentan-2-one 4-Methyl-2-pentanone MIBK	$CH_3COCH_2CH(CH_3)_2$	Class 3
2-Methyl-1-propanol	Isobutyl alcohol 2-Methylpropan-1-ol	$(CH_3)_2CHCH_2OH$	Class 3
N-Methylpyrrolidone	1-Methylpyrrolidin-2-one 1-Methyl-2-pyrrolidinone		Class 2
Nitromethane		CH_3NO_2	Class 2
Pentane	*n*-Pentane	$CH_3(CH_2)_3CH_3$	Class 3
1-Pentanol	Amyl alcohol Pentan-1-ol Pentyl alcohol	$CH_3(CH_2)_3CH_2OH$	Class 3
1-Propanol	Propan-1-ol Propyl alcohol	$CH_3CH_2CH_2OH$	Class 3
2-Propanol	Propan-2-ol Isopropyl alcohol	$(CH_3)_2CHOH$	Class 3
Propyl acetate	Acetic acid propyl ester	$CH_3COOCH_2CH_2CH_3$	Class 3
Pyridine			Class 2
Sulfolane	Tetrahydrothiophene 1,1-dioxide		Class 2
Tetrahydrofuran	Tetramethylene oxide Oxacyclopentane		Class 3
Tetralin	1,2,3,4-Tetrahydro-naphthalene		Class 2
Toluene	Methylbenzene		Class 2
1,1,1-Trichloroethane	Methylchloroform	CH_3CCl_3	Class 1
1,1,2-Trichloroethene	Trichloroethene	$HClC=CCl_2$	Class 2
Xylene[a]	Dimethylbenzene Xylol		Class 2

[a] Usually 60% *m*-xylene, 14% *p*-xylene, 9% *o*-xylene with 17% ethyl benzene.

APPENDIX 2 ADDITIONAL BACKGROUND

A2.1 Environmental Regulation of Organic Volatile Solvents

Several of the residual solvents frequently used in the production of pharmaceuticals are listed as toxic chemicals in Environmental Health Criteria (EHC) monographs and the Integrated Risk Information System (IRIS). The objectives of such groups as the International Programme on Chemical Safety (IPCS), the United States Environmental Protection Agency (USEPA), and the United States Food and Drug Administration (USFDA) include the determination of acceptable exposure levels. The goal is the protection of human health and maintenance of environmental integrity against the possible deleterious effects of chemicals resulting from long-term environmental exposure. The methods involved in the estimation of maximum safe exposure limits are usually based on long-term studies. When long-term study data are unavailable, shorter-term study data can be used with modification of the approach, such as the use of larger safety factors. The approach described therein relates primarily to long-term or *lifetime exposure of the general population* in the ambient environment; that is, ambient air, food, drinking water, and other media.

A2.2 Residual Solvents in Pharmaceuticals

Exposure limits in this guideline are established by referring to methodologies and toxicity data described in EHC and IRIS monographs. However, some specific assumptions about residual solvents to be used in the synthesis and formulation of pharmaceutical products should be taken into account in establishing exposure limits. They are as follows:

(1) Patients (not the general population) use pharmaceuticals to treat their diseases or for prophylaxis to prevent infection or disease.
(2) The assumption of lifetime patient exposure is not necessary for most pharmaceutical products but may be appropriate as a working hypothesis to reduce risk to human health.
(3) Residual solvents are unavoidable components in pharmaceutical production and will often be a part of drug products.
(4) Residual solvents should not exceed recommended levels except in exceptional circumstances.
(5) Data from toxicological studies that are used to determine acceptable levels for residual solvents should have been generated using appropriate protocols such as those described, for example, by Organisation for Economic Co-operation and Development (OECD), EPA, and the FDA *Red Book*.

APPENDIX 3 METHODS FOR ESTABLISHING EXPOSURE LIMITS

The Gaylor–Kodell method of risk assessment (Gaylor DW, Kodell RL [1980]. Linear interpolation algorithm for low dose assessment of toxic substance. *J Environ Pathol* 4:305) is appropriate for Class 1 carcinogenic solvents. Only in cases where reliable carcinogenicity data are available should extrapolation by the use of mathematical models be applied to setting exposure limits. Exposure limits for Class 1 solvents could be determined with the use of a large safety factor (i.e., 10,000 to 100,000) with respect to the no-observed-effect level (NOEL). Detection and quantitation of these solvents should be by state-of-the-art analytical techniques.

Acceptable exposure levels in this guideline for Class 2 solvents were established by calculation of PDE values according to the procedures for setting exposure limits in pharmaceuticals (*Pharmacopeial Forum*, November–December 1989) and the method adopted by IPCS for Assessing Human Health Risk of Chemicals (Environmental Health Criteria 170, WHO, 1994). These methods are similar to those used by the USEPA (IRIS) and the USFDA (*Red Book*) and others. The method is outlined here to give a better understanding of the origin of the PDE values. It is not necessary to perform these calculations in order to use the PDE values tabulated in Section IV of this document.

PDE is derived from the NOEL or the lowest-observed-effect level (LOEL) in the most relevant animal study as follows:

$$\text{PDF} = \frac{\text{NOEL} \times \text{Weight Adjustment}}{\text{F1} \times \text{F2} \times \text{F3} \times \text{F4} \times \text{F5}} \tag{14.1}$$

The PDE is derived preferably from a NOEL. If no NOEL is obtained, the LOEL may be used. Modifying factors proposed here, for relating the data to humans, are the same kind of "uncertainty factors" used in EHC (Environmental Health Criteria 170, World Health Organization, Geneva, 1994) and "modifying factors" or "safety factors" in *Pharmacopeial Forum*. The assumption of 100% systemic exposure is used in all calculations regardless of route of administration.

The modifying factors are as follows:

F1 = A factor to account for extrapolation between species
F1 = 5 for extrapolation from rats to humans
F1 = 12 for extrapolation from mice to humans
F1 = 2 for extrapolation from dogs to humans
F1 = 2.5 for extrapolation from rabbits to humans
F1 = 3 for extrapolation from monkeys to humans
F1 = 10 for extrapolation from other animals to humans

F1 takes into account the comparative surface area:body weight ratios for the species concerned and for humans. Surface area (S) is calculated as

$$S = kM\ 0.67 \tag{14.2}$$

where
M = body mass
the constant k has been taken to be 10

The body weights used in Equation 14.2 are those shown in Table A3.1.

TABLE A3.1
Values Used in the Calculations in This Document

Rat body weight	425 g	Mouse respiratory volume	43 L/day
Pregnant rat body weight	330 g	Rabbit respiratory volume	1440 L/day
Mouse body weight	28 g	Guinea pig respiratory volume	430 L/day
Pregnant mouse body weight	30 g	Human respiratory volume	28,800 L/day
Guinea pig body weight	500 g	Dog respiratory volume	9000 L/day
Rhesus monkey body weight	2.5 kg	Monkey respiratory volume	1150 L/day
Rabbit body weight (pregnant or not)	4 kg	Mouse water consumption	5 mL/day
Beagle dog body weight	11.5 kg	Rat water consumption	30 mL/day
Rat respiratory volume	290 L/day	Rat food consumption	30 g/day

F2 = A factor of 10 to account for variability between individuals

A factor of 10 is generally given for all organic solvents, and 10 is used consistently in this guideline.

F3 = A variable factor to account for toxicity studies of short-term exposure

F3 = 1 for studies that last at least one-half lifetime (1 year for rodents or rabbits; 7 years for cats, dogs, and monkeys)

F3 = 1 for reproductive studies in which the whole period of organogenesis is covered

F3 = 2 for a 6 month study in rodents or a 3.5 year study in nonrodents

F3 = 5 for a 3 month study in rodents or a 2 year study in nonrodents

F3 = 10 for studies of a shorter duration

In all cases, the higher factor has been used for study durations between the time points; for example, a factor of 2 for a 9 month rodent study.

F4 = A factor that may be applied in cases of severe toxicity; for example, nongenotoxic carcinogenicity, neurotoxicity, or teratogenicity. In studies of reproductive toxicity, the following factors are used:

F4 = 1 for fetal toxicity associated with maternal toxicity

F4 = 5 for fetal toxicity without maternal toxicity

F4 = 5 for a teratogenic effect with maternal toxicity

F4 = 10 for a teratogenic effect without maternal toxicity

F5 = A variable factor that may be applied if the NOEL was not established

When only an LOEL is available, a factor of up to 10 could be used depending on the severity of the toxicity.

The weight adjustment assumes an arbitrary adult human body weight for either sex of 50 kg. This relatively low weight provides an additional safety factor against the standard weights of 60 kg or 70 kg that are often used in this type of calculation. It is recognized that some adult patients weigh less than 50 kg; these patients are considered to be accommodated by the built-in safety factors used to determine a PDE. If the solvent was present in a formulation specifically intended for pediatric use, an adjustment for a lower body weight would be appropriate.

As an example of the application of this equation, consider a toxicity study of acetonitrile in mice that is summarized in *Pharmeuropa*, Vol. 9, No. 1, Supplement, April 1997, page S24. The NOEL is calculated to be 50.7 mg/kg/day. The PDE for acetonitrile in this study is calculated as follows:

$$\text{PDF} = \frac{50.7\text{mg kg}^{-1}\text{ day}^{-1} \times 50\text{ kg}}{12 \times 10 \times 5 \times 1 \times 1} = 4.22\text{ mg day}^{-1}$$

In this example,

F1 = 12 to account for the extrapolation from mice to humans

F2 = 10 to account for differences between individual humans

F3 = 5 because the duration of the study was only 13 weeks

F4 = 1 because no severe toxicity was encountered

F5 = 1 because the NOEL was determined

The equation for an ideal gas, $PV = nRT$, is used to convert concentrations of gases used in inhalation studies from units of parts per million to units of milligrams per liter or milligrams per cubic meter. Consider as an example the rat reproductive toxicity study by inhalation of carbon tetrachloride (molecular weight 153.84) that is summarized in *Pharmeuropa*, Vol. 9, No. 1, Supplement, April 1997, page S9.

$$\frac{n}{V} = \frac{P}{RT} = \frac{300 \times 10^{-6}\text{ atm} \times 153840\text{ mg mol}^{-1}}{0.082\text{ L atm K}^{-1}\text{ mol}^{-1} \times 298\text{ K}}$$

$$= \frac{46.15\text{ mg}}{24.45\text{ L}} = 1.89\text{ mg/L}$$

The relationship 1000 L = 1 m^3 is used to convert to milligrams per cubic meter.

15 Electronic Records and Signatures (CFR 21 Part 11 Compliance)

The regulations in 21 CFR part 11 set forth the criteria under which the Agency (Food and Drug Administration [FDA]) considers electronic records, electronic signatures, and handwritten signatures executed to electronic records to be trustworthy, reliable, and generally equivalent to paper records and handwritten signatures executed on paper. This chapter discusses the current revisions as of 1 April 2018 on these compliance issues.

(a) The regulations in this part set forth the criteria under which the agency considers electronic records, electronic signatures, and handwritten signatures executed to electronic records to be trustworthy, reliable, and generally equivalent to paper records and handwritten signatures executed on paper.

(b) This part applies to records in electronic form that are created, modified, maintained, archived, retrieved, or transmitted, under any records requirements set forth in agency regulations. This part also applies to electronic records submitted to the agency under requirements of the Federal Food, Drug, and Cosmetic Act and the Public Health Service Act, even if such records are not specifically identified in agency regulations. However, this part does not apply to paper records that are, or have been, transmitted by electronic means.

(c) Where electronic signatures and their associated electronic records meet the requirements of this part, the agency will consider the electronic signatures to be equivalent to full handwritten signatures, initials, and other general signings as required by agency regulations, unless specifically excepted by regulation(s) effective on or after August 20, 1997.

(d) Electronic records that meet the requirements of this part may be used in lieu of paper records, in accordance with 11.2, unless paper records are specifically required.

(e) Computer systems (including hardware and software), controls, and attendant documentation maintained under this part shall be readily available for, and subject to, FDA inspection.

(f) This part does not apply to records required to be established or maintained by 1.326 through 1.368 of this chapter. Records that satisfy the requirements of part 1, subpart J of this chapter, but that also are required under other applicable statutory provisions or regulations, remain subject to this part.

(g) This part does not apply to electronic signatures obtained under 101.11(d) of this chapter.

(h) This part does not apply to electronic signatures obtained under 101.8(d) of this chapter.

(i) This part does not apply to records required to be established or maintained by part 117 of this chapter. Records that satisfy the requirements of part 117 of this chapter, but that also are required under other applicable statutory provisions or regulations, remain subject to this part.

(j) This part does not apply to records required to be established or maintained by part 507 of this chapter. Records that satisfy the requirements of part 507 of this chapter, but that also are required under other applicable statutory provisions or regulations, remain subject to this part.

(k) This part does not apply to records required to be established or maintained by part 112 of this chapter. Records that satisfy the requirements of part 112 of this chapter, but that also are required under other applicable statutory provisions or regulations, remain subject to this part.

(l) This part does not apply to records required to be established or maintained by subpart L of part 1 of this chapter. Records that satisfy the requirements of subpart L of part 1 of this chapter, but that also are required under other applicable statutory provisions or regulations, remain subject to this part.

(m) This part does not apply to records required to be established or maintained by subpart M of part 1 of this chapter. Records that satisfy the requirements of subpart M of part 1 of this chapter, but that also are required under other applicable statutory provisions or regulations, remain subject to this part.

(n) This part does not apply to records required to be established or maintained by subpart O of part 1 of this chapter. Records that satisfy the requirements of subpart O of part 1 of this chapter, but that also are required under other applicable statutory provisions or regulations, remain subject to this part.

(o) This part does not apply to records required to be established or maintained by part 121 of this chapter. Records that satisfy the requirements of part 121 of this chapter, but that also are required under other applicable statutory provisions or regulations, remain subject to this part.

[62 FR 13464, Mar. 20, 1997, as amended at 69 FR 71655, Dec. 9, 2004; 79 FR 71253, 71291, Dec. 1, 2014; 80 FR 71253, June 19, 2015; 80 FR 56144, 56336, Sept. 17, 2015; 80 FR

74352, 74547, 74667, Nov. 27, 2015; 81 FR 20170, Apr. 6, 2016; 81 FR 34218, May 27, 2016]

Sec. 11.2 Implementation

(a) For records required to be maintained but not submitted to the agency, persons may use electronic records in lieu of paper records or electronic signatures in lieu of traditional signatures, in whole or in part, provided that the requirements of this part are met.

(b) For records submitted to the agency, persons may use electronic records in lieu of paper records or electronic signatures in lieu of traditional signatures, in whole or in part, provided that:

(1) The requirements of this part are met; and

(2) The document or parts of a document to be submitted have been identified in public docket No. 92S-0251 as being the type of submission the agency accepts in electronic form. This docket will identify specifically what types of documents or parts of documents are acceptable for submission in electronic form without paper records and the agency receiving unit(s) (e.g., specific center, office, division, branch) to which such submissions may be made. Documents to agency receiving unit(s) not specified in the public docket will not be considered as official if they are submitted in electronic form; paper forms of such documents will be considered as official and must accompany any electronic records. Persons are expected to consult with the intended agency receiving unit for details on how (e.g., method of transmission, media, file formats, and technical protocols) and whether to proceed with the electronic submission.

Sec. 11.3 Definitions

(a) The definitions and interpretations of terms contained in section 201 of the act apply to those terms when used in this part.

(b) The following definitions of terms also apply to this part:

(1) *Act* means the Federal Food, Drug, and Cosmetic Act (secs. 201-903 (21 U.S.C. 321-393)).

(2) *Agency* means the Food and Drug Administration.

(3) *Biometrics* means a method of verifying an individual's identity based on measurement of the individual's physical feature(s) or repeatable action(s) where those features and/or actions are both unique to that individual and measurable.

(4) *Closed system* means an environment in which system access is controlled by persons who are responsible for the content of electronic records that are on the system.

(5) *Digital signature* means an electronic signature based upon cryptographic methods of originator authentication, computed by using a set of rules and a set of parameters such that the identity of the signer and the integrity of the data can be verified.

(6) *Electronic record* means any combination of text, graphics, data, audio, pictorial, or other information representation in digital form that is created, modified, maintained, archived, retrieved, or distributed by a computer system.

(7) *Electronic signature* means a computer data compilation of any symbol or series of symbols executed, adopted, or authorized by an individual to be the legally binding equivalent of the individual's handwritten signature.

(8) *Handwritten signature* means the scripted name or legal mark of an individual handwritten by that individual and executed or adopted with the present intention to authenticate a writing in a permanent form. The act of signing with a writing or marking instrument such as a pen or stylus is preserved. The scripted name or legal mark, while conventionally applied to paper, may also be applied to other devices that capture the name or mark.

(9) *Open system* means an environment in which system access is not controlled by persons who are responsible for the content of electronic records that are on the system.

SUBPART B: ELECTRONIC RECORDS

Sec. 11.10 Controls for Closed Systems

Persons who use closed systems to create, modify, maintain, or transmit electronic records shall employ procedures and controls designed to ensure the authenticity, integrity, and, when appropriate, the confidentiality of electronic records, and to ensure that the signer cannot readily repudiate the signed record as not genuine. Such procedures and controls shall include the following:

(a) Validation of systems to ensure accuracy, reliability, consistent intended performance, and the ability to discern invalid or altered records.

(b) The ability to generate accurate and complete copies of records in both human readable and electronic form suitable for inspection, review, and copying by the agency. Persons should contact the agency if there are any questions regarding the ability of the agency to perform such review and copying of the electronic records.

(c) Protection of records to enable their accurate and ready retrieval throughout the records retention period.

(d) Limiting system access to authorized individuals.
(e) Use of secure, computer-generated, time-stamped audit trails to independently record the date and time of operator entries and actions that create, modify, or delete electronic records. Record changes shall not obscure previously recorded information. Such audit trail documentation shall be retained for a period at least as long as that required for the subject electronic records and shall be available for agency review and copying.
(f) Use of operational system checks to enforce permitted sequencing of steps and events, as appropriate.
(g) Use of authority checks to ensure that only authorized individuals can use the system, electronically sign a record, access the operation or computer system input or output device, alter a record, or perform the operation at hand.
(h) Use of device (e.g., terminal) checks to determine, as appropriate, the validity of the source of data input or operational instruction.
(i) Determination that persons who develop, maintain, or use electronic record/electronic signature systems have the education, training, and experience to perform their assigned tasks.
(j) The establishment of, and adherence to, written policies that hold individuals accountable and responsible for actions initiated under their electronic signatures, in order to deter record and signature falsification.
(k) Use of appropriate controls over systems documentation including:
    (1) Adequate controls over the distribution of, access to, and use of documentation for system operation and maintenance.
    (2) Revision and change control procedures to maintain an audit trail that documents time-sequenced development and modification of systems documentation.

Sec. 11.30 Controls for Open Systems

Persons who use open systems to create, modify, maintain, or transmit electronic records shall employ procedures and controls designed to ensure the authenticity, integrity, and, as appropriate, the confidentiality of electronic records from the point of their creation to the point of their receipt. Such procedures and controls shall include those identified in 11.10, as appropriate, and additional measures such as document encryption and use of appropriate digital signature standards to ensure, as necessary under the circumstances, record authenticity, integrity, and confidentiality.

Sec. 11.50 Signature Manifestations

(a) Signed electronic records shall contain information associated with the signing that clearly indicates all of the following:
    (1) The printed name of the signer;
    (2) The date and time when the signature was executed; and
    (3) The meaning (such as review, approval, responsibility, or authorship) associated with the signature.
(b) The items identified in paragraphs (a)(1), (a)(2), and (a)(3) of this section shall be subject to the same controls as for electronic records and shall be included as part of any human readable form of the electronic record (such as electronic display or printout).

Sec. 11.70 Signature/Record Linking

Electronic signatures and handwritten signatures executed to electronic records shall be linked to their respective electronic records to ensure that the signatures cannot be excised, copied, or otherwise transferred to falsify an electronic record by ordinary means.

SUBPART C: ELECTRONIC SIGNATURES

Sec. 11.100 General Requirements

(a) Each electronic signature shall be unique to one individual and shall not be reused by, or reassigned to, anyone else.
(b) Before an organization establishes, assigns, certifies, or otherwise sanctions an individual's electronic signature, or any element of such electronic signature, the organization shall verify the identity of the individual.
(c) Persons using electronic signatures shall, prior to or at the time of such use, certify to the agency that the electronic signatures in their system, used on or after August 20, 1997, are intended to be the legally binding equivalent of traditional handwritten signatures.
    (1) The certification shall be submitted in paper form and signed with a traditional handwritten signature, to the Office of Regional Operations (HFC-100), 5600 Fishers Lane, Rockville, MD 20857.
    (2) Persons using electronic signatures shall, upon agency request, provide additional certification or testimony that a specific electronic signature is the legally binding equivalent of the signer's handwritten signature.

Sec. 11.200 Electronic Signature Components and Controls

(a) Electronic signatures that are not based upon biometrics shall:
    (1) Employ at least two distinct identification components such as an identification code and password.

(i) When an individual executes a series of signings during a single, continuous period of controlled system access, the first signing shall be executed using all electronic signature components; subsequent signings shall be executed using at least one electronic signature component that is only executable by, and designed to be used only by, the individual.

(ii) When an individual executes one or more signings not performed during a single, continuous period of controlled system access, each signing shall be executed using all of the electronic signature components.

(2) Be used only by their genuine owners; and

(3) Be administered and executed to ensure that attempted use of an individual's electronic signature by anyone other than its genuine owner requires collaboration of two or more individuals.

(b) Electronic signatures based upon biometrics shall be designed to ensure that they cannot be used by anyone other than their genuine owners.

Sec. 11.300 Controls for Identification Codes/Passwords

Persons who use electronic signatures based upon use of identification codes in combination with passwords shall employ controls to ensure their security and integrity. Such controls shall include:

(a) Maintaining the uniqueness of each combined identification code and password, such that no two individuals have the same combination of identification code and password.

(b) Ensuring that identification code and password issuances are periodically checked, recalled, or revised (e.g., to cover such events as password aging).

(c) Following loss management procedures to electronically deauthorize lost, stolen, missing, or otherwise potentially compromised tokens, cards, and other devices that bear or generate identification code or password information, and to issue temporary or permanent replacements using suitable, rigorous controls.

(d) Use of transaction safeguards to prevent unauthorized use of passwords and/or identification codes, and to detect and report in an immediate and urgent manner any attempts at their unauthorized use to the system security unit, and, as appropriate, to organizational management.

(e) Initial and periodic testing of devices, such as tokens or cards, that bear or generate identification code or password information to ensure that they function properly and have not been altered in an unauthorized manner.

16 Product-Specific Bioequivalence Testing Protocols

To receive approval for an abbreviated new drug application (aNDA), applicants generally must demonstrate, among other things, that their product has the same active ingredient, dosage form, strength, route of administration, and conditions of use as the listed drug, and that the proposed drug product is bioequivalent to the reference listed drug (21 USC 355(j)(2)(A); 21 CFR 314.94(a)). Bioequivalent drug products show no significant difference in the rate and extent of absorption of the therapeutic ingredient (21 USC 355(j)(8); 21 CFR 320.1(e)). Bioequivalence (BE) studies are undertaken in support of aNDA submissions with the goal of demonstrating BE between a proposed generic drug product and its reference listed drug. The regulations governing BE are provided at 21 CFR in part 320.

The U.S. Food and Drug Administration (FDA) has recently begun to promulgate individual BE requirements. To streamline the process for making guidance available to the public on how to design product-specific BE studies, the U.S. FDA will be issuing product-specific BE recommendations (www.fda.gov/cder/ogd/index.htm). Given in the following are the current recommendations for the products of relevance to this specific volume of the book:

Amoxicillin; Clavulanate Potassium Suspension/Oral. *Recommended studies*: Three studies. (1) *Type of study*: Fasting. *Design*: Single-dose, two-way crossover in vivo. *Strength*: 600 mg/EQ 42.9 mg (base)/5 mL. *Subjects*: Normal healthy males and females, general population. *Additional comments*: (2) *Type of study*: Fed. *Design*: Single-dose, two-way crossover in vivo. *Strength*: 600 mg/EQ 42.9 mg (base)/5 mL. *Subjects*: Normal healthy males and females, general population. *Additional comments*: (3) *Type of study*: Fasting. *Design*: Single-dose, two-way crossover in vivo. *Strength*: 400 mg/EQ 57 mg (base)/5 mL. *Subjects*: Normal healthy males and females, general population. *Additional comments*: *Analytes to measure*: Amoxicillin and clavulanate potassium in plasma. *Bioequivalence based on (90% confidence interval [CI])*: Amoxicillin and clavulanate potassium. *Waiver request of in vivo testing*: 200 mg/EQ 28.5 mg (base)/5 mL based on (i) acceptable BE studies on the 400 mg/EQ 57 mg (base)/5 mL strength, (ii) proportional similarity of the 200 mg/EQ 28.5 mg (base)/5 mL and 400 mg/EQ 57 mg (base)/5 mL strengths, and (iii) acceptable in vitro dissolution testing of the 200 mg/EQ 28.5 mg (base)/5 mL and 400 mg/EQ 57 mg (base)/5 mL strengths.

Carbamazepine Suspension/Oral. *Recommended studies*: Two studies. (1) *Type of study*: Fasting. *Design*: Single-dose, two-way crossover in vivo. *Strength*: 100 mg/5 mL. *Subjects*: Normal healthy males and females, general population. *Additional comments*: (2) *Type of study*: Fed. *Design*: Single-dose, two-way crossover in vivo. *Strength*: 100 mg/5 mL. *Subjects*: Normal healthy males and females, general population. *Additional comments*: *Analytes to measure (in appropriate biological fluid)*: Carbamazepine in plasma. *Bioequivalence based on (90% CI)*: Carbamazepine. *Waiver request of in vivo testing*: Not applicable.

Cefixime Suspension/Oral. *Recommended studies*: Two studies. (1) *Type of study*: Fasting. *Design*: Single-dose, two-way crossover in vivo. *Strength*: 200 mg/5 mL. *Subjects*: Normal healthy males and females, general population. *Additional comments*: Females should not be pregnant or lactating, and if applicable, should practice abstention or contraception during the study. (2) *Type of study*: Fed. *Design*: Single-dose, two-way crossover in vivo. *Strength*: 200 mg/5 mL. *Subjects*: Normal healthy males and females, general population. *Additional comments*: Please see comment above. *Analytes to measure (in appropriate biological fluid)*: Cefixime in plasma. *Bioequivalence based on (90% CI)*: Cefixime. *Waiver request of in vivo testing*: 100 mg/5 mL based on (i) acceptable BE studies on the 200 mg strength/5 mL strength, (ii) proportional similarity of the formulations across all strengths, and (iii) acceptable in vitro dissolution testing of all strengths. A dosage unit for a suspension is the labeled strength (5 mL). A total of 12 units from 12 different bottles should be used.

Clarithromycin Granules for Suspension/Oral. *Recommended studies*: Two studies. (1) *Type of study*: Fasting. *Design*: Single-dose, two-way crossover in vivo. *Strength*: 250 mg/5 mL. *Subjects*: Normal healthy males and females, general population. *Additional comments*: (2) *Type of study*: Fed. *Design*: Single-dose, two-way crossover in vivo. *Strength*: 250 mg/5 mL. *Subjects*: Normal healthy males and females, general population. *Additional comments*: *Analytes to measure*: Clarithromycin in plasma. *Bioequivalence based on (90% CI)*: Clarithromycin. *Waiver request of in vivo testing*: 125 mg/5 mL based on (i) acceptable bioequivalence studies on the 250 mg strength/5 mL strength, (ii) proportional similarity of the formulations across

all strengths, and (iii) acceptable in vitro dissolution testing of all strengths.

Deferasirox Tablets for Oral Suspension. *Recommended studies*: One study. *Type of study*: Fasting. *Design*: Single-dose, two-way crossover in vivo. *Strength*: 500 mg. *Subjects*: Normal healthy males and females, general population. *Additional comments*: The following passage is reproduced from the Dosage and Administration section of the labeling: Tablets should be completely dispersed by stirring in water, orange juice, or apple juice until a fine suspension is obtained. Doses of <1 g should be dispersed in 3.5 oz of liquid and doses of >1 g in 7.0 oz of liquid. After swallowing the suspension, any residue should be resuspended in a small volume of liquid and swallowed. Tablets should not be chewed or swallowed whole. *Analytes to measure (in appropriate biological fluid)*: Deferasirox in plasma. *Bioequivalence based on (90% CI)*: Deferasirox. *Waiver request of in vivo testing*: 250 and 125 mg tablets based on (i) acceptable BE studies on the 500 mg strength, (ii) proportionally similar across all strengths, and (iii) acceptable in vitro dissolution testing of all strengths.

Dextromethorphan Polistirex Extended-Release Oral Suspension/Oral. *Recommended studies*: Two studies. (1) *Type of study*: Fasting. *Design*: Single-dose, two-way crossover in vivo. *Strength*: 30 mg/5 mL. *Subjects*: Normal healthy males and females, general population. *Additional comments*: (2) *Type of study*: Fed. *Design*: Single-dose, two-way crossover in vivo. *Strength*: 30 mg/5 mL. *Subjects*: Normal healthy males and females, general population. *Additional comments*: *Analytes to measure (in appropriate biological fluid)*: Dextromethorphan and its metabolite Dextrorphan in plasma. *Bioequivalence based on (90% CI)*: Dextromethorphan. Please submit the metabolite data as supportive evidence of comparable therapeutic outcome. For the metabolite, the following data should be submitted: individual and mean concentrations, individual and mean pharmacokinetic parameters, and geometric means and ratios of means for AUC and C_{max}. *Waiver request of in vivo testing*: Not applicable. A dosage unit for a suspension is the labeled strength (5 mL). A total of 12 units from 12 different bottles should be used. In addition to the method above, for modified-release products, dissolution profiles on 12 dosage units each of test and reference products generated using USP apparatus I at 100 rpm and/or apparatus II at 50 rpm in at least three dissolution media (pH 1.2, 4.5, and 6.8 buffer) should be submitted in the application. Agitation speeds may have to be increased, if appropriate. It is acceptable to add a small amount of surfactant, if necessary. Please include early sampling times of 1, 2, and 4 hours, and continue every 2 hours until at least 80% of the drug is released, to provide assurance against premature release of drug (dose dumping) from the formulation.

Felbamate Oral Suspension/Oral. *Recommended studies*: One study. *Type of study*: Fasting. *Design*: Multiple-dose, two-way steady-state crossover in vivo. *Strength*: 600 mg/5 mL. *Subjects*: Male and nonpregnant female epilepsy patients. *Additional comments*: Please also consider the following additional safety monitoring: (a) If any evidence of bone marrow (hematologic) depression occurs, felbamate treatment should be discontinued and a hematologist consulted to ensure appropriate medical care. (b) Additional criteria for exclusion from the study relative to baseline to be practiced, including (i) twofold increase in the highest, 2 day prestudy seizure frequency, (ii) single, generalized, tonic–clonic seizure if none occurred during pretreatment screening, and/or (iii) significant prolongation of generalized, tonic–clonic seizures. *Analytes to measure*: Felbamate in plasma. (1) Measurements of felbamate are requested on at least two consecutive days immediately prior to pharmacokinetic (PK) analysis days 7 and 14 to confirm steady-state concentrations of felbamate (i.e., additional consecutive measures on days 5, 6, and 12, 13). (2) Because felbamate is rapidly absorbed and reaches a peak plasma concentration within 1 to 3 hours post consumption, please also include blood sampling at 0.25 hours after drug dosing to accurately measure the absorption/distribution phases of the felbamate PK profile. (3) Patients who receive multiples of 600 mg of felbamate per day (1200–4800 mg/day) would be eligible for the study by continuing their established maintenance dose. Because patients will be administered different dosing regimens, the dose needs to be included in the analysis of variance (ANOVA) statistical model. Dose normalization is not advised. (4) No washout period is necessary between treatment periods. (5) You are encouraged to submit protocols for the in vivo bioequivalence studies to be conducted at steady state in patients already taking the reference listed drug (RLD) at a therapeutic dose for review prior to initiating the studies. *Bioequivalence based on (90% CI)*: Felbamate. *Waiver request of in vivo testing*: Not applicable to all strengths of the test and reference products. A dosage unit for a suspension is the labeled strength (5 mL). A total of 12 units from 12 different bottles should be used.

Fosamprenavir Calcium Suspension/Oral. *Recommended studies*: Two studies. (1) *Type of study*: Fasting. *Design*: Single-dose, two-treatment, two-period crossover in vivo. *Strength*: EQ 50 mg Base/mL (Dose = 28 mL corresponding to a dose of 1400 mg). *Subjects*: Normal healthy males and females, general population. *Additional comments*: Females should not be pregnant or lactating, and if applicable, should practice abstention

or contraception during the study. Bottle should be shaken well before drug administration. (2) *Type of study*: Fed. *Design*: Single-dose, two-treatment, two-period crossover in vivo. *Strength*: EQ 50 mg Base/mL (Dose = 28 mL corresponding to a dose of 1400 mg). *Subjects*: Normal healthy males and females, general population. *Additional comments*: Please see comment above. *Analytes to measure (in appropriate biological fluid)*: Amprenavir, the active metabolite of fosamprenavir, in plasma. *Bioequivalence based on (90% CI)*: Amprenavir. *Waiver request of in vivo testing*: Not applicable.

Ibuprofen and Pseudoephedrine Hydrochloride Suspension/Oral. *Recommended studies*: Two studies. (1) *Type of study*: Fasting. *Design*: Single-dose, two-way crossover in vivo. *Strength*: 100 mg/5 mL and 15 mg/5 mL. *Subjects*: Normal healthy males and females, general population. *Additional comments*: (2) *Type of study*: Fed. *Design*: Single-dose, two-way crossover in vivo. *Strength*: 100 mg/5 mL and 15 mg/5 mL. *Subjects*: Normal healthy males and females, general population. *Additional comments*: *Analytes to measure*: Ibuprofen and pseudoephedrine in plasma. *Bioequivalence based on (90% CI)*: Ibuprofen and pseudoephedrine. *Waiver request of in vivo testing*: Not applicable to all strengths of the test and reference products. A dosage unit for a suspension is the labeled strength (5 mL). A total of 12 units from 12 different bottles should be used.

Meloxicam Suspension/Oral. *Recommended studies*: Two studies. (1) *Type of study*: Fasting. *Design*: Single-dose, two-way crossover in vivo dose and suspension. *Strength*: 5 mL of 7.5 mg/5 mL. *Subjects*: Normal healthy males and females, general population. *Additional comments*: Females should not be pregnant, and if applicable, should practice abstinence or contraception during the study. (2) *Type of study*: Fed. *Design*: Single-dose, two-way crossover in vivo dose and suspension. *Strength*: 5 mL of 7.5 mg/5 mL. *Subjects*: Normal healthy males and females, general population. *Additional comments*: Please see comment above. *Analytes to measure (in appropriate biological fluid)*: Meloxicam in plasma. *Bioequivalence based on (90% CI)*: Meloxicam. *Waiver request of in vivo testing*: Not applicable.

Nelfinavir Mesylate Suspension/Oral. *Recommended studies*: Two studies. (1) *Type of study*: Fasting. *Design*: Single-dose, two-treatment, two-period crossover in vivo. *Strength*: 50 mg/scoopful. *Subjects*: Normal healthy males and females, general population. *Additional comments*: (2) *Type of study*: Fed. *Design*: Single-dose, two-treatment, two-period crossover in vivo. *Strength*: 50 mg/scoopful. *Subjects*: Normal healthy males and females, general population. *Additional comments*: *Analytes to measure (in appropriate biological fluid)*: Nelfinavir in plasma. *Bioequivalence based on (90% CI)*: Nelfinavir. *Waiver request of in vivo testing*: Not applicable.

Nevirapine Suspension/Oral. *Recommended studies*: Two studies. (1) *Type of study*: Fasting. *Design*: Single-dose, one-period parallel in vivo. *Strength*: 50 mg/5 mL. *Subjects*: Normal healthy males and females, general population. *Additional comments*: Because of safety concerns of severe life-threatening skin reactions and hepatotoxicity, single-dose parallel study designs in normal healthy subjects are recommended. (2) *Type of study*: Fed. *Design*: Single-dose, one-period parallel in vivo. *Strength*: 50 mg/5 mL. *Subjects*: Normal healthy males and females, general population. *Additional comments*: Please see comments above. *Analytes to measure (in appropriate biological fluid)*: Nevirapine in plasma. *Bioequivalence based on (90% CI)*: Nevirapine. *Waiver request of in vivo testing*: Not applicable.

Omeprazole Powder for Suspension/Oral. *Recommended studies*: One study. *Type of study*: Fasting. *Design*: Single-dose, two-treatment, two-period crossover in vivo. *Strength*: 40 mg/packet. *Subjects*: Normal healthy males and females, general population. *Additional comments*: *Analytes to measure*: Omeprazole in plasma. *Bioequivalence based on (90% CI)*: Omeprazole. *Waiver request of in vivo testing*: 20 mg/packet based on (i) acceptable bioequivalence study on the 40 mg strength, (ii) proportional similarity of the formulations across all strengths, and (iii) acceptable in vitro dissolution testing of all strengths. Since omeprazole powder for oral suspension, 20 mg/packet and 40 mg/packet, is subject to two separate New Drug Applications, two separate aNDAs must be submitted. A waiver of in vivo BE testing is available.

Oxcarbazepine Suspension/Oral. *Recommended studies*: Two studies. 1. *Type of study*: Fasting. *Design*: Single-dose, two-treatment, two-period crossover in vivo. *Strength*: 300 mg/5 mL (600 mg dose). *Subjects*: Normal healthy males and females, general population. *Additional comments*: (2) *Type of study*: Fed. *Design*: Single-dose, two-treatment, two-period crossover in vivo. *Strength*: 300 mg/5 mL (600 mg dose). *Subjects*: Normal healthy males and females, general population. *Additional comments*: *Analytes to measure (in appropriate biological fluid)*: Oxcarbazepine and its 10-hydroxy metabolite (monohydroxy derivative [MHD]) in plasma using an achiral assay. *Bioequivalence based on (90% CI)*: Oxcarbazepine. Please submit the metabolite data as supportive evidence of comparable therapeutic outcome. For the metabolite, the following data should be submitted: individual and mean concentrations, individual and mean pharmacokinetic parameters, and geometric means and ratios of means for AUC and C_{max}. *Waiver request of in vivo testing*: Not applicable. Please note that a dosage unit for a suspension

is the labeled strength (5 mL). A total of 12 units from 12 different bottles should be used.

Phenytoin Suspension/Oral. *Recommended studies*: Two studies. (1) *Type of study*: Fasting. *Design*: Single-dose, two-way crossover in vivo. *Strength*: 125 mg/5 mg (dose of 300 mg). *Subjects*: Normal healthy males and females, general population. *Additional comments*: Washout period of at least 14 days. The single-dose studies for fasting and fed can be conducted as single dose, two-treatment, four periods, replicated design. The strength(s) designated in the Orange Book as the RLD should be used in the studies. (2) *Type of study*: Fed. *Design*: Single-dose, two-way crossover in vivo. *Strength*: 125 mg/5 mg (dose of 300 mg). *Subjects*: Normal healthy males and females, general population. *Additional comments*: Please see comments above. *Analytes to measure*: Phenytoin in plasma. *Bioequivalence based on (90% CI)*: Phenytoin. *Waiver request of in vivo testing*: Not applicable. Please conduct comparative dissolution testing on 12 dosage units of all strengths of the test and reference products using the USP method. A dosage unit for a suspension is the labeled strength (5 mL). A total of 12 units from 12 different bottles should be used.

Posaconazole Suspension/Oral. *Recommended studies*: Two studies. (1) *Type of study*: Fasting. *Design*: Single-dose, two-treatment, two-period crossover in vivo. *Strength*: 40 mg/mL (dose of 400 mg). *Subjects*: Normal healthy males and females, general population. *Additional comments*: Females must have a negative baseline pregnancy test within 24 hours prior to receiving the drug. Females should not be pregnant or lactating, and if applicable, should practice abstention or contraception during the study. (2) *Type of study*: Fed. *Design*: Single-dose, two-treatment, two-period crossover in vivo. *Strength*: 40 mg/mL (dose of 400 mg). *Subjects*: Normal healthy males and females, general population. *Additional comments*: Please see comment above. *Analytes to measure (in appropriate biological fluid)*: Posaconazole in plasma. *Bioequivalence based on (90% CI)*: Posaconazole. *Waiver request of in vivo testing*: Not applicable for product at this Web site. Please note that a dosage unit for a suspension is the labeled strength (mL). A total of 12 units from 12 different bottles should be used.

Sulfamethoxazole; Trimethoprim Suspension/Oral. *Recommended studies*: One study. *Type of study*: Fasting. *Design*: Single-dose, two-treatment, two-period crossover in vivo. *Strength*: 200 mg/40 mg per 5 mL. *Subjects*: Normal healthy males and females, general population. *Additional comments*: *Analytes to measure (in appropriate biological fluid)*: Sulfamethoxazole and trimethoprim in plasma. *Bioequivalence based on (90% CI)*: Sulfamethoxazole and trimethoprim. *Waiver request of in vivo testing*: Not applicable.

Voriconazole Suspension/Oral. *Recommended studies*: One study. *Type of study*: Fasting. *Design*: Single-dose, two-way crossover in vivo. *Strength*: 200 mg/5 mL. *Subjects*: Normal healthy males and females, general population. Females should not be pregnant, and if applicable, should practice abstention or contraception during the study. *Additional comments*: *Analytes to measure (in appropriate biological fluid)*: Voriconazole in plasma. *Bioequivalence based on (90% CI)*: Voriconazole. *Waiver request of in vivo testing*: Not applicable.

17 Formulation Considerations

1. BACKGROUND

Many liquid formulations are inherently immediate-release products. Placing a native drug directly in a liquid solution for delivery eliminates the hydration and disintegration processes that are required to release drug from a solid dosage form. Extending release for a liquid product may be a significant challenge. An aqueous solution of a water-soluble drug can potentially be incorporated into an immediate-release liquid product. Poorly soluble drugs can be incorporated as a suspension; however, the poor solubility may prevent the achievement of immediate release. Regardless of the dissolved or suspended state, the drug must be stable with respect to oxidation and hydrolysis. Depending on drug properties, it may need to retain a consistent active form or morphology during the product shelf life. Also, the formulation itself must taste acceptable to the patient at the dosing concentration.

Stability and solubility concerns alone prevent the application of many drugs directly into a liquid formulation. The bad taste of most drugs limits successful direct incorporation into a liquid dose form depending on the extent of bad taste and the dose/concentration requirement. Due to these constraints, there is a narrow range of drugs that are directly incorporated into a shelf-stable liquid product.

Successful formulations generally are appropriately pH buffered and flavored, and contain any other required stabilizers, suspending agents, and preservatives to meet the stability and delivery goals.

2. ION RESIN COMPLEXES

Ion resin complexes can potentially be used for immediate-release formulations depending on drug affinity for the ion exchange resin; however, they are particularly useful for extended-release liquid formulations. The stability afforded by the bond to the ion exchange resin, coupled with the ability to control drug release from the resin, offers a platform for extended release from an oral liquid product. The key challenges encountered when formulating shelf-stable oral liquid dosage forms include the following:

- Overcoming the bad taste of the drug
- Achieving a desired release profile
- Maintaining drug stability

Ion resin suspension technology offers a potential means of addressing all these concerns. Most drug molecules have basic or acidic functionalities that ionize readily, or they are relatively polar; thus, they can potentially be bound to an appropriately charged ion exchange resin surface to form an ion resin complex. Once bound and in the absence of significant competing ions, the drug is effectively immobilized and in some cases, stabilized with respect to some degradation processes. The bad taste of a drug may be reduced significantly by the ionic binding, which reduces drug availability to taste receptors; thus, it can provide an effective means of taste concealing. The ion resin complex produced by binding a drug to the insoluble polymeric matrix of an ion exchange resin may exhibit the taste and odor properties of the ion exchange resin itself, not of the drug.

Ion resin complexes can be incorporated into a variety of shelf-stable solid oral dosage forms in addition to liquids. Upon ingestion, the high ionic strength of the gut displaces drug from the resin to make it bioavailable. This release from the resin is governed by ion exchange equilibria, and as released drug is taken in by the body, the equilibrium shifts toward complete drug bioavailability. Undigested resin passes through the gastrointestinal tract.

Drug release profiles with this technology can be manipulated through a number of variables, including drug affinity factors, particle size, drug:resin ratio, and the application of controlled-release coatings to the drug–resin complexes. Drug molecules with low affinity for the resin typically maintain an immediate-release profile, as they are easily displaced from the resin in the gut. Drug molecules with high affinity for the resin are more difficult to displace from the resin and may naturally exhibit an extended-release profile. Particle size distribution can significantly affect drug release as well. Typically, smaller particles offer more surface area and therefore, faster drug release than larger particles. The ratio of drug:resin used in the preparation of an ion resin complex can also affect the rate of drug release. While drug release can be controlled to a minor extent for both low- and high-affinity materials through resin selection, particle size, drug:resin ratio, and liquid formulation parameters, the addition of a coating is often needed to achieve a target extended-release pattern. Drug release in these systems is regulated primarily by the diffusion rate of competing ions through the applied membrane, which is controlled by the membrane's thickness and porosity. Release rates of up to 12 and 24 h from a liquid suspension format can be achieved with this technology.

3. ION EXCHANGE RESINS

Ion exchange equilibria are governed by the relative affinity and concentrations of competing ions for available exchange sites. A high-affinity ion will easily displace a low-affinity ion. A low-affinity ion at relatively high concentration can effectively displace a high-affinity ion. The same principle is used in ion exchange water softening systems, where high-affinity divalent ions such as calcium are trapped on a cation exchange resin, as they easily displace low-affinity

sodium ions. When the resin is exhausted and primarily in the calcium form, it is regenerated by passing a saturated solution of sodium chloride over it; the high population of sodium ions effectively displaces the higher-affinity calcium ions to return the resin to the sodium form. A strong cation exchange resin (sulfonate-based Amberlite IRP69), weak cation exchange resins (carboxylate-based Amberlite IRP64 and Amberlite IRP88), and a strong anion exchange resin (quaternary ammonium-based Duolite AP143) are available. Approval is also anticipated for a weak anion exchange resin based on a tertiary amine function. Resin selection is based on several factors, including the anionic or cationic character of the drug and its affinity for the resin. Ion affinity can be controlled somewhat on the weak acid resins through pH adjustments, while affinity for the strong acid resin is relatively fixed by the drug's ionic properties. Additional resins under the trade names Indion, Tulsion, Purolite, and Kyron are used in some regulatory markets.

3.1 Drug Loading

Drug loading on the resin can potentially be done in a flow-through column or bed of the resin; however, it is more commonly done in a batch process by mixing drug and resin together in an appropriate solvent medium. The solvent is commonly water, but other polar solvent systems such as ethanol may be applicable if needed. As the drug dissolves, the drug ions exchange with the counterion of the resin. Loading efficiency is dependent primarily on the equilibrium of the exchange. For maximum loading, the drug:resin ratio is maximized to force the equilibrium to more complete loading. In addition, multiple loading steps can potentially be used to force additional load. For less than maximum loading, a lower drug:resin ratio can be applied.

Temperature, pH, and choice of solvent for the drug loading process can also be manipulated to maximize drug loading. This process works even for low-solubility drugs, because uptake of the drug by the ion exchange resin allows more drug to dissolve until equilibrium is achieved.

To reduce free drug and competing ion content, the drug–resin complex slurry is typically filtered or centrifuged to remove the liquid portion, which contains the displaced counterions of both the drug and resin and remaining free, dissolved drug. The amount of drug lost to meet high loading requirements can be significant; thus, optimization of this loading and washing process can be a critical economic consideration. Additional washing processes can then be used to remove residual free salt ions and residual free drug. The resulting wet cake is then processed as required by the dosage form. This processing could include direct incorporation into a liquid suspension, drying for incorporation into a solid dosage form, or drying and coating for incorporation into a solid or liquid dosage form. If coated particles are incorporated into a liquid suspension product, it is critical that any swelling associated with rehydration has been adequately addressed in the formulation to minimize or eliminate film coat fracturing. Dried drug–resin complexes containing up to ~40% drug load can be achieved depending on the exchange capacity, loading process, drug structure, and coating requirements.

Note that the ionic form of the cation exchangers varies. In general, the counterions are weak-affinity ions that are relatively easy to displace with an ionized drug. Although counterion affinities are all relatively low, the affinity of cations for the cation exchange materials is ranked from potassium, with the highest affinity, to sodium, to hydrogen, with the lowest affinity. The potential ramifications of counterion choice may be of minimal importance, but the following factors should be considered:

Resins are highly porous structures with exchange sites throughout the particles, and they shrink or swell in relation to the ionic form. The shrink and swell is related to ion size with the following size order: drug >K+ >Na+ >H+. Hydration level and degree of cross-linking within the resin will also influence the amount of swell.

Drug ions are larger than the original resin counterions; thus, resins will typically swell with drug load.

Drug will not typically load to the full exchange capacity of the resin due to the exchange equilibrium and steric constraints associated with drug ion size. Typical loadings for Amberlite IRP69 cation exchange resin and Duolite AP143 anion exchange resin are between 5 and 75% and between 5 and 50% of the exchange capacity, respectively.

As drug loads, resin and drug counterions remain in the liquid phase. The hydrogen form of the resin will yield an acidic liquid phase.

If coating of the drug– resin complex is required, the shrink and swell inherent in the resin can have a catastrophic effect on the film coat. The amount of shrink or swell and the steps taken to allow for it are vital to the success of the coating process.

3.2 Coating Drug–Resin Complexes

Coating of the drug resin complex is typically done with the Wurster (bottom spray) fluid-bed coating process using a semipermeable coating polymer such as ethylcellulose. The Wurster process is described in the Taste Concealing section of this book. Unless another means of adequately overcoming the resin shrink and swell factors is employed, the coating is often applied from a solvent vehicle to take advantage of the added film coat strength associated with film coat morphology and higher polymer molecular weight compared with aqueous latex or pseudo-latex systems. High-modulus films may also be used to stretch as the resin swells.

A shelf-stable ion-resin suspension is composed of drug-loaded resin with a coating (if coating is required) along with flavor, viscosity, suspension, and nonionic preservative agents. These suspensions shift to an equilibrium after preparation, as ion exchange processes continuously occur on the suspended drug–resin complex even if a controlled-release membrane has been applied. Although the coating may slow the rate of equilibration, it will eventually reach an equilibrium

point. The complexity of this equilibration can be significant if multiple drug–resin complexes are incorporated into a single product, as residual high-affinity drug will easily displace low-affinity drug. The exchange of drugs between the two drug–resin complexes and varying film coat requirements for the two drugs can significantly shift the release profiles.

4. CYCLODEXTRINS

Inclusion complexes are structures composed of a guest molecule within a host cavity. The most widely used host structures are cyclodextrins. These cyclic oligosaccharides favor the inclusion of nonhydrophilic substances within their toroidal structures. The first observation of cyclodextrins was recorded in 1891, the microorganisms that naturally produce them were first isolated in ~1906, and the first cyclodextrin structure elucidations were reported in 1936 and 1948–1950. A 1953 German patent has been noted to describe many of the potential benefits of cyclodextrin inclusion complexes for drug formulation. There is a significant amount of published literature on cyclodextrins and their uses, and much of it is somewhat redundant. One of the challenges to a formulator is to assimilate it all in order to extract what may be relevant to a particular application. A condensed overview of cyclodextrin use in relation to oral pharmaceutical formulations is attempted in this section.

Cyclodextrins are composed of (α-1,4)-linked α-D-glucopyranose units. Sizes commonly used in pharmaceutical products contain six (α-cyclodextrin or α-CD), seven (β-cyclodextrin or β-CD), and eight units (γ-cyclodextrin or γ-CD). Several derivatives of these natural cyclodextrins have been synthesized or developed to optimize their utility in various ways. The goals of derivatization generally include

- Improved solubility of the cyclodextrin and its guest–host complex
- An improved fit for the guest molecule
- Addition of functional sites (catalytic or otherwise) on the cyclodextrin surface

Derivatives generally substitute an R group for the H atom of one or more hydroxyl functions in the cyclodextrin and/or create a polymeric structure. Methyl and hydroxypropyl derivatives have been successfully commercialized.

β-Cyclodextrin and its derivatives have received most attention in oral pharmaceuticals, since it is most suitably sized for many drug molecules. United States Pharmacopeia (USP)/National Formulary (NF) monographs exist for β-cyclodextrin (Betadex), γ-cyclodextrin (Cyclodextrin, Gamma), and hydroxypropyl-β-cyclodextrin (Hydroxypropyl Betadex). The regulatory status of cyclodextrins continues to evolve. Cyclodextrins are sold under several trade names, including Cavamax, Cavasol, Cavitron, Kleptose, and Trappsol.

The full scope of the potential advantages of cyclodextrin inclusion complexes in oral pharmaceutical formulations includes the following:

- Stabilization of unstable compounds
- Reduced volatility of volatile compounds
- Prevention of irritation due to poorly soluble crystalline materials
- Transformation of liquids to a solid crystalline form
- Increased drug dissolution rate and solubility
- Increased bioavailability
- Taste concealing
- Protection of drug from oxidation or polymerization
- Reduced reactivity of incompatible compounds

Cyclodextrins provide a means to solubilize poorly soluble drugs and stabilize reactive drugs for successful incorporation into solution or suspension liquid dosage forms. Cyclodextrin complexes are often 1:1 pairings of a guest molecule within a cyclodextrin ring; however, complexes of one guest with two or more cyclodextrin ring caps can occur. In addition, association of guest molecules with the outer surface of the cyclodextrin can occur.

Cyclodextrin complexes are typically formed in a liquid environment. Depending on the physical characteristics and needs of the formulation, a variety of methods, including solution, coprecipitation, neutralization, slurry, kneading, and grinding processes, have been employed. In general, water is relatively loosely contained in the cyclodextrin cavity due to the relatively hydrophobic internal surface of the cavity and an unfavorable orientation of the water molecules. Less hydrophilic materials of appropriate size displace the water with relative ease to form a more stable complex. Complexes can be isolated by filtration or centrifugation to yield a clear solution of the soluble complex. Spray drying or lyophilization can be used to create a dry complex.

Potential concerns of cyclodextrin:drug inclusion complex application include the possibility of inducing drug polymorphism or cocrystal formation depending on drug properties and the presence of other formulation components.

Drug release from a complex is generally achieved by displacement with large amounts of water or the presence of competing molecules. The contents of the gut provide water and competing molecules. Drug release is also realized by enzymatic degradation of the cyclodextrin structure in the gut.

18 Pediatric Pharmaceutical EU Legislation

BACKGROUND

Following similar initiatives in the United States that led to the FDAMA (FDA Modernization Act) in 1997, the discussion in Europe to specifically address requirements for drug use in the pediatric population dates back at least to the 1990s, mainly initiated by academic and scientific societies such as the European Society of Developmental Perinatal and Pediatric Pharmacology (ESDP). The basic idea that there is a need to establish a legislative framework with regard to pediatric medicines was one of the outcomes of an expert round table organized by the European Commission at the European Medicines Agency (EMA) in 1997. The European Commission also initiated discussions on the performance of clinical trials in children, mainly in collaboration with the International Conference on Harmonisation (ICH), finally resulting in the ICH guideline "Note for guidance on clinical investigation of medicinal products in the pediatric population" (ICH Topic E11), which entered into force in 2002.

In parallel, at the EMA, the Committee for Proprietary Medicinal Products (CPMP) founded an ad hoc Pediatric Expert Group (PEG). With implementation of Regulation EC no.726/2004, when CPMP was reorganized into the Committee for Medicinal Products for Human Use (CHMP), the PEG was transformed into one of its temporary working parties comprising experts of different areas and also establishing links to other CHMP working parties and the Committee for Orphan Medicinal Products (COMP). The mandate of the PEG was to coordinate activities at the EMA and advise its scientific bodies.

The Council of Health Ministers adopted a resolution addressed to the European Commission in 2000 raising the desire for a legislative proposal on the topic of pediatric medicines with high public health priority. After an extended impact assessment (comprising also economic and social consequences) of such prospective legislation, outlining started with a first draft proposal in 2004. After amendments, agreement was reached in December 2005. The Regulation was adopted by the European Parliament in June 2006, was published in December 2006, and entered into force on January 26, 2007. It comprises Regulation No. 1901/2006 and amending Regulation No. 1902/2006.

THE MAIN POINTS IN THE REGULATION

The Pediatric Regulation sets up a framework governing mandatory requirements and incentives for industry in the development of new medicinal products as well as a series of accompanying measures to facilitate approaches to gain access to and improve the exchange of relevant information on medicinal products in pediatric use. By such means, it aims to facilitate the development and accessibility of medicinal products for use in the pediatric population and to ensure that medicinal products used in children are subject to ethical research of high standards and are appropriately authorized. In addition, the information available on the use of medicinal products in the various pediatric populations should be improved.

It is also stated that this should be achieved without subjecting the pediatric population to unnecessary clinical trials and without delaying the authorization of medicinal products for older age groups; to the latter aim, measures in children can be deferred, which means that studies in children can be initiated and/or completed after the application for marketing authorization in adults is submitted. Clearly, to avoid delays, compliance with the required early submission of pediatric investigation plan (PIP)/waiver applications is critical. One of the cornerstones of the Regulation is establishing a Pediatric Committee (PDCO) within the EMA composed of one member and one alternate member from each member state of the EU (plus Norway and Iceland); for five countries, these two members should also be the representatives in the CHMP. In addition, the European Commission appoints three members + alternates to represent health professionals and three members + alternates to represent pediatric associations. The member states should coordinate their nominations to ensure that scientific areas relevant to pediatric medicinal product development are well represented.

The PDCO has several roles as defined in the Pediatric Regulation; among these are:

- It has to assess and to agree on the content of PIPs for medicinal products as proposed by industry, including agreement on proposed modifications of such PIPs.
- It can also waive the need for a pediatric development or can agree to defer specific developmental steps for specific medicinal products where deemed appropriate.
- On request, it must assess the compliance of an applicant with the agreed PIP.
- On the request of assessing bodies (CHMP or National Competent Authorities), it can be involved in assessing data generated in accordance with an agreed PIP and can formulate opinions on quality, safety, or efficacy for the use of such products in the pediatric population.
- It should advise and assist scientifically in the elaboration of any documents related to fulfilling this regulation.
- It should establish and keep updated a specific inventory of pediatric medicinal product needs.

- It should advise the EMA and the European Commission on conducting research into medicinal products for pediatric use.
- It should advise and support EMA in establishing a European Network of existing national and European networks, investigators, and centers with expertise in performing studies in the pediatric population.

The regulation has put into force the requirement for an agreed opinion with the PDCO prior to an application for marketing authorization (MAA) for any unauthorized medicinal product for human use (Art. 7). In principle, all pediatric subsets/age ranges have to be covered in a PIP. Such PDCO opinions can include agreements on generating data in trials and/or collecting information in compliance with an agreed PIP (with or without deferrals). For all agreed measures, a compliance check prior to MAA submission has to be performed by the PDCO (or by a National Competent Authority [NCA] for non-centralized route applications). A positive outcome is required for a valid MAA. On the other hand, a PDCO opinion can also contain a product-specific waiver or a class waiver, limiting the obligation to conduct certain pediatric studies.

The need for agreement on a PIP is also given in the case of already authorized medicinal products, which are protected either by a supplementary protection certificate (SPC) or by a patent qualifying for such an SPC (Art. 8). For these products, a PIP is needed if an MAA for a new indication, a new pharmaceutical form, or a new route of administration is planned. Several products are exempted from the need for a PIP, including those submitted via the route of a generic, homeopathic, herbal, or well-established use application.

Opinions on agreed PIPs have to contain measures to assess the quality, safety, and efficacy of a medicinal product in all concerned pediatric subsets. They also need to include timelines and measures to adapt the formulation of the medicinal product to make its use more acceptable, easier, safer, or more effective for relevant subsets of the pediatric population.

Waivers can be granted for part or all of the pediatric population. This has to be based on evidence either that a product is not ineffective or unsafe, that a condition for which the product is intended is probable, or that the specific product would represent a significant therapeutic benefit over existing treatments.

This clearly implies that lack of such evidence would not be a reason for waiving a development. Therefore, such waivers can be very specifically limited to one or more pediatric population subsets and/or conditions. The reason why a waiver is granted is part of the opinion, and this information is also published.

One of the challenges of this regulation in the EU is the early point in time when such a proposal should be submitted. Unless duly justified, this should be not later than upon availability of the human pharmacokinetic data in adults. This should not be misinterpreted as a need to start the pediatric development so early; rather, it should ensure that there is sufficient time to integrate the pediatric plan appropriately into the integral development of a product. The actual timing of pediatric trials to be performed would then be agreed by also granting deferrals for the planned measures if a delayed initiation or completion for collecting some data seems appropriate. Such early discussion can, for example, depending on the development planned, safeguard sufficient time in elaborating on age-appropriate formulation efforts without generating delays.

Deferrals can be agreed for the initiation or completion of any measures that are included in a pediatric development plan, if scientifically or technically justifiable on grounds related to public health. In practice, this very often will imply that adult data are available prior to initiating pediatric trials. However, also other reasons could be valid justifications for deferring measures; for example, longer recruitment time. Linking deferral timelines to regulatory milestones rather than scientific reasons (e.g. approved marketing authorization in adults) would not be considered an appropriate justification.

The Pediatric Regulation also foresees a specific voluntary procedure for products not covered by Art. 7 or 8. For already marketed off-patent products, a pediatric indication can be claimed by submitting a dossier including documents establishing quality, safety, and efficacy in the pediatric population, including an age-appropriate formulation. Such a Pediatric Use Marketing Authorisation (PUMA, Art. 30) would qualify for 10 year (market and) data protection if performed in compliance with a prior agreed PIP.

IMPLICATIONS

What does this mean in practical terms? A company that has the intention to develop a new drug product, or plans new pharmaceutical forms/routes or new indications for an approved medicinal product still under patent protection, will have to consider whether this product can fulfil a pediatric need, including all subsets/age ranges up to 18 years. And, it will be required to submit this plan to the EMA PDCO to discuss the planned development or argumentation for waiving or deferring measures in this development plan.

The pediatric needs that exist in the planned condition will have to be considered. Such unmet medical needs are determined based on the occurrence of a condition and lack of or limitations in current therapeutic options. It should be kept in mind that this regulation was introduced to counteract the fact that industry only rarely proceeded in this direction voluntarily.

In practice, drug developers still tend to delay PIP submissions, not having decided yet how this development will look or still looking for arguments to support a desired waiver. For example, companies are unsure about the appropriate design of the pediatric study (e.g. what end point could be feasible, or how many children could be recruited). Furthermore, the need to develop a formulation in smaller children might depend on whether this drug will later be used in a specific (lower) age range. But, again, actually it would facilitate planning to have at least a cursory overview of possible later requirements if they are discussed as early as possible. Should later development generate evidence that pediatric needs or

agreed PIP measures are no longer applicable, there is the option to propose changes via a procedure for modification of an agreed PIP at any time and as often as needed. The risks of delayed submission have become evident in many instances, most notably delays of the planned marketing authorization date due to not having agreed a PIP in time. This is partly due to insufficient understanding of the implications of the Pediatric Regulation, especially in drug developers from outside the EU. Often, it also relates to misunderstandings of how pediatric needs are related to a planned condition, which is often artificially narrowed to focus on the population with the highest marketing potential. Such narrowing would not be supported by the Pediatric Regulation, as very often, there are differences in conditions in the pediatric population as compared with adults. Hence, this would compromise the rationale behind the Regulation, the main aim of which is to increase the knowledge and availability of drugs in children based on generated evidence.

Other difficulties often encountered in late submissions are that data already generated (outside an agreed PIP) are insufficient or that opportunities to cover some points are missed. This can result in seemingly redundant requests, which would be against the intention to prevent unnecessary trials. However, a trial with design flaws (e.g., nonvalid end point, sample size, etc.) cannot be considered as sufficient evidence to justify not repeating a more or less similar trial with appropriate design. Here, the first trial might be considered unethical due to being insufficiently planned. Often, companies are hesitant to include, for example, adolescents in a Phase 2 or 3 development. This could result in a request to include them in a separate trial, which could cause delays before proceeding to younger age groups. Therefore, such decisions should be discussed well in advance to prevent such situations.

It should also be kept in mind that extrapolation of generated data can be used in some cases to supplement the pediatric development. This can, dependent on the medical setting, affect any data from preclinical, efficacy, and safety to dosing and pharmacokinetics. It should also be considered that often, in pediatric settings, fully powered comparative trials might not be feasible. But there are many innovative options for other approaches, which in such cases should be proposed and discussed to find a satisfactory agreement.

In conclusion, while not being an effort that industry will often deliver voluntarily, early involvement of the regulatory bodies will facilitate further planning, and in the case that newly generated evidence would make necessary changes to such a program, this is not hampered by such an approach.

19 Pediatric Formulations

The Paediatric Regulation highlights in its preamble the problems resulting from the absence of suitably adapted medicinal products and specifically mentions the nonavailability of suitable formulations and routes of administration, as well as the use of magistral or officinal formulations of potentially poor quality. These challenges are best known by the pediatric population themselves, their parents, and the healthcare professionals in their daily struggle to adapt and modify the existing medicinal products in an attempt to benefit from the therapeutic advantage of the product. Crushing, splitting, diluting, or dissolving may significantly affect factors such as dosing accuracy, pharmacokinetic (PK) profile or acceptability, and medication errors may occur when doses are prepared or calculated.

Consequently, the regulation clearly states that the PIP must include a thorough description of any measures to adapt the formulation of the medicinal product so as to make its use more acceptable, easier, safer, or more effective for different subsets of the pediatric population.

There are basically three major factors that decide whether a formulation is suitable for the target age group: the formulation must be acceptable to the age group, it must ensure the right dose, and it must be safe. These three factors should be considered and fulfilled for all relevant age groups for which the product is developed. It is therefore expected that the paediatric investigation plan (PIP) application will include a thorough discussion on the proposed formulations and their suitability for the target age groups, covering aspects of acceptability, dosing accuracy, and safety.

Acceptability implies that a formulation can be easily administered to the relevant age groups and is crucial for optimal adherence and intended effect. It covers a range of aspects such as taste, size, volume, complexity of manipulation, local tolerance, and pain. One of the major hurdles for children taking oral medicines is the tablet and capsule size; large sizes may be appropriate for adults but are definitely less suitable for children. Interestingly, information about the size of existing products is often lacking in the initial PIP applications, which could indicate insufficient awareness of this aspect. Size is particularly important if the tablet or capsule is developed to be swallowed whole due to, for example, film coating for taste masking or modified-release design for optimal absorption profile. For such products, crushing and scoring may significantly affect taste, bioavailability, or PK, and therefore, size is crucial for the overall usefulness of the product. Generally, increased attention toward potentially more child-friendly oral solid formulations such as "mini-tablets" and dispersible and orodispersible tablets is highly needed and welcomed, but to date, this is not an approach frequently seen in PIP applications.

Bad taste of oral liquids is a well-known factor that affects medication adherence in children and could be caused by both active substance and excipients. Companies are encouraged to explore avenues to avoid poor pediatric acceptability by optimizing taste masking. This could include standard approaches, such as adding sweeteners or flavors, or more sophisticated methods such as microencapsulation. Careful consideration is needed to balance any taste issue with the strength and volume required.

Although significant clinical experience indicates that many children face major challenges in swallowing tablets and oral liquids, more precise knowledge is still limited about taste preferences and which tablet/capsule sizes are appropriate for which age groups. Consequently, to ensure that children in the relevant age group are actually able to take the medicine as intended, data to support and confirm the acceptability and palatability of the product are requested in the PIPs, for example, as a part of the pediatric clinical studies that will be performed. However, it should be emphasized that early focus on the appropriateness of the formulation is important, as a poorly acceptable formulation might indeed affect the outcome of the pediatric trial performed.

In all cases where a more suitable formulation is not feasible, and there is doubt about whether the formulation (and in particular its size) would be appropriate for the pediatric age group, it is important that alternative approaches are explored and outlined. Recommendations regarding opening capsules, dissolving, dispersing, or crushing tablets, or mixing with food can be very useful for children, parents, or healthcare professionals but would require sufficient considerations of the potential impact on the performance of the drug.

The strength of any liquid form will decide the volume to be withdrawn from a container and given to the pediatric. Dosing small children using strengths suitable for adults will often imply volumes that are too small to accurately administer the dose to the child. Dilution steps to solve the problem with small volumes have been shown to significantly increase the risk of calculation and administration errors and should be avoided if possible. Again, suitable devices to enable accurate dosing are essential.

The osmolality of the administered drug should be appropriate for the target age group. Depending on the route of administration, high-osmolality drugs will have to be diluted to reduce the risk of pain, irritation, necrosis, and necrotizing enterocolitis, elements that can be age dependent. However, whenever dilution is necessary, careful consideration must be given to its impact on the stability of the product, on proper instructions for dilution, and on the volume load.

Although excipients are traditionally thought to be inert and safe, several cases have shown that this is not always true, particularly for very young children, in whom a continuously developing organism may give rise to different excipient safety profiles compared with adults. Significant discussions

have been ongoing for solvents such as ethanol and propylene glycol, preservatives such as thiomersal, benzyl alcohol, and parabens, and solubilizers and colorants. The Paediatric Regulation's call for adapted formulations implies that products intended for use in children must have an acceptable safety profile also in terms of excipients. The PIP should therefore include a thorough presentation of the safety data available for the proposed excipients, justifying the excipient exposure taking into account the target age group, route of administration, and duration of treatment. There are, however, sparse data available specifically relevant to children and in particular, to neonates, and it is generally recommended to avoid excipients with potential safety concerns when developing pediatric formulations. Additional safety data, for example, through juvenile animal studies or additional safety monitoring, might be requested by regulators whenever the excipient safety profile is not fully reassuring.

SPECIFIC CONSIDERATIONS ON FORMULATIONS FOR NEONATES

Neonates, and even more so preterm newborns, are the pediatric groups in whom medicinal products are most often used off label. The need for PK, efficacy, and safety data in this population frequently implies separate clinical trials with careful consideration of the sampling scheme, appropriate end points, and disease characteristics. Particular attention should, however, also be paid to whether the formulation is suitable for this pediatric group, ensuring accurate dosing and safe administration.

In many cases, intravenous administration may be the only feasible route of administration to neonates. Appropriate strength will be vital for, on the one hand, sufficient dosing accuracy, often depending on suitable administration and dosing devices such as pumps, and on the other hand, the limitation in volumes acceptable for neonates with fluid restrictions. In clinical practice, data on compatibility with other commonly administered parenteral drugs will often be needed for treatment to be feasible within the available time and volumes. Therefore, where relevant, such data should be included in the development plan. Ten times dosing error is more often seen in neonatal units due to the fact that the doses are very small compared with the total dose in the vial or bag. Consequently, a separate presentation would often be considered necessary.

Intravenous administration may not always be possible or physico-chemically feasible, for example, due to solubility or stability issues; therefore, in some settings, oral administration is considered necessary and appropriate also for neonates. In such cases, administration through feeding tubes may be necessary and sometimes, the only possible way to administer the drug product. Consequently, factors such as adherence to tube material, particle sizes, viscosity, and rinsing volumes are essential for safe and accurate dosing, and the PIP would have to include data on dose recovery and feasibility of administration through the relevant tubes. Indeed, such elements may also be relevant for older children whenever tube feeding is likely in the target pediatric group.

In summary, any adult presentation will rarely be entirely suitable for smaller children, and especially neonates, and a specific formulation or presentation will often be needed to ensure correct dosing and safe use in these lowest age groups.

COLLABORATION ON PEDIATRIC FORMULATIONS

European and worldwide initiatives have been taken during the last years, also related to formulations. The World Health Organization (WHO)'s campaign "Make medicines child size" and the European Initiative for Paediatric Formulation (EuPFI) are two important examples. The Paediatric Committee (PDCO) and the European Medicines Agency (EMA) have regular contact with the Food and Drug Administration (FDA) and with WHO when relevant, and collaboration is established with EuPFI, where EMA has observer status. As part of its focus on pediatric formulations, PDCO has established a subgroup (PDCO's Formulation Working Group [FWG]). Attention is paid to combined quality, safety, and clinical aspects of formulations. The group consists of PDCO members, national quality experts, clinical pharmacy experts, clinicians, and academic experts and collaborates closely with EuPFI and FDA. A systematic approach to PIP quality aspects aims at a broader and more consistent "cross product assessment."

CONCLUSIONS

The Paediatric Regulation aims at better medicines, including more suitable formulations, for children in Europe. Still in its early phase, the focus on medicines properly adapted for the pediatric population will continue.

The importance of early submission of the PIP is valid also for formulation aspects. The final agreed age groups for which the product is intended will inevitably affect the decision on whether the formulation strategy is optimal, and early agreement on the lower age cut-off will be important for rational formulation development. However, at this point of product development, it is most often not clear whether dose will be critical in terms of dose–response, and whether the need for dose titration is foreseen for other reasons, and such aspects could most likely also influence the choice of formulation. It should be emphasized that for proper dose finding in the pediatric population, a certain degree of flexibility in dosing is normally needed, and wide dose banding (often due to existing adult formulations that to a limited degree, would allow dosing flexibility) could compromise the results of the pediatric clinical trials. Therefore, depending on the lower age cut-off for the development plan and/or the properties of the active substance, a preliminary formulation for use in clinical trials that allows dosing flexibility might be needed. Obviously, in addition to dosing accuracy, both acceptability and safety of such formulations should also be carefully considered. The modification of the preliminary formulation into the product intended to be marketed might necessitate bridging studies depending on the active substance and the formulations proposed.

It is important that the pharmaceutical forms developed have a certain degree of robustness in terms of practical handling and ease of administration to make them useful and safe in both in-hospital and homecare settings if applicable. This is particularly relevant for medicines for children, since several different caregivers are often involved in addition to the child itself. Dosing device, presentation, and proper instructions are vital factors to increase adherence and to reduce the risk of medication errors and should be adapted to the target pediatric group.

Companies are indeed encouraged to consider new technology and innovative approaches to meet the need for pediatric-specific formulations. In this context, it is also important to remind drug developers that the need for flexible dosage forms, in terms of both dosing adjustment and flexibility of mode of administration, is significant also in other populations; for example, geriatric patients, patients with feeding tubes, and intensive care. Some of the apparently pediatric-specific factors will be valid also for these settings, and pediatric formulation development should therefore be an early and integrated part of the overall drug development program.

20 SOP and Specification to Establish Electronic Submission to Regulatory Agencies

1. PURPOSE

The purpose of this document is to instruct the user in regard to the roles and responsibilities with establishment of the electronic Common Technical Document (eCTD) system at COMPANY for submissions to the United States Food and Drug Administration (US-FDA).

2. SCOPE

This procedure impacts Information Technology (IT), Publishing, Regulatory Affairs (RA), and Compliance Departments.

3. DEFINITIONS AND ABBREVIATIONS

List definitions, key terms, and abbreviations used throughout the document along with their meaning. List all definitions in alphabetical order.

CA—Certificate Authority
CDER—Center for Drug Evaluation and Research
CSC—Computer Science Corporation
CTD—Common Technical Document
eCTD—Electronic CTD
ESG—Electronic Submission Gateway
FDA—Food and Drug Administration
HTML—Hypertext Markup Language
ISI Toolbox—A program that works with Adobe Acrobat in the generation and navigation of pdf files compliant with FDA ESG requirements
ISI Writer—A Word template program that assists authors in writing compliant CTD files for submissions
ISI—Image Solutions Inc.
JCE—Java Cryptography Extension
JRE—Java Runtime Environment
pdf—Portable Document Format
PKI—Public Key Infrastructure
Secure e-mail—E-mail that has been setup with an electronic signature to send e-mail communications to and from the FDA for information request and submissions

4. RESPONSIBILITIES

4.1 Information Technology

4.1.1 Provide technical support for e-mail establishment.
4.1.2 Provide electronic signature certificate installation.
4.1.3 Install software programs.
4.1.4 Install updates to the system as an administrator.

4.2 Regulatory Affairs

4.2.1 Establish communication link to FDA for secure e-mail and ESG.
4.2.2 Request a pre-assigned application number.
4.2.3 Establish the ESG with the FDA.

4.3 Publishing

4.3.1 Harmonize all submission word files into a common file format template using ISI Writer.
4.3.2 Generate pdf files from the ISI Writer templates using ISI Toolbox.
4.3.3 Link pdf files following CDER requirements.
4.3.4 Generate eCTD HTML backbone for electronic submission.
4.3.5 Check the eCTD HTML file for errors using Global Submit.

5. MATERIALS AND EQUIPMENT

List the materials and equipment required to execute the procedure. If there are not any to list, write Not Applicable.

5.1 Materials

5.1.1 ISI Writer, CSC
5.1.2 ISI Toolbox
5.1.3 eCTD Express, CSC
5.1.4 Adobe Acrobat® Professional, current version
5.1.5 Global Submit
5.1.6 Outlook current version with SP1
5.1.7 Internet Explorer or check compatibility

5.2 Equipment

5.2.1 Dedicated computer for ESG with ISI writer and ISI toolbox installed.
5.2.2 Computers capable of running ISI writer installed with Word current version.
5.2.3 Server with eCTD Express installed.

6. HEALTH AND SAFETY

Not Applicable.

7. PROCEDURE

7.1 Secure E-mail Setup

7.1.1 Apply for a secure e-mail with the FDA by contacting secureemail@fda.hhs.gov. Instructions will arrive from the FDA regarding the process to setup S/MIME encryption.
7.1.2 Purchase an outsourced digital certificate through an approved FDA electronic signature CA using PKI conforming to X.509 version 3 standard. COMPANY uses Globalsign as a primary provider.
7.1.3 Install the digital certificate following the manufacturer's instructions. See Appendix C in the FDA guidance (http://www.fda.gov/ForIndustry/ElectronicSubmissionsGateway/ucm334781.htm).
7.1.4 Create a new e-mail "To: Cert-query@fda.hhs.gov" with the Subject: "Keith.Robertson@fda.hhs.gov". Digitally sign the e-mail by opening the options tab and selecting "Sign."
7.1.5 Within 5 minutes, a response e-mail will arrive with the proxy certificate public key.
7.1.6 Open the e-mail, right click on the "From" field, and select "Add to Outlook Contacts." With the contacts tab open, select the "Certificates button," and click on the properties tab on the right. From the Certificate Properties, click the Trust tab, select "Explicitly trust this Certificate," and click OK.
7.1.7 Send an e-mail to Keith.Robertson@fda.hhs.gov confirming that the preceding steps have been completed. The FDA will set up the profile and confirm that the digital signing works.
7.1.8 A confirmation e-mail will be sent from the FDA confirming the secure e-mail.

7.2 Requesting a Pre-Assigned Application Number

7.2.1 Establish a secure e-mail account.
7.2.2 Send one e-mail per application request to cder-appnumrequest@fda.hhs.gov with the information presented in Exhibit I.

7.3 ESG Account Setup

7.3.1 Follow Section 7.1 to set up secure e-mail.
7.3.2 Apply for a test account by sending an e-mail to esgprep@fda.hhs.gov
7.3.3 Submit a "Letter of Non-Repudiation Agreement" to the FDA. See Exhibit II.
7.3.4 Locate the COMPANY guidance compliant test submission following CDER guidelines.
7.3.5 Locate the COMPANY 2 GB prepared load test submission.
7.3.6 Locate your public key for your personal digital certificate.
7.3.7 Install JRE and JCE following the instructions on the FDA website (http://www.fda.gov/ForIndustry/ElectronicSubmissionsGateway/ucm334783.htm).
7.3.8 Once the activation e-mail is received, configure the firewall as detailed within the e-mail.
7.3.9 Follow the link within the e-mail from the FDA (step 7.3.2) to access the test account.
7.3.10 Follow the instructions on the FDA website for sending a web-based test submission (www.fda.gov/ForIndustry/ElectronicSubmissionsGateway/ucm114659.htm).
7.3.11 Send a guidance compliant test submission.
7.3.12 Send a connectivity test to CDER with submission type GDUFA_Facility_Registration.
7.3.13 Send a load test to "Testing (GWTEST)" center and submission type "Size Test."
7.3.14 The FDA will review the test files. Note that this can take up to 2 weeks.
7.3.15 An e-mail will be sent detailing the process for registering for a production account.
7.3.16 Follow the e-mail (step 7.3.15) to register for a production account. Within 48 hours, the production account will be active. Note that the computer the test account was sent from needs to be the same computer for the production account. This is the dedicated computer for ESG.

00	Date	####	Name	New procedure to define the roles and responsibilities for the establishment of the eCTD.

11. ICH eCTD SPECIFICATION

11.1 Introduction

The International Conference for Harmonisation (ICH) M4 Expert Working Group (EWG) has defined the Common Technical Document (CTD). The ICH M2 EWG has defined, in the current document, the specification for the Electronic Common Technical Document (eCTD). The eCTD is defined as an interface for industry to Agency transfer of regulatory information while at the same time taking into consideration the facilitation of the creation, review, life cycle management, and archival of the electronic submission. The eCTD specification lists the criteria that will make an electronic submission technically valid. The focus of the specification is to provide the ability to transfer the registration application electronically from industry to a regulatory authority. Industry to industry and Agency to Agency transfer is not addressed.

The specification is divided into a series of main sections followed by a number of appendices in which detailed technical specifications are given. It will provide a mechanism whereby parts of the specification will be updated or adjusted to agreed new technologies or standards on an independent basis without the necessity of updating it all. This aspect will be covered in the chapter Change Control.

11.2 Background

The specification for the eCTD is based upon content defined within the CTD issued by the ICH M4 EWG. The CTD describes the organization of modules, sections, and documents. The structure and level of detail specified in the CTD have been used as the basis for defining the eCTD structure and content, but where appropriate, additional details have been developed within the eCTD specification.

The philosophy of the eCTD is to utilize open standards. Open standards, including proprietary standards, which through their widespread usage can be considered de facto standards, are deemed to be appropriate in general.

11.3 Scope

The CTD as defined by the M4 EWG does not cover the full submission that is to be made in a region. It describes only modules 2 to 5, which are common across all regions. It does not describe the content of module 1, the Regional Administrative Information and Prescribing Information, nor does it describe documents that can be submitted as amendments or variations to the initial application.

The value of production of a specification for the creation of an electronic submission based only upon the modules described in the CTD would be limited. Therefore, the M2 EWG has produced a specification for the eCTD that is applicable to all modules of initial registration applications and for other submissions of information throughout the life cycle of the product, such as variations and amendments.

This document describes the parts of the registration application that are common to all regions and some of the life cycle requirements for products. The parts of the registration application that are specific to a region will be covered by regional guidance. However, the backbone has been developed to handle both the regional and the common parts of submissions.

11.4 Requirements

The specification is designed to support high-level functional requirements such as the following:

- Copy and paste
- Viewing and printing of documents
- Annotation of documentation
- Facilitating the exporting of information to databases
- Searching within and across applications
- Navigation throughout the eCTD and its subsequent amendments/variations

11.5 Change Control

11.5.1 Introduction

The specification for the eCTD is likely to change with time. Factors that could affect the content of the specification include, but are not limited to,

- Change in the content of the CTD, either through the amendment of information at the same level of detail or by provision of more detailed definition of content and structure
- Change to the regional requirements for applications that are outside the scope of the CTD
- Updating of standards that are already in use within the eCTD
- Identification of new standards that provide additional value for the creation and/or usage of the eCTD
- Identification of new functional requirements
- Experience of use of the eCTD by all parties

The first specification for an eCTD is an ICH M2 Step 4 document. The Specification includes an appendix for the modules of the CTD. Each appendix consists of (or includes) detailed information for the structure and format to be used in preparing a CTD module.

It is understood that technology will continue to evolve at a rapid pace. There could also be changes to the CTD. Information technology capabilities and requirements will also evolve in the pharmaceutical industry and in the regulatory authorities. The change control process described in this section allows the eCTD Specification to be updated to meet new requirements and to take advantage of technology improvements. Each appendix should be updated as needed independently of the remainder of the document.

11.5.2 Process

The eCTD Specification Change Control Board (CCB) is authorized by the ICH Steering Committee to make changes to the eCTD Specification to keep pace with advancing technology. Since the issuance of guidelines is the responsibility of the regulatory authorities, in line with the standards ICH process, the regulatory authorities are the voting members of the CCB. Industry representatives from each of the three regions, and Health Canada as observer, are nonvoting members of the CCB. The position of chair of the CCB rotates on an annual basis among the regulatory authority members.

The three regulatory authorities represented in the ICH M2 Expert Working Group are responsible for initiating changes to the eCTD Specification based on industry or regulatory input. A change can be proposed by any of the regulatory authorities. A group or individual, not a member of an ICH regulatory authority, can propose a change to the specification, including recommendation for experts to be invited, by submitting the proposal to one of the regional regulatory authorities.

The CCB meets on a regular schedule to discuss, evaluate, and agree on proposed changes to the specification. During these meetings, the members of the CCB and other invited parties evaluate the proposed changes. The decision to accept a change to the eCTD Specification is made by a unanimous vote of the regulatory authority representatives.

The agreed changes to the Specification will be published for public comment in each region. Comments are collected and considered by the CCB and will be adopted in modified or unmodified form or rejected. The updated part of the eCTD Specification will be agreed upon and signed by the three regional regulatory authorities and will be published as required in each region. The planned implementation date and transition period for each change in each region are included in the published description of the change. Adopted changes will normally be published on an annual basis except for emergency changes, such as an error in critical metadata, as defined by the CCB, which will be published immediately upon adoption. The CCB will provide guidance that will indicate how existing submissions and those currently undergoing late-stage compilation should be updated.

Regulatory authorities will support submissions described by at least two consecutive versions of the eCTD Specification. The regulatory authority intends to keep all versions of the Specification for as long as needed to process eCTD submissions that are on file with a regulatory authority.

The CCB will establish its meeting schedule at the first meeting of the CCB. The first meeting will be at the same time as the ICH Steering Committee.

11.5.3 Procedure

Change requests should be submitted to a regulatory authority. Change requests received at least 30 days before a

scheduled CCB meeting will be placed on the agenda for that meeting. Change requests received less than 30 days before a CCB meeting will be placed on the agenda for the following meeting.

Change requests should contain as much of the following information as possible:

- A description of the problem that the change is intended to solve.
- The proposed solution(s)—this consists of a description of the solution(s) and the text of the changes to affected documents.
- A detailed description of any testing or research that was done to support the solution(s) being proposed.
- Advice on backward compatibility issues, if any.

The CCB will maintain a public list of requests and the status of each request. New change requests will be posted to the list within 30 days of their receipt.

11.6 Approach to Documentation and Use of the eCTD Specification

The approach to the management of the Specification for the eCTD is to divide the documentation into a series of independent but related appendices. This will facilitate the maintenance of the Specification, as it will not require that all documentation be updated even for a small change to one part of the Specification. Each appendix can be updated independently as and when required, thus being able to more readily support the currency of the Specification as a whole.

Taylor & Francis
Taylor & Francis Group
http://taylorandfrancis.com

Appendix 1: Overall Architecture

1.1 GUIDING DESIGN PRINCIPLES

This appendix defines the basic principles that drove the design and architecture of the electronic Common Technical Document (eCTD). Detailed specifications are defined in Appendices 2 and 6.

1.2 BUSINESS MODEL

The business process to be supported can be described as follows:

Industry ↔ Message ↔ Agency

The business process defines specific requirements for the message.

The primary focus of the eCTD is to provide a data interchange message between the industry and agencies. The industry initiates the process by creating the initial submission in terms of an electronic CTD. Throughout the lifecycle of this process, additional information will be submitted to update or modify the information contained in the initial submission; for example, supplements, amendments, variations, etc. The agency can submit acknowledgements, queries, and requests to the industry. These are considered simple messages utilizing electronic mail or other transport formats. The overall architecture of the eCTD is designed to provide a commonly agreed-upon submission and submission structure that imposes minimal restriction on the industry and agencies.

1.3 MODULAR STRUCTURE OF THE eCTD

The structure of the electronic submission in terms of organization and navigation should be consistent with the modular structure of the CTD. The goal of this design principle is to standardize the electronic format of the common parts of the eCTD.

1.4 XML-BASED eCTD

The XML eCTD DTD (Document Type Definition) defines the overall structure of the submission. The purpose of the XML backbone is twofold: (1) to manage metadata for the entire submission and each document within the submission and (2) to constitute a comprehensive table of contents and provide corresponding navigation aids. Metadata on submission level includes information about submitting and receiving organizations, manufacturer, publisher, ID and kind of the submission, and related data items. Examples of metadata at the document level are versioning information, language, descriptive information such as document names, checksums, etc. Details are defined in Appendix 6.

The XML instance of any submission should be created and validated according to the XML eCTD DTD as defined in Appendix 8.

The XML eCTD DTD describes the hierarchical structure according to the CTD as defined by the International Conference on Harmonisation (ICH) M4 expert working group. It includes multiple hierarchical levels depending on the specific module as defined in the CTD. The actual submission can include more hierarchical levels below those defined in the CTD. The XML eCTD instance covers the entire submission including all hierarchical levels and includes references to each individual file.

The submission should include a style sheet that supports presentation of the XML instance and navigation according to the table of contents, and provides access to all documents within the submission. A standard style sheet is defined and provided by the ICH M2 Expert Working Group (EWG). Presentation and navigation via other style sheets on the receiving side should be possible.

The XML eCTD DTD includes a reference for each document to the physical file within the folder structure. The XML eCTD DTD includes attributes for descriptive names of folders and documents.

1.5 MULTIPLE REGION SUPPORT

The scope of each submission is global according to the Common Technical Document, meaning that modules 2 through 5 of a submission are intended for all regions with the exception of selected documents (e.g., in the quality module) that have a regional scope. Module 1 of a submission is regional in nature.

The DTD as defined by the ICH M2 EWG specifies the structure of the common parts of the eCTD, primarily focusing on module 2 through 5. It allows linking to regional DTDs for module 1, which will be defined by the authorities in each region.

1.6 LIFE CYCLE MANAGEMENT

The applicant creates a submission that is stored in a local repository. The applicant submits the initial submission to the agency, which imports the submission into another local repository. The nature and kind of the local repositories are not within the scope of the eCTD. The initial submission should be self-contained, meaning that it includes all documents and no references to other submissions. Regional guidance should be consulted if references to other submissions are needed.

Following the initial submission, the applicant can submit incremental updates such as amendments and variations. Updates can refer to documents in the previous submissions. Updates should be designed in such a way that they can be loaded into the repository by fully preserving the initial or previous submission via version control. The XML backbone

should include metadata identifying the update and providing navigation aids to filter for different submission types.

It is preferred that when a CTD is submitted electronically, the entire submission should be in electronic form, with the exception of certain regional forms that currently require written signatures. See Appendix 5 for regional requirements. See Appendix 6 for a description of how to submit a CTD containing both paper and electronic components.

Appendix 2: The eCTD Submission

2.1 INTRODUCTION

This appendix specifies the information technology aspect of the electronic Common Technical Document (eCTD) Submission. Informally, the eCTD Submission is a directory structure with files including the XML eCTD instance, reports, data, and other submission information. The eCTD Submission supports multilingual and multi-region aspects.

2.2 THE eCTD SUBMISSION

An eCTD Submission is a collection of data objects that follows the eCTD Specification. The main function of the eCTD Submission is data exchange. Information systems would have to be created to process the eCTD Submission. The biggest benefits are expected when the eCTD Submission is loaded into an information system that supports the review process. However, one can view an eCTD Submission with a Web browser, as it is Web ready. In the Web environment, the eCTD Submission should be usable without processing in at least the following ways:

- Standalone: Viewable with a Web browser
- Network: Loadable into a Web server

The eCTD Submission is composed of the following:

- Directory Structure
- XML eCTD instance
- Content files

2.2.1 Directory Structure

The directory structure is a structure of directories and files. There should be a reasonable maximum number of entries (directories and files) per directory. The directory structure should follow the rules in this subsection. The files could be in several formats as specified in the following.

The name of the files and directories are identifiers. They should be short. The file names are not intended to convey metadata, though some meaning in the names helps; that is, no random names.

Names for directories and files are recommended in Appendix 4. Any directory names and file names that are added to the eCTD submission by the applicant should be descriptive and logical.

2.2.2 XML eCTD Instance

The instance is in the submission sequence number directory (see Appendix 6). The submission sequence number directory should contain at least two files and one or more directories. One of the files in the submission sequence directory is the instance, and the other is the MD5 checksum of the instance. The instance is the starting file for the processing by an XML processor.

The intention is to have links from the instance to leaf files in the eCTD submission as opposed to creating a single XML document that contains the entire eCTD submission. The instance should contain mostly linking facilities to the leaf files. The instance also contains metadata at the leaf level.

2.3 eCTD TEMPLATE

The ICH Web site includes an eCTD template, which is an empty directory structure with a recommended style sheet. It is an illustration of an eCTD Submission, and it is ready to be populated with the applicant data. Appendix 4 defines the directories used to create this template.

2.4 LOGICAL DOCUMENTS AND FILES

A logical document is comprised of one or more CTD table of contents sections that together contain the minimum amount of information to be exchanged. In general, the XML eCTD DTD maps explicitly to the CTD table of contents, but there are exceptions where the XML eCTD DTD maps to the level of use designated by the appropriate ICH CTD Implementation Working Group (IWG) instead. Ideally, a logical document consists of a single physical file. In the event that the physical file exceeds the recommended maximum file size due to graphics, data content, scanned images, or other large-format content, additional files may make up the logical document. Furthermore, if the logical document consists of multiple file formats, then more than one physical file would be needed. An example of such a case would be PDF and XML data that together represent the logical document.

2.5 FORMATS

Formats should be readable at least for as long as this is needed for the regulatory process. This process could be very long; for example, 50 years. This points to neutral formats: formal standard, industrial standard, vendor independent, text-like, etc. The format should be adapted to the type of data. Appendix 7 describes the way in which these files should be constructed.

The list of agreed formats will be updated as technology evolves and new requirements arise. XML will be the preferred format for all types of data.

2.6 COMMON FORMATS

The common formats that can be included in an eCTD Submission are

- Narrative: Portable Document Format (PDF)
- Structured: Extensible Markup Language (XML)

- Graphic: Whenever possible, use PDF. When appropriate, or when PDF is not possible, use Joint Photographic Experts Group (JPEG), Portable Network Graphics (PNG), Scalable Vector Graphics (SVG) and Graphics Interchange Format (GIF). Special formats for very high resolutions may be appropriate on a case-by-case basis.

2.7 REGIONAL USE OF OTHER FORMATS

Regulatory authorities and applicants could agree to use other formats regionally; that is, noncommon formats or uses of the common formats in a different way. The use of other formats is discouraged, and the intention is to use the common formats as much as possible. The intention of the use of other formats is for transition.

There are two classes of transition:

- Legacy Transition: from the past to the present; that is, old formats to present formats
- Future Transition: from the present to the future; that is, from present formats to new formats. The new formats would normally be candidates for common formats.

2.8 LINKS

Links among objects in the eCTD Submission should be relative. The intention is to make the eCTD submission self-contained. All literature references introduced by the applicant should be included in the submission; for secondary references (references to a reference), absolute links to external objects can be used.

One can always point to a file. The capacity to point to a specific location within a file depends on the linking technology. Different formats allow the use of different linking technologies. See Appendix 7.

2.9 PRESENTATION

Presentation is closely associated with formats. To associate a style sheet with a file, usually, one has to use a linking technology. The linking between the style sheet (which could be in a separate file) and a data file should be relative. In addition, there is the dimension of media. One file could have several style sheets; the one used depends on the medium. For example, there could be one presentation for the screen and another for paper.

2.10 CHECKSUMS

The eCTD Submission should contain checksums for each individual file, including a checksum file for the eCTD XML instance. Initially, the MD5 Message-Digest Algorithm (MD5) should be used for this purpose. Including a checksum for each individual file provides a number of benefits, including:

- The integrity of each file can be verified by comparing the checksum submitted with the file and the computed checksum.
- The checksum can be used to verify that the file has not been altered in the historical archive of the regulatory authority. This is especially useful as the files are migrated from one storage medium to another, as in the case of backup to magnetic tape storage.

2.11 ELEMENT TO FILE DIRECTORY MAPPING

Follow these rules:

- The following rules for the file and directories take precedence.
- Add the corresponding extension to the file.
- If needed, use a reasonable abbreviation.

2.12 FILE EXTENSION

All files should have one and only one file extension. The file extension should be used to indicate the format of the file. For example:

hello.pdf	PDF
hello.rtf	RTF

The mappings between formats and extensions are:

Internet Assigned Numbers Authority (IANA) nomenclature

text/css	css
text/html	html or htm
text/xml	xml
application/pdf	pdf
application/rtf	rtf
application/vnd.ms-excel	xls
image/jpeg	jpg
image/png	png
image/gif	gif

Non-IANA nomenclature

DTD	dtd
XPT (SAS)	xpt
XSL	xsl

The eCTD Submission could use formats not registered with IANA.

The presence of a format in this list does not imply that it would be considered an acceptable format. For formats absent from this list, widely used mapping between the formats and the extensions should be used.

Future direction: if a mechanism (e.g., standard) becomes available that associates the formats with file extension, it should be considered for this specification.

2.13 NAME

Name is a token composed of the following characters:

- Letters “a” to “z” [U+0061 to U+007A].
- Digits “0” to “9” [U+0030 to U+0039].
- “-” [HYPHEN-MINUS, U+002D].

The notation “U+” refers to the Unicode [UNICODE] notation.

Correct Names (only the name without the extension):

part-b
myfile
hello

Incorrect names (only the name without the extension):

part a	(“ “; SPACE is not allowed)
myfile.xml	(“.”; FULL STOP is not allowed)
hello:pdf	(“:”; COLON is not allowed)
part_a	(“_”, LOW LINE is not allowed)

Directory name is a name.

File name is one name followed by one name separated by a “.” (FULL STOP, U+002E).

Correct file names (with the extension):

myfile.pdf
hello.cml

Incorrect file names (with the extension):

a part.pdf	(“ ”; SPACE is not allowed)
hello	(missing extension)
hello:xml	(“:”; COLON is not allowed)

The maximum length of a directory name or a file name is 64 characters. Only lower-case letters should be used in all file and directory names. The maximum length of a path is 256 characters. For example, “data/module_1/introduction.html” is the path; “introduction.html” is a File Name.

Document Name is the first Name in the File Name: for example, “docname” in the file name “docname.ext”.

Character encoding

The character encoding (charset) in order of preference is

- Unicode UTF-8, Unicode 16 bits [ISO-10646].
- ISO-8859-1 (Latin-1) or appropriate ISO-8859-x; for example, ISO-8859-7 for Greek.
- The appropriate SHIFT_JIS.
- Other character encoding agreed upon regionally by the regulatory authority and applicant.

Appendix 3: General Considerations for the CTD Modules

3.1 INTRODUCTION

Documents that are provided in the different modules should be formatted as defined by the International Conference on Harmonisation (ICH) Common Technical Document (CTD). There should also be consistency in the way navigation aids are provided. Within each document, bookmarks and hypertext links from the table of contents should be provided to all tables, figures, publications, and appendices.

Hypertext links should be provided throughout the body of these documents to aid efficient navigation to annotations, related sections, publications, appendices, tables, and figures that are not located on the same page. If a list of references is included at the end of a document, there should be hypertext links to the appropriate publication.

Documents should be generated from electronic source documents and not from scanned material, except where access to the source electronic file is not available, or where a signature is required.

3.2 FOLDER AND FILE NAMING CONVENTIONS

A folder and file organization is presented in this specification. This could be used in most cases; however, applicants may modify this specification where appropriate*; for example, to include an additional folder for information where an appropriate folder name is not available in the eCTD specification. It is recommended that applicants maintain folder names listed in this specification. This should not be interpreted to mean that the actual eCTD XML DTD should be changed or altered in any way.

The maximum length of a folder or file name is 64 characters including the extension. Folder or file names should be written in lower case only. All files should have one and only one file extension. The file extension should be used to indicate the format of the file. More details on the naming conventions are given in Appendix 2 and examples in Appendix 4.

Typically, the file name would be the applicant's internal numbering or naming convention for the studies. The following table gives an example of how files could be named.

Description	File Name
Study Report 1	*study-report-1.pdf*
Study Report 2	*study-report-2.pdf*
…	…
Study Report n	*study-report-n.pdf*

* Regulatory authorities should be notified of additions and changes to the folder structure according to regional guidance.

Data listings can be included as part of a study report document or as a separate appendix. An example of such file names follows.

Description	File Name
Study Report 1	*study-report-1.pdf*
Study Report 1 Data	*study-report-1-data.pdf*
Study Report 2	*study-report-2.pdf*
Study Report 2 Data	*study-report-2-data.pdf*
…	…
Study Report n	*study-report-n.pdf*
Study Report n Data	*study-report-n-data.pdf*

Regional requirements can provide for the submission of the data listings as a data file. Reference should be made to regional guidances.

3.3 SCREENSHOTS AND FOLDER HIERARCHY

Screenshots are provided in the following chapters for all modules down to the level of hierarchy as described in this appendix. The representations are in alphabetical order due to the nature of the computer operating system and are therefore not entirely consistent with the sequence of the CTD. In a web browser, the content will appear in the order of the CTD table of contents.

Detailed options on the folders and files are provided in Appendix 4 in case the applicant chooses to submit more granular documents. It is not mandatory to use the full folder hierarchy. Empty directories can be omitted.

3.4 MODULE 1 ADMINISTRATIVE INFORMATION AND PRESCRIBING INFORMATION

The name of the folder for module 1 should be *module-1.*

This module contains administrative information that is unique for each region. Regional guidance will provide the specific instructions on how to provide the administrative forms and detailed prescribing information. Please refer to Appendix 5 when preparing module 1.

3.5 MODULE 2 SUMMARIES

The files in this module should be provided as PDF text with the exception of a few embedded images when needed.

The name of the folder for module 2 should be *module-2*. The folders in module 2 should be named as follows.

Section in CTD	Description	Folder Name
2.3	Quality Overall Summary	*quality-overall-summary*
2.6	Nonclinical Written and Tabulated Summary	*nonclinical-summary*
2.7	Clinical Summary	*clinical-summary*

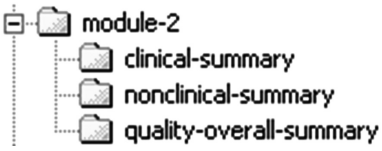

FIGURE 3.1 Screenshot of the folder structure of module 2

Other sections at this level not listed here can typically be submitted as individual files.

The folder hierarchy for module 2 is presented in the screenshot in Figure 3.1.

3.6 MODULE 3 QUALITY

The name of the folder for module 3 should be *module-3*. The folders in module 3 should be named as follows.

Section in CTD	Description	Folder Name
3.2	Body of Data	*body-of-data*
3.2.S	Drug Substance	*drug-substance*
3.2.S	Drug Substance [Drug Substance Name] [Manufacturer][a]	*substance-1-manufacturer-1*
3.2.S.1	General Information	*general-information*
3.2.S.2	Manufacture	*manufacture*
3.2.S.3	Characterisation	*characterization*
3.2.S.4	Control of Drug Substance	*control-drug-substance*
3.2.S.4.1	Analytical Procedures	*analytical-procedures*
3.2.S.4.2	Validation Analytical Procedures	*validation-analyt-procedures*
3.2.S.7	Stability	*stability*
3.2.P	Drug Product[b]	*drug-product*
3.2.P	Product 1	*product-1*
3.2.P.3	Manufacture	*manufacture*
3.2.P.4	Control of Excipients	*control-excipients*
3.2.P.4	Excipient 1	*excipient-1*
3.2.P.5	Control of Drug Product	*control-drug-product*
3.2.P.5.1	Analytical Procedures	*analytical-procedures*
3.2.P.5.2	Validation Analytical Procedures	*validation-analyt-procedures*
3.2.P.8	Stability	*stability*
3.2.A	Appendices	*appendices*
3.2.A.1	Facilities and Equipment	*facilities-and-equipment*
3.2.A.2	Adventitious Agents Safety Evaluation	*adventitious-agents*
3.2.A.3	Novel Excipient 1[c]	*novel-excipient-name-1*
3.2.R	Regional Information[d]	*regional-information*
3.3	Literature References	*references*

[a] Each drug substance manufacturer should be placed in a separate subordinate folder. Folders and files should be created for each drug substance-manufacturer section included in the submission in accordance with the hierarchy identified in the following chapters.

[b] Each drug product should be placed in a separate subordinate folder. Folders and files should be created for each drug product section included in the submission in accordance with the hierarchy identified in the following chapters. Reference should be made to regional guidance to determine whether the inclusion of multiple products within a single application is considered appropriate.

[c] The folder name should include the name of the novel excipient, abbreviated as necessary to remain within the 64 character limit.

[d] This folder should be included where regional information is appropriate. Reference should be made to regional guidance for the types of nformation to be included in this section.

The folder hierarchy for module 3 is presented in the screenshot in Figure 3.2.

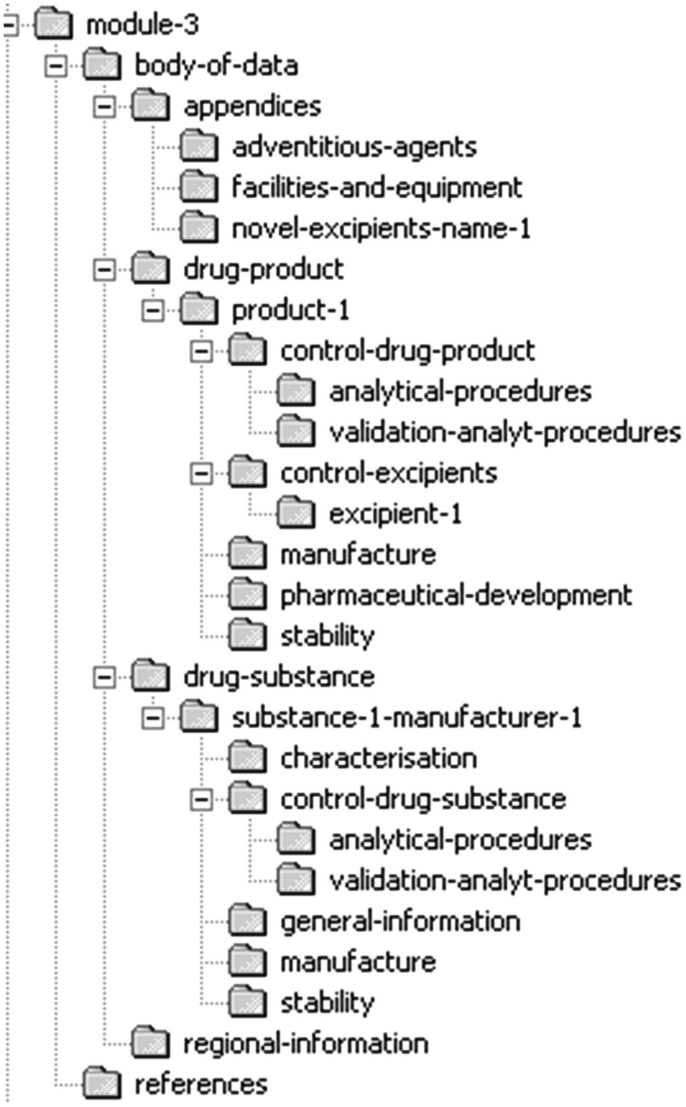

FIGURE 3.2 Screenshot of the folder structure of module 3

3.7 MODULE 4 NONCLINICAL STUDY REPORTS

The name of the folder for module 4 should be *module-4*. The folders in module 4 should be named as follows.

Section in CTD	Description	Folder Name
4.2	Study Reports	*study-reports*
4.2.1	Pharmacology	*pharmacology*
4.2.1.1	Primary Pharmacodynamics	*Primary-pharmacodynamics*
4.2.1.2	Secondary Pharmacodynamics	*secondary-pharmacodynamics*
4.2.1.3	Safety Pharmacology	*safety-pharmacology*
4.2.1.4	Pharmacodynamic Drug Interactions	*pd-drug-interactions*
4.2.2	Pharmacokinetics	*pharmacokinetics*
4.2.2.1	Analytical Methods and Validation Reports (if separate reports are available)	*analyt-methods-validation*
4.2.2.2	Absorption	*absorption*
4.2.2.3	Distribution	*distribution*
4.2.2.4	Metabolism	*metabolism*
4.2.2.5	Excretion	*excretion*
4.2.2.6	Pharmacokinetic Drug Interactions (nonclinical)	*pk-drug-interactions*
4.2.2.7	Other Pharmacokinetic Studies	*other-pk-studies*
4.2.3	Toxicology	*toxicology*
4.2.3.1	Single-Dose Toxicity (in order by species, by route)	*single-dose-toxicity*
4.2.3.2	Repeat-Dose Toxicity (in order by species, by route, by duration, including supportive toxicokinetic evaluations)	*repeat-dose-toxicity*
4.2.3.3	Genotoxicity	*genotoxicity*
4.2.3.3.1	In vitro	*in-vitro*
4.2.3.3.2	In vivo (including supportive toxicokinetic evaluations)	*in-vivo*
4.2.3.4	Carcinogenicity (including supportive toxicokinetic evaluations)	*carcinogenicity*
4.2.3.4.1	Long-term studies (in order by species, including range-finding studies that cannot be appropriately included under repeat-dose toxicity or pharmacokinetics)	*long-term-studies*
4.2.3.4.2	Short- or medium-term studies (including range-finding studies that cannot be appropriately included under repeat-dose toxicity or pharmacokinetics)	*short-medium-term-studies*
4.2.3.4.3	Other studies	*other-studies*
4.2.3.5	Reproductive and Developmental Toxicity (including range-finding studies and supportive toxicokinetic evaluations)	*repro-development-toxicity*
4.2.3.5.1	Fertility and early embryonic development	*fertility-embryonic-develop*
4.2.3.5.2	Embryo-fetal development	*embryo-fetal-develop*
4.2.3.5.3	Prenatal and postnatal development, including maternal function	*pre-postnatal-develop*
4.2.3.5.4	Studies in which the offspring (juvenile animals) are dosed and/or further evaluated	*juvenile*
4.2.4	Local Tolerance	*local-tolerance*
4.2.5	Other Toxicity Studies (if available)	*other-toxicity-studies*
4.2.5.1	Antigenicity	*antigenicity*
4.2.5.2	Immunotoxicity	*immunotoxicity*
4.2.5.3	Mechanistic studies (if not included elsewhere)	*mechanistic-studies*
4.2.5.4	Dependence	*dependence*
4.2.5.5	Metabolites	*metabolites*
4.2.5.6	Impurities	*impurities*
4.2.5.7	Other	*other*
4.3	Literature References	*references*

The folder hierarchy for module 4 is presented in the screenshot in Figure 3.3.

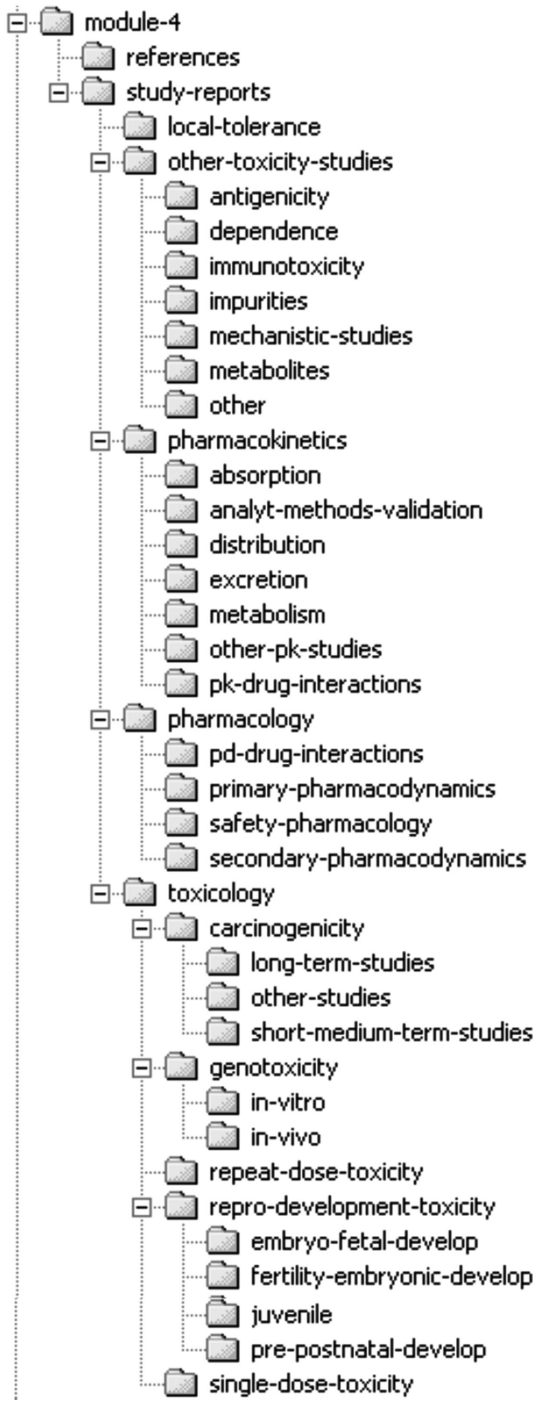

FIGURE 3.3 Screenshot of the folder structure of module 4

3.8 MODULE 5 CLINICAL STUDY REPORTS

The name of the folder for module 5 should be *module-5*. The folders in module 5 should be named as follows.

Section in CTD	Description	Folder Name
5.3	Clinical Study Reports	*clinical-study-reports*
5.3.1	Reports of Biopharmaceutic Studies	*biopharmaceutic-studies*
5.3.1.1	Bioavailability (BA) Study Reports	*bioavailability*
5.3.1.2	Comparative BA and Bioequivalence (BE) Study Reports	*comparative-ba-be*

Appendix 4: File Organization for the eCTD

Each item in the file organization table that is included in this appendix includes the following information: the following table covers files that constitute the backbone itself plus necessary additional files to make the submission complete, readable, and processable.

Where file names are presented in italics, typically, applicants would substitute these with file names in accordance with their own naming conventions.

Sequential number		Each item in the table has a unique sequentially assigned reference number. These reference numbers can change with each version of this appendix.
	Number	**CTD section number**
	Title	**CTD title**
	Element	**Element name in the Backbone**
	File/Directory	**Full path of the File/Directory. The file extension corresponds to the file type; that is, the "pdf" extension is only illustrative. Refer to Table 6.1, Appendix 6 for details for the head of the path name.**
	Comment	**Comments**

APPENDIX 4 (CONTINUED)

27	Number	2.7.1
	Title	Summary of Biopharmaceutic and Associated Analytical Methods
	Element	m2-7-1-summary-of-biopharmaceutic-and-associated-analytical-methods
	File	module-2/clinical-summary/summary-biopharm.pdf
	Comment	Typically, this logical document should consist of a single file. The CTD defines further heading levels, and navigation should be provided within the document to these subheadings.
28	Number	2.7.2
	Title	Summary of Clinical Pharmacology Studies
	Element	m2-7-2-summary-of-clinical-pharmacology-studies
	File	module-2/clinical-summary/summary-clin-pharm.pdf
	Comment	Typically, this logical document should consist of a single file. The CTD defines further heading levels, and navigation should be provided within the document to these subheadings.
29	Number	2.7.3
	Title	Summary of Clinical Efficacy—*Indication*
	Element	m2-7-3-summary-of-clinical-efficacy
	File	module-2/clinical-summary/summary-clin-efficacy-*indication.pdf*
	Comment	The folder name should always include the indication being claimed (abbreviated if appropriate); for example, "summary-clin-efficacy-asthma." Where there is more than one indication (e.g., asthma and migraine), then the first indication has a folder "summary-clin-efficacy-asthma" and the second "summary-clin-efficacy-migraine." Typically, this logical document should consist of a single file. The CTD defines further heading levels, and navigation should be provided within the document to these subheadings.
30	Number	2.7.4
	Title	Summary of Clinical Safety
	Element	m2-7-4-summary-of-clinical-safety
	File	module-2/clinical-summary/summary-clin-safety.pdf
	Comment	Typically, this logical document should consist of a single file. The CTD defines further heading levels, and navigation should be provided within the document to these subheadings.
31	Number	2.7.5
	Title	References
	Element	m2-7-5-references
	File	module-2/clinical-summary/references.pdf
	Comment	
32	Number	2.7.6
	Title	Synopses of Individual Studies
	Element	m2-7-6-synopses-of-individual-studies
	File	module-2/clinical-summary/synopses-indiv-studies.pdf
	Comment	These synopses should already be located in the Clinical Study Reports in Module 5 and should not, therefore, be repeated in Module 2. It is considered sufficient to provide hyperlinks to the locations in Module 5.
33	Number	3
	Title	Quality
	Element	m3-quality

	Comment	
35	Number	3.2.S
	Title	Drug Substance
	Element	m3-2-s-drug-substance
	Directory	module-3/body-of-data/drug-substance
	Comment	

(*Continued*)

APPENDIX 4 (CONTINUED)

36	Number	3.2.S
	Title	Drug Substance—*Drug Substance Name-Manufacturer*
	Element	m3-2-s-drug-substance
	Directory	module-3/body-of-data/drug-substance/*substance-1-manufacturer-1*
	Comment	The folder name should always include the name of the drug substance (e.g., ranitidine) through the inclusion of the International Non-proprietary Name to give "ranitidine-hydrochloride." Similarly, for manufacturer, the folder name should always include the name of the manufacturer (e.g., *ranitidine-manufacturer-1*). Where there is more than one manufacturer, the drug substance folder should be repeated but with an indication of each manufacturer concerned included in the folder name: the first instance, for example, *drug-substance-1- manufacturer-1* and the second *drug-substance-1-manufacturer-2*. Where there is more than one drug substance (e.g., ranitidine hydrochloride and cimetidine), then the first drug substance has a folder "ranitidine-hydrochloride" and the second "cimetidine." In this example, a set of folders can include *ranitidine-manufacturer-1* *ranitidine-manufacturer-2* *cimetidine-manufacturer-1* *cimetidine-manufacturer-2* Typically, the applicant would include the specific manufacturer(s) (and/or site) in the folder name.
37	Number	3.2.S.1

	Element	m3-2-a-2-adventitious-agents-safety-evaluation
	File	module-3/body-of-data/appendices/adventitious-agents/*adventitious-agents-report-3.pdf*
	Comment	
116	Number	3.2.A.3
	Title	Novel Excipients-*Name*
	Element	m3-2-a-3-novel-excipients
	Directory	module-3/body-of-data/appendices/novel-excipients-*name-1*
	Comment	The name of any novel excipient should be included in the folder name. If there is more than one novel excipient, then each folder should have unique identification through the use of different names; for example, "novel-excipient-*name-1*" and "novel-excipient-*name-2*." The directory/file structure would typically follow that of the drug substance section in Module 3. Refer to regional guidances for the need for such information to be included in the submission directly as opposed to its inclusion in a Drug Master File.

	Comment	The applicant can choose to submit this logical document as a single file or multiple files. If multiple files are used, they should be organized and named in accordance with the naming of sections of a clinical study report as defined in the ICH E3 guideline. It is possible to have the additional graphic file(s) inserted directly into the PDF file, thus making management of the file easier. Alternatively, the applicant can choose to manage these independently. This comment is applicable to all study reports in Module 5.

Appendix 5: Region-Specific Information Including Transmission and Receipt

5.1 INTRODUCTION

This section describes region-specific information for content that is not explicitly included in the Common Technical Document and logistical details appropriate for the transmission and receipt of submissions using the electronic Common Technical Document (eCTD).

5.2 REGION-SPECIFIC INFORMATION: MODULE 1

This module contains administrative information that is unique for each region. There will be local requirements for both the content and electronic component of module 1. The eCTD backbone was developed to allow the transfer of this regional information to be included in a regulatory dossier.

Regional guidance will provide the specific instructions on how to provide the administrative forms and detailed prescribing information. Please refer to this information and Appendix 6 when preparing Module 1. Module 1 includes all administrative documents (e.g., forms and certifications) and labeling, including the documents described in regional guidance.

Not all regionally specific documents are included in Module 1. Technical reports required for a specific region should be placed in Modules 2 to 5. These reports should be included in the module most appropriate for the content of the information provided.

Each region provides specific guidance on the format and content of the regional requirements of each module. Table 5.1 provides contact information for each region.

5.3 SUBMISSION ADDRESSES

Submissions should be sent directly to the appropriate regulatory authority. Information needed to send physical media to each regulatory authority is found at the reference location in Table 5.2.

5.4 MEDIA

Regulatory authorities are prepared to accept electronic submissions provided on the media listed in Table 5.3. To optimize processing efficiency, we recommend choosing media with a capacity most appropriate to the size of the submission. Whenever possible, applicants should choose media capable of holding the submission on the smallest number of units. For example, for a submission that has a size of 50 megabytes, use 1 CD-ROM instead of 50 floppy disks.

5.5 COVER LETTER

Applicants should provide a cover letter as a PDF file (cover.pdf). A paper cover letter should also be included with non-electronic portions of the submission (such as forms with signatures or seals, and certifications). The cover letter should include

- A description of the submission, including appropriate regulatory information
- A listing of the sections of the submission filed as paper, electronic, or both paper and electronic
- A description of the electronic submission, including type and number of electronic media, approximate size of the submission, and if appropriate, format used for DLT tapes.
- A statement that the submission is virus free with a description of the software used to check the files for viruses
- The printed contents of the index-md5.txt file as an appendix
- The regulatory and information technology points of contact for the submission

5.6 PREPARING THE MEDIA

CD-ROMs should be packaged carefully to ensure that they arrive in a usable condition. Particularly vulnerable are diskettes and CD-ROM jewel cases shipped in envelopes without bubble-type protective material or stiff backing. The use of a jiffy-type bag by itself to ship media will not provide adequate protection for shipping electronic media.

5.7 TRANSPORT

Secure data exchange over the Internet is the recommended means for transporting submissions. However, until the regulatory authorities can develop secure electronic gateways, submissions should continue to be physically transported by courier or registered mail.

5.8 SECURITY

An MD5 checksum should be included for each physical file in the eCTD. The checksum allows the recipient to verify the integrity of the physical files in the submission. The XML eCTD document type definition (DTD) provides the location of the files, and a tag name contains the checksums.

TABLE 5.3
Recommendations for Submission Media

Example Size of Submission	1.1.2. Media and Format	1. Regulatory Authority
Less than 1.4 MB	3.5 inch DOS Formatted Floppy Disks	EU
Less than 10 MB	3.5 inch DOS Formatted Floppy Disks	United States
Less than 650 MB	CD-ROM ISO 9660—Joliet	EU, Japan
Less than 7 GB	CD-ROM ISO 9660—Joliet	Japan, United States, Canada
Greater than 7 GB	Digital Tape—Compaq DLT 20/40 and 10/20 GB format using NT server 4.0 with NT backup or BackupExec	United States
More than 650 MB	DVD	EU, Canada

A checksum of the XML eCTD instance should be included. Applicants should name this checksum file index-md5.txt and include it as a file in the same directory as the XML eCTD instance. Applicants should print the contents of the index-md5.txt file and include the paper copy with the paper cover letter for the submission.

An applicant can provide the eCTD as an encrypted file in accordance with the ICH M2 Recommendation 4.1, if the regulatory body has implemented it. This solution allows the eCTD to be encrypted and transferred over the Internet (if Internet receipt is implemented regionally) or to be encrypted on one of the approved physical media standards. The purpose of encryption is to protect the privacy of the confidential information and to ensure that it is only available to the authorized receiver. Encryption is always appropriate when the eCTD is sent via the Internet.

Encryption is not considered necessary if the information is sent using a physical medium, although encryption is an option. The applicant should assume all liability for the medium until it is delivered to the regulatory authority.

Applicants should not include any file-level security settings or password protection for individual files in the eCTD. Applicants should allow printing, changes to the document, selecting text and graphics, and adding or changing notes and

form fields. Internal security and access control processes in the regulatory authority should maintain the integrity of the submitted files.

5.9 RECEIPT

Upon arrival at the regulatory authority, the submission is archived according to local regulations. A read-only copy of the submission is then made available to the review community in the regulatory authority. This is typically done by placing the copy on a network server.

5.10 ACKNOWLEDGMENT

Each regulatory authority should acknowledge the receipt of the eCTD submission according to the policy and procedure of the individual regulatory authority. Applicants should use the address in Table 5.1 to find guidance regarding acknowledgments.

Appendix 6: The eCTD XML Submission

6.1 BACKGROUND

There are many factors that have influenced the design of the electronic Common Technical Document (eCTD). Some that have had a more significant impact on the design are:

- The submissions should accommodate full regulatory dossiers, supplements, amendments, and variations.
- The submissions should be able to accommodate regional requirements that are represented in regional guidance documents, regulations, and statutes.
- The technology should be extensible so that as technology changes, the new electronic solutions can be accommodated.

The eCTD is designed around the concept of a backbone. The backbone is similar to a container that holds the files that are part of the submission. The backbone is based on an XML Document Type Definition (DTD). There is a close relationship between the logical documents defined in the CTD and entities in the backbone. The backbone will provide the navigation links to the various files and information that make up the submission.

The file that is produced based on the XML eCTD DTD is the eCTD XML instance or XML backbone. The XML backbone allows more than one entry or link to point to the same physical file. This should be done with caution, since it can be more difficult for the regulatory authority to manage the life cycle of that file if there is more than one pointer to the file.

6.2 FILE NAMES AND DIRECTORY STRUCTURE

Recipients of the eCTD should be able to directly navigate through the submission at the folder and file level, that is, without benefit of a customized end user application. The structure of the eCTD and instructions for how to create folder names facilitate this type of navigation.

In order to preserve the navigational linkages that can be present in the documents contained in the eCTD, the directory structure should be preserved by the agencies. The navigational links should be relative links within a module.

Specific folder and file names have been defined in Appendix 4. The top level for the directory structure will vary by region. The identification of the top-level folder uniquely identifies the submission in a region. The submission identification should be used as the folder name in the top-level directory. For example, if the submission number were CTD 123456, the root directory would be named "ctd-123456." The original submission and subsequent amendments and variations should use the same top-level folder name. Submissions should be differentiated by a subfolder named according to the sequence number of the submission in that region. Table 6.1 and Figure 6.1 illustrate this naming convention.

The regional administrative xml backbone file, if supplied, should be in the region-specific module-1 folder for each submission. The DTD for the regional xml backbone file should be in the util folder for each submission.

Table 6.2 presents the file locations for the example in Figure 6.1.

6.3 LIFE CYCLE MANAGEMENT

It is important for the recipients of the eCTD to be able to establish the location of the submission in the life cycle of a product.

The eCTD is capable of containing initial submissions, supplements, amendments, and variations. There are no uniform definitions for these terms in the three regions, but amendments and supplements are terms used in the United States. Variations apply in Europe. The variations, supplements, and amendments are used to provide additional information to an original regulatory dossier. For example, if a new manufacturer for the drug substance were being proposed, this would result in submission of an amendment or supplement to the Food and Drug Administration (FDA) and a variation to Europe. When regulatory authorities request additional information, the information is also provided as a variation, supplement, or amendment to the original submission. Therefore, the regulatory agencies should have a way to manage the life cycle for the submission. This function should be provided by each regulatory authority in the form of guidance, which can include regional DTDs and specifications. Each regional DTD should be referenced in the eCTD DTD by the submitter.

The eCTD DTD provides some facilities for life cycle management at the file level. When revisions are sent to a regulatory authority, the new file should be submitted as a leaf element associated with the same tag name as the file being amended or deleted. The "modified-file" attribute of the leaf element should contain the name and relative directory path of the file being amended, replaced, or deleted. This will allow the regulatory authority to accurately locate the original file and update the original file's status.

6.4 OPERATION ATTRIBUTE

The operation attribute is a key to managing each individual file in a submission. The applicant uses the operation attribute to tell the regulatory authority how the applicant intends the files in the submission to be used. The operation attribute describes the relation between files in subsequent submissions during the life cycle of a medicinal product. In the very first submission, all the files will be new. In the second, third, fourth, etc., submission, all the newly submitted files can have different operation attributes due to having or not having a

TABLE 6.1
Submission Designation

Submission number	Sequence number	Type of submission
ctd-123456	0000	Original submission
ctd-123456	0001	First amendment, supplement, or variation
ctd-123456	0002	Second amendment, supplement, or variation
…		
ctd-123456	nnnn	nth amendment, supplement, or variation

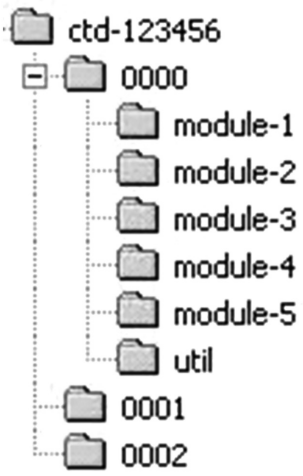

FIGURE 6.1 You should submit the xml backbone as a single file named index.xml, which should be placed in the submission sequence number folder for that submission. In the example shown in Figure 6.1, there should be an index.xml file in folder "0000," folder "0001," and folder "0002." The MD5 checksum file, index-md5.txt, should be in each folder with the corresponding index.xml file. The DTD for index.xml should be in the "util" folder for each submission.

TABLE 6.2
Submission Folder Designation

Submission Folder	Files
ctd-123456/0000	index.xml
	index-md5.txt
ctd-123456/0000/module-1/us	us-regional.xml
ctd-123456/0000/util	ich-ectd-1-0.dtd
	us-regional-1-0.dtd
ctd-123456/0001	index.xml
	index-md5.txt
ctd-123456/0001/module-1/us	us-regional.xml

	us-regional-1-0.dtd
ctd-123456/0002	index.xml
	index-md5.txt
ctd-123456/0002/module-1/us	us-regional.xml
ctd-123456/0002/util	ich-ectd-1-0.dtd
	us-regional-1-0.dtd

relation with previously submitted files. Table 6.3 describes the meaning of each allowed value of the operation attribute.

The following cases show examples of the use of each of the operation attribute values. These examples are not a complete list of all possible situations. Consult the appropriate regulatory authority if you have specific questions about the use of the operation attribute.

Case 1—The first submission of a dossier (Table 6.4).

Case 2—Two submissions. Submission 0000 is the first submission of a dossier. Submission 0001 is a subsequent amendment or variation in which the applicant intends to completely replace the structure.pdf file in submission 0000. The intent is to keep the original structure.pdf for historical purposes but to consider only the contents of the 0001\structure.pdf as relevant to the review. These two submissions could be described as follows (Table 6.5):

- Submission 0000 is the first submission of the file structure.pdf, and this file is the current version of this file.
- Submission 0001, which is submitted at a later time, is the submission of the file structure.pdf, which is now current and replaces the file structure.pdf in submission 0000.

Case 3—Two submissions. Submission 0000 is the first submission of a dossier. Submission 0001 is an amendment or variation where the applicant intends to add new information to the original structure.pdf file, which was submitted in submission 0000. The intent is to have the reviewer consider the contents of both files relevant to the submission. These two submissions could be described as follows (Table 6.6):

- Submission 0000 is the first submission of the file structure.pdf, and this file is the current version of this file.
- Submission 0001, which is submitted at a later time, is the submission of the file structure.pdf, which is the current file but contains information that should be appended to file structure.pdf in submission 0000. Both files should be considered relevant to the review of the dossier.

Case 4—Two submissions. Submission 0000 is the first submission of a dossier. Submission 0001 is an amendment or variation where the applicant intends to delete a file in the previous submission. The intent is to have the reviewer disregard the contents of the original file, possibly because it should not have been submitted with the original dossier. These two submissions could be described as follows (Table 6.7):

- Submission 0000 is the first submission of the file structure.pdf, and this file is the current version of this file.
- Submission 0001, which is submitted at a later time, requests that the file structure.pdf in submission 0000 be deleted and no longer considered relevant to the review of the dossier.

TABLE 6.3
Understanding the Operation Attribute

Operation attribute value	Meaning	What the reviewer might see when using the Agency review software: This file	Previous file
New	The file has no relationship with files submitted previously.	Current	
Append	The file itself is new, but due to the relation this file has with a previously submitted file, the attribute is "append." The append status is linked to a previously submitted file on which this operation has to be executed. The previously submitted file is indicated by the "modified file" attribute of the leaf element.	Current	Current-Appended
Replace	The file itself is new, but due to the relation this file has with a previously submitted file, the attribute is "replace." The "replace" status is linked to a previously submitted file on which this operation is executed. The previously submitted file is indicated by the "modified file" attribute of the leaf element.	Current	Replaced
Delete	There is no new file submitted in this case. Instead, the leaf has the operation of "delete," and the "modified-file" attribute identifies the file in a previous submission that is to be considered no longer relevant to the review.		No longer relevant to the review

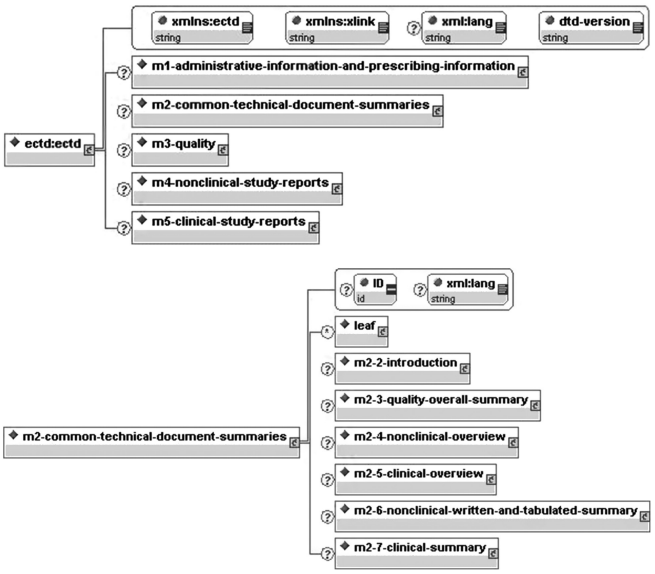
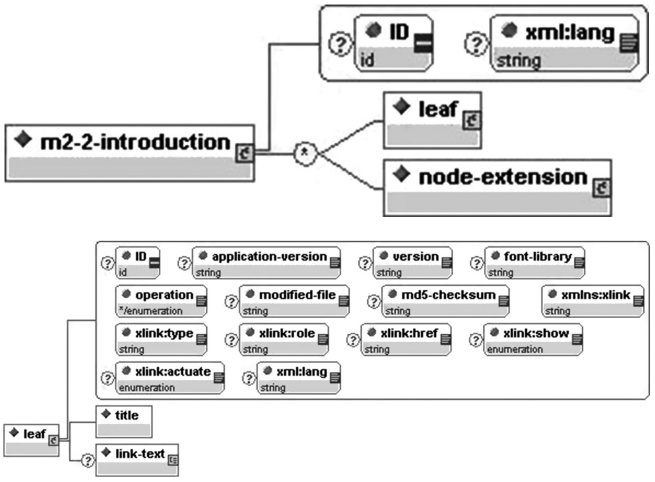
6.5 DTD CONTENT MODEL

The content model of the eCTD is derived from the organization of the CTD. The graphic representation of a portion of the content model is shown below. The content model is hierarchical, starting at the "ectd" and going down to a specific item to be included in the submission. This example shows how the section of the CTD containing summaries is structured.



Once the appropriate tag has been selected, use the <leaf> element and attributes to specify a file in the submission. See "Instructions for preparing the eCTD" in this appendix for details.



6.6 eCTD ELEMENT/ATTRIBUTE INSTRUCTIONS

The eCTD consists of five primary submodules:

- m1-administrative-information-and-prescribing-information
- m2-common-technical-document-summaries
- m3-quality
- m4-nonclinical-study-reports
- m5-clinical-study-reports

Each of the first five submodules is further decomposed into subelements, each with a distinct <tag> that represents a CTD table of contents location. The steps should be completed as shown in the following example, where all files are submitted for modules 1 through 5:

1. You should select a tag element that best corresponds to the CTD table of contents location for a document or file being submitted. For example, select the tag <m2-4-nonclinical-overview> to submit the nonclinical overview document.
2. You should create a child <leaf> element underneath the <m2-4-nonclinical-overview> tag.
3. You should provide the relative location and file name of the actual file containing the nonclinical overview in the "xlink:href" attribute for the <leaf> element.
4. You should provide a descriptive title for the file that contains the nonclinical overview in the <title> element of the <leaf>.
5. You should provide information for the appropriate attributes of the <leaf> element as described in Table 6.3.

Table 6.8 describes each of these elements and attributes in further detail.

6.7 INSTRUCTIONS FOR A SIMPLE NEW SUBMISSION

The following XML fragment demonstrates the submission of a clinical overview of efficacy as a single PDF document.

```
<?xml version = "1.0" encoding = "UTF-8"?>
<!DOCTYPE ectd:ectd SYSTEM "util/dtd/ich-ectd-1-0.dtd">
<ectd:ectd xmlns:ectd = "http://www.ich.org/ectd"
xmlns:xlink = "http://www.w3c.org/1999/xlink">
  <m2-common-technical-document-summaries>
    <m2-5-clinical-overview>
       <m2-5-4-overview-of-efficacy xml:lang = "en">
          <leaf operation = "new" xlink:type =
                "simple" checksum =
                "e854d3002c02a61fe5cbe926fd97b001"
                xlink:href = "module-2/clinical-
                summary/efficacy-overview.pdf"
                application-version = "Acrobat 5">
         <title>Overview of efficacy</title>
        </leaf>
      </m2-5-4-overview-of-efficacy>
    </m2-5-clinical-overview>
  </m2-common-technical-document-summaries>
</ectd:ectd>
```

This submission includes the file "efficacy-overview.pdf" in the relative directory "module-2/clinical-summary" (i.e., the one starting below the Dossier number and submission sequence directories). The file is "new" and has a descriptive name of "Overview of efficacy."

The regional review application should treat this as a new submission to be associated with the submission identified in CTD module 1, which is region specific.

If this is the first submission for Dossier CTD 123456, all the files in this submission are in the ctd-123456\0000 directory and below.

6.8 INSTRUCTIONS FOR AN AMENDMENT, SUPPLEMENT, OR VARIATION

In the previous example, an efficacy overview was submitted. In this example, it is replaced by an updated version.

To replace a file, add the replacement file <leaf> element under the same tag element as the original file. If this is the second submission for Dossier CTD 123456, all the files in this submission are in the ctd-123456\0001 directory and below.

```
<?xml version = "1.0" encoding = "UTF-8"?>
<!DOCTYPE ectd:ectd SYSTEM "util/dtd/ich-ectd-1-0.dtd">
<ectd:ectd xmlns:ectd = "http://www.ich.org/ectd"
xmlns:xlink = "http://www.w3c.org/1999/xlink">
  <m2-common-technical-document-summaries>
    <m2-5-clinical-overview>
      <m2-5-4-overview-of-efficacy xml:lang = "en">
        <leaf operation = "replace"
                xlink:type = "simple" checksum =
                "e854d3002c02a61fe5cbe926fd973401"
                xlink:href = "module2/clinical-
                summary/efficacy-overview v2.pdf"
                application-version = "Acrobat 5"
                modified-file = "0000/module2/
                clinical-summary/efficacy-overview.pdf">
          <title>Overview of efficacy</title>
        </leaf>
       </m2-5-4-overview-of-efficacy>
     </m2-5-clinical-overview>
  </m2-common-technical-document-summaries>
</ectd:ectd>
```

6.9 INSTRUCTIONS FOR MULTIPLE INDICATIONS*

Multiple therapeutic indications use an additional attribute associated with the <m2-7-3-summary-of-clinical-efficacy> and the <m5-3-5-reports-of-efficacy-and-safety-studies> elements to allow multiple indications to be submitted. Table 6.9 shows the use of these attributes.

Note that the indication attribute is used by the regulatory authority to apply to all the table of contents tags beneath the <m2-7-3-summary-of-clinical-efficacy> and <m5-3-5-reports-of-efficacy-and-safety-studies> tags. This is an example of a section of the instance showing the submission of information about two indications:

```

</ectd:ectd>
```

* Note that these XML examples are examples only and do not necessarily contain all the elements and attributes that you should use when preparing an eCTD submission.

TABLE 6.8
eCTD Elements

Element	Attribute	Description/Instructions	Example
Any table of contents tag such as <m2-4-nonclinical-overview>		A table of contents tag represents a grouping of one or more files related to a specific section of the CTD.	
		One or more child <leaf> elements can be declared for a parent table of contents tag.	
		It is possible to extend a table of contents tag by providing a <node-extension> element. This can be done at the lowest level of the defined table of contents tags but should be done only when absolutely necessary. See the section "Instructions for extending eCTD tag elements" in this appendix.	
	ID	A unique identifier for this location in the XML instance.	
	xml:lang	The primary language used by the files in this entire section of the submission. Use ISO-639 standard language abbreviations.	en
<leaf>		A leaf corresponds to a file.	
		One or more child leaf elements can be submitted for a parent table of contents tag.	
	application-version	The version of the software application that was used to create this file.	Acrobat 5
	Font-library	The commercial name of the font or font library needed to properly view the submitted file.	
	ID	Unique identifier for this location in the XML instance.	
	checksum	The checksum value for the file being submitted.	e854d3002c02a61fe5cbe926fd97b001
	checksum-type	The checksum algorithm used.	MD5
	modified-file	The name of the file to be modified as indicated in the "operation" attribute. This file name should include the relative path to the file. If no file is being modified, then you should not supply the "modified-file" attribute.	/0000/module-2/clinical-summary/references.pdf
	operation	Indicates the operation to be performed on the "modified-file". You should select one of the following valid values: new, replace, append, delete.	new
		See the section Operation Attribute in this appendix for details on the meaning of these values.	
	Version	The file submitter's internal version number or version identification for the report.	V23.5
	xlink:actuate	Not Currently Used.	
	xlink:href	Provide the pointer to the actual file. Use the relative path to the file and the file name.	module-2/clinical-summary/references.pdf
	xlink:role	Not Currently Used.	
	xlink:show	Not Currently Used.	
	xlink:type	Fixed value of "simple."	simple
<title>		This element is associated with a "leaf" and provides a description of the file being submitted.	study report 1234
	ID	Unique identifier for this location in the XML instance.	ID050520

TABLE 6.9
Use of Attributes for Multiple Therapeutic Indications

Element	Attribute	Description/Instructions	Example
<m2-7-3-summary-of-clinical-efficacy>	Indication	Name of the indication	pain
<m5-3-5-reports-of-efficacy-and-safety-studies>	Indication	Name of the indication	pain

6.10 INSTRUCTIONS FOR MULTIPLE DRUG SUBSTANCES, MANUFACTURERS, AND PRODUCTS

Multiple drug substances use additional attributes associated with the <m3-2-s-drug-substance> element to allow unique combinations of the drug substance name and manufacturer to be submitted. Table 6.10 shows the use of these attributes.

This is an example of a section of the instance showing the submission of information about two drug substances, one of which is supplied by two manufacturers:

```
<m3-2-body-of-data>
  <m3-2-s-drug-substance substance =
       "acetaminophen" manufacturer = "my
supplier">
    <leaf operation = "new" xlink:type = "simple"
        xlink:href =
                "module-3/body-of-data/drug-
                substance/acetaminophen-my-supplier/
                acetaminophen.pdf">
      <title>acetaminophen/my supplier data</title>
    </leaf>
  </m3-2-s-drug-substance>
  <m3-2-s-drug-substance substance =
                "acetaminophen" manufacturer = "bulk
                company 2">
    <leaf operation = "new" xlink:type = "simple"
                xlink:href =
                "module-3/body-of-data/drug-
                substance/acetaminophen-bulk-
                company-2/acetaminophen2.pdf">
      <title>acetaminophen/company 2 data</title>
    </leaf>
  </m3-2-s-drug-substance>
  <m3-2-s-drug-substance substance = "codeine"
                manufacturer = "drug company 2">
    <leaf operation = "new" xlink:type = "simple"
                xlink:href =
                "module-3/body-of-data/drug-
                substance/codeine-drug-company-2/
                codeine-quality-data.pdf">
      <title>codeine data</title>
    </leaf>
  </m3-2-s-drug-substance>
</m3-2-body-of-data>
```

Multiple drug products use additional attributes associated with the <m3-2-p-drug-product> element to allow unique combinations of the drug product name and dosage form to be submitted. Table 6.11 shows the use of these attributes.

This is an example of a section of the instance showing the submission of information about two drug products:

```
<m3-2-body-of-data>
  <m3-2-p-drug-product product-name = "wonder drug"
        dosageform = "capsules">
    <leaf operation = "new" xlink:type = "simple"
        xlink:href =
                "module-3/body-of-data/drug-product/
                wonder-drug/specifications1.pdf">
      <title>wonder drug capsule product
information</title>
    </leaf>
  </m3-2-p-drug-product>
  <m3-2-p-drug-product product-name = "wonder drug"
        dosageform = "tablets">
    <leaf operation = "new" xlink:type = "simple"
        xlink:href =
                "module-3/body-of-data/drug-product/
                wonder-drug/specifications2.pdf">
                <title>wonder drug tablet product
data</title>
        </leaf>
  </m3-2-p-drug-product>
</m3-2-body-of-data>
```

6.11 INSTRUCTIONS FOR EXTENDING XML eCTD DTD ELEMENTS

An applicant can extend the definition of an element by creating node extensions beneath a defined table of contents tag. Using node extensions is discouraged and should only be done when there is no other feasible means to submit information. The child element <node-extension> should be used for each new table of contents node created. The <title> element value is inherited from the parent element. You should follow the following principles when using <node-extension>:

1. You should only extend the lowest level of defined elements. For example, you can extend the <m2-3-r-regional-information> element but not the <m2-3-quality-overall-summary> element, since the latter is not the lowest element defined in the table of contents.
2. Do not extend the element more than one level. For example, you should not extend <node-extension> <title>special-fda-summary</title> </node-extension> with another <node-extension>.

The following is an example of a section of the eCTD instance in which an applicant extends the <m2-3-r-regional-information> to provide specific regional information as requested by a regulatory authority. The title element associated with

TABLE 6.10
Use of Attributes for Multiple Drug Substances

Element	Attribute	Description/Instructions	Example
<m3-2-s-drug-substance>	Substance	Name of one of the drug substances	Acetaminophen
	Manufacturer	Name of the manufacturer of the drug substance	My supplier

TABLE 6.11
Use of Attributes for Multiple Drug Products

Element	Attribute	Description/Instructions	Example
<m3-2-p-drug-product>	Product-name	Name of one of the drug products	Wonder drug
	Dosageform	Name of the dosage form of the drug product	Capsules

the <node-extension> describes the extension. Alternatively, the regional information in this example could have been provided as a <leaf> element under the <m2-3-r-regional-information> element without the use of a "node extension."

```
<m2-common-technical-document-summaries>
  <m2-3-quality-overall-summary>
    <m2-3-r-regional-information>
      <node-extension>
        <title>special-fda-summary</title>
        <leaf operation = "new" xlink:type =
         "simple" xlink:href =
                 "module-2/quality-overall-summary/
                 regional/fda/fda-extra-quality-sum.pdf">
          <title> FDA extra quality summary </title>
        </leaf>
      </node-extension>
    </m2-3-r-regional-information>
  </m2-3-quality-overall-summary>
</m2-common-technical-document-summaries>
```

To update a file that has been submitted as an extended node, you should submit the replacement file using exactly the same element and "node extension" information, including the <title> element for the <node-extension>. This makes it possible for the regulatory authority to locate the original file and update its status.

6.12 INSTRUCTIONS FOR SUBMITTING SECTIONS AS PAPER

During the transition to fully electronic submissions of the CTD, some sections can be submitted as paper only. These sections should be identified in the XML eCTD instance by including a PDF file in the instance that describes the content and location of the paper section. For example, the PDF file might consist of only one page with the name of the CTD document and the physical volume number and tab identifier. The <title> element in the XML eCTD instance could indicate that this is a paper submission.

This is an example of the instance showing the submission of a paper efficacy overview document.

```
<m2-5-clinical-overview>
     <m2-5-4-overview-of-efficacy xml:lang = "en">
       <leaf operation = "new" xlink:type =
        "simple" checksum =
                "e854d3002c02a61fe5cbe926fd97b001"
                xlink:href = "module-2/clinical-
                summary/efficacy-overview.pdf"
                application-version = "Acrobat 5">
          <title>Paper Submission </title>
        </leaf>
     </m2-5-4-overview-of-efficacy>
   </m2-5-clinical-overview>
```

Appendix 7: Specification for Submission Formats

7.1 INTRODUCTION

This appendix describes the way in which files should be constructed for inclusion in the electronic Common Technical Document (eCTD). The file formats included in this section are those formats that are commonly used in electronic submissions. Other formats can be used according to guidance published in each region.

7.2 PDF

Adobe Portable Document Format (PDF) is a published format created by Adobe Inc. (www.adobe.com). It is not necessary to use a product from Adobe or from any specific company to produce PDF documents. PDF is accepted as a standard for documents defined in this specification. The following recommendations support the creation of PDF files that Agencies can review effectively. For any specification of the Japanese version of Adobe Acrobat, or where Japanese characters will be in the file, please refer to the regional guidance.

To ensure that PDF files can be accessed efficiently, PDF files should be no larger than 50 megabytes. The files should be saved in "optimized," form.

7.2.1 Version

Agencies should be able to read all PDF files with version 4.0 or higher of the Acrobat Reader. Agencies should not need any additional software to read and navigate the PDF files. However, review can be facilitated through the use of Adobe Acrobat, since significantly more functionality is available in this product than with Acrobat Reader.

7.2.2 Fonts

PDF viewing software automatically substitutes a font to display text if the font used to create the text is unavailable on the reviewer's computer. Font substitution can affect a document's appearance and structure, and in some cases, it can affect the information conveyed by a document. Agencies cannot guarantee the availability of any fonts except Times New Roman, Arial, Courier, and fonts supported in the Acrobat product set itself. Therefore, all additional fonts used in the PDF files should be embedded to ensure that those fonts will always be available to the reviewer. When embedding fonts, all characters for the font should be embedded, not just a subset of the fonts being used in the document.

One problem associated with embedding fonts is that embedding requires additional computer storage space. Three techniques to help limit the storage space taken by embedding fonts are

- Limiting the number of fonts used in each document
- Using only True Type or Adobe Type 1 fonts
- Avoiding customized fonts

Resizing a document because the contents are too small to read is inefficient. Times New Roman, 12-point font, the font used for this document, is adequate in size for reading narrative text and should be used whenever possible. It is sometimes tempting to use fonts that are smaller than 12 point in tables and charts, but this should be avoided whenever possible. When choosing a point size for tables, a balance should be made between providing sufficient information on a single page that may facilitate data comparisons for the reviewer and still achieving a point size that remains legible. The corollary of this is that if the point size is made larger, more tables might be necessary, which can complicate data comparisons for a reviewer, since data might now be included in separate tables. Generally, point sizes 9 and 10 are considered acceptable in tables, but smaller point sizes should be avoided.

7.2.3 Use of Color Fonts

The use of a black font color is recommended. Blue font can be used for hypertext links. If a font color other than black is used, light colors that do not print well on grayscale printers should be avoided. Color reproduction can be tested prior to submission by printing sample pages from the document using a grayscale printer. The use of background shadowing should be avoided.

7.2.4 Page Orientation

Pages should be properly oriented so that all portrait pages are presented in portrait and all landscape pages are presented in landscape. To achieve this, the page orientation of landscape pages should be set to landscape prior to saving the PDF document in its final form.

7.2.5 Page Size and Margins

The print area for pages should fit on a sheet of A4 or Letter paper. A sufficient margin (at least 2.5 cm) on the left side of each page should be provided in order to avoid obscuring information if the reviewer subsequently prints and binds the pages for temporary use. For pages in landscape orientation (typically tables and publications), smaller margins are allowable (at least 2.0 cm at the top and 0.8 cm left and right) so as

to allow more information, displayed legibly, on the page (see Section 7.2.3, Fonts). It is acceptable that header and footer information appears within these margins but not so close to the page edge that it may risk being lost upon printing.

7.2.6 Source of Electronic Document

PDF documents produced by scanning paper documents are usually inferior to those produced from an electronic source document. Scanned documents are more difficult to read and do not allow reviewers to search or copy and paste text for editing. They should be avoided where possible.

7.2.7 Methods for Creating PDF Documents and Images

The method used for creating PDF documents should produce the best replication of a paper document. To ensure that the paper and PDF version of the document are the same, the document should be printed from the PDF version. Documents that are available only in paper should be scanned at resolutions that will ensure the pages are legible both on the computer screen and when printed. At the same time, the file size should be limited. It is recommended that scanning be undertaken at a resolution of 300 dots per inch (dpi) to balance legibility and file size. The use of grayscale or color is discouraged because of file size. After scanning, resampling to a lower resolution should be avoided.

When PDF files containing images are created, the images should not be downsampled. Downsampling does not preserve all the pixels in the original. For PDF images, one of the following lossless compression techniques should be used:

- For lossless compression of color and grayscale images, use Zip/Flate (one technique with two names). This is specified in Internet RFC 1950 and RFC 1951 (http://info.internet.isi.edu/in-notes/rfc/files/rfc1950.txt).
- For lossless compression of black and white images, use the CCITT Group 4 Fax compression technique. It is specified as CCITT recommendations T.6 (1988)—*Facsimile coding schemes and coding control functions for Group 4 facsimile apparatus*.

Paper documents containing hand-written notes should be scanned at 300 dpi. Hand-written notes should be done in black ink for clarity.

For photographs, the image should be obtained with a resolution of 600 dpi. If black and white photos are submitted, 8 bit grayscale images should be considered. If color photos are submitted, 24 bit RGB images should be considered. A captured image should not be subjected to nonuniform scaling (i.e., sizing).

Gels and karyotypes should be scanned directly rather than from photographs. Scanning should be at 600 dpi and 8 bit grayscale depth.

Plotter output graphics should be scanned or captured digitally at 300 dpi.

High-pressure liquid chromatography or similar images should be scanned at 300 dpi.

Applicants should validate the quality of the renditions.

7.2.8 Hypertext Linking and Bookmarks

Hypertext links and bookmarks are techniques used to improve navigation through PDF documents. Hypertext links can be designated by rectangles using thin lines or by blue text.

In general, for documents with a table of contents, bookmarks for each item listed in the table of contents should be provided, including all tables, figures, publications, other references, and appendices. These bookmarks are essential for efficient navigation through documents. In general, including a bookmark to the main table of contents for a submission or module is helpful. The bookmark hierarchy should be made identical to the table of contents with no additional bookmark levels beyond those present in the table of contents.

Each additional level increases the need for space to read the bookmarks. The use of no more than four levels in the hierarchy is recommended.

Hypertext links throughout the body of the document to supporting annotations, related sections, references, appendices, tables, or figures that are not located on the same page are helpful and improve navigation efficiency. Relative paths should be used when creating hypertext links to minimize the loss of hyperlink functionality when folders are moved between disk drives. Absolute links that reference specific drives and root directories will no longer work once the submission is loaded onto the Agency's network servers.

When creating bookmarks and hyperlinks, the magnification setting *Inherit Zoom* should be used so that the destination page displays at the same magnification level that the reviewer is using for the rest of the document.

7.2.9 Page Numbering

If a submission includes more than one document, no additional volume or page numbering is necessary. Only page numbers for individual documents are needed.

It is easier to navigate through an electronic document if the page numbers for the document and the PDF file are the same. To accomplish this, the initial page of the document should be numbered page 1, with no use of Roman numerals or unnumbered pages in the document. If this is not done, Acrobat Reader would include such numbering within its page count and thus, put the Acrobat numbering out of synchrony with the internal document page numbers.

Two exceptions to this rule can occur, details of which can be found in the guidance for the modules of the CTD:

- Firstly, where a document is split because of its size (e.g. >50 MB), under which circumstances the second or subsequent file should be numbered consecutively to that of the first or preceding file

- Secondly, where several small documents with their own internal page numbering have been brought together into a single file, under which circumstances it is not considered necessary to provide additional page numbering, but the start of each subdocument should be bookmarked

7.2.10 Document Information Fields

Document information fields should not be used for the common portions of the eCTD, but they may be appropriate for some of the regional documents. Recommendations for the document information fields will be provided in the regional guidance for the specific submission type.

7.2.11 Open Dialog Box

The open dialog box sets the document view when the file is opened. The initial view of the PDF files should be set as *Bookmarks* and *Page*. If there are no bookmarks, the initial view as *Page* only should be set. The *Magnification* and *Page Layout* should be set as default.

7.2.12 Security

No security settings or password protection for PDF files should be included. Security fields should be set to allow printing, changes to the document, selecting text and graphics, and adding or changing notes and form fields.

7.2.13 Indexing PDF Documents

Full text indices can be used to help find specific documents and/or search for text within documents. When a document or group of documents is indexed, all words and numbers in the file and all information stored in the Document Information fields are stored in special index files that are functionally accessible using the search tools available in Acrobat. Portions of a document that are imaged are not indexed. Even if the document only contains images, the text in the Document Information fields of the file will be indexed.

These full text indices should not be confused with a table of contents. Adobe Acrobat Catalog is one example of a tool that can be used to index PDF documents. Indices should not require extensions or additions to off-the-shelf Acrobat programs.

Further recommendations for full text indices will be provided in regional guidance.

7.2.14 Use of Acrobat Plug-Ins

It is considered acceptable to use plug-ins to assist in the creation of a submission. However, the review of the submission should not require the use of any plug-ins in addition to those provided with Adobe Acrobat, because Agencies should not be required to archive additional plug-in functionality.

7.3 XML FILES

A working group at the World Wide Web Consortium (W3C) developed XML. It is a nonproprietary language developed to improve on previous markup languages, including standard generalized markup language (SGML) and hypertext markup language (HTML).

Information in an XML file is divided into specific pieces. These pieces are called *objects* or *element types*. The element type identifies the piece of information. For example, the name of the company submitting a registration application in eCTD format for review is identified with the element type <applicant>. All element type names are bracketed using the special characters <>. Inside the XML document, the element type name is placed just prior to the piece of information and after the information. This is called *tagging*. So, in the XML file, the applicant could be tagged as follows <applicant>Worldwide Pharmaceuticals Inc.</applicant>. The / prior to the element type denotes that this is the end of the information about the applicant.

By using a hierarchical structure, XML allows you to relate two or more elements. This is accomplished by nesting one element within another.

Additional information about the element type is provided by attributes. Attributes are placed within the element types and are surrounded by “”. For example, if you wanted to show that the applicant name is presented in the English language, you could add this piece of information as an attribute. This could be represented in the XML file as <applicant XML:LANG=“EN”> Worldwide Pharmaceuticals Inc.</applicant>.

XML files are read by a parser found in Internet browsers. Style sheets provide the browser with the information to create tables, fonts, and colors for display.

The specific names of the element types and attributes as well as the valid syntax, structure, and format for defining the XML elements are included in a file called document type declaration (DTD). If the XML document does not follow the DTD, then the file will not be able to be used properly.

The top three lines of the XML file should include the XML version, the style sheet type and address, and the DTD name and address.

Additional information about the XML standard can be found at the W3C Web site at www.w3c.org.

7.4 SVG FILES

SVG is a language for describing two-dimensional graphics in XML. SVG allows for three types of graphic objects: vector graphic shapes (e.g., paths consisting of straight lines and curves), images, and text. Graphical objects can be grouped, styled, transformed, and composited into previously rendered objects. Text can be in any XML namespace suitable to the application, which enhances the searchability and accessibility of the SVG graphics. The feature set includes nested transformations, clipping paths, alpha masks, filter effects, template objects, and extensibility.

SVG drawings can be dynamic and interactive. The Document Object Model (DOM) for SVG, which includes the full XML DOM, allows straightforward and efficient vector graphics animation via scripting. A rich set of event handlers such as onmouseover and onclick can be assigned to any SVG graphical object. Because of its compatibility and leveraging of other Web standards, features such as scripting can be done on SVG elements and other XML elements from different namespaces simultaneously within the same Web page.*

The specific use of SVG in a submission should be discussed with the regulatory authority.

* This description of SVG is from the W3C Web page www.w3c.org/graphics/svg

Appendix 8: XML eCTD DTD

```
<!-- eCTD Version 0.96 renamed to version 1.0
   Jan 10 - Feb 6, 2002
   Added keywords attribute to leaf element
    This attribute is expected to be a comma-separated
         list of keywords
   Removed 3+ level of detail in
m2-4-nonclinical-overview
   Removed 4+ level of detail in
    m2-6-nonclinical-written-and-tabulated-summary
   Removed 3+ level of detail in m2-7-clinical-summary
   Removed 3+ level of detail in m2-5-clinical-overview
   Changed name of leaf attribute md5-checksum to checksum
   Added attribute checksum-type to leaf element
   Added attribute manufacturer to
    m2-3-p-drug-product and m3-2-p-drug-product
  Removed 4+ level of detail in m2-3-quality-overall-summary
   Removed 6+ level of detail in
m3-2-p-2-pharmaceutical-development
-->

<!-- eCTD Version 0.95 -->
<!-- Oct 20, 2001 -->
<!-- Changes according to testing feedback -->
<!-- See separate sheet -->

<!-- eCTD Version 0.92 -->
<!-- Changed incorrect m2-7-4-5-3 attribute -->
<!-- Added namespace info to leaf and xref elements -->

<!-- eCTD Version 0.91 -->
<!-- June 4, 2001 -->
<!-- changed m2-7-3 to be 0 or more instead of 0 or 1 -->

<!-- eCTD Version 0.9 -->
<!-- ICH Tokyo Meeting: May 24, 2001 -->

Appendix 9: Glossary

The intended content of this section is the definition of terms used in the set of documentation associated with the eCTD.

Architecture: A general term for the design and construction of computer systems, including technical infrastructure, information (data), and applications.

ASCII: American Standard Code for Information Interchange. A specification for representing text as computer-readable information.

Browser: A program that allows the user to read hypertext, to view contents of Web pages, and to navigate from one page to another; for example, Microsoft Internet Explorer and Microsoft Edge, Google Chrome, and Mozilla Firefox.

Common Technical Document (CTD): A harmonized format for a regulatory dossier that is considered acceptable in Japan, Europe, the United States, and Canada.

Decryption: Reversing encryption.

Directory (see also Folder): The operating system method of organizing and providing access to individual files. Also called a Folder.

DTD: Document Type Definition. A hierarchical organization or representation of the information contents of a document utilized by SGML or XML.

eCTD: The electronic format of the ICH Common Technical Document.

Encryption: The process of reversibly confusing text or data using a secret formula.

EWG: Expert Working Group.

Folder (see also Directory): The operating system method of organizing and providing access to individual files. Also called a Directory.

HTML: Hypertext Markup Language. Commonly used to format Web pages.

Hypertext: A system that enables links to be established between specific words or figures in a document to other text, tables, or images, allowing quick access to the linked items (such as on the World Wide Web).

ICH: International Conference on Harmonisation of Technical Requirements for Registration of Pharmaceuticals for Human Use.

Infrastructure: The basic support services for computing: the hardware, operating system, and network on which applications and data are stored and on which the database management systems run.

Internet: The world-wide network of computers for accessing, sending, sharing, and transferring information between sites at different locations. It is uncontrolled and unadministered, and when you connect to the Internet, you actually become a part of it.

ISO: International Standards Organization. Founded in 1946, it is the principal international standards-setting organization.

Leaf: The eCTD DTD XML element that describes the content to be provided. The leaf consists of a file and the metadata associated with that file. Such files are placed in a directory structure that is similar to branches of a tree.

LOGICAL DOCUMENT

One or more CTD table of contents sections that together contain the minimum amount of information to be exchanged. Ideally, this is a single physical file.

M2: Multidisciplinary Group 2 (Electronic Standards for the Transfer of Regulatory Information [ESTRI]) of ICH.

Network: A communication system that connects different computers and enables them to share peripherals such as printers, disk drives, and databases. Users (clients) can access applications and databases connected by the network.

Node Extension: The extension of the definition of an element beneath a defined table of contents tag.

PDF: Portable Document Format. A proprietary (Adobe Inc.) de facto standard for the electronic transfer of documents.

SGML: Standardized Generalized Markup Language. An ISO standard for describing structured information in a platform-independent manner.

Software or Software Application: Computer programs or applications. There are two principle types: system software, for example, a computer operating system or a utility program (sometimes called a driver) for printing, and application software, for example, an accounts package or computer-assisted design (CAD) program.

Standard: A technical specification that addresses a business requirement, has been implemented in viable commercial products, and to the extent practical, complies with recognized standards organizations such as ISO.

Web page: Any page on the World Wide Web. The page usually offers the reader the ability to jump to other topics of interest.

World Wide Web (WWW): Segment of the Internet offering point and click (hypertext) access to information as text, image, or sound on an enormous number of topics from around the world.

XML: Extensible Markup Language. An ISO standard for describing structured information in a platform-independent manner.

		Compliance 1 2 3[a]	Remarks	EU-Guide
1	**PERSONNEL**			
1.1	Qualified personnel available?	☐☐☐		2.1
1.2	Organization charts available?	☐☐☐		2.2
1.3	Job descriptions available?	☐☐☐		2.2
1.4	Responsibilities clearly defined?	☐☐☐		2.2
	Key Personnel			
	Responsible persons designated for			
1.5	• Production?	☐☐☐		2.5
1.6	• Quality control?	☐☐☐		2.6
1.7	Are they independent of each other?	☐☐☐		2.3
1.8	Are joint functions clearly defined?	☐☐☐		2.7
1.9	Are the responsible persons working full time?	☐☐☐		2.3
1.10	Do the responsible persons have the appropriate formulation, knowledge, and experience?	☐☐☐		2.1/2.2
1.11	Do the relevant departments have enough personnel?	☐☐☐		2.1
	Training			
1.12	Continuous training programs for the production and QC staff?	☐☐☐		2.8
1.13	Initial job training for all employees?	☐☐☐		2.9
1.14	Teaching aids (videos, slides, and brochures) available?	☐☐☐		2.9
1.15	External training courses for the staff?	☐☐☐		2.9
1.16	Training records?	☐☐☐		2.9
1.17	Special training in sensitive areas (sterile production and toxic substances)?	☐☐☐		2.10
1.18	Information for visitors to the manufacturing area?	☐☐☐		2.11
2	**HYGIENE**			
	Personnel Hygiene			
	Detailed written hygiene programs for			
2.1	• Clothing?	☐☐☐		2.13
2.2	• Use of washrooms?	☐☐☐		2.13
2.3	• Behavior in production areas?	☐☐☐		2.13
2.4	Precautions against sick personnel or personnel with open wounds in production?	☐☐☐		2.14
	Medical examination:			
2.5	• On recruitment?	☐☐☐		2.15
2.6	• Regular reexaminations?	☐☐☐		2.15
	Duty of notification after			
2.7	• Trips to tropical countries?	☐☐☐		2.15
2.8	• Cases of contagious illness in the family?	☐☐☐		2.15
2.9	Instructions for appropriate working clothes?	☐☐☐		2.16
2.10	Absence of food and drink (chewing gum!) in the working area?	☐☐☐		2.17
2.11	Measures against contact with open product (gloves etc.)?	☐☐☐		2.18
2.12	Instructions for hand washing in production?	☐☐☐		2.19
2.13	Change of clothes when entering and leaving the production area?	☐☐☐		5.19
2.14	Change rooms and toilets easily within reach?	☐☐☐		3.31
2.15	Toilets and restrooms sufficiently separated from production areas?	☐☐☐		3.30/3.31
2.16	Workshops separate from production areas?	☐☐☐		3.32
2.17	Laboratory animal rooms totally segregated from production rooms?	☐☐☐		3.33
3	**WAREHOUSE**			
	Rooms, General			
3.1	Suitable for the intended use?	☐☐☐		3
3.2	• Adequate size?	☐☐☐		3
3.3	• Clean?	☐☐☐		3

(*Continued*)

		Compliance 1 2 3[a]	Remarks	EU-Guide
3.4	Located and designed to exclude external contamination?	☐☐☐		3.1
3.5	Appropriate level of maintenance?	☐☐☐		3.2
3.6	Maintenance works possible without contamination risk?	☐☐☐		3.2
3.7	Appropriate lighting and air-conditioning?	☐☐☐		3.3
3.8	Recording of temperature and humidity?	☐☐☐		3.3
3.9	Protection against the entry of insects or other animals?	☐☐☐		3.4
3.10	Controlled access for authorized personnel only?	☐☐☐		3.5
	Rooms, Special Requirements			
	Type of warehousing:			
3.11	Separation of goods sufficient?	☐☐☐		3.18
3.12	Provision for different storage temperatures?	☐☐☐		3.19
3.13	Goods receiving zone weather protected?	☐☐☐		3.20
3.14	Cleaning zone for incoming goods?	☐☐☐		3.20
3.15	Separate quarantine area with controlled access?	☐☐☐		3.21
3.16	Separate, protected sampling area?	☐☐☐		3.22
	Separate and safe storage of			
3.17	• Returned goods?	☐☐☐		3.23
3.18	• Rejected goods?	☐☐☐		3.23
3.19	Separate and safe storage of highly active, toxic, or dangerous substances?	☐☐☐		3.24
3.20	Safe storage of narcotics?	☐☐☐		3.24
3.21	Safe storage of printed packaging materials?	☐☐☐		3.25
3.22	Security measurements against theft?	☐☐☐		3.25
3.23	Smoke detectors?	☐☐☐		3.25
3.24	Fire extinguishing system?	☐☐☐		3.25
	Operations			
3.25	Reception, sampling, and labeling according to written procedures?	☐☐☐		5.2
3.26	Is a sampling plan available?	☐☐☐		Suppl. 4
3.27	Cleaning of incoming containers?	☐☐☐		5.3
3.28	Investigation and recording of damaged deliveries?	☐☐☐		5.4
3.29	First In First Out (FIFO) principle?	☐☐☐		5.7
3.30	Inventory system?	☐☐☐		5.8
3.31	Can the location of materials be detected at all times?	☐☐☐		
3.32	Incoming goods: containers and seals intact?	☐☐☐		5.27
3.33	Incoming goods: conformity with bill of delivery?	☐☐☐		5.27
	Labeling of incoming containers with			
3.34	• Internal name and code?	☐☐☐		5.29
3.35	• Allocated batch number?	☐☐☐		5.29
3.36	• Quarantine status?	☐☐☐		5.29
3.37	• Expiry date or reanalysis date?	☐☐☐		5.29
3.38	Identity test for each incoming container?	☐☐☐		5.29
3.39	Are the sampled containers marked?	☐☐☐		5.30
3.40	Are reference samples taken?	☐☐☐		5.30
3.41	Safe storage of printed packaging materials?	☐☐☐		5.41
3.42	Lot tracing of all packaging materials possible?	☐☐☐		5.42
3.43	Are excessive packaging materials destroyed?	☐☐☐		5.43

Release of starting materials by physical/inventory checks on raw materials, packaging materials, and finished goods:

Item	Stocks: Physical	Stocks: Inventory	Storage conditions

4	**DISPENSING/ASSEMBLING**			
	Rooms, General			
4.1	Suitable for the intended use?	☐☐☐		3
4.2	• Adequate size?	☐☐☐		3
4.3	• Clean?	☐☐☐		3
4.4	Located and designed to exclude external contamination?	☐☐☐		3.1
4.5	Appropriate level of maintenance?	☐☐☐		3.2
4.6	Maintenance works possible without contamination risk?	☐☐☐		3.2
4.7	Appropriate lighting and air-conditioning?	☐☐☐		3.3
4.8	Recording of temperature and humidity?	☐☐☐		
4.9	Protection against the entry of insects or other animals?	☐☐☐		3.4
4.10	Controlled access for authorized personnel only?	☐☐☐		3.5
	Rooms, Special Requirements			
4.11	Segregated from production and warehouse?	☐☐☐		3.13
4.12	Separate weighing cabins?	☐☐☐		3.13
4.13	Separate air handling unit (AHU) for each cabin?	☐☐☐		3.12
	Air pressure gradient from weighing cabin → corridor:			3.3
4.14	Dust extraction systems available?	☐☐☐		5.11
	Operations			
4.15	Balances regularly calibrated?	☐☐☐		3.41
4.16	Only pharmaceutical raw materials in this area?	☐☐☐		5.17
4.17	Check on remains from previous materials before entering of new materials into a weighing cabin?	☐☐☐		5.9/5.35
4.18	Only one material in one cabin?	☐☐☐		5.9
4.19	Are dispensed materials correctly labeled?	☐☐☐		5.29
4.20	Only released products in the dispensing?	☐☐☐		5.31
4.21	Cleaning SOPs for the dispensing?	☐☐☐		4.28
4.22	Previously dispensed material recorded on weighing protocol?	☐☐☐		4.8
4.23	Safety measures against mix-ups during assembling (e.g., cage pallets)?	☐☐☐		5.32/5.34
5	**SOLIDS MANUFACTURING**			
	Field of activity:			
	• Granulation	☐		
	• Compression	☐		
	• Encapsulation	☐		
	• Film and sugar coating	☐		
	• Visual inspection (capsules, tablets, etc.)	☐		
	• Premix (human)	☐		
	Rooms, General			
5.1	Suitable for the intended use?	☐☐☐		3
5.2	• Adequate size?	☐☐☐		3
5.3	• Clean?	☐☐☐		3
5.4	Located and designed to exclude external contamination?	☐☐☐		3.1
5.5	Appropriate level of maintenance?	☐☐☐		3.2
5.6	Maintenance works possible without contamination risk?	☐☐☐		3.2
5.7	Appropriate lighting and air-conditioning?	☐☐☐		3.3
5.8	Recording of temperature and humidity?	☐☐☐		
5.9	Protection against the entry of insects or other animals?	☐☐☐		3.4
5.10	Controlled access for authorized personnel only?	☐☐☐		3.5
	Rooms, special requirements			
5.11	Separate manufacturing area for penicillins/cephalosporins or highly sensitizing substances?	☐☐☐		3.6
5.12	Only for processing of pharmaceuticals?	☐☐☐		3.6
5.13	Logical flow of materials?	☐☐☐		3.7

(*Continued*)

		Compliance 1 2 3[a]	Remarks	EU-Guide
5.14	Walls, floors, and ceilings: smooth surface and free of cracks?	☐☐☐		3.8
5.15	Easy cleaning possible?	☐☐☐		3.10
5.16	Adequate drains with traps and grilles?	☐☐☐		3.11
5.17	Appropriate air handling system?	☐☐☐		3.12
	Air pressure gradient from working bay → corridor: Classification according to EC guide?			
5.18	Appropriate dust extraction system?	☐☐☐		3.14
5.19	Appropriate lighting?	☐☐☐		3.16
5.20	Separate rest rooms?	☐☐☐		3.30
5.21	Changing rooms designed to avoid contamination?	☐☐☐		3.31
5.22	Toilets segregated from manufacturing areas?	☐☐☐		3.31
	Equipment			
5.23	Suitable for the intended use?	☐☐☐		3.34
5.24	Well maintained?	☐☐☐		3.34
5.25	Written and validated cleaning procedures?	☐☐☐		3.36
5.26	Maintenance without contamination risk (separate area)?	☐☐☐		3.35
5.27	Equipment in contact with product: suitable materials quality?	☐☐☐		3.39
5.28	Machinery equipped with measuring and control devices?	☐☐☐		3.40
5.29	Calibration at fixed intervals according to written procedures?	☐☐☐		3.41
5.30	Calibration records available?	☐☐☐		3.41
5.31	Contents and flow direction marked on pipes?	☐☐☐		3.42
5.32	Pipes for distilled and demineralized water regularly monitored and sanitized?	☐☐☐		3.43
5.33	Not functioning equipment in the production area (if yes: clearly marked)?	**Y N**		3.44
5.34	Status of cleanliness indicated?	☐☐☐		5.13
5.35	Previous product indicated?	☐☐☐		5.13
	Operations			
5.36	Are written and validated procedures for all manufacturing steps available?	☐☐☐		5.2
5.37	Are all manufacturing steps recorded with actual parameters?	☐☐☐		5.2
5.38	Check of each single container of the starting materials (contents, weight, and identity)?	☐☐☐		5.3
5.39	Limits for yields?	☐☐☐		5.8

	• Active substances?	☐☐☐		
	• Packaging material?	☐☐☐		

[a] 1. Fulfilled or available; 2. partially fulfilled; 3. not fulfilled or not available.

GLOSSARY

Acceptance Criteria: Numerical limits, ranges, or other suitable measures for acceptance of test results.

Active Pharmaceutical Ingredient (API) (or Drug Substance): Any substance or mixture of substances intended to be used in the manufacture of a drug (medicinal) product and that, when used in the production of a drug, becomes an active ingredient of the drug product. Such substances are intended to furnish pharmacological activity or other direct effect in the diagnosis, cure, mitigation, treatment, or prevention of disease or to affect the structure and function of the body.

Air Lock: An enclosed space with two or more doors, which is interposed between two or more rooms, for example, of differing classes of cleanliness, for the purpose of controlling the airflow between those rooms when they need to be entered. An air lock is designed for use either by people or for goods and/or equipment.

API Starting Material: A raw material, intermediate, or API that is used in the production of an API and that is incorporated as a significant structural fragment into the structure of the API. An API Starting Material can be an article of commerce, a material purchased from one or more suppliers under contract or commercial agreement, or produced in house. API Starting Materials are normally of defined chemical properties and structure.

Authorized Person: The person recognized by the national regulatory authority as having the responsibility for ensuring that each batch of finished product has been manufactured, tested, and approved for release in compliance with the laws and regulations in force in that country.

Batch (or Lot): A specific quantity of material produced in a process or series of processes so that it is expected to be homogeneous within specified limits. In the case of continuous production, a batch may correspond to a defined fraction of the production. The batch size can be defined either by a fixed quantity or by the amount produced in a fixed time interval.

Batch Number (or Lot Number): A unique combination of numbers, letters, and/or symbols that identifies a batch (or lot) and from which the production and distribution history can be determined.

Batch Records: All documents associated with the manufacture of a batch of bulk product or finished product. They provide a history of each batch of product and of all circumstances pertinent to the quality of the final product.

Bioburden: The level and type (e.g., objectionable or not) of microorganisms that can be present in raw materials, API starting materials, intermediates, or APIs. Bioburden should not be considered contamination unless the levels have been exceeded or defined objectionable organisms have been detected.

Bulk Product: Any product that has completed all processing stages up to, but not including, final packaging.

Calibration: The demonstration that a particular instrument or device produces results within specified limits by comparison with those produced by a reference or traceable standard over an appropriate range of measurements. The set of operations that establish, under specified conditions, the relationship between values indicated by an instrument or system for measuring (especially weighing), recording, and controlling, or the values represented by a material measure, and the corresponding known values of a reference standard. Limits for acceptance of the results of measuring should be established.

Clean Area: An area with defined environmental control of particulate and microbial contamination, constructed and used in such a way as to reduce the introduction, generation, and retention of contaminants within the area.

Computer System: A group of hardware components and associated software designed and assembled to perform a specific function or group of functions. A process or operation integrated with a computer system.

Consignment (or Delivery): The quantity of a pharmaceutical(s) made by one manufacturer and supplied at one time in response to a particular request or order. A consignment may comprise one or more packages or containers and may include material belonging to more than one batch.

Contamination: The undesired introduction of impurities of a chemical or microbiological nature, or of foreign matter, into or on to a starting material or intermediate during production, sampling, packaging or repackaging, and storage or transport.

Contract Manufacturer: A manufacturer performing some aspect of manufacturing on behalf of the original manufacturer.

Critical: Describes a process step, process condition, test requirement, or other relevant parameter or item that must be controlled within predetermined criteria to ensure that the API meets its specification.

Critical Operation: An operation in the manufacturing process that may cause variation in the quality of the pharmaceutical product.

Cross-Contamination: Contamination of a material or product with another material or product. Contamination of a starting material, intermediate product, or finished product with another starting material or product during production.

Deviation: Departure from an approved instruction or established standard.

Drug (Medicinal) Product: The dosage form in the final immediate packaging intended for marketing. (See ICH Guidance Q1A.)

Drug Substance: See Active Pharmaceutical Ingredient.

Expiry Date (or Expiration Date): The date placed on the container/labels of an API designating the time during which the API is expected to remain within established shelf-life specifications if stored under defined conditions, and after which it should not be used.

Finished Product: A finished dosage form that has undergone all stages of manufacture, including packaging in its final container and labeling.

Impurity: Any component present in the intermediate or API that is not the desired entity.

Impurity Profile: A description of the identified and unidentified impurities present in an API.

In-Process Control: Checks performed during production in order to monitor and if necessary, to adjust the process to ensure that the product conforms to its specifications. The control of the environment or equipment may also be regarded as a part of in-process control.

Intermediate: A material produced during steps of the processing of an API that undergoes further molecular change or purification before it becomes an API. Intermediates may or may not be isolated. Partly processed product that must undergo further manufacturing steps before it becomes a bulk product.

Large-Volume Parenterals: Sterile solutions intended for parenteral application with a volume of 100 mL or more in one container of the finished dosage form.

Lot: See Batch.

Lot Number: See Batch Number.

Manufacture: All operations of receipt of materials, production, packaging, repackaging, labeling, relabeling, quality control, release, storage, and distribution of APIs and related controls.

Manufacturer: A company that carries out operations such as production, packaging, repackaging, labeling, and relabeling of pharmaceuticals.

Marketing Authorization (Product License, Registration Certificate): A legal document issued by the competent drug regulatory authority that establishes the detailed composition and formulation of the product and the pharmacopoeial or other recognized specifications of its ingredients and of the final product itself, and includes details of packaging, labeling, and shelf life.

Master Formula: A document or set of documents specifying the starting materials with their quantities and the packaging materials, together with a description

of the procedures and precautions required to produce a specified quantity of a finished product as well as the processing instructions, including the in-process controls.

Master Record: A document or set of documents that serve as a basis for the batch documentation (blank batch record).

Material: A general term used to denote raw materials (starting materials, reagents, and solvents), process aids, intermediates, APIs, and packaging and labeling materials.

Mother Liquor: The residual liquid that remains after the crystallization or isolation processes. A mother liquor may contain unreacted materials, intermediates, levels of the API, and/or impurities. It may be used for further processing.

Packaging: All operations, including filling and labeling, that a bulk product has to undergo in order to become a finished product. Filling of a sterile product under aseptic conditions, or a product intended to be terminally sterilized, would not normally be regarded as part of packaging.

Packaging Material: Any material intended to protect an intermediate or API during storage and transport. Any material, including printed material, employed in the packaging of a pharmaceutical, but excluding any outer packaging used for transportation or shipment. Packaging materials are referred to as primary or secondary according to whether or not they are intended to be in direct contact with the product.

Pharmaceutical Product: Any material or product intended for human or veterinary use presented in its finished dosage form, or as a starting material for use in such a dosage form, that is subject to control by pharmaceutical legislation in the exporting state and/or the importing state.

Procedure: A documented description of the operations to be performed, the precautions to be taken, and measures to be applied directly or indirectly related to the manufacture of an intermediate or API.

Process Aids: Materials, excluding solvents, used as an aid in the manufacture of an intermediate or API that do not themselves participate in a chemical or biological reaction (e.g., filter aid, activated carbon, and so on).

Process Control: See In-Process Control.

Production: All operations involved in the preparation of a pharmaceutical product, from receipt of materials, through processing, packaging and repackaging, and labeling and relabeling, to completion of the finished product.

Qualification: Action of proving and documenting that equipment or ancillary systems are properly installed, work correctly, and actually lead to the expected results. Qualification is part of validation, but the individual qualification steps alone do not constitute process validation.

Quality Assurance (QA): The sum total of the organized arrangements made with the object of ensuring that all APIs are of the quality required for their intended use and that quality systems are maintained.

Quality Control (QC): Checking or testing that specifications are met.

Quality Unit(s): An organizational unit independent of production that fulfills both Quality Assurance and Quality Control responsibilities. This can be in the form of separate QA and QC units or a single individual or group, depending upon the size and structure of the organization.

Quarantine: The status of starting or packaging materials, intermediates, or bulk or finished products isolated physically or by other effective means while a decision is awaited on their release, rejection, or reprocessing.

Raw Material: A general term used to denote starting materials, reagents, and solvents intended for use in the production of intermediates or APIs.

Reconciliation: A comparison between the theoretical quantity and the actual quantity.

Recovery: The introduction of all or part of previous batches (or of redistilled solvents and similar products) of the required quality into another batch at a defined stage of manufacture. It includes the removal of impurities from waste to obtain a pure substance or the recovery of used materials for a separate use.

Reference Standard, Primary: A substance that has been shown by an extensive set of analytical tests to be authentic material that should be of high purity.

Reference Standard, Secondary: A substance of established quality and purity, as shown by comparison to a primary reference standard, used as a reference standard for routine laboratory analysis.

Reprocessing: Subjecting all or part of a batch or lot of an in-process drug, bulk process intermediate (final biological bulk intermediate), or bulk product of a single batch/lot to a previous step in the validated manufacturing process due to failure to meet predetermined specifications. Reprocessing procedures are foreseen as occasionally necessary for biological drugs and in such cases, are validated and preapproved as part of the marketing authorization.

Retest Date: The date when a material should be reexamined to ensure that it is still suitable for use.

Reworking: Subjecting an in-process or bulk process intermediate (final biological bulk intermediate) or final product of a single batch to an alternate manufacturing process due to a failure to meet predetermined specifications. Reworking is an unexpected occurrence and is not preapproved as part of the marketing authorization.

Self-Contained Area: Premises that provide complete and total separation of all aspects of an operation, including personnel and equipment movement, with well-established procedures, controls, and monitoring.

This includes physical barriers as well as separate air-handling systems but does not necessarily imply two distinct and separate buildings.

Signature (Signed): See definition for signed.

Signed (Signature): The record of the individual who performed a particular action or review. This record can be initials, a full handwritten signature, a personal seal, or an authenticated and secure electronic signature.

Solvent: An inorganic or organic liquid used as a vehicle for the preparation of solutions or suspensions in the manufacture of an intermediate or API.

Specification: A list of detailed requirements with which the products or materials used or obtained during manufacture have to conform. They serve as a basis for quality evaluation.

Standard Operating Procedure (SOP): An authorized written procedure giving instructions for performing operations not necessarily specific to a given product or material (e.g., equipment operation, maintenance, and cleaning; validation; cleaning of premises and environmental control; sampling and inspection). Certain SOPs may be used to supplement product-specific master and batch production documentation.

Starting Material: Any substance of a defined quality used in the production of a pharmaceutical product, but excluding packaging materials.

Validation: A documented program that provides a high degree of assurance that a specific process, method, or system will consistently produce a result meeting predetermined acceptance criteria. Action of proving, in accordance with the principles of GMP, that any procedure, process, equipment, material, activity, or system actually leads to the expected results (see also Qualification).

Validation Protocol: A written plan stating how validation will be conducted and defining acceptance criteria. For example, the protocol for a manufacturing process identifies processing equipment, critical process parameters/operating ranges, product characteristics, sampling, test data to be collected, number of validation runs, and acceptable test results.

Yield, Expected: The quantity of material or the percentage of theoretical yield anticipated at any appropriate phase of production based on previous laboratory, pilot-scale, or manufacturing data.

Yield, Theoretical: The quantity that would be produced at any appropriate phase of production, based upon the quantity of material to be used, in the absence of any loss or error in actual production.

Drug Name	Dosage Form	USP Apparatus	Speed (rpm)	Medium	Volume (mL)	Recommended Sampling Times (min)	Date Updated
Acyclovir	Suspension	II (Paddle)	50	0.1 N HCl	900	10, 20, 30, 45, and 60	February 20, 2004

Cefprozil monohydrate	Suspension	II (Paddle)	25	Water (deaerated)	900	5, 10, 15, and 30	January 21, 2004
Ceftibuten dihydrate	Suspension	II (Paddle)	50	0.05 M phosphate buffer, pH 7.0	1000	10, 20, 30, and 45	January 21, 2004
Cephalexin	Suspension	II (Paddle)	25	Water	900	5, 10, 20, and 30	July 25, 2007
Clarithromycin	Suspension	II (Paddle)	50	0.05 M phosphate buffer, pH 6.8	900	10, 20, 30, 45, and 60	January 23, 2004
Dextromethorphan polistirex	Suspension	II (Paddle)	50	0.1 N HCl	500	30, 60, 90, and 180	March 4, 2006
Erythromycin ethylsuccinate	Suspension	II (Paddle)	75	Monobasic sodium phosphate, pH 6.8 buffer with 1% SLS buffer	900	10, 20, 30, 45, and 60	January 27, 2004
Felbamate	Suspension	II (Paddle)	50	Water (deaerated)	900	5, 10, 15, and 30	January 28, 2004
Fluconazole (200 mg/5 mL)	Suspension	II (Paddle)	50	Water (deaerated)	900	10, 20, 30, and 45	January 30, 2004
Fluconazole (50 mg/5 mL)	Suspension	II (Paddle)	50	Water (deaerated)	500	10, 20, 30, and 45	January 30, 2004
Fosamprenavir calcium	Suspension oral	II (Paddle)	25	10 mM HCl	900	5, 10, 15, and 20	December 3, 2007
Griseofulvin	Suspension	II (Paddle)	50	0.54% SLS	1000	10, 20, 30, and 45	April 9, 2007
Ibuprofen/pseudoephedrine HCl	Suspension	II (Paddle)	50	0.05 M phosphate buffer, pH 7.2	900	5, 10, 15, and 30	February 4, 2004
Linezolid	Suspension	II (Paddle)	50	0.05 M phosphate buffer, pH 6.8	900	10, 20, 30, and 45	January 14, 2008
Meloxicam	Suspension	II (Paddle)	25	Phosphate buffer at pH 7.5	900	5, 10, 15, and 30	January 26, 2006
Mesalamine enema	Suspension, enema	II (Paddle)	50	Phosphate buffer, pH 7.2	900	5, 10, 15, and 30	June 18, 2007
Mycophenolate mofetil	Suspension	II (Paddle)	40	0.1 N HCl	900	5, 10, 20, and 30	February 10, 2004
Nevirapine	Suspension	II (Paddle)	25	0.1 N HCl	900	10, 20, 30, 45, and 60	February 11, 2004
Oxcarbazepine	Suspension	II (Paddle)	75	1% SDS in water	900	10, 20, 30, and 45	February 12, 2004
Paroxetine HCl	Suspension	II (Paddle)	100	SGF without enzyme	900	10, 20, 30, and 45	February 13, 2004
Phenytoin	Suspension			Refer to USP			June 18, 2007
Posaconazole	Suspension oral	II (Paddle)	25	0.3% SLS	900	10, 20, 30, and 45	December 3, 2007
Sucralfate	Suspension	II (Paddle)	75	0.1 N HCl/0.067 M KCl, pH 1.0	900	10, 20, 30, and 45	March 4, 2006
Sulfamethoxazole/trimethoprim	Suspension	II (Paddle)	50	1 mL of 0.2 N HCl in water	900	10, 20, 30, 45, 60, and 90	February 25, 2004
Sulfisoxazole acetyl	Suspension oral (pediatric)	II (Paddle)	30	1% SLS in 0.1 N HCl	900	15, 30, 45, 60, and 90	August 17, 2006
Voriconazole	Suspension	II (Paddle)	50	0.1 N HCl	900	10, 20, 30, and 45	January 3, 2007

Liquid Formulations

ABACAVIR SULFATE ORAL SOLUTION

Ziagen oral solution is for oral administration. One milliliter of Ziagen oral solution contains abacavir sulfate equivalent to 20 mg of abacavir (20 mg/mL) in an aqueous solution and the inactive ingredients artificial strawberry and banana flavors, citric acid (anhydrous), methyl paraben and propyl paraben (added as preservatives), propylene glycol, saccharin sodium, sodium citrate (dihydrate), and sorbitol solution.

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
20.00	1	Abacavir; use abacavir hemisulfate	23.40
344.40	2	Sorbitol 70%	344.40
0.30	3	Sodium saccharin	0.30
2.00	4	Strawberry flavor	2.00
2.00	5	Banana flavor	2.00
QS	6	Sodium citrate dihydrate for pH adjustment	10.00
QS	7	Citric acid anhydrous for pH adjustment	7.00
1.50	8	Methylparaben	1.50
0.18	9	Propylparaben	0.18
50.00	10	Propylene glycol	50.00
QS	11	Hydrochloric acid dilute for pH adjustment to 4.0	QS
QS	12	Sodium hydroxide for pH adjustment	QS

Manufacturing Directions

1. The pH range for this solution is from 3.8 to 4.5.
2. Load 40% of the propylene glycol to an appropriately sized stainless steel vessel, add methylparaben and propylparaben with mixing, and mix until dissolved.
3. Place purified water into a stainless steel manufacturing tank equipped with a suitable mixer to approximately 40% of final batch volume.
4. Add sorbitol solution to the manufacturing tank.
5. While mixing, add item 1 and mix until dissolved.
6. While continuing to mix the solution, the paraben/glycol solution, the remaining propylene glycol, artificial strawberry flavor, artificial banana flavor, saccharin sodium, citric acid anhydrous, and sodium citrate dihydrate are added and mixed until dissolved.
7. Turn off the mixer, bring the solution to a volume of 500 L, and mix until a homogeneous solution is achieved.
8. Measure and adjust pH to 3.8 to 4.5 with sodium hydroxide or hydrochloric acid.
9. Filter the solution through a clarifying filter into an appropriately sized receiving vessel.

ACETAMINOPHEN, CHLORPHENIRAMINE, AND PSEUDOEPHEDRINE SYRUP

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
24.00	1	Acetaminophen (fine powder)	24.00
3.00	2	Pseudoephedrine HCl	3.00
0.44	3	Chlorpheniramine maleate (10% excess)	0.49
14.00	4	Ascorbic acid	14.00
2.40	5	Sodium hydroxide	2.40
1.00	6	Edetate disodium (sodium EDTA)	1.00
0.50	7	Saccharin sodium	0.50
2.00	8	Sodium metabisulfite (sodium disulfite)	2.00
80.00	9	Alcohol (ethanol, 95%)	80.00
100.00	10	Propylene glycol	100.00
100.00	11	Sorbitol (70% solution)	100.00
250.00	12	Glycerin (glycerol)	250.00
300.00	13	Sucrose	300.00
0.04	14	Quinoline yellow	0.04
0.25	15	Pineapple flavor	0.25
QS	16	Purified water	QS to 1 L

Manufacturing Directions

1. Add 200 g of item 16 to the manufacturing vessel and heat to 90°C to 95°C.
2. Add item 13 while mixing at slow speed at a temperature of 90°C to 95°C.
3. Mix for 1 hour at high speed.
4. Add items 10, 11, and 12 to the manufacturing vessel while mixing at high speed. Mix for 10 minutes.
5. Cool the temperature to 50°C while mixing at slow speed.
6. Add 70 g of item 9 to the syrup solution while mixing at slow speed.
7. Load item 1 into the manufacturing vessel while mixing at high speed.
8. Mix for 30 minutes to obtain a clear solution. Check the clarity of the solution.
9. Flush the solution with nitrogen gas for 5 minutes at 1 bar.

10. Add items 2, 4, 6, and 8 to the manufacturing vessel while mixing at slow speed.
11. Dissolve item 3 in 2 g of item 16 (25°C) and check that the solution is complete.
12. Add the solution to the manufacturing vessel while mixing at slow speed.
13. Dissolve item 15 in 10 g of item 9 in a stainless steel container and add to the manufacturing vessel while mixing at slow speed.
14. Dissolve items 5 and 7 in 20 g of item 16 (25°C) and add to the manufacturing vessel while mixing at slow speed.
15. Dissolve item 14 in 2 g of item 16 (25°C).
16. Transfer the color solution to the manufacturing vessel while mixing at slow speed.
17. Rinse the container of color solution with 2 g of item 16 (25°C); then, transfer the rinsings to the manufacturing vessel, and mix for 5 minutes at high speed.
18. Bring the volume up to 1 L with item 16, and finally, mix for 15 to 20 minutes at high speed.
19. Check and record the pH (limit: 5.1–5.2). If required, adjust pH with 10% citric acid or 10% sodium citrate solution.
20. Assemble the filter press with 13.1 T-1000 12 sheets (K 800 14 sheets). Use changeover plate. Wash the filters using purified water (25°C) by passing through filters at 0.2 bar; discard the washings. Filter the syrup at 1.5 bar. Recirculate about 20 to 30 mL syrup.
21. Connect the hose to the manufacturing vessel, and transfer the filtered syrup to the storage vessel.

ACETAMINOPHEN DROPS

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
739.00	1	Propylene glycol	739.00
90.00	2	Acetaminophen	90.00
17.50	3	Saccharin sodium	17.50
8.75	4	Sodium chloride	8.75
0.05	5	FD&C Red dye No. 40[a]	0.05
2.50	6	Purified water, USP	2.50
2.00	7	Wild cherry artificial flavor	2.00
65.00	8	Alcohol (ethanol; 190 proof; Nonbeverage), USP	65.00
QS	9	Deionized purified water, USP	QS to 1 L

[a] Check for local regulatory allowance to use red dyes.

Manufacturing Directions

Caution: Ensure that the solution in the tank never exceeds 65°C.

1. Add 739 g of propylene glycol to jacketed mixing tank, and start heating with slow mixing.
2. Dissolve dye in 2.5 mL of purified water, and add to tank while mixing.
3. Rinse container with small amount of purified water, and add to tank.
4. While mixing, add acetaminophen, saccharin sodium, and sodium chloride.
5. Hold at 60 C to 65 C with continued moderate mixing until all are in solution.
6. Force cool to less than 30°C with slow mixing.
7. Blend flavor with alcohol, and add to tank with slow mixing.
8. Add purified water with mixing QS to make 1 L.
9. Mix well with moderate agitation until uniform.
10. Filter through an 8 µm Millipore membrane (or equivalent).

ACETAMINOPHEN ORAL SUSPENSION

Bill of Materials

Scale (mg/5 mL)	Item	Material Name	Qty/L (g)
250.00	1	Acetaminophen (micronized) (2.0% excess)	51.00
2500.00	2	Sucrose	500.00
5.00	3	Methylparaben	1.00
1.50	4	Propylparaben	0.30
0.30	5	Sodium citrate	0.06
35.00	6	Glycerin (glycerol)	7.00
400.00	7	Glycerin (glycerol)	80.00
2000.00	8	Sorbitol (70%)	400.00
10.00	9	Xanthan gum (Keltrol® F)	2.00
0.50	10	Dye	0.10
22.50	11	Flavor	4.50
3.50	12	Strawberry flavor	0.70
—	13	Purified water	QS to 1 L

Manufacturing Directions

Note: Acetaminophen dispersion should be uniformly mixed. If acetaminophen dispersion is either added to hot syrup base or homogenized for a long time, flocculation may appear. While handling the syrup or mucilage or drug dispersion, the handling loss should not be more than 1%. If it exceeds 1%, a poor suspension may result.

1. Add 180 g of purified water to the mixer, and heat to 90°C.
2. Dissolve items 3 and 4 while mixing.
3. Add and dissolve item 2 while mixing.
4. Cool down to approximately 50°C to 55°C.
5. Add and dissolve item 5 while mixing.
6. Filter the syrup through T-1500 filters washed with purified water.
7. Collect the syrup in a clean stainless steel tank.

8. Disperse item 9 in item 6 in a separate stainless steel container.
9. Add 40 g of hot purified water (90°C) at once while mixing.
10. Mix for 20 minutes to make a homogeneous smooth mucilage.
11. Mix item 7 in 10 g of purified water (25°C) in a separate stainless steel container.
12. Add item 1 while mixing with stirrer.
13. Mix for 25 minutes to make uniform suspension.
14. Add sugar syrup and mucilage to the mixer.
15. Rinse the container of mucilage with 15 g of purified water, and add the rinsings to the mixer.
16. Cool to 25°C while mixing.
17. Add item 1 dispersion to the mixer.
18. Rinse the container of dispersion with 15 g of purified water, and add the rinsings to the mixer.
19. Check the suspension for uniformity of dispersion.
20. Mix for additional 5 minutes at 18 rpm and a vacuum of 0.5 bar, if required.
21. Add item 8 to the mixer, and mix for 10 minutes.
22. Dissolve item 10 in 7 g of purified water, and add to the mixer.
23. Disperse item 11 in 7 g of purified water, and add to the mixer.
24. Add item 12 to the mixer.
25. Add cold purified water (25°C) to bring the volume up to 1 L.
26. Homogenize for 5 minutes at low speed under a vacuum of 0.5 bar, 18 rpm, and temperature of 25°C.
27. Check the dispersion for uniformity.
28. Check the pH (limit: 5.7 ± 0.5 at 25°C). If required, adjust the pH with a 20% solution of citric acid or sodium citrate.
29. Transfer the suspension through a 630 μm sieve to the stainless steel storage tank after mixing for 5 minutes at 18 to 20 rpm at room temperature.

ACETAMINOPHEN RECTAL SOLUTION

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
QS	1	Vehicle (Pluronic P105 44.21%, propylene glycol 52.635, water 3.16%)	QS to 1 L
50.00	2	Acetaminophen micronized	50.00

Manufacturing Directions

1. Mill and screen the acetaminophen to further reduce the particle size.
2. Add the acetaminophen into a clean vessel.
3. Add propylene glycol to the vessel.
4. Subsequently, add the poloxamer and water to the vessel. Mix until uniform.

ACETAMINOPHEN SUSPENSION

Bill of Materials

Scale (mg/10 mL)	Item	Material Name	Qty/L (g)
500.00	1	Acetaminophen (powder)	50.00
50.00	2	Citric acid (powder)	5.00
50.00	3	Sodium citrate	5.00
500.00	4	Kollidon® CL-M	50.00
10.00	5	Orange flavor	1.00
3000.00	6	Dextrose	300.00
QS	7	Water	589.00

Manufacturing Directions

1. Prepare the solution of dextrose in water and add the other solid ingredients with stirring in the following sequence: citric acid, sodium citrate, orange flavor, Kollidon® CL-M, and acetaminophen.
2. A white homogeneous suspension is obtained that is a practically tasteless, stable suspension showing almost no sedimentation over 24 hours and good redispersibility (easily homogenized by shaking two or three times).

ACETAMINOPHEN SYRUP

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
569.00	1	Sucrose (granulated sugar), NF	569.00
2.00	2	Sodium citrate (dihydrate powder), USP	2.000
1.00	3	Citric acid (anhydrous powder), USP	1.000
1.00	4	Saccharin sodium (powder), USP	1.000
1.00	5	Sodium chloride (powder), USP	1.000
204.00	6	Propylene glycol, USP	204.000
35.00	7	Acetaminophen, USP	35.000
77.11	8	Alcohol (ethanol; 190 proof), USP	77.11
0.12	9	Cherry flavor (artificial), N59456/A	0.120
0.12	10	FD&C Red No. 40	0.100
QS	11	Deionized purified water, USP	400.000
—	12	HyFlo filter aid	QS

Manufacturing Directions

1. Add 300 mL of purified water to a jacketed stainless steel mixing tank. Start heating.
2. Add sugar with mixing.
3. Heat to 60°C to 65°C and hold. Mix for complete solution.

4. Add, while mixing, sodium citrate, citric acid, saccharin sodium, and sodium chloride. Mix for complete solution.
5. Add propylene glycol with mixing.
6. Add acetaminophen powder with moderate mixing.
7. Continue mixing at 60°C to 65°C for complete solution.
8. Force cool to 25°C to 30°C with slow mixing.
9. Blend cherry flavor with approximately twice its volume of alcohol, and add with mixing.
10. Rinse the container with several portions of alcohol, and add. Mix until uniform.
11. Dissolve red dye in approximately 4 g of slightly warmed (50–60°C) purified water, and add with mixing.
12. Rinse the container twice with approximately 1.5 g purified water, and add. Mix until uniform.
13. Adjust volume to 1 L with purified water. Mix well.
14. Add a small amount of HyFlo filter aid to the mixing tank, and continue to mix slowly while filtering.
15. Filter through press until sparkling clear.
16. Use clarifying pad backed by lint-free filter paper.

ACETAMINOPHEN SYRUP

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
50.00	1	Acetaminophen (Merck)	50.00
50.00	2	Sorbitol (crystalline)	50.00
40.00	3	Cyclamate sodium	40.00
1.00	4	Strawberry flavor	1.00
200.00	5	Kollidon® 25	200.00
150.00	6	Glycerol	150.00
200.00	7	1,2-Propylene glycol	200.00
310.00	8	Water	310.00

Manufacturing Directions

1. First dissolve Kollidon® 25 and then the other solid components in the solvent mixture of glycerol, propylene glycol, and water.
2. The clear solution has a slightly bitter taste.
3. The solution remains clear for more than 1 week at 6°C and for more than 3 months at 25°C and 40°C.
4. The color of the solution changes only a little during 3 months at 25°C and 40°C.
5. To prevent discoloration during storage, 0.2% to 0.5% of cysteine could be added as antioxidant.

ACETAMINOPHEN SYRUP FOR CHILDREN

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
25.00	1	Acetaminophen (crystalline)	25.00
300.00	2	Kollidon® 25 or Kollidon® 30	300.00
60.00	3	Glycerol	600.00
40.00	4	Sodium cyclamate	40.00
QS	5	Orange flavor	<1.0
QS	6	Raspberry flavor	2.00
QS	7	Water	575.00

Manufacturing Directions

1. Dissolve Kollidon® in water, add acetaminophen and cyclamate, heat to 50°C, and stir to obtain a clear solution.
2. Dissolve the flavors, and mix with glycerol.
3. The obtained syrup is a viscous, clear, sweet, and only slightly bitter liquid.

ACETAMINOPHEN SYRUP

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
50.0	1	Acetaminophen (Merck)	50.0
50.0	2	Sorbitol, crystalline	50.0
40.0	3	Cyclamate sodium	40.0
1.0	4	Strawberry flavor	1.0
200.0	5	Kollidon® 25	200.0
150.0	6	Glycerol	150.0
200.0	7	1,2-Propylene glycol	200.0
310.0	8	Water	310.0

Manufacturing Directions

1. Dissolve first Kollidon® 25 and then, the other solid components in the solvent mixture of glycerol, propylene glycol, and water.
2. The result is a clear solution of low viscosity having only a slightly bitter taste. To prevent discoloration during storage, 0.2% to 0.5% cysteine could be added as an antioxidant.

ACETAMINOPHEN SYRUP

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
569.00	1	Sucrose (sugar granulated)	569.00
2.00	2	Sodium citrate dihydrate powder	2.000
1.00	3	Acid citric anhydrous powder	1.000
1.00	4	Saccharin sodium powder	1.000
1.00	5	Sodium chloride powder	1.000
204.00	6	Propylene glycol	204.000
35.00	7	Acetaminophen	35.000
77.11	8	Alcohol (ethanol) 190 proof	77.112
0.12	9	Flavor cherry artificial N59456/A	0.1200
0.12	10	Dye Red FD&C N40	0.1200
QS	11	Water purified	400.000
QS	12	Filter aid HyFlo	QS

Manufacturing Directions

1. Add 300 mL purified water to a jacketed stainless steel mixing tank. Start heating.
2. Add sugar with mixing.
3. Heat to 60°C to 65°C, and hold. Mix for complete solution.
4. Add, while mixing, sodium citrate, citric acid, sodium saccharin, and sodium chloride. Mix for complete solution. Add propylene glycol by mixing.
5. Add acetaminophen powder with moderate mixing. Continue mixing at 60°C to 65°C for complete solution. Force cool to 25°C to 30°C with slow mixing.
6. Blend cherry flavor with approximately twice its volume of alcohol and add with mixing. Rinse the container with several portions of alcohol, and add. Mix until uniform.
7. Dissolve red dye in approximately 4 g of slightly warmed (50–60°C) purified water, and add by mixing. Rinse the container twice with approximately 1.5 g purified water, and add to step 6.
8. Mix until uniform. Adjust volume to 1 L with purified water. Mix well.
9. Add a small amount of HyFlo filter aid to the mixing tank, and continue to mix slowly while filtering.
10. Filter through press until sparkling clear. Use clarifying pad backed by lint-free filter paper.

ACNE SCRUB

Bill of Materials

Scale (mg/g)	Item	Material Name	Qty/kg (g)
20.00	1	Magnesium aluminum silicate magnabrite HV	20.00
582.00	2	Water	582.00
100.00	3	Propylene glycol	100.00
150.00	4	Mineral oil and acetylated lanolin alcohol	150.00
30.00	5	Glyceryl stearate and PEG-100 stearate	30.00
14.00	6	Myristyl propionate	14.00
100.00	7	PEG-600	100.00
4.00	8	Eucalyptus oil	4.00
QS	9	Preservatives	QS

Manufacturing Directions

1. Slowly sift item 1 into water, mixing until smooth.
2. Heat to 75°C.
3. Heat items 3 to 6 separately, mix, and heat to 70°C.
4. Add this portion to item 1 dispersion, and mix well until smooth.
5. Add item 7 to mixture, and mix.
6. Finally, add items 8 and 9, and mix until cool.
7. If using parabens, prepare a solution in a portion of water and add before adding item 8 and after allowing parabens to cool to 50°C.

ACYCLOVIR ORAL SUSPENSION (2% = 200 MG/10 ML)

Formulation

Acyclovir, 2 g; Kollidon® CL-M, 6 g; Kollidon® 30, 3 g; sorbitol, 28 g; citric acid, 0.5 g; preservative, QS; water, 60.5 g.

Manufacturing Directions

1. Suspend acyclovir and Kollidon® CL-M in the solution of the other components under vigorous stirring.

ACYCLOVIR ORAL SUSPENSION

Scale (mg/5 mL)	Item	Material Name	Qty/L (g)
215.00	**1**	**Acyclovir**	**43.00**
5.00	2	Methylparaben	1.00
1.00	3	Propylparaben	0.20
75.00	4	Microcrystalline cellulose (Avicel™ RC-591)	15.00
750.00	5	Glycerin (glycerol)	150.00
2250.00	6	Sorbitol (70% solution)	450.00
20.00	7	Orange, banana dry flavor	4.00
—	8	Water purified	QS to 1 L

Manufacturing Directions

1. Disperse item 1 in item 6. Keep stirring for 1 hour.
2. Heat 333.33 g of item 8 in mixer to 90°C to 95°C. Dissolve items 2 and 3 while mixing. Cool to 30°C.
3. Disperse items 4 and 5 in a stainless steel container, and keep stirring for 1 hour.
4. Add step 3 into step 2 at 30°C. Mix and homogenize for 5 minutes at high speed under vacuum 0.5 bar.
5. Add step 1 into step 2, and mix for 5 minutes.
6. Disperse item 7 in 13.33 g of item 8. Add into step 2.
7. Make up the volume with item 8. Finally, homogenize for 5 minutes at high speed under vacuum 0.5 bar.

ACYCLOVIR ORAL SUSPENSION

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
20.00	1	Acyclovir	20.00
60.00	2	Kollidon® CL-M	60.00
30.00	3	Kollidon® 30	30.00
28.00	4	Sorbitol	28.00
0.50	5	Citric acid	0.50
QS	6	Preservative	QS
QS	7	Water purified	QS to 1 L

Manufacturing Directions

1. Suspend item 1 and item 2 in the solution of items 3 through 7.
2. Mix vigorously to suspend.
3. Fill.

ADAPALENE SOLUTION

Differin® solution, containing adapalene, is used for the topical treatment of acne vulgaris. Each milliliter of Differin solution contains adapalene 0.1% (1 mg) in a vehicle consisting of polyethylene glycol 400 and SD alcohol 40-B, 30% (w/v).

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
1.00	1	Adapalene	1.00
700.00	2	Polyethylene glycol 400	700.00
QS	3	Alcohol	QS to 1 L

Manufacturing Directions

1. Add and dissolve item 1, and mix.
2. Place items 1 and 2 in a suitable mixing vessel. Stir.

ALBENDAZOLE ORAL SUSPENSION

Bill of Materials

Scale (mg/5 mL)	Item	Material Name	Qty/L (g)
100.000	1	Albendazole	20.00
7.500	2	Saccharin sodium	1.50
7.500	3	Potassium sorbate	1.50
550.000	4	Propylene glycol	110.00
15.000	5	Xanthan gum	3.00
2.500	6	Passion fruit flavor 502010A	0.50
7.500	7	Polysorbate 80 (Tween 80)	1.50
2.000	8	Citric acid	0.40
2.500	9	Vanilla dry flavor	0.50
2.500	10	Blood orange dry flavor	0.50
QS to 5 mL	11	Water purified	QS to 1 L

Manufacturing Directions

This product dispersion should be uniformly mixed and levigated. Xanthan gum dispersion should be uniform and smooth.

1. Disperse items 1 and 6 in 100 g of item 4 in a stainless steel container using a stirrer.
2. Dissolve item 7 in 100 g of item 11 (50–60°C) in a stainless steel container while stirring with the stirrer. Cool to 25°C to 30°C. Add in to step 1 while mixing.
3. Levigate to make smooth slurry, and keep aside for 2 hours.

4. Make slurry of item 5 in 10 g of item 4 in a stainless steel container while stirring with the stirrer. Add 200 g of item 11 (25–30°C) while stirring, and continue stirring for 30 minutes.
5. Dissolve item 8 in 10 g of item 11 (25–30°C) in a stainless steel container using a spatula.
6. Add 500 g of item 11 (25–30°C) into mixer. Dissolve items 2 and 3 while mixing.
7. Add the content from steps 1, 2, and 3 into step 4. Mix and homogenize at 25°C to 30°C, mixer speed 18 rpm, homogenizer high speed, and vacuum 0.4 to 0.6 bar for 10 minutes.
8. Add items 9 and 10 in step 4.
9. Mix and homogenize at 25°C to 30°C, mixer speed 18 rpm, homogenizer at high speed, and vacuum 0.4 to 0.6 bar for 15 minutes.
10. Make up the volume with item 11. Mix for 20 minutes.
11. Check the suspension for homogeneity. Transfer the suspension through a 630 micron sieve to stainless steel storage tank. It is important that you do not store the bulk suspension for more than 48 hours in the storage tank without stirring. Before sending for filling in packaging, stir for at least 30 minutes for uniform dispersion to avoid problems with content uniformity.

ALBENDAZOLE SUSPENSION

Bill of Materials

Scale (mg/5 mL)	Item	Material Name	Qty/L (g)
200.00	1	Albendazole	40.00
1.25	2	Simethicone	0.24
5.00	3	Tween 80	1.00
15.00	4	Xanthan gum	3.00
1950.00	5	Sucrose	390.00
650.00	6	Sorbitol	130.00
20.00	7	Sodium benzoate	4.00
20.00	8	Potassium sorbate	4.00
3.00	9	Citric acid	0.60
QS	10	Flavor	QS
QS	11	Water purified	QS to 1 L

Manufacturing Directions

1. Place in a tank 20% of item 11, and heat to 90°C.
2. Add and dissolve item 7; reduce temperature to 40°C, and add item 3.
3. In a separate vessel, add and dissolve item 9 in a portion of item 11.
4. Add step 3 to step 2.
5. In a separate vessel, disperse item 4 in 40% of item 11 at 65°C, and allow to hydrate to make it into a paste. Cool to room temperature.
6. Add to step 5 through a stainless steel filter.
7. In a separate vessel, add and make a paste of items 1 (passed through No. 100 mesh), 3, and 6. Add to step 6.
8. Add item 2. Stir well.
9. Add flavor and item 11 to make up the volume.

ALBUTEROL INHALATION SOLUTION

Each milliliter of Proventil inhalation solution 0.083% contains 0.83 mg albuterol (as 1 mg albuterol sulfate) in an isotonic aqueous solution containing sodium chloride and benzalkonium chloride; sulfuric acid is used to adjust the pH between 3 and 5. The 0.083% solution requires no dilution before administration by nebulization. Proventil inhalation solution 0.083% contains no sulfiting agents. It is supplied in 3 mL high-density polyethylene (HDPE) bottles for unit-dose dispensing. AccuNeb (albuterol sulfate) inhalation solution is supplied in two strengths in unit-dose vials. Each unit-dose vial contains either 0.75 mg of albuterol sulfate (equivalent to 0.63 mg of albuterol) or 1.50 mg of albuterol sulfate (equivalent to 1.25 mg of albuterol) with sodium chloride and sulfuric acid in a 3 mL isotonic, sterile aqueous solution. Sodium chloride is added to adjust the isotonicity of the solution, and sulfuric acid is added to adjust the pH of the solution to 3.5.

ALBUTEROL INHALATION SOLUTION

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
1.25	1	(R)-Albuterol; use albuterol sulfate	1.50
27.00	2	Sodium chloride	27.00
QS	3	Sulfuric acid	QS
QS	4	Water purified	QS to 1 L

Manufacturing Directions

1. Place all items in a suitable stainless steel vessel, and mix. Keep nitrogen flushing throughout and also into item 4 before adding other ingredients.
2. Check and adjust pH, using sulfuric acid, to 3.5.
3. Fill.

ALGINIC ACID + ALUMINUM HYDROXIDE + MAGNESIUM SILICATE TABLETS (500 MG + 100 MG + 25 MG)

Bill of Materials

Scale (mg/tablet)	Item	Material Name	Qty/1000 Tablets (g)
500.00	1	Alginic acid	500.00
100.00	2	Aluminum hydroxide dried gel (Giulini)	100.00
25.00	3	Magnesium trisilicate	25.00
170.00	4	Sodium bicarbonate	170.00
160.00	5	Sorbitol crystalline	160.00
627.00	6	Sucrose crystalline	627.00
900.00	7	Ludipress®	900.00
70.00	8	Kollidon® VA 64	70.00
50.00	9	Magnesium stearate	50.00
5.00	10	Vanillin	5.00

Manufacturing Directions

1. Pass all components through a 0.8 mm sieve. Mix, and press with high-compression force.

ALPHA-BISABOLOL AQUEOUS MOUTHWASH SOLUTION

Bill of Materials

Scale (mg/g)	Item	Material Name	Qty/kg (g)
2.00.00	1	Alpha-bisabolol, natural (BASF)	2.00
QS	2	Flavor	QS
25.00	3	Cremophor RH 40	25.00
50.00	4	Glycerol	50.00
1.00	5	Saccharin sodium	1.00
QS	6	Preservative	QS
922.00	7	Water	922.00

Manufacturing Directions

1. Heat mixture of items 1 to 3 to approximately 60°C, and slowly add the warm solution of items 4 to 7 (60°C).
2. The clear, colorless liquid has low viscosity.

ALPHA-BISABOLOL BUCCAL OR TOPICAL SOLUTION

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
1.20	1	Alpha-bisabolol (racemic) (BASF)	1.20
10.00	2	Cremophor RH 40	10.00
0.10	3	Butylhydroxytoluene (BHT)	0.10
QS	4	Preservative	QS
990.00	5	Water	990.00

Manufacturing Directions

Heat mixture of items 1 to 3 to approximately 60°C, stir well, and slowly add the warm solution of items 4 in 5 to obtain a clear solution.

ALPHA-BISABOLOL ETHANOLIC MOUTHWASH SOLUTION

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
10.00	1	Alpha-bisabolol, racemic (BASF)	10.00
100.00	2	Flavor	100.00
60.00	3	Cremophor RH 40	60.00
10.00	4	Glycerol	10.00
2.00	5	Saccharin sodium	2.00
818.00	6	Ethanol, 96%	818.00

Manufacturing Directions

1. Heat mixture of items 1 to 3 to approximately 60°C, and slowly add the warm solution of items 4 to 6.
2. The clear, colorless liquid can be diluted with water.

ALPHA-BISABOLOL MOUTHWASH SOLUTION

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
5.00	1	(–)Alpha-Bisabolol, natural (BASF)	5.00
50.00	2	Lutrol F 127 [1]	50.00
QS	3	Flavor	QS
100.00	4	Propylene glycol (pharma)	100.00
300.00	5	Ethanol 96%	300.00
545.00	6	Water	545.00

Manufacturing Directions

1. Prepare solution of items 1 through 5, and slowly add the water.
2. The clear, colorless solution should have a pH of 8. Do not adjust.

ALUMINUM HYDROXIDE + MAGNESIUM SILICATE CHEWABLE TABLETS (120 MG + 250 MG)

Bill of Materials

Scale (mg/tablet)	Item	Material Name	Qty/1000 Tablets (g)
120.00	1	Aluminum hydroxide dried gel (Giulini)	120.00
250.00	2	Magnesium trisilicate	250.00
232.00	3	Ludipress®	232.00
6.00	4	Aerosil® 200	6.00
6.00	5	Magnesium stearate	6.00
12.00	6	Cyclamate sodium	12.00
1.50	7	Menthol	1.50

Manufacturing Directions

Mix all components, pass through a 0.8 mm sieve, and press with a compression force of 20 kN at 640 mg.

ALUMINUM CHLORIDE SOLUTION

Aluminum chloride (hexahydrate) 6.25% (w/v) in anhydrous ethyl alcohol (SD alcohol 40) 96% (v/v).

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
62.50	1	Aluminum chloride hexahydrate	62.50
QS	2	Alcohol anhydrous	QS to 1 L

Manufacturing Directions

1. Place items 1 and 2 in a suitable stainless steel container, and mix.
2. Fill.

ALUMINUM HYDROXIDE AND MAGNESIUM CARBONATE DRY SYRUP

Bill of Materials

Scale (mg/g)	Item	Material Name	Qty/kg (g)
200.00	1	Aluminum hydroxide dry gel (Giulini)	200.00
200.00	2	Basic magnesium carbonate	200.00
240.00	3	Kollidon® CL-M	240.00
211.50	4	Sorbitol (crystalline)	211.50
41.30	5	Orange flavor	41.30
82.60	6	Kollidon® 30	82.60
3.30	7	Coconut flavor	3.30
4.13	8	Banana flavor	4.13
4.13	9	Saccharin sodium	4.13
8.26	10	Water	8.26

Manufacturing Directions

1. Granulate mixture of items 1 to 5 with solution of items 6 to 10, pass through a sieve, and dry.
2. Shake 58 g of the granules with 100 mL of water.
3. Product remains homogeneous and without sedimentation for more than 24 hours.

ALUMINUM HYDROXIDE AND MAGNESIUM HYDROXIDE ANTACID SUSPENSION

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
5.00	1	Purified bentonite (Veegum® HS)	5.00
2.00	2	Xanthan gum (Rhodigel)	2.00
401.00	3	Water	401.00
200.00	4	Sorbitol (70%)	200.00
360.00	5	Aluminum hydroxide gel	360.00
320.00	6	Magnesium hydroxide, USP	320.00
QS	7	Preservative, flavor	QS

Manufacturing Directions

1. Slowly add a dry blend of item 1 and 2 to item 3, agitating with maximum available shear until a smooth and uniform mix is obtained.
2. Mix items 4 to 6 together in another vessel until uniform, and then add to previous mix.
3. Agitate until uniform.
4. Add item 7, and mix until uniform.

ALUMINUM HYDROXIDE AND MAGNESIUM HYDROXIDE ANTACID SUSPENSION

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
200.00	1	Magnesium aluminum silicate (Magnabrite S) (5% suspension)	200.00
2.00	2	Methylparaben	2.00
1.00	3	Propylparaben	1.00
0.50	4	Saccharin sodium	0.50
500.00	5	Aluminum hydroxide/magnesium hydroxide fluid gel	500.00
3.00	6	Polysorbate 80	3.00
2.00	7	Flavor	2.00
291.50	8	Deionized water	291.50

Manufacturing Directions

1. Add the parabens and saccharin to item 1 with stirring until dissolved (may heat to 80°C to dissolve).
2. Add item 5 with mixing.
3. Finally, add items 6 and 7. Mix well.
4. Add item 8 to final volume

ALUMINUM HYDROXIDE AND MAGNESIUM HYDROXIDE SUSPENSION

Bill of Materials

Scale (mg/5 mL)	Item	Material Name	Qty/L (g)
405.000	1	Aluminum hydroxide gel	290.0000
100.000	2	Magnesium hydroxide paste 30%	67.0000
0.210	3	Ammonia solution 25%	0.0420
0.053	4	Ammonia solution 25%	0.0106
10.000	5	Methylparaben	2.0000
0.250	6	Menthol	0.0500
3.000	7	Propylparaben	0.6000
1.000	8	Peppermint oil	0.2000
50.000	9	Propylene glycol	10.0000
1.250	10	Saccharin sodium	0.2500
150.00	11	Sorbitol (70% solution)	30.0000
4.500	12	Sodium hypochlorite 5%	0.9000
1.250	13	Sodium hypochlorite 5%	0.2500
15.000	14	Magnesium aluminum silicate (Veegum HV)	3.0000
—	15	Water purified	QS to 1 L

Note: Quantity of the sodium hypochlorite solution to be adjusted according to the assay.

Manufacturing Directions

1. Disperse item 14 in 60 g of hot item 15 (70–80°C) in stainless steel vessel using stirrer.
2. Continue stirring for 30 minutes.
3. Transfer the dispersion into mixer (e.g., Krieger) vessel by vacuum and mix for 30 minutes at mixer speed 16/32.
4. Cool down to 30°C. Add 200 g of hot item 15 (70–80°C) into the mixer.
5. Mix and homogenize at 1420 rpm, mixer speed 16/32, vacuum 0.5 bar for 30 minutes.
6. Cool down to 30°C.
7. Add 1 kg of item 15 (70°C) to a suitable vessel, and heat to 85°C to 90°C for 1 hour.
8. Cool to 20°C to 25°C.
9. Mix items 4 and 13, and immediately add to item 15 (20–25°C) in the storage vessel.
10. Mix for 2 minutes. Store in a previously cleaned storage vessel.
11. Load item 2 and 100 g of item 15 (25–30°C) in a stainless steel mixing vessel with lid and stirrer.
12. Mix for 5 minutes at medium speed.
13. Transfer by vacuum into mixer. Load 80 g of item 1 and 80 g of item 15 (25–30°C) from step 12 in a stainless steel mixing vessel with lid and stirrer.
14. Mix for 5 minutes at medium speed. Transfer by vacuum into mixer.
15. Load 80 g of item 1 and 80 g of item 15 (25–30°C) from step 12 in a stainless steel mixing vessel with lid and stirrer. Mix for 5 minutes at medium speed. Transfer by vacuum into mixer.
16. Load 80 g of item 1 and 80 g of item 15 (25–30°C) from step 12 in a stainless steel mixing vessel with lid and stirrer.
17. Mix for 5 minutes at medium speed. Transfer by vacuum into mixer. Load 50 g of item 1 and 50 g of item 15 (25–30°C) from step 12 in a stainless steel mixing vessel with lid and stirrer.
18. Mix for 5 minutes at medium speed. Transfer by vacuum into mixer. Transfer item 11 into mixer by vacuum.
19. Dissolve item 10 in 2 g of item 15 (25–30°C), and transfer into mixer. Mix and homogenize for 30 minutes at 1420 rpm under vacuum 0.5 bar.
20. Dissolve items 5 and 7 in item 9 (50–60°C) by stirring in stainless steel container in a water bath.
21. Dissolve items 8 and 6, and add to parabens–glycol solution.
22. Mix well; add to mixer. Mix, and homogenize for 10 minutes under vacuum 0.5 bar.
23. Mix items 3, 12, and 2 g of item 15, and immediately add to the mixer. Mix for 10 minutes without vacuum.
24. Add cold item 15 to make up the volume up to 1 L. Mix for 15 minutes.
25. Transfer the suspension through 630 micron sieve to the stainless steel storage tank. Final pH 7.5 to 8.0, density 1.04 to 1.06.

ALUMINUM HYDROXIDE AND MAGNESIUM HYDROXIDE SUSPENSION

Bill of Materials

Scale (mg/5 mL)	Item	Material Name	Qty/L (g)
200.00	1	Aluminum hydroxide gel	40.00
80.00	2	Magnesium hydroxide paste 30%	16.00
150.00	3	Sorbitol (70% solution)	30.00
10.00	4	Methylparaben	2.00
1.00	5	Propylparaben	0.20
2.00	6	Saccharin sodium	0.40
15.00	7	Magnesium aluminum silicate (Veegum HV)	3.00
0.20	8	Ammonia solution 25%	0.04
4.50	9	Sodium hypochlorite 5%	0.90
100.00	10	Propylene glycol	20.00
0.75	11	Lemon-mint flavor	0.15
—	12	Water purified	QS to 1 L

Manufacturing Directions

1. See previous entry for manufacturing directions for Aluminum Hydroxide and Magnesium Hydroxide Suspension.

ALUMINUM HYDROXIDE AND MAGNESIUM HYDROXIDE SUSPENSION

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
5.00	1	Purified bentonite (Veegum HS)	5.00
2.00	2	Xanthan gum (Rhodigel)	2.00
401.00	3	Water	401.00
200.00	4	Sorbitol 70%	200.00
360.00	5	Aluminum hydroxide gel	360.00
320.00	6	Magnesium hydroxide	320.00
QS	7	Preservative, flavor	QS

Manufacturing Directions

1. Add a dry blend of items 1 and 2 to item 3 slowly, agitating with maximum available shear until a smooth and uniform mix is obtained.
2. Mix together items 4 to 6 in another vessel until uniform, add to the above mix, and agitate until uniform.
3. Add item 7, and mix until uniform.

ALUMINUM HYDROXIDE AND MAGNESIUM HYDROXIDE SUSPENSION

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
40.0	1	Aluminum hydroxide	40.0
40.0	2	Magnesium hydroxide	40.0
50.0 g	3	Cremophor RH 40	50.0
1.0	4	Silicon oil DC 200 (Serva)	1.0
100.0	5	Kollidon® CL-M	100.0
QS	6	Water	76.9

Manufacturing Directions

1. Mix Cremophor RH 40 well with the silicon oil.
2. Add the water and suspend the solid substances.

ALUMINUM HYDROXIDE AND MAGNESIUM HYDROXIDE SUSPENSION

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
200.0	1	Magnesium aluminum silicate (Magnabrite S) 5% suspension	200.0
2.0	2	Methylparaben	2.0
1.0	3	Propylparaben	1.0
0.5	4	Saccharin sodium	0.5
500.0	5	Aluminum hydroxide–magnesium hydroxide fluid gel	500.0
3.0	6	Polysorbate 80	3.0
2.0	7	Flavor	2.0
291.5	8	Water purified	291.5

Manufacturing Directions

1. Add the parabens and saccharin to item 1 with stirring until dissolved (may heat to 80°C to dissolve).
2. Add item 5 with mixing. Finally, add items 6 and 7.
3. Mix well.

ALUMINUM HYDROXIDE AND MAGNESIUM HYDROXIDE SUSPENSION

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
405.00	1	Aluminum hydroxide gel	290.00
100.00	2	Magnesium hydroxide paste (30%)	67.00
0.21	3	Ammonia solution (25%)	0.04
0.05	4	Ammonia solution (25%)	0.01
10.00	5	Methyl paraben	2.00
0.25	6	Menthol	0.05

1.00	8	Peppermint oil	0.20
50.00	9	Propylene glycol	10.00
1.25	10	Saccharin sodium	0.25
150.00	11	Sorbitol (70% solution)	30.00
4.50	12	Sodium hypochlorite (5%)	0.90
1.25	13	Sodium hypochlorite (5%)	0.25
15.00	14	Magnesium aluminum silicate (Veegum® HV)	3.00
QS	15	Purified water	QS to 1 L

Note: The quantity of the sodium hypochlorite solution should be adjusted according to the assay.

Manufacturing Directions

1. Disperse item 14 in 60 g of hot purified water (70–80°C) in stainless steel vessel using a stirrer. Continue stirring for 30 minutes.
2. Transfer the dispersion into mixer (e.g., Krieger) vessel by vacuum, and mix for 30 minutes at 16/32 mixer speed.
3. Cool down to 30°C.
4. Add 200 g of hot purified water (70–80°C) to the mixer.
5. Mix and homogenize at 1420 rpm, mixer speed of 16/32, and vacuum of 0.5 bar for 30 minutes.
6. Cool down to 30°C.
7. Add 1 kg of purified water (70°C) to a suitable vessel, and heat to 85°C to 90°C for 1 hour.
8. Cool to 20°C to 25°C.
9. Mix items 13 and 4, and immediately add to purified water (20–25°C) in the storage vessel.
10. Mix for 2 minutes. Store in a previously cleaned storage vessel.
11. Load item 2 and 100 g of purified water (25–30°C) in a stainless steel mixing vessel with lid and stirrer.
12. Mix for 5 minutes at medium speed.
13. Transfer by vacuum into mixer.
14. Load 80 g of item 1 and 80 g of purified water (25–30°C) from step 12 in a stainless steel mixing vessel with lid and stirrer. Mix for 5 minutes at medium speed. Transfer by vacuum into mixer.
15. Load 50 g of item 1 and 50 g of purified water (25–30°C) from step 11 in a stainless steel mixing vessel with lid and stirrer.
16. Mix for 5 minutes at medium speed. Transfer by vacuum into mixer.
17. Transfer item 11 into mixer by vacuum.
18. Dissolve item 10 in 2 g of purified water (25–30°C) and transfer to mixer.
19. Mix and homogenize for 30 minutes at 1420 rpm under vacuum of 0.5 bar.
20. Dissolve items 5 and 7 in item 9 (50–60°C) by stirring in stainless steel container in a water bath.
21. Dissolve items 8 and 6, and add to parabens/glycol solution. Mix well, and add to mixer.
22. Mix, and homogenize for 10 minutes under vacuum of 0.5 bar.
23. Mix items 12 and 3 and 2 g of purified water, and immediately add to the mixer.
24. Mix for 10 minutes without vacuum.
25. Add cold purified water to bring the volume up to 1 L. Mix for 15 minutes.
26. Transfer the suspension through 630 µm sieve to the stainless steel storage tank. Final pH is 7.5 to 8.0, and density is 1.04 to 1.06.

ALUMINUM HYDROXIDE AND MAGNESIUM HYDROXIDE SUSPENSION

Bill of Materials

Scale (mg/5 mL)	Item	Material Name	Qty/L (g)
200.00	1	Aluminum hydroxide gel	40.00

100.00	5	Kollidon® CL-M	100.00
QS	6	Water	76.90

Manufacturing Directions

1. Mix Cremophor RH 40 well with the silicon oil, add the water, and suspend the solid substances.

ALUMINUM HYDROXIDE, MAGNESIUM HYDROXIDE, AND SIMETHICONE SUSPENSION

Bill of Materials

Scale (g/5 mL)	Item	Material Name	Qty/L (g)
215.00	1	Aluminum hydroxide gel	43.00
80.00	2	Magnesium hydroxide paste (30%)	16.00
25.00	3	Simethicone emulsion (simethicone antifoam M30)	18.50
150.00	4	Sorbitol (70% solution)	30.00
0.20	5	Ammonia solution 25%	0.04
10.00	6	Methylparaben	2.00
1.00	7	Propylparaben	0.20
28.00	8	Methylcellulose 4000 (Methocel A4M)	5.60
2.00	9	Saccharin sodium	0.40
4.50	10	Sodium hypochlorite (5%)	0.90
1.00	11	Lemon-mint flavor	0.20
QS	12	Purified water	QS to 1 L

Manufacturing Directions

See manufacturing directions for Aluminum Hydroxide and Magnesium Hydroxide Suspension.

ALUMINUM HYDROXIDE, MAGNESIUM HYDROXIDE, AND SIMETHICONE SUSPENSION

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
27.00	1	Simethicone 30%	27.00
30.00	2	Cremophor RH 40	30.00
70.00	3	Water	70.00
80.00	4	Aluminum hydroxide dry gel (Giulini)	80.00
80.00	5	Magnesium hydroxide	80.00
90.00	6	Kollidon® CL-M	90.00
100.00	7	Sorbitol (crystalline)	100.00
4.00	8	Banana flavor	4.00
5.00	9	Coconut flavor	5.00
1.00	10	Saccharin sodium	1.00
QS	11	Water	QS to 1 L
QS	12	Citric acid (to adjust pH)	QS

Manufacturing Directions

1. Mix Cremophor RH 40 with simethicone, and heat to about 50°C, stirring well.
2. Add warm water.
3. Dissolve the flavors and saccharin in water, and suspend aluminum hydroxide, magnesium hydroxide, and Kollidon® CL-M.
4. Add emulsion of items 1 to 3 to the stirred suspension of items 4 to 11, and adjust the pH to about 9 with item 12, if needed.

ALUMINUM HYDROXIDE, MAGNESIUM HYDROXIDE, AND SIMETHICONE SUSPENSION

Bill of Materials

Scale (mg/5 mL)	Item	Material Name	Qty/L (g)
215.00	1	Aluminum hydroxide gel	43.00
80.00	2	Magnesium hydroxide paste 30%	16.00
25.00	3	Simethicone emulsion (simethicone antifoam M30)	18.50
150.00	4	Sorbitol (70% solution)	30.00
0.20	5	Ammonia solution 25%	0.04
10.00	6	Methylparaben	2.00
1.00	7	Propylparaben	0.20
28.00	8	Methylcellulose 4000 (Methocel A4M)	5.60
2.00	9	Saccharin sodium	0.40
4.50	10	Sodium hypochlorite 5%	0.90
1.00	11	Lemon-mint flavor	0.20
—	12	Water purified	QS to 1 L

Manufacturing Directions

1. See previous entry for manufacturing directions for Aluminum Hydroxide, Magnesium Hydroxide, and Simethicone Suspension.

ALUMINUM HYDROXIDE, MAGNESIUM HYDROXIDE, AND SIMETHICONE SUSPENSION

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
27.00	1	Simethicone 30%	27.00
30.00	2	Cremophor RH 40	30.00
70.00	3	Water	70.00
80.00	4	Aluminum hydroxide dry gel (Giulini)	80.00
80.00	5	Magnesium hydroxide	80.00
90.00	6	Kollidon® CL-M	90.00
100.00	7	Sorbitol, crystalline	100.00
4.00	8	Banana flavor	4.00
5.00	9	Coconut flavor	5.00
1.00	10	Saccharin sodium	1.00
QS	11	Water	QS to 1 L
QS	12	Citric acid to adjust pH to 9	QS

Manufacturing Directions

1. Mix Cremophor RH 40 with simethicone, and heat to about 50°C, stirring well.
2. Add the warm water.
3. Dissolve the flavors and saccharin in water, and suspend aluminum hydroxide, magnesium hydroxide, and Kollidon® CL-M.
4. Add emulsion of items 1 to 3 to the stirred suspension of items 4 to 11, and adjust pH to about 9 with item 12 if needed.

ALUMINUM HYDROXIDE, MAGNESIUM HYDROXIDE, AND SIMETHICONE TABLETS

Bill of Materials

Scale (mg/tablet)	Item	Material Name	Qty/1000 Tablets (g)
200.00	1	Aluminum hydroxide gel (dried)	200.00
200.00	2	Magnesium hydroxide powder	200.00
200.00	3	Mannitol	200.00
45.00	4	Sorbitol powder	45.00
65.00	5	Dextrose (glucose) monohydrate	65.00
16.50	6	Povidone (PVP K-30)	16.50
2.50	7	Saccharin sodium	2.50
1.00	8	FD&C Yellow dye No.10 lake	1.00
2.50	9	Mint flavor (dry)	2.50
1.50	10	Lemon flavor (dry)	1.50
25.00	11	Simethicone GS granules	84.00
315.00	12	Dextrates (Emdex®)	315.00
1.00	13	Colloidal silicon dioxide (Aerosil® 200)	1.00
6.00	14	Magnesium stearate	6.00
—	15	Purified water	160.00

Manufacturing Directions

1. Processing should be done at relative humidity of 50% ± 5% and temperature of 26°C ± 1°C.
2. Dissolve items 4, 5, and 7 in cold purified water (25–30°C) by using stirrer, and then, add item 6 while mixing.
3. Add item 8, and disperse the color completely.
4. Check final weight; if required, adjust with purified water.
5. Load items 1, 2, and 3 into mixer, and mix for 5 minutes using mixer and chopper at high speed.
6. Add binding solution at a rate of 16 to 20 g/min to the dry powders in mixer while mixing at low speed. Mix for 2 to 3 minutes. Scrape the sides, blade, and lid of the mixer.
7. Mix, and chop at low speed for an additional 2 to 3 minutes or until the granules stop flying around the chopper. Add extra purified water if required, and continue mixing until a satisfactory mass is obtained. Record extra quantity of purified water added.
8. Unload the wet mass into clean Aeromatic bowl for drying.
9. Avoid big lump formation, as this leads to nonuniform drying.
10. Dry the wet mass in an Aeromatic fluid bed dryer at 60°C for 90 minutes.
11. After 30 minutes of drying, scrape the semidried granules to break up the lumps to promote uniform drying.
12. Pass the dried granules through a 1.5 mm sieve using a granulator at medium speed. Collect in stainless steel drums.

13. Load the granules into blender.
14. Add items 11 and 12 to stainless steel drum, and mix for 2 minutes using drum mixer; then, load into the blender, and mix along with the granules for 2 minutes.
15. Pass items 9, 10, 13, and 14 through sifter using 250 µm sieve.
16. Load the sieved material into blender, and mix for 2 minutes. Unload into stainless steel drums.
17. Check temperature and humidity of the room before beginning compression.
18. Compress 1.2 g per tablet using 15.8 mm flat punch at relative humidity of 50% ± 5% at a temperature of 26°C ± 1°C.

AMINACRINE HYDROCHLORIDE TOPICAL SOLUTION

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
1.00	1	Aminacrine hydrochloride	1.00
60.00	2	Thymol	60.00
100.00	3	Glyceryl monostearate	100.00
30.00	4	Cetostearyl alcohol	30.00
20.00	5	Polyoxyl 40 stearate	20.00
100.00	6	Liquid paraffin	100.00
5.00	7	Cetrimide	5.00
1.50	8	Isopropyl alcohol	1.50
QS	9	Water purified	QS to 1 L

Manufacturing Directions

1. Place item 6 in a suitable stainless steel vessel, and add and dissolve item 1 by heating to 65°C.
2. Place items 3 to 5, 7, and 9 in a separate vessel, and mix.
3. Add preceding items to step 1.
4. On cooling, add items 8 and 2, and mix.
5. Fill.

Aminolevulinic Acid HCl for Topical Solution (20%). Aminolevulinic acid HCl for topical solution, 20%, contains the hydrochloride salt of aminolevulinic acid, an endogenous 5-carbon aminoketone. The stick for topical application is a two-component system consisting of a plastic tube containing two sealed glass ampules and an applicator tip. One ampule contains 1.5 mL of solution vehicle comprising alcohol (ethanol content = 48% v/v), water, laureth-4, isopropyl alcohol, and polyethylene glycol. The other ampule contains 354 mg of aminolevulinic acid hydrochloride as a dry solid. The applicator tube is enclosed in a protective cardboard sleeve and cap. The 20% topical solution is prepared just before the time of use by breaking the ampules and mixing the contents by shaking the stick applicator.

AMOXICILLIN POWDER FOR SUSPENSION

Bill of Materials

Scale (mg/5 mL)[a]	Item	Material Name	Qty/5 L (g)
125.00	1	Amoxicillin; use amoxicillin trihydrate, 8% excess	143.50
1.04	2	Simethicone A	1.04
111.11	3	Caster sugar	111.11
444.44	4	Caster sugar	444.44
2479.86	5	Caster sugar	2479.86
23.33	6	Sodium citrate	23.33
1.67	7	Xanthan gum	1.67
13.33	8	Blood orange dry flavor	13.33
0.74	9	Vanilla dry flavor	0.74
4.44	10	Orange, banana dry flavor	4.44
14.44	11	Aerosil® 200	14.44

[a] After reconstitution

Manufacturing Directions

1. Place items 3 and 2 in a mixer, and mix for 2 minutes.
2. Add item 4 and items 6 to 11, and mix for 5 minutes.
3. Pass through Fitz mill, impact forward at high speed using sieve 24228.
4. In a separate mixer, place items 5 and 1, and mix well, passing through a sifter.
5. Add to step 3, and mix for 20 minutes.
6. Fill 65 g for 100 mL and 39 g for 60 mL pack size.

AMOXICILLIN–CLAVULANATE SYRUP

Bill of Materials

Scale (g/60 mL volume)	Item	Material Name	Qty/kg (g)
1.500	1	Amoxicillin (1.25 g/60 mL);[a] use amoxicillin trihydrate	215.67
0.393	2	Potassium clavulanate (equivalent to clavulanic acid 0.312 g)	56.59
0.150	3	Xanthan gum	21.56
1.800	4	Hydroxypropyl methylcellulose	258.80
0.150	5	Saccharin sodium	21.56
0.300	6	Colloidal silica	43.13
0.010	7	Succinic acid	1.44
1.500	8	Silica gel	215.67
0.180	9	Peach dry flavor	26.39
0.230	10	Strawberry dry flavor	33.99
0.730	11	Lemon dry flavor	105.16

[a] 6.955 g/60 mL: 156 mg/5 mL syrup 60 mL (125 mg amoxicillin and 31.25 mg clavulanic acid).

Manufacturing Directions

Throughout the process of manufacturing and filling, maintain relative humidity of NMT 40%.

1. Mill 50% of amoxicillin trihydrate, saccharin sodium (dried to NMT 2% moisture by Karl Fischer method), and succinic acid through a No. 100 mesh sieve using Fitz mill or equivalent with blades forward.
2. Transfer to a blending mixer, and mix for 15 minutes.
3. Mill remaining amoxicillin trihydrate through a No. 100 mesh using Fitz mill or equivalent, and mix with the screened powders; mix for 15 minutes.
4. Mill xanthan gum and hydroxypropyl methylcellulose (dried to NMT 2% moisture at 105°C for 2 hours), colloidal silica, and silica gel through a No. 100 screen using Fitz mill or equivalent with knives forward. Add to the mixture in step 2, and mix for 15 minutes at medium speed.
5. Screen all dry flavors through a No. 100 mesh screen, and add to this mixture.
6. Fill dry powder approximately 7 g in dry 60 mL glass bottles at a fill weight based on the assay of the active constituent.

AMOXICILLIN–CLAVULANATE SYRUP

Bill of Materials

Scale (mg/5 mL)	Item	Material Name	Per L/g
400.00	1	Amoxicillin as trihydrate	80.00
57.00	2	Clavulanic acid as potassium salt	11.40
2.69	3	Citric acid	0.54
8.33	4	Sodium citrate	1.67
28.10	5	Microcrystalline cellulose and sodium carboxymethylcellulose	5.62
10.00	6	Xanthan gum	2.00
16.67	7	Colloidal silicon dioxide	3.33
216.60	8	Silicon dioxide	43.32
13.30	9	Strawberry flavor	2.66
15.00	10	Caramel flavor	3.00
6.70	11	Saccharin sodium	1.34
QS	12	Cellulose microcrystallinea	qs

[a] Total amount filled per bottle to deliver 12 doses is 15 g for 400 and 600 mg label of amoxicillin; for 200 and 300 mg amoxicillin label, the total fill weight is 12 g; adjust using item 12. Use the preceding method to manufacture the final product.

AMPICILLIN POWDER FOR SUSPENSION

Bill of Materials

Scale (mg/5 mL)	Item	Material Name	Qty/5 L (g)
125.00	1	Ampicillin; use ampicillin trihydrate, 8% excess	144.25
1.00	2	Simethicone A	1.00
138.90	3	Caster sugar	138.90
27.44	4	Sodium citrate	27.44
7.00	5	Xanthan gum	7.00
15.00	6	Blood orange dry flavor	15.00
0.78	7	Vanilla dry flavor	0.78
7.55	8	Strawberry dry flavor	7.55
10.00	9	Aerosil® 200	10.00
138.90	10	Caster sugar	138.90
2747.90	11	Caster sugar	2747.90

Manufacturing Directions

1. All operations to be completed in relative humidity 45% to 55% and temperature 23°C to 25°C.
2. Place items 2 and 3 in a suitable blender, and mix for 5 minutes.
3. Place in a separate mixer items 1 and 4 to 10, and mix for 5 minutes.
4. Add step 2 into step 3, and mix for 10 minutes.
5. Add item 11, and mix for 10 minutes.
6. Fill 65 g for 100 mL pack and 39 g for 60 mL pack. For 250 mg strength, adjust active ingredient, and adjust with item 11.

AMPICILLIN POWDER FOR SUSPENSION

Bill of Materials

Scale (mg/g)	Item	Material Name	Qty/kg (g)
50.00	1	Ampicillin trihydrate	50.00
50.00	2	Sodium citrate	50.00
21.00	3	Citric acid crystalline	21.00
50.00	4	Sodium gluconate	50.00
400.00	5	Sorbitol crystalline	400.00
60.00	6	Kollidon® CL-M	60.00
15.00	7	Orange flavor	15.00
5.00	8	Lemon flavor	5.00
4.00	9	Saccharin sodium	4.00

Manufacturing Directions

1. Mix all components, and fill appropriate amount.

AMPICILLIN AND CLOXACILLIN OILY SUSPENSION

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
15.00	1	Ampicillin sodium	15.00
40.00	2	Cloxacillin sodium	40.00
30.00	3	Lutrol F 68	30.00
QS	4	Antioxidant	QS
915.00	5	Castor oil	915.00

Manufacturing Directions

1. Place items 4 and 5 in a suitable stainless steel jacketed vessel; heat to 50°C. Do not overheat, as castor oil may decompose.
2. Add and dissolve item 3.
3. Add and dissolve items 1 and 2.
4. Homogenize and fill.

AMPRENAVIR CAPSULES

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
150.00	1	Amprenavir	150.00
400.00	2	D-alpha-tocopheryl polyethylene glycol 1000 succinate (TPGS)	400.00
200.50	3	Polyethylene glycol 400	200.50
39.40	4	Polyethylene glycol 400	39.40

Manufacturing Directions

1. Place item 2 in a suitable stainless steel-jacketed vessel, and heat to 50°C until liquefied.
2. Add item 3 (90%) at 50°C, and mix until homogeneous solution obtained.
3. Increase temperature to 65°C, add item 1, and stir to dissolve.
4. Add item 4 and balance of item 2, cool to room temperature, and apply vacuum to remove air entrapped.
5. Fill in size 12 oblong, white opaque soft gelatin capsules using a capsule-filling machine.
6. Dry the capsule shells to moisture of 3% to 6% water and a shell hardness of 7 to 10 N, and pack in a suitable container.

AMPRENAVIR CAPSULES

The capsules are available for oral administration in strengths of 50 and 150 mg. Each 50 mg capsule contains the inactive ingredients D-alpha-tocopheryl polyethylene glycol 1000 succinate (TPGS), polyethylene glycol 400 (PEG 400) 246.7 mg, and propylene glycol 19 mg. Each 150 mg capsule contains the inactive ingredients TPGS, PEG 400 740 mg, and propylene glycol 57 mg. The capsule shell contains the inactive ingredients D-sorbitol and sorbitans solution, gelatin, glycerin, and titanium dioxide. The soft gelatin capsules are printed with edible red ink. Each 150 mg capsule contains 109 U vitamin E in the form of TPGS. The total amount of vitamin E in the recommended daily adult dose is 1744 U.

AMPRENAVIR ORAL SOLUTION

One milliliter of Agenerase oral solution contains 15 mg of amprenavir in solution and the inactive ingredients acesulfame potassium, artificial grape bubble-gum flavor, citric acid (anhydrous), D-alpha-tocopheryl polyethylene glycol 1000 succinate (TPGS), menthol, natural peppermint flavor, polyethylene glycol 400 (PEG 400) (170 mg), propylene glycol (550 mg), saccharin sodium, sodium chloride, and sodium citrate (dihydrate). Solutions of sodium hydroxide and/or diluted hydrochloric acid may have been added to adjust pH. Each milliliter of Agenerase oral solution contains 46 U vitamin E in the form of TPGS. Propylene glycol is in the formulation to achieve adequate solubility of amprenavir.

ANISE OIL SOLUTION

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
10.00	1	Anise oil	10.00
17.00	2	Cremophor RH 40	17.00
340.00	3	Ethanol	340.00
QS	4	Preservatives	QS
633.00	5	Water	633.00

Manufacturing Directions

1. Mix the anise oil with Cremophor RH 40, and heat to approximately 65°C.
2. Stir vigorously, and slowly add the hot solution of items 3 to 5 to produce a clear or slightly opalescent, colorless liquid.

ANTIPYRINE AND BENZOCAINE ELIXIR

Each milliliter contains antipyrine 54 mg, benzocaine 14 mg, and glycerin anhydrous QS to volume (also contains oxyquinoline sulfate).

ANTISEPTIC WET WIPES

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
3.75	1	Cetrimonium bromide	3.75
0.15	2	Chlorhexidine gluconate	0.15
10.0–20.0	3	Polysorbate 20	10.0–20.0
10.0–20.0	4	Glycerin	10.0–20.0
QS	5	Deionized water	QS to 1 L

Manufacturing Directions

1. Preblend Polysorbate 20 and optionally a perfume.
2. Combine remaining components with stirring, add perfume/Polysorbate 20, and blend.
3. Stir until clear.
4. Package in wipes.

APRACLONIDINE HYDROCHLORIDE OPHTHALMIC SOLUTION

Each milliliter of Iopidine® 0.5% ophthalmic solution contains apraclonidine hydrochloride 5.75 mg equivalent to apraclonidine base 5 mg, benzalkonium chloride 0.01%, sodium chloride, sodium acetate, sodium hydroxide or hydrochloric acid (pH 4.4–7.8), and purified water.

ASCORBIC ACID SOLUTION

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
100.00	1	Ascorbic acid	100.00
QS	2	Propylene glycol	QS to 1 L

Manufacturing Directions

Keep under CO2 protection at all times. Avoid contact with iron. Use stainless steel or glass-lined equipment only. Propylene glycol must be water white.

1. Load 86.8 g propylene glycol into a glass-lined or suitable stainless steel-jacketed tank. While mixing, heat to 70°C to 80°C. Bubble CO2 gas into the propylene glycol from the bottom of the tank.
2. Add and dissolve the ascorbic acid into the propylene glycol with a minimum of stirring under CO2 protection.
3. When the ascorbic acid is in solution, immediately cool to approximately 25°C while continuing to mix. Also, while cooling, change CO2 addition from tank bottom to tank top.
4. QS to 1 L using propylene glycol, and mix for at least 10 minutes.
5. Use a prefilter pad and a lint-free filter paper, E&D No. 950 or its equivalent; alternatively, a Sparkler filter (or equivalent) may be used.
6. Recirculate the product through the filter press until sparkling clear.
7. Flush a suitable storage tank with CO2 gas, and continue CO2 gas protection while product is being collected.
8. Filter the product into the storage tank, and hold under CO2 protection.
9. Flush headspace of storage tank with CO2 gas protection.

ATOVAQUONE SUSPENSION

Mepron suspension is a formulation of microfine particles of atovaquone. The atovaquone particles, reduced in size to facilitate absorption, are significantly smaller than those in the previously marketed tablet formulation. Mepron suspension is for oral administration and is bright yellow with a citrus flavor. Each teaspoonful (5 mL) contains 750 mg of atovaquone and the inactive ingredients benzyl alcohol, flavor, poloxamer 188, purified water, saccharin sodium, and xanthan gum.

ATOVAQUONE SUSPENSION

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
150.00	1	Atovaquone microfluidizeda	150.00
5.00	2	Poloxamer 188	5.00
10.00	3	Benzyl alcohol	10.00
QS	4	Water purified	QS to 1 L

[a] Preparation of microfluidized particles of atovaquone: 600 mL of a mixture consisting of 2.5% w/v atovaquone in 0.25% w/v aqueous Celacol M2500 and passed through fluidizer such as model 120B Microfluidizer connected to a 90 psi pneumatic supply and adjusted to produce a fluid pressure of 15,000 psi. Recirculate continuously through the interaction chamber for at least 45 minutes (65–77 passes) to achieve particle size lower than 3 microns.

Manufacturing Directions

1. Place items 4 and 3 in a suitable stainless steel vessel, and mix well.
2. Add and mix item 2 with gentle mixing.
3. Add gradually item 1 and mix; pass through homogenizer.

AZELASTINE HYDROCHLORIDE NASAL SPRAY

Astelin nasal spray contains 0.1% azelastine hydrochloride in an aqueous solution at pH 6.8 ± 0.3. It also contains benzalkonium chloride (125 μg/mL), edetate disodium (EDTA),

hydroxypropyl methylcellulose, citric acid, dibasic sodium phosphate, sodium chloride, and purified water.

AZELASTINE HYDROCHLORIDE NASAL SPRAY

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
1.00	1	Azelastine hydrochloride	1.00
0.50	2	Edetic acid disodium dehydrate	0.50
6.80	3	Sodium chloride	6.80
0.125	4	Benzalkonium chloride	0.125
0.44	5	Citric acid	0.44
6.48	6	Sodium monohydrogen phosphate·12H2O	6.48
1.00	7	Hydroxypropyl methylcellulose–Methocel E4M	1.00
QS	8	Water purified	QS to 1 L

Manufacturing Directions

1. Place 90% of item 8 in a suitable stainless steel vessel.
2. Dissolve, in the following order, azelastine hydrochloride, edetic acid, sodium chloride, benzalkonium chloride, citric acid, and sodium monohydrogen phosphate, and mix well.
3. Bring to volume with item 8.
4. Pass the solution through a membrane filter of pore size 0.22 microns.
5. The filtrate has a pH value of 6.8 ± 0.3.
6. Fill in plastic bottles that are closed with a conventional spray insert or into plastic or glass bottles that are closed with a conventional pump sprayer. In the latter case, pumps with nasal spray inserts are, for example, used that spray approximately 0.14 mL of solution per actuation. In this manner, 0.14 mg of azelastine hydrochloride is sprayed into the nose per actuation in the form of the solution.

AZITHROMYCIN SUSPENSION

Bill of Materials

Scale (mg/5 mL)	Item	Material Name	Qty/L (g)
200.0000	1	Azithromycin; use azithromycin dehydrate	69.30
4.4100	2	Sucrose	883.00
0.0650	3	Sodium phosphate 12 hydrate	13.00

0.0200	5	Sodium cyclamate	4.00
0.0200	6	Sodium saccharin	2.00
0.0250	7	Glycamil	5.00
0.5000	8	Starch pregelatinized	100.00
0.0200	9	Flavor	4.00
0.0550	10	Flavor	11.00
0.0400	11	Flavor	8.00
0.7500	12	Sorbitol 70%	150.00
0.7500	13	Propylene glycol	140.00
0.0075	14	Methyl paraben	1.50
0.0015	15	Propyl paraben	0.30
QS	16	Water purified	QS to 1 L

Manufacturing Directions

1. Place in a suitable stainless steel double-cone blender sucrose, sodium phosphate, xanthan gum, sodium cyclamate, sodium saccharin, glycamil, and starch pregelatinized.
2. Mix for 15 minutes.
3. Mill the mixture in step 2 using a hammer mill (hammer forward) equipped with a 2-mm screen at high speed.
4. Place into a double-cone mixer the mixture from step 3 and add azithromycin and flavors.
5. Mix for 15 minutes.
6. Fill 11.01 g per bottle. The bottle must be reconstituted with 10 mL of the diluent (see step below) to obtain 16.5 mL of suspension with concentration of 200 mg/5 mL.
7. Prepare the diluent by first dissolving items 14 and 15 in item 13 at 69°C to 70°C, then mix with items 12 and 16.

AZITHROMYCIN SUSPENSION

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
50.00	1	Azithromycin dihydrate	50.00
50.00	2	Sodium citrate	50.00
20.00	3	Citric acid	20.00
600.00	4	Sucrose	600.00
90.00	5	Kollidon® CL-M	90.00
5.00	6	Cremophor RH 40	5.00
2.00	7	Chocolate flavor	2.00
100.00	8	Water purified	100.00
QS	9	Water purified	QS to 1 L

Manufacturing Directions

1. Charge items 1 to 5 in a suitable mixing vessel, and mix.
2. In a separate vessel, add and mix items 6 to 8, and add to step 1. Mix.
3. Bring to volume. Homogenize and fill.

AZULENE SOLUTION

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
10.00	1	Azulene	10.00
30.00	2	Cremophor RF 40	30.00
QS	3	Water purified	QS to 1 L

Manufacturing Directions

1. Charge items 1 and 2 in a suitable mixing vessel, and heat to 60°C.
2. In a separate vessel, heat item 3 to 60°C, and then add to step 1. Mix well for a clear solution.

AZULENE SOLUTION (1%)

Manufacturing Directions

1. Mix 1 g azulene and 3 g Cremophor RH 40, and heat to approximately 60°C.
2. Slowly add the water (60°C) to 100 mL, and cool to room temperature.

BARIUM SULFATE ORAL SUSPENSION

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
230.00	1	Barium sulfate	230.00
11.50	2	Kollidon® 90F	11.50
0.92	3	Carboxymethylcellulose sodium	0.92
0.70	4	Sodium bisulfite	0.70
QS	5	Preservatives	QS
QS	6	Water purified	QS to 1 L

Manufacturing Directions

1. Charge 90% of item 6 in a suitable jacketed vessel.
2. Add and mix preservatives and item 3. Mix well. Allow to hydrate.
3. Add item 2, and mix well until clear solution is obtained.
4. Add item 1, and mix to a smooth suspension. Homogenize if necessary.

BECLOMETHASONE DIPROPIONATE INHALATION AEROSOL

It is a pressurized, metered-dose aerosol intended for oral inhalation only. Each unit contains a solution of beclomethasone dipropionate in propellant HFA-134a (1,1,1,2-tetrafluoroethane) and ethanol. The 40 µg strength delivers 40 µg of beclomethasone dipropionate from the actuator and 50 µg from the valve. The 80 µg strength delivers 80 µg of beclomethasone dipropionate from the actuator and 100 µg from the valve. It is a metered-dose manual-pump spray unit containing a suspension of beclomethasone dipropionate monohydrate equivalent to 0.084% w/w beclomethasone dipropionate in an aqueous medium containing microcrystalline cellulose, carboxymethylcellulose sodium, dextrose, benzalkonium chloride, polysorbate 80, and phenylethyl alcohol. The suspension is formulated at a target pH of 6.4 with a range of 5.5 to 6.8 over its shelf life.

BECLOMETHASONE DIPROPIONATE INHALATION AEROSOL

Bill of Materials

Scale (µg/mg)	Item	Material Name	Qty/kg (g)
1.60	1	Beclomethasone dipropionate	1.60
35.20	2	Ethanol	35.20
0.16	3	Oleic acid	0.16
960.00	4	HFA 227	960.00

Manufacturing Directions

1. Load beclomethasone dipropionate into a pressure addition vessel and dissolve with stirring in ethanol in which oleic acid has been previously dissolved.
2. After sealing and evacuation of step 1, add item 4, which has previously been aerated with carbon dioxide and adjusted to a pressure of 6.5 bar (20°C) in another pressure vessel with stirring. The solution obtained is dispensed into aluminum containers sealed with metered valves by means of the pressure-filling technique (e.g., units from Pamasol W. Maeder, Pfaffikon, Switzerland).

BECLOMETHASONE DIPROPIONATE AND SALBUTAMOL SULFATE NASAL SPRAY

Manufacturing Directions

1. Dissolve 15.6 g beclomethasone dipropionate in 811 g ethanol, which contains 3 g oleic acid.
2. Mix the clear solution with 7.3 kg HFA 227.
3. Add the mixture obtained to 9.4 g of initially introduced salbutamol sulfate and adequately homogenized.
4. After conclusion of the homogenization, dilute the mixture with 2 kg HFA 227 that has been aerated with carbon dioxide and adjusted to a pressure of 5 bar (20°C), diluted, and finally homogenized.
5. Dispense the finished preparation into aluminum containers sealed with metering valves by means of the pressure-filling technique.

BENZETHONIUM CHLORIDE SOLUTION

Benzethonium chloride 1%, water, amphoteric 2, aloe vera gel, DMDM hydantoin, and citric acid.

BENZETHONIUM CHLORIDE AND BENZOCAINE TOPICAL ANESTHETIC

Benzethonium chloride 0.2%, benzocaine 20%; inactive ingredients: acetulan, aloe vera oil, menthol, methyl paraben, *N*-butane/P152a (65:35), PEG 400, monolaurate, and polysorbate 85.

BENZOCAINE AND TETRACAINE TOPICAL SOLUTION

Bill of Materials

Scale (g/100 mL)	Item	Material Name	Qty/L (g)
14.00	1	Benzocaine	140.00
2.00	2	Butyl aminobenzoate	20.00
2.00	3	Tetracaine hydrochloride	20.00
0.50	4	Benzalkonium chloride	5.00
0.005	5	Cetyl dimethyl ethyl ammonium bromide	0.05
QS	6	Water purified	QS to 1 L

BENZYL BENZOATE SOLUTION

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
100.00	1	Benzyl benzoate	100.00
220.00	2	Cremophor RH 40	220.00
410.00	3	Ethanol (96%)	410.00
270.00	4	Water	270.00

Manufacturing Directions

1. Heat the mixture of benzyl benzoate and Cremophor RH 40 to approximately 60°C.
2. Stir strongly, and slowly add the water.
3. Finally, add the ethanol to produce a clear, colorless liquid.

BETA-ESTRADIOL VAGINAL SOLUTION

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
QS	1	Vehicle (Pluronic P105 45%, propylene glycol 48%, water 7%)	QS to 1 L
0.10	2	Beta-estradiol	0.10
QS	3	Perfumes	QS

Manufacturing Directions

1. Add the beta-estradiol and propylene glycol into a clean vessel.
2. Subsequently, add the poloxamer and water to the vessel.
3. Mix until uniform.

BETAMETHASONE SYRUP

Celestone syrup contains 0.6 mg betamethasone in each 5 mL. The inactive ingredients for celestone syrup include alcohol; cellulose, powdered; citric acid, anhydrous; FD&C Red No. 40; FD&C Yellow No. 6; flavor cherry artificial 13506457 IFF; flavor orange natural terpeneless 73502530 IFF; propylene glycol; sodium benzoate; sodium chloride; sorbitol solution; sugar, granulated; and water, purified.

BISMUTH CARBONATE SUSPENSION

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
266.66 mg	1	Light kaolin	266.66
8.30 mg	2	Pectin	8.30
6.70 mg	3	Bismuth carbonate	6.70
9.40 mg	4	Cellulose (microcrystalline; AvicelTM RC-591)	9.40
1.40 mg	5	Methylparaben	1.40
0.20 mg	6	Saccharin sodium	0.20
0.40 mg	7	Aspartame	0.40
40.00 mL	8	Sorbitol	40.00 mL
5.00 mL	9	Ethanol	5.00 mL
QS	10	Deionized water	QS to 1 L

Manufacturing Directions

1. Dissolve item 2 in hot water.
2. Disperse item 1 in 75 mL of item 10 at room temperature.
3. With constant agitation, add item 3, and continue stirring.
4. Mix, and cool to room temperature.
5. Disperse item 4 in item 10, and add it to the batch.
6. Dissolve item 2 in item 1 dispersion, and add to the batch.
7. Dissolve items 6 and 7 in water, and add to the batch.
8. Add flavor, color, and water to volume.
9. Pass through homogenizer or colloid mill if necessary.

BISMUTH SUBSALICYLATE SUSPENSION

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
15.00	1	Magnesium aluminum silicate (Magnabrite K)	15.00
1.50	2	Methylcellulose	1.50
910.00	3	Deionized water	910.00
0.50	4	Saccharin sodium	0.50
30.00	5	Bismuth subsalicylate	30.00
4.00	6	Salicylic acid	4.00
10.00	7	Sodium salicylate	10.00
29.00	8	Ethanol	29.00
QS	9	Preservatives	QS
QS	10	Colorings	QS

Manufacturing Directions

1. Dry blend items 1 and 2, and slowly add them to item 3, agitating until smooth.
2. Add items 4 to 7 to this dispersion, gradually mixing well each time.
3. Finally, add items 8 to 10 to smooth mix.

BROMAZEPAM DROPS

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
2.50	1	Bromazepam	2.50
5.00	2	Saccharin sodium	5.00
0.10	3	Sequestrene disodium	0.10
5.00	4	Flavor	5.00
25.00	5	Flavor	25.00
QS	6	Sodium hydroxide for pH adjustment	QS
50.00	7	Water purified	50.00
QS	8	Propylene glycol	QS to 1 L

Manufacturing Directions

1. Place item 8 in a suitable stainless steel mixing vessel, and while stirring, add item 3 and dissolve.
2. Add item 7, and stir continuously. Add item 2 and then item 1, and stir to dissolve.
3. Add flavors and mix.
4. Check and adjust pH to 5, if necessary, using item 5.
5. Make up volume with item 8.

BROMHEXINE HYDROCHLORIDE SYRUP

Bill of Materials

Scale (mg/5 mL)	Item	Material Name	Qty/L (g)
4.00	1	Bromhexine HCl	0.80
1000.00	2	Glycerin (glycerol)	200.00
10.00	3	Benzoic acid	2.00
1.70	4	All fruits flavor	0.34
5.00	5	Tartaric acid	1.00
151.58	6	Alcohol (ethanol, 95%)	30.31
2857.00	7	Sorbitol (70% solution)	571.40
10.00	8	Sodium carboxymethyl cellulose (sodium CMC)	2.00
0.72	9	Sodium hydroxide pellets	0.14
QS	10	Purified water	QS to 1 L

Manufacturing Directions

1. Add 250 g of item 10 to the manufacturing vessel, and heat to 65°C to 70°C.
2. Add 20 g of item 2 in a separate stainless steel container, and mix item 8 using an Ekato stirrer, carefully avoiding lump formation.
3. Transfer the slurry to the manufacturing vessel, and continue mixing to make a clear mucilage. Avoid air entrapment.
4. Cool to 30°C while mixing at slow speed. Transfer the mucilage to container.
5. Load 100 g of item 2 to the manufacturing vessel.
6. Add item 6 in a separate stainless steel container, and dissolve item 3 using stirrer.
7. Add 60 g of item 2 to the container while mixing at slow speed.
8. Add and dissolve item 1 to the container while mixing at slow speed. Avoid splashing of the solution. Ensure bromhexine is dissolved completely.
9. Add item 4 to the container, and mix well.
10. Transfer the solution to the manufacturing vessel while mixing at high speed.
11. Rinse the container with 20 g of item 2, and transfer the rinsing to the manufacturing vessel while mixing.
12. Rinse the container with 20 g of item 10, and transfer the rinsing to the manufacturing vessel while mixing.
13. Add 15 g of item 10 in a separate stainless steel container.
14. Dissolve item 5 using a stirrer, and transfer it to the manufacturing vessel while mixing. Check for clarity of the solution in the manufacturing vessel. The solution must be clear without any undissolved particles of the drug.
15. Add item 7 to the manufacturing vessel while mixing at high speed.
16. Transfer the cooled mucilage of item 8 to the manufacturing vessel used in step 15 while mixing at slow speed.
17. Check and record the pH of the solution (limit: 3.3–3.6).
18. Dissolve item 9 in 5 g of cooled item 10 (30°C) in a separate stainless steel container.
19. Adjust the pH of the syrup in the manufacturing vessel using the sodium hydroxide solution.
20. Add sodium hydroxide solution, small portions at a time. Mix well, and check the pH after every addition. Adjust the pH to 3.5 (limit: 3.3–3.6).
21. Bring the volume up to 1 L with item 10, and finally, mix for 15 to 20 minutes at high speed.
22. Check and record the pH (limit: 3.3–3.6).
23. Filter the syrup at 1.5 bar.
24. Recirculate.

BROMHEXINE HYDROCHLORIDE SYRUP—ALCOHOL FREE

Bill of Materials

Scale (mg/5 mL)	Item	Material Name	Qty/L (g)
4.00	1	Bromhexine HCl	0.80
1000.00	2	Glycerin (glycerol)	200.00
12.00	3	Sodium benzoate	2.40
1.70	4	All fruit flavor	0.34
17.00	5	Tartaric acid	3.40
2250.00	6	Sorbitol (70% solution)	450.00
10.00	7	Sodium carboxymethyl cellulose (sodium CMC)	2.00
QS	8	Purified water	QS to 1 L

Manufacturing Directions

1. Add 240 g of item 8 (25°C) to the manufacturing vessel.
2. Add item 5, and mix for 20 minutes at high speed.
3. Load 180 g of item 2 into the manufacturing vessel, and mix for 3 minutes.
4. Add item 1 to the manufacturing vessel, and mix for 30 minutes at high speed.
5. Add 20 g of item 2 in a suitable vessel, and levigate item 7 using stirrer, carefully avoiding lump formation.
6. Add 40 g of item 8 (70°C) to the stainless steel container while mixing to make a clear mucilage; mix for 15 minutes. Avoid air entrapment.
7. Cool down to 25°C to 30°C while mixing at slow speed.

8. Transfer the mucilage to the manufacturing vessel.
9. Rinse the vessel with 10 g of item 8, and transfer to the manufacturing vessel.
10. Mix at slow speed for 20 minutes.
11. Transfer item 6 to the manufacturing vessel while mixing. Mix at low speed for 5 minutes.
12. Add 20 g of item 8 (25°C) in a separate stainless steel container, and dissolve item 3 using an Ekato stirrer until a clear solution is obtained.
13. Transfer this solution to the manufacturing vessel, and mix at low speed for 3 minutes.
14. Add item 4 to the manufacturing vessel, and mix at low speed for 3 minutes.
15. Record the pH of the solution (limit: 3.3–3.7). Adjust the pH of the solution with 10% solution of sodium hydroxide, if required.
16. Make the volume up to 1 L with item 8 (25°C), and finally, mix for 15 to 20 minutes at high speed.
17. Filter the syrup at 1.5 bar.
18. Recirculate.

BROMHEXINE HYDROCHLORIDE SYRUP

Bill of Materials

Scale (mg/5 mL)	Item	Material Name	Qty/L (g)
4.00	1	Bromhexine HCl	0.80
1000.00	2	Glycerin (glycerol)	200.00
10.00	3	Benzoic acid	2.00
1.00	4	All fruits flavor	0.34
50.00	5	Tartaric acid	1.00
151.50	6	Alcohol (ethanol 95%)	30.31
2857..00	7	Sorbitol (70% solution)	571.40
10.00	8	Carboxymethylcellulose sodium (sodium CMC)	2.00
0.70	9	Sodium hydroxide pellets	0.14
QS	10	Water purified	QS to 1 L

Manufacturing Directions

1. Add 250 g of item 10 to a suitable stainless steel manufacturing vessel, and heat to 65°C to 70°C.
2. Add 20 g of item 2 in a separate stainless steel container, and mix item 8 using Ekato stirrer, carefully avoiding lump formation.
3. Transfer the slurry to the manufacturing vessel while continuing to mix to make a clear mucilage. Avoid air entrapment.
4. Cool down to 30°C while mixing at slow speed.
5. Transfer the mucilage to container. Load 100 g of item 2 to the manufacturing vessel.
6. Add item 6 in a separate stainless steel container, and dissolve item 3 using stirrer.
7. Add 60 g of item 2 to the container while mixing at slow speed.
8. Add and dissolve item 1 to the container while mixing at slow speed. Avoid splashing of the solution. Check that bromhexine is dissolved completely.
9. Add item 4 to the container, and mix well. Transfer the solution to the manufacturing vessel while mixing at high speed.
10. Rinse the container with 20 g of item 2, and transfer the rinsings to the manufacturing vessel while mixing.
11. Rinse the container with 20 g of item 10, and transfer the rinsings to the manufacturing vessel while mixing. Add 15 g of item 10 in a separate stainless steel container, dissolve item 5 using stirrer, and transfer to the manufacturing vessel while mixing.
12. Check clarity of the solution in manufacturing vessel. The solution must be clear without any undissolved particles of the drug.
13. Add item 7 to the manufacturing vessel while mixing at high speed.
14. Transfer the cooled mucilage of item 8 to the manufacturing vessel used in step 13 while mixing at slow speed.
15. Check and record the pH of the solution (limit: 3.3–3.6).
16. Dissolve item 9 in 5 g of cooled item 10 (30°C) in a separate stainless steel container.
17. Adjust the pH of the syrup in manufacturing vessel using the sodium hydroxide solution. Add sodium hydroxide solution in small portions at a time. Mix well, and check the pH after every addition. Adjust the pH to 3.5 (limit: 3.3–3.6).
18. Make up the volume to 1 L with item 10, and finally, mix for 15 to 20 minutes at high speed. Check and record the pH (limit: 3.3–3.6). Filter the syrup at 1.5 bar. Recirculate.

BUDESONIDE INHALER

Bill of Materials

Scale (mg/g)	Item	Material Name	Qty/kg (g)
20.00	1	Budesonide	20.00
1190.00	2	Oleic acid	1190.00
1372.00	3	Trichloromonofluoromethane (propellant 11)	1372.00
2745.00	4	Dichlorodifluoromethane (propellant 12)	2745.00
1373.00	5	Dichlorotetrafluoroethane (propellant 114)	1373.00

Manufacturing Directions

1. Mix oleic acid in trichloromonofluoromethane in a suitable mixer.
2. Suspend budesonide in step 1 while mixing. Homogenize for 10 minutes.

3. On quality control release, fill the suspension 2.582 g in aluminum containers.
4. Crimp the valve, and pressurize with the mixture of dichlorodifluoromethane and dichlorotetrafluoromethane, 4.118 g per container.

BUTAMIRATE CITRATE SYRUP

Bill of Materials

Scale (mg/5 mL)	Item	Material Name	Qty/5 L (g)
4.00	1	Butamirate citrate	4.00
12.50	2	Citric acid monohydrate	12.50
1750.00	3	Sorbitol	1750.00
1250.00	4	Glycerin	1250.00
6.25	5	Saccharin sodium	6.25
5.00	6	Sodium benzoate	5.00
10.00	7	Lemon flavor	10.00
QS	8	Sodium hydroxide	2.50
QS	9	Water purified	QS to 5 L

Manufacturing Directions

1. Dissolve items 2 to 4 in item 9 (90%).
2. Add and dissolve item 1.
3. Add items 5 to 7.
4. Add item 8.
5. Bring to volume.

CAFFEINE CITRATE ORAL SOLUTION

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
10.00	1	Caffeine; use caffeine citrate	20.00
5.00	2	Citric acid monohydrate	5.00
8.30	3	Sodium citrate monohydrate	8.30
QS	4	Water purified	QS to 1 L

Manufacturing Directions

1. Dissolve item 1 in a solution of items 2 and 3 in item 4.
2. Adjust pH to 4.7.

CALCIPOTRIENE SOLUTION

Dovonex® (calcipotriene solution) scalp solution 0.005% is a colorless topical solution containing 0.005% calcipotriene in a vehicle of isopropanol (51% v/v), propylene glycol, hydroxypropyl cellulose, sodium citrate menthol, and water.

CALCITONIN NASAL SPRAY

Calcitonin-salmon, 2200 U/mL (corresponding to 200 U/0.09 mL actuation), sodium chloride, benzalkonium chloride, nitrogen, hydrochloric acid (added as necessary to adjust pH), and purified water.

CALCITONIN NASAL SPRAY

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
0.1375	1	Salmon calcitonin, 10% excess	0.152
7.500	2	Sodium chloride	7.500
0.100	3	Benzalkonium chloride	0.100
QS	4	Hydrochloric acid (1 N) to adjust pH	QS
QS	5	Water purified	QS to 1 L

Manufacturing Directions

1. Charge items 1 (90%), 2, and 3 in a suitable stainless steel mixing vessel under protection of nitrogen gas, and mix well.
2. Measure and adjust pH to 3.7 using item 4.
3. Filter through 0.20 micron filter.
4. Add balance of item 1 in item 5 to step 3. Mix.
5. Fill into a spray nasal dispenser with a solution volume of 2 mL. The composition comprises approximately 550 MRC units active ingredient per milliliter, and the applicator delivers a quantity comprising 55 units per actuation.

CALCIUM CARBONATE AND GUAR GUM SUSPENSION

Bill of Materials

Scale (mg/5 mL)	Item	Material Name	Qty/L (g)
400.000	1	Calcium carbonate	80.000
3935.000	2	Water purified	787.000
1000.000	3	Sorbitol solution (70%)	200.000
13.000	4	Xanthan gum	2.600
5.000	5	Hydroxyethyl cellulose	1.000
120.000	6	Magnesium hydroxide	24.000
25.000	7	Flavor strawberrya	5.000
1.425	8	Saccharin sodium	0.285
100.000	9	Guar gum	20.000

[a] Powder flavor is used; can change according to requirement.

Manufacturing Directions

This is a preservative-free formula; shelf-life stability is achieved by maintaining the pH of the suspension above 9 through the addition of magnesium hydroxide. The absence of preservatives makes it a more palatable formula but requires extra care in the manufacturing process. Rigidly control the microbial specification of all ingredients. Thoroughly clean all equipment, and rinse with 1% sodium hypochlorite solution before use. Finally, rinse with purified water.

1. In a clean vessel, heat item 2 to 90°C, and maintain for 20 minutes. Cool to room temperature.
2. In approximately 90% of the quantity of item 2, add item 3 to step 1, and mix well. Set aside the balance of quantity of item 2 for bringing to volume the suspension in step 8.
3. Add by sprinkling items 3, 4, and 9, gradually mixing aggressively to ensure fine dispersion; the powders may be passed through an appropriate sieve to break any lumps.
4. Mix for 30 minutes.
5. Add and mix item 1 for 15 minutes after passing through a fine mesh to break any lumps.
6. Add item 6 after passing through 100 mesh screen, and mix for 15 minutes.
7. Add flavor and sweetener, and stir for another 15 minutes. Bring to volume (if necessary), and mix for 10 minutes.
8. Check the pH of suspension to 9 and above. Add small quantity of magnesium hydroxide if needed to bring pH to above 9.
9. Heat the suspension in a covered container for 30 minutes at 68°C (maintain 68°C for 30 minutes); this is a pasteurizing step to reduce microbial load.
10. Fill in clean bottles tested for microbial contamination.

CALCIUM IODIDE AND ASCORBIC ACID SYRUP

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
311.60	1	Glucose liquid (corn syrup)	311.60
53.90	2	Glycerin (96%)	53.90
30.00	3	Anhydrous calcium iodide; use calcium iodide solution 27% w/w	111.11
1.00	4	Ascorbic acid (white powder)	1.00
485.30	5	Sucrose (granulated sugar)	485.30
0.80	6	Saccharin sodium (powder)a	0.80
8.00	7	Sodium cyclamate (XIII powder)	8.00
1.31	8	Honey artificial flavor, AU-73	1.31
0.33	9	Floral mint artificial flavor	0.33
51.53	10	Alcohol (ethanol; 190 proof)	51.53
0.60	11	Isoproterenol sulfate (powder)	0.60
0.05	12	FD&C Yellow dye No. 5	
0.25	13	Caramel (acid proof)	0.25
QS	14	Water purified	~344.0 mL

[a] Use 1.2 g of saccharin to replace cyclamate; adjust balance with sucrose.

Manufacturing Directions

Isoproterenol is toxic; wear a dust mask, and avoid contact. The product is sensitive to oxidation. Manufacture under N2 protection, and protect product from light and heat; all water must be boiled, cooled, and gassed with nitrogen.

1. Load glucose and glycerin into a suitable mixing tank.
2. Add 187 mL purified water to tank with mixing.
3. Begin bubbling N2 protection for the balance of the process.
4. Add and dissolve saccharin sodium and sodium cyclamate, if used, with mixing.
5. Add calcium iodide to the tank with good mixing.
6. Add and dissolve ascorbic acid and sugar.
7. Dissolve the flavors in alcohol, and add with mixing to the main batch.
8. Dissolve isoproterenol in 10 to 13 mL of water, and add with mixing to the main batch.
9. Dissolve dye in 3.5 mL purified water, and add solution to tank with mixing. (*Note*: Dye may be deleted.) Add caramel with mixing to main batch.
10. Move N2 source from the bottom to the top of the tank.
11. Turn off mixer.
12. Allow to stand overnight under N2 protection to let entrapped gases escape.
13. QS to 1 L. Mix for 1 hour.
14. Filter and circulate product through a suitable filter press until sparkling clear.

CARBAMAZEPINE ORAL SUSPENSION 2%

Formulation

Carbamazepine (Flavine), 2 g; 1,2-propylene glycol, 20 g; Kollidon® 90F, 3 g; saccharin sodium, 0.1 g; sodium citrate, 1 g; sorbitol, crystalline, 25 g; Kollidon® CL-M, 7 g; water, 41.9 g.

Manufacturing Directions

1. Stir the mixture of carbamazepine and propylene glycol for at least 2 hours.
2. Add Kollidon® 90F, saccharin, sodium citrate, and the water, and stir again until these components are dissolved.
3. Dissolve sorbitol in this mixture, and add Kollidon® CL-M to the well-stirred suspension to obtain a homogeneous suspension.

CARBETAPENTANE TANNATE AND CHLORPHENIRAMINE SUSPENSION

Bill of Materials

Scale (mg/5 mL)	Item	Material Name	Qty/5 L (g)
30.00	1	Carbetapentane tannate	30.00
4.00	2	Chlorpheniramine tannate	4.00
50.00	3	Pectin medium viscosity	50.00
1000.00	4	Kaolin colloidal powder	1000.00
35.00	5	Magnesium aluminum silicate	35.00
10.00	6	Benzoic acid	10.00
2.50	7	Methyl paraben	2.50
1000.00	8	Sucrose	1000.00
0.75	9	Saccharin sodium	0.75
225.00	10	Glycerin	225.00
0.91	11	Flavor black currant imitation	0.91
2.28	12	Flavor strawberry with other flavors	2.28
0.45	13	Purpose shade “R” dye	0.45
0.80	14	FD&C Red No. 3 dye	0.80
0.30	15	FD&C Yellow No. 5	0.30
3.17	16	Sodium hydroxide solution 50%	3.17
	17	Purified water, deionized	QS to 5 mL

Manufacturing Directions

1. Combine items 1 to 5 and mix thoroughly.
2. Add water to make a slurry.
3. Add items 7 to 16, mix vigorously using purified water, and QS to final volume.

CARNITINE AND COENZYME Q SOLUTION

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
1.00	1	Coenzyme Q10	1.00
1.00	2	Lutrol E 400	1.00
4.00	3	Cremophor RH 40	4.00
QS	4	Preservative	QS
QS	5	Water	QS to 1 L
40.00	6	Carnitine	40.00

Manufacturing Directions

1. Heat the mixture of items 1 to 5 to 60°C, and stir well.
2. Add and dissolve item 6 after cooling to room temperature.

CEFACLOR SUSPENSION

Bill of Materials

Scale (mg/5 mL)	Item	Material Name	Qty/L (g)
250.00	1	Cefaclor	50.00
5.00	2	Emulsion silicone 30%	1.00
7.50	3	Xanthan gum	1.50
10.00	4	Starch modified	2.00
4.00	5	Erythrosine aluminum lake	0.80
20.00	6	Flavor	4.00
0.75	7	Sodium lauryl sulfate	0.15
3.00	8	Methylcellulose	0.60
2960.00	9	Sucrose	592.00

Note: For 125 mg dose, adjust the final quantity with sucrose.

CEFADROXIL MONOHYDRATE ORAL SUSPENSION

Duricef for oral suspension contains the following inactive ingredients: FD&C Yellow No. 6, flavors (natural and artificial), polysorbate 80, sodium benzoate, sucrose, and xanthan gum.

CEFPODOXIME PROXETIL ORAL SUSPENSION

Each 5 mL of Vantin oral suspension contains cefpodoxime proxetil equivalent to 50 or 100 mg of cefpodoxime activity after constitution and the following inactive ingredients: artificial flavorings, butylated hydroxyanisole, carboxymethylcellulose sodium, microcrystalline cellulose, carrageenan, citric acid, colloidal silicon dioxide, croscarmellose sodium, hydroxypropyl cellulose, lactose, maltodextrin, natural

flavorings, propylene glycol alginate, sodium citrate, sodium benzoate, starch, sucrose, and vegetable oil.

CEFPODOXIME PROXETIL ORAL SUSPENSION

Bill of Materials

Scale (mg/g)	Item	Material Name	Qty/kg (g)
100.00	1	Cefpodoxime proxetil with excess	123.50
563.75	2	Sucrose	563.75
290.00	3	D-Mannitol	290.00
1.25	4	Saccharin sodium	1.25
20.00	5	Hydroxypropyl cellulose	20.00
0.50	6	Dye Yellow No. 5	0.50
1.00	7	Ethylenediamine tetraacetate disodium	1.00
QS	8	Orange essence	QS
QS	9	Water purified	QS

Manufacturing Directions

1. Place item 1, sucrose, D-mannitol, saccharin sodium, and disodium ethylenediamine tetraacetate in an agitating granulator.
2. Granulate the mixture by agitation while spraying it with a binder of hydroxypropyl cellulose and Yellow No. 5 in water.
3. Pass wet mass through a 42 mesh screen in an extrusion granulator.
4. Dry the granules in a fluidized-bed granulator.
5. Spray the granules with orange essence.
6. Dry granules further in the fluid-bed dryer.
7. Pass granules through 30 mesh sieve, and fill.

When purified water is added to the resulting dry syrup at a concentration of item 1 of 49.4 mg/mL, the dry syrup rapidly dissolves in it to give a clear orange solution.

CEFPODOXIME PROXETIL FOR ORAL SUSPENSION

Each 5 mL of Vantin oral suspension contains cefpodoxime proxetil equivalent to 50 or 100 mg of cefpodoxime activity after constitution and the following inactive ingredients: artificial flavorings, butylated hydroxyanisole, carboxymethylcellulose sodium, microcrystalline cellulose, carrageenan, citric acid, colloidal silicon dioxide, croscarmellose sodium, hydroxypropyl cellulose, lactose, maltodextrin, natural flavorings, propylene glycol alginate, sodium citrate, sodium benzoate, starch, sucrose, and vegetable oil.

Ceftin for oral suspension, when reconstituted with water, provides the equivalent of 125 or 250 mg of cefuroxime (as cefuroxime axetil) per 5 mL of suspension. Ceftin for oral suspension contains the inactive ingredients polyvinylpyrrolidone K30, stearic acid, sucrose, and tutti-frutti flavoring.

CEFUROXIME AXETIL SUSPENSION

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
25.00	1	R-Cefuroxime axetil	25.00
0.40 mL	2	Sorbitol solution 70%	0.40 L
20.00	3	Saccharin	20.00
QS	4	Water purified	QS to 1 L

Manufacturing Directions

1. Place the sorbitol solution and 20% of item 5 in a mixing vessel.
2. Add item 1, and mix vigorously to form a suspension.
3. Add items 3 and any flavors, if needed, and mix.
4. Bring to volume.
5. Fill.

CETIRIZINE HYDROCHLORIDE SYRUP

Bill of Materials

Scale (mg/5 mL)	Item	Material Name	Qty/L (g)
5.00	1	Cetirizine hydrochloride	1.03
1750.00	2	Lycosin 80/55	350.00
600.00	3	Sorbitol 70%	120.00
5.00	4	Sodium citrate	1.00
300.00	5	Propylene glycol	60.00
4.50	6	Methyl paraben	0.90
0.50	7	Propyl paraben	0.10
3.75	8	Saccharin sodium	0.75
10.00	9	Flavor raspberry	2.00
QS	10	Water purified	QS to 1 L

Manufacturing Directions

1. Charge 30% of item 10 in a stainless steel jacketed kettle and heat to 90°C to 95°C.
2. Add and dissolve items 6 and 7; cool to 40°C.
3. Add to preceding step item 4 and item 8, and mix to dissolve.
4. Add items 2, 3, and 5, and mix to dissolve.
5. In a separate vessel, place 30% of item 10 and add to it item 1, mix to dissolve, and then add to step 4.
6. Add flavor(s), and bring to volume with item 10.

CHLOPHEDIANOL, IPECAC, EPHEDRINE, AMMONIUM CHLORIDE, CARBINOXAMINE, AND BALSAM TOLU SYRUP

Bill of Materials

Scale (mg/tablet)	Item	Material Name	Qty/L (g)
0.001 mL	1	Ipecac fluid extract	1.00 mL
5.00	2	Chlophedianol hydrochloride	5.00
1.32	3	Ephedrine hydrochloride (powder)	1.32
8.80	4	Ammonium chloride (reagent-grade granules)	8.80
0.80	5	Carbinoxamine maleate	0.80
0.90	6	Methylparaben	0.90
0.10	7	Propylparaben	0.10
6.25	8	Balsam of Tolu (eq. aqueous extract)	6.25
2.66	9	Saccharin sodium (dihydrate powder)	2.66
319.22	10	Sucrose (granulated sugar)	319.22
238.33	11	Glucose liquid (corn syrup)	238.33
83.93	12	Sorbitol solution (calculate as 70% sorbitol crystals)	83.93
40.00	13	Alcohol	40.00
166.67 mcg	14	FD&C Red dye (Amaranth E123)	166.67 mg
0.80	15	Raspberry flavor	0.80
100.00	16	Propylene glycol	100.00
QS	17	HyFlo filter aid	0.50
QS	18	Water purified	~450.00 mL

Manufacturing Directions

1. Charge balsam of Tolu and 25 mL of water in a steam bath.
2. Raise the temperature, stirring continuously to mix water with the balsam.
3. Boil for half an hour, and allow to decant while cooling.
4. Discard extracted balsam of Tolu.
5. Filter the supernatant liquid through filter paper, and store apart.
6. Charge 150 mL water in a jacketed mixing tank, and heat to boiling.
7. Add and dissolve parabens with mixing.
8. Add and dissolve sugar with constant mixing.
9. Heat to 70°C to 75°C.
10. Once sugar is dissolved, add glucose, sorbitol, and saccharin sodium. Mix well until dissolved.
11. Dissolve ammonium chloride in 28 mL water.
12. Add to mixing tank.
13. Add extract of balsam of Tolu from first step with mixing. Mix well, and cool to 25°C to 30°C.
14. Add and dissolve ephedrine and carbinoxamine in 20 mL water, and add to mixing tank. Mix well.
15. Add and dissolve chlophedianol in 50 g of propylene glycol, and add to mixing tank.
16. Add balance of propylene glycol to mixing tank.
17. Add and dissolve Ipecac fluid extract and raspberry flavor in alcohol.
18. Add to mixing tank.
19. Dissolve dye in 5 mL water, and add to tank with continuous mixing.
20. Rinse container with 5 mL of water, and add rinsings.
21. Adjust to volume with purified water.
22. Add HyFlo filter aid to syrup, and mix well.
23. Recirculate through filter press or equivalent until sparkling clear.

CHLOPHEDIANOL, IPECAC, EPHEDRINE, AMMONIUM CHLORIDE, CARBINOXAMINE, AND BALSAM TOLU SYRUP

Bill of Materials

Scale (mg/ml)	Item	Material Name	Qty/L (g)
0.001 mL	1	Ipecac fluid extract	1.000 mL
5.000	2	Chlophedianol hydrochloride	5.000
1.320	3	Ephedrine hydrochloride	1.320
8.800	4	Ammonium chloride	8.800
0.800	5	Carbinoxamine maleate	0.800
0.900	6	Methylparaben	0.900
0.100	7	Propylparaben	0.100
6.250	8	Balsam, tolu (aqueous extract)	6.250
2.660	9	Saccharin sodium powder dihydrate	2.660
319.220	10	Sucrose (sugar, granulated)	319.22
238.330	11	Glucose liquid (corn syrup)	238.33
83.933	12	Sorbitol solution 70%	83.93
40.000	13	Alcohol (ethanol)	40.000
166.670	14	Dye red	0.160
0.800	15	Flavor	0.800
100.000	16	Propylene glycol	100.000
QS	17	Filter aid HyFlo	0.500
QS	18	Water purified	~450.000 mL

Manufacturing Directions

1. Charge balsam tolu and 25 mL of water in a steam bath.
2. Raise the temperature, stirring continuously, to mix water with balsam. Boil for half an hour, and allow decanting while cooling. Discard extracted balsam tolu. Filter the supernatant liquid through filter paper, and store apart.
3. Charge 150 mL water in a jacketed mixing tank; heat to boiling.

4. Add and dissolve parabens with mixing. Add and dissolve sugar with constant mixing. Heat to 70°C to 75°C.
5. Once sugar is dissolved, add glucose, sorbitol, and saccharin sodium.
6. Mix well until dissolved.
7. Dissolve ammonium chloride in 28 mL water. Add to mixing tank.
8. Add extract balsam tolu with mixing.
9. Mix well, and cool to 25°C to 30°C. Add and dissolve ephedrine and carbinoxamine in 20 °mL water, and add to mixing tank. Mix well.
10. Add and dissolve chlophedianol in 50 g of propylene glycol, and add to mixing tank. Add balance of propylene glycol to mixing tank.
11. Add and dissolve Ipecac fluid extract and flavor raspberry in alcohol. Add to mixing tank. Dissolve dye in 5 mL water; add to tank with continuous mixing.
12. Rinse container with 5 mL of water, and add rinsings.
13. Adjust to volume with purified water.
14. Add filter aid HyFlo to syrup and mix well.
15. Recirculate through filter press or equivalent until sparkling clear.

CHLORAMPHENICOL PALMITATE ORAL OR TOPICAL EMULSION (2.5% = 250 mg/10 mL)

Formulation

I. Chloramphenicol palmitate, 2.5 g; Lutrol E 400, 4 g; Cremophor RH 40, 4 g
II. Sucrose, crystalline, 40 g; water, 40 g
III. Water, add 100 mL

Manufacturing Directions

1. Mix components I at 70°C to obtain a clear solution.
2. Cool to 40°C, and add this solution slowly to the well-stirred solution II.
3. Fill up with III to 100 mL.

CHLORAMPHENICOL PALMITATE ORAL OR TOPICAL EMULSION (5% = 500 mg/10 mL)

Formulation

I. Chloramphenicol palmitate, 5 g; Lutrol E400, 6 g; Cremophor RH 40, 4 g
II. Sucrose, crystalline, 40 g; preservative, QS; water, 45 g

Manufacturing Directions

1. Mix components I at 70°C to obtain a clear solution, and cool to approximately 40°C.
2. Add the warm solution II slowly to the well-stirred solution I.

CHLORAMPHENICOL OPHTHALMIC SOLUTION

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
30.00	1	Chloramphenicol	30.00
150.00	2	Kollidon® 25	150.00
QS	3	Preservatives	QS
QS	4	Water purified	QS to 1 L

Manufacturing Directions

1. Charge 90% of item 4 in a stainless steel jacketed vessel and heat to 90°C to 95°C.
2. Add and dissolve preservatives.
3. Add and dissolve item 2.
4. Add and stir item 1 until a clear solution is obtained.
5. Optionally add 0.2% to 0.5% cysteine as antioxidant to prevent discoloration of item 2.

CHLORAMPHENICOL PALMITATE ORAL OR TOPICAL EMULSION

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
25.00	1	Chloramphenicol palmitate	25.00
40.00	2	Lutrol E 400	40.00
40.00	3	Cremophor RH 40	40.00
400.00	4	Sucrose	400.00
400.00	5	Water purified	400.00
QS	6	Water purified	QS to 1 L

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
50.00	1	Chloramphenicol palmitate	50.00
60.00	2	Lutrol E 400	60.00
40.00	3	Cremophor RH 40	40.00
400.00	4	Sucrose	400.00
450.00	5	Water purified	450.00
QS	6	Water purified	QS to 1 L

Manufacturing Directions

1. Charge items 1 to 3 in a suitable stainless steel jacketed vessel. Heat to 70°C to obtain a clear solution.
2. Cool to 40°C.
3. In a separate vessel, add and dissolve items 4 and 5, and then add this solution to step 2.
4. Bring to volume with item 6. Mix.

CHLORHEXIDINE GEL

Bill of Materials

Scale (mg/g)	Item	Material Name	Qty/kg (g)
20.00	1	Chlorhexidine diacetate	20.00
300.00	2	1,2-Propylene glycol (pharma)	300.00
220.00	3	Lutrol F 127	220.00
460.00	4	Water	460.00

Manufacturing Directions

1. Dissolve chlorhexidine diacetate in propylene glycol at >70°C.
2. Stir well, and slowly add Lutrol F 127 and water.
3. Maintain the temperature until the air bubbles escape.
4. A clear, colorless gel is obtained.

CHLORPHENIRAMINE MALEATE SYRUP

Bill of Materials

Scale (mg/5 mL)	Item	Material Name	Qty/L (g)
2.00	1	Chlorpheniramine maleate	0.40
3000.00	2	Sucrose	600.00
4.50	3	Methylparaben	0.90
1.50	4	Propylparaben	0.30
1.00	5	Citric acid (monohydrate)	0.20
2.40	6	Sodium citrate	0.48
2.00	7	Green banana flavor	0.40
—	8	Purified water	QS to 1 L

Manufacturing Directions

1. Add 500 g of purified water to the manufacturing vessel, and heat to 95°C to 98°C.
2. Add items 3 and 4 while mixing to dissolve at high speed.
3. Mix for 5 minutes.
4. Add item 2 while mixing at slow speed.
5. Maintain a temperature of 95°C to 98°C.
6. Mix for 1 hour at high speed.
7. Cool down to 30°C while mixing at slow speed.
8. Dissolve items 5 and 6 in 20 g of cooled purified water (25°C).
9. Transfer the solution to the manufacturing vessel while mixing at high speed.
10. Mix for 2 minutes.
11. Add 8 g of cold purified water (25–30°C) in a separate container, and dissolve item 1 by using stirrer.
12. Mix for 10 minutes, and transfer to the manufacturing vessel.
13. Rinse the container with 2 g of cooled purified water (25°C), and transfer the rinsings to the manufacturing vessel while mixing at high speed.
14. Add item 7 to the manufacturing vessel while mixing.
15. Mix for 10 minutes at high speed.
16. Bring the volume up to 1 L with purified water, and finally, mix for 15 to 20 minutes at high speed.
17. Check and record the pH (limit: 5.0–5.2 at 25°C).
18. If required, adjust pH with 10% citric acid or 10% sodium citrate solution.
19. Filter the syrup at 1.5 bar.
20. Bubble the syrup with nitrogen gas.

CHLOROXYLENOL SURGICAL SCRUB

Chloroxylenol 3% and cocamidopropyl PG-dimonium chloride phosphate 3%. Inactive ingredients: water, sodium lauryl sulfate, cocamide DEA, propylene glycol, cocamidopropyl betaine, citric acid, tetrasodium EDTA, aloe vera gel, hydrolyzed animal protein, and D&C Yellow No. 10. In addition, chloroxylenol 5%, terpineol 10%, absolute alcohol 20%, soft potassium soap 8.5%, and caramel 25% and lemon oil QS in a water base.

CICLOPIROX TOPICAL SOLUTION

Each gram of Penlac nail lacquer (ciclopirox) topical solution, 8%, contains 80 mg ciclopirox in a solution base consisting of ethyl acetate, isopropyl alcohol, and butyl monoester of poly(methylvinyl ether/maleic acid) in isopropyl alcohol. Ethyl acetate and isopropyl alcohol are solvents that vaporize after application.

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
80.00	1	Ciclopirox	80.00
330.00	2	Ethyl acetate	330.00
300.00	3	Butyl monoester of poly(methylvinyl ether/maleic acid) in isopropyl alcohol (50%)	300.00
QS	4	Isopropyl alcohol	QS to 1 L

Manufacturing Directions

1. Place item 4 in a suitable stainless steel vessel in an explosion-proof room.
2. Add item 2 and item 3 in a separate vessel, mix, and add to step 1.
3. Add item 1 and mix; seal immediately.

CIMETIDINE SYRUP

Bill of Materials

Scale (mg/5 mL)	Item	Material Name	Qty/L(g)
200.00	1	Cimetidine; use cimetidine hydrochloride	45.80
0.161 mL	2	Alcohol	32.50 mL
5.000	3	Methylparaben	1.00
1.000	4	Propylparaben	0.20
20.000	5	Pluronic F68	4.00
0.500 mL	6	Propylene glycol	100.00 mL
20.000	7	Saccharin sodium	4.00
15.000	8	Sodium chloride	3.00
27.000	9	Disodium hydrogen phosphate	5.40
0.500 mL	10	Sorbitol solution 70%	100.00 mL
2.070 g	11	Sucrose	414.00
0.050	11	Yellow dye	0.01
0.0014	12	Flavor	0.28 mL
0.0014	13	Flavor	0.28 mL
2.000	14	Sweetener additional	0.40
QS	15	Water purified	QS to 1 L

Manufacturing Directions

1. Place items 3 and 4 in a stainless steel vessel, and add 70% item 15; heat to 80°C to 90°C to dissolve.
2. In a separate vessel, add and mix items 5 through 11.
3. Add step 2 to step 1.
4. Add and dissolve remaining items, and mix.
5. Fill.

CIPROFLOXACIN HYDROCHLORIDE AND HYDROCORTISONE OTIC SUSPENSION

Ciprofloxacin hydrochloride and hydrocortisone otic suspension contains the synthetic broad-spectrum antibacterial agent ciprofloxacin hydrochloride, combined with the anti-inflammatory corticosteroid hydrocortisone, in a preserved, nonsterile suspension for otic use. Each milliliter contains ciprofloxacin hydrochloride (equivalent to 2 mg ciprofloxacin), 10 mg hydrocortisone, and 9 mg benzyl alcohol as a preservative. The inactive ingredients are polyvinyl alcohol, sodium chloride, sodium acetate, glacial acetic acid, phospholipon 90HB (modified lecithin), polysorbate, and purified water. Sodium hydroxide or hydrochloric acid may be added for adjustment of pH.

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
2.00	1	Ciprofloxacin (use ciprofloxacin hydrochloride)	2.33
10.00	2	Hydrocortisone	10.00
1.00	3	Polysorbate 80	1.00
20.00	4	Polyvinyl alcohol	20.00
1.50	5	Phospholipon 90H (lecithin)	1.50
9.00	6	Benzyl alcohol	9.00
7.00	7	Acetic acid glacial	7.00
4.10	8	Sodium acetate trihydrate	4.10
9.00	9	Sodium chloride	9.00
QS	10	Hydrochloric acid 1 N for pH adjustment	QS
QS	11	Sodium hydroxide 1 N for pH adjustment	QS
QS	12	Water purified	QS to 1 L

Manufacturing Directions

1. Use well-passivated stainless steel vessels; use only sodium vapor lamps or yellow light in the manufacturing area. Avoid forming foam during transfer of liquids.
2. Place approximately 1 L of item 12 in a suitable vessel, heat to 90°C to 95°C, and then cool to 20°C to 25°C under a nitrogen environment and hold for later use for premixing, rinsing, and final volume makeup.
3. To 50% of volume of item 11, add item 4 at 90°C to 95°C.
4. Add and mix item 5 while maintaining nitrogen blanket cover. Cool to 40°C to 50°C.
5. Add and mix item 6 and cool to 20°C to 25°C.
6. In a separate vessel, mix acetic acid, sodium chloride, and sodium acetate trihydrate in approximately 10% of item 12 as prepared in step 1.
7. In a separate vessel, place item 2 and item 3 and 30% of item 12, mix, and then pass through a micronizing chamber.
8. Add to step 6, and mix well.
9. Add item 1, 20% of item 12, and portions of item 7 to a separate vessel, and then add to the main batch.
10. Bring to volume.
11. Adjust pH to 4.75 using item 10 or 11 as needed. Fill.

CISAPRIDE SUSPENSION

Bill of Materials

Scale (mg/5 mL)	Item	Material Name	Qty/L (g)
5.00	1	Cisapride; use cisapride monohydrate	1.04
9.00	2	Methylparaben	1.80
1.00	3	Propylparaben	0.20
1000.00	4	Sucrose	200.00
50.00	5	Microcrystalline cellulose (Avicel™ RC 591)	10.00
12.50	6	Methylcellulose 4000	2.50
5.00	7	Sodium chloride	1.00
2.50	8	Polysorbate 80 (Tween 80)	0.50
2.50	9	All fruit flavor	0.50
—	10	Water purified	QS to 1 L

Manufacturing Directions

Cisapride dispersion should be uniformity mixed or levigated. Avicel™ RC-591 and methylcellulose dispersion should be uniform and smooth.

1. Mix item 8 in 100 g of item 10 (35–40°C) in a stainless steel vessel, using stirrer. Add item 1 and mix to make smooth dispersion and keep aside. Check the smoothness of dispersion.
2. Add 185 g of item 10 to a suitable mixer, and heat to 90°C to 95°C. Dissolve items 2 and 3 while mixing. Add and dissolve item 4 while mixing.
3. Cool down to approximately 50°C to 55°C.
4. Filter the syrup through T-1500 filter pads (8–10) washed with purified water. Collect the syrup in clean stainless steel tank. Avoid any loss of syrup quantity.
5. Disperse item 6 in 150 g of hot item 10 (70–80°C) in mixer while mixing.
6. Mix and homogenize at temperature 70°C to 80°C, mixer speed 18 rpm, homogenizer high speed, and vacuum 0.4 to 0.6 bar for 5 minutes.
7. Cool down to 25°C to 30°C with continuous mixing. Check the smoothness of dispersion.
8. Disperse item 5 in 250 g of item 10 (25–30°C) in stainless steel vessel, using stirrer. Keep on stirring for 30 minutes to make smooth dispersion. Check the smoothness of dispersion.
9. Transfer syrup to mixer. Transfer Avicel™ mucilage to mixer.
10. Mix at high homogenizer speed and under vacuum for 5 minutes.
11. Dissolve item 7 in 10 g of item 10, and add to mixer while mixing. Add drug dispersion to mixer.
12. Rinse the drug container with 40 g of item 10, and add the rinsings to mixer.
13. Add item 9 to mixer while mixing.
14. Add item 10 up to final volume 1 L.
15. Finally, mix and homogenize for 5 minutes at mixer speed 18 rpm, homogenizer at high speed, and vacuum 0.4 to 0.6 bar.
16. Check the suspension for homogeneity. Transfer the suspension through 630 micron sieve to the stainless steel storage tank, previously sanitized.

CITALOPRAM HYDROBROMIDE ORAL SOLUTION

Celexa oral solution contains citalopram HBr equivalent to 2 mg/mL citalopram base. It also contains the following inactive ingredients: sorbitol, purified water, propylene glycol, methyl paraben, natural peppermint flavor, and propyl paraben.

CLARITHROMYCIN SUSPENSION, 125 mg/5 ml RECONSTITUTED

Bill of Materials

Item	Material Name	Qty/kg (g)
1	Clarithromycin	35.47
2	Carbopol 974P	21.28
3	Polyvinylpyrrolidone K90	4.96
4	Water purified	145 mL
5	Hydroxypropyl methylcellulose phthalate HP-55	43.17
6	Castor oil	4.56
7	Acetone, approximate	172 mL
8	Ethanol, approximate	164 mL
9	Potassium sorbate	5.96
10	Sucrose	600.80
11	Maltodextrin	67.58
12	Water purified	10 mL
13	Xanthan gum	1.08
14	Flavor dry	10.14
15	Silicon dioxide	1.42
16	Citric acid	1.20
17	Titanium dioxide	10.14
18	Maltodextrin	13.50
19	Sucrose	QS to 1 kg

Manufacturing Directions

1. This product requires coated clarithromycin granules. Add polyvinylpyrrolidone to water and mix.
2. Use water to granulate a blend of clarithromycin and Carbopol 974P.
3. Dry granules at 70°C until loss on drying is NMT 5%.
4. Collect fraction between 177 and 420 microns.
5. Regranulate smaller particles to meet this range.
6. Blend the regranulate from step 5.

7. Prepare coating solution by adding ethanol, acetone, hydroxypropyl methylcellulose phthalate, and castor oil in a mixing vessel; mix until solution is clear.
8. Coat granules in step 6 in a particle coater, and dry to loss on drying of NMT 5%.
9. Sift coated granules, and retain the fraction between 149 and 590 microns.
10. In a separate vessel, dissolve potassium sorbate in purified water.
11. Blend sucrose and the maltodextrin until a homogeneous mix is achieved.
12. Granulate the step 11 mixture with step 10.
13. Dry the granulation until loss on drying is NMT 1%.
14. Mill dried granules, and blend.
15. Mix to clarithromycin-coated granules in appropriate quantity, add silicon dioxide, and blend. Fill appropriate quantity.
16. Reconstitute 3.13 g to yield 125 mg/5 mL solution.

CLINDAMYCIN PHOSPHATE TOPICAL SOLUTION

Cleocin T topical solution and Cleocin T topical lotion contain clindamycin phosphate at a concentration equivalent to 10 mg clindamycin per milliliter. Cleocin T topical gel contains clindamycin phosphate at a concentration equivalent to 10 mg clindamycin per gram. Each Cleocin T topical solution pledget applicator contains approximately 1 mL of topical solution. Clindamycin phosphate is a water-soluble ester of the semisynthetic antibiotic produced by a 7(S)-chlorosubstitution of the 7(R)-hydroxyl group of the parent antibiotic lincomycin. The solution contains isopropyl alcohol 50% v/v, propylene glycol, and water.

CLOTRIMAZOLE TOPICAL SOLUTION

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
30.00	1	Clotrimazole	30.00
300.00	2	Cremophor RH 40	300.00
QS	3	Preservatives	QS
340.00	4	Alcohol	340.00
330.00	5	Water purified	QS to 1 L

Manufacturing Directions

1. Place items 1 and 2 in a stainless steel jacketed mixing vessel. Heat to 60°C, and mix well.
2. In a separate vessel, place items 3 to 5 at 90°C, and add to step 1.
3. Mix well, and fill.

CLOTRIMAZOLE TOPICAL SOLUTION (3%)

Formulation

I. Clotrimazole, 3 g; Cremophor RH 40, 30 g
II. Preservative, QS; ethanol 96%, 34 g; water, 33 g

Manufacturing

Dissolve clotrimazole in Cremophor RH 40 at approximately 60°C, stir strongly, and slowly add the hot solution II.

CODEINE PHOSPHATE AND ACETAMINOPHEN ELIXIR

Each 5 mL of elixir contains codeine phosphate 12 mg, acetaminophen 120 mg, alcohol 7%, citric acid, propylene glycol, sodium benzoate, saccharin sodium, sucrose, natural and artificial flavors, and FD&C Yellow No. 6.

COLISTIN SULFATE, NEOMYCIN, THONZONIUM BROMIDE, AND HYDROCORTISONE OTIC SUSPENSION

Cortisporin-TC otic suspension with neomycin and hydrocortisone (colistin sulfate–neomycin sulfate–thonzonium bromide–hydrocortisone acetate otic suspension) is a sterile aqueous suspension containing in each milliliter: colistin base activity, 3 mg (as the sulfate); neomycin base activity, 3.3 mg (as the sulfate); hydrocortisone acetate, 10 mg (1%); thonzonium bromide, 0.5 mg (0.05%); polysorbate 80, acetic acid, and sodium acetate in a buffered aqueous vehicle. Thimerosal (mercury derivative), 0.002%, is added as a preservative. The suspension is a nonviscous liquid, buffered at pH 5, for instillation into the canal of the external ear or direct application to the affected aural skin.

COTRIMOXAZOLE ORAL SUSPENSION

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
40.00	1	Trimethoprim micronized (98% particles less than 50 microns)	8.00
200.00	2	Sulfamethoxazole powder (100% particles less than 50 microns)	40.00
20.00	3	Magnesium aluminum silicate (Veegum HV)	4.00
22.50	4	Carboxymethylcellulose sodium	4.50
350.00	5	Glycerin	70.00
400.00	6	Propylene glycol	80.00
5.00	7	Polyvinylpyrrolidone (polyvinylpyrrolidone K-30)	1.00
20.00	8	Polysorbate 80	4.00
12.50	9	Colloidal silicon dioxide (Aerosil® 200)	2.50
375.00	10	Sorbitol (70% solution)	75.00
5.00	11	Saccharin sodium	1.00
3.00	12	Citric acid	0.60
2200.00	13	Sucrose	440.00
5.00	14	Methylparaben	1.00
1.50	15	Propylparaben	0.30
0.035	16	Raspberry red color	0.007
0.025	17	FD&C Red No. 40	0.005
5.00	18	Banana flavor	1.00
5.00	19	Apricot flavor	1.00
—	20	Water purified	QS to 1 L

Manufacturing Directions

1. Disperse item 4 in item 5 in a stainless steel vessel, using stirrer. Check that the dispersion is even.
2. Disperse item 3 in the dispersion of items 4 and 5 (sodium CMC-glycerol) at step 1, using stirrer. Check that the final dispersion is even.
3. Add 100 g of hot item 20 (75–85°C) to the dispersion at step 2 while stirring to make the mucilage. Mix for 30 minutes using stirrer.
4. Keep aside the mucilage, for hydration, overnight in a well-closed container.
5. Add item 6 in a stainless steel container, and mix items 2 and 1 while mixing, using stirrer to make homogeneous slurry.
6. Add 100 g of cold item 20 (25–30°C) in a stainless steel container, and dissolve item 7 to make a clear solution. Add item 8 while mixing to make a clear solution; then add item 9 while mixing at slow speed.
7. Transfer the mix from step 6 to the slurry of sulfa-trimethoprim step 3 while mixing.
8. Mix for 30 minutes.
9. Add item 10 to the slurry. Mix for 10 minutes.
10. Add 250 g of item 20 in mixer, and heat to 90°C to 95°C.
11. Add items 14 and 15 while mixing to dissolve; homogenize at high speed for 2 minutes.
12. Add item 13 to the parabens solution at step 11. Mix well to dissolve completely.
13. Cool down to 30°C.
14. Filter the syrup through T-1500 filters using filter press. (Wash the filters with cooled item 20 approximately 100 mL before use.) Collect the filtered syrup in stainless steel containers.
15. Wash the mixer with item 20.
16. Load items 4 and 3 (CMC-Veegum) mucilage from step 2 to the mixer. Homogenize while mixing for 2 minutes at high speed under vacuum 0.4 to 0.6 bar, mixer speed 20 rpm, and temperature 25°C. Check the suspension for uniformity.
17. Load the sulfa-trimethoprim slurry from step 5 to the mixer. Homogenize while mixing for 10 minutes at high speed under vacuum 0.4 to 0.6 bar, mixer speed 20 rpm, and temperature 25°C. Check the suspension for uniformity.
18. Transfer the sugar syrup from step 7 to the mixer. Homogenize while mixing for 2 minutes at high speed under vacuum 0.4 to 0.6 bar, mixer speed 20 rpm, and temperature 25°C. Check the suspension for uniformity.
19. Dissolve item 12 in 4 g of cooled item 20, and transfer to the mixer while mixing.
20. Dissolve item 11 in 10 g of cooled item 20, and transfer to the mixer while mixing.
21. Dissolve items 16 and 17 and FD&C Red No. 40 in 1 g of cooled item 20, and transfer to the mixer while mixing.
22. Mix items 18 and 19, and transfer to the mixer while mixing.
23. Add cold item 20 to make up the volume to 1 L.
24. Set the mixer on high speed, 20 rpm, manual mode, vacuum 0.4 to 0.6 bar, and temperature 25°C. Mix for 15 minutes.
25. Check and record the pH (limit: 5.5–5.8) at 25°C. If required, adjust pH with 10% citric acid or 10% sodium citrate solution.
26. Transfer the suspension through 630 micron sieve to the stainless steel storage tank, previously sanitized by 70% ethanol.

CROMOLYN SODIUM NASAL SPRAY

Each milliliter of NasalCrom nasal spray contains 40 mg of cromolyn sodium in purified water with 0.01% benzalkonium chloride to preserve and 0.01% EDTA to stabilize the solution. Each metered spray releases the same amount of medicine, 5.2 mg cromolyn sodium.

CROMOLYN SODIUM ORAL CONCENTRATE

Each 5 mL ampule of oral concentrate contains 100 mg cromolyn sodium in purified water. It is an unpreserved, colorless

solution supplied in a low-density polyethylene plastic unit-dose ampule with 8 ampules per foil pouch.

CROSPOVIDONE ORAL SUSPENSION (2000 MG/10 ML)

Formulation

Kollidon® CL-M, 20 g; sorbitol, crystalline, 10 g; Kollidon® 90F, 2 g; preservatives, QS; flavor, QS; water, add 100 mL.

Manufacturing Directions

Dissolve sorbitol, Kollidon® 90F, the preservatives, and the flavors in the water; add Kollidon® CL-M; and homogenize by shaking.

CYCLOSPORIN ORAL SOLUTION

Cyclosporin oral solution: Each milliliter contains cyclosporin 100 mg and alcohol 12.5% by volume dissolved in an olive oil, Labrafil M 1944CS (polyoxyethylated oleic glycerides), vehicle that must be further diluted with milk, chocolate milk, or orange juice before oral administration.

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
100.00	1	Cyclosporin	100.00
125.00	2	Alcohol	125.00
532.00	3	Olive oil	532.00
242.50	4	Labrafil M 1944CS	242.50

Manufacturing Directions

1. Place items 2 to 4 in a mixing vessel, and stir well.
2. Homogenize step 1.
3. Add item 1, and homogenize again.
4. Fill.

CYCLOSPORIN SOFT GELATIN CAPSULES

Cyclosporin capsules are available in 25and 100 mg strengths. Each 25 or 100 mg capsule contains cyclosporin 25 mg and alcohol 12.7% by volume. Inactive ingredients: corn oil, gelatin, glycerol, Labrafil M 2125CS (polyoxyethylated glycolyzed glycerides), red iron oxide , sorbitol, titanium dioxide, and other ingredients.

DESMOPRESSIN ACETATE NASAL SPRAY

Desmopressin acetate is a synthetic analog of the natural pituitary hormone 8-arginine vasopressin, an antidiuretic hormone affecting renal water conservation. It contains 1.5 mg/mL desmopressin acetate in an aqueous solution adjusted with hydrochloric acid to pH 4; chlorobutanol (5 mg) and sodium chloride (9 mg) are the inactive ingredients. The compression pump delivers 0.1 mL (150 µg) of solution per spray; 2.5 mL bottle.

DEXAMETHASONE ELIXIR

Dexamethasone elixir contains 0.5 mg of dexamethasone in each 5 mL. Benzoic acid, 0.1%, is added as a preservative. It also contains alcohol 5%. Inactive ingredients are FD&C Red No. 40, flavors, glycerin, purified water, and sodium saccharin.

DEXTROMETHORPHAN AND CHLORPHENIRAMINE MALEATE SOLUTION

Bill of Materials

Scale (mg/mg)	Item	Material Name	Qty/kg (g)
14.70	1	Dextromethorphan base	14.70
2.60	2	Chlorpheniramine maleate	
QS	2	Vehicle (Pluronic F 127 55.67%, ethanol 26.55%, and water 17.79%)	QS to 1 kg
3.00	3	Sodium saccharin	3.00
QS	4	Flavors and colors (menthol, eucalyptus oil, and benzocaine)	QS
0.50	5	Monoammonium glycyrrhizinate	0.50

Manufacturing Directions

1. Mill and screen the menthol and benzocaine to reduce the product particle size.
2. Add the menthol, benzocaine, sodium saccharin, and monoammonium glycyrrhizinate into a clean vessel.
3. Add eucalyptus oil and ethanol to the vessel.
4. Subsequently, add the poloxamer and water to the vessel. Mix until uniform.

DEXTROMETHORPHAN, PSEUDOEPHEDRINE, AND CHLORPHENIRAMINE MALEATE SYRUP

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
2.00	1	Dextromethorphan hydrobromide	2.00
4.00	2	D-Pseudoephedrine hydrochloride	4.00
0.40	3	Chlorpheniramine maleate	0.40
25.00	4	Sorbitol syrup	25.00
0.20	5	Saccharin sodium	0.20
3.00	6	Hydroxyethyl cellulose (Natrosol®)	3.00
2.50	7	Sodium benzoate	2.50
1.05	8	Banana flavor	1.05
1.10	9	Custard flavor	1.10
1.20	10	Trisodium citrate dihydrate (powder)	1.20
QS	11	Deionized water	QS 1 L

Manufacturing Directions

1. In a suitable stainless steel vessel, combine sorbitol syrup, hydroxyethyl cellulose, and deionized water; mix well.
2. Add sodium benzoate, and stir again for 5 minutes.
3. After obtaining a clear solution, stir the hydroxyethyl cellulose suspension, rinse the container with deionized water, and transfer the rinsings to the vessel.
4. Heat the vessel to 40°C to 50°C and stir the mix for 1 hour.
5. After 1 hour, a clear gel without lumps is obtained.
6. Dilute the gel with sorbitol syrup, and cool to 30°C.
7. In a separate vessel, add deionized water and heat while stirring to 50°C.
8. After reaching this temperature, dissolve, in this order, dextromethorphan hydrobromide, chlorpheniramine maleate, and pseudoephedrine hydrochloride and saccharin sodium.
9. Cool the solution to 25°C.
10. In a suitable stainless steel container, add deionized water, and while stirring, dissolve trisodium citrate under 0.6 bar vacuum and high speed.
11. Transfer the active substance solution to the syrup vehicle.
12. Rinse the vessel twice with deionized water.
13. Add while stirring (low) the custard and banana flavors.
14. Mix for 10 minutes.
15. Then, while stirring, add the solution from previous step; keep stirring for 15 minutes at moderate speed.
16. Stop stirring, and check pH (5.9–6.2); adjust with 10% trisodium citrate solution; after each addition, where necessary, stir for 5 minutes before recording pH again.
17. Finally, make up the volume with deionized water, and stir once more for 15 minutes under vacuum (0.6 bar) at moderate speed.
18. Stop stirring, and remove vacuum; check final volume once more.
19. Filter the clear syrup under compressed air pressure, first through a filter of 330 µm and then through a 20 µm filter of propylene type.

DEXTROMETHORPHAN LIQUID

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
22.00	1	Dextromethorphan base	22.00
QS	2	Vehicle (Pluronic 33.56%, ethanol 10.51%, water 13.42%, propylene glycol 42.51%)[a]	QS to 1 L
1.00	3	Sodium metabisulfite	1.00
1.00	4	Disodium EDTA	1.00
4.00	5	Sodium saccharin	4.00
1.50	6	Monoammonium glycyrrhizinate	1.50
5.00	7	Acesulfame	5.00
14.00	8	Flavor	14.00

[a] Alternate vehicle composition: Pluronic F 27 29.08%, ethanol 10.51%, water 24.61%, propylene glycol 35.80%. Second alternate vehicle: Pluronic F127 40.27%, ethanol 10.51%, water 13.42%, propylene glycol 35.80%.

Manufacturing Directions

1. Add propylene glycol and poloxamer to a clean vessel (main mix).
2. While stirring, heat the mixture as appropriate to sufficiently melt the poloxamer.
3. Once a uniform solution is obtained, remove from heat source, and continue mixing.
4. In a separate vessel (alcohol premix), add alcohol, dextromethorphan base, and monoammonium glycyrrhizinate, and mix until uniform.
5. In another vessel (water premix), add water, EDTA, sodium saccharin, acesulfame, and sodium metabisulfite. Mix until all materials are dissolved.
6. Add the alcohol-containing premix to the main mixing vessel containing the poloxamer.
7. Mix until uniform.
8. While stirring, add the water-containing premix to the main vessel, and continue to mix until uniform.
9. Add desired flavor component, and mix until uniform.
10. The preparation has a viscosity of approximately 0.67 Pa seconds and a triggered viscosity ratio at a 50% dilution with water of 10.5. If using alternate vehicle composition (see table footnote), the preparation has a viscosity of approximately 0.97 Pa seconds and a triggered viscosity ratio at a 50% dilution with

water of 4.95. If using the second alternate vehicle, the preparation has a viscosity of approximately 2.14 Pa seconds and a triggered viscosity ratio at a 50% dilution.

DEXTROMETHORPHAN LIQUID

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
QS	1	Vehicle (Pluraflo 1220 40.90%, ethanol 10.22%, propylene glycol 46.83%, anhydrous glycerin 2.05%)	QS to 1 L
22.00	2	Dextromethorphan base	22.00
QS	3	Flavors	QS

Manufacturing Directions

1. Weigh the dextromethorphan into a clean vessel, add the ethanol, and begin mixing.
2. Add propylene glycol, and mix until uniform and clear.
3. Add Pluraflo and mix. Add glycerin, and mix until uniform.
4. Add desired flavor component, and mix until uniform.

DEXTROMETHORPHAN, PSEUDOEPHEDRINE, AND CHLORPHENIRAMINE MALEATE SYRUP

Bill of Materials

Scale (mg/tablet)	Item	Material Name	Qty/L (g)
20.00	1	Dextromethorphan hydrobromide	20.00
40.00	2	D-Pseudoephedrine hydrochloride	40.00
4.00	3	Chlorpheniramine maleate	4.00
250.00	4	Sorbitol syrup	250.00
2.00	5	Saccharin sodium	2.00
30.00	6	Hydroxyethyl cellulose (Natrosol HHY)	30.00
25.00	7	Sodium benzoate	25.00
10.50	8	Banana flavor	10.50
11.00	9	Custard flavor	11.00
12.00	10	Trisodium citrate dihydrate powder	12.00
QS	11	Water purified	QS

Manufacturing Directions

1. In a suitable vessel, add sorbitol syrup, hydroxyethyl cellulose, and purified water; mix well.
2. Add sodium benzoate, and stir again for 5 minutes.
3. After obtaining clear solution, put under stirring hydroxyethyl cellulose suspension, rinse the container with purified water, and transfer the rinsings to the vessel.
4. Heat the vessel to 40°C to 50°C, and keep the mix stirring for 1 hour.
5. After 1 hour, a clear gel without lumps is obtained.
6. The gel is then diluted with sorbitol syrup and cooled to 30°C.
7. In a separate vessel, add purified water, and heat under stirring to 50°C.
8. After reaching this temperature, dissolve sequentially dextromethorphan hydrobromide, chlorpheniramine maleate and pseudoephedrine hydrochloride, and saccharin sodium.
9. Cool the solution to 25°C.

DEXTROMETHORPHAN SOLUTION

10. In a suitable stainless steel container, add purified water, and under stirring, dissolve trisodium citrate under 0.6 bar and high speed.
11. The active substance solution from step 10 is transferred to the syrup vehicle.
12. The vessel is rinsed twice with purified water.
13. In the larger vessel, add under stirring (low) the custard flavor and banana flavor, and mix for 10 minutes.
14. Then, under stirring, add the solution from step 13; keep stirring for 15 minutes at moderate speed.
15. Stop stirring, and check pH (5.9–6.2); adjust with 10% trisodium citrate solution; after each addition, where necessary, stir for 5 minutes before recording pH again.
16. Finally, make up the volume with purified water, and stir once more for 15 minutes under vacuum (0.6 bar) at moderate speed. Stop stirring and vacuum; check final volume once more.
17. Clear syrup is filtered under compressed air pressure first through a filter of 330 microns and then through a 20 micron filter of propylene type.

Bill of Materials

Scale mg/mg	Item	Material Name	Qty/kg (g)
14.70	1	Dextromethorphan base	14.70
QS	2	Vehicle (Pluronic F 127 55.51%, ethanol 26.48%, and water 18.01%)	QS to 1 kg
3.00	3	Sodium saccharin	3.00
QS	4	Flavors and colors	QS
0.50	5	Monoammonium glycyrrhizinate	0.50

Manufacturing Directions

1. Add the dextromethorphan base, sodium saccharin, and monoammonium glycyrrhizinate into a clean vessel.
2. Add ethanol and then the poloxamer and water. Mix until clear and uniform.
3. Good pourable formula.

Dextrose, Levulose, and Phosphoric Acid Solution Emetrol is an oral solution containing balanced amounts of dextrose (glucose) and levulose (fructose) and phosphoric acid with controlled hydrogen ion concentration. Available in original lemon-mint or cherry flavor. Each 5 mL teaspoonful contains dextrose (glucose), 1.87 g; levulose (fructose), 1.87 g; phosphoric acid, 21.5 mg; glycerin; methyl paraben; purified water; and D&C Yellow No. 10 and natural lemon-mint flavor in lemon-mint Emetrol, and FD&C Red No. 40 and artificial cherry flavor in cherry Emetrol.

DIAZEPAM RECTAL SOLUTION

aBill of Materials

Scale (mg/2.5 mL)	Item	Material Name	Qty/L (g)
10.00	1	Diazepam	4.00
2.50	2	Benzoic acid	1.00
250.00	3	Alcohol	100.00
1000.00	4	Propylene glycol	400.00
122.50	5	Sodium benzoate	49.00
37.50	6	Benzyl alcohol	19.00
QS	7	Water purified	QS to 1 L

Manufacturing Directions

1. Dissolve benzoic acid in absolute alcohol previously warmed to 35°C.
2. Add diazepam to step 1; stir to dissolve.
3. Separately mix together polypropylene glycol and benzyl alcohol.
4. Separately dissolve sodium benzoate in one-fourth quantity of purified water, and filter through a 0.6 µm Millipore filter.
5. Under heavy stirring, mix together steps 2 and 3.
6. Bring to volume with water under stirring, and filter through a 0.22 µm Millipore filter.
7. Fill solution into rectal tubes; fill volume 2.9 mL.

DICLOFENAC ORAL SOLUTION

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
15.00	1	Diclofenac sodium	15.00
25.00	2	Kollidon® 30	25.00
5.00	3	Cremophor RH 40	5.00
400.00	4	Sucrose crystalline	400.00
QS	5	Water purified	QS to 1 L

Manufacturing Directions

1. Dissolve items 2 to 5 in a suitable stainless steel vessel.
2. Add item 1, and dissolve.
3. Fill.

DIDANOSINE FOR ORAL SOLUTION

Videx buffered powder for oral solution is supplied for oral administration in single-dose packets containing 100, 167, or 250 mg of didanosine. Packets of each product strength also contain a citrate–phosphate buffer (composed of dibasic sodium phosphate, sodium citrate, and citric acid) and sucrose.

DIGOXIN ELIXIR PEDIATRIC

This is a stable solution of digoxin specially formulated for oral use in infants and children. Each milliliter contains 50 µg (0.05 mg) digoxin. The lime-flavored elixir contains the inactive ingredients alcohol 10%, methyl paraben 0.1% (added as a preservative), citric acid, D&C Green No. 5, D&C Yellow No. 10, flavor, propylene glycol, sodium phosphate, and sucrose. Each package is supplied with a specially calibrated dropper to facilitate the administration of accurate dosage even in premature infants. Starting at 0.2 mL, this 1 mL dropper is marked in divisions of 0.1 mL, each corresponding to 5 µg (0.005 mg) digoxin.

DIHYDROERGOTAMINE MESYLATE DROPS

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
2.00	1	Dihydroergotamine mesylate, 10% excess	2.20
153.00	2	Glycerin	153.00
48.25	3	Alcohol	48.25
QS	4	Methanesulfonic acid	QS
QS	5	Sodium hydroxide	QS
QS	6	Water purified	QS to 1 L
QS	7	Nitrogen gas	QS

Manufacturing Directions

The product is highly susceptible to oxidation and should be manufactured under continuous bubbling and cover of nitrogen; the oxygen level should be below 10 ppm at all times; the nitrogen gas used should be filtered through a 0.45 micron membrane filter; also, protect product from light; all tubing used for transferring product should be of stainless steel, Teflon, or silicon.

1. Heat sufficient quantity of item 6 to 95°C, and hold for 1 hour. Begin bubbling nitrogen for 1 hour; cool slowly to 22°C while continuing to bubble nitrogen.
2. Place glycerin in another suitable glass-lined or stainless steel container.
3. In another stainless steel container, place alcohol, and bubble it with nitrogen for more than 2 hours.
4. Check oxygen levels in step 1 to less than 1 ppm.
5. Flush a suitable tank with nitrogen, transfer approximately 700 mL of purified water from previous step, and begin bubbling nitrogen.
6. Add approximately 40 mL of purified water from step 4 to step 2, and bubble nitrogen again for 1 hour; do not discontinue bubbling throughout manufacturing process.
7. Weigh the alcohol container, add 49 g of alcohol to water in preceding step, and stir.
8. Dilute approximately 0.03 mL of methanesulfonic acid with purified water to make a 20% solution; measure pH, and adjust to 3.25.
9. Add item 1 to batch, and stir until completely dissolved.
10. Add glycerin/water mixture to the batch, and adjust volume to 995 mL.
11. Dissolve 4 g of sodium hydroxide in 100 mL purified water, and use this solution to adjust pH of step 10 to 3.75; stir for 1 minute, and recirculate for at least 5 minutes.
12. Adjust the volume to 1 L with item 6.
13. Filter through previously sterilized 0.22 micron filter, and fill in presterilized amber-colored bottle with nitrogen flushing.

DIPHENHYDRAMINE AND AMMONIUM CHLORIDE SYRUP

Bill of Materials

Scale (mg/5 mL)	Item	Material Name	Qty/L (g)
131.50	1	Ammonium chloride	26.30
15.00	2	Caramel	5.00
11.00	3	Citric acid	2.20
13.50	4	Diphenhydramine hydrochloride	2.70
200.00	5	Alcohol	40.00
318.00	6	Glycerin	63.60
1.10	7	Menthol	0.22
5.00	8	Flavor	1.00
9.80	9	Saccharin sodium	1.96
12.00	10	Sodium benzoate	2.40
2750.00	11	Sugar	550.00
QS	12	Water purified	QS to 1 L

Manufacturing Directions

1. Place one-half of item 12 in a suitable stainless steel mixing vessel, heat to 90°C to 95°C, and add and mix item 11. Mix for 1 hour at 90°C to 95°C.
2. Cool to room temperature.
3. In separate vessels, place 100 mL of item 12 in each, and mix items 3, 4, and 10 separately. Then, mix them all together, and stir well.
4. Add item 6 to step 2, and mix well.
5. In 100 mL of water, dissolve item 4, and add to step 4.
6. Dissolve item 2 in 100 mL of water, and add to step 5.
7. In a separate vessel, place item 5, and add and mix items 7 and 8.
8. Add step 7 into step 6, and make up volume.

DIPHENHYDRAMINE HYDROCHLORIDE LIQUID

Bill of Materials

Scale (mg/5 mL)	Item	Material Name	Qty/L (g)
12.50	1	Diphenhydramine hydrochloride	2.50
1000.00	2	Lycasin 80/55	200.00
12.00	3	Sodium benzoate	2.40
4.40	4	Citric acid monohydrate	0.88
7.60	5	Sodium citrate	1.52
5.00	6	Saccharin sodium	1.00
250.00	7	Propylene glycol	50.00
1.25	8	Menthol	1.25
5.00	9	Flavor	1.00
QS	10	Water purified	QS to 1 L

Manufacturing Directions

1. Place 600 mL of item 10 in a stainless steel vessel, and bring to boil; cool to 40°C to 50°C.
2. Add and mix items 2 to 4, and stir to dissolve; mix for another 10 minutes.
3. In a separate vessel, place 100 mL of item 10, and add and mix item 6.
4. In a separate vessel, place 100 mL of item 10, and add and mix item 1. Add to step 1.
5. Add steps 2 and 3 to step 1, and mix well.
6. Add item 2, and mix again.
7. In a separate vessel, add and mix item 7 to 9. Add to step 6, and make up volume.
8. Fill.

DORNASE-ALPHA INHALATION SOLUTION

Each Pulmozyme single-use ampule will deliver 2.5 mL of the solution to the nebulizer bowl. The aqueous solution contains 1.0 mg/mL dornase alfa, 0.15 mg/mL calcium chloride dihydrate, and 8.77 mg/mL sodium chloride. The solution contains no preservative. The nominal pH of the solution is 6.3.

DOXERCALCIFEROL CAPSULES

Doxercalciferol, the active ingredient in Hectorol, is a synthetic vitamin D analog that undergoes metabolic activation in vivo to form 1(alpha),25-dihydroxyvitamin D_2 (1(alpha),25-(OH)2D2), a naturally occurring biologically active form of vitamin D_2. Hectorol is available as soft gelatin capsules containing 2.5 µg doxercalciferol. Each capsule also contains fractionated triglyceride of coconut oil, ethanol, and butylated hydroxyanisole. The capsule shells contain gelatin, glycerin, titanium dioxide, and D&C Yellow No. 10.

DYPHYLLINE, GUAIFENESIN ELIXIR

Each 15 mL (one tablespoonful) of elixir contains dyphylline 100 mg, guaifenesin 100 mg, alcohol (by volume) 17%, citric acid, FD&C Yellow No. 6, flavor (artificial), purified water, saccharin sodium, sodium citrate, and sucrose.

ELECTROLYTE LAVAGE SOLUTION

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
60.00	1	Polyethylene glycol 3350	60.00
1.46	2	Sodium chloride	1.46
0.75	3	Potassium chloride	0.75
1.68	4	Sodium bicarbonate	1.68
5.68	5	Sodium sulfate	5.68
0.81	6	Flavor	0.81

Manufacturing Directions

The values given in the BOM pertain to solution on reconstitution of one flavor pack. When dissolved in sufficient water to make 4 L, the final solution contains 125 mEq/L sodium, 10 mEq/L potassium, 20 mEq/L bicarbonate, 80 mEq/L sulfate, 35 mEq/L chloride, and 18 mEq/L polyethylene glycol 3350. The reconstituted solution is isoosmotic and has a mild, salty taste. Colyte flavor packs are available in citrus berry, lemon lime, cherry, and pineapple. This preparation can be used without the Colyte flavor packs and is administered orally or via a nasogastric tube. Each citrus berry flavor pack (3.22 g) contains hydroxypropyl methylcellulose 2910, citrus berry powder, saccharin sodium, and colloidal silicon dioxide. Each lemon lime flavor pack (3.22 g) contains lemonlime NTA powder, hydroxypropyl methylcellulose 2910, Prosweet® powder natural, saccharin sodium, and colloidal silicon dioxide. Each cherry flavor pack (3.22 g) contains hydroxypropyl methylcellulose 2910, artificial cherry powder, saccharin sodium, and colloidal silicon dioxide. Each pineapple flavor pack (3.22 g) contains hydroxypropyl methylcellulose 2910, pineapple flavor powder, Magnasweet, saccharin sodium, and colloidal silicon dioxide.

EPLERENONE SOLUTION

Bill of Materials

Scale (mg/L) or mL/L	Item	Material Name	Quantity mg or mL/L
2.50 mg	1	Eplerenone	2.50 mg/L
200 mL	2	Ethanol	200 mL
100 mL	3	Propylene glycol	100 mL
100 mL	4	Glycerol 70%	100 mL
QS	5	Water	QS

ERYTHROMYCIN DROPS

Bill of Materials

Scale (mg/2.5 mL)	Item	Material Name	Qty/kg (g)
	1	Sodium carboxymethyl cellulose	0.41
	2	Dye Red FD&C No. 3	0.13
	3	Sucrose	796.81
	4	Sodium citrate dihydrate	52.60
	5	Sodium carboxymethyl cellulose	13.10
	6	Magnesium aluminum silicate type IB Veegum F	7.90
	7	Water purified	66 mL
100.00	8	Erythromycin; use erythromycin ethylsuccinate citrate, washed (850 µg/mg)	123.50
	9	Flavor	3.94

Manufacturing Directions

Erythromycin ethylsuccinate (item 9) is factored in based on the potency used in the Bill of Materials. Excess of up to 5% erythromycin may be included. The weight of sugar (item 3) is adjusted to compensate for potency variation and excess of the erythromycin ethylsuccinate to maintain the standard quantity at 1000 g.

1. Dissolve the sodium carboxymethyl cellulose (item 1) and the dye (if used) in 50 mL hot purified water. Stir until the sodium carboxymethyl cellulose is completely in solution. Allow to cool before using.
2. Screen the sucrose through a 2 mm aperture screen into a mixer.
3. Mill the remaining ingredients, with the exception of the flavor, through a 1-B band (1.27\mm aperture or similar) or 0 band (686 micron aperture or similar) with impact forward at high speed, or screen through a 840 micron aperture screen.
4. Load the milled or screened ingredients into the mixer with the screened sucrose, and dry blend for not less than 5 minutes.
5. Mass with the solution from step 1 and QS using purified water, if necessary. Mixer must not be stopped, and the sides must be scraped down several times during the massing operation to minimize the presence of white particles in the final granulation. Do not allow massed granules to stand.
6. Screen the wet mass through a 16 mm aperture mesh (hammer mill) or a 4 mm aperture screen (oscillating granulator), and spread evenly onto trays.
7. Dry granules in an oven at between 49°C and 55°C to NMT 1.0% loss on drying (15 minutes Brabender, or equivalent, at 105°C), or loss on drying at 60°C at 5 mm of mercury for 3 hours.
8. Screen the cooled, dried granules through a 1.19 mm aperture screen, and grind coarsely through 2-AA band (1.98 mm aperture, or similar), medium speed, knives forward, or screen through a 1.4 mm aperture screen on an oscillating granulator. Protect granules from excessive exposure to moisture.
9. Screen the flavor through a 600 micron aperture screen with an equal portion of granulation.
10. Fill into suitable approved bottles at the theoretical fill weight.

ERYTHROMYCIN TOPICAL SOLUTION

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
500.00	1	Polyethylene glycol 400	100.00
20.00	2	Erythromycin; use erythromycin base, 15% excess	25.55
0.32	3	Acetone	65.40 mL
77% (v/v)	4	Alcohol	840.00 mL
QS	5	Nitrogen gas	QS

Manufacturing Directions

Product is sensitive to moisture. Every effort should be made to avoid exposure or incorporation of moisture into the product, because the stability of the final product is affected. Check mixing tank to make sure it is clean and dry. Mixing tank must be purged with nitrogen gas, as directed, at the start of and during manufacture to replace most of the air in the mixing tank and to reduce the possibility of fire or explosion if there should be a spark.

Transfer and filling hose lines must be approved for use with solvents.

1. Place polyethylene glycol 400 into a suitable nitrogen-purged tank; keep nitrogen cover and purging on.
2. Add and mix acetone.
3. Add item 2 (quantity adjusted for potency) and mix.
4. Turn the agitator, sample, and adjust volume.

ESTRADIOL NASAL SPRAY

Manufacturing Directions

1. Place 2.6 g of estradiol into a pressure-addition vessel, and dissolve with stirring in 405.6 g of ethanol in which 0.26 g of oleic acid has previously been dissolved.
2. After sealing and evacuation thereof, add, with stirring, 6.7 kg of HFA 134a (propellant) that has previously been aerated with carbon dioxide and adjusted to a pressure of at most 6.5 bar (20°C) in another pressure-addition vessel.
3. Dispense the formulation obtained into aluminum containers sealed with metering valves by means of the pressure-filling technique.

ETHCHLORVYNOL GELATIN CAPSULE (200 MG)

Bill of Materials

Scale (mg/capsule)	Item	Material Name	Qty/1000 capsules (g)
200.00	1	Ethchlorvynol	200.00
150.00	2	Polyethylene glycol 400	150.00
211.00	3	Gelatin colored opaque	211.00
—	4	Acetone, approximate[a]	86.00

[a] Used for cleaning purposes only and not present in final product.

Manufacturing Directions

Polyethylene glycol should be weighed into clean, dry, light-resistant containers and sealed under nitrogen protection. Bulk container should be flushed with nitrogen and resealed.

1. Mix ethchlorvynol, polyethylene glycol 400, and glycerin (if used) in an open stainless steel drum until uniform.
2. Cover with loose-fitting polyethylene cover, permitting gas to escape. Fumes will discolor metal. Retest if held for more than 1 month before encapsulating.
3. Mix gelatin to uniform consistency with minimal introduction of air. Encapsulate using the drug mixture into 1000 capsules using gelatin mass red opaque and 6.6 m size die roll.
4. Dry 3 days in a drying room at 20°C to 22°C and 22% to 33% relative humidity or lower.
5. Inspect and remove culls. Optionally, wash with acetone, or rinse twice with methylene chloride if used in place of acetone.
6. Finishing: fill.

EUCALYPTOL SOLUTION

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
80.00	1	Eucalyptol	80.00
40.00	2	Cremophor RH 40	40.00
QS	3	Preservative	QS
QS	4	Water	QS to 1 L

Manufacturing Directions

1. Mix eucalyptol and Cremophor at 65°C, stir well, and slowly add the warm solution of item 3 to produce a clear or slightly opalescent, colorless liquid.

EUCALYPTOL SOLUTION (8%)

Formulation

I. Eucalyptol, 8 g; Cremophor RH 40, 4 g
II. Preservative, QS; water, add 100 mL

Manufacturing Directions

1. Mix eucalyptol and Cremophor at 65°C, stir well, and add slowly the warm solution II.

EUCALYPTUS AND MINT EMULSION

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
427.50	1	Distilled water	427.50
375.00	2	Eucalyptamint	375.00
70.00	3	Sodium stearoyl lactylate (Pationic® SSL)	70.00
35.00	4	PEG-20 hydrogenated lanolin (Supersat ANS4)	35.00
17.50	5	Ritasynt IP	17.50
80.00	6	Cetearyl alcohol, polysorbate 60, PEG-15 stearate, and steareth-20 (Ritachol 1000)	80.00

Manufacturing Directions

1. Heat item 1 to 71°C.
2. Combine rest of the ingredients in another container, and heat to 71°C.
3. Slowly add water at 71°C, and mix for 1 hour.
4. Cool the mixture to 35°C to 45°C and fill.

FENTANYL CITRATE NASAL SPRAY

1. Charge 2.6 g of fentanyl citrate into a pressure addition vessel, and dissolve with stirring in 405.6 g of ethanol in which 0.26 g of oleic acid has previously been dissolved.
2. After sealing and evacuation thereof, 6.7 kg of HFA 134a, which has previously been aerated with carbon dioxide and adjusted to a pressure of at most 6.5 bar (20°C) in another pressure addition vessel, is added with stirring.
3. The formulation obtained is dispensed into aluminum containers sealed with metering valves by means of the pressure-filling technique.

FERROUS SULFATE ORAL SOLUTION

Bill of Materials

Scale (mg/5 mL)	Item	Material Name	Qty/L (g)
75.00[a]	1	Ferrous sulfate	125.00
294.00	2	Sucrose	490.00
147.00	3	Maltitol solution (Lycasin 80/55)	245.00
0.30	4	Citric acid (monohydrate)	0.50
0.90	5	Citric acid (monohydrate)	1.50
0.060	6	FD&C Yellow No. 6 (sunset yellow FCF)	1.00
3.120	7	Guarana flavor 12144–33	5.20
0.33	8	Potassium sorbate	0.55
0.30	9	Saccharin sodium	0.50
—	10	Water purified	QS to 1 L

[a] Equivalent to 15 mg iron (Fe).

Manufacturing Directions

Bubble nitrogen throughout the process. Check and record pH of item 10 (limit: 5.0–6.5).

1. Collect 166.67 g of item 10 in mixer.
2. Heat to 90°C to 95°C for 10 minutes.
3. Add item 8. Stir to dissolve to a clear solution.
4. Add item 2. Stir to dissolve to a clear solution.
5. Add item 3. Stir for 10 minutes, and cool to 30°C to 35°C.
6. Dissolve item 4 in 10 g of item 10 (30–35°C), and add to first step.
7. Dissolve item 9 in 10 g of item 10 (30–35°C), and add to first step.
8. Dissolve item 5 in 273.33 g of item 10 (30–35°C). Then, add item 1 to the clear solution, and dissolve slowly without aeration.
9. Add to mixer at first step.
10. Dissolve item 6 in 10 g of item 10 (25–30°C), and add to first step.
11. Add item 7 to first step. Mix at low speed for 10 minutes.
12. Make volume up to 1 L with item 10.
13. Check and record pH. Target pH: 2.20 (limit: between 1.95 and 5.15).
14. Filter the drops with recirculation.
15. Transfer the filtered drops into storage vessel under nitrogen blanket.
16. Use nitrogen blanket in the tank throughout the storage and filling period.

FERROUS SULFATE ORAL SYRUP

Bill of Materials

Scale (mg/5 mL)	Item	Material Name	Qty/L (g)
200.000[a]	1	Ferrous sulfate	40.000
3350.000	2	Sucrose	670.000
750.000	3	Maltitol solution (Lycasin 80/55)	150.000
4.166	4	Citric acid (monohydrate)	0.83
8.334	5	Citric acid (monohydrate)	1.667
0.500	6	Color	0.100
15.500	7	Flavor	3.100
—	8	Water purified	QS to 1 L

[a] Equivalent to 40 mg elemental iron.

Manufacturing Directions

Bubble nitrogen throughout the process.

1. Heat 300 g of item 8 to 95°C.
2. Add item 2 while stirring at low speed.
3. Dissolve to clear solution by stirring at 95°C.
4. Add item 3. Stir at low speed, and cool to 25°C to 30°C.
5. Dissolve item 4 in 17 g of item 8, and add to first step.
6. Dissolve item 5 in 180 g of item 8 in a separate stainless steel container. Then, add item 1 to the clear solution, and dissolve slowly without aeration.
7. Add to first step.
8. Dissolve item 6 in 16 g of item 8, and add to first step.
9. Add item 7 to first step. Mix at low speed for 10 minutes.
10. Make volume up to 1 L with item 8. Check and record pH (limit: between 2 and 5). Filter the syrup at 1.5 bar.
11. Recirculate approximately 100 to 150 mL of syrup.
12. Use nitrogen blanket in the tank throughout the storage period.

FIR NEEDLE OIL SOLUTION

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
30.00	1	Fir needle oil (Frey & Lau)	30.00
50.00	2	Camphora	50.00
60.00	3	Cremophor RH 40	60.00
403.00	4	Ethanol (96%)	403.00
457.00	5	Water	457.00

Manufacturing Directions

1. Mix the active ingredients with Cremophor RH 40, and heat to 50°C to 60°C.
2. Add the ethanol to the well-stirred solution; then, slowly add the warm water to produce a clear or slightly opalescent liquid.
3. The amount of Cremophor RH 40 required depends on the type of fir needle oil.

FLUCONAZOLE ORAL SUSPENSION

Diflucan for oral suspension contains 350 or 1400 mg of fluconazole and the following inactive ingredients: sucrose, sodium citrate dihydrate, citric acid anhydrous, sodium benzoate, titanium dioxide, colloidal silicon dioxide, xanthan gum, and natural orange flavor. After reconstitution with 24 mL of distilled water or purified water, each milliliter of reconstituted suspension contains 10 or 40 mg of fluconazole.

FLUNISOLIDE SPRAY

Nasarel is a metered-dose manual-pump spray unit containing 0.025% w/w flunisolide in an aqueous medium containing benzalkonium chloride, butylated hydroxytoluene, citric acid, EDTA, polyethylene glycol 400, polysorbate 20, propylene glycol, sodium citrate dihydrate, sorbitol, and purified water. Sodium hydroxide or hydrochloric acid may be added to adjust the pH to approximately 5.2. It contains no fluorocarbons. Each 25 mL spray bottle contains 6.25 mg of flunisolide.

FLUOCINONIDE TOPICAL SOLUTION

Lidex topical solution contains fluocinonide 0.5 mg/mL in a solution of alcohol (35%), citric acid, diisopropyl adipate, and propylene glycol. In this formulation, the active ingredient is totally in solution.

FLUOROURACIL SOLUTION

Efudex solution consists of 2% or 5% fluorouracil on a weight/weight basis, compounded with propylene glycol, tris(hydroxymethyl)aminomethane, hydroxypropyl cellulose, parabens (methyl and propyl), and disodium edetate.

FLUOROURACIL TOPICAL SOLUTION

Fluoroplex 1% topical solution contains fluorouracil 1%, propylene glycol, sodium hydroxide or hydrochloric acid to adjust the pH, and purified water.

FLUTICASONE SUSPENSION SPRAY

Manufacturing Directions

1. Weigh 2 g of fluticasone propionate and 0.02 g delta-tocopherol into a pressure-addition vessel.
2. After sealing and evacuation of the addition vessel, add, with stirring, 1.5 kg of HFA 134a that has previously been aerated with carbon dioxide and adjusted to a pressure of 4.5 bar (20°C) in another pressure addition vessel.
3. Dispense the suspension obtained into aluminum containers sealed with metering valves by means of the pressure-filling technique.

FOOT BATH

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
200.00	1	Polysorbate 20	200.00
2.50	2	Menthol	2.50
10.00	3	α-Bisabolol	10.00
20.00	4	Disodium undecylenamido MEA-sulfosuccinate	20.00
20.00	5	Perfume (menthol compatible)	20.00
QS	6	Deionized water	QS to 1 L
QS	7	Preservative, color	QS

Manufacturing Directions

1. Predissolve menthol, alpha-bisabolol, and perfume in Polysorbate 20.
2. Add mixture to the water phase while stirring.
3. Stir until homogeneous, and then fill.

FUROSEMIDE SYRUP

Bill of Materials

Scale (mg/5 mL)	Item	Material Name	Qty/L (g)
5.00	1	Furosemide, 5% excess	1.05
9.00	2	Methylparaben	1.80
1.00	3	Propylparaben	0.20
1500.00	4	Sorbitol 70%	300.00
500.00	5	Glycerin	100.00
500.00	6	Propylene glycol	100.00
0.50	7	FD&C Yellow No. 6	0.10
2.50	8	Orange flavor	0.50
QS	9	Sodium hydroxide	0.44
QS	10	Water purified	QS to 1 L

Manufacturing Directions

1. Place 20% of item 10 to a suitable stainless steel jacketed vessel.
2. Add items 2 and 3, and heat to 90°C to 95°C to dissolve. Cool to 40°C after complete dissolution.
3. In a separate vessel, place items 4, 5, and 6, and mix well.

4. Dissolve item 9 in a portion of item 10 in a separate vessel.
5. Add item 1 to step 4, and mix well.
6. In a separate vessel, dissolve item 7 in a portion of item 10.
7. Add to step 6.
8. Add step 2 to step 7.
9. Add item 8, and mix well.
10. Fill.

GABAPENTIN ORAL SOLUTION

Gabapentin solution contains 250 mg/5 mL of gabapentin. The inactive ingredients for the oral solution are glycerin, xylitol, purified water, and artificial cool strawberry anise flavor.

GALANTAMINE HYDROBROMIDE ORAL SOLUTION

Reminyl is available as a 4 mg/mL galantamine hydrobromide oral solution. The inactive ingredients for this solution are methyl parahydroxybenzoate, propylparahydroxybenzoate, sodium saccharin, sodium hydroxide, and purified water.

GLUCOSE, FRUCTOSE, AND PHOSPHORIC ACID ANTIEMETIC SOLUTION

Emetrol is an oral solution containing balanced amounts of dextrose (glucose) and levulose (fructose) and phosphoric acid with controlled hydrogen ion concentration. Available in original lemon-mint or cherry flavor. Each 5 mL teaspoonful contains dextrose (glucose), 1.87 g; levulose (fructose), 1.87 g; phosphoric acid, 21.5 mg; glycerin; methyl paraben; purified water; D&C Yellow No. 10; natural lemon-mint flavor in lemon-mint Emetrol; and FD&C Red No. 40 and artificial cherry flavor in cherry Emetrol.

GLYCOL FOAM, NONAQUEOUS

Bill of Materials

Scale (mg/g)	Item	Material Name	Qty/kg (g)
40.00	1	Polawax A31	4.00
710.00	2	Propylene glycol	71.00
150.00	3	Ethanol DEB100	15.00

Manufacturing Directions

1. Dissolve Polawax in propylene glycol/ethanol.
2. Pack into containers, and pressurize.
3. Ethanol may be omitted if desired.
4. In aerosol pack, 90% concentrate and 10% propellant 12/114 may be used.
5. Propylene glycol is a suitable vehicle for glycol-soluble medicaments.
6. This formulation provides a mousse for such a system.

GRAMICIDIN OPHTHALMIC SOLUTION

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
130.00	1	Gramicidin	130.00
1.00	2	Cremophor RH 40	1.00
10.00	3	Alcohol	10.00
QS	4	Preservatives	QS
QS	5	Water purified	QS to 1 L

Manufacturing Directions

1. Place items 1 and 2 in a suitable mixing and jacketed vessel; heat to 65°C, and mix.
2. Cool to room temperature.
3. In a separate vessel, add and mix items 3 to 5.
4. Add to step 2. Mix and fill.

GUAIFENESIN, PSEUDOEPHEDRINE, CARBINOXAMINE, AND CHLOPHEDIANOL DROPS

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
20.00	1	Guaifenesin	20.00
400.00	2	Sucrose	400.00
240.00	3	Glucose liquid	240.00
120.00	4	Sorbitol solution	120.00
3.00	5	Saccharin sodium powder dihydrate	3.00
2.50	6	Sodium benzoate powder	2.50
30.00	7	Pseudoephedrine hydrochloride	30.00
1.00	8	Carbinoxamine maleate	1.00
6.60	9	Chlophedianol hydrochloride	6.60
105.00 mcg	10	Dye red E123 (Amaranth)	105.00 mg
3.75 mcg	11	Dye blue FD&C No. 1	3.75 mg
QS	12	Acid hydrochloric	QS
50.00 mcg	13	Menthol crystals	50.0 mg
2.75	14	Flavors	2.75
65.00 mcg	15	Oil orange terpeneless No. 54125	65.00 mg
5.66	16	Alcohol 190 proof (10% ex)	5.92
0.52 g	17	Filter aid HyFlo	0.52
420.00 g	18	Water purified, distilled approximate	420.00

Manufacturing Directions

1. Place 260 mL purified water into a suitable tank.
2. Begin heating water to 70°C to 80°C while adding guaifenesin and sucrose with stirring.
3. Continue stirring to dissolve ingredients.
4. Remove heat, and add glucose liquid and sorbitol to solution from step 3 with stirring.
5. Add saccharin sodium, sodium benzoate, pseudoephedrine hydrochloride, carbinoxamine maleate, and chlophedianol hydrochloride to solution from step 4. Stir well to dissolve all ingredients.
6. Dissolve dye red E123 and FD&C No. 1 in 10 mL warm, purified water.
7. Add dye solution to solution from step 6 with stirring. Cool solution to 30°C to 35°C.
8. QS to 975 mL using purified water and mix well.
9. Adjust to pH 4.25 (range 4.0–4.5) with hydrochloric acid (ca. 0.65 g/L of drops).
10. Stir well after each addition of acid. Dissolve menthol, flavors, and orange oil in alcohol; add mixture to solution from preceding step with good stirring.
11. Stir the solution slowly for 2 hours.
12. Allow to stand overnight to cool and remove entrapped air.
13. QS to 1 L with purified water, and stir well.
14. Add filter aid HyFlo to solution, and mix well.
15. Recirculate through filter press or equivalent until sparkling clean.

HALOPERIDOL ORAL LIQUID

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
2.00	1	Haloperidol	2.00
11.00	2	Lactic acid	11.00
0.20	3	Propylparaben	0.20
1.90	4	Methylparaben	1.90
QS	5	Sodium hydroxide for pH adjustment, approximate	0.24
QS	6	Water purified, approximate	990.00 mL
QS	7	Nitrogen gas	QS
QS	8	Lactic acid	QS

Manufacturing Directions

1. Charge approximately 700 mL of water into a suitable mixing tank. Add and dissolve lactic acid with stirring; while mixing, add haloperidol. Mix until complete solution (approximately 15 minutes).
2. Charge 240 mL of water into a separate container, and heat to boiling. Add and dissolve methyl- and propylparabens. Mix until complete solution. Add this solution to step 1 solution.
3. Check pH. If necessary, adjust to pH 2.75 (range: 2.5–3.0) with 2% sodium hydroxide. Continue mixing for 10 minutes after addition of sodium hydroxide. Record pH and amount of sodium hydroxide added. Lactic acid (No. 8) may also be used to adjust pH.
4. QS to 1 L with water, and mix well.
5. Filter solution through 8 micron membrane filter (or similar) into a suitable container under nitrogen protection.
6. Fill under nitrogen.

HEPARIN NASAL SPRAY

Charge 5 g of heparin into a pressure-addition vessel, and suspend with stirring 50 g of ethanol in which 0.25 g of lecithin has previously been dissolved. After sealing and evacuation thereof, 1.5 kg of HFA 227 that has previously been aerated with carbon dioxide and adjusted to a pressure of 4.5 bar (20°C) in another pressure addition vessel is added with stirring and homogenized. The suspension obtained is dispensed into aluminum containers sealed with metering valves by means of the pressure-filling technique.

HYDROCODONE BITARTRATE ELIXIR

Each 5 mL contains hydrocodone bitartrate 2.5 mg, acetaminophen 167 mg, and 7% alcohol. In addition, the liquid contains the following inactive ingredients: citric acid anhydrous, ethyl maltol, glycerin, methyl paraben, propylene glycol, propyl paraben, purified water, saccharin sodium, sorbitol solution, sucrose, D&C Yellow No. 10 and FD&C Yellow No. 6 as coloring, and natural and artificial flavoring.

Hydrocodone Polistirex Extended-Release Suspension: Each teaspoonful (5 mL) of Tussionex Pennkinetic extended-release suspension contains hydrocodone polistirex equivalent to 10 mg of hydrocodone bitartrate and chlorpheniramine polistirex equivalent to 8 mg of chlorpheniramine maleate Tussionex. Inactive ingredients: ascorbic acid, D&C Yellow No. 10, ethylcellulose, FD&C Yellow No. 6, flavor, high-fructose corn syrup, methylparaben, polyethylene glycol 3350, polysorbate 80, pregelatinized starch, propylene glycol, propylparaben, purified water, sucrose, vegetable oil, and xanthan gum.

Hydromorphone Hydrochloride Oral Liquid: Hydromorphone hydrochloride, a hydrogenated ketone of morphine, is a narcotic analgesic. Each 5 mL (one teaspoon) contains 5 mg of hydromorphone hydrochloride. In addition, other ingredients include purified water, methylparaben, propylparaben, sucrose, and glycerin. It may contain traces of sodium bisulfite.

HYDROXYZINE PAMOATE ORAL SUSPENSION

Hydroxyzine pamoate 25 mg/5 mL; inert ingredients for the oral suspension formulation are carboxymethylcellulose sodium, lemon flavor, propylene glycol, sorbic acid, sorbitol solution, and water.

HYOSCINE BUTYLBROMIDE SYRUP

Bill of Materials

Scale (mg/5 mL)	Item	Material Name	Qty/L (g)
5.00	1	Hyoscine butylbromide	1.00
3300.00	2	Sugar	660.00
5.00	3	Methyl paraben	1.00
1.50	4	Propyl paraben	0.30
962.50	5	Sorbitol 70%	19.30
10.00	6	Sodium saccharin	2.00
35.00	7	Sodium chloride	7.00
0.70	8	Citric acid monohydrate	0.14
0.75	9	Sodium citrate	0.15
10.00	10	Flavor	2.00
5.00	11	Flavor	1.00
5.00	12	Flavor	1.00
QS	13	Water purified	QS to 1 L

Manufacturing Directions

1. In a suitable stainless steel container, place 300 mL item 13, and heat to 90°C to 95°C.
2. Add and dissolve items 3 and 4.
3. Add item 2, and dissolve.
4. Add item 5, and dissolve. Cool to room temperature
5. In 10 mL item 13, add and dissolve items 6 and 7, and add to step 4.
6. In 10 mL item 13, add and dissolve item 8, and add to step 4.
7. In 10 mL item 13, add and dissolve item 7, and add to step 4.
8. In 20 mL item 13, add and dissolve item 1, and add to step 4.
9. Add flavors.
10. Make up volume, and fill.

HYOSCYAMINE SULFATE ELIXIR

Levsin elixir contains 0.125 mg hyoscyamine sulfate per 5 mL with 20% alcohol for oral administration. Levsin elixir also contains, as inactive ingredients, FD&C Red No. 40, FD&C Yellow No. 6, flavor, glycerin, purified water, sorbitol solution, and sucrose.

IBUPROFEN TOPICAL SOLUTION

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
QS	1	Vehicle (Pluronic P105 63.16%, ethanol 18.95%, water 17.89%)	QS to 1 L
50.00	2	Ibuprofen	50.00

Manufacturing Directions

1. Screen the ibuprofen to reduce the particle size.
2. Add the ibuprofen into a clean vessel.
3. Add ethanol to the vessel.
4. Subsequently, add the poloxamer and water to the vessel.
5. Mix until uniform.

IBUPROFEN PEDIATRIC SUSPENSION

Bill of Materials

Scale (mg/5 mL)	Item	Material Name	Qty/L (g)
100.00	1	Ibuprofen, low density[a]	20.00
3000.00	2	Sucrose	600.00
10.00	3	Sodium benzoate	2.00
5.00	4	Saccharin sodium	1.00
5.00	5	Edetate disodium (sodium EDTA)	1.00
500.00	6	Glycerin (glycerol)	100.00
500.00	7	Sorbitol (70% solution)	100.00
10.00	8	Xanthan gum (Keltrol-F)	2.00
20.00	9	Microcrystalline cellulose (Avicel™ RC591)	4.00
5.00	10	Polysorbate 80 (Tween 80)	1.00
8.50	11	Citric acid	1.70
1.35	12	FD&C Red No. 40	0.27
7.50	13	Mixed fruits flavor	1.50
5.00	14	Strawberry flavor	1.00
QS	15	Purified water	QS to 1 L

[a] Meets USP criteria with the following additional requirements: 100% particle size below 50 μm and tapped density of 0.3 to 0.4 g/mL.

Manufacturing Directions

1. Heat 302 g of item 15 to 90°C, and dissolve item 2 while mixing in mixer.
2. Cool to approximately 50°C.
3. Add items 3, 5, 4, 11, and 7 to mixer while mixing, and dissolve.
4. Filter the syrup through Seitz Supra 2600 filters in clean stainless steel tank.
5. In a clean stainless steel vessel, dissolve item 10 in 35 g of item 15 (40°C).
6. Add item 1 slowly while mixing with stirrer.
7. Mix for 30 minutes to make uniform dispersion. *Caution*: Avoid excessive foaming.
8. Disperse items 8 and 9 in item 6 in a clean and dry stainless steel container using stirrer.
9. Add 75 g of hot item 15 (70–90°C) at once while mixing.
10. Mix for 20 minutes to make a homogeneous smooth mucilage.
11. Add approximately 500 g syrup, ibuprofen dispersion, and mucilage to the mixer.

12. Rinse the containers of ibuprofen dispersion and mucilage with 50 g of item 15 (40°C).
13. Add the rinsings to the mixer.
14. Set the mixer: temperature, 25°C; speed, 18 rpm; and manual mode vacuum at 0.5 bar.
15. Mix for 3 minutes at low homogenizer speed.
16. Mix for 2 minutes at homogenizer high speed. Check the suspension for uniformity of dispersion.
17. Homogenize for additional 3 minutes at high speed, if required.
18. Add the balance of the syrup (approximately 507.6 g) from previous step to the mixer.
19. In a separate container, dissolve item 12 in 6 g of cooled item 15 (40°C), and transfer to the mixer.
20. Add items 13 and 14 to the mixer.
21. Set the mixer: temperature, 25°C; speed, 18 rpm; manual mode vacuum at 0.5 bar.
22. Mix for 15 minutes.
23. Mix for 5 minutes at homogenizer low speed.
24. Mix for 5 minutes at homogenizer high speed.
25. Check the suspension for uniformity.
26. Adjust the final volume to 1 L by using purified water.

IRON INFANT DROPS

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
0.18	1	Propylparaben	0.18
0.022	2	Methylparaben	0.02
1000.00	3	Sorbitol solution	1.00 kg
4.00	4	Citric acid (hydrous powder)	4.00
125.00	5	Iron sulfate	125.00
0.106	6	Sodium metabisulfite	0.10
0.50	7	Guarana flavor (artificial)	0.50
20.00	8	Alcohol (ethanol)	900.14
0.14	9	Dye	0.14
QS	9	Sodium hydroxide	QS
QS	10	Citric acid (powder)	1 QS
QS	11	Purified water	QS to 1 L
QS	12	HyFlo filter aid	1.00
QS	13	Liquid nitrogen	QS
QS	14	Carbon dioxide gas	QS

Manufacturing Directions

The product is susceptible to oxidation. No effort should be spared to protect it from atmospheric air. Maintain CO_2 or nitrogen atmosphere where indicated. The product must be manufactured and held in a glass-lined or stainless steel tank. Product waiting to be filled should be either in a closed tank with a CO_2 atmosphere or in an open tank covered with polyethylene sheeting taped tightly with a constant slow stream of CO_2 gas flowing into the tank headspace. Avoid vortex formation throughout processing.

1. Place 144 mL of purified water into a mixing tank.
2. Heat to 95°C to 100°C, and add parabens with strong agitation.
3. Add sorbitol solution and citric acid (item 4) while mixing.
4. Bring solution to 90°C while mixing.
5. Cool the solution while mixing to 60°C to 65°C, and hold at this temperature with CO_2 or nitrogen gas bubbling into it.
6. CO_2 gas protection is continued for the remainder of the manufacturing process.
7. Add ferrous sulfate, and dissolve while mixing, holding at 60°C to 65°C.
8. Cool to 25°C with mixing.
9. Add sodium metabisulfite, and dissolve while mixing.
10. Avoid vortex formation.
11. Dissolve dye in 2 mL of freshly boiled purified water, and add to the tank. Mix.
12. Dissolve the guarana flavor in alcohol, add to the tank, and mix.
13. Check pH (range: 1.8–2.2). Adjust if necessary with a solution of 10% sodium hydroxide or a solution of 10% citric acid.
14. Make up to volume with freshly boiled purified water, and mix.
15. Readjust to volume if necessary with freshly boiled purified water, and mix.
16. Add HyFlo filter aid, and mix. Filter through press until clear.
17. Bubble CO_2 or nitrogen gas into the clear filtrate for 5 minutes; then seal tank, and hold product under CO_2 or nitrogen protection.

IRON POLYSTYRENE AND VITAMIN C SYRUP

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
125.00	1	Glycerin	125.00
1.40	2	Methylparaben	1.40
0.16	3	Propylparaben	0.16
79.61	4	Sorbitol; use sorbitol solution	364.33
3.30	5	Xanthan gum	3.30
10.00	6	Sucrose (granulated)	100.00
0.20	7	Saccharin (insoluble)	2.00
105.00	8	Elemental iron; use iron polystyrene sulfonate	530.31
50.00	9	Ascorbic acid, USP (35% excess)	61.95
0.10	10	Flavor	1.00 mL
0.10	11	Flavor (artificial guarana)	1.00 mL
QS	12	Sodium hydroxide	QS
QS	13	Dye	2.00
9.50	14	Distilled purified water	~95.00 mL
10.00	15	Sorbitol solution	~10.00

Manufacturing Directions

1. Add glycerin (item 1) to the tank.
2. Commence heating with agitation.
3. Add and disperse parabens.
4. Continue heating to 70°C to 80°C, and mix until solution is complete.
5. Force cool to 30°C; then add and disperse xanthan gum (item 5).
6. Add sorbitol solution (item 4) and 80 mL of purified water (item 14), and heat with mixing to 60°C to 70°C until the xanthan gum is fully dissolved.
7. Add and disperse saccharin and sugar (items 6 and 7).
8. Mix at 60°C to 70°C until dispersion is complete.
9. Force cool to 25°C to 30°C with continuous mixing.
10. Commence N_2 gas protection, and maintain for the remainder of the manufacturing process.
11. Add and disperse ascorbic acid.
12. Continue mixing for 30 minutes at 25°C to 30°C.
13. *Note*: Use suitable stainless steel high-powered stirrer.
14. Mix the iron polystyrene sulfonate milled slurry in the original epoxy-lined drums under N_2 gas protection until uniform.
15. Add the slurry to the main batch, and mix for 30 minutes at 25°C to 30°C.
16. *Note*: Avoid scraping the epoxy lining of the steel drum while mixing and use a plastic or rubber scraper to assist in complete transfer of the mixed slurry. Add and disperse the flavors. Mix well.
17. Check and record pH. Adjust pH using a 20% sodium hydroxide solution (1 g in 5 mL water) to a value of 3 (range: 2.8–3.2).
18. Dissolve the dye in 5 to 7 mL of water at 40°C to 45°C by stirring for 10 minutes.
19. Add this solution to the main batch through a 420 µm screen with mixing.
20. Rinse container with 2 to 3 mL water at 40°C to 45°C, and add to bulk through a 420 µm screen.
21. Continue to mix under vacuum until mixture is uniform.
22. Pass the suspension through the colloid mill at a gap setting of 100 to 150 µm.
23. Adjust the flow rate such that the temperature rise of the suspension does not exceed 10°C.
24. Collect the milled suspension in a stainless steel jacketed tank with vacuum.
25. Mix at 25°C to 30°C under vacuum until a uniform suspension is achieved.
26. Flush the bulk suspension with nitrogen, and seal.
27. Hold at 25°C to 30°C.

IBUPROFEN SOLUTION

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
20.00	1	Ibuprofen	20.00
200.00	2	Cremophor RH 40	200.00
QS	3	Preservatives	QS
QS	4	Water purified	QS to 1 L

Manufacturing Directions

1. In a suitable stainless steel jacketed vessel, add and suspend item 1 in item 2 by heating it to 60°C.
2. In a separate vessel, add items 3 and 4, heat to 90°C to 95°C to dissolve preservatives, and add to step 1.
3. Mix and fill.

IBUPROFEN SUSPENSION

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
40.00	1	Ibuprofen	40.00
250.00	2	Sucrose	250.00
80.00	3	Kollidon® CL-M	80.00
20.00	4	Kollidon® 90F	20.00
20.00	5	Sodium citrate	20.00
QS	6	Water purified	QS to 1 L

Manufacturing Directions

1. Charge items 2 and 4 to 6 (40%) in a suitable mixer.
2. Add and suspend item 3.
3. Add and disperse item 1. Homogenize if necessary.
4. Bring to volume with item 6. Mix and fill.

IBUPROFEN SUSPENSION, SUGAR FREE

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
40.00	1	Ibuprofen	40.00
10.00	2	Cremophor RH 40	100.00
50.00	3	Lutron F 68	50.00
QS	4	Preservatives	QS
QS	5	Water purified	QS to 1 L

Manufacturing Directions

1. Dissolve Lutrol F 68 and the preservatives in purified water.

2. In a separate vessel, add and mix items 1 and 2.
3. Add to step 1.
4. Homogenize if necessary.
5. Bring to volume with item 5. Mix and fill.

IBUPROFEN AND DOMPERIDONE MALEATE SUSPENSION

Bill of Materials

Scale (mg/5 mL)	Item	Material Name	Qty/L (g)
200.00	1	Ibuprofen	40.00
20.00	2	Domperidone maleate	4.00
2.50	3	Colloidal cellulose	0.50
15.00	4	Glycerin	3.00
10.00	5	Sorbitol	2.00
1.00	6	Kaolin	0.20
1.00	7	Polysorbate 80	0.20
QS	8	Water	QS

Manufacturing Directions

1. Add item 7 to the water, followed by the addition of glycerin with stirring.
2. Add the domperidone and ibuprofen and the colloidal cellulose, sorbitol, and kaolin (as thickeners) with continued stirring until a satisfactory suspension is formed.

INSULIN INHALATION SPRAY

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
10.00	1	Insulin	10.00
9.00	2	Brij 98	9.00
10.00	3	Sodium lauryl sulfate	10.00
200.00	4	Alcohol, anhydrous	200.00
QS	5	HFA 134a (1,1,1,2-tetrafluoroethane)	QS to 1 L

Manufacturing Directions

1. Weigh insulin in a clean glass container, dissolve in acid buffer, and titrate to a pH of 7 with Tris buffer.
2. Add Brij 98 and sodium lauryl sulfate to the insulin solution to form a homogeneous solution.
3. Lyophilize and suspend dried particles in a nonaqueous suspension medium of ethanol, and then mix with hydrofluoroalkane (HFA) 134a.
4. Fill the formulation in a pressure-resistant container fitted with a metering valve.

IPRATROPIUM BROMIDE INHALATION SOLUTION

Atrovent inhalation solution is administered by oral inhalation with the aid of a nebulizer. It contains ipratropium bromide 0.02% (anhydrous basis) in a sterile, isotonic saline solution, pH adjusted to 3.4 (3–4) with hydrochloric acid.

IPRATROPIUM BROMIDE NASAL SPRAY

Atrovent (ipratropium bromide) nasal spray 0.03% is a metered-dose manual-pump spray unit that delivers 21 μg (70 μL) ipratropium bromide per spray on an anhydrous basis in an isotonic, aqueous solution with pH adjusted to 4.7. It also contains benzalkonium chloride, EDTA, sodium chloride, sodium hydroxide, hydrochloric acid, and purified water. Each bottle contains 165 or 345 sprays.

Manufacturing Directions

1. 2.25 g of micronized ipratropium bromide and 11.25 g of micronized salbutamol are weighed into a pressure addition vessel.
2. After sealing and evacuation thereof, 10.5 kg of HFA 227 that has previously been aerated with carbon dioxide and adjusted to a pressure of 6.25 bar (20°C) in another pressure addition vessel is added.
3. After homogenization of this mixture, the suspension obtained is dispensed into aluminum containers sealed with metering valves by means of the pressure-filling technique.

ISOPROTERENOL SULFATE AND CALCIUM IODIDE SYRUP

Manufacturing Directions

Bill of Materials

Scale (mg/5 mL)	Item	Material Name	Qty/L (g)
1.569	1	Glucose liquid	311.60
269.500	2	Glycerin	53.90
150.000	3	Calcium iodide anhydrous; use calcium iodide solution 27%	111.11
5.000	4	Ascorbic acid	1.00
2.428	5	Sucrose	485.30
4.000	6	Saccharin sodium	0.80
5.000	7	Sodium cyclamate	1.00
6.550	8	Flavor honey	1.31
1.660	9	Flavor mint	0.33
0.260	10	Alcohol 190 proof	51.53
3.000	11	Isoproterenol sulfate	0.60
0.250	12	Dye yellow	0.05
1.250	13	Caramel	0.25
QS	14	Water purified	QS to 1 L

Manufacturing Directions

1. Charge in a stainless steel tank items 1, 2, 5, 6, 7, and 10 and 90% of item 14. Mix well; heat if necessary.
2. In a separate vessel, add and dissolve items 4, 8, 9, 12, and 13 in item 14; mix well, and add to step 1.
3. Add remaining items, mix, and bring to volume. Fill.

ISOTRETINOIN CAPSULES

Isotretinoin, a retinoid, is available in 10, 20, and 40 mg soft gelatin capsules for oral administration. Each capsule also contains beeswax, butylated hydroxyanisole, EDTA, hydrogenated soybean oil flakes, hydrogenated vegetable oil, and soybean oil. Gelatin capsules contain glycerin and parabens (methyl and propyl) with the following dye systems: 10 mg, iron oxide (red) and titanium dioxide; 20 mg, FD&C Red No. 3, FD&C Blue No. 1, and titanium dioxide; 40 mg, FD&C Yellow No. 6, D&C Yellow No. 10, and titanium dioxide. Chemically, isotretinoin is 13-cis-retinoic acid and is related to both retinoic acid and retinol (vitamin A). It is a yellow-orange to orange crystalline powder with a molecular weight of 300.44.

ITRACONAZOLE ORAL SOLUTION

Itraconazole oral solution contains 10 mg of itraconazole per milliliter, solubilized by hydroxypropyl-(beta)-cyclodextrin (400 mg/mL) as a molecular inclusion complex. The solution is clear and yellowish in color with a target pH of 2. Other ingredients are hydrochloric acid, propylene glycol, purified water, sodium hydroxide, sodium saccharin, sorbitol, cherry flavor 1, cherry flavor 2, and caramel flavor.

KAOLIN, PECTIN, AND ALUMINUM HYDROXIDE SUSPENSION

Bill of Materials

Scale (mg/5 mL)	Item	Material Name	Qty/L (g)
147.600	1	Sodium methylparaben	4.92
6.720	2	Sodium propylparaben	0.69
36.000	3	Magnesium aluminum silicate type IA	1.20
5832.000	4	Kaolin (powder)	194.40
130.000	5	Pectin	4.33
120.000	6	Sodium CMC (premium, low viscosity)	4.00
210.000	7	Cyclamate calcium	7.00
21.00	8	Saccharin calcium (powder)	0.70
15.375	9	Flavor	0.51
1.234	10	Flavor	41.13
QS	11	Distilled purified water (approx.)	QS
QS	12	Citric acid (anhydrous powder)	QS
QS	13	Water purified, distilled	QS
QS	14	Acid citric anhydrous powder	QS
63.300	15	Aluminum hydroxide	12.72

Manufacturing Directions

1. Charge 600 mL of water into a suitable jacketed mixing tank.
2. Add methylparaben and propylparaben to the tank, and heat to 90°C to 95°C.
3. Cool to 70°C, add the magnesium aluminum silicate, and mix for 30 minutes or until evenly dispersed.
4. Hold temperature at 70°C.
5. Add kaolin with constant mixing at 70°C until evenly dispersed.
6. Add pectin and mix for 2 hours, maintaining the temperature of 70°C.
7. Add sodium CMC premium low viscosity and mix for at least 30 minutes, maintaining the temperature at 70°C. Cool to 60°C, and hold at this temperature.
8. Add aluminum hydroxide gel, and mix under vacuum.
9. Add in order cyclamate calcium and saccharin calcium and mix thoroughly for 20 minutes. While mixing, cool to room temperature, and allow to stand overnight to hydrate.
10. After overnight standing (minimum 12 hours), mix for 30 minutes.
11. Add and mix flavors. Check and record pH (range: 4.5–7.5). If pH is more than 7.5, adjust with a 60% solution of citric acid to the desired pH.

12. Add water to 1 L, and mix thoroughly for 3 hours.
13. Strain product through muslin cloth into holding tanks, and cover.

KAOLIN–PECTIN SUSPENSION

Bill of Materials

Scale (mg/5 mL)	Item	Material Name	Qty/L (g)
147.60	1	Sodium methylparaben	4.92
6.72	2	Sodium propylparaben	0.224
36.00	3	Magnesium aluminum silicate type IA (Veegum)	1.20
5.832 g	4	Kaolin powder	194.40
130.00	5	Pectin	4.33
120.00	6	Sodium CMC premium low viscosity	4.00
210.00	7	Cyclamate calcium	7.00
21.00	8	Saccharin calcium powder	0.70
15.37	9	Flavor	0.51
1.23	10	Flavor	41.13
QS	11	Water purified approximate	QS
QS	12	Acid citric anhydrous powder	QS

Manufacturing Directions

1. Charge 600 mL of water into a suitable jacketed mixing tank.
2. Add the methylparaben and propylparaben to the tank, and heat to 90°C to 95°C.
3. Cool to 70°C, add the magnesium aluminum silicate, and mix for 30 minutes or until evenly dispersed.
4. Hold temperature at 70°C.
5. Add kaolin with constant mixing at 70°C until evenly dispersed.
6. Add pectin, and mix for 2 hours, maintaining the temperature of 70°C.
7. Add the sodium CMC premium low viscosity and mix for at least 30 minutes, maintaining the temperature at 70°C.
8. Cool to 60°C, and hold at this temperature. Add in order cyclamate calcium and saccharin calcium, and mix thoroughly for 20 minutes.
9. While mixing, cool to room temperature, and allow to stand overnight to hydrate. After overnight standing (minimum 12 hours), mix for 30 minutes.
10. Mix while adding the flavors.
11. Check and record pH (range: 4.5–7.5). If pH is above 7.5, adjust with a 60% solution of citric acid to the desired pH.
12. Add water to 1 L, and mix thoroughly for 3 hours. Strain product through muslin cloth into holding tanks, and cover.

KAOLIN–PECTIN SUSPENSION

Bill of Materials

Scale (mg/5 mL)	Item	Material Name	Qty/L (g)
147.60	1	Sodium methylparaben	4.920
6.72	2	Sodium propylparaben	0.220
36.00	3	Magnesium aluminum silicate Type IA (Veegum)	1.200
486.60	4	Kaolin powder	0.190
43.40	5	Pectin	4.330
120.00	6	Sodium CMC premium low viscosity	4.000
210.00	7	Cyclamate calcium	7.000
21.00	8	Saccharin calcium	0.700
15.37	9	Flavor	0.510
1.23	10	Flavor	0.041

Manufacturing Directions

1. Charge 600 mL of water into a suitable jacketed mixing tank.
2. Add the methylparaben and propylparaben to the tank, and heat to 90°C to 95°C.
3. Cool to 70°C, add the magnesium aluminum silicate, and mix for 30 minutes or until evenly dispersed.
4. Hold temperature at 70°C.
5. Add kaolin with constant mixing at 70°C until evenly dispersed.
6. Add pectin, and mix for 2 hours, maintaining a temperature of 70°C.
7. Add the premium low-viscosity sodium CMC and mix for at least 30 minutes, maintaining a temperature of 70°C.
8. Cool to 60°C, and hold at this temperature.
9. Add, in order, cyclamate calcium and saccharin calcium, and mix thoroughly for 20 minutes.
10. While mixing, cool to room temperature, and allow to stand overnight to hydrate.
11. After overnight standing (minimum 12 hours), mix for 30 minutes.
12. Add flavors while mixing.
13. Check and record pH (range: 4.5–7.5). If pH is more than 7.5, adjust with a 60% solution of citric acid to the desired pH.
14. Add water to 1 L, and mix thoroughly for 3 hours.
15. Strain product through muslin cloth into holding tanks, and cover.

KETOPROFEN TOPICAL SOLUTION

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
QS	1	Vehicle (pluronic F 127 56.12%, ethanol 30.61, water 13.27%)	QS to 1 L
20.00	2	Ketoprofen	20.00
QS	3	Perfumes	QS

Manufacturing Directions

1. Screen the ketoprofen to reduce the particle size.
2. Add the ketoprofen into a clean vessel.
3. Add ethanol to the vessel.
4. Subsequently, add poloxamer and water to the vessel.
5. Mix until uniform.

KETOTIFEN SYRUP

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
0.20	1	Ketotifen hydrogen fumarate with excess	0.27
0.10	2	Flavor	0.10
0.17	3	Propylparaben	0.17
0.33	4	Methylparaben	0.33
2.10	5	Citric acid anhydrous	2.10
3.20	6	Disodium hydrogen phosphate anhydrous	3.20
20.00	7	Ethanol	20.00
300.00	8	Sucrose	300.00
350.00	9	Sorbitol	350.00
QS	10	Water purified	QS to 1 L

Manufacturing Directions

1. Take 1.5 L of purified water, heat to 90°C to 95°C, allow to cool down to 30°C, and bubble with nitrogen gas. Keep for batch preparation.
2. Dissolve the parabens in 1 L of ethanol in a separate vessel, and stir until the solution is completely clear. Add citric acid, disodium hydrogen phosphate anhydrous, sucrose, and sorbitol, and stir slowly to dissolve until clear solution is obtained. Cool to room temperature.
3. In a separate container, dissolve ketotifen hydrogen fumarate in ethanol until clear.
4. Add the flavor to the alcoholic solution of ketotifen, and dissolve.
5. Add the alcoholic mixture slowly to the syrup while stirring at room temperature, avoiding entrapment of air.
6. Pass the syrup through 100 mesh screen and then through filter press until sparkling clear.

LAMIVUDINE ORAL SOLUTION

Epivir oral solution is for oral administration. One milliliter of Epivir oral solution contains 10 mg lamivudine (10 mg/mL) in an aqueous solution and the inactive ingredients artificial strawberry and banana flavors, citric acid (anhydrous), methylparaben, propylene glycol, propylparaben, sodium citrate (dihydrate), and sucrose.

One milliliter of Epivir-HBV oral solution contains 5 mg of lamivudine (5 mg/mL) in an aqueous solution and the inactive ingredients artificial strawberry and banana flavors, citric acid (anhydrous), methylparaben, propylene glycol, propylparaben, sodium citrate (dihydrate), and sucrose.

LEVALBUTEROL HYDROCHLORIDE INHALATION SOLUTION

Xopenex (levalbuterol HCl) inhalation solution is supplied in unit-dose vials and requires no dilution before administration by nebulization. Each 3 mL unit-dose vial contains either

0.63 mg of levalbuterol (as 0.73 mg of levalbuterol HCl) or

1.25 mg of levalbuterol (as 1.44 mg of levalbuterol HCl), sodium chloride to adjust tonicity, and sulfuric acid to adjust the pH to 4.0 (3.3–4.5).

LEVOCARNITINE ORAL SOLUTION

Each 118 mL container of Carnitor (levocarnitine) oral solution contains 1 g of levocarnitine/10 mL. It also contains artificial cherry flavor, D,L-malic acid, purified water, and sucrose syrup. Methylparaben and propylparaben are added as preservatives. The pH is approximately 5.

LINEZOLID FOR ORAL SUSPENSION

Zyvox for oral suspension is supplied as an orange-flavored granule/powder for constitution into a suspension for oral administration. Following constitution, each 5 mL contains 100 mg of linezolid. Inactive ingredients are sucrose, citric acid, sodium citrate, microcrystalline cellulose and carboxymethylcellulose sodium, aspartame, xanthan gum, mannitol, sodium benzoate, colloidal silicon dioxide, sodium chloride, and flavors.

LITHIUM CARBONATE SOLUTION

Each 5 mL of syrup for oral administration contains lithium ion (Li^+) 8 mEq (equivalent to amount of lithium in 300 mg of lithium carbonate) and alcohol 0.3% v/v.

LITHIUM CITRATE SYRUP

Each 5 mL of syrup for oral administration contains lithium ion 8 mEq (equivalent to amount of lithium in 300 mg of lithium carbonate) and alcohol 0.3% v/v. Lithium citrate syrup is a palatable oral dosage form of lithium ion. Lithium citrate is prepared in solution from lithium hydroxide and citric acid in a ratio approximating dilithium citrate.

LOMUSTINE NASAL SPRAY

Manufacturing Directions

1. Place 112.5 g of micronized lomustine into a pressure addition vessel.
2. After sealing and evacuation thereof, add 10.5 kg of HFA 227 that has been aerated with carbon dioxide and adjusted to a pressure of 4.5 bar (20°C) in another pressure addition vessel, in which 312 g of ethanol has been initially introduced.
3. After homogenization of this mixture, dispense the formulation obtained into aluminum containers sealed with metering valves by means of the pressure-filling technique.

LORACARBEF FOR ORAL SUSPENSION

After reconstitution, each 5 mL of Lorabid for oral suspension contains loracarbef equivalent to 100 (0.286 mmol) or 200 mg (0.57 mmol) anhydrous loracarbef activity. The suspensions also contain cellulose, FD&C Red No. 40, flavors, methylparaben, propylparaben, simethicone emulsion, sodium carboxymethylcellulose, sucrose, and xanthan gum.

LORATADINE SYRUP

Bill of Materials

Scale (mg/5 mL)	Item	Material Name	Qty/L (g)
5.00	1	Loratadine	1.00
3000.00	2	Sucrose	600.00
10.00	3	Sodium benzoate	2.00
2.50	4	Saccharin sodium	0.50
12.50	5	Citric acid (monohydrate)	2.50
250.00	6	Glycerin (glycerol)	50.00
765.00	7	Propylene glycol	153.00
6.87	8	Hydrochloric acid 37% (concentrated)	1.51
6.25	9	All fruit flavor	1.25
1.50	10	Raspberry flavor	0.30
—	11	Water purified	QS to 1 L

Manufacturing Directions

Hydrochloric acid (concentrated) is very corrosive. Care should be taken during handling. Rubber gloves and protective goggles should be worn during dispensing and manufacturing.

1. Add 380 g of item 11 to a stainless steel manufacturing vessel, and heat to 90°C to 95°C.
2. Add item 2 while mixing at slow speed at a temperature of 90°C to 95°C. Cool to 50°C.
3. Add items 3 to 6 in order while mixing at low speed at 50°C. Mix for 15 minutes at low speed. Cool to 30°C.
4. Take 13.53 g of item 11 in a stainless steel container. Add item 8 carefully. Add hydrochloric acid solution quantity 13.675 g to the manufacturing vessel. Adjust the pH between 2.3 and 2.4. If required, add the additional quantity and record. Discard the remaining quantity. Mix for 5 minutes.
5. Dissolve item 1 in 145 g of item 7 in a stainless steel drum while stirring. Add to the manufacturing vessel.
6. Rinse the stainless steel drum with 8 g of item 7. Transfer to manufacturing vessel.
7. Add items 9 and 10 into manufacturing vessel. Mix for 5 minutes at low speed.
8. Make up the volume to 1 L with item 11.
9. Filter and fill.

MAFENIDE ACETATE TOPICAL SOLUTION

Sulfamylon for 5% topical solution is provided in packets containing 50 g of sterile mafenide acetate to be reconstituted in 1000 mL of sterile water for irrigation or 0.9% sodium chloride irrigation. After mixing, the solution contains 5% w/v of mafenide acetate. The solution is an antimicrobial preparation suitable for topical administration.

MAGALDRATE INSTANT POWDER FOR DRY SYRUP

Bill of Materials

Scale (mg/sachet)	Item	Material Name	Qty/1000 Sachets (g)
800.00	1	Magaldrate	800.00
640.00	2	Kollidon® CL-M	640.00
200.00	3	Sorbitol, crystalline	200.00
40.00	4	Orange flavor	40.00
40.00	5	Kollidon® 90F	40.00
4.00	6	Coconut flavor	4.00
4.00	7	Banana flavor	4.00
0.80	8	Saccharin sodium	0.80
QS	9	Water	~ 280 mL

Manufacturing Directions

1. Granulate mixture 1 to 4 with solution of items 5 to 9, and pass through a 0.8 mm sieve to obtain free-flowing granules.
2. Fill 2 g in sachets or 20 g in a 100 mL flask. Instant granules in sachets: Suspend 2 g (1 sachet) in a glass of water (800 mg magaldrate).

MAGALDRATE SUSPENSION

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
100.00	1	Magaldrate USP	100.00
80.00	2	Kollidon® CL-M	80.00
20.00	3	Kollidon® 90F	20.00
10.00	4	Orange flavor	10.00
0.50	5	Coconut flavor	0.50
0.80	6	Banana flavor	0.80
0.20	7	Saccharin sodium	0.20
QS	8	Preservatives	QS
QS	9	Water	QS to 1 L

Manufacturing Directions

1. Dissolve or suspend all the solids in water under aseptic conditions; pH should be approximately 9.

MAGALDRATE WITH SIMETHICONE SUSPENSION

Bill of Materials

Scale (mg/5 mL)	Item	Material Name	Qty/L (g)
QS	1	Distilled purified water	285.00 mL
9.00	2	Methylparaben	1.80
1.00	3	Propylparaben	0.20
5.00	4	Benzoic acid	1.00
3.75	5	Saccharin sodium (dihydrate powder)	0.75
400.00	6	Magaldrate (wet cake; 18–20%)	400.00
1.00 g	7	Sorbitol solution (70%)	260.00
12.50	8	Silicon dioxide (colloidal) (International)	2.50
QS	9	Citric acid (hydrous powder)	QS
200.00	10	Dimethyl polysiloxane emulsion (30%)	40.00
0.005 mL	11	Flavor	1.00 mL
1.26 g	12	Glycerin	252.00
25.00 g	13	Potassium citrate monohydrate	5.00
13.30	14	Xanthan gum	2.66

Manufacturing Directions

This product is highly prone to microbial contamination. All equipment coming into contact with the product should be treated with a freshly prepared sodium hypochlorite solution (100 ppm) made with freshly boiled and cooled-down water on the day of use. Bottles and caps should also be so treated. Freshly boiled and cooled deionized water should be used for rinsing.

1. Charge 285 mL purified water into a suitable jacketed tank, and heat to 90°C to 95°C.
2. Add and dissolve parabens, benzoic acid, saccharin sodium, and potassium citrate.
3. While maintaining temperature at 85°C to 90°C, add, in small quantities, half the quantity of magaldrate cake or powder, if used, and disperse well.
4. Adjust speed of the agitator and homogenizer to ensure effective mixing and to maintain free mobility of the suspension. Add sorbitol solution and mix well.
5. Raise the temperature, if necessary, maintaining temperature at 85°C to 90°C.
6. Add in small quantities the remaining half of the magaldrate cake or powder, and disperse well.
7. Mix for 1 hour, and then remove heat. (Adjust speed of the agitator and homogenizer to maintain the mobility of suspension.) Separately blend colloidal silicon dioxide with xanthan gum, and disperse the blend in glycerin with constant mixing.
8. While maintaining temperature at 85°C to 95°C, add and disperse the suspension from the previous step to the main tank, and mix well.
9. Avoid lump formation at any stage.
10. Cool to room temperature.
11. Add dimethyl polysiloxane emulsion, and mix well.
12. Add flavor, and mix well.
13. Dissolve citric acid in twice the quantity of purified water, and adjust pH if necessary.
14. Check and record pH (range: 7.5–8.0). Add purified water to volume, and mix well for a minimum of 30 minutes.
15. Filter through a 180 µm aperture nylon cloth, and store in a suitable tank.

MAGALDRATE WITH SIMETHICONE SUSPENSION

Bill of Materials

Scale (mg/5 mL)	Item	Material Name	Qty/L (g)
QS	1	Water purified	QS to 1 L
9.00	2	Methylparaben	1.80
1.00	3	Propylparaben	0.20
5.00	4	Acid benzoic	1.00
3.75	5	Saccharin sodium powder dihydrate	0.75
2.00 g	6	Magaldrate wet cake (18 to 20%)	400.00
1.00 g	7	Sorbitol solution	260.00
12.50	8	Silicon dioxide colloidal (international)	2.50
QS	9	Acid citric powder hydrous	QS
200.00	10	Dimethyl polysiloxane emulsion (30%)	40.00
0.005 mL	11	Flavor	1.000 mL
1.26 g	12	Glycerin	252.00
25.00 g	13	Potassium citrate monohydrate	5.00
13.30	14	Xanthan gum	2.66

Manufacturing Directions

This product is highly prone to microbial contamination. All equipment coming into contact with the product should be treated with a freshly prepared sodium hypochlorite solution (100 ppm) made with freshly boiled and cooled town water on the day of use. Bottles and caps should also be so treated. Freshly boiled and cooled purified water should be used for rinsing.

1. Charge 285 mL purified water into a suitable jacketed tank, and heat to 90°C to 95°C.
2. Add and dissolve parabens, acid benzoic, saccharin sodium, and potassium citrate.
3. While maintaining temperature at 85°C to 90°C, add, in small quantities, half the quantity of magaldrate cake or powder, if used, and disperse well. (Adjust the speed of agitator and of the homogenizer to ensure effective mixing and to maintain free mobility of the suspension.)
4. Add sorbitol solution and mix well. Raise the temperature, if necessary, maintaining temperature at 85°C to 90°C.
5. Add, in small quantities, the remaining half of magaldrate cake or powder, and disperse well. Mix for 1 hour, and then remove heat. (Adjust the speed of the agitator and of the homogenizer to maintain the mobility of suspension.)
6. Separately blend silicon dioxide colloidal with xanthan gum, and disperse the blend in glycerin with constant mixing.
7. While maintaining temperature at 85°C to 95°C, add and disperse the suspension from previous step to the main tank, and mix well. Avoid lump formation at any stage. Cool to room temperature.
8. Add dimethyl polysiloxane emulsion, and mix well.
9. Add flavor and mix well. Dissolve acid citric in twice the quantity of purified water, and adjust pH if necessary. Check and record pH (range: 7.5–8.0).
10. Add purified water to volume, and mix well for a minimum of 30 minutes.
11. Filter through a 180 micron aperture nylon cloth, and store in a suitable tank.

MEBENDAZOLE ORAL SUSPENSION

Bill of Materials

Scale (mg/5 mL)	Item	Material Name	Qty/L (g)
102.00	1	Mebendazole[a]	20.40
10.00	2	Methylparaben	2.00
1.00	3	Propylparaben	0.20
750.00	4	Propylene glycol	150.00
8.25	5	Sodium citrate	1.65
7.50	6	Saccharin sodium	1.50
0.55	7	Citric acid (monohydrate)	0.11
52.50	8	Microcrystalline cellulose	10.50
25.00	9	Carboxymethylcellulose sodium	5.00
7.50	10	Polysorbate 80	1.50
12.50	11	All fruits flavor	2.50
—	12	Water purified	QS to 1 L

[a] 2 mg/5 mL mebendazole added as an extra to compensate the loss on drying and assay of the material.

Manufacturing Directions

1. Load 300 g of item 12 (25–30°C) in mixer. In it dissolve items 5, 6, and 7 while stirring at a speed of 18 rpm.
2. Dissolve items 2 and 3 in 30 g of item 4 (45°C) in a stainless steel container while stirring by stirrer.
3. Cool to 25°C to 30°C.
4. Add the paraben solution into step 1 while mixing.
5. Disperse item 8 in 200 g of item 12 (25–30°C) in a stainless steel container while stirring by stirrer. Keep aside for 1 hour for complete hydration.
6. Disperse item 9 in 100 g of item 12 (70°C) in a stainless steel container while stirring by stirrer.
7. Cool to 25°C to 30°C. Keep aside for 1 hour for complete gelation. Cooling is necessary for gelation.

8. Dissolve item 10 in 20 g of item 12 (50°C) in a stainless steel container while stirring by stirrer.
9. Cool to 30°C. Add 120 g of item 4 while mixing.
10. Disperse item 1 while mixing. Keep aside for complete levitation.
11. Add the microcrystalline cellulose dispersion and sodium CMC dispersion from step 3 and step 4 into mixer in step 1. Mix and homogenize at mixer speed 18 rpm, homogenizer low speed, and vacuum 0.4 to 0.6 bar for 10 minutes.
12. Add the mebendazole dispersion from step 5 into mixer in step 1. Mix and homogenize at mixer speed 18 rpm, homogenizer low speed, and vacuum 0.4 to 0.6 bar for 10 minutes.
13. Add item 11 into step 6. Make up the volume to 1 L with item 12. Mix at a speed of 18 rpm for 5 minutes.
14. Check the suspension for homogeneity. Transfer the suspension through 630 micron sieve to stainless steel storage tank, previously sanitized by 70% ethanol.

MEBENDAZOLE SUSPENSION

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
20.00	1	Mebendazole	20.00
30.00	2	Lutrol F 127	30.00
1.80	3	Methylparaben	1.80
0.20	4	Propylparaben	0.20
QS	5	Water purified	QS

Manufacturing Directions

1. Place 80% of item 5 in a stainless steel jacketed vessel. Heat to 90°C to 95°C.
2. Add items 3 and 4, and stir to dissolve.
3. Cool to 40°C, and add item 2. Stir to dissolve completely.
4. Add item 1 and mix well. Homogenize if necessary.

MEGESTROL ACETATE ORAL SUSPENSION

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
40.00	1	Megestrol acetate	40.00
100.00	2	Glycerin	100.00
100.00	3	Sorbitol	100.00
0.30	4	Polysorbate 90	0.30
2.20	5	Xanthan gum	2.20
2.00	6	Sodium benzoate	2.00
0.60	7	Sodium citrate	0.60
50.00	8	Sucrose	50.00
0.80	9	Lemon flavor	0.80
QS	10	Water purified	QS to 1 L

Megace oral suspension is supplied as an oral suspension containing 40 mg of micronized megestrol acetate per milliliter. Megace oral suspension contains the following inactive ingredients: alcohol (maximum of 0.06% v/v from flavor), citric acid, lemon-lime flavor, polyethylene glycol, polysorbate 80, purified water, sodium benzoate, sodium citrate, sucrose, and xanthan gum.

Manufacturing Directions

1. Place glycerol, sorbitol, and polysorbate in a suitable container. Mix well.
2. Place xanthan gum in a separate vessel with item 10, and allow overnight hydration.
3. Add sodium citrate, sucrose, sodium benzoate, and flavor to step 1, and then add step 2 to step 1.
4. Pass the gum slurry through a screen.
5. Add megestrol acetate, and pass the suspension through a colloid mill or homogenizer to provide a uniform oral suspension.

MENTHOL AND BENZOCAINE SOLUTION

Bill of Materials

Scale (mg/mg)	Item	Material Name	Qty/kg (g)
QS	1	Vehicle (Pluronic F 108 56.79%, ethanol 21.69%, water 21.52%)	QS to 1 kg
10.00	2	Menthol	10.00
20.00	3	Benzocaine	20.00
0.05	4	Eucalyptus oil	0.05
1.00	5	Sodium saccharin	1.00
0.50	6	Monoammonium glycyrrhizinate	0.50
QS	7	Flavors and colors	QS

Manufacturing Directions

1. Mill and screen the menthol and benzocaine to reduce the product particle size.
2. Add the menthol, benzocaine, sodium saccharin, and monoammonium glycyrrhizinate into a clean vessel.
3. Add eucalyptus oil and ethanol to the vessel.
4. Subsequently, add the poloxamer and water to the vessel.
5. Mix until uniform.

MENTHOL MOUTHWASH

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
10.00	1	Menthol	10.00
10.00	2	Eucalyptus oil	10.00
40.00	3	Cremophor RH 40	40.00
4.50	4	Saccharin sodium	4.50
2.00	5	Sodium citrate	2.00
5.00	6	Citric acid	5.00
50.00	7	Lutrol F 127	50.00
67.00	8	Ethanol 96%	67.00
QS	9	Sicovit colorant	QS
801.00	10	Water	801.00

Manufacturing Directions

1. Mix components 1 to 3, and heat to approximately 60°C.
2. Prepare solution of items 4 to 10, heat to approximately 60°C, and add it slowly to the well-stirred mixture of items 1 to 3.
3. Clear, colored liquids having a fresh mint taste are the desired result.

MESALAMINE RECTAL SUSPENSION ENEMA

The active ingredient in rectal suspension enema, a disposable (60 mL) unit, is mesalamine, also known as 5-aminosalicylic acid. Each rectal suspension enema unit contains 4 g of mesalamine. In addition to mesalamine, the preparation contains the inactive ingredients carbomer 934P, EDTA, potassium acetate, potassium metabisulfite, purified water, and xanthan gum. Sodium benzoate is added as a preservative. The disposable unit consists of an applicator tip protected by a polyethylene cover and lubricated with white petrolatum. The unit has a one-way valve to prevent backflow of the dispensed product.

MESALAMINE RECTAL SUSPENSION

Each rectal suspension enema unit contains 4 g of mesalamine. In addition to mesalamine, the preparation contains the inactive ingredients carbomer 934P, EDTA, potassium acetate, potassium metabisulfite, purified water, and xanthan gum. Sodium benzoate is added as a preservative.

METFORMIN LIQUID

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
100.00	1	Metformin hydrochloride	100.00
400.00	2	Xylitol	400.00
5.00	3	Potassium bicarbonate	5.00
1.20	4	Potassium sorbate	1.20
2.75	5	Sodium saccharin	2.75
0.004 mL	6	Hydrochloric acid	4.00 mL
2.75	7	Wild cherry flavor	2.75
QS	8	Water purified	QS to 1 L

Manufacturing Directions

1. Under continuous stirring, add potassium bicarbonate and metformin hydrochloride to purified water, and dissolve to get a clear solution.
2. Add hydrochloric acid solution as a dilute solution (approximately 1 M) to the mixture of the previous step. This results in carbon dioxide gas formation (effervescent gas).
3. Add xylitol at a temperature of NMT 31°C, and stir to get a clear solution.
4. Continue stirring, and add artificial cherry flavor and saccharin.
5. Adjust the pH to a range of 4.6 to 4.9 using dilute solution of hydrochloric acid (if required).
6. Make up the volume, filter through clarifying grade filter, and fill in approved container.

METOCLOPRAMIDE ORAL SOLUTION

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
4.00	1	Metoclopramide HCl, 10% excess	4.40
0.76	2	Saccharin sodium	0.76
1.00	3	Sorbic acid	1.00
1.48	4	Sodium metabisulfite (sodium disulfite)	1.48
0.10	5	Polyoxyl 35 castor oil (Cremophor EL)	0.10
5.20	6	Sodium citrate	5.20
8.52	7	Citric acid (monohydrate)	8.52
—	8	Water purified	QS to 1 L

Manufacturing Directions

1. Load 80 g of item 8 to the mixer, and heat to 90°C to 95°C.
2. Dissolve items 2 and 3 while stirring. Mix for 15 minutes at high speed to get clear solution.
3. Cool the temperature to 25°C.
4. Transfer the solution to drops manufacturing vessel.
5. Add item 5 to the drops manufacturing vessel at step 4 while stirring to dissolve.
6. Add 8 g of item 8 (25°C) in a separate container, dissolve items 6 and 7 using stirrer, and transfer to the drops manufacturing vessel at step 5.
7. Add item 4 to the drops manufacturing vessel at step 6 while mixing.
8. Add 5 g of item 8 (25°C) in a separate container, and dissolve item 1 using stirrer.
9. Transfer this solution to the drops manufacturing vessel at step 7 while mixing.
10. Check and record the pH (limit: 3.4–3.6).
11. Adjust the pH if required using 5% aqueous solution of citric acid or sodium citrate.
12. Make up the volume to 1 L with item 8 (25°C).
13. Assemble the membrane filter of 0.2 °micron. Filter the solution, and collect the filtrate in clean HDPE containers.

METOCLOPRAMIDE SYRUP

Bill of Materials

Scale (mg/5 mL)	Item	Material Name	Qty/L (g)
30.00	1	Hydroxyethyl cellulose	6.00
4.00	2	Methylparaben	0.80
1.00	3	Propylparaben	0.20
5.00	4	Sorbic acid	1.00
14.25	5	Citric acid (monohydrate)	2.85
4.60	6	Sodium citrate	0.92
7.50	7	Saccharin sodium	1.50
5.00	8	Metoclopramide HCl (14% excess)	1.14
40.00	9	Alcohol (ethanol 95%)	8.00
25.00	10	Propylene glycol	5.00
6.50	11	Flavor	1.30
10.00	12	Caramel	2.00
0.50	13	Flavor	0.10
—	14	Water purified	QS to 1 L

Manufacturing Directions

1. Add 200 g of item 14 to the mixer, and heat to 90°C.
2. Sprinkle item 1 slowly while mixing at 20 rpm in manual mode. Check that item 1 is dispersed completely without forming lumps.
3. Start the homogenizer at high speed with recirculation, vacuum 0.4 bar.
4. Homogenize for 15 minutes at high speed. Cool to approximately 60°C.
5. Add 200 g of item 14 in a storage container.
6. Transfer the homogenized mucilage to the storage container (step 5).
7. Add 500 g of item 14 to the syrup vessel, and heat to 90°C.
8. Add items 2, 3, and 4 to the syrup vessel, and mix at high speed for 15 minutes to dissolve. Start cooling until temperature reaches 50°C to 60°C.
9. Withdraw a portion of the solution, and check that it is clear and colorless.
10. Transfer the mucilage to the syrup vessel, and mix at high speed for 15 minutes. Start cooling, and cool to 30°C.
11. Add 20 g of item 4 (25°C) in a separate container, dissolve items 5 and 6 by using stirrer, and add solution to the manufacturing vessel.
12. Add 10 g of item 14 (25°C) in a separate container, dissolve item 7 by using stirrer, and add solution to the manufacturing vessel.
13. Withdraw a portion of the solution, and check that it is clear and colorless.
14. Add 10 g of item 14 (25°C) in a separate container, dissolve item 8 by using stirrer, and add solution to the manufacturing vessel.
15. Rinse the container with 5 g of item 14 cooled to 25°C, and transfer the rinsings to the syrup vessel. Mix at high speed for 20 minutes.
16. Withdraw a portion of the solution, and check that it is clear and colorless.
17. Mix items 9 and 10 in a clean stainless steel container. Add items 11, 12, and 13, and mix well manually.
18. Transfer the solution to the manufacturing vessel, and mix for 15 minutes at high speed.
19. Make up the volume to 1 L with item 14 (25°C), and finally, mix for 20 minutes at high speed.
20. Check and record the color and pH (limit: 2.9–3.1). Color should be clear to faint yellow.
21. Suspend 1 g of the filter aid in 40 g of cooled item 14 (25°C), and stir well. Allow the filter aid to settle. Decant off the water.
22. Transfer the washed filter aid to the syrup vessel while mixing. Mix for 30 minutes at high speed.
23. Assemble the filter press.
24. Wash the filters using approximately 250 L purified water (25°C) by passing through filters at 0.2 bar.
25. Filter the syrup at 1 bar. Recirculate approximately 100 to 150 °mL syrup.
26. Transfer the filtered syrup to the storage vessel.

METRONIDAZOLE SUSPENSION

Bill of Materials

Scale (mg/5 mL)	Item	Material Name	Qty/L (g)
125.00	1	Metronidazole (use metronidazole benzoate)	40.20
7.50	2	Methylparaben	1.50
1.00	3	Propylparaben	0.20
2500.00	4	Sucrose	500.00
7.50	5	Saccharin sodium	1.50
8.75	6	Sodium phosphate monobasic	1.75
8.75	7	Sodium phosphate dibasic	1.75
40.00	8	Magnesium aluminum silicate	8.00
30.00	9	Microcrystalline cellulose	6.00
650.00	10	Propylene glycol	130.00
7.50	11	Lemon flavor	1.50
7.50	12	Bergamot flavor	1.50
—	13	Water purified	QS to 1 L

Note: For 200 mg/5 mL strength, use 64.400 g of metronidazole benzoate.

Manufacturing Directions

1. Disperse item 1 in item 10 in a stainless steel vessel, using stirrer. Make smooth slurry, and keep aside for use later.
2. Add 186 g of item 13 to a vessel, and heat to 90°C to 95°C. Dissolve items 2 and 3 while mixing.
3. Add and dissolve item 4 while mixing at a temperature of 90°C to 95°C.
4. Cool down to 50°C to 55°C.
5. In a stainless steel container, dissolve item 5 in 4 g of item 13, and add to the vessel while mixing.
6. Filter the syrup. Collect the syrup in stainless steel tank.
7. Disperse item 8 in 120 g of hot item 13 (70–75°C) in stainless steel vessel using stirrer. Keep on stirring for 30 minutes. Transfer the dispersion into mixer by vacuum.
8. Mix and homogenize at temperature 70°C to 80°C, mixer speed 18 rpm, homogenizer at high speed, and vacuum 0.4 to 0.6 bar for 10 minutes.
9. Cool down to 25°C to 30°C.
10. Disperse item 9 in 120 g of item 13 in stainless steel vessel using stirrer. Keep on stirring for 30 minutes to make smooth dispersion.
11. Transfer the filtered syrup from step 7, and transfer microcrystalline cellulose mucilage from step 4 to mixer. Set the mixer to 25°C to 30°C, 18 rpm, high speed, and vacuum 0.4 to 0.6 bar.
12. Mix, and homogenize for 10 minutes.
13. Dissolve items 6 and 7 in 12 g of item 13, and add to mixer while mixing.
14. Add metronidazole benzoate and propylene glycol dispersion (step 1) to mixer.
15. Rinse the drug container with 10 g of item 13, and add the rinsings to mixer to avoid loss.
16. Add items 11 and 12 to mixer. Make up the volume to 1 L with item 13.
17. Mix, and homogenize for 20 minutes at high speed, vacuum 0.4 to 0.6 bar. Check the suspension for homogeneity. Transfer the suspension through 630 micron sieve to stainless steel storage tank, previously sanitized by 70% ethanol.
18. Do not store the bulk suspension more than 48 hours in the storage tank without stirring. Before filling, stir not less than 30 minutes for uniform dispersion to avoid problems of content uniformity.

MINERAL AND MULTIVITAMIN SYRUP

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
6.65	1	Hypophosphorous acid	6.655
16.47	2	Calcium hypophosphite	16.47
31.68	3	Calcium lactate (powder)	31.68
1.00	4	Methylparaben	1.00
0.20	5	Propylparaben	0.20
1.00	6	Benzoic acid	1.00
150.00	7	Sucrose (granular)	150.00
5.20	8	Ferrous gluconate	5.20
2.00	9	Niacinamide (5% excess)	2.10
0.328	10	Riboflavin-5-phosphate sodium	0.33
1.00	11	D-Pantothenyl alcohol (dexpanthenol; 20% excess)	1.20
0.60 µg	12	Vitamin B_{12} (cyanocobalamin) (35% excess)	0.81 mg
0.20	13	Pyridoxine hydrochloride	0.20
0.30	14	Thiamine hydrochloride (regular powder) (55% excess)	0.46
4.782	15	Flavor, raspberry blend	4.78
1.945	16	Flavor, chocolate	1.945
0.642	17	Orange oil (terpeneless, No. 54125)	0.64
0.21	18	Lime oil, distilled	0.215
4.28	19	Alcohol	4.28
2.50	20	Saccharin sodium	2.50
10.00	21	Ascorbic acid (white powder/EP) (45% excess)	14.50
3.00	22	Caramel (acid proof)	3.00
2.00	23	Anhydrous citric acid	2.00
10.0 µg	24	Butylated hydroxyanisole (BHA)	10.00 mg
3.39	25	Corn oil	3.39
0.40	26	Vitamin A palmitate (1.5 MM U/g) (40% excess)	0.56
0.08	27	Viosterol in corn oil (syn. oleovitamin D; 1000 mg/g) (40% excess)	0.112
1.5 g	28	Acacia (special grade)	1.50
0.127	29	Sodium lauryl sulfate (acetone-washed)	0.127
171.00	30	Deionized, purified water	~171
QS	31	Glucose liquid (corn syrup)	QS to 1 L

Manufacturing Directions

Do not expose this preparation to direct sunlight during manufacturing. Riboflavin is sensitive to light.

1. Add 83.7 mL purified water to a stainless steel jacketed tank.
2. Add calcium hypophosphite, calcium lactate, the parabens, and benzoic acid.
3. Heat mixture to 60°C with agitation.
4. Shut off mixer, and wash tank until free of all powders with 25.9 mL purified water.
5. Heat to and maintain a maximum temperature of 100°C until solution is complete. Do not agitate. Avoid loss of water through evaporation; cover opening of tank.
6. After solution occurs, take sample from bottom of tank, and examine for clarity. Solution must be clear.
7. Add hypophosphorous acid (if used) with mixing.
8. Turn off heat, add 222 g glucose, and start agitator. (*Caution*: Use CO_2 cover throughout; wherever water is used, it should be CO_2-saturated water.) Dissolve ferrous gluconate in 7.4 mL water CO_2-saturated by heating.
9. Add 278 g glucose with mixing. Add and dissolve sugar.
10. Allow solution to cool to 35°C, and mix well.
11. To 29.6 mL water, add and dissolve nicotinamide, riboflavin, D-pantothenyl alcohol, vitamin B_{12}, pyridoxine, and thiamine. Mix until solution is complete, and add to tank. Dissolve by heat if necessary.
12. Place raspberry blend flavor and chocolate flavor into tank; place saccharin into tank, and mix until dissolved.
13. Charge ascorbic acid into tank. Mix well.
14. Charge caramel into tank, and mix well.
15. Dissolve citric acid in 3 mL water, and add.
16. Heat corn oil to 50°C to 60°C, and add and dissolve BHA. Ensure the BHA is completely dissolved before continuing.
17. Cool to room temperature. While cooling oil mixture, saturate with CO_2, and maintain heavy CO_2 coverage for balance of operation.
18. Set aside a small amount of this mixture as a rinse for the vitamin A and viosterol containers in previous step.
19. Add vitamin A palmitate and viosterol to the cool corn oil mixture, rinsing the containers with the oil reserved in step 17
20. Add the rinse to the bulk. Mix well.
21. Add the acacia to the oil mixture with good mixing.
22. Dissolve sodium lauryl sulfate in 3 mL CO_2-saturated purified water. To avoid excessive foaming, do not bubble CO_2 gas through the water/sodium lauryl sulfate solution.
23. Add the sodium lauryl sulfate solution to the oil mixture, and stir to a thick creamy emulsion.
24. Add 7.56 g glucose to the emulsion with mixing.
25. Blend 13.33 mL CO_2-saturated purified water with 77.04 g glucose, and add emulsion with stirring.
26. Recycle primary emulsion back into holding tank while setting mill.
27. Homogenize until all oil globules are less than 8 µm in diameter using colloid mill with a very fine setting. Do not change mill setting after removing sample unless samples are unacceptable.
28. Add primary emulsion to syrup solution with mixing; add glucose QS to 965 mL, and mix well. Allow to stand overnight to vent entrapped air.
29. Adjust the volume to 1 L using glucose or glucose and CO_2-saturated water.
30. Strain through 149 µm aperture or similar screen into clean reserve tank, and recheck volume.

MINOXIDIL SOLUTION

Minoxidil 5% w/v; alcohol, 30% v/v; propylene glycol, 50% v/v; and purified water.

MINT–MENTHOL MOUTHWASH

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
20.00	1	Mint oil	20.00
0.40	2	Menthol	0.40
0.90	3	Eucalyptus oil	0.90
10.00	4	Alpha-bisabolol (BASF)	10.00
0.60	5	Thymian oil	0.60
40.00	6	Cremophor RH 40	40.00
4.50	7	Saccharin sodium	4.50
2.00	8	Sodium citrate	2.00
5.00	9	Citric acid	5.00
0.20	10	Sodium fluoride	0.20
50.00	11	Glycerol	50.00
50.00	12	Lutrol F 127	50.00
0.60	13	Salicylic acid	0.60
1.00	14	Benzoic acid	1.00
175.00	15	Sorbitol, crystalline	175.00
216.00	16	Ethanol 96%	216.00
QS	17	Sicovit colorant	QS
QS	18	Water	48.4

Manufacturing Directions

1. Mix components 1 to 6, and heat to approximately 60°C.
2. Prepare solution of items 7 to 18, and heat to approximately 60°C.
3. Add this solution slowly to the well-stirred mixture of items 1 to 6. The result is a clear, colored liquid having a fresh mint taste.

MINT OIL SOLUTION

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
35.00	1	Peppermint oil	35.00
138.00	2	Cremophor RH 40	138.00
520.00	3	Ethanol 96%	520.00
QS	4	Water	307.00

Manufacturing Directions

1. Mix the peppermint oil with Cremophor RH 40, stir well, and slowly add ethanol and water.
2. Clear, colorless liquid is of low viscosity.

MOMETASONE FUROATE NASAL SPRAY

Nasonex nasal spray, 50 µg, is a metered-dose manual-pump spray unit containing an aqueous suspension of mometasone furoate monohydrate equivalent to 0.05% w/w mometasone furoate, calculated on the anhydrous basis, in an aqueous medium containing glycerin, microcrystalline cellulose and carboxymethylcellulose sodium, sodium citrate, 0.25% w/w phenylethyl alcohol, citric acid, benzalkonium chloride, and polysorbate 80. The pH is between 4.3 and 4.9.

MONOSULFIRAM SOLUTION

Bill of Materials

Scale (%, w/w)	Item	Material Name	Qty/kg (g)
25.00	1	Monosulfiram	250.00
10.00	2	Dispersol	100.00
QS	3	Methylated spirit	QS to 1 kg

Manufacturing Directions

1. Liquefy item 1 by warming to 40 C.
2. Place item 3 in a suitable dry stainless steel mixing vessel.
3. Add item 2 to step 2, and then add item 1 with constant stirring until clear solution obtained.
4. Filter through a suitable clarifying filter.

MULTIVITAMIN AND CALCIUM SYRUP

Bill of Materials

Scale (mg/g)	Item	Material Name	Qty/100 g (mg)
0.10	1	Vitamin A palmitate	10.00
0.50 µg	2	Vitamin D 40 million IU/g	0.05
1.00	3	Vitamin E acetate, BASF	100.00
0.02	4	Butylhydroxytoluene	2.00
45.00	5	Cremophor RH 40	4.50 g
100.00	6	Water	10.00 g
450.00	7	Saccharose	45.00 g
2.00	8	Methylparaben	200.00
0.80	9	Citric acid	80.00
96.00	10	Glycerol	9.60 g
0.70	11	Calcium gluconate	70.00
250.00	12	Water	25.00 g
0.15	13	Thiamine hydrochloride, BASF	15.00
0.15	14	Riboflavin 5[1]-phosphate sodium	15.00
0.55	15	Nicotinamide	55.00
0.15	16	Pyridoxine hydrochloride	15.00
3.00	17	Ascorbic acid, crystalline	300.00
1.00	18	Sorbic acid	100.00
50.00	19	Propylene glycol (Pharma)	5.00 g

Manufacturing Directions

1. Heat items 1 to 5 and item 6 separately to approximately 60°C, and mix slowly, stirring well to obtain a clear solution.
2. Dissolve items 7 to 9 in the hot solution of items 10 to 12 to obtain a clear solution.
3. Mix all the solutions upon cooling, and add solutions of items 13 to 19; adjust the pH value to 4.0 to 4.1.
4. Pass nitrogen through the solution for 10 minutes, and fill in bottles under nitrogen cover.

MULTIVITAMIN AND MINERAL SYRUP

Bill of Materials

Scale (mg/tablet)	Item	Material Name	Qty/L (g)
6.65	1	Hypophosphorous acid (50% pure)	6.655
16.47	2	Calcium hypophosphite	16.47
31.68	3	Calcium lactate (powder)	31.68
1.00	4	Methylparaben	1.00
0.20	5	Propylparaben	200.00 mg
1.00	6	Acid benzoic	1.00
150.00	7	Sucrose	150.00
5.20	8	Ferrous gluconate	5.20
2.00	9	Niacinamide (white powder) (5% excess)	2.10
0.32	10	Riboflavin-5-phosphate sodium	328.77 mg
1.00	11	D-Pantothenyl alcohol (dexpanthenol; 20% excess)	1.20
0.00060	12	Vitamin B_{12} (cyanocobalamin; 35% excess)	810.00 µg
0.20	13	Pyridoxine hydrochloride	200.00 mg
0.30	14	Thiamine hydrochloride (powder, regular) (55% excess)	465.00 mg
4.78	15	Flavor, raspberry blend	4.782
1.94	16	Flavor, chocolate	1.945
0.64	17	Orange oil, terpeneless No. 54125	642.00 mg
0.21	18	Lime oil (distilled)	214.975 mg
4.28	19	Alcohol (ethanol, 190 proof)	4.28
2.50	20	Saccharin sodium	2.50
10.00	21	Acid ascorbic (45% excess)	14.50
3.00	22	Caramel (acid proof)	3.00
2.00	23	Anhydrous citric acid	2.00
0.0010	24	Butylated hydroxyanisole (BHA)	10.0 mg
3.39	25	Corn oil	3.39
0.56	26	Vitamin A palmitate (1.5 MM UA/g) (40% excess)	560.00 mg
0.08	27	Viosterol in corn oil (syn. oleovitamin D; 1000 mD/g; D_3 in arachis oil) (40%) excess)	112.00 mg
1.50	28	Acacia	1.50
0.12	29	Sodium lauryl sulfate (acetone washed)	127.41 mg
171.00	30	Purified water	~171
QS	31	Glucose liquid	QS to 1 L

Manufacturing Directions

Do not expose this preparation to direct sunlight during manufacturing. Riboflavin is sensitive to light.

1. Add 83.7 mL of purified water to a stainless steel jacketed tank.
2. Add calcium hypophosphite, calcium lactate, parabens, and benzoic acid.
3. Heat mixture to 60°C with agitation.
4. Shut off mixer, and wash tank free of all powders with 25.9 mL purified water.
5. Heat to and maintain a maximum temperature of 100°C until solution is complete. Do not agitate. Avoid loss of water through evaporation. Cover opening of tank. After solution occurs, take sample from bottom of tank, and examine for clarity. Solution must be clear.
6. Add acid hypophosphorous (if used) with mixing.
7. Turn off heat, add 222 g glucose, and start agitator. (*Caution*: Use CO_2 cover throughout; wherever water is used, it should be CO_2-saturated water.) Dissolve ferrous gluconate in 7.4 mL water CO_2 saturated by heating.
8. Add 278 g glucose with mixing. Add and dissolve sugar.
9. Allow solution to cool to 35°C and mix well.
10. To 29.6 mL water, add and dissolve nicotinamide, riboflavin, D-pantothenyl alcohol, vitamin B_{12}, pyridoxine, and thiamine.
11. Mix until solution is complete and add to tank. Dissolve by heat, if necessary.
12. Place raspberry blend flavor and chocolate flavor into tank.
13. Place saccharin into tank and mix until dissolved.
14. Place ascorbic acid into tank and mix well.
15. Place caramel into tank and mix well.
16. Dissolve citric acid in 3 mL water and add this solution to above.
17. Heat corn oil to 50°C to 60°C and add and dissolve BHA. Ensure the BHA is completely dissolved before continuing.
18. Cool to room temperature. While cooling oil mixture, saturate with CO_2 and maintain heavy CO_2 coverage for balance of operation.
19. Set aside a small amount of this mixture as a rinse for the vitamin A and viosterol containers in previous step.
20. Add vitamin A palmitate and viosterol to the cool corn oil mixture, rinsing the containers with the oil reserved earlier.
21. Add the rinse to the bulk and mix well.
22. Add the acacia to the oil mixture with good mixing.
23. Dissolve sodium lauryl sulfate in 3 mL CO_2-saturated purified water. To avoid excessive foaming, do not bubble CO_2 gas through the water/sodium lauryl sulfate solution.
24. Add the sodium lauryl sulfate solution to the oil mixture and stir to a thick creamy emulsion.
25. Add 7.56 g glucose to the emulsion with mixing.
26. Blend 13.33 mL CO_2-saturated purified water with77.04 g glucose and add emulsion with stirring.
27. Recycle primary emulsion back into the holding tank while setting mill.
28. Homogenize until all oil globules are less than 8 µm indiameter using colloid mill with a very fine

setting. After setting mill, sample. Do not change mill setting after removing sample unless samples are unacceptable.
29. Add primary emulsion to syrup solution with mixing; add glucose QS to 965 mL and mix well.
30. Allow to stand overnight to vent entrapped air. Adjust the volume to 1 L using glucose or glucose and CO_2 saturated water.
31. Strain through 149 µm aperture or similar screen into clean reserve tank and recheck volume.

MULTIVITAMIN DROPS

Bill of Materials

Scale (mg/g)	Item	Material Name	Qty/kg (g)
13600 IU	1	Vitamin A palmitate (1.7 MM IU/g)	8.00
5200 IU	2	Vitamin D3 (40 MM IU/g)	0.13
5.00	3	Vitamin E acetate	5.00
150.0	4	Cremophor EL (or Cremophor RH 40)	150.00
2.00	5	Parabens (Methyl and propyl)	2.00
525.00	6	Water purified	525.00
4.00	7	Thiamine hydrochloride	4.00
2.00	8	Riboflavin 5-phosphate sodium	2.00
2.00	9	Pyridoxine hydrochloride	2.00
2.00	10	Nicotinamide	2.00
0.20	11	Sodium bisulfite	0.20
200.00	12	Propylene glycol	200.00
QS	13	Water purified	10.00
QS	14	Hydrochloric acid	QS

Manufacturing Directions

1. Heat mixture of items 1 to 4 to approximately 60°C; stir strongly and slowly add solution of items 5 and 6 (60°C).
2. To the obtained clear solution, add solution of items 7 to 13.
3. Adjust the pH with item 14 to approximately 4 and QS to volume.

MULTIVITAMIN INFANT DROPS

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
1125 IU	1	Vitamin A palmitate (1.7 mm IU/g) (50% excess)	1.324
416 IU	2	Vitamin D (40 mm IU/g) (cholecalciferol, 25% excess)	0.013
5.00	3	Vitamin E (oily; α-tocopheryl acetate)	5.00
52.50	4	Ascorbic acid (50% excess)	52.50
0.375	5	Thiamine hydrochloride (50% excess)	0.75
0.40	6	Pyridoxine hydrochloride	0.40
8.00	7	Nicotinamide	8.00
0.00125	8	Cyanocobalamin (50% excess)	0.0025
0.82	9	Riboflavin sodium phosphate (5% excess as riboflavin)	0.865
2.50	10	Poloxyl 20 cetostearyl ether (Cetomacrogol 1000)	2.50
12.50	11	Polysorbate 80 (Tween 80)	12.50
0.50	12	Edetate disodium (sodium EDTA)	0.50
3.75	13	Sodium hydroxide	3.75
0.25	14	Saccharin sodium	0.25
300.00	15	Glycerin (glycerol)	300.00
500.00	16	Sorbitol (70% solution)	500.00
50.00	17	Propylene glycol	50.00
1.50	18	Flavor	1.50
3.00	19	Flavor	3.00
1.50	20	Flavor	1.50
—	21	Purified water	QS to 1 L

Manufacturing Directions

The product is a microemulsion and thermolabile. The temperature of solution must not exceed 25°C at the time of processing. Store bulk at temperature 15°C to 20°C under nitrogen protection to avoid discoloration and precipitation. Period of storage should not exceed 48 hours prior to filling in the bottle.

1. Check and record pH of item 21 (limit: 5.0–6.5) and collect 250 g of it in manufacturing vessel. Heat to 90°C to 95°C for 10 minutes, then cool to 20°C to 25°C.
2. Bubble nitrogen gas into cooled item 21 for 20 minutes.
3. Load 200 g of item 21 from first step to the manufacturing vessel.
4. Bubble nitrogen gas during all stages of the process.
5. Charge items 4 to 9 and 12 to 14 one by one to the manufacturing vessel while mixing.
6. Check that all materials are dissolved completely. Solution should be clear.

7. Add item 11 in a separate stainless steel container and heat to 45°C.
8. Mix items 1, 2, 3, and 10 one by one.
9. Mix for 1 hour at slow speed.
10. Add oil phase preparation to the aqueous phase at a rate of 2 mL/min while mixing; keep on bubbling nitrogen gas throughout the process.
11. Add items 15 and 16 to the manufacturing vessel one by one while mixing.
12. Keep on bubbling nitrogen gas throughout the process.
13. Add items 18 to 20 in item 17 and add to the manufacturing vessel while mixing.
14. Adjust the volume to 1 L using nitrogen-bubbled item 21.
15. Mix for 10 minutes at slow speed without aeration.
16. Check pH (limit: 3.7–4.5).
17. Filter the product at 1.5 bar.
18. Recirculate approximately 100 to 150 mL of product.
19. Transfer the filtered product to the storage vessel under a nitrogen blanket.

MULTIVITAMIN INFANT DROPS

Bill of Materials

Scale (mg/0.6 mL)	Item	Material Name	Qty/L
675.00	1	Glycerin, USP (96%)	675.00 g
10.00	2	Nicotinamide niacinamide (white powder) (5% excess)	17.50 g
2.74	3	Riboflavin-51-phosphate sodium (0% excess)	2.74 g
0.50	4	Methyl paraben (powder)	500.00 mg
1.00	5	Benzoic acid	1.00 g
2.10	6	Saccharin sodium (powder)	2.10 g
1.50	7	Thiamine HCl (45% excess)	3.625 g
0.60	8	Pyridoxine HCl	833.34 mg
50.00	9	Ascorbic acid (white powder) (20% excess)	100.00 g
0.257	10	Orange oil terpeneless No. 54125	257.789 mg
0.095	11	Alcohol (ethanol)	95.50 mg
80.00	12	Polysorbate 80	80.00 g
0.186	13	Butylated hydroxyanisole	186.92 mg
400 IU	14	Vitamin D viosterol in corn oil (oleovitamin D) (25% excess)	833.34 mg
5000 IU	15	Vitamin A; use vitamin A palmitate (1500000 AU/g) (50% excessa)	16.66 g
QS	16	Purified water	329 g
QS	17	Carbon dioxide gas	QS

[a] Excess includes 20% manufacturing loss and 30% stability excess.

Manufacturing Directions

Use carbon dioxide cover at all time and use stainless steel 316 or higher resistant equipment.

1. Add 300 mL of purified water and the glycerin into a suitable jacketed tank. Start mixing.
2. Add, in this order, nicotinamide, riboflavin-5-phosphate sodium, Aspetoform M, benzoic acid, and saccharin sodium.
3. Continue mixing for balance of process.
4. Heat to 90°C to 100°C to dissolve ingredients.
5. In a separate tank, boil at least 15 mL of purified water for at least 15 minutes.
6. Cool while bubbling CO2 gas into it and hold at 30°C or lower for use later for making up the volume.
7. Start cooling the main tank. When the temperature reaches 50°C to 60°C, start bubbling CO2 gas through the solution from the bottom of the tank.
8. Continue cooling to 25°C. Continue the CO2 gas protection for the balance of the process.
9. Add and dissolve thiamine HCl, pyridoxine HCl, and ascorbic acid.
10. Dissolve orange oil in alcohol and add.
11. Load approximately 5.25 g of polysorbate 80 into a separate stainless steel container.
12. Heat to 50°C to 60°C; add the butylated hydroxyanisole and dissolve with mixing. Remove heat.
13. Add remaining polysorbate 80 into the container, setting aside a sufficient quantity for rinsing the vitamin containers.
14. Bubble in CO2 gas while mixing slowly. Stop mixing.
15. Add viosterol and vitamin A palmitate.
16. Rinse bottles with remaining polysorbate 80 and drain.
17. Mix slowly for at least 30 minutes or longer, if necessary, to provide a clear solution. Continue to bubble CO2 gas for the entire mixing period.
18. Change CO2 gas protection on main mixing tank to the top to prevent excessive foaming upon addition of polysorbate 80 solution.
19. Add polysorbate 80 solution to the main tank from the bottom of the tank to the top to prevent excessive foaming. Stop mixing.
20. If the volume is less than 1000 mL, adjust the volume with CO2-saturated purified water made above to 1000 mL; mix for at least 1 hour.
21. In a separate tank, boil at least 115 mL of purified water for at least 15 minutes.
22. Cool while bubbling CO2 gas into it, and hold at 30°C or lower for use later. Stop mixing.
23. Allow to stand for at least 4 hours to eliminate entrapped CO2 gas.
24. Readjust volume to 1000 mL with CO2-saturated purified water; mix for at least 1 hour. Stop mixing.

25. Filter through lint-free paper and do not use filter aids.
26. Recirculate product back to mixing tank until clear.
27. Flush storage tank with CO2 gas and continue CO2 gasprotection until product has been filled.
28. Average intake dose is 0.60 mL.

MULTIVITAMIN MINERAL SYRUP

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
6.65	1	Acid hypophosphorous (50% pure)	6.65

1.00	11	D-Pantothenyl alcohol (dexpanthenol) (20% excess)	1.20
0.60	12	Vitamin B12 (cyanocobalamin) (35% excess)	810.00 µg
0.20	13	Pyridoxine hydrochloride	200.00 mg
0.30	14	Thiamine hydrochloride (regular powder) (55% excess)	465.00 mg
4.78	15	Flavor	4.78
1.94	16	Flavor	1.94
0.64	17	Orange oil, terpeneless	642.00 mg
0.21	18	Lime oil, distilled	214.97 mg
4.28	19	Alcohol (190 proof)	4.28
2.50	20	Saccharin sodium	2.50
14.50	21	Acid ascorbic (white powder/EP) (45% excess)	14.50
3.00	22	Caramel (acid proof)	3.00
2.00	23	Anhydrous citric acid (powder/EP)	2.00
0.01	24	Butylated hydroxyanisole (BHA)	10.00 mg
3.39	25	Corn oil	3.39
0.40	26	Vitamin A palmitate (TN, 1.5 MM UA/g) (40% excess)	560.00 mg
0.08	27	Viosterol in corn oil (syn. oleovitamin D; 1000 mD/g; D3 in arachis oil) (40% excess)	112.00 mg
1.50	28	Acacia	1.50
0.12	29	Sodium lauryl sulfate (acetone washed)	127.41 mg
171.00	30	Deionized, purified water	171.00
QS	31	Glucose liquid	QS to 1 L

Manufacturing Directions

Do not expose this preparation during manufacturing to direct sunlight. Riboflavin is sensitive to light.

1. Add 83.7 mL of purified water to a stainless steel jacketed tank.
2. Add calcium hypophosphite, calcium lactate, parabens, and benzoic acid.
3. Heat mixture to 60°C with agitation.
4. Shut off mixer and wash tank free of all powders with 25.9 mL purified water.
5. Heat mixture to and maintain a maximum temperature of 100°C until solution is complete. Do not agitate. Avoid loss of water through evaporation. Cover opening of tank.
6. After solution occurs, take sample from bottom of tank and examine for clarity. Solution must be clear.
7. Add acid hypophosphorous (if used) with mixing.
8. Turn off heat, add 222 g glucose, and start agitator. (*Caution*: Use CO_2 cover throughout; wherever water is used, it should be CO_2-saturated water.) Dissolve ferrous gluconate in 7.4 mL water CO_2 saturated by heating.
9. Add 278 g glucose with mixing. Add and dissolve sugar.
10. Allow solution to cool to 35°C and mix well.
11. To 29.6 mL water, add and dissolve nicotinamide, riboflavin, D-pantothenyl alcohol, vitamin B_{12}, pyridoxine, and thiamine. Mix until solution is complete, and add to tank. Dissolve by heat if necessary.
12. Charge flavors into tank.
13. Charge saccharin into tank, and mix until dissolved.
14. Charge ascorbic acid into tank, and mix well.
15. Charge caramel into tank, and mix well, Dissolve citric acid in 3 mL water and add to tank.
16. Heat corn oil to 50°C to 60°C, and add and dissolve BHA. Ensure the BHA is completely dissolved before continuing.
17. Cool to room temperature. While cooling oil mixture, saturate with CO_2, and maintain heavy CO_2 coverage for balance of operation.
18. Set aside a small amount of this mixture as a rinse for the vitamin A and viosterol containers.
19. Add vitamin A palmitate TN and viosterol to the cool corn oil mixture, rinsing the containers with the reserved oil.
20. Add the rinse to the bulk. Mix well.
21. Add the acacia to the oil mixture with good mixing.
22. Dissolve sodium lauryl sulfate in 3 mL CO_2-saturated purified water.
23. To avoid excessive foaming, do not bubble CO_2 gas through the water/sodium lauryl sulfate solution.
24. Add the sodium lauryl sulfate solution to the oil mixture, and stir to a thick creamy emulsion.
25. Add 7.56 g glucose to the emulsion with mixing.

26. Blend 13.33 mL CO_2-saturated purified water with 77.04 g glucose, and add emulsion with stirring.
27. Recycle primary emulsion back into holding tank while setting mill.
28. Homogenize until all oil globules are less than 8 µm in diameter using colloid mill with a very fine setting.
29. Add primary emulsion to syrup solution with mixing; add glucose QS to 965 mL, and mix well.
30. Allow to stand overnight to vent entrapped air.
31. Adjust the volume to 1 L using glucose or glucose and CO_2-saturated water.
32. Strain through 149 µm aperture or similar screen into clean reserve tank, and recheck volume.
33. Seal tank under heavy CO_2 until filled.

MULTIVITAMIN SYRUP

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/100 mL
170.00 IU	1	Vitamin A palmitate (1.7 U/g)	10.00
2.00 IU	2	Vitamin D (40 million IU/g)	0.05
1.00	3	Vitamin E acetate	100.00
0.02	4	Butylhydroxytoluene	2.00
45.00	5	Cremophor RH 40	4.50 g
100.00	6	Water	10.00 g
450.00	7	Saccharose	45.00 g
2.00	8	Methylparaben	200.00
0.08	9	Citric acid	80.00
9.60	10	Glycerol	9.60 g
250.00	11	Water	25.00 g
0.15	12	Thiamine hydrochloride	15.00
0.15	13	Riboflavin 51-phosphate sodium	15.00
0.55	14	Nicotinamide	55.00
0.15	15	Pyridoxine hydrochloride	15.00
3.00	16	Ascorbic acid (crystalline)	300.00
1.00	17	Sorbic acid	100.00
5.00	18	Propylene glycol (pharma)	5.00 g

Manufacturing Directions

1. Mix items 1 through 5, and heat to 60°C.
2. Separately heat item 2 to approximately 60°C.
3. Mix these two solutions slowly, stirring well to obtain a clear solution.
4. Dissolve items 7 to 9 in the hot solution of items 10 and 11 to obtain a clear solution.
5. Add to solution from step 4.
6. Add items 12 to 18, and adjust the pH to 4.0 to 4.2.
7. Pass nitrogen through the solution for 10 minutes, and fill under nitrogen cover. Provides 1 to 2 RDA/20 mL.

MULTIVITAMIN SYRUP

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/100 mL (mg)
0.17	1	Vitamin A palmitate (1.7 MM IU/g)	17.00
0.001	2	Vitamin D3 (40 MM IU/g)	0.10
0.01	3	Butylhydroxytoluene	1.00
30.00	4	Cremophor RH 40	3.00 g
1.00	5	Parabens	100.00
170.00	6	Water	17.00 g

0.20	8	Riboflavin phosphate sodium	20.00
0.20	9	Pyridoxine hydrochloride	20.00
2.50	10	Ascorbic acid (crystalline)	250.00
50.00	11	Water	5.00 g
—	12	Sugar syrup	Add 100 mL

Manufacturing Directions

1. Heat mixture of items 1 to 4 to approximately 65°C.
2. Stir well, and very slowly add item 6 to warm solution (65°C).
3. Mix with solution of items 7 to 11, and add item 12 to make up the volume. *Note*: Parabens are generally a 1:10 ratio of methyl- and propylparaben.

MULTIVITAMIN WITH FLUORIDE INFANT DROPS

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
8.00	1	Niacin; use niacinamide (5% excess)	8.332
0.60	2	Riboflavin, USP; use riboflavin-5[1]–phosphate sodium (2% excess)	0.83
0.50	3	Methylparaben	0.50
1.00	4	Benzoic acid	1.00
5000 IU	5	Vitamin E; use D-α-tocopheryl PEG-1000 succinate (20% excess)	13.826
400 IU	6	Vitamin D; use viosterol in corn oil (syn. oleovitamin D) (25% excess)	0.522
1500 IU (0.45)	7	Vitamin A palmitate (synthetic A palmitate, 1 MM U/g), USP	1.44
35.00	8	Ascorbic acid (white powder), USP (33% excess)	46.55
0.50	9	Thiamine hydrochloride (44% excess)	0.72
0.40	10	Pyridoxine; use pyridoxine hydrochloride	0.486
0.25	11	Fluoride; use sodium fluoride (powder)	0.5526
4.013	12	Caramel (acid proof)	4.013
0.257	13	Orange oil terpeneless	0.257
QS	14	Alcohol (ethanol; 190 proof)	10.00 mL
QS	15	Distilled purified water	QS
QS	16	Acid hydrochloric	QS
QS	17	Sodium hydroxide	QS
QS	18	Carbon dioxide gas	QS

Manufacturing Directions

Use only stainless steel tanks, and minimize vortex formation to prevent aeration. Product attacks glass, so avoid contact with glass.

1. Charge 350 mL of purified water into the stainless steel jacketed main tank.
2. Start mixing.
3. Add, in this order, niacinamide, riboflavin, sodium fluoride, methylparaben, and benzoic acid.
4. Rinse the interior walls of the tank with approximately 16 mL purified water.
5. Continue mixing for the balance of the process.
6. Heat the main tank to 95°C to dissolve ingredients.
7. When the solution is complete, cool below 85°C (range: 80–90°C).
8. The main tank will have to be heated to 85°C for this step.
9. Add vitamin E to another tank, if necessary, by heating vitamin E container.
10. Melt vitamin E in the tank.
11. Add viosterol and vitamin A, and heat to 60°C to 65°C with mixing.
12. Start bubbling in CO_2.
13. Mix slowly for 10 minutes or longer to produce a clear solution.
14. Start CO_2 gas protection on the main mixing tank, and continue for the balance of the process.
15. With the main batch at 85°C to 90°C, add the solution of vitamins E, D, and A at 60°C to 65°C with mixing.
16. The addition may cause the temperature of the main batch to drop below the specified range, so readjust to 85°C to 90°C.
17. Mix and maintain at this temperature until solution is complete, after which cool to below 30°C.
18. Add the glycerin with mixing.
19. Adjust the temperature to 25°C ± 5°C, and maintain at this temperature before proceeding.
20. Add and dissolve with mixing, in this order, ascorbic acid, thiamine, pyridoxine, and caramel.
21. Rinse the caramel container with approximately 3 mL of water, and add the rinsings.
22. Rinse the tank inner walls and mixer shaft with approximately 3 mL water.
23. Dissolve the orange oil with mixing in the alcohol, and add to the solution.
24. Continue mixing for at least 30 minutes to ensure a homogeneous product.
25. Stop mixing, and take pH (range: 3.1–3.3). If necessary, adjust with 10% sodium hydroxide or 10% hydrochloric acid, prepared by adding 1 mL hydrochloric acid (reagent-grade) with 3.3 mL purified water. Mix.
26. Stop mixing, and allow to stand for at least 4 hours to eliminate entrapped CO_2 gas.
27. In a properly cleaned separate tank, boil at least 65 mL of purified water for at least 15 minutes.
28. Cool while bubbling CO_2 into it, and hold at 30°C.
29. Adjust pH to the range of 3.1 to 3.3.
30. Filter using a lint-free paper; do not use filter aids.
31. Recirculate product back to main mixing tank until clear.
32. Flush a storage tank with CO_2 for at least 10 minutes with the CO_2 valve completely open.
33. Filter product into this storage tank.
34. Fill under CO_2 cover.

MULTIVITAMIN DROPS

Bill of Materials

Scale (mg/g)	Item	Material Name	Qty/kg (g)
8.00	1	Vitamin A palmitate 1.7 mm U/g (BASF)	8.00
0.130	2	Vitamin D_3 40 mm U/g	0.130

2.00	9	Pyridoxine hydrochloride (BASF)	2.00
2.00	10	Nicotinamide	2.00
0.20	11	Sodium bisulfite	0.20
200.00	12	Propylene glycol	200.00
QS	13	Water	10.00 g
QS	14	Hydrochloric acid	QS

Manufacturing Directions

1. Heat mixture of items 1 to 4 to approximately 60°C, and stir strongly.
2. Slowly add solution of items 5 and 6 at 60°C.
3. To the obtained clear solution, add solution of items 7 to 13.
4. Adjust the pH, with item 14, to approximately 4.
5. Bring to volume.

MULTIVITAMIN SYRUP

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/100 mL (g)
0.170	1	Vitamin A palmitate 1.7 MM U/g (BASF)	17.0 mg
0.001	2	Vitamin D3 40 MM U/g	0.1 mg
0.010	3	Butylhydroxytoluene	1.0 mg
30.000	4	Cremophor RH 40	3.00
1.000	5	Parabens	0.10
170.000	6	Water	17.00
0.500	7	Thiamine hydrochloride (BASF)	0.05
0.200	8	Riboflavin phosphate sodium	0.02
0.200	9	Pyridoxine hydrochloride (BASF)	0.02
2.500	10	Ascorbic acid, crystalline (BASF)	0.25
50.000	11	Water	5
QS	12	Sugar syrup	QS to 100 mL

Manufacturing Directions

1. Heat mixture of items 1 to 4 to about 65°C, and stir well.
2. Add item 6 very slowly to the warm solution (65°C).
3. Mix with solution of items 7 to 11, and add item 12 to make up the volume. Parabens are generally a 1:10 ratio of methyl and propyl paraben.

MULTIVITAMIN SYRUP

Bill of Materials

Scale (mg/mL)	Item	Material Nam	Qty/100 mL (g)
170.00 U	1	Vitamin A palmitate 1.7 MM U/g (BASF)	0.010
2.00 U	2	Vitamin D 40 MM U/g	0.05 mg
1.00	3	Vitamin E acetate (BASF)	0.10
0.020	4	Butylhydroxytoluene	0.0020
45.0	5	Cremophor RH 40	4.50
100.00	6	Water	10.00
450.00	7	Saccharose	45.00
2.00	8	Methylparaben	0.20
0.080	9	Citric acid	0.080
9.60	10	Glycerol	9.60
250.00	11	Water	25.00
0.150	12	Thiamine hydrochloride (BASF)	0.015
0.150	13	Riboflavin 5'-phosphate sodium	0.015
0.55	14	Nicotinamide	0.055
0.150	15	Pyridoxine hydrochloride (BASF)	0.015
3.00	16	Ascorbic acid, crystalline (BASF)	0.30
1.00	17	Sorbic acid	0.10
5.00	18	Propylene glycol	5.00

Manufacturing Directions

1. Heat items 1 to 5 and item 2 separately to approximately 60°C, and mix slowly with stirring to obtain a clear solution.
2. Dissolve items 7 to 9 in the hot solution of items 10 and 11 to obtain a clear solution.
3. Mix the cool solutions, and then add items 12 to 18, and adjust the pH value to 4.0 to 4.2.
4. Pass nitrogen for 10 min through the solution, and fill under nitrogen cover. Provides 1 to 2 RDA/20 mL.

MULTIVITAMIN WITH FLUORIDE—INFANT DROPS

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/1000 L (g)
8.00	1	Niacin; use niacinamide, 5% excess	8.33
0.60	3	Riboflavin; use riboflavin-5'-phosphate sodium 2% excess	0.84
0.50 g	5	Methylparaben	0.50
1.00	6	Acid benzoic	1.00
5000 U	7	Vitamin E; use D-alpha tocopheryl polyethylene glycol 1000 succinate, 20% excess	13.82
400 U	9	Vitamin D; use viosterol in corn oil (synthetic oleovitamin D, 25% excess)	0.52
1500 U (0.45 mg)	11	Vitamin A palmitate synthetic A palmitate 1 MM U/g	1.44
35.00	14	Acid, ascorbic white powder, 33% excess	46.55
0.50	15	Thiamine hydrochloride, 44% excess	0.72
0.40	16	Pyridoxine; use pyridoxine hydrochloride	0.48
0.25	18	Fluoride; use sodium fluoride powder	0.55
4.01	20	Caramel acid proof	4.01
0.26	21	Oil orange terpeneless	0.25
0.00001 mL	22	Alcohol, ethanol, 190 proof	0.101 mL
QS	23	Water purified, distilled	QS
QS	24	Acid hydrochloric	QS
QS	25	Sodium hydroxide	QS
QS	26	Carbon dioxide gas	QS

Manufacturing Directions

Use only stainless steel tanks; minimize vortex formation to prevent aeration. Product attacks glass; avoid contact with glass.

1. Charge 350 mL of purified water into the stainless steel jacketed main tank.
2. Start mixing. Add, in order, niacinamide, riboflavin, sodium fluoride, methylparaben, and benzoic acid.
3. Rinse the interior walls of tank with approximately 16 mL purified water.
4. Continue mixing for the balance of the process.
5. Heat the main tank to 95°C to dissolve ingredients. When the solution is complete, cool below 85°C (range 80–90°C).
6. Add vitamin E to another tank, if necessary, by heating vitamin E container. Melt vitamin E in the tank.
7. Add viosterol and vitamin A, and heat to 60°C to 65°C with mixing.
8. Start bubbling in CO_2. Mix slowly for 10 minutes or longer to produce a clear solution. Start CO_2 gas protection on the main mixing tank, and continue for the balance of the process.
9. With the main batch at 85°C to 90°C, add the solution of vitamins E, D, and A at 60°C to 65°C with mixing. The addition may cause the temperature of the main batch to drop below the specified range; readjust to 85°C to 90°C.
10. Mix, and maintain at this temperature until solution is complete, after which cool to below 30°C. Add the glycerin with mixing. Adjust the temperature to the 25°C to 5°C range, and maintain at this temperature before proceeding.
11. Add and dissolve with mixing in the following order: ascorbic acid, thiamine, pyridoxine, and caramel. Rinse the caramel container with approximately 3 mL of water, and add the rinsings.
12. Rinse the tank inner walls and mixer shaft with approximately 3 mL water.
13. Dissolve the orange oil with mixing in the alcohol, and add to solution.
14. Continue mixing for at least 30 minutes to ensure a homogeneous product.
15. Stop mixing. and take pH (range: 3.1–3.3). If necessary, adjust with 10% sodium hydroxide or 10% hydrochloric acid (prepared by adding 1 mL hydrochloric acid, reagent grade, with 3.3 mL purified water). Mix.
16. Stop mixing, and allow to stand for at least 4 hours to eliminate entrapped CO_2 gas.
17. In a separate tank, properly cleaned, boil at least 65 mL of purified water for at least 15 minutes, cool while bubbling CO_2 into it, hold at 30°C, and adjust pH in the range 3.1 to 3.3.
18. Filter using a lint-free paper; do not use filter aids.
19. Recirculate product back to main mixing tank until clear. Flush a storage tank with CO_2 for at least 10 minutes with the CO_2 valve completely open.
20. Filter product into this storage tank. Fill under carbon dioxide cover.

NAFARELIN ACETATE NASAL SOLUTION

Synarel nasal solution contains nafarelin acetate (2 mg/mL, content expressed as nafarelin base) in a solution of benzalkonium chloride, glacial acetic acid, sodium nitride, polysorbate 80, aroma, and water. The solution is isotonic with a pH of 7. It contains no chlorofluorocarbons.

NAPROXEN SUSPENSION

Naprosyn (naproxen) suspension for oral administration contains 125 mg/5 mL of naproxen in a vehicle containing sucrose, magnesium aluminum silicate, sorbitol solution, and

sodium chloride (30 mg/5 mL, 1.5 mEq), methylparaben, fumaric acid, FD&C Yellow No. 6, imitation pineapple flavor, imitation orange flavor, and purified water. The pH of the suspension ranges from 2.2 to 3.7.

NEVIRAPINE SUSPENSION

Viramune oral suspension is for oral administration. Each 5 mL of Viramune suspension contains 50 mg nevirapine (as nevirapine hemihydrate). The suspension also contains the following excipients: carbomer 934P, methylparaben, propylparaben, sorbitol, sucrose, polysorbate 80, sodium hydroxide, and water.

NICOTINE SPRAY

Each 10 mL spray bottle contains 100 mg nicotine (10 mg/mL) in an inactive vehicle containing disodium phosphate, sodium dihydrogen phosphate, citric acid, methylparaben, propylparaben, EDTA, sodium chlorhydroxide or hydrochloric acid (to adjust pH), sorbitol, and purified water.

NIMESULIDE SUSPENSION

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
10.00	1	Nimesulide	10.00
400.00	2	Sucrose	400.00
49.00	3	Propylene glycol	49.00
1.00	4	Methylparaben	1.00
0.20	5	Propylparaben	0.20
2.80	6	Sodium benzoate	2.80
0.20	7	Disodium edetate	0.20
0.50	8	Sodium citrate	0.50
0.10 mL	9	Sorbitol solution 70%	100 mL
4.00	10	Carboxymethyl cellulose sodium	4.00
2.00	11	Aerosil™ 200	2.00
3.30	12	Citric acid	3.30
1.00	13	Hydroxypropyl methylcellulose	1.00
0.48	14	Simethicone emulsion	0.48
QS	15	Flavor	QS
QS	16	Water purified	QS to 1 L

Manufacturing Directions

1. In a suitable stainless steel container, heat item 16 to 70°C.
2. Add and dissolve sodium benzoate, disodium edetate, and sodium citrate.
3. Filter through a filter press.
4. Add sugar till completely dissolved.
5. Filter again through a filter press.
6. In a separate container, place propylene glycol and sorbitol solution. Add carboxymethyl cellulose and Aerosil™, homogenize, and store for a few hours.
7. Add and mix in step 5 hydroxypropyl methylcellulose and simethicone emulsion.
8. Add item 1, and make a slurry in step 6.
9. Add step 7 into step 4, and make up the volume with item 16.

NIMODIPINE CAPSULES

Each liquid-filled capsule contains 30 mg nimodipine in a vehicle of glycerin, peppermint oil, purified water, and polyethylene glycol 400. The soft gelatin capsule shell contains gelatin, glycerin, purified water, and titanium dioxide.

NITROGLYCERIN LINGUAL SPRAY

Nitrolingual pumpspray (nitroglycerin lingual spray 400 µg) is a metered-dose spray containing nitroglycerin. This product delivers nitroglycerin (400 µg per spray, 75 or 200 metered sprays) in the form of spray droplets onto or under the tongue. Inactive ingredients are medium-chain triglycerides, dehydrated alcohol, medium-chain partial glycerides, and peppermint oil.

NOREPHEDRINE SYRUP

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
40.00	1	DL-Norephedrine hydrochloride	40.00
10.00	2	Parabens	10.00
50.00	3	Saccharin sodium	50.00
30.00	4	Kollidon® 90F	30.00
500.00	5	Sorbitol solution	500.00
460.00	6	Water	460.00

Manufacturing Directions

1. Dissolve the parabens in the hot water (90–95°C).
2. Add the sorbitol, cool to room temperature, and dissolve the other components.
3. To prevent discoloration of Kollidon® in the solution during storage, 0.1% to 0.5% of cysteine could be added as antioxidant.
4. Flavors should be added to adjust the required taste.

NOREPHEDRINE SYRUP

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
40.00	1	DL-norephedrine hydrochloride	40.00
4.00	2	Parabens	4.00
5.00	3	Saccharin sodium	5.00
3.00	4	Kollidon® 90F	3.00
500.00	5	Sorbitol solution	500.00
460.00	6	Water	460.00

Manufacturing Directions

1. Dissolve the parabens in the hot water, add the sorbitol, cool to room temperature, and dissolve the other components.
2. To prevent discoloration of Kollidon® in the solution during storage, 0.1% to 0.5% cysteine could be added as an antioxidant.
3. Flavors should be added to adjust the taste as needed.

NYSTATIN ORAL SUSPENSION

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
21.05	1	Nystatin microfine (particle size not less than 90% below 45 (nm), 100% below 80 (im; based on potency of 5500 U/g anhydrous; adjust accordingly; 10% overage)	21.050
600.00	2	Sucrose	600.000
1.80	3	Methyl paraben	1.8000
0.20	4	Propyl paraben	0.2000
150.00	5	Sorbitol (70% solution)	150.000
5.00	6	Microcrystalline cellulose	5.000
10.00	7	Glycerin	10.000
2.00	8	Carboxymethylcellulose sodium	2.000
2.00	9	Polysorbate 80	2.000
50.00	10	Glycerin	50.000
2.50	11	Saccharin sodium	2.500
2.00	12	Flavor	2.000
30.00	13	Alcohol (ethanol 95%)	30.000
QS	14	Sodium hydroxide	0.174
QS	15	Hydrochloric acid (37%)	0.296
—	16	Water purified	QS to 1 L

Manufacturing Directions

1. Add 200 g of item 16 (90–95°C) into mixer, and heat to 90°C to 95°C. Dissolve items 3 and 4 while mixing. Add and dissolve item 2 while mixing at a speed of 18 rpm.
2. Cool down to approximately 50°C to 55°C.
3. Filter the syrup. Collect the syrup in a clean stainless steel tank. Avoid any loss of syrup. Clean the mixer.
4. Transfer the sugar syrup from the stainless steel tank into the mixer.
5. Add 100 g of item 5 into mixer while mixing.
6. Disperse item 6 in the mixture of 50 g of item 16 (25–30°C) and 50 g of item 5 in a stainless steel drum while mixing with stirrer.
7. Disperse item 8 in item 7 in a stainless steel drum while mixing with stirrer. Add 30 g of item 16 (90°C) to the solution. Stir until it becomes clear. Cool to 30°C.
8. Transfer the dispersion from step 3 and 4 into mixer.
9. Mix and homogenize under vacuum 0.4 to 0.6 bar for 10 minutes.
10. Stop homogenizer, and keep continuously mixing.
11. Dissolve item 9 in 50 g of item 16 (50°C) in a stainless steel container while mixing by stirrer.
12. Add item 10 into it. Disperse item 1 while stirring by stirrer. Cool to 30°C.
13. Add the drug dispersion into mixer while mixing.
14. Dissolve item 11 in 15 g of item 16 (25–30°C) in a stainless steel container while stirring by stirrer. Add to mixer while mixing.
15. Add items 12 and 13 into mixer while mixing.
16. Homogenize high speed and vacuum 0.4 to 0.6 bar. Mix and homogenize for 10 minutes.
17. Dissolve item 14 in 7 g of item 16 in a stainless steel container. Add slowly into the mixer while mixing.
18. Dissolve item 15 carefully in 7 g of item 16 in a stainless steel container. Slowly add the required quantity into mixer to adjust the pH between 6.8 and 7.1.
19. Make up the volume with item 16 to 1 L. Mix for 5 minutes.

NYSTATIN SUSPENSION

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
22.50	1	Nystatin	22.50
57.50	2	Kollidon® CL-M	57.50
20.00	3	Kollidon® 90F	20.00
248.00	4	Sorbitol	248.00
5.00	5	Citric acid	5.00
QS	6	Water purified	QS to 1 L

Manufacturing Directions

1. Charge items 1, 2, and 4 in a suitable stainless steel vessel, and suspend in item 6; mix well.
2. Add item 3 slowly while stirring and in small portions, and then follow up with vigorous stirring to obtain smooth suspension. Homogenize if necessary.
3. Fill.

OFLOXACIN OTIC SOLUTION

Floxin otic contains 0.3% (3 mg/mL) ofloxacin with benzalkonium chloride (0.0025%), sodium chloride (0.9%), and water for injection. Hydrochloric acid and sodium hydroxide are added to adjust the pH to 6.5 ± 0.5.

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
3.00	1	Ofloxacin	3.00
QS	2	Vehicle (Pluraflo 1220 45.48%, ethanol 5.05%, propylene glycol 41.23%, anhydrous glycerin 8.24)	QS to 1 L
QS	3	Perfumes	QS

Manufacturing Directions

1. Add propylene glycol, Pluraflo, glycerin, and ethanol to a clean vessel.
2. While stirring, add ofloxacin. Stir until a clear solution is obtained.
3. Add perfume, and mix until uniform.

OMEPRAZOLE SOLUTION

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
20.00	1	Omeprazole free base	20.00
QS	2	Vehicle (Pluronic F127 34.07%, ethanol 10.43%, propylene glycol 42.18%)	1.00 L
1.00	3	Sodium metabisulfite	1.00
1.00	4	Disodium EDTA	1.00
2.50	5	Sodium saccharin	2.50
1.10	6	Monoammonium glycyrrhizinate	1.10
3.50	7	Acesulfame	3.50
QS	8	Flavor	QS

Manufacturing Directions

1. Add propylene glycol and poloxamer to a clean vessel (main mix).
2. While stirring, heat the mixture as appropriate to sufficiently melt the poloxamer.
3. Once a uniform solution is obtained, remove from heat source, and continue mixing.
4. In a separate vessel (alcohol premix), add alcohol, omeprazole base, and monoammonium glycyrrhizinate, and mix until uniform. In another vessel (water premix), add water, EDTA, sodium saccharin, acesulfame, and sodium metabisulfite.
5. Mix until all materials are dissolved.
6. Add the alcohol-containing premix to the main mixing vessel containing the poloxamer.
7. Mix until uniform.
8. While stirring, add the water-containing premix to the main vessel, and continue to mix until uniform.
9. Subsequently, add desired flavor component, and mix until uniform.

ONDANSETRON HYDROCHLORIDE DIHYDRATE ORAL SOLUTION

Each 5 mL of Zofran oral solution contains 5 mg of ondansetron HCl dihydrate equivalent to 4 mg of ondansetron. Zofran oral solution contains the inactive ingredients citric acid anhydrous, purified water, sodium benzoate, sodium citrate, sorbitol, and strawberry flavor.

ORCIPRENALINE SULFATE AND CLOBUTINOL HYDROCHLORIDE SYRUP

Bill of Materials

Scale (mg/5 mL)	Item	Material Name	Qty/L (g)
10.00	1	Natrosol 250 M	2.00
5.00	2	Sodium benzoate	1.00
10.00	3	Saccharin sodium	2.00
35.00	4	Ammonium chloride	7.00
26.24	5	Citric acid	5.25
4.00	6	Sodium citrate	0.80
2500.00	7	Sorbitol 70%	500.00
500.00	8	Glycerin	100.00
5.00	9	Orciprenaline sulfate, 5% excess	1.05
20.00	10	Clobutinol hydrochloride	4.20
40.40	11	Alcohol	8.00
0.20	12	Anise oil	0.04
QS	13	Water purified	QS to 1 L

Manufacturing Directions

1. In a suitable stainless steel mixing vessel, place 250 mL of item 13, and heat to 70°C to 75°C. Add item 1, and mix well; cool to room temperature.
2. In 10 mL of item 13, add and dissolve item 2 and 3, and add to step 2.
3. In 20 mL of item 13, add and dissolve item 4, and add to preceding step.

4. In a separate vessel, add items 50 mL of item 13 and item 8, and mix well; add to step 4.
5. In 50 mL of item 13, add item 10, mix well, and add to step 5.
6. In 50 mL of item 13, add item 9, mix well, and add to step 6.
7. Adjust pH to 3.1 to 3.2 using item 5.
8. Filter through 100 micron filter and then through filter pads.
9. Make up volume, and fill.

OXITROPIUM AND FORMOTEROL NASAL SPRAY

1. Place 4.5 g of micronized oxitropium bromide and 0.675 g of micronized formoterol fumarate into a pressure addition vessel.
2. After sealing and evacuation thereof, add 10.5 kg of HFA 227, which has previously been aerated with carbon dioxide and adjusted to a pressure of 6.25 bar (20°C) in another pressure addition vessel.
3. After homogenization of this mixture, dispense the suspension obtained into aluminum containers sealed with metering valves by means of the pressure-filling technique.

Oxycodone Hydrochloride Oral Concentrate Solution: Each 1 mL of Oxyfast concentrate solution contains oxycodone hydrochloride, 20 mg citric acid, FD&C Yellow No. 10, sodium benzoate, sodium citrate, sodium saccharine, and water.

Oxymetazoline Hydrochloride Congestion Nasal Spray: Each milliliter of Afrin severe congestion nasal spray contains oxymetazoline hydrochloride 0.05%. It also contains benzalkonium chloride, benzyl alcohol, camphor, EDTA, eucalyptol, menthol, polysorbate 80, propylene glycol, sodium phosphate dibasic, sodium phosphate monobasic, and water.

OXYMETAZOLINE HYDROCHLORIDE NASAL SOLUTION

Bill of Materials

Scale (g/100 mL)	Item	Material Name	Qty/L (g)
0.025	1	Oxymetazoline hydrochloride	0.25
0.03	2	Benzalkonium chloride (50% solution)	0.30
0.05	3	Disodium edetate (sodium EDTA)	0.50
0.025	4	Sodium hydroxide (1 N solution)	0.25
1.02	5	Monobasic sodium phosphate	10.20
2.80	6	Dibasic sodium phosphate	28.00
—	7	Water purified	QS to 1 L

Manufacturing Directions

Oxymetazoline hydrochloride is toxic. There is a risk of serious intoxication if inhaled or swallowed. This product is a colorless, odorless, membrane-filtered solution. Thus, make sure that the receiving tank for the filtered solution is cleaned and free of any contamination.

1. Heat 1 kg of item 7 to 85°C to 90°C in the manufacturing vessel. Hold the temperature at 85°C to 90°C for 30 minutes.
2. Cool item 7 to 30°C, and transfer into mobile tank.
3. Add 900 g of cold item 7 (from step 2) into manufacturing vessel.
4. Dissolve items 1 to 6 one by one while mixing in manufacturing vessel containing cold item 7.
5. After completion of addition, mix for 20 more minutes.
6. Make up the volume to 1 L with cold item 7, and finally, mix for 20 minutes.
7. Check and record the pH (limit: 6.8 ± 0.1).
8. Filter the solution through Sartorius prefilter and membrane filter 0.2 μm into receiving tanks.

OXYMETAZOLINE MOISTURIZING NASAL SPRAY

Each milliliter of Afrin extra moisturizing nasal spray contains oxymetazoline hydrochloride, 0.05%. It also contains benzalkonium chloride, EDTA, glycerin, polyethylene glycol, polyvinylpyrrolidone, propylene glycol, sodium phosphate dibasic, sodium phosphate monobasic, and water.

OXYMETAZOLINE NASAL SPRAY

Each milliliter of Afrin original nasal spray and pump mist contains oxymetazoline hydrochloride 0.05%. It also contains benzalkonium chloride, EDTA, polyethylene glycol, polyvinylpyrrolidone, propylene glycol, sodium phosphate dibasic, sodium phosphate monobasic, and water.

OXYMETAZOLINE SINUS NASAL SPRAY

Each milliliter of Afrin sinus nasal spray contains oxymetazoline hydrochloride 0.05%. It also contains benzalkonium chloride, benzyl alcohol, camphor, EDTA, eucalyptol, menthol, polysorbate 80, propylene glycol, sodium phosphate dibasic, sodium phosphate monobasic, and water.

OXYMETAZOLINE NASAL SOLUTION

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
QS	1	Vehicle (Pluronic F127 40.27%, ethanol 26.18%, water 33.55%)	QS to 1 L
0.50	2	Oxymetazoline	0.50
1.50	3	Tyloxapol	1.50
0.40	4	Dibasic sodium phosphate	0.40
1.30	5	Monobasic potassium phosphate	1.30
0.40	6	Benzalkonium chloride	0.40
2.60	7	Chlorhexidine gluconate	2.60
0.10	8	Disodium EDTA	0.10

Manufacturing Directions

1. Add the dibasic sodium phosphate, monobasic potassium phosphate, disodium EDTA, benzalkonium chloride, and oxymetazoline HCl to a clean vessel.
2. Add tyloxapol, chlorhexidine gluconate, and ethanol to the vessel.
3. Subsequently, add the poloxamer and water to the vessel.
4. Mix until uniform.

PEPTIDE TOPICAL LIQUID

Formulation

Peptide such as thymic fraction 5, glycerin 44.5, propylene glycol 44.9, methyl nicotinate 0.1, water 50, polysorbate 80, 0.5% by weight.

PHENIRAMINE MALEATE SYRUP

Bill of Materials

Scale (mg/5 mL)	Item	Material Name	Qty/L (g)
15.00	1	Pheniramine maleate	3.00
2980.00	2	Sugar	596.00
5.40	3	Methylparaben	1.08
0.60	4	Propylparaben	0.11
0.60	5	Citric acid monohydrate	0.11
1.50	6	Sodium citrate	0.30
3.50	7	Flavor	0.70
QS	8	Water purified	QS to 1 L

Manufacturing Directions

1. Charge 700 mL item 8 in a suitable mixing vessel, and heat to 90°C to 95°C.
2. Add and mix item 2.
3. Add items 3 and 4, and mix to dissolve.
4. In separate vessels in approximately 100 mL item 8, add and dissolve items 5 to 7 and item 1 separately.
5. Add the two mixtures in step 3 to step 2 at room temperature.
6. Make up the volume.

PHENOBARBITAL, HYOSCYAMINE SULFATE, ATROPINE SULFATE, AND SCOPOLAMINE HYDROBROMIDE ELIXIR

Each 5 mL (teaspoonful) of elixir (23% alcohol) contains phenobarbital 16.2 mg, hyoscyamine sulfate 0.1037 mg, atropine sulfate 0.0194 mg, and scopolamine hydrobromide 0.0065 mg; D&C Yellow No. 10, FD&C Blue No. 1, FD&C Yellow No. 6, flavors, glucose, saccharin sodium, and water.

PHENYLEPHRINE TANNATE AND CHLORPHENIRAMINE TANNATE PEDIATRIC SUSPENSION

Rynatan® pediatric suspension is an antihistamine/nasal decongestant combination available for oral administration as a suspension. Each 5 mL (one teaspoonful) of the slate purple-colored, natural strawberry, artificial currant-flavored suspension contains phenylephrine tannate 5 mg, chlorpheniramine tannate 4.5 mg, benzoic acid, FD&C Blue No. 1, FD&C Red No. 3, FD&C Red No. 40, FD&C Yellow No. 5, flavors (natural and artificial), glycerin, kaolin, magnesium aluminum silicate, methylparaben, pectin, purified water, saccharin sodium, and sucrose.

PHENYLEPHRINE TANNATE AND PYRILAMINE TANNATE SUSPENSION

RYNA-12 S suspension is an antihistamine/nasal decongestant combination available for oral administration as a suspension. Each 5 mL (one teaspoonful) of the pink-colored, natural strawberry, artificial currant-flavored suspension contains phenylephrine tannate 5 mg, pyrilamine tannate 30 mg, benzoic acid, FD&C Red No. 3, flavors (natural and artificial), glycerin, kaolin, magnesium aluminum silicate, methyl paraben, pectin, purified water, saccharin sodium, and sucrose.

PHENYLPROPANOLAMINE, CHLORPHENIRAMINE, DEXTROMETHORPHAN, AND VITAMIN C SYRUP

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
150.00	1	Polyethylene glycol 400	150.00
21.66	2	Acetaminophen	21.66
0.075 mL	3	Glycerin	75.000 mL
0.35 mL	4	Sorbitol solution	350.000 mL
1.00	6	Acid, benzoic	1.00
1.75	7	Saccharin sodium, powder, dihydrate	1.75
0.91	8	Phenylpropanolamine hydrochloride	0.92
0.065	9	Chlorpheniramine maleate (10% excess)	0.073
0.66	10	Dextromethorphan hydrobromide	0.67
20.00	11	Sodium CMC premium low viscosity	0.02
70.00	12	Dye	0.070
6.00	13	Dye	0.006
5.00	14	Ascorbic acid; use sodium ascorbate fine powder	5.62
0.50	15	Flavor orange	0.50
0.25	16	Flavor orange	0.25
QS	17	Carbon dioxide gas	QS
QS	18	Water purified	QS to 1 L

Manufacturing Directions

1. In a covered stainless steel container, heat 500 mL water to boiling. Boil for 30 minutes.
2. Turn off the heat, and while keeping the container covered, cool the water to 30°C while purging it with carbon dioxide.
3. Keep this water in a covered container blanketed with carbon dioxide gas, and use where indicated.
4. Transfer to the main stainless steel mixing tank the polyethylene glycol 400, cover, start bubbling CO_2 gas, and then while mixing, slowly heat to 60°C to 65°C. Maintain at this temperature.
5. While mixing, add and dissolve the acetaminophen. Maintain the temperature and CO_2 protection.
6. When all the acetaminophen has dissolved, add, while mixing, the glycerin and sorbitol.
7. Continue mixing while maintaining the temperature and CO_2 gas protection until used later. Do not allow the temperature to go above 65°C. During this mixing period, remove samples through the bottom valve of the mixing tank, and inspect for clarity. Return samples to the mixing tank.
8. Continue mixing and sampling until absolutely clear.
9. In a separate stainless steel mixing tank, add 300 mL water, cover, and then heat to 90°C.
10. While maintaining at this temperature, start bubbling CO_2 gas and then while mixing, add and dissolve successively the benzoic acid, saccharin sodium, and phenylpropanolamine hydrobromide.
11. Continue mixing until all have dissolved. Reduce the temperature to 60°C to 65°C while mixing. Do not force cool.
12. To the solution in the main mixing tank, add, while mixing and bubbling CO_2 gas, the solution from the preceding step. Rinse the container with two lots of 5 mL carbon dioxide–saturated water, and add the rinsings to the batch while mixing.
13. Continue mixing for 15 minutes while maintaining the temperature at 60°C to 65°C and CO_2 gas protection.
14. While mixing the batch, sprinkle on the sodium CMC.
15. Continue mixing until all the sodium CMC has been dispersed. Check to be sure there are no undissolved lumps.
16. Add CO_2-saturated water from step 15 and mix while cooling the batch to 30°C. Dissolve the dyes in 10 mL carbon dioxide–saturated water, and then add to the batch with mixing.
17. Rinse the container with two lots of 5 mL of the same water, and add the rinsings to the batch. Mix until a homogeneously colored batch is formed.
18. Stop bubbling in CO_2 gas, but maintain CO_2 protection of the tank headspace. In a stainless steel container, dissolve the sodium ascorbate in 25 mL carbon dioxide–saturated water, taking care to minimize exposure of the solution to air or light.
19. Mix all solutions, add rinsings where necessary, and continue mixing for 15 minutes.
20. Add the flavors, complete the batch to 1 L with carbon dioxide–saturated water, and mix well for 1 hour.
21. Stop mixing, saturate the headspace with CO_2, and leave overnight to release any entrapped air.

PHENYLPROPANOLAMINE, CHLORPHENIRAMINE, DEXTROMETHORPHAN, AND VITAMIN C SYRUP

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
150.00	1	PEG-400 (low color), NF	150.00
21.66	2	Acetaminophen, USP	21.66
0.075 mL	3	Glycerin, USP (96%)	75.00 mL
0.35 mL	4	Sorbitol; use sorbitol solution, USP	350.00 mL
1.00	5	Benzoic acid, USP	1.00
1.75	6	Saccharin sodium (dihydrate powder), USP	1.75
0.91	7	Phenylpropanolamine hydrochloride, USP	916.70 mg
0.06	8	Chlorpheniramine maleate, USP (plus 10% manufacturing)	73.30 mg
0.66	9	Dextromethorphan hydrobromide, USP	667.00 mg
20.00	10	Sodium CMC (premium low viscosity)	20.00
70.00	11	Dye	70.00 mg
6.00	12	Dye	6.00 mg
5.00	13	Ascorbic acid; use sodium ascorbate (fine powder)	5.62
0.50	14	Flavor, orange	500.00 mg
0.25	15	Flavor, orange	250.00 mg
QS	16	Carbon dioxide gas	QS
QS	17	Purified water, USP	QS to1 L

Manufacturing Directions

Manufacture under complete CO_2 protection. Bubble the CO_2 gas through the solution from the bottom of the tank.

If excessive foaming occurs, change CO_2 gas protection from the bottom to the top of the tank. Minimize vortex formation while mixing to prevent aeration of the product.

1. In a covered stainless steel container, heat 500 mL of water to boiling. Boil for 30 minutes.
2. Turn off the heat; while keeping the container covered, cool the water to 30°C while purging the water with CO_2.
3. Keep this water in a covered container blanketed with CO_2 gas, and use where indicated.
4. Transfer the PEG-400 to the main stainless steel mixing tank, and cover.
5. Start bubbling CO_2 gas; while mixing, slowly heat to 60°C to 65°C. Maintain at this temperature.
6. While mixing, add and dissolve the acetaminophen. Maintain the temperature and CO_2 protection.
7. When all the acetaminophen has dissolved, add, while mixing, the glycerin and sorbitol.
8. Continue mixing while maintaining the temperature and CO_2 gas protection until mixture is used later.
9. Do not allow the temperature to go above 65°C.
10. During this mixing period, remove samples through the bottom valve of the mixing tank, and inspect for clarity; return samples to the mixing tank. Continue mixing and sampling until absolutely clear.
11. In a separate stainless steel mixing tank, heat 300 mL of water, covered, to 90°C.
12. While maintaining at this temperature, start bubbling CO_2 gas.
13. While mixing, add and dissolve successively the benzoic acid, saccharin sodium, and phenylpropanolamine hydrobromide. Continue mixing until all have dissolved.
14. Reduce the temperature to 60°C to 65°C while mixing. Do not force-cool.
15. Add the solution from preceding step to the solution in the main mixing tank while mixing and bubbling CO_2 gas.
16. Rinse the container with two lots of 5 mL of CO_2-saturated water, and add the rinsings to the batch while mixing.
17. Continue mixing for 15 minutes while maintaining the temperature at 60°C to 65°C and under CO_2 gas protection.
18. While mixing the batch, sprinkle on the sodium CMC.
19. Continue mixing until all the sodium CMC has been dispersed.
20. Check on the absence of any undissolved lumps.
21. Add CO_2-saturated water from step 3 to 900 mL, and mix while cooling the batch to 30°C.
22. Dissolve the dyes in 10 mL of CO_2-saturated water, and then add to the batch with mixing.
23. Rinse the container with two lots of 5 mL of the same water, and add the rinsings to the batch.
24. Mix until a homogeneously colored batch is formed.
25. Stop bubbling in CO_2 gas, but maintain CO_2 protection of the tank headspace.
26. In a stainless steel container, dissolve the sodium ascorbate in 25 mL of CO_2-saturated water, taking care to minimize exposure of the solution to air or light.
27. Mix all solutions, add rinsings where necessary, and continue mixing for 15 minutes.
28. Add the flavors, complete the batch to 1 L with CO_2 saturated water, and mix well for 1 hour.
29. Stop mixing, saturate the headspace with CO_2, and leave overnight to release any entrapped air.

PHENYLPROPANOLAMINE CONTROLLED-RELEASE CAPSULES

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
33.00	1	Phenylpropanolamine	33.00
QS	2	Vehicle (Pluraflo 1220 70.12%, ethanol 2.26%, anhydrous glycerin 16.35%)	QS to 1 L
1.00	3	Sodium metabisulfite	1.00
1.00	4	Disodium EDTA	1.00

Manufacturing Directions

1. Add alcohol, propylene glycol, EDTA, sodium metabisulfite, and phenylpropanolamine to a clean vessel, and begin mixing.
2. Subsequently, add Pluraflo and glycerin to the vessel.
3. Mix until uniform.
4. This liquid may be filled into hard gelatin capsules that are then banded to prevent leakage, or it may be used as the fill for a soft elastic gelatin capsule. One capsule is made to contain 0.75 mL of the liquid and, taken three times daily, provides controlled release of the phenylpropanolamine active. After swallowing, the gelatin shell dissolves in the gastrointestinal tract, and the liquid fill immediately transforms into a slow-dissolving gel that provides controlled release of the phenylpropanolamine.

PHENYTOIN SUSPENSION

Each teaspoonful of suspension contains 125 mg phenytoin, with maximum alcohol content not greater than 0.6%. It also contains carboxymethylcellulose sodium; citric acid, anhydrous; flavors; glycerin; magnesium aluminum silicate; polysorbate 40; purified water; sodium benzoate; sucrose; vanillin; and FD&C Yellow No. 6.

PHENYTOIN SUSPENSION

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
50.00	1	Phenytoin	50.00
80.00	2	Kollidon® CL-M	80.00
10.00	3	Kollidon® 90F	10.00
QS	4	Preservative	QS
QS	5	Water purified	QS to 1 L

Manufacturing Directions

1. Charge in a suitable stainless steel-jacketed vessel item 5, and heat to 90°C to 95°C.
2. Add and dissolve preservatives (e.g., parabens). Stir to complete solution.
3. Cool to 40°C.
4. Add item 3, and dissolve.
5. Add item 2, and suspend.
6. Add item 1, and suspend. Homogenize if necessary.
7. Fill.

PIPENZOLATE METHYL BROMIDE AND PHENOBARBITAL DROPS

Bill of Materials

Scale (mg/5 mL)	Item	Material Name	Qty/L (g)
20.00	1	Pipenzolate methyl bromide	4.00
30.00	2	Phenobarbital	6.00
350.00	3	Alcohol	70.00
1000.00	4	Propylene glycol	200.00
450.00	5	Propylene glycol	90.00
33.00	6	Sodium saccharin	6.66
2500.00	7	Glycerin	500.00
5.00	8	Peppermint oil	1.00
1.65	9	Flavor	0.33
1.65	10	Flavor	0.33
0.20	11	Dye	0.04
10.00	12	Sodium citrate	2.00
17.70	13	Citric acid monohydrate	3.54
QS	14	Water purified	QS to 1 L

Manufacturing Directions

1. Charge 150 mL item 14 in a suitable stainless steel vessel, heat to 90°C for 1 hour, and then cool to room temperature.
2. Add items 1, 6, 11, 12, and 13, and mix well.
3. In a separate vessel, place items 4 and 7, and mix well for 10 minutes.
4. In a separate vessel, place items 2, 3, 5, flavors, and item 7, and mix well.
5. Add step 4 to step 3, and mix well.
6. Add step 5 to step 1, make up volume, and mix well.
7. Fill.

PODOFILOX SOLUTION

Condylox is the brand name of podofilox, an antimitotic drug that can be chemically synthesized or purified from the plant families *Coniferae* and *Berberidaceae* (e.g., species of Juniperus and Podophyllum). Condylox 0.5% solution is formulated for topical administration. Each milliliter of solution

contains 5 mg of podofilox in a vehicle containing lactic acid and sodium lactate in alcohol 95%.

POLIDOCANOL WOUND SPRAY

Bill of Materials

Scale (mg/g)	Item	Material Name	Qty/kg (g)
5.00	1	Polidocanol	5.00
50.00	2	Kollidon® VA 64	50.00
50.00	3	Ethocel® 20	50.00
20.00	4	Lutrol E 400	20.00
675.00	5	Ethyl acetate	675.00
200.00	6	Isopropanol	200.00

Manufacturing Directions

1. Dissolve the items 1 to 4 in the solvent mixture of items 5 and 6.
2. Fill the solution into spray cans with the necessary quantity of propellant (e. g., propane/butane) or in a mechanical pump bottle.

POLYVINYLPYRROLIDONE–IODINE GARGLE SOLUTION

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
10.00	1	Polyvinylpyrrolidone–iodine, powder, 35% excess	13.500
10.00	2	Glycerin (96%)	10.000
QS	3	Water purified	QS to 1 L

Manufacturing Directions

Wear gloves and mask during all phases of manufacturing and filling. Do not keep the lid of the manufacturing or storage tank open unless necessary, as iodine may be liberated.

1. Add 600 mL purified water to a suitable stainless steel manufacturing tank.
2. Add polyvinylpyrrolidone–iodine powder slowly to first step (with continuous stirring).
3. Stir for 30 minutes or until a clear brown solution is obtained.
4. Add glycerin to the manufacturing tank. Stir until uniform solution is obtained.
5. Make up volume to 1 L with purified water, and mix well for 5 minutes.
6. Check pH (range: 2–4). Filter the solution through a 100 mesh nylon cloth, and transfer to a stainless steel storage tank.
7. Keep the storage tank tightly closed.

POLYVINYLPYRROLIDONE–IODINE GARGLE SOLUTION CONCENTRATE

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
100.00	1	Polyvinylpyrrolidone–Iodine 30/06	100.00
10.00	2	Propylene glycol (pharma)	10.00
90.00	3	Ethanol 96%	90.00
800.00	4	Water	800.00

Manufacturing Directions

1. Dissolve the polyvinylpyrrolidone–iodine in the solvent mixture.
2. Brown transparent liquid: Dilute 10 mL of the concentrate with approximately 100 mL water before use.

POLYVINYLPYRROLIDONE–IODINE LIQUID SPRAY

Bill of Materials

Scale (mg/g)	Item	Material Name	Qty/kg (g)
100.00	1	Polyvinylpyrrolidone–Iodine 30/06	100.00
150.00	2	Kollidon® VA 64	150.00
750.00	3	*n*-Propanol	750.00
750.00	4	Ethanol	750.00

Manufacturing Directions

1. Dissolve Kollidon® VA 64 in the mixture of solvents.
2. Slowly add polyvinylpyrrolidone–iodine to the well-stirred solution.
3. Fill in aerosol cans with propellants such as propane and butane or with manual valves.

POLYVINYLPYRROLIDONE–IODINE MOUTHWASH

Bill of Materials

Scale (mg/g)	Item	Material Name	Qty/kg (g)
100.0	1	Polyvinylpyrrolidone–Iodine	100.0
5.0	2	Sodium saccharin	5.0
2.0	3	Menthol	2.0
0.5	4	Oil aniseed	0.5
0.5	5	Eucalyptus oil	0.5
160.0	6	Polyethylene glycol 400	160.0
300.0	7	Ethanol	300.0
440.0	8	Water purified	440.0

Manufacturing Directions

1. Dissolve polyvinylpyrrolidone–iodine powder and sodium saccharin in 440 g water to obtain a clear solution.
2. In a separate container, add alcohol, and mix and dissolve aniseed oil, eucalyptus oil, menthol, and polyethylene glycol 400 to obtain a clear solution.
3. Add solution from step 1 and mix with stirring. Package in HDPE plastic bottles.

POLYVINYLPYRROLIDONE–IODINE MOUTHWASH AND GARGLE SOLUTION CONCENTRATE

Bill of Materials

Scale (mg/g)	Item	Material Name	Qty/kg (g)
75.00	1	Polyvinylpyrrolidone–Iodine 30/06	75.00
5.00	2	Saccharin sodium	5.00
150.00	3	Water	150.00
2.00	4	Menthol	2.00
1.00	5	Anise oil + eucalyptus oil, 1+1	1.00
150.00	6	Lutrol E 400	150.00
500.00	7	Ethanol 96%	500.00

Manufacturing Directions

1. Dissolve polyvinylpyrrolidone–iodine and saccharin in water, and mix with solution of items 4 to 7.
2. A brown, transparent liquid having a fresh odor is formed.
3. Dilute 10 to 20 mL with a glass of water. A brown liquid is obtained having a fresh taste.

POLYVINYLPYRROLIDONE–IODINE SCRUB

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
75.00	1	Polyvinylpyrrolidone–iodine, powder, 40% excess	105.000
250.00	2	Sodium lauryl sulfate	250.000
35.00	3	Lauric diethanolamide	35.000
QS	4	Water purified, distilled	QS to 1 L

Manufacturing Directions

1. Add 600 mL purified water to a suitable stainless steel manufacturing tank.
2. Add, by sprinkling, sodium lauryl sulfate in the manufacturing tank.
3. Continue to mix slowly under vacuum, and begin to heat until product temperature is 70°C.
4. Continue to mix vigorously under vacuum at 65°C to 70°C for 15 minutes or until completely dissolved. Do not add detergent quickly, as a gel may form that is difficult to dissolve. Stop mixer, release vacuum, and open tank.
5. Add and disperse the previously broken lauric diethanolamide in the warmed solution in preceding step.
6. Maintain vacuum, and then mix vigorously for 30 minutes at 65°C to 70°C or until completely dissolved.
7. Slowly cool under vacuum to room temperature with slow mixing. Do not force cool with cold water; otherwise, the mixture will adhere to the walls of the manufacturing tank.
8. When temperature reaches 30°C, release vacuum, and open tank.
9. While mixing slowly, add polyvinylpyrrolidone–iodine in small portions.
10. Rinse the container of polyvinylpyrrolidone–iodine with 150 mL purified water, and add to the main tank. Do not keep the lid of the manufacturing or storage tank open unless necessary, as iodine may be liberated.
11. Mix under vacuum until a clear, reddish-brown solution is obtained.
12. Make volume to 1 L with purified water, and mix well under vacuum for at least 15 minutes to ensure product uniformity and to deaerate the product.
13. Stop mixing, release the vacuum, and open the tank.
14. Check and record pH (range: 3–6).
15. Filter the solution through 100 mesh nylon cloth.

POLYVINYLPYRROLIDONE–IODINE SOLUTION

Bill of Materials

Scale (mg/g)	Item	Material Name	Qty/kg (g)
100.00	1	Polyvinylpyrrolidone–iodine 30/06	100.00
0.230	2	Texapon K 12	0.230
1.40	3	Sodium biphosphate	1.40
0.30	4	Sodium citrate	0.30
20.80	5	Sodium hydroxide solution, 1 M	20.80
10.00	6	Glycerol	10.00
864.20	7	Water	864.20

Manufacturing Directions

1. Dissolve Texapon K 12 in solution of items 3 to 7.
2. Slowly add polyvinylpyrrolidone–iodine to the well-stirred solution. This creates a brown, transparent liquid having a pH of 4.5.

POLYVINYLPYRROLIDONE–IODINE SOLUTION

Bill of Materials

Scale (mg/g)	Item	Material Name	Qty/kg (g)
100.00	1	Polyvinylpyrrolidone–Iodine 30/06	100.00
10.00	2	Natrosol® HR 250	10.00
2.00	3	Lutrol F 127	2.00
32.00	4	Sodium hydroxide, 1 M solution	32.00
856.00	5	Water	856.00

Manufacturing Directions

1. Dissolve Lutrol F 127 and then Natrosol® in the water.
2. As soon as both are dissolved, slowly add the polyvinylpyrrolidone–iodine to the well-stirred solution.
3. Adjust the pH with the sodium hydroxide solution to about 3.5.

POLYVINYLPYRROLIDONE–IODINE SOLUTION

Bill of Materials

Scale (mg/g)	Item	Material Name	Qty/kg (g)
20.00	1	Tylose M 300	20.00
2.00	2	Texapon K 12	2.00
595.00	3	Citric acid solution 0.1 M	595.00
283.00	4	Sodium biphosphate solution 0.2 M	283.00

Manufacturing Directions

1. Dissolve Tylose M 300 in the mixture of the citric acid and sodium biphosphate solutions.
2. Add Texapon, and slowly dissolve the polyvinylpyrrolidone–iodine. This creates a brown, clear solution having a desirable viscosity and a pH of 3 to 4.

POLYVINYLPYRROLIDONE–IODINE SOLUTION

Bill of Materials

Scale (mg/g)	Item	Material Name	Qty/kg (g)
100.00	1	Polyvinylpyrrolidone–iodine 30/06	100.00
3.00	2	Lutrol F 127	3.00
5.00	3	Lutrol E 400	5.00
432.00	4	Citric acid 0.1 M solution	432.00
460.00	5	$Na_2HPO_4 \cdot 12H_2O$ 0.2 M solution	460.00

Manufacturing Directions

1. Dissolve the polyvinylpyrrolidone–iodine (and Lutrol F 127) in the mixture of the buffer solutions (and Lutrol E 400).
2. A brown, clear solution is formed that has a low viscosity and a pH of about 4.5.
3. Items 2 and 3 can be deleted and compensated with item 5.

POLYVINYLPYRROLIDONE–IODINE SOLUTION

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/1000 Tabs. (g)
100.00	1	Polyvinylpyrrolidone–iodine powder, 35% excess	135.00
9.318	2	Acid, citric, anhydrous, powder	9.318
14.62	3	Sodium phosphate, dibasic, anhydrous	14.62
QS	4	Water purified, distilled	QS to 1 L

Manufacturing Directions

1. Add 600 mL purified water to a suitable stainless steel manufacturing tank. With gentle stirring, add citric acid into the purified water in the manufacturing tank.
2. Stir for 10 minutes or until completely dissolved. During this mixing period, remove samples from the bottom valve of the manufacturing tank, and inspect for clarity.
3. Return samples to the manufacturing tank.

4. Continue mixing and sampling until the solution is completely clear.
5. With gentle stirring, add sodium phosphate, dibasic, into the solution. Stir for 10 minutes or until completely dissolved. During this mixing period, remove samples from the bottom valve of the manufacturing tank, and inspect for clarity. Return samples to the manufacturing tank.
6. Continue mixing and sampling until the solution is completely clear. Make up volume to 1 L with purified water, and mix well for 5 minutes.
7. Check and record pH (range: 4.8–5.2). Filter the solution through a 100 mesh nylon cloth.
8. Transfer into a suitable stainless steel storage tank, and keep tightly closed. This solution should be freshly prepared, and should not be stored for more than 24 hours.
9. Dissolve polyvinylpyrrolidone–iodine in about 600 mL citric acid–phosphate buffer (pH 5) solution (made previously) in a suitable stainless steel mixing tank.
10. Stir evenly for 10 minutes or until a clear, brown solution is obtained. Make up volume to 1 L with citric acid–phosphate buffer solution.
11. Mix well for 10 minutes.
12. Check and record pH (range: 3.0–4.5).
13. Filter the solution through a 100 mesh nylon cloth.
14. Transfer into a suitable stainless steel storage tank, and keep tightly closed.

POLYVINYLPYRROLIDONE–IODINE SURGICAL SCRUB

Bill of Materials

Scale (mg/g)	Item	Material Name	Qty/kg (g)
75.00	1	Polyvinylpyrrolidone–Iodine 30/06	75.00
250.00	3	Lutensit AES	250.00
40.00	4	Monoamide 150 MAW	40.00
QS	6	Floral bouquet	QS
635.00	7	Water	635.00

Manufacturing Directions

1. Dissolve monoamide in hot water, and cool to room temperature.
2. Dissolve polyvinylpyrrolidone–iodine.
3. Add Lutensit to form a brown, clear, viscous solution.

POLYVINYLPYRROLIDONE–IODINE SURGICAL SCRUB

Bill of Materials

Scale (mg/g)	Item	Material Name	Qty/kg (g)
75.00	1	Polyvinylpyrrolidone–Iodine 30/06	75.00
250.00	2	Neutronyx S 60	250.00
40.00	3	Super Amide L 9	40.00
QS	4	Floral bouquet	QS
635.00	5	Water	635.00

Manufacturing Directions

1. Dissolve Super Amide in hot water, and then cool.
2. Dissolve polyvinylpyrrolidone–iodine, and add Neutronyx.
3. A brown, clear viscous solution is formed, with pH of about 3.4.

POLYVINYLPYRROLIDONE–IODINE VAGINAL DOUCHE CONCENTRATE

Bill of Materials

Scale (mg/g)	Item	Material Name	Qty/kg (g)
100.00	1	Polyvinylpyrrolidone-iodine 30/06	100.00
5.00	2	Lutrol E 400	5.00
3.00	3	Lutrol F 127	3.00
432.00	4	Citric acid, 0.1 M solution	432.00
460.00	5	$Na_2HPO_4 \cdot 12H_2O$, 0.2 M solution	460.00

Manufacturing Directions

1. Dissolve polyvinylpyrrolidone–iodine and Lutrol F 127 in the mixture of the buffer solutions with Lutrol E 400.
2. A brown, clear solution is created having a low viscosity and a pH of about 4.3.

POLYVINYLPYRROLIDONE–IODINE VISCOUS SOLUTION

Bill of Materials

Scale (mg/g)	Item	Material Name	Qty/kg (g)
10.00	1	Polyvinylpyrrolidone–Iodine 30/06	10.00
15.00	2	Natrosol HR 250	15.00
QS	3	Buffer	QS
QS	4	Water	975.00

Manufacturing Directions

1. Dissolve polyvinylpyrrolidone–iodine and Natrosol in the well-stirred water.
2. Clear, brown, viscous liquid (viscosity [Brookfield] of 7500 mPas) is obtained.

POLYVINYLPYRROLIDONE–IODINE MOUTHWASH

Bill of Materials

Scale (mg/g)	Item	Material Name	Qty/kg (g)
100.00	1	Polyvinylpyrrolidone (PVP)–Iodine	100.00
5.00	2	Saccharin sodium	5.00
2.00	3	Menthol	2.00
0.50	4	Aniseed oil	0.50
0.50	5	Eucalyptus oil	0.50
160.00	6	PEG-400	160.00
300.00	7	Ethanol	300.00
QS	8	Purified water	QS to 1 kg

Manufacturing Directions

1. Dissolve PVP–iodine powder and saccharin sodium in 440 g of water to obtain a clear solution.
2. In a separate container, add alcohol.
3. Mix and dissolve aniseed oil, eucalyptus oil, menthol, and PEG-400 to obtain a clear solution.
4. QS with water.
5. Add solution from step 4 and mix with stirring.
6. Package in HDPE plastic bottles.

POVIDONE–IODINE CONCENTRATES FOR BROILERS AND CATTLE

Bill of Materials

Scale (mg/g)	Item	Material Name	Qty/kg (g)
200.00	1	Polyvinylpyrrolidone (PVP)–Iodine 30/06	200.00
50.00	2	Texapon® K 12	50.00
50.00	3	Cremophor NP 14	50.00
73.00	4	Tartaric acid	73.00
43.00	5	Sulfuric acid, diluted	43.00
100.00	6	Ethanol 96%	100.00
QS	7	Water	QS to 1 kg

Manufacturing Directions

1. Dissolve surfactant items 2 and 3 in solution of items 4 to 7, and slowly add PVP–iodine.
2. Brown, transparent liquids having a pH of about 1 is obtained.
3. Dilute about 3 mL of the concentrate with 1 L of water prior to use.

POVIDONE–IODINE FOAM SPRAY

Bill of Materials

Scale (mg/g)	Item	Material Name	Qty/kg (g)
100.00	1	Polyvinylpyrrolidone (PVP)–Iodine 30/06	100.00
0.10	2	Cremophor A 25	0.10
QS	3	Water	QS to 1 kg

Manufacturing Directions

1. Dissolve PVP–iodine in the solution of Cremophor A 25 in water.
2. Fill the aerosol cans with 90 parts of this solution and 10 parts of propane plus 1 part butane.

POVIDONE–IODINE GARGLE

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
10.00	1	Polyvinylpyrrolidone-Iodine (powder) (35% excess)	13.50
10.00	2	Glycerin, USP (96%)	10.00
—	3	Purified water, USP	QS to1 L

Manufacturing Directions

Wear gloves and mask during all phases of manufacturing and filling. Do not keep the lid of the manufacturing or storage tank open unless necessary, as iodine may be liberated.

1. Add 600 mL purified water to a suitable stainless steel manufacturing tank.
2. Slowly add povidone–iodine powder to the water (with continuous stirring).
3. Stir for 30 minutes or until a clear, brown solution is obtained.
4. Add glycerin to the manufacturing tank.
5. Stir until uniform solution is obtained.
6. Make up volume to 1 L with purified water, and mix well for 5 minutes.
7. Check pH (range: 2.0–4.0).
8. Filter the solution through a 100 mesh nylon cloth, and transfer to a stainless steel storage tank.
9. Keep the storage tank tightly closed.

POVIDONE–IODINE GARGLE SOLUTION CONCENTRATE

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
100.00	1	Polyvinylpyrrolidone (PVP)–Iodine 30/06	100.00
10.00	2	Propylene glycol	10.00
90.00	3	Ethanol (96%)	90.00
800.00	4	Water	800.00

Manufacturing Directions

1. Dissolve the PVP–iodine in the solvent mixture to produce a brown transparent liquid.
2. Dilute 10 mL of the concentrate with approximately 100 mL of water prior to use.

POVIDONE–IODINE LIQUID SPRAY

Bill of Materials

Scale (mg/g)	Item	Material Name	Qty/kg (g)
100.00	1	Polyvinylpyrrolidone (PVP)–Iodine 30/06	100.00
150.00	2	Kollidon® VA 64	150.00
750.00	3	*n*-Propanol	750.00
750.00	4	Ethanol	750.00

Manufacturing Directions

1. Dissolve Kollidon® VA 64 in the mixture of solvents, and slowly add PVP–iodine to the well-stirred solution.
2. Fill in aerosol cans with propellants such as propane and butane or with manual valves.

POVIDONE–IODINE MOUTHWASH AND GARGLE SOLUTION CONCENTRATE

Bill of Materials

Scale (mg/g)	Item	Material Name	Qty/kg (g)
75.00	1	Polyvinylpyrrolidone (PVP)–Iodine 30/06	75.00
5.00	2	Saccharin sodium	5.00
150.00	3	Water	150.00
2.00	4	Menthol	2.00
1.00	5	Anise oil + eucalyptus oil (1+1)	1.00
150.00	6	Lutrol E 400	150.00
500.00	7	Ethanol (96%)	500.00

POVIDONE–IODINE POWDER SPRAY

Bill of Materials

Scale (mg/g)	Item	Material Name	Qty/kg (g)
250.00	1	Polyvinylpyrrolidone (PVP)–Iodine 30/06	250.00
250.00	2	Maize PO_4 aerosol	250.00
15.00	3	Isopropyl myristate	15.00
100.00	4	Dow Corning® 344 fluid	100.00
500.00	5	Pentane	500.00
220.00	6	Propane + butane (1+3)	220.00

Manufacturing Directions

1. Suspend PVP–iodine and maize PO_4 aerosol in the liquid mixture of items 3 to 5.
2. Fill in aerosol cans with the propellants.

POVIDONE–IODINE PUMP SPRAY

Bill of Materials

Scale (mg/g)	Item	Material Name	Qty/kg (g)
10.00	1	Polyvinylpyrrolidone (PVP)–Iodine 30/06	10.00
100.00	2	Water	100.00
1.00	3	Potassium iodide	1.00
100.00	4	Xylitol	100.00
787.50	5	Propylene glycol	787.50
1.00	6	Menthol (crystalline)	1.00
0.50	7	Peppermint oil (double rectified)	0.50

Manufacturing Directions

1. Dissolve potassium iodide in water, warm up to 40°C, and dissolve xylitol.
2. At room temperature, dilute with propylene glycol, dissolve PVP–iodine, and add flavors to produce a clear, brown liquid with a sweet, refreshing taste.

POVIDONE–IODINE SHAMPOO

Bill of Materials

Scale (mg/g)	Item	Material Name	Qty/kg (g)
75.00	1	Polyvinylpyrrolidone (PVP)–Iodine 30/06	75.00
250.00	2	Neutronyx® S 60	250.00
40.00	3	Super Amide® L9	40.00
5.0–7.0	4	Natrosol® 250 HR	5.0–7.0
—	5	Water	QS to 1 kg

Manufacturing Directions

1. Dissolve Super Amide® and Natrosol® in hot water (about 60°C); then, dissolve PVP–iodine.
2. After cooling, incorporate Neutronyx®.
3. A brown, clear solution is obtained.
4. The viscosity can be changed by modification of the amount of Natrosol® 250 HR.

POVIDONE–IODINE SOLUTION

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
100.00	1	Povidone–Iodine powder (35% excess)	135.00
9.318	2	Anhydrous citric acid (powder)	9.318
14.62	3	Anhydrous sodium phosphate (dibasic)	14.62
QS	4	Purified water	QS to 1 L

Manufacturing Directions

Wear gloves and mask during all phases of manufacturing and filling. Do not keep the lid of the manufacturing or storage tank open unless necessary, as iodine may be liberated.

1. Citric acid–phosphate buffer solution (pH 5): Add 600 mL purified water to a suitable stainless steel manufacturing tank.
2. With gentle stirring, add citric acid to the purified water in the manufacturing tank.
3. Stir for 10 minutes or until completely dissolved.
4. During this mixing period, remove samples from the bottom valve of the manufacturing tank, and inspect for clarity.
5. Return samples to the manufacturing tank.
6. Continue mixing and sampling until the solution is completely clear.
7. With gentle stirring, add dibasic sodium phosphate to the solution.
8. Stir for 10 minutes or until completely dissolved.
9. During this mixing period, remove samples from the bottom valve of the manufacturing tank, and inspect for clarity.
10. Return samples to the manufacturing tank.
11. Continue mixing and sampling until the solution is completely clear.
12. Make up volume to 1 L with purified water, and mix well for 5 minutes.
13. Check and record pH (range: 4.8–5.2).
14. Filter the solution through a 100 mesh nylon cloth.
15. Transfer into a suitable stainless steel storage tank, and keep tightly closed.
16. This solution should be freshly prepared and should not be stored for more than 24 hours.
17. Preparation of solution: Dissolve povidone–iodine in approximately 600 mL of citric acid/phosphate buffer (pH 5) solution in a suitable stainless steel mixing tank.
18. Stir evenly for 10 minutes or until a clear brown solution is obtained.
19. Make up volume to 1 L with citric acid/phosphate buffer solution.

20. Mix well for 10 minutes.
21. Check and record pH (range: 3.0–4.5).
22. Filter the solution through a 100 mesh nylon cloth.
23. Transfer into a suitable stainless steel storage tank, and keep it tightly closed.

POVIDONE–IODINE SOLUTION

Bill of Materials

Scale (mg/g)	Item	Material Name	Qty/kg (g)
100.00	1	Polyvinylpyrrolidone (PVP)–Iodine 30/06	100.00
3.00	2	Lutrol F 127	3.00
5.00	3	Lutrol E 400	5.00
432.00	4	Citric acid (0.1 M solution)	432.00
460.00	5	$Na_2HPO_4 \cdot 12H_2O$ (0.2 M solution)	460.00

Manufacturing Directions

1. Dissolve the PVP–iodine (and Lutrol F 127) in the mixture of buffer solutions (and Lutrol E 400).
2. Brown clear solutions having a low viscosity and pH of approximately 4.5.
3. Items 2 and 3 can be deleted and compensated with item 5.

POVIDONE–IODINE SOLUTION

Bill of Materials

Scale (mg/g)	Item	Material Name	Qty/kg (g)
100.00	1	Polyvinylpyrrolidone (PVP)–Iodine 30/06	100.00
0.23	2	Texapon® K 12	0.23
1.40	3	Sodium biphosphate	1.40
0.30	4	Sodium citrate	0.30
20.80	5	Sodium hydroxide (1 M solution)	20.80
10.00	6	Glycerol	10.00
QS	7	Water	QS to 1 kg

Manufacturing Directions

1. Dissolve Texapon K 12 in solution of items 3 to 7, and slowly add PVP–iodine to the well-stirred solution.
2. The brown, transparent liquid has a pH of 4.5.

POVIDONE–IODINE SOLUTION

Bill of Materials

Scale (mg/g)	Item	Material Name	Qty/kg (g)
100.00	1	Polyvinylpyrrolidone (PVP)–Iodine 30/06	100.00
10.00	2	Natrosol® HR 250	10.00
2.00	3	Lutrol F 127	2.00
32.00	4	Sodium hydroxide (1 M solution)	32.00
QS	5	Water	QS to 1 kg

Manufacturing Directions

1. Dissolve Lutrol F 127 and then Natrosol® in the water.
2. As soon as both are dissolved, slowly add the PVP–iodine to the well-stirred solution.
3. Adjust the pH with the sodium hydroxide solution to approximately 3.5.

POVIDONE–IODINE SOLUTION

Bill of Materials

Scale (mg/g)	Item	Material Name	Qty/kg (g)
20.00	1	Tylose® M 300	20.00
2.00	2	Texapon® K 12	2.00
595.00	3	Citric acid (0.1 M solution)	595.00
283.00	4	Sodium biphosphate (0.2 M solution)	283.00

Manufacturing Directions

1. Dissolve Tylose® M 300 in the mixture of the citric acid and sodium biphosphate solutions.
2. Add Texapon®, and slowly dissolve the PVP–iodine.
3. The brown, clear solution has a pH of 3 to 4.

POVIDONE–IODINE SCRUB

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
75.00	1	Polyvinylpyrrolidone–Iodine (powder) (40% excess)	105.00
250.00	2	Sodium lauryl sulfate	250.00
35.00	3	Lauric diethanolamide	35.00
—	4	Distilled purified water, USP	QS to 1 L

Manufacturing Directions

1. Add 600 mL purified water to a suitable stainless steel manufacturing tank.
2. Add, by sprinkling, the sodium lauryl sulfate to the manufacturing tank.
3. Continue to mix slowly under vacuum, and begin to heat until product temperature is 70°C.
4. Continue to mix vigorously under vacuum at 65°C to 70°C for 15 minutes or until completely dissolved.
5. (*Note*: Do not add detergent quickly, as a gel may form that is difficult to dissolve.) Stop mixer, release vacuum, and open tank.
6. Add and disperse the previously broken lauric diethanolamide in the warmed solution from the previous step.
7. Maintain vacuum, and mix vigorously for 30 minutes at 65°C to 70°C or until completely dissolved.
8. Slowly cool under vacuum to room temperature with slow mixing. (*Note*: Do not force cool with cold water; otherwise, the mixture will adhere to the walls of the manufacturing tank.) When temperature reaches 30°C, release vacuum, and open tank.
9. While mixing slowly, add povidone–iodine in small portions.
10. Rinse the container of povidone–iodine with 150 mL purified water, and add to the main tank. (*Note*: Do not keep the lid of the manufacturing or storage tank open unless necessary, as iodine may be liberated.) Mix under vacuum until a clear reddish-brown solution is obtained.
11. Make volume up to 1 L with purified water, and mix well under vacuum for at least 15 minutes to ensure product uniformity and to deaerate the product.
12. Stop mixing, release the vacuum, and then open the tank.
13. Check and record pH (range: 3–6).
14. Filter the solution through 100 mesh nylon cloth.

POVIDONE–IODINE SURGICAL SCRUB

Bill of Materials

Scale (mg/g)	Item	Material Name	Qty/kg (g)
75.00	1	Polyvinylpyrrolidone (PVP)–Iodine 30/06	75.00
250.00	2	Neutronyx® S 60	250.00
40.00	3	Super Amide® L9	40.00
QS	4	Floral bouquet	QS
QS	5	Water	QS to 1 kg

Manufacturing Directions

1. Dissolve Super Amide® in hot water, cool, dissolve PVP–iodine, and add Neutronyx® to produce a brown, clear viscous solution with pH of approximately 3.4.

POVIDONE–IODINE SURGICAL SCRUB

Bill of Materials

Scale (mg/g)	Item	Material Name	Qty/kg (g)
75.00	1	Polyvinylpyrrolidone (PVP)–Iodine 30/06	75.00
250.00	2	Lutensit® AES	250.00
40.00	3	Monoamide® 150 MAW	40.00
QS	4	Floral bouquet	QS
QS	5	Water	QS to 1 kg

Manufacturing Directions

1. Dissolve Monoamide® in hot water, cool, dissolve PVP–iodine, and add Lutensit® to produce a brown, clear, viscous solution.

POVIDONE–IODINE VAGINAL DOUCHE CONCENTRATE

Bill of Materials

Scale (mg/g)	Item	Material Name	Qty/kg (g)
100.00	1	Polyvinylpyrrolidone (PVP)–Iodine 30/06	100.00
5.00	2	Lutrol E 400	5.00
3.00	3	Lutrol F 127	3.00
432.00	4	Citric acid (0.1 M solution)	432.00
460.00	5	$Na_2HPO_4 \cdot 12H_2O$ (0.2 M solution)	460.00

Manufacturing Directions

1. Dissolve PVP–iodine and Lutrol F 127 in the mixture of buffer solutions with Lutrol E 400.
2. The brown, clear solution has a low viscosity and pH of approximately 4.3.

POVIDONE–IODINE VISCOUS SOLUTION

Bill of Materials

Scale (mg/g)	Item	Material Name	Qty/kg (g)
10.00	1	Polyvinylpyrrolidone (PVP)–Iodine 30/06	10.00
15.00	2	Natrosol® HR 250	15.00
QS	3	Buffer	QS
QS	4	Water	975.00

Manufacturing Directions

1. Dissolve PVP–iodine and Natrosol® in the well-stirred buffered solution in water to produce a clear brown viscous liquid.
2. Viscosity (Brookfield) is 7500 mPa.

PREDNISONE ORAL SOLUTION

Each 5 mL oral solution contains prednisolone 5 mg and alcohol 5% or 30%. Inactive ingredients include alcohol, citric acid, disodium edetate, fructose, hydrochloric acid, maltol, peppermint oil, polysorbate 80, propylene glycol, saccharin sodium, sodium benzoate, vanilla flavor, and water. Prednisone 30% alcohol solution contains citric acid, poloxamer 188, propylene glycol, and water.

PREDNISOLONE SODIUM PHOSPHATE ORAL SOLUTION

Pediapred (prednisolone sodium phosphate) oral solution is a dye-free, colorless to light-straw-colored, raspberry-flavored solution. Each 5 mL (teaspoonful) of Pediapred contains 6.7 mg prednisolone sodium phosphate (5 mg prednisolone base) in a palatable, aqueous vehicle.

PREDNISOLONE SYRUP

The syrup contains 15 or 5 mg prednisolone in each 5 mL. Benzoic acid 0.1% is added as a preservative. The syrup also contains alcohol 5%, citric acid, edetate disodium, glycerin, propylene glycol, purified water, sodium saccharin, sucrose, artificial wild cherry flavor, and FD&C Blue No. 1 and Red No. 40.

PROGESTERONE CAPSULES

Progesterone capsules contain micronized progesterone for oral administration. Capsules are available in multiple strengths to afford dosage flexibility for optimum management. Capsules contain 100 or 200 mg micronized progesterone. The inactive ingredients for 100 mg capsules include peanut oil, gelatin, glycerin, lecithin, titanium dioxide, D&C Yellow No. 10, and FD&C Red No. 40. The inactive ingredients for 200 mg capsules include peanut oil, gelatin, glycerin, lecithin, titanium dioxide, D&C Yellow No. 10, and FD&C Yellow No. 6.

PROMETHAZINE AND CODEINE SYRUP

Each teaspoon (5 mL) of Phenergan VC with codeine contains 10 mg codeine phosphate (*Warning*—this may be habit forming), 6.25 mg promethazine hydrochloride, and 5 mg phenylephrine hydrochloride in a flavored syrup base with a pH between 4.8 and 5.4; alcohol, 7%. The inactive ingredients present are artificial and natural flavors, citric acid, D&C Red No. 33, FD&C Yellow No. 6, glycerin, saccharin sodium, sodium benzoate, sodium citrate, sodium propionate, water, and other ingredients.

PROMETHAZINE AND DEXTROMETHORPHAN SYRUP

Each teaspoon (5 mL) of Phenergan with dextromethorphan contains 6.25 mg promethazine hydrochloride and 15 mg dextromethorphan hydrobromide in a flavored syrup base with a pH between 4.7 and 5.2; alcohol, 7%. The inactive ingredients present are artificial and natural flavors, citric acid, D&C Yellow 10, FD&C Yellow 6, glycerin, saccharin sodium, sodium benzoate, sodium citrate, sodium propionate, water, and other ingredients.

PROMETHAZINE HYDROCHLORIDE SYRUP

Each teaspoon (5 mL) of Phenergan syrup plain contains 6.25 mg promethazine hydrochloride in a flavored syrup base with a pH between 4.7 and 5.2; alcohol, 7%. The inactive ingredients present are artificial and natural flavors, citric acid, D&C Red No. 33, D&C Yellow No. 10, FD&C Blue No. 1, FD&C Yellow No. 6, glycerin, saccharin sodium, sodium benzoate, sodium citrate, sodium propionate, water, and other ingredients. Each teaspoon (5 L) of Phenergan syrup fortis contains 25 mg promethazine hydrochloride in a flavored syrup base with a pH between 5.0 and 5.5; alcohol, 1.5%. The inactive ingredients present are artificial and natural flavors, citric acid, saccharin sodium, sodium benzoate, sodium propionate, water, and other ingredients.

PROMETHAZINE HYDROCHLORIDE SYRUP

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
1.00	1	Promethazine HCl (5% excess)	1.05
675.00	2	Sucrose	675.00
1.00	3	Citric acid (monohydrate)	1.00
2.40	4	Sodium citrate	2.40
0.50	5	Ascorbic acid	0.50
0.25	6	Sodium metabisulfite (sodium disulfite)	0.25
0.25	7	Anhydrous sodium sulfite	0.25
50.00	8	Alcohol (ethanol, 95%)	50.00
0.15	9	Flavor	0.15
0.30	10	Flavor	0.30
0.50	11	Polysorbate 80 (Tween 80)	0.50
0.15	12	Caramel color	0.15
QS	13	Purified water	QS to 1 L

Manufacturing Directions

Promethazine hydrochloride undergoes thermal and photochemical oxidation. Protect from light, heat, and oxygen as practicable. Avoid vortex or overmixing to avoid air entrapment. Use nitrogen gas whenever necessary to expel air.

1. Add 400 g of item 13 to the manufacturing vessel, and heat to 90°C to 95°C.
2. Add item 2 while mixing at slow speed.
3. After addition of item 2, mix for 30 minutes at high speed and a temperature of 90°C to 95°C.
4. Cool down to 30°C to 35°C while mixing at low speed.
5. Add items 3 and 4 to the manufacturing vessel while mixing, and mix until dissolved.
6. Add items 6 and 7 to the manufacturing vessel while mixing, and mix until dissolved.
7. Add item 5 to the manufacturing vessel while mixing, and mix until dissolved.
8. Mix items 9 and 10 with items 8 and 11 in a separate container by using stirrer.
9. Mix for 10 minutes, and add to the manufacturing vessel while mixing.
10. Add 8 g cold purified water (25–30°C) to a separate container, and dissolve item 12 by using stirrer.
11. Mix for 10 minutes, and add to the manufacturing vessel while mixing.
12. Start flushing the syrup with nitrogen gas pressure at 20 to 40 psi.
13. Add 10 g of cold purified water (cooled and flushed with N_2 gas) in a separate container with lid.
14. Pass nitrogen gas at 20 to 40 psi pressure for 15 minutes.
15. Dissolve item 1 in nitrogen-flushed cold purified water (25–30°C) by using stirrer.
16. Mix for 10 minutes, and add to the manufacturing vessel while mixing. Do not produce vortex.
17. Bring volume up to 1 L with nitrogen-flushed purified water.
18. Continue flushing nitrogen gas at 20 to 40 psi pressure for 30 minutes while mixing at slow speed.
19. Check and record the pH (limit: 4.5–5.5). If required, adjust pH with 10% citric acid or 10% sodium citrate solution.
20. Filter the syrup at 1.5 bar.
21. Recirculate approximately 20 to 30 mL syrup.
22. Transfer the filtered syrup to the storage vessel.
23. Flush with nitrogen gas, and seal the tank.

PROMETHAZINE RECTAL SOLUTION

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
QS	1	Pluronic L62	QS to 1 L
2.50	2	Promethazine hydrochloride	2.50

Manufacturing Directions

1. Mill and screen the promethazine hydrochloride to reduce particle size.
2. Add the poloxamer and the promethazine hydrochloride into a clean vessel.
3. Mix until uniform.

PROMETHAZINE RECTAL SOLUTION

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
QS	1	Pluronic L62	QS to 1 L
10.00	2	Carbopol 974	10.00
2.50	3	Promethazine hydrochloride	2.50

Manufacturing Directions

1. Mill the promethazine hydrochloride to reduce particle size.
2. Sieve the carbomer and promethazine hydrochloride, and add to a clean vessel.
3. Add the poloxamer. Mix until uniform.

PSEUDOEPHEDRINE HYDROCHLORIDE SYRUP

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
6.00	1	Pseudoephedrine HCl (3.0% excess)	6.18
600.00	2	Sucrose	600.00
100.00	3	Glycerin (glycerol)	100.00
100.00	4	Sorbitol (70% solution)	100.00
15.00	5	Propylene glycol	15.00
1.00	6	Methylparaben	1.00
0.30	7	Propylparaben	0.30
0.50	8	Saccharin sodium	0.50
0.02	9	Dye (if needed)	0.02
0.05	10	Menthol	0.05
0.13	11	Citric acid	0.13
1.15	12	Sodium citrate	1.15
QS	13	Purified water	QS to 1 L

Manufacturing Directions

1. Add 390 g of purified water to the manufacturing vessel, and heat to 90°C to 95°C.
2. Add items 6 and 7 while mixing to dissolve at high speed.
3. Add item 2 while mixing at slow speed at a temperature of 90°C to 95°C.
4. Mix for 1 hour at high speed.
5. Cool down to 50°C while mixing at slow speed.
6. Dissolve items 8 and 12 in 10 g of item 13, and add to the manufacturing vessel while mixing at high speed.
7. Dissolve item 11 in 10 g purified water, and add to the manufacturing vessel while mixing at high speed.
8. Load items 4 and 3 into the manufacturing vessel using a transfer pump while mixing at high speed.
9. Mix for 5 minutes.
10. Cool down to 30°C while mixing at slow speed.
11. Add 20 g of item 13 (30°C) in a separate container, and dissolve item 1 by using stirrer.
12. Mix for 10 minutes, and add to the manufacturing vessel while mixing at high speed.
13. Add 6 g of item 13 in a separate container, and dissolve item 9 manually.
14. Add color to the manufacturing vessel while mixing at high speed.
15. Dissolve item 10 in item 5.
16. Add this flavor mixture to the manufacturing vessel while mixing at high speed.
17. Bring the volume up to 1 L with item 13, and finally mix, for 15 to 20 minutes at high speed.
18. Check and record the pH (limit: 5.5–6.5 at 25°C).
19. If required, adjust pH with 20% citric acid or 20% sodium citrate solution.
20. Filter the syrup at 1.5 bar.
21. Recirculate approximately 100 to 150 mL syrup.

PSEUDOEPHEDRINE HYDROCHLORIDE AND CARBINOXAMINE MALEATE ORAL DROPS

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
500.00	1	Sucrose	500.00
300.00	2	Glucose liquid	300.00
150.00	3	Glycerin (96%)	150.00
30.00	4	D-Pseudoephedrine hydrochloride	30.00
1.00	5	Carbinoxamine maleate	1.00
4.00	6	Saccharin sodium (powder)	4.00
2.50	7	Sodium benzoate (powder)	2.50
1.25	8	Flavor	1.25
0.03	9	Dye	0.03
0.03	10	Dye	0.03
QS	11	Hydrochloric acid reagent-grade bottles	QS
QS	12	HyFlo filter aid	1.32
QS	13	Purified water	455.00
QS	14	Sodium hydroxide for pH adjustment	QS

Manufacturing Directions

1. Charge 315 mL of deionized water into a suitable tank.
2. Begin heating water to 60°C to 70°C while adding sucrose with stirring.
3. Stir until sugar is dissolved.
4. Remove heat.
5. Add glucose liquid and 125 g of glycerin in this step.
6. Add and dissolve D-pseudoephedrine hydrochloride, carbinoxamine maleate, saccharin sodium, and sodium benzoate with mixing.
7. Cool solution to 30°C to 35°C.
8. Mix flavor with 25 g of glycerin.
9. (*Note*: Temperature of syrup must not be higher than 35°C.) Dissolve dyes, if used, in 5 mL of deionized water, and add to syrup with mixing.
10. Adjust to pH 4.25 (range: 4.0–4.5), if necessary, with hydrochloric acid or sodium hydroxide.
11. QS to 1 L with deionized water, and mix well.
12. Allow product to stand overnight to let entrapped air escape.
13. Readjust volume to 1 L with deionized water.
14. Add and mix 1.320 g of HyFlo filter aid to the product.
15. Circulate through a press.
16. Filter into tank for filling.

PSEUDOEPHEDRINE AND CARBINOXAMINE DROPS

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
500.00	1	Sucrose	500.00
300.00	2	Glucose liquid	300.00
150.00	3	Glycerin	150.00
30.00	4	Pseudoephedrine hydrochloride	30.00
1.00	5	Carbinoxamine maleate	1.00
4.00	6	Saccharine sodium	4.00
2.50	7	Sodium benzoate	2.50
1.25	8	Flavor blackcurrant	1.25
0.032	9	Dye red	0.032
0.036	10	Dye yellow	0.036
QS	11	Hydrochloric acid, to adjust pH	QS
1.32	12	Filter aid HyFlo	1.32
QS	13	Water purified	QS to 1 L
QS	14	Sodium hydroxide, to adjust pH	QS

Manufacturing Directions

1. Charge 315 mL purified water into a suitable tank.
2. Begin heating water to 60°C to 70°C while adding sugar with stirring. Stir until sugar is dissolved.
3. Remove heat. Add glucose liquid and 40 g sorbitol solution with mixing. Hold balance of sorbitol for step 6.
4. Add and dissolve D-pseudoephedrine HCl, carbinoxamine maleate, saccharin sodium, and sodium benzoate with mixing.
5. Cool solution to 30°C to 35°C.
6. Mix flavors with balance of sorbitol, and add to syrup.
7. Add glycerin. Temperature of syrup must not be higher than 35°C.
8. Dissolve dyes, if used, in 5 mL purified water and add to syrup with mixing. Adjust to pH 4.25 (range: 4.0–4.5), if necessary, with hydrochloric acid or sodium hydroxide.
9. QS to 1 L with purified water, and mix well.
10. Allow product to stand overnight to let entrapped air escape. Readjust volume to 1 L.
11. Add and mix 1.32 g of filter aid HyFlo to the product. Circulate through a press until sparkling clear.
12. Filter into tank for filling. Fill into suitable approved containers.

PSEUDOEPHEDRINE HYDROCHLORIDE SYRUP

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
6.00	1	Pseudoephedrine HCl, 3% excess	6.18
600.00	2	Sucrose	600.00
100.00	3	Glycerin (glycerol)	100.00
100.00	4	Sorbitol (70% solution)	100.00
15.00	5	Propylene glycol	15.00
1.00	6	Methylparaben	1.00
0.30	7	Propylparaben	0.30
0.50	8	Saccharin sodium	0.50
0.02	9	Dye (if needed)	0.02
0.05	10	Menthol	0.05
0.132	11	Citric acid	0.13
1.150	12	Sodium citrate	1.15
—	13	Water purified	QS to 1 L

Manufacturing Directions

1. Add 390 g of item 13 to the manufacturing vessel, and heat to 90°C to 95°C.
2. Add items 6 and 7 while mixing to dissolve at high speed.
3. Add item 2 while mixing at slow speed. Temperature 90°C to 95°C.
4. Mix for 1 hour at high speed. Cool down to 50°C while mixing at slow speed.
5. Dissolve items 8 and 12 in 10 g of item 13, and add to the manufacturing vessel while mixing at high speed.
6. Dissolve item 11 in 10 g of item 13, and add to the manufacturing vessel while mixing at high speed. Load items 4 and 3 into the manufacturing vessel using transfer pump while mixing at high speed.
7. Mix for 5 minutes. Cool down to 30°C while mixing at slow speed.
8. Add 20 g of item 13 (30°C) in a separate container, and dissolve item 1 by using stirrer.
9. Mix for 10 minutes, and add to the manufacturing vessel while mixing at high speed. Add 6 g of item 13 in a separate container, and dissolve item 9 manually.
10. Add color to the manufacturing vessel while mixing at high speed.
11. Dissolve item 10 in item 5. Add this flavor mixture to the manufacturing vessel while mixing at high speed. Make up the volume to 1 L with item 13, and finally, mix for 15 to 20 minutes at high speed.
12. Check and record the pH (limit: 5.5–6.5 at 25°C).
13. If required, adjust pH with 20% citric acid or 20% sodium citrate solution.
14. Filter the syrup at 1.5 bar. Recirculate about 100 to 150 mL syrup.

RIBAVIRIN INHALATION SOLUTION

Virazole is a brand name for ribavirin, a synthetic nucleoside with antiviral activity. Virazole for inhalation solution is a sterile, lyophilized powder to be reconstituted for aerosol administration. Each 100 mL glass vial contains 6 g ribavirin, and when reconstituted to the recommended volume of 300 mL with sterile water for injection or sterile water for inhalation (no preservatives added), contains 20 mg of ribavirin per milliliter, with a pH of approximately 5.5. Aerosolization is to be carried out in a small particle aerosol generator (SPAG-2) nebulizer only.

RISPERIDONE ORAL SOLUTION

Risperdal is available as a 1 mg/mL oral solution. The inactive ingredients for this solution are tartaric acid, benzoic acid, sodium hydroxide, and purified water.

RITONAVIR CAPSULES

Norvir soft gelatin capsules are available for oral administration in a strength of 100 mg ritonavir with the following inactive ingredients: butylated hydroxytoluene, ethanol, gelatin, iron oxide, oleic acid, polyoxyl 35 castor oil, and titanium dioxide.

RITONAVIR ORAL SOLUTION

Norvir oral solution is available for oral administration as 80 mg/mL ritonavir in a peppermint and caramel-flavored vehicle. Each 8 oz bottle contains 19.2 g ritonavir. Norvir oral solution also contains ethanol, water, polyoxyl 35 castor oil, propylene glycol, anhydrous citric acid to adjust pH, saccharin sodium, peppermint oil, creamy caramel flavoring, and FD&C Yellow No. 6.

RITONAVIR AND LOPINAVIR ORAL SOLUTION

Kaletra oral solution is available for oral administration as 80 mg lopinavir and 20 mg ritonavir per milliliter with the following inactive ingredients: acesulfame potassium, alcohol, artificial cotton candy flavor, citric acid, glycerin, high-fructose corn syrup, Magnasweet-110 flavor, menthol, natural and artificial vanilla flavor, peppermint oil, polyoxyl 40 hydrogenated castor oil, polyvinylpyrrolidone, propylene glycol, saccharin sodium, sodium chloride, sodium citrate, and water.

RIVASTIGMINE TARTRATE ORAL SOLUTION

Exelon oral solution is supplied as a solution containing rivastigmine tartrate, equivalent to 2 mg/mL rivastigmine base for oral administration. Inactive ingredients are citric acid, D&C Yellow No. 10, purified water, sodium benzoate, and sodium citrate.

SALBUTAMOL AEROSOL

Bill of Materials

Scale (mg/g)	Item	Material Name	Qty/1000 units (g)
1.17	1	Salbutamol, 10% excess	26.40
0.11	2	Oleic acid, 10% excess	2.64
277.61	3	Trichloromonofluoromethane	5664.00
721.09	4	Dichlorodifluoromethane	14,700.00

Manufacturing Directions

1. Filter approximately 5 kg of the trichloromonofluoromethane and the oleic acid through a suitable 0.2 micron filter into a stainless steel concentrate container.
2. Slowly add the salbutamol to the solution in step 1, and mix for about 15 minutes.
3. Filter most of the remaining trichloromonofluoromethane through a suitable 0.2 micron filter into the suspension holding tank.
4. Add the slurry from step 2 to the holding tank.
5. Rinse the concentrate container with filtered trichloromonofluoromethane, and add the rinses to the holding tank.
6. Make up the final mass of 5.693 kg with filtered trichloromonofluoromethane.
7. Mix for 5 minutes. Sample (to determine nonvolatile matter, range: 0.49–0.53 w/w).
8. Fill 5.7 g of suspension into a clean aluminum vial, and immediately crimp on the metering valve. Pressure fill, through metering valve, sufficient dichlorodifluoromethane to produce a final fill weight of 20.4 g. Check-weigh each aerosol to ensure that the fill weight is in the range of 20 to 20.8 g. At the start of manufacture, fill the vials, and apply nonmetering valves. Pressure-test these vials using a special gauge adaptor to ensure the correct propellant mix is being used. The internal pressure measured at 22°C should be 50 to 60 psi.
9. Store the filled aerosols for a period of 2 weeks, and check the weight again.
10. Test each aerosol by actuation to ensure correct operation.

SALBUTAMOL SYRUP SUGAR FREE

Bill of Materials

Scale (mg/5 mL)	Item	Material Name	Qty/L (g)
20.75	1	Citric acid (monohydrate)	4.15
10.00	2	Sodium benzoate	2.00
6.25	3	Sodium citrate	1.25
3.75	4	Saccharin sodium	0.75
2.00	5	Salbutamol sulfate, 20% excess	0.48
5.00	6	Sodium chloride	1.00
5.00	7	Strawberry flavor	1.00
10.00	8	Tangerine flavor	2.00
15.00	9	Hydroxypropyl methylcellulose (Methocel E4M)	3.00
—	10	Water purified	QS to 1 L

Manufacturing Directions

1. Add 700 g of item 10 to the manufacturing vessel, and heat to 70°C.
2. Add item 9 slowly while mixing at low speed. Mix for 30 minutes.
3. Cool down to 25°C with continuous mixing at low speed.
4. Add 20 g of item 10 (25°C) in a separate stainless steel container, dissolve items 3, 4, and 6, and add to the manufacturing vessel.
5. Add 20 g of item 10 (25°C) in a separate container, dissolve item 1, and add to the manufacturing vessel.
6. Add 20 g of item 10 (25°C) in a separate container, dissolve item 2, and add to the manufacturing vessel.
7. Add 20 g of item 10 (25°C) in a separate container, dissolve item 5 and add to the manufacturing vessel,
8. Add items 7 and 8 to the manufacturing vessel while mixing.
9. Make up the volume to 1 L with item 10 (25°C), and finally, mix for 20 minutes at high speed.
10. Assemble the Seitz filter press, and wash the filters using about 250 L purified water (25°C) by passing through filters at 0.2 bar.
11. Filter the syrup at 1.5 bar. Recirculate about 30 to 40 mL syrup.
12. Transfer the filtered syrup to the storage vessel.

SALBUTAMOL SYRUP

Bill of Materials

Scale (mg/5 mL)	Item	Material Name	Qty/L (g)
2.00	1	Salbutamol sulfate (20%)	0.480
2500.00	2	Sucrose	500.000
5.00	3	Methylparaben	1.000
1.00	4	Propylparaben	0.20
5.00	5	Citric acid (monohydrate)	1.00
2.80	6	Sodium citrate	0.57
1000.00	7	Sorbitol (70% solution)	200.00
1.10	8	Flavor	0.22
1.10	9	Flavor	0.22
50.00	10	Propylene glycol	10.00
—	11	Water purified	QS to 1 L

Manufacturing Directions

1. See previous formulation.

SALICYLIC ACID COLLODION

Salicylic acid 17% w/w, alcohol, 26.3% w/w, t-butyl alcohol, denatonium benzoate, flexible collodion, and propylene glycol dipelargonate.

SALMETEROL XINAFOATE INHALATION AEROSOL

Salmeterol xinafoate inhalation aerosol contains salmeterol xinafoate as the racemic form of the 1-hydroxy-2-naphthoic acid salt of salmeterol. It is a pressurized, metered-dose aerosol unit for oral inhalation. It contains a microcrystalline suspension of salmeterol xinafoate in a mixture of two chlorofluorocarbon propellants (trichlorofluoromethane and dichlorodifluoromethane) with lecithin. 36.25 µg of salmeterol xinafoate is equivalent to 25 µg of salmeterol base. Each actuation delivers 25 µg of salmeterol base (as salmeterol xinafoate) from the valve and 21 µg of salmeterol base (as salmeterol xinafoate) from the actuator. Each 6.5 g canister provides 60 inhalations, and each 13 g canister provides 120 inhalations.

SALMETEROL XINAFOATE INHALATION AEROSOL

Bill of Materials

Scale (mg/application)	Item	Material Name	Qty/1000 applications (g)
0.25	1	Salmeterol (used as salmeterol xinafoate)	0.250
7.28	2	Miglyol 829 (caprylic/capric diglycerol succinate)	7.280
0.15	3	Peppermint oil	0.150
0.18	4	Menthol	0.180
113.00	5	*n*-Butane	QS to 113.000

Manufacturing Directions

1. Transfer Miglyol 829 by pumping from the released and tared container into mixing vessel.
2. After pumping Miglyol 829, set the propeller with optimum circulation and revolution to ensure no air entrapment.
3. Weigh out required amount of salmeterol xinafoate, and transfer directly into mixing vessel while mixing slowly.
4. Keep the preparation under stirring without interruption or change in rpm.
5. Dissolve menthol in peppermint oil at 25°C by slow stirring in another mixing vessel. Continue stirring until the solution becomes clear.
6. Transfer the clean menthol solution (step 5) into step 4 while stirring at the set speed. Continue stirring for 1 hour.
7. Store the base solution in aluminum can with polyethylene stopper and screw cap.

SCOPOLAMINE NASAL SPRAY

Charge 2.6 g scopolamine into a pressure addition vessel, and dissolve with stirring in 405.6 g ethanol in which 1.26 g of oleic acid has previously been dissolved. After sealing and evacuation thereof, 6.7 kg of HFA 134a that has previously been aerated with carbon dioxide and adjusted to a pressure of 8 bar in another pressure addition vessel is added by stirring. The solution obtained is dispensed into aluminum containers sealed with metering valves by means of the pressure-filling technique.

SELENIUM SULFIDE SHAMPOO WITH CONDITIONER

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
10.00	1	Selenium sulfide	10.00
2.00	2	Methylparaben	2.00
10.00	3	Magnesium aluminum silicate type IIA	10.00
20.00	4	Titanium	20.00
0.17	5	Dye	0.17
230.00	6	Sodium alkyl ether sulfate/sulfonate	230.00
30.00	7	Cocamide DEA surfactant	30.00
40.00	8	Cocoamphocarboxyglycinate	40.00
10.00	9	Hydrolyzed protein	10.00
4.00	10	Perfume	4.00
QS	11	Citric acid	QS
QS	12	Sodium chloride	QS
QS	13	Deionized purified water	QS to 1 L

Note: Item 11 is used for pH adjustment, if necessary, and item 12 is used for viscosity adjustment, if necessary.

Manufacturing Directions

1. Selenium sulfide is toxic; handle carefully, and use approved respiratory protection.
2. Add 7 mL purified water to an appropriate mill containing full-charge alumina grinding cylinder media.
3. Add selenium sulfide.
4. Seal the mill, and agitate for approximately 10 minutes to wet down the powdered material.
5. Recycle for approximately 5 minutes with the pump set at 1040 mmHg.
6. Stop agitation.
7. If necessary, add purified water (25–30°C) to nearly cover the grinding media.
8. Seal the mill, and recirculate the slurry for 1 to 2 hours with the pump set to obtain the required particle size specifications for the selenium sulfide.
9. Load 250 mL of purified water into a suitable jacketed mixing tank, and heat to 60°C to 70°C.
10. With good stirring, add and dissolve methyl paraben.
11. Slowly add and disperse the magnesium aluminum silicate. Continue mixing until fairly smooth.
12. Stop mixing, and allow to hydrate for 1 hour.
13. Add and disperse titanium dioxide.
14. Mix for 30 minutes.
15. With good stirring, add the selenium sulfide slurry, and rinse the mill with purified water.
16. Mix for 30 minutes.
17. Stop mixing, and add sodium lauryl ether sulfate/sulfonate.
18. Mix slowly for 5 minutes.

19. Add cocamide DEA.
20. Mix slowly for approximately 3 minutes.
21. Add coco-amphocarboxyglycinate.
22. Mix slowly for 30 minutes.
23. Separately dissolve hydrolyzed protein (hydrogel) in 4 mL of purified water, and mix until uniform.
24. Add solution from step 23 to the tank, and mix until uniform.
25. Add perfume, and mix for 1 minute.
26. Dissolve dye in 2 mL warm purified water (50–60°C), and add to mixing tank.
27. Mix until uniform.
28. Check and record pH; adjust to 4.5 to 5.0, if necessary, using citric acid. Record amount of citric acid used and the adjusted pH.
29. Add purified water QS to 980 mL, and mix for 30 minutes.
30. Check and record viscosity.
31. If necessary, adjust by adding sodium chloride.
32. Deaerate by slow stirring under vacuum or use of a suitable deaerator.
33. Mix for 1 hour.

SERTRALINE HYDROCHLORIDE ORAL CONCENTRATE

Sertraline hydrochloride is a selective serotonin reuptake inhibitor for oral administration. It is chemically unrelated to other selective serotonin reuptake inhibitors or tricyclic, tetracyclic, or other available antidepressant agents. It is supplied in a multidose 60 mL bottle. Each milliliter of solution contains sertraline hydrochloride equivalent to 20 mg of sertraline. The solution contains the following inactive ingredients: glycerin, alcohol (12%), menthol, and butylated hydroxytoluene. The oral concentrate must be diluted before administration.

SERTRALINE HYDROCHLORIDE SOLUTION

Zoloft oral concentrate is available in a multidose 60 mL bottle. Each milliliter of solution contains sertraline hydrochloride equivalent to 20 mg of sertraline. The solution contains the following inactive ingredients: glycerin, alcohol (12%), menthol, and butylated hydroxytoluene.

SIMETHICONE DROPS

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
144.00	1	Simethicone emulsion 30% (Simethicone Antifoam M30)[a]	144.00
60.00	2	Polyethylene glycol (PEG 6000)	60.00
1.50	3	Xanthan gum (Keltrol F)	1.50
1.50	4	Methylcellulose 4000 (Methocel A4M)	1.50
1.50	5	Potassium sorbate	1.50
1.20	6	Methylparaben	1.20
0.20	7	Propylparaben	0.20
1.500	8	Saccharin sodium	1.50
0.80	9	Banana green flavor	0.80
1.02	10	Citric acid (monohydrate)	1.02
0.24	11	Sodium citrate powder	0.24
—	12	Water purified	QS to 1 L

[a] Equivalent to 43.2 mg of simethicone.

Manufacturing Directions

1. Load 240 g of item 12 in mixer. Heat to 90°C to 95°C. Dissolve items 6 and 7 by mixing with recirculation for 5 minutes.
2. Load item 2 in mixer. Mix to clear solution at 90°C to 95°C for 5 minutes under vacuum 0.4 to 0.6 bar.
3. Cool down to 25°C to 30°C. Take the PEG–paraben solution out of the mixer, and keep in a stainless steel container.
4. Load 512 g of item 12 in mixer. Heat to 90°C to 95°C, and then cool to 65°C to 70°C.
5. Take out 208 g of item 12 (65–70°C) from the mixer in a stainless steel container. Disperse item 3 by continuous stirring by mixer.
6. Disperse item 4 in mixer containing item 12 at 65°C to 70°C (step 4) while mixing and homogenizing at high speed for 5 minutes under vacuum 0.4 to 0.6 bar.
7. Cool to 20°C to 25°C with continuous mixing and recirculation.
8. Add PEG–paraben solution from step 3 to mixer while mixing at speed 18 rpm.
9. Add item 3 mucilage from step 5 to mixer while mixing at speed 18 rpm.
10. Homogenize at high speed under vacuum 0.4 to 0.6 bar for 5 minutes while mixing.
11. Dissolve items 5 and 8 in 12 g of item 12 in a stainless steel container, and add to mixer while mixing.
12. Add item 1 to the mixer while mixing.
13. Rinse the container of item 1 (step 12) with 12 g of item 12, and add the rinsings to the mixer.
14. Add item 9 to the mixer while mixing.

15. Mix and homogenize at low speed under vacuum 0.4 to 0.6 bar for 5 minutes.
16. pH is a critical factor for simethicone emulsion. Limit is between 4.4 and 4.6. Carefully adjust the pH.
17. Add item 12 (25–30°C) to make up the volume to 1°L.
18. Mix at slow speed under vacuum 0.4 to 0.6 bar for 5 minutes.
19. Filter the bulk through 630 micron sieve in a clean stainless steel storage tank.

SIROLIMUS SOLUTION

Sirolimus is an immunosuppressive agent. Sirolimus is a macrocyclic lactone produced by *Streptomyces hygroscopicus.* It is available for administration as an oral solution containing 1 mg/mL sirolimus; the inactive ingredients include phosphatidylcholine, propylene glycol, mono- and diglycerides, ethanol, soy fatty acids, ascorbyl palmitate, and polysorbate 80. The oral solution contains 1.5% to 2.5% ethanol.

SODIUM CHLORIDE NASAL DROPS

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
90.00	1	Sodium chloride	90.00
3.00	2	Benzalkonium chloride solution 5%	3.00
QS	3	Water purified	QS to 1 L

Manufacturing Directions

1. Charge 50% item 1 in a suitable stainless steel container, and heat to 85°C to 90°C.
2. Add and dissolve item 2 at room temperature.
3. Add item 1, and make up volume.

STAVUDINE FOR ORAL SUSPENSION

Zerit (stavudine) for oral solution is supplied as a dye-free, fruit-flavored powder in bottles with child-resistant closures providing 200 mL of 1 mg/mL stavudine solution on constitution with water per label instructions. The powder for oral solution contains the following inactive ingredients: methylparaben, propylparaben, sodium carboxymethylcellulose, sucrose, and antifoaming and flavoring agents.

SUCRALFATE SUSPENSION

Carafate suspension for oral administration contains 1 g sucralfate per 10 mL. Carafate suspension also contains colloidal silicon dioxide, FD&C Red No. 40, flavor, glycerin, methylcellulose, methylparaben, microcrystalline cellulose, purified water, simethicone, and sorbitol solution.

Bill of Materials

Scale (mg/5 mL)	Item	Material Name	Qty/L (g)
1000.00	1	Sucralfate	200.00
5.00	2	Methylparaben	1.00
1.50	3	Propylparaben	0.30
1500.00	4	Sorbitol 70%	300.00
2.50	5	Saccharin sodium	0.50
20.00	6	Natrosol 250M	4.00
30.00	7	Avicel™ HC 591	6.00
20.00	8	Sodium phosphate dibasic	4.00
7.50	9	Sodium phosphate monobasic	1.50
1.00	10	Lemon flavor	0.20
QS	11	Water purified	QS to 1 L

Manufacturing Directions

1. Place 40% of item 11 in a stainless steel jacketed vessel, and heat to 90°C to 95°C.
2. Add items 2 and 3, and mix to dissolve. Cool to 40°C.
3. Place item 11 and item 6 in a separate vessel at 70°C to 80°C, and stir for 30 minutes.
4. Add and disperse item 7 in step 3.
5. Transfer to step 1, and mix to disperse.
6. In a separate vessel, add and mix item 4 with items 1 and 11.
7. Add to step 6.
8. Add flavor, and bring to volume.

SULFACETAMIDE SODIUM AND SULFUR CLEANSER AND SUSPENSION

Each gram of Plexion (sodium sulfacetamide 10% and sulfur 5%) cleanser contains 100 mg sodium sulfacetamide and 50 mg sulfur in a cleanser base containing water, sodium methyl oleyltaurate, sodium cocoyl isethionate, disodium oleamido MEA sulfosuccinate, cetyl alcohol, glyceryl stearate and PEG-100 stearate, stearyl alcohol, PEG-55 propylene glycol oleate, magnesium aluminum silicate, methylparaben, disodium EDTA, butylated hydroxytoluene, sodium thiosulfate, fragrance, xanthan gum, and propylparaben. Each gram of Plexion (sodium sulfacetamide 10% and sulfur 5%) topical suspension contains 100 mg sodium sulfacetamide and 50 mg sulfur in a topical suspension containing water, propylene glycol, isopropyl myristate, light mineral oil, polysorbate 60, sorbitan monostearate, cetyl alcohol, hydrogenated cocoglycerides, stearyl alcohol, fragrances, benzyl alcohol, glyceryl stearate and PEG-100 stearate, dimethicone, zinc ricinoleate, xanthan gum, disodium EDTA, and sodium thiosulfate.

SULFADIAZINE AND TRIMETHOPRIM VETERINARY ORAL SUSPENSION

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
400.00	1	Sulfadiazine	400.00
80.00	2	Trimethoprim	80.00
50.00	3	Sodium hydroxide	50.00
20.00	4	Kollidon® CL-M	20.00
QS	5	Water purified	QS to 1 L

Manufacturing Directions

1. Place item 3 into a stainless steel vessel along with item 5. Mix and dissolve.
2. Add and suspend item 4. Mix well.
3. Add and suspend items 1 and 2. Homogenize if necessary.
4. Fill.

SULFAMETHOXAZOLE AND TRIMETHOPRIM SUSPENSION

Bill of Materials

Scale (mg/5 mL)	Item	Material Name	Qty/L (g)
200.00	1	Sulfamethoxazole	40.00
40.00	2	Trimethoprim	8.00
2.50	3	Carrageenan (Hydrogel 843T)	0.50
18.75	4	Tragacanth	3.75
2.50	5	Saccharin sodium dihydrate	0.50
0.625	6	Anise oil	0.125
3.125	7	Methylparaben	0.625
2.70	8	Propylparaben	0.54
2.17	9	Alcohol dehydrated	0.435
2914.00	10	Sorbitol solution	582.80
403.75	11	Glycerin	80.75
QS	12	Water purified	QS to 1 L

Manufacturing Directions

1. Add and disperse Hydrogel 843T in approximately 8 mL purified water.
2. Heat 30 mL purified water to 100°C, and add to dispersion from step 1 with mixing.
3. Let stand overnight.
4. Load trimethoprim and 7 g sulfamethoxazole into a suitable mixer. Blend.
5. Moisten blend with approximately 25 mL water.
6. Spread mass as small pancakes onto oven trays, and dry at 50°C for approximately 14 hours.
7. Retain balance of sulfamethoxazole for later use.
8. While mixing, add 75 mL water. Mix until homogeneous.
9. Charge approximately 350 mL water into a suitable stainless steel mixing tank. Add and dissolve saccharin with mixing.
10. Add tragacanth, and continue mixing for 4 hours.
11. Separately add and dissolve the following ingredients in alcohol: methyl paraben, propyl paraben, and anise oil.
12. Add solution from preceding step and sorbitol to the preparation from step 1. Mix for 3 hours, and let stand overnight.
13. Add gel from previous step with mixing. Mix for approximately 15 minutes.
14. Pass trimethoprim/sulfamethoxazole mass from step 4 and balance of sulfamethoxazole through a 595 micron aperture screen in Fitz mill, knives forward, medium speed, and slowly add to main tank with continuous agitation.
15. Add glycerin to main tank with mixing.
16. Pass the whole batch through a colloid mill until particle size and homogeneity meet specifications. Rinse mill and other equipment with purified water. Add the rinsings to the batch, and mix.
17. If necessary, deaerate the product mixing under vacuum (ca. 20–25 in. of mercury). Release vacuum, and check volume.
18. Bring to volume with water, and mix.
19. Stir the suspension until homogeneous. Fill while stirring.

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
80.00	1	Sulfamethoxazole	80.00
16.00	2	Trimethoprim	16.00
30.00	3	Kollidon® CL-M	30.00
100.00	4	Sucrose	100.00
QS	5	Water purified	QS to 1 L
2.00	6	Vanillin	2.00
2.00	7	Flavor chocolate	2.00

Manufacturing Directions

1. Place items 4 and 5in a suitable stainless steel jacketed vessel. Heat to dissolve.
2. Cool to 40°C.
3. Add, after passing through 200 mesh sieve, items 1 to 3 into step 2. Mix to dissolve.
4. Add flavors. Mix and fill.

SULFAMETHOXAZOLE AND TRIMETHOPRIM SUSPENSION

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
80.00	1	Sulfamethoxazole	80.00
16.00	2	Trimethoprim	16.00
50.00	3	Sucrose	5.00
30.00	4	Lutrol F 127 or Lutrol F 68	30.00
QS	5	Water purified	QS to 1 L
QS	6	Vanillin	QS
QS	7	Flavor chocolate	QS

Manufacturing Directions

1. Place items 3 and 4 in a suitable stainless steel jacketed vessel. Heat to dissolve.
2. Cool to 40°C.
3. Add, after passing through a 200 mesh sieve, items 1, 2, and 4 into step 2. Mix to dissolve.
4. Add item 5, flavors, if used. Mix and fill.

SULFATHIAZOLE VETERINARY ORAL SOLUTION

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
8.00	1	Sulfathiazole	8.00
225.00	2	Kollidon® 25	225.00
QS	3	Preservative	QS
QS	4	Water purified	QS to 1 L

Manufacturing Directions

1. Charge item 4 in a suitable stainless steel jacketed vessel. Heat to 70°C.
2. Add and disperse item 2.
3. Add and dissolve item 1 to a clear solution.
4. Filter, if necessary, and fill.
5. Optionally, an antioxidant such as 0.02% sodium bisulfite or 0.5% cysteine may be added if necessary.

SULFIDOXINE SOLUTION

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
20.00	1	Sulfidoxine	20.00
680.00	2	Lutrol E 400	680.00
QS	3	Preservatives	QS
QS	4	Water purified	QS to 1 L

Manufacturing Directions

1. Place items 1 and 2 in a suitable stainless steel jacketed vessel. Heat to 60°C, and mix.
2. In a separate vessel, place item 4, heat to 90°C to 95°C, and then add item 3 (e.g., parabens) and dissolve. Cool to 40°C.
3. Add step 2 into step 1. Mix to clear solution.

SULFIDOXINE AND PYRIMETHAMINE SUSPENSION

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
2.70	1	Tylose	2.70
1.00	2	Methylparaben	1.00
0.20	3	Propylparaben	0.20
600.00	4	Sugar	600.00
0.15	5	Sodium hydroxide	0.15
6.00	6	Trisodium citrate dehydrate	6.00
2.00	7	Benzoic acid	2.00
100.00	8	Sorbitol syrup	100.00
4.00	9	Tween 80	4.00
100.00	10	Sulfadoxine micronized	100.00
5.00	11	Pyrimethamine	5.00
0.20	12	Flavor	0.20
0.20	13	Flavor	0.20
0.20	14	Flavor	0.20
QS	15	Water purified	QS to 1 L

Manufacturing Directions

1. Boil a suitable quantity of item 15, cool down to 70°C, and add and dissolve items 2 and 3.
2. Add item 1 and dissolve in item 15 in a separate container and then add to step 1.
3. In a separate container, add and dissolve sodium hydroxide, sodium citrate, and benzoic acid in item 15, and add to step 1.
4. Add and mix sorbitol with Tween 60 and item 10, stir for 15 minutes, and add to preceding step.
5. Add item 11 to preceding step, and mix to dissolve.
6. Add flavors, and bring to volume.

SUMATRIPTAN NASAL SPRAY

Each Imitrex nasal spray contains 5 or 20 mg of sumatriptan in a 100 μL unit-dose aqueous buffered solution containing monobasic potassium phosphate, anhydrous dibasic sodium phosphate, sulfuric acid, sodium hydroxide, and purified water. The pH of the solution is approximately 5.5. The osmolality of the solution is 372 or 742 mOsmol for the 5 and 20 mg Imitrex nasal spray, respectively.

Manufacturing Directions

1. Charge 2.6 g of sumatriptan into a pressure addition vessel, and dissolve with stirring in 405.6 g ethanol in which 0.26 g oleic acid has previously been dissolved.
2. After closing and evacuation thereof, 6.7 kg HFA 134a that has previously been aerated with carbon dioxide and adjusted to a pressure of 7 bar (20°C) in another pressure addition vessel is added with stirring.
3. The preparation obtained is dispensed into aluminum containers sealed with metering valves by means of the pressure-filling technique.

TERFENADINE ORAL SUSPENSION

Bill of Materials

Scale (mg/5 mL)	Item	Material Name	Qty/L (g)
30.00	1	Terfenadine, 8% excess	6.48
2250.00	2	Sucrose	450.00
7.50	3	Sodium methylparaben	1.50
2.500	4	Sodium propylparaben	0.50
300.00	5	Propylene glycol	60.00
15.00	6	Polysorbate 80 (Tween 80)	3.00
50.00	7	Benzyl alcohol	10.00
0.24	8	Anise oil	0.048
15.00	9	Magnesium aluminum silicate (Veegum HV)	3.00
125.00	10	Glycerin	25.00
18.74	11	Carboxymethylcellulose sodium	3.74
0.76	12	Citric acid (monohydrate)	0.15
—	13	Water purified	QS to 1 L

Manufacturing Directions

1. Add 240 g of item 13 to the mixer, and heat to 90°C. Add and dissolve item 2 while mixing.
2. Add and dissolve items 3 and 4 in the mixer at step 1 while mixing at speed 18 to 20 rpm for 15 minutes.
3. Cool down to about 50°C to 55°C.
4. Filter the syrup.
5. Collect the syrup in clean stainless steel tank.
6. Clean mixer with item 13, and transfer the filtered syrup from step 4. Maintain temperature at 35°C.
7. Add 80 g of item 13 (70°C) in a separate stainless steel container, and disperse item 9 by using stirrer. Keep aside for 1 hour for hydration.
8. Add item 10 in a separate stainless steel container, and disperse item 11 while mixing with stirrer.
9. Add 80 g of item 13 (70°C) while mixing. Make a gel, and keep aside.
10. Add 160 g of item 13 (60°C) in a separate stainless steel container.
11. Dissolve item 6. Avoid foam formation. Add item 1 slowly while mixing at slow speed. Add item 5 while mixing at slow speed. Keep the solution aside.
12. Transfer items 1, 9, and 11 dispersions from steps 3, 4, and 5, respectively, to the mixer.
13. Mix at speed 18 rpm for 10 minutes.
14. Mix item 8 in item 7, and add to the mixer. Mix for 2 minutes.
15. Dissolve item 12 in 3.2 g of item 13, and add to the mixer. Mix for 2 minutes.
16. Add cold item 13 (25°C) to make up the volume to 1 L.
17. Homogenize for 10 minutes at high speed under vacuum 0.5 bar, 18 to 20 rpm, and temperature 25°C.
18. Check the dispersion for uniformity.
19. Check the pH (limit: 8–9 at 25°C). If required, adjust the pH with 20% solution of citric acid or sodium citrate.
20. Filter the suspension through a 500 micron sieve to storage tank.

TERFENADINE SUSPENSION

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
12.00	1	Terfenadine	12.00
30.00	2	Lutrol F 127	30.00
36.00	3	Cremophor RH 40	36.00
QS	4	Preservatives	QS
QS	5	Water purified	QS to 1 L

Manufacturing Directions

1. Place item 5 in a suitable stainless steel jacketed vessel, and heat to 40°C.
2. Add and dissolve item 2 and 3 in step 1.
3. While stirring, add item 1, and suspend.
4. Homogenize if necessary, and fill.

THEOPHYLLINE SODIUM GLYCINATE ELIXIR

Bill of Materials

Scale (mg/5 mL)	Item	Material Name	Qty/L (g)
125.00	1	Theophylline sodium glycinate[a]	25.00
4000.00	2	Sucrose	800.00
7.50	3	Sodium benzoate	1.50
0.75	4	Saccharin sodium	0.15
0.025	5	FD&C Red No. 40	0.005
1.00	6	Flavor	0.20
QS	7	Water purified	QS to 1 L

[a] 125 mg theophylline sodium glycinate is equivalent to 60 mg theophylline hydrate.

Manufacturing Directions

1. Add 400 g of item 7 to the manufacturing vessel, and heat to 95°C to 98°C. Add items 3 and 4 to dissolve. Mix for 10 minutes at low speed.
2. Add item 2 while mixing at low speed, temperature 95°C to 98°C. When addition is over, mix for 30 minutes at high speed.
3. Cool to 30°C while mixing at low speed.
4. Add 50 g of item 7 (25–30°C) in a separate container, and dissolve item 1 by using stirrer. Mix for 10 minutes, and transfer to the manufacturing vessel at step 3.
5. Rinse the container (step 3) with 1 g of item 7 (25–30°C), and transfer the rinsings to the manufacturing vessel while mixing at low speed.
6. Dissolve item 5 in 1 g of item 7 in a stainless steel container with slow stirring by stirrer. Transfer to the manufacturing vessel while mixing at low speed.
7. Add item 6 to the manufacturing vessel step 4 while mixing. Mix for 10 minutes at low speed.
8. Make up the volume to 1 L with item 7, and finally, mix for 5 to 10 minutes at high speed.
9. Check and record the pH (limit: 8.5–9.0 at 25°C).
10. Filtration: Assemble the filter press. Wash the filters using about 1 L of purified water (25°C) by passing through filters at 0.2 bar. Filter the syrup at 1.5 bar. Recirculate about 20 to 30 mL syrup.
11. Transfer the filtered syrup to the storage vessel.

THIABENDAZOLE SUSPENSION

Mintezol (thiabendazole) is an anthelmintic provided as a suspension, containing 500 mg thiabendazole per 5 mL. The suspension also contains sorbic acid 0.1% added as a preservative. Inactive ingredients in the tablets are acacia, calcium phosphate, flavors, lactose, magnesium stearate, mannitol, methylcellulose, and sodium saccharin. Inactive ingredients in the suspension are an antifoam agent, flavors, polysorbate, purified water, sorbitol solution, and tragacanth.

THIOTHIXENE ORAL CONCENTRATE

Ingredients are thiothixene (2–30 mg/30 mL), alcohol, cherry flavor, dextrose, passion fruit flavor, sorbitol solution, and water.

TIMOLOL MALEATE OPHTHALMIC DROPS

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
2.50	1	Timolol maleate	2.50
QS	2	Vehicle (Pluraflo 1220 92.37%, ethanol 2.11%, anhydrous glycerin 5.16%)	QS to 1 L

Manufacturing Directions

1. Add timolol. Cover tightly, and stir until a clear solution is obtained.
2. Add glycerin, ethanol, and Pluraflo to a clean vessel.

TOLNAFTATE FOOT CARE MICROEMULSION

Bill of Materials

Scale (mg/g)	Item	Material Name	Qty/kg (g)
155.00	1	Ethoxydiglycol	155.00
130.00	2	Polyglyceryl-6 dioleate	130.00
450.00	3	PEG-8 caprylic/capric glycerides	450.00
10.00	4	Tolnaftate	10.00
100.00	5	Water purified	100.00
50.00	6	Apricot kernel oil PEG-6 esters	50.00
100.00	7	Caprylic/Capric triglycerides	100.00
5.00	8	Chlorocresol	5.00

Manufacturing Directions

1. Mix items 1 to 3, and dissolve item 4 in this mixture.
2. Add items 5 to 8, and mix until uniform.

TOLU BALSAM COUGH SYRUP

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
11.03	1	Tolu balsam tincture	11.03
2.50	2	Magnesium carbonate	2.50
15.00	3	Sucrose	15.00
QS	4	Water purified	90.000 mL
0.77	5	Methylparaben	0.77
0.086	6	Propylparaben	0.086
514.36	7	Sucrose	0.51
129.24	8	Glycerin (96%)	0.13
2.00	9	Dextromethorphan hydrobromide	2.00
1.00	10	Ephedrine HCl[a]	1.00
8.00	11	Ammonium chloride	8.00
0.40	12	Chlorpheniramine maleate	0.40
1.00	13	Phenylephrine hydrochloride	1.00
333.32	14	Glucose liquid	0.33
0.35	15	Flavor	0.35
0.15	16	Flavor	0.15
1.02	17	Ipecac fluid extract	1.01
8.57	18	Alcohol[b]	8.57
0.0375	19	Dye	0.037
QS	20	Acid hydrochloric	QS
QS	21	Water purified	QS to 1 L

[a] May be deleted.

[b] Tolu balsam tincture contains 80% alcohol. Use this item optionally to dissolve flavors.

Manufacturing Directions

1. Charge tolu balsam tincture into mixing tank, and add magnesium carbonate.
2. Mix well to suspend.
3. Add sugar (item 3) with mixing. Add 90 mL purified water (item 4), and mix thoroughly.
4. Allow to set for 1 hour.
5. Mix periodically while circulating through filter.
6. Solution must be brilliantly clear. Filter, and save for next part.
7. Charge 210.5 mL purified water (item 21) into suitable tank.
8. Add and dissolve parabens M and P with heat 90°C to 95°C and mixing.
9. Add and dissolve sugar (item 7) with mixing.
10. Heat if necessary. Add glycerin, continue agitation, and cool to room temperature. Add filtrate from preceding step to cooled syrup.
11. Add and dissolve the following ingredients with mixing: dextromethorphan HBr, ephedrine HCl (if used), ammonium chloride, chlorpheniramine maleate, and phenylephrine HCl.
12. Add glucose. Mix well. Add and dissolve in alcohol: flavors and ipecac fluid extract.
13. Add to tank, or in a separate container add flavors and ipecac extract to 10 mL glucose liquid, and mix. Add this to the main mixture.
14. Rinse the container with a further 5 mL glucose liquid, and add the rinsings to the mixture.
15. Add the remaining glucose liquid. Mix well.
16. Dissolve in 1.75 mL purified water, and add.
17. Check pH (range: 4–5). Adjust to pH 4 to 5 with hydrochloric acid.
18. Make the volume to 1 L with purified water.
19. Filter until sparkling clear. Add 0.5 g Hyflo® to mixing tank, mixing until uniform.
20. Filter into tank for filling.

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
11.03	1	Tolu balsam tincture	11.03
2.50	2	Magnesium carbonate (powder)	2.50
15.00	3	Sucrose (granulated sugar)	15.00
QS	4	Purified water	90.00 mL
0.77	5	Methylparaben	0.77
0.086	6	Propylparaben	0.086
514.36	7	Sucrose (granulated sugar)	514.36
129.24	8	Glycerin (96%)	129.24
2.00	9	Dextromethorphan hydrobromide	2.00
1.00	10	Ephedrine HCl (powder)	1.00
8.00	11	Ammonium chloride	8.00
0.40	12	Chlorpheniramine maleate	0.40
1.00	13	Phenylephrine HCl	1.00
333.32	14	Glucose (liquid)	333.32
0.35	15	Flavor	0.35
0.15	16	Flavor	0.15
1.01	17	Ipecac (fluid extract)	1.01
8.57	18	Alcohol (ethanol, 190 proof)	8.57
0.037	19	Dye	0.037
QS	20	Hydrochloric acid (reagent-grade bottles)	QS
QS	21	Purified water	212.00 mL

Manufacturing Directions

1. Charge tolu balsam tincture into mixing tank, and add magnesium carbonate.
2. Mix well to suspend.
3. Add sugar (item 3) with mixing.
4. Add 90 mL purified water (item 4), and mix thoroughly.
5. Allow to set for 1 hour.
6. Mix periodically while circulating through Shriver filter (or equivalent).
7. Solution must be brilliantly clear.
8. Filter, and save for next part.
9. Charge 210.5 mL purified water (item 21) into suitable tank.
10. Add and dissolve parabens with heat (90–95°C) and mixing.

11. Add and dissolve sugar (item 7) with mixing. Heat if necessary.
12. Add glycerin, continue agitation, and cool to room temperature.
13. To cooled syrup, add filtrate from previous step.
14. Add and dissolve the following ingredients with mixing: dextromethorphan hydrobromide, ephedrine HCl, ammonium chloride, chlorpheniramine maleate, and phenylephrine HCl.
15. Add glucose. Mix well.
16. Add and dissolve flavors and Ipecac fluid extract in 190 proof alcohol.
17. To the tank or in a separate container, add flavors and Ipecac extract to 10 mL of glucose liquid, and mix.
18. Add this mixture to the main mixture.
19. Rinse the container with a further 5 mL of liquid glucose, and add the rinsings to the mixture.
20. Add the remaining liquid glucose. Mix well.
21. Dissolve in 1.75 mL purified water, and add.
22. Check pH (range: 4–5).
23. Use hydrochloric acid to adjust pH to 4 to 5, with 4.5 being optimum (~0.3 mL HCl per liter of syrup).
24. QS to 1 L with purified water.
25. Filter until sparkling clear.
26. Add a suitable filter aid, and mix until uniform.
27. Filter into tank for filling.

TRETINOIN SOLUTION (50 MG/100 G)

Formulation

I. Tretinoin (BASF), 0.05 g; Cremophor RH 40, 14.0 g; propylene glycol, 15.0 g; butylhydroxytoluene, 0.05 g; alpha-bisabolol nat. (BASF), 0.1 g
II. Water, 70.0 g; parabens/sorbic acid, QS

Manufacturing Directions

1. Heat mixture I to 40°C to 50°C to obtain a clear solution.
2. Introduce this warm solution slowly into solution II. It forms a clear yellow solution.

TRETINOIN SOLUTION

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
0.50	1	Tretinoin (BASF)	0.50
140.00	2	Cremophor RH 40	140.00
150.00	3	Propylene glycol	150.00
0.50	4	Butylated hydroxytoluene	0.50
1.00	5	Alpha bisabolol natural (BASF)	1.00
QS	6	Water purified	QS to 1 L
QS	7	Parabens	QS
QS	8	Sorbic acid	QS

Manufacturing Directions

1. Charge items 1 to 5 in a suitable stainless steel jacketed vessel. Heat to 40°C to 50°C to obtain a clear solution.
2. In a separate jacketed vessel, place item 6, and heat to 90°C to 95°C.
3. Add and dissolve items 7 and 8. Cool to 40°C.
4. Add step 3 into step 1.
5. Mix to clear solution.
6. Filter if necessary, and fill.

TRIAMCINOLONE ACETONIDE NASAL SPRAY

Tri-Nasal spray is a metered-dose manual-spray pump in an amber polyethylene terephthalate bottle with 0.05% w/v triamcinolone acetonide in a solution containing citric acid, EDTA, polyethylene glycol 3350, propylene glycol, purified water, sodium citrate, and 0.01% benzalkonium chloride as a preservative. Tri-Nasal Spray pH is 5.3.

Manufacturing Directions

Dissolve 20 g triamcinolone acetonide in 1.5 kg ethanol. The solution is dispensed into open aluminum containers, and these are sealed with suitable metering valves. The containers are filled by means of the pressure-filling technique with a total of 4 kg HFA 227 that has been aerated with carbon dioxide and adjusted to a pressure of 5 bar (20°C).

TRICLOSAN ORAL SOLUTION

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
QS	1	Vehicle (Pluronic F108 55.80%, ethanol 21.30%, water 22.90%)	QS to 1 L
2.80	2	Triclosan monophosphate	2.80
10.00	3	Menthol	10.00
1.00	4	Sodium saccharin	1.00
0.50	5	Monosodium glycyrrhizinate	0.50
QS	6	Flavors and colors	QS

Manufacturing Directions

1. Mill and screen the menthol and triclosan monophosphate to reduce particle size.
2. Add the menthol, triclosan monophosphate, sodium saccharin, and monoammonium glycyrrhizinate into a clean vessel.
3. Add propylene glycol to the vessel.
4. Subsequently, add the poloxamer and water to the vessel.
5. Mix until uniform.

TRIPROLIDINE AND PSEUDOEPHEDRINE HYDROCHLORIDE SYRUP

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
0.25	1	Triprolidine HCl, 4.8% excess	0.26
6.00	2	Pseudoephedrine HCl, 3.0% excess	6.18
600.00	3	Sucrose	600.00
100.00	4	Glycerin (glycerol)	100.00
100.00	5	Sorbitol (70% solution)	100.00
15.00	6	Propylene glycol	15.00
1.00	7	Methylparaben	1.00
0.30	8	Propylparaben	0.30
0.50	9	Saccharin sodium	0.50
0.04	10	Quinoline yellow	0.04
0.05	11	Menthol	0.05
0.25	12	Raspberry flavor	0.25
1.15	13	Sodium citrate	1.15
QS	14	Water purified	QS to 1 L

Manufacturing Directions

1. Add 400 g of item 14 to the manufacturing vessel, and heat to 90°C to 95°C.
2. Add items 7 and 8 while mixing to dissolve at high speed.
3. Add item 3 while mixing at slow speed. Temperature 90°C to 95°C.
4. Mix for 1 hour at high speed. Cool down to 50°C while mixing at slow speed.
5. Add items 9 and 13 to the manufacturing vessel while mixing at high speed.
6. Load items 5 and 4 into the manufacturing vessel using transfer pump while mixing at high speed.
7. Add 20 g of cold item 14 (30°C) in a separate container, and dissolve items 1 and 2 by using stirrer.
8. Mix for 10 minutes, and add to the manufacturing vessel while mixing at high speed.
9. Add 1 g of item 14 in a separate container, and dissolve item 10 manually.
10. Add color to the manufacturing vessel while mixing at high speed. Dissolve item 11 in item 12. Then, add item 6 to it. Add this flavor mixture to the manufacturing vessel while mixing at high speed.
11. Make up the volume to 1 L with item 14, and finally, mix for 15 to 20 minutes at high speed.
12. Check and record the pH (limit: 5.8–6.8 at 25°C).
13. If required, adjust pH with 20% citric acid or 20% sodium citrate solution.
14. Filter the syrup at 1.5 bar. Recirculate about 20 to 30 mL syrup.

TULOBUTEROL SYRUP

B.ill of Materials

Scale (mg/5 mL)	Item	Material Name	Qty/L (g)
1.00	1	Tulobuterol hydrochloride	0.20
5.00	2	Water purified	100.00 mL
3.75	3	Glycerin	75.00 mL
0.03	4	Methylparaben	0.60
0.0075	5	Propylparaben	0.15
QS	6	Red dye	25.00 mg
QS	7	Flavor	5.00
QS	8	Sorbitol (70%)	QS to 1 L

Manufacturing Directions

1. Heat 50 mL water to approximately 80°C and 95°C in a suitable vessel.
2. Add the methylparaben and propylparaben. Rinse the containers with some of the remaining water if necessary. Stir until dissolved, maintaining temperature at about 80°C.
3. Warm about 340 mL sorbitol solution to 40°C and 55°C in a suitable vessel.
4. Transfer the warm sorbitol to the final mixing vessel and add the hot paraben solution from step 2, stirring continuously. Rinse paraben solution container with 5 mL hot water, and add to the bulk.
5. Dissolve tulobuterol and dye in about 25 mL remaining water, rinsing the containers with some of the remaining water if necessary.
6. Add the solution from the preceding step to the final vessel, mixing continuously. It is important to ensure

all of the colored solution is transferred. Rinse the container with a portion of the remaining water.
7. Add the glycerol and flavor to the bulk solution. Rinse the glycerol container with the remaining water, and add to the bulk. Make up to volume with the sorbitol solution.
8. Mix gently until a uniform syrup is obtained, avoiding incorporation of air bubbles.
9. If necessary, circulate through a filter press until sparkling clear.
10. Pass filtered clear syrup into a suitable holding tank.

TOLNAFTATE FOOT CARE MICROEMULSION

Bill of Materials

Scale (mg/g)	Item	Material Name	Qty/kg (g)
155.00	1	Ethoxydiglycol	155.00
130.00	2	Polyglyceryl-6 dioleate	130.00
450.00	3	PEG-8 caprylic/capric glycerides	450.00
10.00	4	Tolnaftate	10.00
100.00	5	Deionized water	100.00
50.00	6	Apricot kernel oil PEG-6 esters	50.00
100.00	7	Caprylic/Capric triglycerides	100.00
5.00	8	Chlorocresol	5.00

Manufacturing Directions

1. Mix items 1 to 3, and dissolve item 4 in this mixture.
2. Add items 5 to 8, and mix until uniform.

TRIPROLIDINE AND PSEUDOEPHEDRINE HYDROCHLORIDE SYRUP

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
0.25	1	Triprolidine HCl (4.8% excess)	0.26
6.00	2	Pseudoephedrine HCl (3.0% excess)	6.18
600.00	3	Sucrose	600.00
100.00	4	Glycerin (glycerol)	100.00
100.00	5	Sorbitol (70% solution)	100.00
15.00	6	Propylene glycol	15.00
1.00	7	Methylparaben	1.00
0.30	8	Propylparaben	0.30
0.50	9	Saccharin sodium	0.50
0.04	10	Quinoline yellow	0.04
0.05	11	Menthol	0.05
0.25	12	Raspberry flavor	0.25
1.15	13	Sodium citrate	1.15
QS	14	Purified water	QS to 1 L

Manufacturing Directions

1. Add 400 g of purified water to the manufacturing vessel, and heat to 90°C to 95°C.
2. Add items 7 and 8 while mixing to dissolve at high speed.
3. Add item 3 while mixing at slow speed (temperature: 90–95°C).
4. Mix for 1 hour at high speed.
5. Cool down to 50°C while mixing at slow speed.
6. Add items 9 and 13 to the manufacturing vessel while mixing at high speed.
7. Load items 5 and 4 into the manufacturing vessel using a transfer pump while mixing at high speed.
8. Add 20 g of cold purified water (30°C) in a separate container, and dissolve items 1 and 2 by using stirrer.
9. Mix for 10 minutes, and add to the manufacturing vessel while mixing at high speed.
10. Add 1 g of purified water in a separate container, and manually dissolve item 10.
11. Add color to the manufacturing vessel while mixing at high speed.
12. Dissolve item 11 in item 12, and then add item 6.
13. Add this flavor mixture to the manufacturing vessel while mixing at high speed.
14. Bring the volume up to 1 L with item 14, and finally, mix for 15 to 20 minutes at high speed.
15. Check and record the pH (limit: 5.8–6.8 at 25°C).
16. If required, adjust pH with 20% citric acid or 20% sodium citrate solution.
17. Filter the syrup at 1.5 bar.
18. Recirculate about 20 to 30 mL syrup.

UNDECYLENIC ACID AND CHLOROXYLENOL SOLUTION

This is an antifungal solution for topical use containing 25% undecylenic acid and 3% chloroxylenol as its active ingredients in a penetrating oil base. Available in 1 oz bottles with special brush applicator.

UREA PEROXIDE EAR DROPS

Bill of Materials

Scale (mg/g)	Item	Material Name	Qty/kg (g)
65.00	1	Urea peroxide (40% excess)	91.00
15.00	2	Sodium citrate (dihydrate, powder)	15.00
5.00	3	Polysorbate 20 (Tween 20)	5.00
2.50	4	Tartaric acid (12663)	2.50
QS	5	Anhydrous glycerin	QS
QS	6	Nitrogen	QS

Manufacturing Directions

1. Add 500 mL of glycerin into a suitable tank.
2. Start mixing at slow speed, and heat the contents to 70°C to 75°C.
3. Flood tank with nitrogen, increase mixing speed, and slowly add sodium citrate.
4. Add tartaric acid.
5. Mix for at least 30 minutes or until dissolved.
6. Maintain the temperature at 70°C to 75°C.
7. When sodium citrate is completely dissolved, cool to 25°C to 30°C with constant mixing.
8. Prepare urea peroxide by breaking up lumps and screening to remove large particles.
9. Wear gloves.
10. Add an additional 250 to 300 mL of glycerin into tank.
11. Add urea peroxide slowly to prevent lumping while mixing constantly.
12. Mix at high speed after addition.
13. Add polysorbate 20 with constant mixing, and QS to final volume with glycerin.
14. Mix for at least 30 minutes and until solution is clear.
15. Pass solution through an approximately No. 100 mesh (150 μm or similar) screen, and collect in clean, dry carboys. (The filter support screen in a Millipore holder may be used for filtering; the solution is too viscous to flow through a membrane or any cellulosic filter.)

VALPROIC ACID CAPSULES

Valproic acid is a carboxylic acid designated as 2-propylpentanoic acid. It is also known as dipropylacetic acid. Capsules and syrup are antiepileptics for oral administration. Each soft elastic capsule contains 250 mg valproic acid. Inactive ingredients for the 250 mg capsules are corn oil, FD&C Yellow No. 6, gelatin, glycerin, iron oxide, methylparaben, propylparaben, and titanium dioxide.

VALPROIC ACID SYRUP

Valproic acid is a carboxylic acid designated as 2-propylpentanoic acid. It is also known as dipropylacetic acid. Capsules and syrup are antiepileptics for oral administration. The syrup contains the equivalent of 250 mg valproic acid per 5 mL as the sodium salt. Inactive ingredients are FD&C Red No. 40, glycerin, methylparaben, propylparaben, sorbitol, sucrose, water, and natural and artificial flavors.

VANCOMYCIN HYDROCHLORIDE ORAL SOLUTION

Vancocin HCl for oral solution contains vancomycin hydrochloride equivalent to 10 g (6.7 mmol) or 1 g (0.67 mmol) vancomycin. Calcium disodium edetate, equivalent to 0.2 mg edetate per gram of vancomycin, is added at the time of manufacture. The 10 g bottle may contain up to 40 mg of ethanol per gram of vancomycin.

VITAMIN A AND VITAMIN D INFANT DROPS

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
1500 IU	1	Vitamin A palmitate (1.7 MM IU/g) (50% excess)	1.323
400 IU	2	Vitamin D (40 MM IU/g) (Cholecalciferol) (25% excess)	0.012
10.00	3	Polysorbate 80 (Tween 80)	10.00
0.88	4	Vitamin E (oily; α-tocopheryl acetate)	0.88
0.50	5	Edetate disodium (sodium EDTA)	0.50
1.00	6	Ascorbic acid	1.00
0.10	7	Saccharin sodium	0.10
600.00	8	Glycerin (glycerol)	600.00
100.00	9	Sorbitol (70% solution)	100.00
50.00	10	Propylene glycol	50.00
1.00	11	Flavor	1.00
1.50	12	Flavor	1.50
QS	13	Dye	QS
QS	14	Dye	QS
—	15	Purified water	QS to 1 L

Manufacturing Directions

1. This product is a microemulsion and thermolabile preparation. The temperature of solution must not exceed 25°C at the time of processing. Store bulk at a temperature of 15°C to 20°C under nitrogen protection. Period of storage should not exceed 48 hours prior to filling in the bottle.
2. Collect 200 g of purified water in a melting vessel.
3. Heat to 90°C to 95°C for 10 minutes, and then cool to 20°C to 25°C.
4. Bubble nitrogen gas into purified water for 20 minutes.
5. Load 100 g of purified water into the manufacturing vessel.
6. Bubble nitrogen gas during all stages of the processing.
7. Add items 5, 6, and 7 one by one to the manufacturing vessel while mixing.
8. Check that all materials are dissolved completely.
9. Add items 8 and 9 and 20 g of item 10 one by one to the manufacturing vessel while mixing at slow speed.
10. Mix for 5 minutes.
11. Avoid aeration.
12. Add item 3 in a stainless steel container.
13. Mix items 1, 2, and 4 one by one using a stirrer.

14. Mix for 1 hour at slow speed.
15. Avoid aeration.
16. Add the oil phase to the aqueous phase in the manufacturing vessel at a rate of 4 mL/min while mixing; keep on bubbling nitrogen gas throughout the process.
17. Dissolve items 11 and 12 in 30 g of item 10 in a stainless steel container by slow stirring.
18. Add to manufacturing vessel while mixing.
19. Dissolve items 14 and 13 in 40 g of purified water (25–30°C) in a stainless steel container with slow stirring.
20. Add to manufacturing vessel while mixing.
21. Adjust the volume to 1.0 L with cooled purified water.
22. Check and record the volume and pH (limit: 2.5–4.8).
23. Filter the solution through a prefilter and 0.2 μm membrane filter into the receiving tank.
24. Bubble with nitrogen gas for 15 minutes.
25. Store the solution with a nitrogen blanket.

VITAMIN A AND D INFANT DROPS

Bill of Materials

Scale (mg/g)	Item	Material Name	Qty/L (g)
30,000 IU	1	Vitamin A palmitate (1.7 MM IU/g)	1.90
3000 IU	2	Vitamin D3 (40 MM IU/g)	7.50 mg
12.00	3	Cremophor (relative humidity, 40%)	12.00
0.30	4	Butylhydroxytoluene	0.30
10.00	5	Lutrol E 400	10.00
0.80	6	Paraben	0.80
0.20	7	Sorbic acid	0.20
QS	8	Water	QS to 1 L

Manufacturing Directions

1. Heat mixture of items 1 to 5 and solution of items 6 to 8 to about 65°C, and add this slowly to the well-stirred mixture of items 1 to 5.
2. Clear or slightly opalescent yellow liquid is obtained.

VITAMIN A AND VITAMIN D3 DROPS

Bill of Materials

Scale (mg/g)	Item	Material Name	Qty/L (g)
30,000 U	1	Vitamin A palmitate 1.7 million U/g	1.90
3000 U	2	Vitamin D3 40 million U/g	7.5 mg
12.0	3	Cremophor RH 40	12.00
0.3	4	Butylhydroxytoluene	0.30
10.0	5	Lutrol E 400	10.00
0.8	6	Parabens (propyl and methyl)	0.80
0.2	7	Sorbic acid	0.20
74.8	8	Water purified	74.80

Manufacturing Directions

1. Heat mixture of items 1 to 5 and solution of items 6 to 8 to about 65°C.
2. Add this slowly to the well-stirred mixture of items 1 to 5. Yellow clear or slightly opalescent liquid is obtained.

VITAMIN A AND VITAMIN D3 ORAL SOLUTION

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (mg)
1000 IU	1	Vitamin A palmitate (1.7 MM IU/g)	60.00
100 IU	2	Vitamin D3 (40 MM IU/g)	0.30
0.002	3	Butylhydroxytoluene	0.20
3.00	4	Cremophor EL or Cremophor (relative humidity, 40%)	3.00 g
QS	5	Preservative	QS
QS	6	Flavor	QS
QS	7	Water	QS to 1 L

Manufacturing Directions

1. Heat mixture of items 1 to 4 to about 65°C, stir well, and slowly add the hot solution of item 5 (65°C).
2. Cool to room temperature and add item 6 to obtain a clear, yellow liquid.

VITAMIN A AND VITAMIN D3 SYRUP

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
30,000 IU	1	Vitamin A palmitate (1.7 MM IU/g)	19.00
10,000 IU	2	Vitamin D3 (40 MM IU/g)	0.25
70.00 mg	3	Cremophor (relative humidity, 40%)	7.00
QS	4	Sugar syrup (50%)	QS to 1 L

Manufacturing Directions

1. Heat mixture of items 1 to 3 to approximately 45°C, stir well, and slowly add item 4 to obtain a clear, yellow liquid (pH 6.2).

VITAMIN A AND VITAMIN E DROPS

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
25,000 U	1	Vitamin A palmitate 1.7 million U/g	15.00
50.00	2	Vitamin E acetate	50.00
210.00	3	Cremophor RH 40[a]	210.00
QS	4	Preservative	QS
QS	5	Water purified	QS to 1 L

[a] The quantity is reduced by 1.0 g if DL-alpha-tocopherol is also added at 1.0 g level in the formulation.

Manufacturing Directions

1. Mix the vitamins with Cremophor RH 40 (and DL-alpha-tocopherol, if used) at 60°C.
2. Add solution of preservatives (at 37°C) slowly, with stirring. Clear, yellow, viscous liquids are formed.

VITAMIN A AND VITAMIN E DROPS

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
5000 U	1	Vitamin A palmitate 1.7 million U/g	3.33
50.00	2	Vitamin E acetate	60.00
150.00	3	Cremophor RH 40	150.00
150.00	4	Alcohol	150.00
QS	5	Water purified	QS to 1 L

Manufacturing Directions

1. Heat mixture of items 1 to 3 to about 65°C. Stir well.
2. Slowly add the mixture of items 4 and 5. Color is yellow, and clarity should be clear (turbidity units: 25 FTU). It must be tested to see whether the ethanol concentration has a sufficient preservative efficiency. The addition of butylhydroxytoluene as antioxidant is recommended.

VITAMIN A AND VITAMIN E DROPS

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L
25,000 IU	1	Vitamin A palmitate (1.7 Mio IU/g)	1.50
50.00	2	Vitamin E acetate	5.00
210.00	3	Cremophor (relative humidity, 40%)[a]	21.00
QS	5	Preservative	QS
QS	6	Water	71.50

[a] The quantity is reduced by 1.0 g if 1.0 g of D,L-*α*-tocopherol is also added in the formulation.

Manufacturing Directions

1. Mix the vitamins with Cremophor (and D,L-*α*-tocopherol, if used) at 60°C.
2. Add solution of preservatives (at 37°C) slowly, with stirring to produce clear, yellow, viscous liquids.

VITAMIN A CONCENTRATE, WATER-MISCIBLE

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
100,000 U	1	Vitamin A palmitate 1.7 million U/g	65.00
2.00	2	Butylhydroxytoluene	2.00
210.00	3	Cremophor RH 40	210.00
QS	4	Preservative	QS
QS	5	Water purified	QS to 1 L

Manufacturing Directions

1. Heat the mixture of items 1 to 3 to about 65°C. Stir well.
2. Add very slowly the warm solution of items 4 and 5 (65°C). Clear, yellow liquid, miscible with water, is formed.

VITAMIN A DROPS

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/1000 Tablets (g)
50,000 IU	1	Vitamin A palmitate (1.7 Mio IU/g)	3.00
110.00	2	Cremophor (relative humidity, 40%)	11.00
1.00	3	Butylhydroxytoluene	0.10
QS	4	Water	85.90

Manufacturing Directions

1. Heat the mixture of items 1 to 3 to about 65°C. Stir well.
2. Slowly add the hot water (65°C) to obtain a clear or slightly opalescent yellow solution of low viscosity.
3. Lutrol E 400 can be added at a level of 5% (compensated for by item 4).

VITAMIN A DROPS

Manufacturing Directions

1. Heat the mixture of items 1 to 3 to approximately 65°C. Stir well.
2. Slowly add the hot water (65°C). The solution should be yellow and clear or slightly opalescent and of low viscosity. Lutrol E 400 can be added at a level of 5%, compensated by item 4.

VITAMIN B COMPLEX SYRUP

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
0.66	1	Dexpanthenol	0.66
4.40	2	Nicotinamide	4.44
0.22	3	Pyridoxine HCl	0.22
0.60	4	Riboflavin-5-phosphate sodium	0.60
1.50	5	Thiamine HCl	1.50
350.00	6	Sorbitol (70% solution)	350.00
11.20	7	Propylene glycol	11.20
0.84	8	Methylparaben	0.84
0.16	9	Propylparaben	0.16
550.00	10	Maltitol solution (Lycasin 80/55)	550.00
0.15	11	Edetate disodium (sodium EDTA)	0.15
3.72	12	Citric acid (monohydrate)	3.72
3.72	13	Sodium citrate	3.72
2.50	14	Sodium benzoate	2.50
0.50	15	Saccharin sodium	0.50
150.00	16	Glycerin (glycerol)	150.00
1.50	17	Flavor	1.50
1.00	18	Flavor	1.00
—	19	Water purified	QS to 1 L

Manufacturing Directions

1. Load items 6, 10, and 16 in a suitable manufacturing vessel, and mix for 5 minutes.
2. Dissolve items 8 and 9 in item 7 in a stainless steel container.
3. Put the whole container in hot water (60–70°C), and stir to dissolve.
4. Add the clear solution to mixer.
5. Dissolve items 11 and 12 in 40 g of item 19 in a stainless steel container.
6. Add the clear solution to mixer.
7. Dissolve items 13, 14, and 15 in 50 g of item 19 in a stainless steel container. Add the clear solution to mixer, and mix for 5 minutes.
8. Dissolve item 1 in 10 g of item 19 in a stainless steel container.
9. Add the clear solution to mixer. Dissolve items 3 and 5 in 10 g of item 19 in a stainless steel container. Add the clear solution to mixer.
10. Dissolve items 2 and 4 in 30 g of item 19 in a stainless steel container.
11. Add the clear yellow solution to mixer, and mix for 5 minutes.
12. Add items 17 and 18 to mixer. Make up the volume up to 1 L with item 19, and finally, mix for 15 to 20 minutes.
13. Check and record the pH (limit: 4.4–4.8 at 25°C). If required, adjust pH with 20% citric acid or 20% sodium citrate solution.
14. Filter the syrup at 1.5 bar. Recirculate about 200 to 300 mL syrup.
15. Transfer the filtered syrup to the storage vessel, flushing with nitrogen gas. Store the syrup under nitrogen blanket NMT 2 days before filling.

VITAMIN B COMPLEX SYRUP

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
0.60	1	Thiamine hydrochloride (BASF)	0.60
0.55	2	Riboflavin 5-phosphate sodium	0.55
2.50	3	Nicotinamide	2.50
12.00	4	Dexpanthenol (BASF)	12.00
0.55	5	Pyridoxine hydrochloride	5.50
2.00	6	Sorbic acid	20.00
0.050	7	EDTA sodium	0.50
2.25	8	Vanillin	22.50
465.00	9	Sucrose	465.00
25.00	10	Kollidon® 25	25.00
90.00	11	Glycerin	90.00
100.00	12	Propylene glycol	100.00
QS	13	Water purified	QS to 1 L

Manufacturing Directions

1. Charge glycerin, propylene glycol, and purified water in a suitable stainless steel jacketed vessel. Heat to 65°C.
2. Add and dissolve sucrose in step 1.
3. Cool to room temperature.
4. Add and dissolve all other items.
5. Filter if necessary. Fill.

VITAMIN B COMPLEX AND VITAMIN C SYRUP

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
0.150	1	Thiamine hydrochloride	0.15
0.15	2	Riboflavin phosphate sodium	0.15
0.70	3	Nicotinamide	0.70
0.035	4	Dexpanthenol	0.035
0.15	5	Pyridoxine hydrochloride	0.15
2.25	6	Ascorbic acid, crystalline	2.25
0.28	7	Orange aroma	0.28
0.56	8	EDTA sodium	0.56
186.50	9	Propylene glycol (pharma) + water (2:1)	186.50
0.15	10	Parabens	0.155
84.30	11	Sorbitol, crystalline	84.30
562.50	12	Sucrose, crystalline	562.50
QS	13	Water purified	QS to 1 L

Manufacturing Directions

1. Dissolve items 1 to 8 in item 2.
2. Prepare solution of items 10 to 13 by heating, cool, and mix with solution balance of formulation.
3. Adjust to pH 4.2 to 4.5. Adjust volume with item 13; use more if necessary. Use nitrogen as inert gas during packaging.

VITAMIN B COMPLEX (WITHOUT B12) SYRUP

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
570.00	1	Sucrose	570.00
70.00	2	Glycerin	70.00
3.72	3	Citric acid (monohydrate)	3.72
1.00	4	Edetate disodium (sodium EDTA)	1.00
0.90	5	Calcium pantothenate, 10% excess	1.00
5.70	6	Sodium citrate	5.70
0.84	7	Methylparaben	0.84
0.18	8	Propylparaben	0.18
1.90	9	Benzoic acid	1.90
1.14	10	Strawberry flavor manefils	1.14
9.60	11	Alcohol	9.60
1.50	12	Thiamine HCl, 50% excess	1.50
0.20	13	Pyridoxine hydrochloride, 10% excess	0.22
4.00	14	Nicotinamide, 10% excess	4.40
0.30	15	Riboflavin sodium phosphate, 50% excess	0.60
—	16	Water purified	QS to 1 L

Manufacturing Directions

1. Flush with nitrogen gas (purity 99.95%).
2. Add 400 g of item 16 to the manufacturing vessel, and heat to 90°C to 95°C.
3. Add item 1 while mixing at low speed. After addition of item 1, mix for 30 to 35 minutes at high speed and temperature 90°C to 95°C.
4. Cool to 40°C while mixing at low speed.
5. Disperse 1 g filter aid in 10 g cooled item 16 (25–30°C) in a stainless steel container to prepare a slurry.
6. Add the slurry to syrup in syrup vessel. Mix for 15 minutes at high speed.
7. Filter the syrup at 1.5 bar.
8. Recirculate about 40 to 60 mL syrup.
9. Transfer the filtered syrup to the storage vessel. Recharge the filtered syrup to the manufacturing vessel. Start mixing.
10. Add item 2 to the syrup vessel while mixing at high speed.
11. Add item 3 to the syrup vessel while mixing to dissolve at high speed.
12. Dissolve item 4 in 6 g of cooled item 16 (25–30°C), and add to the syrup vessel while mixing at high speed.
13. Dissolve item 5 in 6 g of cooled item 16, and add to the syrup vessel while mixing at high speed for 30 minutes.

14. Dissolve item 6 in 10 g of cooled item 16 (25–30°C), and add to the syrup vessel while mixing at high speed.
15. Dissolve items 7, 8, 9, and 10 in item 11 in a stainless steel container, and add to the syrup vessel while mixing at high speed for 15 minutes.
16. Dissolve items 12 and 13 in 6 g of cooled item 16 (25–30°C) in a separate stainless steel container, and add to the syrup vessel while mixing at high speed.
17. Rinse the container with 1 g of cooled item 16 (25–30°C), and add the rinsing to the syrup vessel while mixing at high speed.
18. Flush the vessel with nitrogen gas purity 99.95% for 15 minutes.
19. Dissolve item 14 in 9 g of cooled item 16 in a separate stainless steel container, and add to the syrup vessel while mixing at high speed.
20. Rinse the container with 1 g of cooled item 16 (25–30°C), and add the rinsing to the syrup vessel while mixing at high speed.
21. Dissolve item 15 in 4 g of cooled item 16 (25–30°C) in a separate stainless steel container, and add to the syrup vessel while mixing at high speed.
22. Rinse the container with 1 g of cooled item 16, and add the rinsings to the syrup vessel while mixing at high speed.
23. Make up the volume to 1 L with cooled item 16 (25–30°C), and finally, mix for 15 minutes at high speed.
24. Check and record the pH (limit: 4.3–4.7 at 25°C).
25. If required, adjust pH with 10% solution of citric acid or sodium citrate.
26. Flush the syrup with nitrogen gas purity 99.95% for 15 minutes.
27. Close the tank. Hold the syrup for 12 hours. Filter the syrup at 1.5 bar. Recirculate about 40 to 60 mL syrup.
28. Transfer the filtered syrup to the storage vessel.

VITAMIN B COMPLEX, A, C, D, AND CALCIUM DROPS

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
675.00	1	Glycerin	675.00
16.66	2	Niacinamide powder white	16.66
2.739	3	Riboflavin-51-phosphate sodium, 3% excess	2.822
0.500	4	Methyl paraben	0.500
1.0	5	Acid benzoic	1.00
105.0	6	Saccharin sodium powder	105.00
73.360	7	Calcium chloride granules (dihydrate)	73.36
28.785	8	Ferrous gluconate	28.78
2.25	9	Thiamine HCl powder regular, 35% excess	3.37
1.000	10	Pyridoxine hydrochloride	1.00
83.33	11	Acid ascorbic white powder, 35% excess	112.50
0.258	12	Oil orange terpeneless	0.25
0.081	13	Alcohol	0.081
80.00	14	Polysorbate 80	80.00
0.167	15	Butylated hydroxyanisole	0.16
0.666	16	Viosterol in corn oil (synthetic oleovitamin D USP 1000 mD/g), 25% excess	0.83
0.056	17	Vitamin A palmitate 1,500,000 U/g	0.056
10.000	18	Caramel acid proof	10.00
QS	19	Water purified	QS to 1 L

Manufacturing Directions

Product must not stand more than 1 week before filling. Avoid unnecessary exposure of product to light, air, and heat. Manufacture and store product under complete CO_2 protection. Avoid vigorous mixing.

1. Charge glycerin and 210 mL purified water into a stainless steel jacketed tank.
2. Add with mixing in the following order: niacinamide, riboflavin, ascorbic acid.
3. Continue mixing, heat to 95°C to 100°C, and hold to completely dissolve the ingredients.
4. Add, in portions, calcium chloride, and stir until complete solution.
5. Continue mixing and cool to 70°C to 75°C. Add with mixing and dissolve ferrous gluconate at 70°C to 75°C. Check for absence of nondissolved material.
6. Check volume, and if necessary, replace the purified water lost by heating with additional purified water, previously boiled, QS to 750 mL.
7. Cool with mixing to room temperature 25°C to 30°C while bubbling CO_2 gas through. Continue the CO_2 gas bubbling for balance of process.

8. Add and dissolve each ingredient in the order named: thiamine HCl, pyridoxine HCl, and ascorbic acid. Dissolve oil orange in ethyl alcohol and add with stirring.
9. Heat polysorbate 80 to 50°C to 60°C, and hold for approximately 10 minutes with slow mixing.
10. Add and dissolve butylated hydroxyanisole.
11. Mix slowly, and saturate with CO_2 while cooling to 25°C to 30°C.
12. Add and dissolve viosterol in corn oil and vitamin A palmitate, riboflavin-51-phosphate sodium, methylparaben, benzoic acid, and saccharin sodium, mixing well with CO_2 gas blowing.
13. Add polysorbate solution to main batch, and mix thoroughly. Rinse container with a portion of main batch.
14. Heat 50\mL purified water to 35°C to 40°C while bubbling CO_2 gas through.
15. Add caramel color. Mix well until uniform.
16. Add to main batch. Rinse container with a small quantity of purified water that has been previously saturated with CO_2 gas.
17. Add to main batch. Add purified water that has been previously saturated with CO_2 gas.
18. Bring to volume.
19. Filter without using filter aid. Cycle to achieve clarity. Keep carbon dioxide cover.

VITAMIN B COMPLEX AND IRON SYRUP

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
910.00	1	Sorbitol solution	910.00
0.019	2	Propylparaben	0.019
0.170	3	Methylparaben	0.170
1.500	4	Niacinamide powder white	1.500
0.300	5	Riboflavin	0.300
103.600	6	Propylene glycol	103.60
126.400	7	Glycerin	126.40
26.132	8	Iron sulfate granular	26.13
0.0375	9	Dye	0.037
0.250	10	Pyridoxine hydrochloride	0.25
1.200	11	Saccharin sodium powder dihydrate	1.20
22.000	12	Sodium cyclamate powder	22.00
30.000	13	Acid ascorbic white powder	30.00
0.800 g	14	Sodium bicarbonate	0.80
0.360	15	Thiamine hydrochloride powder regular	0.36
0.625	16	D-Pantothenyl alcohol (dexpanthenol FCC)	0.62
0.0020	17	Vitamin B_{12} (cyanocobalamin)	0.002
0.007	18	Flavor	0.700 mL
QS	19	Water purified	QS to 1 L
QS	20	Filter aid HyFlo	QS
QS	21	Acid hydrochloric	QS
QS	22	Sodium hydroxide	QS

Manufacturing Directions

1. Manufacture under complete CO_2 protection.
2. Load 780 g (portion of item 2) of sorbitol solution into a stainless steel jacketed tank. Remaining sorbitol to be used later.
3. Add parabens (unless added previously), niacinamide, and riboflavin to the sorbitol or glucose solution.
4. Heat solution to 85°C to 90°C, and mix until the ingredients are dissolved.
5. Remove heat. While mixing, cool the main solution to 50°C to 60°C.
6. Hold at this temperature while bubbling CO_2 into it. CO_2 protection is continued for the remainder of the manufacturing procedure.
7. Heat 50 mL purified water to boiling, and bubble CO_2 into it while cooling to 55°C.
8. Add and dissolve, with mixing, iron sulfate with 30 mL purified water at 55°C. Use CO_2 protection.
9. Warm the solution to 50°C to 55°C while mixing to dissolve. Then, add the solution slowly, with good mixing, to the solution.
10. The addition in step 9 should be made as soon as possible to prevent oxidation. Add the pyridoxine, saccharin sodium, and sodium cyclamate, and mix until dissolved.
11. Cool the solution to 30°C. Add the ascorbic acid with good stirring to 78 g of reserved sorbitol; make a slurry. Use a container that has plenty of headspace.
12. Add the sodium bicarbonate slowly in small portions to the ascorbic acid slurry with stirring until all the powder has been added and most of the foaming has stopped.
13. Add this slurry slowly to the solution from the preceding step with vigorous mixing until a uniform solution results.
14. Rinse the mixing container with 22 g of the reserved sorbitol, and add to the product with stirring.
15. Add and dissolve thiamine hydrochloride with mixing. If necessary, warm the D-pantothenyl alcohol until liquefied, and add it to the 0.5 mL CO_2-saturated purified water.
16. Use an additional 0.5 mL CO_2-saturated purified water to thoroughly rinse the container of D-pantothenyl alcohol, and add this to the D-pantothenyl alcohol solution.
17. Mix the D-pantothenyl alcohol solution thoroughly until homogeneously dispersed.
18. Add the D-pantothenyl alcohol solution to the main solution with mixing. Use an additional 0.5 mL CO_2-saturated purified water to rinse out the container in which the D-pantothenyl alcohol solution is made, and add to the product with mixing.
19. Dissolve vitamin B_{12} in 0.5 mL purified water to make a clear solution, and add this solution to the product with good mixing.

20. Dissolve the flavor in 10 g of propylene glycol, reserved from earlier step, with good stirring. Add this solution to the product with good mixing. Check pH (range: 3.0–3.3). Adjust, if necessary, with a solution of 10% sodium hydroxide or 10% hydrochloric acid depending on the test results.
21. Adjust the volume of the product with the remaining 30 g of the sorbitol solution, or if necessary, purified water, to 1 L.
22. Mix for 1 hour. Allow to stand overnight to eliminate entrapped CO_2 gas. Readjust volume to 1 L with purified water. Mix for 1 hour. Filter by adding HyFlo filter aid and mixing it, followed by passing through filter press. Do not allow temperature to exceed 30°C. Bubble CO_2 gas into clear filtrate for 5 minutes. Then, seal tank and hold product under CO_2 protection.

VITAMIN B COMPLEX AND VITAMIN C SYRUP

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
0.15	1	Thiamine hydrochloride	0.15
0.15	2	Riboflavin phosphate sodium	0.15
0.70	3	Nicotinamide	0.70
0.035	4	Dexpanthenol	0.035
0.150	5	Pyridoxine hydrochloride	0.15
2.25	6	Ascorbic acid (crystalline)	2.25
0.28	7	Orange aroma	0.28
0.56	8	EDTA sodium	0.56

0.30	18	Lemon oil terpeneless	0.30
0.84	19	Strawberry oil composed	0.84
—	20	Purified water	QS to 1 L

Manufacturing Directions

This product is an aqueous solution of water-soluble vitamins with oily vitamin A palmitate and cholecalciferol solubilized in water using the surfactant system of Tween 80 and cetomacrogol. This syrup is a solubilized oil surfactant system and is liable to heat and rate of mixing. The temperature of the solution must not exceed 30°C at the time of final mixing.

The final mixing must be in continuous manner without any interruption. For the preparation of oily phase, the container must be dry.

1. Before start of batch, cool approximately 80 mL purified water, and flush with nitrogen gas (purity 99.95%). Use this water for making solutions and for adjusting the volume.
2. Add 420 g of item 20 to the manufacturing vessel, and heat to 90°C to 95°C.
3. Add items 2 and 3 while mixing to dissolve.
4. Add item 1 while mixing at slow speed. After addition of item 1, mix for 30 to 35 minutes at high speed, temperature 90°C to 95°C. Cool to 25°C to 30°C while mixing at low speed.
5. Bubble nitrogen gas for 10 minutes. Add item 4 to the syrup while mixing at high speed to dissolve.

6. Add item 5 to the syrup while mixing at high speed to dissolve.
7. Add 4 g of item 20 (25°C) in a separate container, and dissolve item 6 by using stirrer.
8. Transfer the cooled item 6 solution to the syrup tank while mixing at high speed. Mix for 15 minutes.
9. Check pH of the syrup (limit: 3.75–3.85). Add items 7 to 11 one by one to the syrup in manufacturing vessel while mixing at high speed to dissolve.
10. Mix for 10 minutes. Add 6 g of cold item 20 (25°C) in a separate container, and dissolve item 12.
11. Add to the manufacturing vessel while mixing at high speed. Rinse the container with cooled item 20, about 2 mL, transfer the rinsings to the syrup-manufacturing vessel, and mix well at high speed.
12. Add item 13 to the manufacturing vessel while mixing at high speed.
13. Warm item 14 to 70°C in a separate stainless steel container in water bath.
14. Warm item 16 to 70°C, and mix well with item 14 under nitrogen atmosphere.
15. Add item 15 while mixing. Melt item 17 in stainless steel container, and add with stirring to mix well.
16. Cool to 30°C while mixing under nitrogen atmosphere.
17. Add items 18 and 19 to the oily phase solution, and mix for 15 minutes at high speed.
18. Check and record the volume of oily phase. Start mixing, and continue mixing. Mixing must be continuous.
19. Start the addition of oily phase solution in a thin stream. Do not stop mixing during addition of oily phase. After the addition is over, mix for a further 15 minutes at high speed.
20. Rinse the oily phase vessel with a sufficient quantity of syrup from the syrup vessel. Transfer the rinsings to the syrup vessel.
21. Make up the volume to 1 L with cooled item 20 (25°C), and finally, mix for 20 minutes at high speed.
22. Check and record the pH (limit: 3.75–3.85 at 25°C). Filter the syrup at 1.5 bar. Recirculate about 40 to 60 mL syrup.

VITAMIN B COMPLEX, VITAMIN A, VITAMIN C, VITAMIN D, AND VITAMIN E PEDIATRIC DROPS

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
8333 IU	1	Vitamin A palmitate (1.7 M IU/g) (50% excess)	7.35
666 IU	2	Vitamin D (40 M IU/g) (cholecalciferol)	0.021
75.00	3	Polysorbate 80 (Tween 80)	75.00
0.005	4	Lemon oil terpeneless	0.50
0.88	5	Vitamin E (oily) (α-tocopheryl acetate)	0.88
0.50	6	Edetate disodium (sodium EDTA)	0.50
83.33	7	Ascorbic acid (30% excess)	108.33
1.00	8	Saccharin sodium	1.00
2.50	9	Thiamine hydrochloride (50% excess)	3.75
16.66	10	Nicotinamide (5% excess)	17.50
0.833	11	Pyridoxine hydrochloride (5.6% excess)	0.88
2.00	12	Riboflavin sodium phosphate (7.9% excess as riboflavin)	2.16
700.00	13	Glycerin (glycerol)	700.00
250.00	14	Purified water	250.00

Manufacturing Directions

1. This product is a microemulsion and is a thermolabile preparation.
2. The temperature of the solution must not exceed 25°C at the time of processing.
3. Add 200 g of purified water to the manufacturing vessel.
4. Bubble nitrogen gas during all stages of the process.
5. Place items 6 to 12 one by one into the manufacturing vessel while mixing.
6. Check that all materials are dissolved completely.
7. Load item 13 into the manufacturing vessel while mixing at slow speed.
8. Mix for 5 minutes.
9. Add item 3 in a separate stainless steel container.
10. Mix items 1, 2, 4, and 5 one by one using stirrer.
11. Mix for 1 hour at slow speed.
12. Add oil-phase preparation to the aqueous phase at a rate of 4 mL/min while mixing at slow speed, and continue nitrogen gas bubbling throughout the process.
13. Rinse the oil-phase container with 50 g of nitrogen-bubbled and cooled purified water, and transfer the rinsings to the manufacturing vessel.
14. Adjust the volume to 1 L using nitrogen-bubbled purified water.
15. Mix for 15 minutes at slow speed.

16. Check and record the volume and pH (limit: pH 2.8–4.2).
17. Filter the solution through a Sartorius prefilter and 0.2 µm membrane filter into receiving tank.
18. Bubble with nitrogen gas for 15 minutes.

VITAMIN B COMPLEX, VITAMIN C, AND IRON SYRUP

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
QS	1	Glucose (liquid), NF	QS to 1 L
225.00	2	Purified water, USP	225.00
0.30	3	Methylparaben	0.30
1.00	4	Acid benzoic, USP	1.00
5.00	5	Alcohol (ethanol; 190 proof, nonbeverage), USP	5.00
10.00	6	Nicotinamide niacinamide (white powder), USP	10.00
10.00	7	Riboflavin; use riboflavin 5 phosphate sodium	1.64
2.00	8	Pyridoxine hydrochloride, USP	2.00
20.00	9	Ascorbic acid (white powder), USP	20.00
0.03	10	Dye	0.03
0.02	11	Dye	0.02
2.00	12	Thiamine hydrochloride (powder, regular), USP with excess	2.40

0.028 mL	16	Flavor	2.80 mL
QS	17	Hydrochloric acid	2.00 mL
QS	18	Carbon dioxide gas	QS

Manufacturing Directions

1. This preparation is susceptible to oxidation and must be protected from air and sunlight at all times.
2. Carbon dioxide must be used extensively to prevent oxygen from reacting with the materials.
3. All purified water must be boiled prior to use for 10 minutes and cooled under CO_2 protection.
4. Place 100 mL of purified water into a suitably sized stainless steel tank.
5. Add the riboflavin, nicotinamide, benzoic acid, and paraben.
6. Rinse the tank down with 10 mL purified water, seal, and heat with mixing to 95°C.
7. Continue mixing and heating for 15 minutes until solution is complete.
8. Commence cooling with continuous mixing.
9. When the solution has cooled to 50 to 70°C, add and dissolve the sugar.
10. Commence CO_2 protection when the temperature reaches 40°C.
11. Slurry the ascorbic acid in 75 or 110 mL of CO_2-saturated purified water (use the smaller quantity only if using a total of 225 mL water), and add to bulk solution when temperature has reached 25°C to 35°C.
12. Rinse the ascorbic acid vessel with 10 mL purified water, and add rinsings to bulk.
13. Mix for at least 30 minutes.
14. Dissolve thiamine and pyridoxine in 20 mL CO_2-saturated purified water, and add to bulk solution at 25 to 35°C.
15. Add 10 mL CO_2-saturated purified water to the D-pantothenyl alcohol, and warm on a water bath until solution is complete.
16. Add vitamin B_{12}, and mix until dissolved.
17. Add and dissolve dyes.
18. Add this solution to the bulk solution, and mix thoroughly.
19. Mix flavor with 95% of alcohol, and add to the bulk solution.
20. Rinse the container with the remaining alcohol, and add to the bulk with vigorous agitation.
21. Check pH (range: 3.0–3.3).
22. Use hydrochloric acid to adjust if necessary.
23. Adjust the final volume with liquid glucose.
24. Filter through suitable medium until clear and bright.

VITAMIN C DROPS

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
100.00	1	Ascorbic acid (white powder), USP	100.00
979.00	2	Propylene glycol, USP	979.00

Manufacturing Directions

1. Keep under CO_2 protection at all times. Avoid contact with iron. Use stainless steel or glass-lined equipment only.
2. Load 868 g propylene glycol into a glass-lined or suitable stainless steel jacketed tank.
3. While mixing, heat to 70 to 80°C.
4. Bubble CO_2 gas into the propylene glycol from the bottom of the tank.
5. Add and dissolve the ascorbic acid into the propylene glycol with a minimum of stirring under CO_2 protection.
6. When the ascorbic acid is in solution, immediately cool to approximately 25°C while continuing to mix.

7. Also, while cooling, change adding CO_2 from the bottom of the tank to adding it at the top of the tank.
8. QS to 1 L, using propylene glycol, and mix for at least 10 minutes.
9. Use a prefilter pad and a lint-free filter paper; recirculate the product through the filter press until sparkling clear.

VITAMIN E AND BENZOCAINE SOLUTION

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
50.00	1	Vitamin E acetate	50.00
20.00	2	Benzocaine	20.00
50.00	3	Lutrol F 127	50.00
250.00	4	Cremophor (relative humidity, 40%)	250.00
2.00	5	Sorbic acid	2.00
628.00	6	Water	628.00

Manufacturing Directions

1. Dissolve sorbic acid and benzocaine in water at 60°C. Slowly add the heated mixture of vitamin E acetate and Cremophor at a relative humidity of 40% and temperature of 60°C to 65°C.
2. Cool the clear solution to about 5°C, and dissolve Lutrol F 127 to obtain a clear, colorless viscous liquid.

VITAMIN E CONCENTRATE, WATER-MISCIBLE

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
105.00	1	Vitamin E acetate	105.00
250.00	2	Cremophor (relative humidity, 40%)	250.00
QS	3	Preservative	QS
QS	4	Water	QS to 1 L

Manufacturing Directions

1. Heat the mixture of items 1 and 2 and solution of item 3 in item 4 separately to about 65°C.
2. Slowly add to the well-stirred solution to obtain a clear, colorless liquid that is miscible with water.

VITAMIN E DROPS

Bill of Materials

Scale (mg/mL)	Item	Material Name	Qty/L (g)
50.00	1	Vitamin E acetate	50.00
160.00	2	Cremophor (relative humidity, 40%)	160.00
QS	3	Preservative	QS
QS	4	Water	QS to 1 L

Manufacturing Directions

1. Heat mixture of items 1 and 2 and solution of item 3 in 4 to about 65°C.
2. Add them slowly to obtain a clear or lightly opalescent, colorless liquid.

VITAMIN E SOFT GEL CAPSULES

Bill of Materials

Scale (mg/capsule)	Item	Material Name	Qty/1000 Capsules (g)
400.00	1	Vitamin E preparation, USP	400.00
25.00	2	Soybean oil, USP	25.00
QS	3	Gelatin mass (clear)	QS

Manufacturing Directions

1. Weigh items 1 and 2, and transfer into a suitable stainless steel container, mix for a minimum of 1 hour, screen, and transfer to tanks through a No. 80 to No. 100 mesh stainless sieve.
2. Encapsulate 425 mg of mixture into size 7.5 oval capsules using clear gelatin mass.

VITAMIN E SOLUTION WITH ETHANOL

Bill of Materials

Scale (mg/tablet)	Item	Material Name	Qty/L (g)
0.10	1	Vitamin E acetate	0.10
4.00–5.00	2	Cremophor, EL	4.00–5.00
570.00	3	Water	570.00
380.00	4	Ethanol (96%)	380.00

Manufacturing Directions

1. Heat mixture of item 1 and 2 to about 60°C. Stir well.

2. Slowly add the warm solvent mixture of items 3 and 4 to obtain a clear, colorless liquid of low viscosity.

XYLOMETAZOLINE HYDROCHLORIDE NASAL SOLUTION

Bill of Materials

Scale (g/100 mL)	Item	Material Name	Qty/L (g)
0.100	1	Xylometazoline HCl	1.00
0.100	2	Disodium edetate (sodium EDTA)	1.00
0.700	3	Sodium chloride	7.00
0.030	4	Benzalkonium chloride (50% solution)	0.30
0.285	5	Monobasic sodium phosphate	2.85
0.306	6	Dibasic sodium phosphate	3.06
—	7	Water purified	QS to 1 L

Manufacturing Directions

This product is a colorless membrane-filtered solution; therefore, ensure that the storage tanks for solution are cleaned and free of any contamination. Use freshly boiled and cooled purified water for the manufacturing. Prepare approximately 2 L of freshly boiled and cooled purified water, and store in a clean stainless steel storage vessel.

1. Add 800 g of item 7 (20–25°C) to the manufacturing vessel.
2. Dissolve items 2 to 6 one by one in step 1 while mixing for 10 minutes. Check the clarity of the solution.
3. Dissolve item 1 in 100 g of item 7 (25–30°C) in a stainless steel container, and add to the manufacturing vessel.
4. Rinse the drug container with 20 g of item 7, and add the rinsings to the manufacturing vessel.
5. Make the volume up to 1 L with item 7 (20–25°C), and finally, mix for 5 minutes.
6. Check and record the pH at 25°C (limit: 6.3 ± 0.2).
7. Check the cleanliness of the storage tank. Filter the solution through a prefilter and membrane filter, 0.2 micron, into the storage tank. Recirculate first 200 to 300 mL solution.
8. Store the filtered solution in tightly closed stainless steel storage tank. Do not store more than 24 hours in stainless steel storage tank after manufacturing.

XYLOMETAZOLINE HYDROCHLORIDE CHILDREN'S NASAL SOLUTION

Bill of Materials

Scale (g/100 mL)	Item	Material Name	Qty/L (g)
0.05	1	Xylometazoline hydrochloride	0.50
0.10	2	Disodium edetate (Sodium EDTA)	1.00
0.70	3	Sodium chloride	7.00
0.30	4	Benzalkonium chloride (50% solution)	0.30
0.28	5	Monobasic sodium phosphate	2.85
0.30	6	Dibasic sodium phosphate	3.06
—	7	Water purified	QS to 1 L

Manufacturing Directions

1. See previous preparation.

ZINC PYRITHIONE SHAMPOO

Bill of Materials

Scale (mg/g)	Item	Material Name	Qty/1000 Tablets (g)
547.50	1	Deionized water	547.50
7.50	2	Hydroxyethyl cellulose	7.50
347.00	3	TEA-lauryl sulfate	347.00
43.00	4	PEG-20 lanolin alcohol ether	43.00
20.00	5	Glycol stearate	20.00
15.00	6	Cocamide MEA	15.00
10.00	7	Zinc pyrithione (48%)	20.00
QS	8	Fragrance, preservative	QS

Manufacturing Directions

1. Add item 2 to the water, and mix.
2. In a separate vessel, combine items 3 to 5, heat to 80°C, and mix.
3. Cool to 50°C.
4. Add items 6 and 7, and mix.
5. Add this mixture to mixture of item 2.
6. Cool to 40°C, and add item 8.

Commercial Pharmaceutical Products

Abilify (aripiprazole) 1 mg/mL oral solution. The inactive ingredients for this solution include fructose, glycerin, DL-lactic acid, methylparaben, propylene glycol, propylparaben, sodium hydroxide, sucrose, and purified water. The oral solution is flavored with natural orange cream and other natural flavors.

Accuzyme spray contains papain, USP (6.5×10^5 USP units of activity based on Lot I0C389 per gram of spray) and urea, USP 10% in a base composed of anhydrous lactose, cetearyl alcohol and ceteth-20 phosphate and dicetyl phosphate, fragrance, glycerin, methylparaben, mineral oil, potassium phosphate monobasic, propylparaben, purified water, and sodium hydroxide.

Aerobid (flunisolide) inhaler is delivered in a metered-dose aerosol system containing a microcrystalline suspension of flunisolide as the hemihydrate in propellants (trichloromonofluoromethane, dichlorodifluoromethane, and dichlorotetrafluoroethane) with sorbitan trioleate as a dispersing agent. AEROBID-M also contains menthol as a flavoring agent. Each activation delivers approximately 250 µg of flunisolide to the patient. One Aerobid Inhaler System is designed to deliver at least 100 metered inhalations.

Alupent® (metaproterenol sulfate USP) Inhalation Aerosol containing 75 mg of metaproterenol sulfate as micronized powder is sufficient medication for 100 inhalations. The Alupent Inhalation Aerosol containing 150 mg of metaproterenol sulfate as micronized powder is sufficient medication for 200 inhalations. Each metered dose delivers through the mouthpiece 0.65 mg of metaproterenol sulfate (each milliliter contains 15 mg). The inert ingredients are dichlorodifluoromethane, dichlorotetrafluoroethane, and trichloromonofluoromethane as propellants, and sorbitan trioleate.

Astelin® (azelastine hydrochloride) Nasal Spray, 137 micrograms (µg), contains 0.1% azelastine hydrochloride in an aqueous solution at pH 6.8 ± 0.3. It also contains benzalkonium chloride (125 µg/mL), edetate disodium, hypromellose, citric acid, dibasic sodium phosphate, sodium chloride, and purified water.

Avar™ Cleanser (sodium sulfacetamide 10% and sulfur 5%) in each gram contains 100 mg of sodium sulfacetamide and 50 mg of colloidal sulfur in a mild aqueous-based cleansing vehicle containing purified water USP, sodium magnesium silicate, sodium thiosulfate, propylene glycol, sodium lauryl sulfate, cetyl alcohol, stearyl alcohol, phenoxyethanol, and fragrance.

Beconase AQ Nasal Spray. Beclomethasone dipropionate monohydrate, the active component of Beconase AQ Nasal Spray, is in a metered-dose, manual pump spray unit containing a microcrystalline suspension of beclomethasone dipropionate, monohydrate equivalent to 42 µg of beclomethasone dipropionate, calculated on the dried basis, in an aqueous medium containing microcrystalline cellulose, carboxymethylcellulose sodium, dextrose, benzalkonium chloride, polysorbate 80, and 0.25% v/w phenylethyl alcohol. The pH through expiry is 5.0 to 6.8.

Celexa® (citalopram HBr) oral solution contains citalopram HBr equivalent to 2 mg/mL citalopram base. It also contains the following inactive ingredients: sorbitol, purified water, propylene glycol, methylparaben, natural peppermint flavor, and propylparaben.

Clarinex Syrup is a clear orange-colored liquid containing 0.5 mg/1 mL desloratadine. The syrup contains the following inactive ingredients: propylene glycol USP, sorbitol solution USP, citric acid (anhydrous) USP, sodium citrate dihydrate USP, sodium benzoate NF, disodium edetate USP, and purified water USP. It also contains granulated sugar, natural and artificial flavor for bubble gum, and FDC Yellow #6 dye.

Clindets® (Clindamycin Phosphate Pledgets) contain clindamycin phosphate, USP at a concentration equivalent to 10 mg clindamycin per milliliter in a vehicle of isopropyl alcohol 52% v/v, propylene glycol, and water. Each Clindets® pledget applicator contains approximately 1 mL of Clindamycin Phosphate Topical Solution. Clindamycin Phosphate Topical Solution has a pH range between 4.0 and 7.0.

Clobex® (clobetasol propionate) Spray, 0.05%, contains clobetasol propionate, a synthetic fluorinated corticosteroid, for topical use. Each gram of CLOBEX® (clobetasol propionate) Spray, 0.05% contains 0.5 mg of clobetasol propionate in a vehicle base composed of alcohol, isopropyl myristate, sodium lauryl sulfate, and undecylenic acid.

Clobex® (clobetasol propionate) Shampoo, 0.05%, contains clobetasol propionate, a synthetic fluorinated corticosteroid, for topical dermatologic use. Each milliliter of CLOBEX® (clobetasol propionate) Shampoo, 0.05%, contains clobetasol propionate, 0.05%, in a shampoo base consisting of alcohol, citric acid, coco-betaine, polyquaternium-10, purified water, sodium citrate, and sodium laureth sulfate. Each gram of CLOBEX® (clobetasol propionate) Lotion, 0.05%, contains 0.5 mg of clobetasol propionate in a vehicle base composed of hypromellose, propylene glycol, mineral oil, polyoxyethylene glycol 300 isostearate, carbomer 1342, sodium hydroxide. and purified water.

Colace® Syrup (docusate sodium) (in each tablespoonful [15 ml]): docusate sodium 60 mg. Inactive ingredients: citric acid, D&C Red No. 33, FD&C Red No. 40, flavors, glycerin, propylene glycol, purified water, sodium citrate, sodium saccharin, and sorbitol. Colace® Liquid 1% Solution: each mL contains 10 mg of docusate sodium.

Custodiol® contains 0.8766 g sodium chloride; 0.6710 g potassium chloride; 0.1842 g potassium hydrogen 2-ketoglutarate; 0.8132 g magnesium chloride·$6H_2O$; 3.7733 g histidine HCl·H_2O; 27.9289 g histidine; 0.4085 g tryptophan; 5.4651 g mannitol; 0.0022 g calcium chloride·$2H_2O$ in sterile water for injection. Anion: Cl −50 mVal. Physical properties: pH

7.02–7.20 at 25 °C (77 ° F) (pH 7.4–7.45 at 4 °C [39.2 °F]). Osmolality: 310 mOsmol/kg.

Depacon solution, valproate sodium, is the sodium salt of valproic acid designated as sodium 2-propylpentanoate. It is available in 5 mL single-dose vials for intravenous injection. Each milliliter contains valproate sodium equivalent to 100 mg valproic acid, edetate disodium 0.40 mg, and water for injection to volume. The pH is adjusted to 7.6 with sodium hydroxide and/or hydrochloric acid. The solution is clear and colorless.

Depakene Syrup (valproic acid): FD&C Red No. 40, glycerin, methylparaben, propylparaben, sorbitol, sucrose, water, and natural and artificial flavors.

Dextromethorphan–Pseudoephedrine. Active ingredients: each 0.8 mL contains: 2.5 mg dextromethorphan hydrobromide, USP; 7.5 mg pseudoephedrine hydrochloride, USP. Inactive ingredients: citric acid, flavors, glycerin, high-fructose corn syrup, maltol, menthol, polyethylene glycol, propylene glycol, sodium benzoate, sorbitol, sucrose, and water.

Dilaudid Oral Liquid (hydromorphone hydrochloride). Each 5 mL (1 teaspoon) of Dilaudid Oral Liquid contains 5 mg of hydromorphone hydrochloride. In addition, other ingredients include purified water, methylparaben, propylparaben, sucrose, and glycerin. Dilaudid Oral Liquid may contain traces of sodium metabisulfite.

Diuril (Chlorothiazide) Oral Suspension. Diuril contains 250 mg of chlorothiazide per 5 mL, alcohol 0.5 percent, with methylparaben 0.12 percent, propylparaben 0.02 percent, and benzoic acid 0.1 percent added as preservatives. The inactive ingredients are D&C Yellow No. 10, flavors, glycerin, purified water, sodium saccharin, sucrose, and tragacanth.

Dovonex® (calcipotriene solution) Scalp Solution, 0.005%, is a colorless topical solution containing 0.005% calcipotriene in a vehicle of isopropanol (51% v/v), propylene glycol, hydroxypropyl cellulose, sodium citrate, menthol, and water.

Ferrochel® (elemental iron) 70 mg. Each soft gelatin capsule for oral administration contains, ferrous fumarate (elemental iron) 81 mg, vitamin C as Ester-C®, ascorbic acid (as calcium ascorbate) 60 mg, threonic acid (as calcium threonate) 0.8 mg, folic acid, USP 1 mg, and vitamin B12 (cyanocobalamin) 10 µg. Ferrochel® (ferrous bis-glycinate chelate) is a registered trademark of Albion International, Inc., Clearfield, Utah, and is protected under U.S. Patent Nos. 4, 599, 152 and 4, 830, 716. Ester-C® is a patented pharmaceutical-grade material consisting of calcium ascorbate and calcium threonate. Ester-C® is a licensed trademark of Zila Nutraceuticals, Inc. Inactive ingredients: soybean oil, gelatin, glycerin, lecithin (unbleached), yellow beeswax, titanium dioxide, methyl paraben, ethyl vanillin, FD&C Yellow No. 6, FD&C Red No. 40, propyl paraben, and FD&C Blue No. 1.

E.E.S. (erythromycin ethylsuccinate) is an ester of erythromycin suitable for oral administration. E.E.S 200 Liquid: Each 5 mL teaspoonful of fruit-flavored suspension contains erythromycin ethylsuccinate equivalent to 200 mg of erythromycin. E.E.S. 400 Liquid: Each 5 mL teaspoonful of orange-flavored suspension contains erythromycin ethylsuccinate equivalent to 400 mg of erythromycin. Inactive ingredients: E.E.S. 200 Liquid: FD&C Red No. 40, methylparaben, polysorbate 60, propylparaben, sodium citrate, sucrose, water, xanthan gum, and natural and artificial flavors; E.E.S. 400 Liquid: D&C Yellow No. 10, FD&C Yellow No. 6, methylparaben, polysorbate 60, propylparaben, sodium citrate, sucrose, water, xanthan gum, and natural and artificial flavors.

Efudex Solutions and Cream are topical preparations containing the fluorinated pyrimidine 5-fluorouracil. Efudex Solution consists of 2% or 5% fluorouracil on a weight/weight basis, compounded with propylene glycol, tris (hydroxymethyl) aminomethane, hydroxypropyl cellulose, parabens (methyl and propyl), and disodium edetate.

Epinephrine Inhalation. Active ingredient: (in each inhalation) epinephrine 0.22 mg. Inactive ingredients: ascorbic acid, dehydrated alcohol (34%), dichlorodifluoromethane (CFC 12), dichlorotetrafluoroethane (CFC 114), hydrochloric acid, nitric acid, and purified water.

Epivir (also known as 3TC) is lamivudine, a white to off-white crystalline solid with a solubility of approximately 70 mg/mL in water at 20 °C. Epivir Oral Solution is for oral administration. One milliliter (1 mL) of Epivir Oral Solution contains 10 mg of lamivudine (10 mg/mL) in an aqueous solution and the inactive ingredients artificial strawberry and banana flavors, citric acid (anhydrous), methylparaben, propylene glycol, propylparaben, sodium citrate (dihydrate), and sucrose (200 mg).

Epivir-HBV is lamivudine, a white to off-white crystalline solid with a solubility of approximately 70 mg/mL in water at 20 °C. Epivir-HBV Oral Solution is for oral administration. One milliliter (1 mL) of Epivir-HBV Oral Solution contains 5 mg of lamivudine (5 mg/mL) in an aqueous solution and the inactive ingredients artificial strawberry and banana flavors, citric acid (anhydrous), methylparaben, propylene glycol, propylparaben, sodium citrate (dihydrate), and sucrose (200 mg).

Exelon® (rivastigmine tartrate) Oral Solution is supplied as a solution containing rivastigmine tartrate, equivalent to 2 mg/mL of rivastigmine base for oral administration. Inactive ingredients are citric acid, D&C Yellow No. 10, purified water, sodium benzoate, and sodium citrate.

Fleet® Phospho-soda® EZ-Prep™ contains: active ingredients: each 15 mL contains monobasic sodium phosphate monohydrate 7.2 g and dibasic sodium phosphate heptahydrate 2.7 g.

Flovent HFA 44 µg Inhalation Aerosol, Flovent HFA 110 µg Inhalation Aerosol, and Flovent HFA 220 µg Inhalation Aerosol contain fluticasone propionate. Flovent HFA 44 µg Inhalation Aerosol, Flovent HFA 110 µg Inhalation Aerosol, and FLOVENT HFA 220 µg Inhalation Aerosol are pressurized, metered-dose aerosol units intended for oral inhalation only. Each unit contains a microcrystalline suspension of fluticasone propionate (micronized) in propellant HFA-134a (1,1,1,2-tetrafluoroethane). It contains no other excipients. Each 10.6 g canister (44 µg) and each 12 g canister (110 and 220 µg) provides 120 inhalations. Flovent HFA should be primed before using for the first time by releasing four test sprays into the air away from the face, shaking well before

each spray. In cases where the inhaler has not been used for more than 7 days, or when it has been dropped, prime the inhaler again by shaking well and releasing one test spray into the air away from the face. This product does not contain any chlorofluorocarbon (CFC) as the propellant. Under standardized in vitro test conditions, Flovent Diskus 50 µg delivers 46 µg of fluticasone propionate when tested at a flow rate of 60 L/min for 2 seconds. In adult patients with obstructive lung disease and severely compromised lung function (mean forced expiratory volume in 1 second [FEV 1] 20% to 30% of predicted), mean peak inspiratory flow (PIF) through a Diskus® is 82.4 L/min (range, 46.1 to 115.3 L/min). In children with asthma 4 and 8 years old, mean PIF through Flovent Diskus is 70 and 104 L/min, respectively (range, 48 to 123 L/min).

Flumadine® (rimantadine hydrochloride) (5 mL) of the syrup contains 50 mg of rimantadine hydrochloride in a dye-free, aqueous solution containing citric acid, parabens (methyl and propyl), saccharin sodium, sorbitol, and flavors.

Fluticasone propionate, Flonase Nasal Spray. Flonase Nasal Spray, 50 µg, is an aqueous suspension of microfine fluticasone propionate for topical administration to the nasal mucosa by means of a metering, atomizing spray pump. Flonase Nasal Spray also contains microcrystalline cellulose and carboxymethylcellulose sodium, dextrose, 0.02% w/w benzalkonium chloride, polysorbate 80, and 0.25% w/w phenylethyl alcohol, and has a pH between 5 and 7. It is necessary to prime the pump before first use or after a period of nonuse (1 week or more). After initial priming (six actuations), each actuation delivers 50 µg of fluticasone propionate in 100 mg of formulation through the nasal adapter. Each 16 g bottle of Flonase Nasal Spray provides 120 metered sprays. After 120 metered sprays, the amount of fluticasone propionate delivered per actuation may not be consistent, and the unit should be discarded.

Fosamax (alendronate sodium) oral solution contains 91.35 mg of alendronate monosodium salt trihydrate, which is the molar equivalent to 70 mg of free acid. Each bottle also contains the following inactive ingredients: sodium citrate dihydrate and citric acid anhydrous as buffering agents, sodium saccharin, artificial raspberry flavor, and purified water. Added as preservatives are sodium propylparaben 0.0225% and sodium butylparaben 0.0075%.

Frotical (Calcitonin) calcitonin-salmon (rDNA origin) Nasal Spray is provided in a 3.7 mL fill glass bottle as a solution for intranasal administration with sufficient medication for at least 30 doses. Each spray delivers 200 international units calcitonin-salmon in a volume of 0.09 mL. Active ingredient: Calcitonin-salmon 2200 international units/mL, corresponding to 200 international units per actuation (0.09 mL). Inactive ingredients: sodium chloride USP, citric acid USP, phenylethyl alcohol USP, benzyl alcohol NF, polysorbate 80 NF, hydrochloric acid NF or sodium hydroxide NF (added as necessary to adjust pH), and purified water USP.

Gengraf® (cyclosporine capsules, USP [MODIFIED]) is a modified oral formulation of cyclosporine that forms an aqueous dispersion in an aqueous environment. Gengraf® Capsules (cyclosporine capsules, USP [MODIFIED]) are available in 25 mg and 100 mg strengths. Each 25 mg capsule contains cyclosporine, 25 mg; alcohol, USP, absolute, 12.8% v/v (10.1% wt/vol.). Each 100 mg capsule contains cyclosporine, 100 mg; alcohol, USP, absolute, 12.8% v/v (10.1% wt/vol.). Inactive ingredients: FD&C Blue No. 2, gelatin NF, polyethylene glycol NF, polyoxyl 35 castor oil NF, polysorbate 80 NF, propylene glycol USP, sorbitan monooleate NF, and titanium dioxide.

Gets The Dry Out® and Visine® Pure Tears Portables Preservative Free Lubricant Eye. Glycerin 0.2%, hypromellose 0.2%, and polyethylene glycol 400 1%.

Gordochom containing 25% undecylenic Acid and 3% chloroxylenol as its active ingredients in a penetrating oil base.

Guaifenesin. Active ingredient: (in each 5 mL tsp) Guaifenesin, USP 100 mg. Inactive ingredients: caramel, citric acid, FD&C Red No. 40, flavors, glucose, glycerin, high-fructose corn syrup, menthol, saccharin sodium, sodium benzoate, and water.

Hydroquinone USP 4% also contains avobenzone, ceteareth-20, cetostearyl alcohol, citric acid, diethylaminoethyl stearate, dimethicone, edetate disodium, glyceryl dilaurate, glyceryl monostearate, glyceryl stearate, PEG-100 stearate, hydroxyethyl cellulose, methylparaben, octyldodecyl stearoyl stearate, octinoxate, oxybenzone, polysorbate 80, propylene glycol, propyl gallate, propylparaben, purified water, Quaternium-26, sodium metabisulfite, sodium PCA, squalane, ubiquinone, stearyl alcohol, water, glycerin, and *Rumex occidentalis* extract.

Ibpurofen. Active ingredient: (in each 5 mL) Ibuprofen 100 mg. Inactive ingredients: (Fruit Flavor) artificial flavors, carboxymethylcellulose sodium, citric acid, edetate disodium, FD&C Red No. 40, glycerin, microcrystalline cellulose, polysorbate 80, purified water, sodium benzoate, sorbitol solution, sucrose, and xanthan gum. Inactive ingredients: (Grape Flavor) acetic acid, artificial flavor, butylated hydroxytoluene, carboxymethylcellulose sodium, citric acid, edetate disodium, FD&C Blue No. 1, FD&C Red No. 40, glycerin, microcrystalline cellulose, polysorbate 80, propylene glycol, purified water, sodium benzoate, sorbitol solution, sucrose, and xanthan gum. Inactive ingredients: (Blue Raspberry Flavor) carboxymethylcellulose sodium, citric acid, edetate disodium, FD&C Blue no. 1, glycerin, microcrystalline cellulose, natural and artificial flavors, polysorbate 80, propylene glycol, purified water, sodium benzoate, sodium citrate, sorbitol solution, sucrose, and xanthan gum.

ibuprofen. Ibuprofen 200 mg. Inactives: FD&C Green no. 3, gelatin, light mineral oil, pharmaceutical ink, polyethylene glycol, potassium hydroxide, purified water, sorbitan, and sorbitol.

Ibuprofen Liquid Gel. Active ingredients (in each LiquiGel): Solubilized ibuprofen equal to 200 mg ibuprofen (present as the free acid and potassium salt); pseudoephedrine HCl 30 mg. Inactive ingredients (liqui-gels): D&C Yellow No. 10, FD&C Red No. 40, fractionated coconut oil, gelatin, pharmaceutical ink, polyethylene glycol, potassium hydroxide, purified water, sorbitan, and sorbitol.

Imitrex (sumatriptan) Nasal Spray contains sumatriptan. Each Imitrex Nasal Spray contains 5 or 20 mg of sumatriptan in a 100 µL unit dose aqueous buffered solution containing monobasic potassium phosphate NF, anhydrous dibasic sodium phosphate USP, sulfuric acid NF, sodium hydroxide NF, and purified water USP. The pH of the solution is approximately 5.5. The osmolality of the solution is 372 or 742 mOsmol for the 5 and 20 mg Imitrex Nasal Spray, respectively.

Indocin Suspension for oral use contains 25 mg of indomethacin per 5 mL, alcohol 1%, and sorbic acid 0.1% added as a preservative and the following inactive ingredients: antifoam AF emulsion, flavors, purified water, sodium hydroxide or hydrochloric acid to adjust pH, sorbitol solution, and tragacanth.

Iron Protein Succinylate is a proprietary stabilized iron compound. The iron is wrapped in a casein protective layer, which allows the iron to pass through the stomach to the intestinal tract for immediate, safe, and efficacious absorption. Ferretts IPS liquid is for use as a dietary supplement. Each 1 mL contain: 2.67 mg iron. Serving Size:15 mL; amount per 15 mL, iron 40 mg (from Iron Protein Succinylate). Other ingredients: Purified water, sorbitol solution, propylene glycol, casein (milk protein), strawberry flavor, sodium hydroxide, methylparaben sodium, propylparaben sodium, and saccharin sodium.

Kaletra (lopinavir/ritonavir) oral solution is available for oral administration as 80 mg lopinavir and 20 mg ritonavir per milliliter with the following inactive ingredients: acesulfame potassium, alcohol, artificial cotton candy flavor, citric acid, glycerin, high-fructose corn syrup, Magnasweet-110 flavor, menthol, natural and artificial vanilla flavor, peppermint oil, polyoxyl 40 hydrogenated castor oil, povidone, propylene glycol, saccharin sodium, sodium chloride, sodium citrate, and water.

Kaopectate®. Each 15 mL of Kaopectate® Anti-Diarrheal contains bismuth subsalicylate 262 mg, contributing 130 mg total salicylates. Kaopectate® Anti-Diarrheal is low sodium, with each 15 mL tablespoonful containing 10 mg sodium. Extra Strength Kaopectate®. Each 15 mL of Extra Strength Kaopectate® Anti-Diarrheal contains bismuth subsalicylate 525 mg, contributing 236 mg total salicylates. Extra Strength Kaopectate® is low sodium. Each 15 mL tablespoonful contains sodium 11 mg.

Keppra® oral solution contains 100 mg of levetiracetam per milliliter. Inactive ingredients: ammonium glycyrrhizinate, citric acid monohydrate, glycerin, maltitol solution, methylparaben, potassium acesulfame, propylparaben, purified water, sodium citrate dihydrate, and natural and artificial flavor.

Lexapro® (escitalopram oxalate) oral solution contains escitalopram oxalate equivalent to 1 mg/mL escitalopram base. It also contains the following inactive ingredients: sorbitol, purified water, citric acid, sodium citrate, malic acid, glycerin, propylene glycol, methylparaben, propylparaben, and natural peppermint flavor.

Loprox® (ciclopirox) Shampoo 1% contains the synthetic antifungal agent ciclopirox. Each gram (equivalent to 0.96 mL) of LOPROX Shampoo contains 10 mg ciclopirox in a shampoo base consisting of purified water USP, sodium laureth sulfate, disodium laureth sulfosuccinate, sodium chloride USP, and laureth-2. Loprox Shampoo is a colorless, translucent solution.

Loratadine. Active ingredient (in each 5 mL teaspoon): Loratadine, 5 mg. Inactive ingredients: artificial flavor, citric acid, glycerin, propylene glycol, purified water, sodium benzoate, and sucrose.

Lortab Elixir. Hydrocodone bitartrate and acetaminophen is supplied in liquid form for oral administration. It is affected by light. Lortab elixir contains per 5 mL, hydrocodone bitartrate 2.5 mg; acetaminophen 167 mg; alcohol 7%. In addition, the liquid contains the following inactive ingredients: citric acid anhydrous, ethyl maltol, glycerin, methylparaben, propylene glycol, propylparaben, purified water, saccharin sodium, sorbitol solution, and sucrose, with D&C Yellow No. 10 and FD&C Yellow No. 6 as coloring and natural and artificial flavoring.

Lotrimin Topical Solution contains 10 mg clotrimazole, USP in a nonaqueous vehicle of PEG 400 NF.

Marinol® Dronabinol Capsules for oral administration. Marinol® Capsules are supplied as round, soft gelatin capsules containing either 2.5 mg, 5 mg, or 10 mg dronabinol. Each Marinol® Capsule is formulated with the following inactive ingredients: FD&C Blue No. 1 (5 mg), FD&C Red No. 40 (5 mg), FD&C Yellow No. 6 (5 mg and 10 mg), gelatin, glycerin, methylparaben, propylparaben, sesame oil, and titanium dioxide.

Megace® ES (megestrol acetate) oral suspension contains megestrol acetate. Megace® ES (megestrol acetate) is a concentrated formula supplied as an oral suspension containing 125 mg of megestrol acetate per milliliter. Megace® ES (megestrol acetate) oral suspension contains the following inactive ingredients: alcohol (max 0.06% v/v from flavor), artificial lime flavor, citric acid monohydrate, docusate sodium, hydroxypropyl methylcellulose (hypromellose), natural and artificial lemon flavor, purified water, sodium benzoate, sodium citrate dihydrate, and sucrose.

Mepron (atovaquone) Suspension is a formulation of microfine particles of atovaquone. The atovaquone particles, reduced in size to facilitate absorption, are significantly smaller than those in the previously marketed tablet formulation. Mepron Suspension is for oral administration and is bright yellow with a citrus flavor. Each teaspoonful (5 mL) contains 750 mg of atovaquone and the inactive ingredients benzyl alcohol, flavor, poloxamer 188, purified water, saccharin sodium, and xanthan gum.

Miacalcin® (calcitonin-salmon) Nasal Spray is provided in a 3.7 mL fill glass bottle as a solution for nasal administration. This is sufficient medication for at least 30 doses. Active ingredient: calcitonin-salmon, 2200 IU per mL (corresponding to 200 IU per 0.09 mL actuation). Inactive ingredients: sodium chloride, benzalkonium chloride, hydrochloric acid (added as necessary to adjust pH), and purified water.

Migranal® is ergotamine hydrogenated in the 9,10 position as the mesylate salt. Migranal® (dihydroergotamine mesylate,

USP) Nasal Spray is provided for intranasal administration as a clear, colorless to faintly yellow solution in an amber glass vial containing dihydroergotamine mesylate, USP, 4.0 mg; caffeine, anhydrous, USP, 10.0 mg; dextrose, anhydrous, USP, 50.0 mg; carbon dioxide, USP, QS; purified water, USP, QS 1.0 mL.

Namenda® (memantine hydrochloride) oral solution contains memantine hydrochloride in a strength equivalent to 2 mg of memantine hydrochloride in each milliliter. The oral solution also contains the following inactive ingredients: sorbitol solution (70%), methylparaben, propylparaben, propylene glycol, glycerin, natural peppermint flavor #104, citric acid, sodium citrate, and purified water.

Nasacort® HFA Nasal Aerosol contains triamcinolone acetonide. Nasacort HFA Nasal Aerosol is a metered-dose aerosol unit containing a microcrystalline suspension of triamcinolone acetonide in tetrafluoroethane (HFA-134a) and dehydrated alcohol USP 0.7% w/w. Each canister contains 15 mg of triamcinolone acetonide.

Nasonex Nasal Spray, 50 µg mometasone furoate monohydrate, is a metered-dose, manual pump spray unit containing an aqueous suspension of mometasone furoate monohydrate equivalent to 0.05% w/w mometasone furoate calculated on the anhydrous basis, in an aqueous medium containing glycerin, microcrystalline cellulose and carboxymethylcellulose sodium, sodium citrate, citric acid, benzalkonium chloride, and polysorbate 80. The pH is between 4.3 and 4.9. After initial priming (10 actuations), each actuation of the pump delivers a metered spray containing 100 mg of suspension containing mometasone furoate monohydrate equivalent to 50 µg of mometasone furoate calculated on the anhydrous basis. Each bottle of Nasonex Nasal Spray, 50 µg, provides 120 sprays.

Neoral® is an oral formulation of cyclosporine that immediately forms a microemulsion in an aqueous environment. Neoral® Soft Gelatin Capsules (cyclosporine capsules, USP) Modified are available in 25 mg and 100 mg strengths. Each 25 mg capsule contains cyclosporine 25 mg; alcohol, USP dehydrated 11.9% v/v (9.5% wt/vol.). Each 100 mg capsule contains cyclosporine 100 mg; alcohol, USP dehydrated 11.9% v/v (9.5% wt/vol.). Inactive ingredients: Corn oil-mono-di-triglycerides, polyoxyl 40 hydrogenated castor oil NF, DL-(alpha)-tocopherol USP, gelatin NF, glycerol, iron oxide black, propylene glycol USP, titanium dioxide USP, carmine, and other ingredients.

Neoral® Oral Solution (cyclosporine oral solution, USP) modified is available in 50 mL bottles. Each milliliter contains cyclosporine 100 mg/mL; alcohol, USP dehydrated 11.9% v/v (9.5% wt/vol.). Inactive Ingredients: Corn oil-mono-di-triglycerides, polyoxyl 40 hydrogenated castor oil NF, DL-(alpha)-tocopherol USP, and propylene glycol USP.

Neurontin® (gabapentin) Oral Solution containing 250 mg/5 mL of gabapentin. The inactive ingredients for the oral solution are glycerin, xylitol, purified water, and artificial cool strawberry anise flavor.

Nicotrol® Inhaler (nicotine inhalation system) consists of a mouthpiece and a plastic cartridge delivering 4 mg of nicotine from a porous plug containing 10 mg nicotine. The cartridge is inserted into the mouthpiece prior to use. Nicotine is the active ingredient; inactive components of the product are menthol and a porous plug, which are pharmacologically inactive. Nicotine is released when air is inhaled through the inhaler.

Nicotrol® NS (nicotine nasal spray) is an aqueous solution of nicotine intended for administration as a metered spray to the nasal mucosa. Each 10 mL spray bottle contains 100 mg nicotine (10 mg/mL) in an inactive vehicle containing disodium phosphate, sodium dihydrogen phosphate, citric acid, methylparaben, propylparaben, edetate disodium, sodium chloride, polysorbate 80, aroma, and water. The solution is isotonic with a pH of 7. It contains no chlorofluorocarbons. After priming of the delivery system for NICOTROL NS, each actuation of the unit delivers a metered-dose spray containing approximately 0.5 mg of nicotine. The size of the droplets produced by the unit is in excess of 8 microns. One NICOTROL NS unit delivers approximately 200 applications.

Nitrolingual® Pumpspray (nitroglycerin lingual spray 400 µg) is a metered dose spray containing nitroglycerin. This product delivers nitroglycerin (400 µg per spray, 60 or 200 metered sprays) in the form of spray droplets onto or under the tongue. Inactive ingredients: medium-chain triglycerides, dehydrated alcohol, medium-chain partial glycerides, and peppermint oil.

Norvir (ritonavir) oral solution also contains ethanol, water, polyoxyl 35 castor oil, propylene glycol, anhydrous citric acid to adjust pH, saccharin sodium, peppermint oil, creamy caramel flavoring, and FD&C Yellow No. 6.

Omnicef® (cefdinir) for oral suspension after reconstitution contains 125 mg cefdinir per 5 mL or 250 mg cefdinir per 5 mL and the following inactive ingredients: sucrose, NF; citric acid, USP; sodium citrate, USP; sodium benzoate, NF; xanthan gum, NF; guar gum, NF; artificial strawberry and cream flavors; silicon dioxide, NF; and magnesium stearate, NF.

Oxsoralen-Ultra Lotion. Each milliliter of Oxsoralen Lotion contains 10 mg methoxsalen in an inert vehicle containing alcohol (71% v/v), propylene glycol, acetone, and purified water.

Oxyfast® Oral Concentrate Solution. Each 1 mL of Oxyfast Concentrate Solution contains oxycodone hydrochloride 20 mg. Inactive ingredients: citric acid, D&C Yellow No. 10, sodium benzoate, sodium citrate, sodium saccharin, and water.

Panafil Spray contains papain, USP (not less than 405,900 units of activity based on Lot IOC389 per gram of spray); urea, USP 10%; and chlorophyllin copper complex sodium, USP 0.5% in a base composed of anhydrous lactose, cetearyl alcohol and ceteth-20 phosphate and dicetyl phosphate, glycerin, methylparaben, mineral oil, propylparaben, purified water, and sodium hydroxide.

Paxil CR (paroxetine hydrochloride) Suspension for Oral Administration: Each 5 mL of orange-colored, orange-flavored liquid contains paroxetine hydrochloride equivalent to paroxetine, 10 mg. Inactive ingredients consist of polacrilin

potassium, microcrystalline cellulose, propylene glycol, glycerin, sorbitol, methylparaben, propylparaben, sodium citrate dihydrate, citric acid anhydrate, sodium saccharin, flavorings, FD&C Yellow No. 6, and simethicone emulsion, USP.

Pediapred (prednisolone sodium phosphate, USP) Oral Solution is a dye-free, colorless to light straw-colored, raspberry-flavored solution. Each 5 mL (teaspoonful) of Pediapred contains 6.7 mg prednisolone sodium phosphate (5 mg prednisolone base) in a palatable, aqueous vehicle. Pediapred also contains dibasic sodium phosphate, edetate disodium, methylparaben, purified water, sodium biphosphate, sorbitol, and natural and artificial raspberry flavor.

Penlac® Nail Lacquer (ciclopirox) Topical Solution, 8%, contains a synthetic antifungal agent, ciclopirox. It is intended for topical use on fingernails and toenails and immediately adjacent skin. Each gram of Penlac® Nail Lacquer (ciclopirox) Topical Solution, 8%, contains 80 mg ciclopirox in a solution base consisting of ethyl acetate, NF; isopropyl alcohol, USP; and butyl monoester of poly(methylvinyl ether/maleic acid) in isopropyl alcohol. Ethyl acetate and isopropyl alcohol are solvents that vaporize after application. Penlac® Nail Lacquer (ciclopirox) Topical Solution, 8%, is a clear, colorless to slightly yellowish solution.

Plexion. Sodium sulfacetamide. Each gram of Plexion® (sodium sulfacetamide USP 10% and sulfur USP 5%) Cleanser contains 100 mg of sodium sulfacetamide USP and 50 mg of sulfur USP in a cleanser base containing purified water USP, sodium methyl oleyltaurate, sodium cocoyl isethionate, disodium oleamido MEA sulfosuccinate, cetyl alcohol NF, glyceryl stearate (and) PEG-100 stearate, stearyl alcohol NF, PEG-55 propylene glycol oleate, magnesium aluminum silicate, methylparaben NF, edetate disodium USP, butylated hydroxytoluene, sodium thiosulfate USP, fragrance, xanthan gum NF, and propylparaben NF. Each cloth of Plexion® (sodium sulfacetamide USP 10% and sulfur USP 5%) Cleansing Cloths is coated with a cleanser-based formulation. Each gram of this cleanser-based formulation contains 100 mg of sodium sulfacetamide USP and 50 mg of sulfur USP. The cleanser base consists of purified water USP, sodium methyl oleyltaurate, sodium cocoyl isethionate, disodium laureth sulfosuccinate (and) sodium lauryl sulfoacetate, disodium oleamido MEA sulfosuccinate, glycerin USP, sorbitan monooleate NF, glyceryl stearate (and) PEG-100 stearate, stearyl alcohol NF, propylene glycol (and) PEG-55 propylene glycol oleate, cetyl alcohol NF, edetate disodium USP, methylparaben NF, PEG-150 pentaerythrityl tetrastearate, butylated hydroxytoluene NF, sodium thiosulfate USP, *Aloe vera* gel decolorized, allantoin, alpha bisabolol natural, fragrance, and propylparaben NF. Each gram of Plexion SCT® (sodium sulfacetamide USP 10% and sulfur USP 5%) contains 100 mg of sodium sulfacetamide USP and 50 mg of sulfur USP in a cream containing purified water USP, kaolin USP, glyceryl stearate (and) PEG-100 stearate, witch hazel USP, silicon dioxide, magnesium aluminum silicate, benzyl alcohol NF, water (and) propylene glycol (and) *Quillaia saponaria* extract, xanthan gum NF, sodium thiosulfate USP, and fragrance. Each gram of Plexion® (sodium sulfacetamide USP 10% and sulfur USP 5%) Topical Suspension contains 100 mg of sodium sulfacetamide USP and 50 mg of sulfur USP in a suspension containing purified water USP, propylene glycol USP, isopropyl myristate NF, light mineral oil NF, polysorbate 60, sorbitan monostearate NF, cetyl alcohol NF, hydrogenated coco-glycerides, stearyl alcohol NF, fragrances, benzyl alcohol NF, glyceryl stearate (and) PEG-100 stearate, dimethicone NF, zinc ricinoleate, xanthan gum NF, edetate disodium USP, and sodium thiosulfate USP.

Prevacid for Delayed-Release Oral Suspension is composed of the active ingredient, lansoprazole, in the form of enteric-coated granules and also contains inactive granules. The packets contain lansoprazole granules that are identical to those contained in Prevacid Delayed-Release Capsules and are available in 15 mg and 30 mg strengths. Inactive granules are composed of the following ingredients: confectioner's sugar, mannitol, docusate sodium, ferric oxide, colloidal silicon dioxide, xanthan gum, crospovidone, citric acid, sodium citrate, magnesium stearate, and artificial strawberry flavor. The lansoprazole granules and inactive granules, present in unit dose packets, are constituted with water to form a suspension and consumed orally.

Proventil HFA (albuterol sulfate) Inhalation Aerosol contains a microcrystalline suspension of albuterol sulfate in propellant HFA-134a (1,1,1,2-tetrafluoroethane), ethanol, and oleic acid. Each actuation delivers 120 μg albuterol sulfate, USP from the valve and 108 μg albuterol sulfate, USP from the mouthpiece (equivalent to 90 μg of albuterol base from the mouthpiece). Each canister provides 200 inhalations.

Proventil Inhalation Solution contains albuterol sulfate. Proventil Inhalation Solution is a clear, colorless to light yellow solution and requires no dilution before administration by nebulization. Each milliliter of Proventil Inhalation Solution 0.083% contains 0.83 mg of albuterol (as 1.0 mg of albuterol sulfate) in an isotonic aqueous solution containing sodium chloride. Sulfuric acid may be added to adjust pH (3–5). Proventil Inhalation Solution contains no sulfiting agents or preservatives.

Prozac® (fluoxetine hydrochloride) oral solution contains fluoxetine hydrochloride equivalent to 20 mg/5 mL (64.7 μmol) of fluoxetine. It also contains alcohol 0.23%, benzoic acid, flavoring agent, glycerin, purified water, and sucrose.

Rapamune® (sirolimus) is available for administration as an oral solution containing 1 mg/mL sirolimus. The inactive ingredients in Rapamune® Oral Solution are Phosal 50 PG® (phosphatidylcholine, propylene glycol, mono- and diglycerides, ethanol, and soy fatty acids. Oral Solution contains 1.5%–2.5% ethanol.

Retrovir (zidovudine) Syrup is for oral administration. Each teaspoonful (5 mL) of Retrovir Syrup contains 50 mg of zidovudine and the inactive ingredients sodium benzoate 0.2% (added as a preservative), citric acid, flavors, glycerin, and liquid sucrose. Sodium hydroxide may be added to adjust pH.

Rhinocort Aqua Nasal Spray (Budesonide) is an unscented, metered-dose, manual-pump spray formulation containing a micronized suspension of budesonide in an aqueous medium.

Microcrystalline cellulose and carboxymethyl cellulose sodium, dextrose anhydrous, polysorbate 80, disodium edetate, potassium sorbate, and purified water are contained in this medium; hydrochloric acid is added to adjust the pH to a target of 4.5. Rhinocort Aqua Nasal Spray delivers 32 μg of budesonide per spray. Each bottle of Rhinocort Aqua Nasal Spray 32 μg contains 120 metered sprays after initial priming.

Robitussin CF. Active ingredients: (in each 5 mL tsp Robitussin CF) dextromethorphan HBr, USP 10 mg, guaifenesin, USP 100 mg, and pseudoephedrine HCl, USP 30 mg; (in each 2.5 mL Robitussin Cough & Cold Infant Drops) dextromethorphan HBr, USP 5 mg, guaifenesin, USP 100 mg, and pseudoephedrine HCl, USP 15 mg; (in each 5 mL tsp Robitussin DM, Robitussin Sugar Free Cough) dextromethorphan HBr, USP 10 mg and guaifenesin, USP 100 mg; (in each 2.5 mL Robitussin DM Infant Drops) dextromethorphan HBr, USP 5 mg, guaifenesin, USP 100 mg, and pseudoephedrine HCl, USP 30 mg. Inactive ingredients (Robitussin DM): citric acid, FD&C Red No. 40, flavors, glucose, glycerin, high-fructose corn syrup, menthol, saccharin sodium, sodium benzoate, and water. Inactive ingredients (Robitussin Sugar Free Cough): acesulfame potassium, citric acid, flavors, glycerin, methylparaben, polyethylene glycol, povidone, propylene glycol, saccharin sodium, sodium benzoate, and water. Inactive ingredients (Robitussin DM Infant Drops): citric acid, FD&C Red No. 40, flavors, glycerin, high-fructose corn syrup, maltitol, maltol, polyethylene glycol, povidone, propylene glycol, saccharin sodium, sodium benzoate, sodium chloride, sodium citrate, and water. Robitussin DM Infant Drops in 1 fl oz bottles: active ingredients (in each 5 mL tsp): Guaifenesin, USP 100 mg; inactive Ingredients: citric acid, FD&C Red No. 40, flavors, glucose, glycerin, high-fructose corn syrup, maltol, menthol, propylene glycol, saccharin sodium, sodium benzoate, and water. Active ingredients (in each 5 mL tsp): chlorpheniramine maleate, USP 1 mg, dextromethorphan HBr, USP 7.5 mg, and pseudoephedrine HCl, USP 15 mg; inactive ingredients: citric acid, FD&C Red No. 40, glycerin, high-fructose corn syrup, natural and artificial flavors, propylene glycol, purified water, saccharin sodium, sodium benzoate, sodium chloride, and sodium citrate. Active ingredients (in each drop): Natural Honey Center and Honey Lemon Tea: Menthol, USP 5 mg; Honey Citrus and Almond with Natural Honey Center: Menthol, USP 2.5 mg; inactive ingredients: Natural Honey Center: caramel, corn syrup, glycerin, high-fructose corn syrup, honey, natural herbal flavor, sorbitol, and sucrose; Honey Lemon Tea: caramel, citric acid, corn syrup, honey, natural flavor, sucrose, and tea extract; Honey Citrus: citric acid, corn syrup, flavors, honey, and sucrose; Almond with Natural Honey Center: caramel, corn syrup, glycerin, honey, natural almond flavor, natural anise flavor, natural coriander flavor, natural fennel flavor, natural honey flavor and other natural flavors, sorbitol, and sucrose. Inactive ingredients: citric acid, D&C Red No. 33, FD&C Yellow No. 6, flavor, glycerin, high- fructose corn syrup, polyethylene glycol, purified water, sodium benzoate, sodium citrate, sorbitol solution, and sucralose. Active ingredient (in each drop): Menthol Eucalyptus: Menthol, USP 10 mg; Cherry and Honey-Lemon: Menthol, USP 5 mg. Active ingredients (in each 5 mL tsp): acetaminophen, USP 160 mg, chlorpheniramine maleate, USP 1 mg, dextromethorphan HBr, USP 5 mg, and pseudoephedrine HCl, USP 15 mg. Inactive ingredients: Menthol Eucalyptus: corn syrup, eucalyptus oil, flavor, and sucrose; Cherry: corn syrup, FD&C Red No. 40, flavor, methylparaben, propylparaben, sodium benzoate, and sucrose; Honey-Lemon: citric acid, corn syrup, D&C Yellow No. 10, FD&C Yellow No. 6, honey, lemon oil, methylparaben, povidone, propylparaben, sodium benzoate, and sucrose.

Sandimmune® Oral Solution (cyclosporine oral solution, USP) is available in 50 mL bottles. Each milliliter contains cyclosporine, USP 100 mg and alcohol, Ph. Helv. 12.5% by volume dissolved in an olive oil, Ph. Helv./Labrafil M 1944 CS (polyoxyethylated oleic glycerides) vehicle, which must be further diluted with milk, chocolate milk, or orange juice before oral administration.

Sandimmune® Soft Gelatin Capsules (cyclosporine capsules, USP) are available in 25 mg and 100 mg strengths. Each 25 mg capsule contains cyclosporine, USP 25 mg and alcohol, USP dehydrated max 12.7% by volume. Each 100 mg capsule contains cyclosporine, USP 100 mg and alcohol, USP dehydrated max 12.7% by volume. Inactive ingredients: corn oil, gelatin, glycerol, Labrafil M 2125 CS (polyoxyethylated glycolyzed glycerides), red iron oxide (25 mg and 100 mg capsule only), sorbitol, titanium dioxide, and other ingredients.

Sulfamylon® For 5% Topical Solution is provided in packets containing 50 g of sterile mafenide acetate to be reconstituted in 1000 mL of sterile water for irrigation, USP or 0.9% sodium chloride irrigation, USP. After mixing, the solution contains 5% w/v of mafenide acetate. The solution is an antimicrobial preparation suitable for topical administration. The solution is not for injection. The reconstituted solution may be held for up to 28 days after preparation if stored in unopened containers.

Suprane® (desflurane, USP), a nonflammable liquid administered via vaporizer, is a general inhalation anesthetic. Desflurane is a colorless, volatile liquid below 22.8 °C. Desflurane does not corrode stainless steel, brass, aluminum, anodized aluminum, nickel plated brass, copper, or beryllium.

Tahitian Noni® Juice is reconstituted *Morinda citrifolia* fruit juice from pure juice puree from French Polynesia, natural grape juice concentrate, natural blueberry juice concentrate, and natural flavors. Not made from dried or powdered *Morinda citrifolia*.

Triaz® (benzoyl peroxide) 3%, 6%, and 9% Gels, Triaz® (benzoyl peroxide) 3%, 6%, and 9% Cleansers, and Triaz® (benzoyl peroxide) 3%, 6%, and 9% Pads are topical, gel-based, benzoyl peroxide–containing preparations for use in the treatment of acne vulgaris. Triaz 3% Gel contains benzoyl peroxide USP 3% as the active ingredient in a gel-based formulation consisting of purified water USP, C12-15 alkyl benzoate, glycerin USP, cetearyl alcohol, polyacrylamide (and) C13-14 isoparaffin (and) laureth-7, glyceryl stearate (and) PEG-100 stearate, steareth-2, steareth-20, dimethicone,

glycolic acid, zinc lactate, lactic acid USP, edetate disodium USP, and sodium hydroxide NF.

Trileptal® (oxcarbazepine) is available as a 300 mg/5 mL (60 mg/mL) oral suspension containing the following inactive ingredients: ascorbic acid; dispersible cellulose; ethanol; macrogol stearate; methyl parahydroxybenzoate; propylene glycol; propyl parahydroxybenzoate; purified water; sodium saccharin; sorbic acid; sorbitol; and yellow-plum-lemon aroma.

Tussionex. Each teaspoonful (5 mL) of Tussionex Pennkinetic Extended-Release Suspension contains hydrocodone polistirex equivalent to 10 mg of hydrocodone bitartrate and chlorpheniramine polistirex equivalent to 8 mg of chlorpheniramine maleate. Hydrocodone Polistirex: sulfonated styrene–divinylbenzene copolymer complex with 4,5(alpha)-epoxy-3-methoxy-17-methylmorphinan-6-one. Chlorpheniramine Polistirex: sulfonated styrene–divinylbenzene copolymer complex with 2-[p-chloro-(alpha)-[2-(dimethylamino)ethyl]-benzyl]pyridine. Inactive ingredients: ascorbic acid, D&C Yellow No. 10, ethylcellulose, FD&C Yellow No. 6, flavor, high-fructose corn syrup, methylparaben, polyethylene glycol 3350, polysorbate 80, pregelatinized starch, propylene glycol, propylparaben, purified water, sucrose, vegetable oil, and xanthan gum.

Witch Hazel 50%. Inactive ingredients: *Aloe barbadensis* gel, capryl/capramidopropyl betaine, citric acid, diazolidinyl urea, glycerin, methylparaben, propylene glycol, propylparaben, sodium citrate, and water.

Zmax (azithromycin extended release) for oral suspension contains the active ingredient azithromycin (as azithromycin dihydrate). Zmax is a single-dose, extended-release formulation of microspheres for oral suspension containing azithromycin (as azithromycin dihydrate) and the following excipients: glyceryl behenate, poloxamer 407, sucrose, sodium phosphate tribasic anhydrous, magnesium hydroxide, hydroxypropyl cellulose, xanthan gum, colloidal silicon dioxide, titanium dioxide, artificial cherry flavor, and artificial banana flavor. Each bottle contains azithromycin dihydrate equivalent to 2.0 g of azithromycin. It is constituted with 60 mL of water, and the entire contents are administered orally as a single dose.

Zoloft oral concentrate is available in a multidose 60 mL bottle. Each milliliter of solution contains sertraline hydrochloride equivalent to 20 mg of sertraline. The solution contains the following inactive ingredients: glycerin, alcohol (12%), menthol, and butylated hydroxytoluene (BHT).

Zomig® (zolmitriptan) Nasal Spray contains zolmitriptan and is supplied as a clear to pale yellow solution of zolmitriptan, buffered to pH 5.0. Each ZOMIG Nasal Spray contains 5 mg of zolmitriptan in a 100 µL unit dose aqueous buffered solution containing citric acid anhydrous USP, disodium phosphate dodecahydrate USP, and purified water USP. ZOMIG Nasal Spray is hypertonic. The osmolarity of ZOMIG Nasal Spray 5 mg is 420 to 470 mOsmol.

Zyrtec syrup is a colorless to slightly yellow syrup containing cetirizine hydrochloride at a concentration of 1 mg/mL (5 mg/5 mL) for oral administration. The pH is between 4 and 5. The inactive ingredients of the syrup are banana flavor; glacial acetic acid; glycerin; grape flavor; methylparaben; propylene glycol; propylparaben; sodium acetate; sugar syrup; and water.

To the memory of Dr. Norman L. Farnsworth

Dr. Norman L. Farnsworth passed away in 2011; a leader in research, a fine and kind human, and my teacher and colleague, who taught me the value of persistence—he created remarkable changes in the science of pharmacognosy.

PART II Manufacturing Formulations

PART III Commercial Pharmaceutical Formulations

Preface to the Series—Third Edition

I am humbled by the wide praise and acceptance of the last two editions of the *Handbook of Pharmaceutical Formulations*, a six-volume series that found home in the R&D laboratories of just about every pharmaceutical company, both generic and branded, and in the classrooms of pharmaceutical technology; and the regulatory agencies used this treatise to compare the quality of pharmaceutical products. In creating this work, back in 2004, my primary objective was to provide a ready source of safe and scalable generic and new pharmaceutical formulations that take a long time to develop and incur a substantial cost, to enable the availability of affordable medicines.

Each of the six volumes in the series has a structured content. Part I includes regulatory guidance, formulation steps, references to active ingredients and excipients, and a self-audit guidance for cGMP compliance. Chapters of common interest to all volumes are distributed across the six volumes, such as the formulations for coating solutions are presented in Volume 5 (OTC), though they are also pertinent to Volume 1 (Compressed Dosage Forms), and global bioequivalence testing guidelines are provided in Volume 4 (Semisolids), though they apply to all volumes. Part II includes scalable formulations and Part III, where applicable, other general formulations. The appendices include a listing of excipients used in FDA approved products and a cGMP compliance self-testing tool. Whereas the main focus of the guidance provided in the handbook pertains to compliance with FDA requirements, these apply equally to EU requirements, and, as a result, to any global agency.

The third edition also gets several significant additions; now each volume includes a self-audit template, several chapters advising how to stay cGMP compliant, including a listing of most common FDA citations to look out for in the audits, a global regulatory focus and an updated list of excipients and the level of their incorporation in the FDA-approved products. The number of formulations is also increased, and the OTC volume now contains several cosmetic formulations, and the semisolid product volume also includes details on chewing gum delivery systems.

The updating of formulations is always cumulative as there is little need to remove any formulation provided previously—if it was right then, it shall remain good now. However, a variety of new drug delivery systems have evolved since the second edition was published, so I have included more details on these formulations, although some of these may not be available to practice due to possible limitations on the intellectual property.

As always, I advise the formulators to be aware of any intellectual property infringements as I cannot provide a guarantee to this effect.

Finally, I wish to acknowledge the leaders of the pharmaceutical world, to whom each of the volumes is dedicated. I have made a few changes to those whom the volumes are dedicated, to recognize those who have since passed away; they provided a role model to me and thousands of leaders and students of pharmacy over the decades of their careers. They are gone, but not without leaving an indelible mark on the profession.

I also consider myself fortunate to have the sponsorship and assistance of the great folks at the CRC Press, more particularly Jessica Poile and Hilary LaFoe. The teams at the CRC Press were very kind to put up with my redundant changes to the manuscript and were extremely generous in their advice in balancing the scientific and practical knowledge and, above all, making sure that the book was framed and published in the highest professional presentation. As always, I take responsibility for any mistakes and errors in my writing, and I am always open to suggestions by the readers to make future editions. I can be contacted at niazi@niazi.com.

Preface to the Series—Second Edition

The science and the art of pharmaceutical formulation keeps evolving as new materials, methods, and machines become readily available to produce more reliable, stable, and release-controlled formulations. At the same time, globalization of sourcing of raw and finished pharmaceuticals brings challenges to regulatory authorities and results in more frequent revisions to the current good manufacturing practices, regulatory approval dossier requirements, and the growing need for cost optimization. Since the publication of the first edition of this book, a lot has changed in all of these areas of importance to pharmaceutical manufacturers. The second edition builds on the dynamic nature of the science and art of formulations and provides an evermore useful handbook that should be highly welcomed by the industry, the regulatory authorities, as well as the teaching institutions.

The first edition of this book was a great success as it brought under one umbrella the myriad of choices available to formulators. The readers were very responsive and communicated with me frequently pointing out to the weaknesses as well as the strengths of the book. The second edition totally revised attempts to achieve these by making major changes to the text, some of which include:

1. Complete, revised errors corrected and subject matter reorganized for easy reference. Whereas this series has six volumes differentiated on the basis of the type of dosage form and a separate inclusion of the U.S. OTC products, ideally the entire collection is needed to benefit from the myriad of topics relating to formulations, regulatory compliance, and dossier preparation.
2. Total number of pages is increased from 1684 to 2726.
3. Total number of formulations is expanded by about 30% with many newly approved formulations.
4. Novel formulations are now provided for a variety of drugs; these data are collected from the massive intellectual property data and suggest toward the future trend of formulations. While some of these formulations may not have been approved in the United States or Europe, these do provide additional choices, particularly for the NDA preparation. As always, it is the responsibility of the manufacturer to assure that the intellectual property rights are not violated.
5. A significant change in this edition is the inclusion of commercial products; while most of this information is culled out from the open source such as the FOIA (http://www.fda.gov/foi/default.htm), I have made attempts to reconstruct the critical portions of it based on what I call the generally acceptable standards. The drug companies are advised to assure that any intellectual property rights are not violated and this applies to all information contained in this book. The freedom of information act (FOIA) is an extremely useful conduit for reliable information and manufacturers are strongly urged to make use of this information. Whereas this information is provided free of charge, the process of obtaining the information may be cumbersome, in which case, commercial sources of these databases can prove useful, particularly for the non-U.S. companies.
6. Also included are the new Good Manufacturing Guidelines (2007) with amendments (2008) for the United States and similar updates for European Union and WHO; it is strongly urged that the companies discontinue using all old documents as there are significant changes in the revised form, and many of them are likely to reduce the cost of GMP compliance.
7. Details on design of clean rooms is a new entry that will be of great use to sterile product manufacturers; whereas the design and flow of personnel and material flow is of critical nature, regulatory agencies view these differently and the manufacturer is advised always to comply with most stringent requirements.
8. Addition of a self-auditing template in each volume of the series. While the cGMP compliance is a complex issue and the requirements diversified across the globe, the basic compliance remains universal. I have chosen the European Union guidelines (as these are more in tune with the ICH) to prepare a self-audit module that I recommend that every manufacturer adopt as a routine to assure GMP compliance. In most instances reading the template by those responsible for compliance with keep them sensitive to the needs of GMP.
9. OTC products cross-referenced in other volumes where appropriate. This was necessary since the regulatory authorities worldwide define this class of drug differently. It is important to iterate that regardless of the prescription or the OTC status of a product, the requirements for compliance with the cGMP apply equally.
10. OTC monograph status is a new section added to the OTC volume and this should allow manufacturers to chose appropriate formulations that may not require a filing with the regulatory agencies; it is important to iterate that an approved OTC monograph includes details of formulation including the types and quantities of active drug and excipients, labeling, and presentation. To qualify the exemption, the manufacturer must comply with the monograph in its entirety. However, subtle modifications that are merely cosmetic in nature and where there is an evidence that

the modification will not affect the safety and efficacy of the products can be made but require prior approval of the regulatory agencies and generally these approvals are granted.

11. Expanded discussion on critical factors in the manufacturing of formulations provided; from basic shortcuts to smart modifications now extend to all dosage forms. Pharmaceutical compounding is one of the oldest professions and whereas the art of formulations has been relegated to more objective parameters, the art nevertheless remains. An experienced formulator, like an artist, would know what goes with what and why; he avoids the pitfalls and stays with conservative choices. These sections of the book present advice that is time tested, although it may appear random at times; this is intended for experienced formulators.
12. Expanded details on critical steps in the manufacturing processes provided but to keep the size of the book manageable, and these are included for prototype formulations. The reader is advised to browse through similar formulations to gain more insight. Where multiple formulations are provided for the same drug, it intended to show the variety of possibilities in formulating a drug and whereas it pertains to a single drug, the basic formulation practices can be extended to many drugs of same class or even of diversified classes. Readers have often requested that more details be provided in the Manufacturing Direction sections. Whereas sufficient details are provided, this is restricted to prototype formulations to keep the size of the book manageable and to reduce redundancy.
13. Addition of a listing of approved excipients and the level allowed by regulatory authorities. This new section allows formulators a clear choice on which excipients to choose; the excipients are reported in each volume pertaining to the formulation type covered. The listing is drawn from the FDA-approved entities. For the developers of an ANDA, it is critical that the level of excipients be kept within the range generally approved to avoid large expense in justifying any unapproved level. The only category for which the listing is not provided separately is the OTC volume since it contains many dosage forms and the reader is referred to dosage form-specific title of the series. The choice of excipients forms keeps increasing with many new choices that can provide many special release characteristics to the dosage forms. Choosing correct excipients is thus a tedious exercise and requires sophisticated multivariate statistical analysis. Whereas the formulator may choose any number of novel or classical components, it is important to know the levels of excipients that are generally allowed in various formulations to reduce the cost of redundant exercises; I have therefore included, as an appendix to each volume, a list of all excipients that are currently approved by the U.S. FDA along their appropriate levels. I suggest that a formula- tor consult this table before deciding on which level of excipient to use; it does not mean that the excipient cannot be used outside this range but it obviates the need for a validation and lengthy justification studies in the submission of NDAs.
14. Expanded section on bioequivalence submission was required to highlight the recent changes in these requirements. New entries include a comprehensive listing of bioequivalence protocols in abbreviated form as approved by the U.S. FDA; these descriptions are provided in each volume where pertinent. To receive approval for an ANDA, an applicant must generally demonstrate, among other things, equivalence of the active ingredient, dosage form, strength, route of administration and conditions of use as the listed drug, and that the proposed drug product is bioequivalent to the reference listed drug [21 USC 355(j)(2)(A); 21 CFR 314.94(a)]. Bioequivalent drug products show no significant difference in the rate and extent of absorption of the therapeutic ingredient [21 U.S.C. 355(j)(8); 21 CFR 320.1(e)]. BE studies are undertaken in support of ANDA submissions with the goal of demonstrating BE between a proposed generic drug product and its reference listed drug. The regulations governing BE are provided at 21 CFR in part 320. The U.S. FDA has recently begun to promulgate individual bioequivalence requirements. To streamline the process for making guidance available to the public on how to design product-specific BE studies, the U.S. FDA will be issuing product-specific BE recommendations (www.fda.gov/cder/ogd/index.htm). To make this vital information available, an appendix to each volume includes a summary of all currently approved products by the U.S. FDA where a recommendation on conducting bioequivalence studies is made available by the U.S. FDA. When filing an NDA or an ANDA, the filer is faced with the choice of defending the methods used to justify the bioavailability or bioequivalence data. The U.S. FDA now allows application for waiver of bioequivalence requirement; a new chapter on this topic has been added along with details of the dissolution tests, where applicable, approved for various dosage forms.
15. Dissolution testing requirements are included for all dosage forms where this testing is required by the FDA. Surrogate testing to prove efficacy and compliance is getting more acceptance at regulatory agencies; in my experience, a well-designed dissolution test is the best measure of continuous compliance. Coupled with chapters on waivers of bioequivalence testing, this information on dissolution testing should be great value to all manufacturers; it is recommended that manufacturers develop their own in-house specifications, more stringent than those allowed in these listings and the USP.

16. Best-selling products (top 200 prescription products) are identified with an asterisk and a brand name where applicable; in all instances, composition of these products is provided and formulation of generic equivalents. Despite the vast expansion of pharmaceutical sales and shifting of categories of blockbuster drugs, basic drugs affecting gastrointestinal tract, vascular system, and brain remain most widely prescribed.
17. Updated list of approved coloring agents in the United States, Canada, European Union, and Japan is included to allow manufactures to design products for worldwide distribution.
18. Tablet-coating formulations that meet worldwide requirements of color selection are included in the Volume 1 (compressed solids) and Volume 5 (OTC) because these represent the products often coated.
19. Guidelines on preparing regulatory filings are now dispersed throughout the series depending on where these guidelines are more crucial. However, the reader would, as before, need access to all volumes to benefit from the advice and guidelines provided.

As always, comments and criticism from the readers are welcomed and these can be sent to me at Niazi@pharmsci.com or Niazi@niazi.com. I would try to respond to any inquiries requiring clarification of the information enclosed in these volumes.

I would like to express deep gratitude to Sherri R. Niziolek and Michelle Schmitt-DeBonis at Informa, the publisher of this work, for seeing an immediate value to the readers in publishing the second edition of this book and allowing me enough time to prepare this work. The diligent editing and composing staff at Informa, particularly Joseph Stubenrauch, Baljinder Kaur and others are highly appreciated. Regardless, all errors and omissions remain altogether mine.

In the first edition, I had dedicated each volume to one of my mentors; the second edition continues the dedication to these great teachers.

Preface to the Series—First Edition

No industry in the world is more highly regulated than the pharmaceutical industry because of potential threat to a patient's life from the use of pharmaceutical products. The cost of taking a new chemical entity (amortized over the cost of all molecules racing) to final regulatory approval is a staggering $800 million, making the pharmaceutical industry one of the most research-intensive industries in the world. In the year 2004, it is anticipated that the industry will spend about $20 billion on research and development. The generic market of drugs as the new entities come off patent is one of the fastest growing segments of the pharmaceutical industry, with every major multinational company having a significant presence in this field.

Whereas many stages of new drug development are inherently constrained with time, the formulation of drugs into desirable dosage forms remains an area where expediency can be practiced with appropriate knowledge by those who have mastered the skills of pharmaceutical formulations. The Handbook of Pharmaceutical Manufacturing Formulations is the first major attempt to consolidate the available knowledge about formulations in a comprehensive, and by nature a rather voluminous, presentation.

The book is divided into six volumes, based strictly on the type of formulation science involved in the development of these dosage forms: sterile products, compressed solids, uncompressed solids, liquid products, semisolid products, and OTC products. The separation of OTC products, even though they may easily fall into one of the other five categories, is made to comply with the industry norms of separate research divisions for OTC products. Sterile products require skills related to sterilization of product, and of less importance is the bioavailability issue, which is an inherent problem of compressed dosage forms. These types of considerations have led to the classification of products into these six categories.

Each volume includes a description of regulatory filing techniques for the formulations described. Also included are the current regulatory guidelines on cGMP compliance specific to the dosage form. Advice is offered on how to scale up the production batches.

It is expected that formulation scientists will use this information to benchmark their internal development protocols and cut the race to file short by adopting formulae that have survived the test of time. Many of us who have worked in the pharmaceutical industry suffer from a close paradigm when it comes to selecting formulations—"not invented here" perhaps reigns in the mind of many seasoned formulations scientists subconsciously when they prefer to choose only a certain platform for development. It is expected that with the quick review of possibilities available to formulate made available in this book, scientists will benefit from the experience of others.

For the teachers of formulation sciences, this series offers a wealth of information. Whether it is a selection of a preservative system or the choice of a disintegrant, the series offers a wide choice to study and rationalize.

Many have assisted me in the development of this work that has taken years to compile, and I thank scores of my graduate students and colleagues for their help. A work of this size cannot be produced without errors, although I hope that these errors do not distract the reader from the utility of the book. I would sincerely appreciate if readers point out these mistakes for corrections in future editions.

Preface to the Volume—First Edition

The semisolid drugs category is composed of ointments, creams, gels, suppositories, and special topical dosage forms. They share many common attributes of consistency, presentation, preservation requirement, and the route of administration, mainly topical. As a result, grouping them together for the purpose of defining common formulation practices and problems is justified. The topical dosage forms present unique opportunities to design novel drug delivery systems such as patches and other transdermal systems. Some of these are described in the volume, but the reader is referred to specific patents issued, wherein greater details are readily obtainable. In selecting the formulations, I have tried to provide representative techniques and technologies involved in the preparation of semisolid products; for example, I have included a significant number of what is called "base" formulation, a formulation that can easily carry a drug, depending on the proportion involved. Obviously, considerations such as incompatability of the drug with the ingredients is of pivotal importance; these base formulations of stable emulsions provide a good starting point in the development of new products or even when a different topical consistency is desired. I have also made an effort to highlight those formulations that are currently approved in the United States and provide them as they appear in the Physicans Desk Reference, where possible. Obviously, where the formulations are straightforward, I have chosen to only give the composition or mere identification of ingredients to conserve space for those formulations that need more elaborate description.

The regulatory agencies impose certain specific requirements on the formulation and efficacy determination of drugs contained in these formulations. For example, the cGMP factors, scale-up and postapproval changes, and dermatological testing for irritation or photosensitivity are some of the specified elements.

In this volume, we present over 350 formulations and, in keeping with the tradition in other volumes, a chapter on formulation-related matters. In the regulatory section, we offer a difficult area of compliance, changes to approved new drug applications (NDAs), and abbreviated new drug applications (ANDAs), particularly with reference to semisolid drugs. The stability considerations, particularly the evolving guidelines of the International Conference on Harmonization (ICH), are detailed in this volume, with particular reference to stability-testing requirements in postapproval stages. Unique to this category is the dermal testing of products, including photosensitivity-testing requirements that are still evolving. It is noteworthy that much of the regulatory discussion presented here is drawn from the requirements of the U.S. Food and Drug Administration (FDA) and the harmonized guidelines with the ICH listings. Although it is likely that some of the requirements and recommendations made here might change, it is unlikely that the basic thrust in establishing these guidelines will change. As always, the applicants are highly encouraged to communicate with the FDA on the changes made to these guidelines and especially for any significant changes made to compliance requirements. The Web site of the FDA, http://www.fda.gov, is very comprehensive and continuously evolving; pay special attention to the withdrawal and finalization of guidelines provided. Of particular importance is the listing of new and withdrawn guidelines (http://www.fda.gov/cder/guidance/New-Revised-Withdrawn.PDF), which should be reviewed periodically.

Chapter 1 provides details on how to handle changes made to approved NDAs or ANDAs; this is a significant topic for continued compliance with the cGMP requirements but, unfortunately, the one that is most easily misunderstood or misconstrued. For example, at what level of change should the FDA be informed, either before making a change or after? What happens if a change is made inadvertently and later discovered; how to report this change? Years of experience teaches me that a manufacturer can never be too careful in avoiding a 483 issuance when it comes to changes made to NDAs or ANDAs. The situation gets extremely complex when there are multiple dosage forms, for which the requirements may be different.

Chapter 2 gets into details of changes made pursuant to discussion in chapter 1 when it comes to semisolid drugs. A more detailed description of level of changes is described here, and advice is provided on when to conduct a regulatory review.

Chapter 3 continues the themes developed in the first two chapters and applies to changes made to equipment. This is a topic of special interest to the FDA because in the processing of semisolid products, the equipment plays a pivotal role. The mixing of drugs within the base media is highly affected by the process and mechanism of mixing used. Also, because of the nature of product manufactured, often the cleaning and validation of equipment become serious issues.

Chapter 4 is a comprehensive review of the present thinking of the regulatory authorities on how the stability studies should be designed and conducted and how the data should be interpreted; the induction of ICH guidelines and an attempt to streamline the requirements of testing new drug products have resulted in much dispute when it comes to global marketing of products. Should the stability testing be done at all environmental regional standards, or is it possible to extrapolate these data based on accelerated stability testing? These are some of the questions answered in this chapter, wherein the FDA and ICH guidelines are merged.

Chapter 5 extends the discussion on stability-testing protocols to retest periods and elaborates on the procedures used for continued testing of products.

Chapter 6 introduces a topic of great importance in the development of semisolid, and particularly dermal, products: skin irritation and sensitization studies. Whereas the standard test protocols have almost become universal in their

nature, it is always advised that these should be agreed on, most appropriately in a pre-investigational new drug application (IND) filing. Established in 1988, the Office of Drug Evaluation IV (ODE IV) Pre-IND Consultation Program is designed to facilitate and foster informal early communications between the divisions of ODE IV and potential sponsors of new therapeutics for the treatment of bacterial infections, HIV, opportunistic infections, transplant rejection, and other diseases. The program is intended to serve sponsors of all drug products that may be submitted to any division within ODE IV, including but not limited to drugs for the treatment of life-threatening illnesses [21 CFR 312.82(a)]. Pre- IND advice may be requested for issues related to drug development plans; data needed to support the rationale for testing a drug in humans; the design of nonclinical pharmacology, toxicology, and drug activity studies; data requirements for an IND application; and regulatory requirements for demonstrating safety and efficacy. Included among the ODE IV Pre-IND Program activities are coordination of all Pre-IND interactions with the FDA Topical Microbicide Working Group.

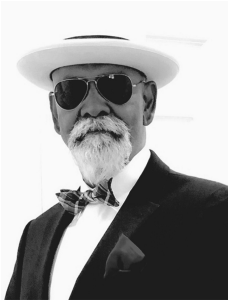
Chapter 7 deals with the topic of photosensitivity caused by drugs; photosafety is a serious issue in the development of topical products. It is worth noting here that certain classes of drugs such as quinolone antibiotics are generally regarded unsafe without thorough testing for photosensitivity. Does photosensitivity correlate with carcinogenicity? These are questions of importance to the regulatory authorities. Chapter 8 includes a variety of topics related to formulation of semisolid drugs, from cGMP considerations to packaging and validation issues; these topics are collated for their particular importance, but the discussions provided are not comprehensive, and the reader is referred to standard texts on formulation theories, particularly where establishing a preservative system is required.

I am grateful to CRC Press for taking this lead in publishing what is possibly the largest such work in the field of pharmaceutical manufacturing. It has been a distinct privilege to have known Mr. Stephen Zollo, the Senior Editor at CRC Press, for years. Stephen has done more than any editor can to encourage me into completing this work on a timely basis. The editorial assistance provided by CRC Press staff was indeed exemplary, particularly the help given by Erika Dery, Naomi Lynch, and others. Although much care has gone into correcting errors, any errors remaining are altogether mine. I shall appreciate the readers bringing these to my attention for correction in future editions of this volume (niazi@pharmsci.com).

This volume is dedicated to John G. Wagner, the John G. Searle Professor Emeritus of Pharmaceutics in the College of Pharmacy and Professor Emeritus of Pharmacology in the Medical School, who passed away recently. Born in Weston, Ontario, Canada, in 1921, Wagner served in the Canada Air Force during World War II and then worked as a research scientist for the Upjohn Co. from 1953 to 1968, joining the University of Medicine in 1968. Wagner was the author of two books and coauthor of more than 340 articles. Throughout his life he received numerous awards, including the American Pharmaceutical Association (APhA) Ebert Prize, 1961; Academy Fellow of the AphA Academy of Pharmaceutical Sciences, 1969; the Centennial Achievement Award, Ohio State University, 1970; the Host-Madsen Medal, Federation Internationale Pharmaceutique, 1972; Outstanding Leadership and Research Award, Delta Chapter of Phi Lambda Epsilon, 1983; AAPS Fellow, American Association of Pharmaceutical Scientists, 1986; and Distinguished Professor, Michigan Association of Governing Boards, 1988. Following retirement, Wagner worked as a consultant to Upjohn, Schering Corp., Warner-Lambert/Parke-Davis, the Food and Drug Administration, and others. John Wagner became famous with the publication of his book, Biopharmaceutics and Relevant Pharmacokinetics; he then followed with other books on the subject of pharmacokinetics. This was the time, in the early 1970s, when the discipline of mathematical pharmacokinetics was in its infancy; its creation spearheaded by such giants as Sid Riegelman, Milo Gibaldi, and Gerhard Levy. John took the lead in infusing complex mathematics to the resolution of pharmacokinetic modeling approach; his savvy of introducing Laplace transforms to all kinetics problems bears well in my mind. I never found it difficult to get lost somewhere in the long chain of mathematical transformations; John could easily make any model mathematically awesome. I met John several times when I had invited him to speak at the institutions where I was working to frequent meetings at the Academy of Pharmaceutical Science. John was a slim, trim man who spoke with a comparably lean choice of words. He was indeed a leader, a remarkable educator, and someone who left many indelible impressions on the students in his era—including me.

Sarfaraz K. Niazi, Ph.D.
Deerfield, Illinois, U.S.A.

About the Author



Sarfaraz K. Niazi has been teaching and conducting research in the pharmaceutical industry for over 40 years. He has authored hundreds of scientific papers, scores of textbooks, handbooks and literary books on the topics of pharmaceutical formulation, biopharmaceutics, pharmacokinetics, bioprocessing, recombinant engineering, as well as poetry and philosophy. He is also an inventor with 100+ patents in the fields of bioprocessing, technology, drug and dosage form delivery systems; he is also licensed to practice law before the U.S. Patent and Trademark Office. He has formulated hundreds of products ranging from the most popular consumer products to complex generics and biotechnology-derived products. Dr. Niazi advises regulatory agencies and the pharmaceutical industry internationally on making safe and effective drugs affordable (www.pharmsci.com). He can be contacted at niazi@niazi.com.

1 Waiver of In Vivo Bioequivalence Study

I. INTRODUCTION

Bioavailability (BA) and bioequivalence (BE) studies are expensive to conduct, and given the need for a multitude of these studies in the development of an NDA or ANDA, there had always existed a need to justify these needs on scientific grounds. This is particularly important for the generic drug industry since the generic competitors must keep their cost of regulatory approval to as low a level as possible. Recently, guidelines have emerged that would allow waiver of both BA and BE studies in some situations. There are also provisions available for the sponsor to challenge the requirement, and if the basic criteria set are met, there is a very good possibility of receiving waivers. These waivers are intended to apply to the following:

- Subsequent in vivo BA or BE studies of formulations after the initial establishment of the in vivo BA of immediate-release (IR) dosage forms during the IND period.
- In vivo BE studies of IR dosage forms in ANDAs. Regulations at 21 CFR part 320 address the requirements for BA and BE data for approval of drug applications and supplemental applications.

Provision for waivers of in vivo BA/BE studies (biowaivers) under certain conditions is provided at 21 CFR 320.22.

Waiver for bioequivalence testing therefore becomes a topic of great interest worldwide. Several consortiums have debated this topic for years, and a consensus has begun to develop on this topic. A large number of policy documents address this topic including the published FDA and ICH guidelines, Health Canada's Guideline on Preparation of DIN Submissions, WHO document (1999) entitled "Marketing Authorization of Pharmaceutical Products with Special Reference to Multisource (Generic) Products: a Manual for Drug Regulatory Authorities, Multisource (Generic) Pharmaceutical Products: Guidelines on Registration Requirements to Establish Interchangeability," Note for Guidance on the Investigation of Bioavailability and Bioequivalence, Committee for Proprietary Medicinal Products (CPMP), 26 July 2001 (CPMP/EWP/QWP/98), and Pan-American Network on Regulatory Harmonization: Bioavailability and Bioequivalence working group 2004.

The requirement for the in vivo bioequivalence study may be waived for certain generic products [21 USC 360 b (n) (1) (E)]. Categories of products which may be eligible for waivers include, but are not limited to, the following:

- Parenteral solutions intended for injection by the intravenous, subcutaneous, or intramuscular routes of administration
- Oral solutions or other solubilized forms
- Topically applied solutions intended for local therapeutic effects. Other topically applied dosage forms intended for local therapeutic effects for nonfood animals only
- Inhalant volatile anesthetic solutions

This guidance provides recommendations for sponsors of investigational new drug applications (INDs), new drug applications (NDAs), abbreviated new drug applications (ANDAs), and supplements to these applications that wish to request a waiver of in vivo BA or BE studies for IR solid oral dosage forms. These waivers apply to

1. Subsequent in vivo BA or BE studies of formulations after the initial establishment of the in vivo BA of IR dosage forms during the IND period and
2. In vivo BE studies of IR dosage forms in ANDAs

Regulations at 21 CFR Part 320 address the requirements for BA and BE data for approval of drug applications and supplemental applications. Provision for waivers of in vivo BA/BE studies (biowaivers) under certain conditions is provided at 21 CFR 320.22. This guidance explains when biowaivers can be requested for IR solid oral dosage forms based on an approach termed the biopharmaceutics classification system (BCS).

II. THE BIOPHARMACEUTICALS CLASSIFICATION SYSTEM

The BCS is a scientific framework for classifying drug substances based on their aqueous solubility and intestinal permeability. When combined with the dissolution of the drug product, the BCS takes into account three major factors that govern the rate and extent of drug absorption from IR solid oral dosage forms: Dissolution, solubility, and intestinal permeability. According to the BCS, drug substances are classified as follows:

Class 1: High solubility—high permeability
Class 2: Low solubility—high permeability
Class 3: High solubility—low permeability
Class 4: Low solubility—low permeability

In addition, IR solid oral dosage forms are categorized as having rapid or slow dissolution. Within this framework, when certain criteria are met, the BCS can be used as a drug development tool to help sponsors justify requests for biowaivers. There are several factors that affect classification of drugs in different classes. Table 1.1 expands this classification to include a more detailed description including the effect of transporter efflux factors.

TABLE 1.1
The Biopharmaceutics Classification System (BCS) as Defined by the FDA and Modified by Recent Findings

	High Solubility (e.g., When the Highest dose Strength is Soluble in 250 mL or Less of Aqueous Media Over a pH Range of 1–7.5 at 37°C)	**Low Solubility**
High permeability (e.g., absorption >90% compared to intravenous dose) (drug + metabolite)	Class 1: (generally about 8% of new leads) • High solubility • High permeability • Rapid dissolution for biowaiver • Route of elimination: Metabolism, extensive • Transporter effects: Minimal Examples: Abacavir; Acetaminophen; Acyclovir[b]; Amiloride[S, I]; Amitryptyline[S, I]; Antipyrine; Atropine; Buspirone[C]; Caffeine; Captopril; Chloroquine[S, I]; Chlorpheniramine; Cyclophosphamide; Desipramine; Diazepam; Diltiazem[S, I]; diphenhydramine; Disopyramide; Doxepin; oxycycline; Enalapril; Ephedrine; Ergonovine; Ethambutol; Ethinyl estradiol; Fluoxetine[I]; Glucose; Imipramine[I]; Ketoprofen; Ketorolac; Labetalol; Levodopa[S]; Levofloxacin[S]; Lidocaine[I]; Lomefloxacin; Meperidine; Metoprolol; Metronidazole; Midazolam[S, I]; Minocycline; Misoprostol; Nifedipine[S]; Phenobarbital; Phenylalanine; Prednisolone; Primaquine[S]; Promazine; Propranolol[I]; Quinidine[S,I]; Rosiglitazone; Salicylic acid; Theophylline; Valproic acid; Verapamil[I]; Zidovudine	Class 2: • Low solubility • High permeability • Route of elimination: Metabolism, extensive. • Transporter: Efflux transporter effects predominant Examples: Amiodarone[I]; Atorvastatin[S, I]; Azithromycin[S, I]; Carbamazepine[S, I]; Carvedilol; Chlorpromazine[I]; Ciprofloxacin[S]; Cisapride[S]; Cyclosporine[S, I]; Danazol; Dapsone; Diclofenac; Diflunisal; Digoxin[S]; Erythromycin[S, I]; Flurbiprofen; Glipizide; Glyburide[S, I]; Griseofulvin; Ibuprofen; Indinavir[S]; Indomethacin; Itraconazole[S, I]; Ketoconazole[I]; Lansoprazole[I]; Lovastatin[S, I]; Mebendazole; Naproxen; Nelfinavir[S, I]; Ofloxacin; Oxaprozin; Phenazopyridine; Phenytoin[S]; Piroxicam; Raloxifene[S]; Ritonavir[S, I]; Saquinavir[S, I]; Saquinavir[S, I]; Sirolimus[S]; Spironolactone[I]; Tacrolimus[S, I]; Talinolol[S]; Tamoxifen[I]; Terfenadine[I]; Warfarin
Low permeability	Class 3: • High solubility • Low permeability • Route of elimination: Renal and/or biliary elimination of unchanged drug; metabolism poor • Transporter: Absorptive effects predominant Examples: Acyclovir; Amiloride[S, I]; Amoxicillin[S, I]; Atenolol; Atropine; Bidisomide; Bisphosphonates; Captopril; Cefazolin; Cetirizine; Cimetidine[S]; Ciprofloxacin[S]; Cloxacillin; Dicloxacillin[S]; Erythromycin[S, I]; Famotidine; Fexofenadine[S]; Folinic acid; Furosemide; Ganciclovir; Hydrochlorothiazide; Lisinopril; Metformin; Methotrexate; Nadolol; Penicillins; Pravastatin[S]; Ranitidine[S]; Tetracycline; Trimethoprim[S]; Valsartan; Zalcitabine	Class 4: • Low solubility • Low permeability • Route of elimination: Renal and/or biliary elimination of unchanged drug; metabolism poor • Transporter: Absorptive and efflux transporters can be predominant Examples: Amphotericin B; Chlorothiazide; Chlorthalidone; Ciprofloxacin[S]; Colistin; Furosemide; Hydrochlorothiazide; Mebendazole; Methotrexate; Neomycin

Note: The compounds listed in italic are those falling in more than one category by different authors, which could be a result of the definition of the experimental conditions. The compounds listed in bold are primarily CYP3A substrates where metabolism accounts for more than 70% of the elimination; superscript I and/or S indicate P-gp inhibitors and/or substrate, respectively. The Class 1 and Class 2 compounds are eliminated primarily via metabolism, whereas Class 3 and Class 4 compounds are primarily eliminated unchanged into the urine and bile.

Observed in vivo differences in the rate and extent of absorption of a drug from two pharmaceutically equivalent solid oral products may be due to differences in drug dissolution in vivo. However, when the in vivo dissolution of an IR solid oral dosage form is rapid in relation to gastric emptying and the drug has high permeability, the rate and extent of drug absorption is unlikely to be dependent on drug dissolution and/or gastrointestinal transit time. Under such circumstances, demonstration of in vivo BA or BE may not be necessary for drug products containing Class 1 drug substances, as long as the inactive ingredients used in the dosage form do not significantly affect absorption of the active ingredients. The BCS approach outlined in this guidance can be used to justify biowaivers for *highly soluble* and *highly permeable* drug substances (i.e., Class 1) in IR solid oral dosage forms that exhibit *rapid in vitro dissolution* using the recommended test methods [21 CFR 320.22(e)].

Several generalizations can be made about the interplay of transporters and the BCS classification.

a. Transporter effects are minimal for Class 1 compounds. The high permeability/high solubility of such compounds allows high concentrations in the gut to saturate any transporter, both efflux and absorptive. Class 1 compounds may be substrates for both uptake and efflux transporters in vitro in cellular systems under the right conditions [e.g., midazolam and nifedipine are substrates for P-glycoprotein (P-gp)], but transporter effects will not be important clinically. It is therefore possible that some compounds that should be considered Class 1 in terms of drug absorption and disposition are not Class 1 in BCS due to the requirement of good solubility and rapid dissolution at low pH values. Such pH effects would not be limiting in vivo where absorption takes place from the intestine. Examples of this include the NSAIDs diclofenac, diflunisal, flurbiprofen, indomethacin, naproxen, and piroxicam; warfarin is almost completely bioavailable. In contrast, ofloxacin is listed as Class 2 because of its low solubility at pH 7.5.
b. Efflux transporter effects will predominate for Class 2 compounds. The high permeability of these compounds will allow ready access into the gut membranes, and uptake transporters will have no effect on absorption, but the low solubility will limit the concentrations coming into the enterocytes, thereby preventing saturation of the efflux transporters. Consequently, efflux transporters will affect the extent of oral bioavailability and the rate of absorption of Class 2 compounds.
c. Transporter-enzyme interplay in the intestines will be important primarily for Class 2 compounds that are substrates for CYP3A and Phase 2 conjugation enzymes. For such compounds, intestinal uptake transporters will generally be unimportant due to the rapid permeation of the drug molecule into the enterocytes as a function of their high lipid solubility. That is, absorption of Class 2 compounds is primarily passive and a function of lipophilicity. However, because of the low solubility of these compounds, there will be little opportunity to saturate apical efflux transporters and intestinal enzymes such as cytochrome P450 3A4 (CYP3A4) and UDP-glucuronosyltransferases (UGTs). Thus, changes in transporter expression and inhibition or induction of efflux transporters will cause changes in intestinal metabolism of drugs that are substrates for the intestinal metabolic enzymes. Note the large number of Class 2 compounds in Table 1.1 that are primarily substrates for CYP3A (compounds listed in bold) as well as substrates or inhibitors of the efflux transporter P-gp (indicated by superscripts S and I, respectively). Work in our laboratory has characterized this interplay in the absorptive process for the investigational cysteine protease inhibitor K77 (28,32) and sirolimus (29), substrates for CYP3A and P-gp, and more recently for raloxifene (33), a substrate for UGTs and P-gp.
d. Absorptive transporter effects will predominate for Class 3 compounds. For Class 3 compounds, sufficient drug will be available in the gut lumen due to good solubility, but an absorptive transporter will be necessary to overcome the poor permeability characteristics of these compounds. However, intestinal apical efflux transporters may also be important for the absorption of such compounds when sufficient enterocyte penetration is achieved via an uptake transporter.

Table 1.2 lists model drugs suggested for use in establishing suitability of a permeability method. The permeability of these compounds was determined based on data available to the FDA. Potential *internal standards* (IS) and *efflux pump substrates* (ES) are also identified.

For application of the BCS, an apparent passive transport mechanism can be assumed when one of the following conditions is satisfied:

- A linear (pharmacokinetic) relationship between the dose (e.g., relevant clinical dose range) and measures of BA (area under the concentration–time curve) of a drug is demonstrated in humans.
- Lack of dependence of the measured in vivo or in situ permeability is demonstrated in an animal model on initial drug concentration (e.g., 0.01, 0.1, and 1 times the highest dose strength dissolved in 250 mL) in the perfusion fluid.
- Lack of dependence of the measured in vitro permeability on initial drug concentration (e.g., 0.01, 0.1, and 1 times the highest dose strength dissolved in 250 mL) is demonstrated in donor fluid and transport direction (e.g., no statistically significant difference in the rate of transport between the apical-to-basolateral and basolateral-to-apical direction for the drug concentrations selected) using a suitable in vitro cell culture method that has been shown to express known efflux transporters (e.g., P-gp).

TABLE 1.2
Model Drugs to Establish Permeability of Drugs

Drug	Permeability Class
Antipyrine	High (potential IS candidate)
Caffeine	High
Carbamazepine	High
Fluvastatin	High
Ketoprofen	High
Metoprolol	High (potential IS candidate)
Naproxen	High
Propranolol	High
Theophylline	High
Verapamil	High (potential ES candidate)
Amoxicillin	Low
Atenolol	Low
Furosemide	Low
Hydrochlorthiazide	Low
Mannitol	Low (potential IS candidate)
Methyldopa	Low
Polyethylene glycol (400)	Low
Polyethylene glycol (1000)	Low
Polyethylene glycol (4000)	Low (zero permeability marker)
Ranitidine	Low

To demonstrate suitability of a permeability method intended for application of the BCS, a rank-order relationship between test permeability values and the extent of drug absorption data in human subjects should be established using a sufficient number of model drugs. For in vivo intestinal perfusion studies in humans, six model drugs are recommended. For in vivo or in situ intestinal perfusion studies in animals and for in vitro cell culture methods, 20 model drugs are recommended. Depending on study variability, a sufficient number of subjects, animals, excised tissue samples, or cell monolayers should be used in a study to provide a reliable estimate of drug permeability. This relationship should allow precise differentiation between drug substances of low- and high-intestinal permeability attributes.

For demonstration of suitability of a method, model drugs should represent a range of low (e.g., <50%), moderate (e.g., 50–89%), and high (≥90%) absorption. Sponsors may select compounds from the list of drugs and/or chemicals provided in Attachment A, or they may choose to select other drugs for which there is information available on mechanism of absorption and reliable estimates of the extent of drug absorption in humans.

After demonstrating suitability of a method and maintaining the same study protocol, it is not necessary to retest all selected model drugs for subsequent studies intended to classify a drug substance. Instead, a low- and a high-permeability model drug should be used as IS (i.e., included in the perfusion fluid or donor fluid along with the test drug substance). These two IS are in addition to the fluid volume marker (or a zero-permeability compound such as Polyethylene glycol 4000) that is included in certain types of perfusion techniques (e.g., closed loop techniques). The choice of IS should be based on compatibility with the test drug substance (i.e., they should not exhibit any significant physical, chemical, or permeation interactions). When it is not feasible to follow this protocol, the permeability of IS should be determined in the same subjects, animals, tissues, or monolayers, following evaluation of the test drug substance. The permeability values of the two IS should not differ significantly between different tests, including those conducted to demonstrate suitability of the method. At the end of an in situ or in vitro test, the amount of drug in the membrane should be determined.

For a given test method with set conditions, selection of a high-permeability internal standard with permeability in close proximity to the low-/high-permeability class boundary may facilitate classification of a test drug substance. For instance, a test drug substance may be determined to be highly permeable when its permeability value is equal to or greater than that of the selected internal standard with high permeability.

The recommended methods for determining solubility, permeability, and in vitro dissolution are discussed below.

A. Solubility

The solubility class boundary is based on the highest dose strength of an IR product that is the subject of a biowaiver request. A drug substance is considered *highly soluble* when the highest dose strength is soluble in 250 mL or less of aqueous media over the pH range of 1 to 7.5. The volume estimate of 250 mL is derived from typical BE study protocols that prescribe administration of a drug product to fasting human volunteers with a glass (about 8 ounces) of water.

B. Permeability

The permeability class boundary is based indirectly on the extent of absorption (fraction of dose absorbed, not systemic BA) of a drug substance in humans and directly on measurements of the rate of mass transfer across human intestinal membrane. Alternatively, nonhuman systems capable of predicting the extent of drug absorption in humans can be used (e.g., in vitro epithelial cell culture methods). In the absence of evidence suggesting instability in the gastrointestinal tract, a drug substance is considered *highly permeable* when the extent of absorption in humans is determined to be 90% or more of an administered dose based on a mass balance determination or in comparison to an intravenous reference dose.

C. Dissolution

In this guidance, an IR drug product is considered *rapidly dissolving* when no less than 85% of the labeled amount of the drug substance dissolves within 30 min, using U.S. Pharmacopoeia (USP) Apparatus I at 100 rpm (or Apparatus II at 50 rpm) in a volume of 900 mL or less in each of the following media:

1. 0.1 N HCl or Simulated Gastric Fluid USP without enzymes
2. A pH 4.5 buffer
3. A pH 6.8 buffer or Simulated Intestinal Fluid USP without enzymes

III. METHODOLOGY FOR CLASSIFYING A DRUG SUBSTANCE AND FOR DETERMINING THE DISSOLUTION CHARACTERISTICS OF A DRUG PRODUCT

The following approaches are recommended for classifying a drug substance and determining the dissolution characteristics of an IR drug product according to the BCS.

A. Determining Drug Substance Solubility Class

An objective of the BCS approach is to determine the equilibrium solubility of a drug substance under physiological pH conditions. The pH-solubility profile of the test drug substance should be determined at $37 \pm 1°C$ in aqueous media with a pH in the range of 1 to 7.5. A sufficient number of pH conditions should be evaluated to accurately define the pH-solubility profile. The number of pH conditions for a solubility determination can be based on the ionization characteristics of the test drug substance. For example, when the pKa of a drug is in the range of 3 to 5, solubility should be determined at pH = pKa, pH = pKa + 1, pH = pKa −1, and at pH = 1 and 7.5. A minimum of three replicate determinations of solubility in each pH condition is recommended. Depending on study variability, additional replication may be necessary to provide a reliable estimate of solubility. Standard buffer solutions described in the USP are considered appropriate for use in solubility studies. If these buffers are not suitable for physical or chemical reasons, other buffer solutions can be used. Solution pH should be verified after addition of the drug substance to a buffer. Methods other than the traditional shake-flask method, such as acid or base titration methods, can also be used with justification to support the ability of such methods to predict equilibrium solubility of the test drug substance. Concentration of the drug substance in selected buffers (or pH conditions) should be determined using a validated stability-indicating assay that can distinguish the drug substance from its degradation products (www.fda.gov/cder/guidance/P147_9604#P147_9604). If degradation of the drug substance is observed as a function of buffer composition or pH, it should be reported along with other stability data recommended in Section III.B.3.

The solubility class should be determined by calculating the volume of an aqueous medium sufficient to dissolve the highest dose strength in the pH range of 1 to 7.5. A drug substance should be classified as highly soluble when the highest dose strength is soluble in ≤ 250 mL of aqueous media over the pH range of 1 to 7.5.

B. Determining Drug Substance Permeability Class

The permeability class of a drug substance can be determined in human subjects using mass balance, absolute BA, or intestinal perfusion approaches. Recommended methods not involving human subjects include in vivo or in situ intestinal perfusion in a suitable animal model (e.g., rats), in vitro permeability methods using excised intestinal tissues, or monolayers of suitable epithelial cells. In many cases, a single method may be sufficient (e.g., when the absolute BA is 90% or more, or when 90% or more of the administered drug is recovered in urine). When a single method fails to conclusively demonstrate a permeability classification, two different methods may be advisable. Chemical structure or certain physicochemical attributes of a drug substance (e.g., partition coefficient in suitable systems) can provide useful information about its permeability characteristics. Sponsors may wish to consider use of such information to further support a classification.

1. Pharmacokinetic Studies in Humans

a. Mass Balance Studies

Pharmacokinetic mass balance studies using unlabeled, stable isotopes or a radiolabeled drug substance can be used to document the extent of absorption of a drug. Depending on the variability of the studies, a sufficient number of subjects should be enrolled to provide a reliable estimate of extent of absorption. Because this method can provide highly variable estimates of drug absorption for many drugs, other methods described below may be preferable.

b. Absolute Bioavailability Studies

Oral BA determination using intravenous administration as a reference can be used. Depending on the variability of the studies, a sufficient number of subjects should be enrolled in a study to provide a reliable estimate of the extent of absorption. When the absolute BA of a drug is shown to be 90% or more, additional data to document drug stability in the gastrointestinal fluid is not necessary.

The following methods can be used to determine the permeability of a drug substance from the gastrointestinal tract: (1) in vivo intestinal perfusion studies in humans, (2) in vivo or in situ intestinal perfusion studies using suitable animal models, (3) in vitro permeation studies using excised human or animal intestinal tissues, or (4) in vitro permeation studies across a monolayer of cultured epithelial cells.

In vivo or in situ animal models and in vitro methods, such as those using cultured monolayers of animal or human epithelial cells, are considered appropriate for passively transported drugs. The observed low permeability of some drug substances in humans could be caused by efflux of drugs via membrane transporters such as P-gp. When the efflux transporters are absent in these models, or their degree of expression is low compared to that in humans, there may be a greater likelihood of misclassification of permeability class for a drug subject to efflux compared to a drug transported passively. Expression of known transporters in selected study systems

should be characterized. Functional expression of efflux systems (e.g., P-gp) can be demonstrated with techniques such as bidirectional transport studies, demonstrating a higher rate of transport in the basolateral-to-apical direction as compared to apical-to-basolateral direction using selected model drugs or chemicals at concentrations that do not saturate the efflux system (e.g., cyclosporin A, vinblastine, rhodamine 123). An acceptance criterion for intestinal efflux that should be present in a test system cannot be set at this time. Instead, this guidance recommends limiting the use of nonhuman permeability test methods for drug substances that are transported by passive mechanisms. Pharmacokinetic studies on dose linearity or proportionality may provide useful information for evaluating the relevance of observed in vitro efflux of a drug. For example, there may be fewer concerns associated with the use of in vitro methods for a drug that has a higher rate of transport in the basolateral-to-apical direction at low drug concentrations but exhibits linear pharmacokinetics in humans.

Poor absorption or permeation is more likely when there are more than five H-bond donors, ten H-bond acceptors, the molecular weight is greater than 500, and the calculated Log P is greater than 5. This is also often referred to as Rule of 5 of Lipinski. However, Lipinski specifically states that the Rule of 5 only holds for compounds that are *not* substrates for active transporters. Since almost all drugs are substrates for some transporter, much remains to be studied about Lipinski's rule. In addition, unless a drug molecule can passively gain intracellular access, it is not possible to simply investigate whether the molecule is a substrate for efflux transporters.

2. Intestinal Permeability Methods

The following methods can be used to determine the permeability of a drug substance from the gastrointestinal tract:

1. In vivo intestinal perfusion studies in humans
2. In vivo or in situ intestinal perfusion studies using suitable animal models
3. In vitro permeation studies using excised human or animal intestinal tissues
4. In vitro permeation studies across a monolayer of cultured epithelial cells

In vivo or in situ animal models and in vitro methods, such as those using cultured monolayers of animal or human epithelial cells, are considered appropriate for passively transported drugs. The observed low permeability of some drug substances in humans could be caused by efflux of drugs via membrane transporters such as P-gp. When the efflux transporters are absent in these models, or their degree of expression is low compared with that in humans, there may be a greater likelihood of misclassification of permeability class for a drug subject to efflux compared with a drug transported passively. Expression of known transporters in selected study systems should be characterized. Functional expression of efflux systems (e.g., P-gp) can be demonstrated with techniques such as bidirectional transport studies, demonstrating a higher rate of transport in the basolateral-to-apical direction as compared with apical-to-basolateral direction using selected model drugs or chemicals at concentrations that do not saturate the efflux system (e.g., cyclosporin A, vinblastine, rhodamine 123). An acceptance criterion for intestinal efflux that should be present in a test system cannot be set at this time. Instead, this guidance recommends limiting the use of nonhuman permeability test methods for drug substances that are transported by passive mechanisms. Pharmacokinetic studies on dose linearity or proportionality may provide useful information for evaluating the relevance of observed in vitro efflux of a drug. For example, there may be fewer concerns associated with the use of in vitro methods for a drug that has a higher rate of transport in the basolateral-to-apical direction at low drug concentrations but exhibits linear pharmacokinetics in humans.

For application of the BCS, an apparent passive transport mechanism can be assumed when one of the following conditions is satisfied:

- A linear (pharmacokinetic) relationship between the dose (e.g., relevant clinical dose range) and measures of BA (area under the concentration–time curve, AUC) of a drug is demonstrated in humans.
- Lack of dependence of the measured in vivo or in situ permeability is demonstrated in an animal model on initial drug concentration (e.g., 0.01, 0.1, and 1 H the highest dose strength dissolved in 250 mL) in the perfusion fluid.
- Lack of dependence of the measured in vitro permeability on initial drug concentration (e.g., 0.01, 0.1, and 1 H the highest dose strength dissolved in 250 mL) is demonstrated in donor fluid and transport direction (e.g., no statistically significant difference in the rate of transport between the apical-to-basolateral and basolateral-to-apical direction for the drug concentrations selected), using a suitable in vitro cell culture method that has been shown to express known efflux transporters (e.g., P-gp).

To demonstrate suitability of a permeability method intended for application of the BCS, a rank-order relationship between test permeability values and the extent of drug absorption data in human subjects should be established using a sufficient number of model drugs. For in vivo intestinal perfusion studies in humans, six model drugs are recommended. For in vivo or in situ intestinal perfusion studies in animals and for in vitro cell culture methods, 20 model drugs are recommended. Depending on study variability, a sufficient number of subjects, animals, excised tissue samples, or cell monolayers should be used in a study to provide a reliable estimate of drug permeability. This relationship should allow precise differentiation between drug substances of low- and high-intestinal permeability attributes.

Given below is a description of various approaches available to study permeability characteristics.

a. Surrogate Methods

As the U.S. FDA has begun accepting recommendations for waiver of bioequivalence requirement, protocols that prove extremely expensive in the drug development cycle, there is a greater need to develop surrogate models that one day may prove useful in securing waivers for all classes of drugs. Generally, the methods available currently show that the complexity of assay is directly proportional to its correlation with absorption of drugs in humans. Studies that correlated Log P with human absorption profile and the suitability or lead candidates are elaborated in Chapter 4. In this chapter, we will examine more complex assay systems. Data from both complex biological and artificial permeation assays can provide valuable information regarding the absorption of a drug.

Drug transport across epithelial cell barriers, especially the human small intestine, is difficult to predict. The intestinal epithelial cell barrier is a sophisticated organ that has evolved over hundreds of millions of years to become a "smart," effective, and selective xenobiotic screen. Nevertheless, there is large interindividual variability in the intestinal transport of drugs. Genetic variability in key proteins is believed to be causal. There is a pressing need to better understand the key processes and how the system components interact at the molecular, cellular, and tissue level to control drug transport and determine drug absorption in the small intestine.

Is it feasible to construct an in silico framework to represent the drug absorption in the small intestine at the cellular level in concert with the update molecular biochemical mechanism? This new generation of models and computational tools might integrate the available and emerging information at different levels to better account for and predict observed experimental results. Predicting aqueous solubility with in silico tools is a key drug property. It is, however, difficult to measure accurately, especially for poorly soluble compounds, and thus numerous in silico models have been developed for its prediction. Some in silico models can predict aqueous solubility of simple, uncharged organic chemicals reasonably well; however, solubility prediction for charged species and drug-like chemicals is not very accurate. However, extrapolating solubility data to intestinal absorption from pharmacokinetic and physicochemical data and elucidating crucial parameters for absorption and the potential for improvement of bioavailability are important at the pre-formulation stages.

The poor oral bioavailability of drugs is generally assumed to be due to physiochemical problems, which result in poor solubility in the gastrointestinal tract (GI tract) or difficulty in diffusion through the small intestine epithelial membrane. Furthermore, the biochemical process also contributes to oral bioavailability. The in vitro cell culture models of the intestinal epithelial cell barrier have evolved to become widely used experimental devices.

The permeability assay uses an artificial membrane composed of hexadecane. The automated systems comprise a multiwell system.

b. Parallel Artificial Membrane Permeability Analysis

Early drug discovery ADME assays, such as fast Caco-2 screens (see below), can help in rejecting test compounds that lack good pharmaceutical profiles. A cost-effective, high-throughput method—parallel artificial membrane permeability analysis (PAMPA)—that uses a phospholipid artificial membrane that models passive transport of epithelial cells is becoming increasingly popular. The PAMPA assay uses a range of lipid components that model a variety of different plasma membranes. The support membrane is 0.45 μm Hydrophobic Polyvinylidene Fluoride, 130 μm thick, and the artificial membrane is lecithin in dodecane; recommended incubation time is 16 to 24 hours. The permeability and PAMPA assays as described above are robust and reproducible assays for determining passive, transcellular compound permeability. Permeability and PAMPA are automation compatible, relatively fast (4–16 hours), inexpensive, and straightforward, and their results correlate with human drug absorption values from published methods. The PAMPA assay provides the benefits of a more biologically relevant system. It is also possible to tailor the lipophilic constituents so that they mimic specific membranes such as the blood–brain barrier. Optimization of incubation time, lipid mixture, and lipid concentration will also enhance the assay's ability to predict compound permeability.

Modifications of permeability and PAMPA systems have been reported, for example, using the pION PAMPA Evolution 96 System with double-sink and gut-box (www.pion-inc.com/products.htm) as a new surrogate assay that predicts the gastrointestinal tract absorption of candidate drug molecules at different pH conditions. Using Beckman Coulter's Biomek® FX Single Bridge Laboratory Automation Workstation PAMPA Assay System that features a 30-minute incubation time and an on-deck integrated Gut-Box™ and a SpectraMax® microplate spectrophotometer, the permeability coefficients of drug standards with diverse physiochemical properties can be compared from both PAMPA and Caco-2 assays automated using the Biomek FX Workstation.

These automated assays can be used for high-throughput ADME screening in early drug discovery. The Double-Sink PAMPA permeability assay mimics in vivo conditions by the use of a chemical sink in the acceptor wells and pH gradient in the donor wells. The use of the pION Gut-Box integrated on the deck has shortened the PAMPA assay incubation time to 30 min. The permeability coefficient and rank order correlate well with data obtained using the in vitro Caco-2 assay and in vivo permeability properties measured in rat intestinal perfusions.

c. Caco-2 Drug Transport Assays

Drug absorption generally occurs either through passive transcellular or paracellular diffusion, active carrier transport, or active efflux mechanisms. Several methods have been developed to aid in the understanding of the absorption of new lead compounds. The most common ones use an immortalized cell line (e.g., Caco-2, MDCK, etc.) to mimic the intestinal epithelium. These in vitro models provide more predictive

permeability information than artificial membrane systems (i.e., PAMPA and permeability assays, described above) based on the cells' ability to promote (active transport) or resist (efflux) transport. Various in vitro methods are listed in U.S. FDA guidelines, acceptable to evaluate the permeability of a drug substance, including monolayer of suitable epithelial cells, and one such epithelial cell line that has been widely used as a model system of intestinal permeability is the Caco-2 cell line.

The kinetics of intestinal drug absorption, permeation enhancement, chemical moiety structure–permeability relationships, dissolution testing, in vitro/in vivo correlation, bioequivalence, and the development of novel polymeric materials are closely associated with the concept of Caco-2. Since most drugs are known to absorb via intestines without using cellular pumps, passive permeability models came into the limelight. In a typical Caco-2 experiment, a monolayer of cells is grown on a filter separating two stacked micro well plates. The permeability of drugs through the cells is determined after the introduction of a drug on one side of the filter. The entire process is automated, and when used in conjunction with chromatography and/or mass spectroscopy detection, it enables any drug's permeability to be determined. The method requires careful sample analysis to calculate permeability correctly. Limitations of Caco-2 experiments are the 21 days to prepare a stable monolayer, as well as the stringent storage conditions; however, tight-junction formation prior to use is the better choice. The villus in the small intestine contains more than one cell type, the Caco-2 cell line does not produce the mucus as observed in the small intestine, and no P-450 metabolizing enzyme activity has been found in the Caco-2 cell line. Test compound solubility may pose a problem in Caco-2 assays because of the assay conditions. Finally, Caco-2 cells also contain endogenous transporter and efflux systems, the latter of which works against the permeability process and can complicate data interpretation for some drugs.

The Caco-2 cell line is heterogeneous and is derived from a human colorectal adenocarcinoma. Caco-2 cells are used as in vitro permeability models to predict human intestinal absorption because they exhibit many features of absorptive intestinal cells. This includes their ability to spontaneously differentiate into polarized enterocytes that express high levels of brush border hydrolases and form well-developed junctional complexes. Consequently, it becomes possible to determine whether passage is transcellular or paracellular based on a compound's transport rate. Caco-2 cells also express a variety of transport systems including dipeptide transporters and P-gp. Because of these features, drug permeability in Caco-2 cells correlates well with human oral absorption, making Caco-2 an ideal in vitro permeability model. Additional information can be gained on metabolism and potential drug–drug interactions as the drug undergoes transcellular diffusion through the Caco-2 transport model.

Although accurate and well researched, the Caco-2 cell model requires a high investment of time and resources. Depending on a number of factors, including initial seeding density, culturing conditions, and passage number, Caco-2 cells can take as many as 20 days to reach confluence and achieve full differentiation. During this 20-day period, they require manual or automated exchange of media as frequently as every other day. The transport assays consume valuable drug compounds and normally require expensive, post-transport sample analyses (e.g., LC/MS). Therefore, the use of the Caco-2 transport model in a high-throughput laboratory setting is only possible if the platform is robust, automation compatible, reproducible, and provides high-quality data that correlate well with established methodologies.

The Millipore MultiScreen® Caco-2 assay system is a reliable 96-well platform for predicting human oral absorption of drug compounds (using Caco-2 cells or other cell lines whose drug transport properties have been well characterized). The MultiScreen system format is automation compatible and is designed to offer more cost effective, higher-throughput screening of drugs than a 24-well system. The MultiScreen Caco-2 assay system exhibits good uniformity of cell growth and drug permeability across all 96 wells and low variability between production lots. The plate design supports the use of lower volumes of expensive media and reduced amounts of test compounds. Using the MultiScreen Caco-2 assay system, standard drug compounds are successfully categorized as either "high" or "low" permeable, as defined by FDA, and the permeability data correlate well with established human absorption values.

Historically, it has been shown that a sigmoidal relationship exists between drug absorption rates as measured with the in vitro Caco-2 model and human absorption. Caco-2 cells are heterogeneous, and their properties in final culture may differ based on the selection pressures of a particular laboratory. Direct comparison of compound permeability rates between laboratories is not possible unless the same Caco-2 cells and conditions are used. Therefore, transport rates and permeability classification ranges of specific drugs are expected to vary between reported studies. Most important is the ability to successfully classify compounds as low-, medium-, or high-permeable drugs and produce transport results that correlate to established human absorption values.

Several modifications of Caco-2 cell model have been tested; for example, CYP3A4-Transfected Caco-2 cells are also used to define the biochemical absorption barriers. Oral bioavailability and intestinal drug absorption can be significantly limited by metabolizing enzymes and efflux transporters in the gut. The most prevalent oxidative drug-metabolizing enzyme present in the intestine is CYP3A4. Currently, more than 50% of the drugs on the market metabolized by P450 enzymes are metabolized by CYP3A4. Oral absorption of CYP3A4 substrates can also be limited by the multidrug resistance transporter P-gp, because there is extensive substrate overlap between these two proteins. P-gp is an ATP-dependent transporter on the apical plasma membrane of enterocytes that functions to limit the entry of drugs into the cell. There is significant interaction between CYP3A4 and P-gp in the intestine. Although Caco-2 cells express a variety of uptake and efflux transporters found in the human intestine, a major drawback to the use of Caco-2 cells is that

they lack CYP3A4. As such, no data regarding the importance of intestinal metabolism on limiting drug absorption can be obtained from normal Caco-2 cells. Caco-2 cells pretreated with 1, 25-dihydroxyvitamin-D_3 (vitamin D_3) express higher levels of CYP3A4 compared with Caco-2 but still underestimate the amount of CYP3A4 in the human intestine. CYP3A4-transfected Caco-2 cells that P-gp can enhance drug metabolism and significantly decrease intestinal drug absorption.

d. Animal Model Testing

Whereas the quantity of substance available at the pre-formulation stages is generally small, in some instances, early animal testing for absorption potential is needed, particularly if the solid form of the new drug offers many options such as amorphous forms, solvates, and so forth. The absorption models used in animals are well described and will not be discussed here. Establishing good in vitro–in vivo correlation at this stage proves useful because of limited access to sufficient compound to run the entire absorption profiles. The "in vitroin vivo correlation" (IVIVC) analysis can be made extensive, or general conclusions drawn from limited studies; the choice depends on the amount of compound available and the nature or robustness of correlation observed.

e. In Vitro–In Vivo Correlation

The selection of a drug candidate marks the most crucial stage in the lifecycle of drug development. Such selection is primarily based on the drug "developability" criteria, which include physicochemical properties of the drug and the results obtained from preliminary studies involving several in vitro systems and in vivo animal models, which address efficacy and toxicity issues. During this stage, exploring the relationship between in vitro and in vivo properties of the drug in animal models provides an idea about the feasibility of the drug delivery system for a given drug. In such correlations, study designs including study of more than one formulation of the modified-release dosage forms and a rank order of release (fast/slow) of the formulations should be incorporated. Even though the formulations and methods used at this stage are not optimal, they prompt better design and development efforts in the future.

There are four levels of IVIVC that have been described in the FDA guidance, which include levels A, B, C, and multiple C.

- Level A Correlation: This correlation represents a point-to-point relationship between in vitro dissolution and in vivo dissolution (input/absorption rate). Level A IVIVC is also viewed as a predictive model for the relationship between the entire in vitro release time course and entire in vivo response time course. In general, correlations are linear at this level. Although a concern regarding acceptable nonlinear correlation has been addressed, no formal guidance on the nonlinear IVIVC has been established. Level A correlation is the most informative and very useful from a regulatory perspective.
- Level B Correlation: In level B correlation, the mean in vivo dissolution or mean residence time is compared to the mean in vitro dissolution time by using statistical moment analytical methods. This type of correlation uses all of the in vitro and in vivo data; thus, it is not considered as a point-to-point correlation. This is of limited interest and use because more than one kind of plasma curve produces similar mean residence time.
- Level C Correlation: This correlation describes a relationship between the amount of drug dissolved (e.g., % dissolved at 1 hour) at one time point and one pharmacokinetic parameter (e.g., either AUC or C_{max}). Level C correlation is considered the lowest correlation level as it does not reflect the complete shape of the plasma concentration time curve. Similarly, a multiple level C correlation relates one or more pharmacokinetic parameters to the percent drug dissolved at several time points of the dissolution profile and thus may be more useful. Level B and C correlations can be useful in early formulation development, including selecting the appropriate excipients, to optimize manufacturing processes, for quality control purposes, and to characterize the release patterns of newly formulated immediate-release and modified-release products relative to the reference.

The most basic IVIVC models are expressed as a simple linear equation between the in vivo drug absorption and in vitro drug dissolved (released).

Several commercial software programs are available to study IVIVC, for example, PDx-IVIVC (www.globomaxservice.com/pdxivivc.htm), which is a comprehensive IVIVC software program that performs deconvolution, calculating the fraction or percentage of drug absorbed and correlating it with in vitro fraction or percentage dissolved data. It also allows level C correlations (single or multiple) wherein a single-point relationship between a dissolution parameter, for example, percent dissolved in 4 hours, and a pharmacokinetic parameter (e.g., AUC, C_{max}, T_{max}) is determined. A successful IVIVC model can be developed if in vitro dissolution is the rate-limiting step in the sequence of events leading to appearance of the drug in the systemic circulation following oral or other routes of administration. Thus, the dissolution test can be used as a surrogate for bioequivalence studies (involving human subjects) if the developed IVIVC is predictive of in vivo performance of the product.

3. Instability in the Gastrointestinal Tract

Determining the extent of absorption in humans based on mass balance studies using total radioactivity in urine does not take into consideration the extent of degradation of a drug in the gastrointestinal fluid before intestinal membrane permeation. In addition, some methods for determining permeability could be based on loss or clearance of a drug from fluids perfused into the human or animal gastrointestinal tract either

in vivo or in situ. Documenting the fact that drug loss from the gastrointestinal tract arises from intestinal membrane permeation, instead of a degradation process, will help establish permeability. Stability in the gastrointestinal tract may be documented using gastric and intestinal fluids obtained from human subjects. Drug solutions in these fluids should be incubated at 37°C for a period that is representative of in vivo drug contact with these fluids (e.g., 1 hour in gastric fluid and 3 hours in intestinal fluid). Drug concentrations should then be determined using a validated stability-indicating assay method. Significant degradation (>5%) of a drug in this protocol could suggest potential instability. Obtaining gastrointestinal fluids from human subjects requires intubation and may be difficult in some cases. Use of gastrointestinal fluids from suitable animal models or simulated fluids such as Gastric and Intestinal Fluids USP can be substituted when properly justified.

C. Determining Drug Product Dissolution Characteristics and Dissolution Profile Similarity

Dissolution testing should be carried out in USP Apparatus I at 100 rpm or Apparatus II at 50 rpm using 900 mL of the following dissolution media (www.fda.gov/cder/guidance/P192_20127#P192_20127):

1. NHCl or Simulated Gastric Fluid USP without enzymes
2. A pH 4.5 buffer
3. A pH 6.8 buffer or Simulated Intestinal Fluid USP without enzymes

For capsules and tablets with gelatin coating, Simulated Gastric and Intestinal Fluids USP (with enzymes) can be used.

Dissolution testing apparatus used in this evaluation should conform to the requirements in USP (<711> Dissolution). Selection of the dissolution testing apparatus (USP Apparatus I or II) during drug development should be based on a comparison of in vitro dissolution and in vivo pharmacokinetic data available for the product. The USP Apparatus I (*basket method*) is generally preferred for capsules and products that tend to float, and USP Apparatus II (*paddle method*) is generally preferred for tablets. For some tablet dosage forms, in vitro (but not in vivo) dissolution may be slow due to the manner in which the disintegrated product settles at the bottom of a dissolution vessel. In such situations, USP Apparatus I may be preferred over Apparatus II. If the testing conditions need to be modified to better reflect rapid in vivo dissolution (e.g., use of a different rotating speed), such modifications can be justified by comparing in vitro dissolution with in vivo absorption data (e.g., a relative BA study using a simple aqueous solution as the reference product).

A minimum of 12 dosage units of a drug product should be evaluated to support a biowaiver request. Samples should be collected at a sufficient number of intervals to characterize the dissolution profile of the drug product (e.g., 10, 15, 20, and 30 min).

When comparing the test and reference products, dissolution profiles should be compared using a similarity factor (f_2). The similarity factor is a logarithmic reciprocal square root transformation of the sum of squared error and is a measurement of the similarity in the percent (%) of dissolution between the two curves.

$$f_2 = 50 \times \log\left\{\left[1 + (1/n)_{t=1^n}\left(R_t - T_t\right)^2\right] - 05 \times 100\right\}$$

Two dissolution profiles are considered similar when the f_2 value is >50. To allow the use of mean data, the coefficient of variation should not be more than 20% at the earlier time points (e.g., 10 min) and should not be more than 10% at other time points. Note that when both test and reference products dissolve 85% or more of the label amount of the drug in >15 min using all three dissolution media recommended previously, the profile comparison with an f_2 test is unnecessary.

IV. ADDITIONAL CONSIDERATIONS FOR REQUESTING A BIOWAIVER

When requesting a BCS-based waiver for in vivo BA/BE studies for IR solid oral dosage forms, applicants should note that the following factors could affect their request or the documentation of their request.

A. Excipients

Excipients can sometimes affect the rate and extent of drug absorption. In general, using excipients that are currently in FDA-approved IR solid oral dosage forms will not affect the rate or extent of absorption of a highly soluble and highly permeable drug substance that is formulated in a rapidly dissolving IR product. To support a biowaiver request, the quantity of excipients in the IR drug product should be consistent with the intended function (e.g., lubricant). When new excipients or atypically large amounts of commonly used excipients are included in an IR solid dosage form, additional information documenting the absence of an impact on the BA of the drug may be requested by the FDA. Such information can be provided with a relative BA study using a simple aqueous solution as the reference product. Large quantities of certain excipients, such as surfactants (e.g., polysorbate 80) and sweeteners (e.g., mannitol or sorbitol) may be problematic, and sponsors are encouraged to contact the review division when this is a factor.

B. Prodrugs

Permeability of prodrugs will depend on the mechanism and (anatomical) site of conversion to the drug substance. When it is demonstrated that the prodrug-to-drug conversion occurs predominantly after intestinal membrane permeation, the permeability of the prodrug should be measured. When this conversion occurs prior to intestinal permeation, the permeability of the drug should be determined. Dissolution and

pH-solubility data on both prodrugs and drugs can be relevant. Sponsors may wish to consult with appropriate review staff before applying the BCS approach to IR products containing prodrugs.

C. Exceptions

BCS-based biowaivers are not applicable for the following.

1. Narrow Therapeutic Range Drugs

This guidance defines narrow therapeutic range drug products (www.fda.gov/cder/guidance/P223_24901#P223_24901) as those containing certain drug substances that are subject to therapeutic drug concentration or pharmacodynamic monitoring or where product labeling indicates a narrow therapeutic range designation. Examples include digoxin, lithium, phenytoin, theophylline, and warfarin. Because not all drugs subject to therapeutic drug concentration or pharmacodynamic monitoring are narrow therapeutic range drugs, sponsors should contact the appropriate review division to determine whether a drug should be considered as having a narrow therapeutic range.

2. Products Designed to Be Absorbed in the Oral Cavity

A request for a waiver of in vivo BA/BE studies based on the BCS is not appropriate for dosage forms intended for absorption in the oral cavity (e.g., sublingual or buccal tablets).

V. REGULATORY APPLICATIONS OF THE BCS

A. INDs/NDAs

Evidence demonstrating in vivo BA or information to permit the FDA to waive this evidence must be included in NDAs [21 CFR 320.21(a)]. A specific objective is to establish in vivo performance of the dosage form used in the clinical studies that provided primary evidence of efficacy and safety. The sponsor may wish to determine the relative BA of an IR solid oral dosage form by comparison with an oral solution, suspension, or intravenous injection [21 CFR 320.25 (d)(2) and 320.25 (d)(3)]. The BA of the clinical trial dosage form should be optimized during the IND period.

Once the in vivo BA of a formulation is established during the IND period, waivers of subsequent in vivo BE studies, following major changes in components, composition, or method of manufacture [e.g., similar to SUPAC-IR level 3 changes (www.fda.gov/cder/guidance/P239_26745#P239_26745)], may be possible using the BCS. BCS-based biowaivers are applicable to the to-be-marketed formulation when changes in components, composition, or method of manufacture occur to the clinical trial formulation, as long as the dosage forms have rapid and similar in vitro dissolution profiles (see Sections II and III). This approach is useful only when the drug substance is highly soluble and highly permeable (BCS Class 1), and the formulations pre- and post-change are *pharmaceutical equivalents* [under the definition at 21 CFR 320.1 (c)]. BCS-based biowaivers are intended only for BE studies. They do not apply to food effect BA studies or other pharmacokinetic studies.

B. aNDAs

BCS-based biowaivers can be requested for rapidly dissolving IR test products containing highly soluble and highly permeable drug substances, provided that the reference-listed drug product is also rapidly dissolving and the test product exhibits similar dissolution profiles to the reference-listed drug product (see Sections II and III). This approach is useful when the test and reference dosage forms are pharmaceutical equivalents. The choice of dissolution apparatus (USP Apparatus I or II) should be the same as that established for the reference-listed drug product.

C. Post-Approval Changes

BCS-based biowaivers can be requested for significant post-approval changes (e.g., level 3 changes in components and composition) to a rapidly dissolving IR product containing a highly soluble, highly permeable drug substance, provided that dissolution remains rapid for the post-change product and both pre- and post-change products exhibit similar dissolution profiles (see Sections II and III). This approach is useful only when the drug products pre- and post-change are pharmaceutical equivalents.

VI. DATA TO SUPPORT A REQUEST FOR BIOWAIVERS

The drug substance for which a waiver is being requested should be highly soluble and highly permeable. Sponsors requesting biowaivers based on the BCS should submit the following information to the FDA for review by the Office of Clinical Pharmacology and Biopharmaceutics (for NDAs) or Office of Generic Drugs, Division of Bioequivalence (for aNDAs).

A. Data Supporting High Solubility

Data supporting high solubility of the test drug substance should be developed (see Section III.A). The following information should be included in the application:

- A description of test methods, including information on analytical method and composition of the buffer solutions
- Information on chemical structure, molecular weight, nature of the drug substance (acid, base, amphoteric, or neutral), and dissociation constants [pKa(s)]
- Test results (mean, standard deviation, and coefficient of variation) summarized in a table under solution pH, drug solubility (e.g., mg/mL), and volume of media required to dissolve the highest dose strength
- A graphic representation of mean pH-solubility profile

B. Data Supporting High Permeability

Data supporting high permeability of the test drug substance should be developed (see Section III.B). The following information should be included in the application:

- For human pharmacokinetic studies, information on study design and methods used along with the pharmacokinetic data.
- For direct permeability methods, information supporting the suitability of a selected method that encompasses a description of the study method, criteria for selection of human subjects, animals, or epithelial cell line, drug concentrations in the donor fluid, description of the analytical method, method used to calculate extent of absorption or permeability, and, where appropriate, information on efflux potential (e.g., bidirectional transport data).
- A list of selected model drugs along with data on extent of absorption in humans (mean, standard deviation, and coefficient of variation) used to establish suitability of a method, permeability values for each model drug (mean, standard deviation, and coefficient of variation), permeability class of each model drug, and a plot of the extent of absorption as a function of permeability (mean, standard deviation, or 95% confidence interval) with identification of the low- and high-permeability class boundary and selected internal standard. Information to support high permeability of a test drug substance should include permeability data on the test drug substance, the IS (mean, standard deviation, and coefficient of variation), stability information, data supporting passive transport mechanism where appropriate, and methods used to establish high permeability of the test drug substance.

C. Data Supporting Rapid and Similar Dissolution

For submission of a biowaiver request, an IR product should be rapidly dissolving. Data supporting rapid dissolution attributes of the test and reference products should be developed (see Section III.C). The following information should be included in the application:

- A brief description of the IR products used for dissolution testing, including information on batch or lot number, expiration date, dimensions, strength, and weight.
- Dissolution data obtained with 12 individual units of the test and reference products using recommended test methods in Section III.C. The percentage of labeled claims dissolved at each specified testing interval should be reported for each individual dosage unit. The mean percent (%) dissolved, range (highest and lowest) of dissolution, and coefficient of variation (relative standard deviation) should be tabulated. A graphic representation of the mean dissolution profiles for the test and reference products in the three media should also be included.
- Data supporting similarity in dissolution profiles between the test and reference products in each of the three media, using the f_2 metric.

D. Additional Information

The manufacturing process used to make the test product should be described briefly to provide information on the method of manufacture (e.g., wet granulation vs. direct compression). A list of excipients used, the amount used, and their intended functions should be provided. Excipients used in the test product should have been used previously in FDA-approved IR solid oral dosage forms. When requesting a BCS-based waiver for in vivo BA/BE studies for IR solid oral dosage forms, applicants should note that the following factors can affect their request or the documentation of their request:

1. Excipients

Excipients can sometimes affect the rate and extent of drug absorption. In general, using excipients that are currently in FDA-approved IR solid oral dosage forms will not affect the rate or extent of absorption of a highly soluble and highly permeable drug substance that is formulated in a rapidly dissolving IR product. To support a biowaiver request, the quantity of excipients in the IR drug product should be consistent with the intended function (e.g., lubricant). When new excipients or atypically large amounts of commonly used excipients are included in an IR solid dosage form, additional information documenting the absence of an impact on BA of the drug may be requested by the agency. Such information can be provided with a relative BA study using a simple aqueous solution as the reference product. Large quantities of certain excipients, such as surfactants (e.g., polysorbate 80) and sweeteners (e.g., mannitol or sorbitol), may be problematic, and sponsors are encouraged to contact the review division when this is a factor.

2. Prodrugs

Permeability of prodrugs will depend on the mechanism and (anatomical) site of conversion to the drug substance. When the prodrug-to-drug conversion is shown to occur predominantly after intestinal membrane permeation, the permeability of the prodrug should be measured. When this conversion occurs prior to intestinal permeation, the permeability of the drug should be determined. Dissolution and pH-solubility data on both prodrug and drug can be relevant. Sponsors may wish to consult with appropriate review staff before applying the BCS approach to IR products containing prodrugs.

3. Exceptions

BCS-based biowaivers are not applicable for the following.

a. Narrow Therapeutic Range Drugs

The narrow therapeutic range drug products are defined as those containing certain drug substances that are subject to therapeutic drug concentration or pharmacodynamic monitoring, and/or where product labeling indicates a narrow therapeutic range designation. Examples include digoxin, lithium, phenytoin, theophylline, and warfarin. Because not all drugs subject to therapeutic drug concentration or pharmacodynamic monitoring are narrow therapeutic range drugs, sponsors should contact the appropriate review division to determine whether a drug should be considered to have a narrow therapeutic range.

b. Products Designed to Be Absorbed in the Oral Cavity

A request for a waiver of in vivo BA/BE studies based on the BCS is not appropriate for dosage forms intended for absorption in the oral cavity (e.g., sublingual or buccal tablets).

Fast-dissolving/-disintegrating tablets (FDDTs) disintegrate and/or dissolve rapidly in the saliva without the need for water and are thus of importance for patients who cannot or will not swallow. Some tablets are designed to dissolve in saliva remarkably fast, within a few seconds, and are true fast-dissolving tablets. Others contain agents to enhance the rate of tablet disintegration in the oral cavity and are more appropriately termed fast-disintegrating tablets, as they may take up to a minute to completely disintegrate. These tablets, if absorbed through the buccal cavity, avoid the first pass liver metabolism, and claims have been made for improvement of bioavailability using these platforms. Some of the key formulation considerations for FDDTs include the need to mask the taste and the most obvious method to do so is to include sweeteners and flavors; however, these are not a sufficient means for taste-masking many bitter drugs. Thus, most of the FDDT technologies incorporate unique forms of taste masking including adsorption onto or complexation with carriers and spray coating of drug particles. Frequently, the active drug powder is coated, and the coating does not completely dissolve until the drug has been swallowed. Drugs that are particle coated are more appropriately termed fast disintegrating due to the delayed release of the active molecule until they are swallowed. Additionally, effervescence is a physical method of taste masking used in some of the FDDTs. Details about the technology are sketchy as they pertain mostly to proprietary methods.

Currently, four fast-dissolving/-disintegrating technologies have reached the U.S. market: Zydis® (R.P. Scherer, Inc., Basking Ridge, NJ), WOWTABtm (Yamanouchi Pharma Technologies, Inc., Palo Alto, CA), and OraSolv® and DuraSolv® (Cima Labs, Inc., Brooklyn Park, MN). Three others are available outside the United States: FlashDose® (Fuisz Technologies, Ltd., Chantilly, VA), Flashtab® (Prographarm Group, Saint Cloud, France), and OraQuick™ (KV Pharmaceutical Co., Inc., St. Louis, MO). Examples of products available in the United States include:

Zydis Products

- Claritin Reditab: Micronized loratadine (10 mg), citric acid, gelatin, mannitol, mint flavor
- Feldene Melt: Piroxicam (10 or 20 mg), gelatin, mannitol, aspartame, citric anhydrous
- Maxalt-MLT: Rizatriptan (5 or 10 mg), gelatin, mannitol, aspartame, peppermint flavor
- Pepcid RPD: Famotidine (20 or 40 mg), gelatin, mannitol, aspartame
- Zyprexa Zydis: Olanzapine (5, 10, 15, or 20 mg), gelatin, mannitol, aspartame, methylparaben sodium, propylparaben sodium
- Zofran ODT: Ondansetron (4 or 8 mg), aspartame, gelatin, mannitol, methlparaben sodium, propylparaben sodium, strawberry flavor
- Dimetapp Quick Dissolve Children's Cold and Allergy Tablets (OTC)

OraSolv Products

- Remeron Soltab: Mirtazepine (15, 30, or 45 mg), aspartame, citric acid, crospovidone, hydroxypropyl methylcellulose, magnesium stearate, mannitol, microcrystalline cellulose, polymethacrylate, povidone, sodium bicarbonate, starch, sucrose, orange flavor
- Tempra FirstTabs: Acetaminophen (80 or 160 mg), inactive ingredients including mannitol (currently available in Canada)
- Triaminic Softchew (OTC)

DuraSolv Products

- NuLev: Hyoscyamine sulfate (0.125 mg), aspartame, colloidal silicon dioxide, crospovidone, mint flavoring, magnesium stearate, mannitol, microcrystalline cellulose
- Zomig ZMT: Zolmitriptan (2.5 mg), mannitol, microcrystalline cellulose, crospovidone, aspartame, sodium bicarbonate, citric acid, anhydrous, colloidal silicon dioxide, magnesium stearate, orange flavor

WOWTAB Products

- Benadryl Allergy & Sinus Fastmelt (OTC)
- Children's Benadryl Allergy & Cold Fastmelt (OTC)
- Most FDDTs lack the mechanical strength common to traditional tablets. Many products are very lightweight and fragile requiring them to be individually packaged. Because of the formulation of FDDTs, they are also more susceptible to degradation via temperature and humidity.

Animal Products In general, the generic product being considered for a waiver contains the same active and inactive ingredients in the same dosage form and concentration and has the same pH and physicochemical characteristics as an approved pioneer product. However, the CVM will consider bioequivalence waivers for nonfood animal topical products

with certain differences in the inactive ingredients of the pioneer and generic products.

If a waiver of the in vivo bioequivalence and/or the tissue residue study/studies is granted for a food animal drug product, then the withdrawal period established for the pioneer product will be assigned to the generic product. Sponsors may apply for waivers of in vivo bioequivalence studies prior to submission of the ANADAs (Abbreviated New Drug Applications).

Species Selection A bioequivalence study generally should be conducted for each species for which the pioneer product is approved on the label, with the exception of "minor" species [as defined in section 514.1 (d) (1) of Title 21 of the Code of Federal Regulations] on the label.

Subject Characteristics Ordinarily, studies should be conducted with healthy animals representative of the species, class, gender, and physiological maturity for which the drug is approved. The bioequivalence study may be conducted with a single gender for which the pioneer product is approved, unless there is a known interaction of formulation with gender. An attempt should be made to restrict the weight of the test animals to a narrow range in order to maintain the same total dose across study subjects. The animals should not receive any medication prior to testing for a period of 2 weeks or more, depending upon the biological half-life of the ancillary drug.

Human Food Safety Considerations The toxicology and tolerance developed for the pioneer animal drug are applied to generic copies of the drug. The CVM has concluded that in addition to a bioequivalence study, a tissue residue depletion study should be conducted for approval of a generic animal drug product in a food-producing species. Two drug products may have the same plasma disposition profile at the concentrations used to assess product bioequivalence but may have very different tissue disposition kinetics when followed out to the withdrawal time for the pioneer product. Therefore, to show the withdrawal period at which residues of the generic product will be consistent with the tolerance for the pioneer product, a tissue residue depletion study is necessary.

The results of a bioequivalence study or tissue residue depletion study in one animal species cannot generally be extrapolated to another species. Possible species differences in drug partitioning or binding in tissues could magnify a small difference in the rate or extent of drug absorbed into a large difference in marker residue concentrations in the target tissue. Therefore, for a pioneer product labeled for more than one food-producing species, a bioequivalence study and a tissue residue depletion study will generally be requested for each major food-producing species on the label.

A traditional withdrawal study, as described in CVM's guidance number 3, "General Principles for Evaluating the Safety of Compounds Used in Food-Producing Animals," is considered the best design for collecting data useful for the calculation of a preslaughter withdrawal period for drugs used in food-producing animals. In the traditional withdrawal study, 20 animals are divided into four or five groups of four to five animals each. Groups of animals are slaughtered at carefully preselected time points following the last administration of the test product, and the edible tissues are collected for residue analysis. A statistical tolerance limit approach is used to determine when, with 95% confidence, 99% of treated animals would have tissue residues below the codified limits.

For purposes of calculating a withdrawal period for a generic animal drug, only the generic product would be tested (i.e., not the pioneer product), and only the marker residue in the target tissue would be analyzed. Other study designs will be considered on a case-by-case basis. Sponsors are encouraged to submit the proposed tissue residue depletion protocol for CVM concurrence before proceeding with the withdrawal study.

The generic animal drug will be assigned the withdrawal time supported by the residue depletion data or the withdrawal time currently assigned to the pioneer product, whichever is the longer.

The generic animal drug sponsor may request a shorter withdrawal period for the generic product by supplementing the ANADA and providing tissue residue data necessary to support the shorter withdrawal period request. Such a supplement will be reviewed under the agency's policy for Category II supplements. For a Category II supplement, a reevaluation of the safety (or effectiveness) data in the parent application (i.e., the pioneer NADA) may be required [21 CFR 514.106 (b) (2)]. The CVM will ordinarily approve a request for a shorter withdrawal period when the residue data are adequate and when no other human food safety concerns for the drug are evident.

Under 21 CFR 514.1(b)(7), applications are required to include a description of practicable methods for determining the quantity, if any, of the new animal drug in or on food, and any substance formed in or on food because of its use, and the proposed tolerance or withdrawal period or other use restrictions to ensure that the proposed use of the drug will be safe. For certain drug products, a tissue residue depletion study is not needed to ensure that residues of the test product will be consistent with the codified drug tolerance at the withdrawal time assigned to the reference product. These include but may not be limited to products for which a waiver of in vivo bioequivalence testing is granted and products for which the assay method used in the blood level bioequivalence study is sensitive enough to measure blood levels of the drug for the entire withdrawal period assigned to the reference product. Other requests for waiver of the tissue residue study will be considered on a case-by-case basis.

CVM will not request that the assay methodology used to determine the withdrawal period for the generic product be more rigorous than the approved methodology used to determine the existing withdrawal period for the pioneer product. If an analytical method other than the approved method of analysis is used, the generic sponsor should provide data comparing the alternate method to the approved method.

2 Quality Risk Management

I. INTRODUCTION

Risk management principles are effectively used in many areas of business and government including finance, insurance, occupational safety, public health, pharmacovigilance, and by agencies regulating these industries. Although there are some examples of the use of *quality risk management* in the pharmaceutical industry today, they are limited and do not represent the full contributions that risk management has to offer. In addition, the importance of *quality systems* has been recognized in the pharmaceutical industry, and it is becoming evident that quality risk management is a valuable component of an effective quality system.

It is commonly understood that *risk* is defined as the combination of the probability of occurrence of *harm* and the *severity* of that harm. However, achieving a shared understanding of the application of risk management among diverse *stakeholders* is difficult because each stakeholder might perceive different potential harms, place a different probability on each harm occurring, and attribute different severities to each harm. In relation to pharmaceuticals, although there are a variety of stakeholders, including patients and medical practitioners as well as government and industry, the protection of the patient by managing the risk to quality should be considered of prime importance.

The manufacturing and use of a drug (medicinal) product, including its components, necessarily entail some degree of risk. The risk to its quality is just one component of the overall risk. It is important to understand that product *quality* should be maintained throughout the *product lifecycle* such that the attributes that are important to the quality of the drug (medicinal) product remain consistent with those used in the clinical studies. An effective quality risk management approach can further ensure the high quality of the drug (medicinal) product to the patient by providing a proactive means to identify and control potential quality issues during development and manufacturing. Additionally, use of quality risk management can improve the decision making if a quality problem arises. Effective quality risk management can facilitate better and more informed decisions, can provide regulators with greater assurance of a company's ability to deal with potential risks, and can beneficially affect the extent and level of direct regulatory oversight.

The purpose of this document is to offer a systematic approach to quality risk management. It serves as a foundation or resource document that is independent of, yet supports, other ICH quality documents and complements existing quality practices, requirements, standards, and guidelines within the pharmaceutical industry and regulatory environment. It specifically provides guidance on the principles and some of the tools of quality risk management that can enable more effective and consistent risk-based decisions, both by regulators and by industry, regarding the quality of drug substances and drug (medicinal) products across the product lifecycle. It is not intended to create any new expectations beyond the current regulatory requirements.

It is neither always appropriate nor always necessary to use a formal risk management process (using recognized tools and/or internal procedures, e.g., standard operating procedures). The use of informal risk management processes (using empirical tools and/or internal procedures) can also be considered acceptable. Appropriate use of quality risk management can facilitate but does not obviate industry's obligation to comply with regulatory requirements and does not replace appropriate communications between industry and regulators.

II. SCOPE

This guideline provides principles and examples of tools for quality risk management that can be applied to different aspects of pharmaceutical quality. These aspects include development, manufacturing, distribution, and the inspection and submission/review processes throughout the lifecycle of drug substances, drug (medicinal) products, biological, and biotechnological products (including the use of raw materials, solvents, excipients, packaging, and labeling materials in drug (medicinal) products, biological, and biotechnological products).

III. PRINCIPLES OF QUALITY RISK MANAGEMENT

Two primary principles of quality risk management are as follows:

- The evaluation of the risk to quality should be based on scientific knowledge and ultimately link to the protection of the patient.
- The level of effort, formality, and documentation of the quality risk management process should be commensurate with the level of risk.

IV. GENERAL QUALITY RISK MANAGEMENT PROCESS

Quality risk management is a systematic process for the assessment, control, communication, and review of risks to the quality of the drug (medicinal) product across the product lifecycle. A model for quality risk management is outlined in Figure 2.1. Other models could be used. The emphasis on each component of the framework might differ from case to case, but a robust process will incorporate consideration of all

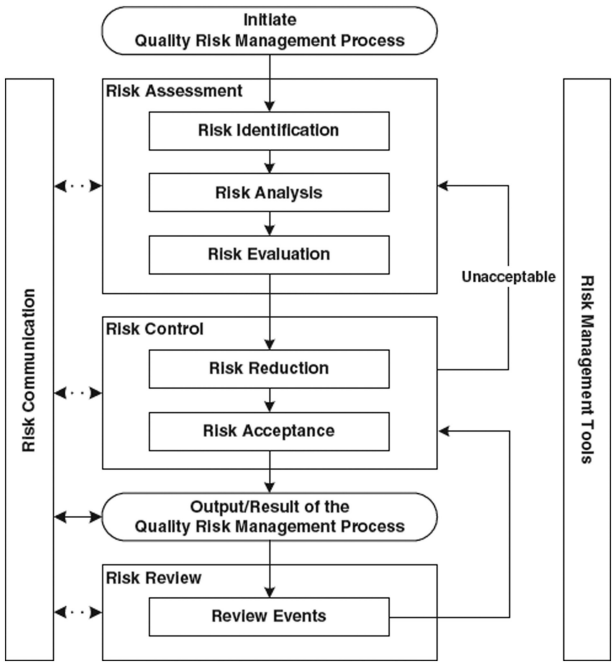

FIGURE 2.1 Overview of a typical quality risk management process.

the elements at a level of detail that is commensurate with the specific risk.

Decision nodes are not shown in Figure 2.1, because decisions can occur at any point in the process. These decisions might be to return to the previous step and seek further information, to adjust the risk models, or even to terminate the risk management process based upon information that supports such a decision. *Note*: "Unacceptable" in the flowchart does not only refer to statutory, legislative, or regulatory requirements but also to the need to revisit the risk assessment process.

A. Responsibilities

Quality risk management activities are usually, but not always, undertaken by interdisciplinary teams. When teams are formed, they should include experts from the appropriate areas (e.g., quality unit, business development, engineering, regulatory affairs, production operations, sales and marketing, legal, statistics, and clinical) in addition to individuals who are knowledgeable about the quality risk management process.

Decision makers *should*

- Take responsibility for coordinating quality risk management across various functions and departments of their organization and
- Assure that a quality risk management process is defined, deployed, and reviewed and that adequate resources are available

B. Initiating a Quality Risk Management Process

Quality risk management should include systematic processes designed to coordinate, facilitate, and improve science-based decision making with respect to risk. Possible steps used to initiate and plan a quality risk management process might include the following:

- Define the problem and/or risk question, including pertinent assumptions identifying the potential for risk.
- Assemble background information and/or data on the potential hazard, harm, or human health impact relevant to the risk assessment.
- Identify a leader and necessary resources.
- Specify a timeline, deliverables, and appropriate level of decision making for the risk management process.

C. Risk Assessment

Risk assessment consists of the identification of hazards and the analysis and evaluation of risks associated with exposure to those hazards (as defined below). Quality risk assessments begin with a well-defined problem description or risk question. When the risk in question is well defined, an appropriate risk management tool (see examples in Section V) and the types of information needed to address the risk question will be more readily identifiable. As an aid to clearly defining the risk(s) for risk assessment purposes, three fundamental questions are often helpful:

1. What might go wrong?
2. What is the likelihood (probability) it will go wrong?
3. What are the consequences (severity)?

Risk identification is a systematic use of information to identify hazards referring to the risk question or problem description. Information can include historical data, theoretical analysis, informed opinions, and the concerns of stakeholders. Risk identification addresses the "What might go wrong?" question, including identifying the possible consequences. This provides the basis for further steps in the quality risk management process.

Risk analysis is the estimation of the risk associated with the identified hazards. It is the qualitative or quantitative process of linking the likelihood of occurrence and severity of harms. In some risk management tools, the ability to detect the harm (detectability) also factors in the estimation of risk.

Risk evaluation compares the identified and analyzed risk against given risk criteria. Risk evaluations consider the strength of evidence for all three of the fundamental questions.

In doing an effective risk assessment, the robustness of the data set is important because it determines the quality of the output. Revealing assumptions and reasonable sources of uncertainty will enhance confidence in this output and/or help identify its limitations. Uncertainty is due to combination of incomplete knowledge about a process and its expected or unexpected variability. Typical sources of uncertainty include gaps in knowledge, gaps in pharmaceutical science and process understanding, sources of harm (e.g., failure modes of a process, sources of variability), and probability of detection of problems.

The output of a risk assessment is either a quantitative estimate of risk or a qualitative description of a range of risk. When risk is expressed quantitatively, a numerical probability is used. Alternatively, risk can be expressed using qualitative descriptors, such as "high," "medium," or "low," which should be defined in as much detail as possible. Sometimes a "risk score" is used to further define descriptors in risk ranking. In quantitative risk assessments, a risk estimate provides the likelihood of a specific consequence, given a set of risk-generating circumstances. Thus, quantitative risk estimation is useful for one particular consequence at a time. Alternatively, some risk management tools use a relative risk measure to combine multiple levels of severity and probability into an overall estimate of relative risk. The intermediate steps within a scoring process can sometimes employ quantitative risk estimation.

D. Risk Control

Risk control includes decision making to reduce and/or accept risks. The purpose of risk control is to reduce the risk to an acceptable level. The amount of effort used for risk control should be proportional to the significance of the risk. Decision makers might use different processes, including benefit–cost analysis, for understanding the optimal level of risk control.

Risk control might focus on the following questions:

- Is the risk above an acceptable level?
- What can be done to reduce or eliminate risks?
- What is the appropriate balance among benefits, risks, and resources?
- Are new risks introduced as a result of the identified risks being controlled?

Risk reduction focuses on processes for mitigation or avoidance of quality risk when it exceeds a specified (acceptable) level (see Figure 2.1). Risk reduction might include actions taken to mitigate the severity and probability of harm. Processes that improve the detectability of hazards and quality risks might also be used as part of a risk control strategy. The implementation of risk reduction measures can introduce new risks into the system or increase the significance of other existing risks. Hence, it might be appropriate to revisit the risk assessment to identify and evaluate any possible change in risk after implementing a risk reduction process.

Risk acceptance is a decision to accept risk. Risk acceptance can be a formal decision to accept the residual risk, or it can be a passive decision in which residual risks are not specified. For some types of harms, even the best quality risk management practices might not entirely eliminate risk. In these circumstances, it might be agreed that an appropriate quality risk management strategy has been applied and that quality risk is reduced to a specified (acceptable) level. This (specified) acceptable level will depend on many parameters and should be decided on a case-by-case basis.

E. Risk Communication

Risk communication is the sharing of information about risk and risk management between the decision makers and others. Parties can communicate at any stage of the risk management process (see Figure 2.1: Dashed arrows). The output/result of the quality risk management process should be appropriately communicated and documented (see Figure 2.1: Solid arrows). Communications might include those among interested parties, for example, regulators and industry, industry and the patient, within a company, industry or regulatory authority, etc. The included information might relate to the existence, nature, form, probability, severity, acceptability, control, treatment, detectability, or other aspects of risks to quality. Communication need not be carried out for each and every risk acceptance. Between the industry and regulatory authorities, communication concerning quality risk management decisions might be effected through existing channels as specified in regulations and guidances.

F. Risk Review

Risk management should be an ongoing part of the quality management process. A mechanism to review or monitor events should be implemented.

The output/results of the risk management process should be reviewed to take into account new knowledge and experience. Once a quality risk management process has been initiated, that process should continue to be used for events that might impact the original quality risk management decision, whether these events are planned (e.g., results of product review, inspections, audits, change control) or unplanned (e.g., root cause from failure investigations, recall). The frequency of any review should be based upon the level of risk. Risk review might include reconsideration of risk acceptance decisions (Section D).

V. RISK MANAGEMENT METHODOLOGY

Quality risk management supports a scientific and practical approach to decision making. It provides documented, transparent, and reproducible methods to accomplish steps of the quality risk management process based on current knowledge about assessing the probability, severity, and sometimes detectability of the risk.

Traditionally, risks to quality have been assessed and managed in a variety of informal ways (empirical and/or internal procedures) based on, for example, compilation of observations, trends, and other information. Such approaches continue to provide useful information that might support topics such as handling of complaints, quality defects, deviations, and allocation of resources.

Additionally, the pharmaceutical industry and regulators can assess and manage risk using recognized risk management tools and/or internal procedures (e.g., standard operating procedures). Below is a non-exhaustive list of some of these tools (further details in Annex I and Chapter 8):

- Basic risk management facilitation methods (flowcharts, check sheets, etc.)
- Failure Mode Effects Analysis (FMEA)
- Failure Mode, Effects, and Criticality Analysis (FMECA)
- Fault Tree Analysis (FTA)
- Hazard Analysis and Critical Control Points (HACCP)
- Hazard Operability Analysis (HAZOP)
- Preliminary Hazard Analysis (PHA)
- Risk ranking and filtering
- Supporting statistical tools

It might be appropriate to adapt these tools for use in specific areas pertaining to drug substance and drug (medicinal) product quality. Quality risk management methods and the supporting statistical tools can be used in combination (e.g., Probabilistic Risk Assessment). Combined use provides flexibility that can facilitate the application of quality risk management principles.

The degree of rigor and formality of quality risk management should reflect available knowledge and be commensurate with the complexity and/or criticality of the issue to be addressed.

VI. INTEGRATION OF QUALITY RISK MANAGEMENT INTO INDUSTRY AND REGULATORY OPERATIONS

Quality risk management is a process that supports science-based and practical decisions when integrated into quality systems (see Annex II). As outlined in the introduction, appropriate use of quality risk management does not obviate industry's obligation to comply with regulatory requirements. However, effective quality risk management can facilitate better and more informed decisions, can provide regulators with greater assurance of a company's ability to deal with potential risks, and might affect the extent and level of direct regulatory oversight. In addition, quality risk management can facilitate better use of resources by all parties.

Training of both industry and regulatory personnel in quality risk management processes provides for greater understanding of decision-making processes and builds confidence in quality risk management outcomes.

Quality risk management should be integrated into existing operations and documented appropriately. Annex II provides examples of situations in which the use of the quality risk management process might provide information that could then be used in a variety of pharmaceutical operations. These examples are provided for illustrative purposes only and should not be considered a definitive or exhaustive list. These examples are not intended to create any new expectations beyond the requirements laid out in the current regulations.

Examples for industry and regulatory operations (see Annex II):

- Quality management

  Examples for industry operations and activities (see Annex II):
- Development
- Facility, equipment, and utilities
- Materials management
- Production
- Laboratory control and stability testing
- Packaging and labeling

  Examples for regulatory operations (see Annex II):
- Inspection and assessment activities

While regulatory decisions will continue to be taken on a regional basis, a common understanding and application of quality risk management principles could facilitate mutual confidence and promote more consistent decisions among regulators on the basis of the same information. This collaboration could be important in the development of policies and guidelines that integrate and support quality risk management practices.

GLOSSARY

Decision Maker(s): Person(s) with the competence and authority to make appropriate and timely quality risk management decisions.

Detectability: The ability to discover or determine the existence, presence, or fact of a hazard.

Harm: Damage to health, including the damage that can occur from loss of product quality or availability.

Hazard: The potential source of harm (ISO/IEC Guide 51).

Product Lifecycle: All phases in the life of the product from the initial development through marketing until the product's discontinuation.

Quality: The degree to which a set of inherent properties of a product, system, or process fulfills requirements [see ICH Q6A definition specifically for "quality" of drug substance and drug (medicinal) products].

Quality Risk Management: A systematic process for the assessment, control, communication, and review of risks to the quality of the drug (medicinal) product across the product lifecycle.

Quality System: The sum of all aspects of a system that implements quality policy and ensures that quality objectives are met.

Requirements: The explicit or implicit needs or expectations of the patients or their surrogates (e.g., healthcare professionals, regulators, and legislators). In this document, "requirements" refers not only to statutory, legislative, or regulatory requirements but also to such needs and expectations.

Risk: The combination of the probability of occurrence of harm and the severity of that harm (ISO/IEC Guide 51).

Risk Acceptance: The decision to accept risk (ISO Guide 73).

Risk Analysis: The estimation of the risk associated with the identified hazards.

Risk Assessment: A systematic process of organizing information to support a risk decision to be made

within a risk management process. It consists of the identification of hazards and the analysis and evaluation of risks associated with exposure to those hazards.

Risk Communication: The sharing of information about risk and risk management between the decision maker and other stakeholders.

Risk Control: Actions implementing risk management decisions (ISO Guide 73).

Risk Evaluation: The comparison of the estimated risk to given risk criteria using a quantitative or qualitative scale to determine the significance of the risk.

Risk Identification: The systematic use of information to identify potential sources of harm (hazards) referring to the risk question or problem description.

Risk Management: The systematic application of quality management policies, procedures, and practices to the tasks of assessing, controlling, communicating, and reviewing risk.

Risk Reduction: Actions taken to lessen the probability of occurrence of harm and the severity of that harm.

Risk Review: Review or monitoring of output/results of the risk management process considering (if appropriate) new knowledge and experience about the risk.

Severity: A measure of the possible consequences of a hazard.

Stakeholder: Any individual, group, or organization that can affect, be affected by, or perceive itself to be affected by a risk. Decision makers might also be stakeholders. For the purposes of this guideline, the primary stakeholders are the patient, healthcare professional, regulatory authority, and industry.

Trend: A statistical term referring to the direction or rate of change of a variable(s).

ANNEX I: RISK MANAGEMENT METHODS AND TOOLS

The purpose of this annex is to provide a general overview of and references for some of the primary tools that might be used in quality risk management by industry and regulators. The references are included as an aid to gain more knowledge and detail about the particular tool. This is not an exhaustive list. It is important to note that no one tool or set of tools is applicable to every situation in which a quality risk management procedure is used.

I.1 Basic Risk Management Facilitation Methods

Some of the simple techniques that are commonly used to structure risk management by organizing data and facilitating decision making are as follows:

- Flowcharts
- Check Sheets
- Process Mapping
- Cause and Effect Diagrams (also called an Ishikawa diagram or fish bone diagram)

I.2 Failure Mode Effects Analysis

FMEA (see IEC 60812) provides for an evaluation of potential failure modes for processes and their likely effect on outcomes and/or product performance. Once failure modes are established, risk reduction can be used to eliminate, contain, reduce, or control the potential failures. FMEA relies on product and process understanding. FMEA methodically breaks down the analysis of complex processes into manageable steps. It is a powerful tool for summarizing the important modes of failure, factors causing these failures, and the likely effects of these failures.

Potential Areas of Use(s)

FMEA can be used to prioritize risks and monitor the effectiveness of risk control activities.

FMEA can be applied to equipment and facilities and might be used to analyze a manufacturing operation and its effect on product or process. It identifies elements/operations within the system that render it vulnerable. The output/results of FMEA can be used as a basis for design or further analysis or to guide resource deployment.

I.3 Failure Mode, Effects, and Criticality Analysis

FMEA might be extended to incorporate an investigation of the degree of severity of the consequences, their respective probabilities of occurrence, and their detectability, thereby becoming a Failure Mode Effect and Criticality Analysis (FMECA; see IEC 60812). In order for such an analysis to be performed, the product or process specifications should be established. FMECA can identify places where additional preventive actions might be appropriate to minimize risks.

Potential Areas of Use(s)

FMECA application in the pharmaceutical industry should mostly be used for failures and risks associated with manufacturing processes; however, it is not limited to this application. The output of an FMECA is a relative risk "score" for each failure mode, which is used to rank the modes on a relative risk basis.

I.4 Fault Tree Analysis

The FTA tool (see IEC 61025) is an approach that assumes failure of the functionality of a product or process. This tool evaluates system (or subsystem) failures one at a time but can combine multiple causes of failure by identifying causal chains. The results are represented pictorially in the form of a tree of fault modes. At each level in the tree, combinations of fault modes are described with logical operators (AND, OR, etc.). FTA relies on the experts' process understanding to identify causal factors.

Potential Areas of Use(s)

FTA can be used to establish the pathway to the root cause of the failure. FTA can be used to investigate complaints or deviations in order to fully understand their root cause and to

ensure that intended improvements will fully resolve the issue and not lead to other issues (i.e., solve one problem yet cause a different problem). FTA is an effective tool for evaluating how multiple factors affect a given issue. The output of an FTA includes a visual representation of failure modes. It is useful both for risk assessment and in developing monitoring programs.

I.5 Hazard Analysis and Critical Control Points

HACCP is a systematic, proactive, and preventive tool for assuring product quality, reliability, and safety (see WHO Technical Report Series No 908, 2003, Annex 7). It is a structured approach that applies technical and scientific principles to analyze, evaluate, prevent, and control the risk or adverse consequence(s) of hazard(s) due to the design, development, production, and use of products.

HACCP consists of the following seven steps:

(1) Conduct a hazard analysis, and identify preventive measures for each step of the process.
(2) Determine the critical control points.
(3) Establish critical limits.
(4) Establish a system to monitor the critical control points.
(5) Establish the corrective action to be taken when monitoring indicates that the critical control points are not in a state of control.
(6) Establish system to verify that the HACCP system is working effectively.
(7) Establish a record-keeping system.

Potential Areas of Use(s)

HACCP might be used to identify and manage risks associated with physical, chemical, and biological hazards (including microbiological contamination). HACCP is most useful when product and process understanding is sufficiently comprehensive to support identification of critical control points. The output of a HACCP analysis is risk management information that facilitates monitoring of critical points not only in the manufacturing process but also in other lifecycle phases.

I.6 Hazard Operability Analysis

HAZOP (see IEC 61882) is based on a theory that assumes that risk events are caused by deviations from the design or operating intentions. It is a systematic brainstorming technique for identifying hazards using so-called "guide-words." "Guide-words" (e.g., No, More, Other Than, Part of, etc.) are applied to relevant parameters (e.g., contamination, temperature) to help identify potential deviations from normal use or design intentions. It often uses a team of people with expertise covering the design of the process or product and its application.

Potential Areas of Use(s)

HAZOP can be applied to manufacturing processes, including outsourced production and formulation as well as the upstream suppliers, equipment, and facilities for drug substances and drug (medicinal) products. It has also been used primarily in the pharmaceutical industry for evaluating process safety hazards. As is the case with HACCP, the output of a HAZOP analysis is a list of critical operations for risk management. This facilitates regular monitoring of critical points in the manufacturing process.

I.7 Preliminary Hazard Analysis

PHA is a tool of analysis based on applying prior experience or knowledge of a hazard or failure to identify future hazards, hazardous situations, and events that might cause harm, as well as to estimate their probability of occurrence for a given activity, facility, product, or system. The tool consists of (1) the identification of the possibilities that the risk event happens, (2) the qualitative evaluation of the extent of possible injury or damage to health that could result, (3) a relative ranking of the hazard using a combination of severity and likelihood of occurrence, and (4) the identification of possible remedial measures.

Potential Areas of Use(s)

PHA might be useful when analyzing existing systems or prioritizing hazards where circumstances prevent a more extensive technique from being used. It can be used for product, process, and facility design as well as to evaluate the types of hazards for the general product type, then the product class, and finally the specific product. PHA is most commonly used early in the development of a project when there is little information on design details or operating procedures; thus, it will often be a precursor to further studies. Typically, hazards identified in the PHA are further assessed with other risk management tools such as those in this section.

I.8 Risk Ranking and Filtering

Risk ranking and filtering is a tool for comparing and ranking risks. Risk ranking of complex systems typically requires evaluation of multiple diverse quantitative and qualitative factors for each risk. The tool involves breaking down a basic risk question into as many components as needed to capture factors involved in the risk. These factors are combined into a single relative risk score that can then be used for ranking risks. "Filters," in the form of weighting factors or cut-offs for risk scores, can be used to scale or fit the risk ranking to management or policy objectives.

Potential Areas of Use(s)

Risk ranking and filtering can be used to prioritize manufacturing sites for inspection/audit by regulators or industry. Risk ranking methods are particularly helpful in situations in which the portfolio of risks and the underlying consequences to be managed are diverse and difficult to compare using a single tool. Risk ranking is useful when management needs to evaluate both quantitatively assessed and qualitatively assessed risks within the same organizational framework.

I.9 Supporting Statistical Tools

Statistical tools can support and facilitate quality risk management. They can enable effective data assessment, aid in determining the significance of the data set(s), and facilitate more reliable decision making. A listing of some of the principal statistical tools commonly used in the pharmaceutical industry is provided below:

- Control Charts, for example
  - Acceptance Control Charts (see ISO 7966)
  - Control Charts with Arithmetic Average and Warning Limits (see ISO 7873)
  - Cumulative Sum Charts (see ISO 7871)
  - Shewhart Control Charts (see ISO 8258)
  - Weighted Moving Average
- Design of Experiments
- Histograms
- Pareto Charts
- Process Capability Analysis

ANNEX II: POTENTIAL APPLICATIONS FOR QUALITY RISK MANAGEMENT

This annex is intended to identify potential uses of quality risk management principles and tools by industry and regulators. However, the selection of particular risk management tools is completely dependent upon specific facts and circumstances.

These examples are provided for illustrative purposes and only suggest potential uses of quality risk management. This annex is not intended to create any new expectations beyond the current regulatory requirements.

II.1 Quality Risk Management as Part of Integrated Quality Management

Documentation

To review current interpretations and application of regulatory expectations.

To determine the desirability of and/or develop the content for SOPs, guidelines, etc.

Training and Education

To determine the appropriateness of initial and/or ongoing training sessions based on education, experience, and working habits of staff, as well as on a periodic assessment of previous training (e.g., its effectiveness).

To identify the training, experience, qualifications, and physical abilities that allow personnel to perform an operation reliably and with no adverse impact on the quality of the product.

Quality Defects

To provide the basis for identifying, evaluating, and communicating the potential quality impact of a suspected quality defect, complaint, trend, deviation, investigation, out of specification result, etc.

To facilitate risk communications and determine appropriate action to address significant product defects, in conjunction with regulatory authorities (e.g., recall).

Auditing/Inspection

To define the frequency and scope of audits, both internal and external, taking into account factors such as

- Existing legal requirements
- Overall compliance status and history of the company or facility
- Robustness of a company's quality risk management activities
- Complexity of the site
- Complexity of the manufacturing process
- Complexity of the product and its therapeutic significance
- Number and significance of quality defects (e.g., recall)
- Results of previous audits/inspections
- Major changes of building, equipment, processes, key personnel
- Experience with manufacturing of a product (e.g., frequency, volume, number of batches)
- Test results of official control laboratories

Periodic Review

To select, evaluate, and interpret trend results of data within the product quality review.

To interpret monitoring data (e.g., to support an assessment of the appropriateness of revalidation or changes in sampling).

Change Management/Change Control

To manage changes based on knowledge and information accumulated in pharmaceutical development and during manufacturing.

To evaluate the impact of the changes on the availability of the final product.

To evaluate the impact on product quality of changes to the facility, equipment, material, manufacturing process, or technical transfers.

To determine appropriate actions preceding the implementation of a change, for example, additional testing, (re)qualification, (re)validation, or communication with regulators.

Continual Improvement

To facilitate continual improvement in processes throughout the product lifecycle.

II.2 Quality Risk Management as Part of Regulatory Operations

Inspection and Assessment Activities

To assist with resource allocation including, for example, inspection planning and frequency, and inspection and assessment intensity (see "Auditing" section in Annex II.1).

To evaluate the significance of, for example, quality defects, potential recalls, and inspectional findings.

To determine the appropriateness and type of post-inspection regulatory follow-up.

To evaluate information submitted by industry including pharmaceutical development information.

To evaluate impact of proposed variations or changes.

To identify risks which should be communicated between inspectors and assessors to facilitate better understanding of how risks can be or are controlled [e.g., parametric release, Process Analytical Technology (PAT)].

II.3 Quality Risk Management as Part of Development

To design a quality product and its manufacturing process to consistently deliver the intended performance of the product (see ICH Q8).

To enhance knowledge of product performance over a wide range of material attributes (e.g., particle size distribution, moisture content, flow properties), processing options, and process parameters.

To assess the critical attributes of raw materials, solvents, active pharmaceutical ingredient (API) starting materials, APIs, excipients, or packaging materials.

To establish appropriate specifications, identify critical process parameters, and establish manufacturing controls (e.g., using information from pharmaceutical development studies regarding the clinical significance of quality attributes and the ability to control them during processing).

To decrease variability of quality attributes:

- Reduce product and material defects and
- Reduce manufacturing defects

To assess the need for additional studies (e.g., bioequivalence, stability) relating to scale up and technology transfer.

To make use of the "design space" concept (see ICH Q8).

II.4 Quality Risk Management for Facilities, Equipment, and Utilities

Design of Facility/Equipment

To determine appropriate zones when designing buildings and facilities, for example,

- Flow of material and personnel
- Minimize contamination
- Pest control measures
- Prevention of mix-ups
- Open vs. closed equipment
- Clean rooms vs. isolator technologies
- Dedicated or segregated facilities/equipment

To determine appropriate product contact materials for equipment and containers (e.g., selection of stainless-steel grade, gaskets, lubricants).

To determine appropriate utilities [e.g., steam, gases, power source, compressed air, HVAC (heating, ventilation, and air conditioning), water].

To determine appropriate preventive maintenance for associated equipment (e.g., inventory of necessary spare parts).

Hygiene Aspects in Facilities

To protect the product from environmental hazards, including chemical, microbiological, and physical hazards (e.g., determining appropriate clothing and gowning, hygiene concerns).

To protect the environment (e.g., personnel, potential for cross-contamination) from hazards related to the product being manufactured.

Qualification of Facility/Equipment/Utilities

To determine the scope and extent of qualification of facilities, buildings, and production equipment and/or laboratory instruments (including proper calibration methods).

Cleaning of Equipment and Environmental Control

To differentiate efforts and decisions based on the intended use (e.g., multi- vs. single-purpose, batch vs. continuous production).

To determine acceptable (specified) cleaning validation limits.

Calibration/Preventive Maintenance

To set appropriate calibration and maintenance schedules.

Computer Systems and Computer-Controlled Equipment

To select the design of computer hardware and software (e.g., modular, structured, fault tolerance).

To determine the extent of validation, for example,

- Identification of critical performance parameters
- Selection of the requirements and design
- Code review
- The extent of testing and test methods and
- Reliability of electronic records and signatures

II.5. Quality Risk Management as Part of Materials Management

Assessment and Evaluation of Suppliers and Contract Manufacturers

To provide a comprehensive evaluation of suppliers and contract manufacturers (e.g., auditing, supplier quality agreements).

Starting Material

To assess differences and possible quality risks associated with variability in starting materials (e.g., age, route of synthesis).

Use of Materials

To determine whether it is appropriate to use material under quarantine (e.g., for further internal processing).

To determine appropriateness of reprocessing, reworking, use of returned goods.

Storage, Logistics, and Distribution Conditions

To assess the adequacy of arrangements to ensure maintenance of appropriate storage and transport conditions (e.g., temperature, humidity, container design).

To determine the effect on product quality of discrepancies in storage or transport conditions (e.g., cold chain management) in conjunction with other ICH guidelines.

To maintain infrastructure (e.g., capacity to ensure proper shipping conditions, interim storage, handling of hazardous materials and controlled substances, customs clearance).

To provide information for ensuring the availability of pharmaceuticals (e.g., ranking risks to the supply chain).

II.6. Quality Risk Management as Part of Production

Validation

To identify the scope and extent of verification, qualification, and validation activities (e.g., analytical methods, processes, equipment, and cleaning methods).

To determine the extent for follow-up activities (e.g., sampling, monitoring, and revalidation).

To distinguish between critical and noncritical process steps to facilitate design of a validation study.

In-Process Sampling and Testing

To evaluate the frequency and extent of in-process control testing (e.g., to justify reduced testing under conditions of proven control).

To evaluate and justify the use of PAT in conjunction with parametric and real-time release.

Production Planning

To determine appropriate production planning (e.g., dedicated, campaign, and concurrent production process sequences).

II.7. Quality Risk Management as Part of Laboratory Control and Stability Studies

Out of Specification Results

To identify potential root causes and corrective actions during the investigation of out of specification results.

Retest Period/Expiration Date

To evaluate adequacy of storage and testing of intermediates, excipients, and starting materials.

II.8. Quality Risk Management as Part of Packaging and Labeling

Design of Packages

To design the secondary package for the protection of primary packaged product (e.g., to ensure product authenticity, label legibility).

Selection of Container Closure System

To determine the critical parameters of the container closure system.

Label Controls

To design label control procedures based on the potential for mix-ups involving different product labels, including different versions of the same label.

3 Pharmaceutical Quality System

I. PHARMACEUTICAL QUALITY SYSTEM

A. Introduction

This document establishes a new ICH tripartite guideline describing a model for an effective *quality* management system for the pharmaceutical industry, referred to as the *Pharmaceutical Quality System*. Throughout this guideline, the term "pharmaceutical quality system" refers to the ICH Q10 model.

ICH Q10 describes one comprehensive model for an effective pharmaceutical quality system that is based on International Standards Organization (ISO) quality concepts, includes applicable Good Manufacturing Practice (GMP) regulations, and complements ICH Q8 "Pharmaceutical Development" and ICH Q9 "Quality Risk Management." ICH Q10 is a model for a pharmaceutical quality system that can be implemented throughout the different stages of a product lifecycle. Much of the content of ICH Q10 applicable to manufacturing sites is currently specified by regional GMP requirements. ICH Q10 is not intended to create any new expectations beyond current regulatory requirements. Consequently, the content of ICH Q10 that is additional to current regional GMP requirements is optional.

ICH Q10 demonstrates industry and regulatory authorities' support of an effective pharmaceutical quality system to enhance the quality and availability of medicines around the world in the interest of public health. Implementation of ICH Q10 throughout the product lifecycle should facilitate *innovation* and *continual improvement* and strengthen the link between pharmaceutical development and manufacturing activities.

B. Scope

This guideline applies to the systems supporting the development and manufacture of pharmaceutical drug substances (i.e., API) and drug products, including biotechnology and biological products, throughout the product lifecycle.

The elements of ICH Q10 should be applied in a manner that is appropriate and proportionate to each of the product lifecycle stages, recognizing the differences among and the different goals of each stage (see Section 3).

For the purposes of this guideline, the product lifecycle includes the following technical activities for new and existing products:

- Pharmaceutical development:
  - Drug substance development
  - Formulation development (including container/closure system)
  - Manufacture of investigational products
  - Delivery system development (where relevant)
  - Manufacturing process development and scale-up
  - Analytical method development
- Technology transfer:
  - New product transfers during development through manufacturing
  - Transfers within or between manufacturing and testing sites for marketed products
- Commercial manufacturing:
  - Acquisition and control of materials
  - Provision of facilities, utilities, and equipment
  - Production (including packaging and labeling)
  - Quality control and assurance
  - Release
  - Storage
  - Distribution (excluding wholesaler activities)
- Product discontinuation:
  - Retention of documentation
  - Sample retention
  - Continued product assessment and reporting

C. Relationship of ICH Q10 to Regional GMP Requirements, ISO Standards, and ICH Q7

Regional GMP requirements, the ICH Q7 Guideline, "Good Manufacturing Practice Guide for Active Pharmaceutical Ingredients," and ISO quality management system guidelines form the foundation for ICH Q10. To meet the objectives described below, ICH Q10 augments GMPs by describing specific quality system elements and management responsibilities. ICH Q10 provides a harmonized model for a pharmaceutical quality system throughout the lifecycle of a product and is intended to be used together with regional GMP requirements.

The regional GMPs do not explicitly address all stages of the product lifecycle (e.g., development). The quality system elements and management responsibilities described in this guideline are intended to encourage the use of science- and risk-based approaches at each lifecycle stage, thereby promoting continual improvement across the entire product lifecycle.

D. Relationship of ICH Q10 to Regulatory Approaches

Regulatory approaches for a specific product or manufacturing facility should be commensurate with the level of product and process understanding, the results of *quality risk management*, and the effectiveness of the pharmaceutical quality system. When implemented, the effectiveness of the

pharmaceutical quality system can normally be evaluated during a regulatory inspection at the manufacturing site. Potential opportunities to enhance science- and risk-based regulatory approaches are identified in Annex 1. Regulatory processes will be determined by region.

E. ICH Q10 Objectives

Implementation of the Q10 model should result in achievement of three main objectives, which complement or enhance regional GMP requirements.

1. Achieve Product Realization

To establish, implement, and maintain a system that allows the delivery of products with the quality attributes appropriate to meet the needs of patients, health care professionals, regulatory authorities (including compliance with approved regulatory filings), and other internal and external customers.

2. Establish and Maintain a State of Control

To develop and use effective monitoring and control systems for process performance and product quality, thereby providing assurance of continued suitability and *capability of processes*. Quality risk management can be useful in identifying the monitoring and control systems.

3. Facilitate Continual Improvement

To identify and implement appropriate product quality improvements, process improvements, variability reduction, innovations, and pharmaceutical quality system enhancements, thereby increasing the ability to fulfil quality needs consistently. Quality risk management can be useful for identifying and prioritizing areas for continual improvement.

F. Enablers: Knowledge Management and Quality Risk Management

Use of *knowledge management* and quality risk management will enable a company to implement ICH Q10 effectively and successfully. These enablers will facilitate achievement of the objectives described in section IE above by providing the means for science- and risk-based decisions related to product quality.

1. Knowledge Management

Product and process knowledge should be managed from development through the commercial life of the product up to and including product discontinuation. For example, development activities using scientific approaches provide knowledge for product and process understanding. Knowledge management is a systematic approach to acquiring, analyzing, storing, and disseminating information related to products, manufacturing processes, and components. Sources of knowledge include, but are not limited to, prior knowledge (public domain or internally documented), pharmaceutical development studies, technology transfer activities, process validation studies over the product lifecycle, manufacturing experience, innovation, continual improvement, and *change management* activities.

2. Quality Risk Management

Quality risk management is integral to an effective pharmaceutical quality system. It can provide a proactive approach to identifying, scientifically evaluating, and controlling potential risks to quality. It facilitates continual improvement of process performance and product quality throughout the product lifecycle. ICH Q9 provides principles and examples of tools for quality risk management that can be applied to different aspects of pharmaceutical quality.

G. Design and Content Considerations

(a) The design, organization, and documentation of the pharmaceutical quality system should be well structured and clear to facilitate common understanding and consistent application.

(b) The elements of ICH Q10 should be applied in a manner that is appropriate and proportionate to each of the product lifecycle stages, recognizing the different goals and knowledge available for each stage.

(c) The size and complexity of the company's activities should be taken into consideration when developing a new pharmaceutical quality system or modifying an existing one. The design of the pharmaceutical quality system should incorporate appropriate risk management principles. While some aspects of the pharmaceutical quality system can be company-wide and others site-specific, the effectiveness of the pharmaceutical quality system is normally demonstrated at the site level.

(d) The pharmaceutical quality system should include appropriate processes, resources, and responsibilities to provide assurance of the quality of *outsourced activities* and purchased materials.

(e) Management responsibilities, as described in Section 2, should be identified within the pharmaceutical quality system.

(f) The pharmaceutical quality system should include the following elements, as described in Section 3: Process performance and product quality monitoring, *corrective* and *preventive action*, change management, and management review.

(g) *Performance indicators*, as described in Section 4, should be identified and used to monitor the effectiveness of processes within the pharmaceutical quality system.

H. Quality Manual

A *Quality Manual* or equivalent documentation approach should be established and should contain the description of the pharmaceutical quality system. The description should include

(a) The *quality policy* (see Section 2).
(b) The scope of the pharmaceutical quality system.
(c) Identification of the pharmaceutical quality system processes, as well as their sequences, linkages, and interdependencies. Process maps and flow charts can be useful tools to facilitate depicting pharmaceutical quality system processes in a visual manner.
(d) Management responsibilities within the pharmaceutical quality system (see Section 2).

II. MANAGEMENT RESPONSIBILITY

Leadership is essential to establish and maintain a company-wide commitment to quality and for the performance of the pharmaceutical quality system.

A. Management Commitment

(a) *Senior management* has the ultimate responsibility to ensure an effective pharmaceutical quality system is in place to achieve the *quality objectives* and that roles, responsibilities, and authorities are defined, communicated, and implemented throughout the company.
(b) Management should
    (1) Participate in the design, implementation, monitoring, and maintenance of an effective pharmaceutical quality system.
    (2) Demonstrate strong and visible support for the pharmaceutical quality system and ensure its implementation throughout their organization.
    (3) Ensure a timely and effective communication and escalation process exists to raise quality issues to the appropriate levels of management.
    (4) Define individual and collective roles, responsibilities, authorities, and interrelationships of all organizational units related to the pharmaceutical quality system. Ensure these interactions are communicated and understood at all levels of the organization. An independent quality unit/structure with authority to fulfil certain pharmaceutical quality system responsibilities is required by regional regulations.
    (5) Conduct management reviews of process performance and product quality and of the pharmaceutical quality system.
    (6) Advocate continual improvement.
    (7) Commit appropriate resources.

B. Quality Policy

(a) Senior management should establish a quality policy that describes the overall intentions and direction of the company related to quality.
(b) The quality policy should include an expectation to comply with applicable regulatory requirements and should facilitate continual improvement of the pharmaceutical quality system.
(c) The quality policy should be communicated to and understood by personnel at all levels in the company.
(d) The quality policy should be reviewed periodically for continuing effectiveness.

C. Quality Planning

(a) Senior management should ensure the quality objectives needed to implement the quality policy are defined and communicated.
(b) Quality objectives should be supported by all relevant levels of the company.
(c) Quality objectives should align with the company's strategies and be consistent with the quality policy.
(d) Management should provide the appropriate resources and training to achieve the quality objectives.
(e) Performance indicators that measure progress against quality objectives should be established, monitored, communicated regularly, and acted upon as appropriate as described in Section 4.1 of this document.

D. Resource Management

(a) Management should determine and provide adequate and appropriate resources (human, financial, materials, facilities, and equipment) to implement and maintain the pharmaceutical quality system and continually improve its effectiveness.
(b) Management should ensure that resources are appropriately applied to a specific product, process, or site.

E. Internal Communication

(a) Management should ensure appropriate communication processes are established and implemented within the organization.
(b) Communications processes should ensure the flow of appropriate information between all levels of the company.
(c) Communication processes should ensure the appropriate and timely escalation of certain product quality and pharmaceutical quality system issues.

F. Management Review

(a) Senior management should be responsible for pharmaceutical quality system governance through management review to ensure its continuing suitability and effectiveness.
(b) Management should assess the conclusions of periodic reviews of process performance and product quality and of the pharmaceutical quality system, as described in Sections 3 and 4.

G. Management of Outsourced Activities and Purchased Materials

The pharmaceutical quality system, including the management responsibilities described in this section, extends to the control and review of any outsourced activities and quality of purchased materials. The pharmaceutical company is ultimately responsible to ensure processes are in place to assure the control of outsourced activities and quality of purchased materials. These processes should incorporate quality risk management and include

(a) Assessing, prior to outsourcing operations or selecting material suppliers, the suitability and competence of the other party to carry out the activity or provide the material using a defined supply chain (e.g., audits, material evaluations, qualification).
(b) Defining the responsibilities and communication processes for quality-related activities of the involved parties. For outsourced activities, this should be included in a written agreement between the contract giver and contract acceptor.
(c) Monitoring and review of the performance of the contract acceptor or the quality of the material from the provider and the identification and implementation of any needed improvements.
(d) Monitoring incoming ingredients and materials to ensure they are from approved sources using the agreed supply chain.

H. Management of Change in Product Ownership

When product ownership changes (e.g., through acquisitions), management should consider the complexity of this and ensure:

(a) The ongoing responsibilities are defined for each company involved.
(b) The necessary information is transferred.

III. CONTINUAL IMPROVEMENT OF PROCESS PERFORMANCE AND PRODUCT QUALITY

This section describes the lifecycle stage goals and the four specific pharmaceutical quality system elements that augment regional requirements to achieve the ICH Q10 objectives, as defined in section IE. It does not restate all regional GMP requirements.

A. Lifecycle Stage Goals

The goals of each product lifecycle stage are described below.

1. Pharmaceutical Development

The goal of pharmaceutical development activities is to design a product and its manufacturing process to consistently deliver the intended performance and meet the needs of patients and health care professionals, and regulatory authorities' and internal customers' requirements. Approaches to pharmaceutical development are described in ICH Q8. The results of exploratory and clinical development studies, while outside the scope of this guidance, are inputs to pharmaceutical development.

2. Technology Transfer

The goal of technology transfer activities is to transfer product and process knowledge between development and manufacturing and within or between manufacturing sites to achieve product realization. This knowledge forms the basis for the manufacturing process, *control strategy*, process validation approach, and ongoing continual improvement.

3. Commercial Manufacturing

The goals of manufacturing activities include achieving product realization, establishing and maintaining a state of control, and facilitating continual improvement. The pharmaceutical quality system should assure that the desired product quality is routinely met, suitable process performance is achieved, the set of controls is appropriate, improvement opportunities are identified and evaluated, and the body of knowledge is continually expanded.

4. Product Discontinuation

The goal of product discontinuation activities is to manage the terminal stage of the product lifecycle effectively. For product discontinuation, a predefined approach should be used to manage activities such as retention of documentation and samples and continued product assessment (e.g., complaint handling and stability) and reporting in accordance with regulatory requirements.

B. Pharmaceutical Quality System Elements

The elements described below might be required in part under regional GMP regulations. However, the Q10 model's intent is to enhance these elements in order to promote the lifecycle approach to product quality. These four elements are:

- Process performance and product quality monitoring system
- Corrective action *and* preventive action *(CAPA) system*
- Change management system
- Management review of process performance and product quality

These elements should be applied in a manner that is appropriate and proportionate to each of the product lifecycle stages, recognizing the differences among, and the different goals of, each stage. Throughout the product lifecycle, companies are encouraged to evaluate opportunities for innovative approaches to improve product quality.

Each element is followed by a table of example applications of the element to the stages of the pharmaceutical lifecycle.

1. Process Performance and Product Quality Monitoring System

Pharmaceutical companies should plan and execute a system for the monitoring of process performance and product quality to ensure a state of control is maintained. An effective monitoring system provides assurance of the continued capability of processes and controls to produce a product of desired quality and to identify areas for continual improvement. The process performance and product quality monitoring system should (Table 3.1):

(a) Use quality risk management to establish the control strategy. This can include parameters and attributes related to drug substance and drug product materials and components, facility and equipment operating conditions, in-process controls, finished product specifications, and the associated methods and frequency of monitoring and control. The control strategy should facilitate timely *feedback/feedforward* and appropriate corrective action and preventive action.
(b) Provide the tools for measurement and analysis of parameters and attributes identified in the control strategy (e.g., data management and statistical tools).
(c) Analyze parameters and attributes identified in the control strategy to verify continued operation within a state of control.
(d) Identify sources of variation affecting process performance and product quality for potential continual improvement activities to reduce or control variation.
(e) Include feedback on product quality from both internal and external sources, for example, complaints, product rejections, nonconformances, recalls, deviations, audits and regulatory inspections, and findings.
(f) Provide knowledge to enhance process understanding, enrich the *design space* (where established), and enable innovative approaches to process validation.

2. Corrective Action and Preventive Action System

The pharmaceutical company should have a system for implementing corrective actions and preventive actions resulting from the investigation of complaints, product rejections, nonconformances, recalls, deviations, audits, regulatory inspections and findings, and trends from process performance, and product quality monitoring. A structured approach to the investigation process should be used with the objective of determining the root cause. The level of effort, formality, and documentation of the investigation should be commensurate with the level of risk, in line with ICH Q9. CAPA methodology should result in product and process improvements and enhanced product and process understanding (Table 3.2).

3. Change Management System

Innovation, continual improvement, the outputs of process performance, and product quality monitoring and CAPA drive change. In order to evaluate, approve, and implement these changes properly, a company should have an effective change management system. There is generally a difference in formality of change management processes prior to the initial regulatory submission and after submission, where changes to the regulatory filing might be required under regional requirements (Table 3.3).

The change management system ensures continual improvement is undertaken in a timely and effective manner.

TABLE 3.1
Application of Process Performance and Product Quality Monitoring System throughout the Product Lifecycle

Pharmaceutical Development	Technology Transfer	Commercial Manufacturing	Product Discontinuation
Process and product knowledge generated and process and product monitoring conducted throughout development can be used to establish a control strategy for manufacturing.	Monitoring during scale-up activities can provide a preliminary indication of process performance and the successful integration into manufacturing. Knowledge obtained during transfer and scale-up activities can be useful in further developing the control strategy.	A well-defined system for process performance and product quality monitoring should be applied to assure performance within a state of control and to identify improvement areas.	Once manufacturing ceases, monitoring such as stability testing should continue to completion of the studies. Appropriate action on marketed product should continue to be executed according to regional regulations.

TABLE 3.2
Application of Corrective Action and Preventive Action System throughout the Product Lifecycle

Pharmaceutical Development	Technology Transfer	Commercial Manufacturing	Product Discontinuation
Product or process variability is explored. CAPA methodology is useful where corrective actions and preventive actions are incorporated into the iterative design and development process.	CAPA can be used as an effective system for feedback, feedforward, and continual improvement.	CAPA should be used, and the effectiveness of the actions should be evaluated.	CAPA should continue after the product is discontinued. The impact on product remaining on the market should be considered as well as other products, which might be impacted.

TABLE 3.3
Application of Change Management System throughout the Product Lifecycle

Pharmaceutical Development	Technology Transfer	Commercial Manufacturing	Product Discontinuation
Change is an inherent part of the development process and should be documented; the formality of the change management process should be consistent with the stage of pharmaceutical development.	The change management system should provide management and documentation of adjustments made to the process during technology transfer activities.	A formal change management system should be in place for commercial manufacturing. Oversight by the quality unit should provide assurance of appropriate science- and risk-based assessments.	Any changes after product discontinuation should go through an appropriate change management system.

It should provide a high degree of assurance that there are no unintended consequences of the change.

The change management system should include the following, as appropriate for the stage of the lifecycle:

(a) Quality risk management should be utilized to evaluate proposed changes. The level of effort and formality of the evaluation should be commensurate with the level of risk.
(b) Proposed changes should be evaluated relative to the marketing authorization, including design space, where established, and/or current product and process understanding. There should be an assessment to determine whether a change to the regulatory filing is required under regional requirements. As stated in ICH Q8, working within the design space is not considered a change (from a regulatory filing perspective). However, from a pharmaceutical quality system standpoint, all changes should be evaluated by a company's change management system.
(c) Proposed changes should be evaluated by expert teams contributing the appropriate expertise and knowledge from relevant areas (e.g., Pharmaceutical Development, Manufacturing, Quality, Regulatory Affairs, and Medical), to ensure the change is technically justified. Prospective evaluation criteria for a proposed change should be set.
(d) After implementation, an evaluation of the change should be undertaken to confirm the change objectives were achieved and that there was no deleterious impact on product quality.

4. Management Review of Process Performance and Product Quality

Management review should provide assurance that process performance and product quality are managed over the lifecycle. Depending on the size and complexity of the company, management review can be a series of reviews at various levels of management and should include a timely and effective communication and escalation process to raise appropriate quality issues to senior levels of management for review (Table 3.4).

(a) The management review system should include
  (1) The results of regulatory inspections and findings, audits and other assessments, and commitments made to regulatory authorities.
  (2) Periodic quality reviews, that can include
    (i) Measures of customer satisfaction such as product quality complaints and recalls
    (ii) Conclusions of process performance and product quality monitoring and
    (iii) The effectiveness of process and product changes including those arising from corrective action and preventive actions
  (3) Any follow-up actions from previous management reviews.
(b) The management review system should identify appropriate actions, such as:

TABLE 3.4
Application of Management Review of Process Performance and Product Quality throughout the Product Lifecycle

Pharmaceutical Development	Technology Transfer	Commercial Manufacturing	Product Discontinuation
Aspects of management review can be performed to ensure adequacy of the product and process design.	Aspects of management review should be performed to ensure the developed product and process can be manufactured at commercial scale.	Management review should be a structured system, as described above, and should support continual improvement.	Management review should include such items as product stability and product quality complaints.

(1) Improvements to manufacturing processes and products
(2) Provision, training, and/or realignment of resources
(3) Capture and dissemination of knowledge

IV. CONTINUAL IMPROVEMENT OF THE PHARMACEUTICAL QUALITY SYSTEM

This section describes activities that should be conducted to manage and continually improve the pharmaceutical quality system.

A. Management Review of the Pharmaceutical Quality System

Management should have a formal process for reviewing the pharmaceutical quality system on a periodic basis. The review should include

(a) Measurement of achievement of pharmaceutical quality system objectives
(b) Assessment of performance indicators that can be used to monitor the effectiveness of processes within the pharmaceutical quality system, such as:
  (1) Complaint, deviation, CAPA, and change management processes
  (2) Feedback on outsourced activities
  (3) Self-assessment processes including risk assessments, trending, and audits
  (4) External assessments such as regulatory inspections and findings and customer audits

B. Monitoring of Internal and External Factors Impacting the Pharmaceutical Quality System

Factors monitored by management can include

(a) Emerging regulations, guidance, and quality issues that can impact the pharmaceutical quality system
(b) Innovations that might enhance the pharmaceutical quality system
(c) Changes in business environment and objectives
(d) Changes in product ownership

C. Outcomes of Management Review and Monitoring

The outcome of management review of the pharmaceutical quality system and monitoring of internal and external factors can include

(a) Improvements to the pharmaceutical quality system and related processes
(b) Allocation or reallocation of resources and/or personnel training
(c) Revisions to quality policy and quality objectives
(d) Documentation and timely and effective communication of the results of the management review and actions, including escalation of appropriate issues to senior management

GLOSSARY

ICH and ISO definitions are used in ICH Q10 where they exist. For the purpose of ICH Q10, where the words "requirement," "requirements," or "necessary" appear in an ISO definition, they do not necessarily reflect a regulatory requirement. The source of the definition is identified in parentheses after the definition. Where no appropriate ICH or ISO definition was available, an ICH Q10 definition was developed.

Capability of a Process: Ability of a process to realize a product that will fulfil the requirements of that product. The concept of process capability can also be defined in statistical terms. (ISO 9000:2005)

Change Management: A systematic approach to proposing, evaluating, approving, implementing, and reviewing changes. (ICH Q10)

Continual Improvement: Recurring activity to increase the ability to fulfil requirements. (ISO 9000:2005)

Control Strategy: A planned set of controls, derived from current product and process understanding, that assures process performance and product quality. The controls can include parameters and attributes related to drug substance and drug product materials and components, facility and equipment operating conditions, in-process controls, finished product specifications, and the associated methods and frequency of monitoring and control. (ICH Q10)

Corrective Action: Action to eliminate the cause of a detected nonconformity or other undesirable situation. *Note*: Corrective action is taken to prevent recurrence whereas preventive action is taken to prevent occurrence. (ISO 9000:2005)

Design Space: The multidimensional combination and interaction of input variables (e.g., material attributes) and process parameters that have been demonstrated to provide assurance of quality. (ICH Q8)

Enabler: A tool or process which provides the means to achieve an objective. (ICH Q10)

Feedback: The modification or control of a process or system by its results or effects.

Feedforward: The modification or control of a process using its anticipated results or effects. (Oxford Dictionary of English. Oxford University Press; 2003)

Feedback/feedforward can be applied technically in process control strategies and conceptually in quality management. (ICH Q10)

Innovation: The introduction of new technologies or methodologies. (ICH Q10)

Knowledge Management: Systematic approach to acquiring, analyzing, storing, and disseminating information related to products, manufacturing processes, and components. (ICH Q10)

Outsourced Activities: Activities conducted by a contract acceptor under a written agreement with a contract giver. (ICH Q10)

Performance Indicators: Measurable values used to quantify quality objectives to reflect the performance of an organization, process, or system, also known as "performance metrics" in some regions. (ICH Q10)

Pharmaceutical Quality System (PQS): Management system to direct and control a pharmaceutical company with regard to quality. (ICH Q10 based upon ISO 9000:2005)

Preventive Action: Action to eliminate the cause of a potential nonconformity or other undesirable potential situation. *Note*: Preventive action is taken to prevent occurrence whereas corrective action is taken to prevent recurrence. (ISO 9000:2005)

Product Realization: Achievement of a product with the quality attributes appropriate to meet the needs of patients, health care professionals, and regulatory authorities (including compliance with marketing authorization) and internal customers' requirements. (ICH Q10)

Quality: The degree to which a set of inherent properties of a product, system, or process fulfils requirements. (ICH Q9)

Quality Manual: Document specifying the quality management system of an organization. (ISO 9000:2005)

Quality Objectives: A means to translate the quality policy and strategies into measurable activities. (ICH Q10)

Quality Planning: Part of quality management focused on setting quality objectives and specifying necessary operational processes and related resources to fulfil the quality objectives. (ISO 9000:2005)

Quality Policy: Overall intentions and direction of an organization related to quality as formally expressed by senior management. (ISO 9000:2005)

Quality Risk Management: A systematic process for the assessment, control, communication, and review of risks to the quality of the drug (medicinal) product across the product lifecycle. (ICH Q9)

Senior Management: Person(s) who direct and control a company or site at the highest levels with the authority and responsibility to mobilize resources within the company or site. (ICH Q10 based in part on ISO 9000:2005)

State of Control: A condition in which the set of controls consistently provides assurance of continued process performance and product quality. (ICH Q10)

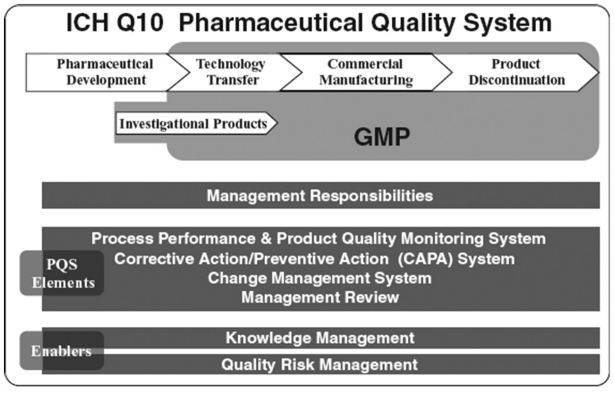
ANNEX 1

Potential Opportunities to Enhance Science- and Risk-Based Regulatory Approaches[a]

Scenario	Potential Opportunity
1. Comply with GMPs	Compliance-status quo
2. Demonstrate effective pharmaceutical quality system, including effective use of quality risk management principles (e.g., ICH Q9 and ICH Q10)	Opportunity to • Increase use of risk-based approaches for regulatory inspections Opportunity to • Facilitate science-based pharmaceutical quality assessment • Enable innovative approaches to process validation and • Establish real-time release mechanisms
3. Demonstrate product and process understanding, including effective use of quality risk management principles (e.g., ICH Q8 and ICH Q9)	
4. Demonstrate effective pharmaceutical quality system and product and process understanding, including the use of quality risk management principles (e.g., ICH Q8, ICH Q9, and ICH Q10)	Opportunity to • Increase use of risk-based approaches for regulatory inspections • Facilitate science-based pharmaceutical quality assessment • Optimize science- and risk-based post-approval change processes to maximize benefits from innovation and continual improvement • Enable innovative approaches to process validation and • Establish real-time release mechanisms

[a] Note*:* This annex reflects potential opportunities to enhance regulatory approaches. The actual regulatory process will be determined by region.

ANNEX 2



This diagram illustrates the major features of the ICH Q10 pharmaceutical quality system (PQS) model. The PQS covers the entire lifecycle of a product including pharmaceutical development, technology transfer, commercial manufacturing, and product discontinuation as illustrated by the upper portion of the diagram. The PQS augments regional GMPs

as illustrated in the diagram. The diagram also illustrates that regional GMPs apply to the manufacture of investigational products.

The next horizontal bar illustrates the importance of management responsibilities explained in Section 2 to all stages of the product lifecycle. The following horizontal bar lists the PQS elements, which serve as the major pillars under the PQS model. These elements should be applied appropriately and proportionally to each lifecycle stage recognizing opportunities to identify areas for continual improvement.

The bottom set of horizontal bars illustrates the enablers: Knowledge management and quality risk management, which are applicable throughout the lifecycle stages. These enablers support the PQS goals of achieving product realization, establishing and maintaining a state of control, and facilitating continual improvement.

4 Pharmaceutical Development

I. INTRODUCTION

Where a company chooses to apply quality by design and quality risk management (ICH Q9, Quality Risk Management), linked to an appropriate pharmaceutical quality system, then opportunities arise to enhance science- and risk-based regulatory approaches, which is the subject of this chapter.

A. Approaches to Pharmaceutical Development

In all cases, the product should be designed to meet patients' needs and the intended product performance. Strategies for product development vary from company to company and from product to product. The approach to, and extent of, development can also vary and should be outlined in the submission. An applicant might choose either an empirical approach or a more systematic approach to product development. An illustration of the potential contrasts of these approaches is shown in Appendix 1. A more systematic approach to development (also defined as quality by design) can include, for example, incorporation of prior knowledge, results of studies using design of experiments, use of quality risk management, and use of knowledge management (see ICH Q10) throughout the lifecycle of the product. Such a systematic approach can enhance the process to achieve quality and help the regulators to better understand a company's strategy. Product and process understanding can be updated with the knowledge gained over the product lifecycle.

A greater understanding of the product and its manufacturing process can create a basis for more flexible regulatory approaches. The degree of regulatory flexibility is predicated on the level of relevant scientific knowledge provided in the registration application. It is the knowledge gained and submitted to the authorities, and not the volume of data collected, that forms the basis for science- and risk-based submissions and regulatory evaluations. Nevertheless, appropriate data demonstrating that this knowledge is based on sound scientific principles should be presented with each application.

Pharmaceutical development should include, at a minimum, the following elements:

- Defining the target product profile as it relates to quality, safety, and efficacy, considering for example, the route of administration, dosage form, bioavailability, dosage, and stability
- Identifying critical quality attributes (CQAs) of the drug product, so that those product characteristics having an impact on product quality can be studied and controlled
- Determining the quality attributes of the drug substance, excipients etc., and selecting the type and amount of excipients to deliver drug product of the desired quality
- Selecting an appropriate manufacturing process
- Identifying a control strategy

An enhanced, quality by design approach to product development would additionally include the following elements:

- A systematic evaluation, understanding, and refining of the formulation and manufacturing process, including
  - Identifying, through, for example, prior knowledge, experimentation, and risk assessment, the material attributes and process parameters that can have an effect on product CQAs.
  - Determining the functional relationships that link material attributes and process parameters to product CQAs
- Using the enhanced process understanding in combination with quality risk management to establish an appropriate control strategy, which can, for example, include a proposal for design space(s) and/or real-time release.

As a result, this more systematic approach could facilitate continual improvement and innovation throughout the product lifecycle (see ICH Q10 Pharmaceutical Quality System).

II. ELEMENTS OF PHARMACEUTICAL DEVELOPMENT

The section that follows elaborates, by means of description and example, possible approaches to gaining a more systematic, enhanced understanding of the product and process under development. The examples given are purely illustrative and are not intended to create new regulatory requirements.

A. Target Product Profile

A target product profile is a prospective and dynamic summary of the quality characteristics of a drug product that ideally will be achieved to ensure that the desired quality, and hence the safety and efficacy, of a drug product is realized. The target product profile forms the basis of design for the development of the product.

Considerations for the target product profile should include

- Dosage form and route of administration
- Dosage form strength(s)
- Therapeutic moiety release or delivery and pharmacokinetic characteristics (e.g., dissolution; aerodynamic performance) appropriate to the drug product dosage form being developed
- Drug product quality criteria (e.g., sterility, purity) appropriate for the intended marketed product

B. Critical Quality Attributes

A CQA is a physical, chemical, biological, or microbiological property or characteristic that should be within an appropriate limit, range, or distribution to ensure the desired product quality. CQAs are generally associated with the drug substance, excipients, intermediates, and drug product.

Drug product CQAs include the properties that impart the desired quality, safety, and efficacy. CQAs of solid oral dosage forms are typically those aspects affecting product purity, potency, stability, and drug release. CQAs for other delivery systems can additionally include more product-specific aspects, such as aerodynamic properties for inhaled products, sterility for parenterals, and adhesive force for transdermal patches. For drug substances or intermediates, the CQAs can additionally include those properties (e.g., particle size distribution, bulk density) that affect downstream processability.

Drug product CQAs are used to guide the product and process development. Potential drug product CQAs can be identified from the target product profile and/or prior knowledge. The list of potential CQAs can be modified when the formulation and manufacturing process are selected and as product knowledge and process understanding increase. Quality risk management can be used to prioritize the list of potential CQAs for subsequent evaluation. Relevant CQAs can be identified by an iterative process of quality risk management and experimentation that assesses the extent to which their variation can have an impact on the quality of the drug product.

C. Linking Material Attributes and Process Parameters to CQAs—Risk Assessment

Risk assessment is a valuable science-based process used in quality risk management (see ICH Q9) that can aid in identifying which material attributes and process parameters have an effect on product CQAs. While the risk assessment is typically performed early in the pharmaceutical development, it can be helpful to repeat the risk assessment as information and greater knowledge become available.

Risk assessment tools can be used to identify and rank parameters (e.g., operational, equipment, input material) with potential to have an impact on product quality based on prior knowledge and initial experimental data. For an illustrative example, see Appendix 2. The initial list of potential parameters can be quite extensive but is likely to be narrowed as process understanding is increased. The list can be refined further through experimentation to determine the significance of individual variables and potential interactions. Once the significant parameters are identified, they can be further studied (e.g., through a combination of design of experiments, mathematical models, or studies that lead to mechanistic understanding) to achieve a higher level of process understanding.

D. Design Space

The linkage between the process inputs (input variables and process parameters) and the critical quality attributes can be described in the design space.

1. Selection of Variables

The risk assessment and process development experiments described in Section 2.3 can not only lead to an understanding of the linkage and effect of process inputs on product CQAs but also help identify the variables and their ranges within which consistent quality can be achieved. These input variables can thus be selected for inclusion in the design space.

An explanation should be provided in the application to describe what variables were considered, how they affect the process and product quality, and which parameters were included or excluded in the design space. An input variable or process parameter need not be included in the design space if it has no effect on delivering CQAs when the input variable or parameter is varied over the full potential range of operation. The control of these variables would be under GMP. However, the knowledge gained from studies should be described in the submission.

2. Defining and Describing a Design Space in a Submission

A design space can be defined in terms of ranges of input variables or parameters or through more complex mathematical relationships. It is possible to define a design space as a time-dependent function (e.g., temperature and pressure cycle of a lyophilization cycle) or as a combination of variables such as principal components of a multivariate model. Scaling factors can also be included if the design space is intended to span multiple operational scales. Analysis of historical data can provide the basis for establishing a design space. Regardless of how a design space is developed, it is expected that operation within the design space will result in a product meeting the defined quality attributes.

Examples of different potential approaches to presentation of a design space are presented in Appendix 2.

3. Unit Operation Design Space(s)

The applicant can choose to establish independent design spaces for one or more unit operations or to establish a single design space that spans multiple operations. While a separate design space for each unit operation is often simpler to develop, a design space that spans the entire process can provide more operational flexibility. For example, in the case of a drug product that undergoes degradation in solution before lyophilization, the design space to control the extent of degradation (e.g., concentration, time, temperature) could be expressed for each unit operation or as a sum over all unit operations.

4. Relationship of Design Space to Scale and Equipment

When defining a design space, the applicant should keep in mind the type of operational flexibility desired. A design

space can be developed at small scale or pilot scale. The applicant should justify the relevance of a design space developed at small or pilot scale to the proposed production-scale manufacturing process and discuss the potential risks in the scale-up operation.

If the applicant wishes the design space to be applicable to multiple operational scales, the design space should be described in terms of relevant scale-independent parameters. For example, if a product was determined to be shear sensitive in a mixing operation, the design space could include shear rate, rather than agitation rate. Dimensionless numbers and/or models for scaling also can be included as part of the design space description.

The creation of a design space can be helpful for technology transfer or site changes. The subsequent regulatory processes will be region-specific.

5. Design Space vs. Proven Acceptable Ranges

A combination of proven acceptable ranges does not constitute a design space. However, proven acceptable ranges based on univariate experimentation can provide some knowledge about the process.

6. Design Space and Edge of Failure

It can be helpful to know where edges of failure could be or to determine potential failure modes. However, it is not an essential part of establishing a design space.

E. Control Strategy

A control strategy is designed to consistently ensure product quality.

The elements of the control strategy discussed in Section P.2 of the dossier should describe and justify how in-process controls and the controls of input materials (drug substance and excipients), container closure system, intermediates, and end products contribute to the final product quality. These controls should be based on product, formulation, and process understanding and should include, at a minimum, control of the critical parameters and attributes.

A comprehensive pharmaceutical development approach will generate process and formulation understanding that identifies sources of variability. Critical sources of variability that can lead to product failures should be identified, appropriately understood, and managed or controlled. Understanding sources of variability and their impact on downstream processes or processing, intermediate products, and finished product quality can provide flexibility for shifting of controls upstream and minimize the need for end product testing. This process understanding, in combination with quality risk management (see ICH Q9), will support the control of process parameters so that the variability of raw materials can be compensated for in an adaptable process to deliver consistent product quality.

This process understanding enables an alternative, manufacturing paradigm where the variability of input materials might not need to be tightly constrained. Instead, it can be possible to design an adaptive process step (a step that is responsive to the input materials) to ensure consistent product quality.

Enhanced understanding of product performance can justify the use of surrogate tests or support real-time release in lieu of end-product testing. For example, disintegration could serve as a surrogate for dissolution for fast-disintegrating solid forms with highly soluble drug substances. Unit dose uniformity performed in-process [e.g., using weight variation coupled with near infrared (NIR) assay] can enable real-time release and provide an increased level of quality assurance compared to the traditional end-product testing using compendial content uniformity standards.

Elements of a control strategy can include, but are not limited to, the following:

- Control of input material attributes (e.g., drug substance, excipients, primary packaging materials) based on an understanding of their impact on processability or product quality
- Product specification(s)
- Controls for unit operations that have an impact on downstream processing or end-product quality (e.g., the impact of drying on degradation, particle size distribution of the granulate on dissolution)
- In-process or real-time release in lieu of end-product testing
- A monitoring program (e.g., full product testing at regular intervals) for verifying multivariate prediction models

A control strategy can include redundant or alternative elements, if justified. For example, one element of the control strategy could rely on end-product testing, whereas an additional or alternative element could depend on real-time release using process analytical technology (PAT). The use of these alternative elements should be described in the submission.

Adoption of the principles in this guideline can support the justification of alternative approaches to the setting of specification attributes and acceptance criteria as described in Q6A and Q6B.

F. Product Lifecycle Management and Continual Improvement

Throughout the product lifecycle, companies have opportunities to evaluate innovative approaches to improve product quality (see ICH Q10).

For example, once approved, a design space provides the applicant flexibility to optimize and adjust a process as managed under their quality system. A design space is not necessarily static in nature and should be periodically reassessed to ensure that the process is working as anticipated to deliver product quality attributes. For certain design spaces using mathematical models (e.g., chemometrics models of NIR)

periodic maintenance could be essential to ensure the models' performance (e.g., checking calibration) or to update the model based upon additional data. Expansion, reduction, or redefinition of the design space could be desired upon gaining additional process information.

III. SUBMISSION OF PHARMACEUTICAL DEVELOPMENT AND RELATED INFORMATION IN CTD FORMATS

Pharmaceutical development information is submitted in Section P.2 of the Common Technical Document (CTD). Other information resulting from pharmaceutical development studies could be accommodated by the CTD format in a number of different ways, and some specific suggestions are provided below. Certain aspects (e.g., product lifecycle management, continual improvement) of this guidance are handled under the applicant's pharmaceutical quality system (see ICH Q10) and need not be submitted in the registration application.

A. Quality Risk Management and Product and Process Development

Quality risk management can be used at many different stages during product and process development and manufacturing implementation. The assessments used to guide and justify development decisions can be included in the relevant sections of P.2. For example, risk analyses and functional relationships linking material attributes to product CQAs can be included in P.2.1, P.2.2, and P.2.3. Risk analyses linking the design of the manufacturing process to product quality can be included in P.2.3.

B. Design Space

As an element of the proposed manufacturing process, the design space(s) can be described in the section of the application that includes the description of the manufacturing process and process controls (P.3.3). If appropriate, additional information can be provided in the section of the application that addresses the controls of critical steps and intermediates (P.3.4). The relationship of the design space(s) to the overall control strategy can be explained in the section of the application that includes the justification of the drug product specification (P.5.6). The product and manufacturing process development sections of the application (P.2.1, P.2.2, and P.2.3) are appropriate places to summarize and describe product and process development studies that provide the basis for the design space(s).

C. Control Strategy

The section of the application that includes the justification of the drug product specification (P.5.6) is a good place to summarize the control strategy. The summary should be clear about the various roles played by different components of the control strategy. However, detailed information about input material controls and process controls should still be provided in the appropriate CTD format sections [e.g., drug substance section (S), control of excipients (P.4), description of manufacturing process and process controls (P.3.3), controls of critical steps and intermediates (P.3.4)].

D. Drug Substance Related Information

If drug substance CQAs have the potential to affect the CQAs or manufacturing process of the drug product, some discussion of drug substance CQAs can be appropriate in the pharmaceutical development section of the application (e.g., P.2.1).

GLOSSARY

Control Strategy: A planned set of controls, derived from current product and process understanding, that assures process performance and product quality. The controls can include parameters and attributes related to drug substance and drug product materials and components, facility and equipment operating conditions, in-process controls, finished product specifications, and the associated methods and frequency of monitoring and control (ICH Q10).

Critical Quality Attribute (CQA): A physical, chemical, biological, or microbiological property or characteristic that should be within an appropriate limit, range, or distribution to ensure the desired product quality.

Critical Process Parameter: A process parameter whose variability has an impact on a critical quality attribute and therefore should be monitored or controlled to ensure the process produces the desired quality.

Edge of Failure: The boundary to a variable or parameter, beyond which the relevant quality attributes or specification cannot be met.

Proven Acceptable Range: A characterized range of a process parameter for which operation within this range, while keeping other parameters constant, will result in producing a material meeting relevant quality criteria.

Quality by Design: A systematic approach to development that begins with predefined objectives and emphasizes product and process understanding and process control, based on sound science and quality risk management.

Real-time release: The ability to evaluate and ensure the acceptable quality of in-process and/or final product based on process data, which typically include a valid combination of assessed material attributes and process controls.

APPENDIX 1: DIFFERING APPROACHES TO PHARMACEUTICAL DEVELOPMENT[A]

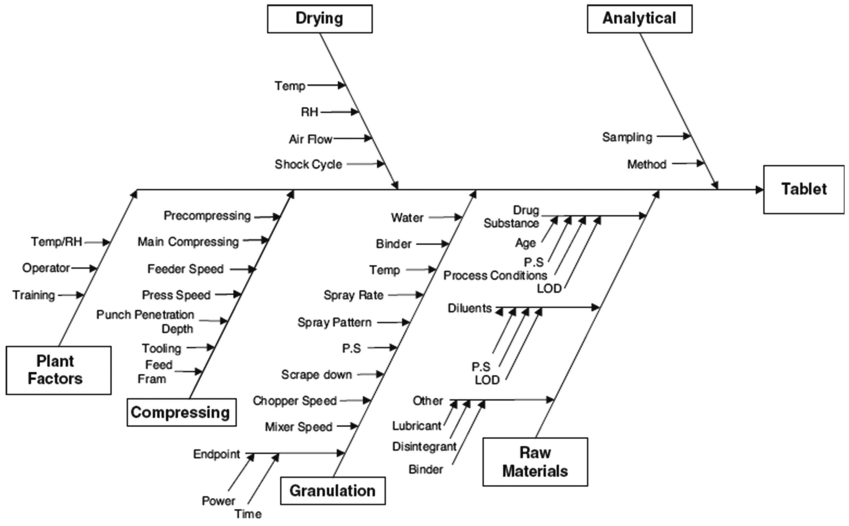
Aspect	Minimal Approach	Enhanced, Quality by Design Approach
Overall pharmaceutical development	• Mainly empirical • Developmental research often conducted one variable at a time	• Systematic, relating mechanistic understanding of input material attributes and process parameters to drug product CQAs • Multivariate experiments to understand product and process • Establishment of design space • PAT tools utilized
Manufacturing process	• Fixed • Validation primarily based on initial full-scale batches • Focus on optimization and reproducibility	• Adjustable within design space • Lifecycle approach to validation and, ideally, continuous process verification • Focus on control strategy and robustness • Use of statistical process control methods
Process controls	• In-process tests primarily for go/no-go decisions • Off-line analysis	• PAT tools utilized with appropriate feedforward and feedback controls • Process operations tracked and trended to support continual improvement efforts post-approval
Product specifications	• Primary means of control • Based on batch data available at time of registration	• Part of the overall quality control strategy • Based on desired product performance with relevant supportive data
Control strategy	• Drug product quality controlled primarily by intermediate and end-product testing	• Drug product quality ensured by risk-based control strategy for well-understood product and process • Quality controls shifted upstream, with the possibility of real-time release or reduced end-product testing
Lifecycle management	• Reactive (i.e., problem solving and corrective action)	• Preventive action • Continual improvement facilitated

[a] Note: This table is intended only to illustrate some potential contrasts between what might be considered a minimal approach and an enhanced approach regarding different aspects of pharmaceutical development and lifecycle management. It is not intended to specifically define the approach. Current practices in the pharmaceutical industry vary and typically lie between these approaches.

APPENDIX 2: ILLUSTRATIVE EXAMPLES

Example of Use of a Risk Assessment Tool

For example, a cross-functional team of experts could work together to develop an Ishikawa (fishbone) diagram that identifies all potential variables which can have an impact on the desired quality attribute. The team could then rank the variables based on probability, severity, and detectability using failure mode effect analysis (FMEA) or similar tools based on prior knowledge and initial experimental data. Design of experiments or other experimental approaches could then be used to evaluate the impact of the higher ranked variables, to gain greater understanding of the process, and to develop a proper control strategy.



Ishikawa Diagram

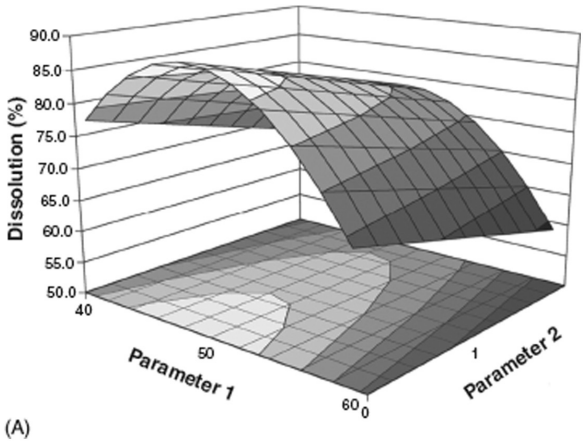
Example of Depiction of Interactions

Figure 4.1 depicts the effect of interactions, or lack thereof, between three process parameters on the level of degradation product Y. The figure shows a series of two-dimensional plots showing the effect of interactions among three process parameters (initial moisture content, temperature, mean particle size) of the drying operation of a granulate (drug product intermediate) on degradation product Y. The relative slopes of the lines or curves within a plot indicate if interaction is present. In this example, initial moisture content and temperature are interacting, but initial moisture content and mean particle size are not, nor are temperature and mean particle size.

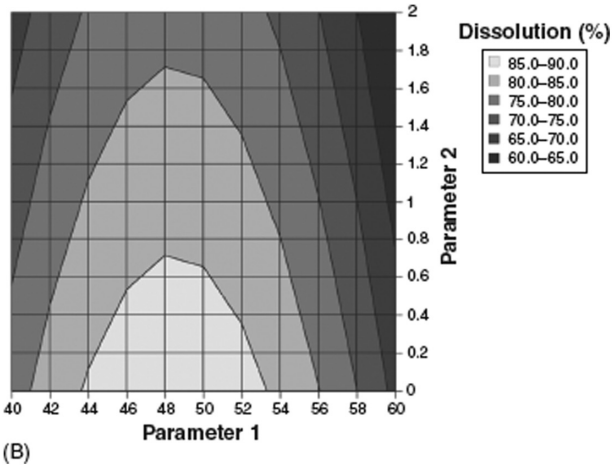
Illustrative Examples of Presentation of Design Space

Where multiple parameters are involved, the design space can be presented for two parameters, in a manner similar to the examples shown above, at different values (e.g., high, middle, low) within the range of the third parameter, the fourth parameter, and so on. A stacked plot of these design spaces can be considered, if appropriate (see Figures 4.1, 4.2 and 4.3).

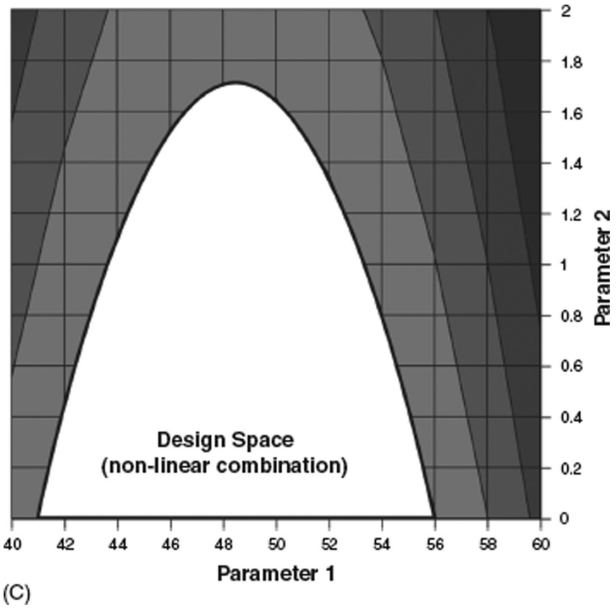
- Parameter 1 has a range of 41 to 56.
- Parameter 2 has a lower limit of 0 and an upper limit that is a function of parameter.
- Parameter 1 has a range of 44 to 53.
- Parameter 2 has a range of 0 to 1.1.



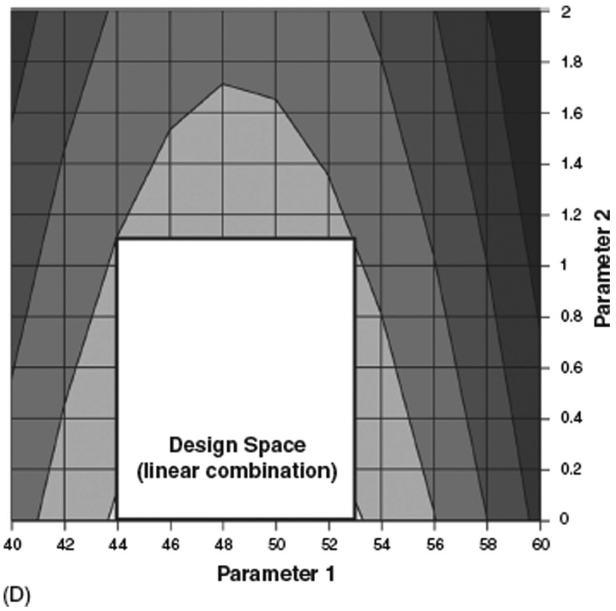
(A)



(B)



(C)



(D)

FIGURE 4.1 Design space described with the aid of response surface plot (A) or contour plot (B) and defined by nonlinear (C) or linear combination (D) of process parameter ranges. In this example, the effects of the two parameters are additive, but the two parameters do not interact. (A) Response surface plot of dissolution as a function of two parameters of a granulation operation. Dissolution above 80% is desired. (B) Contour plot of dissolution from Example 1A. (C) Design space for granulation parameters, defined by a nonlinear combination of their ranges, that delivers satisfactory dissolution (i.e., >80%). In this example, the design space can be optionally expressed by equations that describe the boundaries, that is. (D) Design space for granulation parameters, defined by a linear combination of their ranges, that delivers satisfactory dissolution (i.e., >80%). This design space is a subset of the nonlinear design space from Example 1C and can be optionally expressed as shown in Figure 4.2.

FIGURE 4.1 (Continued)

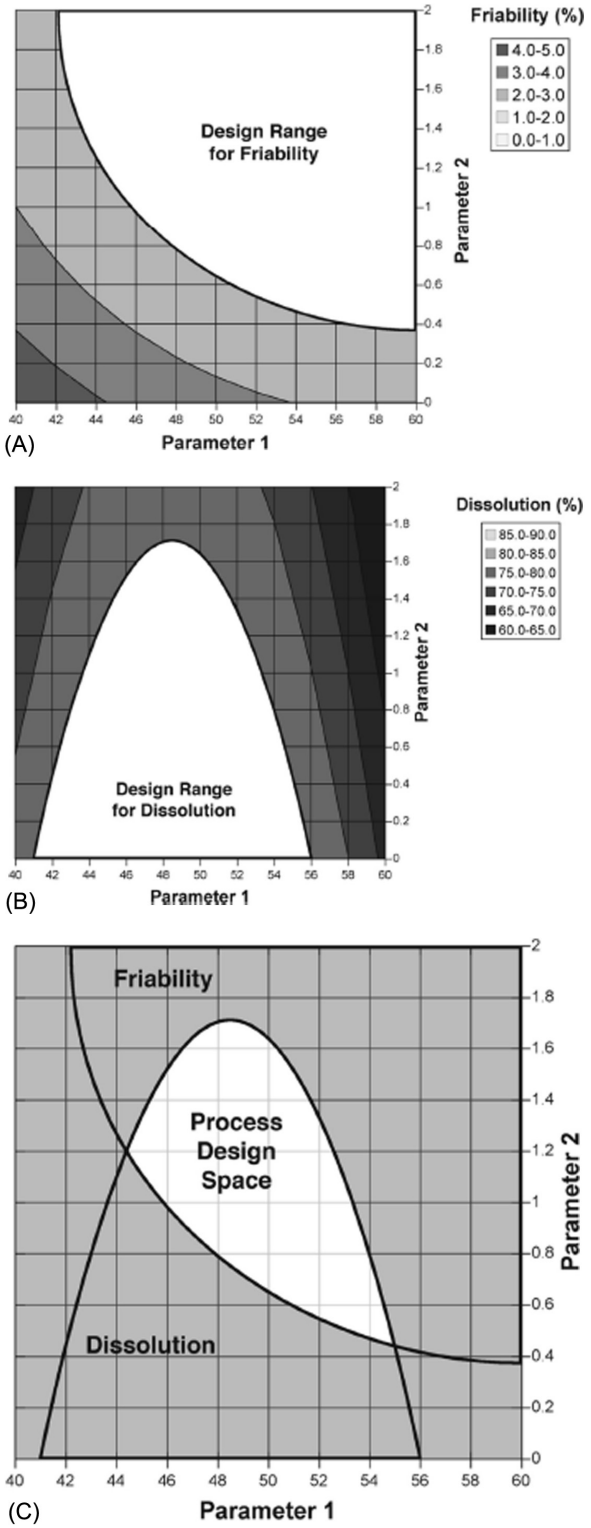


FIGURE 4.2 Design space determined from the common region of successful operating ranges for multiple CQAs. The relations of two CQAs, that is, friability and dissolution, to two process parameters of a granulation operation are shown in (A) and (B). (C) The overlap of these regions and the maximum ranges of the potential design space. (A) Contour plot of friability as a function of parameters 1 and 2. (B) Contour plot of dissolution as a function of parameters 1 and 2. (C) Potential process design space, comprised of the overlap region of design ranges for friability and or dissolution.

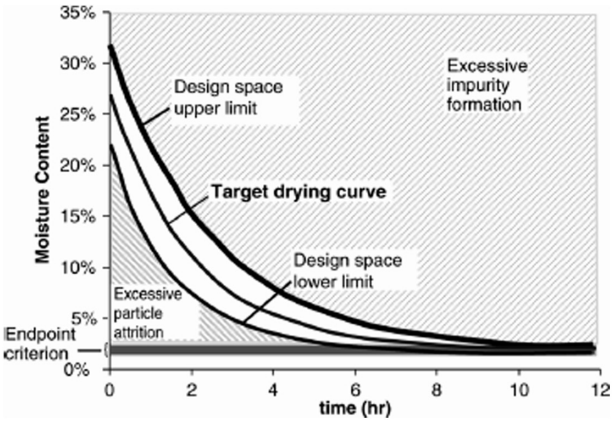

FIGURE 4.3 The design space for a drying operation that is dependent upon the path of temperature and/or pressure over time. The end point for moisture content is 1–2%. Operating above the upper limit of the design space can cause excessive impurity formation, while operating below the lower limit of the design space can result in excessive particle attrition.

5 Scale-Up and Post-Approval Changes for Nonsterile Semisolid Dosage Forms: Manufacturing Equipment

To ensure continuing product quality and performance characteristics of the semisolid topical formulations, regulatory approvals are required for changes to

1. Components or composition
2. Manufacturing (process and equipment)
3. Scale-up/scale-down of manufacture and
4. Site of manufacture of a semisolid formulation during the post-approval period

It is important to define

1. The levels of change
2. Recommended chemistry, manufacturing, and controls tests to support each level of change
3. Recommended in vitro release tests or in vivo bioequivalence tests to support each level of change
4. Documentation to support the change

The effect that scale-up and post-approval changes may have on the stability of the drug product should be evaluated. For general guidance on conducting stability studies, see the FDA *Guideline for Submitting Documentation for the Stability of Human Drugs and Biologics.* For scale-up and post-approval changes submissions, the following points should also be considered:

A. In most cases, except those involving scale-up, stability data from pilot scale batches will be acceptable to support the proposed change.
B. Where stability data show a trend toward potency loss or degradant increase under accelerated conditions, it is recommended that historical accelerated stability data from a representative pre-change batch be submitted for comparison. It is also recommended that under these circumstances, all available long-term data on test batches from ongoing studies be provided in the supplement. Submission of historical accelerated and available long-term data would facilitate review and approval of the supplement.
C. A commitment should be included to conduct long-term stability studies through the expiration dating period, according to the approved protocol, on either the first or first three (see below for details) production batches and to report the results in subsequent annual reports.

Definition of level 1 changes are those that are unlikely to have any detectable effect on formulation quality and performance. Examples:

A. Deletion or partial deletion of an ingredient intended to affect the color, fragrance, or flavor of the drug product.
B. Any change in an excipient up to 5% of approved amount of that excipient. The total additive effect of all excipient changes should not be more than 5%. Changes in the composition should be based on the approved target composition and not on previous level 1 changes in the composition. A change in diluent (q.s. excipient) caused by component and composition changes in excipient may be made and is excluded from the 5% change limit.
C. Change in a supplier of a structure-forming excipient that is primarily a single chemical entity (purity 95%) or change in a supplier or technical grade of any other excipient.

Level 2 changes are defined as those that could have a significant effect on formulation quality and performance. Examples:

A. Changes of >5% and <10% of approved amount of an individual excipient; the total additive effect of all excipient changes should not be more than 10%.
B. Changes in the composition should be based on the approved target composition and not on previous level 1 or level 2 changes in the composition.
C. Changes in diluent (q.s. excipient) caused by component and composition changes in excipients are acceptable and are excluded from the 10% change limit.
D. Change in supplier of a structure-forming excipient not covered under level 1.
E. Change in the technical grade of structure-forming excipient.
F. Change in particle size distribution of the drug substance if the drug is in suspension.

Level 3 changes are defined as those that are likely to have a significant effect on formulation quality and performance. Examples:

A. Any qualitative and quantitative changes in an excipient beyond the ranges noted in level 2 change.
B. Change in crystalline form of the drug substance, if the drug is in suspension.

I. PRESERVATIVE

For semisolid products, any change in the preservative may affect the quality of the product. If any quantitative or qualitative changes are made in the formulation, additional testing should be performed. No in vitro release documentation or in vivo bioequivalence documentation is needed for preservative changes.

II. MANUFACTURING CHANGES

Manufacturing changes may affect both equipment used in the manufacturing process and the process itself. A level 1 change is a change from nonautomated or nonmechanical equipment to automated or mechanical equipment to transfer ingredients or a change to alternative equipment of the same design and operating principles. A level 2 change is a change in equipment to a different design or different operating principles or a change in type of mixing equipment, such as high shear to low shear and vice versa. No level 3 changes are anticipated in this category.

III. PROCESS

Level 1 changes include changes such as rate of mixing, mixing times, operating speeds, and holding times within approved application ranges, in addition to the order of addition of components (excluding actives) to either the oil or water phase. Level 2 changes include changes such as rate of mixing, mixing times, rate of cooling, operating speeds, and holding times outside approved application ranges for all dosage forms in addition to any changes in the process of combining the phases. No level 3 changes are anticipated in this category.

A. Batch Size (Scale-Up or Scale-Down)

The minimum batch size for the NDA pivotal clinical trial batch or the ANDA/AADA biobatch is at least 100 kg or 10% of a production batch, whichever is larger. All scale changes should be properly validated and may be inspected by appropriate agency personnel. Level 1 changes in batch size are those up to and including a factor of ten times the size of the pivotal clinical trial or biobatch, where the equipment used to produce the test batch or batches is of the same design and operating principles, the batch or batches are manufactured in full compliance with current good manufacturing practice (cGMPs), and the same standard operating procedures (SOPs) and controls, as well as the same formulation and manufacturing procedures, are used on the test batch or batches and on the full-scale production batch or batches. Level 2 changes in batch size are those from beyond a factor of ten times the size of the pivotal clinical trial or biobatch, where the equipment used to produce the test batch or batches is of the same design and operating principles, the batch or batches is manufactured in full compliance with cGMPs, and the same SOPs and controls, as well as the same formulation and manufacturing procedures, are used on the test batch or batches and on the full-scale production batch or batches. No level 3 changes are anticipated in this category.

IV. MANUFACTURING SITE

Manufacturing site changes consist of changes in location in the site of manufacture, packaging and filling operations, or testing for both company-owned and contract manufacturing facilities, and they do not include any other level 2 or 3 changes, for example, changes in scale, manufacturing (including process or equipment), and components or composition. New manufacturing locations should have had a satisfactory cGMP inspection within the past 2 years. A stand-alone analytical testing laboratory site change may be submitted as a Changes Being Effected Supplement if the new facility has a current and satisfactory cGMP compliance profile with the FDA for the type of testing operation in question. The supplement should contain a commitment to use the same test methods employed in the approved application, written certification from the testing laboratory stating that they are in conformance with cGMPs, and a full description of the testing to be performed by the testing laboratory. If the facility has not received a satisfactory cGMP inspection for the type of testing involved, a prior approval supplement is recommended. No stability data are needed for a change in a stand-alone analytical facility. Level 1 changes consist of site changes within a single facility where the same equipment, SOPs, environmental conditions (e.g., temperature and humidity) and controls, and personnel common to both manufacturing sites are used and where no changes are made to the manufacturing batch records, except for administrative information and the location of the facility. “Common” is defined as employees already working on the campus who have suitable experience with the manufacturing process.

Level 2 changes consist of site changes within a contiguous campus or between facilities in adjacent city blocks, where similar equipment, SOPs, environmental conditions (e.g., temperature and humidity) and controls, and personnel common to both manufacturing sites are used and where no changes are made to the manufacturing batch records, except for administrative information and the location of the facility. Level 3 changes consist of a site change in manufacturing site to a different campus. A different campus is defined as one that is not on the same original contiguous site or where the facilities are not in adjacent city blocks. To qualify as a level 3 change, similar equipment, SOPs, environmental conditions, and controls should be used in the manufacturing process at the new site. Changes should not be made to the manufacturing batch records except when consistent with other level 1 changes. Administrative information, location, and language translation may be revised as needed. Any change to a new contract manufacturer also constitutes a level 3 change.

MANUFACTURING EQUIPMENT

I. INTRODUCTION

Any equipment changes should be validated in accordance with cGMPs. The resulting data will be subject to examination by field investigators during routine GMP inspections.

The information here is presented in broad categories of unit operation (particle size reduction or separation, mixing, emulsification, deaeration, transfer, and packaging).

Under scale-up and post-approval changes (semisolid) (SUPAC-SS), equipment within the same class and subclass are considered to have the same design and operating principle. For example, a change from a planetary mixer from manufacturer A to another planetary mixer from manufacturer B would not represent a change in design or operating principle and would be considered the same.

A change from equipment in one class to equipment in a different class would usually be considered a change in design and operating principle. For example, a change from a planetary mixer to a dispersator mixer demonstrates a change in operating principle from low-shear convection mixing to high-shear convection mixing. These types of equipment would be considered different under SUPAC-SS.

Applicants should carefully consider and evaluate on a case-by-case basis changes in equipment that are in the same class but different subclasses. In many situations, these changes in equipment would be considered similar. For example, in Section III, Mixing, under the convection mixers, low shear, a change from an impeller mixer (subclass) to a planetary mixer (subclass) represents a change within a class and between subclasses. Provided the manufacturing process with the new equipment is validated, this change would likely not need a Changes Being Effected Supplement. At the time of such a change the applicant should have available the scientific data and rationale used to make this determination. It is up to the applicant to determine the filing category.

II. PARTICLE SIZE REDUCTION AND SEPARATION

A. Definitions

1. Unit Operations

a. Particle Size Reduction

Particle size reduction is the mechanical process of breaking particles into smaller pieces via one or more size-reduction mechanisms. The mechanical process used is generally referred to as milling.

i. Particle A particle is either a discrete crystal or a grouping of crystals, generally known as an agglomerate.

ii. Particle Size Reduction Mechanisms

- Impact—particle size reduction caused by applying an instantaneous force perpendicular to the particle or agglomerate surface; the force can result from particle-to-particle or particle-to-mill surface collision.
- Attrition—particle size reduction by applying force parallel to the particle surface.
- Compression—particle size reduction by applying a force slowly (as compared with impact) to the particle surface toward the center of the particle.
- Cutting—particle size reduction by applying a shearing force to a material.

b. Particle Separation

Particle separation is particle size classification according to particle size alone.

2. Operating Principles

a. Fluid Energy Milling

Fluid energy milling is particle size reduction by high speed particle-to-particle impact or attrition (also known as micronizing).

b. Impact Milling

Particle size reduction by high-speed mechanical impact or impact with other particles (also known as milling, pulverizing, or comminuting) is known as impact milling.

c. Cutting

Cutting is particle size reduction by mechanical shearing.

d. Compression Milling

Particle size reduction by compression stress and shear between two surfaces is known as compression milling.

e. Screening

Particle size reduction by mechanically induced attrition through a screen (commonly referred to as milling or deagglomeration) is called screening.

f. Tumble Milling

Tumble milling is particle size reduction by attrition, using grinding media.

g. Separating

Particle segregation based on size alone, without any significant particle size reduction (commonly referred to as screening or bolting), is also known as separating.

B. Equipment Classifications

1. Fluid Energy Mills

Fluid energy mill subclasses have no moving parts and primarily differ in the configuration or shape of their chambers, nozzles, and classifiers.

- Fixed target
- Fluidized bed
- Loop or oval
- Moving target
- Opposed jet
- Opposed jet with dynamic classifier
- Tangential jet

2. Impact Mills

Impact mill subclasses primarily differ in the configuration of the grinding heads, chamber grinding liners (if any), and classifiers.

- Cage
- Hammer air swept
- Hammer conventional
- Pin or disc

3. Cutting Mills

Although cutting mills can differ in whether the knives are movable or fixed, and in classifier configuration, no cutting mill subclasses have been identified.

4. Compression Mills

Although compression mills, also known as roller mills, can differ in whether one or both surfaces move, no compression mill subclasses have been identified.

5. Screening Mills

Screening mill subclasses primarily differ in the rotating element.

- Oscillating bar
- Rotating impeller
- Rotating screen

6. Tumbling Mills

Tumbling mill subclasses primarily differ in the grinding media used and whether the mill is vibrated.

- Ball media
- Rod media
- Vibrating

7. Separators

Separator subclasses primarily differ in the mechanical means used to induce particle movement.

- Centrifugal
- Vibratory or shaker

Note that if a single piece of equipment is capable of performing multiple discrete unit operations, it has been evaluated solely for its ability to affect particle size or separation.

III. MIXING

A. Definitions

1. Unit Operation

Mixing is the reorientation of particles relative to one another to achieve uniformity or randomness. This process can include wetting of solids by a liquid phase, dispersion of discrete particles, or deagglomeration into a continuous phase. Heating and cooling via indirect conduction may be used in this operation to facilitate phase mixing or stabilization.

2. Operating Principles

a. Convection Mixing, Low Shear

Convection mixing, low shear, is a mixing process with a repeated pattern of cycling material from top to bottom in which dispersion occurs under low power per unit mass through rotating low shear forces.

b. Convection Mixing, High Shear

Convection mixing, high shear, is a mixing process with a repeated pattern of cycling material from top to bottom in which dispersion occurs under high power per unit mass through rotating high shear forces.

c. Roller Mixing (Milling)

Also known as milling, roller mixing is a mixing process by high mechanical shearing action where compression stress is achieved by passing material between a series of rotating rolls. This is commonly referred to as compression or roller milling.

d. Static Mixing

In static mixing, material passes through a tube with stationary baffles. The mixer is generally used in conjunction with an in-line pump.

B. Equipment Classification

1. Convection Mixers, Low Shear

This group of mixers normally operates under low-shear conditions and is broken down by impeller design and movement. Design can also include a jacketed vessel to facilitate heat transfer.

- Anchor or sweepgate
- Impeller
- Planetary

2. Convection Mixers, High Shear

These mixers normally operate only under high-shear conditions. Subclasses are differentiated by how the high shear is introduced into the material, such as by a dispersator with serrated blades or homogenizer with rotor stator.

- Dispersator
- Rotor stator

3. Roller Mixers (Mills)

No roller mixer subclasses have been identified.

4. Static Mixers

No static mixer subclasses have been identified.

Note that if a single piece of equipment is capable of performing multiple discrete unit operations, it has been evaluated solely for its ability to mix materials.

5. Low-Shear Emulsifiers

Although low-shear emulsification equipment (mechanical stirrers or impellers) can differ in the type of fluid flow imparted to the mixture (axial-flow propeller or radial-flow turbines), no subclasses have been defined.

IV. TRANSFER

A. Definitions

1. Unit Operation

Transfer is the controlled movement or transfer of materials from one location to another.

2. Operating Principles

a. Passive

Passive transfer is the movement of materials across a non-mechanically induced pressure gradient, usually through a conduit or pipe.

b. Active

The movement of materials across a mechanically induced pressure gradient, usually through conduit or pipe, is known as active transfer.

B. Equipment Classification

1. Low Shear

Equipment used for active or passive material transfer, with a low degree of induced shear, is classified as "low-shear" equipment:

- Diaphragm
- Gravity
- Peristaltic
- Piston
- Pneumatic
- Rotating lobe
- Screw or helical screw

2. High Shear

Active or mechanical material transfer with a high degree of induced shear is performed by what is known as "high-shear" equipment:

- Centrifugal or turbine
- Piston
- Rotating gear

A single piece of equipment can be placed in either a low- or high-shear class, depending on its operating parameters. If a single piece of equipment is capable of performing multiple discrete unit operations, the unit has been evaluated solely for its ability to transfer materials.

V. PACKAGING

A. Definitions

1. Unit Operation

a. Holding

The process of storing product after completion of manufacturing process and before filling final primary packs is known as holding.

b. Transfer

Transfer is the process of relocating bulk finished product from holding to filling equipment using pipe, hose, pumps, or other associated components.

c. Filling

Filling is the delivery of target weight or volume of bulk finished product to primary pack containers.

d. Sealing

A device or process for closing or sealing primary pack containers, known collectively as sealing, follows the filling process.

2. Operating Principles

a. Holding

The storage of liquid, semisolids, or product materials in a vessel that may or may not have temperature control or agitation is called holding.

b. Transfer

The controlled movement or transfer of materials from one location to another is known as transfer.

c. Filling

Filling operating principles involve several associated subprinciples. The primary package can be precleaned to remove particulates or other materials by the use of ionized air, vacuum, or inversion. A holding vessel equipped with an auger, gravity, or pressure material feeding system should be used. The vessel may or may not be able to control temperature or agitation. Actual filling of the dosage form into primary containers can involve a metering system based on an auger, gear, orifice, peristaltic, or piston pump. A headspace blanketing system can also be used.

d. Sealing

Primary packages can be sealed using a variety of methods, including conducted heat and electromagnetic (induction or microwave) or mechanical manipulation (crimping or torqueing).

B. Equipment Classification

1. Holders

Although holding vessels can differ in their geometry and ability to control temperature or agitation, their primary differences are based on how materials are fed. Feeding devices include the following:

- Auger
- Gravity
- Pneumatic (nitrogen, air, etc.)

2. Fillers

The primary differences in filling equipment are based on how materials are metered. Different varieties of filling equipment include the following:

- Auger
- Gear pump

- Orifice
- Peristaltic pump
- Piston

3. Sealers

The differences in primary container sealing are based on how energy is transferred or applied. Energy transfer can be accomplished via the following:

- Heat
- Induction
- Microwave
- Mechanical or crimping
- Torque

6 Good Manufacturing Practice Guide for Active Pharmaceutical Ingredients

1. INTRODUCTION

1.1. Objective

This document (Guide) is intended to provide guidance regarding good manufacturing practice (GMP) for the manufacturing of active pharmaceutical ingredients (APIs) under an appropriate system for managing quality. It is also intended to help ensure that APIs meet the requirements for quality and purity that they purport or are represented to possess.

In this Guide "manufacturing" is defined to include all operations of receipt of materials, production, packaging, repackaging, labeling, relabeling, quality control (QC), release, storage and distribution of APIs, and the related controls. In this Guide the term "should" indicates recommendations that are expected to apply unless shown to be inapplicable or replaced by an alternative demonstrated to provide at least an equivalent level of quality assurance (QA). For the purposes of this Guide, the terms "current good manufacturing practices" and "good manufacturing practices" are equivalent.

The Guide as a whole does not cover safety aspects for the personnel engaged in the manufacture, nor aspects of protection of the environment. These controls are inherent responsibilities of the manufacturer and are governed by national laws.

This Guide is not intended to define registration/filing requirements or modify pharmacopoeial requirements. This Guide does not affect the ability of the responsible regulatory agency to establish specific registration/filing requirements regarding APIs within the context of marketing/manufacturing authorizations or drug applications. All commitments in registration/filing documents must be met.

1.2. Regulatory Applicability

Within the world community, materials may vary as to the legal classification as an API. When a material is classified as an API in the region or country in which it is manufactured or used in a drug product, it should be manufactured according to this Guide.

1.3. Scope

This Guide applies to the manufacture of APIs for use in human drug (medicinal) products. It applies to the manufacture of sterile APIs only up to the point immediately prior to the APIs being rendered sterile. The sterilization and aseptic processing of sterile APIs are not covered by this guidance but should be performed in accordance with GMP guidelines for drug (medicinal) products as defined by local authorities.

This Guide covers APIs that are manufactured by chemical synthesis, extraction, cell culture/fermentation, by recovery from natural sources, or by any combination of these processes. Specific guidance for APIs manufactured by cell culture/fermentation is described in Section 18.

This Guide excludes all vaccines, whole cells, whole blood and plasma, blood and plasma derivatives (plasma fractionation), and gene therapy APIs. However, it does include APIs that are produced using blood or plasma as raw materials. Note that cell substrates (mammalian, plant, insect or microbial cells, tissue or animal sources including transgenic animals) and early process steps may be subject to GMP but are not covered by this Guide. In addition, the Guide does not apply to medical gases, bulk-packaged drug (medicinal) products, and manufacturing/control aspects specific to radiopharmaceuticals.

Section 19 contains guidance that only applies to the manufacture of APIs used in the production of drug (medicinal) products specifically for clinical trials (investigational medicinal products).

An "API Starting Material" is a raw material, intermediate, or an API that is used in the production of an API and that is incorporated as a significant structural fragment into the structure of the API. An API Starting Material can be an article of commerce, a material purchased from one or more suppliers under contract or commercial agreement, or produced in-house. API Starting Materials normally have defined chemical properties and structure.

The company should designate and document the rationale for the point at which production of the API begins. For synthetic processes, this is known as the point at which "API Starting Materials" are entered into the process. For other processes (e.g., fermentation, extraction, purification), this rationale should be established on a case-by-case basis. Table 6.1 gives guidance on the point at which the API Starting Material is normally introduced into the process.

From this point on, appropriate GMP as defined in this Guide should be applied to these intermediate and/or API manufacturing steps. This would include the validation of critical process steps determined to impact the quality of the API. However, it should be noted that the fact that a company chooses to validate a process step does not necessarily define that step as critical.

The guidance in this document would normally be applied to the steps shown in gray in Table 6.1. It does not imply that all steps shown should be completed. The stringency of GMP in API manufacturing should increase as the process proceeds from early API steps to final steps, purification, and packaging. Physical processing of APIs, such as granulation, coating, or

TABLE 6.1
Application of This Guide to API Manufacturing

Type of Manufacturing	Application of This Guide to Steps (Shown in Gray) Used in This Type of Manufacturing				
Chemical manufacturing	Production of the API Starting Material	Introduction of the API Starting Material into process	Production of intermediate(s)	Isolation and purification	Physical processing and packaging
API derived from animal sources	Collection of organ, fluid, or tissue	Cutting, mixing, and/or initial processing	Introduction of the API Starting Material into process	Isolation and purification	Physical processing and packaging
API extracted from plant sources	Collection of plants	Cutting and initial extraction(s)	Introduction of the API Starting Material into process	Isolation and purification	Physical processing and packaging
Herbal extracts used as API	Collection of plants	Cutting and initial extraction		Further extraction	Physical processing and packaging
API consisting of comminuted or powdered herbs	Collection of plants and/or cultivation and harvesting	Cutting/comminuting			Physical processing and packaging
Biotechnology: Fermentation/cell culture	Establishment of master cell bank and working cell bank	Maintenance of working cell bank	Cell culture and/or fermentation	Isolation and purification	Physical processing and packaging
"Classical" fermentation to produce an API	Establishment of cell bank	Maintenance of the cell bank	Introduction of the cells into fermentation	Isolation and purification	Physical processing and packaging

physical manipulation of particle size (e.g., milling, micronizing), should be conducted at least to the standards of this Guide.

This GMP Guide does not apply to steps prior to the introduction of the defined "API Starting Material."

2. QUALITY MANAGEMENT

2.1. Principles

- 2.10 Quality should be the responsibility of all persons involved in manufacturing.
- 2.11 Each manufacturer should establish, document, and implement an effective system for managing quality that involves the active participation of management and appropriate manufacturing personnel.
- 2.12 The system for managing quality should encompass the organizational structure, procedures, processes, and resources, as well as activities necessary to ensure confidence that the API will meet its intended specifications for quality and purity. All quality-related activities should be defined and documented.
- 2.13 There should be a quality unit(s) that is independent of production and that fulfills both QA and QC responsibilities. This can be in the form of separate QA and QC units or a single individual or group, depending upon the size and structure of the organization.
- 2.14 The persons authorized to release intermediates and APIs should be specified.
- 2.15 All quality-related activities should be recorded at the time they are performed.
- 2.16 Any deviation from established procedures should be documented and explained. Critical deviations should be investigated, and the investigation and its conclusions should be documented.
- 2.17 No materials should be released or used before the satisfactory completion of evaluation by the quality unit(s) unless there are appropriate systems in place to allow for such use (e.g., release under quarantine as described in Section 10.20 or the use of raw materials or intermediates pending completion of evaluation).
- 2.18 Procedures should exist for notifying responsible management in a timely manner of regulatory inspections, serious GMP deficiencies, product defects, and related actions (e.g., quality-related complaints, recalls, regulatory actions, etc.).

2.2. Responsibilities of the Quality Unit(s)

- 2.20 The quality unit(s) should be involved in all quality-related matters.
- 2.21 The quality unit(s) should review and approve all appropriate quality-related documents.

- 2.22 The main responsibilities of the independent quality unit(s) should not be delegated. These responsibilities should be described in writing and should include but not necessarily be limited to
  - 1. Releasing or rejecting all APIs. Releasing or rejecting intermediates for use outside the control of the manufacturing company.
  - 2. Establishing a system to release or reject raw materials, intermediates, packaging, and labeling materials.
  - 3. Reviewing completed batch production and laboratory control records of critical process steps before release of the API for distribution.
  - 4. Making sure that critical deviations are investigated and resolved.
  - 5. Approving all specifications and master production instructions.
  - 6. Approving all procedures impacting the quality of intermediates or APIs.
  - 7. Making sure that internal audits (self-inspections) are performed.
  - 8. Approving intermediate and API contract manufacturers.
  - 9. Approving changes that potentially impact intermediate or API quality.
  - 10. Reviewing and approving validation protocols and reports.
  - 11. Making sure that quality-related complaints are investigated and resolved.
  - 12. Making sure that effective systems are used for maintaining and calibrating critical equipment.
  - 13. Making sure that materials are appropriately tested and the results are reported.
  - 14. Making sure that there are stability data to support retest or expiry dates and storage conditions on APIs and/or intermediates where appropriate.
  - 15. Performing product quality reviews (as defined in Section 2.5).

2.3. Responsibility for Production Activities

- The responsibility for production activities should be described in writing and should include but not necessarily be limited to
  - 1. Preparing, reviewing, approving, and distributing the instructions for the production of intermediates or APIs according to written procedures.
  - 2. Producing APIs and, when appropriate, intermediates according to preapproved instructions.
  - 3. Reviewing all production batch records and ensuring that these are completed and signed.
  - 4. Making sure that all production deviations are reported and evaluated and that critical deviations are investigated and the conclusions are recorded.
  - 5. Making sure that production facilities are clean and when appropriate disinfected.
  - 6. Making sure that the necessary calibrations are performed and records kept.
  - 7. Making sure that the premises and equipment are maintained and records kept.
  - 8. Making sure that validation protocols and reports are reviewed and approved.
  - 9. Evaluating proposed changes in product, process, or equipment.
  - 10. Making sure that new and, when appropriate, modified facilities and equipment are qualified.

2.4. Internal Audits (Self-Inspection)

- 2.40 In order to verify compliance with the principles of GMP for APIs, regular internal audits should be performed in accordance with an approved schedule.
- 2.41 Audit findings and corrective actions should be documented and brought to the attention of responsible management of the firm. Agreed corrective actions should be completed in a timely and effective manner.

2.5. Product Quality Review

- 2.50 Regular quality reviews of APIs should be conducted with the objective of verifying the consistency of the process. Such reviews should normally be conducted and documented annually and should include at least
  - A review of critical in-process control and critical API test results
  - A review of all batches that failed to meet established specification(s)
  - A review of all critical deviations or nonconformances and related investigations
  - A review of any changes carried out to the processes or analytical methods
  - A review of results of the stability monitoring program
  - A review of all quality-related returns, complaints, and recalls and
  - A review of adequacy of corrective actions
- 2.51 The results of this review should be evaluated and an assessment made of whether corrective action or any revalidation should be undertaken. Reasons for such corrective action should be documented. Agreed corrective actions should be completed in a timely and effective manner.

3. PERSONNEL

3.1. Personnel Qualifications

- 3.10 There should be an adequate number of personnel qualified by appropriate education, training, and/or experience to perform and supervise the manufacture of intermediates and APIs.

- 3.11 The responsibilities of all personnel engaged in the manufacture of intermediates and APIs should be specified in writing.
- 3.12 Training should be regularly conducted by qualified individuals and should cover, at a minimum, the particular operations that the employee performs and GMP as it relates to the employee's functions. Records of training should be maintained. Training should be periodically assessed.

3.2. Personnel Hygiene

- 3.20 Personnel should practice good sanitation and health habits.
- 3.21 Personnel should wear clean clothing suitable for the manufacturing activity with which they are involved, and this clothing should be changed when appropriate. Additional protective apparel, such as head, face, hand, and arm coverings, should be worn when necessary, to protect intermediates and APIs from contamination.
- 3.22 Personnel should avoid direct contact with intermediates or APIs.
- 3.23 Smoking, eating, drinking, chewing, and the storage of food should be restricted to certain designated areas separate from the manufacturing areas.
- 3.24 Personnel suffering from an infectious disease or having open lesions on the exposed surface of the body should not engage in activities that could result in compromising the quality of APIs. Any person shown at any time (either by medical examination or supervisory observation) to have an apparent illness or open lesions should be excluded from activities where the health condition could adversely affect the quality of the APIs until the condition is corrected or qualified medical personnel determine that the person's inclusion would not jeopardize the safety or quality of the APIs.

3.3. Consultants

- 3.30 Consultants advising on the manufacture and control of intermediates or APIs should have sufficient education, training, and experience, or any combination thereof, to advise on the subject for which they are retained.
- 3.31 Records should be maintained stating the name, address, qualifications, and type of service provided by these consultants.

4. BUILDINGS AND FACILITIES

4.1. Design and Construction

- 4.10 Buildings and facilities used in the manufacture of intermediates and APIs should be located, designed, and constructed to facilitate cleaning, maintenance, and operations as appropriate to the type and stage of manufacture. Facilities should also be designed to minimize potential contamination. Where microbiological specifications have been established for the intermediate or API, facilities should also be designed to limit exposure to objectionable microbiological contaminants as appropriate.
- 4.11 Buildings and facilities should have adequate space for the orderly placement of equipment and materials to prevent mix-ups and contamination.
- 4.12 Where the equipment itself (e.g., closed or contained systems) provides adequate protection of the material, such equipment can be located outdoors.
- 4.13 The flow of materials and personnel through the building or facilities should be designed to prevent mix-ups or contamination.
- 4.14 There should be defined areas or other control systems for the following activities:
  - Receipt, identification, sampling, and quarantine of incoming materials, pending release or rejection
  - Quarantine before release or rejection of intermediates and APIs
  - Sampling of intermediates and APIs
  - Holding rejected materials before further disposition (e.g., return, reprocessing, or destruction)
  - Storage of released materials
  - Production operations
  - Packaging and labeling operations
  - Laboratory operations
- 4.15 Adequate, clean washing and toilet facilities should be provided for personnel. These washing facilities should be equipped with hot and cold water as appropriate, soap or detergent, air driers or single service towels. The washing and toilet facilities should be separate from, but easily accessible to, manufacturing areas. Adequate facilities for showering and/or changing clothes should be provided, when appropriate.
- 4.16 Laboratory areas/operations should normally be separated from production areas. Some laboratory areas, in particular those used for in-process controls, can be located in production areas, provided the operations of the production process do not adversely affect the accuracy of the laboratory measurements and the laboratory and its operations do not adversely affect the production process or intermediate or API.

4.2. Utilities

- 4.20 All utilities that could impact on product quality (e.g., steam, gases, compressed air, and heating, ventilation and air conditioning) should be qualified and appropriately monitored, and action should be taken when limits are exceeded. Drawings for these utility systems should be available.
- 4.21 Adequate ventilation, air filtration, and exhaust systems should be provided, where appropriate.

These systems should be designed and constructed to minimize risks of contamination and cross-contamination and should include equipment for control of air pressure, microorganisms (if appropriate), dust, humidity, and temperature, as appropriate to the stage of manufacture. Particular attention should be given to areas where APIs are exposed to the environment.

- 4.22 If air is recirculated to production areas, appropriate measures should be taken to control risks of contamination and cross-contamination.
- 4.23 Permanently installed pipework should be appropriately identified. This can be accomplished by identifying individual lines, documentation, computer control systems, or alternative means. Pipework should be located to avoid risks of contamination of the intermediate or API.
- 4.24 Drains should be of adequate size and should be provided with an air break or a suitable device to prevent back-siphonage, when appropriate.

4.3. Water

- 4.30 Water used in the manufacture of APIs should be demonstrated to be suitable for its intended use.
- 4.31 Unless otherwise justified, process water should, at a minimum, meet World Health Organization (WHO) guidelines for drinking (potable) water quality.
- 4.32 If drinking (potable) water is insufficient to assure API quality, and tighter chemical and/or microbiological water quality specifications are called for, appropriate specifications for physical/chemical attributes, total microbial counts, objectionable organisms, and/or endotoxins should be established.
- 4.33 Where water used in the process is treated by the manufacturer to achieve a defined quality, the treatment process should be validated and monitored with appropriate action limits.
- 4.34 Where the manufacturer of a nonsterile API either intends or claims that it is suitable for use in further processing to produce a sterile drug (medicinal) product, water used in the final isolation and purification steps should be monitored and controlled for total microbial counts, objectionable organisms, and endotoxins.

4.4. Containment

- 4.40 Dedicated production areas, which can include facilities, air handling equipment, and/or process equipment, should be employed in the production of highly sensitizing materials, such as penicillins or cephalosporins.
- 4.41 Dedicated production areas should also be considered when material of an infectious nature or high pharmacological activity or toxicity is involved (e.g., certain steroids or cytotoxic anticancer agents) unless validated inactivation and/or cleaning procedures are established and maintained.
- 4.42 Appropriate measures should be established and implemented to prevent cross-contamination from personnel, materials, etc. moving from one dedicated area to another.
- 4.43 Any production activities (including weighing, milling, or packaging) of highly toxic nonpharmaceutical materials such as herbicides and pesticides should not be conducted using the buildings and/or equipment being used for the production of APIs. Handling and storage of these highly toxic nonpharmaceutical materials should be separate from APIs.

4.5. Lighting

- 4.50 Adequate lighting should be provided in all areas to facilitate cleaning, maintenance, and proper operations.

4.6. Sewage and Refuse

- 4.60 Sewage, refuse, and other waste (e.g., solids, liquids, or gaseous by-products from manufacturing) in and from buildings and the immediate surrounding area should be disposed of in a safe, timely, and sanitary manner. Containers and/or pipes for waste material should be clearly identified.

4.7. Sanitation and Maintenance

- 4.70 Buildings used in the manufacture of intermediates and APIs should be properly maintained and repaired and kept in a clean condition.
- 4.71 Written procedures should be established assigning responsibility for sanitation and describing the cleaning schedules, methods, equipment, and materials to be used in cleaning buildings and facilities.
- 4.72 When necessary, written procedures should also be established for the use of suitable rodenticides, insecticides, fungicides, fumigating agents, and cleaning and sanitizing agents to prevent the contamination of equipment, raw materials, packaging/labeling materials, intermediates, and APIs.

5. PROCESS EQUIPMENT

5.1. Design and Construction

- 5.10 Equipment used in the manufacture of intermediates and APIs should be of appropriate design and adequate size and suitably located for its intended use, cleaning, sanitization (where appropriate), and maintenance.

- 5.11 Equipment should be constructed so that surfaces that contact raw materials, intermediates, or APIs do not alter the quality of the intermediates and APIs beyond the official or other established specifications.
- 5.12 Production equipment should only be used within its qualified operating range.
- 5.13 Major equipment (e.g., reactors, storage containers) and permanently installed processing lines used during the production of an intermediate or API should be appropriately identified.
- 5.14 Any substances associated with the operation of equipment, such as lubricants, heating fluids, or coolants, should not contact intermediates or APIs so as to alter their quality beyond the official or other established specifications. Any deviations from this should be evaluated to ensure that there are no detrimental effects upon the fitness for purpose of the material. Wherever possible, food-grade lubricants and oils should be used.
- 5.15 Closed or contained equipment should be used whenever appropriate. Where open equipment is used, or equipment is opened, appropriate precautions should be taken to minimize the risk of contamination.
- 5.16 A set of current drawings should be maintained for equipment and critical installations (e.g., instrumentation and utility systems).

5.2. Equipment Maintenance and Cleaning

- 5.20 Schedules and procedures (including assignment of responsibility) should be established for the preventative maintenance of equipment.
- 5.21 Written procedures should be established for cleaning of equipment and its subsequent release for use in the manufacture of intermediates and APIs. Cleaning procedures should contain sufficient details to enable operators to clean each type of equipment in a reproducible and effective manner. These procedures should include
  - Assignment of responsibility for cleaning of equipment
  - Cleaning schedules, including, where appropriate, sanitizing schedules
  - A complete description of the methods and materials, including dilution of cleaning agents used to clean equipment
  - When appropriate, instructions for disassembling and reassembling each article of equipment to ensure proper cleaning
  - Instructions for the removal or obliteration of previous batch identification
  - Instructions for the protection of clean equipment from contamination prior to use
  - Inspection of equipment for cleanliness immediately before use, if practical and
  - Establishing the maximum time that may elapse between the completion of processing and equipment cleaning, when appropriate
- 5.22 Equipment and utensils should be cleaned, stored, and, where appropriate, sanitized or sterilized to prevent contamination or carryover of a material that would alter the quality of the intermediate or API beyond the official or other established specifications.
- 5.23 Where equipment is assigned to continuous production or campaign production of successive batches of the same intermediate or API, equipment should be cleaned at appropriate intervals to prevent buildup and carryover of contaminants (e.g., degradants or objectionable levels of microorganisms).
- 5.24 Nondedicated equipment should be cleaned between production of different materials to prevent cross-contamination.
- 5.25 Acceptance criteria for residues and the choice of cleaning procedures and cleaning agents should be defined and justified.
- 5.26 Equipment should be identified as to its contents and its cleanliness status by appropriate means.

5.3. Calibration

- 5.30 Control, weighing, measuring, monitoring, and test equipment that is critical for assuring the quality of intermediates or APIs should be calibrated according to written procedures and an established schedule.
- 5.31 Equipment calibrations should be performed using standards traceable to certified standards, if existing.
- 5.32 Records of these calibrations should be maintained.
- 5.33 The current calibration status of critical equipment should be known and verifiable.
- 5.34 Instruments that do not meet calibration criteria should not be used.
- 5.35 Deviations from approved standards of calibration on critical instruments should be investigated to determine if these could have had an impact on the quality of the intermediate(s) or API(s) manufactured using this equipment since the last successful calibration.

5.4. Computerized Systems

- 5.40 GMP-related computerized systems should be validated. The depth and scope of validation depends on the diversity, complexity, and criticality of the computerized application.
- 5.41 Appropriate installation qualification and operational qualification should demonstrate the suitability of computer hardware and software to perform assigned tasks.

- 5.42 Commercially available software that has been qualified does not require the same level of testing. If an existing system was not validated at time of installation, a retrospective validation could be conducted if appropriate documentation is available.
- 5.43 Computerized systems should have sufficient controls to prevent unauthorized access or changes to data. There should be controls to prevent omissions in data (e.g., system turned off and data not captured). There should be a record of any data change made, the previous entry, who made the change, and when the change was made.
- 5.44 Written procedures should be available for the operation and maintenance of computerized systems.
- 5.45 Where critical data are being entered manually, there should be an additional check on the accuracy of the entry. This can be done by a second operator or by the system itself.
- 5.46 Incidents related to computerized systems that could affect the quality of intermediates or APIs or the reliability of records or test results should be recorded and investigated.
- 5.47 Changes to the computerized system should be made according to a change procedure and should be formally authorized, documented, and tested. Records should be kept of all changes, including modifications and enhancements made to the hardware, software, and any other critical component of the system. These records should demonstrate that the system is maintained in a validated state.
- 5.48 If system breakdowns or failures would result in the permanent loss of records, a backup system should be provided. A means of ensuring data protection should be established for all computerized systems.
- 5.49 Data can be recorded by a second means in addition to the computer system.

6. DOCUMENTATION AND RECORDS

6.1. Documentation System and Specifications

- 6.10 All documents related to the manufacture of intermediates or APIs should be prepared, reviewed, approved, and distributed according to written procedures. Such documents can be in paper or electronic form.
- 6.11 The issuance, revision, superseding, and withdrawal of all documents should be controlled with maintenance of revision histories.
- 6.12 A procedure should be established for retaining all appropriate documents (e.g., development history reports, scale-up reports, technical transfer reports, process validation reports, training records, production records, control records, and distribution records). The retention periods for these documents should be specified.
- 6.13 All production, control, and distribution records should be retained for at least 1 year after the expiry date of the batch. For APIs with retest dates, records should be retained for at least 3 years after the batch is completely distributed.
- 6.14 When entries are made in records, these should be made indelibly in spaces provided for such entries, directly after performing the activities, and should identify the person making the entry. Corrections to entries should be dated and signed and leave the original entry still readable.
- 6.15 During the retention period, originals or copies of records should be readily available at the establishment where the activities described in such records occurred. Records that can be promptly retrieved from another location by electronic or other means are acceptable.
- 6.16 Specifications, instructions, procedures, and records can be retained either as originals or as true copies such as photocopies, microfilm, microfiche, or other accurate reproductions of the original records. Where reduction techniques such as microfilming or electronic records are used, suitable retrieval equipment and a means to produce a hard copy should be readily available.
- 6.17 Specifications should be established and documented for raw materials, intermediates where necessary, APIs, and labeling and packaging materials. In addition, specifications may be appropriate for certain other materials, such as process aids, gaskets, or other materials used during the production of intermediates or APIs that could critically impact on quality. Acceptance criteria should be established and documented for in-process controls.
- 6.18 If electronic signatures are used on documents, they should be authenticated and secure.

6.2. Equipment Cleaning and Use Record

- 6.20 Records of major equipment use, cleaning, sanitization and/or sterilization, and maintenance should show the date, time (if appropriate), product, and batch number of each batch processed in the equipment, and the person who performed the cleaning and maintenance.
- 6.21 If equipment is dedicated to manufacturing one intermediate or API, then individual equipment records are not necessary if batches of the intermediate or API follow in traceable sequence. In cases where dedicated equipment is employed, the records of cleaning, maintenance, and use can be part of the batch record or maintained separately.

6.3. Records of Raw Materials, Intermediates, API Labeling and Packaging Materials

- 6.30 Records should be maintained including
  - The name of the manufacturer, identity, and quantity of each shipment of each batch of raw

materials, intermediates, or labeling and packaging materials for APIs; the name of the supplier; the supplier's control number(s), if known, or other identification number; the number allocated on receipt; and the date of receipt
    - The results of any test or examination performed and the conclusions derived from this
    - Records tracing the use of materials
    - Documentation of the examination and review of API labeling and packaging materials for conformity with established specifications and
    - The final decision regarding rejected raw materials, intermediates, or API labeling and packaging materials
- 6.31 Master (approved) labels should be maintained for comparison to issued labels.

6.4. Master Production Instructions (Master Production and Control Records)

- 6.40 To ensure uniformity from batch to batch, master production instructions for each intermediate and API should be prepared, dated, and signed by one person and independently checked, dated, and signed by a person in the quality unit(s).
- 6.41 Master production instructions should include
    - The name of the intermediate or API being manufactured and an identifying document reference code, if applicable.
    - A complete list of raw materials and intermediates designated by names or codes sufficiently specific to identify any special quality characteristics.
    - An accurate statement of the quantity or ratio of each raw material or intermediate to be used, including the unit of measure. Where the quantity is not fixed, the calculation for each batch size or rate of production should be included. Variations to quantities should be included where they are justified.
    - The production location and major production equipment to be used.
    - Detailed production instructions, including the
        - Sequences to be followed
        - Ranges of process parameters to be used
        - Sampling instructions and in-process controls with their acceptance criteria, where appropriate
        - Time limits for completion of individual processing steps and/or the total process, where appropriate and
    - Expected yield ranges at appropriate phases of processing or time
    - Where appropriate, special notations and precautions to be followed or cross-references to these.
    - The instructions for storage of the intermediate or API to assure its suitability for use, including the labeling and packaging materials and special storage conditions with time limits, where appropriate.

6.5. Batch Production Records (Batch Production and Control Records)

- 6.50 Batch production records should be prepared for each intermediate and API and should include complete information relating to the production and control of each batch. The batch production record should be checked before issuance to assure that it is the correct version and a legible accurate reproduction of the appropriate master production instruction. If the batch production record is produced from a separate part of the master document, that document should include a reference to the current master production instruction being used.
- 6.51 These records should be numbered with a unique batch or identification number, dated, and signed when issued. In continuous production, the product code together with the date and time can serve as the unique identifier until the final number is allocated.
- 6.52 Documentation of completion of each significant step in the batch production records (batch production and control records) should include
    - Dates and, when appropriate, times
    - Identity of major equipment (e.g., reactors, driers, mills, etc.) used
    - Specific identification of each batch, including weights, measures, and batch numbers of raw materials, intermediates, or any reprocessed materials used during manufacturing
    - Actual results recorded for critical process parameters
    - Any sampling performed
    - Signatures of the persons performing and directly supervising or checking each critical step in the operation
    - In-process and laboratory test results
    - Actual yield at appropriate phases or times
    - Description of packaging and label for intermediate or API
    - Representative label of API or intermediate if made commercially available
    - Any deviation noted, its evaluation, investigation conducted (if appropriate), or reference to that investigation if stored separately and
    - Results of release testing
- 6.53 Written procedures should be established and followed for investigating critical deviations or the failure of a batch of intermediate or API to meet specifications. The investigation should extend to other batches that may have been associated with the specific failure or deviation.

6.6. Laboratory Control Records

- 6.60 Laboratory control records should include complete data derived from all tests conducted to ensure compliance with established specifications and standards, including examinations and assays, as follows:
  - A description of samples received for testing, including the material name or source, batch number or other distinctive code, date sample was taken, and, where appropriate, the quantity and date the sample was received for testing.
  - A statement of or reference to each test method used.
  - A statement of the weight or measure of sample used for each test as described by the method; data on or cross-reference to the preparation and testing of reference standards, reagents, and standard solutions.
  - A complete record of all raw data generated during each test, in addition to graphs, charts, and spectra from laboratory instrumentation, properly identified to show the specific material and batch tested.
  - A record of all calculations performed in connection with the test, including, for example, units of measure, conversion factors, and equivalency factors.
  - A statement of the test results and how they compare with established acceptance criteria.
  - The signature of the person who performed each test and the date(s) the tests were performed.
  - The date and signature of a second person showing that the original records have been reviewed for accuracy, completeness, and compliance with established standards.
- 6.61 Complete records should also be maintained for
  - Any modifications to an established analytical method
  - Periodic calibration of laboratory instruments, apparatus, gauges, and recording devices
  - All stability testing performed on APIs and
  - Out-of-specification (OOS) investigations

6.7. Batch Production Record Review

- 6.70 Written procedures should be established and followed for the review and approval of batch production and laboratory control records, including packaging and labeling, to determine compliance of the intermediate or API with established specifications before a batch is released or distributed.
- 6.71 Batch production and laboratory control records of critical process steps should be reviewed and approved by the quality unit(s) before an API batch is released or distributed. Production and laboratory control records of noncritical process steps can be reviewed by qualified production personnel or other units following procedures approved by the quality unit(s).
- 6.72 All deviation, investigation, and OOS reports should be reviewed as part of the batch record review before the batch is released.
- 6.73 The quality unit(s) can delegate to the production unit the responsibility and authority for release of intermediates, except for those shipped outside the control of the manufacturing company.

7. MATERIALS MANAGEMENT

7.1. General Controls

- 7.10 There should be written procedures describing the receipt, identification, quarantine, storage, handling, sampling, testing, and approval or rejection of materials.
- 7.11 Manufacturers of intermediates and/or APIs should have a system for evaluating the suppliers of critical materials.
- 7.12 Materials should be purchased against an agreed specification, from a supplier or suppliers approved by the quality unit(s).
- 7.13 If the supplier of a critical material is not the manufacturer of that material, the name and address of that manufacturer should be known by the intermediate and/or API manufacturer.
- 7.14 Changing the source of supply of critical raw materials should be treated according to Section 13, Change Control.

7.2. Receipt and Quarantine

- 7.20 Upon receipt and before acceptance, each container or grouping of containers of materials should be examined visually for correct labeling (including correlation between the name used by the supplier and the in-house name, if these are different), container damage, broken seals, and evidence of tampering or contamination. Materials should be held under quarantine until they have been sampled, examined, or tested as appropriate and released for use.
- 7.21 Before incoming materials are mixed with existing stocks (e.g., solvents or stocks in silos), they should be identified as correct, tested, if appropriate, and released. Procedures should be available to prevent discharging incoming materials wrongly into the existing stock.
- 7.22 If bulk deliveries are made in nondedicated tankers, there should be assurance of no cross-contamination from the tanker. Means of providing this assurance could include one or more of the following:
  - Certificate of cleaning
  - Testing for trace impurities
  - Audit of the supplier
- 7.23 Large storage containers, and their attendant manifolds, filling and discharge lines should be appropriately identified.

- 7.24 Each container or grouping of containers (batches) of materials should be assigned and identified with a distinctive code, batch, or receipt number. This number should be used in recording the disposition of each batch. A system should be in place to identify the status of each batch.

7.3. Sampling and Testing of Incoming Production Materials

- 7.30 At least one test to verify the identity of each batch of material should be conducted, with the exception of the materials described below in Section 7.32. A supplier's Certificate of Analysis can be used in place of performing other tests, provided that the manufacturer has a system in place to evaluate suppliers.
- 7.31 Supplier approval should include an evaluation that provides adequate evidence (e.g., past quality history) that the manufacturer can consistently provide material meeting specifications. Full analyses should be conducted on at least three batches before reducing in-house testing. However, as a minimum, a full analysis should be performed at appropriate intervals and compared with the Certificates of Analysis. Reliability of Certificates of Analysis should be checked at regular intervals.
- 7.32 Processing aids, hazardous or highly toxic raw materials, other special materials, or materials transferred to another unit within the company's control do not need to be tested if the manufacturer's Certificate of Analysis is obtained, showing that these raw materials conform to established specifications. Visual examination of containers, labels, and recording of batch numbers should help in establishing the identity of these materials. The lack of on-site testing for these materials should be justified and documented.
- 7.33 Samples should be representative of the batch of material from which they are taken. Sampling methods should specify the number of containers to be sampled, which part of the container to sample, and the amount of material to be taken from each container. The number of containers to sample and the sample size should be based upon a sampling plan that takes into consideration the criticality of the material, material variability, past quality history of the supplier, and the quantity needed for analysis.
- 7.34 Sampling should be conducted at defined locations and by procedures designed to prevent contamination of the material sampled and contamination of other materials.
- 7.35 Containers from which samples are withdrawn should be opened carefully and subsequently reclosed. They should be marked to indicate that a sample has been taken.

7.4. Storage

- 7.40 Materials should be handled and stored in a manner to prevent degradation, contamination, and cross-contamination.
- 7.41 Materials stored in fiber drums, bags, or boxes should be stored off the floor and, when appropriate, suitably spaced to permit cleaning and inspection.
- 7.42 Materials should be stored under conditions and for a period that have no adverse effect on their quality and should normally be controlled so that the oldest stock is used first.
- 7.43 Certain materials in suitable containers can be stored outdoors, provided identifying labels remain legible and containers are appropriately cleaned before opening and use.
- 7.44 Rejected materials should be identified and controlled under a quarantine system designed to prevent their unauthorized use in manufacturing.

7.5. Reevaluation

- 7.50 Materials should be reevaluated as appropriate to determine their suitability for use (e.g., after prolonged storage or exposure to heat or humidity).

8. PRODUCTION AND IN-PROCESS CONTROLS

8.1. Production Operations

- 8.10 Raw materials for intermediate and API manufacturing should be weighed or measured under appropriate conditions that do not affect their suitability for use. Weighing and measuring devices should be of suitable accuracy for the intended use.
- 8.11 If a material is subdivided for later use in production operations, the container receiving the material should be suitable and should be so identified that the following information is available:
  - Material name and/or item code
  - Receiving or control number
  - Weight or measure of material in the new container and
  - Reevaluation or retest date if appropriate
- 8.12 Critical weighing, measuring, or subdividing operations should be witnessed or subjected to an equivalent control. Prior to use, production personnel should verify that the materials are those specified in the batch record for the intended intermediate or API.
- 8.13 Other critical activities should be witnessed or subjected to an equivalent control.
- 8.14 Actual yields should be compared with expected yields at designated steps in the production process. Expected yields with appropriate ranges should be established based on previous laboratory, pilot scale, or manufacturing data. Deviations in yield associated with critical process steps should be investigated to

determine their impact or potential impact on the resulting quality of affected batches.
- 8.15 Any deviation should be documented and explained. Any critical deviation should be investigated.
- 8.16 The processing status of major units of equipment should be indicated either on the individual units of equipment or by appropriate documentation, computer control systems, or alternative means.
- 8.17 Materials to be reprocessed or reworked should be appropriately controlled to prevent unauthorized use.

8.2. Time Limits

- 8.20 If time limits are specified in the master production instruction (see Section 6.41), these time limits should be met to ensure the quality of intermediates and APIs. Deviations should be documented and evaluated. Time limits may be inappropriate when processing to a target value (e.g., pH adjustment, hydrogenation, drying to predetermined specification) because completion of reactions or processing steps are determined by in-process sampling and testing.
- 8.21 Intermediates held for further processing should be stored under appropriate conditions to ensure their suitability for use.

8.3. In-Process Sampling and Controls

- 8.30 Written procedures should be established to monitor the progress and control the performance of processing steps that cause variability in the quality characteristics of intermediates and APIs. In-process controls and their acceptance criteria should be defined based on the information gained during the development stage or historical data.
- 8.31 The acceptance criteria and type and extent of testing can depend on the nature of the intermediate or API being manufactured, the reaction or process step being conducted, and the degree to which the process introduces variability in the product's quality. Less stringent in-process controls may be appropriate in early processing steps, whereas tighter controls may be appropriate for later processing steps (e.g., isolation and purification steps).
- 8.32 Critical in-process controls (and critical process monitoring), including the control points and methods, should be stated in writing and approved by the quality unit(s).
- 8.33 In-process controls can be performed by qualified production department personnel and the process adjusted without prior quality unit(s) approval if the adjustments are made within preestablished limits approved by the quality unit(s). All tests and results should be fully documented as part of the batch record.
- 8.34 Written procedures should describe the sampling methods for in-process materials, intermediates, and APIs. Sampling plans and procedures should be based on scientifically sound sampling practices.
- 8.35 In-process sampling should be conducted using procedures designed to prevent contamination of the sampled material and other intermediates or APIs. Procedures should be established to ensure the integrity of samples after collection.
- 8.36 OOS investigations are not normally needed for in-process tests that are performed for the purpose of monitoring and/or adjusting the process.

8.4. Blending Batches of Intermediates or APIs

- 8.40 For the purpose of this document, blending is defined as the process of combining materials within the same specification to produce a homogeneous intermediate or API. In-process mixing of fractions from single batches (e.g., collecting several centrifuge loads from a single crystallization batch) or combining fractions from several batches for further processing is considered to be part of the production process and is not considered to be blending.
- 8.41 OOS batches should not be blended with other batches for the purpose of meeting specifications. Each batch incorporated into the blend should have been manufactured using an established process and should have been individually tested and found to meet appropriate specifications prior to blending.
- 8.42 Acceptable blending operations include but are not limited to
  - Blending of small batches to increase batch size and
  - Blending of tailings (i.e., relatively small quantities of isolated material) from batches of the same intermediate or API to form a single batch
- 8.43 Blending processes should be adequately controlled and documented, and the blended batch should be tested for conformance to established specifications where appropriate.
- 8.44 The batch record of the blending process should allow traceability back to the individual batches that make up the blend.
- 8.45 Where physical attributes of the API are critical (e.g., APIs intended for use in solid oral dosage forms or suspensions), blending operations should be validated to show homogeneity of the combined batch. Validation should include testing of critical attributes (e.g., particle size distribution, bulk density, and tap density) that may be affected by the blending process.
- 8.46 If the blending could adversely affect stability, stability testing of the final blended batches should be performed.

- 8.47 The expiry or retest date of the blended batch should be based on the manufacturing date of the oldest tailings or batch in the blend.

8.5. Contamination Control

- 8.50 Residual materials can be carried over into successive batches of the same intermediate or API if there is adequate control. Examples include residue adhering to the wall of a micronizer, residual layer of damp crystals remaining in a centrifuge bowl after discharge, and incomplete discharge of fluids or crystals from a processing vessel upon transfer of the material to the next step in the process. Such carryover should not result in the carryover of degradants or microbial contamination that may adversely alter the established API impurity profile.
- 8.51 Production operations should be conducted in a manner that will prevent contamination of intermediates or APIs by other materials.
- 8.52 Precautions to avoid contamination should be taken when APIs are handled after purification.

9. PACKAGING AND IDENTIFICATION LABELING OF APIs AND INTERMEDIATES

9.1. General

- 9.10 There should be written procedures describing the receipt, identification, quarantine, sampling, examination and/or testing and release, and handling of packaging and labeling materials.
- 9.11 Packaging and labeling materials should conform to established specifications. Those that do not comply with such specifications should be rejected to prevent their use in operations for which they are unsuitable.
- 9.12 Records should be maintained for each shipment of labels and packaging materials showing receipt, examination, or testing, and whether accepted or rejected.

9.2. Packaging Materials

- 9.20 Containers should provide adequate protection against deterioration or contamination of the intermediate or API that may occur during transportation and recommended storage.
- 9.21 Containers should be clean and, where indicated by the nature of the intermediate or API, sanitized to ensure that they are suitable for their intended use. These containers should not be reactive, additive, or absorptive so as to alter the quality of the intermediate or API beyond the specified limits.
- 9.22 If containers are reused, they should be cleaned in accordance with documented procedures and all previous labels should be removed or defaced.

9.3. Label Issuance and Control

- 9.30 Access to the label storage areas should be limited to authorized personnel.
- 9.31 Procedures should be used to reconcile the quantities of labels issued, used, and returned and to evaluate discrepancies found between the number of containers labeled and the number of labels issued. Such discrepancies should be investigated, and the investigation should be approved by the quality unit(s).
- 9.32 All excess labels bearing batch numbers or other batch-related printing should be destroyed. Returned labels should be maintained and stored in a manner that prevents mix-ups and provides proper identification.
- 9.33 Obsolete and outdated labels should be destroyed.
- 9.34 Printing devices used to print labels for packaging operations should be controlled to ensure that all imprinting conforms to the print specified in the batch production record.
- 9.35 Printed labels issued for a batch should be carefully examined for proper identity and conformity to specifications in the master production record. The results of this examination should be documented.
- 9.36 A printed label representative of those used should be included in the batch production record.

9.4. Packaging and Labeling Operations

- 9.40 There should be documented procedures designed to ensure that correct packaging materials and labels are used.
- 9.41 Labeling operations should be designed to prevent mix-ups. There should be physical or spatial separation from operations involving other intermediates or APIs.
- 9.42 Labels used on containers of intermediates or APIs should indicate the name or identifying code, the batch number of the product, and storage conditions, when such information is critical to assure the quality of intermediate or API.
- 9.43 If the intermediate or API is intended to be transferred outside the control of the manufacturer's material management system, the name and address of the manufacturer, quantity of contents, and special transport conditions and any special legal requirements should also be included on the label. For intermediates or APIs with an expiry date, the expiry date should be indicated on the label and Certificate of Analysis. For intermediates or APIs with a retest date, the retest date should be indicated on the label and/or Certificate of Analysis.
- 9.44 Packaging and labeling facilities should be inspected immediately before use to ensure that all materials not needed for the next packaging operation have been removed. This examination should

be documented in the batch production records, the facility log, or other documentation system.
- 9.45 Packaged and labeled intermediates or APIs should be examined to ensure that containers and packages in the batch have the correct label. This examination should be part of the packaging operation. Results of these examinations should be recorded in the batch production or control records.
- 9.46 Intermediate or API containers that are transported outside of the manufacturer's control should be sealed in a manner such that, if the seal is breached or missing, the recipient will be alerted to the possibility that the contents may have been altered.

10. STORAGE AND DISTRIBUTION

10.1. Warehousing Procedures

- 10.10 Facilities should be available for the storage of all materials under appropriate conditions (e.g., controlled temperature and humidity when necessary). Records should be maintained of these conditions if they are critical for the maintenance of material characteristics.
- 10.11 Unless there is an alternative system to prevent the unintentional or unauthorized use of quarantined, rejected, returned, or recalled materials, separate storage areas should be assigned for their temporary storage until the decision as to their future use has been taken.

10.2. Distribution Procedures

- 10.20 APIs and intermediates should only be released for distribution to third parties after they have been released by the quality unit(s). APIs and intermediates can be transferred under quarantine to another unit under the company's control when authorized by the quality unit(s) and if appropriate controls and documentation are in place.
- 10.21 APIs and intermediates should be transported in a manner that does not adversely affect their quality.
- 10.22 Special transport or storage conditions for an API or intermediate should be stated on the label.
- 10.23 The manufacturer should ensure that the contract acceptor (contractor) for transportation of the API or intermediate knows and follows the appropriate transport and storage conditions.
- 10.24 A system should be in place by which the distribution of each batch of intermediate and/or API can be readily determined to permit its recall.

11. LABORATORY CONTROLS

11.1. General Controls

- 11.10 The independent quality unit(s) should have at its disposal adequate laboratory facilities.
- 11.11 There should be documented procedures describing sampling, testing, approval or rejection of materials, and recording and storage of laboratory data. Laboratory records should be maintained in accordance with Section 6.6.
- 11.12 All specifications, sampling plans, and test procedures should be scientifically sound and appropriate to ensure that raw materials, intermediates, APIs, and labels and packaging materials conform to established standards of quality and/or purity. Specifications and test procedures should be consistent with those included in the registration/filing. There can be specifications in addition to those in the registration/filing. Specifications, sampling plans, and test procedures, including changes to them, should be drafted by the appropriate organizational unit and reviewed and approved by the quality unit(s).
- 11.13 Appropriate specifications should be established for APIs in accordance with accepted standards and consistent with the manufacturing process. The specifications should include a control of the impurities (e.g., organic impurities, inorganic impurities, and residual solvents). If the API has a specification for microbiological purity, appropriate action limits for total microbial counts and objectionable organisms should be established and met. If the API has a specification for endotoxins, appropriate action limits should be established and met.
- 11.14 Laboratory controls should be followed and documented at the time of performance. Any departures from the above described procedures should be documented and explained.
- 11.15 Any OOS result obtained should be investigated and documented according to a procedure. This procedure should require analysis of the data, assessment of whether a significant problem exists, allocation of the tasks for corrective actions, and conclusions. Any resampling and/or retesting after OOS results should be performed according to a documented procedure.
- 11.16 Reagents and standard solutions should be prepared and labeled following written procedures. "Use by" dates should be applied as appropriate for analytical reagents or standard solutions.
- 11.17 Primary reference standards should be obtained as appropriate for the manufacture of APIs. The source of each primary reference standard should be documented. Records should be maintained of each primary reference standard's storage and use in accordance with the supplier's recommendations. Primary reference standards obtained from an officially recognized source are normally used without testing if stored under conditions consistent with the supplier's recommendations.
- 11.18 Where a primary reference standard is not available from an officially recognized source, an

"in-house primary standard" should be established. Appropriate testing should be performed to establish fully the identity and purity of the primary reference standard. Appropriate documentation of this testing should be maintained.

- 11.19 Secondary reference standards should be appropriately prepared, identified, tested, approved, and stored. The suitability of each batch of secondary reference standard should be determined prior to first use by comparing against a primary reference standard. Each batch of secondary reference standard should be periodically requalified in accordance with a written protocol.

11.2. Testing of Intermediates and APIs

- 11.20 For each batch of intermediate and API, appropriate laboratory tests should be conducted to determine conformance to specifications.
- 11.21 An impurity profile describing the identified and unidentified impurities present in a typical batch produced by a specific controlled production process should normally be established for each API. The impurity profile should include the identity or some qualitative analytical designation (e.g., retention time), the range of each impurity observed, and classification of each identified impurity (e.g., inorganic, organic, solvent). The impurity profile is normally dependent upon the production process and origin of the API. Impurity profiles are normally not necessary for APIs from herbal or animal tissue origin. Biotechnology considerations are covered in ICH Guideline Q6B.
- 11.22 The impurity profile should be compared at appropriate intervals against the impurity profile in the regulatory submission or compared against historical data in order to detect changes to the API resulting from modifications in raw materials, equipment operating parameters, or the production process.
- 11.23 Appropriate microbiological tests should be conducted on each batch of intermediate and API where microbial quality is specified.

11.3. Validation of Analytical Procedures (see Section 12)

11.4. Certificates of Analysis

- 11.40 Authentic Certificates of Analysis should be issued for each batch of intermediate or API on request.
- 11.41 Information on the name of the intermediate or API including where appropriate its grade, the batch number, and the date of release should be provided on the Certificate of Analysis. For intermediates or APIs with an expiry date, the expiry date should be provided on the label and Certificate of Analysis. For intermediates or APIs with a retest date, the retest date should be indicated on the label and/or Certificate of Analysis.
- 11.42 The Certificate should list each test performed in accordance with compendial or customer requirements, including the acceptance limits and the numerical results obtained (if test results are numerical).
- 11.43 Certificates should be dated and signed by authorized personnel of the quality unit(s) and should show the name, address, and telephone number of the original manufacturer. Where the analysis has been carried out by a repacker or reprocessor, the Certificate of Analysis should show the name, address, and telephone number of the repacker/reprocessor and a reference to the name of the original manufacturer.
- 11.44 If new Certificates are issued by or on behalf of repackers/reprocessors, agents, or brokers, these Certificates should show the name, address, and telephone number of the laboratory that performed the analysis. They should also contain a reference to the name and address of the original manufacturer and to the original batch Certificate, a copy of which should be attached.

11.5. Stability Monitoring of APIs

- 11.50 A documented, ongoing testing program should be designed to monitor the stability characteristics of APIs, and the results should be used to confirm appropriate storage conditions and retest or expiry dates.
- 11.51 The test procedures used in stability testing should be validated and be stability indicating.
- 11.52 Stability samples should be stored in containers that simulate the market container. For example, if the API is marketed in bags within fiber drums, stability samples can be packaged in bags of the same material and in smaller-scale drums of similar or identical material composition to the market drums.
- 11.53 Normally the first three commercial production batches should be placed on the stability monitoring program to confirm the retest or expiry date. However, where data from previous studies show that the API is expected to remain stable for at least 2 years, fewer than three batches can be used.
- 11.54 Thereafter, at least one batch per year of API manufactured (unless none is produced that year) should be added to the stability monitoring program and tested at least annually to confirm the stability.
- 11.55 For APIs with short shelf lives, testing should be done more frequently. For example, for those biotechnological/biological and other APIs with shelf lives of 1 year or less, stability samples should be

obtained and should be tested monthly for the first 3 months and at 3-month intervals after that. When data exist that confirm that the stability of the API is not compromised, elimination of specific test intervals (e.g., 9-month testing) can be considered.
- 11.56 Where appropriate, the stability storage conditions should be consistent with the ICH guidelines on stability.

11.6. Expiry and Retest Dating

- 11.60 When an intermediate is intended to be transferred outside the control of the manufacturer's material management system and an expiry or retest date is assigned, supporting stability information should be available (e.g., published data, test results).
- 11.61 An API expiry or retest date should be based on an evaluation of data derived from stability studies. Common practice is to use a retest date, not an expiration date.
- 11.62 Preliminary API expiry or retest dates can be based on pilot scale batches if the pilot batches employ a method of manufacture and procedure that simulates the final process to be used on a commercial manufacturing scale and the quality of the API represents the material to be made on a commercial scale.
- 11.63 A representative sample should be taken for the purpose of performing a retest.

11.7. Reserve/Retention Samples

- 11.70 The packaging and holding of reserve samples is for the purpose of potential future evaluation of the quality of batches of API and not for future stability testing purposes.
- 11.71 Appropriately identified reserve samples of each API batch should be retained for 1 year after the expiry date of the batch assigned by the manufacturer, or for 3 years after distribution of the batch, whichever is the longer. For APIs with retest dates, similar reserve samples should be retained for 3 years after the batch is completely distributed by the manufacturer.
- 11.72 The reserve sample should be stored in the same packaging system in which the API is stored or in one that is equivalent to or more protective than the marketed packaging system. Sufficient quantities should be retained to conduct at least two full compendial analyses or, when there is no pharmacopoeial monograph, two full specification analyses.

12. VALIDATION

12.1. Validation Policy

- 12.10 The company's overall policy, intentions, and approach to validation, including the validation of production processes, cleaning procedures, analytical methods, in-process control test procedures, computerized systems, and persons responsible for design, review, approval, and documentation of each validation phase, should be documented.
- 12.11 The critical parameters/attributes should normally be identified during the development stage or from historical data, and the ranges necessary for the reproducible operation should be defined. This should include:
  - Defining the API in terms of its critical product attributes
  - Identifying process parameters that could affect the critical quality attributes of the API and
  - Determining the range for each critical process parameter expected to be used during routine manufacturing and process control
- 12.12 Validation should extend to those operations determined to be critical to the quality and purity of the API.

12.2. Validation Documentation

- 12.20 A written validation protocol should be established that specifies how validation of a particular process will be conducted. The protocol should be reviewed and approved by the quality unit(s) and other designated units.
- 12.21 The validation protocol should specify critical process steps and acceptance criteria as well as the type of validation to be conducted (e.g., retrospective, prospective, concurrent) and the number of process runs.
- 12.22 A validation report that cross-references the validation protocol should be prepared, summarizing the results obtained, commenting on any deviations observed, and drawing the appropriate conclusions, including recommending changes to correct deficiencies.
- 12.23 Any variations from the validation protocol should be documented with appropriate justification.

12.3. Qualification

- 12.30 Before starting process validation activities, appropriate qualification of critical equipment and ancillary systems should be completed. Qualification is usually carried out by conducting the following activities, individually or combined:
  - Design Qualification (DQ): Documented verification that the proposed design of the facilities, equipment, or systems is suitable for the intended purpose.
  - Installation Qualification (IQ): Documented verification that the equipment or systems, as installed or modified, comply with the approved design, the manufacturer's recommendations, and/or user requirements.

- Operational Qualification (OQ): Documented verification that the equipment or systems, as installed or modified, perform as intended throughout the anticipated operating ranges.
- Performance Qualification (PQ): Documented verification that the equipment and ancillary systems, as connected together, can perform effectively and reproducibly based on the approved process method and specifications.

12.4. Approaches to Process Validation

- 12.40 Process validation is the documented evidence that the process, operated within established parameters, can perform effectively and reproducibly to produce an intermediate or API meeting its predetermined specifications and quality attributes.
- 12.41 There are three approaches to validation. Prospective validation is the preferred approach, but there are exceptions where the other approaches can be used. These approaches and their applicability are listed below.
- 12.42 Prospective validation should normally be performed for all API processes as defined in Section 12.12. Prospective validation performed on an API process should be completed before the commercial distribution of the final drug product manufactured from that API.
- 12.43 Concurrent validation can be conducted when data from replicate production runs are unavailable because only a limited number of API batches have been produced, API batches are produced infrequently, or API batches are produced by a validated process that has been modified. Prior to the completion of concurrent validation, batches can be released and used in final drug product for commercial distribution based on thorough monitoring and testing of the API batches.
- 12.44 An exception can be made for retrospective validation for well-established processes that have been used without significant changes to API quality due to changes in raw materials, equipment, systems, facilities, or the production process. This validation approach may be used where
  (1) Critical quality attributes and critical process parameters have been identified.
  (2) Appropriate in-process acceptance criteria and controls have been established.
  (3) There have not been significant process/product failures attributable to causes other than operator error or equipment failures unrelated to equipment suitability.
  (4) Impurity profiles have been established for the existing API.
- 12.45 Batches selected for retrospective validation should be representative of all batches made during the review period, including any batches that failed to meet specifications, and should be sufficient in number to demonstrate process consistency. Retained samples can be tested to obtain data to retrospectively validate the process.

12.5. Process Validation Program

- 12.50 The number of process runs for validation should depend on the complexity of the process or the magnitude of the process change being considered. For prospective and concurrent validation, three consecutive successful production batches should be used as a guide, but there may be situations where additional process runs are warranted to prove consistency of the process (e.g., complex API processes or API processes with prolonged completion times). For retrospective validation, generally data from 10 to 30 consecutive batches should be examined to assess process consistency, but fewer batches can be examined if justified.
- 12.51 Critical process parameters should be controlled and monitored during process validation studies. Process parameters unrelated to quality, such as variables controlled to minimize energy consumption or equipment use, need not be included in the process validation.
- 12.52 Process validation should confirm that the impurity profile for each API is within the limits specified. The impurity profile should be comparable to or better than historical data and, where applicable, the profile determined during process development or for batches used for pivotal clinical and toxicological studies.

12.6. Periodic Review of Validated Systems

- 12.60 Systems and processes should be periodically evaluated to verify that they are still operating in a valid manner. Where no significant changes have been made to the system or process, and a quality review confirms that the system or process is consistently producing material meeting its specifications, there is normally no need for revalidation.

12.7. Cleaning Validation

- 12.70 Cleaning procedures should normally be validated. In general, cleaning validation should be directed to situations or process steps where contamination or carryover of materials poses the greatest risk to API quality. For example, in early production it may be unnecessary to validate equipment cleaning procedures where residues are removed by subsequent purification steps.
- 12.71 Validation of cleaning procedures should reflect actual equipment usage patterns. If various APIs or intermediates are manufactured in the same

equipment and the equipment is cleaned by the same process, a representative intermediate or API can be selected for cleaning validation. This selection should be based on the solubility and difficulty of cleaning and the calculation of residue limits based on potency, toxicity, and stability.

- 12.72 The cleaning validation protocol should describe the equipment to be cleaned, procedures, materials, acceptable cleaning levels, parameters to be monitored and controlled, and analytical methods. The protocol should also indicate the type of samples to be obtained and how they are collected and labeled.
- 12.73 Sampling should include swabbing, rinsing, or alternative methods (e.g., direct extraction), as appropriate, to detect both insoluble and soluble residues. The sampling methods used should be capable of quantitatively measuring levels of residues remaining on the equipment surfaces after cleaning. Swab sampling may be impractical when product contact surfaces are not easily accessible due to equipment design and/or process limitations (e.g., inner surfaces of hoses, transfer pipes, reactor tanks with small ports or handling toxic materials, and small intricate equipment such as micronizers and microfluidizers).
- 12.74 Validated analytical methods having sensitivity to detect residues or contaminants should be used. The detection limit for each analytical method should be sufficiently sensitive to detect the established acceptable level of the residue or contaminant. The method's attainable recovery level should be established. Residue limits should be practical, achievable, verifiable, and based on the most deleterious residue. Limits can be established based on the minimum known pharmacological, toxicological, or physiological activity of the API or its most deleterious component.
- 12.75 Equipment cleaning/sanitization studies should address microbiological and endotoxin contamination for those processes where there is a need to reduce total microbiological count or endotoxins in the API or other processes where such contamination could be of concern (e.g., nonsterile APIs used to manufacture sterile products).
- 12.76 Cleaning procedures should be monitored at appropriate intervals after validation to ensure that these procedures are effective when used during routine production. Equipment cleanliness can be monitored by analytical testing and visual examination, where feasible. Visual inspection can allow detection of gross contamination concentrated in small areas that could otherwise go undetected by sampling and/or analysis.

12.8. Validation of Analytical Methods

- 12.80 Analytical methods should be validated unless the method employed is included in the relevant pharmacopoeia or other recognized standard reference. The suitability of all testing methods used should nonetheless be verified under actual conditions of use and documented.
- 12.81 Methods should be validated to include consideration of characteristics included within the ICH guidelines on validation of analytical methods. The degree of analytical validation performed should reflect the purpose of the analysis and the stage of the API production process.
- 12.82 Appropriate qualification of analytical equipment should be considered before starting validation of analytical methods.
- 12.83 Complete records should be maintained of any modification of a validated analytical method. Such records should include the reason for the modification and appropriate data to verify that the modification produces results that are as accurate and reliable as the established method.

13. CHANGE CONTROL

- 13.10 A formal change control system should be established to evaluate all changes that may affect the production and control of the intermediate or API.
- 13.11 Written procedures should provide for the identification, documentation, appropriate review, and approval of changes in raw materials, specifications, analytical methods, facilities, support systems, equipment (including computer hardware), processing steps, labeling and packaging materials, and computer software.
- 13.12 Any proposals for GMP relevant changes should be drafted, reviewed, and approved by the appropriate organizational units and reviewed and approved by the quality unit(s).
- 13.13 The potential impact of the proposed change on the quality of the intermediate or API should be evaluated. Classification procedure may help in determining the level of testing, validation, and documentation needed to justify changes to a validated process. Changes can be classified (e.g., as minor or major) depending on the nature and extent of the changes and the effects these changes may impart on the process. Scientific judgment should determine what additional testing and validation studies are appropriate to justify a change in a validated process.
- 13.14 When implementing approved changes, measures should be taken to ensure that all documents affected by the changes are revised.
- 13.15 After the change has been implemented, there should be an evaluation of the first batches produced or tested under the change.
- 13.16 The potential for critical changes to affect established retest or expiry dates should be evaluated. If necessary, samples of the intermediate or

API produced by the modified process can be placed on an accelerated stability program and/or can be added to the stability monitoring program.
- 13.17 Current dosage form manufacturers should be notified of changes from established production and process control procedures that can impact the quality of the API.

14. REJECTION AND REUSE OF MATERIALS

14.1. Rejection

- 14.10 Intermediates and APIs failing to meet established specifications should be identified as such and quarantined. These intermediates or APIs can be reprocessed or reworked as described below. The final disposition of rejected materials should be recorded.

14.2. Reprocessing

- 14.20 Introducing an intermediate or API, including one that does not conform to standards or specifications, back into the process and reprocessing by repeating a crystallization step or other appropriate chemical or physical manipulation steps (e.g., distillation, filtration, chromatography, milling) that are part of the established manufacturing process is generally considered acceptable. However, if such reprocessing is used for a majority of batches, such reprocessing should be included as part of the standard manufacturing process.
- 14.21 Continuation of a process step after an in-process control test has shown that the step is incomplete is considered to be part of the normal process. This is not considered to be reprocessing.
- 14.22 Introducing unreacted material back into a process and repeating a chemical reaction is considered to be reprocessing unless it is part of the established process. Such reprocessing should be preceded by careful evaluation to ensure that the quality of the intermediate or API is not adversely impacted due to the potential formation of byproducts and overreacted materials.

14.3. Reworking

- 14.30 Before a decision is taken to rework batches that do not conform to established standards or specifications, an investigation into the reason for nonconformance should be performed.
- 14.31 Batches that have been reworked should be subjected to appropriate evaluation, testing, stability testing if warranted, and documentation to show that the reworked product is of equivalent quality to that produced by the original process. Concurrent validation is often the appropriate validation approach for rework procedures. This allows a protocol to define the rework procedure, how it will be carried out, and the expected results. If there is only one batch to be reworked, then a report can be written and the batch released once it is found to be acceptable.
- 14.32 Procedures should provide for comparing the impurity profile of each reworked batch against batches manufactured by the established process. Where routine analytical methods are inadequate to characterize the reworked batch, additional methods should be used.

14.4. Recovery of Materials and Solvents

- 14.40 Recovery (e.g., from mother liquor or filtrates) of reactants, intermediates, or the API is considered acceptable, provided that approved procedures exist for the recovery and the recovered materials meet specifications suitable for their intended use.
- 14.41 Solvents can be recovered and reused in the same processes or in different processes, provided that the recovery procedures are controlled and monitored to ensure that solvents meet appropriate standards before reuse or comingling with other approved materials.
- 14.42 Fresh and recovered solvents and reagents can be combined if adequate testing has shown their suitability for all manufacturing processes in which they may be used.
- 14.43 The use of recovered solvents, mother liquors, and other recovered materials should be adequately documented.

14.5. Returns

- 14.50 Returned intermediates or APIs should be identified as such and quarantined.
- 14.51 If the conditions under which returned intermediates or APIs have been stored or shipped before or during their return or the condition of their containers casts doubt on their quality, the returned intermediates or APIs should be reprocessed, reworked, or destroyed, as appropriate.
- 14.52 Records of returned intermediates or APIs should be maintained. For each return, documentation should include the following:
  - Name and address of the consignee
  - Intermediate or API, batch number, and quantity returned
  - Reason for return
  - Use or disposal of the returned intermediate or API

15. COMPLAINTS AND RECALLS

- 15.10 All quality-related complaints, whether received orally or in writing, should be recorded and investigated according to a written procedure.
- 15.11 Complaint records should include

- Name and address of complainant
- Name (and, where appropriate, title) and phone number of person submitting the complaint
- Complaint nature (including name and batch number of the API)
- Date complaint is received
- Action initially taken (including dates and identity of person taking the action)
- Any follow-up action taken
- Response provided to the originator of complaint (including date response sent) and
- Final decision on intermediate or API batch or lot

- 15.12 Records of complaints should be retained in order to evaluate trends, product-related frequencies, and severity with a view to taking additional and, if appropriate, immediate corrective action.
- 15.13 There should be a written procedure that defines the circumstances under which a recall of an intermediate or API should be considered.
- 15.14 The recall procedure should designate who should be involved in evaluating the information, how a recall should be initiated, who should be informed about the recall, and how the recalled material should be treated.
- 15.15 In the event of a serious or potentially life-threatening situation, local, national, and/or international authorities should be informed and their advice sought.

16. CONTRACT MANUFACTURERS (INCLUDING LABORATORIES)

- 16.10 All contract manufacturers (including laboratories) should comply with the GMP defined in this Guide. Special consideration should be given to the prevention of cross-contamination and to maintaining traceability.
- 16.11 Contract manufacturers (including laboratories) should be evaluated by the contract giver to ensure GMP compliance of the specific operations occurring at the contract sites.
- 16.12 There should be a written and approved contract or formal agreement between the contract giver and the contract acceptor that defines in detail the GMP responsibilities, including the quality measures, of each party.
- 16.13 The contract should permit the contract giver to audit the contract acceptor's facilities for compliance with GMP.
- 16.14 Where subcontracting is allowed, the contract acceptor should not pass to a third party any of the work entrusted to him under the contract without the contract giver's prior evaluation and approval of the arrangements.
- 16.15 Manufacturing and laboratory records should be kept at the site where the activity occurs and be readily available.
- 16.16 Changes in the process, equipment, test methods, specifications, or other contractual requirements should not be made unless the contract giver is informed and approves the changes.

17. AGENTS, BROKERS, TRADERS, DISTRIBUTORS, REPACKERS, AND RELABELERS

17.1. Applicability

- 17.10 This section applies to any party other than the original manufacturer who may trade and/or take possession, repack, relabel, manipulate, distribute, or store an API or intermediate.
- 17.11 All agents, brokers, traders, distributors, repackers, and relabelers should comply with GMP as defined in this Guide.

17.2. Traceability of Distributed APIs and Intermediates

- 17.20 Agents, brokers, traders, distributors, repackers, or relabelers should maintain complete traceability of APIs and intermediates that they distribute. Documents that should be retained and available include the following:
  - Identity of original manufacturer
  - Address of original manufacturer
  - Purchase orders
  - Bills of lading (transportation documentation)
  - Receipt documents
  - Name or designation of API or intermediate
  - Manufacturer's batch number
  - Transportation and distribution records
  - All authentic Certificates of Analysis, including those of the original manufacturer
  - Retest or expiry date

17.3. Quality Management

- 17.30 Agents, brokers, traders, distributors, repackers, or relabelers should establish, document, and implement an effective system of managing quality, as specified in Section 2.

17.4. Repackaging, Relabeling, and Holding of APIs and Intermediates

- 17.40 Repackaging, relabeling, and holding of APIs and intermediates should be performed under appropriate GMP controls, as stipulated in this Guide, to avoid mix-ups and loss of API or intermediate identity or purity.
- 17.41 Repackaging should be conducted under appropriate environmental conditions to avoid contamination and cross-contamination.

17.5. Stability

- 17.50 Stability studies to justify assigned expiration or retest dates should be conducted if the API or intermediate is repackaged in a different type of container than that used by the API or intermediate manufacturer.

17.6. Transfer of Information

- 17.60 Agents, brokers, distributors, repackers, or relabelers should transfer all quality or regulatory information received from an API or intermediate manufacturer to the customer and from the customer to the API or intermediate manufacturer.
- 17.61 The agent, broker, trader, distributor, repacker, or relabeler who supplies the API or intermediate to the customer should provide the name of the original API or intermediate manufacturer and the batch number(s) supplied.
- 17.62 The agent should also provide the identity of the original API or intermediate manufacturer to regulatory authorities upon request. The original manufacturer can respond to the regulatory authority directly or through its authorized agents, depending on the legal relationship between the authorized agents and the original API or intermediate manufacturer. (In this context "authorized" refers to authorized by the manufacturer.)
- 17.63 The specific guidance for Certificates of Analysis included in Section 11.4 should be met.

17.7. Handling of Complaints and Recalls

- 17.70 Agents, brokers, traders, distributors, repackers, or relabelers should maintain records of complaints and recalls, as specified in Section 15, for all complaints and recalls that come to their attention.
- 17.71 If the situation warrants, the agents, brokers, traders, distributors, repackers, or relabelers should review the complaint with the original API or intermediate manufacturer in order to determine whether any further action, either with other customers who may have received this API or intermediate or with the regulatory authority, or both, should be initiated. The investigation into the cause for the complaint or recall should be conducted and documented by the appropriate party.
- 17.72 Where a complaint is referred to the original API or intermediate manufacturer, the record maintained by the agents, brokers, traders, distributors, repackers, or relabelers should include any response received from the original API or intermediate manufacturer (including date and information provided).

17.8. Handling of Returns

- 17.80 Returns should be handled as specified in Section 14.52. The agents, brokers, traders, distributors, repackers, or relabelers should maintain documentation of returned APIs and intermediates.

18. SPECIFIC GUIDANCE FOR APIS MANUFACTURED BY CELL CULTURE/FERMENTATION

18.1. General

- 18.10 Section 18 is intended to address specific controls for APIs or intermediates manufactured by cell culture or fermentation using natural or recombinant organisms and that have not been covered adequately in the previous sections. It is not intended to be a stand-alone section. In general, the GMP principles in the other sections of this document apply. Note that the principles of fermentation for "classical" processes for production of small molecules and for processes using recombinant and nonrecombinant organisms for production of proteins and/or polypeptides are the same, although the degree of control will differ. Where practical, this section will address these differences. In general, the degree of control for biotechnological processes used to produce proteins and polypeptides is greater than that for classical fermentation processes.
- 18.11 The term "biotechnological process" (biotech) refers to the use of cells or organisms that have been generated or modified by recombinant DNA, hybridoma, or other technology to produce APIs. The APIs produced by biotechnological processes normally consist of high molecular weight substances, such as proteins and polypeptides, for which specific guidance is given in this section. Certain APIs of low molecular weight, such as antibiotics, amino acids, vitamins, and carbohydrates, can also be produced by recombinant DNA technology. The level of control for these types of APIs is similar to that employed for classical fermentation.
- 18.12 The term "classical fermentation" refers to processes that use microorganisms existing in nature and/or modified by conventional methods (e.g., irradiation or chemical mutagenesis) to produce APIs. APIs produced by "classical fermentation" are normally low molecular weight products such as antibiotics, amino acids, vitamins, and carbohydrates.
- 18.13 Production of APIs or intermediates from cell culture or fermentation involves biological processes such as cultivation of cells or extraction and purification of material from living organisms. Note that there may be additional process steps, such as physicochemical modification, that are part of the manufacturing process. The raw materials used (media, buffer components) may provide the potential for growth of microbiological contaminants. Depending on the source, method of preparation, and the intended use of the API or intermediate, control of bioburden, viral contamination, and/or endotoxins during manufacturing and monitoring of the process at appropriate stages may be necessary.

- 18.14 Appropriate controls should be established at all stages of manufacturing to assure intermediate and/or API quality. While this Guide starts at the cell culture/fermentation step, prior steps (e.g., cell banking) should be performed under appropriate process controls. This Guide covers cell culture/fermentation from the point at which a vial of the cell bank is retrieved for use in manufacturing.
- 18.15 Appropriate equipment and environmental controls should be used to minimize the risk of contamination. The acceptance criteria for quality of the environment and the frequency of monitoring should depend on the step in production and the production conditions (open, closed, or contained systems).
- 18.16 In general, process controls should take into account:
  - Maintenance of the working cell bank (where appropriate)
  - Proper inoculation and expansion of the culture
  - Control of the critical operating parameters during fermentation/cell culture
  - Monitoring of the process for cell growth, viability (for most cell culture processes), and productivity where appropriate
  - Harvest and purification procedures that remove cells, cellular debris, and media components while protecting the intermediate or API from contamination (particularly of a microbiological nature) and from loss of quality
  - Monitoring of bioburden and, where needed, endotoxin levels at appropriate stages of production and
  - *Viral safety concerns as described in ICH Guideline Q5A* Quality of Biotechnological Products: Viral Safety Evaluation of Biotechnology Products Derived from Cell Lines of Human or Animal Origin
- 18.17 Where appropriate, the removal of media components, host cell proteins, other process-related impurities, product-related impurities, and contaminants should be demonstrated.

18.2. Cell Bank Maintenance and Record Keeping

- 18.20 Access to cell banks should be limited to authorized personnel.
- 18.21 Cell banks should be maintained under storage conditions designed to maintain viability and prevent contamination.
- 18.22 Records of the use of the vials from the cell banks and storage conditions should be maintained.
- 18.23 Where appropriate, cell banks should be periodically monitored to determine suitability for use.
- *18.24 See ICH Guideline Q5D* Quality of Biotechnological Products: Derivation and Characterization of Cell Substrates Used for Production of Biotechnological/Biological Products *for a more complete discussion of cell banking.*

18.3. Cell Culture/Fermentation

- 18.30 Where aseptic addition of cell substrates, media, buffers, and gases is needed, closed or contained systems should be used where possible. If the inoculation of the initial vessel or subsequent transfers or additions (media, buffers) are performed in open vessels, there should be controls and procedures in place to minimize the risk of contamination.
- 18.31 Where the quality of the API can be affected by microbial contamination, manipulations using open vessels should be performed in a biosafety cabinet or similarly controlled environment.
- 18.32 Personnel should be appropriately gowned and take special precautions handling the cultures.
- 18.33 Critical operating parameters (e.g., temperature, pH, agitation rates, addition of gases, pressure) should be monitored to ensure consistency with the established process. Cell growth, viability (for most cell culture processes), and, where appropriate, productivity should also be monitored. Critical parameters will vary from one process to another, and for classical fermentation, certain parameters (cell viability, for example) may not need to be monitored.
- 18.34 Cell culture equipment should be cleaned and sterilized after use. As appropriate, fermentation equipment should be cleaned, and sanitized or sterilized.
- 18.35 Culture media should be sterilized before use when appropriate to protect the quality of the API.
- 18.36 There should be appropriate procedures in place to detect contamination and determine the course of action to be taken. This should include procedures to determine the impact of the contamination on the product and those to decontaminate the equipment and return it to a condition to be used in subsequent batches. Foreign organisms observed during fermentation processes should be identified as appropriate, and the effect of their presence on product quality should be assessed, if necessary. The results of such assessments should be taken into consideration in the disposition of the material produced.
- 18.37 Records of contamination events should be maintained.
- 18.38 Shared (multiproduct) equipment may warrant additional testing after cleaning between product campaigns, as appropriate, to minimize the risk of cross-contamination.

18.4. Harvesting, Isolation, and Purification

- 18.40 Harvesting steps, either to remove cells or cellular components or to collect cellular components after disruption, should be performed in equipment and areas designed to minimize the risk of contamination.
- 18.41 Harvest and purification procedures that remove or inactivate the producing organism, cellular debris,

and media components (while minimizing degradation, contamination, and loss of quality) should be adequate to ensure that the intermediate or API is recovered with consistent quality.
- 18.42 All equipment should be properly cleaned and, as appropriate, sanitized after use. Multiple successive batching without cleaning can be used if intermediate or API quality is not compromised.
- 18.43 If open systems are used, purification should be performed under environmental conditions appropriate for the preservation of product quality.
- 18.44 Additional controls, such as the use of dedicated chromatography resins or additional testing, may be appropriate if equipment is to be used for multiple products.

18.5. Viral Removal/Inactivation Steps

- *18.50 See the ICH Guideline Q5A* Quality of Biotechnological Products: Viral Safety Evaluation of Biotechnology Products Derived from Cell Lines of Human or Animal Origin *for more specific information*.
- 18.51 Viral removal and viral inactivation steps are critical processing steps for some processes and should be performed within their validated parameters.
- 18.52 Appropriate precautions should be taken to prevent potential viral contamination from previral to post-viral removal/inactivation steps. Therefore, open processing should be performed in areas that are separate from other processing activities and have separate air handling units.
- 18.53 The same equipment is not normally used for different purification steps. However, if the same equipment is to be used, the equipment should be appropriately cleaned and sanitized before reuse. Appropriate precautions should be taken to prevent potential virus carryover (e.g., through equipment or environment) from previous steps.

19. APIs FOR USE IN CLINICAL TRIALS

19.1. General

- 19.10 Not all the controls in the previous sections of this Guide are appropriate for the manufacture of a new API for investigational use during its development. Section 19 provides specific guidance unique to these circumstances.
- 19.11 The controls used in the manufacture of APIs for use in clinical trials should be consistent with the stage of development of the drug product incorporating the API. Process and test procedures should be flexible to provide for changes as knowledge of the process increases and clinical testing of a drug product progresses from preclinical stages through clinical stages. Once drug development reaches the stage where the API is produced for use in drug products intended for clinical trials, manufacturers should ensure that APIs are manufactured in suitable facilities using appropriate production and control procedures to ensure the quality of the API.

19.2. Quality

- 19.20 Appropriate GMP concepts should be applied in the production of APIs for use in clinical trials with a suitable mechanism of approval of each batch.
- 19.21 A quality unit(s) independent from production should be established for the approval or rejection of each batch of API for use in clinical trials.
- 19.22 Some of the testing functions commonly performed by the quality unit(s) can be performed within other organizational units.
- 19.23 Quality measures should include a system for testing of raw materials, packaging materials, intermediates, and APIs.
- 19.24 Process and quality problems should be evaluated.
- 19.25 Labeling for APIs intended for use in clinical trials should be appropriately controlled and should identify the material as being for investigational use.

19.3. Equipment and Facilities

- 19.30 During all phases of clinical development, including the use of small-scale facilities or laboratories to manufacture batches of APIs for use in clinical trials, procedures should be in place to ensure that equipment is calibrated, clean, and suitable for its intended use.
- 19.31 Procedures for the use of facilities should ensure that materials are handled in a manner that minimizes the risk of contamination and cross-contamination.

19.4. Control of Raw Materials

- 19.40 Raw materials used in production of APIs for use in clinical trials should be evaluated by testing or received with a supplier's analysis and subjected to identity testing. When a material is considered hazardous, a supplier's analysis should suffice.
- 19.41 In some instances, the suitability of a raw material can be determined before use based on acceptability in small-scale reactions (i.e., use testing) rather than on analytical testing alone.

19.5. Production

- 19.50 The production of APIs for use in clinical trials should be documented in laboratory notebooks, batch records, or by other appropriate means. These

documents should include information on the use of production materials, equipment, processing, and scientific observations.

- 19.51 Expected yields can be more variable and less defined than the expected yields used in commercial processes. Investigations into yield variations are not expected.

19.6. Validation

- 19.60 Process validation for the production of APIs for use in clinical trials is normally inappropriate, where a single API batch is produced or where process changes during API development make batch replication difficult or inexact. The combination of controls, calibration, and, where appropriate, equipment qualification assures API quality during this development phase.
- 19.61 Process validation should be conducted in accordance with Section 12 when batches are produced for commercial use, even when such batches are produced on a pilot or small scale.

19.7. Changes

- 19.70 Changes are expected during development, as knowledge is gained and the production is scaled up. Every change in the production, specifications, or test procedures should be adequately recorded.

19.8. Laboratory Controls

- 19.80 While analytical methods performed to evaluate a batch of API for clinical trials may not yet be validated, they should be scientifically sound.
- 19.81 A system for retaining reserve samples of all batches should be in place. This system should ensure that a sufficient quantity of each reserve sample is retained for an appropriate length of time after approval, termination, or discontinuation of an application.
- 19.82 Expiry and retest dating as defined in Section 11.6 applies to existing APIs used in clinical trials. For new APIs, Section 11.6 does not normally apply in early stages of clinical trials.

19.9. Documentation

- 19.90 A system should be in place to ensure that information gained during the development and the manufacture of APIs for use in clinical trials is documented and available.
- 19.91 The development and implementation of the analytical methods used to support the release of a batch of API for use in clinical trials should be appropriately documented.
- 19.92 A system for retaining production and control records and documents should be used. This system should ensure that records and documents are retained for an appropriate length of time after the approval, termination, or discontinuation of an application.

GLOSSARY

Acceptance Criteria: Numerical limits, ranges, or other suitable measures for acceptance of test results.

Active Pharmaceutical Ingredient (API) (or Drug Substance): Any substance or mixture of substances intended to be used in the manufacture of a drug (medicinal) product and that, when used in the production of a drug, becomes an active ingredient of the drug product. Such substances are intended to furnish pharmacological activity or other direct effect in the diagnosis, cure, mitigation, treatment, or prevention of disease or to affect the structure and function of the body.

API Starting Material: A raw material, intermediate, or an API that is used in the production of an API and that is incorporated as a significant structural fragment into the structure of the API. An API Starting Material can be an article of commerce, a material purchased from one or more suppliers under contract or commercial agreement, or produced in-house. API Starting Materials are normally of defined chemical properties and structure.

Batch (or Lot): A specific quantity of material produced in a process or series of processes so that it is expected to be homogeneous within specified limits. In the case of continuous production, a batch may correspond to a defined fraction of the production. The batch size can be defined either by a fixed quantity or by the amount produced in a fixed time interval.

Batch Number (or Lot Number): A unique combination of numbers, letters, and/or symbols that identifies a batch (or lot) and from which the production and distribution history can be determined.

Bioburden: The level and type (e.g., objectionable or not) of microorganisms that can be present in raw materials, API Starting Materials, intermediates, or APIs. Bioburden should not be considered contamination unless the levels have been exceeded or defined objectionable organisms have been detected.

Calibration: The demonstration that a particular instrument or device produces results within specified limits by comparison with those produced by a reference or traceable standard over an appropriate range of measurements.

Computer System: A group of hardware components and associated software, designed and assembled to perform a specific function or group of functions.

Computerized System: A process or operation integrated with a computer system.

Contamination: The undesired introduction of impurities of a chemical or microbiological nature, or of foreign matter, into or onto a raw material, intermediate, or API during production, sampling, packaging or repackaging, storage or transport.

Contract Manufacturer: A manufacturer performing some aspect of manufacturing on behalf of the original manufacturer.

Critical: Describes a process step, process condition, test requirement, or other relevant parameter or item that must be controlled within predetermined criteria to ensure that the API meets its specification.

Cross-Contamination: Contamination of a material or product with another material or product.

Deviation: Departure from an approved instruction or established standard.

Drug (Medicinal) Product: The dosage form in the final immediate packaging intended for marketing (Reference Q1A).

Drug Substance: See Active Pharmaceutical Ingredient.

Expiry Date (or Expiration Date): The date placed on the container/labels of an API designating the time during which the API is expected to remain within established shelf life specifications if stored under defined conditions and after which it should not be used.

Impurity: Any component present in the intermediate or API that is not the desired entity.

Impurity Profile: A description of the identified and unidentified impurities present in an API.

In-Process Control (or Process Control): Checks performed during production in order to monitor and, if appropriate, to adjust the process and/or to ensure that the intermediate or API conforms to its specifications.

Intermediate: A material produced during steps of the processing of an API that undergoes further molecular change or purification before it becomes an API. Intermediates may or may not be isolated. (*Note*: This Guide only addresses those intermediates produced after the point that the company has defined as the point at which the production of the API begins.)

Lot: See Batch.

Lot Number: See Batch Number.

Manufacture: All operations of receipt of materials, production, packaging, repackaging, labeling, relabeling, quality control, release, storage, and distribution of APIs and related controls.

Material: A general term used to denote raw materials (starting materials, reagents, solvents), process aids, intermediates, APIs, and packaging and labeling materials.

Mother Liquor: The residual liquid which remains after the crystallization or isolation processes. A mother liquor may contain unreacted materials, intermediates, levels of the API, and/or impurities. It may be used for further processing.

Packaging Material: Any material intended to protect an intermediate or API during storage and transport.

Procedure: A documented description of the operations to be performed, the precautions to be taken, and measures to be applied directly or indirectly related to the manufacture of an intermediate or API.

Process Aids: Materials, excluding solvents, used as an aid in the manufacture of an intermediate or API that do not themselves participate in a chemical or biological reaction (e.g., filter aid, activated carbon, etc.).

Process Control: See In-Process Control.

Production: All operations involved in the preparation of an API from receipt of materials through processing and packaging of the API.

Qualification: Action of proving and documenting that equipment or ancillary systems are properly installed, work correctly, and actually lead to the expected results. Qualification is part of validation, but the individual qualification steps alone do not constitute process validation.

Quality Assurance (QA): The sum total of the organized arrangements made with the object of ensuring that all APIs are of the quality required for their intended use and that quality systems are maintained.

Quality Control (QC): Checking or testing that specifications are met.

Quality Unit(s): An organizational unit independent of production which fulfills both Quality Assurance and Quality Control responsibilities. This can be in the form of separate QA and QC units or a single individual or group, depending upon the size and structure of the organization.

Quarantine: The status of materials isolated physically or by other effective means pending a decision on their subsequent approval or rejection.

Raw Material: A general term used to denote starting materials, reagents, and solvents intended for use in the production of intermediates or APIs.

Reference Standard, Primary: A substance that has been shown by an extensive set of analytical tests to be authentic material that should be of high purity. This standard can be (1) obtained from an officially recognized source, (2) prepared by independent synthesis, (3) obtained from existing production material of high purity, or (4) prepared by further purification of existing production material.

Reference Standard, Secondary: A substance of established quality and purity, as shown by comparison to a primary reference standard, used as a reference standard for routine laboratory analysis.

Reprocessing: Introducing an intermediate or API, including one that does not conform to standards or specifications, back into the process and repeating a crystallization step or other appropriate chemical or physical manipulation steps (e.g., distillation, filtration, chromatography, milling) that are part of the established manufacturing process. Continuation of a process

step after an in-process control test has shown that the step is incomplete if considered to be part of the normal process and not reprocessing.

Retest Date: The date when a material should be reexamined to ensure that it is still suitable for use.

Reworking: Subjecting an intermediate or API that does not conform to standards or specifications to one or more processing steps that are different from the established manufacturing process to obtain acceptable quality intermediate or API (e.g., recrystallizing with a different solvent).

Signature (signed): See definition for signed.

Signed (signature): The record of the individual who performed a particular action or review. This record can be initials, full handwritten signature, personal seal, or authenticated and secure electronic signature.

Solvent: An inorganic or organic liquid used as a vehicle for the preparation of solutions or suspensions in the manufacture of an intermediate or API.

Specification: A list of tests, references to analytical procedures, and appropriate acceptance criteria that are numerical limits, ranges, or other criteria for the test described. It establishes the set of criteria to which a material should conform to be considered acceptable for its intended use. "Conformance to specification" means that the material, when tested according to the listed analytical procedures, will meet the listed acceptance criteria.

Validation: A documented program that provides a high degree of assurance that a specific process, method, or system will consistently produce a result meeting predetermined acceptance criteria.

Validation Protocol: A written plan stating how validation will be conducted and defining acceptance criteria. For example, the protocol for a manufacturing process identifies processing equipment, critical process parameters/operating ranges, product characteristics, sampling, test data to be collected, number of validation runs, and acceptable test results.

Yield, Expected: The quantity of material or the percentage of theoretical yield anticipated at any appropriate phase of production based on previous laboratory, pilot scale, or manufacturing data.

Yield, Theoretical: The quantity that would be produced at any appropriate phase of production, based upon the quantity of material to be used, in the absence of any loss or error in actual production.

7 Validation of Analytical Procedures

I. INTRODUCTION

The objective of validation of an analytical procedure is to demonstrate that it is suitable for its intended purpose. A tabular summation of the characteristics applicable to identification, control of impurities, and assay procedures is included. Other analytical procedures may be considered in future additions to this document.

II. TYPES OF ANALYTICAL PROCEDURES TO BE VALIDATED

The four most common types of analytical procedures are as follows:

- Identification tests
- Quantitative tests for impurities' content
- Limit tests for the control of impurities
- Quantitative tests of the active moiety in samples of drug substance or drug product or other selected component(s) in the drug product

Although there are many other analytical procedures, such as dissolution testing for drug products or particle size determination for drug substance, these have not been addressed in the initial text on validation of analytical procedures. Validation of these additional analytical procedures is equally important to those listed herein and may be addressed in subsequent documents.

A brief description of the types of tests considered in this document is provided below.

- Identification tests are intended to ensure the identity of an analyte in a sample. This is normally achieved by comparison of a property of the sample (e.g., spectrum, chromatographic behavior, chemical reactivity, etc.) to that of a reference standard.
- Testing for impurities can be either a quantitative test or a limit test for the impurity in a sample. Either test is intended to accurately reflect the purity characteristics of the sample. Different validation characteristics are required for a quantitative test than for a limit test.
- Assay procedures are intended to measure the analyte present in a given sample. In the context of this document, the assay represents a quantitative measurement of the major component(s) in the drug substance. For the drug product, similar validation characteristics also apply when assaying for the active or other selected component(s). The same validation characteristics may also apply to assays associated with other analytical procedures (e.g., dissolution).

The objective of the analytical procedure should be clearly understood since this will govern the validation characteristics which need to be evaluated. Typical validation characteristics which should be considered are listed below:

Accuracy
Precision
Repeatability
Intermediate Precision
Specificity
Detection Limit
Quantitation Limit
Linearity
Range

Each of these validation characteristics is defined in the attached Glossary. The table lists those validation characteristics regarded as the most important for the validation of different types of analytical procedures. This list should be considered typical for the analytical procedures cited, but occasional exceptions should be dealt with on a case-by-case basis. It should be noted that robustness is not listed in the table but should be considered at an appropriate stage in the development of the analytical procedure.

Furthermore revalidation may be necessary in the following circumstances:

- Changes in the synthesis of the drug substance
- Changes in the composition of the finished product and
- Changes in the analytical procedure

The degree of revalidation required depends on the nature of the changes. Certain other changes may require validation as well.

Type of Analytical Procedure Characteristics	Identification	Testing for Impurities Quantitation	Limit	Assay-Dissolution (Measurement Only)—Content/Potency
Accuracy	–	+	–	+
Precision				
Repeatability	–	+	–	+
Intermediate Precision	–	+[a]	–	+[a]
Specificity[b]	+	+	+	+
Detection Limit	–	–[c]	+	–
Quantitation Limit	–	+	–	–
Linearity	–	+	–	+
Range	–	+	–	+

– Signifies that this characteristic is not normally evaluated

+ Signifies that this characteristic is normally evaluated

[a] In cases where reproducibility (see Glossary) has been performed, Intermediate Precision is not needed.

[b] Lack of specificity of one analytical procedure could be compensated by other supporting analytical procedure(s).

[c] May be needed in some cases.

VALIDATION METHODOLOGY OVERVIEW

I. INTRODUCTION

All relevant data collected during validation and formulae used for calculating validation characteristics should be submitted and discussed as appropriate.

Approaches other than those set forth in this guideline may be applicable and acceptable. It is the responsibility of the applicant to choose the validation procedure and protocol most suitable for their product. However, it is important to remember that the main objective of validation of an analytical procedure is to demonstrate that the procedure is suitable for its intended purpose. Because of their complex nature, analytical procedures for biological and biotechnological products in some cases may be approached differently than in this document.

Well-characterized reference materials, with documented purity, should be used throughout the validation study. The degree of purity necessary depends on the intended use.

In accordance with the parent document, and for the sake of clarity, this document considers the various validation characteristics in distinct sections. The arrangement of these sections reflects the process by which an analytical procedure may be developed and evaluated.

In practice, it is usually possible to design the experimental work such that the appropriate validation characteristics can be considered simultaneously to provide a sound, overall knowledge of the capabilities of the analytical procedure, for instance, specificity, linearity, range, accuracy, and precision.

II. SPECIFICITY

An investigation of specificity should be conducted during the validation of identification tests, the determination of impurities, and the assay. The procedures used to demonstrate specificity will depend on the intended objective of the analytical procedure.

It is not always possible to demonstrate that an analytical procedure is specific for a particular analyte (complete discrimination). In this case, a combination of two or more analytical procedures is recommended to achieve the necessary level of discrimination.

A. Identification

Suitable identification tests should be able to discriminate between compounds of closely related structures, which are likely to be present. The discrimination of a procedure may be confirmed by obtaining positive results (perhaps by comparison with a known reference material) from samples containing the analyte, coupled with negative results from samples, which do not contain the analyte. In addition, the identification test may be applied to materials structurally similar to or closely related to the analyte to confirm that a positive response is not obtained. The choice of such potentially interfering materials should be based on sound scientific judgment with a consideration of the interferences that could occur.

B. Assay and Impurity Test(s)

For chromatographic procedures, representative chromatograms should be used to demonstrate specificity, and individual components should be appropriately labeled. Similar considerations should be given to other separation techniques.

Critical separations in chromatography should be investigated at an appropriate level. For critical separations, specificity can be demonstrated by the resolution of the two components, which elute closest to each other.

In cases where a nonspecific assay is used, other supporting analytical procedures should be used to demonstrate overall specificity. For example, where a titration is adopted to assay the drug substance for release, the combination of the assay and a suitable test for impurities can be used.

The approach is similar for both assay and impurity tests.

1. Impurities Are Available

For the assay, this should involve demonstration of the discrimination of the analyte in the presence of impurities and/or excipients; practically, this can be done by spiking pure substances (drug substance or drug product) with appropriate levels of impurities and/or excipients and demonstrating that the assay result is unaffected by the presence of these materials (by comparison with the assay result obtained on unspiked samples).

For the impurity test, the discrimination may be established by spiking drug substance or drug product with appropriate levels of impurities and demonstrating the separation of

these impurities individually and/or from other components in the sample matrix.

2. Impurities Are Not Available

If impurity or degradation product standards are unavailable, specificity may be demonstrated by comparing the test results of samples containing impurities or degradation products to a second well-characterized procedure, for example, pharmacopoeial method or other validated analytical procedure (independent procedure). As appropriate, this should include samples stored under relevant stress conditions: Light, heat, humidity, acid/base hydrolysis, and oxidation.

- For the assay, the two results should be compared.
- For the impurity tests, the impurity profiles should be compared.

Peak purity tests may be useful to show that the analyte chromatographic peak is not attributable to more than one component (e.g., diode array, mass spectrometry).

III. LINEARITY

A linear relationship should be evaluated across the range (see Section 3) of the analytical procedure. It may be demonstrated directly on the drug substance (by dilution of a standard stock solution) and/or separate weighings of synthetic mixtures of the drug product components, using the proposed procedure. The latter aspect can be studied during investigation of the range.

Linearity should be evaluated by visual inspection of a plot of signals as a function of analyte concentration or content. If there is a linear relationship, test results should be evaluated by appropriate statistical methods, for example, by calculation of a regression line by the method of least squares. In some cases, to obtain linearity between assays and sample concentrations, the test data may need to be subjected to a mathematical transformation prior to the regression analysis. Data from the regression line itself may be helpful to provide mathematical estimates of the degree of linearity.

The correlation coefficient, y-intercept, slope of the regression line, and residual sum of squares should be submitted. A plot of the data should be included. In addition, an analysis of the deviation of the actual data points from the regression line may also be helpful for evaluating linearity.

Some analytical procedures, such as immunoassays, do not demonstrate linearity after any transformation. In this case, the analytical response should be described by an appropriate function of the concentration (amount) of an analyte in a sample.

For the establishment of linearity, a minimum of five concentrations is recommended. Other approaches should be justified.

IV. RANGE

The specified range is normally derived from linearity studies and depends on the intended application of the procedure. It is established by confirming that the analytical procedure provides an acceptable degree of linearity, accuracy, and precision when applied to samples containing amounts of analyte within or at the extremes of the specified range of the analytical procedure.

The following minimum specified ranges should be considered:

- For the assay of a drug substance or a finished (drug) product: Normally from 80% to 120% of the test concentration.
- For content uniformity, covering a minimum of 70% to 130% of the test concentration, unless a wider more appropriate range, based on the nature of the dosage form (e.g., metered dose inhalers), is justified.
- For dissolution testing: +/–20% over the specified range.

For example, if the specifications for a controlled released product cover a region from 20%, after 1 hour, up to 90%, after 24 hours, the validated range would be 0% to 110% of the label claim.

- For the determination of an impurity: From the reporting level of an impurity to 120% of the specification.
- For impurities known to be unusually potent or to produce toxic or unexpected pharmacological effects, the detection/quantitation limit should be commensurate with the level at which the impurities must be controlled.
  Note: For validation of impurity test procedures carried out during development, it may be necessary to consider the range around a suggested (probable) limit.
- If assay and purity are performed together as one test and only a 100% standard is used, linearity should cover the range from the reporting level of the impurities[1] to 120% of the assay specification.

V. ACCURACY

Accuracy should be established across the specified range of the analytical procedure.

A. Assay

1. Drug Substance

Several methods of determining accuracy are available:

(a) Application of an analytical procedure to an analyte of known purity (e.g., reference material).
(b) Comparison of the results of the proposed analytical procedure with those of a second well-characterized procedure, the accuracy of which is stated and/or defined [independent procedure, see Assay and Impurity Test(s)].
(c) Accuracy may be inferred once precision, linearity, and specificity have been established.

2. Drug Product

Several methods for determining accuracy are available:

1. Application of the analytical procedure to synthetic mixtures of the drug product components to which known quantities of the drug substance to be analyzed have been added.
2. In cases where it is impossible to obtain samples of all drug product components, it may be acceptable either to add known quantities of the analyte to the drug product or to compare the results obtained from a second, well-characterized procedure, the accuracy of which is stated and/or defined [independent procedure, see Assay and Impurity Test(s)].
3. Accuracy may be inferred once precision, linearity, and specificity have been established.

B. Impurities (Quantitation)

Accuracy should be assessed on samples (drug substance/drug product) spiked with known amounts of impurities.

In cases where it is impossible to obtain samples of certain impurities and/or degradation products, it is considered acceptable to compare results obtained by an independent procedure [see Assay and Impurity Test(s)]. The response factor of the drug substance can be used.

It should be clear how the individual or total impurities are to be determined, for example, weight/weight or area percent, in all cases with respect to the major analyte.

C. Recommended Data

Accuracy should be assessed using a minimum of nine determinations over a minimum of three concentration levels covering the specified range (e.g., three concentrations/three replicates each of the total analytical procedure).

Accuracy should be reported as percent recovery by the assay of known added amount of analyte in the sample or as the difference between the mean and the accepted true value together with the confidence intervals.

VI. PRECISION

Validation of tests for assay and for quantitative determination of impurities includes an investigation of precision.

A. Repeatability

Repeatability should be assessed using:

(a) A minimum of nine determinations covering the specified range for the procedure (e.g., three concentrations/three replicates each) or
(b) A minimum of six determinations at 100% of the test concentration

B. Intermediate Precision

The extent to which intermediate precision should be established depends on the circumstances under which the procedure is intended to be used. The applicant should establish the effects of random events on the precision of the analytical procedure. Typical variations to be studied include days, analysts, equipment, etc. It is not considered necessary to study these effects individually. The use of an experimental design (matrix) is encouraged.

C. Reproducibility

Reproducibility is assessed by means of an interlaboratory trial. Reproducibility should be considered in case of the standardization of an analytical procedure, for instance, for inclusion of procedures in pharmacopoeias. These data are not part of the marketing authorization dossier.

D. Recommended Data

The standard deviation, relative standard deviation (coefficient of variation), and confidence interval should be reported for each type of precision investigated.

VII. DETECTION LIMIT

Several approaches for determining the detection limit are possible, depending on whether the procedure is a non-instrumental or instrumental. Approaches other than those listed below may be acceptable.

A. Based on Visual Evaluation

Visual evaluation may be used for non-instrumental methods but may also be used with instrumental methods.

The detection limit is determined by the analysis of samples with known concentrations of analyte and by establishing the minimum level at which the analyte can be reliably detected.

B. Based on Signal-to-Noise

This approach can only be applied to analytical procedures which exhibit baseline noise.

Determination of the signal-to-noise ratio is performed by comparing measured signals from samples with known low concentrations of analyte with those of blank samples and establishing the minimum concentration at which the analyte can be reliably detected. A signal-to-noise ratio between 3 or 2:1 is generally considered acceptable for estimating the detection limit.

C. Based on the Standard Deviation of the Response and the Slope

The detection limit (*DL*) may be expressed as:

$$DL = \frac{3.3\tilde{A}}{S}$$

where,

σ = the standard deviation of the response
S = the slope of the calibration curve

The slope S may be estimated from the calibration curve of the analyte. The estimate of σ may be carried out in a variety of ways, for example:

1. Based on the Standard Deviation of the Blank

Measurement of the magnitude of analytical background response is performed by analyzing an appropriate number of blank samples and calculating the standard deviation of these responses.

2. Based on the Calibration Curve

A specific calibration curve should be studied using samples containing an analyte in the range of *DL*. The residual standard deviation of a regression line or the standard deviation of y-intercepts of regression lines may be used as the standard deviation.

D. Recommended Data

The detection limit and the method used for determining the detection limit should be presented. If *DL* is determined based on visual evaluation or based on the signal-to-noise ratio, the presentation of the relevant chromatograms is considered acceptable for justification.

In cases where an estimated value for the detection limit is obtained by calculation or extrapolation, this estimate may subsequently be validated by the independent analysis of a suitable number of samples known to be near or prepared at the detection limit.

VIII. QUANTITATION LIMIT

Several approaches for determining the quantitation limit are possible, depending on whether the procedure is a non-instrumental or instrumental. Approaches other than those listed below may be acceptable.

A. Based on Visual Evaluation

Visual evaluation may be used for non-instrumental methods but may also be used with instrumental methods.

The quantitation limit is generally determined by the analysis of samples with known concentrations of analyte and by establishing the minimum level at which the analyte can be quantified with acceptable accuracy and precision.

B. Based on Signal-to-Noise Approach

This approach can only be applied to analytical procedures that exhibit baseline noise.

Determination of the signal-to-noise ratio is performed by comparing measured signals from samples with known low concentrations of analyte with those of blank samples and by establishing the minimum concentration at which the analyte can be reliably quantified. A typical signal-to-noise ratio is 10:1.

C. Based on the Standard Deviation of the Response and the Slope

The quantitation limit (*QL*) may be expressed as:

$$QL = \frac{10\tilde{A}}{S}$$

where

σ = the standard deviation of the response
S = the slope of the calibration curve

The slope S may be estimated from the calibration curve of the analyte. The estimate of σ may be carried out in a variety of ways, for example:

1. Based on Standard Deviation of the Blank

Measurement of the magnitude of analytical background response is performed by analyzing an appropriate number of blank samples and calculating the standard deviation of these responses.

2. Based on the Calibration Curve

A specific calibration curve should be studied using samples containing an analyte in the range of *QL*. The residual standard deviation of a regression line or the standard deviation of y-intercepts of regression lines may be used as the standard deviation.

D. Recommended Data

The quantitation limit and the method used for determining the quantitation limit should be presented.

The limit should be subsequently validated by the analysis of a suitable number of samples known to be near or prepared at the quantitation limit.

IX. ROBUSTNESS

The evaluation of robustness should be considered during the development phase and depends on the type of procedure under study. It should show the reliability of an analysis with respect to deliberate variations in method parameters.

If measurements are susceptible to variations in analytical conditions, the analytical conditions should be suitably controlled or a precautionary statement should be included in the procedure. One consequence of the evaluation of robustness should be that a series of system suitability parameters (e.g., resolution test) is established to ensure that the validity of the analytical procedure is maintained whenever used.

Examples of typical variations are:

- Stability of analytical solutions
- Extraction time

In the case of liquid chromatography, examples of typical variations are:

- Influence of variations of pH in a mobile phase
- Influence of variations in mobile phase composition
- Different columns (different lots and/or suppliers)
- Temperature
- Flow rate

In the case of gas chromatography, examples of typical variations are:

- Different columns (different lots and/or suppliers)
- Temperature
- Flow rate

X. SYSTEM SUITABILITY TESTING

System suitability testing is an integral part of many analytical procedures. The tests are based on the concept that the equipment, electronics, analytical operations, and samples to be analyzed constitute an integral system that can be evaluated as such. System suitability test parameters to be established for a particular procedure depend on the type of procedure being validated. See pharmacopoeias for additional information.

20. FDA Bioanalytical Method Validation Guidance for Industry

A. Introduction

This guidance helps sponsors of investigational new drug applications (INDs) or applicants of new drug applications (NDAs), abbreviated new drug applications (ANDAs), biologic license applications (BLAs), and supplements validate bioanalytical methods used in human clinical pharmacology, bioavailability (BA), and bioequivalence (BE) studies that require pharmacokinetic, toxicokinetic, or biomarker concentration evaluation. This guidance can also inform the development of bioanalytical methods used for nonclinical studies that require toxicokinetic or biomarker concentration data. For studies related to the veterinary drug approval process such as investigational new animal drug applications (INADs), new animal drug applications (NADAs), and abbreviated new animal drug applications (ANADAs), this guidance may apply to blood and urine BA, BE, and pharmacokinetic studies.

The information in this guidance applies to bioanalytical procedures such as chromatographic assays (CCs) and ligand binding assays (LBAs) that quantitatively determine the levels of drugs, their metabolites, therapeutic proteins, and biomarkers in biological matrices such as blood, serum, plasma, urine, and tissue such as skin.

This final guidance incorporates public comments to the revised draft published in 2013 and provides recommendations for the development, validation, and in-study use of bioanalytical methods. The recommendations can be modified with justification, depending on the specific type of bioanalytical method. This guidance reflects advances in science and technology related to validating bioanalytical methods.

In general, FDA's guidance documents do not establish legally enforceable responsibilities. Instead, guidances describe the Agency's current thinking on a topic and should be viewed only as recommendations, unless specific regulatory or statutory requirements are cited. The use of the word *should* in Agency guidances means that something is suggested or recommended but not required.

B. Background

The 2001 guidance for industry on *Bioanalytical Method Validation* was originally based on the deliberations of two workshops described in publications entitled:

- *Analytical Methods Validation: Bioavailability, Bioequivalence, and Pharmacokinetic Studies*[1]
- *Bioanalytical Methods Validation: A Revisit With a Decade of Progress*[2]

Additional workshops, summarized in the following publications, have informed subsequent revisions (e.g., the 2013 draft guidance for industry entitled *Bioanalytical Method Validation*[3]):

- *Quantitative Bioanalytical Methods Validation and Implementation: Best Practices for Chromatographic and Ligand Binding Assays*[4]
- *The AAPS/FDA Workshop on Incurred Sample Reanalysis*[5]
- *The AAPS Workshop on Crystal City V—Quantitative Bioanalytical Method Validation and Implementation: 2013 Revised FDA Guidance*[6]

Validated analytical methods for the quantitative evaluation of analytes (i.e., drugs, including biologic products, and their metabolites) and biomarkers in a given biological matrix (e.g., blood, plasma, serum, or urine) are critical for the successful conduct of nonclinical, biopharmaceutics, and clinical pharmacology studies. These validated methods provide critical data to support the safety and effectiveness of drugs and biologic products. Validating the analytical method ensures that the data are reliable by addressing certain key questions, including:

- Does the method measure the intended analyte? For example, does anything interfere with the measurement, and is the method specific or selective for the analyte?
- What is the variability associated with these measurements? For example, what are the accuracy and precision of the method?
- What is the range in measurements that provide reliable data? For example, what is the sensitivity of the method [e.g., what is the lower limit of quantitation

(LLOQ) of the method, and what is the upper limit of quantitation the method (ULOQ)?]?
- How do sample collection, handling, and storage affect the reliability of the data from the bioanalytical method? For example, what steps need to be followed while collecting samples? Do the samples need to be frozen during shipping? What temperatures are required to store the samples, and how long can the samples be stored?

When changes are made to a validated method, the sponsor should conduct additional validation (i.e., partial or cross validation).

The fit-for-purpose (FFP) concept states that the level of validation should be appropriate for the intended purpose of the study. The key questions listed above should be evaluated relative to the stage of drug development. Pivotal studies submitted in an NDA, BLA, or ANDA that require regulatory decision making for approval, safety, or labeling, such as BE or pharmacokinetic studies, should include bioanalytical methods that are fully validated. Exploratory methods that would not be used to support regulatory decision making (e.g., candidate selection) may not require such stringent validation. This FFP concept applies to drugs, their metabolites, and biomarkers.

The analytical laboratory conducting toxicology studies for regulatory submissions should adhere to 21 CFR 58, Good Laboratory Practices (GLPs).[7] The bioanalytical method for human BA, BE, and pharmacokinetic studies must meet the criteria specified in 21 CFR 320 Bioequivalence and Bioavailability Requirements (i.e., 21 CFR 320.29).

The following sections discuss the development, validation, and in-study use of bioanalytical methods and how best to document validation methods and results. Refer to the Glossary for the definitions of assay parameters and analytical terms used in this guidance.

C. Bioanalytical Method Development and Validation

1. Guiding Principles

The purpose of bioanalytical method development is to define the design, operating conditions, limitations, and suitability of the method for its intended purpose and to ensure that the method is optimized for validation.

Before the development of a bioanalytical method, the sponsor should understand the analyte of interest (e.g., determine the physicochemical properties of the drug, in vitro and in vivo metabolism, and protein binding) and consider aspects of any prior analytical methods that may be applicable.

The elements and acceptance criteria of method development and validation are summarized in Table 7.1. Table 7.2 describes how the sponsor should document the development and validation of the bioanalytical assay and where it should be stored or submitted.

Method development involves optimizing the procedures and conditions involved with extracting and detecting the analyte. Method development includes the optimization of the following bioanalytical parameters (which are discussed in greater detail in Section III.B) to ensure that the method is suitable for validation:

- Reference standards
- Critical reagents
- Calibration curve
- Quality control samples (QCs)
- Selectivity and specificity
- Sensitivity
- Accuracy
- Precision
- Recovery
- Stability of the analyte in the matrix

Bioanalytical method development does not require extensive record keeping or notation. However, the sponsor should record the changes to procedures as well as any issues and their resolutions during development of the bioanalytical method to provide a rationale for any changes during the development of the method.

Bioanalytical method validation proves that the optimized method is suited to the analysis of the study samples. The sponsor should:

- Conduct a full validation of any new bioanalytical method for the analysis of a new drug entity, its metabolite(s), or biomarkers.
- Conduct a full validation for any revisions to an existing validated method that adds a metabolite or an additional analyte.
- Establish a detailed, written description [e.g., protocol, study plan, and/or standard operating procedure (SOP)] for the bioanalytical method before initiating validation. The description should identify procedures that control critical parameters in the method (e.g., environmental, matrix, procedural variables) from the time of collection of the samples to the time of analysis to minimize their effects on the measurement of the analyte in the matrix.
- Document and report (in the method validation report) all experiments used to make claims or draw conclusions about the validity of the method.
- Validate the measurement of each analyte in the biological matrix. The specific recommendations and acceptance criteria for each bioanalytical parameter are listed in Table 7.1.

2. Bioanalytical Parameters of CCs and LBAs

The bioanalytical parameters applicable to CCs and LBAs are discussed below. Issues unique to either CCs or LBAs are specifically identified.

1. Reference Standards and Critical Reagents

The sponsor should appropriately characterize and document (e.g., determine the identity, purity, and stability) all reference standards and critical reagents, such as antibodies, labeled analytes, and matrices, and store them under defined conditions.

a. Reference Standards The purity of reference standards used to prepare calibrators and QCs can affect the study data. Therefore, the sponsor should use authenticated analytical reference standards with known identities and purities to prepare solutions of known concentrations. The reference standard should be identical to the analyte; however, when this scenario is not possible, the sponsor can use an established chemical form (e.g., free base, free acid, or salt) of known purity.

The sponsor should provide the Certificates of Analysis (CoA), including the source, lot number, and expiration date [with the exception of United States Pharmacopeia (USP) standards] for commercially available reference standards. For internally or externally generated reference standards that do not have a CoA, the sponsor should provide evidence of the standard's identity and purity in addition to the source and the lot number. When using expired reference standards, the sponsor should provide an updated CoA or re-establish the identity and purity of the standard. If the reference standard expires, the sponsor should not make stock solutions with this lot of standard unless the standard's purity is re-established. For internal standards (ISs), the sponsor does not have to provide a CoA or evidence of purity if it demonstrates that the IS is suitable for the specific use (e.g., lack of interference with an analyte).

b. Critical Reagents The sponsor should appropriately characterize and document (i.e., determine the identity, purity, and stability) the critical reagents, including—but not limited to—any reference standards, antibodies, labeled analytes, and matrices.

Assay validation is important when there are changes to the critical reagents, such as lot-to-lot changes or switches to another reagent. For example, if there are changes to the labeled analytes, detector reagents, or antibodies, the sponsor should:

- Evaluate binding and re-optimize assays
- Verify performance with a standard curve and QCs
- Evaluate cross-reactivities

2. Calibration Curve

During method development, the sponsor should choose the quantitation range of the assay and the concentrations of the calibration standards on the basis of the concentration range expected in a particular study. For LBAs, in addition to the calibration standards, anchor points outside the range of quantification can facilitate the fitting of the curve. Anchor points should not be used as part of the acceptance criteria for the run. For most LBAs, calibration (standard) curves are inherently nonlinear, and in general, more calibration standards are needed to define the fit over the calibration curve range for LBAs than for CCs. In addition, the response–error relationship for LBA standard curves is a variable function of the mean response (i.e., heteroscadisticity).

The sponsor should use the simplest model that adequately describes the concentration–response relationship, as well as an appropriate weighting scheme and regression equation. For LBAs, the concentration–response relationship is most often fitted to a four- or five-parameter logistic model, although other models can be assessed.

When the method is validated, the calibration curve should be continuous and reproducible. The sponsor should prepare the calibration standards in the same biological matrix as the samples in the intended study. Study samples may contain more than one analyte. The sponsor should generate a calibration curve for each analyte in the sample. When surrogate matrices are necessary, the sponsor should justify and validate the calibration curves.

The requirements for the calibration curve, including the LLOQ, ULOQ, as well as the acceptance criteria are listed in Table 7.1.

3. Quality Control Samples

Quality controls are used to assess the precision and accuracy of an assay and the stability of the samples. Sponsors should prepare QCs in the same matrix as the study samples to be assayed with the validated method. Freshly prepared QCs are recommended for precision and accuracy analyses during method development, as stability data are generally not available at this time.

During method validation, QCs evaluate the performance of a method and the stability of an analyte. Performance QCs are included in validation runs to determine the precision and accuracy of the method (see Section III.B). Stability QCs evaluate the stability of an analyte under various stress conditions (refer to Section III.B for the selection of QC concentrations).

The sponsor should prepare any calibration standards and QCs from separate stock solutions. However, if the sponsor can demonstrate the precision and accuracy in one validation run using calibrators and QCs prepared from separate stock solutions, then the sponsor can use calibrators and QCs prepared from the same stock solution in subsequent runs. The sponsor should make up calibrators and QCs in lots of blank matrix that is free of interference or matrix effects.

4. Selectivity and Specificity

During method development, the sponsor should verify that the substance being measured is the intended analyte to minimize or avoid interference. Selectivity of the method is routinely demonstrated by analyzing blank samples of the appropriate biological matrix (e.g., plasma) from multiple sources. Depending on the intended use of the assay, the impact of hemolyzed samples, lipemic samples, or samples from special populations can be included in the selectivity

assessment. When using liquid chromatography/mass spectrometry (LC/MS) methods, the sponsor or applicant should determine the effects of the matrix on ion suppression, ion enhancement, or extraction efficiency. Internal standards should be assessed to avoid interference with the analyte. Potential interfering substances in a biological matrix include endogenous matrix components such as metabolites, decomposition products—and from the actual study—concomitant medications and other xenobiotics. If a stabilizer or enzyme inhibitor is used during sample collection, the sponsor should evaluate the potential for interference on the quantitation of the analyte. Sponsors should make a scientific judgment about the need to assess these (and any other) potential interferences during method development.

During validation, the sponsor should confirm that the assay is free of potential interfering substances including endogenous matrix components, metabolites, anticipated concomitant medications, etc. If the study sample contains more than one analyte and the analytes are intended to be quantified by different methods, the sponsor should test each method for interference from the other analyte.

The sponsor should analyze blank samples of the appropriate biological matrix (e.g., plasma) from at least six (for CCs) or ten (for LBAs) individual sources. The sponsor should ensure that there are no matrix effects throughout the application of the method. Refer to Table 7.1 for details of selectivity and specificity requirements and acceptance criteria.

For LBAs, it is important to investigate any interference originating from structurally or physiologically similar analytes (i.e., exogenous interference) or matrix effects (i.e., endogenous interference). Investigating exogenous interference involves determining the cross-reactivity of molecules that could potentially interfere with the binding interaction, including molecules structurally related to the drug, any metabolites, concomitant medications (and their significant metabolites), or endogenous matrix components. The sponsor should evaluate each factor individually and in combination with the analyte of interest to determine its ability to cause interference. Matrix effects evaluation involves comparing calibration curves in multiple sources of the biological matrix against a calibration curve in the matrix for parallelism (serial dilution of incurred samples) and nonspecific binding. The sponsor should eliminate or minimize any significant interference. If such attempts are unsuccessful, the sponsor could consider the development of an orthogonal method to eliminate or minimize the interference.

Carryover between samples can occur in analytical methods. The sponsor should eliminate any carryover during method development. If carryover cannot be eliminated, the sponsor should assess the impact of any carryover during method validation on the accuracy of the study sample concentrations.

5. *Sensitivity*

The LLOQ defines the method sensitivity and should be determined during method development. The method should be developed and validated such that it will be able to meet the requirements necessary for the intended study samples. The LLOQ evaluation can be done separately or as part of the precision and accuracy assessment for the calibration range. The specific recommendations to validate sensitivity are listed in Table 7.1.

6. *Accuracy, Precision, and Recovery*

Evaluating the accuracy and precision across the quantitation range during method development is essential to determine whether the method is ready for validation and involves analyzing replicate QCs at multiple concentrations across the assay range. Specifically, the sponsor should evaluate the performance at the LLOQ, low, mid, and high QCs (and the ULOQ for LBAs) to determine if the method is suitable to analyze study samples.

Method validation experiments for estimating accuracy and precision should include a minimum of three (for CCs) or six (for LBAs) independent runs [i.e., accuracy and precision (A & P) runs; see Table 7.1] conducted over several days. Each A & P run should include a calibration curve and multiple QC concentrations that are analyzed in replicates. The sponsor should determine the accuracy and precision of the method based on the performance of the QC in the A & P runs. The specific validation requirements for accuracy and precision and A & P runs are listed in Table 7.1. The sponsor should use freshly prepared calibrators and QCs in all A & P runs. Use of freshly prepared QCs in all A & P runs is preferred; however, if this is not possible, the sponsor should use freshly prepared QCs in one or more A & P runs.

The sponsor should optimize the recovery of the analyte to ensure that the extraction is efficient and reproducible. Recovery need not be 100%, but the extent of the recovery of an analyte and of the ISs should be consistent and reproducible. The sponsor should perform recovery experiments by comparing the analytical results of extracted samples with corresponding extracts of blanks spiked with the analyte post-extraction (i.e., to represent 100% recovery).

Recovery evaluation is not necessary for LBAs unless sample extraction is involved. Recovery experiments should be performed as described in Table 7.1.

7. *Stability*

During method development, the sponsor should determine the chemical stability of the analyte in a given matrix, including the effects of sample collection, handling, and storage of the analyte. The sponsor should assess autosampler, benchtop, processed or extracted samples, freeze-thaw, stock solution, and long-term stability of the analyte. The sponsor should assess the stability in the same matrix as that intended for in-study samples; however, when the matrix is rare, the sponsor can explore the use of suitable surrogate matrices.

For drugs administered as fixed combinations, or part of a specific drug regimen, the stability of the analyte should be assessed in the presence of the other drug. The sponsor should also consider the stability of the analyte in the

presence of other co-medications that are known to be regularly administered to patients for the indication of the drug under development.

Depending on the analyte as well as the sample collection and assay conditions, evaluating the stability of the analyte in whole blood during method development can be useful. For example, a drug can be unstable in whole blood or adsorb to cellular components during collection.

During validation, stability evaluations should cover the expected sample conditions before receipt at the analytical site (e.g., at the clinical site, during shipment, and at all other secondary sites) as well as during receipt and analysis at the analytical site. Validation of drug stability in a biological fluid is a function of the storage conditions, the physicochemical properties of the drug, the matrix, and the container system. The stability of an analyte in a particular matrix and container system is relevant only to that matrix and container system and should not be extrapolated to other matrices and container systems.

If the storage conditions changed or the sample analysis occurred outside of the validated storage condition, the stability should be re-established under these new conditions. Stability testing of the analyte in whole blood should be revalidated if necessary (e.g., if the analytes are unstable during blood collection). The specific recommendations and acceptance criteria for stability are listed in Table 7.1.

Matrix-related stability experiments should compare stability QCs against freshly prepared calibration curves and freshly prepared QCs. Although the use of freshly prepared calibrators and QCs is the preferred approach, in some cases (e.g., for macromolecules), it may be necessary to freeze them overnight. In such cases, the sponsor should provide valid justification and demonstrate the freeze-thaw stability.

All stability determinations (see list below) should use a set of samples prepared from a freshly made stock solution of the analyte in the appropriate analyte-free, interference-free biological matrix.

- **Autosampler stability**: The sponsor should demonstrate the stability of extracts in the autosampler only if the autosampler storage conditions are different or not covered by extract (processed sample) stability.
- **Bench-top stability**: The sponsor should determine the stability of samples under the laboratory handling conditions that are expected for the study samples (e.g., the stability of samples maintained at room temperature or stored in an ice bucket).
- **Extract (or processed sample) stability**: The sponsor should assess the stability of processed samples, including the residence time in the autosampler against freshly prepared calibrators.
- **Freeze-thaw stability**: The sponsor should assess the stability of the sample after a minimum of three freeze-thaw cycles. QC samples should be thawed and analyzed according to the same procedures as the study samples. QC samples should be frozen for at least 12 hours between cycles. Freeze-thaw stability QCs should be compared to freshly prepared calibration curves and QCs.
- **Long-term stability**: The sponsor should determine the long-term stability of the sample over a period of time equal to or exceeding the time between the date of first sample collection and the date of last sample analysis. The storage temperatures studied should be the same as those used to store study samples. Long-term stability QCs should be compared to freshly prepared calibration curves and QCs. Determination of stability at –20°C would cover stability at colder temperatures.
- **Stock solution stability**: Stock solutions should not be made from reference materials that are about to expire unless the purity of the analyte in the stock solutions is re-established. When the stock solution exists in a different state (e.g., solution vs. solid) or in a different buffer composition (which is generally the case for macromolecules) from the certified reference standard, the sponsor should generate stability data on stock solutions to justify the duration of stock solution storage stability.

8. *Dilution Effects*

If the method measures diluted samples, the integrity of the dilution should be monitored during validation by diluting QC samples above the ULOQ with like matrix to bring to within quantitation range, and the accuracy and precision of these diluted QCs should be demonstrated. Dilutions used during the validation should mimic the expected dilutions in the study. The prozone effect should be demonstrated in LBAs. Refer to the specific recommendations and acceptance criteria in Table 7.1.

9. *Partial and Cross Validations*

The following section defines other types of methods validation.

a. *Partial Validation*

Partial validations evaluate modifications of already validated bioanalytical methods. Partial validation can range from as little as one intra-assay accuracy and precision determination to a nearly full validation. Raw data on partial validations should be retained at the analytical site for inspection when requested. Typical bioanalytical method modifications or changes that fall into this category include, but are not limited to, the following:

- Bioanalytical method transfers between laboratories
- Changes in analytical methodology (e.g., a change in detection systems)
- Changes in sample processing procedures
- Changes in sample volume (e.g., the smaller volume of pediatric samples)
- Changes in instruments and/or software platforms

- Extensions of the assay range
- Changes in the anticoagulant (but not changes in the counter-ion) in harvesting biological fluids (e.g., heparin to EDTA)
- Changes in the matrix within species (e.g., switching from human plasma to human blood) or changes to the species within the matrix (e.g., switching from rat plasma to mouse plasma)
- Changes to the matrices (e.g., cerebrospinal fluid)
- Demonstrating the selectivity of an analyte in the presence of concomitant medications
- Changes in LBA critical reagents (e.g., lot-to-lot changes, changes in reagents)

b. Cross Validation

Cross validation is a comparison of validation parameters of two or more bioanalytical methods or techniques that are used to generate data within the same study or across different studies.

Also, cross validation is necessary when sample analyses within a single study are conducted at more than one site or more than one laboratory. In such cases, cross validation with shared matrix QCs and non-pooled subject samples should be conducted at each site or laboratory to establish interlaboratory reliability. Pooled incurred samples can be used when insufficient volume exists. An SOP or validation plan should define the criteria a priori.

3. Validated Methods: Expectations of In-Study Analysis and Reporting

This section describes the expectations for the use of a validated bioanalytical method for routine drug analysis. The specific recommendations and acceptance criteria are listed in Table 7.1.

- If system suitability is assessed, a specific SOP should be used. System suitability, including apparatus conditioning and instrument performance, should be determined using samples that are independent of the current study calibrators, QCs, and study samples. Records of system suitability should be maintained and available for audits.
- Calibration curves and QCs should be included in all analytical runs (see Table 7.1 for details). The QCs should cover the expected study sample concentration range.
- Typically, the same curve fitting, weighting, and goodness-of-fit determined during validation should be used for the calibration curve within the study. Changes in the response–function relationship between the validation and study sample analyses indicate potential problems. A SOP should be developed a priori to address such issues.
- Total QCs should number at least 5% of the total samples analyzed or be at least six in number (low-, mid-, and high-QCs, in duplicate), whichever is greater (see Table 7.1 for details). Duplicate low-, mid-, and high-QCs should be used on all distinct processing batches within a run.
- If the study sample concentrations are clustered in a narrow range of the standard curve, additional QCs should be added to cover the sample range. If the additional QC concentrations are not bracketed by QCs validated before the study, the accuracy and precision of the additional QCs should be demonstrated before continuing with the analysis. If the partial validation is acceptable, samples that have already been analyzed do not require reanalysis.
- The QCs should be interspersed with study samples during processing and analysis.
- In each analytical run, the lack of analyte interference at the LLOQ should be confirmed (see Table 7.1 for Selectivity and Sensitivity).
- The analytical run fails if the calibration and/or QC acceptance criteria are not met (see Table 7.1).
- QC results (including outliers) from analytical runs that meet the acceptance criteria should be included in the estimation of accuracy and precision during the study's sample analysis. The QC results from all analytical runs (passed and failed) should be reported, but QC results from failed runs need not be included as part of the estimation of accuracy and precision.
- If the bioanalytical method necessitates separation of the overall analytical run into distinct processing batches (e.g., groups of samples processed at distinctly different times or by different analysts), each distinct batch should process duplicate QCs at all levels (e.g., low, middle, high) along with the study samples. Examples might include when the number of samples exceeds the capacity of a 96-well plate or when a solid phase extraction manifold cannot accommodate all samples. See Table 7.1 for what constitutes an acceptable run based on QC acceptance criteria. A distinct batch or batches in an analytical run may be rejected when it fails to meet QC acceptance criteria, but the remaining batches may pass provided that the analytical run meets the overall QC acceptance criteria.
- Study samples with concentrations listed below the LLOQ should be reported as below the LLOQ (BQL). Study samples with concentrations above the ULOQ should be diluted and re-analyzed, or the standard curve should be extended and revalidated.
- Study sample dilutions should use the same matrix (e.g., human plasma to human plasma).
- Assays of all study samples of an analyte in a biological matrix should be completed within the time period for which stability data are available. If sample handling conditions are changed or exceed

validated stability data, then the stability of the sample should be established at the new conditions.
- For CCs, the IS response should be monitored for variability. An SOP should be developed a priori to address issues with IS variability.
- Drift should be monitored, and its impact on the accuracy of the estimated unknown sample concentrations, if any, should be addressed (e.g., the impact of drift on the accuracy of interspersed QCs).
- All study samples from a subject should be analyzed in a single run, especially for studies designed with repeated measures from individual subjects (e.g., crossover or sequential design required for BE studies). If other approaches are taken, the sponsor or applicant should justify the approach and take steps to minimize the variability between periods.
- Carryover, if any, should be monitored, and its impact on the quantitation of study samples should be addressed.
- Incurred sample reanalysis (ISR) should be performed (see Section IV, Table 7.1 and Table 7.2).
- An SOP or guideline describing the reasons for a repeat analysis should be established a priori. Repeat analysis is acceptable only for assignable causes (e.g., the samples are above the ULOQ, there are sample processing errors, there is an equipment failure, the chromatography is poor). The SOP should include the acceptance criteria for reanalysis, and the sponsor or applicant should report final values. The specific recommendations are described in Table 7.1 and Table 7.2. The rationale, approach, and all data for the repeat analysis and reporting should be clearly documented.
- For study samples involving multiple analytes, a valid result for one analyte should not be rejected because of another analyte failing the acceptance criteria.
- If a unique or disproportionately high concentration of a metabolite is discovered in human studies, a fully validated assay may need to be developed for the metabolite, depending upon its activity (refer to the FDA guidance for industry entitled *Safety Testing of Drug Metabolites*).[8]
- An SOP or guideline for sample data re-integration for CCs should be established a priori. This SOP or guideline should define the criteria for re-integration and how the re-integration will be performed. The rationale for the re-integration should be clearly described and documented. Audit trails should be maintained. Original and re-integrated data should be documented and reported.

D. Incurred Sample Reanalysis

ISR is a necessary component of bioanalytical method validation and verifies the reliability of the reported study sample analyte concentrations. ISR is conducted by repeating the analysis of a subset of subject or patient samples from a given study in separate runs, preferably during the study, to critically support the precision and accuracy measurements established with the QCs. The original and repeat analyses should be conducted using the same bioanalytical method procedures. If a bulk frozen calibration curve was used for the original analysis, then it is acceptable to use a frozen curve for the ISR evaluation. The calibration curve, QCs, and study samples for the ISR evaluation should be extracted or processed separately from those used in the original runs. Incurred samples should not be pooled. ISR should be conducted in all studies submitted in an NDA, BLA, or ANDA that provide pivotal data for the approval or labeling of the product, regardless of the matrix. For instance, ISR is expected for all in vivo human BE studies in ANDAs or all pivotal pharmacokinetic, pharmacodynamic, and biomarker studies in NDAs or BLAs. For non-clinical safety studies, the performing laboratory should conduct ISR at least once for each method and species. Table 7.1 lists the sample requirements and acceptance criteria for ISR. Written SOPs should be established for the conduct of ISR and to guide an investigation in the event of ISR failure to resolve the lack of reproducibility. All aspects of ISR evaluations should be documented to allow reconstruction of the study, as well as guide any investigations (see Table 7.2).

The percentage difference of the results between the original study and the repeat study is determined with the following equation:

$$\left[\left(\text{Repeat} - \text{Original}\right) * 100\right] / \text{Mean}$$

E. Additional Issues

1. Endogenous Compounds

For analytes that are also endogenous compounds, the accuracy of the measurement of the analytes poses a challenge when the assay cannot distinguish between the therapeutic agent and the endogenous counterpart. In such situations, the following approaches are recommended to validate and monitor assay performance. Other approaches, if justified by scientific principles, can also be considered.

- The biological matrix used to prepare calibration standards should be the same as the study samples and free of the endogenous analyte. To address the suitability of using an analyte-free biological matrix, the matrix should be demonstrated to have: (1) no measurable endogenous analyte; and (2) no matrix effect or interference when compared to the biological matrix. The use of alternate matrices (e.g., buffers, dialyzed serum) for the preparation of calibration standards should be justified. The QCs should be prepared by spiking known quantities of the analyte in the same biological matrix as the study samples. The endogenous concentrations of

the analyte in the biological matrix should be evaluated before QC preparation (e.g., by replicate analysis). The concentrations for the QCs should account for the endogenous concentrations in the biological matrix (i.e., additive) and be representative of the expected study concentrations.
- Parallelism should be evaluated for assays for endogenous compounds.

2. Biomarkers

The recommendations in this guidance only pertain to the validation of assays to measure in vivo biomarker concentrations in biological matrices such as blood or urine. Considerable effort also goes into defining the biological function of biomarkers, and confusion may arise regarding terminology (e.g., biomarker method validation vs. biomarker qualification).

Biomarkers are increasingly used to assess the effects of new drugs and therapeutic biological products in patient populations. Because of the important roles biomarkers can play in evaluating the safety, activity, or effectiveness of a new medical product, it is critical to ensure the integrity of the data generated by assays used to measure them. Biomarkers can be used for a wide variety of purposes during drug development; therefore, an FFP approach should be used when determining the appropriate extent of method validation. When biomarker data will be used to support regulatory decision making, such as the pivotal determination of safety and/or effectiveness or to support dosing instructions in product labeling, the assay should be fully validated.

For assays intended to support early drug development (e.g., candidate selection, go-no-go decisions, proof-of-concept), the sponsor should incorporate the extent of method validation they deem appropriate.

Method validation for biomarker assays should address the same questions as method validation for drug assays. The accuracy, precision, sensitivity, selectivity, parallelism, range, reproducibility, and stability of a biomarker assay are important characteristics that define the method. The approach used for drug assays should be the starting point for validation of biomarker assays, although the FDA realizes that some characteristics may not apply or that different considerations may need to be addressed.

3. Diagnostic Kits

Diagnostic kits are sometimes co-developed with new drug or therapeutic biological products as analytical methods that are used during the development of new drugs and therapeutic biologics. The recommendations in this section of the guidance do not apply to commercial diagnostic kits intended for point-of-care patient diagnosis (e.g., companion diagnostic kits), which are addressed in the following CDRH guidance documents:

- *Principles for Co-development of an In Vitro Companion Diagnostic Device with a Therapeutic Product*[9]
- *In Vitro Companion Diagnostic Devices*

However, when commercial diagnostic kits are repurposed as analytical methods to measure the concentrations of drugs, therapeutic biologics, or biomarkers in development, the FDA has the following recommendations:

- LBA kits with various detection platforms are sometimes used to determine analyte concentrations in pharmacokinetic or pharmacodynamic studies when the reported results must exhibit sufficient precision and accuracy. Because such kits are generally developed for use as clinical diagnostic tools, their suitability for use in such studies should be demonstrated.
- Diagnostic kit validation data provided by the manufacturer may not ensure that the kit method is reliable for drug development purposes. In such situations, the performance of diagnostic kits should be assessed in the facility conducting the sample analysis.

Validation considerations for kit assays include, but are not limited to, the following examples:

- Site-specific validation should be performed. The specificity, accuracy, precision, and stability of the assay should be demonstrated under actual conditions of use. Modifications from kit processing instructions should be completely validated.
- Kits that use sparse calibration standards (e.g., one- or two-point calibration curves) should include in-house validation experiments to establish the calibration curve with a sufficient number of standards across the calibration range as specified in Table 7.1.
- Actual QC concentrations should be known. Concentrations of QCs expressed as ranges are not sufficient for quantitative applications. In such cases, QCs with known concentrations should be prepared and used, independent of the kit-supplied QCs.
- Standards and QCs should be prepared in the same matrix as the subject samples. Kits with standards and QCs prepared in a matrix different from the subject samples should be justified, and appropriate cross-validation experiments should be performed. Refer to Section V.A of this guidance for additional discussion.
- If the analyte source (i.e., reference standard) in the kit differs from that of the subject samples (e.g., the sample is a protein isoform of the reference standard), testing should evaluate differences in assay performance of the kit reagents.
- If multiple kit lots are used within a study, lot-to-lot variability and comparability should be addressed for any critical reagents.

- Individual batches using multiple assay plates (e.g., 96-well ELISA plates) should include sufficient replicate QCs on each plate to monitor the accuracy of the assay. Acceptance criteria should be established for the individual plates and the overall analytical run (refer to Table 7.1 and Section III.B).

4. Bridging Data from Multiple Bioanalytical Technologies

The FDA encourages the development and use of new bioanalytical technologies. However, the use of two different bioanalytical technologies for the development of a drug may generate data for the same product that could be difficult to interpret. This outcome can occur when one platform generates drug concentrations that differ from another platform. Therefore, when a new platform is used in the development of a drug, the data it produces should be bridged to that of the other method. This is best accomplished by assessing the output of both methods with a set of incurred samples (a minimum of 20 samples). In cases where one method produces data with a constant bias relative to the other, concentrations can be mathematically transformed by that factor to allow for appropriate study interpretation. Sponsors are encouraged to seek feedback from the appropriate FDA review division early in drug development. The use of two methods for BE studies in ANDAs is discouraged.

5. Dried Blood Spots

Dried blood spot (DBS) technology has been under development for several years. The benefits of DBS include reduced blood sample volumes collected for drug analysis as well as ease of collection, storage, and transportation. Additional validation of this sampling approach is essential before using DBS in regulatory studies. This validation should address, at a minimum, the effects of the following issues: storage and handling temperatures, homogeneity of sample spotting, hematocrit, stability, carryover, and reproducibility, including ISR. Correlative studies with traditional sampling should be conducted during drug development. Sponsors are encouraged to seek feedback from the appropriate FDA review division early in drug development.

F. Documentation

General and specific SOPs and good record keeping are essential to a properly validated analytical method. The data generated for bioanalytical method development and/or validation should be documented and available for data audit and inspection. Documentation at the analytical site and for submission to the FDA is described in Table 7.2.

All relevant documentation necessary for reconstructing the study as it was conducted and reported should be maintained in a secure environment. Relevant documentation includes, but is not limited to, source data, protocols and reports, records supporting procedural, operational, and environmental concerns, and correspondence records between all involved parties.

Regardless of the documentation format (i.e., paper or electronic), records should be contemporaneous with the event, and subsequent alterations should not obscure the original data. The basis for changing or reprocessing data should be documented with sufficient detail, and the original record should be maintained.

1. Summary Information

Summary information should include the following items:

- A summary of assay methods used for each study protocol should be included. Each summary should provide the protocol number, the protocol title, the assay type, the assay method identification code, the bioanalytical report code, and the effective date of the method.
- For each analyte, a summary table of all the relevant method validation reports should be provided, including partial validation and cross validation reports. The table should include the assay method identification code, the type of assay, the reason for the new method or additional validation (e.g., to lower the limit of quantification), and the dates of final reports. Changes made to the method should be clearly identified.
- A summary table cross-referencing multiple identification codes should be provided when an assay has different codes for the assay method, the validation reports, and the bioanalytical reports.

2. Documentation for Method Validation and Bioanalytical Reports

Refer to Table 7.2 for the FDA's recommended documentation for method validation and bioanalytical reports.

G. APPENDIX

TABLE 7.1
Recommendations and Acceptance Criteria for Bioanalytical Method Validation and In-Study Conduct (Refer to Sections III.A and III.B for Additional Information)

	Validation Recommendations		
Parameters	**Chromatographic Assays (CCs)**	**Ligand Binding Assays (LBAs)**	**In-Study Analysis Recommendations**
Calibration Curve	Elements: • A blank (no analyte, no IS), a zero calibrator (blank plus IS), and at least six, non-zero calibrator levels covering the quantitation range, including LLOQ in every run. • All blanks and calibrators should be in the same matrix as the study samples. • The concentration–response relationship should be fit with the simplest regression model. Acceptance Criteria: • Non-zero calibrators should be ±15% of nominal(theoretical) concentrations, except at LLOQ where the calibrator should be ±20% of the nominal concentrations in each validation run. • 75% and a minimum of six non-zero calibrator levels should meet the above criteria in each validation run.	Elements: • A blank and at least six, non-zero calibrator levels covering the quantitation range, including LLOQ per validation run. • Calibration curves are usually run in duplicate. • Additional calibrators may be used as anchor points. • All blanks and calibrators should be in the same matrix as the study samples. • The concentration–response relationship is usually fit with a four- or five-parameter logistic model. Other models may be acceptable with justification. Acceptance Criteria: • Non-zero calibrators should be ±20% of nominal (theoretical) concentrations, except at LLOQ and ULOQ where the calibrator should be ±25% of the nominal concentrations in each validation run. • 75% and a minimum of six non-zero calibrator levels should meet the above criteria in each validation run. • Anchor points should not be included in the curve fit.	Elements: • A blank, a zero, and at least six (in duplicate for LBAs) non-zero calibrator levels covering the expected range, including LLOQ per analytical run. • All blanks and calibrators should be in the same matrix as the study samples. • The in-study analysis should use the same regression model as used in validation. Acceptance Criteria: • CC: Non-zero calibrators should be ±15%, except at LLOQ where the calibrator should be • ±20% of nominal concentrations in each run. • LBA: Non-zero calibrators should be ±20%, except at LLOQ and ULOQ where the calibrator should be ±25% of nominal concentrations in each run. • CC and LBA: 75% and a minimum of six non-zero calibrator levels should meet the above criteria in each run.
	Only data points that fail to meet acceptance criteria may be excluded. Exclusion should not change the model used.		
Quality Controls (QC)	Elements: • For A & P Runs: Four QCs, including LLOQ, low (L: defined as three times the LLOQ), mid (M: defined as mid-range), and high (H: defined as high-range) from at least five replicates in at least three runs. • For Other Validation Runs: L, M, and H QCs in duplicates. Acceptance Criteria: • Refer to A & P Runs, Other Validation Runs, and Stability Evaluations.	Elements: • For A& P Runs: Five QCs, including LLOQ, L, M, H, and ULOQ from at least three replicates in at least six runs. • For Other Validation Runs: L, M, and H QCs in duplicates. Acceptance Criteria: • Refer to A & P Runs, Other Validation Runs, and Stability Evaluations.	Elements: • ≥ three QC levels (L, M, amd H) and ≥ two replicates per QC level in each analytical run. • Total QCs should be 5% of unknown samples • or ≥ six, whichever number is greater. • If the analytical runs consist of distinct processing batches, the QC acceptance criteria should be applied for the whole run and for each distinct batch within the runs. Acceptance Criteria: • CC: ≥67% of QCs should be ±15% of the nominal, and ≥50% of QCs per level should be • ±15% of their nominal. • LBA: ≥67% of QCs should be ±20% of the • nominal, and ≥50% of QCs per level should be • ±20% of their nominal.

(*Continued*)

TABLE 7.1 (CONTINUED)
Recommendations and Acceptance Criteria for Bioanalytical Method Validation and In-Study Conduct (Refer to Sections III.A and III.B for Additional Information)

	Validation Recommendations		
Parameters	**Chromatographic Assays (CCs)**	**Ligand Binding Assays (LBAs)**	**In-Study Analysis Recommendations**
	Elements: • Analyze blank samples of the appropriate biological matrix from at least six individual sources.	Elements: • Investigate parallelism (for endogenous products). • Conduct an analysis of blank samples in the matrix from ≥ ten individual sources.	CC Acceptance Criteria: • In each analytical run, the blank and zero calibrators should be free of interference at the retention times of the analyte and the internal standard. • In each analytical run, the internal standard response in the blank should not exceed 5% of average internal standard response of the calibrators and QCs. LBA Acceptance Criteria: • The blank should be free of interference for the analyte. • Parallelism should be conducted if not done during validation.
Selectivity	Acceptance Criteria: • Blank and zero calibrators should be free of interference at the retention times of the analyte(s) and the IS. • Spiked samples should be ±20% LLOQ. • The IS response in the blank should not exceed 5% of the average IS responses of the calibrators and QCs.	Acceptance Criteria: • For ≥80% of sources, unspiked matrix should be BQL, and spiked samples should be ±25% at LLOQ, and ±20% at H QC.	
Specificity	Elements: • The method specificity should be assessed for interference by cross-reacting molecules, concomitant medications, bio-transformed species, etc.	Elements: • The method specificity should be assessed for interference by cross-reacting molecules, concomitant medications, bio-transformed species, etc. • Potential interfering materials should be added to calibration curves in buffer.	Elements: • Check as needed.
	Acceptance Criteria: • See Selectivity above.	Acceptance Criteria: • QCs should meet ±20%, or 25% at the LLOQ and ULOQ.	
Carryover	Elements: • The impact of carryover on the accuracy of the study sample concentrations should be assessed. Acceptance Criteria: • Carryover should not exceed 20% of LLOQ.	Not applicable	Elements: • Carryover, if any, should be monitored, and its impact on the quantitation of study samples should be addressed. Acceptance Criteria: • Carryover should not exceed 20% of LLOQ.
Sensitivity	Elements: • The lowest nonzero standard on the calibration curve defines the sensitivity (LLOQ). Acceptance Criteria: • The analyte response at the LLOQ should be ≥ five times the analyte response of the zero calibrator. • The accuracy should be ±20% of nominal concentration (from ≥ five replicates in at least three runs). • The precision should be ±20% CV (from ≥ five replicates in at least three runs).	Elements: • The lowest nonzero standard on the calibration curve defines the sensitivity (LLOQ). Acceptance Criteria: • The accuracy should be ±25% of the nominal concentration (from ≥ three replicates in at least six runs). • The precision should be ±25% CV (from ≥ three replicates in at least six runs). • The total error should be ≤40%.	Acceptance Criteria: In each analytical run: • The analyte response at the LLOQ should be ≥ five times the analyte response of the zero calibrator (CC). • The A & P for CC should be ±20% of nominal concentration. • The A & P for LBA should be ±25% of nominal concentration. • If the above criteria are not met, the next higher calibrator can be selected as the new LLOQ or the next lower point if the ULOQ fails (provided the resulting calibration curve meets acceptance criteria) and does not change the calibration model.

(*Continued*)

TABLE 7.1 (CONTINUED)
Recommendations and Acceptance Criteria for Bioanalytical Method Validation and In-Study Conduct (Refer to Sections III.A and III.B for Additional Information)

	Validation Recommendations		
Parameters	**Chromatographic Assays (CCs)**	**Ligand Binding Assays (LBAs)**	**In-Study Analysis Recommendations**
	Elements: • A & P should be established with at least three independent A & P runs, four QC levels per run (LLOQ, L, M, H QC), and ≥ five replicates per QC level.	Elements: • A & P should be established with at least six independent A & P runs, five QC levels per run (LLOQ, L, M, H, ULOQ QC), and ≥ three replicates per QC level.	Elements: • Not applicable
Accuracy and Precision (A & P)	• A & P Run Acceptance Criteria: • The run should meet the calibration curve acceptance criteria and include the LLOQ calibrator.	• A & P Run Acceptance Criteria: • The run should meet the calibration acceptance criteria and include the LLOQ calibrator.	
	• This run has no QC acceptance criteria.	• This run has no QC acceptance criteria.	Accuracy: Between runs: • CC: ± 15% of nominal concentrations. • LBA: ± 20% of nominal concentrations.
	Accuracy: Within-run and between runs: • ±15% of nominal concentrations; except • ±20% at LLOQ.	Accuracy: Within-run and between runs: • ±20% of nominal concentrations; except • ±25% at LLOQ, ULOQ.	
	Precision: Within-run and between runs: • ±15% CV, except ±20% CV at LLOQ.	Precision: Within-run and between runs: • ± 20% CV, except ± 25% at LLOQ, ULOQ.	Precision: Between runs: • CC: ±15% CV. • LBA: ±20% CV.
	Total Error: • Not applicable.	Total Error: • QCs should be ±30%, except at LLOQ, ULOQ ±40%.	Total Error: • Not applicable.
Other Validation Runs	Elements: • ≥ three QC levels (L, M, H) in at least duplicates in each run.	Elements: • ≥ three QC levels (L, M, H) in at least duplicates in each run.	• Not applicable.
	Run Acceptance Criteria: • Meet the calibration acceptance criteria • ≥67% of QCs should be ±15% of the nominal (theoretical) values, ≥50% of QCs per level should be ±15% of their nominal concentrations.	Run Acceptance Criteria: • Meet the calibration acceptance criteria • ≥67% of QCs should be ±20% of the nominal (theoretical) values, and ≥50% of QCs per level should be ±20% of their nominal concentrations.	
Recovery	Elements: • Extracted samples at L, M, and H QC concentrations vs. extracts of blanks • spiked with the analyte post extraction (at L, M, and H).	Elements: • Need to be demonstrated only if extraction is involved.	
Stability	Elements: • For auto-sampler, bench-top, extract, freeze-thaw, stock solution, and long-term stability, per format least three replicates at L and H QC concentrations.	Elements: • For auto-sampler, bench-top, extract, freeze-thaw, stock solution/reagent, and long-term stability, perform at least three replicates at Land H QC concentrations.	Elements: • Update stability parameters (e.g., long-term) as needed.
	Acceptance Criteria: • The accuracy (% nominal) at each level should be ±15%.	Acceptance Criteria: • The accuracy (% nominal) at each level should be ±20%.	

(*Continued*)

TABLE 7.1 (CONTINUED)
Recommendations and Acceptance Criteria for Bioanalytical Method Validation and In-Study Conduct (Refer to Sections III.A and III.B for Additional Information)

	Validation Recommendations		
Parameters	**Chromatographic Assays (CCs)**	**Ligand Binding Assays (LBAs)**	**In-Study Analysis Recommendations**
Dilution	Elements: • QCs for planned dilutions, five replicates per dilution factor: • Accuracy: ±15% of nominal concentrations. • Precision: ±15% CV.	Elements: • QCs for planned dilutions. • Demonstrate dilution linearity. • Demonstrate lack of prozone effect, i.e., increasing analyte concentration results in no change or decreased signals compared to the preceding concentration. • Five replicates per dilution factor: • Accuracy: ±20% of nominal concentrations. • Precision: ±20% CV.	Elements: • Dilution QC (if not a validated pre-study). Acceptance Criteria: • Same as described under "QCs" above.
Incurred Sample Reanalysis (ISR)	• Not applicable.	• Not applicable.	Elements: • Sample size: • 10% reanalysis of the first 1000 samples, and • 5% reanalysis of the remaining samples. • Sample selection: • Around C_{max} and in the elimination phase. Acceptance Criteria: • CC: 67% should be ±20% of the mean. • LBA: 67% should be ±30% of the mean.
Repeat Analysis	• No reanalysis of individual calibrators and QCs is permitted.	• No reanalysis of individual calibrators and QCs is permitted.	• Reanalysis should be based on reasons described in a pre-existing SOP. • No reanalysis of calibrators and QCs. • At least the same number of replicates for repeats as originally tested. • No confirmatory repeats for BE studies.

TABLE 7.2
Documentation and Reporting (Refer to Sections III.B and VI for Additional Information)

Items	**Documentation at the Analytical Site**	**Validation Report[a]**	**Analytical Study Report[a]**
System Suitability	• Dates, times, QCs, or samples used for suitability testing	• Not applicable	• Not applicable
Synopsis	• Not applicable	• Synopsis of method development (e.g., evolution of methods with multiple revisions, unique aspects) • Overall summary information	• Not applicable
Reference Standards and Critical Reagents	• Certificate of Analysis (CoA) or purity, stability/expiration data, batch number, and manufacturer • Log records of receipt, use, and storage • If expired, recertified CoA or retest of purity and identity with retest dates • Internal standard CoA, purity or demonstration of suitability	• Batch/lot number, purity, and expiration (see Appendix VII, Table 7.4) • If expired, purity and stability at the time of use and retest dates	• Batch/lot number, purity, and expiration (see Appendix VII, Table 7.4) • If expired, purity and stability at the time of use and retest dates

GLOSSARY

Accuracy: The accuracy of an analytical procedure expresses the closeness of agreement between the value, which is accepted either as a conventional true value or an accepted reference value and the value found. This is sometimes termed trueness.

Accuracy: Accuracy is the degree of closeness of the determined value to the nominal or known true value under prescribed conditions. Accuracy is also sometimes termed trueness.

Analyte: An analyte is the specific chemical moiety being measured; it can be an intact drug, a biomolecule or its derivative, a metabolite, or a degradation product in a biologic matrix.

Analytical Procedure: The analytical procedure refers to the way of performing the analysis. It should describe in detail the steps necessary to perform each analytical test. This may include but is not limited to the sample, the reference standard and the reagents preparations, use of the apparatus, generation of the calibration curve, use of the formulae for the calculation, etc.

Analytical run: An analytical run is a complete set of analytical and study samples with an appropriate number of standards and QCs for their validation. Several runs can be completed in one day, or one run may take several days to complete.

Assay (content or potency): To provide an exact result, which allows an accurate statement on the content or potency of the analyte in a sample.

Autosampler stability: Autosampler stability is the stability of the analyte in the processed sample under the conditions in the autosampler.

Batch: For purposes of this guidance, a batch is a number of unknown samples from one or more patients in a study and QCs that are processed at one time.

Bench-top stability: Bench-top stability is the stability of an analyte in a matrix under conditions of sample handling during sample processing.

Between run: Between run refers to the distinct period between or among several analytical or validation runs.

Biological matrix: A biological matrix is discrete material of biological origin that can be sampled and processed in a reproducible manner. Examples are blood, serum, plasma, urine, feces, cerebrospinal fluid, saliva, sputum, and various discrete tissues.

Blank: A blank is a sample of a biological matrix to which no analytes have been added that is used to assess the selectivity of the bioanalytical method.

Calibration curve: The calibration curve—also known as the standard curve—is the relationship between the instrument response and the calibration standards within the intended quantitation range.

Calibrators/Calibration standards: Calibrators, or calibration standards, refer to a biological matrix to which a known amount of analyte has been added. Calibration standards are used to construct calibration curves from which the concentrations of analytes in QC samples and in-study samples are determined.

Carryover: Carryover is the appearance of an analyte in a sample from a preceding sample.

Critical reagents: Critical reagents are requisite components of an assay, which include antibodies, labeled analytes, matrices, etc.

Detection Limit: The detection limit of an individual analytical procedure is the lowest amount of analyte in a sample, which can be detected but not necessarily quantitated as an exact value.

Dilutional linearity: Dilutional linearity demonstrates the accurate measurement of concentrations of spiked samples (i.e., QCs) exceeding the quantitation range when serially diluted to within the quantitative assay range.

Extract stability: Extract stability assesses the degradation of the processed sample relative to the starting material.

Extract: An extract is a sample treated to remove impurities or interfering substances (also known as a processed sample).

Freeze-thaw stability: Freeze-thaw stability refers to the stability of the analyte in the matrix upon freezing and thawing.

Freshly prepared: Freshly prepared refers to QC sample preparation (i.e., spiked) on the day of the experiment, not frozen before use.

Full validation: Full validation refers to the establishment of all validation parameters that apply to sample analysis for the bioanalytical method for each analyte.

Heteroscadisticity: Heteroscadisticity occurs when the variance of a response is not constant but changes with the response.

Hook effect: The hook effect occurs when increasing analyte concentrations result in no change or decreased signals when compared to the preceding concentration.

Identification: To ensure the identity of an analyte.

Incurred sample reanalysis (ISR): ISR is the repeated measurement of an analyte's concentration from study samples to demonstrate reproducibility. Incurred samples: Incurred samples are study samples or samples from subjects or patients who were dosed.

Interference: Interference refers to the action of sample components, including structurally similar analytes, metabolites, impurities, degradants, or matrix components, that may impact quantitation of the analyte of interest. Refer to Selectivity and Matrix effect for further information.

Intermediate Precision: Intermediate precision expresses within-laboratories variations: Different days, different analysts, different equipment, etc.

Internal standard (IS): ISs are test compounds (e.g., structurally similar analogs, stable isotope labeled compounds) added to both calibration standards and

samples at known and constant concentrations to facilitate quantification of the target analyte(s).

Lack of specificity: Lack of specificity of an individual analytical procedure may be compensated by other supporting analytical procedure(s).

Linearity: The linearity of an analytical procedure is its ability (within a given range) to obtain test results, which are directly proportional to the concentration (amount) of analyte in the sample.

Long-term stability: Long-term stability assesses the degradation of an analyte in the matrix relative to the starting material after periods of frozen storage.

Lower limit of quantification (LLOQ): The LLOQ is the lowest amount of an analyte that can be quantitatively determined with acceptable precision and accuracy.

Matrix effect: The matrix effect is a direct or indirect alteration or interference in response because of the presence of unintended analytes (for analysis) or other interfering substances in the sample.

Method: A method is a comprehensive description of all procedures used in the collection, storage, and analysis of samples.

Nominal concentration: The nominal concentration is the actual or intended concentration of the calibrator or quality control samples.

Non-zero calibrator: A non-zero calibrator is a calibrator to which the internal standard is added.

Parallelism: Parallelism demonstrates that the serially diluted incurred sample response curve is parallel to the calibration curve. Parallelism is a performance characteristic that can detect potential matrix effects and interactions between critical reagents in an assay.

Precision: The precision of an analytical procedure expresses the closeness of agreement (degree of scatter) between a series of measurements obtained from multiple sampling of the same homogeneous sample under the prescribed conditions. Precision may be considered at three levels: Repeatability, intermediate precision, and reproducibility. Precision should be investigated using homogeneous, authentic samples. However, if it is not possible to obtain a homogeneous sample, it may be investigated using artificially prepared samples or a sample solution. The precision of an analytical procedure is usually expressed as the variance, standard deviation, or coefficient of variation of a series of measurements. Precision is the closeness of agreement (i.e., degree of scatter) among a series of measurements obtained from multiple sampling of the same homogenous sample under the prescribed conditions.

Processed sample: A processed sample is the final extract (before instrumental analysis) of a sample that has been subjected to various manipulations (e.g., extraction, dilution, concentration).

Processing batch: A processing batch is a group of unknown samples from one or more study subjects, calibrators, and a set of QCs that are subjected to the analytical methodology together.

Prozone: The prozone is an effect observed when increasing analyte concentrations result in either no change or decreased detector response when compared to the preceding concentration (also see the Hook effect).

Purity Tests: To ensure that all the analytical procedures performed allow an accurate statement of the content of impurities of an analyte, that is, related substances test, heavy metals, residual solvents content, etc.

Quality control sample (QC): A QC is a biological matrix with a known quantity of analyte that is used to monitor the performance of a bioanalytical method and to assess the integrity and validity of the results of study samples analyzed in an individual run.

Quantification range: The quantification range is the range of concentrations, including the ULOQ and the LLOQ, that can be reliably and reproducibly quantified with accuracy and precision with a concentration–response relationship.

Quantitation Limit: The Quantitation Limit of an individual analytical procedure is the lowest amount of analyte in a sample, which can be quantitatively determined with suitable precision and accuracy. The Quantitation Limit is a parameter of quantitative assays for low levels of compounds in sample matrices and is used particularly for the determination of impurities and/or degradation products.

Range: The range of an analytical procedure is the interval between the upper and lower concentration (amounts) of analyte in the sample (including these concentrations) for which it has been demonstrated that the analytical procedure has a suitable level of precision, accuracy, and linearity.

Reproducibility: Reproducibility is the precision between two laboratories. It also represents the precision of the method under the same operating conditions over a short period of time.

Recovery: Recovery refers to the extraction efficiency of an analytical process, reported as a percentage of the known amount of an analyte carried through the sample extraction and processing steps of the method.

Reference standard: A reference standard is a chemical substance of known purity and identity which is used to prepare calibration standards and quality controls. Three types of reference standards are usually used: (1) certified (e.g., USP compendial standards), (2) commercially supplied, and (3) custom-synthesized.

Re-integration: Re-integration is a reanalysis of the chromatographic peak.

Repeatability: Repeatability expresses the precision under the same operating conditions over a short interval of time. Repeatability is also termed intra-assay precision.

Reproducibility: Reproducibility expresses the precision between laboratories (collaborative studies, usually applied to standardization of methodology).

Response function: Response function is the mathematical expression that describes the relationship between known sample concentrations and the response of the instrument (also refer to Calibration curve).

Robustness: The robustness of an analytical procedure is a measure of its capacity to remain unaffected by small but deliberate variations in method parameters and provides an indication of its reliability during normal usage.

Sample: A sample is a generic term encompassing controls, blanks, unknowns, and processed samples.

Selectivity: Selectivity is the extent to which the method can determine a particular compound in the analyzed matrices without interference from matrix components.

Sensitivity: Sensitivity is defined as the lowest analyte concentration in the matrix that can be measured with acceptable accuracy and precision (i.e., LLOQ).

Specificity: Specificity is the ability to assess unequivocally the analyte in the presence of components, which may be expected to be present. Typically, these might include impurities, degradants, matrix, etc. Specificity is the ability of the method to assess, unequivocally, the analyte in the presence of other components that are expected to be present (e.g., impurities, degradation products, matrix components, etc.).

Spiked samples: A spiked sample is a general term that refers to calibrators (calibration standards) and quality controls.

Stability: Stability is a measure of the intactness an analyte (lack of degradation) in a given matrix under specific storage and use conditions relative to the starting material for given time intervals.

Standard curve: Refer to Calibration curve.

Stock solution: A stock solution refers to an analyte in a solvent or mixture of solvents at a known concentration, which is used to prepare calibrators or QCs.

Study samples: Study samples refer to samples from subjects or patients enrolled in a study.

System suitability: System suitability is a determination of instrument performance (e.g., sensitivity and chromatographic retention) by analyzing a set of reference standards before the analytical run.

Total error: Total error is the sum of the absolute value of the errors in accuracy (%) and precision (%). Total error is reported as percent (%) error.

Unknown: An unknown is a biological sample that is the subject of the analysis.

Upper limit of quantification (ULOQ): The ULOQ is the highest amount of an analyte in a sample that can be quantitatively determined with precision and accuracy.

Within-run: Within-run refers to the time period during a single analytical or validation run.

Zero calibrator: A zero calibrator is a blank sample to which the internal standard is added.

8 Bioequivalence Testing of Topical Drugs

For topical dermatologic drug products, PK measurements in blood, plasma, and/or urine are usually not feasible to document BE because topical dermatologic products generally do not produce measurable concentrations in extracutaneous biological fluids. The BE determination for these products is thus often based on PD or clinical studies. An additional approach is to document BE through reliance on measurement of the active moiety(ies) in the stratum corneum. This approach is termed dermatopharmacokinetics (DPK). Although measurement of the active moiety(ies) in blood or urine is not regarded as an acceptable measurement of BE for dermatologic drug products, it may be used to measure systemic exposure.

I. INACTIVE INGREDIENTS

During the investigational new drug (IND) process for an NDA, the safety of inactive ingredients in a topical drug product should be documented by specific studies or may be based on a prior history of successful use in the same amount administered via the same route of administration in an approved product. The requisite safety studies to establish the safety of a new excipient during the investigational new drug (IND) process should be discussed with appropriate review staff at the FDA. For an ANDA, the safety of inactive ingredients in an ANDA can be based on a prior history of successful use in an NDA or ANDA. If the inactive ingredients in an ANDA are not the same as the reference listed drug, the applicant should demonstrate to the agency that the changes(s) do not affect the safety and/or efficacy of the proposed drug product. In some instances, a comparative bioavailability study will satisfy this recommendation. If preclinical or clinical studies are needed to demonstrate the safety of inactive ingredients(s) in the generic drug product, the ANDA may not be approved. In this circumstance, the applicant may wish to resubmit their application as an NDA under the provisions of 505(b)(1) or (b)(2) of the act.

II. WAIVER OF BIOEQUIVALENCE

In accordance with 21 CFR 314.94(a)(9)(v), generally, the test (generic) product intended for topical use must contain the same inactive ingredients as the RLD. For all topical drug products intended for marketing under an abbreviated application, documentation of in vivo bioequivalence is required under 21 CFR 320.21(b). For a topical solution drug product, in vivo bioequivalence may be waived if the inactive ingredients in the product are qualitatively identical and quantitatively essentially the same compared to the listed drug. In this setting, quantitatively *essentially the same* means that the amount/concentration of the inactive ingredient(s) in the test product cannot differ by more than ±5% of the amount/concentration of the listed drug. Where a test solution differs qualitatively or quantitatively from the listed drug, in vivo BE may be waived, provided the sponsor submits evidence that the difference does not affect safety and/or efficacy of the product at the time a waiver is requested.

III. BIOEQUIVALENCE APPROACHES

Comparative clinical trials are generally difficult to perform, highly variable, and insensitive. For these reasons, other approaches, such as DPK or pharmacodynamic (PD), may be used for BE determination.

A. Dermatopharmacokinetic Approaches

The DPK approach is comparable to a blood, plasma, urine PK approach applied to the stratum corneum. DPK encompasses drug concentration measurements with respect to time and provides information on drug uptake, apparent steady-state levels, and drug elimination from the stratum corneum based on a stratum corneum concentration–time curve.

When applied to diseased skin, topical drug products induce one or more therapeutic responses, where onset, duration, and magnitude depend on the relative efficiency of three sequential processes, namely, (1) the release of the drug from the dosage form, (2) penetration of the drug through the skin barrier, and (3) generation of the desired pharmacological effect. Because topical products deliver the drug directly to or near the intended site of action, measurement of the drug uptake into and drug elimination from the stratum corneum can provide a DPK means of assessing the BE of two topical drug products. Presumably, two formulations that produce comparable stratum corneum concentration–time curves may be BE, just as two oral formulations are judged BE if they produce comparable plasma concentration–time curves. Even though the target site for topical dermatologic drug products in some instances may not be the stratum corneum, the topical drug must still pass through the stratum corneum, except in instances of damage, to reach deeper sites of action. In certain instances, the stratum corneum itself is the site of action. For example, in fungal infections of the skin, fungi reside in the stratum corneum, and therefore DPK measurement of an antifungal drug in the stratum corneum represents direct measurement of drug concentration at the site of action. In instances where the stratum corneum is disrupted or damaged, in vitro drug release may provide additional information toward the BE assessment. In this context, the drug release rate may reflect drug delivery directly to the dermal skin site without passage through the stratum corneum. For antiacne drug products, target sites are the hair follicles and sebaceous glands. In this setting, the drug diffuses through the stratum corneum, epidermis, and

dermis to reach the site of action. The drug may also follow follicular pathways to reach the sites of action. The extent of follicular penetration depends on the particle size of the active ingredient if it is in the form of a suspension. Under these circumstances, the DPK approach is still expected to be applicable because studies indicate a positive correlation between the stratum corneum and follicular concentrations. Although the exact mechanism of action for some dermatologic drugs is unclear, the DPK approach may still be useful as a measure of BE because it has been demonstrated that the stratum corneum functions as a reservoir, and stratum corneum concentration is a predictor of the amount of drug absorbed.

For reasons thus cited, DPK principles should be generally applicable to all topical dermatologic drug products including antifungal, antiviral, antiacne, antibiotic, corticosteroid, and vaginally applied drug products. The DPK approach can thus be the primary means to document BA/BE. Additional information, such as comparative in vitro release data and particle size distribution of the active ingredient between the RLD and the test product, may provide additional supportive information. Generally, BE determinations using DPK studies are performed in healthy subjects because skin where disease is present demonstrates high variability and changes over time. Use of healthy subjects is consistent with similar use in BE studies for oral drug products.

A DPK approach is not generally applicable (1) when a single application of the dermatologic preparation damages the stratum corneum, (2) for otic preparations except when the product is intended for otic inflammation of the skin, and (3) for ophthalmic preparations because the cornea is structurally different from the stratum corneum. The following three sections of the guidance provide general procedures for conducting a BA/BE study using DPK methodology.

1. Performance and Validation of the Skin Stripping Technique

DPK studies should include validation of both analytical methods and the technique of skin stripping. Since the DPK approach involves two components of validation (sampling and analytical method), overall DPK variability may be greater than with other methodologies. For analytical methods, levels of accuracy, precision, sensitivity, specificity, and reproducibility should be documented according to established procedures. Although the forearm, back, thigh, or other part of the body can be used for skin stripping studies, most studies are conducted on the forearm, for reasons of convenience. Care should be taken to avoid any damage with physical, mechanical, or chemical irritants (e.g., soaps, detergents, agents). Usual hydration and environmental conditions should be maintained. After washing prior to treatment, sufficient time, preferably 2 hours, should be allowed to normalize the skin surface. Detailed and workable standard operating procedures (SOPs) for area and amount of drug application, excess drug removal, and skin stripping methodology should be developed. The product's stability during the course of the study should be established. If the product is unstable, the rate and extent of degradation in situ over the period should be determined accurately so that a correction factor may be applied. Skin on both left and right arms of healthy subjects may be used to provide eight or more sites per arm. The size of the skin stripping area is important to allow collection of a sufficient drug in a sample to achieve adequate analytical detectability. Inter- and intra-arm variability should be assessed, and the treatment sites should be randomized appropriately. If a sponsor or applicant is using multiple investigators to conduct a single study, the reproducibility of skin stripping data between the investigators should be established. Either of the following approaches are recommended:

- A dose–response relationship between the drug concentration in the applied dosage form and the drug concentration in the stratum corneum should be established using the skin stripping method. A DPK dose–response relationship is analogous to a dose proportionality study performed with solid oral dosage forms. This type of study can be readily performed using three different strengths of the formulations. These can be marketed or specially manufactured products. Alternatively, a solution of the active drug representing three concentrations can be prepared for this purpose. Amount of drug in the stratum corneum at the end of a specified time interval, such as 3 hours, can provide a dose–response relationship.
- The skin stripping method should be capable of detecting differences of ±25% in the strength of a product. This can be determined by applying different concentrations (e.g., 75%, 100%, 125%) of a test dosage form such as a simple solution to the skin surface for a specified exposure time such as 3 hours, executing the skin stripping method, and performing the appropriate statistical tests comparing the strength applied to the measured drug concentration in the stratum corneum.

Using the reference product, the approximate minimum time required for drug to reach saturation level in the stratum corneum should be determined. This study establishes the time point at which the elimination phase of the study may be initiated.

The drug concentration–time profile may vary with the drug, the drug potency class, formulation, subject, sites of application, circadian rhythm, ambient temperature, and humidity. These factors should be considered and controlled as necessary.

Circadian rhythms may be present and may affect the measurement of skin stripping drug concentration if the drug is also an endogenous chemical (e.g., corticosteroid or retinoic acid). In such circumstances, the baseline concentration of the endogenous compound should be measured over time from sites where no drug product has been applied.

IV. SAMPLE PILOT STUDY

The reference drug product is randomly applied to eight sites on one forearm, with skin stripping performed at incremental

times after application (e.g., 15, 30, 60, and 180 minutes) (see Figure 8.1). One site is used for each time point. Four additional sites at 180 minutes on the same arm should be assessed to provide a total of five replicates for the same time point. An additional site with no application of a drug product should be sampled as a control, yielding a total of nine sampling sites. The contralateral forearm may be used to assess dose–response and sensitivity relationships by applying at least three concentrations of the drug product or simple drug solution for 180 minutes in duplicates. Two additional applications of the reference drug product on the same arm should be tested for 180 minutes as well to provide additional information about inter- and intra-arm variability and reproducibility. A control site with no drug application should also be included for a total of nine sites on the contralateral arm. The pilot study should be carried out in at least six subjects. Stratum corneum samples are removed according to procedures described below and analyzed for drug concentration. Standard procedures should be followed in all elements of the study and should be carried through all subsequent studies.

A. DPK Bioequivalence Study Protocol

1. Protocol and Subject Selection

Healthy volunteers with no history of previous skin disease or atopic dermatitis and with healthy, homogeneous forearm (or other) skin areas sufficient to accommodate at least eight treatment and measurement sites (time points) should be recruited. The number of subjects to be entered may be obtained from power calculations using intra- and intersubject variability from the pilot study. Because skin stripping is highly sensitive to specific study site factors, care should be taken to perfecting the technique and enrolling a sufficient number of subjects. The following study design is based on a crossover study design, where the crossover occurs at the same time using both arms of a single subject. A crossover design in which subjects are studied on two different occasions may also be employed. If this design is employed, at least 28 days should be allowed to rejuvenate the harvested stratum corneum.

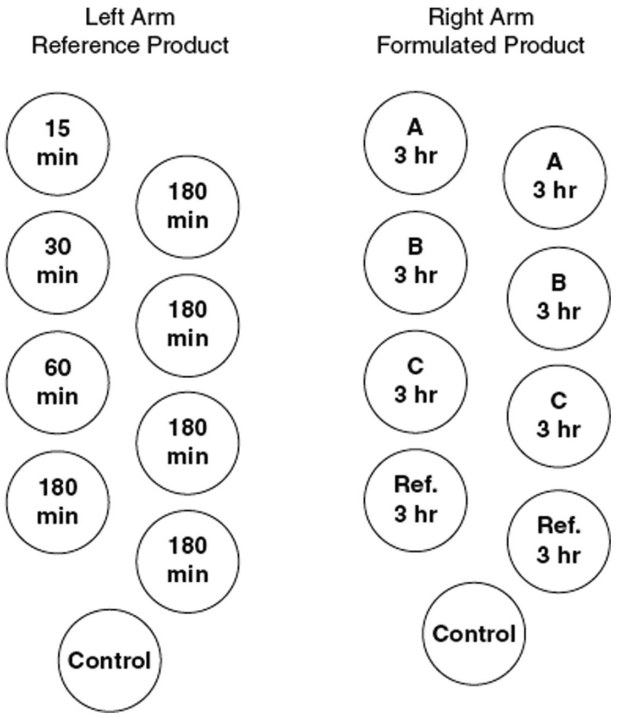

FIGURE 8.1 Schematic for drug application and removal sites for pilot study. (A) to (C) represent three concentrations of the drug product or drug solution.

2. Application and Removal of Test and Reference Products

The treatment areas are marked using a template without disturbing or injuring the stratum corneum/skin. The size of the treatment area will depend on multiple factors including drug strength, analytical sensitivity, the extent of drug diffusion, and exposure time. The stratum corneum is highly sensitive to certain environmental factors. To avoid bias and to remain within the limits of experimental convenience and accuracy, the treatment sites and arms should be randomized. Uptake, steady-state, and elimination phases, as described in more detail below, may be randomized between the right and left arms in a subject. Exposure time points in each phase may be randomized among various sites on each arm. The test and reference products for a particular exposure time point may be applied on adjacent sites to minimize differences. Test and reference products should be applied concurrently on the same subjects according to a SOP that has been previously developed and validated. The pre-marked sites are treated with predetermined amounts of the products (e.g., 5 mg/sq cm) and covered with a nonocclusive guard. Occlusion is used only if recommended in product labeling. Removal of the drug product is performed according to SOPs at the designated time points, using multiple cotton swabs or Q-tips with care to avoid stratum corneum damage. In case of certain oily preparations such as ointments, washing the area with a mild soap may be needed before skin stripping. If washing is carried out, it should be part of an SOP.

3. Sites and Duration of Application

The BE study should include measurements of drug uptake into the stratum corneum and drug elimination from skin. Each of these elements is important to establish bioavailability and/or bioequivalence of two products, and each may be affected by the excipients present in the product. A minimum of eight sites should be employed to assess uptake/elimination from each product. The time to reach steady state in the stratum corneum should be used to determine timing of samples. For example, if the drug reaches steady state in 3 hours, 0.25, 0.5, 1, and 3 hours posttreatment may be selected to determine uptake, and 4, 6, 8, and 24 hours may be used to assess elimination. A *zero* time point (control site away from test sites) on each subject should be selected to provide baseline data. If the test/reference drug products are studied on both forearms, randomly selected sites on one arm may

be designated to measure drug uptake/steady state. Sites on the contralateral arm may then be designated to measure drug elimination. During drug uptake, both the excess drug removal and stratum corneum stripping times are the same so that the stratum corneum stripping immediately follows the removal of the excess drug. In the elimination phase, the excess drug is removed from the sites at the steady-state time point, and the stratum corneum is harvested at succeeding times over 24 hours to provide an estimate of an elimination phase (see Figure 8.2).

4. Collection of Sample

Skin stripping proceeds first with the removal of the first one to two layers of stratum corneum with two adhesive tapes strip/disc applications, using a commercially available product (e.g., D-Squame, Transpore). These first two tape strips contain the generally unabsorbed, as opposed to penetrated or absorbed, drug and therefore should be analyzed separately from the rest of the tape strips. The remaining stratum corneum layers from each site are stripped at the designated time intervals. This is achieved by stripping the site with an additional ten adhesive tape strips. All ten tape strips obtained from a given time point are combined and extracted, with drug content determined using a validated analytical method. The values are generally expressed as amounts/area (e.g., ng/cm) to maintain uniformity in reported values. Data may be computed to obtain full drug concentration–time profiles, $C_{max\text{-}ss}$, $T_{max\text{-}ss}$, and AUCs for the test and reference products.

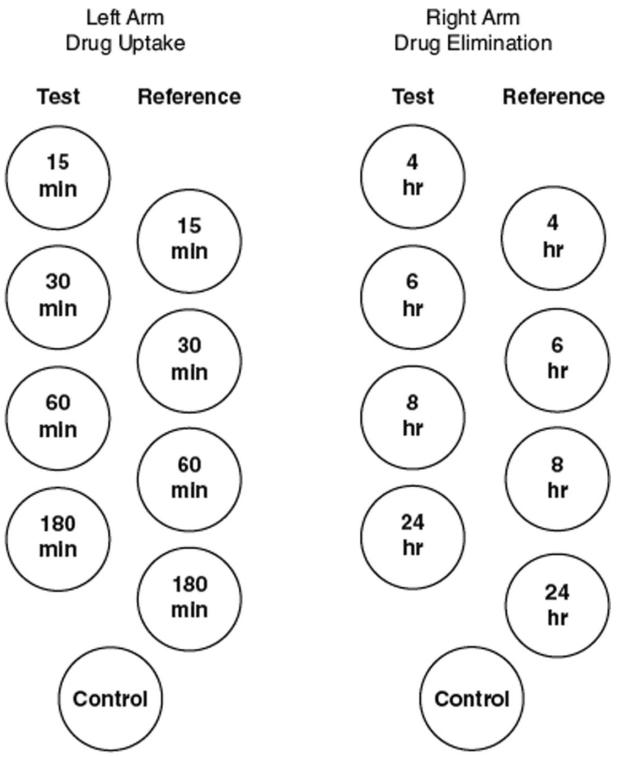

FIGURE 8.2 Schematic for drug uptake and drug elimination for bioequivalence study.

5. Procedure for Skin Stripping

The general test procedures in either the pilot study or the pivotal BA/BE study are summarized below.

To assess drug uptake:

- Apply the test and/or reference drug products concurrently at multiple sites.
- After an appropriate interval, remove the excess drug from a specific site by wiping three times lightly with a tissue or cotton swab.
- Using information from the pilot study, determine the appropriate times of sample collection to assess drug uptake.
- Repeat the application of adhesive tape two times, using uniform pressure, discarding these first two tape strips.
- Continue stripping at the same site to collect ten more stratum corneum samples.
- Care should be taken to avoid contamination with other sites.
- Repeat the procedure for each site at other designated time points.
- Extract the drug from the combined ten skin strippings, and determine the concentration using a validated analytical method.
- Express the results as amount of drug per square cm treatment area of the adhesive tape.

To assess drug elimination:

- Apply the test and reference drug product concurrently at multiple sites chosen based on the results of the pilot study. Allow sufficient exposure period to reach apparent steady-state level.
- Remove any excess drug from the skin surface as described previously, including the first two skin strippings.
- Collect skin stripping samples using ten successive tape strips at time intervals based on the pilot study and analyze them for drug content.

B. Metrics and Statistical Analyses

A plot of stratum corneum drug concentration vs. a time profile should be constructed to yield stratum corneum metrics of C_{max}, T_{max}, and AUC. The two one-sided hypotheses at the $p = 0.05$ level of significance should be tested for AUC and C_{max} by constructing the 90% confidence interval (CI) for the ratio between the test and reference averages. Individual subject parameters, as well as summary statistics (average, standard deviation, coefficient of variation, 90% CI) should be reported. For the test product to be BE, the 90% CI for the ratio of means (population geometric means based on log-transformed data) of test and reference treatments should fall within 80% to 125% for

AUC and 70% to 143% for C_{max}. Alternate approaches in the calculation of metrics and statistics are acceptable with justification.

V. PHARMACODYNAMIC APPROACHES

Sometimes topically applied dermatologic drug products produce direct/indirect PD responses that may be useful to measure BE. For example, topically applied corticosteroids produce a vasoconstrictor effect that results in skin blanching. This PD response has been correlated with corticosteroid potency and efficacy. Based on this PD response, FDA issued a guidance entitled *Topical Dermatological Corticosteroids: In Vivo Bioequivalence* (June, 1995). The guidance recommends that a pilot study be conducted to assess the dose–response characteristics of the corticosteroid followed by a formal study to assess BE. Topically applied retinoid produces transepidermal water loss that may be used as a PD measure to assess BE.

A. In Vitro Release Approaches (Lower Strength)

Usually, only one strength of a topical dermatologic drug product is available although sometimes two or, rarely, three strengths may be marketed. When multiple strengths are available, a standard practice is to create lower strengths by altering the percentage of active ingredients without otherwise changing the formulation or its manufacturing process. Topical dermatologic drug products usually contain relatively small amounts of the active drug substance, usually ≤5% and frequently ≤1%. In this setting, changes in the active ingredient may have little impact on the overall formulation.

Safety and efficacy should be documented for all strengths of topical drug products in the NDA submissions. Using some of the approaches suggested in this guidance, BA may also be documented for the highest strength. For lower strengths, where documentation of BA is considered important, this guidance suggests that in vitro release may be performed. Similarly, for an ANDA, when bioequivalence has been documented for the highest strength, in vitro release may also be used to waive in vivo studies to assess bioequivalence between these lower strengths and the corresponding strengths of the RLD. If this approach suggests bioinequivalence, further studies may be important.

To support the BE of lower strengths in an ANDA, the following conditions are important.

- Formulations of the two strengths should differ only in the concentration of the active ingredient and equivalent amount of the diluent.
- No differences should exist in manufacturing process and equipment between the two strengths.
- For an ANDA, the RLD should be marketed at both higher and lower strengths.
- For an ANDA, the higher strength of the test product should be BE to the higher strength of RLD.

In vitro drug release rate studies should be measured under the same test conditions for all strengths of both the test and RLD products. The in vitro release rate should be compared between (1) the RLD at both the higher (RHS) and lower strengths (RLS), and (2) the test (generic) products at both higher (THS) and lower strengths (TLS). Using the in vitro release rate, the following ratios and comparisons should be made:

Release rate of RHS/Release rate of RLS ≈ Release rate of THS/Release rate of TLS

The ratio of the release rates of the two strengths of the test products should be about the same as the ratio of the release rate of reference products, that is:

(Release rate of RHS × Release rate of TLS)/Release rate of RLS × Release rate of THS) ≈ 1. Using appropriate statistical methods, the standard BE interval (80–120) for a lower strength comparison of test and reference products should be used.

After approval, a sponsor may wish to develop an intermediate strength of a topical dermatologic drug product when two strengths have been approved and are in the marketplace. In this case, the in vitro release rate of the intermediate strength should fall between the in vitro release rates of the upper and lower strengths. Modifications of the approach described in this section of the guidance can thus be applied, providing all strengths differ only in the amount of active ingredient and do not differ in manufacturing processes and equipment.

B. In Vitro Release: Extension of the Methodology

Drug release from semisolid formulations is a property of the dosage form. Current scientific consensus is that in vitro release is an acceptable regulatory measure to signal inequivalence in the presence of certain formulation and manufacturing changes. With suitable validation, in vitro release may be used to assess batch-to-batch quality, replacing a series of tests that in the aggregate assess product quality and drug release (e.g., particle size determination, viscosity, and rheology). Because topical dosage forms are complex dosage forms, manufacturers should optimize the in vitro release test procedure for their product in a manner analogous to the use of in vitro dissolution to assess the quality of extended-release products from batch to batch. In addition, in vitro release might be used in a sponsor-specific comparability protocol to allow more extensive post-approval changes in formulation and/or manufacturing, provided that BE between two products representing the extremes of the formulation and manufacturing changes have been shown to be bioequivalent, using approaches recommended earlier in this document.

C. Systemic Exposure Studies

To ensure safety, and, when appropriate, comparable safety, information on systemic exposure is important for certain types of topical dermatologic drug products, such as retinoid and high-potency corticosteroids. The degree of systemic exposure for the majority of topical dermatologic drug products may be determined via standard in vivo blood, plasma, or urine PK techniques. For corticosteroids, an in vivo assessment of the HPA axis suppression test may provide the information. For other topical dermatologic drug products, such tests may not be needed.

9 Active Pharmaceutical Ingredients: GMP Compliance and Inspection

COMPLIANCE

I. INTRODUCTION

The U.S. FDA has recently updated a program in its Compliance Program Guidance Manual chapter on Drug Quality Assurance, entitled *Active Pharmaceutical Ingredient (API) Process Inspection* (Compliance Program). The program has been updated to address API compliance with the adulteration provisions of the Federal Food, Drug, and Cosmetic Act (the Act) in light of FDAs efforts as part of its "Pharmaceutical CGMPs for the 21st Century" initiative. Among other things, the revised program elaborates on the Agency's current risk-based, systems approach to inspections as it applies to the manufacture of APIs and incorporates an ICH-developed guidance document, ICH Q7A, to clarify appropriate good manufacturing practice requirements for APIs.

Active pharmaceutical ingredients, colloquially referred to as "APIs," are considered adulterated

> if it is a drug and the methods used in, or the facilities or controls used for, its manufacture, processing, packing, or holding do not conform to or are not operated or administered in conformity with current good manufacturing practice to assure that such drug meets the requirements of … safety and has the identity and strength, and meets the quality and purity characteristics, which it purports or is represented to possess.

The act does not distinguish between APIs and drug products regarding what constitutes adulteration or current good manufacturing practices (cGMPs). However, FDA has delineated the two. FDA has promulgated regulations establishing the cGMPs for finished pharmaceuticals, found in 21 CFR Parts 210 and 211, but has not developed similar regulations specifically for APIs or drug components.

FDA has consistently maintained that the concepts provided for finished pharmaceutical cGMPs in parts 210 and 211 are valid and applicable "in concept" when considering API manufacturing. Among the several concepts described in the finished pharmaceutical cGMPs are the ideas of building quality into the drug by using suitable equipment and employing appropriate personnel, establishing and implementing adequate written procedures and controls to assure that the processes and controls used in manufacturing are valid, and ensuring drug stability throughout the product's intended use period.

Although the concepts are universal, as FDA contends, the processes used in the manufacture of APIs and drug products are not. In fact, the process characteristics of an API and a drug product are fundamentally different. API processing includes chemical and biological processing, including synthesis, fermentation, extraction, and purification, while drug product processing includes physical processing, such as granulating, dissolving, mixing, and compressing. Because of this difference, API and drug product processing employ distinct facilities, equipment, and processes. This process distinction results in differences in process water quality, in process controls, process validation, reprocessing and rework, and recovery of materials and solvents. To help illuminate what constitutes cGMPs for APIs, FDA has adopted as part of the Compliance Program an internationally harmonized guidance, *ICH Q7A, Good Manufacturing Practice Guidance for Active Pharmaceutical Ingredients*, which was developed under the auspices of the International Conference on Harmonization of Technical Requirements for Registration of Pharmaceuticals for Human Use (ICH) and which specifically addresses the distinctive attributes of API processes.

As FDA reminds in the Compliance Program, the guidance represents its current thinking on cGMPs for APIs. Moreover, the Compliance Program adopts the ICH Q7A definition of "active pharmaceutical ingredient," which is defined under the guidance as

> any substance or mixture of substances intended to be used in the manufacture of a drug product and that, when used in the production of a drug, becomes an active ingredient in the drug product. Such substances are intended to furnish pharmacological activity or other direct effect in the diagnosis, cure, mitigation, treatment or prevention of disease, or to affect the structure and function of the body.

The adoption and incorporation of ICH Q7A into the Compliance Program reaffirms FDA's abandonment of its March 1998 Draft Guidance to Industry on *Manufacturing, Processing, or Holding Active Pharmaceutical Ingredients*, even though the document has not been officially withdrawn. Thus, ICH Q7A is essential to the Compliance Program; not only does it establish the definition FDA applies to determine what constitutes an API, but it also serves as the guidelines to FDA for inspecting the processes of API manufacturers. Nevertheless, even given ICH Q7A's importance to the Compliance Program, FDA openly acknowledges there are approaches not considered in ICH Q7A that may meet the cGMP requirements for API manufacture and that such approaches may be used if they satisfy the underlying statutory requirement. This position reflects FDA's current "science-based" policies.

II. FDA'S RISK-BASED, SYSTEMS APPROACH TO API INSPECTIONS

FDA maintains the goal of conducting inspections of API firms once every 2 years. In addition, the Center for Drug Evaluation and Research supplements this biennial target by providing additional API firms for inspection pursuant to Agency performance goals. FDA applies a risk-based strategy in inspecting these API manufacturers. This means that the frequency and depth of coverage of inspections is expected to reflect the relative risks associated with a firm's operations, including elements such as the firm's compliance history, the types of technology employed by the firm, and the intended use of the finished API. The risk-based approach allows the agency to adjust the regulatory scrutiny in a given circumstance to a level proportionate to the public health risks involved, to apply a uniform approach to the regulatory inspection process, and to place resources into the most useful and needed inspections.

The Compliance Program defines FDA's systems-based approach for the conduct of API inspections, which has been customized to evaluate API processes rather than drug product processes. Inspections of API facilities include an audit of two or more "systems," which are described generally by FDA as:

Quality System: The Quality System assures overall compliance with cGMPs and a company's internal procedures and specification.

Facilities and Equipment System: The Facilities and Equipment System comprises the physical environment and resources used to produce APIs.

Materials System: The Materials System includes the mechanisms by which starting materials, intermediates, and containers are controlled, including validation of computerized control processes, storage, and distribution controls.

Production System: The Production System is the scheme for controlling the manufacture of APIs; this includes in-process sampling/testing and process validation.

Packaging and Labeling System: The Packaging and Labeling System consists of elements that control the packaging and labeling of intermediates and APIs.

Laboratory Control System: The Laboratory Control System is the system used to direct laboratory procedures, testing, analytical methods development, and methods validation or verification, as well as the stability program.

These six areas of measures and activities form the basis of FDA's general regulatory inspection scheme.

As noted, every inspection of an API facility conducted by FDA includes a review of the Quality System. FDA will also apply its risk-based approach and select one or more additional systems for review. By reviewing at least two of the six systems, FDA believes it can adequately assess the overall "health" of the manufacturing practices utilized by the firm and forms an opinion of overall cGMP compliance based solely on the systems reviewed. FDA considers the inspection of the Quality System and the other selected systems to be applicable to each API product using the system and encourages inspectors to select a sufficient number and type of APIs to adequately review the system's coverage. The selected APIs are intended and expected to be representative of the firm's overall cGMP capabilities.

The Quality System

During each inspection, FDA will scrutinize an API manufacturer's Quality System, an assessment FDA views as having two phases. First, the inspector will evaluate whether the Quality Unit has fulfilled its responsibility to review and approve all procedures related to production, quality assurance, and quality controls and whether the procedures are adequate to fulfill their stated purpose, including associated record-keeping systems. Second, the inspector will assess the data collected pursuant to these specified procedures to identify quality problems. The Quality System evaluation may trigger a review of other major systems that were not otherwise slated for inspection.

Under the Compliance Program, an inspector is instructed to review and assess specified written and approved procedures and corresponding documentation resulting from implementation of the specified procedures that characterize an API manufacturer's Quality System. These include procedures and data regarding:

- The adequacy of staffing, as well as the training and qualification of employees in quality control functions
- The conduct of periodic quality reviews and complaint reviews
- Any discrepancy and failure investigations related to manufacturing and testing
- Batches manufactured since last inspection (to appraise any rejections or conversions)
- Change control
- Returns and salvages
- Rejects
- Reprocessing/reworking events
- Recalls
- The system for raw material release
- Stability failures and
- The status of validation activities

MANUFACTURING FACILITY INSPECTION

PART I—BACKGROUND

General

APIs are subject to the adulteration provisions of Section 501(a)(2)(B) of the act, which requires all drugs to be manufactured in conformance with cGMP. No distinction is made between an API and a finished pharmaceutical in the act,

and the failure of either to comply with cGMP constitutes a violation of the act. FDA has not promulgated cGMP regulations specifically for APIs or drug components (as we have for finished pharmaceuticals). Thus, the use of "cGMP" in this document refers to the requirements of the act rather than the requirements of 21CFR Parts 210 and 211 regulations for finished pharmaceuticals.

FDA has long recognized that the cGMP requirements in the good manufacturing practice regulations for finished pharmaceuticals (21 CFR Parts 210 and 211) are valid and applicable in concept to API manufacturing. These concepts include, among others, building quality into the drug by using suitable equipment and employing appropriately qualified and trained personnel, establishing adequate written procedures and controls designed to assure manufacturing processes and controls are valid, establishing a system of in-process material and final drug tests, and ensuring stability of drugs for their intended period of use. In 2001, FDA adopted an internationally harmonized guidance to industry on API cGMPs in conjunction with regulatory partners in the International Conference on Harmonization of Technical Requirements for Registration of Pharmaceuticals for Human Use (ICH). This guidance is ICH Q7A, *Good Manufacturing Practice Guidance for Active Pharmaceutical Ingredients.* ICH Q7A represents the FDA's current thinking on cGMPs for APIs. Thus, API and related manufacturing and testing facilities that follow this guidance generally will be considered to comply with the statutory cGMP requirement. However, alternate approaches may be used if such approaches satisfy the requirements of Section 501(a)(2)(B) of the act as long as the approach ensures that the API meets its purported or represented purity, identity, and quality characteristics.

The term "active pharmaceutical ingredient" (API) is used in this program consistent with the meaning of this term as defined in ICH Q7A. An active pharmaceutical ingredient is defined in ICH Q7A as

> any substance or mixture of substances intended to be used in the manufacture of a drug product and that, when used in the production of a drug, becomes an active ingredient in the drug product. Such substances are intended to furnish pharmacological activity or other direct effect in the diagnosis, cure, mitigation, treatment or prevention of disease or to affect the structure and function of the body.

Currently, other terms are also used by FDA and industry to mean an API. "Drug substance" and "bulk pharmaceutical chemical" (BPC) are the terms commonly used to mean API and, for BPC, inactive ingredients. The use of these terms to describe active ingredients may be considered equivalent to the term used here, API.

FDA expects API manufacturers to apply cGMPs to the API process beginning with the use of starting materials, and to validate critical process steps that impact the quality and purity of the final API. Controls over material quality are expected to increase as the process approaches the final API. The level of control needed is highly dependent on the manufacturing process and increases throughout the process as it proceeds from early intermediate steps to final isolation and purification steps. The appropriate level of control depends on the risk or criticality associated with each specific process step.

ICH Q7A contains general guidance to industry on the extent and application of cGMP for manufacturing APIs under an appropriate system for managing quality. It is also intended to help ensure that APIs meet the quality and purity characteristics that they purport or are represented to possess. ICH Q7A is to be used as a guideline for inspecting API manufacturers and related facilities. If an investigator believes that a particular practice conforming to this guidance is believed to be deficient, the investigator or district should consult with CDER DMPQ before making an observation that is in conflict with ICH Q7A. A firm may also use alternate approaches to those described in ICH Q7A.

API manufacturers must register, and APIs in commercial distribution must be listed under Section 510(g) of the act unless exempted under 21 CFR 207.10. Foreign drug manufacturers are also required to register and list all drugs imported or offered for import into the United States. Refer to 21 CFR 207.40 for additional information on establishment registration and drug listing requirements for foreign drug facilities.

The inspection guidance in this program is structured for the efficient use of resources planned for routine surveillance coverage of API manufacturing facilities, recognizing that in-depth coverage of all systems and all processes is not feasible for all firms on a biennial basis. It also provides for follow-up compliance coverage as needed.

Scope of APIs Covered by This Program

An API process is a related series of operations which result in the preparation of an active pharmaceutical ingredient. Major operations or steps in an API process may include multistep chemical synthesis and fermentation, purification, crystallization, drying, milling, packing, labeling, and testing.

Some drugs processed similarly to an API may in fact be bulk finished product and subject to the requirements of 21 CFR Parts 210 and 211. If the drug material will not undergo further processing or compounding after its synthesis/fermentation/extraction but is merely repackaged into market containers, it is a bulk finished product. However, investigators should use this program as guidance when covering the synthesis/fermentation processes that result in such APIs rather than the program for dosage forms (CP 7356.002).

This program does not cover all vaccines, whole cells, whole blood and plasma, blood and plasma derivatives (plasma fractionation), and gene therapy APIs as these drugs are regulated under the jurisdiction of the Center for Biologics Evaluation and Research.

The following APIs are to be inspected using CP7256.002M, Inspections of Licensed Biological Therapeutic Drug Products:

- Biotechnology-derived APIs, including those expressed from mammalian or bacterial cell cultures
- Polypeptides

Neither this Compliance Program nor ICH Q7A will provide guidance on the sterilization and aseptic processing of sterile APIs (see Q7A Section 1.3). Investigators are to use the finished product regulations (21 CFR 210 and 211) as guidance and follow CP 7356.002A, *Sterile Drug Process Inspections*, when inspecting the sterile processing of APIs labeled as sterile. Investigators are also to use FDA guidance on aseptic processing, *Sterile Drug Products Produced by Aseptic Processing—Current Good Manufacturing Practice*, 2004, in evaluating aseptic processing conditions for sterile APIs.

PART II—IMPLEMENTATION

Objective

The primary objective of this Compliance Program is to provide comprehensive cGMP inspectional coverage of the domestic and foreign API industry in all profile classes (i.e., types of API manufacturing processes) to determine whether a manufacturer is operating in a state of control. An API manufacturer is considered to be operating in a state of control when it employs conditions and practices that assure compliance with the intent of Section 501(a)(2)(B) of the act. A firm in a state of control produces APIs for which there is an adequate level of assurance of quality, identity, and purity.

A firm is not in a sufficient state of control if any one system, as defined in this program, is found to be significantly noncompliant with cGMPs, such that the quality, identity, and purity of the API resulting from that system cannot be adequately assured. Documented cGMP deficiencies provide the evidence for concluding that a system is not operating in a state of control. See Part V, *Regulatory/Administrative Strategy*, for a discussion of compliance actions based on inspection findings demonstrating that a system(s) is not in a state of control.

Profile classes generalize inspection coverage from a small number of specific APIs to all APIs in that class. This program establishes a systems approach to further generalize inspection coverage from a small number of profile classes to an overall evaluation of the firm. This allows for preapproval program inspections to focus on the specific issues related to a given application and improves the review process by providing timely and efficient support for application decisions.

Inspection of API manufacturers should be conducted and reported using the system definitions and organization in this Compliance Program. Focusing on systems, rather than just profile classes, will increase efficiency in conducting inspections because the systems are often applicable to multiple profile classes. An inspection under this program is profileable and will result in a determination of acceptability/non-acceptability for all API profile classes. Inspection coverage should be representative of all API profile classes manufactured by the firm. All other profile classes should be covered under the main program CP 7356.002, or related program circular, as appropriate.

Program Management Instructions

The Field will conduct API manufacturing inspections and maintain profiles or other monitoring systems with the goal that each API firm will receive biennial inspectional coverage. CDER will also identify firms for inspection coverage under this program to fulfill CDER and agency annual performance goals and as part of an initiative to ensure risk-based prioritization of inspection coverage.

Unless specifically directed by CDER, the District Office is responsible for determining the frequency and depth of coverage given to each API firm consistent with this Compliance Program's instructions. cGMP inspectional coverage under this program shall be sufficient to assess the state of compliance for each firm.

An inspection under this program is defined as audit coverage of two or more systems (the "systems" are defined below in this section and are consistent with the main program, 7356.002), with mandatory coverage of the Quality System. Inspecting at least two systems (i.e., the Quality System and one other system) will provide the basis for an overall cGMP decision.

Coverage of a system should be sufficiently detailed, with specific examples selected, so that the system inspection outcome reflects the state of control in that system for every profile class. If a particular representative system is adequate, it should be adequate for all profile classes manufactured by the firm.

If an API selected for inspection coverage is associated with a unique processing or control function in a system not chosen for coverage, you may cover the unique function for that API. In doing so, you need not give full coverage to that system. For example, if an API chosen for coverage uses high purity water alone in its manufacture, you may inspect the water purification system without having to give full inspection coverage of the Materials System.

In some circumstances, it may not be possible to generalize certain deficiencies in a system to all API profile classes. If so, the unaffected profile classes may be considered acceptable if found otherwise acceptable.

Selecting unique functions within a system will be at the discretion of the investigator. Any given inspection need not cover every system.

Complete inspection of one system may necessitate further follow-up of some aspects of another system to fully document the findings. However, this coverage does not constitute nor require complete coverage of the other system.

A general scheme of systems for auditing the manufacture of API consists of the following:

1. *Quality System* assures overall compliance with cGMPs and internal procedures and specifications.
2. *Facilities and Equipment System* includes activities which provide an appropriate physical environment and resources used in the production of APIs.
3. *Materials System* includes measures and activities to control starting materials, intermediates, and containers. It includes validation of computerized and

inventory control processes, storage, and distribution controls.
4. *Production System* includes measures and activities to control the manufacture of APIs, including in-process sampling and testing, and process validation.
5. *Packaging and Labeling System* includes measures and activities that control the packaging and labeling of intermediates and APIs.
6. *Laboratory Control System* includes measures and activities related to laboratory procedures, testing, analytical methods development and methods validation or verification, and the stability program.

Detailed inspection coverage guidance under these systems is given in Appendix A of this program.

Inspection Planning

This program is intended to provide for a risk-based inspection strategy. Inspection depth should therefore reflect appropriate risks associated with a particular firm's operations, such as the firm's compliance history, the technology employed, the labeled and purported characteristics, and the intended use in the finished product, if known, of the APIs.

When a system is inspected, the inspection of that system may be considered applicable to all API products which use it. Investigators should select an adequate number and type of APIs to accomplish coverage of the system. APIs selected for coverage should be representative of the firm's overall abilities in manufacturing within cGMPs. (A profile classification scheme is used to categorize APIs by the nature of their processing, as described below.)

Profile class codes or APIs selected for coverage are to be representative of all APIs processed at the firm being inspected. Profile class codes may also be grouped by similarity, such that coverage of one profile class is sufficient to demonstrate cGMP conditions for another profile class. For example, inspecting a CSS API could amount to surrogate coverage of CSN. Similarly, inspecting a CBI could amount to surrogate coverage of other profile classes, such as CFN, CFS, and perhaps CEX.

The public health significance of certain cGMP deviations may be lower when the API is intended for a dosage form that has no dosage limitation, such as in products like calamine lotion or some OTC-medicated shampoos. Such APIs should be given inspection coverage of reduced depth and intensity.

Profile Classes

The inspection findings will be used as the basis for updating all profile classes in the profile screen of the FACTS EIR coversheet that is used to record profile/class determinations. *Normally, an inspection under this system approach will result in all profile classes being updated.* Effective with this program circular is a list of profile class codes that are used to report the processes covered during API inspections. These are as follows:

Profile Class	Full Description
CSN	Non-sterile API by chemical synthesis
CSS	Sterile API by chemical synthesis
CFN	Non-sterile API by fermentation
CFS	Sterile API by fermentation
CEX	Plant/animal extraction API
CTL	Control testing laboratory
CTX	Testing laboratory plus manufacturer
CRU	Crude bulk not elsewhere classified (CRU of bulk intermediates, and contract micronizers)

Types of Inspections

There are two basic types of inspections: Surveillance and compliance. Surveillance inspections are conducted on a routine basis to satisfy FDA's responsibilities to inspect drug manufacturing facilities. Compliance inspections are conducted in response to violative surveillance inspections and when a need arises to inspect a facility for-cause.

This program follows the approach in the main Compliance Program, 7356.002. There are two alternate approaches to inspect a facility to satisfy FDA inspection obligations; these are termed "Full Inspection" and "Abbreviated Inspection." These are described in Part III, *Inspectional*, of this program.

PART III—INSPECTIONAL

Inspections of API manufacturers, whether foreign or domestic, should be conducted by experienced investigators with education and/or training particularly in fermentation (see also 7356.002M for additional inspection guidance) and chemical synthesis manufacturing methods. Use of chemists and/or microbiologists during API inspections is recommended, particularly for evaluating laboratory operations (e.g., analytical methods evaluation, analytical data, laboratory procedures, and instrumentation), analytical review of methods used to establish impurity profiles, fermentation manufacturing processes, and complex multistep chemical synthesis processes.

Investigators conducting API inspections must understand the basic differences between the processes used for the production of APIs and those used for finished dosage forms. APIs are usually produced by chemical synthesis or by cell culture and extraction. Thus, the production of APIs typically involves significant changes of starting materials or intermediates by various chemical, physical, and biological processing steps. The ultimate objective in API processing generally is to achieve a pure compound of certain identity, whereas the ultimate objective of finished dosage form manufacturing generally is to achieve the uniform distribution of an API among many dosing units designed to deliver a precise amount of API to a specific area of the body.

Since manufacturers of APIs are often referenced in many drug applications, each inspection should cover representative APIs when covering the systems selected (e.g., if inspecting the Production System for a site making an API

by fermentation and another by synthesis, the inspection should include physical inspection and audit a sampling of records for both types of processing). This strategy, together with the classification of all profile classes upon completion of the inspection, will maximize the use of agency resources and avoid repeated visits to the same manufacturing site to cover different API profile classes referenced in subsequent applications. Any inspection of an API manufacturer should be recorded as a cGMP qualifying inspection.

Inspections should cover any specific APIs referenced in the assignment and any other representative APIs not inspected in the last 2 years. For foreign API firms, investigators should cover only APIs intended to be marketed or already marketed in the United States.

APIs selected for coverage should include those that are referenced in drug applications, are therapeutically significant, are intended for use in parenteral drug products, are difficult to manufacture, or are documented as having past compliance problems. However, this does not preclude the selection of less therapeutically significant APIs to evaluate specific APIs (or profile classes) not previously given in-depth coverage at the facility.

Investigators conducting API inspections should understand the general inspection strategy set forth in this program. Recognizing that API firms vary greatly in size, diversity of operations, and quality assurance systems, investigators should carefully plan their inspectional strategy at each firm. Further guidance on preparing an inspection strategy appears later.

Investigators should also review the firm's rationale for the point at which cGMPs begin, which is expected to vary by type of process (e.g., synthetic, fermentation, extraction, purification).

For an API inspection that is initiated by a preapproval assignment, CP 7346.832, Pre-Approval Inspections/ Investigations, inspection time should be reported under the appropriate program assignment codes referenced in both Compliance Programs based on the actual time spent in each program.

Inspection Approaches

This program provides two surveillance inspectional options:

Full Inspection Option and Abbreviated Inspection Option

Either option may satisfy the biennial inspection requirement.

Full Inspection Option

The full inspection option is a surveillance or compliance inspection which is meant to provide a broad and in-depth evaluation of the firm's conformity to cGMPs. The full inspection option is an inspection of at least four of the six systems as listed in Part II and Appendix A of this program, one of which must be the Quality System.

A Full Inspection Is Appropriate

a. For an initial FDA inspection of a facility, or after a significant change in management or organizational procedures, such as might occur after a change in ownership.
b. For a firm with a history of noncompliance or a recidivist firm whose ability to comply is short-lived. To determine if the firm meets this criterion, the District should use all information at its disposal, such as current and past inspection findings, results of sample analyses, complaints, recalls, and compliance actions.
c. To evaluate if important changes have occurred in the firm's state of control by comparing current operations against the EIR for the previous Full Inspection (e.g., by conducting a Full Inspection at every fourth inspection cycle.) In addition to changes in management or ownership, the following types of changes are typical of those that warrant the full inspection option:
    1. New potential for cross-contamination arising through changes in processing or type of APIs using that equipment
    2. Use of new technology requiring new expertise, significant equipment changes and/or additions, or new facilities
d. When District management or CDER specifically requests this option.
e. To follow up on a Warning Letter or other regulatory action.

Abbreviated Inspection Option

The abbreviated inspection option is a surveillance or compliance inspection which is meant to provide an efficient update evaluation of the firm's conformity to cGMPs. A satisfactory Abbreviated Inspection will provide documentation for continuing a firm in an acceptable cGMP compliance status. The abbreviated inspection option is an inspection audit of at least two systems but not more than three systems, one of which must be the Quality System. During the course of an Abbreviated Inspection, verification of Quality System activities may require limited coverage in other systems.

An Abbreviated Inspection is appropriate when the full inspection option is not warranted, including the following:

- To maintain surveillance over a historically compliant firm's activities and to provide input to the firm on maintaining and improving the cGMP level of assurance of quality of its APIs.
- When an intended Full Inspection finds objectionable conditions as listed in Part V of this program in one or more systems (a minimum of two systems must be completed) and District management and, as necessary, CDER Office of Compliance, concurs with reducing inspection coverage in order to expedite the issuance of a Warning Letter to correct violations.

Compliance Inspections

Compliance inspections are inspections done "for-cause" and to evaluate or verify corrective actions after a regulatory action has been taken. The coverage given in compliance inspections must be related to the areas found deficient and subjected to corrective actions.

In addition, coverage must be given to other systems because a determination must be made on the overall compliance status of the firm after the corrective actions are taken. The firm is expected to address all of its operations in its corrective action plan after a previously violative inspection, not just the deficiencies noted in the FDA-483. The full inspection option should be used for a compliance inspection, especially if the abbreviated inspection option was used during the violative inspection.

Compliance inspections include "For-Cause Inspections." For-Cause Inspections are for the purpose of investigating a specific problem that has come to the attention of the agency and may not result in the coverage of systems as described in this program. The problem may be identified by a complaint, recall, or other indicator of defective API or poorly controlled process. Coverage of these problems may be assigned under other Compliance Programs or PACs; however, expansion of the coverage to a cGMP inspection is to be reported under this program. For-Cause Inspections may be assigned under this program as the need arises.

Selecting Systems for Coverage

A complete description of each system and the areas for coverage are in Appendix A of this program. The selection of the system(s) for coverage and the relative depth or intensity of audit coverage should take into consideration the relative significance of a particular system for the firm's specific operating conditions, history of previous coverage, and history of cGMP compliance. It is expected that a Full Inspection will not be conducted every two years at most firms. Districts should select different systems for inspection coverage as a cycle of Abbreviated Inspections is carried out to build comprehensive information on the firm's total manufacturing activities over time.

Preparing the Inspection Strategy

This guidance is in addition to that given in the *Investigations Operations Manual*.

1. Select two or more, as appropriate, systems for inspection coverage as guided by this program (see Inspection Approaches above). Appendix A contains a detailed description of the inspection coverage to be given each system when selected for inspection.
2. Select significant APIs for inspection coverage, if not specified in the assignment. Significant APIs are those which use all the systems in the firm very broadly and/or use special manufacturing features, e.g., complex chemical synthesis, highly sensitizing material, material of an infectious nature, or a new chemical entity made under an approved drug application. Review the firm's FACTS listing, Drug Master Files (DMF), or A/NDA files.
3. If a CDER product or cGMP/regulatory reviewer (compliance officer) is assigned to participate as a member of the inspection team, the lead investigator is to brief them on the intended inspection strategy and explain their supporting role and responsibilities for the inspection. The lead investigator should consult the reviewer on any specific A/NDA Chemistry, Manufacturing and Controls issues (whether premarket or postmarket) to be covered during the inspection.
4. Review the impurity profile for each API process to be covered during the inspection and compare these to the impurity profiles submitted in the application or DMF, if filed. (Investigators and Chemists should be particularly familiar with USP <1086> Impurities in Official Articles.) If the impurity profile has not been filed to CDER, review the guidance on establishing impurity profiles in ICH Q3A and Q3C.
5. Review any compendia monographs for the APIs to be inspected to verify conformity, as appropriate.
6. Before or during the inspection, determine if the firm has made process changes by comparing current operations against the EIR for the previous inspection. Also compare the current operations with those filed in the DMF or the drug application to determine whether the firm is complying with commitments made to the agency. (See also CP 7346.832 for conducting a preapproval inspection of an API.) The following changes are typical of those that would warrant extensive coverage during the inspection:
   a. New potential for cross-contamination arising through changes in API processes or product-type lines, to include processing numerous APIs of varying toxicity in common equipment and/or facilities.
   b. Use of new technology requiring new expertise, significantly new equipment, or new facilities.
   c. Changes in starting materials, intermediates, equipment, facilities, support systems, processing steps, packaging materials, or computer software, particularly those that are not referenced in the DMF or application.
7. For foreign firms, Division of Field Investigations (DFI) will assist investigators in obtaining file information from the appropriate CDER reviewing division or compliance unit. Investigators may also request background information about the site assigned for inspection directly from the U.S. Agent before the initiation of the inspection.

Special Inspection Reporting Instructions

Investigators should describe in the EIR their inspection coverage and findings in sufficient detail for further agency evaluation of the firm's state of control and conformance to cGMPs.

ICH Q7A may be used as a guideline in describing coverage and any findings and deficiencies observed. However, do not reference specific ICH Q7A sections in the FDA 483 observations or in the EIR. The FDA 483, if issued, is to be organized into sections for each of the systems covered. In addition to the *Investigations Operations Manual* format and information reporting requirements, all EIRs of API manufacturers must include

1. A list of APIs manufactured (or categories of drugs, if many) along with the general manufacturing process for each (e.g., chemical synthesis, fermentation, extraction of botanical material)
2. For foreign API manufacturers, the names, titles, complete mailing address, telephone and fax number of the firm's U.S. Agent
3. For foreign API manufacturers, a report of all APIs imported into the United States in the last 2 years, their consignees, and an estimate of the frequency and quantity of shipments to these consignees
4. A description of each of the systems selected for coverage, (i.e., areas, processes, and operations), what was covered, who was interviewed, and what manufacturing activities were taking place during the inspection
5. An explanation of the choice of APIs selected for coverage and
6. Any significant changes to a firm's packaging, labeling, product line, or processes, particularly those changes not properly filed, submitted, or reported in a DMF or A/NDA

Special Instructions for Foreign Drug Inspections

The DFI schedules foreign inspections, makes travel arrangements for inspection teams, and resolves logistical problems. CDER's Office of Compliance, Foreign Inspection Team (FIT), receives and reviews all foreign establishment inspection reports, receives and reviews all foreign firms' responses to an FDA 483, and handles all correspondence regarding inspection outcomes with foreign firms. CDER/FIT maintains the complete file for each foreign drug facility.

Investigators should instruct management at foreign firms to submit their original written response to an FDA 483 directly to CDER's Office of Compliance, with a copy to the investigator. The original response with appropriate documentation should be submitted to the following address:

Food and Drug Administration
Foreign Inspection Team, HFD-325
Division of Manufacturing and Product Quality
Center for Drug Evaluation and Research
11919 Rockville Pike
Rockville, Maryland 20852–2784
USA

Investigators and analysts are to submit their written comments to a foreign firm's response to their issued FDA 483 directly to CDER's FIT as soon as possible. After appropriate district office review and endorsement, all foreign establishment inspection reports will be promptly forwarded to FIT for review and final classification.

FIT will draft and coordinate the issuance of Warning Letters, Untitled Letters, and other correspondence to foreign firms. FIT will also recommend automatic detention of foreign firms/APIs, make recommendations to review units, and request follow-up inspections, as appropriate.

PART IV—ANALYTICAL

API samples collected by the investigator for the purpose of evaluating quality are to be submitted to the appropriate servicing laboratory. A list of each analyzing laboratory for API testing is maintained in Compliance Program Guidance 7356.002 and 7346.832. However, it should be noted that physical API samples are not required to support regulatory or administrative action against a violative firm or drug.

Forensic Chemistry Center (FCC) will request profile (also called "forensic" and "fingerprint") samples of both foreign and domestic source APIs directly from the manufacturer. Investigators are to collect API samples for profile analysis only upon specific request for collection from FCC. Such requests will be made through DFI. If an investigator is instructed to collect a profile sample, FCC will provide specific instructions as to method and amount of collection and shipping. FCC contact information is in Part VI, *Program Contacts*.

Prior to each foreign API site inspection, DFI will provide FCC with the inspection dates, the investigator's name, firm's name, address, telephone number, fax number, FEI number, any related product and application numbers, and the name of the contact person. FCC will then directly request a sample from the firm as needed. FCC may contact the investigator to request their collection of any specific information. The inspection dates will provide FCC information so they can access FACTS to obtain the EIR coversheet.

FCC is responsible for API profile sample collection and analysis and will provide periodic reports of such analysis and assist CDER in evaluating this program's effectiveness.

PART V—REGULATORY/ ADMINISTRATIVE STRATEGY

An inspection report that documents that one or more systems is out of control should be classified OAI (Office Action Indicated). Districts may recommend the issuance of a Warning Letter in accordance with the RPM (Regulatory Procedure Manual). Normally, the issuance of a Warning Letter or the taking of other regulatory or administrative action should result in a classification of all profile classes as unacceptable. A CDER disapproval of a recommendation for Warning Letter or other regulatory action should result in a classification of all profile classes as acceptable.

A Warning Letter with a cGMP charge [i.e., 501(a)(2)(B) adulteration] involving a domestic API manufacturer requires

CDER review and concurrence before issuance. See and follow FDA *Regulatory Procedures Manual* procedures for clearing Warning Letters and Untitled Letters.

A recommendation for regulatory action for API cGMP deficiencies is to cite the statute [501(a)(2)(B) or United States Code, 21 USC 351(a)(2)(B)] and not the finished pharmaceutical regulations at 21CFR 210 and 211. A recommendation should also not cite to ICH Q7A but may use ICH Q7A as a guideline in describing the deficiencies observed. Any regulatory action based upon cGMP noncompliance for APIs should demonstrate how the observed deviations could or did result in actual or potential defects or risk to contamination. In evaluating whether to recommend regulatory or administrative action, consider the critical attributes of the API, its therapeutic significance, and its intended use in finished drug product manufacturing.

Evidence that supports a significant deficiency or pattern of deficiencies within a system may demonstrate the failure of a system. A failure of a system puts all drugs at risk and is to be promptly corrected. The following lists the deficiencies that should result in a recommendation for regulatory action to CDER; other deficiencies may also warrant regulatory action:

1. Contamination of APIs with filth, objectionable microorganisms, toxic chemicals, or significant amounts of other types of chemicals, or a reasonable potential for such contamination because of a finding of a demonstrated route of contamination. (Facilities and Equipment System; Production System)
2. Failure to show that API batches conform to established specifications, such as NDA, USP, customer specifications, and label claims. See also Compliance Policy Guide (CPG) 7132.05. (Quality System)
3. Failure to comply with commitments in drug applications, including DMFs, which should be accurate and current with respect to all required information, such as manufacturing process, impurity profiles (if filed), and other specifications or procedures associated with the manufacture of the API. (Quality System)
4. Distribution of an API that does not conform to established specifications. (Quality System)
5. Deliberate blending of API batches to dilute or hide filth or other noxious contaminants or blending to disguise a critical quality defect in an attempt to obtain a batch that meets its specifications. (Production System)
6. Failure to demonstrate that water, including validation of the process water purification system, and any other solvents used in the final step of the API process are chemically and microbiologically suitable for their intended use and do not adversely alter the quality of the API. (Materials System)
7. Lack of adequate validation of critical steps in the API process, particularly concerning final separation and purification of the API or when there is evidence that an API process is not adequately controlled. Lack of adequate control may be indicated by repeated batch failures or wide variation in final yields as compared to process average over time. See also the revised CPG 7132c.08, *Process Validation Requirements for Drug Products and Active Pharmaceutical Ingredients Subject to Pre-Market Approval*. (Quality System; Production System)
8. Implementation of retrospective process validation for an existing API process when the process has changed significantly, when the firm lacks impurity profile data, or when there is evidence of repeated batch failures due to process variability. (Quality System; Production System)
9. Failure to establish an impurity profile for each API process. FDA expects manufacturers to establish complete impurity profiles for each API as part of the process validation effort. This includes collecting data on (1) actual and potential organic impurities that may arise during synthesis, purification, and storage of the API; (2) inorganic impurities that may derive from the API process; and (3) organic and inorganic solvents used during the manufacturing process that are known to carry over to the API. Impurity profile testing of each batch or after a specified number of batches may detect new impurities that may appear because of a deliberate or nondeliberate change in the API manufacturing process. (Laboratory Control System)
10. Failure to show that a reprocessed batch complies with all established standards, specifications, and characteristics. (Quality System; Laboratory Control System)
11. Failure to test for residues of organic/inorganic solvents used during manufacturing that may carry over to the API using analytical procedures with appropriate levels of sensitivity. (Laboratory Control System)
12. Failure to have a formal process change control system in place to evaluate changes in starting materials, facilities, support systems, equipment, processing steps, and packaging materials that may affect the quality of APIs. (All systems)
13. Failure to maintain batch and quality control records. (Quality System)
14. Incomplete stability studies to establish API stability for the intended period of use, and/or failure to conduct forced degradation studies on APIs to isolate, identify, and quantify potential degradants that may arise during storage. (Laboratory Control System)
15. Use of laboratory test methods that are inadequate or have not been validated or the use of an inadequately qualified or untraceable reference standard. (Laboratory Control System)
16. Packaging and labeling in such a way that introduces a significant risk of mislabeling. (Packaging and Labeling System)

PART VII—CENTER RESPONSIBILITIES

Center responsibilities are as described in Drug Manufacturing Inspections Compliance Program Guidance 7356.002 and Pre-Approval Inspection/Investigations Compliance Program Guidance 7346.832.

Appendix A: Description of Each System and Areas of Coverage

Quality System

Assessment of the Quality System has two phases. The first phase is to evaluate whether the Quality Unit has fulfilled the responsibility to review and approve all procedures related to production, quality control, and quality assurance and assure the procedures are adequate for their intended use. This also includes the associated recordkeeping systems. The second phase is to assess the data collected to identify quality problems and may link to other major systems for inspectional coverage.

For each of the following bulleted items, the firm should have written and approved procedures and documentation resulting therefrom. The firm's adherence to written procedures should be verified through observation whenever possible. These areas are not limited to the final APIs only but may also include starting materials and intermediates. These areas may indicate deficiencies not only in this system but also in other systems that would warrant expansion of coverage. All areas under this system should be covered; however, the actual depth of coverage may vary from the planned inspection strategy depending upon inspectional findings.

- Adequacy of staffing to ensure fulfillment of quality unit duties.
- Periodic quality reviews as described in ICH Q7A Section 2.5, *Product Quality Review*; inspection audit coverage should include API types that are representative of manufacturing at this site; inspection audit should also examine some batch and data records associated with each API quality review to verify that the firm's review was sufficiently complete; and audit should confirm that the firm has identified any trends and has corrected or mitigated sources of unacceptable variation.
- Complaint reviews (quality and medical): Documented, evaluated, and investigated in a timely manner, and also these include corrective action where appropriate. Determine whether pattern of complaints and records of internal rejection or reprocessing/reworking of API batches warrant expanding the inspection.
- Discrepancy and failure investigations related to manufacturing and testing: Documented, evaluated, critical deviations investigated in a timely manner and expanded to include any related APIs and material, and also these include corrective action where appropriate.
- Change control (including "process improvements"): Documented, evaluated, approved, and need for revalidation assessed.
- Returns/salvages: Assessment, investigation expanded where warranted, and final disposition.
- Rejects: Investigation expanded where warranted and corrective action where appropriate.
- System to release raw materials.
- Batches manufactured since last inspection to evaluate any rejections or conversions (i.e., from drug to nondrug use) due to processing problems.
- Reprocessing and/or reworking events are properly approved and evaluated for impact on material quality.

- Recalls (including any attempt to recover distributed API not meeting its specifications or purported quality), determine cause, and corrective actions taken.
- Stability failures: Investigation expanded where warranted and disposition. Determine if stability data supports API retest or expiry dates and storage conditions.
- Validation: Status of validation/revalidation activities (e.g., computer, manufacturing process, laboratory methods), such as reviews and approvals of validation protocols and reports.
- Training/qualification of employees in quality control unit functions.

ICH Q7A references for Quality System are as follows:

- Section 2, Quality Management
- Section 13, Change Control
- Section 14, Rejection and Reuse of Materials
- Section 15, Complaints and Recalls
- Section 16, Contract Manufacturers (including laboratories)

FACILITIES AND EQUIPMENT SYSTEM

For each of the following, the firm should have written and approved procedures and documentation resulting therefrom. The firm's adherence to written procedures should be verified through observation whenever possible. These areas may indicate deficiencies not only in this system but also in other systems that would warrant expansion of coverage. When this system is selected for coverage in addition to the Quality System, all areas listed below should be covered; however, the actual depth of coverage may vary from the planned inspection strategy depending upon inspectional findings.

1. Facilities
   - Cleaning and maintenance
   - Facility layout, flow of materials and personnel for prevention of cross-contamination, including from processing of nondrug materials
   - Dedicated areas or containment controls for highly sensitizing materials (e.g., penicillin, β-lactams, steroids, hormones, and cytotoxics)
   - Utilities such as steam, gas, compressed air, heating, ventilation, and air-conditioning should be qualified and appropriately monitored (*note*: this system includes only those utilities whose output is not intended to be incorporated into the API, such as water used in cooling-/heating-jacketed vessels)
   - Lighting, sewage and refuse disposal, washing, and toilet facilities
   - Control system for implementing changes in the building
   - Sanitation of the building including use of rodenticides, fungicides, insecticides, cleaning, and sanitizing agents
   - Training and qualification of personnel
2. Process Equipment
   - Equipment installation, operational, performance qualification where appropriate.
   - Appropriate design, adequate size, and suitably located for its intended use.
   - Equipment surfaces should not be reactive, additive, or absorptive of materials under process so as to alter their quality.
   - Equipment (e.g., reactors, storage containers) and permanently installed processing lines should be appropriately identified.
   - Substances associated with the operation of equipment (e.g., lubricants, heating fluids, or coolants) should not come into contact with starting materials, intermediates, final APIs, and containers.
   - Cleaning procedures and cleaning validation and sanitization studies should be reviewed to verify that residues, microbial, and, when appropriate, endotoxin contamination are removed to below scientifically appropriate levels.
   - Calibrations using standards traceable to certified standards, preferably NIST, USP, or counterpart, recognized national government standard-setting authority.
   - Equipment qualification, calibration, and maintenance, including computer qualification/validation and security.
   - Control system for implementing changes in the equipment.
   - Documentation of any discrepancy (a critical discrepancy investigation is covered under the Quality System).
   - Training and qualification of personnel.

ICH Q7A references for Facilities and Equipment System are as follows:

- Section 4, Buildings and Facilities
- Section 5, Process Equipment
- Section 6, Documentation and Records

MATERIALS SYSTEM

For each of the following, the firm should have written and approved procedures and documentation resulting therefrom. The firm's adherence to written procedures should be verified through observation whenever possible. These areas are not limited to the final API only but may also incorporate starting materials and intermediates. These areas may indicate deficiencies not only in this system but also in other systems that would warrant expansion of coverage. When this system is selected for coverage in addition to the Quality System, all areas listed below should be covered; however, the actual depth of coverage may vary from the planned inspection strategy depending upon inspectional findings.

- Training/qualification of personnel.
- Identification of starting materials and containers.

- Storage conditions.
- Holding of all material and APIs, including reprocessed material, under quarantine until tested or examined and released.
- Representative samples are collected, tested, or examined using appropriate means and against appropriate specifications.
- A system for evaluating the suppliers of critical materials.
- Rejection of any starting material, intermediate, or container not meeting acceptance requirement.
- Appropriate retesting/reexamination of starting materials, intermediates, or containers.
- First-in/first-out use of materials and containers.
- Quarantine and timely disposition of rejected materials.
- Suitability of process water used in the manufacture of API, including as appropriate the water system design, maintenance, validation, and operation.
- Suitability of process gas used in the manufacture of API (e.g., gas use to sparge a reactor), including as appropriate the gas system design, maintenance, validation, and operation.
- Containers and closures should not be additive, reactive, or absorptive.
- Control system for implementing changes.
- Qualification/validation and security of computerized or automated process.
- Finished API distribution records by batch.
- Documentation of any discrepancy (a critical discrepancy investigation is covered under the Quality System).

ICH Q7A references for Materials System are as follows:

- Section 7, Materials Management
- Section 10, Storage and Distribution
- Section 4.3, Water
- Section 6, Documentation and Records

PRODUCTION SYSTEM

For each of the following, the firm should have written and approved procedures and documentation resulting therefrom. The firm's adherence to written procedures should be verified through observation whenever possible. These areas are not limited to the final API only but may also incorporate starting materials and intermediates. These areas may indicate deficiencies not only in this system but also in other systems that would warrant expansion of coverage. When this system is selected for coverage in addition to the Quality System, all areas listed below should be covered; however, the actual depth of coverage may vary from the planned inspection strategy depending upon inspectional findings.

- Training/qualification of personnel.
- Establishment, adherence, and documented performance of approved manufacturing procedures.
- Control system for implementing changes to process.
- Controls over critical activities and operations.
- Documentation and investigation of critical deviations.
- Actual yields compared with expected yields at designated steps.
- Where appropriate established time limits for completion of phases of production.
- Appropriate identification of major equipment used in production of intermediates and API.
- Justification and consistency of intermediate specifications and API specification.
- Implementation and documentation of process controls, testing, and examinations (e.g., pH, temperature, purity, actual yields, clarity).
- In-process sampling should be conducted using procedures designed to prevent contamination of the sampled material.
- Recovery (e.g., from mother liquor or filtrates) of reactants; approved procedures and recovered materials meet specifications suitable for their intended use.
- Solvents can be recovered and reused in the same processes or in different processes provided that solvents meet appropriate standards before reuse or commingling.
- API micronization on multiuse equipment and the precautions taken by the firm to prevent or minimize the potential for cross-contamination.
- Process validation, including validation and security of computerized or automated process.
- Master batch production and control records.
- Batch production and control records.
- Documentation of any discrepancy (a critical discrepancy investigation is covered under the Quality System).

ICH Q7A references for Production System are as follows:

- Section 6, Documentation and Records
- Section 8, Production and In-Process Controls
- Section 12, Validation
- Section 18, Specific Guidance for APIs Manufactured by Cell Culture/Fermentation

See also 7356.0002M for additional inspection guidance on fermentation, extraction, and purification processes.

PACKAGING AND LABELING SYSTEM

For each of the following, the firm should have written and approved procedures and documentation resulting therefrom. The firm's adherence to written procedures should be verified through observation whenever possible. These areas are not limited to the final API only but may also incorporate starting materials and intermediates. These areas may indicate deficiencies not only in this system but also in other systems that

would warrant expansion of coverage. When this system is selected for coverage in addition to the Quality System, all areas listed below should be covered; however, the actual depth of coverage may vary from the planned inspection strategy depending upon inspectional findings.

- Training/qualification of personnel
- Acceptance operations for packaging and labeling materials
- Control system for implementing changes in packaging and labeling operations
- Adequate storage for labels and labeling, both approved and returned after issued
- Control of labels which are similar in size, shape, and color for different APIs
- Adequate packaging records that will include specimens of all labels used
- Control of issuance of labeling, examination of issued labels, and reconciliation of used labels
- Examination of the labeled finished APIs
- Adequate inspection (proofing) of incoming labeling
- Use of lot numbers, destruction of excess labeling bearing lot/control numbers
- Adequate separation and controls when labeling more than one batch at a time
- Adequate expiration or retest dates on the label
- Validation of packaging and labeling operations including validation and security of computerized process
- Documentation of any discrepancy (a critical discrepancy investigation is covered under the Quality System)

ICH Q7A references for Packaging and Labeling System are as follows:

- Section 9, Packaging and Identification Labeling of APIs and Intermediates
- Section 17, Agents, Brokers, Traders, Distributors, Repackers, and Relabellers (applies to the handling of APIs after original site of manufacture and before receipt by the dosage manufacturer)

LABORATORY CONTROL SYSTEM

For each of the following, the firm should have written and approved procedures and documentation resulting therefrom. The firm's adherence to written procedures should be verified through observation whenever possible. These areas are not limited to the final API only but may also incorporate starting materials and intermediates. These areas may indicate deficiencies not only in this system but also in other systems that would warrant expansion of coverage. When this system is selected for coverage in addition to the Quality System, all areas listed below should be covered; however, the actual depth of coverage may vary from the planned inspection strategy depending upon inspectional findings.

- Training/qualification of personnel.
- Adequacy of staffing for laboratory operations.
- Adequacy of equipment and facility for intended use.
- Calibration and maintenance programs for analytical instruments and equipment.
- Validation and security of computerized or automated processes.
- Reference standards: Source, purity and assay, and tests to establish equivalency to current official reference standards as appropriate.
- System suitability checks on chromatographic systems.
- Specifications, standards, and representative sampling plans.
- Validation/verification of analytical methods.
- Required testing is performed on the correct samples and by the approved or filed methods or equivalent methods.
- Documentation of any discrepancy (a critical discrepancy investigation is covered under the Quality System).
- Complete analytical records from all tests and summaries of results.
- Quality and retention of raw data (e.g., chromatograms and spectra).
- Correlation of result summaries to raw data; presence and disposition of unused data.
- Adherence to an adequate out of specification procedure, which includes timely completion of the investigation.
- Test methods for establishing a complete impurity profile for each API process (*note*: impurity profiles are often process related).
- Adequate reserve samples; documentation of reserve samples' examination.
- Stability testing program, including demonstration of stability-indicating capability of the test methods.

ICH Q7A references for Laboratory System are as follows:

- Section 11, Laboratory Controls
- Section 6, Documentation and Records
- Section 12, Validation

ICH Q7A Sections 3, Personnel, and 6, Documentation and Records, apply to all systems. Section 19, APIs for Use in Clinical Trials, applies to APIs intended for the production of dosages solely for use in a clinical trial.

The organization and personnel, including appropriate qualifications and training, employed in any given system, will be evaluated as part of that system's operation. Production, control, or distribution records are required to maintain cGMPs and those selected for review should be included for inspection audit within the context of each of the above systems. Inspection of contract companies should be within the system for which the intermediate or API or service is contracted and also include evaluation of their Quality System.

GLOSSARY

Acceptance Criteria: Numerical limits, ranges, or other suitable measures for acceptance of test results.

Active Pharmaceutical Ingredient (API) (or Drug Substance): Any substance or mixture of substances intended to be used in the manufacture of a drug (medicinal) product and that, when used in the production of a drug, becomes an active ingredient of the drug product. Such substances are intended to furnish pharmacological activity or other direct effect in the diagnosis, cure, mitigation, treatment, or prevention of disease or to affect the structure and function of the body.

Air lock: An enclosed space with two or more doors, which is interposed between two or more rooms, for example, of differing classes of cleanliness, for the purpose of controlling the airflow between those rooms when they need to be entered. An air lock is designed for use either by people or for goods and/or equipment.

API: Active Pharmaceutical Ingredient.

API Starting Material: A raw material, intermediate, or an API that is used in the production of an API and that is incorporated as a significant structural fragment into the structure of the API. An API Starting Material can be an article of commerce, a material purchased from one or more suppliers under contract or commercial agreement, or produced in-house. API Starting Materials are normally of defined chemical properties and structure.

Authorized Person: The person recognized by the national regulatory authority as having the responsibility for ensuring that each batch of finished product has been manufactured, tested, and approved for release in compliance with the laws and regulations in force in that country.

Batch (or Lot): A specific quantity of material produced in a process or series of processes so that it is expected to be homogeneous within specified limits. In the case of continuous production, a batch may correspond to a defined fraction of the production. The batch size can be defined either by a fixed quantity or by the amount produced in a fixed time interval. A defined quantity of starting material, packaging material, or product processed in a single process or series of processes so that it is expected to be homogeneous. It may sometimes be necessary to divide a batch into a number of sub-batches, which are later brought together to form a final homogeneous batch. In the case of terminal sterilization, the batch size is determined by the capacity of the autoclave. In continuous manufacture, the batch must correspond to a defined fraction of the production, characterized by its intended homogeneity. The batch size can be defined either as a fixed quantity or as the amount produced in a fixed time interval.

Batch Number (or Lot Number): A unique combination of numbers, letters, and/or symbols that identifies a batch (or lot) and from which the production and distribution history can be determined. A distinctive combination of numbers and/or letters which uniquely identifies a batch on the labels, its batch records, and corresponding Certificates of Analysis, and so forth.

Batch Records: All documents associated with the manufacture of a batch of bulk product or finished product. They provide a history of each batch of product and of all circumstances pertinent to the quality of the final product.

Bioburden: The level and type (e.g., objectionable or not) of microorganisms that can be present in raw materials, API starting materials, intermediates, or APIs. Bioburden should not be considered contamination unless the levels have been exceeded or defined objectionable organisms have been detected.

Bulk Product: Any product that has completed all processing stages up to, but not including, final packaging.

Calibration: The demonstration that a particular instrument or device produces results within specified limits by comparison with those produced by a reference or traceable standard over an appropriate range of measurements. The set of operations that establish, under specified conditions, the relationship between values indicated by an instrument or system for measuring (especially weighing), recording, and controlling, or the values represented by a material measure, and the corresponding known values of a reference standard. Limits for acceptance of the results of measuring should be established.

CDER: Center for Drug Evaluation and Research, FDA.

Clean Area: An area with defined environmental control of particulate and microbial contamination, constructed and used in such a way as to reduce the introduction, generation, and retention of contaminants within the area.

Computer System: A group of hardware components and associated software, designed and assembled to perform a specific function or group of functions. A process or operation integrated with a computer system.

Consignment (or Delivery): The quantity of a pharmaceutical(s), made by one manufacturer and supplied at one time in response to a particular request or order. A consignment may comprise one or more packages or containers and may include material belonging to more than one batch.

Contamination: The undesired introduction of impurities of a chemical or microbiological nature, or of foreign matter, into or onto a raw material, intermediate, or API during production, sampling, packaging or repackaging, storage, or transport.

Contract Manufacturer: A manufacturer performing some aspect of manufacturing on behalf of the original manufacturer.

Critical: Describes a process step, process condition, test requirement, or other relevant parameter or item that must be controlled within predetermined criteria to ensure that the API meets its specification.

Critical Operation: An operation in the manufacturing process that may cause variation in the quality of the pharmaceutical product.

Cross-Contamination: Contamination of a material or product with another material or product. Contamination of a starting material, intermediate product, or finished product with another starting material or product during production.

Deviation: Departure from an approved instruction or established standard.

DMPQ: Division of Manufacturing and Product Quality, FDA.

Drug (Medicinal) Product: The dosage form in the final immediate packaging intended for marketing. (Reference Q1A)

Drug Substance: See Active Pharmaceutical Ingredient.

EES: Establishment Evaluation System.

EIR: Establishment Inspection Report.

Expiry Date (or Expiration Date): The date placed on the container/labels of an API designating the time during which the API is expected to remain within established shelf life specifications if stored under defined conditions, and after which it should not be used.

FCC: Forensic Chemistry Center.

FEI: Federal Employment Identification.

Finished Product: A finished dosage form that has undergone all stages of manufacture, including packaging in its final container and labeling.

Impurity: Any component present in the intermediate or API that is not the desired entity.

Impurity Profile: A description of the identified and unidentified impurities present in an API.

In-Process Control: Checks performed during production in order to monitor and, if necessary, to adjust the process to ensure that the product conforms to its specifications. The control of the environment or equipment may also be regarded as a part of in-process control.

Intermediate: A material produced during steps of the processing of an API that undergoes further molecular change or purification before it becomes an API. Intermediates may or may not be isolated. Partly processed product that must undergo further manufacturing steps before it becomes a bulk product.

Large-Volume Parenterals: Sterile solutions intended for parenteral application with a volume of 100 mL or more in one container of the finished dosage form.

Lot: See Batch.

Lot Number: See Batch Number.

Manufacturer: A company that carries out operations such as production, packaging, repackaging, labeling, and relabeling of pharmaceuticals.

Marketing Authorization (Product License, Registration Certificate): A legal document issued by the competent drug regulatory authority that establishes the detailed composition and formulation of the product and the pharmacopoeial or other recognized specifications of its ingredients and of the final product itself and includes details of packaging, labeling, and shelf life.

Master Formula: A document or set of documents specifying the starting materials with their quantities and the packaging materials, together with a description of the procedures and precautions required to produce a specified quantity of a finished product as well as the processing instructions, including the in-process controls.

Master Record: A document or set of documents that serves as a basis for the batch documentation (blank batch record).

Material: A general term used to denote raw materials (starting materials, reagents, and solvents), process aids, intermediates, APIs, and packaging and labeling materials.

Mother Liquor: The residual liquid which remains after the crystallization or isolation processes. A mother liquor may contain unreacted materials, intermediates, levels of the API, and/or impurities. It may be used for further processing.

OAI: Office Action Indicated.

Packaging: All operations, including filling and labeling, that a bulk product has to undergo in order to become a finished product. Filling of a sterile product under aseptic conditions or a product intended to be terminally sterilized would not normally be regarded as part of packaging.

Packaging Material: Any material intended to protect an intermediate or API during storage and transport. Any material, including printed material, employed in the packaging of a pharmaceutical but excluding any outer packaging used for transportation or shipment. Packaging materials are referred to as primary or secondary according to whether or not they are intended to be in direct contact with the product.

PACS: Picture archiving and communication systems.

Pharmaceutical Product: Any material or product intended for human or veterinary use presented in its finished dosage form or as a starting material for use in such a dosage form, that is subject to control by pharmaceutical legislation in the exporting state and/or the importing state.

Procedure: A documented description of the operations to be performed, the precautions to be taken, and measures to be applied directly or indirectly related to the manufacture of an intermediate or API.

Process Aids: Materials, excluding solvents, used as an aid in the manufacture of an intermediate or API that do not themselves participate in a chemical or biological reaction (e.g., filter aid, activated carbon).

Process Control: See In-Process Control.

Production: All operations involved in the preparation of a pharmaceutical product, from receipt of materials, through processing, packaging and repackaging, labeling and relabeling, to completion of the finished product.

Qualification: Action of proving and documenting that equipment or ancillary systems are properly installed, work correctly, and actually lead to the expected results. Qualification is part of validation, but the individual qualification steps alone do not constitute process validation.

Quality Assurance (QA): The sum total of the organized arrangements made with the object of ensuring that all APIs are of the quality required for their intended use and that quality systems are maintained.

Quality Control (QC): Checking or testing that specifications are met.

Quality Unit(s): An organizational unit independent of production which fulfills both Quality Assurance and Quality Control responsibilities. This can be in the form of separate QA and QC units or a single individual or group, depending upon the size and structure of the organization.

Quarantine: The status of starting or packaging materials, intermediates, or bulk or finished products isolated physically or by other effective means while a decision is awaited on their release, rejection, or reprocessing.

Raw Material: A general term used to denote starting materials, reagents, and solvents intended for use in the production of intermediates or APIs.

Reconciliation: A comparison between the theoretical quantity and the actual quantity.

Recovery: The introduction of all or part of previous batches (or of redistilled solvents and similar products) of the required quality into another batch at a defined stage of manufacture. It includes the removal of impurities from waste to obtain a pure substance or the recovery of used materials for a separate use.

Reference Standard, Primary: A substance that has been shown by an extensive set of analytical tests to be authentic material that should be of high purity.

Reference Standard, Secondary: A substance of established quality and purity, as shown by comparison to a primary reference standard, used as a reference standard for routine laboratory analysis.

Reprocessing: Subjecting all or part of a batch or lot of an in-process drug, bulk process intermediate (final biological bulk intermediate), or bulk product of a single batch/lot to a previous step in the validated manufacturing process due to failure to meet predetermined specifications. Reprocessing procedures are foreseen as occasionally necessary for biological drugs and, in such cases, are validated and preapproved as part of the marketing authorization.

Retest Date: The date when a material should be reexamined to ensure that it is still suitable for use.

Reworking: Subjecting an in-process or bulk process intermediate (final biological bulk intermediate) or final product of a single batch to an alternate manufacturing process due to a failure to meet predetermined specifications. Reworking is an unexpected occurrence and is not preapproved as part of the marketing authorization.

Self-Contained Area: Premises which provide complete and total separation of all aspects of an operation, including personnel and equipment movement, with well-established procedures, controls, and monitoring. This includes physical barriers as well as separate air-handling systems but does not necessarily imply two distinct and separate buildings.

Signature (Signed): See definition for Signed.

Signed (Signature): The record of the individual who performed a particular action or review. This record can be initials, full handwritten signature, personal seal, or authenticated and secure electronic signature.

Solvent: An inorganic or organic liquid used as a vehicle for the preparation of solutions or suspensions in the manufacture of an intermediate or API.

Specification: A list of detailed requirements with which the products or materials used or obtained during manufacture have to conform. They serve as a basis for quality evaluation.

Standard Operating Procedure (SOP): An authorized written procedure giving instructions for performing operations not necessarily specific to a given product or material (e.g., equipment operation, maintenance, and cleaning; validation; cleaning of premises and environmental control; sampling and inspection). Certain SOPs may be used to supplement product-specific master and batch production documentation.

Starting Material: Any substance of a defined quality used in the production of a pharmaceutical product but excluding packaging materials.

Validation: A documented program that provides a high degree of assurance that a specific process, method, or system will consistently produce a result meeting predetermined acceptance criteria. Action of proving, in accordance with the principles of GMP, that any procedure, process, equipment, material,

activity, or system actually leads to the expected results (see also Qualification).

Validation Protocol: A written plan stating how validation will be conducted and defining acceptance criteria. For example, the protocol for a manufacturing process identifies processing equipment, critical process parameters/operating ranges, product characteristics, sampling, test data to be collected, number of validation runs, and acceptable test results.

Yield, Expected: The quantity of material or the percentage of theoretical yield anticipated at any appropriate phase of production based on previous laboratory, pilot-scale, or manufacturing data.

Yield, Theoretical: The quantity that would be produced at any appropriate phase of production, based upon the quantity of material to be used, in the absence of any loss or error in actual production.

10 Test Procedures and Acceptance Criteria for New Chemical Drug Substances and Drug Products

I. INTRODUCTION

A. Objective of the Guideline

This guideline is intended to assist to the extent possible, in the establishment of a single set of global specifications for new drug substances and new drug products. It provides guidance on the setting and justification of acceptance criteria and the selection of test procedures for new drug substances of synthetic chemical origin, and new drug products produced from them, which have not been registered previously in the United States, the European Union, or Japan.

B. Background

A specification is defined as a list of tests, references to analytical procedures, and appropriate acceptance criteria, which are numerical limits, ranges, or other criteria for the tests described. It establishes the set of criteria to which a drug substance or drug product should conform to be considered acceptable for its intended use. "Conformance to specifications" means that the drug substance and/or drug product, when tested according to the listed analytical procedures, will meet the listed acceptance criteria. Specifications are critical quality standards that are proposed and justified by the manufacturer and approved by regulatory authorities as conditions of approval.

Specifications are one part of a total control strategy for the drug substance and drug product designed to ensure product quality and consistency. Other parts of this strategy include thorough product characterization during development, upon which specifications are based, and adherence to Good Manufacturing Practices, for example, suitable facilities, a validated manufacturing process, validated test procedure, raw material testing, in-process testing, stability testing, etc.

Specifications are chosen to confirm the quality of the drug substance and drug product rather than to establish full characterization and should focus on those characteristics found to be useful in ensuring the safety and efficacy of the drug substance and drug product.

C. Scope of the Guideline

The quality of drug substances and drug products is determined by their design, development, in-process controls, GMP controls, and process validation and by specifications applied to them throughout development and manufacture. This guideline addresses specifications, that is, those tests, procedures, and acceptance criteria which play a major role in assuring the quality of the new drug substance and new drug product at release and during shelf life. Specifications are an important component of quality assurance but are not its only component. All of the considerations listed above are necessary to ensure consistent production of drug substances and drug products of high quality.

This guideline addresses only the marketing approval of new drug products (including combination products) and, where applicable, new drug substances; it does not address drug substances or drug products during the clinical research stages of drug development. This guideline may be applicable to synthetic and semisynthetic antibiotics and synthetic peptides of low molecular weight; however, it is not sufficient to adequately describe specifications of higher molecular weight peptides and polypeptides and biotechnological/biological products. The ICH guideline *Specifications: Test Procedures and Acceptance Criteria for Biotechnological/Biological Products* addresses guideline specifications, tests, and procedures for biotechnological/biological products. Radiopharmaceuticals, products of fermentation, oligonucleotides, herbal products, and crude products of animal or plant origin are similarly not covered.

Guidance is provided with regard to acceptance criteria, which should be established for all new drug substances and new drug products, that is, universal acceptance criteria, and those that are considered specific to individual drug substances and/or dosage forms. This guideline should not be considered all encompassing. New analytical technologies, and modifications to existing technology, are continually being developed. Such technologies should be used when justified.

Dosage forms addressed in this guideline include solid oral dosage forms, liquid oral dosage forms, and parenterals (small and large volume). This is not meant to be an all-inclusive list or to limit the number of dosage forms to which this guideline applies. The dosage forms presented serve as models, which may be applicable to other dosage forms, which have not been discussed. The extended application of the concepts in this guideline to other dosage forms, for example, to inhalation dosage forms (powders, solutions, etc.), to topical formulations (creams, ointments, gels), and to transdermal systems, is encouraged.

II. GENERAL CONCEPTS

The following concepts are important in the development and setting of harmonized specifications. They are not universally applicable, but each should be considered in particular circumstances. This guideline presents a brief definition of each concept and an indication of the circumstances under which it may be applicable. Generally, proposals to implement these concepts should be justified by the applicant and approved by the appropriate regulatory authority before being put into effect.

A. Periodic or Skip Testing

Periodic or skip testing is the performance of specified tests at release on preselected batches and/or at predetermined intervals, rather than on a batch-to-batch basis with the understanding that those batches not being tested still must meet all acceptance criteria established for that product. This represents a less than full schedule of testing and should therefore be justified and presented to and approved by the regulatory authority prior to implementation. This concept may be applicable to, for example, residual solvents and microbiological testing, for solid oral dosage forms. It is recognized that only limited data may be available at the time of submission of an application (see Section 2.5). This concept should therefore generally be implemented post-approval. When tested, any failure to meet acceptance criteria established for the periodic test should be handled by proper notification of the appropriate regulatory authority(ies). If these data demonstrate a need to restore routine testing, then batch-by-batch release testing should be reinstated.

B. Release vs. Shelf Life Acceptance Criteria

The concept of different acceptance criteria for release vs. shelf-life specifications applies to drug products only; it pertains to the establishment of more restrictive criteria for the release of a drug product than are applied to the shelf life. Examples where this may be applicable include assay and impurity (degradation product) levels. In Japan and the United States, this concept may only be applicable to in-house criteria and not to the regulatory release criteria. Thus, in these regions, the regulatory acceptance criteria are the same from release throughout shelf life; however, an applicant may choose to have tighter in-house limits at the time of release to provide increased assurance to the applicant that the product will remain within the regulatory acceptance criterion throughout its shelf life. In the European Union, there is a regulatory requirement for distinct specifications for release and for shelf life where different.

C. In-Process Tests

In-process tests, as presented in this guideline, are tests which may be performed during the manufacture of either the drug substance or drug product, rather than as part of the formal battery of tests which are conducted prior to release.

In-process tests, which are only used for the purpose of adjusting process parameters within an operating range, for example, hardness and friability of tablet cores which will be coated and individual tablet weights, are not included in the specification.

Certain tests conducted during the manufacturing process, where the acceptance criterion is identical to or tighter than the release requirement, (e.g., pH of a solution) may be sufficient to satisfy specification requirements when the test is included in the specification. However, this approach should be validated to show that test results or product performance characteristics do not change from the in-process stage to finished product.

D. Design and Development Considerations

The experience and data accumulated during the development of a new drug substance or product should form the basis for the setting of specifications. It may be possible to propose excluding or replacing certain tests on this basis. Some examples are:

- Microbiological testing for drug substances and solid dosage forms which have been shown during development not to support microbial viability or growth (see Decision Trees 6 and 8).
- Extractables from product containers where it has been reproducibly shown that either no extractables are found in the drug product or the levels meet accepted standards for safety.
- Particle size testing may fall into this category, may be performed as an in-process test, or may be performed as a release test, depending on its relevance to product performance.
- Dissolution testing for immediate release solid oral drug products made from highly water-soluble drug substances may be replaced by disintegration testing, if these products have been demonstrated during development to have consistently rapid drug-release characteristics [see Decision Trees 7(1) through 7(2)].

E. Limited Data Available at Filing

It is recognized that only a limited amount of data may be available at the time of filing, which can influence the process of setting acceptance criteria. As a result, it may be necessary to propose revised acceptance criteria as additional experience is gained with the manufacture of a particular drug substance or drug product (e.g., acceptance limits for a specific impurity). The basis for the acceptance criteria at the time of filing should necessarily focus on safety and efficacy.

When only limited data are available, the initially approved tests and acceptance criteria should be reviewed as more information is collected, with a view towards possible modification. This could involve loosening, as well as tightening, acceptance criteria as appropriate.

F. Parametric Release

Parametric release can be used as an operational alternative to routine release testing for the drug product in certain cases when approved by the regulatory authority. Sterility testing for terminally sterilized drug products is one example. In this case, the release of each batch is based on satisfactory results from monitoring specific parameters, for example, temperature, pressure, and time during the terminal sterilization phase(s) of drug product manufacturing. These parameters can generally be more accurately controlled and measured, so that they are more reliable in predicting sterility assurance than is end-product sterility testing. Appropriate laboratory tests (e.g., chemical or physical indicator) may be included in the parametric release program. It is important to note that the sterilization process should be adequately validated before parametric release is proposed, and maintenance of a validated state should be demonstrated by revalidation at established intervals. When parametric release is performed, the attribute which is indirectly controlled (e.g., sterility), together with a reference to the associated test procedure, still should be included in the specifications.

G. Alternative Procedures

Alternative procedures are those which may be used to measure an attribute when such procedures control the quality of the drug substance or drug product to an extent that is comparable or superior to the official procedure. Example: For tablets that have been shown not to degrade during manufacture, it may be permissible to use a spectrophotometric procedure for release as opposed to the official procedure, which is chromatographic. However, the chromatographic procedure should still be used to demonstrate compliance with the acceptance criteria during the shelf life of the product.

H. Pharmacopoeial Tests and Acceptance Criteria

References to certain procedures are found in pharmacopoeias in each region. Wherever they are appropriate, pharmacopoeial procedures should be utilized. Whereas differences in pharmacopoeial procedures and/or acceptance criteria have existed among the regions, a harmonized specification is possible only if the procedures and acceptance criteria defined are acceptable to regulatory authorities in all regions.

The full utility of this guideline is dependent on the successful completion of harmonization of pharmacopoeial procedures for several attributes commonly considered in the specification for new drug substances or new drug products. The Pharmacopoeial Discussion Group (PDG) of the European Pharmacopoeia, the Japanese Pharmacopoeia, and the United States Pharmacopeia has expressed a commitment to achieving harmonization of the procedures in a timely fashion.

Where harmonization has been achieved, an appropriate reference to the harmonized procedure and acceptance criteria is considered acceptable for a specification in all three regions. For example, after harmonization sterility data generated using the JP procedure, as well as the JP procedure itself and its acceptance criteria, are considered acceptable for registration in all three regions. To signify the harmonized status of these procedures, the pharmacopoeias have agreed to include a statement in their respective texts which indicates that the procedures and acceptance criteria from all three pharmacopoeias are considered equivalent and are, therefore, interchangeable.

Since the overall value of this guideline is linked to the extent of harmonization of the analytical procedures and acceptance criteria of the pharmacopoeias, it is agreed by the members of the Q6A expert working group that none of the three pharmacopoeias should change a harmonized monograph unilaterally. According to the PDG procedure for the revision of harmonized monographs and chapters, "no pharmacopoeia shall revise unilaterally any monograph or chapter after sign-off or after publication."

I. Evolving Technologies

New analytical technologies, and modifications to existing technology, are continually being developed. Such technologies should be used when they are considered to offer additional assurance of quality or are otherwise justified.

J. Impact of Drug Substance on Drug Product Specifications

In general, it should not be necessary to test the drug product for quality attributes uniquely associated with the drug substance. For example, it is normally not considered necessary to test the drug product for synthesis impurities, which are controlled in the drug substance and are not degradation products. Refer to the ICH guideline *Impurities in New Drug Products* for detailed information.

K. Reference Standard

A reference standard, or reference material, is a substance prepared for use as the standard in an assay, identification, or purity test. It should have a quality appropriate to its use. It is often characterized and evaluated for its intended purpose by additional procedures other than those used in routine testing. For new drug substance reference standards intended for use in assays, the impurities should be adequately identified and/or controlled, and purity should be measured by a quantitative procedure.

III. GUIDELINES

A. Specifications: Definition and Justification

1. Definition of Specifications

A specification is defined as a list of tests, references to analytical procedures, and appropriate acceptance criteria, which are numerical limits, ranges, or other criteria for the tests

described. It establishes the set of criteria to which a new drug substance or new drug product should conform to be considered acceptable for its intended use. "Conformance to specifications" means that the drug substance and/or drug product, when tested according to the listed analytical procedures, will meet the listed acceptance criteria. Specifications are critical quality standards that are proposed and justified by the manufacturer and approved by regulatory authorities as conditions of approval.

It is possible that, in addition to release tests, a specification may list in-process tests as defined below, periodic (skip) tests, and other tests, which are not always conducted on a batch-by-batch basis. In such cases, the applicant should specify which tests are routinely conducted batch-by-batch and which tests are not, with an indication and justification of the actual testing frequency. In this situation, the drug substance and/or drug product should meet the acceptance criteria if tested.

It should be noted that changes in the specification after approval of the application may need prior approval by the regulatory authority.

2. Justification of Specifications

When a specification is first proposed, justification should be presented for each procedure and each acceptance criterion included. The justification should refer to relevant development data, pharmacopoeial standards, test data for drug substances and drug products used in toxicology and clinical studies, and results from accelerated and long-term stability studies, as appropriate. Additionally, a reasonable range of expected analytical and manufacturing variability should be considered. It is important to consider all of this information.

Approaches other than those set forth in this guideline may be applicable and acceptable. The applicant should justify alternative approaches. Such justification should be based on data derived from the new drug substance synthesis and/or the new drug product manufacturing process. This justification may consider theoretical tolerances for a given procedure or acceptance criterion, but the actual results obtained should form the primary basis for whatever approach is taken.

Test results from stability and scale-up/validation batches, with emphasis on the primary stability batches, should be considered in setting and justifying specifications. If multiple manufacturing sites are planned, it may be valuable to consider data from these sites in establishing the initial tests and acceptance criteria. This is particularly true when there is limited initial experience with the manufacture of the drug substance or drug product at any particular site. If data from a single representative manufacturing site are used in setting tests and acceptance criteria, product manufactured at all sites should still comply with these criteria.

Presentation of test results in graphic format may be helpful in justifying individual acceptance criteria, particularly for assay values and impurity levels. Data from development work should be included in such a presentation, along with stability data available for new drug substance or new drug product batches manufactured by the proposed commercial processes. Justification for proposing exclusion of a test from the specification should be based on development data and on process validation data (where appropriate).

B. Universal Tests/Criteria

Implementation of the recommendations in the following section should take into account the ICH guidelines *Text on Validation of Analytical Procedures* and *Validation of Analytical Procedures: Methodology.*

1. New Drug Substances

The following tests and acceptance criteria are considered generally applicable to all new drug substances.

(a) *Description*: A qualitative statement about the state (e.g., solid, liquid) and color of the new drug substance. If any of these characteristics change during storage, this change should be investigated and appropriate action taken.

(b) *Identification*: Identification testing should optimally be able to discriminate between compounds of closely related structure which are likely to be present. Identification tests should be specific for the new drug substance, for example, infrared spectroscopy. Identification solely by a single chromatographic retention time, for example, is not regarded as being specific. However, the use of two chromatographic procedures, where the separation is based on different principles or a combination of tests into a single procedure, such as HPLC/UV diode array, HPLC/MS, or GC/MS, is generally acceptable. If the new drug substance is a salt, identification testing should be specific for the individual ions. An identification test that is specific for the salt itself should suffice.

New drug substances, which are optically active may also need specific identification testing or performance of a chiral assay. Please refer to 3.3.1.d) in this guideline for further discussion of this topic.

(c) *Assay*: A specific, stability-indicating procedure should be included to determine the content of the new drug substance. In many cases, it is possible to employ the same procedure (e.g., HPLC) for both assay of the new drug substance and quantitation of impurities.

In cases where use of a nonspecific assay is justified, other supporting analytical procedures should be used to achieve overall specificity. For example, where titration is adopted to assay the drug substance, the combination of the assay and a suitable test for impurities should be used.

(d) *Impurities*: Organic and inorganic impurities and residual solvents are included in this category. Refer to the ICH guidelines *Impurities in New Drug Substances* and *Residual Solvents in Pharmaceuticals* for detailed information.

Decision Tree 1 addresses the extrapolation of meaningful limits on impurities from the body of data generated during development. At the time of filing, it is unlikely that sufficient data will be available to assess process consistency. Therefore, it is considered inappropriate to establish acceptance criteria, which tightly encompass the batch data at the time of filing (see Section 2.5).

2. New Drug Products

The following tests and acceptance criteria are considered generally applicable to all new drug products:

(a) *Description*: A qualitative description of the dosage form should be provided (e.g., size, shape, and color). If any of these characteristics change during manufacture or storage, this change should be investigated and appropriate action taken. The acceptance criteria should include the final acceptable appearance. If color changes during storage, a quantitative procedure may be appropriate.

(b) *Identification*: Identification testing should establish the identity of the new drug substance(s) in the new drug product and should be able to discriminate between compounds of closely related structure which are likely to be present. Identity tests should be specific for the new drug substance, for example, infrared spectroscopy. Identification solely by a single chromatographic retention time, for example, is not regarded as being specific. However, the use of two chromatographic procedures, where the separation is based on different principles, or combination of tests into a single procedure, such as HPLC/UV diode array, HPLC/MS, or GC/MS, is generally acceptable.

(c) *Assay*: A specific, stability-indicating assay to determine strength (content) should be included for all new drug products. In many cases, it is possible to employ the same procedure (e.g., HPLC) for both assay of the new drug substance and quantitation of impurities. Results of content uniformity testing for new drug products can be used for quantitation of drug product strength, if the methods used for content uniformity are also appropriate as assays.

In cases where use of a nonspecific assay is justified, other supporting analytical procedures should be used to achieve overall specificity. For example, where titration is adopted to assay the drug substance for release, the combination of the assay and a suitable test for impurities can be used. A specific procedure should be used when there is evidence of excipient interference with the nonspecific assay.

(d) *Impurities*: Organic and inorganic impurities (degradation products) and residual solvents are included in this category. Refer to the ICH guidelines *Impurities in New Drug Products* and *Residual Solvents in Pharmaceuticals* for detailed information.

Organic impurities arising from degradation of the new drug substance and impurities that arise during the manufacturing process for the drug product should be monitored in the new drug product. Acceptance limits should be stated for individual specified degradation products, which may include both identified and unidentified degradation products as appropriate, and total degradation products. Process impurities from the new drug substance synthesis are normally controlled during drug substance testing and therefore are not included in the total impurities limit. However, when a synthesis impurity is also a degradation product, its level should be monitored and included in the total degradation product limit. When it has been conclusively demonstrated via appropriate analytical methodology that the drug substance does not degrade in the specific formulation, and under the specific storage conditions proposed in the new drug application, degradation product testing may be reduced or eliminated upon approval by the regulatory authorities.

Decision Tree 2 addresses the extrapolation of meaningful limits on degradation products from the body of data generated during development. At the time of filing, it is unlikely that sufficient data will be available to assess process consistency. Therefore, it is considered inappropriate to establish acceptance criteria which tightly encompass the batch data at the time of filing (see Section 2.5).

C. Specific Tests/Criteria

In addition to the universal tests listed above, the following tests may be considered on a case by case basis for drug substances and/or drug products. Individual tests/criteria should be included in the specification when the tests have an impact on the quality of the drug substance and drug product for batch control. Tests other than those listed below may be needed in particular situations or as new information becomes available.

1. New Drug Substances

(a) *Physicochemical properties*: These are properties such as pH of an aqueous solution, melting point/range, and refractive index. The procedures used for the measurement of these properties are usually unique and do not need much elaboration, for example, capillary melting point, Abbé refractometry. The tests performed in this category should be determined by the physical nature of the new drug substance and by its intended use.

(b) *Particle size*: For some new drug substances intended for use in solid or suspension drug products, particle size can have a significant effect on dissolution rates, bioavailability, and/or stability. In such instances, testing for particle size distribution should be carried out using an appropriate procedure, and acceptance criteria should be provided.

Decision Tree 3 provides additional guidance on when particle size testing should be considered.

(c) *Polymorphic forms*: Some new drug substances exist in different crystalline forms, which differ in their physical properties. Polymorphism may also include solvation or hydration products (also known as pseudopolymorphs) and amorphous forms. Differences in these forms could, in some cases, affect the quality or performance of the new drug products. In cases where differences exist which have been shown to affect drug product performance, bioavailability, or stability, then the appropriate solid state should be specified.

Physicochemical measurements and techniques are commonly used to determine whether multiple forms exist. Examples of these procedures are: Melting point (including hot-stage microscopy), solid state IR, X-ray powder diffraction, thermal analysis procedures (such as DSC, TGA, and DTA), Raman spectroscopy, optical microscopy, and solid-state NMR.

Decision Trees 4(1) through 4(3) provide additional guidance on when, and how, polymorphic forms should be monitored and controlled.

Note: These decision trees should be followed sequentially. Trees 1 and 2 consider whether polymorphism is exhibited by the drug substance and whether the different polymorphic forms can affect performance of the drug product. Tree 3 should only be applied when polymorphism has been demonstrated for the drug substance and shown to affect these properties. Tree 3 considers the potential for change in polymorphic forms in the drug product and whether such a change has any effect on product performance.

It is generally technically very difficult to measure polymorphic changes in drug products. A surrogate test (e.g., dissolution) [see Decision Tree 4(3)] can generally be used to monitor product performance, and polymorph content should only be used as a test and acceptance criterion of last resort.

(d) *Tests for chiral new drug substances*: Where a new drug substance is predominantly one enantiomer, the opposite enantiomer is excluded from the qualification and identification thresholds given in the ICH guidelines on *Impurities in New Drug Substances* and *Impurities in New Drug Products* because of practical difficulties in quantifying it at those levels. However, that impurity in the chiral new drug substance and the resulting new drug product(s) should otherwise be treated according to the principles established in those guidelines.

Decision Tree 5 summarizes when and if chiral identity tests, impurity tests, and assays may be needed for both new drug substances and new drug products, according to the following concepts:

Drug substance: *Impurities.* For chiral drug substances, which are developed as a single enantiomer, control of the other enantiomer should be considered in the same manner as for other impurities. However, technical limitations may preclude the same limits of quantification or qualification from being applied. Assurance of control also could be given by appropriate testing of a starting material or intermediate, with suitable justification.

Assay. An enantioselective determination of the drug substance should be part of the specification. It is considered acceptable for this to be achieved either through use of a chiral assay procedure or by the combination of an achiral assay together with appropriate methods of controlling the enantiomeric impurity.

Identity. For a drug substance developed as a single enantiomer, the identity test(s) should be capable of distinguishing both enantiomers and the racemic mixture. For a racemic drug substance, there are generally two situations where a stereospecific identity test is appropriate for release/acceptance testing: (1) where there is a significant possibility that the enantiomer might be substituted for the racemate, or (2) when there is evidence that preferential crystallization may lead to unintentional production of a nonracemic mixture.

Drug product: Degradation products. Control of the other enantiomer in a drug product is considered necessary unless racemization has been shown to be insignificant during manufacture of the dosage form and on storage.

Assay: An achiral assay may be sufficient where racemization has been shown to be insignificant during manufacture of the dosage form and on storage. Otherwise a chiral assay should be used, or alternatively, the combination of an achiral assay plus a validated procedure to control the presence of the opposite enantiomer may be used.

Identity: A stereospecific identity test is not generally needed in the drug product release specification. When racemization is insignificant during manufacture of the dosage form and on storage, stereospecific identity testing is more appropriately addressed as part of the drug substance specification. When racemization in the dosage form is a concern, chiral assay or enantiomeric impurity testing of the drug product will serve to verify identity.

(e) *Water content*: This test is important in cases where the new drug substance is known to be hygroscopic or degraded by moisture or when the drug substance is known to be a stoichiometric hydrate. The acceptance criteria may be justified with data on the effects

of hydration or moisture absorption. In some cases, a loss on drying procedure may be considered adequate; however, a detection procedure that is specific for water (e.g., Karl Fischer titration) is preferred.

(f) *Inorganic impurities*: The need for inclusion of tests and acceptance criteria for inorganic impurities (e.g., catalysts) should be studied during development and based on knowledge of the manufacturing process. Procedures and acceptance criteria for sulfated ash/residue on ignition should follow pharmacopoeial precedents; other inorganic impurities may be determined by other appropriate procedures, for example, atomic absorption spectroscopy.

(g) *Microbial limits*: There may be a need to specify the total count of aerobic microorganisms, the total count of yeasts and molds, and the absence of specific objectionable bacteria (e.g., *Staphylococcus aureus*, *Escherichia coli*, *Salmonella*, *Pseudomonas aeruginosa*). These should be suitably determined using pharmacopoeial procedures. The type of microbial test(s) and acceptance criteria should be based on the nature of the drug substance, method of manufacture, and the intended use of the drug product. For example, sterility testing may be appropriate for drug substances manufactured as sterile, and endotoxin testing may be appropriate for drug substances used to formulate an injectable drug product.

Decision Tree 6 provides additional guidance on when microbial limits should be included.

2. New Drug Products

Additional tests and acceptance criteria generally should be included for particular new drug products. The following selection presents a representative sample of both the drug products and the types of tests and acceptance criteria, which may be appropriate. The specific dosage forms addressed include solid oral drug products, liquid oral drug products, and parenterals (small and large volume). Application of the concepts in this guideline to other dosage forms is encouraged. Note that issues related to optically active drug substances and to solid-state considerations for drug products are discussed in Part 3.3.1. of this guideline.

a. General Considerations

The following tests are applicable to tablets (coated and uncoated) and hard capsules. One or more of these tests may also be applicable to soft capsules and granules.

(a) *Dissolution*: The specification for solid oral dosage forms normally includes a test to measure release of drug substance from the drug product. Single-point measurements are normally considered to be suitable for immediate-release dosage forms. For modified-release dosage forms, appropriate test conditions and sampling procedures should be established. For example, multiple time point sampling should be performed for extended-release dosage forms, and two-stage testing (using different media in succession or in parallel, as appropriate) may be appropriate for delayed-release dosage forms. In these cases, it is important to consider the populations of individuals who will be taking the drug product (e.g., achlorhydric elderly) when designing the tests and acceptance criteria. In some cases [see Section 3.3.2.1 b) Disintegration], dissolution testing may be replaced by disintegration testing [see Decision Tree 7 (1)].

For immediate-release drug products where changes in dissolution rate have been demonstrated to significantly affect bioavailability, it is desirable to develop test conditions which can distinguish batches with unacceptable bioavailability. If changes in formulation or process variables significantly affect dissolution and such changes are not controlled by another aspect of the specification, it may also be appropriate to adopt dissolution test conditions which can distinguish these changes [see Decision Tree 7(2)].

Where dissolution significantly affects bioavailability, the acceptance criteria should be set to reject batches with *unacceptable* bioavailability. Otherwise, test conditions and acceptance criteria should be established which pass clinically acceptable batches [see Decision Tree 7(2)]. For extended-release drug products, in vitro/in vivo correlation may be used to establish acceptance criteria when human bioavailability data are available for formulations exhibiting different release rates. Where such data are not available, and drug release cannot be shown to be independent of in vitro test conditions, then acceptance criteria should be established on the basis of available batch data. Normally, the permitted variability in mean release rate at any given time point should not exceed a total numerical difference of ±10% of the labeled content of drug substance (i.e., a total variability of 20%: A requirement of 50% ± 10% thus means an acceptable range from 40% to 60%), unless a wider range is supported by a bioequivalency study [see Decision Tree 7(3)].

(b) *Disintegration*: For rapidly dissolving (dissolution >80% in 15 minutes at pH 1.2, 4.0, and 6.8) products containing drugs which are highly soluble throughout the physiological range (dose/solubility volume <250 mL from pH 1.2 to 6.8), disintegration may be substituted for dissolution. Disintegration testing is most appropriate when a relationship to dissolution has been established or when disintegration is shown to be more discriminating than dissolution. In such cases, dissolution testing may not be necessary. It is expected that development information will be provided to support the robustness of the formulation and manufacturing process with respect to the selection of dissolution vs. disintegration testing [see Decision Tree 7(1)].

(c) *Hardness/friability*: It is normally appropriate to perform hardness and/or friability testing as an in-process control (see Section 2.3). Under these circumstances, it is normally not necessary to include these attributes in the specification. If the characteristics of hardness and friability have a critical impact on drug product quality (e.g., chewable tablets), acceptance criteria should be included in the specification.

(d) *Uniformity of dosage units*: This term includes both the mass of the dosage form and the content of the active substance in the dosage form; a pharmacopoeial procedure should be used. In general, the specification should include one or the other but not both. If appropriate, these tests may be performed in-process; the acceptance criteria should be included in the specification. When weight variation is applied for new drug products exceeding the threshold value to allow testing uniformity by weight variation, applicants should verify during drug development that the homogeneity of the product is adequate.

(e) *Water content*: A test for water content should be included when appropriate. The acceptance criteria may be justified with data on the effects of hydration or water absorption on the drug product. In some cases, a loss on drying procedure may be considered adequate; however, a detection procedure which is specific for water (e.g., Karl Fischer titration) is preferred.

(f) *Microbial limits*: Microbial limit testing is seen as an attribute of Good Manufacturing Practice, as well as of quality assurance. In general, it is advisable to test the drug product unless its components are tested before manufacture and the manufacturing process is known, through validation studies, not to carry a significant risk of microbial contamination or proliferation. It should be noted that, whereas this guideline does not directly address excipients, the principles discussed here may be applicable to excipients as well as to new drug products. Skip testing may be an appropriate approach in both cases where permissible. (See Decision Tree 6 for microbial testing of excipients.)

Acceptance criteria should be set for the total count of aerobic microorganisms, the total count of yeasts and molds, and the absence of specific objectionable bacteria (e.g., *S. aureus*, *E. coli*, *Salmonella*, *Pseudomonas aeruginosa*). These should be determined by suitable procedures, using pharmacopoeial procedures, and at a sampling frequency or time point in manufacture which is justified by data and experience. The type of microbial test(s) and acceptance criteria should be based on the nature of the drug substance, method of manufacture, and the intended use of the drug product. With acceptable scientific justification, it should be possible to propose no microbial limit testing for solid oral dosage forms.

Decision Tree 8 provides additional guidance on the use of microbial limits testing.

b. Oral Liquids

One or more of the following specific tests will normally be applicable to oral liquids and to powders intended for reconstitution as oral liquids.

(a) *Uniformity of dosage units*: This term includes both the mass of the dosage form and the content of the active substance in the dosage form; a pharmacopoeial procedure should be used. In general, the specification should include one or the other but not both. When weight variation is applied for new drug products exceeding the threshold value to allow testing uniformity by weight variation, applicants should verify during drug development that the homogeneity of the product is adequate. If appropriate, tests may be performed in-process; however, the acceptance criteria should be included in the specification. This concept may be applied to both single-dose and multiple-dose packages.

The dosage unit is considered to be the typical dose taken by the patient. If the actual unit dose, as taken by the patient, is controlled, it may either be measured directly or calculated, based on the total measured weight or volume of drug divided by the total number of doses expected. If dispensing equipment (such as medicine droppers or dropper tips for bottles) is an integral part of the packaging, this equipment should be used to measure the dose. Otherwise, a standard volume measure should be used. The dispensing equipment to be used is normally determined during development.

For powders for reconstitution, uniformity of mass testing is generally considered acceptable.

(b) *pH*: Acceptance criteria for pH should be provided where applicable and the proposed range justified.

(c) *Microbial limits*: Microbial limit testing is seen as an attribute of Good Manufacturing Practice, as well as of quality assurance. In general, it is advisable to test the drug product unless its components are tested before manufacture and the manufacturing process is known, through validation studies, not to carry a significant risk of microbial contamination or proliferation. It should be noted that, whereas this guideline does not directly address excipients, the principles discussed here may be applicable to excipients as well as to new drug products. Skip testing may be an appropriate approach in both cases where permissible. With acceptable scientific justification, it may be possible to propose no microbial limit testing for powders intended for reconstitution as oral liquids.

Acceptance criteria should be set for the total count of aerobic microorganisms, total count of yeasts and molds, and the absence of specific objectionable bacteria

(e.g., *S. aureus*, *E. coli*, *Salmonella*, *Pseudomonas aeruginosa*). These should be determined by suitable procedures, using pharmacopoeial procedures, and at a sampling frequency or time point in manufacture which is justified by data and experience.

Decision Tree 8 provides additional guidance on the use of microbial limits testing.

(d) *Antimicrobial preservative content*: For oral liquids needing an antimicrobial preservative, acceptance criteria for preservative content should be established. Acceptance criteria for preservative content should be based upon the levels of antimicrobial preservative necessary to maintain microbiological quality of the product at all stages throughout its proposed usage and shelf life. The lowest specified concentration of antimicrobial preservative should be demonstrated to be effective in controlling microorganisms by using a pharmacopoeial antimicrobial preservative effectiveness test.

Testing for antimicrobial preservative content should normally be performed at release. Under certain circumstances, in-process testing may suffice in lieu of release testing. When antimicrobial preservative content testing is performed as an in-process test, the acceptance criteria should remain part of the specification.

Antimicrobial preservative effectiveness should be demonstrated during development, during scale-up, and throughout the shelf life (e.g., in stability testing: See the ICH guideline, *Stability Testing of New Drug Substances and Products*), although chemical testing for preservative content is the attribute normally included in the specification.

(e) *Antioxidant preservative content*: Release testing for antioxidant content should normally be performed. Under certain circumstances, where justified by developmental and stability data, shelf-life testing may be unnecessary, and in-process testing may suffice in lieu of release testing where permitted. When antioxidant content testing is performed as an in-process test, the acceptance criteria should remain part of the specification. If only release testing is performed, this decision should be reinvestigated whenever either the manufacturing procedure or the container/closure system changes.

(f) *Extractables*: Generally, where development and stability data show evidence that extractables from the container/closure systems are consistently below levels that are demonstrated to be acceptable and safe, elimination of this test can normally be accepted. This should be reinvestigated if the container/closure system or formulation changes.

Where data demonstrate the need, tests and acceptance criteria for extractables from the container/closure system components (e.g., rubber stopper, cap liner, plastic bottle, etc.) are considered appropriate for oral solutions packaged in non-glass systems or in glass containers with non-glass closures. The container/closure components should be listed and data collected for these components as early in the development process as possible.

(g) *Alcohol content*: Where it is declared quantitatively on the label in accordance with pertinent regulations, the alcohol content should be specified. It may be assayed or calculated.

(h) *Dissolution*: In addition to the attributes recommended immediately above, it may be appropriate (e.g., insoluble drug substance) to include dissolution testing and acceptance criteria for oral suspensions and dry powder products for resuspension. Dissolution testing should be performed at release. This test may be performed as an in-process test when justified by product development data. The testing apparatus, media, and conditions should be pharmacopoeial, if possible, or otherwise justified. Dissolution procedures using either pharmacopoeial or non-pharmacopoeial apparatus and conditions should be validated.

Single-point measurements are normally considered suitable for immediate-release dosage forms. Multiple-point sampling, at appropriate intervals, should be performed for modified-release dosage forms. Acceptance criteria should be set based on the observed range of variation and should take into account the dissolution profiles of the batches that showed acceptable performance in vivo. Developmental data should be considered when determining the need for either a dissolution procedure or a particle size distribution procedure.

(i) *Particle size distribution*: Quantitative acceptance criteria and a procedure for determination of particle size distribution may be appropriate for oral suspensions. Developmental data should be considered when determining the need for either a dissolution procedure or a particle size distribution procedure for these formulations.

Particle size distribution testing should be performed at release. It may be performed as an in-process test when justified by product development data. If these products have been demonstrated during development to have consistently rapid drug-release characteristics, exclusion of a particle size distribution test from the specification may be proposed.

Particle size distribution testing may also be proposed in place of dissolution testing; justification should be provided. The acceptance criteria should include acceptable particle size distribution in terms of the percent of total particles in given size ranges. The mean, upper, and/or lower particle size limits should be well defined.

Acceptance criteria should be set based on the observed range of variation and should take into account the dissolution profiles of the batches that

showed acceptable performance in vivo, as well as the intended use of the product. The potential for particle growth should be investigated during product development; the acceptance criteria should take the results of these studies into account.

(j) *Redispersibility*: For oral suspensions, which settle on storage (produce sediment), acceptance criteria for redispersibility may be appropriate. Shaking may be an appropriate procedure.

The procedure (mechanical or manual) should be indicated. Time required to achieve resuspension by the indicated procedure should be clearly defined. Data generated during product development may be sufficient to justify skip lot testing, or elimination of this attribute from the specification may be proposed.

(k) *Rheological properties*: For relatively viscous solutions or suspensions, it may be appropriate to include rheological properties (viscosity/specific gravity) in the specification. The test and acceptance criteria should be stated. Data generated during product development may be sufficient to justify skip lot testing, or elimination of this attribute from the specification may be proposed.

(l) *Reconstitution time*: Acceptance criteria for reconstitution time should be provided for dry powder products, which require reconstitution. The choice of diluent should be justified. Data generated during product development may be sufficient to justify skip lot testing, or elimination of this attribute from the specification may be proposed.

(m) *Water content*: For oral products requiring reconstitution, a test and acceptance criterion for water content should be proposed when appropriate. Loss on drying is generally considered sufficient if the effect of absorbed moisture vs. water of hydration has been adequately characterized during the development of the product. In certain cases, a more specific procedure (e.g., Karl Fischer titration) may be preferable.

c. Parenteral Drug Products

The following tests may be applicable to parenteral drug products.

(a) *Uniformity of dosage units*: This term includes both the mass of the dosage form and the content of the active substance in the dosage form; a pharmacopoeial procedure should be used. In general, the specification should one or the other but not both and is applicable to powders for reconstitution. When weight variation is applied for new drug products exceeding the threshold value to allow testing uniformity by weight variation, applicants should verify during drug development that the homogeneity of the product is adequate.

If appropriate (see Section 2.3), these tests may be performed in-process; the acceptance criteria should be included in the specification. This test may be applied to both single-dose and multiple-dose packages.

For powders for reconstitution, uniformity of mass testing is generally considered acceptable.

(b) *pH*: Acceptance criteria for pH should be provided where applicable and the proposed range justified.

(c) *Sterility*: All parenteral products should have a test procedure and acceptance criterion for evaluation of sterility. Where data generated during development and validation justify parametric release, this approach may be proposed for terminally sterilized drug products (see Section 2.6).

(d) *Endotoxins/pyrogens*: A test procedure and acceptance criterion for endotoxins, using a procedure such as the limulus amoebocyte lysate test, should be included in the specification. Pyrogenicity testing may be proposed as an alternative to endotoxin testing where justified.

(e) *Particulate matter*: Parenteral products should have appropriate acceptance criteria for particulate matter. This will normally include acceptance criteria for visible particulates and/or clarity of solution, as well as for subvisible particulates as appropriate.

(f) *Water content*: For nonaqueous parenterals, and for parenteral products for reconstitution, a test procedure and acceptance criterion for water content should be proposed when appropriate. Loss on drying is generally considered sufficient for parenteral products, if the effect of absorbed moisture vs. water of hydration has been adequately characterized during development. In certain cases a more specific procedure (e.g., Karl Fischer titration) may be preferred.

(g) *Antimicrobial preservative content*: For parenteral products needing an antimicrobial preservative, acceptance criteria for preservative content should be established. Acceptance criteria for preservative content should be based upon the levels of antimicrobial preservative necessary to maintain microbiological quality of the product at all stages throughout its proposed usage and shelf life. The lowest specified concentration of antimicrobial preservative should be demonstrated to be effective in controlling microorganisms by using a pharmacopoeial antimicrobial preservative effectiveness test.

Testing for antimicrobial preservative content should normally be performed at release. Under certain circumstances, in-process testing may suffice in lieu of release testing where permitted. When antimicrobial preservative content testing is performed as an in-process test, the acceptance criteria should remain part of the specification.

Antimicrobial preservative effectiveness should be demonstrated during development, during scaleup, and throughout the shelf life (e.g., in stability testing: See the ICH guideline, *Stability Testing*

of New Drug Substances and Products), although chemical testing for preservative content is the attribute normally included in the specification.

(h) *Antioxidant preservative content*: Release testing for antioxidant content should normally be performed. Under certain circumstances, where justified by developmental and stability data, shelf-life testing may be unnecessary and in-process testing may suffice in lieu of release testing. When antioxidant content testing is performed as an in-process test, the acceptance criteria should remain part of the specification. If only release testing is performed, this decision should be reinvestigated whenever either the manufacturing procedure or the container/closure system changes.

(i) *Extractables*: Control of extractables from container/closure systems is considered significantly more important for parenteral products than for oral liquids. However, where development and stability data show evidence that extractables are consistently below the levels that are demonstrated to be acceptable and safe, elimination of this test can normally be accepted. This should be reinvestigated if the container/closure system or formulation changes.

Where data demonstrate the need, acceptance criteria for extractables from the container/closure components are considered appropriate for parenteral products packaged in non-glass systems or in glass containers with elastomeric closures. This testing may be performed at release only, where justified by data obtained during development. The container/closure system components (e.g., rubber stopper, etc.) should be listed, and data collected for these components as early in the development process as possible.

(j) *Functionality testing of delivery systems*: Parenteral formulations packaged in prefilled syringes, autoinjector cartridges, or the equivalent should have test procedures and acceptance criteria related to the functionality of the delivery system. These may include control of syringeability, pressure, and seal integrity (leakage), and/or parameters such as tip cap removal force, piston release force, piston travel force, and power injector function force. Under certain circumstances these tests may be performed in process. Data generated during product development may be sufficient to justify skip lot testing or elimination of some or all attributes from the specification.

(k) *Osmolarity*: When the tonicity of a product is declared in its labeling, appropriate control of its osmolarity should be performed. Data generated during development and validation may be sufficient to justify performance of this procedure as an in-process control, skip lot testing, or direct calculation of this attribute.

(l) *Particle size distribution*: Quantitative acceptance criteria and a procedure for determination of particle size distribution may be appropriate for injectable suspensions. Developmental data should be considered when determining the need for either a dissolution procedure or a particle size distribution procedure.

Particle size distribution testing should be performed at release. It may be performed as an in-process test when justified by product development data. If the product has been demonstrated during development to have consistently rapid drug release characteristics, exclusion of particle size controls from the specification may be proposed.

Particle size distribution testing may also be proposed in place of dissolution testing, when development studies demonstrate that particle size is the primary factor influencing dissolution; justification should be provided. The acceptance criteria should include acceptable particle size distribution in terms of the percent of total particles in given size ranges. The mean, upper, and/or lower particle size limits should be well defined.

Acceptance criteria should be set based on the observed range of variation and should take into account the dissolution profiles of the batches that showed acceptable performance in vivo and the intended use of the product. The potential for particle growth should be investigated during product development; the acceptance criteria should take the results of these studies into account.

(m) *Redispersibility*: For injectable suspensions, which settle on storage (produce sediment), acceptance criteria for redispersibility may be appropriate. Shaking may be an appropriate procedure. The procedure (mechanical or manual) should be indicated. Time required to achieve resuspension by the indicated procedure should be clearly defined. Data generated during product development may be sufficient to justify skip lot testing, or elimination of this attribute from the specification may be proposed.

(n) *Reconstitution time*: Acceptance criteria for reconstitution time should be provided for all parenteral products which require reconstitution. The choice of diluent should be justified. Data generated during product development and process validation may be sufficient to justify skip lot testing or elimination of this attribute from the specification for rapidly dissolving products.

GLOSSARY

The following definitions are presented for the purpose of this guideline.

Acceptance Criteria: Numerical limits, ranges, or other suitable measures for acceptance of the results of analytical procedures.

Chiral: Not superimposable with its mirror image, as applied to molecules, conformations, and macroscopic

objects, such as crystals. The term has been extended to samples of substances whose molecules are chiral, even if the macroscopic assembly of such molecules is racemic.

Combination Product: A drug product which contains more than one drug substance.

Degradation Product: A molecule resulting from a chemical change in the drug molecule brought about over time and/or by the action of, for example, light, temperature, pH, water, or by reaction with an excipient and/or the immediate container/closure system. Also called decomposition product.

Delayed Release: Release of a drug (or drugs) at a time other than immediately following oral administration.

Enantiomers: Compounds with the same molecular formula as the drug substance which differ in the spatial arrangement of atoms within the molecule and are nonsuperimposable mirror images.

Extended Release: Products which are formulated to make the drug available over an extended period after administration.

Highly Water-Soluble Drugs: Drugs with a dose/solubility volume of less than or equal to 250 mL over a pH range of 1.2 to 6.8. (e.g., Compound A has as its lowest solubility at 37°C ± 0.5°C, 1.0 mg/mL at pH 6.8, and is available in 100-, 200-, and 400-mg strengths. This drug would be considered a low solubility drug as its dose/solubility volume is greater than 250 mL (400 mg/1.0 mg/mL = 400 mL).

Immediate Release: Allows the drug to dissolve in the gastrointestinal contents, with no intention of delaying or prolonging the dissolution or absorption of the drug.

Impurity: (1) Any component of the new drug substance which is not the chemical entity defined as the new drug substance. (2) Any component of the drug product which is not the chemical entity defined as the drug substance or an excipient in the drug product.

Identified Impurity: An impurity for which a structural characterization has been achieved.

In-Process Tests: Tests which may be performed during the manufacture of either the drug substance or drug product, rather than as part of the formal battery of tests which are conducted prior to release.

Modified Release: Dosage forms whose drug-release characteristics of time course and/or location are chosen to accomplish therapeutic or convenience objectives not offered by conventional dosage forms such as a solution or an immediate release dosage form. Modified release solid oral dosage forms include both delayed and extended release drug products.

New Drug Product: A pharmaceutical product type, for example, tablet, capsule, solution, cream, etc., which has not previously been registered in a region or Member State and which contains a drug ingredient generally, but not necessarily, in association with excipients.

New Drug Substance: The designated therapeutic moiety which has not previously been registered in a region or Member State (also referred to as a new molecular entity or new chemical entity). It may be a complex, simple ester, or salt of a previously approved drug substance.

Polymorphism: The occurrence of different crystalline forms of the same drug substance. This may include solvation or hydration products (also known as pseudopolymorphs) and amorphous forms.

Quality: The suitability of either a drug substance or drug product for its intended use. This term includes such attributes as the identity, strength, and purity.

Racemate: A composite (solid, liquid, gaseous, or in solution) of equimolar quantities of two enantiomeric species. It is devoid of optical activity.

Rapidly Dissolving Products: An immediate release solid oral drug product is considered rapidly dissolving when not less than 80% of the label amount of the drug substance dissolves within 15 minutes in each of the following media: (1) pH 1.2, (2) pH 4.0, and (3) pH 6.8.

Reagent: A substance, other than a starting material or solvent, which is used in the manufacture of a new drug substance.

Solvent: An inorganic or an organic liquid used as a vehicle for the preparation of solutions or suspensions in the synthesis of a new drug substance or the manufacture of a new drug product.

Specification: A list of tests, references to analytical procedures, and appropriate acceptance criteria, which are numerical limits, ranges, or other criteria for the tests described. It establishes the set of criteria to which a drug substance or drug product should conform to be considered acceptable for its intended use. "Conformance to specifications" means that the drug substance and/or drug product, when tested according to the listed analytical procedures, will meet the listed acceptance criteria. Specifications are critical quality standards that are proposed and justified by the manufacturer and approved by regulatory authorities.

Specific Test: A test which is considered to be applicable to particular new drug substances or particular new drug products depending on their specific properties and/or intended use.

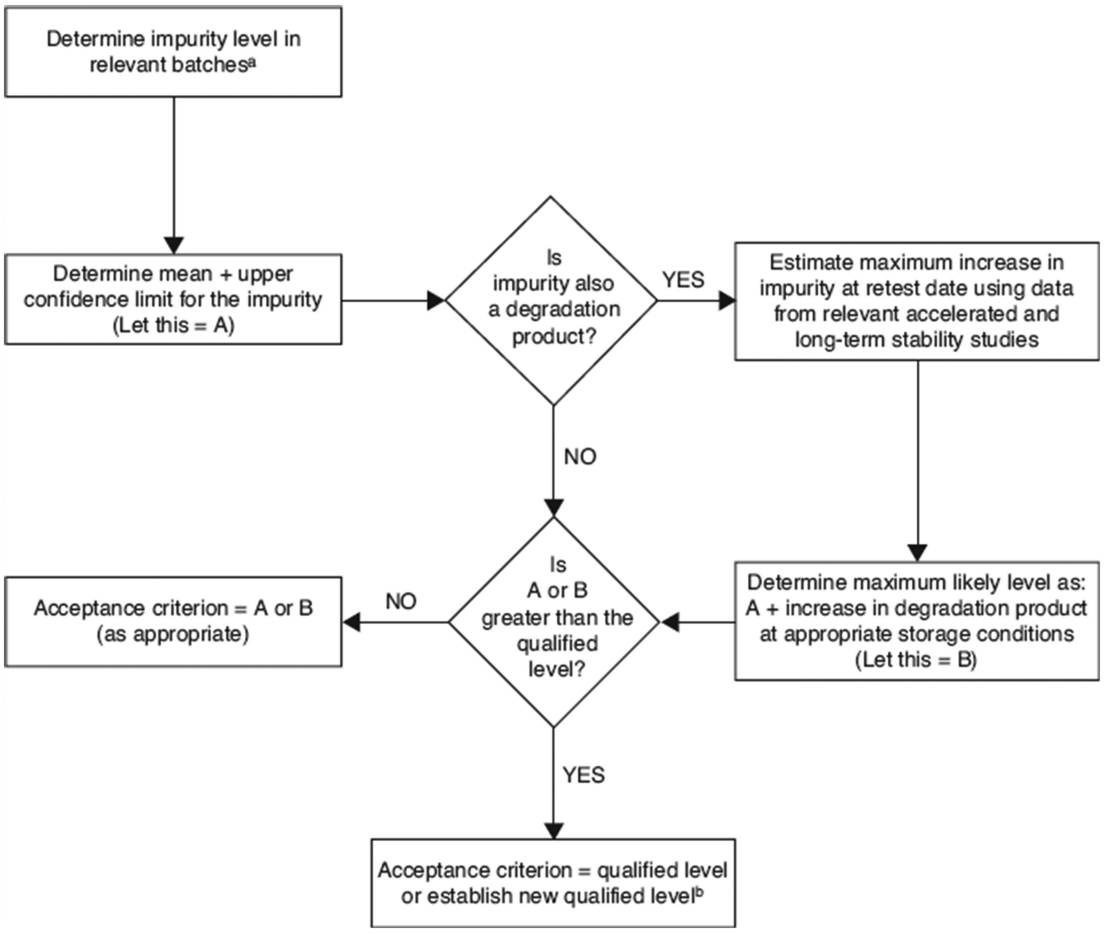
Specified Impurity: An identified or unidentified impurity that is selected for inclusion in the new drug substance or new drug product specification and is individually listed and limited in order to assure the quality of the new drug substance or new drug product.

Unidentified Impurity: An impurity which is defined solely by qualitative analytical properties, (e.g., chromatographic retention time).

Universal Test: A test which is considered to be potentially applicable to all new drug substances or all new drug products, for example, appearance, identification, assay, and impurity tests.

IV. ATTACHMENTS

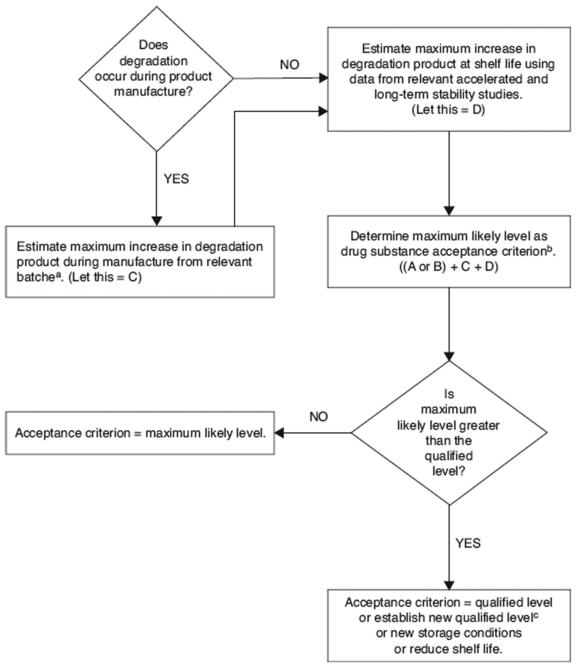
Decision Tree #1 Establishing Acceptance Criterion for a Specified Impurity in a New Drug Substance



[a] Relevant batches are those from development, pilot, and scale-up studies.
[b] Refer to ICH guideline on *Impurities in New Drug Substances.*

Definition: Upper confidence limit = three times the standard deviation of batch analysis data.

Decision Tree #2 Establishing Acceptance Criterion for a Degradation Product in a New Drug Product

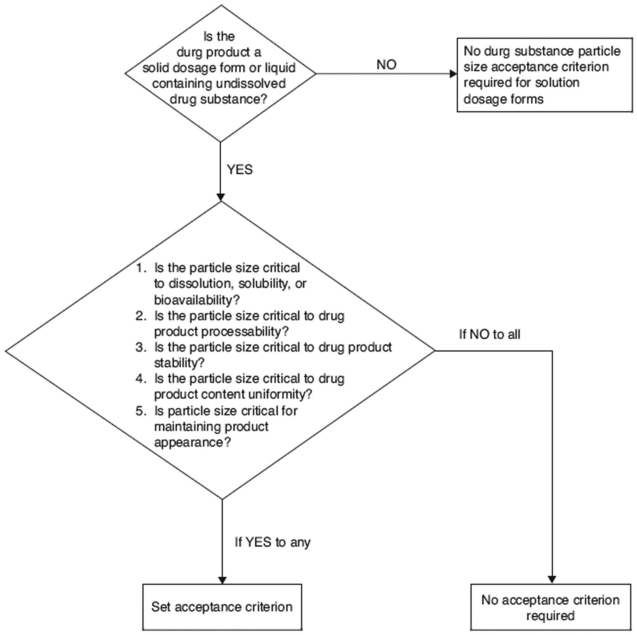


[a] Relevant batches are those from development, pilot, and scale-up studies.

[b] Refer to Decision Tree 1 for information regarding A and B.

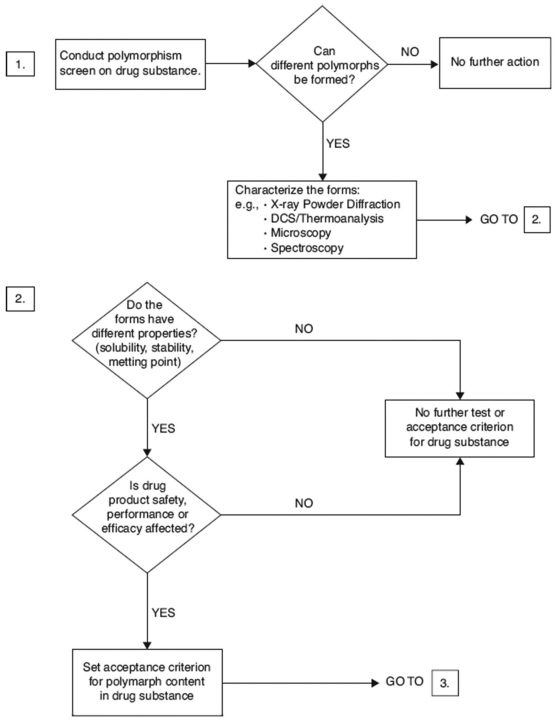
[c] Refer to ICH guideline on *Impurities in New Drug Products*.

Decision Tree #3 Setting Acceptance Criteria for Drug Substance Particle Size Distribution



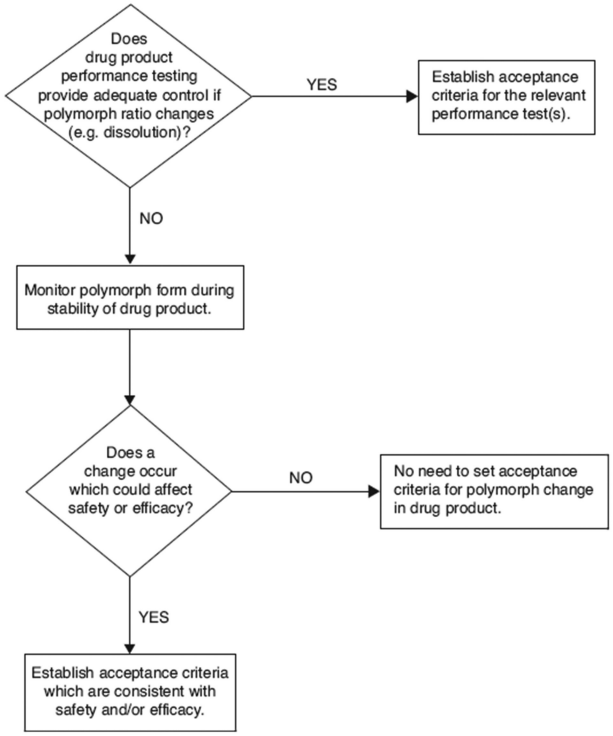
Decision Tree #4 Investigating the Need to set Acceptance Criteria for Polymorphism in Drug Substances and Drug Products

Drug Substances

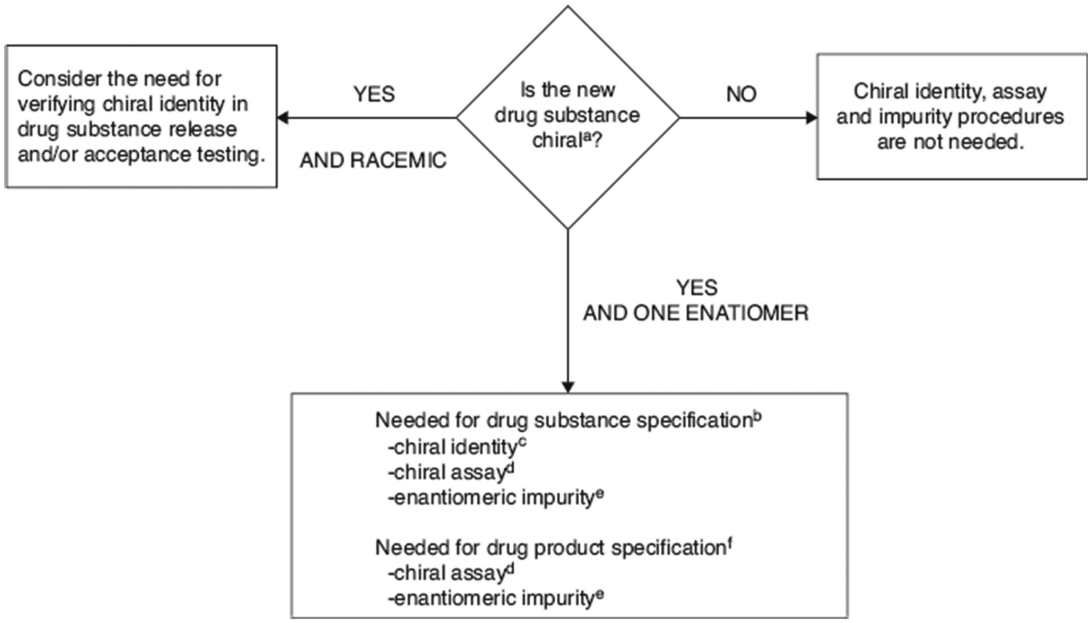


Drug Product—Solid Dosage Form or Liquid Containing Undissolved Drug Substance

N.B.: Undertake the following processes only technically possible to measure polymorph content in the drug product.



Decision Tree #5 Establishing Identity, Assay, and Enantiomeric Impurity Procedures for Chiral New Drug Substances and New Drug Products Containing Chiral Drug Substances



[a] Chiral substances of natural origin are not addressed in this guideline.

[b] As with other impurities arising in and from raw materials used in drug substance synthesis, control of chiral quality could be established alternatively by applying limits to appropriate starting materials or intermediates when justified from developmental studies. This essentially will be the case when there are multiple chiral centers (e.g., three or more) or when control as a step prior to production of the final drug substance is desirable.

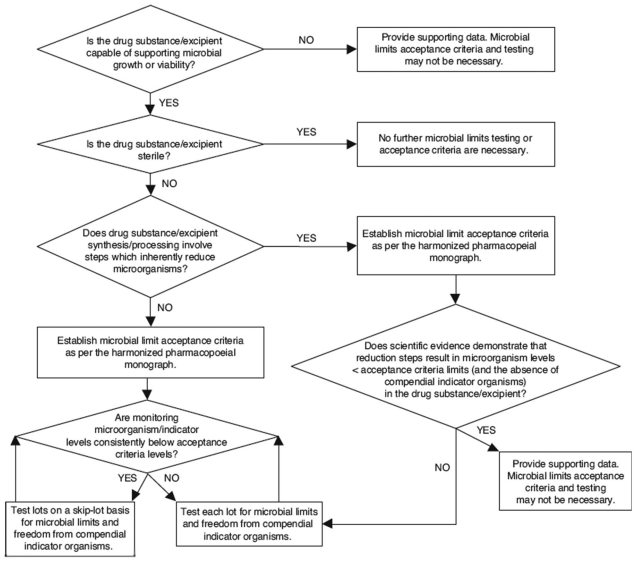
[c] A chiral assay or an enantiomeric impurity procedure may be acceptable in lieu of a chiral identity procedure.

[d] An achiral assay combined with a method for controlling the opposite enantiomer is acceptable in lieu of a chiral assay.

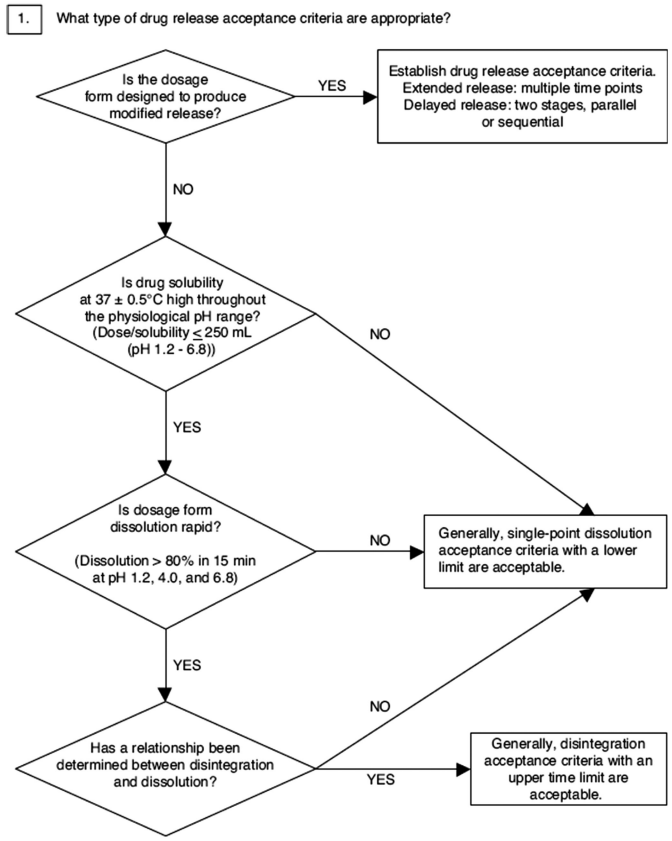
[e] The level of the opposite enantiomer of the drug substance may be derived from chiral assay data or from a separate procedure.

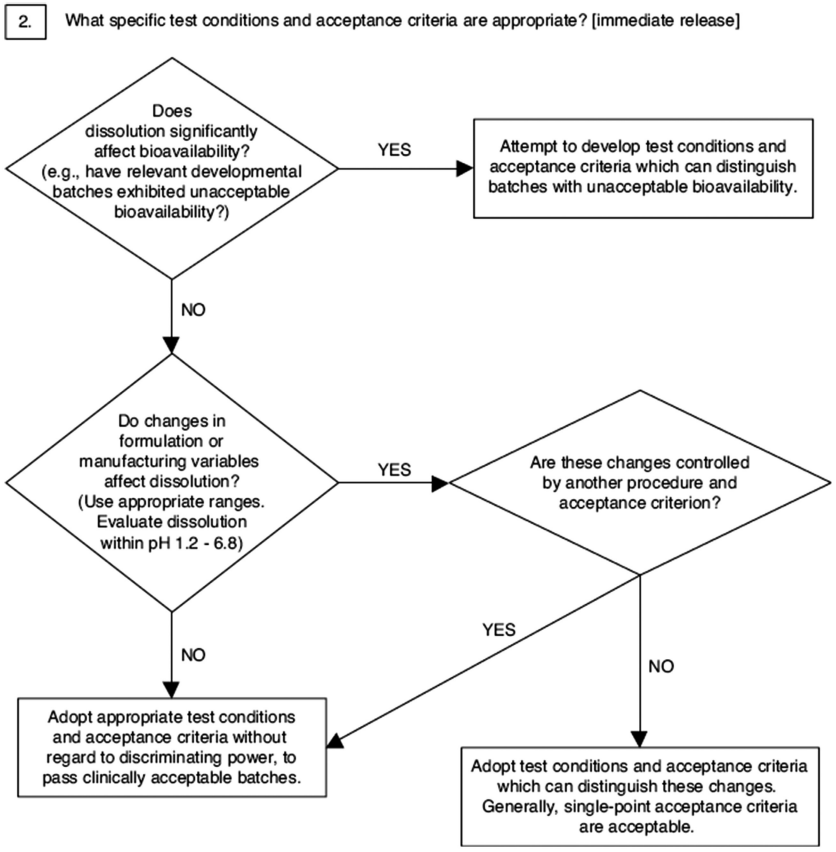
[f] Stereospecific testing of drug product may not be necessary if racerization has been demonstrated to be insignificant during drug product manufacture and during storage of the finished dosage form.

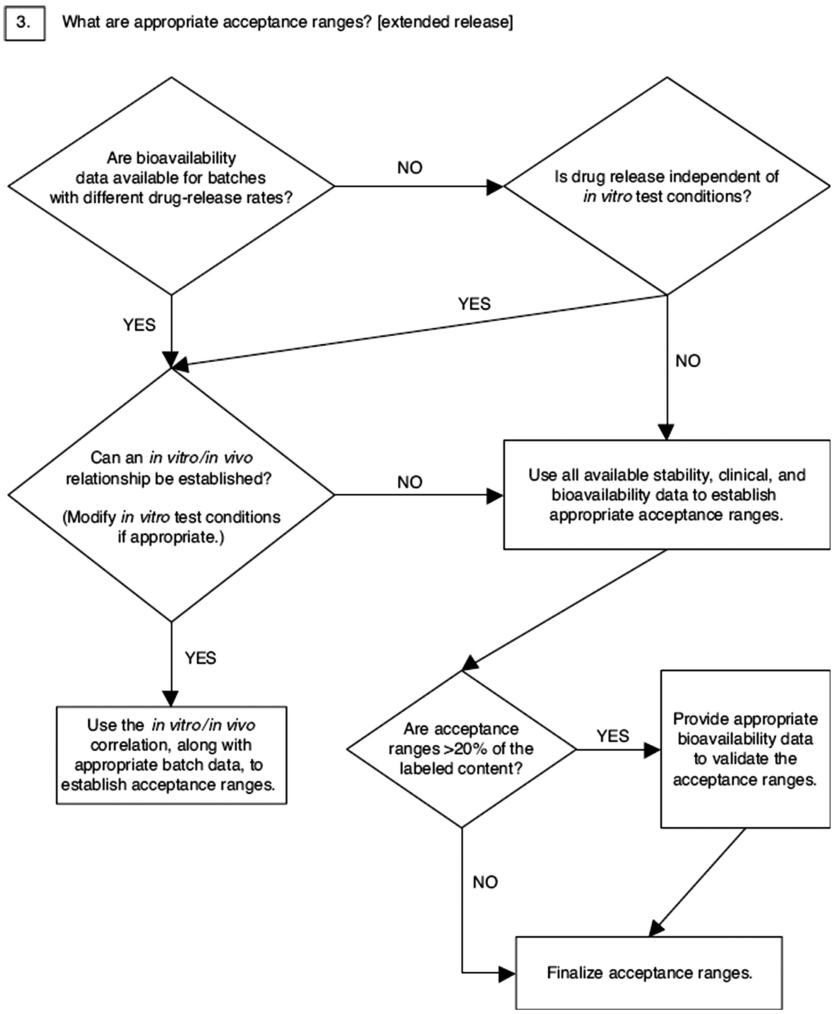
Decision Tree #6 Microbiological Quality Attributes of Drug Substance and Excipients



Decision Trees #7 Setting Acceptance Criteria for Drug Product Dissolution







3. What are appropriate acceptance ranges? [extended release]
Are bioavailability data available for batches with different drug-release rates?
NO
Is drug release independent of *in vitro* test conditions?
YES
YES
NO
Can an *in vitro/in vivo* relationship be established? (Modify *in vitro* test conditions if appropriate.)
NO
Use all available stability, clinical, and bioavailability data to establish appropriate acceptance ranges.
YES
Use the *in vitro/in vivo* correlation, along with appropriate batch data, to establish acceptance ranges.
Are acceptance ranges >20% of the labeled content?
YES
Provide appropriate bioavailability data to validate the acceptance ranges.
NO
Finalize acceptance ranges.

Decision Tree #8 Microbiological Attributes of Nonsterile Drug Products

11 Topical Testing of Transdermal Drug Products

To fully evaluate the equivalence of a transdermal product for an abbreviated new drug application to a reference-listed drug, skin irritation and sensitization should be assessed because the condition of the skin may affect the absorption of a drug from a transdermal system. More severe skin irritation may affect the efficacy or safety of the product.

Transdermal products have properties that may lead to skin irritation or sensitization. The delivery system, or the system in conjunction with the drug substance, may cause these reactions. In the development of transdermal products, dermatologic adverse events are evaluated primarily with animal studies and safety evaluations in the context of large clinical trials generally associated with the submission of new drug applications. Separate skin irritation and skin sensitization studies also are used for this purpose. These latter studies are designed to detect irritation and sensitization under conditions of maximal stress and may be used during the assessment of transdermal drug products for abbreviated new drug applications.

I. STUDY DESIGNS

Recommended designs for skin irritation and skin sensitization studies for the comparative evaluation of transdermal drug products for an abbreviated new drug application are delineated below. Other proposals for studies may be suggested, but potential applicants are advised to consult the Office of Generic Drugs about alternative study designs before the initiation of such a study.

A. Recommendations for a Cumulative Skin Irritation Study

1. Sample Size

The sample size should be 30 subjects.

2. Exclusion Criteria

Dermatologic disease that might interfere with the evaluation of test site reaction should be grounds for exclusion.

3. Duration of Study

The study should last for 22 days.

4. Study Design

The study should be a randomized, controlled, repeat patch test study that compares the test patch with the innovator patch. Placebo patches (transdermal patch without active drug substance) or high- and low-irritancy controls (e.g., sodium lauryl sulfate 0.1% and 0.9% saline) can be included as additional test arms.

5. Patch Application

Each subject applies one of each of the patches to be tested. Test sites should be randomized among patients. Patches should be applied for 23 hours (±1 hour) daily for 21 days to the same skin site. At each patch removal, the site should be evaluated for reaction and the patch reapplied.

Application of a test patch should be discontinued at a site if predefined serious reactions occur at the site of repeated applications. Application at a different site may subsequently be initiated.

6. Evaluations

Scoring of skin reactions and patch adherence should be performed by a trained and blinded observer at each patch removal, using an appropriate scale.

Dermal reactions should be scored on a scale that describes the amount of erythema, edema, and other features indicative of irritations. (See Appendix A for an example of a scoring system that can be used.) The percentage adherence of the transdermal patches should be assessed using a five-point scale (see Appendix B).

7. Data Presentation and Analysis

Individual daily observations should be provided, as well as a tabulation that presents the percentage of subjects with each grade of skin reaction and degree of patch adherence on each study day. The mean cumulative irritation score, the total cumulative irritation score, and the number of days until sufficient irritation occurred to preclude patch application for all the study subjects should be calculated for each test product, and a statistical analysis of the comparative results should be performed (see Appendix C).

B. Recommendations for a Skin Sensitization Study (Modified Draize Test)

1. Sample Size

Two hundred subjects should be sampled.

2. Exclusion Criteria

Exclusion criteria include

a. Dermatologic disease that might interfere with the evaluation of the test site reactions and
b. Use of systemic or topical analgesics or antihistamines within 72 hours of study enrollment or systemic or topical corticosteroids within 3 weeks of study enrollment

3. Duration of Study

The study should last for 6 weeks.

4. Study Design

The study should be a randomized, controlled study on three test products: The test transdermal patch, the innovator patch, and the placebo patch (transdermal patch without the active drug substance).

5. Patch Application

Test sites should be randomized among patients. The study is divided into three sequential periods.

a. Induction Phase

Applications of the test materials should be made to the same skin sites three times weekly for 3 weeks, for a total of nine applications. The patches should remain in place for 48 hours on weekdays and for 72 hours on weekends. Scoring of skin reactions and patch adherence should be performed by a trained and blinded observer at each patch removal, using an appropriate scale.

Dermal reactions should be scored on a scale that describes the amount of erythema, edema, and other features indicative of irritation. (See Appendix A for an example of a scoring system that can be used.) The percentage adherence of the transdermal patches should be assessed using a five-point scale (see Appendix B).

b. Rest Phase

The induction phase is followed by a rest phase of 2 weeks, during which no applications are made.

c. Challenge Phase

The patches should be applied to new skin sites for 48 hours. Evaluation of skin reactions should be made by a trained blinded observer at 30 minutes and at 24, 48, and 72 hours after patch removal. (See Appendix A for an example of a scoring system that can be used.)

6. Data Presentation and Analysis

The individual daily observations should be provided, as well as a tabulation of the percentage of subjects with each grade of skin reaction and degree of patch adherence on each study day. The mean cumulative irritation score and the total cumulative irritation score for all the study subjects should be calculated for each test product, and a statistical analysis of the comparative results should be performed.

A narrative description of each reaction in the challenge phase should be provided, together with the opinion of the investigator as to whether such reactions are felt to be indicative of contact sensitization.

C. Combined Studies

Alternatively, the cumulative skin irritation study and the skin sensitization study can be combined into a single study. The study design would be identical to that described for the skin sensitization study (see Section I.B), except that patch application during the induction phase should be daily for 23 hours (±1 hour) each day over 21 days.

APPENDIX A: SKIN IRRITATION SCORING SYSTEMS

The following scoring system for irritation or sensitization reactions is included as an example of a scoring system that can be used for these studies. Other validated scoring systems can be used in quantifying skin reactions. The inclusion of this system should not be interpreted as an endorsement of the system by the agency. It is provided as an example only.

1. Dermal response:
   0 = no evidence of irritation
   1 = minimal erythema, barely perceptible
   2 = definite erythema, readily visible; minimal edema or minimal papular response
   3 = erythema and papules
   4 = definite edema
   5 = erythema, edema, and papules
   6 = vesicular eruption
   7 = strong reaction spreading beyond test site
2. Other effects:
   A = slight glazed appearance
   B = marked glazing
   C = glazing with peeling and cracking
   D = glazing with fissures
   E = film of dried serous exudate covering all or part of the patch site
   F = small petechial erosions or scabs

APPENDIX B: ADHESION SCORE

The following scoring system is included as an example of a scoring system that can be used for this type of study. Other validated scoring systems may be equally effective in quantifying comparative adhesion of transdermal systems. The inclusion of this system is not to be interpreted as an endorsement of the system by the agency. It is provided as an example only.

An estimate of the adherence of the transdermal system will be rated as follows:

0 ≥90% adhered (essentially no lift off the skin)
1 ≥75% to <90% adhered (some edges only lifting off the skin)
2 ≥50% to <75% adhered (less than half of the system lifting off the skin)
3 ≥50% adhered but not detached (more than half the system lifting off the skin without falling off)
4 = patch detached (patch completely off the skin)

APPENDIX C: STATISTICS

To be considered equivalent for a particular response, the average response for the generic (μ_T) should be between 80% and 125% of the average response for the innovator (μ_R). It is recommended that the response of the generic be equivalent to or better than the innovator. This implies a one-sided test.

For a variable for which low scores are better, such as mean irritation score or total cumulative irritation score, the hypotheses would be

$$H_0 : \mu_T / \mu_R > 1.25$$

$$H_1 : \mu_T / \mu_R \geq 1.25$$

which (assuming that $\mu_R > 0$) implies

$$H_0 : \mu_T - 1.25\mu_R \geq 0$$

$$H_1 : \mu_T - 1.25\mu_R \geq 0$$

The null hypothesis H_0 will be rejected when the upper limit of the 90% confidence interval (that is, the 95% upper confidence bound) for the quantity $\mu_T - 1.25\mu_R$ is less than or equal to zero.

For a variable for which high values are better, such as time to removal score, the hypotheses would be

$$H_0 : \mu_T / \mu_R < 0.80$$

$$H_1 : \mu_T / \mu_R \geq 0.80$$

which (assuming that $\mu_R > 0$) implies

$$H_0 : \mu_T - 0.80\mu_R < 0$$

$$H_0 : \mu_T - 0.80\mu_R \geq 0$$

The null hypothesis H_0 will be rejected in this case when the lower limit of the 90% confidence interval (i.e., the 95% lower confidence bound) for the quantity $\mu_T - 0.80\mu_R$ is greater than or equal to zero.

In either case, if the null hypothesis H_0 is rejected, the generic should be considered equivalent to or better than the innovator.

12 Impurities Profiling
Drug Substance

I. PREAMBLE

This document is intended to provide guidance for registration applications on the content and qualification of impurities in new drug substances produced by chemical syntheses and not previously registered in a region or member state. It is not intended to apply to new drug substances used during the clinical research stage of development. The following types of drug substances are not covered in this guideline: Biological/biotechnological, peptide, oligonucleotide, radiopharmaceutical, fermentation product and semisynthetic products derived therefrom, herbal products, and crude products of animal or plant origin.

Impurities in new drug substances are addressed from the following two perspectives:

Chemistry Aspects include classification and identification of impurities, report generation, listing of impurities in specifications, and a brief discussion of analytical procedures.

Safety Aspects include specific guidance for qualifying those impurities that were not present, or were present at substantially lower levels, in batches of a new drug substance used in safety and clinical studies.

II. CLASSIFICATION OF IMPURITIES

Impurities can be classified into the following categories:

- Organic impurities (process and drug related)
- Inorganic impurities
- Residual solvents

Organic impurities can arise during the manufacturing process and/or storage of the new drug substance. They can be identified or unidentified, volatile or nonvolatile, and include

- Starting materials
- Byproducts
- Intermediates
- Degradation products
- Reagents, ligands, and catalysts

Inorganic impurities can result from the manufacturing process. They are normally known and identified and include

- Reagents, ligands, and catalysts
- Heavy metals or other residual metals
- Inorganic salts
- Other materials (e.g., filter aids, charcoal)

Solvents are inorganic or organic liquids used as vehicles for the preparation of solutions or suspensions in the synthesis of a new drug substance. Since these are generally of known toxicity, the selection of appropriate controls is easily accomplished (see ICH guideline Q3C on residual solvents).

Excluded from this document are (1) extraneous contaminants that should not occur in new drug substances and are more appropriately addressed as GMP issues, (2) polymorphic forms, and (3) enantiomeric impurities.

III. RATIONALE FOR THE REPORTING AND CONTROL OF IMPURITIES

A. Organic Impurities

The applicant should summarize the actual and potential impurities most likely to arise during the synthesis, purification, and storage of the new drug substance. This summary should be based on sound scientific appraisal of the chemical reactions involved in the synthesis, impurities associated with raw materials that could contribute to the impurity profile of the new drug substance, and possible degradation products. This discussion can be limited to those impurities that might reasonably be expected based on knowledge of the chemical reactions and conditions involved.

In addition, the applicant should summarize the laboratory studies conducted to detect impurities in the new drug substance. This summary should include test results of batches manufactured during the development process and batches from the proposed commercial process, as well as the results of stress testing (see ICH guideline Q1A on stability) used to identify potential impurities arising during storage. The impurity profile of the drug substance batches intended for marketing should be compared with those used in development and any differences discussed.

The studies conducted to characterize the structure of actual impurities present in the new drug substance at a level greater than (>) the identification threshold given in Attachment 1 (e.g., calculated using the response factor of the drug substance) should be described. Note that any impurity at a level greater than (>) the identification threshold in any batch manufactured by the proposed commercial process should be identified. In addition, any degradation product observed in stability studies at recommended storage conditions at a level greater than (>) the identification threshold

should be identified. When identification of an impurity is not feasible, a summary of the laboratory studies demonstrating the unsuccessful effort should be included in the application. Where attempts have been made to identify impurities present at levels of not more than (<) the identification thresholds, it is useful also to report the results of these studies.

Identification of impurities present at an apparent level of not more than (≤) the identification threshold is generally not considered necessary. However, analytical procedures should be developed for those potential impurities that are expected to be unusually potent, producing toxic or pharmacological effects at a level not more than (≤) the identification threshold. All impurities should be qualified as described later in this guideline.

B. Inorganic Impurities

Inorganic impurities are normally detected and quantified using pharmacopoeial or other appropriate procedures. Carryover of catalysts to the new drug substance should be evaluated during development. The need for inclusion or exclusion of inorganic impurities in the new drug substance specification should be discussed. Acceptance criteria should be based on pharmacopoeial standards or known safety data.

C. Solvents

The control of residues of the solvents used in the manufacturing process for the new drug substance should be discussed and presented according to the ICH Q3C *Guideline for Residual Solvents.*

IV. ANALYTICAL PROCEDURES

The registration application should include documented evidence that the analytical procedures are validated and suitable for the detection and quantification of impurities (see ICH Q2A and Q2B guidelines for analytical validation). Technical factors (e.g., manufacturing capability and control methodology) can be considered as part of the justification for selection of alternative thresholds based on manufacturing experience with the proposed commercial process. The use of two decimal places for thresholds (see Attachment 1) does not necessarily reflect the precision of the analytical procedure used for routine quality control purposes. Thus, the use of lower precision techniques (e.g., thin-layer chromatography) can be acceptable where justified and appropriately validated. Differences in the analytical procedures used during development and those proposed for the commercial product should be discussed in the registration application.

The quantitation limit for the analytical procedure should be not more than (≤) the reporting threshold.

Organic impurity levels can be measured by a variety of techniques, including those that compare an analytical response for an impurity to that of an appropriate reference standard or to the response of the new drug substance itself. Reference standards used in the analytical procedures for control of impurities should be evaluated and characterized according to their intended uses. The drug substance can be used as a standard to estimate the levels of impurities. In cases where the response factors of the drug substance and the relevant impurity are not close, this practice can still be appropriate, provided a correction factor is applied or the impurities are, in fact, being overestimated. Acceptance criteria and analytical procedures used to estimate identified or unidentified impurities can be based on analytical assumptions (e.g., equivalent detector response). These assumptions should be discussed in the registration application.

V. REPORTING IMPURITY CONTENT OF BATCHES

Analytical results should be provided in the application for all batches of the new drug substance used for clinical, safety, and stability testing, as well as for batches representative of the proposed commercial process. Quantitative results should be presented numerically and not in general terms such as "complies," "meets limit," etc. Any impurity at a level greater than (>) the reporting threshold (see Attachment 1) and total impurities observed in these batches of the new drug substance should be reported with the analytical procedures indicated. Below 1.0%, the results should be reported to two decimal places (e.g., 0.06%, 0.13%); at and above 1.0%, the results should be reported to one decimal place (e.g., 1.3%). Results should be rounded using conventional rules (see Attachment 2). A tabulation (e.g., spreadsheet) of the data is recommended. Impurities should be designated by code number or by an appropriate descriptor, for example, retention time. If a higher reporting threshold is proposed, it should be fully justified. All impurities at a level greater than (>) the reporting threshold should be summed and reported as total impurities.

When analytical procedures change during development, reported results should be linked to the procedure used, with appropriate validation information provided. Representative chromatograms should be provided. Chromatograms of representative batches from analytical validation studies showing separation and detectability of impurities (e.g., on spiked samples), along with any other impurity tests routinely performed, can serve as the representative impurity profiles. The applicant should ensure that complete impurity profiles (e.g., chromatograms) of individual batches are available, if requested.

A tabulation should be provided that links the specific new drug substance batch to each safety study and each clinical study in which the new drug substance has been used.

For each batch of the new drug substance, the report should include

- Batch identity and size
- Date of manufacture
- Site of manufacture
- Manufacturing process
- Impurity content, individual and total
- Use of batches
- Reference to analytical procedure used

VI. LISTING OF IMPURITIES IN SPECIFICATIONS

The specification for a new drug substance should include a list of impurities. Stability studies, chemical development studies, and routine batch analyses can be used to predict those impurities likely to occur in the commercial product. The selection of impurities in the new drug substance specification should be based on the impurities found in batches manufactured by the proposed commercial process. Those individual impurities with specific acceptance criteria included in the specification for the new drug substance are referred to as "specified impurities" in this guideline. Specified impurities can be identified or unidentified.

A rationale for the inclusion or exclusion of impurities in the specification should be presented. This rationale should include a discussion of the impurity profiles observed in the safety and clinical development batches, together with a consideration of the impurity profile of batches manufactured by the proposed commercial process. Specified identified impurities should be included along with specified unidentified impurities estimated to be present at a level greater than (>) the identification threshold given in Attachment 1. For impurities known to be unusually potent or to produce toxic or unexpected pharmacological effects, the quantitation/detection limit of the analytical procedures should be commensurate with the level at which the impurities should be controlled. For unidentified impurities, the procedure used and assumptions made in establishing the level of the impurity should be clearly stated. Specified, unidentified impurities should be referred to by an appropriate qualitative analytical descriptive label (e.g., "unidentified A," "unidentified with relative retention of 0.9"). A general acceptance criterion of not more than (≤) the identification threshold (Attachment 1) for any unspecified impurity and an acceptance criterion for total impurities should be included.

Acceptance criteria should be set no higher than the level that can be justified by safety data and should be consistent with the level achievable by the manufacturing process and the analytical capability. Where there is no safety concern, impurity acceptance criteria should be based on data generated on batches of the new drug substance manufactured by the proposed commercial process, allowing sufficient latitude to deal with normal manufacturing and analytical variation and the stability characteristics of the new drug substance. Although normal manufacturing variations are expected, significant variation in batch-to-batch impurity levels can indicate that the manufacturing process of the new drug substance is not adequately controlled and validated (see ICH Q6A guideline on specifications, Decision Tree No. 1, for establishing an acceptance criterion for a specified impurity in a new drug substance). The use of two decimal places for thresholds (see Attachment 1) does not necessarily indicate the precision of the acceptance criteria for specified impurities and total impurities.

In summary, the new drug substance specification should include, where applicable, the following list of impurities:

Organic Impurities
- Each specified identified impurity
- Each specified unidentified impurity
- Any unspecified impurity with an acceptance criterion of not more than (≤) the identification threshold
- Total impurities

Residual Solvents

Inorganic Impurities

VII. QUALIFICATION OF IMPURITIES

Qualification is the process of acquiring and evaluating data that establishes the biological safety of an individual impurity or a given impurity profile at the level(s) specified. The applicant should provide a rationale for establishing impurity acceptance criterion that includes safety considerations. The level of any impurity present in a new drug substance that has been adequately tested in safety and/or clinical studies would be considered qualified. Impurities that are also significant metabolites present in animal and/or human studies are generally considered qualified. A level of a qualified impurity higher than that present in a new drug substance can also be justified based on an analysis of the actual amount of impurity administered in previous relevant safety studies.

If data are unavailable to qualify the proposed acceptance criterion of an impurity, studies to obtain such data can be appropriate when the usual qualification thresholds given in Attachment 1 are exceeded.

Higher or lower thresholds for qualification of impurities can be appropriate for some individual drugs based on scientific rationale and level of concern, including drug class effects and clinical experience. For example, qualification can be especially important when there is evidence that such impurities in certain drugs or therapeutic classes have previously been associated with adverse reactions in patients. In these instances, a lower qualification threshold can be appropriate. Conversely, a higher qualification threshold can be appropriate for individual drugs when the level of concern for safety is less than usual based on similar considerations (e.g., patient population, drug class effects, clinical considerations). Proposals for alternative thresholds would be considered on a case-by-case basis.

The "Decision Tree for Identification and Qualification" (Attachment 3) describes considerations for the qualification of impurities when thresholds are exceeded. In some cases, decreasing the level of impurity to not more than the threshold can be simpler than providing safety data. Alternatively, adequate data could be available in the scientific literature to qualify an impurity. If neither is the case, additional safety testing should be considered. The studies considered appropriate to qualify an impurity will depend on a number of factors, including the patient population, daily dose, and route and duration of drug administration. Such studies can be conducted on the new drug substance containing the impurities to be controlled, although studies using isolated impurities can sometimes be appropriate.

Although this guideline is not intended to apply during the clinical research stage of development, in the later stages of development the thresholds in this guideline can be useful in evaluating new impurities observed in drug substance batches prepared by the proposed commercial process. Any new impurity observed in later stages of development should be identified if its level is greater than (>) the identification threshold given in Attachment 1 (see the "Decision Tree for Identification and Qualification" in Attachment 3). Similarly, the qualification of the impurity should be considered if its level is greater than (>) the qualification threshold given in Attachment 1. Safety assessment studies to qualify an impurity should compare the new drug substance containing a representative amount of the new impurity with previously qualified material. Safety assessment studies using a sample of the isolated impurity can also be considered.

GLOSSARY

Chemical Development Studies: Studies conducted to scale up, optimize, and validate the manufacturing process for a new drug substance.

Enantiomeric Impurity: A compound with the same molecular formula as the drug substance that differs in the spatial arrangement of atoms within the molecule and is a nonsuperimposable mirror image.

Extraneous Contaminant: An impurity arising from any source extraneous to the manufacturing process.

Herbal Products: Medicinal products containing, exclusively, plant material and/or vegetable drug preparations as active ingredients. In some traditions, materials of inorganic or animal origin can also be present.

Identified Impurity: An impurity for which a structural characterization has been achieved.

Identification Threshold: A limit above (>) which an impurity should be identified.

Impurity: Any component of the new drug substance that is not the chemical entity defined as the new drug substance.

Impurity Profile: A description of the identified and unidentified impurities present in a new drug substance.

Intermediate: A material produced during steps of the synthesis of a new drug substance that undergoes further chemical transformation before it becomes a new drug substance.

Ligand: An agent with a strong affinity to a metal ion.

New Drug Substance: The designated therapeutic moiety that has not been previously registered in a region or member state (also referred to as a new molecular entity or new chemical entity). It can be a complex, simple ester, or salt of a previously approved drug substance.

Polymorphic Forms: Different crystalline forms of the same drug substance. These can include solvation or hydration products (also known as pseudopolymorphs) and amorphous forms.

Potential Impurity: An impurity that theoretically can arise during manufacture or storage. It may or may not actually appear in the new drug substance.

Qualification: The process of acquiring and evaluating data that establishes the biological safety of an individual impurity or a given impurity profile at the level(s) specified.

Qualification Threshold: A limit above (>) which an impurity should be qualified.

Reagent: A substance other than a starting material, intermediate, or solvent that is used in the manufacture of a new drug substance.

Reporting Threshold: A limit above (>) which an impurity should be reported. Reporting threshold is the same as reporting level in Q2B.

Solvent: An inorganic or an organic liquid used as a vehicle for the preparation of solutions or suspensions in the synthesis of a new drug substance.

Specified Impurity: An impurity that is individually listed and limited with a specific acceptance criterion in the new drug substance specification. A specified impurity can be either identified or unidentified.

Starting Material: A material used in the synthesis of a new drug substance that is incorporated as an element into the structure of an intermediate and/or of the new drug substance. Starting materials are normally commercially available and of defined chemical and physical properties and structure.

Unidentified Impurity: An impurity for which a structural characterization has not been achieved and that is defined solely by qualitative analytical properties (e.g., chromatographic retention time).

Unspecified Impurity: An impurity that is limited by a general acceptance criterion, but not individually listed with its own specific acceptance criterion, in the new drug substance specification.

ATTACHMENT 1: THRESHOLDS

Maximum Daily Dose[a]	Reporting Threshold[b,c]	Identification Threshold[c]	Qualification Threshold[c]
≤2 g/day	0.05%	0.10% or 1.0 mg/day intake (whichever is lower)	0.15% or 1.0 mg/day intake (whichever is lower)
>2 g/day	0.03%	0.05%	0.05%

[a] The amount of drug substance administered per day.

[b] Higher reporting thresholds should be scientifically justified.

[c] Lower thresholds can be appropriate if the impurity is unusually toxic.

ATTACHMENT 2: ILLUSTRATION OF REPORTING IMPURITY RESULTS FOR IDENTIFICATION AND QUALIFICATION IN AN APPLICATION

The attachment is only illustrative and is not intended to serve as template for how results on impurities should be presented in an application file. Normally raw data are not presented.

Example 1: 0.5 g Maximum Daily Dose

Reporting threshold = 0.05%
Identification threshold = 0.10%
Qualification threshold = 0.15%

			Action	
"Raw" Result (%)	**Reported Result (%) Reporting Threshold = 0.05%**	**Calculated Total Daily Intake (TDI) (mg) of the Impurity (Rounded Result in mg)**	**Identification (Threshold 0.10% Exceeded?)**	**Qualification (Threshold 0.15% Exceeded?)**
0.044	Not reported	0.2	None	None
0.0963	0.10	0.5	None	None
0.12	0.12[a]	0.6	Yes	None[a]
0.1649	0.16[a]	0.8	Yes	Yes[a]

Example 2: 0.8 g Maximum Daily Dose

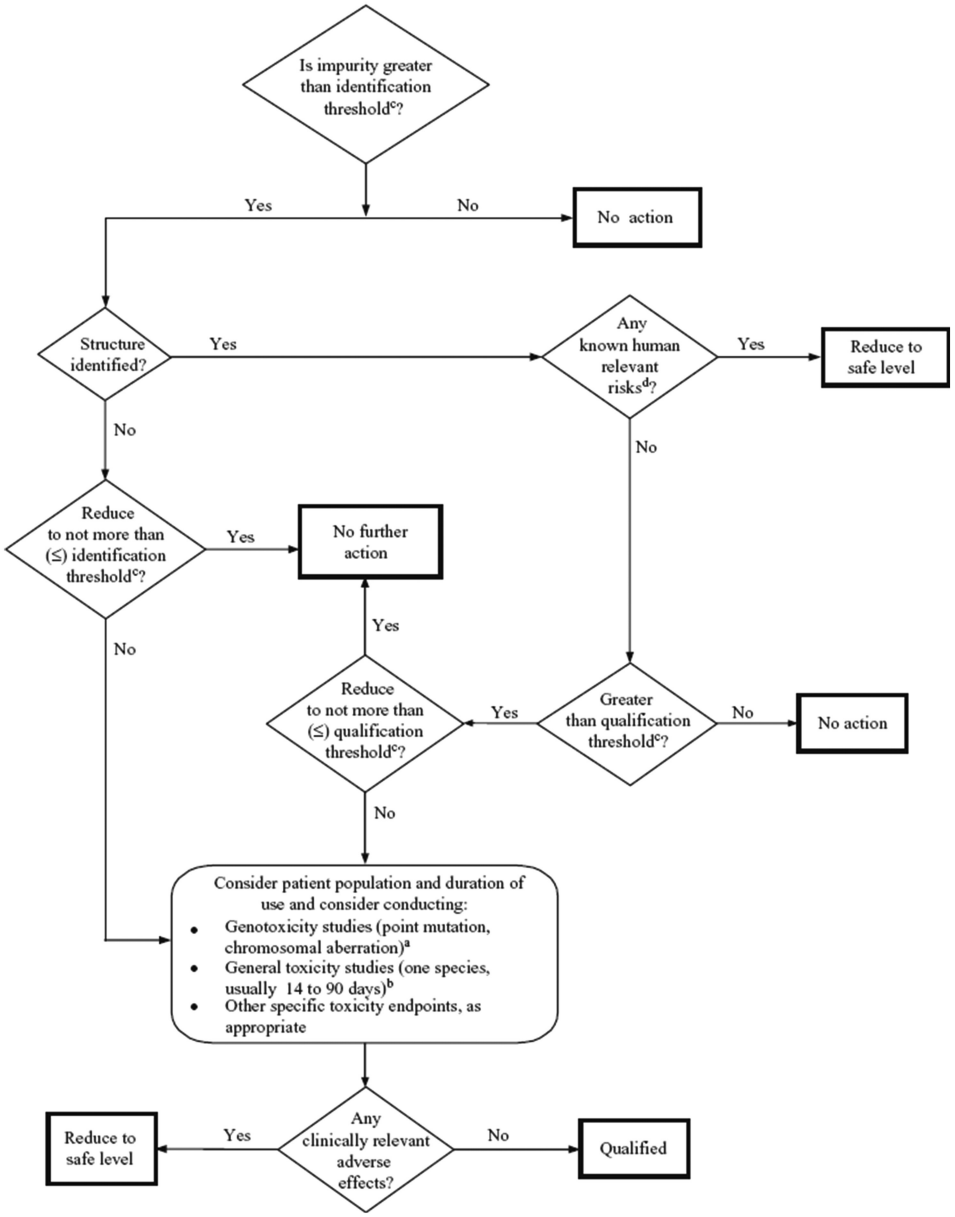
Reporting threshold = 0.05%
Identification threshold = 0.10%
Qualification threshold = 1.0 mg TDI

			Action	
"Raw" Result (%)	**Reported Result (%) Reporting Threshold = 0.05%**	**Calculated Total Daily Intake (TDI) (mg) of the Impurity (Rounded Result in mg)**	**Identification (Threshold 0.10% Exceeded?)**	**Qualification (Threshold 1.0 mg TDI Exceeded?)**
0.066	0.07	0.6	None	None
0.124	0.12	1.0	Yes	None[a,b]
0.143	0.14	1.1	Yes	Yes[a]

[a] After identification, if the response factor is determined to differ significantly from the original assumptions, it may be appropriate to remeasure the actual amount of the impurity present and reevaluate against the qualification threshold (see Attachment 1).

[b] To verify if a threshold is exceeded, a reported result has to be evaluated against the thresholds as follows: When the threshold is described in %, the reported result rounded to the same decimal place as the threshold should be compared directly to the threshold. When the threshold is described in TDI, the reported result should be converted to TDI, rounded to the same decimal place as the threshold, and compared to the threshold. For example, the amount of impurity at 0.12% level corresponds to a TDI of 0.96 mg (absolute amount), which is then rounded up to 1.0 mg; so the qualification threshold expressed in TDI (1.0 mg) is not exceeded.

ATTACHMENT 3: DECISION TREE FOR IDENTIFICATION AND QUALIFICATION



[a] If considered desirable, a minimum screen (e.g., genotoxic potential) should be conducted. A study to detect point mutations and to detect chromosomal aberrations, both in vitro, is considered an appropriate minimum screen.

[b] If general toxicity studies are desirable, one or more studies should be designed to allow comparison of unqualified to qualified material. The study duration should be based on available relevant information and performed in the species most likely to maximize the potential to detect the toxicity of an impurity. On a case-by-case basis, single-dose studies can be appropriate, especially for single-dose drugs. In general, a minimum duration of 14 days and a maximum duration of 90 days would be considered appropriate.

[c] Lower thresholds can be appropriate if the impurity is unusually toxic.

[d] For example, do known safety data for this impurity or its structural class preclude human exposure at the concentration present?

13 Impurities in New Drug Products

I. INTRODUCTION

A. Objective of the Guideline

This document provides guidance for registration applications on the content and qualification of impurities in new drug products produced from chemically synthesized new drug substances not previously registered in a region or member state.

B. Background

This guideline is complementary to the ICH Q3A(R) guideline *Impurities in New Drug Substances*, which should be consulted for basic principles. The ICH Q3C guideline *Residual Solvents* should also be consulted, if appropriate.

C. Scope of the Guideline

This guideline addresses only those impurities in new drug products classified as degradation products of the drug substance or reaction products of the drug substance with an excipient and/or immediate container closure system (collectively referred to as "degradation products" in this guideline). Generally, impurities present in the new drug substance need not be monitored or specified in the new drug product unless they are also degradation products (see ICH Q6A guideline on specifications).

Impurities arising from excipients present in the new drug product or extracted or leached from the container closure system are not covered by this guideline. This guideline also does not apply to new drug products used during the clinical research stages of development. The following types of products are not covered in this guideline: Biological/biotechnological products, peptides, oligonucleotides, radiopharmaceuticals, fermentation products and semisynthetic products derived therefrom, herbal products, and crude products of animal or plant origin. Also excluded from this document are (1) extraneous contaminants that should not occur in new drug products and are more appropriately addressed as good manufacturing practice (GMP) issues, (2) polymorphic forms, and (3) enantiomeric impurities.

II. RATIONALE FOR THE REPORTING AND CONTROL OF DEGRADATION PRODUCTS

The applicant should summarize the degradation products observed during manufacture and/or stability studies of the new drug product. This summary should be based on sound scientific appraisal of potential degradation pathways in the new drug product and impurities arising from the interaction with excipients and/or the immediate container closure system. In addition, the applicant should summarize any laboratory studies conducted to detect degradation products in the new drug product. This summary should also include test results of batches manufactured during the development process and batches representative of the proposed commercial process. A rationale should be provided for exclusion of those impurities that are not degradation products (e.g., process impurities from the drug substance and impurities arising from excipients). The impurity profiles of the batches representative of the proposed commercial process should be compared with the profiles of batches used in development and any differences discussed.

Any degradation product observed in stability studies conducted at the recommended storage condition should be identified when present at a level greater than (>) the identification thresholds given in Attachment 1. When identification of a degradation product is not feasible, a summary of the laboratory studies demonstrating the unsuccessful efforts to identify it should be included in the registration application.

Degradation products present at a level of not more than (≤) the identification threshold generally would not need to be identified. However, analytical procedures should be developed for those degradation products that are suspected to be unusually potent, producing toxic or significant pharmacological effects at levels not more than (≤) the identification threshold. In unusual circumstances, technical factors (e.g., manufacturing capability, a low drug substance to excipient ratio, or the use of excipients that are crude products of animal or plant origin) can be considered as part of the justification for selection of alternative thresholds based upon manufacturing experience with the proposed commercial process.

III. ANALYTICAL PROCEDURES

The registration application should include documented evidence that the analytical procedures have been validated and are suitable for the detection and quantitation of degradation products (see ICH Q2A and Q2B guidelines on analytical validation). In particular, analytical procedures should be validated to demonstrate specificity for the specified and unspecified degradation products. As appropriate, this validation should include samples stored under relevant stress conditions: Light, heat, humidity, acid/base hydrolysis, and oxidation. When an analytical procedure reveals the presence of other peaks in addition to those of the degradation products (e.g., the drug substance, impurities arising from the synthesis of the drug substance, excipients and impurities arising from the excipients), these peaks should be labeled in the chromatograms and their origin(s) discussed in the validation documentation.

The quantitation limit for the analytical procedure should be not more than (≤) the reporting threshold.

Degradation product levels can be measured by a variety of techniques, including those that compare an analytical response for a degradation product to that of an appropriate reference standard or to the response of the new drug substance itself. Reference standards used in the analytical procedures for control of degradation products should be evaluated and characterized according to their intended uses. The drug substance can be used to estimate the levels of degradation products. In cases where the response factors are not close, this practice can still be used if a correction factor is applied or the degradation products are, in fact, being overestimated. Acceptance criteria and analytical procedures, used to estimate identified or unidentified degradation products, are often based on analytical assumptions (e.g., equivalent detector response). These assumptions should be discussed in the registration application.

Differences between the analytical procedures used during development and those proposed for the commercial product should also be discussed.

IV. REPORTING DEGRADATION PRODUCTS CONTENT OF BATCHES

Analytical results should be provided in the registration application for all relevant batches of the new drug product used for clinical, safety, and stability testing, as well as batches that are representative of the proposed commercial process. Quantitative results should be presented numerically and not in general terms such as "complies," "meets limit," etc. Any degradation product at a level greater than (>) the reporting threshold (see Attachment 1), and total degradation products observed in the relevant batches of the new drug product, should be reported with the analytical procedures indicated. Below 1.0%, the results should be reported to the number of decimal places (e.g., 0.06%) in the applicable reporting threshold; at and above 1.0%, the results should be reported to one decimal place (e.g., 1.3%). Results should be rounded using conventional rules (see Attachment 2). A tabulation (e.g., spreadsheet) of the data is recommended. Degradation products should be designated by code number or by an appropriate descriptor, for example, retention time. If a higher reporting threshold is proposed, it should be fully justified. All degradation products at a level greater than (>) the reporting threshold should be summed and reported as total degradation products.

Chromatograms with peaks labeled (or equivalent data if other analytical procedures are used) from representative batches, including chromatograms from analytical procedure validation studies and from long-term and accelerated stability studies, should be provided. The applicant should ensure that complete degradation product profiles (e.g., chromatograms) of individual batches are available, if requested.

For each batch of the new drug product described in the registration application, the documentation should include

- Batch identity, strength, and size
- Date of manufacture
- Site of manufacture
- Manufacturing process
- Immediate container closure
- Degradation product content, individual and total
- Use of batch (e.g., clinical studies, stability studies)
- Reference to analytical procedure used
- Batch number of the drug substance used in the new drug product
- Storage conditions for stability studies

V. LISTING OF DEGRADATION PRODUCTS IN SPECIFICATIONS

The specification for a new drug product should include a list of degradation products expected to occur during manufacture of the commercial product and under recommended storage conditions. Stability studies, knowledge of degradation pathways, product development studies, and laboratory studies should be used to characterize the degradation profile. The selection of degradation products in the new drug product specification should be based on the degradation products found in batches manufactured by the proposed commercial process. Those individual degradation products with specific acceptance criteria included in the specification for the new drug product are referred to as "specified degradation products" in this guideline. Specified degradation products can be identified or unidentified. A rationale for the inclusion or exclusion of degradation products in the specification should be presented. This rationale should include a discussion of the degradation profiles observed in the safety and clinical development batches and in stability studies, together with a consideration of the degradation profile of batches manufactured by the proposed commercial process. Specified identified degradation products should be included along with specified unidentified degradation products estimated to be present at a level greater than (>) the identification threshold given in Attachment 1. For degradation products known to be unusually potent or to produce toxic or unexpected pharmacological effects, the quantitation/detection limit of the analytical procedures should be commensurate with the level at which the degradation products should be controlled. For unidentified degradation products, the procedure used and assumptions made in establishing the level of the degradation product should be clearly stated. Specified unidentified degradation products should be referred to by an appropriate qualitative analytical descriptive label (e.g., "unidentified A," "unidentified with relative retention of 0.9"). A general acceptance criterion of not more than (≤) the identification threshold (Attachment 1) for any unspecified degradation product and an acceptance criterion for total degradation products should also be included.

For a given degradation product, its acceptance criterion should be established by taking into account its acceptance criterion in the drug substance (if applicable), its qualified

level, its increase during stability studies, and the proposed shelf life and recommended storage conditions for the new drug product. Furthermore, each acceptance criterion should be set no higher than the qualified level of the given degradation product.

Where there is no safety concern, degradation product acceptance criteria should be based on data generated from batches of the new drug product manufactured by the proposed commercial process, allowing sufficient latitude to deal with normal manufacturing and analytical variation and the stability characteristics of the new drug product. Although normal manufacturing variations are expected, significant variation in batch-to-batch degradation product levels can indicate that the manufacturing process of the new drug product is not adequately controlled and validated (see ICH Q6A guideline on specifications, Decision Tree No. 2, for establishing an acceptance criterion for a specified degradation product in a new drug product).

In this guideline, the use of two decimal places for thresholds (see Attachment 1) does not necessarily indicate the precision of the acceptance criteria for specified degradation products and total degradation products.

In summary, the new drug product specification should include, where applicable, the following list of degradation products:

- Each specified identified degradation product
- Each specified unidentified degradation product
- Any unspecified degradation product with an acceptance criterion of not more than (≤) the identification threshold
- Total degradation products

VI. QUALIFICATION OF DEGRADATION PRODUCTS

Qualification is the process of acquiring and evaluating data that establishes the biological safety of an individual degradation product or a given degradation profile at the level(s) specified. The applicant should provide a rationale for establishing degradation product acceptance criteria that includes safety considerations. The level of any degradation product present in a new drug product that has been adequately tested in safety and/or clinical studies would be considered qualified. Therefore, it is useful to include any available information on the actual content of degradation products in the relevant batches at the time of use in safety and/or clinical studies. Degradation products that are also significant metabolites present in animal and/or human studies are generally considered qualified. Degradation products could be considered qualified at levels higher than those administered in safety studies based on a comparison between actual doses given in the safety studies and the intended dose of the new drug product. Justification of such higher levels should include consideration of factors such as (1) the amount of degradation product administered in previous safety and/or clinical studies and found to be safe, (2) the increase in the amount of the degradation product, and (3) other safety factors, as appropriate.

If the qualification thresholds given in Attachment 1 are exceeded and data are unavailable to qualify the proposed acceptance criterion of a degradation product, additional studies to obtain such data can be appropriate (see Attachment 3).

Higher or lower thresholds for qualification of degradation products can be appropriate for some individual new drug products based on scientific rationale and level of concern, including drug class effects and clinical experience. For example, qualification can be especially important when there is evidence that such degradation products in certain new drug products or therapeutic classes have previously been associated with adverse reactions in patients. In these instances, a lower qualification threshold can be appropriate. Conversely, a higher qualification threshold can be appropriate for individual new drug products when the level of concern for safety is less than usual based on similar considerations (e.g., patient population, drug class effects, and clinical considerations). Proposals for alternative thresholds would be considered on a case-by-case basis.

The "Decision Tree for Identification and Qualification of a Degradation Product" (Attachment 3) describes considerations for the qualification of degradation products when thresholds are exceeded. In some cases, reducing the level of degradation product (e.g., use of a more protective container closure or modified storage conditions) to not more than (≤) the threshold can be simpler than providing safety data. Alternatively, adequate data could be available in the scientific literature to qualify a degradation product. If neither is the case, additional safety testing should be considered. The studies considered appropriate to qualify a degradation product will depend on a number of factors, including the patient population, daily dose, and route and duration of new drug product administration. Such studies can be conducted on the new drug product or substance containing the degradation products to be controlled, although studies using isolated degradation products can sometimes be appropriate.

Although this guideline is not intended to apply during the clinical research stage of development, in the later stages of development the thresholds in this guideline can be useful in evaluating new degradation products observed in new drug product batches prepared by the proposed commercial process. Any new degradation product observed in later stages of development should be identified (see the "Decision Tree for Identification and Qualification of a Degradation Product" in Attachment 3) if its level is greater than (>) the identification threshold given in Attachment 1. Similarly, qualification of the degradation product should be considered if its level is greater than (>) the qualification threshold given in Attachment 1.

Safety studies should provide a comparison of results of safety testing of the new drug product or drug substance containing a representative level of the degradation product with previously qualified material, although studies using the isolated degradation products can also be considered.

GLOSSARY

Degradation Product: An impurity resulting from a chemical change in the drug substance brought about during manufacture and/or storage of the new drug product by the effect of, for example, light, temperature, pH, water, or by reaction with an excipient and/or the immediate container closure system.

Degradation Profile: A description of the degradation products observed in the drug substance or drug product.

Development Studies: Studies conducted to scale up, optimize, and validate the manufacturing process for a drug product.

Identification Threshold: A limit above (>) which a degradation product should be identified.

Identified Degradation Product: A degradation product for which a structural characterization has been achieved.

Impurity: Any component of the new drug product that is not the drug substance or an excipient in the drug product.

Impurity Profile: A description of the identified and unidentified impurities present in a drug product.

New Drug Substance: The designated therapeutic moiety that has not been previously registered in a region or member state (also referred to as a new molecular entity or new chemical entity). It can be a complex, simple ester, or salt of a previously approved substance.

Qualification: The process of acquiring and evaluating data that establishes the biological safety of an individual degradation product or a given degradation profile at the level(s) specified.

Qualification Threshold: A limit above (>) which a degradation product should be qualified.

Reporting Threshold: A limit above (>) which a degradation product should be reported.

Specified Degradation Product: A degradation product that is individually listed and limited with a specific acceptance criterion in the new drug product specification. A specified degradation product can be either identified or unidentified.

Unidentified Degradation Product: A degradation product for which a structural characterization has not been achieved and that is defined solely by qualitative analytical properties (e.g., chromatographic retention time).

Unspecified Degradation Product: A degradation product that is limited by a general acceptance criterion, but not individually listed with its own specific acceptance criterion, in the new drug product specification.

ATTACHMENT 1: THRESHOLDS FOR DEGRADATION PRODUCTS IN NEW DRUG PRODUCTS

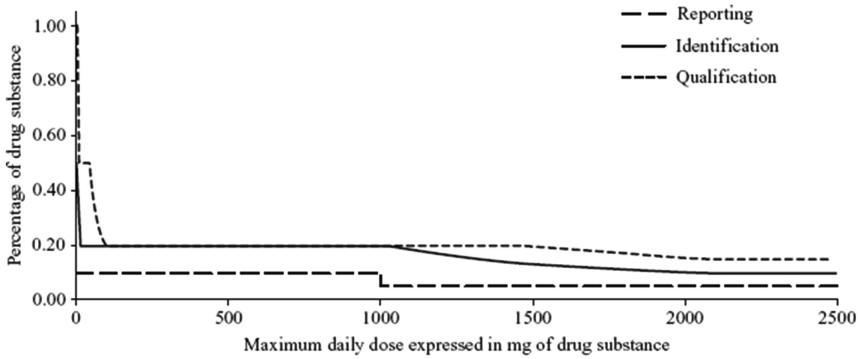
Maximum Daily Dose[a]	Threshold[b,c]
Reporting thresholds	
≤1 g	0.1%
>1 g	0.05%
Identification thresholds	
<1 mg	1.0% or 5 µg TDI, whichever is lower
1 mg–10 mg	0.5% or 20 µg TDI, whichever is lower
>10 mg–2 g	0.2% or 2 mg TDI, whichever is lower
>2 g	0.10%
Qualification thresholds	
<10 mg	1.0% or 50 µg TDI, whichever is lower
10 mg–100 mg	0.5% or 200 µg TDI, whichever is lower
>100 mg–2 g	0.2% or 3 mg TDI, whichever is lower
>2 g	0.15%

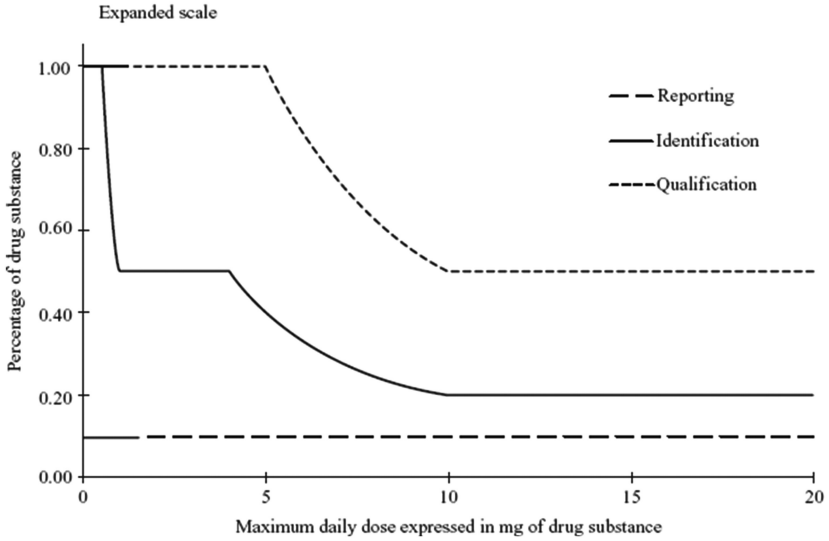
[a] The amount of drug substance administered per day.

[b] Thresholds for degradation products are expressed either as a percentage of the drug substance or as total daily intake (TDI) of the degradation product. Lower thresholds can be appropriate if the degradation product is unusually toxic.

[c] Higher thresholds should be scientifically justified.

Illustration of Thresholds for Reporting, Identification, and Qualification of Degradation Products in New Drug Products as a Function of Maximum Daily Dose[a]





[a] Note: Actual threshold values should be taken from the preceding table in this attachment.

ATTACHMENT 2: ILLUSTRATION OF REPORTING DEGRADATION PRODUCT RESULTS FOR IDENTIFICATION AND QUALIFICATION IN AN APPLICATION

The attachment is only illustrative and is not intended to serve as a template of how results on degradation products should be presented in an application file. Normally raw data are not provided.

Example 1: 50 mg Maximum Daily Dose

Reporting threshold: 0.1%
Identification threshold: 0.2%
Qualification threshold: 200 µg

"Raw" Result (%)	Reported Result (%) Reporting Threshold = 0.05%	Total Daily Intake (TDI) of the Degradation Product (Rounded Result in µg)	Identification Threshold 0.2% Exceeded?	Action Qualification Threshold 200 µg TDI Exceeded?
0.04	Not reported	20	None	None
0.2143	0.2	100	None	None
0.349	0.3[a]	150	Yes	None[a]
0.550	0.6[a]	300	Yes	Yes[a]

Example 2:1.9 g Maximum Daily Dose

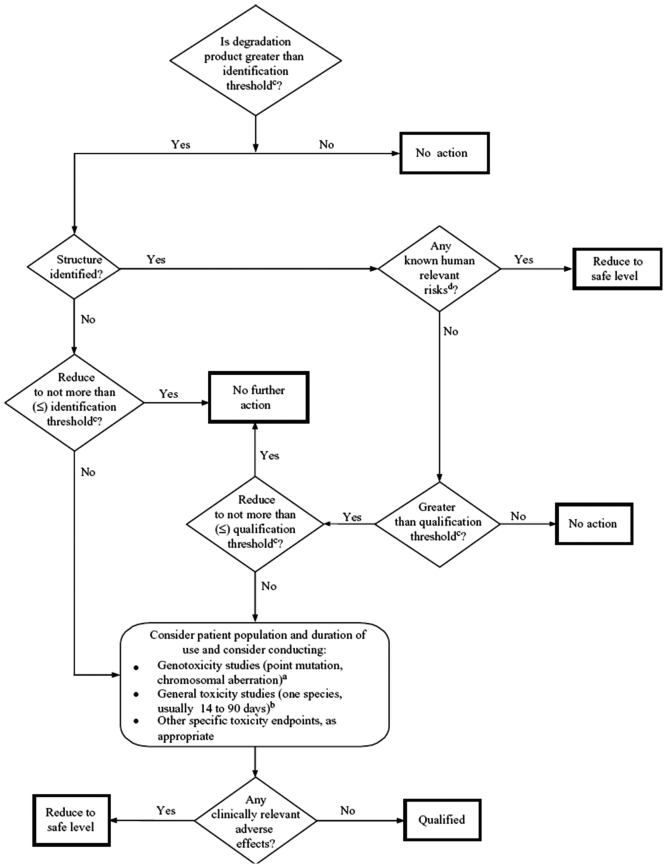
Reporting threshold: 0.05%
Identification threshold: 2 mg
Qualification threshold: 3 mg

"Raw" Result (%)	Reported Result (%) Reporting Threshold = 0.05%	Total Daily Intake (TDI) of the Degradation Product (Rounded Result in mg)	Identification Threshold 2 mg TDI Exceeded?	Action Qualification Threshold 3 mg TDI Exceeded?
0.049	Not reported	1	None	None
0.079	0.08	2	None	None
0.183	0.18[a]	3	Yes	None[a,b]
0.192	0.19[a]	4	Yes	Yes[a]

[a] After identification, if the response factor is determined to differ significantly from the original assumptions, it can be appropriate to remeasure the actual amount of the degradation product present and reevaluate against the qualification threshold (see Attachment 1).

[b] To verify if a threshold is exceeded, a reported result has to be evaluated against the thresholds as follows: When the threshold is described in %, the reported result rounded to the same decimal place as the threshold should be compared directly to the threshold. When the threshold is described in TDI, the reported result should be converted to TDI, rounded to the same decimal place as the threshold, and compared to the threshold, for example, an amount of 0.18% degradation level corresponds to a TDI of 3.4 mg impurity (absolute amount), which is then rounded down to 3 mg; so the qualification threshold expressed in TDI (3 mg) is not exceeded.

ATTACHMENT 3: DECISION TREE FOR IDENTIFICATION AND QUALIFICATION OF A DEGRADATION PRODUCT



[a] If considered desirable, a minimum screen (e.g., genotoxic potential) should be conducted. A study to detect point mutations and to detect chromosomal aberrations, both in vitro, is considered an appropriate minimum screen.

[b] If general toxicity studies are desirable, one or more studies should be designed to allow comparison of unqualified to qualified material. The study duration should be based on available relevant information and performed in the species most likely to maximize the potential to detect the toxicity of a degradation product. On a case-by-case basis, single-dose studies can be appropriate, especially for single-dose drugs. In general, a minimum duration of 14 days and a maximum duration of 90 days would be considered appropriate.

[c] Lower thresholds can be appropriate if the degradation product is unusually toxic.

[d] For example, do known safety data for this degradation product or its structural class preclude human exposure at the concentration present?

14 Formulation Factors in Semisolid Dosage Forms

The subjects covered here are generally applicable to all forms of topical drug products, including those that are intended to be sterile. The topics given below address several problem areas that may be encountered in the production of semisolid drug products (including transdermal products) including their potency, active ingredient uniformity, physical characteristics, microbial purity, and chemical purity.

I. POTENCY UNIFORMITY

Active ingredient solubility and particle size are generally important ingredient characteristics that need to be controlled to ensure potency uniformity in many topical drug products such as emulsions, creams, and ointments. Crystalline form is also important where the active ingredient is dispersed as a solid phase in either the oil or water phase of an emulsion, cream, or ointment.

It is important that active ingredient solubility in the carrier vehicle be known and quantified at the manufacturing step in which the ingredient is added to the liquid phase. The development data should adequately demonstrate such solubility and its validation.

Substances that are very soluble, as is frequently the case with ointments, would be expected to present less of a problem than if the drug substance were to be suspended, as is the case with creams. If the drug substance is soluble, then potency uniformity would be based largely on adequate distribution of the component throughout the mix.

If the active ingredient is insoluble in the vehicle, then in addition to ensuring uniformity of distribution in the mix, potency uniformity depends on control of particle size and use of a validated mixing process. Particle size can also affect the activity of the drug substance because the smaller the particle size, the greater its surface area, which may influence its activity. Particle size also affects the degree to which the product may be physically irritating when applied; in general, smaller particles are less irritating.

Production controls should be implemented that account for the solubility characteristics of the drug substance; inadequate controls can adversely affect product potency, efficacy, and safety. For example, in one instance, residual water remaining in the manufacturing vessel, used to produce an ophthalmic ointment, resulted in partial solubilization and subsequent recrystallization of the drug substance; the substance recrystallized in a larger particle size than expected and thereby raised questions about the product efficacy.

In addition to ingredient solubility and particle size, other physical characteristics and specifications for both ingredients and finished products are important.

II. EQUIPMENT AND PRODUCTION CONTROL

A. Mixers

There are many different kinds of mixers used in the manufacture of topical products. It is important that the design of a given mixer is appropriate for the type of topical product being mixed. One important aspect of mixer design is how well the internal walls of the mixer are scraped during the mixing process. This can present some problems with stainless steel mixers because scraper blades should be flexible enough to remove interior material, yet not rigid enough to damage the mixer itself. In general, good design of a stainless-steel mixer includes blades that are made of some hard plastic, such as Teflon®, which facilitates scrapping of the mixer walls without damaging the mixer.

If the internal walls of the mixer are not adequately scraped during mixing and the residual material becomes part of the batch, the result may be nonuniformity. Such nonuniformity may occur, for example, if operators use handheld spatulas to scrape the walls of the mixer.

Another mixer design concern is the presence of "dead spots" where quantities of the formula are stationary and not subject to mixing. Where such dead spots exist, there should be adequate procedures for recirculation or nonuse of the cream or ointment removed from the dead spots in the tank.

B. Filling and Packaging

Suspension products often require constant mixing of the bulk suspension during filling to maintain uniformity. When validating a suspension manufacturing process, determine how to ensure that the product remains homogeneous during the filling process and establish the data that support the adequacy of the firm's process. When the batch size is large and the bulk suspension is in large tanks, determine how the low levels of bulk suspension near the end of the filling process are handled. If the bulk suspension drops below a level, can this be adequately mixed? This question must be answered. If the residual material is transferred to a smaller tank, how is the consistency in hand mixing assured? The adequacy of the process for dealing with residual material should be demonstrated.

C. Process Temperature Control

Typically, heat is applied in the manufacture of topical products to facilitate mixing or filling operations. Heat may also be generated by the action of high-energy mixers. It is important

to control the temperature within spec parameters, not only to facilitate those operations but also to ensure that product stability is not adversely affected. Excessive temperatures may cause physical or chemical degradation of the drug product, vehicle, active ingredient or ingredients, or preservatives. Furthermore, excessive temperatures may cause insoluble ingredients to dissolve, reprecipitate, or change particle size or crystalline form.

Temperature control is also important where microbial quality of the product is a concern. The processing of topical products at higher temperatures can destroy some of the objectionable microorganisms that may be present. However, elevated temperatures may also promote incubation of microorganisms.

Temperature uniformity within a mixer should be controlled. In addressing temperature uniformity, one should consider the complex interaction among vat size, mixer speed, blade design, viscosity of contents, and rate of heat transfer. Where temperature control is critical, use of recording thermometers to continuously monitor and document temperature measurements is preferred to frequent manual checks. Where temperature control is not critical, it may be adequate to manually monitor and document temperatures periodically by use of handheld thermometers.

III. CLEANING VALIDATION

It is current good manufacturing practice for a manufacturer to establish and follow written standard operating procedures to clean production equipment in a manner that precludes contamination of current and future batches. This is especially critical where contamination may present direct safety concerns, as with a potent drug such as a steroid (e.g., cortisone, and estrogen), antibiotic, or sulfa drug, where there are hypersensitivity concerns.

The insolubility of some excipients and active substance used in the manufacture of topical products makes some equipment, such as mixing vessels, pipes, and plastic hoses, difficult to clean. Often piping and transfer lines are inaccessible to direct physical cleaning. Some firms address this problem by dedicating lines and hoses to specific products or product classes.

It is therefore important that the following considerations be adequately addressed in a cleaning validation protocol and in the procedures that are established for production batches.

A. Detailed Cleaning Procedures

Cleaning procedures should be detailed and provide specific understandable instructions. The procedure should identify equipment, cleaning methods, solvents and detergents approved for use, inspection and release mechanisms, and documentation. For some of the more complex systems, such as clean-in-place systems, it is usually necessary both to provide a level of detail that includes drawings and to provide provision to label valves. The time that may elapse from completion of a manufacturing operation to initiation of equipment cleaning should also be stated where excessive delay may affect the adequacy of the established cleaning procedure. For example, residual product may dry and become more difficult to clean.

B. Sampling Plan for Contaminants

As part of the validation of the cleaning method, the cleaned surface is sampled for the presence of residues. Sampling should be made by an appropriate method, selected on the basis of factors such as equipment and solubility of residues. For example, representative swabbing of surfaces is often used, especially in areas that are hard to clean or where the residue is relatively insoluble. Analysis of rinse solutions for residues has also been shown to be of value where the residue is soluble or difficult to access for direct swabbing. Both methods are useful when there is a direct measurement of the residual substance. However, it is unacceptable to test rinse solutions (such as purified water) for conformance to the purity specifications for those solutions instead of testing directly for the presence of possible residues.

C. Equipment Residue Limits

Because of improved technology, analytical methods are becoming much more sensitive and capable of determining very low levels of residues. Thus, it is important to establish appropriate limits on levels of post-equipment-cleaning residues. Such limits must be safe, practical, achievable, and verifiable and must ensure that residues remaining in the equipment will not cause the quality of subsequent batches to be altered beyond established product specifications. The rationale for residue limits should be established. Because surface residues will not be uniform, it should be recognized that a detected residue level may not represent the maximum amount that may be present. This is particularly true when surface sampling by swabs is performed on equipment.

IV. MICROBIOLOGICAL

A. Controls (Nonsterile Topicals)

The extent of microbiological controls needed for a given topical product will depend on the nature of the product, the use of the product, and the potential hazard to users posed by microbial contamination. This concept is reflected in the current good manufacturing practice regulations at 21 CFR 211.113(a) (Control of Microbiological Contamination) and in the U.S. Pharmacopeia (USP). It is therefore vital that manufacturers assess the health hazard of all organisms isolated from the product.

1. Deionized Water Systems for Purified Water

The microbiological control of deionized water systems used to produce purified water is important. Deionizers are usually excellent breeding areas for microorganisms. The microbial population tends to increase as the length of time between

deionizer service periods increases. Other factors that influence microbial growth include flow rates, temperature, surface area of resin beds, and, of course, the microbial quality of the feed water. These factors should be considered in assessing the suitability of deionizing systems where microbial integrity of the product incorporating the purified water is significant. There should be a suitable routine water monitoring program and a program of other controls as necessary.

It is not necessary to assess and monitor the suitability of a deionizer by relying solely on representations of the deionizer manufacturer. Specifically, product quality could be compromised if a deionizer is serviced at intervals based not on validation studies but, rather, on the "recharge" indicator built into the unit. Unfortunately, such indicators are not triggered by microbial population but, rather, are typically triggered by measures of electrical conductivity or resistance. If a unit is infrequently used, sufficient time could elapse between recharging and sanitizing to allow the microbial population to increase significantly.

Pre-use validation of deionizing systems used to produce purified water should include consideration of such factors as microbial quality of feed water (and residual chlorine levels of feed water where applicable), surface area of ion-exchange resin beds, temperature range of water during processing, operational range of flow rates, recirculation systems to minimize intermittent use and low flow, frequency of use, quality of regenerant chemicals, and frequency and method of sanitization.

A monitoring program used to control deionizing systems should include established water quality and conductivity monitoring intervals, measurement of conditions and quality at significant stages through the deionizer (influent, post-cation, post-anion, post-mixed bed, etc.), microbial conditions of the bed, and specific methods of microbial testing. Frequency of monitoring should be based on the firm's experience with the systems.

Other methods of controlling deionizing systems include establishment of water-quality specifications and corresponding action levels, remedial action when microbial levels are exceeded, documentation of regeneration, and a description of sanitization and sterilization procedures for piping, filters, and so forth.

2. Microbiological Specifications and Test Methods

Microbiological specifications and microbial test methods for each topical product should be well-established to ensure that they are consistent with any described in the relevant application or USP. In general, product specifications should cover the total number of organisms permitted, as well as specific organisms that must not be present. These specifications must be based on use of specified sampling and analytical procedures. Where appropriate, the specifications should describe action levels where additional sampling or speciation of organisms is necessary.

Manufacturers must demonstrate that the test methods and specifications are appropriate for their intended purpose. Where possible, firms should use methods that isolate and identify organisms that may present a hazard to the user under the intended use. It should be noted that the USP does not state methods that are specific for water-insoluble topical products.

One test deficiency to be aware of is inadequate dispersement of a cream or ointment on microbial test plates. Firms may claim to follow USP procedures, yet in actual practice they may not disperse product over the test plate, resulting in inhibited growth as a result of concentrated preservative in the non-dispersed inoculate. The spread technique is critical, and the firm should document that the personnel performing the technique have been adequately trained and are capable of performing the task. Validation of the spread-plate technique is particularly important when the product has a potential antimicrobial affect.

In assessing the significance of microbial contamination of a topical product, both the identification of the isolated organisms and the number of organisms found are significant. For example, the presence of a high number of organisms may indicate that the manufacturing process, component quality, or container integrity may be deficient. Although high numbers of nonpathogenic organisms may not pose a health hazard, they may affect product efficacy and physical/chemical stability. Inconsistent batch-to-batch microbial levels may indicate some process or control failure in the batch. The batch release evaluation should extend to both organism identification and numbers and, if limits are exceeded, there should be an investigation into the cause.

B. Preservative Activity

Manufacturing controls necessary to maintain the anti-microbiological effectiveness of preservatives should be evaluated. For example, for those products that separate on standing, there should be data available that show the continued effectiveness of the preservative throughout the product's shelf life.

For preservative-containing products, finished product testing must ensure that the specified level of preservative is present before release. In addition, preservative effectiveness must be monitored as part of the final ongoing stability program. This can be accomplished through analysis for the level of preservative previously shown to be effective or through appropriate microbiological challenge at testing intervals.

For concepts relating to sterility assurance and bioburden controls on the manufacture of sterile topicals, see the *Guideline on Sterile Drug Products Produced by Aseptic Processing.*

V. CHANGE CONTROL

As with other dosage forms, it is important to carefully control how changes are made in the production of topical products. The procedures should be able to support changes that represent departures from approved and validated manufacturing processes. There should be written change control procedures that have been reviewed and approved by the quality-control unit. The procedures should provide for full description of

the proposed change, the purpose of the change, and controls to ensure that the change will not adversely alter product safety and efficacy. Factors to consider include potency or bioactivity, uniformity, particle size (if the active ingredient is suspended), viscosity, chemical and physical stability, and microbiological quality.

Of particular concern are the effects that formulation and process changes may have on the therapeutic activity and uniformity of the product. For example, changes in vehicle can affect absorption, and processing changes can alter the solubility and microbiological quality of the product.

VI. TRANSDERMAL TOPICAL PRODUCTS

The manufacturing of topical transdermal products (patches) has many problems in scale-up and validation. Problems analogous to production of topical creams or ointments include uniformity of the drug substance and particle size in the bulk gel or ointment. Uniformity and particle size are particularly significant when the drug substance is suspended or partially suspended in the vehicle. Viscosity also needs control because it can affect the absorption of the drug; the dissolution test is important in this regard. Other areas that need special inspectional attention are assembly and packaging of the patch, including adhesion, package integrity (regarding pinholes), and controls to ensure that a dose is present in each unit.

Because of the many quality parameters that must be considered in the manufacture and control of a transdermal dosage form, scale-up may be considerably more difficult than for many other dosage forms. Therefore, special attention should be given to evaluating the adequacy of the process validation efforts. As with other dosage forms, process validation must be based on multiple lots, typically at least three consecutive successful batches. Summary data should be augmented by comparison with selected data contained in supporting batch records, particularly where the data appear unusually uniform or disparate. Given the complexities associated with this dosage form, the tolerances or variances may be broader than for other dosage forms. In addition, batches may not be entirely problem free. Nevertheless, there should be adequate rationale for the tolerances and production experiences, based on appropriate developmental efforts and investigation of problems.

A. General Considerations

In general, semisolid dosage forms are complex formulations having complex structural elements. Often they are composed of two phases (oil and water), one of which is a continuous (external) phase, and the other of which is a dispersed (internal) phase. The active ingredient is often dissolved in one phase, although occasionally the drug is not fully soluble in the system and is dispersed in one or both phases, thus creating a three-phase system. The physical properties of the dosage form depend on various factors, including the size of the dispersed particles, the interfacial tension between the phases, the partition coefficient of the active ingredient between the phases, and the product rheology. These factors combine to determine the release characteristics of the drug as well as other characteristics, such as viscosity.

For a true solution, the order in which solutes are added to the solvent is usually unimportant. The same cannot be said for dispersed formulations, however, because depending on at which phase a particulate substance is added, dispersed matter can distribute differently. In a typical manufacturing process, the critical points are generally the initial separation of a one-phase system into two phases and the point at which the active ingredient is added. Because the solubility of each added ingredient is important for determining whether a mixture is visually a single homogeneous phase, such data, possibly supported by optical microscopy, should usually be available for review. This is particularly important for solutes added to the formulation at a concentration near or exceeding that of their solubility at any temperature to which the product may be exposed. Variations in the manufacturing procedure that occur after either of these events are likely to be critical to the characteristics of the finished product. This is especially true of any process intended to increase the degree of dispersion through reducing droplet or particle size (e.g., homogenization). Aging of the finished bulk formulation before packaging is critical and should be specifically addressed in process validation studies.

B. The Role of In Vitro Release Testing

The key parameter for any drug product is its efficacy as demonstrated in controlled clinical trials. The time and expense associated with such trials make them unsuitable as routine quality control methods. Therefore, in vitro surrogate tests are often used to ensure that product quality and performance are maintained over time and in the presence of change. A variety of physical and chemical tests commonly performed on semisolid products and their components (e.g., solubility, particle size and crystalline form of the active component, viscosity, and homogeneity of the product) have historically provided reasonable evidence of consistent performance. More recently, in vitro release testing has shown promise as a means to comprehensively ensure consistent delivery of the active component or components from semisolid products. An in vitro release rate can reflect the combined effect of several physical and chemical parameters, including solubility and particle size of the active ingredient and rheological properties of the dosage form. In most cases, in vitro release rate is a useful test to assess product sameness between pre-change and post-change products. However, there may be instances in which it is not suitable for this purpose. In such cases, other physical and chemical tests to be used as measures of sameness should be proposed and discussed with the agency. With any test, the metrics and statistical approaches to documentation of "sameness" in quality attributes should be considered. The evidence available at this time for the in vitro–in vivo correlation of release tests for semisolid dosage forms is not as convincing as that for in vitro dissolution as a surrogate for in vivo bioavailability of solid oral dosage forms. Therefore,

the FDA's current position concerning in vitro release testing is as follows:

a. In vitro release testing is a useful test to assess product sameness under certain scale-up and post-approval changes for semisolid products.
b. The development and validation of an in vitro release test are not required for approval of an NDA, ANDA, or AADA, nor is the in vitro release test required as a routine batch-to-batch quality control test.
c. In vitro release testing alone is not a surrogate test for in vivo bioavailability or bioequivalence.
d. The in vitro release rate should not be used for comparing different formulations across manufacturers.

In vitro release is one of several standard methods that can be used to characterize performance characteristics of a finished topical dosage form, that is, semisolids such as creams, gels, and ointments. Important changes in the characteristics of a drug product formula or the thermodynamic properties of the drug or drugs it contains should show up as a difference in drug release. Release is theoretically proportional to the square root of time when the formulation in question is in control of the release process because the release is from a receding boundary. In vitro release method for topical dosage forms is based on an open chamber diffusion cell system such as a Franz cell system, fitted usually with a synthetic membrane. The test product is placed on the upper side of the membrane in the open donor chamber of the diffusion cell, and a sampling fluid is placed on the other side of the membrane in a receptor cell. Diffusion of drug from the topical product to and across the membrane is monitored by assay of sequentially collected samples of the receptor fluid. The in vitro release methodology should be appropriately validated. Sample collection can be automated. Aliquots removed from the receptor phase can be analyzed for drug content by high-pressure liquid chromatography or other analytical methodology. A plot of the amount of drug released per unit area (mcg/cm) against the square root of time yields a straight line, the slope of which represents the release rate. This release rate measure is formulation specific and can be used to monitor product quality. The release rate of the biobatch or currently manufactured batch should be compared with the release rate of the product prepared after a change, as defined in this guidance.

C. In Vivo Bioequivalence Studies

The design of in vivo bioequivalence studies for semisolid dosage forms varies depending on the pharmacological activity of the drug and dosage form. A brief general discussion of such tests follows. The objective is to document the bioequivalence of the drug product for which the manufacture has been changed, as defined in this guidance, compared with the drug product manufactured before the change or with the reference-listed drug. The study design is dependent on the nature of the active drug. The bioequivalence study can be a comparative skin-blanching study as in glucocorticoids (FDA, 1995) or a comparative clinical trial or any other appropriate validated bioequivalence study (e.g., dermatopharmacokinetic study) for the topical dermatological drug product. The assay methodology selected should ensure specificity, accuracy, interday and intraday precision, linearity of standard curves, and adequate sensitivity, recovery, and stability of the samples under the storage and handling conditions associated with the analytical method.

VII. CHEWING GUM

Chewing gum can deliver either pharmaceuticals or nutrients and are known as medicated chewing gum (MCG) and non-MCG. MCG is supposed to act as an extended release dosage form that provides a continuous release of medicine contained. The first MCG was launched in 1924 in United States of America which was called Aspergum®, but an admission of chewing gum as a drug delivery system did not advance until nicotine chewing gum was released at the market. The most important patent on the use of chewing gum involves delivery of bitter drugs by incorporating a release of carbon dioxide that anesthetizes taste buds (US Patent 4639368A, 1985, Niazi inventor). There is a monograph in European Pharmacopoeia (EP) that defines MCG, but the term "chewing gum" was first listed in guidelines as a pharmaceutical dosage form in 1991 and approved by the commission of European communities.

Table 14.1 lists a few examples of the types of MCG marketed.

The ability of chewing gums to release active ingredients into the oral cavity, their steady and rapid action, and capability of both systemic and local delivery make it appropriate for extensive use in food and pharmaceutical industries. Advantages of medicated chewing gums as drug delivery system include:

- Increased rate of effectiveness rather than other oral delivery systems
- Removal of gum at any time, therefore termination of drug delivery
- Reduced risk of overdosing if it's whole swallowed
- Requires no water to drink
- Protection of the susceptible drugs contained from chemical or enzymatic attack in gastrointestinal (GI) tract
- Both systemic and local drug delivery
- High acceptance by children and teenagers
- Low first-pass effect so reduced dose is formulated in chewing gum compared to other oral delivery systems
- Good for rapid delivery
- Fewer side effects
- Reduced risk of intolerance to gastric mucosa
- Good stability against light, oxygen, and moisture[20]
- Annihilation of xerostomia and help tasting and swallowing in people with dry mouth
- Reduced pains and difficulties in swallowing following tonsillectomy

TABLE 14.1
Therapeutic Use and Examples of MCGs

Component	Function and Proportion	Example
Water-Soluble Bulk Portion		
Bulk Sweeteners		
Sugar sweeteners	30–60%, saccharide-coating components	Sucrose, dextrose, maltose, dextrin, dried invert sugar, fructose, levulose, galactose, corn syrup
Sugarless sweeteners		Sorbitol, mannitol, xylitol, hydrogenated starch hvdrolysate, maltitol
High-intensity artificial sweetener	0.02–8%	Sucralose, aspartame, salts of acesulfarne, alitame, saccharin
Flavoring agent	0.01–1%	Essential oils, synthetic flavors, mixture (citrus oils, fruit essences, peppermint oil, spearmint oil, clove oil, oil of wintergreen and anise)
Softener (plasticizer)	0.5–15%, regulating the cohesiveness and modifying the texture	Glycerin, lecithin, aqueous sweetener solutions, sorbitol, hydrogenated starch hydrolysate, corn syrup, tallow, cocoa butter, glycerol monostearate, glycerol triacetate, fatty acid (palmitic, stearic, olic…)
Emulsifier	15–45%, dispersing immiscible compounds	Mono-, di-, tri-, stearyl acetate, lactylic esters
Colorants (FD&C type dye and lake)	0.1%	Fruit and vegetable extracts, titanium oxide
Antioxidant	0.02% of the gum base	Ascorbic acid, tocopherol, butylhydroxytoluene
Anti-tack agent	0.2–0.6%, something that helps chewing gum not adhere to denture fillings and natural teeth	Slip-agent can be used for this purpose which may be comprised of a-cellulose and vegetable proteins Alkaline metal phosphate, malto dextrin
Anti-caking agent	0.5–2%, preventing agglomeration	Precipitated silicon dioxide, solid carbon dioxide
Water-Insoluble Gum Base		
Elastomers		
Natural	15–45%, provides elasticity and cohesiveness	Smoked or liquid latex, guayule, jelutong, lechi-caspi, perilio, sorva, rosadinha, chicle, massaranduba balata, massaranduba chocolate, nispero
Synthetic		Polyisobutylene, isobutylene, -isoprene copolymer, styrene-butadiene copolymers, polyvinyl acetate
Rubber/fat/resin phase (elastomeric plasticizer)	15%, softening elastomeric material	Estrugums: Glycerol esters, pentaerythritol esters of rosins (hydrogenated dimerized and polymerized rosins) Synthetic: Terpene resins
Filler/texturizer	Up to 50%, modifying the texture of gum base	Magnesium and calcium carbonate, ground limestone, silicate types, clay, alumina, talc, titanium oxide, mono-, di-, tri-calcium phosphate, cellulose polymers
Wax (the base may be wax-free)		

- Improves work performance and cognitive function
- Fast bowel recovery after GI surgery
- Reduced hypoglycemic shocks in people taking anti-diabetic drugs
- Stimulates alertness through increased blood flow to brain
- Helps reduce food cravings

Disadvantages of medicated chewing gums:

- Disappearing of drug in oral cavity following salivary dilution
- Different release profiles because of chewing style differences
- Short time of administration due to eating, speaking, and drinking
- Allergic reaction to artificial sweeteners
- Continuous stress on jaws that may cause temporo-mandibular joint disorder
- Teeth decay through being coated by sugar
- Masseter problems
- Stomach irritations, aches, gastric ulcer through continuous swallowing of saliva and even flatulence because of presence of sorbitol in some formulations
- Risk of choking by swallowing gum in under-aged children

Composition

Medicated chewing gums are gums made with a tasteless masticatory gum base that consists of natural or synthetic elastomers. They include excipients such as fillers, softeners, and

sweetening and flavoring agents. Natural gum bases include chicle and smoked natural rubber and are permitted in formulations by the FDA, but modern gum bases are mostly synthetic in origin and approved bases include styrene-butadiene rubber, polyethylene, and polyvinylacetate. Gum base usually forms about 40% of the gum but can comprise up to 65% and is a complex mixture, insoluble in saliva, comprising mainly of elastomer, plasticizers, waxes, lipids, and emulsifiers (see Table 14.2). It will also contain an adjuvant such as talc to modify the texture of the gum and low quantities of additional excipients including colorants and antioxidants such as butylated hydroxyanisole. Elastomers control the gummy texture while the plasticizers and texture agents regulate the cohesiveness of the product. The lipid and waxes melt in the mouth to provide a cooling, lubricating feeling while the juicy feel of the gum texture is from the emulsifiers. The choice and formulation of gum base will affect the release of active ingredient and the texture, stability, and method of manufacture of the product.

The remaining ingredients in the chewing gum itself include drug, sweeteners, softeners, and flavoring and coloring agents. A typical chewing gum formulation is shown in Table 14.3. The sugar is for sweetening the product while the corn syrup keeps the gum fresh and flexible. Softeners or fillers are included to help blend the ingredients and retain moisture. Sugar-free gum has sorbitol, mannitol, aspartame, or saccharin instead of sugar. Optimized chewing gum formulations will require tailoring for each individual product. For example, nicotine-containing gums are formulated with the nicotine within an ion-exchange resin and pH-modifying carbonates and/or bicarbonates to increase the percentage of the drug in its free base form in saliva.

Manufacture of Chewing Gum

The majority of chewing gum delivery systems today are manufactured using conventional gum processes. The gum base is softened or melted and placed in a kettle mixer where sweeteners, syrups, active ingredients, and other excipients are added at a defined time. The gum is then sent to a series of rollers that form it into a thin, wide ribbon. During this process, a light coating of an anti-sticking agent can be added (e.g., magnesium stearate, calcium carbonate, or finely powdered sugar or sugar substitute). Finally, the gum is cut to the desired size and cooled at a carefully controlled temperature and humidity.

As the heating process involved in conventional methods may limit the applicability of the process for formulation of thermally labile drugs, directly compressible, free-flowing powdered gums such as Pharmagum (SPI Pharma) and MedGumBase (Gumbase Co) have been proposed to simplify the process. These formulations can be compacted into a gum tablet using a conventional tablet press and have the potential to simplify the manufacture, facilitating inclusion of a wider range of drugs.

Fusion Method

The first step of a typical process for manufacturing chewing gum is to melt and soften the gum base at about 60°C and place it in a kettle mixer, in which blades soften the base; then other ingredients such as sugar, glycerin, sweeteners, and taste-masking agent are added to the softened base, lately the flavoring agent is added in the mixing procedure at 40°C, then cooling and rolling steps would be done, and the rolled chewing gum would then be cut into pieces of desired shapes and sizes. To make a coated gum tablet, a coating agent should be sprayed to form a uniform surface.

The second type of this method is somewhat different: The primary step of preparation is to set up a mixer (the mixer could be sigma blade or other types of mixers); if a sugar-containing gum is needed, the first step is to add corn syrup to the mixer, and then finely powdered sugar is added gradually. Sugar, used in this step, could be powdered sucrose, dextrose, fructose, corn syrup solids, or combination of them.

After adding these sweeteners, plasticizers are added to modify the texture and regulate the cohesiveness. Glycerin is the most preferable plasticizer used. Other components specified in Table 14.3 could be added to the matrix according to required characteristics, such as fillers, colorants, and flavorings. But it is recommended that flavors be added to the matrix at the end of procedures when the gum base is totally and completely homogenized because most flavors are relatively volatile.

After matrix preparation and completely mixing, the commercially prepared particles of gum base are added to the chamber all at once.

One other method to provide a chewing gum with desired taste, color, and flavor is to mix gum base with favorable and

TABLE 14.2
Typical Formulation of Gum Base

Ingredient	Weight (%)	Example
Elastomer	10	Styrene-butadiene rubber
Plasticizer	30	Rosin esters
Texture agent/filler	35	Calcium carbonate
Wax	15	Paraffin wax
Lipid	7	Soya oil
Emulsifier	3	Lecithin
Miscellaneous	1	Colorant, antioxidant

TABLE 14.3
Example Chewing Gum Formulations

Ingredient (%)	Sugar Gum	Sugar-Free Gum
Gum base	19.4	25.0
Corn syrup	19.8	—
Sorbitol, 70%	—	15.0
Sugar	59.7	—
Glycerin	0.5	6.5
Sorbitol	—	52.3
Flavor	0.6	1.2

suitable sweeteners, corn syrups, starches, flavoring agents, and colorants and then refrigerate and cool it by a freezer apparatus or by contacting with a coolant like carbon dioxide to a temperature below −15°C. This is then crushed and pulverized with a cutter or grinding apparatus to obtain minute particles; then these finely ground particles are heated to a temperature which makes them adhere to each other and form a slick and uniform bulk with consistent texture and low specific gravity. If the fragments are such that they do not self-adhere, low pressure would be applied manually or mechanically before they are warmed to the normal room temperature to thereby promote self-adhesion.

The cooling and grinding steps can be combined by cooling the grinding apparatus. After the grinding step, we can let the coolant (if used) evaporate and disappear from our desired composition.

The minute particles may be coated by edible substances or premixed with powdery materials.

For tableting, compressing punches may be needed, but an anti-adherent agent should be applied to avoid sticking to surfaces of punches.

Direct Compression

A new technology to make a chewing gum tablet is direct compression and tableting with a high-speed standard machine. As explained in a patent, this way of forming chewing gum tablets provides a quickly dissociable chewing gum, but after a few seconds of chewing, particles adhere together to form a uniform and homogenous mass. In this method, we need a granulating agent, most preferably sorbitol which can also act as a sweetener. A lubricant such as magnesium stearate, talc, stearic acid, hydrogenated vegetable oils, and sodium stearyl fumarate is added to formulation before tableting. The first step of this method is dry mixing of gum base, granulating agent, and at least one processing material; then the active ingredient, sweeteners, and other necessary ingredients are added to the formulation in a free-flowing form; then the chewing gum is directly compressed into tablets. In the first step, the temperature should not rise higher than the melting point of the gum base. After obtaining a uniform and slick mass, the temperature would be lowered to add other ingredients.

Evaluation Tests

Content uniformity

Ten MCGs are selected randomly then their contents are measured; if each single content is between 85% and 115% of average content, it will comply with the test, but if one single preparation is out of this range the preparation will not comply with the test.[1]

Mass uniformity

Twenty MCGs are selected randomly and weighed; not more than two single masses should vary from the average mass.

Dissolution test

Mastication devices are designed to simulate human chewing behavior.

Release of Drug

Factors affecting the release of medicament from chewing gum can be divided into three groups: The physicochemical properties of the drug, the gum properties, and chew-related factors, including rate and frequency. Drugs can be incorporated into gums as solids or liquids. For most pharmaceuticals, aqueous solubility of the drug will be a major factor affecting the release rate. In order for drugs to be released, the gum would need to become hydrated; the drugs can then dissolve and diffuse through the gum base under the action of chewing.

For treatment of local conditions, a release period less than 1 h may be desirable, but a faster release may be required if a rapid onset of action is required for a systemically absorbed formulation. There are a number of strategies that can be undertaken in order to achieve the desired release rate. Decreasing the amount of the gum base will enhance the release of lipophilic drugs and addition of excipients designed to promote release can also be considered. Release can be sustained using, for example, ion-exchange resins as described for nicotine-containing gums. Changes in gum texture as a consequence of changes in excipient levels provide a further challenge to controlling the release of drugs. A quantitative measure of gum texture during the process is possible using texture analysis techniques.

15 Pediatric Research Equity Act (PREA) Compliance

INTRODUCTION

PREA amends the Federal Food, Drug, and Cosmetic Act (the Act) by adding Section 505B (21 U.S.C. 355B). PREA requires the conduct of pediatric studies for certain drug and biological products.[2] Specifically, PREA requires new drug applications (NDAs) and biologics licensing applications (BLAs) (or supplements to applications) for a new active ingredient, new indication, new dosage form, new dosing regimen, or new route of administration to contain a pediatric assessment unless the applicant has obtained a waiver or deferral [see Section 505B(a) of the Act]. It also authorizes FDA to require holders of applications for previously approved marketed drugs and biological products who are not seeking approval for one of the changes enumerated above (hereinafter "marketed drugs and biological products") to submit a pediatric assessment under certain circumstances [see Section 505B(b) of the Act].

Although PREA applies to both new applications (or supplements to applications) and already marketed drugs and biological products, this guidance will only provide recommendations on NDAs and BLAs (or supplements to an already approved application) for drugs and biological products under Section 505B(a) of the Act. Issues under Section 505B(b) of the Act related to already marketed drug and biological products for which the sponsor is not seeking one of the enumerated changes may be addressed in future guidance.

This guidance addresses the pediatric assessment,[3] the pediatric plan (see Section V.A), waivers and deferrals, compliance issues, and pediatric exclusivity provisions.

FDA's guidance documents, including this guidance, do not establish legally enforceable responsibilities. Instead, guidances describe the Agency's current thinking on a topic and should be viewed only as recommendations, unless specific regulatory or statutory requirements are cited. The use of the word *should* in Agency guidances means that something is suggested or recommended but not required.

I. BACKGROUND

On December 3, 2003, the Pediatric Research Equity Act (PREA) was signed into law. PREA is the most recent of more than a decade of legislative and regulatory attempts to address the lack of pediatric use information in drug product labeling. In PREA, Congress codified many of the elements of the Pediatric Rule, a final rule issued by FDA on December 2, 1998 (63 FR 66632) and suspended by court order on October 17, 2002.[4]

Under the Pediatric Rule, approval actions taken or applications submitted on or after April 1, 1999, for changes in active ingredient, indication, dosage form, dosing regimen, or route of administration were required to include pediatric assessments for indications for which sponsors were receiving or seeking approval in adults, unless the requirement was waived or deferred.

The Pediatric Rule was designed to work in conjunction with the *pediatric exclusivity* provision of Section 505A of the Act (21 U.S.C. 355a), an incentive signed into law to encourage sponsors or holders of approved applications to voluntarily perform the pediatric studies described in a Written Request[5] issued by FDA, in order to qualify for an additional 6 months of marketing exclusivity.

On January 4, 2002, the Best Pharmaceuticals for Children Act (BPCA) (Public Law 107-109) was enacted. The BPCA reauthorized and amended the pediatric exclusivity incentive program of Section 505A and created new mechanisms for funding pediatric studies that sponsors or holders of approved applications declined to conduct voluntarily. On April 24, 2002, FDA issued an advance notice of proposed rulemaking (ANPRM) soliciting comments on the most appropriate ways to update the Pediatric Rule in a manner consistent with other mechanisms for obtaining studies created by the BPCA.

On October 17, 2002, the U.S. District Court for the District of Columbia held that FDA had exceeded its statutory authority when issuing the Pediatric Rule, and the court suspended its implementation and enjoined its enforcement [*Association of Am. Physicians & Surgeons, Inc. v. FDA*, 226 F. Supp. 2d 204 (D. D.C. 2002)]. When the Court enjoined FDA from enforcing the Pediatric Rule in October 2002, the ANPRM was also rendered obsolete.

As noted above, PREA codified elements of the suspended Pediatric Rule and attempted to fill gaps left by the Pediatric Rule's suspension.

II. OVERVIEW—REQUIREMENTS OF PREA

A. PREA Statutory Requirements

PREA requires all applications (or supplements to an application) submitted under Section 505 of the Act (21 U.S.C. 355) or Section 351 of the Public Health Service Act (PHSA) (42 U.S.C. 262) for a new active ingredient, new indication, new dosage form, new dosing regimen, or new route of administration to contain a pediatric assessment unless the applicant has obtained a waiver or deferral (Section 505B(a) of the Act). It also authorizes FDA to require holders of approved NDAs

and BLAs for marketed drugs and biological products to conduct pediatric studies under certain circumstances (Section 505B(b) of the Act).

In general, PREA applies only to those drugs and biological products developed for diseases and/or conditions that occur in both the adult and pediatric populations. Products intended for pediatric-specific indications will be subject to the requirements of PREA only if they are initially developed for a subset of the relevant pediatric population.

B. Scope of Requirements

1. Applications Affected by PREA

Because Section 4(b) of PREA makes the legislation retroactive, all approved applications for new active ingredients, new indications, new dosage forms, new dosing regimens, and new routes of administration submitted on or after April 1, 1999 (including those approved when the Pediatric Rule was suspended), are subject to PREA. Under PREA, holders of such approved applications that did not previously include pediatric assessments, waivers, or deferrals must submit their pediatric assessments or requests for waiver or deferral [Section 4(b)(2)(B) of PREA]. If a waiver request is denied and/or studies are deferred, FDA will require the applicable studies as post-marketing studies. (For additional information on applicable deferral dates, see Section IV.B and Attachment C.)

2. Orphan Drugs

PREA states, "Unless the Secretary requires otherwise by regulation, this section does not apply to any drug for an indication for which orphan designation has been granted under section 526." FDA has not issued regulations applying PREA to orphan-designated indications. Thus, submission of a pediatric assessment is not required for an application to market a product for an orphan-designated indication, and waivers are not needed at this time. However, if only one indication for a product has orphan designation, a pediatric assessment may still be required for any applications to market that same product for the non-orphan indication(s).

3. Generic Drugs Under 505(j) of the Act [21 U.S.C. 355(j)]

Because PREA applies only to applications (or supplements to applications) for a new active ingredient, new indication, new dosage form, new dosing regimen, or new route of administration, and because an abbreviated new drug application (ANDA) submitted under Section 505(j) of the Act for a duplicate version of a previously approved drug product does not involve such changes, PREA does not impose pediatric assessment requirements on ANDAs for generic drugs. However, ANDAs submitted under an approved suitability petition under Section 505(j)(2)(C) of the Act for changes in dosage form, route of administration, or new active ingredient in combination products are subject to the pediatric assessment requirements that PREA imposes. If clinical studies are required under PREA for a product submitted under an approved suitability petition and a waiver is not granted, that application is no longer eligible for approval under an ANDA.

Because PREA is retroactive, all approved and pending ANDAs submitted on or after April 1, 1999 (when the Pediatric Rule became effective) and prior to December 3, 2003 (when PREA was enacted) under suitability petitions for changes in dosage form, route of administration, or active ingredient in combination products are subject to PREA. Although some ANDAs submitted under suitability petitions after April 1, 1999, and prior to December 3, 2003, would not have been approved as ANDAs had PREA been in effect at the time of approval, PREA's retroactivity does not require FDA to revoke those previous approvals. Instead, as with NDAs and BLAs, holders of approved and pending ANDAs submitted under suitability petitions between April 1, 1999 and December 3, 2003, who have not already obtained waivers, must submit post-approval pediatric studies or a request for a waiver or deferral of the pediatric assessment requirement [Section 505B(a)(2) of the Act]. If a waiver request is denied for a product already submitted or approved in an ANDA based upon a suitability petition during this time frame, FDA will require the applicable studies as post-marketing studies.

III. THE PEDIATRIC ASSESSMENT

A. What Is the Pediatric Assessment? [Section 505B(a)(2) of the Act]

Under PREA, the pediatric assessment contains data gathered from pediatric studies using appropriate formulations for each age group for which the assessment is required and other data that are adequate to:

- Assess the safety and effectiveness of the drug or the biological product for the claimed indications in all relevant pediatric subpopulations
- Support dosing and administration for each pediatric subpopulation for which the drug or the biological product has been assessed to be safe and effective

B. When to Submit the Pediatric Assessment in Compliance with PREA

Under PREA, a pediatric assessment must be submitted at the time an application for a new active ingredient, new indication, new dosage form, new dosing regimen, or new route of administration is submitted to the Agency, unless the requirement for the assessment has been deferred or waived. If a deferral has been granted, the pediatric assessment will be due on or before the date specified by the Agency [Section 505B(a)(3) of the Act].

As noted above, PREA is retroactive and requires pediatric assessments for all applications submitted between April 1, 1999, and the present. To address potential gaps in pediatric information for applications approved between April 1, 1999, and the present resulting from, among other things, the suspension of the Pediatric Rule in October 2002, PREA

provides for waivers or deferrals in cases where pediatric study requirements were never addressed and for extensions of certain deferrals issued previously under the Pediatric Rule (see Attachment C for chart of deferral dates under PREA).

If an application previously was granted a waiver of pediatric studies under the Pediatric Rule, the waiver will continue to apply under PREA [Section 4(b)(2)(A) of PREA].

C. What Types of Data Are Submitted as Part of the Pediatric Assessment?

The data submitted under PREA will depend on the nature of the application, what is known about the product in pediatric populations, and the underlying disease or condition being treated. PREA does not require applicants to conduct separate safety and effectiveness studies in pediatric patients in every case. PREA states:

> If the course of the disease and the effects of the drug are sufficiently similar in adults and pediatric patients, the Secretary may conclude that pediatric effectiveness can be extrapolated from adequate and well-controlled studies in adults, usually supplemented with other information obtained in pediatric patients, such as pharmacokinetic studies. [Section 505B(a)(2)(B)(i) of the Act]

If extrapolation from adult effectiveness data is inappropriate, adequate and well-controlled efficacy studies in the pediatric population may nevertheless be required. Additional information, such as dosing and safety data, could also be important to support pediatric labeling decisions.

PREA further provides, "A study may not be needed in each pediatric age group if data from one age group can be extrapolated to another age group" [Section 505B(a)(2)(B)(ii) of the Act].

Whether or not pediatric studies in more than one age group are necessary depends on expected therapeutic benefit and use in each age group and on whether safety and effectiveness data from one age group can be extrapolated to other age groups. As with the use of adult data, the extrapolation may be supplemented with data to define dosing and safety for the relevant age groups.

Applicants should contact the appropriate review division to discuss the types of pediatric studies needed to complete their pediatric assessments.

IV. THE PEDIATRIC PLAN AND SUBMISSIONS

A. When to Develop a Pediatric Plan

A pediatric plan is a statement of intent that outlines the pediatric studies (e.g., pharmacokinetics/pharmacodynamics, safety, efficacy) that the applicant plans to conduct. The plan should also address the development of an age-appropriate formulation. Furthermore, it should address whether and, if so, under what grounds, the applicant plans to request a waiver of deferral under PREA. Applicants are encouraged to submit their pediatric plans to the Agency as early as possible in the drug development process and to discuss these plans with the Agency at critical points in the development process for a particular drug or biologic.

Early consultation and discussions are particularly important for products intended for life- threatening or severely debilitating illnesses. For these products, FDA encourages applicants to discuss the pediatric plan at pre-investigational new drug (pre-IND) meetings and end-of-phase meetings. For products for life-threatening diseases, the review division will provide its best judgment at the end-of-phase-1 meetings on whether pediatric studies will be required under PREA and, if so, whether the submission will be deferred until after approval. In general, studies of drugs or biological products for diseases that are life-threatening or severely debilitating in pediatric patients and that lack adequate therapy could begin earlier than studies of other products because the urgency of the need for the products may justify early trials despite the relative lack of safety and effectiveness information.

For products that are not intended for treatment of life-threatening or severely debilitating illnesses, applicants are encouraged to submit and discuss the pediatric plan no later than the end-of-phase-2 meeting. Information to support any planned request for a waiver or deferral of pediatric studies also should be submitted as part of the background package for this meeting. The review division will provide its best judgment about (1) the pediatric assessment that will be required for the product, (2) whether its submission can be deferred, and (3) if deferred, the date studies will be due. In addition, if relevant, FDA encourages applicants to include a discussion of their intent to qualify for and the studies needed to earn pediatric exclusivity (see Section VIII for a discussion of PREA and pediatric exclusivity).

When a decision to waive or defer pediatric studies is made at key meetings, the minutes from those meetings reflecting the decision generally will be provided to applicants for their records. Alternatively, a separate letter may be sent to the applicant conveying FDA's decision to either waive or defer the pediatric assessment. If a deferral of studies is granted at the time of the meeting, a due date for submission generally will also be included in the meeting minutes or separate letter.

B. What Ages to Cover in a Pediatric Plan

PREA requires, unless waived or deferred, the submission of a pediatric assessment for certain applications for the claimed indications in all relevant pediatric populations. As discussed in Section VI, PREA authorized FDA to waive assessments when: 1) the drug or biological product does not represent a meaningful therapeutic benefit over existing therapies for pediatric patients and 2) is not likely to be used in a substantial number of pediatric patients [Section 505B(a)(4)(A)(iii) of the Act]. Thus, PREA requires the pediatric assessment to evaluate safety and effectiveness for the claimed indication(s) for each age group in which the drug or biological product is expected to provide a meaningful therapeutic benefit over existing therapies for pediatric patients or is likely to be used in a substantial number7 of pediatric patients.

Under PREA, a drug or biological product is considered to represent a *meaningful therapeutic benefit* over existing therapies if FDA estimates that (1) "if approved, the drug or biological product would represent a significant improvement in the treatment, diagnosis, or prevention of disease, compared with marketed products adequately labeled for that use in the relevant pediatric population," or (2) "the drug or biological product is in a class of products or for an indication for which there is a need for additional options" [Section 505B(c) of the Act].

Improvement over marketed products might be demonstrated by showing (1) evidence of increased effectiveness in treatment, prevention, or diagnosis of disease; (2) elimination or substantial reduction of a treatment-limiting drug reaction; (3) enhancement of compliance; or (4) safety and effectiveness in a new subpopulation for which marketed products are not currently labeled.

The BPCA defines "pediatric studies" or "studies" to include studies in all "pediatric age groups (including neonates in appropriate cases)" in which a drug is anticipated to be used [Section 505A(a) of the Act]. For purposes of satisfying the requirements of PREA, the appropriate age ranges to be studied may vary, depending on the pharmacology of the drug or biological product, the manifestations of the disease in various age groups, and the ability to measure the response to therapy. In general, however, the pediatric population includes patients age "birth to 16 years, including age groups often called neonates, infants, children, and adolescents" [21 CFR 201.57(f)(9)].

The complex medical state of neonates and infants makes it critical to evaluate drugs specifically for their use. The Agency is also aware that trials in neonates and infants pose special ethical issues. FDA generally will require studies in neonates and infants under PREA if the drug represents an important advancement and use in these age groups for the approved indication is anticipated. However, it is possible that partial waivers for these specific age groups might be appropriate under certain circumstances when "necessary studies are impossible or highly impracticable," or when "there is evidence strongly suggesting that the drug or biologic product would be ineffective or unsafe in that age group" [Section 505B(a)(4)(B)(i) and (ii) of the Act].

C. Must the Sponsor Develop a Pediatric Formulation?

PREA requires pediatric assessments to be gathered "using appropriate formulations for each age group for which the assessment is required" [Section 505B(a)(2)(A) of the Act]. Under PREA, applicants must submit requests for approval of the pediatric formulation used in their pediatric studies, and failure to submit such a request may render the product misbranded [Section 505B(d) of the Act]. FDA interprets the language "request for approval of a pediatric formulation" to mean that applicants must submit an application or supplemental application for any not previously approved formulation(s) used to conduct their pediatric studies. Where appropriate, applicants may need to begin the development of a pediatric formulation before initiation of pediatric clinical trials.

PREA does, however, specifically authorize FDA to waive the requirement for pediatric studies in one or more age groups requiring a pediatric formulation if the applicant certifies and FDA finds that "the applicant can demonstrate that reasonable attempts to produce a pediatric formulation necessary for that age group have failed" [Section 505B(a)(4)(B)(iv) of the Act].

This exception is limited to the pediatric groups requiring that formulation [Section 505B(a)(4)(C)]. FDA believes that this partial waiver provision will generally apply to situations where the applicant can demonstrate that unusually difficult technological problems prevented the development of a pediatric formulation. In certain cases, the Agency may seek appropriate external expert opinion (e.g., from an advisory committee) to assess whether a waiver should be granted (see Sections VI.A and B for more detailed information on waivers).

D. When to Initiate Pediatric Studies

As discussed in Section V.A, applicants may initiate pediatric studies of drugs and biologics for life-threatening diseases for which adequate treatment is not available earlier in development than might occur for less serious diseases. The medical need for these products may justify early pediatric trials despite a relative lack of safety and effectiveness data. In some cases, pediatric studies of a drug or biological product for a life-threatening disease may begin as early as phase 1 or phase 2, when the initial safety data in adults become available.

The Agency recognizes that in certain cases scientific and ethical considerations will dictate that pediatric studies should not begin until after approval of the drug or biological product for use in adults—for example, where a product has not shown any benefit over other adequately labeled products in the class, the therapeutic benefit is likely to be low, or the risks of exposing pediatric patients to the new product may not be justified until after the product's safety profile is well established in adults after initial marketing.

The Agency recommends that for products with a narrow therapeutic index, the nature of the disease in the pediatric population to be studied and the context in which the drug will be used should factor into the decision on when to initiate the studies in the affected pediatric patient population. For example, studies for an oncology drug product with a narrow therapeutic index might be conducted in children with a life-threatening cancer at an earlier stage in the drug development process than studies for a new aminoglycoside antimicrobial used to treat acute pyelonephritis infections in children. In the latter case, there are several therapeutic options available, so the investigational drug would likely be studied in children after the approval in adults for this condition.

E. What Information Must Be Submitted to FDA

Pediatric studies of drugs conducted under an investigational new drug application (IND) are subject to the rules governing

INDs, including the content and format requirements of 21 CFR 312.23 and the IND safety and annual reporting requirements described in 21 CFR 312.32 and 312.33, respectively.

- When study reports are submitted as part of an application or supplement to an application, the content and format must meet the relevant general requirements for submission (see 21 CFR 314.50 for NDA requirements and 21 CFR 601.2 for BLA requirements).

V. WAIVERS AND DEFERRALS

A. What Is a Waiver?

PREA authorizes FDA to waive the requirement to submit the pediatric assessment, based on established criteria, for some or all pediatric age groups. FDA can grant a full or partial waiver of the requirements on its own initiative or at the request of an applicant. If an applicant requests a waiver, the applicant should provide written justification for the waiver and evidence to support the request.

B. How to Apply for a Waiver

1. Criteria for Full Waiver [Section 505B(a)(4)(A) of the Act]

On FDA's initiative or at the request of an applicant, FDA will grant a full waiver of the requirement to submit pediatric assessments if the applicant certifies and FDA finds one or more of the following:

(a) Necessary studies are impossible or highly impracticable (because, for example, the number of patients is so small or the patients are geographically dispersed) [Section 505B(a)(4)(A)(i) of the Act].

Another example is a drug or biological product for an indication that has extremely limited applicability to pediatric patients because the pathophysiology of these diseases occurs for the most part in the adult population. FDA would be likely to grant a waiver for studies on products developed for the treatment of these conditions without requiring applicants to provide additional evidence of impossibility or impracticality. For a list of adult-related conditions that may be candidates for a disease-specific waiver, see Attachment A, Sample Waiver Request Form.

(b) There is evidence strongly suggesting that the drug or biological product would be ineffective or unsafe in all pediatric age groups [Section 505B(a)(4)(A)(ii) of the Act].

If a waiver is granted based upon evidence that the drug is unsafe or ineffective in pediatric populations, the applicant must include this information in the labeling for the drug or biological product [Section 505B(a)(4)(D) of the Act].

(c) The drug or biological product (1) does not represent a meaningful therapeutic benefit over existing therapies for pediatric patients and (2) is not likely to be used in a substantial number of pediatric patients [Section 505B(a)(4)(A)(iii) of the Act].

2. Criteria for Partial Waiver [Section 505B(a)(4)(B) of the Act]

On its own initiative or at the request of an applicant, FDA will grant a partial waiver of the requirement to submit pediatric assessments for a drug or biological product with respect to a specific pediatric age group, if the applicant certifies and FDA finds evidence of one or more of the following:

(a) Necessary studies are impossible or highly impracticable (because, for example, the number of patients in that age group is so small or patients in that age group are geographically dispersed) [Section 505B(a)(4)(B)(i) of the Act].

(b) There is evidence strongly suggesting that the drug or biological product would be ineffective or unsafe in that age group [Section 505B(a)(4)(B)(ii) of the Act]. If a partial waiver is granted based on evidence that the drug is unsafe or ineffective in pediatric populations, the applicant must include this information in the labeling for the drug or biological product [Section 505B(a)(4)(D) of the Act].

(c) The drug or biological product (1) does not represent a meaningful therapeutic benefit over existing therapies for pediatric patients in that age group and (2) is not likely to be used by a substantial number of pediatric patients in that age group [Section 505B(a)(4)(B)(iii) of the Act].

(d) The applicant can demonstrate that reasonable attempts to produce a pediatric formulation for that age group have failed [Section 505B(a)(4)(B)(iv) of the Act]. If a waiver is granted on the basis that it is not possible to develop a pediatric formulation, the waiver shall cover only the pediatric groups requiring that formulation [Section 505B(a)(4)(C) of the Act].

3. Information in a Waiver Request

As noted in Section V, discussions with FDA on developing pediatric plans and initiating pediatric studies should occur early in the drug development process. If an applicant believes a full or partial waiver of the pediatric studies requirement is warranted, FDA strongly encourages the applicant to request the waiver at the earliest appropriate time. This guidance includes a sample Waiver Request to assist applicants in providing sufficient information for FDA to determine whether to grant a waiver request (Attachment A). However, the information necessary to support any particular waiver will be determined on a case-by-case basis.

To request a waiver, we recommend an applicant provide:

- Product name, applicant name, and indication
- Age group(s) included in waiver request

- Statutory reason(s) for requesting a waiver, including reference to the applicable statutory authority [i.e., one of 2(a)–(d) in Attachment A]
- Evidence that the request meets the statutory reason(s) for waiver of pediatric assessment requirements
- Applicant Certification

4. Waiver Decision

The Agency will grant a waiver request if FDA determines that any of the criteria for a waiver enumerated in the statute have been met. As noted above, if a full or partial waiver is granted "because there is evidence that a drug or biological product would be ineffective or unsafe in pediatric populations, this information shall be included in the labeling for the drug or biological product" [Section 505B(a)(4)(D) of the Act].

As discussed in Section V, for waivers agreed to at the end-of-phase-2 meetings, the meeting minutes will document the waiver of pediatric assessment requirements. Full or partial waiver documentation (meeting minutes or a letter from FDA) should be submitted in the Clinical Data Section of the NDA or BLA and noted in Form FDA-356h under the "Pediatric Use" part of item 8 and also under item 20, "Other." Under "Other," the applicant should identify the location (volume and page number) of the waiver documentation in the NDA or BLA submission.

Decisions to waive the requirement for submission of pediatric assessments that are made early in the pre-approval development period (e.g., end-of-phase-1 or end-of-phase-2 meetings) reflect the Agency's best judgment at that time. If, prior to approval, the Agency becomes aware of new or additional scientific information that affects the criteria on which the waiver decision was based, the Agency may reconsider its earlier decision. A waiver decision becomes final once issued in the approval letter for an NDA, BLA, or supplement.

C. What Is a Deferral?

A deferral acknowledges that a pediatric assessment is required but permits the applicant to submit the pediatric assessment after the submission of an NDA, BLA, or supplemental NDA or BLA. On its own initiative or at the request of an applicant, FDA may defer the submission of some or all of the pediatric studies until a specified date after approval of the drug or issuance of the license for a biological product for adult use [Section 505B(a)(3) of the Act].

D. How to Apply for a Deferral

1. Criteria for Deferral [Section 505B(a)(3) of the Act]

FDA may defer the timing of submission of some or all required pediatric studies if it finds one or more of the following:

- The drug or biological product is ready for approval for use in adults before pediatric studies are complete [Section 505B(a)(3)(A)(i) of the Act].
- Pediatric studies should be delayed until additional safety or effectiveness data have been collected [Section 505B(a)(3)(A)(ii) of the Act].

OR

- There is another appropriate reason for deferral [Section 505B(a)(3)(A)(iii) of the Act] (e.g., development of a pediatric formulation is not complete).

In addition, to obtain a deferral the applicant must submit certification of the reason(s) for deferring the assessments, a description of the planned or ongoing studies, and evidence that the studies are being conducted or will be conducted with due diligence and at the earliest possible time [Section 505B(a)(3)(B)(i)–(iii) of the Act].

2. Information in a Deferral Request

FDA has provided a sample deferral request checklist to assist applicants in providing sufficient information for FDA to determine whether to grant a deferral request (Attachment B). To request a deferral, we recommend an applicant provide:

- Product name, applicant name, and indication
- Age group(s) included in deferral request
- Where deferral is only requested for certain age groups, reason(s) for not including entire pediatric population in deferral request (e.g., studies have already been completed in other age groups and need not be deferred)
- Reason(s) for requesting a deferral
- Evidence justifying that the proposed product meets the criteria for deferral of the pediatric assessment requirement
- Description of planned or ongoing studies
- Evidence that planned or ongoing studies are proceeding
- Projected date for the submission of the pediatric assessment (deferral date)
- Applicant certification

3. Deferral Decision

The decision to defer and the deferral date will be determined on a case-by-case basis. Considerations used in determining whether and how long to defer submission of the pediatric assessment may include:

- The need for the drug or biologic in pediatric patients
- Availability of sufficient safety data to initiate pediatric trials
- The nature and extent of pediatric data needed to support pediatric labeling
- The existence of substantiated difficulties in enrolling patients
- Evidence of technical problems in developing pediatric formulations

As discussed in Section V.A, the meeting minutes or a separate letter will document the deferral of pediatric assessments agreed to at the end-of-phase-2 meetings. For a deferral granted during the pre-approval development period, it is possible that FDA may reevaluate the length of the deferral closer to the time of approval, taking into account any new information obtained while the product was in development and information reviewed in the NDA or BLA. The pediatric assessments deferred under PREA are required post-marketing studies subject to the annual status reporting and information disclosure provisions of 21 CFR 314.81(b)(2)(vii)(a) and (b) and 21 CFR 601.70.

VI. COMPLIANCE WITH PREA

If a pediatric assessment or a request for approval of a pediatric formulation is not submitted by an applicant in accordance with the statutory requirements, the drug or biological product may be considered misbranded solely because of that failure and subject to relevant enforcement action [Section 505B(d)(1) of the Act]. The failure to submit a pediatric assessment or request for waiver or deferral will not be the basis for withdrawing approval of a drug under Section 505(e) of the Act or the revocation of a license for a biological product under Section 351 of the PHSA [Section 505B(d)(2) of the Act]. However, the Agency could bring injunction or seizure proceedings if a product is found to be misbranded under these provisions.[8]

VII. PREA AND PEDIATRIC EXCLUSIVITY

It is the Agency's policy to offer applicants the opportunity to qualify for *pediatric exclusivity* under Section 505A of the Act for studies required and conducted under PREA. Under that policy, however, FDA will not issue a Written Request for or grant pediatric exclusivity for studies that have been submitted to the Agency before the Written Request is issued. Therefore, an applicant seeking to qualify for pediatric exclusivity should obtain a Written Request for studies from FDA before submitting the pediatric studies to satisfy PREA. [Note that for marketed drugs and biological products, the Agency is required to issue a Written Request prior to requiring studies under PREA (Section 505B(b)(3) of the Act).] To qualify for pediatric exclusivity, the pediatric studies conducted to satisfy the requirements of PREA must also satisfy all of the requirements for pediatric exclusivity under Section 505A of the Act [see Sections 505A(d) and 505A(h) of the Act].

In addition, there is a noteworthy distinction between the scope of the studies requested under the pediatric exclusivity provisions and what is required under PREA. For pediatric exclusivity under the Act, FDA's authority to issue a Written Request extends to the use of an active moiety for all indications that occur in the pediatric population, regardless of whether the indications have been previously approved in adults or approval for those indications is being sought in adults [see Section 505A(a), which refers only to "information relating to the use of a new drug in the pediatric population"]. Under PREA, on the other hand, a pediatric assessment is required only on those indications included in the pending application [Section 505B(a), which addresses "the safety and effectiveness of the drug or biological product for the claimed indications"]. To learn more about eligibility for pediatric exclusivity, applicants should consult the guidance for industry entitled *Qualifying for Pediatric Exclusivity Under Section 505A of the Federal Food, Drug, and Cosmetic Act*[9] or should contact the relevant review division.

VIII. ADDITIONAL INFORMATION

A. Additional Information Concerning PREA

General information about complying with PREA can be obtained from the Division of Pediatric Drug Development (DPDD), 301-594-7337 or 301-827-7777, e-mail pdit@cder.fda.gov.

Additional pediatric information is available at www.fda.gov/cder/pediatric.

Specific information about the types of pediatric studies that must be conducted and requirements for submission of assessments for your drug product can be obtained from the appropriate review division.

B. Additional Information Concerning Pediatric Exclusivity

General information and the latest statistical information regarding pediatric exclusivity are located at www.fda.gov/cder/pediatric. You can also refer to the guidance for industry on *Qualifying for Pediatric Exclusivity Under Section 505A of the Federal Food, Drug, and Cosmetic Act*.

ATTACHMENT A—SAMPLE WAIVER REQUEST

Product name:
IND/NDA/BLA number (as applicable):
Applicant:
Indications(s):

(NOTE: If drug is approved for or you are seeking approval for more than one indication, address the following for each indication.)

1. Identify pediatric age group(s) included in your waiver request.
2. With regard to each age group for which a waiver is sought, state the reason(s) for waiving pediatric assessment requirements with reference to applicable statutory authority (i.e., one of the options (a)–(d) listed below—choose all that apply):
   (a) Studies are impossible or highly impractical (because, for example, the number of pediatric patients is so small or geographically dispersed). If applicable, please check from the following list of adult-related conditions that may qualify the drug product for disease-specific waivers:

____ Age-related macular degeneration	____ Basal cell and squamous cell cancer
____ Alzheimer's disease	____ Breast cancer
____ Amyotrophic lateral sclerosis	____ Colorectal cancer
____ Arteriosclerosis	____ Endometrial cancer
____ Infertility	____ Hairy cell cancer
____ Menopause symptoms	____ Lung cancer (small cell and non-small cell)
____ Osteoarthritis	____ Oropharynx cancers (squamous cell)
____ Parkinson's disease	____ Ovarian cancer (non-germ cell)
	____ Pancreatic cancer
____ Other (please state and justify)	____ Prostate cancer
	____ Renal cell cancer
	____ Uterine cancer

(b) The product would be ineffective or unsafe in one or more of the pediatric age group(s) for which a waiver is being requested.
(c) The product fails to represent a meaningful therapeutic benefit over existing therapies for pediatric patients **and** is unlikely to be used in a substantial number of all pediatric age groups or the pediatric age group(s) for which a waiver is being requested.
(d) Reasonable attempts to produce a pediatric formulation for one or more of the pediatric age group(s) for which the waiver is being requested have failed. Please document previous attempts to make a pediatric formulation, and describe reason for failure.

3. Provide evidence that the statutory reason(s) for waiver of pediatric studies have been met [not necessary if a 2(a) category is checked].
4. Applicant certification.

ATTACHMENT B—SAMPLE DEFERRAL REQUEST

Product name:
IND/NDA/BLA number (as applicable):
Applicant:
Indications(s):

(NOTE: If drug is approved for or you are seeking approval for more than one indication, address the following for each indication.)

1. What pediatric age group(s) are included in your deferral request?
2. Reason(s) for requesting deferral of pediatric studies (address each age group separately and for each age group—choose all that apply):
   (a) Adult studies completed and ready for approval
   (b) Additional post-marketing safety data needed (describe)
   (c) Nature and extent of pediatric data needed (explain)
   (d) Evidence provided of technological problems with development of a pediatric formulation
   (e) Difficulty in enrolling pediatric patients (provide documentation)
   (f) Other (specify)
3. What pediatric age group(s) is/are not included in your deferral request?
4. Reason(s) for not including the pediatric age group(s) listed in number 3 in the deferral request (address each excluded age group separately and for each such age group—choose all that apply):
   (a) Adequate pediatric labeling exists
   (b) Studies completed in the specified age group
   (c) Requesting a waiver
   (d) Currently conducting pediatric studies that will be submitted with application
   (e) Other (specify)
5. Has a pediatric plan been submitted to the Agency?
   - If so, provide date submitted.
   - If not, provide projected date pediatric plan is to be submitted.
6. Suggested deferred date for submission of studies.

ATTACHMENT C—COMPLIANCE DATES FOR APPLICATIONS SUBJECT TO PREA

Categories of Application	Expected Date of Compliance
Application or supplement submitted between 4/1/99 and 12/3/03, no waiver or deferral was granted and no studies were submitted	Immediate unless FDA specifies later date
Application or supplement submitted between 4/1/99 and 10/17/02, studies were deferred to a date after 4/1/99, but no studies were submitted	Deferral date + 411 days
Application or supplement submitted between 10/17/02 and 12/3/03 and approved after 12/3/03, studies were deferred	Immediate unless later date is specified in deferral letter
Applications submitted after 12/3/03, studies were deferred	Date specified in deferral letter

16 Global Regulatory Guidance on Bioequivalence Testing

BACKGROUND

Although the current bioequivalence guidelines and recommendations of the major regional and national health authorities show a fair degree of consistency, a number of outstanding bioequivalence issues and concerns remain to be resolved. The most obvious of these controversial issues, such as the bioequivalence acceptance limits for NTI drugs and HVDs/HVDPs, the use of metabolites for bioequivalence assessment, conditions to grant biowaivers, are not always dealt with in the same way by the various health authorities. Global harmonization should therefore be the next logical step in the continuing process to improve the bioequivalence guidelines as a means to guarantee safe and efficacious drug products for the consumer in all parts of the world. Global harmonization efforts by the International Conference on Harmonization (ICH) and the WHO should be stepped up in collaboration with the regulatory agencies of the Western world as more nations throughout the world have come to rely on low-cost, good-quality multi-source (generic) pharmaceutical products to provide lower healthcare costs without sacrificing important public health goals. However, as pointed out above, consensus on a number of bioequivalence issues has not been reached at this point in time amongst international regulatory agencies. In addition, differing levels of commitment and resources by the various countries and regions constitute another formidable barrier that has to be overcome to harmonize bioequivalence approaches to ensure development of optimally performing and affordable drug products for use by health practitioners and patients in the global community.

Due to significant recognition of the BA/bioequivalence concept all over the world, tremendous advancements have been made by the FDA as well as various national, international, and supra national regulatory authorities. In parallel, pharmaceutical industry and academia are also contributing in the area of assessment of bioequivalence. Currently available approaches to determine bioequivalence of generic products are largely standardized due to discussion and consensus reached among various stakeholders at numerous national and international meetings, conferences, and workshops (e.g., American Association of Pharmaceutical Scientists, Federation Internationale Pharmaceutique). Thus the currently available excellent scientific and regulatory guidance documents are due to the combined efforts of industry, academia, and regulatory scientists.

GLOBAL DIVERSITY

The adaptation of the bioequivalence concept worldwide for years has enabled the production and approval of quality generic products through profound scientific, technical, and regulatory advances (especially through replicate designs, application of BCS, scaled average BE) by various approaches to assess BE for various complex and special groups of drugs. This continuing success story of bioequivalence is based on the contribution to efficacy, safety, and quality by international regulatory authorities, pharma industry researchers, academic researchers, and indeed the efforts from ICH, WHO, and various international conferences. However, a lot remains to be done, especially to promote global harmonization of bioequivalence approaches, which should focus on uniformity, standardization of nomenclature, agreement on general concepts, alternative approaches for locally acting drug products, choice of test procedures, outlier challenge, consideration of bioequivalence criteria and objectives, all of which reflect regulatory decision-making standards, as well as ensuring product quality over time for both innovator and generic drugs. To achieve these objectives efforts should continue from international health organizations, pharmaceutical industries, researchers, and regulatory authorities to understand and to develop more efficient and scientifically valid approaches to assess BE and develop generic drugs in a cost-effective manner.

The magnitude of regulatory influence is often dictated by the availability of resources, expertise, and lack of regulation or its implementation. Thus there is a greater need to harmonize the regulatory environment globally for bioequivalence assessment as far as practicable so that the drug product marketed in different parts and regions of the world would have optimum drug product quality in terms of interchangeability. In recent years, some significant progress has been made towards harmonization; in addition some regulatory authorities are also in the process of cooperating with their counterparts from other countries to harmonize the regulatory requirements while streamlining their own regulatory requirements.

Tremendous work towards harmonization was initiated and completed by some organizations, especially the ICH and the World Health Organization (WHO). ICH is a consortium of regulatory authorities from Europe, Japan, and the United States which has focused primarily on developing guidelines

for standardizing and harmonizing the regulatory requirements, mainly for aspects of chemistry and manufacturing control, safety, and efficacy of new drug product quality. In addition, it has developed specific documents for the content and format of drug product dossiers. It has not yet focused on harmonizing the requirements for approval of generic equivalents. On the other hand, the WHO has made remarkable progress specifically in developing international consensus on the regulatory requirements for assessing bioequivalence for marketing authorization of multi-source pharmaceutical products for interchange-ability, selection of comparator product for bioequivalence assessment, and other related regulatory documents. Apart from the ICH and WHO other European and Asian organizations (national and international) are actively involved in harmonization efforts for assessing of bioequivalence and improving the quality of pharmaceutical products globally.

GLOBAL AGENCIES

Every country now has its own individual regulatory authority as well as regulatory guidance for bioequivalence studies, and the regulatory environment of the respective country of marketing influences the magnitude of assessment of bioequivalence of drug product. The regulatory authorities of various countries and international organizations are listed and briefly described in Table 16.1.

GENERAL ASSESSMENT OF BIOEQUIVALENCE

The global paradigm for the assessment of bioequivalence of different drug products remains based on the fundamental assumption that two products are equivalent when the rate and extent of absorption of the test/generic drug does not show a significant difference from the rate and extent of absorption of the reference/brand drug under similar experimental conditions as defined. Global agencies classify bioequivalence studies in the descending order of preference as:

1. Pharmacokinetic endpoint studies
2. Pharmacodynamic endpoint studies
3. Clinical endpoint studies
4. In vitro endpoint studies

Pharmacokinetic Endpoint Studies

These studies are most widely preferred to assess bioequivalence for drug products, where drug level can be determined in an easily accessible biological fluid (such as plasma, blood, urine) and drug level is correlated with the clinical effect. The statutory definition of BA and bioequivalence, expressed in rate and extent of absorption of the active moiety or ingredient to the site of action, emphasizes the use of pharmacokinetic measures to indicate release of the drug substance from the drug product with absorption into the systemic circulation. Regulatory guidance recommends that measures of systemic exposure be used to reflect clinically important differences between test and reference products in BA and bioequivalence studies. These measures include (i) total exposure AUC_{0-t} or $AUC_{0-\infty}$ for single-dose studies and $AUC_{0-\tau}$ for steady-state studies, (ii) peak exposure (C_{max}), and (iii) early exposure (partial AUC to peak time of the reference product of an immediate-release drug product). Reliance on systemic exposure measures will reflect comparable rate and extent of absorption, which, in turn, will achieve the underlying goal of assuring comparable therapeutic effects. Single-dose studies to document bioequivalence were preferred because they are generally more sensitive in assessing in vivo release of the drug substance from the drug product when compared to multiple-dose studies. Table 16.4 describes the general pharmacokinetic parameters (primary and secondary) for single-dose, multiple-dose, and urinary data.

The following are the circumstances that demand multiple-dose study/steady-state pharmacokinetics:

- Dose- or time-dependent pharmacokinetics
- For modified-release products for which the fluctuation in plasma concentration over a dosage interval at steady state needs to be assessed
- If problems of sensitivity preclude sufficiently precise plasma concentration measurements after single-dose administration
- If the intra-individual variability in the plasma concentration or disposition precludes the possibility of demonstrating bioequivalence in a reasonably sized single-dose study and this variability is reduced at steady state
- When a single-dose study cannot be conducted in healthy volunteers due to tolerability reasons, and a single-dose study is not feasible in patients
- If the medicine has a long terminal half-life, and blood concentrations after a single dose cannot be followed for a sufficient time
- For those medicines that induce their own metabolism or show large intra-individual variability
- For combination products for which the ratio of plasma concentration of the individual substances is important
- If the medicine is likely to accumulate in the body
- For enteric-coated preparations in which the coating is innovative

Under normal circumstances, blood should be the biological fluid sampled to measure drug concentrations. Most drugs may be measured in serum or plasma; however, in some drugs, whole blood (e.g., tacrolimus) may be more appropriate for analysis. If the blood concentrations are too minute to be detected and a substantial amount (40%) of the drug is eliminated unchanged in the urine, the urine may serve as the biological fluid to be sampled (e.g., alendronic acid).

Table 16.2 shows lists the primary pharmacokinetic parameters used in bioavailability and bioequivalence studies.

Urinary-based	Ae(0–t), Ae(0–∞), R_{max}	T_{lag}

Pharmacodynamic Endpoint Studies

Pharmacokinetic studies measure systemic exposure but are generally inappropriate to document local delivery BA and bioequivalence. In such cases, BA may be measured, and bioequivalence may be established, based on a pharmacodynamic study, providing an appropriate pharmacodynamic endpoint is available. Pharmacodynamic evaluation is measurement of the effect on a pathophysiological process, such as a function of time, after administration of two different products to serve as a basis for bioequivalence assessment. Regulatory authorities request justification from the applicant for the use of pharmacodynamic effects/parameters for the establishment of bioequivalence criteria. These studies generally become necessary under two conditions: (1) if the drug and/or metabolite(s) in plasma or urine cannot be analyzed quantitatively with sufficient accuracy and sensitivity; (2) if drug concentration measurement cannot be used as surrogate endpoints for the demonstration of efficacy and safety of the particular pharmaceutical product. The other important specifications for pharmacodynamic studies include (i) a dose–response relationship should be demonstrated; (ii) sufficient measurements should be taken to provide an appropriate pharmacodynamic response profile; (iii) the complete dose–effect curve should remain below the maximum physiological response; (iv) all pharmacodynamic measurements/methods should be validated for specificity, accuracy, and reproducibility. Examples of these pharmacodynamic studies include locally acting drug products and oral inhalation drug products, such as metered dose inhalers and dry powder inhalers, and topically applied dermatologic drug products, such as creams and ointments. Bronchodilator drug products, such as albuterol metered dose inhalers, produce relaxation of smooth muscle of the airways. For these drug products, a pharmacodynamic endpoint, based either on increase in forced expiratory volume in one second (FEV) or on measurement of PD_{20} or PC_{20} (the dose or concentration, respectively, of a challenge agent), is clinically relevant and may be used for BA and bioequivalence studies.

Clinical Endpoint Studies or Comparative Clinical Trials

In the absence of pharmacokinetic and pharmacodynamic approaches, adequate and well-controlled clinical trials may be used to establish bioequivalence. Several international regulatory authorities provide general information about the conduct of clinical studies to establish bioequivalence.

In Vitro Endpoint Studies

More recently, a Biopharmaceutics Classification System (BCS) has categorized drug substances as having either high or low solubility and permeability and drug products as exhibiting rapid dissolution. According to this approach, drug substances may be classified into four primary groups:

1. Highly soluble and highly permeable
2. Highly permeable and poorly soluble
3. Highly soluble and poorly permeable
4. Poorly soluble and poorly permeable

Using this BCS approach, a highly permeable, highly soluble drug substance formulated into a rapidly dissolving drug product may need only in vitro dissolution studies to establish bioequivalence. In addition, in vitro approaches to document bioequivalence for drugs with no known bioavailability problems and approved before 1962 remain acceptable as per FDA regulations. Dissolution tests can also be used to reduce the number of in vivo studies in other circumstances and to

(i) assess batch-to-batch quality and support batch release; (ii) provide process control and quality assurance; and (iii) assess the need for further bioequivalence studies relative to minor post-approval changes, where they function as a signal of bioinequivalence.

DESIGN AND ANALYSIS

The general considerations for the advancement of conducting bioequivalence studies are:

- Study design and protocol
- Bioanalysis
- Selection of appropriate analyte(s)
- Bioequivalence metrics and data treatment
- Statistical approaches and analysis
- Acceptance criteria for bioequivalence

Study Design

Successfully determining the bioequivalence of generic drugs to their respective reference drugs depends mostly on design and managing the conduct of the study such that the highest quality samples are obtained. Some regulatory authorities provide specific information on reference-listed drugs to be used to demonstrate bioequivalence (see Table 16.3).

Attention should also be paid to sizing the study properly (to achieve sufficient statistical power to demonstrate bioequivalence); enrolling subjects as per relevant inclusion and exclusion criteria; ensuring that the appropriate overall design (simple two-period crossover, replicate design to gain direct information on within-subject variability for both test and reference product or parallel design) can adequately address the question at hand; standardization of the environmental conditions (such as, fasting, fed, ambulatory, supine); and ensuring that good clinical practices are strictly adhered to and documented. All of these should be planned a priori and embodied in the overall protocol and study plan for the smooth execution of bioequivalence studies.

Generally the study design and number of studies (single-dose and/or multiple-dose and/or fasting and/or fed) depend on the RLD or reference listed drug product, physicochemical properties of the drug, its pharmacokinetic properties, and proportionality in composition with justification along with respective regulatory guidance and specifications. Table 16.4 describes various study designs generally used for bioequivalence studies.

Genetic variations among ethnic and/or racial backgrounds can alter the drug disposition (e.g., white persons who predominantly express less P-glycoprotein in intestinal epithelial cells than black persons) and thus lead to potential sources of variability in pharmacokinetic parameters apart from geographical, food habits, and metabolic variations. For bioequivalence studies, these problems will be minimized using crossover designs, and hence US and Europe regulatory agencies (but not Japan, Korea, and Mexico, for example) are accepting bioequivalence studies from other countries also, as these factors mostly do not have much effect on test and reference products. Bioequivalence studies should be generally performed on a healthy population unless safety warrants (patient population should be preferred if the risk associated with the drug is higher in healthy populations, e.g., anticancer drugs) as they facilitate the provision of adequate information to detect formulation differences and allow extrapolation of this information to populations for which the brand drug is approved.

The regulatory specifications on strength to be investigated, demographics, sample size, number of studies required, fasting and/or fed requirements, standardization of experimental conditions (fluid intake, posture, and physical activity), add-on design, and sampling and washout criteria are briefly described in Tables 16.5 to 16.12.

As a result of random variation or a larger than expected relative difference, there is no guarantee that the sample size as calculated will pass the standards. If the study is run with the appropriate size and the standards are not met, the sponsor may add more subjects, and this approach is generally referred to as an "add-on" study (see Table 16.11).

Bioanalysis

In a general prospective of BA/bioequivalence studies, bioanalysis should be the subsequent step following clinical operations of the study, and it should be executed with strict adherence to good laboratory practices, standard operating procedures, and specific regulatory requirements. Bioanalysis is a term generally used to describe the quantitative measurement of a compound (drug) or its metabolite in biological fluids, primarily blood, plasma, serum, urine, or tissue extracts. Bioanalysis typically consists of two important components: (1) sample preparation and (2) detection of

TABLE 16.4
Brief Description of Bioavailability and Bioequivalence Testing Designs

Design	Significance	Advantages	Disadvantages
Crossover	• When intra-subject CV (approx. 15%) is usually substantially smaller than that inter-subject CV (approx. 30%) • Generally recommended by all regulatory authorities	• Since the treatments are compared on the same subject, the inter-subject variability does not contribute to the error variability • Subject randomization causes unbiased determination of treatment effects • Large information based on minimum sample size • Straightforward statistical analysis	• Carryover effects and period effects are possible due to inappropriate wash-out period • Long duration • Possibility of more drop outs leads to insufficient power • Not suitable for long half-life drugs • Not optimal for studies in patients and highly variable drugs
Parallel	• If the drug has a very long terminal elimination half-life • Duration of the washout time for the two-period crossover study is so long (if >1 month) • If the intra-subject CV is higher with crossover design	• Design is simple and robust • Drop outs will be comparatively less • Duration of the study is less than crossover study • Study with patients is possible • Straightforward statistical analysis	• Subjects cannot serve as their own controls for intra-subject comparisons • Large sample size is required • Lower statistical power than crossover • Phenotyping mandatory for drugs showing polymorphism
Replicate	• Useful for highly variable drugs (intra-subject CV ≥ 30%)	• Allows comparisons of within-subject variances for the test and reference products • Indicates whether a test product exhibits higher or • lower within-subject variability in the bioavailability measures when compared to the reference product • Provides more information about the intrinsic factors • underlying formulation performance • Reduces the number of subjects needed in the bioequivalence study • The number of subjects required to demonstrate bioequivalence can be reduced by up to about 50% • Design increases the power of the study when the variability in the systemic exposure of the test drug and formulation is high	• Involves larger volume of blood withdrawn from each subject • Longer duration of the entire study • Increased possibility of subject drop outs • Expensive
Variance balanced design	• For more than two formulations • Desirable to estimate the pairwise effects with the same degree of precision	• Allows the choice between two additional candidate test formulations • Comparison of test formulation with several reference formulations • Standard design for the establishment of dose proportionality	• Statistical analysis is more complicated (especially when drop-out rate is high) • May need measures against multiplicity (increasing the sample size)

the desired compound using a validated method. Excellent scientific and regulatory guidance documents are available that outline the requirements for a fully validated method. The application of validated methodology presupposes that the most appropriate analyte is monitored to attest to the question of bioequivalence.

SELECTION OF APPROPRIATE ANALYTE(S)

Each regulatory authority has its own specifications for selection of an appropriate analyte to be measured as well as consideration for bioequivalence. Most commonly, the investigator should consult the relevant regulatory agency for guidance on a particular therapeutic agent. The general considerations are discussed in the following sections.

Parent Drug vs. Metabolite(s)

Bioequivalence based on test/reference comparisons of pharmacokinetic measures serves two purposes: (1) to act as a surrogate for therapeutic equivalence, (2) to provide in vivo evidence of pharmaceutical quality. The overall objective of

TABLE 16.5
Brief Description of the Criteria on Strength to Be Investigated in Bioequivalence Studies

Country	Linear Pharmacokinetics	Nonlinear Pharmacokinetics
Europe and Australia	General: The bioequivalence study should in general be conducted at the highest strength Highly soluble drug and any safety concern: Lower strength acceptable Problems of sensitivity of the analytical method: Highest strength acceptable	For drugs with nonlinear pharmacokinetics characterized by a more than proportional increase in AUC with increasing dose over the therapeutic dose range, the bioequivalence study should in general be conducted at the highest strength. As for drugs with linear pharmacokinetics a lower strength may be justified if the highest strength cannot be administered to healthy volunteers for safety/tolerability reasons. Likewise a higher dose may be used in case of sensitivity problems of the analytical method in line with the recommendations given for products with linear pharmacokinetics above. For drugs with a less than proportional increase in AUC with increasing dose over the therapeutic dose range, bioequivalence should in most cases be established both at the highest strength and at the lowest strength (or strength in the linear range), i.e., in this situation two bioequivalence studies are needed. If the nonlinearity is not caused by limited solubility but is due to, e.g., saturation of uptake transporters and provided that (a) the same manufacturing process is used; (b) qualitative composition of the different strengths is the same; (c) compositions of the strengths are quantitatively proportional; (d) appropriate in vitro dissolution data should confirm the adequacy of waiving additional in vivo bioequivalence testing and the test and reference products do not contain any excipients that may affect gastrointestinal motility or transport protein, it is sufficient to demonstrate bioequivalence of proteins at the lowest strength (or strength in the linear range).
United States	Reference listed drug in the Orange Book; usually the highest strength if formulations are proportionally similar. For an ANDA, conducting an in vivo study on a strength that is not the highest may be appropriate for reasons of safety, subject to approval by the Division of Bioequivalence, Office of Generic Drugs and provided that the following conditions are met: (a) linear elimination kinetics has been shown over the therapeutic dose range; (b) the higher strengths of the test and reference products are proportionally similar to their corresponding lower strength; (c) comparative dissolution testing on the higher strength of the test and reference products is submitted and found to be appropriate.	Not specified
Saudi Arabia	For conventional solid oral drug products, in vivo bioequivalence studies are conducted on the highest strength. This requirement for the lower strengths can be waived provided: (a) in vivo bioequivalence is demonstrated on the highest strengths; (b) in vitro dissolution testing is acceptable; and (c) the formulations for the lower strengths are proportionally similar to the strength which has undergone in vivo bioequivalence testing (i.e., the ratio of active ingredients and excipients between the strengths is essentially the same).	Not specified
Canada	Generally use strength with largest sensitivity to identify differences in formulation. Reference product is: (1) a drug product that has been issued a notice of compliance pursuant to Section C.08.004 of the Food and Drug Regulations and is currently marketed in Canada by the innovator, or (2) a drug product acceptable to the Director.	
Asia	Test products in an application for a generic product are normally compared with the corresponding dosage form of an innovator medicinal product (reference product). The choice of reference product should be justified by the applicant and agreed upon by the regulatory authority. If the innovator product is not available, an alternative comparator product approved by the drug regulatory authority of the country can be used.	
New Zealand	When the drug product is the first market entry of that type of dosage form, the reference product should normally be the innovator's prompt-release formulation. The comparison should be between a single dose of the drug formulation and doses of the prompt-release formulation which it is intended to replace.	
Korea	Reference drug product is an approved drug product (or an approved imported drug product) the safety and efficacy of which have been established or recognized by the Commissioner of the KFDA.	

TABLE 16.6
Regulatory Criteria on Subject Demographics for Bioequivalence Studies

Country	Sex	Age (Years)	Body Mass Index (BMI) (kg/m^2)
India	Male or female	Healthy adult volunteers	Not specified
Asia	Either sex	18–55	18–30; Asians: 18–25
United States	Both sexes	>18	Not specified
Europe	Either sex	>18	18.5–30
Canada	Both sexes	18–55	Height/weight ratio for healthy volunteer subjects should be within 15% of the normal range
Australia	Either sex	18–55	Accepted normal BMI
South Africa	Either sex	18–55	Accepted normal BMI or within 15% of the ideal body mass or any other recognized reference
Russia	Both sexes	19–45	Weight of body does not fall outside the limits ±15% on Ketle total-height index
Korea	Healthy adult	19–55	Not specified
Japan	Healthy adult	Not specified	Not specified
People's Republic of China	Both sexes	18–40	Standard weight range
Mexico	Avoiding pharmacokinetic differences between sexes is well documented; volunteers of just one sex must be included	18–55	Weight 10% from the ideal weight
Saudi Arabia	If females are included in the study, the effects of gender differences and menstrual cycle (if applicable) are examined statistically	18–50	Within 15% of ideal body weight, height, and body build
New Zealand	Both sexes	Age range prior to the onset of age-related physiological changes (usually 18–60)	Average weight (e.g., within ±15% of their ideal weight as given in the current Metropolitan Life Insurance Company Height and Mass Tables)

bioequivalence is to ensure that generic products have efficacy and safety characteristics similar to those of the corresponding reference product. For the most part, traditional bioequivalence studies have been carried out on the basis of measurement of only the parent drug in body fluids such as plasma or serum. In some cases, however, monitoring a metabolite, or the parent and metabolite(s), may be more appropriate. A number of reasons for use of metabolite data have been put forward, such as (i) the parent is an inactive prodrug, (ii) plasma concentrations of the parent drug are too low to monitor because of inadequate assay sensitivity, (iii) the parent drug is metabolized rapidly to an active metabolite, and (iv) the parent drug and a metabolite both have therapeutic activities but the metabolite is present in higher concentrations when the parent drug is rapidly and extensively metabolized such that only metabolite(s) data are available.

Enantiomers vs. Racemates

For BA/bioequivalence studies, measurement of both enantiomers may be important. For bioequivalence studies, measurement of the racemate using an achiral assay has been recommended, without measurement of individual enantiomers except when (i) the enantiomers exhibit different pharmacodynamic characteristics; (ii) the enantiomers exhibit different pharmacokinetics; (iii) the primary activity resides with the minor enantiomers; and (iv) nonlinear absorption is present (as expressed by a change in the enantiomers concentration ratio with change in the input rate of the drug) for at least one of the enantiomers.

Drug Products with Complex Mixtures

Certain drug products may contain complex drug substances, i.e., active moiety or active ingredient(s), which are mixtures of multiple synthetic and/or natural source components. Some or all of the components of these complex drug substances may not be characterized by chemical structure and/or biological activity. In this circumstance, BA and bioequivalence studies may be based on selected markers of peak and total exposure.

TABLE 16.7
Regulatory Criteria on Sample Size for Bioequivalence Studies

Country	Minimum	Sample Size Specifications
India	Should not be <16 unless justified for ethical reasons	The number of subjects required for a study should be statistically significant and should be sufficient to allow for possible withdrawals or removals (drop outs) from the study
Asia	Should not be <12	The number of subjects required is determined by (a) the error variance associated with the primary characteristic to be studied as estimated from a pilot experiment, from previous studies or from published data; (b) the significance level desired; (c) the expected deviation from the reference product compatible with bioequivalence (delta, i.e., percentage difference from 100%); and (d) the required power
United States	12	A sufficient number of subjects should complete the study to achieve adequate power for a statistical assessment
Europe	Should not be <12	The number of subjects to be included in the study should be based on an appropriate sample size calculation
Canada	12	(a) Obtain an estimate of the intra-subject Cv from the literature or from a pilot study; (b) choose one of Figures 3.1 through 3.3 (mentioned in bioequivalence guidance document) by determining which one has the closest rounded-up Cv to that estimated in (a), above; (c) choose an expected true ratio of test over reference means (usually 100%) and move up the graph to the 0.90 probability of acceptance; (d) a linear extrapolation between given sample sizes is adequate. This sample size calculation must be provided in the study protocol. More subjects than the sample size calculation required should be recruited into the study. This strategy allows for possible drop outs and withdrawals
Australia	Should not be <16 unless justified	Same as that of Asian guidelines
South Africa	Should not be <12 (general); 20 subjects (for modified release oral dosage forms)	The number of subjects should be justified on the basis of providing at least 80% power of meeting the acceptance criteria; alternatively, the sample size can be calculated using appropriate power equations, which should be presented in the protocol
Russia	18	In quantity sufficient for ensuring statistical significance of study. Thus capacity of the statistical test for bioequivalence study must be supported at a level of not less than 80% for revealing 20% distinctions between comparison parameter
Korea	12	The number of subjects should meet the requirements for statistical validity. The number of subjects can be determined based on the characteristics of the active component of the pertinent drug product
Japan	20	A sufficient number of subjects for assessing bioequivalence should be included. If bioequivalence cannot be demonstrated because of an insufficient number, an add-on subject study can be performed using not less than half the number of subjects in the initial study. A sample size of 20 (n = 10/group) for the initial study and pooled size of 30 for initial plus add-on subject study may suffice if test and reference products are equivalent in dissolution and similar in average AUC and C_{max}
Saudi Arabia	A number of subjects of less than 24 may be accepted (with a minimum of 12 subjects) when statistically justifiable	Generally recommends a number of 24 normal healthy subjects. Should enroll a number of subjects sufficient to ensure adequate statistical results, which is based on the power function of the parametric statistical test procedure applied. The number of subjects should be determined using appropriate methods taking into account the error variance associated with the primary parameters to be studied (as estimated for a pilot experiment, from previous studies or from published data), the significance level desired ($\alpha = 0.05$), and the deviation from the reference product compatible with bioequivalence (±20%) and compatible with safety and efficacy
New Zealand	12	The number of subjects should provide the study with a sufficient statistical power (usually ≥80%) to detect the allowed difference (usually 20%) between the test and reference medicines for AUC and C_{max} This number (n) may, in many cases, be estimated in advance from published or pilot study data using formulae If the calculated number of subjects appears to be higher than is ethically justifiable, it may be necessary to accept a statistical power which is less than desirable. Normally it is not practical to use more than about 40 subjects in a bioavailability study
Mexico	Sample size must not be <24 subjects considering both sequences, or it must meet the requirement related to a difference to be detected of ±20% for the reference product's mean, associated with a type-i error (*) of 0.05 and a minimal potency of (1-*) of 0.8 for this kind of design. A sample size of <24 subjects must be scientifically justified	
Brazil	The number of healthy volunteers shall at all times assure an adequate statistical power to guarantee reliability of bioequivalence study results	

TABLE 16.8
Regulatory Criteria on Number of Studies Required for Conducting Bioequivalence Studies

Country	Immediate-Release Formulations	Modified-Release Formulations
India	Generally a single-dose, nonreplicate, fasting study Food-effect studies are required (1) when it is recommended that the study drug should be taken with food (as would be in routine clinical practice); (2) when fasting-state studies make assessment of C_{max} and T_{max} difficult. If multiple-study design is important, appropriate dosage administered and sampling be carried out to document attainment of steady state	Should conduct fasting as well as food-effect studies. If multiple-study design is important, appropriate dosage administered and sampling carried out to document attainment of steady state
United States	Generally two studies: • A single-dose, nonreplicate fasting study • A food-effect, nonreplicate study Food effect study can be excepted in the following cases: (1) When both test product and RLD are rapidly dissolving, have similar dissolution profiles, and contain a drug substance with high solubility and high permeability (BCS Class I); or (2) when the dosage and administration section of the RLD label states that the product should be taken only on an empty stomach; or (3) when the RLD label does not make any statements about the effect of food on absorption or administration. If food effect is mentioned in the RLD label and if multiple-study design is important, appropriate dosage administered and sampling be carried out to document attainment of steady state	Should conduct fasting as well as food-effect studies. If multiple-study design is important, appropriate dosage administered and sampling be carried out to document attainment of steady state
Europe and Australia	Generally a single-dose, nonreplicate, fasting study Food-effect studies are required if the Summary of Product Characteristics of the reference product contains specific recommendations in relation to food interaction	Should conduct fasting, food-effect as well as steady-state studies
Canada	Generally comparative BA studies conducted in the fasting state Fed study is acceptable if there is a documented serious safety risk to subjects from single-dose administration of the drug or drug product in the absence of food; then an appropriately designed study conducted in the presence of only a quantity of food sufficient to prevent the toxicity may be acceptable for purposes of bioequivalence assessment. For complicated IR formulations (narrow therapeutic range drugs, highly toxic drugs, and nonlinear drugs): both fasted and fed studies	Usual requirement is for both fasted and fed studies. If multiple-study design is important, appropriate dosage administered and sampling be carried out to document attainment of steady state
South Africa	Should be done under fasting conditions unless food effects affect bioavailability of drug or reference product dosage recommended	Both fed and fasted studies are required. If multiple-study design is important, it should be carried out as per regulatory specifications
Korea	Generally a single-dose, nonreplicate, fasting study	Should conduct fasting, food-effect as well as steady-state studies
Japan	Both fasting as well as food-effect studies	Should conduct fasting, food-effect as well as steady-state studies
Saudi Arabia	Generally a single-dose, nonreplicate, fasting study is required. Food-effect studies are required (1) if there is documented evidence of effect of food on drug absorption, (2) the drug is recommended to be administered with food, (3) the drug may produce gastric irritation under fasting conditions, thus may be taken with food	Should conduct fasting as well as food-effect studies
New Zealand	Generally a single-dose fasting study is required Fed study is required when it is recommended that the drug be given with food, or fasted studies make assessment of C_{max} and T_{max} difficult	Should conduct fasting as well as food-effect studies. Steady-state studies are generally required if the drugs are likely to accumulate along with single-dose studies

BIOEQUIVALENCE METRICS AND DATA TREATMENT

The most frequent data treatment involves analysis of variance using a suitable program such as SAS® (Statistical Analysis System, SAS Institute, Cary, NC) or WinNonlin® (Pharsight Corporation, St. Louis, MO) so that contributions from subject, period, product/formulation, and interactions between these can be examined. Geometric mean ratios and log-transformed data are examined to test the hypothesis that the 90% confidence interval of extent (AUC_{0-t}) and $AUC_{0-\infty}$) and the maximum concentration (C_{max}) fall within the acceptance limits of 80% to 125%. More recently, other data treatments have been popular, which include partial area measurements and exposure metrics including C_{max}/AUC, especially with highly variable drugs (HVDs) and with drugs having a long terminal $t_{1/2}$, specialized dosage forms, and/or whose time to C_{max} is considered important (e.g., certain analgesics). In all of these

TABLE 16.9
Regulatory Criteria for Conducting Fasting and Fed Bioequivalence Studies

Country	Fasting Requirements	Fed-Study Requirement
India	Overnight fast (at least 10 h), with a subsequent fast of 4 h following dosing. For multiple-dose fasting studies, when an evening dose must be given, 2 h before and after the dosing	950–1000 kcal of high-fat breakfast approximately 15 min before dosing (at least 50% of calories must come from fat, 15–20% from proteins and rest from carbohydrates) The vast ethnic and cultural restrictions of the Indian subcontinent preclude the recommendation of a single standard high fat; in this case protocol should specify the appropriate and suitable diet
United States	Following an overnight fast of at least 10 h, with a subsequent fast of 4 h post dose	A high-fat (approximately 50% of total caloric content of the meal), high- calorie (approximately 800–1000 calories) meal is recommended. This test meal should derive approximately 150, 250, and 500–600 calories from protein, carbohydrate, and fat, respectively. The caloric breakdown of the test meal should be provided in the study report. If the caloric breakdown of the meal is significantly different from the one described above, a scientific rationale is required for this difference Following an overnight fast of at least 10 h, subjects should start the recommended meal 30 min prior to dosing. Study subjects should eat this meal in 30 min or less; however, the drug product should be administered 30 min after start of the meal
Europe and Australia	Should fast for at least 8 h prior to dosing, unless otherwise justified, and no food is allowed for at least 4 h post dose	The composition of the meal is recommended to be according to the SPC of the originator product. If no specific recommendation is given in the originator SPC, the meal should be a high-fat (approximately 50% of total caloric content of the meal) and high-calorie (approximately 800 to 1000 kcal) meal. This test meal should derive approximately 150, 250, and 500–600 kcal from protein, carbohydrate, and fat, respectively. The composition of the meal should be described in terms of protein, carbohydrate, and fat content (specified in grams, calories, and relative caloric content (%))
Canada	Following an overnight fast of at least 10 h, with a subsequent fast of 4 h post dose	Should be a representative meal in which sufficient food is given to allow potential perturbation of systemic BA of the drug from the drug product. The sponsor should justify the choice of meal and relate the specific components and timing of food administration Example: Two eggs fried in butter, two strips of bacon, two slices of toast with butter, 120 g of hash browns, and 240 mL of whole milk
South Africa	Fasting prior to dosing and after dosing should be standardized	Use of high-calorie and high-fat meals is recommended
Korea	Should be fasted for at least 10 h before and up to 4 h after the drug administration	High-fat diet should be taken within 20 min in at least a 10-h fasting state. The drug products should be administered 30 min after the meal starts
Saudi Arabia	Following an overnight fast of at least 10 h, with a subsequent fast of 4 h post dose	A high-fat (approximately 50% of total caloric content of the meal), high-calorie (approximately 1000 calories) breakfast. Alternative meals with equivalent nutritional content can be used
New Zealand	After an overnight fast of at least 10 h, with a subsequent fast of 2–4 h following dose administration	The meal should contain approximately 30–40 g of fat

cases, the objective has been to err on the side of protecting the consumer while at times increasing risk to the manufacturer. Hence, over the last 15 years, considerable debate has occurred globally about the fundamental scientific rationale used to establish bioequivalence for some of these "special" cases, in an effort to solve these issues associated with harmonization of drug equivalence approaches.

STATISTICAL APPROACHES

Considerable debate has ensued over the past 20 years on statistical testing and bioequivalence studies. After protracted, wide-ranging, and in-depth discussion among various experts from different locations, specific statistical regulatory guidance is available to investigators conducting bioequivalence studies. The various pharmacokinetic parameters derived from the plasma concentration–time curve are subjected to ANOVA in which the variance is partitioned into components according to subjects, periods, and treatments. The classical null hypothesis test is the hypothesis of equal means, H_0: $\mu_T = \mu_R$ (i.e., products are bioequivalent), where μ_T and μ_R represent the expected mean bioavailabilities of the test and reference products, respectively. The alternate hypothesis therefore is H_1: $\mu_T \neq \mu_R$ (i.e., products are bioinequivalent).

The detection of the difference becomes simply a function of sample size, and since the probable magnitude of the difference is the critical factor, this gives rise to two anomalies: (i) a large difference between two formulations which is nevertheless not statistically significant if error variability is high and/or sample size not large enough, (ii) a small difference,

TABLE 16.10
Regulatory Criteria on Fluid Intake, Posture, and Physical Activity for Bioequivalence Studies

Country	Fluid Intake	Posture and Physical Activity
India	Standardization of fluid intake and physical activity is required, and it should be stated in protocol	
United States	Subjects should be administered the drug product with 240 mL (8 fluid ounces) of water; water is allowed as desired except for 1 h before and 1 h after the drug administration	Standardized
Asia, Europe, and Australia	The drug products should be administered with a standardized volume of fluid (at least 150 mL). Prior to and during each study phase, subjects should be allowed water as desired except for 1hour before and after drug administration	As the bioavailability of an active moiety from a dosage form could be dependent upon gastrointestinal transit times, and regional blood flows, posture and physical activity may need to be standardized
Canada	On the morning of the study, up to 250 mL of water may be permitted up to 2 h before drug administration. The dose should be taken with water of a standard volume (e.g., 150 mL) and at a standard temperature. Two hours after drug administration, 250 mL of xanthine-free fluids is permitted	For most drugs, subjects should not be allowed to recline until at least 2 h after drug ingestion. Physical activity and posture should be standardized as much as possible to limit effects on gastrointestinal blood flow and motility. The same pattern of posture and activity should be maintained for each study day
South Africa	The volume of fluid administered at the time of dosing should be constant (e.g., 200 mL); fluids taken after dosing should also be standardized	Should be standardized
Korea	Drug products should be administered with 240 mL of water; drinking water 1 h before and after the administration of drug products is not allowed	Subjects should not be in a supine position at least 2 h after the administration of drug products and should maintain a posture and do only activities that would minimize the effects on their gastrointestinal blood flow rate and motility
Saudi Arabia	The test or reference products should be administered with about 8 fluid ounces (240 mL) of water; water allowed as desired except for 1 h before and after drug administration	Appropriate restrictions on fluid intake and physical activities should be made
New Zealand	The quantity, type, and timing of food and fluid taken concurrently with the medicine should be stated and should be controlled	Standardization of posture and physical activity is important. Subjects should not be allowed to recline until at least 2 h after oral administration of the medicine

TABLE 16.11
Regulatory "Add-On Criteria" for Conducting Bioequivalence Studies

Country	Add-On Criteria
Europe and Australia	It is acceptable to use a two-stage approach when attempting to demonstrate bioequivalence. An initial group of subjects can be treated and their data analyzed. If bioequivalence has not been demonstrated an additional group can be recruited and the results from both groups combined in a final analysis. If this approach is adopted appropriate steps must be taken to preserve the overall type I error of the experiment and the stopping criteria should be clearly defined prior to the study. The analysis of the first-stage data should be treated as an interim analysis and both analyses conducted at adjusted significance levels
South Africa	If the bioequivalence study was performed with the appropriate size but bioequivalence cannot be demonstrated because of a result of a larger than expected random variation or a relative difference, an add-on subject study can be performed using not less than half the number of subjects in the initial study. Combining is acceptable only if the same protocol was used and preparations from the same batches were used. Add-on designs must be carried out strictly according to the study protocol and standard operating procedures and must be given appropriate statistical treatment, including consideration of consumer risk
Canada	As a result of random variation or a larger than expected relative difference, there is no guarantee that the sample size as calculated will pass the standards. If the study is run with the appropriate size and the standards are not met, the sponsor may add more subjects (a minimum of 12). The same protocol should be used (i.e., same formulations, same lots, same blood sampling times, a minimum number of 12 subjects). The choice to use this strategy, as with all designs, should be declared and justified a priori. The level of confidence should be adjusted using the Bonferroni procedure. The t-value should be that for $P = 0.025$ instead of 0.05
Japan	Also for add-on study an additional ten subjects are recommended along with initial subjects

TABLE 16.12
Regulatory Criteria on Sampling and Washout Period for Conducting Bioequivalence Studies

Country	Sampling Criteria	Washout Criteria
India	*Blood sampling* Should be extended to at least three elimination half-lives; at least three sampling points during absorption phase, three–four at the projected T_{max}, and four points during elimination phase; sampling should be continued for a sufficient period to ensure that AUC_{0-t} to $AUC_{0-\infty}$ is only a small percentage (normally <20%) of the total AUC. Truncated AUC is undesirable except in the presence of enterohepatic recycling	Adequate and ideally it should be ≥five half-lives of the moieties to be measured
United States	*Urinary sampling* Collect urine samples for seven or more half-lives. Blood samples should be drawn at appropriate times to describe the absorption, distribution, and elimination phases of the drug; 12–18 samples, including a pre-dose sample, should be collected per subject per dose; should continue for at least three or more terminal half-lives of the drug	An adequate washout period (e.g., more than five half-lives of the moieties to be measured)
Europe	*Single-dose blood sampling* Sufficient sampling is required; frequent sampling around predicted T_{max}; avoid C_{max} for the first point; accommodate reliable estimate (AUC_{0-t}) covers at least 80% of $AUC_{0-\infty}$; at least three–four points during the terminal log-linear phase; AUC truncated at 72 h (AUC_{0-72h}) may be used as an alternative to AUC_{0-t} or comparison of extent of exposure *Multiple-dose blood sampling* Pre-dose sample should be taken immediately before (within 5 min) dosing, and the last sample is recommended to be taken within 10 min of the nominal time for the dosage interval to ensure an accurate determination of $AUC_{0-\tau}$ *Urinary sampling* Urine should normally be collected over no less than three times the terminal elimination half-life	Sufficient washout period (usually at least five terminal half-lives)
Australia	*Single-dose blood sampling* Should provide adequate estimation of C_{max}; cover plasma concentration time curve long enough to provide a reliable estimation of the extent of absorption; three–four samples during the terminal log-linear phase. AUC truncated at 72 h is permitted for long half-life drugs *Multiple-dose blood sampling* When differences between morning and evening or nightly dosing are known, sampling should be carried out over a full 24-h cycle	Adequate washout period
Canada	*Blood sampling* Sampling should be sufficient to account for at least 80% of the known $AUC_{0-\infty}$, C_{max}, and terminal disposition; three times the terminal half-life of the drug; 12–18 samples should be collected per each subject per dose; four or more points be determined during the terminal log-linear phase *Urine sampling* Urine should be collected over no less than three times the terminal elimination half-life. For a 24-h study, sampling times of 0–2, 2–4, 4–8, 8–12, and 12–24 h are usually appropriate.	Normally should be not less than ten times the mean terminal half-life of the drug. Normally, the interval between study days should not exceed 3–4 weeks
South Africa	*Blood sampling* Sampling should be sufficient to account for at least 80% of the known $AUC_{0-\infty}$, C_{max}; collecting at least three–four samples above the LOQ during the terminal log-linear phase; sampling period is approximately three terminal half-lives of the drug; AUC truncated at 72 h is permitted for long half-life drugs; 12–18 samples should be collected per each subject per dose; at least three–four samples above LOQ should be obtained during the terminal log-linear phase *Urine sampling* Sufficient urine should be collected over an extended period and generally no less than seven times the terminal elimination half-life; for a 24-h study, sampling times of 0–2, 2–4, 4–8, 8–12, and 12–24 h post dose are usually appropriate	Adequate washout period
Korea	*Blood sampling* Sampling should be sufficient to estimate all the required parameters for BA; cover three or more times the terminal half-life; at least two points before T_{max}; sufficient to account for at least 80% of the known $AUC_{0-\infty}$; number of blood samples should be >12; AUC truncated at 72 h is permitted for long half-life drugs *Urine sampling* Adequate number of urine samples should be covered to estimate the amount and excretory rate	Adequate and should be >five times the half-life of the active ingredients

(*Continued*)

TABLE 16.12 (CONTINUED)
Regulatory Criteria on Sampling and Washout Period for Conducting Bioequivalence Studies

Country	Sampling Criteria	Washout Criteria
Saudi Arabia	Sufficient samples are collected to estimate all the required parameters during absorption and elimination for bioequivalence assessment. A sampling period extending to at least four–five terminal elimination half-lives of the drug or four–five the longest half-life of the pertinent analyte (if more than one analyte) is usually sufficient	An adequate washout period (e.g., more than five half-lives of the moieties to be measured)
New Zealand	*Single-dose blood sampling* Sampling should be sufficient to account for at least 80% of the known $AUC_{0-\infty}$; should extend to at least three elimination half-lives of the drug; truncated AUC is undesirable except in unavoidable circumstances like the presence of enterohepatic recycling *Multiple-dose blood sampling* Sampling should be carried out over a full 24-h cycle so that any effects of circadian rhythms may be detected, unless these rhythms can be argued not to have practical significance *Urine sampling* Adequate number of urine samples should be covered to estimate the amount and excretory rate. For a 24-h study, sampling times of 0–2, 2–4, 4–8, 8–12, and 12–24 h are usually appropriate. Where urinary excretion is measured in a single-dose study it is necessary to collect urine for seven or more half-lives	An adequate washout period (at least three times the dominating half-life)

probably of no therapeutic importance whatsoever, which is shown to be statistically significant if error variability is minimal and/or sample size adequately large.

The first case suggests a lack of sensitivity in the analysis and the second an excess of it. Consequently, any practice that increases the variability of the study (sloppy design, assay variability, and within-formulation variability) would reduce the chances of finding a significant difference and hence improve the chances of concluding bioequivalence. The FDA therefore recognized that a finding of no statistical significance in the first case was not necessarily evidence of bioequivalence and consequently asked for a retrospective examination of the power of the test of null hypothesis.

Adequate statistical approaches should be considered to establish the bioequivalence of generic product to that of reference product. Much worldwide discussion and interaction has focused on facilitating the appropriate statistical approaches to establish interchangeability between generic drug and reference drug. The pertinent statistical approaches include (i) study power; (ii) 75/75 rule; and (iii) 90% confidence interval.

Study Power

The conduct of a bioequivalence study should require some prior knowledge of the performance of the products (generic and brand drugs) in the human body so that an appropriate number of test subjects can be enrolled and provide adequate power to test the hypothesis with a reasonable likelihood (i.e., at least 80%) that the two products are indeed bioequivalent. In fact, the alternative hypothesis that two products (generic and brand drugs) are statistically different leads to the conclusion that they are not bioequivalent. The two criteria considered most important to understand are the inherent variability of the drug and the geometric mean ratio between the test and reference product. Both of these parameters can be determined through the conduct of a pilot study (n = 6–12) to determine the proper sample size required for the pivotal study to establish bioequivalence as well as to minimize the possibility of undersizing the study.

75/75 Rule

This approach was the first application wherein individual BE (IBE) was being tested. The biomedical community felt that unless the change in the biological system was greater than 20% to 25%, it would really not pose a significant clinical risk of invalidating the use of one therapeutic strategy vs. another. This formed the basis for the 75/75 rule, which states that two products are equivalent if, and only if, at least 75% of the individuals being tested had ratios (of the various pharmacokinetic parameters obtained from the individual results) between the 75% and 125% limits and the study conducted has the statistical power to detect a 20% difference between the two products. This approach was sound until the arrival of the 90% confidence interval. Later the 75/75 rule lost most of its appeal when it was noted that both the test and reference products each have their own variability, and, therefore, a 90% confidence interval approach was more appropriate for giving some consideration to the differential variability between the test and reference products.

90% Confidence Interval

Westlake was the first to suggest the use of confidence intervals as a BE test to evaluate whether the mean amount of drug absorbed using the test formulation was close to the mean amount absorbed of the reference product. Subsequently, in July 1992, the guidance on *Statistical Procedures for Bioequivalence Studies Using a Standard Two-treatment Crossover Design* was released by the FDA. It was revised

in 2001 and is available as *Statistical Approaches to Establishing Bioequivalence* (www.fda.gov/downloads/Drugs/GuidanceComplianceRegulatoryInformation/Guidances/ ucm070244.pdf). This is based primarily on average BE (ABE), wherein the average values for the pharmacokinetic parameters were determined for the test and reference products and compared using a 90% confidence interval for the ratio of the averages using a two one-sided *t*-tests procedure. The ABE approach for BE, however, has limitations for addressing drug switchability, since it focuses only on the comparison of population averages between the test and reference formulations. This concept was really based on the fact that if the ratios of the two pharmacokinetic parameters of clinical interest (such as AUC, C_{max}) are to be compared, each with their own variability which may or may not be randomly distributed, then such a comparison can truly be done only through a confidence interval approach. This concept is well accepted by almost all regulatory authorities to establish the BE.

ACCEPTANCE CRITERIA FOR BIOEQUIVALENCE

An equivalence approach is generally recommended, which usually relies on (i) a criterion to allow the comparison; (ii) a confidence interval for the criterion; and (iii) a bioequivalence limit, to show that two products are equivalent if, and only if, at least 75% Log transformation of exposure measures (C and AUC) of the individuals being tested had ratios (of the various pharmacokinetic parameters obtained from the individual results) between the 75% and 125% limits, and the study conducted has the statistical power to detect a 20% difference between the two products. This approach was sound until the arrival of the 90% confidence interval. Later the 75/75 rule lost most of its appeal when it was noted that both the test and reference products each have their own variability, and, therefore, a 90% confidence interval approach was more appropriate for giving some consideration to the differential and is generally recommended by various regulatory authorities. To compare measures in these studies, data are generally analyzed by using an average bioequivalence criterion with some considerations allowed for special category drugs.

General

To establish bioequivalence, the calculated 90% confidence interval should fall within a bioequivalence limit of 80% to 125% using logarithm-transformed data (adopted since the concentration parameters C_{max} and AUC may or may not be normally distributed). Currently, the bioequivalence limits of 80% to 125% have been applied to almost all drug products by regulatory authorities. More detailed information on acceptance criteria for bioequivalence is given in Table 16.13.

For Highly Variable Drugs

In the context of bioequivalence, HVDs are considered to be drugs and drug products exhibiting intra-subject variability greater than 30% coefficient of variation in the pharmacokinetic measures, AUC, and/or C_{max}. Due to this high variability a large sample size may be needed in BE

TABLE 16.13
Regulatory Acceptance Criteria for Bioequivalence

	90% Confidence Interval on Log-Transformed Data					
	Single-Dose Study			Steady-State Study		
Country	C_{max}	AUC_{0-t}	$AUC_{0-\infty}$	C_{max}	C_{min}	AUC_{τ}
India	80–125	80–125	80–125	80–125	80–125	80–125
Asia	80–125	80–125	80–125	80–125	80–125	80–125
United States	80–125	80–125	80–125	80–125	80–125	80–125
Europe	80–125	80–125	Not applicable	80–125		80–125
Canada	Ratio must be 80–125. Need to pass also on potency corrected data. Add-on studies may be allowed if intra-CV greater than expected	80–125	Not applicable	80–125	80–125	80–125
Australia	80–125	80–125	Not applicable	80–125	80–125	80–125
South Africa	75–133	80–125	Not applicable	75–133	75–133	80–125 (including % swing and % fluctuation)
Russia	75–133	80–125	80–125	75–133	75–133	80–125
Korea	80–125	80–125	80–125	80–125	80–125	80–125
Mexico	80–125	80–125	Not applicable	80–125	80–125	80–125
Saudi Arabia	80–125	80–125	80–125	80–125	80–125	80–125 (including % swing and % fluctuation)
New Zealand	80–125	80–125	80–125	80–125	80–125	80–125

studies to give adequate statistical power to meet FDA BE limits, and thus designing BE studies for HVDs is challenging. Consequently development of generic products for HVDs is a major concern for the generic drugs industry. Major regulatory agencies also considered different approaches for evaluating bioequivalence of highly variable drugs. From 2004 onward the FDA started looking for alternative approaches to resolve this issue and eventually found that replicate crossover design and scaled average BE provides a good approach for evaluating the bioequivalence of highly variable drugs and drug products as it would effectively decrease sample size, without increasing patient risk. Recently the FDA has issued *Method for Statistical Analysis Using the Reference-Scaled Average Bioequivalence Approach for Progesterone Capsules*, which clearly states how to perform statistical analysis for HVDs, such as progesterone, using the replicate crossover design and reference-scaled ABE approach (more information is available at: www.fda.gov/downloads/Drugs/GuidanceComplianceRegulatoryInformation/Guidances/UCM209294.pdf). The various regulatory agency acceptance criteria for HVDs are given in Table 16.14.

For Narrow Therapeutic Index Drugs (NTIDs)

NTIDs can be defined as drugs that require therapeutic drug concentration or pharmacodynamic monitoring and/or drugs for which drug product labeling indicates a narrow therapeutic range designation. Perhaps tighter restrictions on these drugs would aid in the establishment of truly bioequivalent drug products within this class. Thus, additional testing and controls may be needed to ensure the quality of these drug products. The regulatory acceptance criterion for NTIDs is given in Table 16.14. A list of these drugs is provided in Table 16.15.

THE WORLD HEALTH ORGANIZATION GUIDELINES

The WHO Interchangeability Requirement includes providing a bioequivalence study report that comprises, in the case of multi-source (generic) preparations, a bioequivalence study based on the WHO guidelines. Bioequivalence data are required from all oral preparations except aqueous solutions at the time of administration. Orally or parenterally administered aqueous solutions will be assessed by chemical-pharmaceutical characteristics only. Also, a bioequivalence study is required from preparations indicated for serious conditions requiring assured therapeutic response. All compounds in the present list correspond to this characteristic. Instead of a bioequivalence trial, a comparative clinical trial using clinical or pharmacodynamic endpoints can be presented. These endpoints should be justified and validated for the compound, and the trial should be designed to show equivalence. A trial showing the absence of significant difference cannot be accepted.

The bioequivalence study report should contain at least the following items:

- Description of study design. The most appropriate study type is a two-period randomized crossover study. If other study types were used (e.g., parallel group design), these should be justified by the applicant. In general, a single-dose study with a sufficiently long period for blood samples collection is acceptable.

TABLE 16.14
Regulatory Bioequivalence Acceptance Criteria for Special Class Drugs

	Highly Variable Drugs 90% Confidence Interval Log-Transformed Data		Narrow Therapeutic Index Drugs 90% Confidence Interval Log-Transformed Data	
Country	**C_{max}**	**AUC**	**C_{max}**	**AUC_{0-t}**
Asia	The interval must be prospectively defined, e.g., 0.75–1.33 and justified for addressing in particular any safety or efficacy concerns for patients switched between formulations	In rare cases a wider acceptance range may be acceptable if it is based on sound clinical justification	Acceptance interval may need to be tightened	Acceptance interval may need to be tightened
United States	GMR (80–125) 95% upper bound for $(\mu_T - \mu_R)/\delta^2$ WR # 0.7976 (using scaled average approach)	GMR (80–125) 95% upper bound or $(\mu_T - \mu_R)/\delta^2$ WR # 0.7976 (using scaled average approach)	80–125	80–125
Europe	–	–	90.00–111.11	90.00–111.11
Canada	GMR (80–125)	GMR (80–125) 90% CI (80–125)	–	–
Saudi Arabia	75–133	Wider acceptance range may be acceptable, and this should be justified clinically	90–111	–
Japan	–	–	90.00–111.11	90.00–111.11

TABLE 16.15
Narrow Therapeutic Index Drugs (FDA)

Aminophylline Tablets, ER Tablets	Carbamazepine Tablets, Oral Suspension
Clindamycin Hydrochloride Capsules	Clonidine Hydrochloride Tablets
Clonidine Transdermal Patches	Dyphylline Tablets
Disopyramide Phosphate Capsules, ER Capsules	Ethinyl Estradiol/Progestin Oral Contraceptive Tablets
Guanethidine Sulfate Tablets	Isoetharine Mesylate Inhalation Aerosol
Isoproterenol Sulfate Tablets	Lithium Carbonate Capsules, Tablets, ER Tablets
Metaproterenol Sulfate Tablets	Minoxidil Tablets
Oxtriphylline Tablets, DR Tablets, ER Tablets	Phenytoin, Sodium Capsules (Prompt or Extended), Oral Suspension
Prazosin Hydrochloride Capsules	Primidone Tablets, Oral Suspension
Procainamide Hydrochloride, Capsules, Tablets, ER Tablets	Quinidine Sulfate Capsules, Tablets, ER Tablets
Quinidine Gluconate Tablets, ER Tablets	Theophylline Capsules, ER Capsules, Tablets, ER Tablets
Valproic Acid Capsules, Syrup	Divalproex, Sodium DR Capsules, DR Tablets
Warfarin, Sodium Tablets	

- Information about investigators, study site, study dates.
- Data about preparations used: Manufacturer, place of manufacture, batch number.
- The reference preparation in a bioequivalence study should be a well-known preparation used in most countries of the world. The best acceptable reference is the innovator preparation or product from the WHO list of international comparator products if listed.
- Characterization of study subjects. A bioequivalence study should be normally performed in healthy volunteers. If patients were used, the applicant should justify this. The number of subjects should not be smaller than 12. The study report should contain inclusion and exclusion criteria and listing of demographic data of all subjects.
- Description of study procedures. Administration of test products, meals, times of blood sampling, or urine collection periods should be described in the clinical report.
- Description and validation of drug determination methods in investigated material.
- Analytical method should be validated over the measured drug concentration range. Validation should contain methodology and results of sensitivity, specificity, accuracy, precision, and repeatability determination.
- All measured drug concentrations should be presented.
- Calculation methodology of pharmacokinetic parameters. Non-compartmental analysis is preferred. If modeled parameters were used, these models should be validated for the compound. All measured and calculated pharmacokinetic parameters should be presented in the report.
- Description of statistical methodology and results of statistical calculations. Statistical calculations should be based on the equivalence evaluation. The statistical method of choice is the two one-sided test procedure and the calculation of 90% confidence intervals of the test/reference.
- The main parameters to assess the bioequivalence are area under the plasma concentration–time curve (AUC) and maximum concentrations (C_{max}) ratios.
- The 90% confidence interval for the AUC ratio should lie within a bioequivalence range of 80–125%. In some specific cases of drugs with a narrow therapeutic range the acceptance range may need to be tightened.
- The 90% confidence interval for the C_{max} ratio should lie within a bioequivalence range of 80–125%. In some specific cases of drugs with a narrow therapeutic range the acceptance range may need to be tightened. In certain cases for drugs with an inherently high intra-subject variability, a wider acceptance range (e.g., 75–133%) may be acceptable. The range used must be defined prospectively and should be justified, taking into account safety and efficacy considerations.
- Summary of pharmacology, toxicology, and efficacy of the product. In case of products containing new active ingredients and new combinations of active ingredients, provide full information on safety and efficacy as defined in guidelines by the European Union, the U.S. Food and Drug Administration, or the Japanese Ministry of Health and Welfare.

17 Bioavailability and Bioequivalence Studies Submitted in NDAs or INDs—General Considerations

I. INTRODUCTION

This FDA guidance provides recommendations to sponsors and/or applicants planning to include bioavailability (BA) and bioequivalence (BE) information for drug products in investigational new drug applications (INDs), new drug applications (NDAs), and NDA supplements (referred to as the NDA BA and BE Draft FDA guidance).[1] This FDA guidance contains advice on how to meet the BA and BE requirements set forth in 21 CFR Part 320 as they apply to dosage forms intended for oral administration.[2] The FDA guidance may also be applicable to non-orally administered drug products when reliance on systemic exposure measures is suitable to document BA and BE (e.g., transdermal delivery systems and certain rectal and nasal drug products).[3] The FDA guidance should be helpful for applicants conducting BA and BE studies during the IND period for an NDA and also for applicants conducting BE studies during the post-approval period for certain changes to drug products that are the subject of an NDA.[4] This FDA guidance document is not intended to provide recommendations on studies conducted in support of demonstrating comparability or biosimilarity for biological products licensed under Section 351 of the Public Health Service Act.[5]

When finalized, this FDA guidance will revise and replace the parts of FDA's March 2003 FDA guidance for industry on *Bioavailability and Bioequivalence Studies for Orally Administered Drug Products – General Considerations* (the March 2003 BA and BE FDA guidance) relating to BA and BE studies for INDs, NDAs, and NDA supplements.[6] Since the March 2003 BA and BE FDA guidance was issued, FDA has determined that providing information on BA and BE studies in separate FDA guidance according to application type will be beneficial to sponsors and applicants. Thus, FDA is issuing this NDA BA and BE Draft FDA guidance and, as previously noted, has issued the ANDA BE Draft FDA guidance for ANDA and ANDA supplements.[7]

We recognize that this FDA guidance cannot address every issue pertaining to the assessment of BA or BE studies for INDs and NDAs, so we suggest sponsors and applicants contact the appropriate review division for FDA guidance on specific questions not addressed by this FDA guidance.

FDA's FDA guidance documents, including this FDA guidance, do not establish legally enforceable responsibilities. Instead, FDA guidance documents describe the Agency's current thinking on a topic and should be viewed only as recommendations, unless specific regulatory or statutory requirements are cited. The use of the word *should* in Agency FDA guidance documents means that something is suggested or recommended but not required.

II. BACKGROUND

BA assessment of formulations is a component of new drug development. The approaches of evaluating BA and BE discussed in this FDA guidance are designed to aid FDA evaluation of the safety and effectiveness of a product that is the subject of an IND, NDA, or NDA supplement. In this endeavor, we use the totality of information available in the submission, which includes, among other things, information gathered using the principles of BE, exposure–response evaluations, and clinical trial results. The evaluation of BE in the generic drug context, by contrast, is used to support a determination that a generic product may be substituted for its reference listed drug and involves consideration of different types of data permitted in an ANDA. Accordingly, the approaches discussed in this FDA guidance may differ from similar discussions of BE in the ANDA BE Draft FDA guidance. For example, this NDA BA and BE Draft FDA guidance recommends assessment of the effect of food on BA using the approaches set forth in FDA's 2002 FDA guidance for industry on *Food-Effect Bioavailability and Fed Bioequivalence Studies* (the 2002 Food-Effect FDA guidance). Fasting BE studies generally are sufficient, given the totality of information we consider in evaluating INDs, NDAs, or NDA supplements. In contrast, we recommend in the ANDA BE Draft FDA guidance fed and fasting BE studies that will provide specific information to support a demonstration of BE under Section 505(j) of the FD&C Act and, in turn, to support substitutability. Even though the ANDA BE Draft FDA guidance revises and replaces the parts of the 2002 Food-Effect FDA guidance pertaining to ANDAs and ANDA supplements, this NDA BA and BE Draft FDA guidance does not replace the 2002 Food-Effect FDA guidance relating to studies for INDs, NDAs, and NDA supplements.[8]

A. General

Studies to measure BA and/or establish BE of a product are important elements in support of INDs, NDAs, and NDA supplements. *Bioavailability* means the rate and extent to which the active ingredient or active moiety is absorbed from a drug product and becomes available at the site of action [21 CFR

320.1(a)]. BA data provide an estimate of the fraction of the drug absorbed, as well as providing information related to the pharmacokinetics of the drug.

Bioequivalence means the absence of a significant difference in the rate and extent to which the active ingredient or active moiety in pharmaceutical equivalents or pharmaceutical alternatives become available at the site of drug action when administered at the same molar dose under similar conditions in an appropriately designed study [21 CFR 320.1(e)]. Studies to establish BE between two products are important for certain formulation or manufacturing changes occurring during the drug development and post-approval stages. In BE studies, the exposure profile of a test drug product is compared to that of a reference drug product.

B. Bioavailability

BA for a given formulation provides an estimate of the relative fraction of the orally administered dose that is absorbed into the systemic circulation. BA for orally administered drug products can be documented by comparing a systemic exposure profile to that of a suitable reference product. A profile can be generated by measuring the concentration of active ingredients and/or active moieties over time and, when appropriate, active metabolites over time in samples collected from the systemic circulation. Systemic exposure profiles reflect both release of the drug substance from the drug product and a series of possible pre-systemic/systemic actions on the drug substance after its release from the drug product.

FDA's regulations at 21 CFR 320.25 set forth guidelines for in vivo BA studies. As provided in this regulation, the reference product for BA studies should be a solution, suspension, or intravenous (IV) dosage form [21 CFR 320.25(d)(2) and (3)]. The purpose of conducting a BA study with an oral solution as a reference is to assess the impact of formulation on BA. Conducting a BA study with an IV reference enables assessment of the impact of route of administration on BA and defines the absolute BA of the drug released from the drug product.

C. Bioequivalence

As noted previously, both BA and BE focus on the release of a drug substance from a drug product and subsequent absorption into systemic circulation. As a result, we recommend that approaches to determining BE generally follow approaches similar to those used for BA. Demonstrating BE involves a more formal comparative test that uses specific references with specified criteria for comparisons and predetermined BE limits for such criteria.

1. Preapproval Changes
