What stage of BPH does this patient have?

How should the patient be managed?

TREATMENT

Desired Outcomes[9]

LO 3

- KEY CONCEPT Reducing or eliminating obstructive and irritative voiding symptoms. Drug treatment with an α_1-adrenergic antagonist or 5α-reductase inhibitor is expected to decrease the American Urological Association (AUA) Symptom Score (Table 52–1) by 30% to 50% (or at least by three or more points), improve peak and mean urinary flow rate by at least 1 to 3 mL/s, and decrease PVR to normal (< 50 mL total) when compared with pretreatment baseline values.
- Slowing disease progression. When compared with baseline, symptoms and serum blood urea nitrogen (BUN) and creatinine should improve, stabilize, or decrease to the normal range with treatment.
- Preventing disease complications and reducing the need for surgical intervention.
- Avoiding or minimizing adverse treatment effects.
- Providing economical therapy.
- Maintaining or improving quality of life.

Table 52–1

Questions to Determine the AUA Symptom Score

Directions for the patient: The patient should be asked to respond to each question based on the absence or presence of symptoms over the past month. For each question, the patient can respond using a 1–5 scale, where 0 = not at all or none; 1 = less than 1 time in 5; 2 = less than half of the time; 3 = about half of the time; 4 = more than half of the time; and 5 = almost always

Directions for the clinician: After the patient completes the questionnaire, the scores for individual items should be tallied for a final score. Scores of 0–7 = mild symptoms; scores of 8–19 = moderate symptoms; scores more than 20 = severe symptoms

Questions to Assess Obstructive Voiding Symptoms

1. How often have you had a sensation of not emptying your bladder completely after you finished urinating?
2. How often have you found you stopped and started again several times when you urinated?
3. How often have you had a weak urinary stream?
4. How often have you had to push or strain to begin urinating?

Questions to Assess Irritative Voiding Symptoms

5. How often have you found it difficult to postpone urination?
6. How often have you had to urinate again < 2 hours after you finished urinating?
7. How many times did you most typically get up to urinate from the time you went to bed at night until the time you got up in the morning?

AUA, American Urological Association.

Data from AUA Practice Guidelines Committee. AUA guideline on the management of benign prostatic hyperplasia (2010, reaffirmed 2014). www.auanet.org/content/guidelines-and-quality care/clinical-guidelines.cfm?sub=bph. Last accessed July 31, 2017.

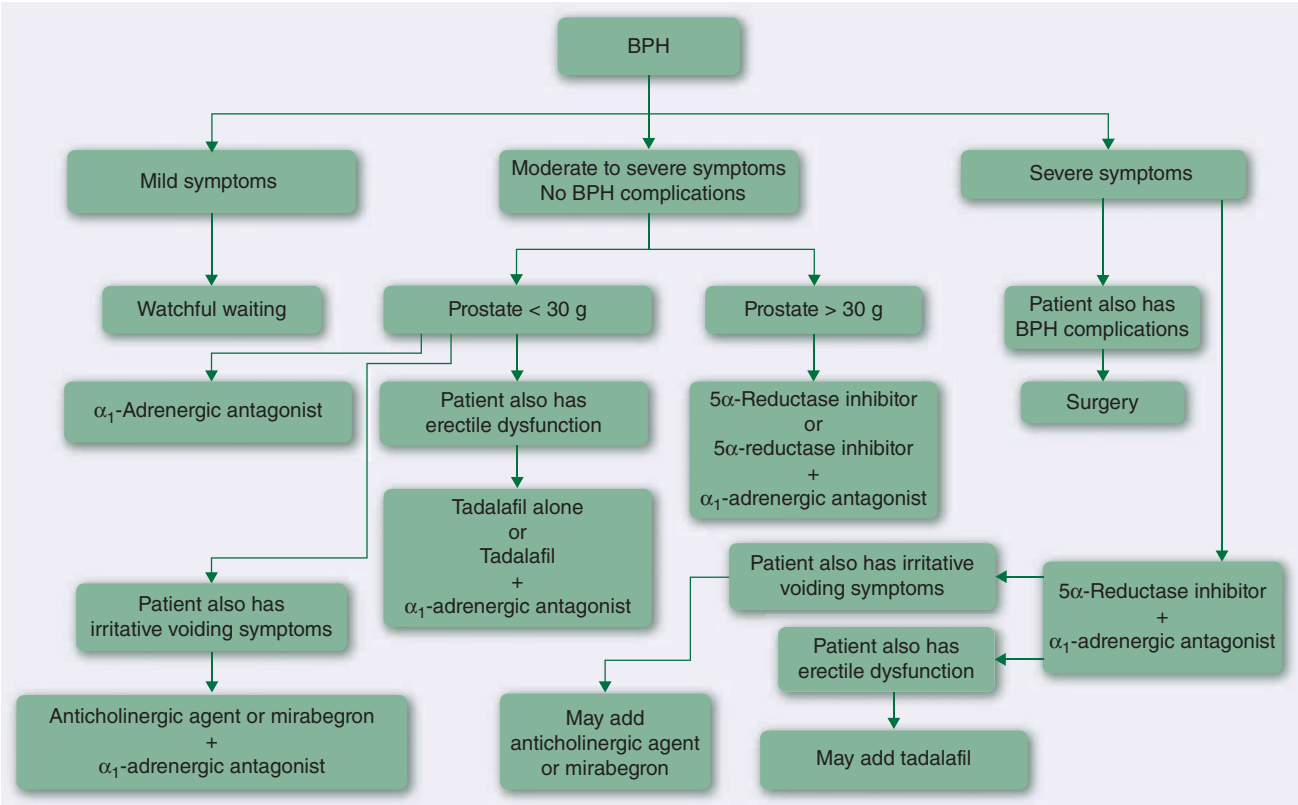

FIGURE 52–1. Algorithm for selection of treatment for BPH based on symptom severity and presence of disease complications.

General Approach to Treatment

Until recently, the principal approach to treatment focused on reducing BPH symptoms (Figure 52–1). However, treatment should also slow disease progression and decrease complications of BPH, particularly in those patients at high risk (Table 52–2).[9,11]

KEY CONCEPT For patients with mild symptoms (AUA Symptom Score of 7 or less) that the patient does not consider to be bothersome, watchful waiting is a reasonable approach to treatment (Table 52–3). The patient is instructed to schedule return visits to the clinician every 6 to 12 months. At each visit,

Table 52–2

Objective Tests Used to Assess the Severity and Complications of BPH

Test	How the Test Is Performed	Normal Test Result	Test Result in Patients with BPH
DRE of the prostate	Physician inserts an index finger into the patient's rectum and palpates the prostate	Prostate is soft, symmetric, mobile; size is 15–20 g (0.5–0.7 oz)	Prostate is enlarged, > 20 g (0.7 oz); no areas of induration or nodularity
Peak and mean urinary flow rate	Patient drinks water until bladder is full; patient empties bladder; volume of urine output and time to empty the bladder are measured; the flow rate (mL/s) is calculated	Peak and mean urinary flow rate are at least 10 mL/s	Peak and mean urinary flow rates are < 10 mL/s
PVR	Measurement of urine left in the bladder after the patient has tried to empty his bladder; assessed by urethral catheterization or ultrasonography	PVR should be 0 mL	PVR > 50 mL is a significant amount of retained urine; this is associated with recurrent urinary tract infection
Urinalysis	Midstream urine is analyzed microscopically for white blood cells and bacteria	Urine should have no white cells or bacteria in it	Urine with white blood cells and bacteria is suggestive of inflammation and infection; if positive, urine is sent for bacteriologic culture
Prostate needle biopsy	Transrectally, a biopsy needle is inserted into the prostate; tissue core is sent to a pathologist for analysis	A normal prostate should have no evidence of BPH or prostate cancer	The biopsy is consistent with BPH
PSA	Blood test for this enzyme, which is secreted by the prostate	< 4 ng/mL (4 mcg/L)	A PSA > 1.5 ng/mL (1.5 mcg/L) is a surrogate marker for an enlarged prostate > 30 g (1.05 oz)

BPH, benign prostatic hypertrophy; DRE, digital rectal examination; PSA, prostate-specific antigen; PVR, postvoid residual urine volume.

Table 52–3

Staging the Severity of BPH Based on AUA Symptom Score and Example Signs of Disease

	AUA Symptom Score	Signs of Disease
Mild	≤ 7	Enlarged prostate on DRE, peak urinary flow rate ≤ 10 mL/s
Moderate	8–19	All of the above, PVR > 50 mL, irritative symptoms
Severe	≥ 20	All of the above plus one or more complications of BPH

The AUA Symptom Score focuses on seven items (incomplete emptying, frequency, intermittency, urgency, weak stream, straining, and nocturia) and asks that the patient quantify the severity of each complaint on a scale of 0 to 5. Thus the score can range from 0 to 35. A decrease in score of 3 points or more is considered a clinically significant improvement.

AUA, American Urological Association; BPH, benign prostatic hyperplasia; DRE, digital rectal examination; PVR, postvoid residual urine volume.

the patient's symptoms are reassessed using the AUA Symptom Scoring Index, and results are compared against the baseline (see Table 52–1). In addition, the patient is educated about implementing nonpharmacologic measures to reduce voiding symptoms (see section on Nonpharmacologic Therapy) and avoiding factors that worsen LUTS (Table 52–4). A digital rectal examination (DRE) is repeated annually. If the patient's symptoms are unchanged, watchful waiting is continued. If the patient's symptoms worsen, specific treatment is initiated.[9] Watchful waiting is effective in approximately 65% of patients with mild LUTS after 5 years.[9,11]

KEY CONCEPT For patients with moderate to severe symptoms and no complications of BPH, the patient is usually offered drug treatment first. α_1-Adrenergic antagonists are preferred over 5α-reductase inhibitors because the former have a faster onset of action (days to a few weeks) and improve symptoms independent of prostate size. α_1-Adrenergic antagonists are preferred for patients with LUTS, who also have a small prostate (< 30 cm^3 [approximately 30 g or 1.05 oz]).

5α-Reductase inhibitors have a delayed onset of peak clinical effect of 6 months and are most effective in patients with moderate to severe LUTS and larger size prostate glands (> 30 g or 1.05 oz). Because of the delay in clinical effect, a 5α-reductase inhibitor is often taken with an α_1-adrenergic antagonist.

With either medication, treatment must be continued as long as the patient responds (Table 52–5).[9]

KEY CONCEPT Combinations of medications to treat moderate or severe symptoms of BPH are more expensive and can cause more adverse effects than single drug treatment. Therefore, combination medication regimens are reserved for patients who have voiding symptoms that do not respond to an adequate trial of single drug treatment or patients who are at high risk of developing complications of BPH. Refer to the section on Combination Therapy for a detailed description of various regimens and their advantages and disadvantages.

LO 7

KEY CONCEPT Surgery is indicated for patients who are at risk of disease progression (ie, those with large prostates [> 30 g or 1.05 oz]), have moderate-severe symptoms and who are unresponsive to or intolerant of drug treatment, or have complications of BPH disease.[9] Although potentially curative, surgery can result in significant morbidity, including erectile dysfunction, **retrograde ejaculation**, **urethral stricture**, urinary incontinence, bleeding, or urinary tract infection. The gold standard is prostatectomy, which can be performed transurethrally using electrocautery or as an open surgical procedure. A transurethral prostatectomy

Table 52–4

Drugs and Diseases That Can Cause Irritative or Obstructive Voiding Symptoms[12]

Pharmacologic Class	Example Drugs	Mechanism of Effect
Androgens	Testosterone	Stimulate prostate enlargement to cause obstructive voiding symptoms
α-Adrenergic agonists	Phenylephrine, pseudoephedrine	Stimulate contraction of prostatic and bladder neck smooth muscle to cause obstructive voiding symptoms
Anticholinergic agents	Antihistamines, phenothiazines, tricyclic antidepressants, antiparkinsonian agents	Block detrusor muscle contraction, thereby impair bladder emptying
Caffeine	Caffeine	Acts like a diuretic to increase urine output
Calcium channel blocker	Nifedipine, diltiazem	Blocks detrusor muscle contraction, and thereby impairs bladder emptying
Diuretics	Thiazides diuretics, loop diuretics	Produce polyuria
Opiates	Morphine, hydromorphone, meperidine	Decrease bladder motility
Sedatives	Benzodiazepines, ethanol	Can cause functional incontinence
Disease[6,12]	**Example Diseases**	**Mechanism of Effect**
Diabetes mellitus		Results in glucosuria, which can cause urinary frequency; also can be associated with a neuropathy of the bladder which can produce irritative symptoms.
Neurologic disorder	Parkinson disease, multiple sclerosis, brain tumors, spinal cord injury	Associated with neurogenic bladder which can produce irritative symptoms
Urethral stricture		Reduces urethral caliber which can cause obstructive symptoms
Meatal stenosis		Blocks urethral opening which can cause obstructive symptoms
Obesity		Causes stress urinary incontinence
Cigarette smoking		Unknown

Clinical Presentation and Diagnosis of BPH

General

In early stages of disease, the patient may complain of obstructive voiding symptoms. If untreated, the disease may progress and the patient may complain of irritative voiding symptoms or acute urinary retention, which can be painful due to maximal distention of the urinary bladder. Also, the patient may be symptomatic of disease complications.

Symptoms

LO 2

Patients may complain of obstructive voiding symptoms (eg, urinary hesitancy, decreased force of urinary stream, straining to void, incomplete bladder emptying, and intermittency) and/or irritative voiding symptoms (eg, urinary frequency, nocturia, and urgency with or without incontinence). A patient with LUTS will typically seek out medical care once the symptoms curb their daily activities, are bothersome to the patient or his significant other, or cause embarrassment. Severity of symptoms should be assessed by the patient using a standardized instrument (eg, the AUA Symptom Scoring Index; Table 52–1). However, a patient's perception of the bothersomeness of his voiding symptoms may not match with the AUA Symptom Score. In this case, after thorough evaluation of the signs and complications of BPH disease, the physician and patient should discuss the bothersomeness of the symptoms and decide together on the most appropriate course of treatment.[1,9]

It should be noted that LUTS is not specific for BPH. LUTS may be due to other urologic disorders including prostate cancer, prostatitis, or neurogenic bladder.

Signs

LO 2

Enlarged prostate on DRE; check for prostate nodules or induration, which would suggest prostate cancer instead of BPH as the cause of the patient's voiding symptoms.

- Distended urinary bladder
- Rule out meatal stenosis or urethral stricture, which could cause voiding symptoms similar to LUTS.
- Check anal sphincter tone as an indirect assessment of peripheral innervation to the detrusor muscle of the bladder.

Complications of Untreated BPH

Upper and lower urinary tract infection, urosepsis, urinary incontinence refractory urinary retention, chronic renal failure, bladder diverticula, bladder stones, or recurrent gross hematuria.

Medical History

- Check the patient's general health, including previous surgery, presence of diabetes mellitus, or medications that may cause or worsen voiding symptoms.
- Have the patient provide a diary of his voiding pattern for the past week: date and time of each voiding, volume voided, and whether or not the patient had urinary leakage during the day.

Laboratory Tests

- Serum PSA: The combination of PSA and DRE of the prostate can be used to screen for prostate cancer, which could also cause an enlarged prostate. Also, PSA is a surrogate marker for an enlarged prostate due to BPH.[9]
- Urinalysis to rule out infection as a cause of the patient's voiding symptoms; also check urinalysis for microscopic hematuria, which typically accompanies BPH.
- Plasma BUN and serum creatinine may be increased as a result of long-standing bladder outlet obstruction. These tests are not routinely performed but rather are reserved for those patients in whom renal dysfunction is suspected.

Other Diagnostic Tests (Table 52–2)

- Decreased peak and mean urinary flow rate (< 10–15 mL/s) on uroflowmetry; decreased urinary flow rate is not specific for BPH; it can also be due to other urologic disorders (eg, urethral stricture, meatal stenosis, or bladder hypotonicity).
- Increased PVR greater than 50 mL
- DRE to check for an enlarged prostate (> 15–20 g [0.5–0.7 oz]).
- A focused neurological examination to check the integrity of innervation to the urinary bladder (that is responsible for bladder emptying).
- Transurethral cystoscopy reveals an enlarged prostate, which decreases urethral lumen caliber; information from this procedure helps the surgeon decide on the best surgical approach.
- Transrectal ultrasound of the prostate; a transrectal probe is inserted to evaluate prostate size and best surgical approach.
- Transrectal prostate needle biopsy to be done if the patient has areas of nodularity or induration on DRE; tissue biopsy can document the presence of prostate cancer.
- LO 2 Computerized tomography of the urinary tract (CT urogram) with contrast will show a thickened bladder wall, hydronephrosis, and retention of contrast in the bladder if the patient has chronic bladder outlet obstruction; this is only indicated in patients with recurrent hematuria, recurrent urinary tract infection, and urolithiasis.
- Filling cystometry provides information on bladder capacity, detrusor contractility, and the presence of uninhibited bladder contractions, which could also cause LUTS.

is typically reserved for prostates of intermediate size (30 g [1.05 oz] to 80 g [2.83 oz]), whereas an open prostatectomy is used for very large prostates (> 80 g [2.83 oz]) or when the patient has BPH and other associated urologic disorders, for example, large bladder stones or bladder diverticula, that can be surgically treated at the same time.[5,9] The newer bipolar technique for performing a TURP, which uses saline irrigating solution, has reduced the incidence of dilutional hyponatremia, a common adverse effect of the older monopolar technique, which uses glycine or sterile water irrigating solution.[6] The outcomes of prostatectomy include an almost immediate improvement of LUTS, an increase of peak urinary flow rate by 6 to 15 mL/s, and a PVR decrease of 30 to 80 mL. The need for reoperation is less than 1%.[6]

LO 5

Table 52–5

Comparison of α-Adrenergic Antagonists, 5α-Reductase Inhibitors, Anticholinergic Agents, Tadalafil, and Mirabegron for Treatment of BPH

Characteristic	α-Adrenergic Antagonists	5α-Reductase Inhibitors	Anticholinergic Agents	Tadalafil	Mirabegron
Relaxes prostatic smooth muscle	Yes	No	No	Yes	No
Reduces size of enlarged prostate	No	Yes	No	No	No
Useful in patients with enlarged prostates	Yes (works independent of the size of the prostate)	Yes	Yes	Yes	No[a]
Efficacy in relieving voiding symptoms and improving flow rate	++	+	+, irritative symptoms	+	+, irritative symptoms
Reduces the frequency of BPH-related complications	No	Yes	No	No	No
Reduces the frequency of BPH-related surgery	No	Yes	No	No	No
Frequency of daily dosing	Once or twice daily, depending on the agent and the dosage formulation	Once daily	Once or twice daily, depending on the agent	Once daily	Once daily
Requirement for up-titration of dose	Yes (for terazosin and doxazosin immediate-release); no (for alfuzosin or silodosin; possibly for doxazosin extended-release and tamsulosin)	No	Yes, depending on the agent	No	Yes, but minimal
Peak onset of action	Days to 6 weeks, depending on need for dose titration	6 months	Days	Days	2–8 weeks
Decreases PSA	No	Yes	No	No	No
Cardiovascular adverse effects	Yes, hypotension	No	Yes, tachycardia	Yes, hypotension	Yes, hypertension, tachycardia
Drug-induced sexual dysfunction	Ejaculation disorders	Decreased libido, erectile dysfunction, ejaculation disorders	Yes, erectile dysfunction	No	No
Significant drug interactions	Antihypertensives Calcium channel blockers β-adrenergic antagonists CYP 3A4 inhibitors CYP 3A4 inducers	CYP 3A4 inhibitors (dutasteride only)	Drugs with anticholinergic effects/side effects Drugs that prolong QT interval CYP 3A4 inhibitors CYP 3A4 inducers	Nitrates Drugs that prolong QT interval CYP 3A4 inhibitors CYP 3A4 inducers α-Adrenergic antagonists	CYP2D6 substrates Drugs that prolong the QT interval

[a]Mirabegron is not FDA-approved for BPH.

BPH, benign prostatic hyperplasia; CYP, cytochrome P-450; PSA, prostate-specific antigen.

To minimize complications of prostatectomy,[13] or in patients who are taking anticoagulants, minimally invasive surgical procedures, such as transurethral incision of the prostate, transurethral needle ablation, transurethral microwave thermotherapy, or transurethral laser ablation, are options.[14,15] A variety of ablative laser energy sources are used to vaporize tissue: holmium, potassium-titanyl-phosphate (KTP or green light), or diode. The choice of energy source is largely determined by the surgeon's level of training, the patient's anatomy, and potential risks for the patient. The potential advantages of minimally invasive surgical procedures include less blood loss, shorter periods of catheterization postoperatively, and no need for hospitalization. However, minimally invasive surgical procedures are associated with a higher reoperation rate than a prostatectomy.[16]

Nonpharmacologic Therapy (Behavioral Modification)

To reduce nocturia, patients should be instructed to stop drinking fluids 3 or 4 hours before going to bed and then void before going to sleep. During the day, timed voidings every 2 to 3 hours, double voiding, toilet mapping (knowing the location of toilets on the way to and from various destinations), or voiding before a long trip may be helpful. Patients should avoid excessive intake of caffeine-containing beverages, sugar-sweetened drinks, and alcohol because these may cause urinary frequency. Patients should avoid taking nonprescription medications that can worsen obstructive voiding symptoms (eg, antihistamines or decongestants) (see Table 52–4). Patients who take a diuretic

should avoid taking it in the evening. Patients are also advised to stop smoking and lose excessive weight. An alteration in the testosterone:estrogen ratio occurs in overweight men because of testosterone conversion to estrogen in adipose tissue, which may contribute to the development of BPH.[17]

Although a variety of herbal agents are used for symptomatic management, including pygeum (African plum), secale cereale (rye pollen), serenoa repens, and hypoxis rooperi (South African star grass), objective evidence of efficacy is lacking.[18]

Pharmacologic Therapy

▶ α_1-Adrenergic Antagonist Monotherapy[19]

KEY CONCEPT α_1-Adrenergic antagonists reduce the dynamic factor causing BPH symptoms. These drugs competitively antagonize α_1-adrenergic receptors, thereby causing relaxation of the bladder neck, prostatic urethra, and prostate smooth muscle.[9,19] A secondary mechanism of action may be that α_1-adrenergic antagonists induce prostatic apoptosis.[20]

All α_1-adrenergic antagonists are considered equally effective in relieving symptoms.[9,19] See Table 52–6. In various clinical trials, 30% to 80% of patients experience improvement in the AUA Symptom Score by 30% to 45%, and 20% to 40% of patients experience urinary flow rate increases of 2 to 3 mL/s. The onset of action is days to weeks, with peak clinical effects observed in several weeks. An adequate clinical trial is at least 2 to 4 weeks of continuous treatment at a full maintenance dose with any of these agents.[9] Durable responses have been demonstrated for many years with continued use. However, some patients will develop disease progression despite treatment. α_1-Adrenergic antagonists are hepatically metabolized. Therefore, in patients with significant hepatic dysfunction, these drugs should be used in the lowest possible dose. With the exception of silodosin, these drugs do not require dosage modification in patients with renal dysfunction.

LO 4

α_1-Adrenergic antagonists can be distinguished by several characteristics:

- *Uroselectivity*. Pharmacologic uroselectivity refers to preferential inhibition of α_{1A}-receptors, which predominate in the prostatic stroma, prostatic urethra, and bladder neck.[19,21] Pharmacologically uroselective α_{1A}-adrenergic antagonists, tamsulosin and silodosin, have the potential to produce less hypotension than other α_1-adrenergic antagonists, because the former have a lower propensity to antagonize α_{1B}-adrenergic receptors in the peripheral vasculature. Silodosin has significantly greater α_{1A}-adrenergic selectivity than tamsulosin and is preferred when a patient has minimal tolerance for any blood pressure–lowering adverse effects.[19,22]

  Despite the potential of inhibiting α-adrenergic receptors in both the prostate and peripheral vasculature, usual doses of alfuzosin, a functionally uroselective α_1-adrenergic antagonist, produce effective relaxation of prostatic smooth muscle with minimal vascular vasodilation.[19]

- KEY CONCEPT Both pharmacologically and functionally uroselective agents appear to be clinically uroselective, in that they improve BPH symptoms with a low potential to cause cardiovascular adverse effects in humans. They are preferred in patients who usually have low blood pressure or those taking multiple antihypertensives.[21,22]

  Pharmacologic and functional uroselectivity are dose-related phenomena. Large daily doses of tamsulosin, silodosin, or alfuzosin may cause loss of uroselectivity, with resultant hypotension and dizziness in some patients.[23]

  Despite the blood pressure–lowering property of α_1-adrenergic antagonists, they are not recommended to be used alone to treat patients with both BPH and essential hypertension. In the ALLHAT study,[24] where doxazosin was compared with other agents for treatment of essential hypertension, it was associated with a higher incidence of congestive heart failure. Therefore, in patients with both hypertension and moderate to severe LUTS, it is recommended that an appropriate antihypertensive be added to an α_1-adrenergic antagonist.

- *Need for up-titration of daily dose*. Up-titration is required for immediate-release terazosin and doxazosin. It is minimally required for extended-release doxazosin and tamsulosin. It is not required for extended-release alfuzosin or silodosin. The need for up-titration with a particular α_1-adrenergic antagonist delays its onset of peak action.

- *Plasma half-life*. α_1-Adrenergic antagonists with short plasma half-lives (eg, prazosin, which is a first generation α_1-adrenergic antagonist) require multiple doses during the day. This is challenging for most patients, and thus prazosin is not recommended for BPH.[9]

- *Dosage formulation*. Immediate-release formulations of terazosin and doxazosin are quickly absorbed and produce high peak plasma levels. Modified- or extended-release formulations of doxazosin, alfuzosin, tamsulosin, and silodosin produce lower peak levels, but more sustained therapeutic plasma levels, than immediate-release formulations and have less potential for producing hypotensive episodes. This allows for initiation of treatment with a therapeutic dose, a faster onset of peak clinical effects, and once daily dosing.[19]

- *Adverse effects*. Hypotensive adverse effects of α_1-adrenergic antagonists can range from asymptomatic blood pressure reductions to dizziness and syncope. This adverse effect occurs in approximately 2% to 14% of treated patients and is most commonly associated with immediate-release terazosin and doxazosin; is less commonly associated with extended-release alfuzosin and extended-release doxazosin; and least commonly associated with tamsulosin and silodosin.[9,19,23] To minimize first-dose syncope from terazosin and doxazosin immediate-release, a slow up-titration from a subtherapeutic dose of 1 mg/day to a therapeutic dose is essential. The first dose should be given at bedtime so that the patient can sleep through the peak serum concentration of the drug when the adverse effect is most likely to occur. A 3- to 7-day interval between each dosage increase should be allowed, and the patient should be maintained on the lowest effective dose of an α_1-adrenergic antagonist. If the patient is noncompliant with his regimen or he skips or interrupts treatment, the α_1-adrenergic antagonist should be restarted using the usual starting dose and then retitrated up. The patient should not be instructed to simply double up on missed doses or resume treatment with the currently prescribed daily dose, as this can lead to significant hypotension or syncope.

Reversible delayed, absent or retrograde ejaculation occur with all α_1-adrenergic antagonists. This is due to pharmacologic blockade of peripheral α_{1A}-adrenergic receptors in the vas deferens and seminal vesicles, which results in decreased antegrade flow of semen to the ejaculatory ducts, or at the bladder neck.[25,26]

Table 52–6

Comparison of Pharmacologic Properties of α_1-Adrenergic Antagonists

	Terazosin	Doxazosin	Alfuzosin	Tamsulosin	Silodosin
Brand name	*	Cardura Cardura-XL	Uroxatral	Flomax	Rapaflo
Generation	Second	Second	Second	Third	Third
Uroselective	No	No	Functionally (Clinically)	Pharmacologically	Pharmacologically
Need for up-titration	Yes	Yes (with immediate-release); possibly (with extended-release)	No	Minimal	No
Daily oral dose (mg)	5–20	2–8, immediate-release; 4–8, extended-release	10	0.4–0.8; (0.8 mg/day dose has not consistently produced clinical improvement over 0.4 mg/day)	8
Recommended dose reduction in patients with renal dysfunction	None needed	None needed	Manufacturer recommends caution in patients with severe renal insufficiency. No specific dosing recommendations provided	If creatinine clearance > 10 mL/min (0.17 mL/s), none needed. Tamsulosin has not been studied in patients with creatinine clearance < 10 mL/min (0.17 mL/s)	If creatinine clearance 30–50 mL/min (0.50–0.83 mL/s), use 4 mg/day. Contraindicated in patients with creatinine clearance < 30 mL/min (0.50 mL/s)
Recommended dose reduction in patients with hepatic dysfunction	Manufacturer provides no specific recommendation. Terazosin should be used cautiously as it undergoes extensive hepatic metabolism	Manufacturer provides no specific recommendation. Doxazosin should be used cautiously as it undergoes extensive hepatic metabolism	Contraindicated in patients with moderate/severe hepatic impairment. Alfuzosin should be used cautiously in patients with mild hepatic impairment	Patients with mild/moderate hepatic impairment require no dosage adjustment. Tamsulosin has not been studied in patients with severe hepatic impairment	Patients with mild/moderate hepatic impairment require no dosage adjustment. Contraindicated in patients with severe hepatic impairment
Best time to take doses	At bedtime	Immediate-release: anytime during the day; however, it is typically given at bedtime Extended-release: anytime during the day	After meals for best oral absorption	On an empty stomach for best oral absorption. If taken 30 minutes after a meal, as recommended by the manufacturer, extent of absorption is reduced, thereby further reducing the potential for hypotensive adverse effects	Take with a meal, which decreases extent of absorption. Theoretically, this would help decrease hypotensive adverse effects
Special administration instructions	None	Do not crush, cut, or chew extended release tablet	Do not crush or chew tablet	Do not crush, chew, or open capsule	May open capsule and sprinkle on applesauce. Must swallow (not chew) applesauce within 5 minutes of preparation. Follow with a full cup of water.
Half-life (hours)	12	22	5	10	13
Formulation	Immediate-release	Immediate-release and extended-release	Extended-release	Modified-release	Modified-release
Cardiovascular adverse effects	++	++	+	0 to +	0 to +
Ejaculation disorders	+	+	+	++	++
Rhinitis	+	+	+	+	+
Malaise	+	+	+	+	+
Major substrate for CYP 3A4	No	Yes	Yes	Yes	Yes

+ minimal; ++ moderate; * terazosin is only available as a generic formulation.

The incidence appears to be dose-related and highest with daily doses of tamsulosin 0.8 mg and silodosin 8 mg, occurring in up to 26% and 28% of treated patients, respectively.[25,27,28] Ejaculation disorders generally do not necessitate discontinuation of treatment as some elderly patients may not be sexually active. Although this adverse effect may decrease a younger patient's satisfaction with the quality of sexual intercourse, ejaculation disorders are not harmful to the patient.

Nasal congestion and malaise occur with α_1-adrenergic antagonists and are an extension of the pharmacologic blockade of α_{1B}-adrenergic receptors in the vasculature of the nasal mucosa and in the central nervous system, respectively. Tolerance often develops to these adverse effects and they rarely require discontinuation of treatment. Avoid use of topical or oral decongestants, as these may exacerbate obstructive voiding symptoms. Cautious use of antihistamines with anticholinergic adverse effects is also recommended in patients with severe BPH and large PVRs, as these drugs may precipitate acute urinary retention.

Floppy iris or small pupil syndrome has been reported with α_1-adrenergic antagonists, most often with selective α_{1A} adrenergic antagonists.[9] In response to tamsulosin, the iris dilator muscle relaxes and the pupil constricts. Pupillary constriction interferes with the surgical procedure and increases the risk of intraoperative and postoperative complications. As a result, when the α_1-adrenergic antagonist–treated patient undergoes cataract surgery, the iris can become flaccid, floppy, or billow out. The iris can prolapse into the incision.[29,30] A patient who plans to undergo cataract surgery is advised to inform his ophthalmologist that he is taking an α_1-adrenergic antagonist. Although the drug will not need to be held or discontinued, the ophthalmologist can plan to use certain surgical techniques to deal with the drug's effect on the iris dilator muscle.[29] Likewise, prior to initiating an α_1-adrenergic antagonist, a patient who needs cataract surgery should have this ophthalmologic procedure performed first, if possible.[30]

- *Potential for drug interactions*. Hypotensive adverse effects of terazosin and doxazosin can be additive with those of diuretics, antihypertensives, and phosphodiesterase type 5 inhibitors (eg, sildenafil). In patients at greatest risk for hypotension, or in those patients who tolerate hypotension poorly, including those with poorly controlled coronary artery disease or severe orthostatic hypotension, tamsulosin or silodosin appear to be the safest choice. In patients who cannot tolerate adverse effects of any α_1-adrenergic antagonist, a 5α-reductase inhibitor or prostatectomy could be considered, particularly if the prostate is enlarged and greater than 30 g (1.05 oz). When initiating a phosphodiesterase type 5 inhibitor, patients who are taking α_1-adrenergic antagonists should be stabilized first on a fixed dose of the α_1-adrenergic antagonist, and then patients should be started on the lowest effective dose of phosphodiesterase type 5 inhibitor to minimize the likelihood of hypotensive effects.[31]

▶ *5α-Reductase Inhibitor Monotherapy*

KEY CONCEPT 5α-Reductase inhibitors reduce the static factor, which results in shrinkage of an enlarged prostate by approximately 15% to 25% after 6 months of continuous treatment. They inhibit 5α-reductase, which is responsible for intraprostatic conversion of testosterone to dihydrotestosterone, the active androgen that stimulates prostate tissue growth. Two subtypes of 5α-reductase, Type I and II, are present in the prostate; the majority is the Type II isoenzyme.[6,32] Finasteride is a selective Type II isoenzyme inhibitor, whereas dutasteride is a nonselective inhibitor of both isoenzymes. When compared with finasteride, dutasteride produces a faster and more complete inhibition of 5α-reductase in prostate cells. However, no difference in clinical efficacy has been demonstrated between these two agents.[9,32,33] Thus finasteride and dutasteride are considered therapeutically equivalent (Table 52–7). It should be noted that 5α-reductase inhibitors may also cause apoptosis of prostate cells, which could contribute to a reduction in prostate gland size.[34]

Table 52–7

Comparison of Pharmacologic Properties of 5α-Reductase Inhibitors

	Finasteride	Dutasteride
Brand name	Proscar	Avodart
Subtype inhibition of the 5α-reductase enzyme	Type II	Types I and II
Percentage decrease of serum dihydrotestosterone level	70–76	90–95
Time to peak onset of reduction in serum dihydrotestosterone level	6 months	1 month
Percentage decrease of intraprostatic dihydrotestosterone	85–90	> 95
Half-life	6.2 hours	5 weeks
Daily dosage (mg)	5	0.5
Dosage formulation	Tablet	Capsule
Instructions for drug administration	Take with or without meals	Take with or without food. Do not open or chew capsules. Swallow capsule whole
Recommended dose reduction in patients with renal dysfunction	None needed	None needed
Recommended dose reduction in patients with hepatic dysfunction	Manufacturer provides no specific recommendation. Finasteride should be used cautiously as it undergoes extensive hepatic metabolism	Manufacturer provides no specific recommendation. Dutasteride should be used cautiously as it undergoes extensive hepatic metabolism

Patient Encounter 2

A 60-year-old man is diagnosed with moderate LUTS secondary to BPH. Because he also has erectile dysfunction and is sexually active, tadalafil 5 mg daily was prescribed. After a month of treatment, the patient reports that he doesn't seem to notice any improvement in his voiding symptoms.

What assessments should be performed?

Let us assume that the patient was adherent to the prescribed regimen and was not taking any other medications or have any medical disorders that could contribute to LUTS. How should the patient be managed?

Finasteride and dutasteride are considered equally effective in relieving LUTS by 15% to 30% in 30% to 70% of patients, increasing the urinary flow rate by 1 to 2 mL/s, and decreasing PVR by 18% to 28%, which is less improvement than that seen with α_1-adrenergic antagonists.[35] A minimum of 6 months is required to evaluate the full clinical effectiveness of treatment. This is a disadvantage in patients with moderate to severe symptoms, as it will take that long to determine whether the drug is or is not effective. Durable responses have been demonstrated in responding patients treated continuously for years. Unlike α_1-adrenergic antagonists, long-term use of 5α-reductase inhibitors is used to prevent BPH-related complications and disease progression. 5-α-Reductase inhibitors have been shown to reduce both the incidence of acute urinary retention by 57% and the need for prostate surgery by 55% in patients with significantly enlarged prostate glands (> 40 g [1.4 oz]) when used continuously for at least four consecutive years.[36,37]

These agents are hepatically metabolized. No specific recommendations for dosage modification are available in patients with significant hepatic dysfunction. No dosage adjustment is needed in patients with renal impairment.

Sexual dysfunction, including decreased libido, erectile dysfunction, ejaculation disorders, and gynecomastia, occurs in 5% to 15% of treated patients.[38] The frequency of sexual dysfunction peaks generally 1 year after the start of treatment,[27] and the incidence of such adverse effects tends to be higher for dutasteride than for finasteride.[33] Recently, a postfinasteride syndrome of persistent sexual dysfunction even after discontinuation of finasteride has been described.[26] Some have suggested that the sexual dysfunction is more likely due to age-related sexual dysfunction, which developed in a patient who coincidentally had been taking finasteride. More studies are needed before any conclusions can be made. Also, dutasteride has been shown to increase insulin resistance in adipose tissue,[39] and may be associated with an increased risk of congestive heart failure.[40] Finally, the 5α-reductase inhibitors are associated with a dose-related increased risk of osteoporosis.[41] Further study is needed to establish cause–effect relationships for these possible adverse effects.

These agents reduce the incidence of prostate cancer by 25%, but are suspected to increase the risk of developing moderate to high grade cancer, if prostate cancer does develop.[42]

Exposure to 5α-reductase inhibitors is contraindicated in pregnant females, as the drugs may cause feminization of a male fetus. Pregnant females should not handle these drugs unless they are wearing gloves.

During continuing treatment of BPH, the patient should undergo an annual repeat PSA and DRE. These agents decrease PSA by a mean of 50% after 6 months of continuous use. A rising PSA level suggests that the patient has worsening BPH, new-onset prostate cancer, or that the patient is noncompliant with his regimen of 5α-reductase inhibitor. An abnormal DRE suggestive of prostate cancer would reveal a nodule or area of induration on the prostate. In such a case, a prostate biopsy is required to rule out prostate cancer.

► *Tadalafil*

Tadalafil is expensive; therefore, the best candidates for treatment are those with BPH and erectile dysfunction, or those patients with LUTS that is not responsive to α-adrenergic antagonists. Tadalafil may be prescribed alone, or along with an α_1-adrenergic antagonist or 5α-reductase inhibitor. Its mechanism is probably due to relaxation of smooth muscle of the urethra, prostate, and bladder neck, which is mediated by increased production of cyclic guanosine monophosphate and hence, nitric oxide, which increases perfusion of the pelvic organs, including the prostate.[43] Tadalafil is comparable to α_1-adrenergic antagonists in relieving LUTS and decreasing the AUA Symptom Score by 3.8 points after 12 weeks; however, it does not produce a clinically significant increase in urinary flow rate or reduce PVR.[43] The usual recommended dose is 5 mg by mouth daily; the dose should be reduced to 2.5 mg daily if the creatinine clearance is 30 to 50 mL/min (0.50–0.83 mL/s). Tadalafil should be avoided if the creatinine clearance is less than 30 mL/min (0.50 mL/s). Tadalafil is contraindicated in patients on nitrates by any route of administration. If the patient is sexually active, tadalafil should not be used in patients with unstable angina, uncontrolled or high-risk arrhythmias, persistent hypotension, poorly controlled hypertension, or New York Heart Association Classification IV congestive heart failure; or patients who have had a myocardial infarction within the past 2 weeks.[44] Common adverse effects include headache, dizziness, flushing, back pain, myalgia, and cyanopsia (Table 52–8).

Although other phosphodiesterase type 5 inhibitors share the same mechanism of action as tadalafil and can improve the AUA Symptom Score, tadalafil is preferred because of its longer plasma half-life, which is theoretically beneficial in the management of BPH, a chronic disease.

► *Anticholinergic Agents*

Irritative voiding symptoms are due to involuntary detrusor muscle contraction in response to small volumes of urine in the bladder. The detrusor muscle is innervated with muscarinic receptors. M_2 receptors comprise 75% of all muscarinic receptors; however, their physiologic function, along with that of M_4 and M_5 receptors, is not well understood. M_3 receptor stimulation is associated with abnormal detrusor contractions, which can cause irritative voiding symptoms.[45]

Anticholinergic agents are indicated when a patient has bothersome irritative voiding symptoms despite treatment with an α_1-adrenergic antagonist. Typically, an anticholinergic agent is added sequentially to an established α_1-adrenergic antagonist regimen. The ideal patient for the combination has a urinary flow rate of at least 10 mL/s and a PVR less than 50 mL. A recent meta-analysis showed that the addition of an anticholinergic agent to an α_1-adrenergic antagonist improved irritative symptoms more than what was observed with the α_1-adrenergic antagonist alone.[46] No cases of urinary retention were reported.

Table 52–8

Summary of Adverse Effects of α-Adrenergic Antagonists, 5α-Reductase Inhibitors, Anticholinergic Agents, and Tadalafil and Management Suggestions

Drug Class	Adverse Reaction	Management Suggestion
α-Adrenergic antagonist	Hypotension	Start with lowest effective dose, give doses at bedtime, and slowly up-titrate at 0.5- to 1-week intervals to a full therapeutic dose, if using immediate-release terazosin or doxazosin. Use tamsulosin, silodosin, extended-release doxazosin, or alfuzosin, as alternatives to immediate-release products, particularly in patients with low blood pressure at baseline or in those taking other antihypertensives.
	Malaise	Educate the patient that this is a common adverse effect; tolerance may develop to malaise. Usually does not require discontinuation of treatment.
	Nasal congestion	Educate the patient that this is a common adverse effect; tolerance may develop to rhinitis. Usually does not require discontinuation of treatment. Avoid decongestants.
	Ejaculation disorders	Educate the patient that this is a common adverse effect and it is not harmful.
	QT interval prolongation	This is a rare but potentially serious adverse effect of alfuzosin only. The patient will most likely have chest pain, dizziness, loss of energy, and pass out. The patient should discontinue the medication and seek immediate notification of the prescriber.
5α-Reductase inhibitor	Gynecomastia	Educate the patient that this may be painful or bothersome, but not harmful.
	Decreased libido	If the patient is sexually active, sexual counseling may be helpful. May be reversible despite continued use of the 5α-reductase inhibitor.
	Erectile dysfunction	The addition of sildenafil or another erectogenic drug may be helpful. May be reversible despite continued use of the 5α-reductase inhibitor.
	Ejaculation disorders	Educate the patient that this may occur but it is not harmful. May be reversible despite continued use of the 5α-reductase inhibitor.
Anticholinergic agent	Dry mouth	Educate the patient that this is a common adverse effect. If drinking fluids and sucking on sugarless hard candy are not effective, the health care provider may switch to another agent in the same class or possibly reduce the daily dose.
	Constipation	This is a common adverse effect. Educate the patient to drink plenty of fluids and eat a high-fiber diet.
	Confusion, drowsiness	If this occurs, consider switching to another agent in the same class with less potential to cross the blood–brain barrier, eg, trospium.
	Acute urinary retention	Do not use anticholinergic agents in patients with a PVR > 250 mL as they are high risk of developing this adverse effect, which is a urologic emergency.
	Increased risk of heat stroke	By decreasing perspiration, patients who are in hot climates and who do not have access to air conditioning, are at risk of heat stroke. Use of anticholinergic agents in elderly who are exposed to these conditions should be avoided.
Tadalafil	Headache	Educate the patient that this is a common adverse effect. It is usually mild, temporary, and does not require treatment discontinuation. If necessary, acetaminophen is usually effective.
	Dizziness	Educate the patient that this is a common adverse effect and does not require treatment. If the patient is taking other blood pressure–lowering medications, stabilize blood pressure on these medications before starting tadalafil.
	Flushing	This is a reversible, dose-related adverse effect that does not require treatment discontinuation.
	Nasal congestion	This is an extension of the vasodilatory effects of tadalafil. It is reversible, dose-related, and does not require treatment discontinuation.
	Visual loss	This can occur any time after tadalafil is started. It is usually painless. The patient should discontinue tadalafil and seek immediate medical attention.
	Back pain	If severe, the patient should report this to the clinician. It may require discontinuation of tadalafil.
	Dyspepsia	Heartburn-like symptoms may occur. Usually, it is mild and does not require treatment.
	Back pain or myalgia	This occurs more often with tadalafil than with the other phosphodiesterase inhibitors. It usually resolves once the drug is stopped. If not severe, tadalafil may be continued as the adverse effect may resolve with continued tadalafil use.
Mirabegron	Hypertension	May need to initiate or adjust existing antihypertensive medications. Educate patient to monitor blood pressure while taking this medication.
	Tachycardia	Educate the patient that this is a common adverse effect. However, if increased pulse rate or palpitations are associated with low blood pressure, chest pain, or difficulty breathing, the patient should seek medical attention.
	Headache	Educate the patient that this is a common adverse effect. It is usually mild, temporary, and does not require treatment discontinuation. If necessary, a low dose of acetaminophen is usually effective.
	Constipation	This is a common adverse effect. Educate the patient to drink plenty of fluids and eat a high-fiber diet.
	Dizziness	Educate the patient that this is a common adverse effect. The patient should monitor blood pressure and seek medical attention if dizziness is moderate or severe.
	Angioedema	In addition to swelling of the face, lips, tongue, and throat, the patient may have shortness of breath and wheezing. This is an allergic reaction that requires immediate discontinuation of the drug and notification of the prescriber. The patient should not continue taking mirabegron unless the prescriber approves doing so.
	QT interval prolongation	This is a rare but potentially serious adverse effect. The patient will most likely have chest pain, dizziness, loss of energy, and pass out. The patient should discontinue the medication and seek immediate notification of the prescriber.

Many anticholinergic agents are available. Darifenacin is the only M_3 uroselective anticholinergic agent. Because M_3 receptors are present in the gastrointestinal tract, and eye, darifenacin can cause constipation, xerostomia, and mydriasis. Refer to the chapter on Urinary Incontinence and Pediatric Enuresis for a discussion of the properties of anticholinergic agents.

If irritative symptoms do not improve after starting an anticholinergic agent, up-titrating the dose or switching to another anticholinergic agent may be helpful. Patients at the highest risk of anticholinergic agent-induced acute urinary retention include those with a PVR of 250 mL or more, low urinary flow rate, or previous history of acute urinary retention.[47] Also, the medication profile of patients should be checked for overall anticholinergic burden, which increases the likelihood of anticholinergic adverse effects, including dry mouth, tachycardia, constipation, confusion, and drowsiness. Finally, elderly patients have a high risk of cognitive impairment from anticholinergic agents, especially those with a history of stroke, head trauma, Parkinson disease, and Alzheimer disease.[47]

▶ *Mirabegron*

In the urinary bladder, 95% of all β-adrenergic receptors are of the β_3 type. Receptor stimulation relaxes the detrusor muscle, but does not interfere with the bladder's contractility.[48]

Mirabegron is a β_3-adrenergic agonist. It causes release of norepinephrine which stimulates β_3-adrenergic receptors. The detrusor muscle relaxes and urine storage in the bladder is improved. Thus, mirabegron reduces irritative voiding symptoms.[48] Although not Food and Drug Administration (FDA)-approved for this indication, mirabegron is an alternative to an anticholinergic agent in patients who poorly tolerate or are at high risk of anticholinergic adverse effects, or when irritative voiding symptoms do not respond to an anticholinergic agent. Mirabegron is typically added to an α_1-adrenergic antagonist.[47] The usual dose is 50 mg by mouth daily. Doses greater than 100 mg have shown no greater efficacy than 50 mg.[47] If the creatinine clearance is 15 to 29 mL/min (0.25–0.49 mL/s), the dose should be reduced to 25 mg daily. Mirabegron should be avoided if the creatinine clearance is less than 15 mL/min (0.25 mL/s) or in patients with poorly controlled hypertension. Common adverse effects of mirabegron include headache, hypertension, tachycardia, constipation, and nasopharyngitis.

▶ *Combination Therapy*

LO 6

KEY CONCEPT A combination of an α_1-adrenergic antagonist and 5α-reductase inhibitor may be considered in symptomatic patients who do not respond to an adequate trial of monotherapy or in symptomatic patients at high risk of BPH complications, that is, those with an enlarged prostate of at least 30 g (1.05 oz.).[9] In such patients, combination therapy will relieve voiding symptoms and also may reduce the risk of developing BPH-related complications by 64% and reduce the need for prostatectomy by 67% after continued use for a minimum of 4 years.[36,37]

The benefit of combination therapy with any α_1-adrenergic antagonist and any 5α-reductase inhibitor is well established. A recent study suggests that initiating a combination regimen in patients with moderate LUTS due to BPH may produce persistent improvements in AUA Symptom Score and urinary flow rate and may reduce the risk of clinical progression after 1 year than treatment with an α_1-adrenergic antagonist alone.[49] To streamline and reduce the cost of treatment regimens, it has been suggested that the α_1-adrenergic antagonist may be discontinued after the first 3 to 12 months of combination therapy; however, the long-term efficacy of doing so remains to be established.[50] Because combination therapy is also associated with low adherence, a commercially available combination formulation of dutasteride 0.5 mg and tamsulosin 0.4 mg is available. In summary, combination therapy generally requires long-term use of an α_1-adrenergic antagonist and 5α-reductase inhibitor, which is more expensive, and is associated with lower adherence and more adverse effects than a single drug regimen. Therefore, clinicians should discuss the advantages and disadvantages of such a combination regimen with the patient before a final decision is made (see Table 52–5).[9]

Several other combination therapy regimens have also been used for moderate to severe LUTS due to BPH. Unlike that of the previously described combination, the published evidence to support newer combinations is limited. One rationale for combined use is that drugs working by different mechanisms to reduce LUTS may provide additional benefit. Tadalafil has been combined with an α_1-adrenergic antagonist or with a 5α-reductase inhibitor. To minimize an additive blood pressure–lowering effect, a uroselective α_{1A}-adrenergic antagonist may be preferred when combined with tadalafil. Similarly, tadalafil can offset erectile dysfunction that commonly occurs with finasteride or dutasteride. As tadalafil is expensive, combination therapy with tadalafil is generally reserved for patients with both moderate or severe LUTS due to BPH and erectile dysfunction.

For patients with moderate or severe irritative voiding symptoms due to BPH that are not responsive to an α_1-adrenergic antagonist alone, an anticholinergic agent may be added. The combination increases urine storage in the bladder and decreases voiding frequency and urgency. Patients at low risk of acute urinary retention should be carefully selected for such combination therapy. These include patients with PVRs less than 50 mL and those with a urinary flow rate of at least 10 mL/s.

For patients who poorly tolerate anticholinergic adverse effects, an alternative is mirabegron, which has been added to an α_1-adrenergic antagonist. A combination of tamsulosin and mirabegron has reduced urinary urgency and frequency and increased urine storage in the bladder when compared to tamsulosin alone.

Patient Encounter 3

A 66-year-old man who has severe obstructive voiding symptoms secondary to BPH presents to clinic. A DRE reveals a prostate of 45 g (1.6 oz) and a PSA of 1.8 ng/mL (1.8 mcg/L). He is started on doxazosin-XL 8 mg daily by mouth. After 1 month, the patient complains that his symptoms have not significantly improved. However, he says that since he started on this medication, he feels lightheaded and dizzy. This patient is also taking hydrochlorothiazide 25 mg daily and valsartan 160 mg daily. A pill count shows that he has been adherent to the prescribed regimen of all of his medications.

Explain the patient's response to doxazosin. Be sure to address the lack of responsiveness as well as adverse effects.

What additional information is needed to develop an individualized treatment plan for this patient?

What treatment options should be considered for this patient?

OUTCOME EVALUATION

KEY CONCEPT Once the peak effects of drug treatment are expected to occur, monitor the drug for effectiveness. This is approximately 2 to 4 weeks after the start of an α_1-adrenergic antagonist, anticholinergic agent, tadalafil, or mirabegron; and 3 and 6 months after the start of a 5α-reductase inhibitor. Assess symptom improvement using the AUA Symptom Scoring Index. A reduction in symptom score by a minimum of 3 points is anticipated. However, it should be noted that the AUA Symptom Score may not match the patient's perception of the bothersomeness of his voiding symptoms. If the patient perceives his symptoms as bothersome, independent of the AUA Symptom Score, consideration should be given to modifying the patient's treatment regimen. Similarly, a patient may regard his symptoms as not bothersome even though the AUA Symptom Score is high. At baseline and during treatment, the clinician should objectively assess symptoms, and check urinary flow rate, PVR, and for the absence of complications of BPH. If the patient shows a response to treatment, instruct the patient to continue the drug regimen and have the patient return at 6-month intervals for monitoring. If the patient shows an inadequate response to treatment, the dose of α_1-adrenergic antagonist can be increased (except for alfuzosin and silodosin) or another drug can be added to reduce the patient's symptoms or until the patient experiences adverse drug effects.

For the α_1-adrenergic antagonists, the severity of hypotensive-related adverse effects, which may manifest as dizziness or syncope, may require a dosage reduction, slower up-titration of the dose, or drug discontinuation. Other adverse effects of α_1-adrenergic antagonists are nasal congestion, malaise, headache, and ejaculation disorders. None of these generally require discontinuation of treatment, and these often improve as treatment continues. For the 5α-reductase inhibitors, the most bothersome adverse effects are decreased libido, erectile dysfunction, and ejaculation disorders. In sexually active males, erectile dysfunction may be improved with erectogenic drugs; however, this adverse effect may necessitate discontinuation of treatment. The adverse effects of anticholinergics are dose-related, and may be poorly tolerated and require drug discontinuation. Whereas tadalafil is well tolerated, mirabegron may increase blood pressure, necessitating the initiation or modification of an existing antihypertensive regimen.

LO 8

Patient Care Process

Collect Information:

- Review the medical history and physical examination.
- Conduct a medication history for medications or dietary supplements that could be contributing to his voiding symptoms (Table 52–4). Identify allergies to medications and other substances. List current medications that the patient may be taking for LUTS and identify dose, start date, response to treatment, and adverse effects of treatment (Tables 52–5 through 52–8).
  - Speak with the patient to identify lifestyle habits, preferences and health beliefs, health goals, and socioeconomic factors that affect medication access and other aspects of care.

Assess the Information:

- Based on the medical history, determine whether the patient has compelling indications for specific medications for BPH, (eg, does the patient also have erectile dysfunction?).
- Based on medical history, signs and symptoms, AUA Symptom Score (Table 52–3), and presence of complications of BPH disease, classify BPH as mild, moderate, or severe.
- Review available laboratory tests, especially serum electrolytes, renal function, and urinalysis.
- Assess the patient's adherence to lifestyle modification measures.
- Assess the efficacy and safety of, and patient adherence to current pharmacotherapy.
- Identify any significant adverse drug effects or interactions from current pharmacotherapy.

Develop a Care Plan:

- If the patient's AUA Symptom Score is in the range of 8–35 despite existing pharmacotherapy for BPH, modify the existing regimen. Consider increasing the dose of the drug, if feasible, or adding a drug to the existing regimen.
- If the patient is not on current pharmacotherapy for BPH but has mild LUTS, initiate lifestyle modifications. If LUTS is moderate to severe, drug therapy is also indicated. Choose medications and doses that are optimal for the patient.

Implement the Care Plan:

- Review lifestyle modification measures that reduce LUTS and reinforce adherence.
- Educate the patient about new or changes to drug therapy, best time to take daily doses, potential adverse effects, and how to self-manage and report adverse effects that might occur.
- Address any patient concerns about BPH and its management.
- Determine whether the patient has insurance coverage or whether recommended agents are included on this patient's insurance formulary.
- Educate the patient on the importance of adherence to the prescribed drug regimen.

Follow-up: Monitor and Evaluate:

- After starting an α_1-adrenergic antagonist, tadalafil, an anticholinergic agent, or mirabegron, assess effectiveness and safety of therapy in 1 month, and then at 6 months. At each visit, repeat the AUA Symptom Scoring Index, check for disease progression, repeat urinary flow rate and PVR, and assess adverse effects of treatment. As long as the patient continues to respond and tolerates the medication well, repeat all assessments at yearly intervals thereafter.
- After starting a 5α-reductase inhibitor, assess effectiveness and safety of therapy at the end of the third and sixth month.

Initial failure to respond to α_1-adrenergic antagonists occurs in 20% to 70% of treated patients. It is likely in these patients that the static factor may predominate as the cause of symptoms in these patients. In these patients, adding a 5α-reductase inhibitor may be helpful. Initial failure to respond to 5α-reductase inhibitors occurs in 30% to 70% of treated patients. It is likely that the dynamic factor may predominate as the cause of symptoms in these patients. Switching to or adding an α_1-adrenergic antagonist may be helpful. In contrast, drug treatment failures after an initial good response to drug therapy will likely be an indication of progressive BPH disease. In such patients, modifying the drug regimen or surgical intervention may be indicated.

Table 52–8 summarizes the adverse effects of the agents used to treat BPH and includes management suggestions for these situations.

Abbreviations Introduced in This Chapter

AUA	American Urological Association
BPH	Benign prostatic hyperplasia
BUN	Blood urea nitrogen
DRE	Digital rectal examination
FDA	Food and Drug Administration
LUTS	Lower urinary tract symptoms
PSA	Prostate-specific antigen
PVR	Postvoid volume
TURP	Transurethral resection of the prostate

53 Urinary Incontinence and Pediatric Enuresis

Sum Lam and Gladys El-Chaar

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

LO

1. Explain the pathophysiology of the major types of urinary incontinence (UI): urge, stress, overflow, and functional.
2. Recognize the signs and symptoms of the major types of UI in individual patients.
3. List the treatment goals for a patient with UI.
4. Compare and contrast available therapeutic agents for managing UI; identify factors that guide drug selection for an individual patient.
5. Formulate a monitoring plan and provide patient counseling for a patient on a given treatment regimen based on patient-specific information.
6. Explain the pathophysiology of pediatric enuresis.
7. List treatment goals; compare and contrast available management strategies for managing pediatric enuresis.
8. Formulate a patient-specific monitoring plan and implement patient counseling for a patient on a given treatment regimen.
9. Describe nonpharmacologic treatment approaches for pediatric enuresis.

URINARY INCONTINENCE

INTRODUCTION

Urinary incontinence (UI) is defined as the complaint of involuntary leakage of urine.[1] It is often associated with other bothersome lower urinary tract symptoms such as urgency, increased daytime frequency, and **nocturia**. Despite its prevalence in both genders, UI remains an underreported health problem that can negatively impact an individual's quality of life. Patients with UI may sense a loss of self-control, independence and self-esteem, and often modify their activities for fear of an "accident." Patients with UI may also suffer from other consequences, including perineal dermatitis and infections, pressure ulcers, urinary tract infections (UTIs), and falls. In the United States, the estimated national cost of urge urinary incontinence (UUI) in 2007 was $66 billion, with projected costs of $83 billion in 2020.[2]

EPIDEMIOLOGY AND ETIOLOGY

The true prevalence of UI is unclear because of varying definitions of UI and reporting bias.[3]

- About 44% of noninstitutionalized persons aged 65 and older reported UI[4]
- 7% to 37% of women aged 20 to 39 report some degree of UI
- 9% to 39% of women aged 60 and older report daily UI
- 11% to 34% of older men report some degree of UI
- 2% to 11% of older men reporting daily UI
- In the noninstitutionalized setting, more than 50% of elderly women and more than 25% of elderly men reported UI
- 46% of short-term and 76% of long-term nursing home residents report UI[4]

UI can result from abnormalities within (intrinsic to) and outside of (extrinsic to) the urinary tract. Within the urinary tract, abnormalities may occur in the urethra (including the bladder outlet and urinary sphincters), the bladder, or a combination of both structures. Focusing on abnormalities in these two structures, a simple classification scheme emerges for all but the rarest intrinsic causes of UI. KEY CONCEPT Accurate diagnosis and classification of UI type is critical to the selection of appropriate drug therapy.

LO 1 PATHOPHYSIOLOGY

Stress Urinary Incontinence[5]

Stress urinary incontinence (SUI) occurs most frequently in women and is related to the underactivity of urethra and/or urethral sphincters, leading to inadequate resistance to impede urine flow from the bladder. SUI occurs when intraabdominal pressure is elevated by exertional activities like exercise, running, lifting, coughing, and sneezing. SUI is usually episodic, associated with small volume leakage and rarely causes nocturia or **enuresis**. The etiology for urethral underactivity is not completely understood, although the loss of the trophic effects of estrogen on the uroepithelium at menopause is thought to be

Patient Encounter 1, Part 1

A 60-year-old woman presents to the clinic complaining of a strong, sudden urge to urinate every 2 to 3 hours while awake. Every day she makes about 8 to 10 trips to a bathroom, and gets up once or twice each night to urinate. She reports no clothes-wetting accidents so far, but is fearful that "it will happen someday in the public." She has stopped "window shopping and walking program" in a huge mall near her house. The activity was her favorite pastime after retirement until 2 months ago when she almost experienced a wetting accident. Since then, she has avoided several social and family events. At this clinic visit, she denies any urinary leakage when she coughs, laughs, or exercises. She is diagnosed with overactive bladder without urinary incontinence. Patient prefers to try an oral drug that is administered once daily. She dislikes the feeling of dry mouth. She has prescription coverage, as well as a secondary private prescription insurance plan for out-of-pocket deductibles and copayments.

What information is suggestive of overactive bladder?

What additional information is necessary to differentiate overactive bladder from stress, overflow, and functional urinary incontinence? Are there any exacerbating factors?

What additional information do you need to know before creating a treatment plan for this patient?

important. The peak of SUI prevalence in the perimenopausal years supports this hypothesis. Clearly established risk factors for SUI include the following:

- Pregnancy (increased risk with increased parity)
- Childbirth (vaginal delivery)
- Menopause
- Cognitive impairment
- Obesity
- Increasing age

SUI is exceedingly rare in males unless the sphincter mechanism is compromised by surgery or trauma. The most common surgeries predisposing to SUI in males are radical prostatectomy for prostate cancer and transurethral resection of the prostate for benign prostatic hyperplasia (BPH).

Urge Urinary Incontinence[5]

UUI is related to the overactivity of detrusor muscle in the bladder, which contracts inappropriately during the filling (urinary storage) phase and generates **urgency**. The bladder contractions are due to the stimulation of muscarinic cholinergic receptors, especially M2 and M3 subtypes. UUI is associated with large volume leakage, sometimes complete bladder emptying, nocturia and enuresis; thus UUI may disrupt sleep. Overactive bladder (OAB) is a symptom syndrome with or without associated UUI.[6]

Most women with UUI or OAB have no identifiable causes (idiopathic), while in men similar symptoms are associated with benign prostatic hyperplasia (see Chapter 52). Overactivity may be myogenic and/or neurogenic. Clearly established risk factors for UUI include:

- Older age
- Neurologic disorders (eg, stroke, Parkinson disease, multiple sclerosis, and spinal cord injury)
- Bladder outlet obstruction (eg, benign or malignant prostatic enlargement or hyperplasia)
- **Hysterectomy**
- Recurrent UTIs

Overflow Urinary Incontinence[5]

Overflow urinary incontinence (OUI) is a less common form of UI in men or women. It is related to urethral overactivity and/or bladder underactivity. In short, the bladder is filled to capacity at all times but cannot empty, causing urine to leak out episodically. If caused by bladder underactivity, the progressively weakened detrusor muscle eventually loses the ability to voluntarily contract, which leads to incomplete voiding and large residual urinary volume after **micturition**. Both myogenic and neurogenic factors have been associated with impaired bladder contractility that leads to OUI. Common neurogenic factors are diabetes, lower spinal cord injury, multiple sclerosis, or radical pelvic surgery.

If OUI is due to urethral overactivity, incomplete bladder emptying occurs because the resistance of the urethra and/or sphincters cannot be overcome by detrusor contractility. In men, this most frequently occurs in cases of long-term chronic bladder outlet obstruction due to BPH, prostate cancer, or abdominal-pelvic surgeries. In women, urethral overactivity is rare, but may result from **cystocele** formation or surgical overcorrection for SUI. In both genders, systemic neurologic diseases such as multiple sclerosis or spinal cord injury may be the etiology.

Functional UI[5]

Functional UI is generally caused by extrinsic factors to the urinary tract, such as:

- Immobility (due to pain, physical limitations)
- Inadequate or delayed access to toileting facilities
- Neurologic impairment (Parkinson disease, multiple sclerosis, spinal cord injury, stroke, apathy due to depression)
- UTIs
- Postmenopausal **atrophic urethritis**, and/or vaginitis

LO 2

Clinical Presentation of Stress Urinary Incontinence (SUI) Related to Urethral Underactivity[5]

General

Usually occurs during activities like exercise, running, lifting, coughing, or sneezing; much more common in females.

Symptoms

Urine leakage volume is proportional to activity level; not associated with nocturia. No SUI with physical inactivity, especially when supine. May develop urgency and frequency as a compensatory mechanism (or independently as a separate component of bladder overactivity).

Diagnostic Tests

Observation of urethral meatus (opening) while patient coughs or strains.

LO 2

Clinical Presentation of Urge Urinary Incontinence (UUI) Related to Bladder Overactivity[5]

General

If sensory input from the lower urinary tract is absent, may have bladder overactivity and urine leakage without urgency. Patient with overactive bladder (OAB) may not have UUI.

Symptoms

Patients with OAB typically present with symptoms of urgency, frequency, nocturia with or without UUI.

Diagnostic Tests

Urodynamic studies are the gold standard for diagnosis. UTI must be ruled out by urinalysis and urine culture.

LO 2

Clinical Presentation of Overflow Urinary Incontinence (OUI) Related to Urethral Overactivity and/or Bladder Underactivity[5]

General

Rare type of UI in both genders. Urethral overactivity is usually due to prostatic enlargement (males) or cystocele formation or surgical overcorrection for SUI (females). Bladder underactivity is usually due to a weakened detrusor muscle.

Symptoms

Lower abdominal fullness, hesitancy, straining to void, decreased force of stream, interrupted stream, sense of incomplete bladder emptying. May have urinary frequency and urgency, as well as abdominal pain if acute urinary retention occurs.

Signs

Increased postvoid residual urine volume.

- Diabetes mellitus (glucosuria leading to polyuria)
- Diabetes insipidus (polyuria due to decreased antidiuretic hormone [ADH])
- Pelvic malignancy (extrinsic pressure on urinary tract structures causing obstruction)
- Constipation or fecal impaction
- Congenital malformations of the urinary tract system

Mixed and Drug-Induced UI[5]

Mixed urinary incontinence (MUI) occurs when two or more types of UI coexist in a given patient, which may lead to diagnostic and therapeutic difficulties. Patients may experience worsening of symptom due to the opposing effects of treatments indicated for specific and different types of UI.

KEY CONCEPT Many medications can influence the lower urinary tract system, and can precipitate or aggravate existing voiding dysfunction that leads to UI (Table 53–1).

CLINICAL PRESENTATION AND DIAGNOSIS

Guidelines are available for the assessment, diagnosis, and management of UI or OAB.[6-10] In general, obtaining a complete medical history and performing a targeted physical examination are essential to correctly classify the type(s) of UI. The degree of annoyance perceived by the patient due to urinary symptoms must be assessed. However, it may not correlate well with quantitative tests such as symptom frequency/severity, use of absorbent products, and postvoid residual (PVR) urine volume (Table 53–2). Major components of the physical examination include the following:[5]

- Abdominal examination for distended bladder, organomegaly, and masses
- Neurologic evaluation of perineum and lower extremities to evaluate lumbosacral nerve function (includes digital rectal

Table 53–1

Medications Influencing Lower Urinary Tract Function

Medication	Effect
Diuretics	Polyuria, frequency, urgency
α-Adrenoceptor antagonists	Urethral relaxation: may relieve obstruction in males, induces/worsens SUI in females
α-Adrenoceptor agonists	Urethral constriction: aggravates obstruction in males (may cause urinary retention), potential SUI treatment in females
Calcium channel blockers (dihydropyridines)	Urethral constriction (may cause urinary retention), especially in males
Opioid analgesics	Impaired bladder contractility (may cause urinary retention)
Sedative-hypnotics	Functional UI due to immobility, delirium, sedation
Psychotherapeutics with anticholinergic properties; anticholinergics	Urinary retention due to impaired bladder contractility or potential UUI treatment
TCAs	Combination of anticholinergic and α-adrenoceptor blocking activities can lead to unpredictable effects on UI
Ethanol	Polyuria and frequency (via effects on ADH), functional UI (delirium, sedation), urgency
ACEIs	Cough leading to SUI (ARBs do not induce cough)
Cyclophosphamide	Hemorrhagic cystitis due to acrolein metabolite (prevent with MESNA)

ACEIs, angiotensin-converting enzyme inhibitors; ADH, antidiuretic hormone (or vasopressin); ARB, angiotensin II receptor blocker; MESNA, sodium 2-mercaptoethanesulfonate; SUI, stress urinary incontinence; TCA, tricyclic antidepressant; UI, urinary incontinence; UUI, urge urinary incontinence.

Table 53–2

Items to Address during Diagnostic Evaluation of UI

Item	Comments
Urine Leakage	
Use of absorbent products	Type(s), quantity, times of day worn
Urine leakage per episode	Dribbling, small or large volumes, intermittently; consistent or varied quantities
Precipitants	Physical activity, excessive fluid intake, drug(s)
Times of day	Daytime/nighttime/both
Symptoms	
Urgency	Frequency, severity, duration from urge onset to micturition
Frequency	Daytime/nighttime/both, how often
Nocturia	How often, proportion associated with UI
Obstructive symptoms	Type(s) (hesitancy, strain to void, decreased force of stream, start and stop stream, sense of incomplete emptying), severity
Lower abdominal fullness	Frequency, severity
Comorbidities	
Current medication use	See Table 53–1. Remember CAMs, OTCs
Evidence of preexisting or new-onset:	
Diabetes mellitus	
Metastatic or genitourinary malignancy	
Multiple sclerosis or other neurologic disease	
CNS disease above the pons	Usually UUI
Spinal cord injury	UUI or OUI, depending on level and degree of completeness of injury
Recent nongenitourinary surgery	Functional UI
Previous local surgery/radiation	Prostate surgery, lower abdominal cavity surgery (direct injury versus denervation), radiation (direct injury)
Gynecologic history	Childbirth (vaginal versus cesarean section), prior gynecologic surgery, hormonal status (pre- versus peri- versus postmenopausal)
Pelvic floor disease	Constipation, diarrhea, fecal incontinence, dyspareunia, sexual dysfunction, pelvic pain
UTI	Dysuria, CVA tenderness, frequency
Gross Hematuria	Possible bladder or other genitourinary cancer

CAM, complementary and alternative medications; CVA, costovertebral angle; OTC, over-the-counter; OUI, overflow urinary incontinence; UTI, urinary tract infection; UUI, urge urinary incontinence.

examination to check rectal tone, reflexes, ability to perform a voluntary pelvic muscle contraction in females; size and surface quality of prostate in males)

- Pelvic examination in women for evidence of prolapse of bladder, small bowel, rectum, or uterus, or signs of estrogen deficiency
- Genital/prostate examination in men
- Urinalysis, PVR urine volume
- Direct observation of urethral meatus (opening) when patient coughs/strains (urine spurt consistent with SUI) (cough stress test)
- Perineal examination for skin maceration, redness, breakdown, ulceration, and evidence of fungal skin infection

Clinicians could inquire about UI and OAB with open- and closed-ended questions:[11]

- Do you leak urine when you cough, sneeze, laugh, etc?
- Do you have to get up more than once at night to urinate?
- Do you feel the urge to urinate frequently?
- How many times do you typically urinate from waking in the morning until going to bed in the evening?
- How many times do you typically wake up to urinate from going to sleep at night until waking in the morning?
- How often do you have a sudden compelling desire to urinate, which is difficult to postpone?
- How often do you leak urine because you cannot postpone the sudden desire to urinate?

TREATMENT

Desired and realistic treatment outcomes should be individualized and discussed with each patient. KEY CONCEPT The treatment goals for UI may change with time, and often require reaching a compromise between efficacy and tolerability of drug therapy.

Desired Outcomes

LO 3

- Restoration of continence
- Reduction of the number of UI episodes (daytime and nighttime) and nocturia
- Prevention or delaying of complications associated with UI (eg, pressure ulcers, skin conditions)
- Minimization of adverse effects and costs related to treatment
- Improvement in quality of life

Nonpharmacologic Treatment

At the primary care level, nonsurgical, nonpharmacologic intervention constitutes the chief approach to the management of UI. It has no adverse reactions, is minimally invasive, and can be utilized adjunctively with other treatment modalities. KEY CONCEPT Nonpharmacologic treatment gives at least an additive effect in efficacy when combined with drug therapy, and can allow the use of lower drug doses. It is ideal for patients who fit the following scenarios:

- Being medically unfit for surgery
- Planning for pregnancies/childbirths, which can compromise the long-term results of certain types of continence surgery

- Having OUI whose condition is not amenable to surgical or drug treatment
- Avoiding drug therapy or surgery due to safety concern or patient preference

These approaches include lifestyle/behavioral modifications, fluid management, scheduled voiding regimens, pelvic floor muscle rehabilitation (PFMR; common term "Kegel exercises"), external neuromodulation, anti-incontinence devices, acupuncture, and supportive interventions.[3,5,12,13] Many of these are best utilized through attendance at multidisciplinary UI clinics staffed by specialized health care providers. Weight loss of 5% to 10% in overweight or obese women has an efficacy similar to that of other nonpharmacologic treatments for treating SUI. Therefore, weight loss and exercise are recommended for obese women with any of the three types of UI.[8,10]

Bladder training and prompted voiding improve symptoms of UUI and MUI. PFMR is an effective treatment for adult women with SUI and MUI.[8] Combination therapy with PFMR plus behavioral training achieved better outcomes than drug therapy in women with UUI. However, these methods require motivation from patients. Medical conditions, such as cognitive dysfunction, may interfere with active participation and compromise efficacy. Regular follow-ups are important for monitoring outcomes and for providing reassurance and support. Lifestyle/behavioral interventions should be continued during drug therapy in patients with UI, even if the results have not fully achieved the desired outcomes. PFMT is strongly recommended for SUI; bladder training may be recommended for UUI; and the combination of both is strongly recommended for MUI.[8,10]

External neuromodulation may include nonimplantable electrical stimulation, percutaneous tibial nerve stimulation, or extracorporeal magnetic stimulation. This treatment option is typically prescribed when traditional PFMR has failed. Anti-incontinence devices, such as bed alarms, catheters, pessaries, penile clamps, and external collection devices, are reserved for special situations depending on patient's symptoms, cognition, mobility status, and overall health status. Supportive interventions such as physical therapy may be beneficial for patients with muscle weakness and slow gait that hinder their ability to reach to the toilet in a timely manner. Lastly, absorbent products provide greater patient confidence in dealing with unpredictable urine loss.[5]

Surgery is rarely an initial treatment for UI; only considered in patients with significantly bothersome symptoms, and when nonsurgical options are undesired or ineffective. Surgery is not as helpful for bladder underactivity, but it can be used to manage urethral overactivity due to BPH and bladder outlet obstruction (via endoscopic incision using a cystoscope). It is most effective for SUI by stabilizing the urethra and bladder neck and/or augmenting urethral resistance. Common approaches are injection of periurethral bulking agents and midurethral sling procedure. In males, SUI is best treated by implanting an artificial urinary sphincter.[5]

Posterior tibial nerve stimulation is an office-based percutaneous treatment for UUI or OAB. Therapy consists of weekly 30-minute treatments with a needle placed posterior to the medial malleolus of the ankle over the course of 3 months. Efficacy appears similar to or slightly better than oral pharmacotherapy.[5]

Surgical treatment for UUI generally consists of implantation of a sacral nerve stimulator (neuromodulation) or endoscopic office based injection of botulinum toxin A directly into the smooth or striated muscle.[5] The injections are performed in the office generally with local anesthesia. The duration of effect of the toxin is about 4 to 8 months after which repeat injection is necessary to maintain effect. Intravesical (bladder) botulinum toxin A injections increased bladder capacity/compliance and improved quality of life in patients with refractory OAB.[5]

Patients with UUI and an elevated PVR urine volume may require intermittent self-catheterization along with frequent voiding between catheterizations. Surgical placement of a suprapubic catheter may be necessary in cases when intermittent catheterization is not possible. Catheterization can be combined with pharmacologic treatment for symptom relief.[5]

Patient Encounter 1, Part 2

PMH: Hypertension, congestive heart failure, diabetes mellitus type 2, mild dementia

FH: Noncontributory

SH: Retired business owner. Lives with husband. Two married daughters (ages 33 and 28 years) live in the same state. Drinks one glass of red wine with dinner everyday. Drinks one cup (16 oz) of coffee in the morning and one cup (8 oz) at lunch

All: NKDA

Meds: Enalapril 5 mg once daily, simvastatin 10 mg once daily, furosemide 40 mg daily, metformin 500 mg twice daily, donepezil 5 mg daily

ROS: Alert and pleasant. (–) UTI, (–) dysuria, lower abdominal fullness, or decreased force of stream, (+) nocturia

PE:

VS: BP 110/70 mm Hg, HR 85 beats/min, RR 20 breaths/min, T 36.8°C (98.3°F), Wt 209 lbs (95 kg), Ht 5'5" (165 cm)

HEENT: PERRLA; EOMI, TMs WNL

Neck/LN: Supple w/o LAD or masses

Lungs/Thorax: CTA

CV: RRR w/o murmurs, rubs, gallops

Abd: Soft, NT/ND w/o masses; (+) BS; bladder not palpable

GU: WNL; no atrophic vaginitis or uterine prolapse

MS/Ext: WNL, no edema

Neuro: DTRs 2+, CN II–XII intact

Labs: All within normal limits. SCr 1.0 mg/dL (88 µmol/L). LFTs within normal limits

Given this additional information, what is your assessment of the patient's condition?

What are the goals of pharmacotherapy for this patient?

What nonpharmacologic and pharmacologic options are available to the patient?

Pharmacologic Treatment

LO 4

The ideal treatment agent must have clinical efficacy, minimal side effects, minimal drug–drug or drug–disease interactions, convenient administration, and affordable cost. KEY CONCEPT Patient characteristics (eg, age, comorbidities, concurrent drug therapies, and ability to adhere to the prescribed regimen) can influence drug therapy selection.[5] Although a recent systematic review has shed light on the comparative data on newer agents,[14] selection of an initial agent should be based on patient individual characteristics.

▶ *Urge Urinary Incontinence*

Anticholinergic/Antimuscarinic

Antimuscarinic agents are the first-line pharmacologic treatment for UUI or OAB (Table 53–3).[6] They are effective in suppressing premature detrusor contractions, enhancing bladder storage, and relieving symptoms. When used with or without bladder training, these agents improved symptoms and quality of life in patients with UUI or OAB; however, they restore continence in less than 15% of patients and reduce episodes of incontinence by only 0.5 to 1 episodes per day.[14,15] They are considered equally effective based on statistical superiority over placebo or active controls.

All antimuscarinic agents have similar contraindications and precautions, including urinary retention, gastric retention, and uncontrolled narrow-angle glaucoma.[5] Older immediate release (IR) agents, such as oxybutynin and tolterodine, have been associated with higher rates of dry mouth, constipation, headache, dyspepsia, dry eyes, cognitive impairment, tachycardia, and urinary retention (Table 53–4). Older patients are especially susceptible to these adverse events. Significant dry mouth can be associated with dental caries, ill-fitting dentures, and swallowing difficulty. Chewing sugarless gum or use of saliva substitutes can help to alleviate dry mouth.

Orthostatic hypotension and sedation can be particularly troublesome to patients with cognitive impairment or at risk for falls. Issues with tolerability and multiple daily dose administration associated with IR products may jeopardize medication adherence and can prevent dose titration to achieve optimal clinical response. Thus, these IR products are not preferred in patients with functional limitations and/or those who are already taking complicated drug regimens. Nevertheless, adverse events are not universal and the severity varies with individuals. Older agents, when initiated at the lowest possible doses and gradually titrated, are reasonable to consider in cases when long-acting products are undesirable (eg, troubles with swallowing).

Extended-release (ER) agents (oxybutynin XL, tolterodine LA, trospium ER, darifenacin ER, fesoterodine ER) cause less dry mouth compared with IR products.[5,7] These products cannot be chewed, crushed, or divided, and must be swallowed whole. Oxybutynin transdermal patch and topical gel are alternatives for patients who cannot take or tolerate oral drugs; they have lower rates of dry mouth but are associated with application site reactions. Rotation of application sites can be helpful to minimize the side effects.

Patients receiving any antimuscarinic agent should be informed about sedation as a possible side effect and warned against operating heavy machinery, such as driving, especially during the initial phase of therapy. Patients with existing cognitive dysfunction or difficulty with balance should be monitored closely for mental status changes and risk for falls. Older individuals are more prone to experience constipation because they are more likely to take medications which affect bowel function. Patients should be advised to contact their physician if they experience severe abdominal pain or become constipated for 3 or more days. Clinicians should monitor potential drug interactions between antimuscarnic agents and acetylcholinesterase inhibitors, which are used to treat dementia (antagonism). Also, concomitant use with any other anticholinergic agents increases side effects.

KEY CONCEPT Antimuscarinic agents should be initiated at the lowest possible dose and gradually titrated upward based on clinical response; however, not to exceed the maximum recommended dose. A trial of at least 4 weeks is required to evaluate its efficacy. Consider switching to another agent if the patient reports intolerable side effects or inadequate symptom relief despite optimized dose and duration.

Mirabegron Mirabegron is a β_3-adrenergic agonist approved in June 2012 for the treatment of OAB with UUI. Like antimuscarinic agents, it reduces urinary frequency and incontinence episodes by less than one per day and is also considered the first-line drug therapy for OAB (see Table 53–3).[6,16] It increases bladder capacity by relaxing the detrusor smooth muscle during the storage phase of the urinary bladder fill-void cycle. It requires 4 to 8 weeks of therapy for optimal efficacy.[16]

Mirabegron is available as ER tablets, and should be swallowed whole without chewing, dividing, or crushing. Most commonly reported adverse reactions are hypertension (7%–11%), nasopharyngitis (4%), UTI (3%–6%), and headache (3%–4%). Patient should be monitored for increased blood pressure and urinary retention, particularly in patients with bladder outlet obstruction or those who are taking anticholinergic drugs.[5] Currently, there is no direct comparison of mirabegron and antimuscarinics for efficacy or tolerability.

Older Agents[5] Tricyclic antidepressants (TCA), such as desipramine, nortriptyline, imipramine, and doxepin, are generally no more effective than oxybutynin IR. They may cause potentially serious adverse effects (eg, orthostatic hypotension, cardiac conduction abnormalities, dizziness, and confusion) and thus should be limited to individuals who have one or more indicated comorbidities (eg, depression or neuropathic pain), patients with MUI (because of their effect of decreasing bladder contractility and increasing outlet resistance), and possibly those with nocturnal incontinence associated with altered sleep patterns. Propantheline, flavoxate, dicyclomine, and hyoscyamine are not recommended due to lack of efficacy and/or significant adverse effects.[5]

▶ *Stress Urinary Incontinence*

The goal of pharmacologic therapy of urethral underactivity is to improve the urethral closure mechanism by:

- Stimulating α-adrenoceptors in the smooth muscle of the proximal urethra and bladder neck
- Enhancing the supportive structures underlying the urethral mucosa
- Enhancing the positive effects of serotonin and norepinephrine in the afferent and efferent pathways of the micturition reflex

In general, systemic pharmacologic therapy is not recommended for SUI.[8,10] PFMT is the first-line therapy in

Patient Encounter 1, Part 3

Based on the information presented, create a care plan for this patient's OAB. Your plan should include:

(a) A statement of the drug-related needs and/or problems

(b) A patient-specific detailed therapeutic plan, including patient counseling to enhance medication adherence, ensure successful therapy, and minimize adverse effects

(c) A plan for follow-up to evaluate therapeutic outcome and drug tolerability

Table 53–3

Approved Drugs for the Management of UUI

Parameter	Oxybutynin	Tolterodine	Trospium Chloride	Solifenacin	Darifenacin	Fesoterodine	Mirabegron
Dosage forms	IR tablets, solution SR-ER tablets, SR-TD patch, topical gel	IR tablets SR-LA capsules	IR tablets ER tablets	IR tablets	ER tablets	ER tablets	ER tablets
Dosing	IR: 2.5–5 mg 2–4 times daily (pediatrics 0.3–0.5 mg/kg/day in three doses) SR (oral): 5–30 mg once daily (pediatrics: 0.3–0.5 mg/kg/day) SR (TD): 3.9 mg/day patch applied twice weekly; available over-the-counter SR (gel): 1 sachet (100 mg) applied once daily	IR: 1 or 2 mg twice daily (pediatrics: 1 mg twice daily) ER: 2 or 4 mg once daily (pediatrics: 2 mg once daily)	IR: 20 mg twice daily ER: 60 mg once daily	5–10 mg once daily	7.5–15 mg once daily	4–8 mg once daily	25 mg once daily, then 50 mg once daily after 8 weeks
Kinetics	Active metabolite (*N*-desethyl) Not altered in renal or hepatic disease or advanced age	Active metabolite (5-hydroxymethyl) Polymorphic metabolism (CYP 2D6) Not altered in advanced age. Significantly altered in hepatic disease (decreased CL in cirrhosis) and renal disease (decreased CL)	Food: decreased F by 70%–80% Significantly altered in renal disease (decreased CL) but not in hepatic disease or advanced age	Metabolized via CYP 3A4 but only one active metabolite (4-hydroxy) Significantly altered in severe renal impairment, moderate hepatic impairment (Child-Pugh B), and advanced age (decreased CL in all)	Complex metabolism (polymorphic CYP 2D6, CYP 3A4) Not altered in advanced age, renal impairment, mild hepatic impairment (Child-Pugh A) Significantly altered in moderate hepatic impairment (Child-Pugh B) (decreased CL)	Prodrug (for 5-hydroxmethyl tolterodine) Inactive metabolites Not altered in advanced age Significantly altered in renal disease (decreased CL) and moderate hepatic impairment (Child-Pugh B) (decreased CL)	Terminal elimination half-life 50 hours Moderate inhibitor of CYP 2D6
Contraindications and precautions	Use with caution if CYP 3A4 inhibitors are also being taken (decreased oxybutynin CL)	Reduce dose 50% in those taking CYP 3A4 inhibitor(s) or with hepatic cirrhosis or with CrCl < 30 mL/min (0.50 mL/s) Antacid-SR (oral) prep, interaction (dose-dumping) (not seen with PPIs)	Give on empty stomach Do not use ER when CrCl < 30 mL/min (0.50 mL/s); use IR 20 mg once daily at bedtime	Do not exceed 5 mg/day if CrCl < 30 mL/min (0.50 mL/s), patient has moderate hepatic impairment, or patient is taking CYP 3A4 inhibitor(s) If severe hepatic impairment, do not use	Do not exceed 7.5 mg/day if patient is taking potent CYP 3A4 inhibitor(s) Use caution if patient is taking moderate CYP 3A4 inhibitor(s) or CYP 3A4 or 2D6 substrate(s) Do not chew, divide, or crush the ER tablets	Do not exceed 4 mg/day if CrCl < 30 mL/min (0.50 mL/s) or patient is taking potent CYP 3A4 inhibitor(s) If severe hepatic impairment, do not use	Limit dose to 25 mg once daily if severe renal impairment or moderate hepatic disease Avoid in end-stage renal disease or severe hepatic impairment, or more BP 180/110 mm Hg Monitor for increased BP and urinary retention Do not chew, divide, or crush

BP, blood pressure; CL, total body clearance; CrCl, creatinine clearance; ER, extended release; F, bioavailability; IR, immediate release; LA, long acting; PPIs, proton pump inhibitors; SR, sustained release; TD, transdermal.

Table 53–4

Adverse Event Incidence Rates with Approved Drugs for Bladder Overactivity[a]

Drug	Dry Mouth (%)	Constipation (%)	Dizziness (%)	Vision Disturbance (%)
Oxybutynin IR	71	15	17	10
Oxybutynin XL	61	13	6	14
Oxybutynin TDS	7	3	NR	3
Oxybutynin gel	10	1	3	3
Tolterodine	35	7	5	3
Tolterodine LA	23	6	2	4
Trospium chloride IR	20	10	NR	1
Trospium chloride XR	11	9	NR	2
Solifenacin	20	9	2	5
Darifenacin	24	18	2	2
Fesoterodine	27	5	NR	3
Mirabegron ER	3	3	3	NR

[a]All values constitute mean data, predominantly using product information from the manufacturers.

IR, immediate-release; LA, long-acting; NR, not reported; TDS, transdermal system; XL, extended-release; XR, extended-release.

women with SUI.[10] Nevertheless, SUI in women is frequently curable by surgery, thus obviating years of drug therapy that may not provide adequate symptom relief. Surgery (tension-free vaginal tape sling) is a more cost-effective therapy of SUI than duloxetine in women failing PFMR.[17] Automatic pelvic exercise devices, incontinence pessaries, and disposable intravaginal bladder support devices can also be considered for SUI.[10]

Estrogens[5] KEY CONCEPT Local vaginal estrogen preparations can effictvely relieve the genitourinary syndrome of menopause, including urinary complaints of frequency, urgency, and SUI.[18] Estrogen products are believed to work by a trophic effect on uroepithelial cells and underlying collagenous subcutaneous tissue, enhancement of local microcirculation by increasing the number of periurethral blood vessels, and enhancement of the number and/or sensitivity of α-adrenoceptors.

Since 1940s, estrogens administered by various routes (oral, transdermal, and local) have been used to manage SUI although recent trials showed them to be no better than placebo. Actually, oral hormone replacement therapy increases the risk of new-onset UI (SUI, UUI, MUI) while carrying numerous short- and long-term risks, including mastodynia, uterine bleeding, nausea, thromboembolism, cardiac/cerebrovascular ischemic events, and breast/endometrial cancer.[19] In contrast, local estrogens (estriol [not available in the United States] tablets, conjugated equine estrogen cream, estradiol rings, pessaries) have demonstrated subjective improvement in SUI and UI in general.[19] Local products, such as estrogen ring, may have dual effects: functioning like an incontinence pessary by supporting the bladder neck while simultaneously providing estrogen locally (Table 53–5).

α-Adrenoceptor Agonists[5] Phenylpropanolamine, ephedrine, and pseudoephedrine have been used alone or with estrogen for mild and moderate SUI. However, recent data showed that they are not better than placebo or PFMR.[18] Phenylpropanolamine has been removed from the market in the United States due to associated risk of ischemic stroke. Ephedrine, although still available by prescription, should not be used for SUI due to toxicity and lack of efficacy data. The major impediment to using α-adrenoceptor agonists is the extensive list of contraindications (see Table 53–5). Side effects of pseudoephedrine, an over-the-counter medication, include hypertension, headache, dry mouth, nausea, insomnia, and restlessness.

Duloxetine This selective serotonin-norepinephrine reuptake inhibitor is approved to treat SUI in Europe, but is off-label in the United States. It enhances central serotonergic and adrenergic tone, which is involved in ascending and descending control of urethral smooth muscle and the internal urinary sphincter, and thereby enhances urethral and urinary sphincter smooth muscle tone during the filling phase.[20] It may benefit incontinence and quality of life in men with SUI after radical prostatectomy.[21]

The use of duloxetine in SUI is complicated by intolerability (eg, high rates of nausea), numerous precautions or contraindications, CYP P450 drug–drug interactions, and possibility of withdrawal symptoms if abruptly discontinued.[20] Due to its modest benefit and intolerability issues, it may be considered only if there are comorbiditeis such as depression, anxiety, fibromyalgia, diabetic neuropathy, and chronic musculoskeletal pain.

The usual dosage is 40 to 80 mg/day (in one or two doses) for 12 weeks. Gradual dose titration (starting from 20 mg once daily for at least 1 week, then titrate no shorter than weekly interval) may help to reduce the risks of nausea, dizziness, and premature therapy cessation. Similarly, taper the dose to avoid withdrawal symptoms if duloxetine is discontinued. Dose reduction of 50% for 2 weeks before discontinuation or slow tapering over 4 to 6 months is reasonable.

▶ *Overflow Incontinence[5]*

There is no established effective pharmacologic therapy for OUI due to bladder underactivity (atonic bladder). A trial of bethanechol (25–50 mg three or four times daily) may be reasonable if contraindications do not exist. Bethanechol is a cholinomimetic that has uncertain efficacy but is associated with bothersome and potentially life-threatening side effects (muscle and abdominal cramping, hypersalivation, diarrhea, and bronchospasm), particularly in patient with preexisting conditions. α-Adrenoceptor antagonists, such as silodosin, prazosin, terazosin, doxazosin, tamsulosin, and alfuzosin, may be beneficial for OUI by relaxing the bladder outflow tract and hence reducing outflow resistance. If pharmacologic therapy fails, intermittent urethral catheterization by the patient or caregiver three or four times per day is recommended. Less satisfactory alternatives include indwelling urethral or suprapubic catheters or urinary diversion. In OUI due to obstruction, such as BPH, the goal of treatment is to relieve the obstruction.

Table 53–5

Drugs Used for SUI[a]

Parameter	Estrogens	Pseudoephedrine	Duloxetine
Dosage forms	Avoid systemic (parenteral, oral, TD); use vaginal: tablet, cream, intravaginal ring	Tablets, solution	DR capsules
Dosing	Estradiol 25-mcg vaginal tablets (insert one PV daily for 14 days, then one PV twice weekly) Estradiol vaginal cream (0.1 mg/g) (2–4 g daily PV for 1–2 weeks; then 1 g PV daily or less frequently) CEE vaginal cream (0.625 mg/gm) (0.5–2 g daily PV; consider 3 weeks on, 1 week off; may be able to decrease frequency of use over time) Estradiol 2-, 12.4-, 24.8-mg vaginal rings (1 ring PV every 3 months)	15–60 mg three times daily	40–80 mg/day in one or two doses for 12 weeks (titrate and taper dosage)
Kinetics	Use local route to minimize systemic F and side effects Estradiol less likely to be absorbed; CEE 1 mg or more daily sufficiently absorbed to cause systemic side effects	Less than 1% of dose is metabolized (inactive metabolites) Primarily renal elimination of unchanged drug Would not expect hepatic impairment to have an effect (no data) Expect significant effect if renal impairment and no effect if advanced age (beyond decreased CrCl with age) (no data)	Extensive metabolism via CYP 2D6 and 1A2 (inactive metabolites) Not altered in advanced age, mild to moderate renal impairment (CrCl 31–80 mL/min [0.51–1.34 mL/s]), mild hepatic impairment (Child-Pugh A) Significantly altered in severe renal disease (CrCl < 30 mL/min [< 0.50 mL/s]) and moderate hepatic impairment (Child-Pugh B)
Contraindications/ precautions	Known or suspected breast or endometrial cancer Abnormal genitourinary bleeding of unknown etiology Active thromboembolism (or history of TE associated with previous estrogen use)	Hypertension, tachyarrhythmias, coronary artery disease, MI, cor pulmonale, hyperthyroidism, renal failure, narrow-angle glaucoma	Multiple drug–drug interactions possible with CYP 2D6 and 1A2 substrates/inhibitors Avoid if CrCl < 30 mL/min (0.50 mL/s) and in all patients with hepatic disease Can raise BP Do not discontinue abruptly (withdrawal syndrome) Suicide risk even in patients without psychiatric disease Avoid in uncontrolled narrow-angle glaucoma (causes mydriasis) Hepatotoxic; avoid in alcoholics even if signs/symptoms of hepatic disease are absent

[a]None of these agents are FDA approved for treatment of SUI. Duloxetine is approved in Europe only.

BP, blood pressure; CEE, conjugated equine estrogens; CrCl, creatinine clearance; CYP, cytochrome P-450; DR, delayed-release; F, bioavailability; MI, myocardial infarction; PV, per vagina; TD, transdermal; TE, thromboembolism.

► *Mixed Urinary Incontinence*[5]

MUI is usually a combination of UUI plus SUI with one dominant component. It accounts for one-third of UI cases in women. A reasonable management approach is a combination of lifestyle/behavioral modifications and PFMR with pharmacotherapy appropriate to the dominant type of UI. For instance, antimuscarinics can be offered in UUI-predominant cases, whereas duloxetine, local estrogen, and α-adrenoceptor agonists in SUI-predominant cases. In some cases, the less dominant form of UI may respond, but usually not to a degree that is considered adequate by the patient. Most experts feel that SUI-predominant MUI is best treated initially using the nonpharmacologic approach plus surgery for SUI. Unfortunately, these patients with MUI are expected to have a lower success rate with surgery compared to those with pure SUI. The urge component may get better, stay the same, or get worse after surgery. Unfortunately, there is no a priori way to predict the response in a given individual.

► *Nocturia*

Desmopressin Nocturia may be caused by a wide array of factors, such as uncontrolled diabetes mellitus, congestive heart failure, bladder/prostate diseases, and use of medications, especially diuretics. Desmopressin is a synthetic vasopressin analog in intransal formulation that was approved in March 2017 in the United States for the treatment of nocturia due to nocturnal polyuria in adults who awaken at least 2 times per night to void. The product carries multiple contraindications which

may limit its use, especially in the elderly. Contraindications include hyponatremia, polydipsia, primary nocturnal enuresis, concomitant use of loop diuretics or glucocorticoids (systemic or inhaled), renal impairment, syndrome of inappropriate ADH secretion, concurrent illness that can cause fluid or electrolyte imbalance, moderate to severe heart failure, and uncontrolled hypertension. Intranasal desmopressin was approved based on clinical studies involving patients aged 50 years or older. The dose for patients younger than 65 years who are not at increased risk for hyponatremia is one spray (1.66 mcg) in either nostril nightly approximately 30 minutes before going to bed. In patients who are 65 years or older, or younger patients at risk for hyponatremia, the starting dose is 0.83 mcg nightly, which can be increased to 1.66 mcg after at least 1 week as needed.[22] Sublingual formulation was approved in Canada for nocturia. Desmopressin oral and sublingual formulations are indicated for primary nocturnal enuresis.

OUTCOME EVALUATION

- Monitor the patient for symptom relief. Has the treatment achieved the desired outcomes jointly developed by the health care team and the patient/caregiver? If so, to what degree? Inspect the daily diary completed by the patient/caregiver and quantitate the clinical response (eg, number of micturitions, number of incontinence episodes, and pad use) since the last visit. If a diary has not been used, ask the patient how many incontinence pads have been used and how they have been doing in terms of "accidents" since the last visit. If appropriate, administer a short-form instrument to measure the impact of symptoms, including quality of life. Compare the findings with previous results.
- Ask patients about adverse effects of drug therapy using a nonleading approach. Ask the patient/caregiver to judge their severity and what measures, if any, they have used to alleviate. Assess medication adherence (ask patient/caregiver about missed doses or do a pill count if the prescription containers are available at the visit).
- The balance of clinical response and tolerability should guide whether the drug dosage is increased, decreased, or left unchanged. Consider stopping/tapering off the regimen and initiate another drug option if bothersome adverse effects compromise patient safety and/or medication adherence.

LO 5

Patient Care Process: Urinary Incontinence

Collect Information:

- Identify urinary symptoms and ask the patient how the symptoms affect his or her daily living.
- Identify exacerbating factors and UI complications.
- Review concurrent medical conditions and obtain a thorough medication history, including use of prescription, nonprescription, and complementary/alternative drug products.
- Identify allergies, or serious adverse events related to the use of medications and other substances.
- Ask the patient and caregiver about their goals of therapy and socioeconomic factors that affect medication access and other aspect of care. In cognitively intact elderly patients, focus communications to elicit the preferences of the patient, not those of potential proxies.

Assess the Information:

- Assess the severity of urinary symptoms. Assess changes in quality of life (physical, psychological, social functioning, and well-being).
- Based on reported signs, symptoms, and exacerbating factors, determine whether a referral to specialized professional is required.
- Evaluate whether or not urinary symptoms could be disease-related or drug induced (see Table 53–1). Determine if any current or previous treatments are/were helpful for UI.

Develop a Care Plan:

- Help the patient and caregiver to set realistic goals of therapy.
- Consider whether lifestyle/behavioral modification, fluid management, and other nonpharmacologic treatment are feasible or desirable.
- Determine whether pharmacotherapy is indicated or desired by patient. Choose appropriate treatment regimen (drug choice, dosage, administration) for his or her type(s) of UI.
- Evaluate the patient for medication adherence, drug-related adverse events, allergies, and drug interactions with concomitant medications or disease states.

Implement the Care Plan:

- Educate the patient on lifestyle modifications that may improve symptoms: smoking cessation (for patients with cough-induced SUI), weight reduction (for those patients with SUI and UUI), constipation prevention in patients at risk, caffeine reduction, and diet/fluid modification. Note the timing and quantity of fluid intake, as well as possibility of avoiding foods or beverages that worsen UI.
- Provide patient education regarding the disease state, lifestyle modifications, and drug therapy (see Tables 53–3 and 53–5).
- Address any patient/caregiver concerns about disease state and its management, including timing of medication intake, potential adverse events, potential drug–drug or drug–disease interactions and importance of treatment adherence.

Follow-up: Monitor and Evaluate:

- Monitor for patient response in 1 or 2 weeks after therapy initiation.
- Develop a plan to assess efficacy after a minimum of 4 weeks.
- Determine whether the patient is experiencing any adverse effects or drug interactions.

PEDIATRIC ENURESIS

INTRODUCTION

UI, referred to as pediatric enuresis, is a common problem in children. In children less than 5 years of age, treatment is unnecessary because spontaneous cure is likely. Pediatric enuresis is subdivided into the following categories to clarify expectations of the condition and response to therapy:[23,24]

- Monosymptomatic enuresis: enuresis in children without other lower urinary tract symptoms or bladder dysfunction
- Primary enuresis: enuresis in children who have never been consistently dry throughout the night
- Secondary enuresis: enuresis in patients who have resumed wetting after a period of dryness of at least 6 months in duration
- Nonmonosymptomatic enuresis: enuresis in children with other lower urinary tract symptoms (eg, urgency, frequency, daytime incontinence, genital or lower urinary tract pain)

The emotional and developmental impacts from enuresis are significant and include social stigma and low self-esteem. Missing camp getaways and sleepovers can have a negative effect on peer relationships.[25]

EPIDEMIOLOGY AND ETIOLOGY

Five to seven million children and adolescents in the United States suffer from nocturnal enuresis; however, with each year of maturity, the percentage of bed-wetters declines by 15% without treatment due to maturation alone.[26] In the enuretic population, 80% to 85% are monosymptomatic, 5% to 10% are nonmonosymptomatic, and less than 5% have an organic cause.[27] Primary enuresis is twice as common as secondary enuresis.[27] The prevalence of enuresis is as follows:

- At 5 years of age: 15% to 25%
- At 12 years of age: 8% (boys) and 4% (girls)
- During adolescence: 1% to 3%

The etiology of enuresis is poorly understood, but there is a clear genetic link. Loci for enuresis are located on chromosomes 5, 12, 13, and 22. Risk factors include a familial link; when both parents have a history of enuresis as children, the child's incidence is 77% as compared to 44% with one parental history.[25,28] Sleep apnea, attention deficit disorder, autism, and obesity are also associated with pediatric enuresis.[25,26] Drug-induced causes of pediatric enuresis include lithium, clozapine, risperidone, valproic acid, selective serotonin reuptake inhibitors, and theophylline. In a minority of cases, psychological factors (eg, divorce of parents, school trauma, sexual abuse, or hospitalization) may contribute to secondary enuresis. Potentially treatable organic causes of enuresis are listed in Table 53–6.

Table 53–6

Major Potentially Treatable Organic Causes of Enuresis

Potentially Treatable by Surgery
- Ectopic ureter
- Lower UTI congenital anomalies
- Neurogenic bladder
- Bladder calculus (stone) or foreign body
- Obstructive sleep apnea

Potentially Treatable by Medications
- UTI
- Diabetes mellitus
- Diabetes insipidus
- Fecal impaction
- Constipation

UTI, urinary tract infection.

PATHOPHYSIOLOGY

LO 6

Microstructural abnormalities and maturational delays of neuronal circuits have been identified in the frontal cortex of children with enuresis.[25] Physiological factors associated with pediatric enuresis include reduced bladder function and/or capacity, altered arousal to a full bladder, detrusor over-activity at night, and/or nocturnal polyuria from lack of circadian rhythm of nocturnal ADH secretion.[25,28]

Definitions applicable to pediatric patients are helpful in discerning the etiology:

- Bladder capacity: (30 + [30 × age] mL)
- Nocturnal polyuria: urine production greater than 130% of expected bladder capacity for age
- Normal functional bladder capacity: maximum voided volume greater than 70% of expected bladder capacity for age

TREATMENT

Desired Outcomes

- Reduction in the number of enuresis episodes and restoration of continence[32]
- Partial response: a 50% to 89% reduction
- Response: 90% or more reduction
- Full response: 100% reduction or less than 1 symptom occurrence monthly
- Prevention of relapse (< 1 symptom recurrence monthly) and maintenance of treatment success[23]
- Continued success: No relapse in 6 months after the interruption of treatment
- Complete success: No relapse in 2 years after the interruption of treatment

Patient Encounter 2, Part 1

A 9-year-old boy is brought into your clinic. His mother seeks advice regarding her child's inability to stay dry for more than a few nights in a row. The child's father had a history of bedwetting until 11 years of age, when it resolved. The mother asks for an over-the-counter medication to help the child. The child is frustrated because he wants to attend a sleep-away camp and is concerned about being teased by his friends. The family recently moved across the country, are stressed, and the child already started classes at the new school.

What additional information do you need to know before creating a treatment plan for this child?

What risk factors does the child have for pediatric enuresis?

Clinical Presentation and Diagnosis: Pediatric Enuresis

Proper assessment of the child or adolescent with enuresis should explore every aspect of UI, including the genitourinary and nervous systems. The minimum assessment should include:[24,28,29]

- Interview of the child and parent(s), being sensitive to the emotional consequences of the enuresis.
- Direct physical examination, looking for enlarged adenoids/tonsils, bladder distention, fecal impaction, abnormal genitalia, spinal cord anomalies, and abnormal neurologic signs (look for an organic cause amenable to surgery or medications; see Table 53–6).
- Obtain urinalysis for glucose, protein, WBC, or leukocyte esterase; obtain urinalysis and urine culture if symptoms of UTI are present.
- A 7 or more day diary of wet and dry nights prior to intervention is useful to monitor the response to treatment.
- Nonmonosymptomatic enuresis may require a more extensive workup, including voiding cystourethrogram, renal and/or bladder ultrasound, urodynamics, and sleep studies.

- Prevention or minimization of disease complications (delay in childhood developmental milestones, adverse psychological effects on the child/caregivers)
- Minimization of adverse effects and costs related to treatment
- Improvement in the quality of life of the child and caregivers

Patient Encounter 2, Part 2

PMH: Unremarkable pregnancy/delivery. Developmental milestones WNL

Immunization: Up to date

FH, SH: Lives with both parents and two siblings, ages 3 and 6 years

Meds: None

ROS: (+) nocturnal incontinence 5 to 6 nights per week; no daytime incontinence; no UTIs, urgency, frequency, dysuria, lower abdominal fullness, or other lower urinary track symptoms; no signs of constipation or fecal impaction

PE:

VS: BP 100/70 mm Hg, P 82 beats/min, RR 16 breaths/min, T 37.0°C (98.6°F)

Resp: Clear breath sounds bilaterally

CV: Clear to auscultation, no murmurs

Abd: Soft, nontender, nondistended; (+) bowel sounds; bladder not palpable

Neuro: WNL (gross sensory, motor, reflexes)

GU, Rectal: Deferred

Labs: Urinalysis WNL

Given this additional information, what is your assessment of this child's enuresis?

Identify your treatment goals for this patient.

What nonpharmacologic and pharmacologic interventions are appropriate for this child?

General Approach to Treatment

Treatment is guided by the findings of the patient assessment. A referral to urologists is needed in cases of daytime wetting, abnormal voiding (eg, unusual posturing, discomfort, straining, poor stream), history of recurrent UTIs, and abnormalities of the genitalia. Psychotherapy is recommended in cases with a true psychological cause.

Guidelines for the evaluation and management of nocturnal enuresis have been developed.[24,28,29] Management of primary monosymptomatic nocturnal enuresis in children may involve one or a combination of interventions. The management of secondary nocturnal enuresis focuses on addressing the underlying contributing factor. However, most children with secondary enuresis are treated in the same manner as those with primary enuresis. The National Institute for Health Care and Excellence guideline algorithm (Figure 53–1) outlines useful treatments and distinguishes approaches based on the child's age, maturity, and abilities, and the frequency of enuresis.[29]

Initial management with education and motivational/behavioral therapy, called urotherapy, (Table 53–7) should be used for 3 to 6 months.[23,27] If this fails, an enuresis alarm or pharmacologic treatment may be chosen. KEY CONCEPT Enuresis alarms are the most effective and lasting first-line therapy. For a faster response or in unmotivated families, desmopressin is an effective and ideal agent for the short-term control of pediatric enuresis, especially for sleepovers or camp attendance. KEY CONCEPT Pharmacotherapy is indicated in patients who have difficulty adhering to nonpharmacologic therapy or if desired outcomes are not achieved with nonpharmacologic therapy. A general approach to therapy selection is:[30]

1. Child with nighttime normal urine output, normal bladder capacity: either alarm or desmopressin therapy
2. Child with reduced bladder capacity: Alarm therapy
3. Child with nocturnal polyuria, normal functional bladder capacity: Desmopressin
4. Child with excessive urine output and reduced nocturnal bladder capacity: Combination of alarm and desmopressin therapy

► *Nonpharmacologic Treatment*

Urotherapy The goal of urotherapy is to regulate bladder emptying and storage. Education about the condition, fluid/diet modification, journal keeping, and behavioral or motivational therapy represent the first steps in managing pediatric enuresis (see Table 53–7).[25,27,31] Motivational therapy allows about 25% of children to achieve 14 consecutive dry nights and 70% of them achieve at least a partial response. About 5% of children experience more than 2 wet nights in 2 weeks. If motivational therapy fails to lead to improvement after 3 to 6 months, active interventions, such as enuresis alarms (Table 53–8) or desmopressin, may be added.[32,33]

Alarm Therapy Enuresis alarms are indicated for motivated families and children with frequent enuresis of more than twice per week. They are the most effective ways of controlling

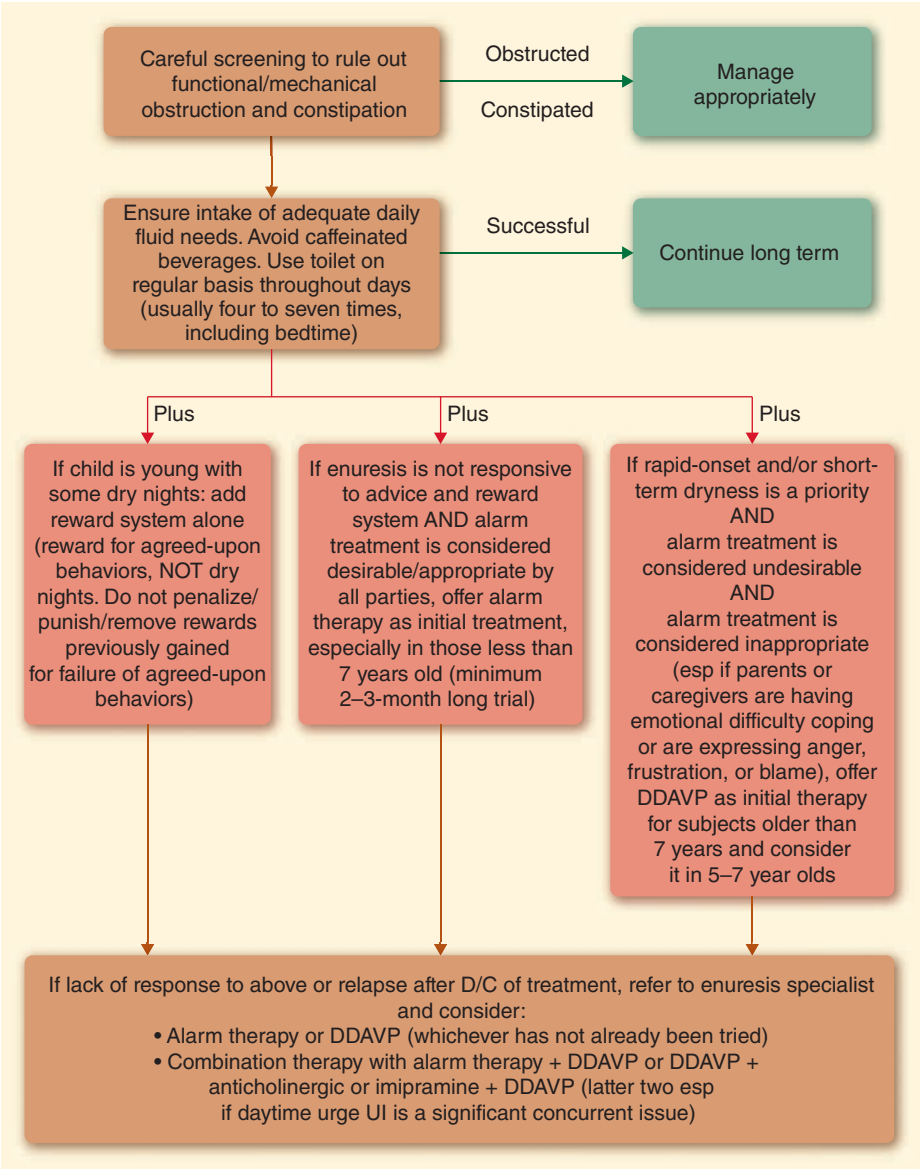

FIGURE 53–1. Enuresis treatment protocol. (D/C, discontinuation; DDAVP, desmopressin; UI, urinary incontinence.) (Modified from Nunes VD, O'Flynn N, Evans J, Sawyer L; Guideline Development Group. Management of bedwetting in children and young people: summary of NICE guidance. BMJ. 2010;341:c5399.)

Table 53–7

Initial Management of Pediatric Enuresis

Education and Advice to Children and Caregivers

- Enuresis is common; it occurs at least once per week in up to 25% of 5-year-old children; enuresis resolves on its own in the majority of children.
- Enuresis is the fault of neither the child nor the caregivers; children should not be punished for bedwetting.
- Reduce the impact of bedwetting by using bed protection and washable/disposable products.
- Keep a calendar of wet and dry nights to determine the effect of interventions.
- Encourage daily fluid intake in the morning and early afternoon. Restrict fluid and solute intake during the evening. A recommendation is to drink 66% of total daily fluid in the morning before the end of the school day and only 30% in the evening, after 5 PM.
- The child should attempt to void every 2–3 hours during the day and just before going to bed; wake the child at night to urinate or lift the sleeping child to the toilet and wake the child to urinate.
- Teach the child to delay urination in the daytime to increase bladder capacity.
- Avoid high-sugar and caffeine-based drinks, particularly in the evening hours.
- Discourage routine use of diapers and pull-ups, except when the child is sleeping away from home.

Motivational Therapy

- Motivational therapy is a good first-line therapy for nocturnal enuresis in younger children between the ages of 5 and 7 years who do not wet the bed every night.
- Motivate the child by keeping a record of progress and giving rewards for accomplished agreed-upon behavior, such as going to the toilet before bedtime. For example, a sticker on a calendar for each night using toilet at bedtime, a book for seven consecutive, etc. Do not use penalties (ie, removal of previously gained rewards).

Table 53–8

Behavioral Treatments for Enuresis

Lifting	Procedure wherein the caregiver takes the child to the toilet at regular intervals during the night to urinate without fully awakening him or her may work as a short-term measure
Night awakening	Procedure wherein the caregiver fully awakens the child to void at regular intervals or randomly, used on a short-term basis
Alarm	An alarm device and a moisture-sensitive sensor are used in combination, with the sensor being placed under the sheets, or more commonly, attached to the child's pajamas or underwear near the urethra. The arousal device is usually an auditory alarm and/or a vibrating belt or pager
Overlearning	This is started at a minimum of 2 weeks after the alarm has rendered the child dry; the child drinks 500 mL (about 16 oz) during the hour before going to bed; alarm use is continued until he or she is dry for 14 consecutive nights with the extra fluid intake; is used to reduce relapse rates seen with alarm use alone
Dry-bed training	This begins with an intensive first night of training that involves increased fluid consumption, hourly awakenings, praise when the bed is dry at hourly awakenings, and, when the alarm goes off, a mild reprimand and cleanliness training (child changes wet clothes and bed linens, remakes the bed, resets the alarm); before going to bed and after each wetting, the child engages in 20 practice trials of appropriate toileting (ie, positive practice): for each practice trial, the child lies in bed, counts to 50, arises and attempts to urinate in the toilet, then returns to bed; on subsequent nights, child is woken only once, usually about 3 hours after the child has gone to bed; after a dry night, the night awakening moves up 30 minutes earlier; it is discontinued when it is scheduled to occur 1 hour after bedtime; after 7 consecutive dry nights, the alarm is discontinued, but is reinstated if two episodes of wetting occur in a 1-week period

nocturnal enuresis and preventing relapses, and may be used in children younger than 7 years. They condition the child or caregiver to wake to the alarm sound or vibration and stop urinating until they go to the toilet. The alarm signals teach the child to wake enough to inhibit bladder contraction in response to the physiologic conditions present before wetting the bed completely. Enuresis alarms are curative in 60% to 80% of the patients, with long-lasting effects in 55% of children.[25,26] Alarm therapy is as effective as desmopressin and more effective than TCAs for pediatric enuresis.[27,31,33] Enuresis alarms can be combined with pharmacotherapy in patients who are partial- or nonresponders to drug therapy alone.[34,35]

The advantage of this therapy is providing a real cure without adverse effects. Because alarms modify conditioning, they are slow in onset and require patience and motivation. Other disadvantages include alarm failure, inability to wake the child, disruption of caregivers and family members, and cost since most are not covered by insurance policies.[27] Follow-up should be assessed 1 to 2 weeks after initiating alarm therapy; however, a full response is not expected to occur until a trial of 3 to 6 months.[27,29] A full response is defined as the achievement of a minimum of 14 consecutive dry nights. If no improvement is seen in 3 to 6 months, alternative interventions should be considered. Enuresis alarm can be reinitiated if a relapse occurs after discontinuation.[27]

Measures that have limited effectiveness in pediatric enuresis include:[25,36]

- Bladder stretching exercises
- Hypnotherapy
- Dietary changes
- Desensitization to allergens
- Acupuncture
- Chiropractic

▶ *Pharmacologic Treatment*

Desmopressin (DDAVP)[30,37] A synthetic analogue of vasopressin, desmopressin decreases urine production by enhancing water reabsorption in the collective tubules. It is indicated for nocturnal enuresis in children with ages 6 years or older who do not respond to initial management (see Figure 53–1), or as an alternative to alarm therapy. Desmopressin is most effective in a child with nocturnal polyuria and normal functional bladder capacity. It decreases the number of wet nights per week by about 1 night. About 30% of children become full responders while on the drug. However, 62% to 82% of them experience relapses.[25,31] Therapies for pediatric enuresis are listed in Table 53–9.

KEY CONCEPT Desmopressin is the drug of choice in pediatric enuresis. As of 2007, the intranasal formulation was no longer FDA-approved for the management of primary nocturnal enuresis due to postmarketing reports of seizures due to hyponatremia. Desmopressin is an alternative therapy to enuresis alarms. It works faster, which allows the child to attend camp or has sleepovers on short notice. Oral tablets may be started at 0.2 mg (one tablet) 1 hour before bedtime to reach peak effects. If response is not achieved in 10 to 14 days, the oral dose may be increased by 0.2 mg to a maximum dose of 0.6 mg. If the child cannot swallow the tablet, it may be crushed and consumed with soft foods. Sublingual tablets of 120 mcg are available outside the United States. They may be given 30 to 60 minutes before bedtime. If response is not achieved after 10 to 14 days, the dose may be increased to a maximum of 240 mcg.[24,31]

Treatment response should be assessed within 1 to 2 weeks. If effective, desmopressin can be continued for 3 to 6 months, administered either nightly, or as needed in special situations. When it is administered daily on a continuous basis, desmopressin should be withheld for 1 week every 3 months to determine whether continued use is necessary.[30] Lack of response to desmopressin may be due to reduced nocturnal bladder capacity, daytime wetting or suboptimal dosing. To minimize relapses, daily desmopressin should be tapered over a 2-week period. To do this, the daily dose may be reduced by one-half or the dose may be given every other day for 2 weeks before discontinuation.

The most serious complication of desmopressin therapy is water intoxication from dilutional hyponatremia and seizures. This occurs most frequently with the nasal formulation. Electrolyte monitoring in patients taking the oral formulation is recommended if comorbidities may exacerbate renal or electrolyte complications. To reduce the risk of water intoxication, children should drink no more than 8 oz (240 mL) of fluid from

Table 53–9

Therapies for Pediatric Enuresis

Therapy (FDA approval)	Dosage form	Dose (generic)	Advantages	Disadvantages	Adverse effects
Enuresis alarms	Sound and/or vibration		• Best response • Low relapse rates	• Requires motivation • Slow-acting	Sleep disruption
Desmopressin (> 6 years of age)	Oral, tablet 0.1 mg, 0.2 mg (generic)	0.2 mg, increased to 0.4 mg (Maximum 0.6 mg)	• Reduces urine volume at night • Faster acting than enuresis alarms	• Low response rate • High rate of relapse	Water intoxication, hyponatremia, seizures
Imipramine (> 6 years of age)	Oral, tablet 10 mg, 25 mg, 50 mg (generic)	10 mg to 25 mg (Maximum: 50 mg if < 12 years of age; 75 mg if > 12 years of age)	• Reduces bladder contractions • Equally effective to desmopressin	• High rate of relapse	Cardiac conduction disturbances; myocardial depression
Anticholinergics: oxybutynin (> 5 years of age)	Oral, tablet 5 mg; Syrup 5 mg/mL (generic)	5 mg once or twice a day	• Reduces bladder contractions • Effective in patients with low functional bladder capacity	Ineffective as monotherapy, use in combination therapy	Constipation, dry mouth
Anticholinergics: Tolterodine (not approved in children)	Oral, tablet 1 mg, 2 mg (generic)	1–2 mg per day	• Reduces bladder contractions • Effective in patients with low functional bladder capacity	Ineffective as monotherapy, use in combination therapy, limited data in children	Constipation, dry mouth

1 hour before to 8 hours after administration of desmopressin. Treatment should be interrupted during episodes of fluid and/or electrolyte imbalance (eg, diarrhea, vomiting, vigorous exercise, fever, or dehydration).[26]

Diuretics play a minor role in the treatment of enuresis for most patients and are not recommended by the enuresis guidelines. However, in cases of poor response to desmopressin or symptom deterioration after established positive response, oral furosemide 0.5 mg/kg in the early morning may be helpful. Furosemide works by reversing the abnormal circadian rhythm of renal tubular sodium handling, which is common in individuals with enuresis.[38]

Imipramine Imipramine was first used in the treatment of enuresis in the 1960s. It is FDA-approved for pediatric enuresis for ages 6 years and older, but is considered a second-line pharmacotherapy option for monosymptomatic enuresis. TCAs are as effective as desmopressin but are associated with more adverse reactions.[27,39] Their place in therapy is in a child who failed alarm and desmopressin therapies. Mechanisms of action of imipramine include anticholinergic and antispasmodic effects, as well as increasing plasma ADH concentrations, and/or lowering arousal threshold.[26,31] Although trials involving other TCAs have been performed, there is insufficient evidence to assess their relative efficacy compared with imipramine.

Response to imipramine, defined as one less wet night per week, is expected in 50% of children. However, relapse rates are up to 67%.[29] The usual initial dose is 10 to 25 mg at bedtime which may be increased if there is no response after 1 week. On average, the bedtime dose is 25 to 50 mg orally once a day. The dose should not exceed 50 mg in children between 6 and 12 years of age and 75 mg in children age 12 or older. After 1 month of successful response, the dose should be reduced to the lowest effective dose. As the patient continues the therapy, the medication is discontinued for a 2-week block every 3 months to reevaluate necessity of drug therapy.[31]

About 25% of children treated with TCAs experience gastrointestinal symptoms. Neurologic adverse effects including nervousness, personality change, or sleep disturbances are reported in approximately 5% of patients. Clinicians should monitor for the possibility of increased suicidality, particularly in children and young adults with preexisting depressive symptoms.[26]

The most serious adverse effects of TCAs are cardiac conduction disturbances, QT prolongation, and myocardial depression, particularly in cases of overdose. A history of sudden cardiac death in the family may preclude the use of TCAs unless cleared by a pediatric cardiologist. Therefore, safer options should be considered before starting any TCA for pediatric enuresis.[24]

Anticholinergics Since anticholinergic agents increase bladder capacity during sleep, they are the primary therapy for a child who has low bladder functional capacity. Monotherapy is ineffective so these agents are used in combination therapy only. Initial doses of IR oxybutynin are 5 mg and tolterodine 1 to 2 mg a day and are titrated upward based on clinical response. Maximal therapeutic effects can be seen within 2 months.[24,31] Children should be monitored for potential adverse events, such as urinary retention (may lead to UTIs), constipation (worsens urinary tract dysfunction), and decreased saliva secretion.

Combinations of Therapies In children who fail to respond to one therapy or who have frequent relapses, combinations of urotherapy, imipramine, oxybutynin, desmopressin, and/or alarm therapy can improve treatment response.[25,26] In a child with small bladder volumes and refractory enuresis, combination therapy with desmopressin and anticholinergic agents is more effective than desmopressin alone.

Other Drugs Various medications, such as indomethacin, phenmetrazine, amphetamine sulfate, ephedrine, atropine, furosemide, diclofenac, and chlorprothixene, have been tried in the treatment of nocturnal enuresis. Data suggest that

indomethacin, diclofenac, and diazepam are superior to placebo, but not better than desmopressin.[40] Current guidelines do not recommend any of these agents for pediatric enuresis.

▶ *Comparison of Therapies*

Multiple meta-analyses have been conducted to compare treatments for enuresis, although most trials enrolled a small number of subjects and were of poor methodological quality.[39,40] Overall, enuresis alarms are the most effective treatment method, from the standpoint of therapy effectiveness and reduced rate of relapse. The initial rate for success (< 1 wet night per month) is 66%, with 55% long-term success rate after discontinuation. Alarm therapy is at least as effective as desmopressin, but has significantly lower relapse rates (46% vs 60%–70% for desmopressin).[41] Combining enuresis alarms and other complex behavioral therapy further reduces relapse rates. There is inadequate data to compare the various commercial brands of alarms available to consumers.

▶ *Treatment of Relapse*

A relapse is defined by more than 1 wet night per month after a period of dryness.[23] When it occurs, consider reinitiation of the intervention which was previously effective (see Figure 53–1). For children with multiple recurrences after discontinuation of desmopressin, gradual dose tapering of desmopressin may be helpful. If relapse occurs following successful treatment with alarm therapy, the addition of desmopressin may be effective.[29] Management of therapy-resistant monosymptomatic nocturnal enuresis may include periodic new trials of the enuresis alarm with or without desmopressin, desmopressin alone, or a trial of imipramine, or a combination therapy that includes oxybutynin.[25]

Nonresponders experience less than 50% improvement in symptoms despite active interventions.[23] When motivated children and families do not respond to at least 3-month therapy of enuresis alarm and/or desmopressin, referral to a specialist (eg, developmental-behavioral pediatrician, pediatric urologist) may be warranted.[25]

Patient Encounter 2, Part 3

Based on the information available, develop a care plan for this patient's enuresis. Your plan should include:

(a) A statement about the drug-related needs and/or problems

(b) A patient-specific detailed therapeutic plan

(c) Monitoring parameters to assess efficacy and safety

OUTCOME EVALUATION

- Monitor the patient for symptom relief in 2 weeks, 1 month, and every 3 months until symptom resolution. Has the treatment plan achieved the desired outcomes jointly developed by the health care team, the patient, and parents/guardians? If so, to what degree? Evaluate the daily diary completed by the patient or parents/guardians since the last

Patient Care Process: Pediatric Enuresis

Collect Information:

- Identify urinary symptoms, exacerbating factors, and family issues.
- Review past medical history.
- Obtain a thorough medication history, including use of prescription, nonprescription, and complementary/alternative drug products.

Assess the Information:

- Determine whether the enuresis is due to secondary causes. Assess whether there are any exacerbating factors or enuresis-related complications.
- Are there any potentially treatable organic or drug-induced causes of enuresis (see Table 53–6)? Assess parental motivation when attempting nonpharmacologic approaches for the treatment of enuresis.
- Could patient's past medical/medication history contribute to enuresis (see Table 53–1)? Determine which, if any, treatments in the past had been helpful.

Develop a Care Plan:

- Establish realistic treatment goals with the involvement of the child and caregiver.
- If patient is already receiving nonpharmacological interventions and/or drug therapy, assess treatment choice, drug dosing, efficacy, adverse effects, adherence, etc.
- Have the child and caregiver given the current treatment plan an adequate duration of trial? How is the child responding to the current treatment plan?
- Patient-specific detailed therapeutic plan: See Table 53–9 for Therapies for pediatric enuresis.

Implement the Care Plan:

- Educate the patient and/or caregiver on pediatric enuresis, urotherapy, and motivational therapy (see Table 53–7). The patient and/or caregiver should be offered behavioral therapy and/or enuresis alarm with proper education using the "teach back" method (see Table 53–8).
- Provide the patient and/or caregiver with education regarding drug therapy (timing of drug administration, adverse effects, potential drug–drug interactions, etc).

Follow-up: Monitor and Evaluate:

- Evaluate the patient for adverse events, allergies, and interactions (drug–drug and drug–disease) and adherence.
- Evaluate treatment response in 1 to 2 weeks after therapy initiation. Adjust medication dosing if needed.
- Allow at least 3 months to assess efficacy of treatment.
- Identify expected adverse effects and educate regarding avoidance and management of these adverse effects.

clinic visit and quantitate the clinical response (the number of dry nights per week, the number of nights with two or more enuresis episodes, etc). If a diary has not been used, elicit from the patient and caregiver the clinical response since last visit. Consider dosage modification or alternative therapy depending on patient response and adverse effects of therapy.

- Elicit adverse events of therapy, including severity, using a nonleading manner. Ask the patient or parents/guardians what measures, if any, were used to alleviate adverse effects. Assess therapy adherence.
- The balance of clinical response, tolerability, and burden on the caregiver will determine the approach to management. As most nonpharmacologic approaches are "all or none" and drug titration is limited by the maximum recommended dose, clinicians may consider changing therapy if clinical results are inadequate over an appropriate trial period.
- Refer patients with refractory enuresis to a health care professional who specializes in the management of bedwetting.

ACKNOWLEDGMENT

The authors and editors wish to acknowledge and thank Dr. David Guay, the primary author of this chapter in the first, second, and third editions of this book.

Abbreviations Introduced in This Chapter

ADH	Antidiuretic hormone
BPH	Benign prostatic hyperplasia
CYP	Cytochrome P450
DDAVP	Desmopressin
ER	Extended release
IR	Immediate release
MUI	Mixed urinary incontinence
OAB	Overactive bladder
OUI	Overflow urinary incontinence
PFMR	Pelvic floor muscle rehabilitation
PVR	Postvoid residual
SUI	Stress urinary incontinence
TCA	Tricyclic antidepressant
UI	Urinary incontinence
UTI	Urinary tract infection
UUI	Urge urinary incontinence

54 Drug Hypersensitivity Reactions

J. Russell May, Desha Jordan, and Kathleen May

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

1. Describe the potential incidence of immunoglobulin-E (IgE)- and non-IgE-mediated (immune and nonimmune) drug hypersensitivity reactions and why it is difficult to obtain accurate estimates.
2. Describe the Gell and Coombs categories of reactions.
3. Identify the classes of drugs most commonly associated with IgE- and non-IgE-mediated drug hypersensitivity reactions.
4. Recommend specific treatment for a patient experiencing anaphylaxis.
5. Recommend an approach to drug selection in patients with multiple drug allergies.
6. Describe how drug desensitization procedures for selected drugs may be useful.

INTRODUCTION

Drug hypersensitivity reactions collectively encompass immunoglobulin E (IgE)- and non-IgE-mediated (immune and nonimmune, or pseudoallergic) drug hypersensitivity reactions. These reactions are rarely confirmed by testing and subject to both over-reporting and under-reporting, making statistical analysis imprecise. KEY CONCEPT Approximately 5% to 10% of adverse drug reactions occur on an allergic or immunologic basis. However, these represent a disproportionate 24% of reported adverse drug reactions in hospitalized patients and are costly, with accompanying morbidity and mortality.[1,2] Between 10% and 20% of hospital inpatients experience drug adverse events versus 7% in the general population, with about one-third possibly due to hypersensitivity; however, many such reactions may not be reported, especially in pediatrics.[1,3,4] Costs of inpatient drug hypersensitivity reactions are estimated to be $275 to $600 million annually.[5] This financial burden includes indirect costs: time and lost labor, use of more expensive alternative medications, and treatment failures, in addition to direct reaction treatment costs. Accurate data regarding outpatient reaction rates are even more difficult to collect. The term "drug allergy" in a patient record/electronic medical record (EMR) often conveys little medical meaning, as such information is self-reported, and may not delineate symptoms or incorporate provider assessment of probable causality (eg, adverse effect vs IgE-mediated). Potential clinical outcomes might therefore range from inappropriately excessive treatment to lack of recognition of anaphylaxis risk. Clearly, an understanding of mechanisms of drug hypersensitivity reactions and how these might be accurately identified, documented, managed, and ideally prevented is of vital importance.

PATHOPHYSIOLOGY

Drug hypersensitivity reactions are a result of diverse mechanisms of immune recognition and activation, resulting in a broad array of clinical findings. The fundamental Gell and Coombs classification, used for decades, remains a framework for considering mechanisms of immunologic drug reactions (Table 54–1).[6,7]

With advances in immunologic understanding, the underlying mechanisms for many drug hypersensitivity reactions have been found to be more complex and interrelated than suggested by the Gell and Coombs classification.[8] However, even with its shortcomings, this classification remains the most commonly used method to initially describe drug reactions resulting from hypersensitivity. KEY CONCEPT Immediate or Type I reactions are those allergic reactions mediated by IgE antibodies specific to the drug; Type II reactions are cytotoxic reactions mediated by drug-specific IgG or IgM antibodies; Type III reactions result from immune complexes circulating in the serum; and Type IV reactions are mediated by cellular mechanisms. Type IV reactions are further subdivided into Type IVa involving recruitment of monocytes, Type IVb with predominantly eosinophils, Type IVc composed of CD4+ or CD8+ T cells, and Type IVd showing neutrophils.[9]

Immune Mechanisms

The cellular immune mechanisms involved in drug hypersensitivity are quite complex.[10] The immune system must first recognize non-self material, or antigens. This recognition is predominantly controlled by T lymphocytes, which have specific surface receptors to accept signals from specialized antigen presenting cells (APCs). Two different signals are typically required for T-cell activation. The presentation of the foreign substance by APC to the T-cell constitutes the first signal. The APC must then concomitantly provide a second signal in addition to the antigen to fully activate the T-cell. If the second signal is not provided, the T-cell becomes nonresponsive or anergic. Thus, the second signal controls the type of immune response that will be initiated by the T-cell.

Depending on the exposure to antigens and the cytokines involved, naïve T-helper cells (CD4+ T-cells) can differentiate

Table 54–1

Reaction Classification, Clinical Symptoms, and Potential Causative Drugs[6,7]

Gell and Coombs Classification	Immune Response	Clinical Symptoms	Potential Causative Drugs[a]
Type I	IgE	Anaphylaxis, urticaria	β-Lactam antibiotics: penicillins (primarily), cephalosporins, carbapenems Non–β-lactam antibiotics: sulfonamides, vancomycin Others: insulins, heparin
Type II	IgG	Hemolytic anemia, thrombocytopenia	Quinidine, methyldopa, penicillins, heparin
Type III	IgG, IgM	Vasculitis, serum sickness, lupus	Penicillins, sulfonamides, radiocontrast agents, phenytoin, minocycline
Type IV			β-Lactam antibiotics, sulfonamides, phenytoin
IVa	Th1 cytokines	Tuberculin reaction eczema	See text for examples
IVb[b]	Th2 cytokines	Maculopapular and bullous exanthema	
IVc[b]	Cytotoxic T cells (CD4 and CD8)	Same as IVb, also eczema, pustular exanthema	
IVd	T-cells (IL-8)	Pustular exanthema	

[a]These drugs represent a list of causative agents. Many drugs can cause these reactions.

[b]IVb and IVc reactions may combine to produce erythema multiforme, Stevens-Johnson syndrome, and toxic epidermal necroylsis.

Ig, Immunoglobulin.

into one of a number of specialized effector T-helper cells, each appearing to have a unique regulatory element, pattern of cytokine production, and function. Type 1 effector T-helper cells, or Th1, are typically associated with activation of T-cells to induce B-cell IgG antibody production and to provide direct T-cell recruitment of cells to kill other cells infected with viruses or intracellular bacteria. Th1 responses are thought to cause certain delayed hypersensitivity reactions (Gell-Coombs Type IV). Th2 immune responses induce B cells to produce IgE, and increase tissue eosinophils, yielding potential immediate allergic reactions (Gell-Coombs Type I) or delayed hypersensitivity (Type IV), respectively. In the case of Type I reactions, specific IgE antibody produced in response to an antigen results in membrane-binding of that IgE to mast cells. Upon repeat exposure to the antigen, crosslinking of IgE on these mast cells occurs, accompanied by massive release of preformed mediators including histamine (H). Other T-helper-effector cell subtypes cause additional inflammatory patterns seen in drug hypersensitivity.

Drugs as Antigens

Many drugs are small molecules, which the immune system does not normally recognize as antigens. This fact has resulted in several hypotheses concerning how drugs can elicit an immune response.[10] The first widely accepted hypothesis was the haptenation hypothesis, which states that the drug becomes covalently bound to a normal "self" protein. The combination of the drug bound to the protein is then large enough to be recognized as foreign by the immune system, leading to an immune response.[10] Another hypothesis is the pro-hapten hypothesis, in which a nonreactive drug becomes chemically reactive during metabolism and then covalently binds to self-proteins. An example of this is sulfamethoxazole metabolism to sulfamethoxazole-nitroso, which is highly reactive. Another hypothesis is the pharmacologic interaction (p-i) hypothesis, which has the drug (or metabolite) directly binding to the T-cell receptor, initiating an immune response. In this case, T-cells are directly activated, despite not interacting with APCs, bypassing the usual signaling requirements.

As suggested by several of these hypotheses, the metabolism of the drug often plays a critical role. The fact that many drugs are primarily metabolized in the liver helps to explain why the liver is often involved in drug hypersensitivity reactions. It has also been recognized that skin **keratinocytes** are a site of drug metabolism. This discovery may help explain why the skin is involved in many forms of reactions elicited by different drugs.[11] Indeed some of the most common of the life-threatening drug reactions are predominately cutaneous, including **Stevens-Johnson syndrome** (SJS), **toxic epidermal necrolysis** (TEN), and drug reaction with eosinophilia and systemic symptoms (DRESS) or drug-induced hypersensitivity syndrome (DIHS).[12]

Nonimmune (Pseudoallergic) Drug Reactions

KEY CONCEPT Reactions occur that clinically resemble IgE-mediated or immune drug reactions but lack an immune basis, sometimes called "pseudoallergic" reactions. These include the entire spectrum of clinical severity, but occur via other, unknown mechanisms.

Nonimmune drug hypersensitivity reactions are important in patient counseling and management considerations. They represent common biological occurrences such as direct histamine release by vancomycin or opiates, whereas immunologic (or IgE-mediated) reactions are based on the structure of the drug. Even a history of mild IgE-triggered symptoms may carry significant potential for anaphylaxis on readministration. In contrast, nonimmune drug reactions tend to remain constant, whether mild or severe, and are dose-related. Ionic radiocontrast media administration, as a classic example, can consistently cause **urticaria** in some, and life-threatening hypotension in others.

Nonimmune drug hypersensitivity reactions, then, are reactions where the components of the immune system are used similarly, but without the "learning" response by T-cells and

Clinical Presentation and Diagnosis of IgE-mediated and other Immune Drug Reactions

Reaction	Mediators Involved	Signs and Symptoms
Anaphylaxis	Ig-E-driven reaction resulting in mast cell degranulation and histamine release.	Skin (eg, pruritus, urticaria), respiratory tract (eg, dyspnea, wheezing), gastrointestinal tract (eg, nausea, cramping), and cardiovascular system (eg, hypotension, tachycardia)
Note: Onset is usually within 30 minutes, but can be 2 hours or more. Treatment must begin immediately. Anaphylaxis may recur 6 to 8 hours after initial exposure, warranting observation for up to 12 hours.		
Cytotoxic Reactions	Drug-specific IgG or IgM antibodies	Hemolytic anemia, thrombocytopenia, granulocytopenia, or agranulocytosis
Immune Complex Reactions	IgG, IgM deposition	Serum sickness-like syndrome (eg, arthralgias, fever, malaise, and urticaria) that typically develops 7 to 14 days after exposure to the causative antigen
Dermatologic Reactions	IgE or cellular mechanisms (See Table 54–1)	See below for dermatologic reaction types

- *Urticaria*: These are itchy, raised, swollen areas on the skin. Also known as hives.
- *Maculopapular rash*: A rash that contains both macules and papules. A macule is a flat, discolored area of the skin, and a papule is a small raised bump. A maculopapular rash is usually a large area that is red and has small bumps.
- *Erythema multiforme*: A rash characterized by papular (small raised bump) or vesicular (blister) lesions and reddening or discoloration of the skin, often in concentric zones about the lesion.
- *Stevens-Johnson syndrome*: A severe expression of erythema multiforme (known as erythema multiforme major). It typically involves the skin and the mucous membranes, with the potential for severe morbidity and even death.
- *Toxic epidermal necrolysis*: A life-threatening skin disorder characterized by blistering and peeling of the top layer of skin.

generally without the much greater danger that true immunologic sensitization implies. Nonimmune drug reactions may be considered as a subtype of idiopathic reactions, rather than an activation of the patient's immune system. The pathophysiology of these reactions is generally unknown, but indicators of immune activation are not seen when they occur. An example is a reaction seen with vancomycin infusion. It typically consists of pruritus, an erythematous rash that involves the face, neck, and upper torso and is usually associated with vancomycin infusions given over less than one hour. This reaction is commonly referred to as red man syndrome.[13]

PROBLEMATIC DRUG CLASSES AND TREATMENT OPTIONS

The first priority is to avoid doing serious harm by administering a drug the patient cannot tolerate. One can frequently establish the likelihood of a relationship between the suspected drug and observed reaction, and also whether it is likely to be an immune or idiopathic reaction, by examining the time course and specific signs and symptoms objectively. Evaluating the patient's physical findings and laboratory values if available (taking into account preexisting diseases) may further clarify the need to change treatments and add therapy for the reaction itself.

Reviewing the original indications for the treatment that caused the reaction is important. For example, in many respiratory illnesses a prescribed antibiotic might be unnecessary. If a particular disease persists and definitive indications for treatment are established, alternatives must be sought, either by adjusting dose or administration rate, finding an effective and unrelated alternative medication, or desensitizing the patient to the original drug.

When adverse drug reactions occur, the health care provider should carefully investigate all aspects of the reaction and assess the potential for it to recur. Many patients have frightening associations of the term "drug allergy" with anaphylaxis, an anxiety that is difficult to allay. In this manner, a label of drug allergy may hamper future medical care, with treatment refusals, nonadherence to therapy, or resultant use of more toxic or less effective alternative treatments. If the original reaction is clearly documented, health care providers can appropriately counsel patients about risk.

Anaphylaxis is a true medical emergency and must be treated immediately. Otherwise, managing allergic reactions begins with discontinuing the offending agent. Understanding the allergic reaction and potential for **cross-allergenicity** between similar drugs will assist in selecting an alternative medication. Desensitization is a management option for certain IgE-mediated drug allergies if there is a definitive indication and alternative therapies are not available. Although any agent may cause an allergic (IgE-mediated), immune or nonimmune (pseudoallergic) reaction, several drugs and drug classes are strongly associated with such reactions (Table 54–2). These classes will be discussed individually.

LO 3

Table 54–2

Problematic Drug Classes

Anticonvulsants

β-Lactam Antibiotics

Hypersensitivity reactions with β-lactam antibiotics, especially penicillin, may encompass any of the Types I through IV Gell-Coombs classifications. The most common reactions are maculopapular and urticarial eruptions.[14] Although rare (< 0.05%), anaphylactic reactions to penicillins cause the greatest concern, because they are responsible for the majority of all drug-induced anaphylaxis deaths in patients, accounting for 75% of all anaphylaxis cases in the United States.[6,15] The treatment of anaphylaxis is given in Table 54–3.[16]

LO 4

The health care professional is faced with a difficult task when approaching a patient who notes a history of penicillin allergy. Although as many as 12% of hospital patients report an allergy to penicillin, about 90% will have negative skin tests.[17] Table 54–4 shows the traditional protocol for penicillin skin testing.[18] This test only evaluates IgE-mediated reactions. A patient with a history of other serious reactions such as erythema multiforme, SJS, or TEN should not receive penicillin and should not be tested.

KEY CONCEPT Penicillins and cephalosporins both have a β-lactam ring joined to an S-containing ring structure (penicillins: a thiazolidine ring; cephalosporins: a dihydrothiazine ring). The extent of cross-allergenicity appears to be relatively low, with an estimate of approximately 4%.[19] *Cross-allergenicity is less likely with newer generation cephalosporins compared with the first-generation agents*. Anaphylactic reactions to cephalosporins are rare, with a predicted range of 0.0001% to 0.1%. Minor skin reactions including urticaria, exanthems, and pruritus are the most common allergic reactions with cephalosporins, showing severe reactions less often than with penicillins.[20]

For other β-lactam agents, the recommendations are fairly straightforward. Carbapenems should be considered potentially cross-reactive with penicillins and used with caution.[21] Monobactams (eg, aztreonam) do not cross-react with any β-lactam drugs except ceftazidime because they share an identical R-group side chain. Other cephalosporins sharing identical R-group specific side chains share cross-reactivity as well.

Table 54–3

Pharmacologic Management of Anaphylactic Reactions[16]

Immediate Intervention

Epinephrine 1:1000 (1 mg/mL)
- Adults: 0.2–0.5 mg IM, repeat every 5 minutes as needed
- Pediatrics: 0.01 mg/kg (maximum 0.3 mg) IM, repeat every 5 minutes as needed

Subsequent Interventions

Normal saline infusion
- Adults: 1–2 L at a rate of 5–10 mL/kg in the first 5 minutes, followed by slow infusion
- Pediatrics: up to 30 mL/kg in the first hour

Epinephrine infusion

If patient is NOT responding to epinephrine injections and volume resuscitation:
- Adults: epinephrine infusion (1 mg in 250 mL D_5W): 1–4 mcg/min, titrating based on clinical response or side effects
- Pediatrics: epinephrine infusion (0.6 × body weight [in kg] = number of mg diluted to a total of 100 mL normal saline: 1 mL/hour delivers 0.1 mcg/kg/min)

Other Considerations after Epinephrine and Fluids

Diphenhydramine
- Adults: 25–50 mg IV or IM
- Pediatrics: 1–1.25 mg/kg (maximum of 300 mg/24 hours)

Ranitidine
- Adults: 50 mg in D_5W 20 mL IV over 5 minutes
- Pediatrics: 1 mg/kg (up to 50 mg) in D_5W 20 mL IV over 5 minutes

Inhaled β-agonist (bronchospasm resistant to epinephrine)
- 2–5 mg in 3 mL of normal saline, nebulized, repeat as needed

Dopamine (hypotension refractory to fluids and epinephrine)
- 2–20 mcg/kg/min titrated to maintain systolic blood pressure > 90 mm Hg

Hydrocortisone (severe or prolonged anaphylaxis)
- Adults: 250 mg IV (prednisone 20 mg can be given orally in mild cases)
- Pediatrics: 2.5–10 mg/kg/24 hours

D_5W, dextrose 5% in water; IM, intramuscularly; IV, intravenous.

Adapted from Lieberman P, Nicklas RA, Oppenheimer J, et al. The diagnosis and management of anaphylaxis practice parameter: 2010 update. J Allergy Clin Immunol. 2010;126:477–480.

Table 54–4

Procedure for Performing Penicillin Skin Testing[18]

A. Percutaneous (Prick) Skin Testing

Materials	Volume
Pre-Pen 6 × 10^6 M	1 Drop
Penicillin G 10,000 Units/mL	1 Drop
β-Lactam drug 3 mg/mL	1 Drop
0.03% albumin-saline control	1 Drop
Histamine control (1 mg/mL)	1 Drop

1. Place a drop of each test material on the volar surface of the forearm.
2. Prick the skin with a sharp needle inserted through the drop at a 45° angle, gently tenting the skin in an upward motion.
3. Interpret skin responses after 15 minutes.
4. A wheal at least 2 × 2 mm with erythema is considered positive.
5. If the prick test is nonreactive, proceed to the intradermal test.
6. If the histamine control is nonreactive, the test is considered uninterpretable.

B. Intradermal Skin Testing

Materials	Volume
Pre-Pen 6 × 10^6 M	0.02 mL
Penicillin G 10,000 Units/mL	0.02 mL
β-Lactam drug 3 mg/mL	0.02 mL
0.03% albumin-saline control	0.02 mL
Histamine control (0.1 mg/mL)	0.02 mL

1. Inject 0.02–0.03 mL of each test material intradermally (amount sufficient to produce a small bleb).
2. Interpret skin responses after 15 minutes.
3. A wheal at least 6 × 6 mm with erythema and at least 3 mm greater than the negative control is considered positive.
4. If the histamine control is nonreactive, the test is considered uninterpretable.

Antihistamines may blunt the response and cause false-negative reactions.

Adapted from Sullivan TJ. Current Therapy in Allergy. St. Louis, MO: Mosby; 1985:57–61.

Sulfonamide Antibiotics

Sulfonamides are compounds that contain a sulfonamide moiety (ie, SO_2NH_2). This group includes sulfonamide antibiotics (sulfonylarylamines), and nonarylamine sulfonamides such as furosemide, thiazide diuretics, sulfonylureas, and celecoxib. The sulfonamide antibiotics contain an aromatic amine at the N4 position and a substituted ring at the N1 position.

Patient Encounter 1

A 21-year-old pregnant woman who is at the end of her first trimester has tested positive on prenatal screening for syphilis. She has a childhood history of penicillin allergy. Further history reveals that as a toddler she received amoxicillin and developed emesis, rash, difficulty breathing, and required emergency department treatment with administration of epinephrine. She has not received penicillin or any derivative since that time.

What is the probable mechanism of the prior amoxicillin reaction?

What should be noted on the patient's medication reaction history?

How might this patient be managed at present?

Allergists generally agree that most, but not all, patients allergic to antimicrobial sulfonamides will tolerate nonarylamine sulfonamides.[22] Predisposition to allergic reactions is a more likely reason for dual sensitivity than cross-reactivity between these differing molecules.[23] The term "sulfa allergy" should not be used as it can be confusing to patients and health care providers. The sulfonamide antibiotics are significant because they account for the largest percentage of antibiotic-induced TEN and SJS cases.[24]

KEY CONCEPT Reactions to sulfonamide antibiotics, ranging from mild (most common) to life-threatening (rare), occur in 2% to 4% of healthy patients, with rates as high as 65% in patients with acquired immunodeficiency syndrome (AIDS).[25] Anaphylaxis or nonimmune **anaphylactoid** reactions almost always occur within 30 minutes but may happen up to 90 minutes after exposure, most commonly after parenteral administration. Isolated **angioedema** or urticaria can occur within minutes to days. Serum sickness occurs within 1 to 2 weeks. Fixed drug eruptions (lesions) occur within 30 minutes to 8 hours. These lesions resolve within 2 to 3 weeks after drug removal. The more severe conditions of SJS and TEN tend to occur 1 to 2 weeks after initiation of therapy. Because trimethoprim-sulfamethoxazole is the drug of choice for patients with *Pneumocystis jiroveci* pneumonia, desensitization may be necessary. A history of SJS or TEN is an absolute contraindication for the desensitization procedure.

Patients with Multiple Antibiotic Allergies

LO 5

Dealing with those who report multiple antibiotic allergies can be challenging. Combining knowledge of cross-allergenicity with a careful assessment of patient history may be helpful in designing an antimicrobial regimen. Table 54–5 outlines a series of questions that can be useful in developing an effective treatment plan.[26] If available and indicated, skin testing may be useful to complete the puzzle. Often with careful assessment, an antibiotic of choice may be used when the patient's initial history would have ruled it out. Based on data gathered, the patient's record should reflect antibiotics safe to use if needed, antibiotics to be avoided, and antibiotics that can be used only after desensitization. Although Table 54–5 was designed with antibiotics in mind, it can be modified for multiple allergy situations.

Aspirin and Nonsteroidal Anti-Inflammatory Drugs

Aspirin and the nonsteroidal anti-inflammatory drugs (NSAIDs) can induce allergic and pseudoallergic reactions. Because these drugs are so widely used, with much over-the-counter use, the health care professional must have a basic understanding of the types of reactions that can occur and how to prevent them. Three types of reactions occur: bronchospasm with rhinoconjunctivitis, urticaria/angioedema, and anaphylaxis. Remember that patients with gastric discomfort or bruising from these agents may inappropriately describe themselves as being "allergic."

Two specific conditions—aspirin-exacerbated respiratory disease (AERD) and chronic idiopathic urticaria (CIU)—are important because they are commonly seen. AERD may include asthma, rhinitis with nasal polyps, and aspirin sensitivity.[27] Upon exposure to aspirin or an NSAID, patients with AERD experience rhinorrhea, nasal congestion, conjunctivitis, laryngospasm, and asthma. CIU exacerbations may also be seen with aspirin or NSAID-induced pseudoallergic reactions, as those with a history of CIU are likely to see a flare of urticaria if aspirin or a cyclooxygenase (COX)-1 inhibiting NSAID is given.[28] Cross-reactions between aspirin and older COX-1 inhibiting NSAIDs exist in patients with AERD and CIU. Even though product warning labels for COX-2 inhibitors state these agents should not be used in these two conditions, there are no reports of cross-reactivity in AERD and only rare reports in CIU.[29]

KEY CONCEPT IgE-mediated urticarial/angioedema reactions and anaphylaxis are associated with aspirin and NSAIDs. Urticaria is the most common form of an IgE-mediated reaction. However, most reactions are the result of metabolic idiosyncrasies, such as aspirin-induced respiratory disease, which may produce severe and even fatal bronchospasm. This class is second only to β-lactams in causing anaphylaxis. Most reactions in this class are

Table 54–5

Multiple Antibiotic Allergies: Obtaining Background Information

For **each** antibiotic to which the patient claims to be allergic, gather the following information:
- What type of infection was being treated?
- Have you ever received the drug without experiencing a reaction?
- How many times have you received the drug and experienced a reaction?
- What was the drug dose and route of administration with the last reaction?
- How many doses did you take before the onset of the last reaction?
- How many doses did you take after the last reaction?
- Can you describe the adverse reaction?
- What was the duration of the reaction?
- What treatment was given for the reaction?
- Was there any permanent damage?

For **each** antibiotic the patient has received and does not claim allergy, gather the following information:
- What was the last type of infection being treated?
- What was the drug dose and route of administration?
- Have you received this drug more than once without reactions?

Other information to be gathered:
- Have you had adverse reactions to any other drugs? If so, give dates and describe the reaction.
- Document any risk factors for allergic reactions such as chronic urticaria, liver or kidney disease, HIV (human immunodeficiency virus), or any other immune deficiencies.

Adapted from Macy E. Multiple antibiotic allergy syndrome. Immunol Allergy Clin North Am 2004;24:533–543.

due to a complex metabolic pattern, which causes increasingly recurrent and severe nasal polyps and often refractory asthma. The metabolic problem is constant once it emerges, accounting for the persistence and difficulty of these clinical problems. The metabolic problem is also capable of causing severe, sometimes fatal, acute reactions to aspirin or many if not all other NSAIDs. Rare reports of non–cross-reactive severe reactions suggest possible specific IgE-mediated reactions to individual NSAIDs, and there are some occurrences of urticaria related to NSAIDs as well. Because aspirin therapy is highly beneficial in primary and secondary prevention in coronary artery disease (CAD), aspirin desensitization should be considered in selected patients. Desensitization is contraindicated in patients who have experienced an aspirin-induced anaphylactoid reaction, hypotension, tachypnea, or altered consciousness. Alternate agents must be used. A comprehensive approach to aspirin-sensitive patients with CAD has been described.[30]

Radiocontrast Media

KEY CONCEPT Radiocontrast media may cause serious, immediate nonimmune hypersensitivity reactions such as urticaria/angioedema, bronchospasm, shock, and death. These reactions have been reduced with the introduction of nonionic, lower osmolality products. Because a small percentage of patients who have reacted previously to radiocontrast media will react if reexposed, several steps (listed below) should be taken to prevent reactions. These steps should also be followed in those with known risk factors: asthma, β-blocker use, and cardiovascular disease.[5] The steps are as follows:

- Determine whether the study is essential.
- Be sure the patient understands the risks.
- Ensure adequate hydration.
- Use nonionic, lower osmolar agents.
- Typical protocols include pretreatment with prednisone 50 mg orally 13, 7, and 1 hour(s) before the procedure and diphenhydramine 50 mg orally 1 hour before the procedure.

Delayed reactions with these agents occur in 1% to 3% of patients.[31] Although reactions are occasionally severe, most are mild and manifest as maculopapular rashes, fixed eruptions, erythema multiforme, and urticarial eruptions.

Patient Encounter 2

A 60-year-old woman with history of rheumatic fever and mitral regurgitation has developed a heart valve infection for which her physician has prescribed a regimen that includes vancomycin. The patient reports that she had an allergic reaction the last time she took vancomycin. Five minutes into the infusion she experienced significant flushing in her face and torso, making her feel very uncomfortable, without additional symptoms.

What kind of reaction did the patient experience previously with vancomycin?

Could vancomycin be used for treatment of this current infection? Discuss rationale.

Opiates

KEY CONCEPT Opiates (morphine, meperidine, codeine, hydrocodone, and others) stimulate mast cell mediator release directly, resulting in pruritus and urticaria with occasional mild wheezing. Though these reactions are not IgE-mediated, many patients state that they are "allergic" to one or more of the opiates. Pretreatment with an antihistamine may reduce these reactions which are rarely, if ever, life-threatening.[6] Avoiding other mast cell degranulating medications while patients require opiates also reduces the chances of frightening and uncomfortable reactions. Patients may also commonly state that they are "allergic" if they have experienced gastrointestinal upset or constipation with opiates. Obtaining a thorough history from the patient will prove useful. If a more serious reaction has occurred, a non-narcotic analgesic should be selected.

Cancer Chemotherapy

Hypersensitivity reactions have occurred with all chemotherapy agents. Reactions are most common with the taxanes, platinum compounds, asparaginases, and epipodophyllotoxins.[14] Reactions range from mild (flushing and rashes) to severe (dyspnea, bronchospasm, urticaria, and hypotension). IgE-mediated Type I reactions are the most common. To reduce the risk, patients are routinely premedicated with corticosteroids and H_1- and H_2-receptor antagonists. The platinum compounds have produced anemia, probably via a cytotoxic immunologic mechanism.

Insulin

Insulin is one of a very few medications that is itself a whole protein and can induce IgE sensitivity directly. This can result in anaphylaxis. Adverse reactions to insulin also include erythema, pruritus, and indurations, which are usually transient and may be injection site related.[32] For sensitivity reactions, treatment options include dexamethasone or desensitization. If the reaction is injection site related, a change in delivery system (ie, insulin pump or inhaled insulin) may be helpful.

Anticonvulsants

A wide range of hypersensitivity reactions, ranging from mild maculopapular skin eruptions to severe life-threatening reactions, can occur with anticonvulsants.[33] Aromatic anticonvulsants, primarily phenytoin, carbamazepine, phenobarbital, and primidone as well as some of the newer agents (lamotrigine, oxcarbazepine, felbamate, and zonisamide) can cause a life-threatening syndrome with symptoms including fever, a maculopapular rash, and evidence of systemic organ involvement. The rash may be mild at first but can progress to **exfoliative dermatitis**, erythema multiforme, SJS, or TEN. This syndrome is known as anticonvulsant hypersensitivity syndrome (AHS) or DRESS. The causative agent should be withdrawn immediately. Cross-sensitivity among aromatic anticonvulsant drugs ranges between 40% and 80%.[34] If a patient is hypersensitive to an aromatic anticonvulsant, a nonaromatic agent (ethosuximide, gabapentin, levetiracetam, topiramate, lacosamide, valproic acid) or the benzodiazepines may be useful.[34]

Drug Desensitization

Drug desensitization may be undertaken for some drugs in the absence of useful alternative medications. The risk of severe systemic reactions and anaphylaxis associated with desensitization must be compared with the risk of not treating the patient. A thorough evaluation should establish that the

drug probably caused the reaction by an allergic mechanism. Because of the dangers involved with drug desensitization, an expert review of the patient's indication for the drug should be conducted. Consider the possibility that the patient does not really need the drug.

KEY CONCEPT Desensitization is a potentially life-threatening procedure and requires continuous monitoring in a hospital setting, with suitable access to emergency treatment and intubation if required. It should only be undertaken under the direction of a physician with suitable training and experience. In such hands, desensitization may present less risk than treatment failure with a less effective alternative medication.

The possibility of readministering a suspected drug may be safely tested by gradual dose escalation in some cases, and there are certainly many more patients who are harmed by inappropriately withholding medications than there are those who suffer significant harm from testing and desensitization.[35]

Only Type I IgE-mediated allergy may be treated by classical desensitization. Desensitization may occur within hours to several weeks, unlike specific immunotherapy injections for inhalant allergy (ie, "allergy shots," which have effects over months to years). The mechanism of drug desensitization is poorly understood but produces temporary drug-specific tolerance of the offending drug. Any interruption of therapy of 24 hours or more requires full repeat desensitization, and abrupt significant increases of dosage have been reported to break through the tolerance with some drugs.

The desensitization process probably involves either: (a) cross-linking small subthreshold numbers of bound IgE molecules gradually depleting mast cells of their mediators, or (b) binding of the IgE by monomers or hapten-protein entities that cannot cross-link the antibody. The low doses used at the beginning of all protocols would provide small amounts of antigen, favoring these mechanisms. Both drug-specific IgE and IgG serum concentrations increase after successful desensitization, but skin test positivity generally decreases.[36]

Patient Encounter 3

A 57-year-old man at the end of a 10-day course of trimethoprim/sulfamethoxazole for resolving MRSA cutaneous infection develops fever of 103°F (39.4°C), a confluent, tender, nonpruritic erythematous rash on his trunk, and blisters along his lower lip. A few days later his truncal skin begins to slough. He is told to avoid "sulfa" antibiotics.

What type of reaction to sulfa antibiotic does this patient have?

What would be the management of this drug hypersensitivity in the future?

Would he be a candidate for drug desensitization?

Oral and intravenous (IV) protocols are available for most drugs in this category, with the oral route producing somewhat milder reactions, but the IV route providing more precision in dosing. IV administration can also be used in unresponsive patients for whom the oral route is not feasible. Protocols generally begin at about 1% of the therapeutic dose and increase in intervals defined by the patient's reaction and the distribution and metabolism of the drug itself. Half-$\log_{10}$ dose increases (about threefold) are often tolerated.

LO 6 Penicillin desensitization is the most common drug desensitization protocol. It is required for penicillin-allergic patients when penicillin is clearly the only treatment option.

Patient Care Process

Collect Information:

- Perform a medication history for use of prescription and nonprescription medications and dietary supplements.
- Review the medical history and physical assessment findings.
- Speak with patient or caregiver to gain their perspective on the reaction.

Assess the Information:

- Based on the medication history, physical examination, and review of systems, determine the likelihood of the reaction being a drug-related problem. See Clinical Presentation and Diagnosis of IgE-mediated and other Immune Drug Reactions. Tables 54–1 and 54–2 may also be helpful.
- Use questions given in Table 54–5 to establish the nature of the reaction and the likelihood it was caused by the suspected drug. For nonantibiotics, the first question regarding infection type is not needed.
- If appropriate, see Table 54–4 for procedures for performing penicillin skin testing.

Develop a Care Plan:

- Document the reaction, in detail, in the patient's medical record.
- Recommend an alternative choice if the prescribed drug is contraindicated, and develop a plan to assess safety and effectiveness.
- Consult with health care professionals trained in desensitization if the patient has a true allergy and no acceptable alternative medication is available.

Implement the Care Plan:

- If reaction is anaphylactic in nature, see Table 54–3.
- The offending drug should be discontinued.
- The treatment goal is relief of symptoms. For mild symptoms such as rash or itching, an antihistamine such as diphenhydramine may be used. For wheezing, bronchodilators such as albuterol may be helpful.
- Recommend an alternative option for the contraindicated drug, or if no alternative is available, consult with appropriate health care professional regarding desensitization.
- Educate patients about drug hypersensitivities so they are able to work with health care providers to avoid these reactions in the future.

Follow-up: Monitor and Evaluate:

- Follow-up daily or more often, if necessary, to assure resolution of the reaction and optimal response to alternate therapy.

LO 6

Protocols have been adopted for most antibiotics. Specific procedures for oral and IV penicillin desensitization have been developed.[37]

Aspirin desensitization is useful in diseases for which low-level antiplatelet action is needed and in the care of patients with aspirin sensitivity and intractable nasal polyps. Lysine aspirin availability in Europe allows desensitization by inhalation at greatly reduced risk. Procedures utilizing ketorolac as a nasal topical application have been proposed in the United States.[38] As with all desensitizations, constant daily administration is required once the desired dose is reached. Several aspirin desensitization protocols have been described in the literature.[39,40]

All desensitization procedures are expected to produce mild symptoms in the patient at some point, and the patient must be made to understand this before doses are started. Mild sensitivity to the drug still remains, and large dose increases as well as missing doses should be avoided. Late complications, such as urticaria, may occur with Type I desensitization, and serum sickness or hemolytic anemia may also occur with high-dose therapy in allergic, desensitized patients.

Some regimens are designed for outpatient administration over much longer time periods and have been used, for example, with allopurinol dermal reactions. Such late-onset morbilliform reactions, sometimes overlapping with erythema multiforme minor, are difficult to evaluate, because it is often unclear to what extent the patients were at risk for a recurrent reaction.

Severe life-threatening reactions not mediated by IgE, such as SJS and TEN, are absolute contraindications to testing, desensitization attempts, and readministration.

OUTCOME EVALUATION

To successfully treat a patient with IgE-mediated or non-IgE (immune or nonimmune) drug hypersensitivity, several goals must be accomplished:

- If a reaction occurs, it must be identified and managed quickly.
- The patient should be educated about the reaction.
- True drug contraindications should be avoided if possible.
- Patients should receive the medications they need or a suitable alternative. If this is not possible due to an IgE-mediated mechanism, desensitization should be considered.
- Patients should always be monitored for adverse drug reactions.

Abbreviations Introduced in This Chapter

AERD	Aspirin-exacerbated respiratory disease
AHS	Anticonvulsant hypersensitivity syndrome
AIDS	Acquired immunodeficiency syndrome
APC	Antigen presenting cell
CAD	Coronary artery disease
CIU	Chronic idiopathic urticaria
COX	Cyclooxygenase
D_5W	Dextrose 5% in water
DIHS	Drug-induced hypersensitivity syndrome
DRESS	Drug reaction with eosinophilia and systemic symptoms
EMR	Electronic medical record
H (H_1, H_2)	Histamine
HIV	Human immunodeficiency virus
Ig	Immunoglobulin (followed by the specific type of immunoglobulin: E, G, or M)
IM	Intramuscular
IV	Intravenous
NSAIDs	Nonsteroidal anti-inflammatory drugs
p-i	Pharmacologic interaction
SJS	Stevens-Johnson syndrome
TEN	Toxic epidermal necrolysis
Th	T-helper cell

55 Solid Organ Transplantation

Steven Gabardi, Spencer T. Martin, and Ali J. Olyaei

LEARNING OBJECTIVES

LO

Upon completion of the chapter, the reader will be able to:

1. Describe the reasons for solid organ transplantation.
2. Differentiate between the functions of cell-mediated and humoral immunity and how they relate to organ transplant.
3. Describe the roles of antigen-presenting cells (APCs) in initiating the immune response.
4. Compare and contrast the types of rejection including hyperacute, acute, chronic, and humoral rejection.
5. Define the terms "host–graft adaptation" and "tolerance," paying close attention to their differences.
6. Discuss the desired therapeutic outcomes and appropriate pharmacotherapy utilized to avoid allograft rejection.
7. Compare and contrast currently available immunosuppressive agents in terms of mechanisms of action, adverse events, and drug–drug interactions (DDI).
8. Develop a therapeutic drug-monitoring plan to assess effectiveness of the immunosuppressive drugs.
9. Design an appropriate therapeutic regimen for the management of immunosuppressive drug complications based on patient-specific information.
10. Write appropriate patient education instructions and identify methods to improve medication adherence following transplantation.

INTRODUCTION

The earliest recorded attempts at organ transplant date back thousands of years.[1] More than a few apocryphal descriptions exist from ancient Egypt, China, India, and Rome describing experimentation with transplantation. However, it was not until the early 1900s that French surgeon, Alexis Carrel, pioneered the art of surgical techniques for transplantation.[1] Together with Charles Guthrie, Carrel experimented in artery and vein transplantation. Using revolutionary methods in **anastomosis** operations and suturing techniques, Carrel laid the groundwork for modern transplant surgery. He was one of the first to identify the dilemma of rejection, an issue that remained insurmountable for nearly half a century.[1]

Prior to the work of Alexis Carrel, malnourishment was the prevailing theory regarding the mechanism of **allograft** rejection.[1] However, in 1910, Carrel noted that tissue damage in the transplanted organ was likely caused by multiple, circulating biological factors. It was not until the late 1940s with the work of Peter Medawar that transplant immunology became better understood. Medawar defined the immunologic nature of rejection using skin allografts. In addition, George Snell observed that grafts shared between inbred animals were accepted but were rejected when transplanted between animals of different strains.[1]

The seminal work by early transplant researchers eventually led to the concept of histocompatibility.[1] Histocompatibility describes the process by which polymorphic genes encode cell membrane antigens that serve as targets for immune response, even within a species. Further research in transplant immunobiology led to more accurate understanding of the alloimmune response.[1]

Joseph Murray performed the first successful organ transplant in 1954, a kidney transplant between identical twins.[1] This was a success largely because no immunosuppression was necessary as donor and recipient were genetically identical. Murray's achievement laid the groundwork for modern-day transplantation. Organ transplants performed in the United States reached a record high of 34,770 in 2017, an almost 25% increase from 2012.

EPIDEMIOLOGY AND ETIOLOGY

Heart

Nearly 6 million Americans are afflicted with heart failure. Cardiac transplantation is the treatment of choice for patients with severe end-stage heart failure. Candidates for cardiac transplantation generally present with New York Heart Association (NYHA) class III or IV symptoms and have an **ejection fraction** of less than 20% (0.20). General indications for cardiac transplantation include rapidly declining cardiac function, requirement of intravenous (IV) inotropes, and a projected 1-year mortality rate of greater than 75%. Mechanical support with an implantable left ventricular assist device may be appropriate as bridge therapy while patients await a viable organ.[1] Most heart transplants are **orthotopic**; however, in certain situations, **heterotopic** cardiac transplants have been performed.

There were 3244 heart transplant procedures in the United States in 2017.[2] Indications for heart transplant include:

LO 1

- Cardiomyopathy (ie, dilated myopathy, hypertrophic cardiomyopathy, restrictive myopathy)
- Congenital heart disease
- Coronary artery disease
- Valvular heart disease

Intestine

An intestine transplant may involve the use of an entire intestine or shortened segment. Most intestine transplants completed in the United States involve the transplant of the full organ and are often performed in conjunction with liver transplantation. Although most intestine transplants involve organs harvested from a deceased donor, recent advances have made it possible for living donor intestinal segment transplants. There were 109 intestine transplants in the United States in 2017.[2] Reasons for intestine transplant include:

LO 1

- Functional bowel problems (ie, Hirschsprung disease, neuronal intestinal dysplasia, pseudoobstruction, protein-losing enteropathy, microvillous inclusion disease)
- Short gut syndrome (ie, intestinal atresia, necrotizing enterocolitis, intestinal volvulus, massive resection secondary to inflammatory bowel disease, tumors, mesenteric thrombosis)

Kidneys

More than 26 million Americans have chronic kidney disease (CKD), with an additional 20 million at increased risk for kidney disease. End-stage renal disease (ESRD) constitutes a small portion of CKD patients, with more than 640,000 diagnosed throughout the United States as of 2012. However, the ESRD population continues to increase. All patients with ESRD should be considered for renal transplantation if they are healthy enough to undergo surgery.

Most kidney transplants are heterotopic, where the kidney is implanted above the pelvic bone and attached to the patient's iliac artery and vein. The ureter of the transplant kidney is attached directly to the recipient's bladder or native ureter. The native kidneys are usually not removed, and data have shown that under most circumstances, removal of the native kidneys does not influence patient survival (ie, survival of the transplant patient, without regard to function or survival of the allograft) and allograft survival.[1] There were 19,849 (14,038 deceased donors and 5811 living donors) kidney transplants performed in the United States in 2017.[2] Reasons for kidney transplant include:

LO 1

- Congenital, familial, and metabolic disorders (ie, congenital obstructive uropathy, Fabry disease, medullary cystic disease, nephrolithiasis)
- Diabetes mellitus (DM)
- Glomerular diseases (ie, antiglomerular basement membrane disease, focal segmental glomerular sclerosis, IgA nephropathy, hemolytic uremic syndrome, systemic lupus erythematosus, Alport syndrome, amyloidosis, membranous nephropathy, Goodpasture syndrome)
- Hypertension
- Neoplasm (ie, renal cell carcinoma, Wilms tumor)
- Polycystic kidney disease
- Renovascular disease
- Tubular and interstitial diseases (ie, analgesic nephropathy, drug-induced nephritis, oxalate nephropathy, radiation nephritis, acute tubular necrosis, sarcoidosis)

Liver

A liver transplant may involve the use of the entire organ or a segment. The majority of cases involve utilizing the full organ. In recent years, segmental transplants have been conducted using living donors. This procedure requires donation of the left hepatic lobe, which accounts for nearly 60% of the overall liver mass. This type of procedure is possible because the liver can regenerate; therefore, both donor and recipient, in theory, will have normal liver function shortly after the transplant procedure. There were 8082 (7715 deceased donors and 367 partial lobe-living donors) liver transplants done in the United States in 2017.[2] Reasons for liver transplant include:

LO 1

- Acute hepatic necrosis (ie, chronic or acute hepatitis B or C)
- Biliary atresia
- Cholestatic liver disease/cirrhosis (ie, primary biliary cirrhosis)
- Metabolic disease (ie, Wilson disease, primary oxalosis)
- Neoplasms (ie, hepatoma, cholangiocarcinoma, hepatoblastoma, bile duct cancer)
- Noncholestatic cirrhosis (ie, alcoholic cirrhosis, postnecrotic cirrhosis, drug-induced cirrhosis)

Lungs

Lung transplants may involve deceased donation of two lungs or a single lung. More recently, lobar transplants from blood group–compatible living donors have been performed for a small segment of the population. Most have been performed on cystic fibrosis patients. On rare occasions, a simultaneous heart–lung transplant occurs. This type of procedure is reserved for patients with severe pulmonary and cardiac disease. There were 2449 (all deceased donors) lung transplants and 29 simultaneous heart–lung transplants in the United States in 2017.[2] Reasons for lung transplant include:

LO 1

- α-1-Antitrypsin deficiency
- Congenital disease (ie, Eisenmenger syndrome)
- Cystic fibrosis
- Emphysema/chronic obstructive pulmonary disease
- Idiopathic pulmonary fibrosis
- Primary pulmonary hypertension

Pancreas

The exact nationwide prevalence of all diseases of the pancreas has not been fully quantified; however, DM, both types 1 and 2, affects nearly 21 million people in the United States. Some people suffering from DM may also be afflicted with ESRD. A small percentage of these patients undergo a simultaneous pancreas-kidney (SPK) transplant, which may be accomplished using organs from deceased or living donors. Transplant of a pancreas may involve either the entire organ or a pancreas segment. Currently, whole-organ transplant is the most common procedure, with a portion of the duodenum often transplanted along with the pancreas. Living donors are often the source of segmental transplants. In recent years, isolation and transplantation of β-islet

cells alone have been completed. Islet transplantation is intended to treat organ dysfunction by replacing nonfunctioning islet cells with new ones. Islet transplants are still considered experimental, and long-term benefit and/or risk of this procedure needs to be studied extensively. Future success of islet cell transplantation is dependent on identifying a nontoxic immunosuppressive combination. There were 213 pancreas transplants and 789 SPK procedures in the United States in 2017.[2] Reasons for pancreas transplant include:

LO 1

- DM (ie, type 1 and 2, DM secondary to chronic pancreatitis or cystic fibrosis)
- Pancreatic cancer

PATHOPHYSIOLOGY

Major Histocompatibility Complex

The primary target of the immune response after organ transplant is the major histocompatibility complex (MHC).[1,3] The MHC is a region of highly polymorphic genes located on the short arm of chromosome 6. The human MHC is referred to as human leukocyte antigen (HLA). HLA is a set of glycoproteins expressed on the surface of most cells. These proteins are involved in immune recognition, which is the discrimination of self from nonself, but are also the principal antigenic determinants of allograft rejection.[1,3]

The HLA have been classified into two major groups, class I and II:

- Class I: expressed on the surfaces of all nucleated cells and recognized by $CD8^+$ cells (ie, cytotoxic T-cells); subclasses are HLA-A, HLA-B, and HLA-C.
- Class II: expressed solely on the surfaces of antigen-presenting cells (APCs). The APCs serve to stimulate $CD4^+$ cells (ie, helper T-cells); subclasses are HLA-DP, HLA-DQ, and HLA-DR.

T and B Lymphocytes

Lymphocytes are one of five kinds of white blood cells. Mature lymphocytes are astonishingly diverse in their functions. The most abundant of the lymphocytes are T lymphocytes (ie, T-cells) and B lymphocytes (ie, B-cells).

▶ *T Lymphocytes*

LO 2

KEY CONCEPT T-cells play a major role in the cell-mediated immune response. These cells are produced in the bone marrow, but mature in the thymus, hence the abbreviation "T." There are three recognized subclasses of T-cells:

- Cytotoxic T-cells ($CD8^+$) promote target cell destruction by activating cellular **apoptosis** or killing the target cell via the release of cytotoxic proteins.
- Helper T-cells ($CD4^+$) are the great communicators of the immune response. Once activated, they proliferate and secrete cytokines that regulate the function of **effector cells**. Some helper T-cells secrete cytokines that recruit cytotoxic T-cells, B-cells, or APCs, whereas others secrete cytokines that turn off the immune response.
- Regulatory T-cells, or suppressor T-cells suppress activation of an immune response.

▶ *B Lymphocytes*

LO 2

B-cells play a large role in the humoral immune response. In humans, B-cells are produced and mature in the bone marrow. The human body produces several types of B-cells. Each is unique, with a distinctive cell surface receptor protein that binds to only one particular antigen. Once B-cells encounter their antigen and receive a cytokine signal from helper T-cells, they can further differentiate into one of two cells, plasma cells or memory B-cells. Plasma cells secrete antibodies that induce the destruction of target antigens through complement recruitment and/or **opsonization**. Memory B-cells play an important role in long-term immunity, as they are capable of rapidly responding to subsequent exposures to their target antigen.

Antigen-Presenting Cells (APCs)

LO 3

KEY CONCEPT An APC is a cell that displays a foreign antigen complexed with MHC on its cell surface. Its major responsibility is to present these foreign antigens to T-cells, which can identify this complex using their T-cell receptors (TCRs). There are three main types of APCs: dendritic cells (DCs), macrophages, and activated B-cells. DCs are present in tissues that are in contact with the environment, such as skin and the lining of the nose, lungs, stomach, and intestines. They are responsible for **phagocytosis**, after which they express the foreign antigen on their cell surface and then migrate to lymphoid tissues to interact with T- and B-cells to initiate the immune response. Macrophages' main role is removal of pathogens and necrotic debris. However, like DCs, macrophages also phagocytize antigens. The first time an antigen is encountered, the DCs and macrophages act as the primary APCs. However, if the same antigen is encountered again, memory B-cells become the most important APC because they initiate the immune response quickly after antigen presentation. It appears that both DCs and macrophages have the most activity in terms of **allorecognition**.

Allorecognition

KEY CONCEPT Recognition of the antigens displayed by the transplanted organ (alloantigens) is the prime event that initiates the immune response against the allograft. There are currently two accepted pathways for allorecognition:

- Direct pathway: Donor APCs migrate out of the allograft into the recipient's lymph nodes and present donor MHC molecules to the recipient's T-cells.
- Indirect pathway: Recipient APCs migrate into the graft and phagocytize alloantigens. The recipient's APCs present donor MHC molecules to the recipient T-cells in lymph nodes.

T-Cell Activation

KEY CONCEPT Whether it is by direct or indirect pathways, for a T-cell to become activated against the allograft, two interactions or signals must take place between the APCs and the recipient's T-cells[1,3]:

- Signal 1 is the interaction of the TCR with the foreign antigens presented by APCs.
- Signal 2 is an interaction between one of several costimulatory receptors and paired ligands on the cell surfaces of the APCs and T cells, respectively. Both interactions must occur simultaneously as Signal 1 in the absence of Signal 2 induces T-cell **anergy**.
- Once activated, T-cells undergo **clonal expansion** under the influence of cytokines, specifically interleukin-2 (IL-2). These steps elicit an antidonor T-cell response that results in graft destruction.

Mechanisms of Acute Rejection

After activation, cytotoxic T-cells emerge from lymphoid organs to infiltrate the graft and trigger the immune response. These cells induce graft destruction via two mechanisms: (a) secretion of cytotoxic proteins (ie, perforin, granzyme) and (b) induction of cellular apoptosis through interaction. Besides the cytotoxic T-cells, several other cell lines may play a role in allograft destruction including B-cells, granulocytes, and natural killer (NK) cells.

Types of Rejection

▶ *Hyperacute Rejection*

LO 4

Hyperacute rejection is an immediate recipient immune response against the allograft due to the presence of preformed recipient antibodies directed against the donor's HLA. This type of reaction generally occurs within minutes of transplantation. The organ must be removed immediately to prevent severe systemic responses. In the case of cardiac or lung transplantation in which the organ cannot be promptly removed, short-term mechanical circulatory support is required until an alternative organ becomes available. Those at the highest risk for hyperacute rejection include any patients who have preformed HLA or ABO blood group antibodies, including those with a history of previous organ transplant or multiple blood transfusions, as well as women who have had children. Hyperacute rejection has been largely eliminated due to routine pretransplant surveillance testing.

▶ *Acute Rejection*

LO 4

Acute rejection is a cell-mediated process that generally occurs early posttransplant; however, it can occur at any time after transplant. This reaction is mediated through alloreactive T-cells. Table 55–1 presents organ-specific signs and symptoms of acute rejection.[1]

▶ *Antibody-Mediated Rejection*

LO 4

Antibody-mediated rejection (AMR) is the process of creating graft-specific antibodies.[4] This type of rejection occurs less frequently than cell-mediated acute rejection. Histologic findings are similar to those of hyperacute rejection, but the severity of rejection is usually less with AMR. AMR is generally characterized by deposition of immunoglobulins and complement in allograft tissues. However, AMR may be diagnosed without the presence of complement. Although rare, donor-specific antibodies (DSA) may be present or develop later following transplant. Presence of DSA is a strong predicator of AMR which might lead to allograft injury and failure following transplantation. Treatment for this type of rejection is not well defined; however, several reports have shown that plasmapheresis, immunoglobulin therapy, rituximab, bortezomib, or eculizumab may be effective.[4]

▶ *Chronic Rejection*

LO 4

Chronic rejection has traditionally been thought of as a slow, insidious form of acute rejection, resulting in worsening organ function over time. The exact immunologic processes of chronic rejection are poorly understood; however, many believe that both the cell-mediated and humoral immune systems and drug-induced toxicities play a vital role in its development. Currently, retransplantation is the only effective treatment option.[1,3]

▶ *Host–Graft Adaptation*

LO 5

"Host–graft adaptation" describes the decreased immune response against the allograft over time.[1,3] This phenomenon is evident by the reduced incidence of acute rejection episodes seen months after transplantation. In theory, host–graft adaptation is thought to be secondary to a weakened T-cell response to donor antigens while patients receive maintenance immunosuppression.[1,3]

Tolerance

LO 5

Tolerance is the process that allows organ-specific antigens to be accepted as self.[1] This means the immune system would cease to respond to the allograft, and immunosuppressive medications would not be required. Immune tolerance has been achieved in the lab, but has yet to be successfully accomplished in humans.[1]

Immunologic Barriers to Transplantation

One of the more common barriers to successful transplantation is the presence of preformed HLA antibodies or ABO blood group incompatibility.[4] In cases in which these antibodies exist, if they are not adequately removed prior to transplant, they are likely to result in AMR and poor graft survival. To improve outcomes, assessment of pretransplant immune risk factors plays

Table 55–1

Organ-Specific Signs and Symptoms of an Acute Rejection Episode[1]

Organ	Clinical Symptoms	Laboratory Signs
Heart	Lethargy, weakness, SOB, DOE, hypotension, tachycardia, atrial flutter, ventricular arrhythmias	Leukocytosis, biopsy positive for mononuclear infiltrates
Kidney	Weight gain, decreased urine output, malaise, hypertension, edema	Increased SCr, BUN, leukocytosis, biopsy positive for lymphocytic infiltration
Intestine	GI symptoms (ie, bloating, cramping, diarrhea, increased stomal output)	There are no reliable biochemical markers for intestine transplant rejection, but biopsies may be helpful
Liver	Graft tenderness and swelling, back pain, anorexia, ileus, tachycardia, jaundice, ascites, encephalopathy	Abnormal LFTs, increased bilirubin, alkaline phosphate, transaminases, biopsy positive for mononuclear cell infiltrate with evidence of tissue damage
Lung	Fever, impaired gas exchange, SOB, malaise, anxiety	Decreased FEV, infiltrate on CXR, biopsy positive for lymphocytic infiltration
Pancreas	Graft tenderness and swelling, polyuria, abdominal pain	Increased FBS, leukocytosis, decreased C-peptide and urinary amylase levels

BUN, blood urea nitrogen; CXR, chest x-ray; DOE, dyspnea on exertion; FBS, fasting blood sugar; FEV, forced expiratory volume; GI, gastrointestinal; LFTs, liver function tests; SCr, serum creatinine; SOB, shortness of breath.

an important role in prevention of immune-mediated allograft injuries. The introduction of pretransplant cross-matching and the use of ABO-compatible donors has largely eliminated hyperacute rejection episodes. However, these immunologic barriers are present in several potential recipients with willing organ donors, and patients are left to wait for a deceased donor or undergo pretransplant immunomodulation in an attempt to prevent these antibodies from affecting the allograft.[4]

▶ *ABO Incompatibility*

The expanding deceased donor waiting list encouraged some centers to evaluate the use of ABO desensitization protocols to transplant patients with ESRD that had willing but ABO-incompatible donors.[4] The desensitization protocol most commonly used in the United States involves reducing ABO antibody titers through plasmapheresis with IV immunoglobulin (IVIG). Use of plasma exchange to achieve an ABO antibody titer of less than 1:8 to 1:32 has resulted in long-term renal transplant results that are comparable to those of ABO-compatible transplants, despite an incidence of acute AMR that approaches 10% to 30%.[4]

TREATMENT

Desired Outcomes

LO 6 KEY CONCEPT The major focus of pharmacotherapy in transplantation is to achieve long-term patient and allograft survival while avoiding major adverse drug reactions.[1,3,5,6] Short-term outcomes (eg, acute rejection rates, 1-year graft survival) have improved significantly since the first successful transplant due to an improved understanding of the immune system and enhancements in surgical techniques, organ procurement, immunosuppression, and posttransplant care. However, the frequency of graft loss remains higher than desired in kidney and heart transplantation.[1,3,5,6]

It is imperative that transplant practitioners be aware of the specific advantages and disadvantages of available immunosuppressants, as well as adverse reactions and drug–drug interaction (DDI) profiles. There are generally three stages of medical immunosuppression: (a) induction therapy, (b) maintenance therapy, and (c) treatment of rejection. KEY CONCEPT

LO 6 Immunosuppressive regimens utilize multiple medications working on different targets of the immune system. Refer to Table 55–2 for a list of all available immunosuppressive agents.[1,5,6]

Table 55–2

Currently Available Immunosuppressive Agents[1,5,6]

Generic Name (Brand Name)	Common Dosage	Common Adverse Effects
Induction Therapy Agents		
Alemtuzumab (Campath)	20–30 mg × single doses	Flu-like symptoms, chills, rigors, fever, rash, myelosuppression
Antithymocyte globulin equine (ATGAM)	15 mg/kg IV × 5–14 days	Flu-like symptoms, chills, rigors, fever, rash, myelosuppression
Antithymocyte globulin rabbit (Thymoglobulin)	1.5 mg/kg IV × 3–7 days	Flu-like symptoms, chills, rigors, fever, rash, myelosuppression
Basiliximab (Simulect)	20 mg IV × 2 doses	None reported compared to placebo
Maintenance Immunosuppressants		
Cyclosporine (Sandimmune, Neoral, Gengraf)	4–5 mg/kg/day by mouth twice a day	Neurotoxicity, gingival hyperplasia, hirsutism, hypertension, hyperlipidemia, glucose intolerance, nephrotoxicity, electrolyte abnormalities
Tacrolimus (Prograf, Astagraf XL, Envarsus XR)	0.05–0.075 mg/kg by mouth twice a day or once daily if using Astagraf XL or Envarsus XR	Neurotoxicity, alopecia, hypertension, hyperlipidemia, glucose intolerance, nephrotoxicity, electrolyte abnormalities
Azathioprine (Imuran)	1–2.5 mg/kg by mouth once a day	Myelosuppression, GI disturbances, pancreatitis
Mycophenolate mofetil (CellCept)	0.5–1.5 gm by mouth twice a day	Myelosuppression, GI disturbances
Enteric-coated MPA (Myfortic)	720 mg by mouth twice a day	Myelosuppression, GI disturbances
Sirolimus (Rapamune)	1–10 mg by mouth once a day	Hypertriglyceridemia, myelosuppression, mouth sores, hypercholesterolemia, GI disturbances, impaired wound healing, proteinuria, lymphocele, pneumonitis
Everolimus (Zortress)	0.75 mg by mouth twice daily	Hypertriglyceridemia, myelosuppression, mouth sores, hypercholesterolemia, GI disturbances, impaired wound healing, proteinuria, lymphocele, pneumonitis
Prednisone (Deltasone)	Maintenance: 2.5–20 mg by mouth once a day	Mood disturbances, psychosis, cataracts, hypertension, fluid retention, peptic ulcers, osteoporosis, muscle weakness, impaired wound healing, glucose intolerance, weight gain, hyperlipidemia
Belatacept (Nulojix)	10 mg/kg on postop days 1 and 4 10 mg/kg at the end of postop weeks 2, 4, 8, and 12 5 mg/kg at the end of postop week 16 and every 4 weeks thereafter	GI disturbances, electrolyte abnormalities, headache

GI, gastrointestinal; IV, intravenous; MPA, mycophenolic acid.

Induction Therapy

LO 6 KEY CONCEPT The goal of induction therapy is to provide a high level of immunosuppression in the early posttransplant period, when the risk of acute rejection is highest.[5] This stage of immunosuppression is initiated intraoperatively and concluded within the first 1 to 10 days after transplantation. Antibody induction therapy is not a mandatory stage of recipient immunosuppression and is typically predicated on immunologic risk. However, since acute rejection is a major concern in solid organ transplant (SOT) recipients and its impact on chronic rejection is undeniable, induction therapy is often considered essential in some organs to optimize outcomes.[5]

▶ *Goals of Induction Therapy*

LO 7 KEY CONCEPT Induction agents are highly immunosuppressive, allowing for significant reductions in acute rejection and improved 1-year graft survival.[5] Due to their unique pharmacologic effect, these agents are often considered essential in patients at high risk for poor short-term outcomes, such as patients with preformed antibodies, history of previous transplants, multiple HLA mismatches, or transplantation of organs with prolonged cold ischemic time, or from expanded-criteria donors. Specifically in renal transplantation, induction therapy plays an important role in preventing early-onset calcineurin inhibitor (CNI)–induced nephrotoxicity. With induction therapy, CNI initiation can be delayed until the graft regains some degree of function. Induction therapy is imperative when employing corticosteroid sparing or avoidance protocols.[5]

The improved short-term outcomes gained from induction therapy come with a degree of risk.[5] By using these highly immunosuppressive agents, particularly the antilymphocyte antibodies (ALA; the antithymocyte antibodies and alemtuzumab), the ability to mount a cell-mediated immune response is significantly reduced, which increases the risk of opportunistic infections and malignancy. Cytokine release syndrome is a common complication of T-cell depleting agents and may require premedications of diphenhydramine and acetaminophen before infusions.[5]

▶ *Currently Available Induction Therapies*

The objective of induction therapy is to prevent acute cellular rejection in the early posttransplant period and prolong allograft survival following transplantation. These agents are categorized as depleting and nondepleting. Depleting agents exert their pharmacological effects through the depletion of T and B lymphocytes (thymoglobulin, antithymocyte globulin equine [e-ATG], alemtuzumab, rituximab), while nondepleted agents exert their pharmacological effects through inhibition of T-cell activation (basiliximab).

LO 7 **Basiliximab** Basiliximab is a chimeric monoclonal antibody that acts as an IL-2 receptor antagonist.[5,7] These receptors are present on almost all activated T cells. Basiliximab inhibits IL-2–mediated activation of lymphocytes, which is an important step in T-cell clonal expansion. Basiliximab is not a T-cell depleting agent and can be given with premedications.

LO 7 The dose of basiliximab is 20 mg IV given 2 hours prior to transplant, followed by a second 20 mg dose on postoperative day 2–4.[5,7] This dosing schedule can be used for both children greater than or equal to 35 kg (77 lb) and adults. Two 10 mg doses with the same dosing schedule should be used for children less than 35 kg (77 lb). There are no specific dosage adjustments needed in renal or hepatic impairment.[5,7] Incidence of all adverse reactions with basiliximab was similar to placebo in trials, and there are no reported DDIs with basiliximab.[5,7]

LO 6 LO 7 **Antithymocyte Globulin Rabbit** Antithymocyte globulin rabbit (r-ATG) is a polyclonal antibody that induces T-cell clearance, but more importantly, it alters T-cell activation, homing, and cytotoxic activities.[7] It is also believed that r-ATG plays a role in inducing T-cell apoptosis. This agent is typically dosed at 1.5 mg/kg/day and is usually administered for 3 to 7 days after transplantation.[5] Many renal transplant centers aim to initiate the first dose intraoperatively to reduce organ reperfusion injury.[8]

Adverse reactions are common and may include fever (63.4%), chills (57.3%), headache (40.2%), nausea (36.6%), diarrhea (36.6%), malaise (13.4%), dizziness (8.5%), **leukopenia** (57.3%), **thrombocytopenia** (36.6%), and generalized pain (46.3%).[9-11] Incidence of infection is 36.6%, with **cytomegalovirus (CMV) disease** occurring in 13.4% of patients. There are no reported DDIs with the use of r-ATG at this time.[5,7]

LO 7 **Antithymocyte Globulin Equine** e-ATG is a polyclonal antibody that contains antibodies against several T-cell surface markers, similar to r-ATG. Compared to other antithymocyte preparations, e-ATG is associated with significant batch to batch variability and reduced efficacy. Most transplant centers prefer to use r-ATG (Thymoglobulin) over e-ATG (ATGAM).

e-ATG is associated with several adverse reactions.[5,7] The most common are fever (63%), chills (43.2%), headache (34.6%), back pain (43.2%), nausea (28.4%), diarrhea (32.1%), dizziness (24.7%), malaise (3.7%), leukopenia (29.6%), and thrombocytopenia (44.4%). Overall incidence of opportunistic infections is 27.2%, with CMV occurring in 11.1% of patients. There are currently no reported pharmacokinetic DDIs.[5,7]

Alemtuzumab Alemtuzumab is a recombinant DNA-derived monoclonal antibody that binds to CD52, which is present on most B and T lymphocytes, macrophages and NK cells, and a subpopulation of granulocytes.[5,7] After complexing with the CD52 cell surface marker, alemtuzumab induces an antibody-dependent cell lysis. This agent produces a rapid and extensive lymphocyte depletion that may take several months to years to return to pretransplant levels. Although it is not Food and Drug Administration (FDA) approved for use in organ transplantation, studies have demonstrated that a single dose of 30 mg IV at the time of transplant is effective in preventing acute rejection.[5]

LO 6 LO 7

Alemtuzumab is associated with serious adverse reactions including anemia (47%), neutropenia (70%), thrombocytopenia (52%), headache (24%), dysesthesias (15%), dizziness (12%), nausea (54%), vomiting (41%), diarrhea (22%), infusion-related reactions (15%–89%), and infection (37%; CMV viremia occurred in 15% of patients).[7] It is very important to premedicate with acetaminophen and diphenhydramine 30 minutes before infusion to reduce the incidence of infusion-related reactions.[5]

Comparative Efficacy There are a few studies that help to delineate the ideal induction therapy agent. Studies comparing r-ATG and e-ATG show that r-ATG is more effective in lowering acute rejection rates and improving 1-, 5- and 10-year allograft outcomes.[9,10,12] Conversely, a study evaluating the use of basiliximab versus r-ATG demonstrated similar short-term efficacy between both groups.[13] However, other analyses of these two agents demonstrated similar results for allograft and patient survival, but a benefit for r-ATG in lowering incidence of acute allograft rejection.[11,14] A more recent analysis showed that alemtuzumab improved transplant outcomes when compared with basiliximab

Patient Encounter Part 1

A 34-year-old man presents to your transplant center for a living-related renal transplant.

PMH:

- ESRD—secondary to focal segmental glomerulosclerosis (FSGS)
- One prior renal transplant from his mother 10 years ago, which failed 1 year ago from presumed nonadherence early after transplant resulting in multiple rejection episodes within the first few years posttransplant.
  - For the previous transplant the patient was maintained on tacrolimus and mycophenolate.
- Hypertension
- Insomnia
- Secondary hyperparathyroidism

FH: Father is alive and living with a history of cardiovascular disease and mother is alive and living with a history of basal cell carcinoma.

SH: The patient works as a mechanical engineer. He admits to social alcohol use (3 or 4 drinks per week) and denies any tobacco or IV drug use.

Admission Meds:

- Metoprolol succinate 50 mg by mouth once a day
- Amlodipine 10 mg by mouth once a day
- Furosemide 20 mg by mouth twice a day
- Zolpidem 10 mg by mouth once a day at bedtime
- Calcitriol 0.25 mg by mouth once a day
- Epo 4000 units intravenously every hemodialysis session

Allergies:

- NKDA

Misc:

- CMV Serostatus: Donor is CMV immunoglobulin G (IgG) positive
- CMV Serostatus: Recipient is CMV IgG negative
- EBV Serostatus: Donor is EBV IgG positive
- EBV Serostatus: Recipient is EBV IgG negative
- Patient has documented G6PD deficiency

Identify your treatment goals for this patient.

Create a plan for induction therapy (ie, would you recommend induction therapy, and if so, which agent?).

in patients with a low immunologic risk, and similar outcomes compared to r-ATG in patients with high immunologic risk.[15] When choosing an agent for induction therapy, one must weigh the risks versus benefits. Overall, the ALAs are considered to be most effective, but are associated with higher incidence of infectious disease and malignancy.[5]

Maintenance Immunosuppressive Therapy

LO 6 The goals of maintenance immunosuppression are to prevent rejection and optimize patient and graft survival.[6] Antirejection medications require careful selection and dose titration to balance the risks of rejection with those of toxicities.

KEY CONCEPT Common maintenance immunosuppressive agents are divided into five classes:

- Calcineurin inhibitors (CNI; cyclosporine and tacrolimus)
- Antiproliferatives (azathioprine and the mycophenolic acid [MPA] derivatives)
- Target of rapamycin (ToR) inhibitors (sirolimus and everolimus)
- Corticosteroids
- Costimulatory blockade (belatacept)

LO 7 Maintenance immunosuppression is generally achieved by combining two or more medications from the different classes, specifically targeting unique components of the immune response.[6] Refer to Figure 55–1 for a schematic representation of these different drug mechanisms and Figure 55–2 for an example protocol for administration of immunosuppressive medications posttransplant. This method of medication selection also minimizes toxicities by choosing agents with different adverse event profiles. Immunosuppressive regimens vary between organ types and transplant centers, but most often include a CNI with an adjuvant agent, plus or minus corticosteroids. Selection of an immunosuppressive regimen should be patient-specific, and one must take into account the patient's comorbidities, medication regimens, and preferences.[6]

▶ *Calcineurin Inhibitors*

KEY CONCEPT The CNIs, cyclosporine and tacrolimus, are considered the cornerstone of modern immunosuppressive protocols. LO 7 The CNIs work by complexing with cytoplasmic proteins (cyclosporine with cyclophilin and tacrolimus with FK binding protein-12).[6,7] These complexes inhibit calcineurin phosphatase, which results in reduced IL-2 gene transcription and a reduction in IL-2 synthesis. This diminishes T-cell activation.[6,7]

Cyclosporine Cyclosporine USP was first approved in 1983, but was associated with a variable oral absorption. The development of a newer formulation, cyclosporine microemulsion USP (ie, modified), introduced in 1994, allowed for more consistent drug exposure due to a more reliable pharmacokinetic profile.[1] Cyclosporine modified is the formulation of choice for most transplant centers utilizing cyclosporine. The two formulations are not interchangeable.[6]

LO 6 The usual oral adult dose of cyclosporine ranges from 3 to 7 mg/kg/day in two divided doses.[7] Appropriate selection of the starting dose depends on the organ type, the patient's comorbidities, and other concomitant immunosuppressive agents utilized. Cyclosporine modified is available as 25 mg and 100 mg capsules and an oral solution. An IV formulation of conventional cyclosporine is also available. When converting a patient from oral to IV, the dosage should be reduced to approximately one-third of the total daily oral dose.[7]

LO 8 Cyclosporine whole-blood trough concentrations (C_0) have traditionally been obtained to help monitor for efficacy and safety. Therapeutic C_0 may range from 50 to 400 ng/mL (mcg/L; 42–333 nmol/L). Target levels should be individualized for each

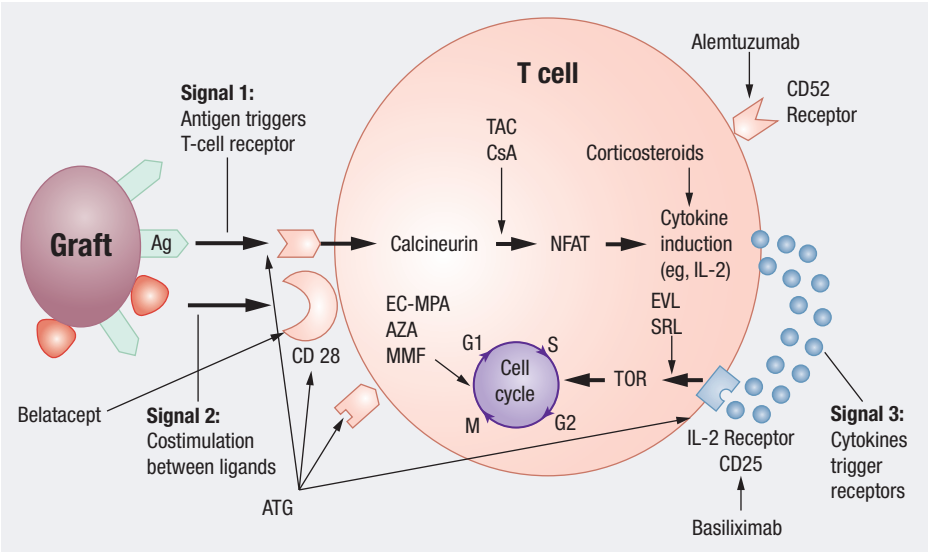

FIGURE 55–1. Identification of the sites of action of the various immunosuppressive medications. Allograft recognition through Signal 1 occurs when the antigen-major histocompatibility complex (MHC) molecule is recognized by the T-cell receptor (TCR). A costimulatory signal, Signal 2, initiates signal transduction with activation of second messengers, one of which is calcineurin. Together, Signal 1 and Signal 2 activate calcineurin phosphatase, which removes phosphates from the nuclear factors, allowing them to enter the nucleus with a subsequent increase in interleukin-2 (IL-2) gene transcription. Signal 3 occurs with the interaction of IL-2, with the IL-2 receptor on the cell membrane surface. This culminates in a signal that passes through the mammalian target of rapamycin (ToR) and induces cell proliferation and production of cytokines specific to the T-cell. (ATG, antithymocyte globulin; AZA, azathioprine; CsA, cyclosporine; EC-MPA, enteric-coated mycophenolic acid; EVL, everolimus; MMF, mycophenolate mofetil; NFAT, nuclear factors; SRL, sirolimus; TAC, tacrolimus.)

patient, usually depending on the organ transplanted, patient's condition, method of assay (liquid chromatography coupled to tandem mass spectrometry [LC-MS/MS], monoclonal, polyclonal), and time since transplantation.[6] Newer studies suggest that monitoring of concentrations at 2 hours postdose (C_2) correlates better with toxicity and efficacy when compared with C_0.[16]

LO 6 **Tacrolimus** Tacrolimus was approved in 1997. Oral starting doses range from 0.1 to 0.2 mg/kg/day in two divided doses. Tacrolimus is available in 0.5 mg, 1 mg, and 5 mg capsules and as an injectable.[7] Two once-daily tacrolimus formulations are also available. Once-daily formulations are not bioequivalent and should not be substituted in clinical practice; however, these differences in their compositions are unlikely to have any major therapeutic benefit. Tacrolimus C_0 should be monitored and maintained between 5 and 15 ng/mL (mcg/L; 6 and 19 nmol/L), again depending on the transplanted organ, patient's condition, and time since transplant.[6]

LO 8

The tacrolimus IV formulation is usually avoided due to the risk of anaphylaxis, because of its castor oil component, and nephrotoxicity.[6] Doses for IV administration are recommended to start at 0.01 mg/kg/day. In an effort to avoid IV tacrolimus, many transplant centers utilize sublingual (SL) tacrolimus in their patients unable to receive the medication by mouth.[6]

LO 7 **Adverse Drug Reactions** KEY CONCEPT One of the major disadvantages of the CNIs is their ability to cause nephrotoxicity. Acute nephrotoxicity has been correlated with high doses and is usually reversible.[7] Chronic CNI toxicity, however, is typically irreversible and linked to chronic drug exposure. Table 55–3 expands on the more common CNI–associated adverse events.[1,6]

Comparative Efficacy Even though cyclosporine and tacrolimus are both CNIs, there are several differences between the two. A meta-analysis comparing cyclosporine to tacrolimus in kidney transplantation showed tacrolimus was associated with significantly lower risk of allograft loss at 6 months and lower rates of acute rejection at 1 year.[17] Tacrolimus is the primary CNI in many transplant centers, due in large part to a more favorable adverse reaction profile.[6]

► *Antiproliferatives*

These agents are considered to be adjuvant to the CNIs or ToR inhibitors.[6]

Azathioprine Azathioprine was approved in 1968 as an adjunct immunosuppressant in renal transplant. Prior to the advent of cyclosporine, the combination of azathioprine and corticosteroids was the mainstay of immunosuppressive therapy. Use of azathioprine has declined markedly due to superiority of the MPA derivatives. KEY CONCEPT Azathioprine is a prodrug for 6-mercaptopurine (6-MP), a purine analog. 6-MP acts as an antimetabolite and inhibits DNA replication with a resultant reduction in T-cell proliferation.[6] It is available in oral and IV dosage forms.[7] The typical oral dose of azathioprine for organ transplantation is 1 to 3 mg/kg once a day.[7] Thiopurine methyltransferase (TPMT) is the main enzyme for inactivation of azathioprine. Approximately 10% of transplant recipients have reduced TPMT activity and are at risk for drug toxicity. Dose reductions due to drug accumulation are needed to avoid toxicities. In addition, the dose should be adjusted for renal function since 6-MP and its metabolites are renally eliminated.[7] Trough concentrations of 6-MP are not monitored; however, most clinicians often monitor for signs of myelosuppression. KEY CONCEPT Myelosuppression (mainly leukopenia and thrombocytopenia) is a frequent, dose-dependent and dose-limiting complication (> 50% of patients) that often prompts dose reductions.[7] Other common adverse events include hepatotoxicity (2%–10%) and adverse gastrointestinal (GI) events (10%–15%;

LO 6 LO 7

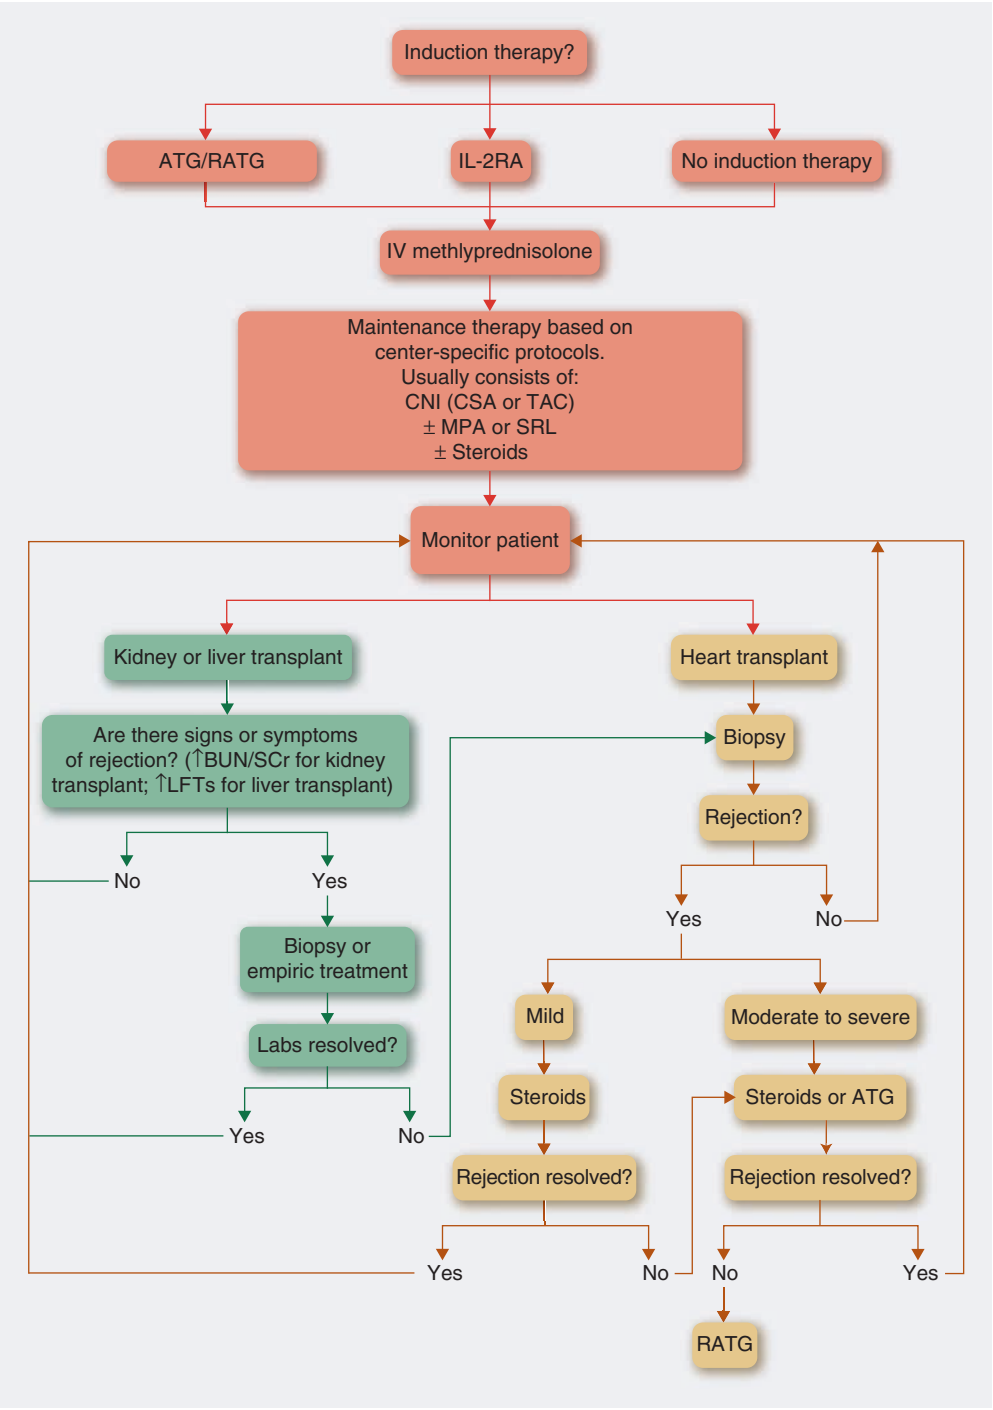

FIGURE 55–2. Example protocol of immunosuppressive medication use in organ transplantation. Center-specific protocols may use rabbit antithymocyte immunoglobulin (RATG), an interleukin-2 receptor antagonist (IL-2RA), or no induction therapy. In any situation, patients receive intravenous (IV) methylprednisone prior to, during, or immediately following the transplant operation. The patient then will begin the maintenance immunosuppressive regimen. The center-specific protocol will specify which calcineurin inhibitor (cyclosporine or tacrolimus) is used in combination with mycophenolate mofetil or sirolimus, with or without steroids. Patients then are monitored for signs and symptoms of rejection. If rejection is suspected, a biopsy can be done for definitive diagnosis, or the patient may be treated empirically for rejection. Empirical treatment generally involves administration of corticosteroids. If signs and symptoms of rejection are resolved with empirical therapy, the patient will continue to be monitored according to the center-specific protocol. If rejection is confirmed by biopsy, treatment may be based on the severity of rejection. High-dose corticosteroids are used most frequently for mild to moderate rejection. RATG can be used for moderate to severe rejections or steroid-resistant rejections. Protocols and algorithms may differ across transplant centers. (ATG, antithymocyte globulin; BUN, blood urea nitrogen; CNI, calcineurin inhibitor; CSA, cyclosporine; LFT, liver function test; MPA, mycophenolic acid; SCr, serum creatinine; SRL, sirolimus; TAC, tacrolimus.) (From Johnson HJ, Schonder KS. Solid Organ Transplantation. In: DiPiro JT, Talbert RL, Yee GC, et al., eds. Pharmacotherapy: A Pathophysiologic Approach. 10th ed. New York: McGraw-Hill; 2017:1402.)

Table 55–3

Management of Common Adverse Effects of Calcineurin Inhibitors (CNIs)[1,6]

Adverse Event	Most Likely Offending CNI	Monitoring Parameters	Therapeutic Management Options
Nephrotoxicity	Either	• SCr • BUN • Urine output • Biopsy-proven CNI-induced nephrotoxicity	• Reduce CNI dose (if possible) • Use of CCB for hypertension control • Modify regimen (change to non-CNI containing regimen [ToR inhibitor or belatacept])[a]
Hypertension[b]	Cyclosporine	• Blood pressure • Heart rate	• Initiate patient-specific antihypertensive therapy • Reduce cyclosporine dose (if possible) • Modify regimen (change to tacrolimus or non-CNI containing regimen)[a]
Hyperlipidemia[b]	Cyclosporine	• Fasting lipid panel	• Initiate patient-specific cholesterol-lowering therapy • Reduce cyclosporine dose (if possible) • Modify regimen (change to tacrolimus or non-CNI containing regimen)[a]
Hyperglycemia[c]	Tacrolimus	• Blood glucose (fasting and nonfasting) • Hemoglobin A_{1c}	• Lifestyle modifications • Reduce tacrolimus dose (if possible) • Reduce steroids (if patient is taking them and if possible) • Initiate patient-specific glucose-lowering therapy (insulin or oral therapy) • Modify regimen (change to cyclosporine or non-CNI containing regimen)[a]
Neurotoxicities[c]	Tacrolimus	• Fine hand tremor • Headache • Mental status changes	• Reduce tacrolimus dose (if possible) • Modify regimen (change from tacrolimus to cyclosporine or non-CNI containing regimen)[a]
Hirsutism	Cyclosporine	• Patient complains of excessive hair growth or male-pattern hair growth	• Reduce cyclosporine dose (if possible) • Cosmetic hair removal • Modify regimen (change to tacrolimus or non-CNI containing regimen)[a]
Alopecia	Tacrolimus	• Patient complains of excessive hair loss	• Reduce tacrolimus dose (if possible) • Hair growth treatments (ie, minoxidil, finasteride in males only) • Consider use of multivitamin with thiamine and folic acid, and/or biotin 5000 mcg daily • Modify regimen (change to cyclosporine or non-CNI containing regimen)[a]
Gingival Hyperplasia	Cyclosporine	• Patient complains of excessive gum growth • Discuss options for therapy with the patient's dentist	• Reduce cyclosporine dose (if possible) • Oral surgery (gum resection) • Modify regimen (change to tacrolimus or non-CNI containing regimen)[a]

[a]Modifying the immunosuppressive regimen increases risk for rejection, even in stable patients. This option should be chosen cautiously and implemented with proper monitoring and follow-up.

[b]Tacrolimus is also associated with hypertension and hyperlipidemia, but to a much lower extent compared to cyclosporine.

[c]Cyclosporine is also associated with hyperglycemia and neurotoxicities, but to a much lower extent compared to tacrolimus.

BUN, blood urea nitrogen; CCB, calcium channel blocker; SCr, serum creatinine; ToR, target of rapamycin.

mostly nausea and vomiting). Importantly, pancreatitis and venoocclusive disease of the liver occur in less than 1% of patients following chronic azathioprine therapy.[7]

Mycophenolic Acid Derivatives Mycophenolate mofetil was approved in 1995 and enteric-coated MPA in 2004. Both agents are considered adjunctive immunosuppressants.[6] KEY CONCEPT Both mycophenolate mofetil and enteric-coated MPA are prodrugs for MPA. MPA acts by inhibiting inosine monophosphate dehydrogenase, a vital enzyme in the de novo pathway of purine synthesis. Inhibition of this enzyme prevents the proliferation of most cells that are dependent on the de novo pathway for purine synthesis, including T- and B-cells.[6] LO 7

Mycophenolate mofetil is available in 250 mg and 500 mg capsules, an oral suspension (100 mg/mL; in cherry syrup), and as an injectable.[7] The recommended starting dose of mycophenolate mofetil is 1000 to 1500 mg given twice daily. The conversion between oral and IV mycophenolate mofetil is 1:1. Enteric-coated MPA is available in 180 mg and 360 mg tablets. The appropriate equimolar conversion between mycophenolate mofetil and enteric-coated MPA is 1000 mg of mycophenolate mofetil to 720 mg of enteric-coated MPA.[6] The recommended starting dose of enteric-coated MPA is 720 mg given twice daily. Conversion of mycophenolate mofetil to enteric-coated MPA has been proven safe. MPA C_0 can be monitored; however, it is not routinely recommended.[6] LO 6 LO 6 LO 8

KEY CONCEPT The most common adverse events associated with these agents are GI (18%–54%; diarrhea, nausea, vomiting, and gastritis) and myelosuppression (20%–40%).[7] Despite LO 7

its enteric coating, enteric-coated MPA has the same degree of GI adverse events as mycophenolate mofetil.[6,18] However, recent data suggest that there is a benefit in converting patients with documented mycophenolate-induced GI disease from mycophenolate mofetil to enteric-coated MPA or to azathioprine.[19]

Comparative Efficacy The MPA derivatives have replaced azathioprine as the primary antiproliferative agent and are generally considered to provide a more specific immunosuppressive effect compared with azathioprine.[6] Mycophenolate mofetil and enteric-coated MPA have similar safety and efficacy data in renal transplant recipients.[18] The decision to choose one agent over another is a purely practitioner-dependent preference.

▶ *Target of Rapamycin Inhibitors*

LO 7 **Sirolimus** KEY CONCEPT Sirolimus inhibits T-cell activation and proliferation by binding to and inhibiting the activation of the mammalian ToR, which suppresses cellular response to IL-2 and other cytokines (ie, IL-4, IL-15).[6,7,20] Studies have shown that sirolimus may be used safely and effectively concomitantly with either cyclosporine or tacrolimus instead of an antiproliferative.[21] Sirolimus can also be used as an alternative agent for patients who do not tolerate CNIs due to nephrotoxicity or other adverse events.[6] At this time, the most exciting data for sirolimus point to its ability to prevent long-term allograft dysfunction when used as a substitute for the CNIs in renal transplant recipients.[20]

Sirolimus is available in 0.5 mg, 1 mg, and 2 mg tablets and a 1 mg/mL oral solution. Although some may elect not to do a loading dose, the package insert indicates that the current approved dosing regimen for sirolimus is a 6 mg loading dose followed by
LO 6 a 2 mg/day maintenance dose.[7] Use of a sirolimus loading dose of 5 to 15 mg/day for 1 to 3 days will allow for a more rapid achievement of adequate immunosuppression.[7] Maintenance doses of sirolimus usually range from 1 to 10 mg/day given once daily. Sirolimus blood C_0 should be maintained between
LO 8 3 and 10 ng/mL (mcg/L; 3 and 11 nmol/L), depending on the institution-specific protocols.[6] Of note, sirolimus has a half-life of approximately 62 hours, which means that it will not reach steady state after dosage changes for several days.[7]

LO 7 KEY CONCEPT The most common adverse events reported with sirolimus are leukopenia (20%), thrombocytopenia (13%–30%), and hyperlipidemia (38%–57%).[7] Other adverse effects include delayed wound healing, anemia, diarrhea, arthralgias, rash, proteinuria, pneumonitis, and mouth ulcers. One analysis suggests that use of sirolimus in kidney transplant recipients can reduce cardiovascular risk compared with CNI–based regimens.[22]
LO 7 Sirolimus has a black-box warning in newly transplanted liver and lung recipients due to severe and potentially life-threatening adverse events.[7] The long-term use of sirolimus in these populations may be appropriate, but not in the initial posttransplant period (ie, 3–6 months posttransplant).

Everolimus Everolimus is a derivative of sirolimus and has the
LO 6 same mechanism of action.[7,23] Everolimus is only indicated for prevention of rejection in low- to moderate-risk renal and liver transplant recipients. This agent is available in 0.25 mg, 0.5 mg, and 0.75 mg tablets. The recommended starting dose is 0.75 to
LO 8 1 mg twice daily without the need for a loading dose. Maintenance everolimus doses should be maximized to achieve a C_0 goal of 3 to 8 ng/mL (mcg/L; 3–8 nmol/L).[7,23] With a significantly shorter
LO 7 half-life compared with sirolimus, everolimus steady state can be reached within 4 to 6 days. The adverse event profile of everolimus is similar to that of sirolimus.[7,23]

▶ *Corticosteroids*

Traditional triple-therapy immunosuppressive regimens have consisted of a primary agent (ie, CNI, ToR inhibitor, belatacept), an antiproliferative, and corticosteroids.[6] In recent years, many renal transplant protocols have focused on corticosteroid sparing or avoidance. Avoidance or sparing of corticosteroids has been supported in the literature, although more studies are needed to help better characterize which patients should
LO 6 follow these protocols.[6,24] A typical taper includes a bolus of IV methylprednisolone 100 to 500 mg at the time of transplant, then tapered over days to months, depending on the type of organ, to a maintenance dose of prednisone 5 to 10 mg/day. Although most centers still use low-dose steroids for immunologically high-risk patients and nonrenal transplant patients, a number of renal transplant programs have developed an immunosuppression protocol that completely withdraws corticosteroids at some
LO 8 point posttransplantation.[6] Therapeutic drug monitoring of corticosteroids is not employed. Corticosteroids are associated
LO 7 with a variety of metabolic toxicities. The most common adverse events are summarized in Table 55–4.[1,6]

KEY CONCEPT Corticosteroids have various effects on immune and inflammatory responses, although their exact mechanism of immunosuppression is not fully understood. It is believed that high doses are directly lymphotoxic, and lower doses act by inhibiting the production of various cytokines that are necessary to amplify the immune response.[6,7]

The most commonly used corticosteroids are methylprednisolone (IV and oral) and prednisone (oral), although prednisolone and dexamethasone are also effective for organ

Table 55–4

Common Adverse Events Associated with Corticosteroids[1,6]

Body System	Adverse Event
Cardiovascular	Hyperlipidemia
	Hypertension
Central nervous system	Anxiety
	Insomnia
	Mood changes
	Psychosis
Dermatologic	Acne
	Diaphoresis
	Ecchymosis
	Hirsutism
	Impaired wound healing

Ocular	Cataracts
	Glaucoma
Respiratory	Epistaxis

transplantation. Corticosteroid doses vary by center-specific protocols, organ type, and patient characteristics.

▶ *Costimulatory Pathway Blocker*

Belatacept KEY CONCEPT Belatacept was approved in 2011 as the first IV biologic maintenance immunosuppressive agent in transplant.[25] Belatacept blocks CD80 and CD86 ligands, found on APCs.[7] The CD80 and CD86 proteins are responsible for stimulating CD28 on inactive T-cells, an essential costimulatory interaction (Signal 2). As detailed previously, Signal 1 without a complementary Signal 2 induces T-cell anergy.[25] Studies have shown that in combination with mycophenolate and corticosteroids, belatacept may be used in place of CNIs, demonstrating similar patient and allograft survival compared to a cyclosporine-based regimen.[26,27] Belatacept improved renal function; however, the incidence and intensity of acute rejection was significantly higher. Belatacept was also associated with improvements in blood pressure and lipid levels.[25]

LO 7

Belatacept is available in a 250 mg vial that requires reconstitution prior to administration.[7] The recommended dosing regimen is 10 mg/kg on the day of transplantation, followed by an additional dose 4 days later, and again at the end of weeks 2, 4, 8, and 12 posttransplant. Beginning at the end of week 16 posttransplant, belatacept is dosed at 5 mg/kg every 4 weeks thereafter.[7,25] Belatacept requires access to an infusion center/suite, or a home infusion service to ensure appropriate administration.

LO 6

The most common adverse effects associated with belatacept are infectious (urinary tract infection, 37%; upper respiratory infection, 15%), GI (diarrhea, 39%; constipation, 33%; nausea, 24%; vomiting, 22%), metabolic (hyperkalemia, 20%; hypokalemia 21%), and central nervous system (CNS; headache, 21%) complications.[7] Other adverse effects include peripheral edema, anemia, leukopenia, hypotension, arthralgia, and insomnia.[25] KEY CONCEPT Belatacept has a black-box warning for increased risk of posttransplant lymphoproliferative disorders (PTLD). Due to this risk, it is recommended that belatacept only be used in patients with a proven preexisting immunity to Epstein-Barr virus (EBV). An additional black-box warning advises against use of belatacept in liver transplant patients due to an increased risk of allograft loss and patient death.[7,25]

LO 7

Treatment of Acute Rejection Episodes

Acute rejection is generally treated with a course of high-dose methylprednisolone (250 to 1000 mg/day IV for 3 days), which is usually sufficient to ameliorate the episode. If the acute rejection episode is resistant to the initial course of steroids, a second course may be administered or the patient may begin therapy with r-ATG (1.5 mg/kg/day for 4 to 14 days).[28] Cellular rejection refractory to these treatments is rare and likely due to underlying causes such as an antibody-mediated component or other diagnosis. Treatments of refractory acute rejection may include alemtuzumab, IVIG, high-dose tacrolimus, or organ irradiation.

Managing Highly Sensitized Patients and Antibody-Mediated Rejection Episodes

The presence of preformed antibodies, high panel-reactive antibodies (PRA), and DSA are major barriers to successful transplantation.[4] This is true mainly because traditional immunosuppressants do not significantly affect the humoral immune system and are ineffective at management of AMR, which is a leading cause of allograft loss in kidney and heart transplant recipients. Without some form of intervention, antibody formation and rejection can significantly impact morbidity and mortality. Two major strategies are used for reduction of DSA pretransplant: (a) high-dose IVIG and (b) plasmapheresis plus low-dose IVIG. Each approach has advantages and disadvantages.[4]

In plasmapheresis or plasma exchange, patients' plasma is removed and replaced with albumin or fresh-frozen plasma.[4] Plasmapheresis produces a rapid reduction of preformed antibodies and allows transplantation to occur. The purpose of IVIG administration is to decrease anti-HLA alloantibody synthesis. The other mechanisms of IVIG are inhibition of complement-mediated injury, reduced B-cell proliferation and NK cells, and a decrease in phagocytosis. Most patients require four to five plasmapheresis sessions with IVIG to remove DSA. In patients at risk for bleeding, the use of albumin should be limited, and fresh-frozen plasma or a combination of both agents should be considered.[4]

In patients who develop AMR posttransplant, there are limited therapeutic options, none of which are FDA-approved. The potential options include plasmapheresis and IVIG, rituximab, bortezomib, and/or eculizumab.[4] All of these agents have an effect on humoral immunity, which may provide benefit to patients with AMR. The mechanisms of plasmapheresis and IVIG were discussed earlier.[4]

Rituximab is a chimeric monoclonal anti-CD20 antibody targeting B-cells.[4,7] This agent directly inhibits B-cell proliferation and induces cellular apoptosis through complement-mediated antibody-dependent cellular cytotoxicity. In an analysis of AMR treatment, the use of rituximab in conjunction with plasmapheresis/IVIG resulted in improved 3-year graft survival (92% vs 50%) and significantly reduced DSA at 3 months compared with high-dose IVIG alone.[29] Unfortunately, plasma cells lack CD20 and are unaffected by rituximab. However, rituximab may play an important role in reducing memory B-cell response. Overall, it appears that rituximab may provide beneficial effects in managing AMR and patients highly sensitized before transplant when used in combination with other therapies.[4]

Bortezomib is a proteasome inhibitor indicated for treatment of multiple myeloma.[4,7] It works by inducing cell-cycle arrest and apoptosis of plasma cells. Desensitization and treatment protocols using bortezomib have utilized doses of 1.3 mg/m^2 from one to four cycles. Acute hepatic dysfunction has rarely been reported; thus, bortezomib should be used cautiously in patients with moderate-to-severe hepatic impairment. Bortezomib has also been associated with significant myelosuppression and peripheral neuropathy. Bortezomib has been used in combination with plasmapheresis and IVIG or rituximab. The reported outcomes of these cases demonstrate graft survival rates of 85% to 100%. Anti-HLA antibodies are decreased by 50% within 2 weeks of therapy and remain suppressed for up to 5 months.[30,31] Bortezomib also seems effective in AMR refractory to plasmapheresis and IVIG.[4]

Eculizumab is a humanized monoclonal antibody directed against complement protein C5.[4,7] It inhibits the cleavage to C5a and C5b, thus preventing the generation of the membrane attack complex (MAC) and reducing antibody-dependent cell lysis. Eculizumab carries an FDA boxed warning of meningococcal infection. Meningococcal vaccination is recommended 14 days prior to eculizumab, but infections have been reported even in vaccinated patients. It is highly recommended to continue penicillin or alternative lifetime therapy in these patients. There are only a few case reports demonstrating eculizumab's efficacy for treating AMR, showing fast improvement of renal function observed within a week after eculizumab use.[4] Eculizumab is an important

agent for the prevention and treatment of atypical hemolytic uremic syndrome (aHUS) posttransplant.

Maintenance Immunosuppressive Therapies—Common Drug–Drug Interactions

KEY CONCEPT As the number of medications a patient takes increases, so does the potential for DDIs. Disease severity, patient age, and organ dysfunction are all risk factors for DDIs. In general, DDIs are either pharmacokinetic or pharmacodynamic interactions:

- Pharmacokinetic interactions result when one drug alters the absorption, distribution, metabolism, or elimination of another drug.
- Pharmacodynamic interactions include additive, synergistic, or antagonistic interactions that can affect efficacy or toxicity.

▶ *Pharmacokinetic Interactions*

Pharmacokinetic DDIs pose a major dilemma with the maintenance immunosuppressants. Pharmacokinetic interactions can either result in: (1) increased concentrations of one or more agents, with an increased risk for drug-induced toxicities, or (2) lowered (ie, subtherapeutic) drug concentrations, possibly leading to allograft rejection. These interactions can be seen during drug absorption, distribution, metabolism, and elimination.

Interactions of Absorption Gut metabolism, modifications in active transport, and changes in intestinal motility and chelation interactions alter absorption of the immunosuppressants. Active transporters (ie, P-glycoprotein [P-gp]) are present in the gut, brain, liver, and kidneys and play an important role in DDIs. P-gp provides a biological barrier, eliminating xenobiotics that may accumulate in these organ systems, thereby having a significant impact on the absorption and distribution of many medications. P-gp affects the absorption of the CNIs and ToR inhibitors. Medications that inhibit or induce the activity of P-gp have a significant impact on bioavailability of some of the immunosuppressive agents. For example, P-gp inhibitors, such as verapamil or quinidine, increase concentrations of cyclosporine, tacrolimus, sirolimus, and everolimus due to reduced P-gp-dependent drug elimination from the systemic circulation.[7]

There is a prominent interaction between the prokinetic agents and the CNIs seen through changes in intestinal motility. Metoclopramide increases the absorption of cyclosporine and tacrolimus by enhancing gastric motility and emptying, resulting in increased CNI concentrations.[7]

Most of the interactions with mycophenolate mofetil and enteric-coated MPA result in reductions in intestinal absorption. Proton pump inhibitors decrease the oral absorption of mycophenolate mofetil, but not enteric-coated MPA.[7] Divalent and trivalent cations (ie, aluminum, magnesium, calcium) decrease MPA absorption through chelation. These agents should be administered at least 1 hour before or 2 hours after MPA. Of note, iron does not appear to interact with the MPA preparations. The clinical implications of these DDIs are unknown, but reductions in MPA exposure can theoretically increase rejection risk.

Interactions of Distribution Interactions of distribution occur most often with highly protein-bound drugs.[7] MPA is the only highly protein bound (97%) maintenance immunosuppressant with an interaction of distribution. Concomitant administration of MPA with salicylates increases MPA-free concentrations. The adverse sequelae of this interaction are unknown. Drug interaction studies have not been conducted with MPA derivatives and other highly protein-bound drugs.

Interactions of Metabolism Oxidative metabolism by cytochrome P-450 (CYP) isozymes is the primary method of xenobiotic metabolism. The CNIs and ToR inhibitors are substrates of the CYP3A isozyme system. Most CYP-mediated metabolism takes place in the liver; however, CYP is also expressed in the intestine, lungs, kidneys, and brain. As CYP3A substrates, it is anticipated that cyclosporine, tacrolimus, sirolimus, and everolimus would experience similar DDIs with known substrates, inhibitors, and inducers of the CYP3A isozyme system.[6] Table 55–5 details clinically relevant DDIs that occur with the calcineurin and ToR inhibitors due to inhibition or induction of the CYP isozyme system.[7] LO 7

Given how extensive some immunosuppressant DDIs are, in some cases empiric dose changes are necessitated when coadministration with an interacting medication cannot be avoided. For example, it is recommended to reduce tacrolimus doses by one-third in patients initiating voriconazole. Some clinicians utilize interactions of metabolism to reduce the dose of an immunosuppressant, such as using diltiazem to treat hypertension, which also helps reduce tacrolimus doses and decrease pill burden.

Not all metabolic DDIs occur through the CYP system. Azathioprine has a considerable interaction with allopurinol and febuxostat that is mediated through the inhibition of xanthine oxidase, which is the enzyme responsible for metabolizing 6-MP to 6-thiouricate.[7] Combining these agents can result in 6-MP accumulation and severe myelosuppression. It is recommended that concomitant therapy with azathioprine and allopurinol or febuxostat be avoided, but if necessary, azathioprine doses must be empirically reduced by 75%.[7]

Interactions of Elimination Mycophenolate is metabolized to MPA-glucuronide (MPAG) via hepatic glucuronosyltransferase, and then excreted in bile for gut elimination.[7] Deconjugation of MPAG to MPA by intestinal flora results in continued MPA absorption several hours after its administration. Some medications (ie, cyclosporine, bile-acid sequestrants) interfere with the biliary excretion of MPAG, thereby eliminating MPA reabsorption in the intestines and lowering the MPA area under the curve (AUC).[7] In this type of interaction, separation of doses is ineffective; therefore, proper patient monitoring is warranted.

▶ *Pharmacodynamic Interactions*

Pharmacodynamic interactions are the backbone of modern immunosuppressive therapies that employ multiple medications with different mechanisms of action resulting in additive immunosuppression. Unfortunately, pharmacodynamic interactions can also be problematic, such as when medications with

Patient Encounter Part 2

Identify your treatment goals for the patient in terms of maintenance immunosuppressants.

Create a plan for maintenance therapy for the patient, making sure to compare and contrast the pros and cons of the different maintenance immunosuppressants.

Identify the need to continue the patient's pretransplant medications, and identify any potential DDIs that may exist with the addition of the maintenance immunosuppressants and the medications that he is currently taking.

Table 55–5

Potential Drug–Drug Interactions with the Calcineurin Inhibitors and Target of Rapamycin Inhibitors Mediated Through the Cytochrome P-450 (CYP) System 3A Isozyme[7]

Substrates[a]		Inducers[b]	Inhibitors[c]
Alfentanil	Loratadine	Carbamazepine	Boceprevir
Alprazolam	Lovastatin	Dexamethasone	Cimetidine
Amiodarone	Nevirapine	Etravirine	Clarithromycin
Amlodipine	Nicardipine	Ethosuximide	Clotrimazole
Atorvastatin	Nifedipine	Isoniazid	Delavirdine
Boceprevir	Omeprazole	Nevirapine	Diltiazem
Cilostazol	Paclitaxel	Phenobarbital	Erythromycin
Cisapride	Propafenone	Phenytoin	Fluconazole
Chlorpromazine	Progesterone	Prednisone	Fluoxetine
Clonazepam	Quetiapine	Rifabutin	Fluvoxamine
Cocaine	Quinidine	Rifampin	Grapefruit juice
Cortisol	Rilpivirine	Rilpivirine	Indinavir
Cyclophosphamide	Rivaroxaban	St. John's wort	Itraconazole
Dantrolene	Sertraline		Ketoconazole
Dapsone	Simvastatin		Miconazole
Diazepam	Tamoxifen		Nefazodone
Disopyramide	Testosterone		Nelfinavir
Enalapril	Tolvaptan		Posaconazole
Estradiol	Triazolam		Rilpivirine
Estrogen	Vandetanib		Ritonavir
Etoposide	Venlafaxine		Saquinavir
Everolimus	Vinblastine		Telapravir
Felodipine	Warfarin		Troleandomycin
Flutamide	Zolpidem		Verapamil
Lidocaine			Voriconazole
			Zafirlukast

[a]Substrates of the CYP3A4 isozyme will compete with cyclosporine, tacrolimus, and sirolimus for metabolism; therefore, concentrations of these medications will be increased (usually by ≤ 20%).

[b]Inducers of the CYP3A4 isozyme will enhance the metabolism of cyclosporine, tacrolimus, and sirolimus; therefore, concentrations of these medications will be decreased.

[c]Inhibitors of the CYP3A4 isozyme will decrease the metabolism of cyclosporine, tacrolimus, and sirolimus; therefore, concentrations of these medications will be increased.

LO 7

similar adverse events are used concomitantly. For example, nephrotoxic agents, such as amphotericin B, aminoglycosides, some HIV agents, and nonsteroidal anti-inflammatory drugs may potentiate the nephrotoxic effects of the calcineurin inhibitors.[7] The use of myelosuppressive agents, such as sulfamethoxazole-trimethoprim (SMZ-TMP) and valganciclovir, could enhance the myelosuppressive effects of induction therapy and the maintenance immunosuppressants.[7] In addition to reviewing prescription medications, it is essential to question patients about the use of nonprescription agents and dietary supplements, as these products also have the potential for significant interactions through methods discussed previously. Some examples are St. John's wort inducing metabolism of CNIs and ToR inhibitors, and willow bark having the potential to worsen CNI-induced nephrotoxicity.

Management of Immunosuppressive Drug Complications

▶ *Opportunistic Infections*

KEY CONCEPT Organ transplant recipients are at increased risk of infectious diseases, which are a chief cause of early morbidity and mortality.[32] The prevalence of posttransplant infection depends on many factors, including clinical risk factors, environmental exposures, and the degree of immunosuppression. Anti-infectives are universally prescribed in this population, and their use can be split into three different categories:

- Prophylaxis: antimicrobials given to prevent infection
- Empiric: preemptive therapy given based on clinical suspicion of an infection
- Treatment: antimicrobials given to manage a documented infection

Posttransplant infections generally occur in a standard pattern; therefore, prevention is a key management strategy.[32] The information in this section is designed to highlight prophylaxis options routinely used in organ transplant recipients. Refer to Table 55–6 for a list of agents used for the prevention of *Pneumocystis jiroveci* pneumonia and CMV disease.[33,34]

LO 9

***Pneumocystis jiroveci* Pneumonia** KEY CONCEPT Without prophylaxis, *P. jiroveci* pneumonia occurs in 5% to 15% of transplant recipients.[33] Antipneumocystis prophylaxis is enormously helpful and generally used in all organ transplant recipients. The duration of prophylaxis is usually 6 to 12 months after transplant, but may be prolonged in highly immunosuppressed patients (ie, active CMV disease, treatment for rejection) or liver or lung recipients. SMZ-TMP is the preferred agent for prophylaxis. One of its major advantages is its broad

Table 55–6

Prophylactic Options for *Pneumocystis jiroveci* Pneumonia and CMV[33,34]

Medication	Dosing	Common Adverse Events
Antipneumocystis Prophylaxis		
Sulfamethoxazole-trimethoprim (Bactrim, Septra, SMZ-TMP, cotrimoxazole)	One SS tablet by mouth once a day[a] One DS tablet by mouth once a day[a] One DS tablet by mouth every M/W/F[a]	Hyperkalemia Myelosuppression Nephrotoxicity Neutropenia Photosensitivity Rash
Pentamidine (NebuPent)	300 mg inhaled every 3–4 weeks	Bronchospasm Cough Hypoglycemia or hyperglycemia
Dapsone (Avlosulfon)	50–100 mg tablet by mouth once a day	Hepatotoxicity Myelosuppression Nephritis
Atovaquone (Mepron)	1500 mg suspension by mouth once a day	Elevated liver transaminases Nausea Rash
Antivirals		
Valganciclovir (Valcyte)	450–900 mg by mouth once a day[a]	Stomach upset Myelosuppression Headache
Ganciclovir (Cytovene)	5 mg/kg IV every day; or 1000 mg by mouth three times a day[a]	Stomach upset Myelosuppression Rash
Valacyclovir (Valtrex)	1–2 g by mouth four times a day[a]	Stomach upset Myelosuppression Headache
CMV hyperimmune globulin (CytoGam) and polyvalent IVIG	The maximum recommended total dosage per infusion is 150 mg/kg beginning within 72 hours of transplantation Follow-up doses and time intervals depend on the type of organ transplanted	Stomach upset Fevers and chills Flushing

[a]Dose adjustment required in renal insufficiency.

CMV, cytomegalovirus; DS, double-strength (800 mg SMZ, 160 mg TMP); IVIG, intravenous immunoglobulin; IV, intravenous; M/W/F, Monday, Wednesday, and Friday; SS, single-strength (400 mg SMZ, 80 mg TMP); SMZ, sulfamethoxazole; TMP, trimethoprim.

spectrum of activity. Not only is it effective against *Pneumocystis*, but it also has activity against *Toxoplasma* and other common bacterial infections. Patients who have sulfa allergies, glucose-6 phosphate dehydrogenase (G6PD) deficiency, or are intolerant of SMZ-TMP should be given one of the second-line treatments. Unfortunately, the second-line agents are antiparasitics and have no meaningful activity against common bacteria. These agents include dapsone, atovaquone, and pentamidine.[33]

LO 9

Cytomegalovirus CMV is a concerning opportunistic pathogen in transplantation due to its association with poor outcomes.[34] **CMV infection** is present in 30% to 97% of the general population, but CMV disease is typically restricted to immunocompromised hosts. The risk of CMV disease is highest among CMV-naive recipients who receive a CMV-positive organ (donor+/recipient–). Other factors that augment the risk of CMV disease include organ type (lung and pancreas recipients are highest risk) and immunosuppressive agents (ALA use increases risk). CMV disease characteristically occurs within the first 3 to 6 months posttransplantation, but delayed onset disease has been seen in patients receiving antiviral prophylaxis. Patients with CMV infection may present with flu-like symptoms, including fever, chills, aches, malaise, and fatigue. CMV infection may result in more profound symptoms in the immunosuppressed patient, including leukopenia, thrombocytopenia, and organ dysfunction.[34]

LO 9

KEY CONCEPT Several antivirals have proven effective in preventing and treating CMV.[34] Valacyclovir and valganciclovir, prodrugs of acyclovir and ganciclovir, respectively, have improved bioavailability compared with their parent compounds and offer the advantage of less frequent dosing. CMV prophylaxis is typically continued for the first 200 days, or longer, after transplantation. Although valganciclovir and IV ganciclovir are considered the prophylaxis agents of choice in most organ transplant recipients, national guidelines allow for consideration of prophylaxis with CMV hyperimmune globulin in heart and lung transplant populations. Both IV ganciclovir and oral valganciclovir may be used for preemptive therapy or for treatment of established CMV disease.[34] The adverse events are similar among these agents and include myelosuppression and GI effects.[7]

Fungal Infections Fungal infections are an important cause of morbidity and mortality in SOT recipients.[35] Immunologic (ie, immunosuppressants, CMV infection), anatomic (ie, tissue ischemia and damage), and surgical (ie, duration of surgery, transfusion requirements) factors contribute to the risk for invasive fungal infections. Mucocutaneous candidiasis (ie, oral thrush, esophagitis) is associated with corticosteroids and ALA.

LO 9

KEY CONCEPT Oral nystatin or clotrimazole troches are effective prophylactic options for the prevention of thrush. However, clotrimazole inhibits the CYP3A system in the gut and can

alter immunosuppressive levels.[7] The use of systemic antifungal prophylaxis, such as oral fluconazole, is controversial due to the potential for DDIs and risk of developing resistance. The American Society of Transplantation has recommended antifungal prophylaxis in liver, lung, intestine, and pancreas transplantation.[36,37] The choice of agents depends on the fungal risk in that particular population. For example, liver, intestine, and pancreas transplant recipients are at high risk for candidiasis; therefore, the use of medications that cover *Candida* spp. is crucial, such as the triazoles (ie, fluconazole, itraconazole) or echinocandins (ie, caspofungin, micafungin, anidulafungin). Lung transplant recipients are at high risk for aspergillosis; therefore, it is imperative to use antifungal prophylaxis that covers *Aspergillus* spp., such as the echinocandins, polyenes (ie, amphotericin B, lipid-based amphotericin B products) or new generation triazoles (ie, voriconazole, posaconazole).[36,37]

LO 9

Polyomavirus One infection complication seen only in renal transplant recipients is polyomavirus. In humans, there are two known pathologic polyoma strains, BK and JC. These viruses are rarely associated with disease in immunocompetent individuals. During periods of immunosuppression, the virus is reactivated and can be associated with significant morbidity.[38]

In renal transplant recipients, the major diseases caused by BK virus (BKV) are tubulointerstitial nephritis and ureteral stenosis.[38] Polyomavirus-associated nephropathy (PyVAN) presents with evidence of allograft dysfunction, resulting in either an asymptomatic acute or slowly progressive rise in serum creatinine (SCr) concentrations. Some studies have reported that PyVAN may affect up to 10% of renal transplant recipients, frequently resulting in permanent renal dysfunction or allograft loss.[38]

Patient Encounter Part 3

Identify your treatment goals for the patient in terms of antimicrobial prophylaxis.

Create a plan for the patient's antimicrobial prophylaxis, making sure to compare and contrast the pros and cons of the different agents in this patient.

LO 9

Currently, treatment options for BKV are limited, and management recommendations are generally focused on reductions in immunosuppression. There is a lack of a directed antiviral intervention; however, some centers have utilized IVIG, cidofovir, leflunomide, and the fluoroquinolone antibiotics to manage BKV infections. All of these agents have been reported to provide some benefit in managing BKV in anecdotal cases.[38]

LO 9

Vaccination Vaccination is one of the most effective means of preventing infection and related complications.[39] However, there is a valid concern that SOT recipients may mount an inadequate response to vaccination due to immunosuppression. Required vaccinations should be administered prior to transplantation so that an appropriate antibody response can develop (Table 55–7).[39] If this strategy is pursued, the earlier a vaccine is administered,

Table 55–7

Recommended Vaccinations Pre- and Posttransplant[39]

	Administration		
Vaccine	**Before SOT**	**After SOT**	**Additional Information**
Hepatitis A	X		Immunize as soon as possible during course of disease
Hepatitis B	X		Immunize as soon as possible during course of disease (before transplant, administer 40 mcg dose in a series of three to four doses)
Herpes Zoster	X		Live[a] virus, administer ≥ 14 days before immunosuppressant agents are initiated (experts advise 1 month before)
Human Papilloma Virus	X		Recommended for females aged 9–26, no recommendations for SOT
Influenza	X	X	Annual vaccination with inactivated intramuscular formulation recommended before and after SOT
Measles-Rubella	X		Live[a] virus, administer to patients who are seronegative, *before* transplant, or in women of childbearing age for prevention of congenital rubella syndrome
Pneumococcal	X	X	23-valent polysaccharide vaccine should be given once before transplant and boosters at 3 and 5 years after initial dose
Tetanus/Diptheria	X		TDaP booster indicated for < 65 years old (may be given ≤ 2 years after last TDaP booster in SOT patients)
Varicella	X		Live[a] virus, administer to patients who are seronegative, *before* transplant

[a]All live vaccines are contraindicated post solid organ transplant (SOT), as they can cause serious infection.

Live vaccines:

- Bacillus Calmette-Guerin
- Herpes zoster
- Live intranasal attenuated influenza
- Live oral typhoid
- Measles-rubella
- Vaccinia (smallpox)
- Varicella

TDaP, tetanus, diphtheria, and pertussis.

the more effective it may be, as end-stage organ failure can also contribute to a decreased immune response.[39]

In general, the weakest response to vaccine is within the first 6 months posttransplantation due to the intense level of immunosuppression during this period.[39] Vaccination within 6 months of transplant may be considered on a case-by-case basis in those patients who are at high risk of developing infection. Use of inactive vaccines is preferred in transplant recipients due to the relative risk of infection associated with live vaccines. Health care workers and family members who are in close contact with transplant recipients and have received a live vaccine should consider use of respiratory masks for at least 7 days after vaccination and adhere to strict oral and hand hygiene.[39]

▶ *Hypertension*

LO 9 KEY CONCEPT Cardiovascular disease has been identified as the leading cause of death in organ transplant recipients.[40] Posttransplant hypertension is associated with increased cardiac morbidity and patient mortality in transplant patients and is also an independent risk factor for allograft dysfunction. Based on all of the available posttransplant morbidity and mortality data, it is imperative that posttransplant hypertension be identified and managed appropriately.[40]

There are several mechanisms responsible for posttransplant hypertension including renal dysfunction, increased sensitivity to endothelin-1 and angiotensin, increased density of glucocorticoid receptors in the vascular smooth muscle, and decreased production of vasodilatory prostaglandins. However, one of the most easily recognized causes of posttransplant hypertension is the use of corticosteroids and CNIs. Corticosteroids cause sodium and water retention, thus increasing blood pressure, whereas CNIs reduce glomerular filtration rate (GFR) and renal blood flow, increase systemic and intrarenal vascular resistance, promote sodium retention, reduce concentrations of systemic vasodilators (ie, prostacyclin, nitric oxide), and increase concentrations of thromboxanes. Compared with cyclosporine, tacrolimus displays significantly less severe hypertension, and patients taking tacrolimus require fewer antihypertensive medications after transplant.[40]

LO 9 **Treatment** KEY CONCEPT Controlling hypertension after transplant is essential in preventing cardiac morbidity and mortality and prolonging graft survival. The target blood pressure in transplant recipients should be less than 130/80 mm Hg, consistent with national hypertension guidelines.[40]

Lifestyle Modifications To achieve a goal blood pressure, lifestyle modifications including diet, exercise, sodium restriction, and smoking cessation are recommended.[40] Unfortunately, lifestyle modifications alone are often inadequate in high-risk populations, and antihypertensive medications are usually initiated early after transplant.[40]

LO 9 **Immunosuppressive Regimen Modification** Because tacrolimus has shown the propensity to cause less severe hypertension compared to cyclosporine, conversion from cyclosporine-based immunosuppression to tacrolimus-based immunosuppression may be one way to reduce the severity of hypertension in transplant recipients. KEY CONCEPT Conversion to a ToR inhibitor or belatacept, which are not associated with hypertension, may also be an alternative to the CNIs in patients with difficult-to-treat hypertension. Corticosteroid taper or withdrawal are effective strategies for lowering blood pressure, but are not warranted in all clinical situations.[40]

LO 9 **Antihypertensive Agents** There is no single class of antihypertensive medications recognized as the ideal agent. Numerous factors must be considered when determining appropriate treatment, including the safety and efficacy data of available agents, patient-specific comorbidities, and medication cost.[40] A large majority of patients often require multiple medications to achieve goal blood pressure, and combination therapy is regarded as appropriate first-line therapy.[40]

The limited clinical studies support the use of calcium channel blockers (CCB) posttransplantation. Dihydropyridine calcium channel blockers have been associated with a higher GFR and lower incidence of allograft loss. The dihydropyridine calcium channel blockers have demonstrated an ability to reverse nephrotoxicity associated with cyclosporine and tacrolimus. The use of diltiazem and verapamil is discouraged for the treatment of hypertension because of potential drug interactions and lack of strong evidence in renal and liver transplant recipients. The addition of diltiazem to patients' regimens after cardiac transplant has also been shown to retard progression of cardiac allograft vasculopathy. β-Blockers and thiazide diuretics have proven benefits in reducing cardiovascular disease–associated morbidity and mortality in the general population.[40] Tolerability permitting, these agents are to be considered 2nd and 3rd therapies in most transplant recipients. The angiotensin-converting enzyme (ACE) inhibitors and angiotensin receptor blockers (ARB) have definite benefits in patients with nephropathy and are believed to have renoprotective effects in most patients. However, due to their ability to cause an initial increase in SCr, these agents should be used cautiously when combined with the CNIs. In general, antihypertensive therapy should focus on agents with proven benefits in reducing the progression of cardiovascular disease and must be tailored to a patient's needs.[40]

▶ *Hyperlipidemia*

LO 9 KEY CONCEPT Hyperlipidemia is seen in as high as 60% of transplant patients.[41] As a result of elevated cholesterol levels, transplant recipients are not only at increased risk of atherosclerotic events, but also allograft vasculopathy. Hyperlipidemia, along with other types of cardiovascular disease, is now one of the primary causes of morbidity and mortality in long-term transplant survivors.[41]

Elevated cholesterol levels in transplant patients are due to age, genetic disposition, renal dysfunction, DM, proteinuria, body weight, and immunosuppressive therapy. Many of the immunosuppressive agents can produce elevations in serum lipid levels.[41]

LO 9 **Treatment** KEY CONCEPT Lowering cholesterol has shown to significantly decrease severe rejection and transplant vasculopathy and improve 1-year survival in heart transplant recipients.[42] Although these results cannot be extrapolated to other transplant populations, they do demonstrate the potential benefits of aggressive cholesterol lowering in organ transplant recipients. Due to high prevalence of cardiovascular disease among organ transplant recipients, most practitioners consider these patients to be high risk for lipid lowering. Many guidelines state a target LO 9 calculated low-density lipoprotein cholesterol (LDL-C) level of less than 100 mg/dL (2.59 mmol/L) in high-risk patients.[41] Note: national guidelines for treating hyperlipidemia in the general population are often followed, despite their lack of transplant recommendations. Refer to Chapter 12, Dyslipidemias, for additional information.

LO 9 **Lifestyle Modifications** Generally, lowering cholesterol in patients begins with therapeutic lifestyle changes, including a reduction in saturated fat and cholesterol intake and an increase in moderate physical activity.[43] However, lifestyle modifications alone rarely allow a patient to achieve goal LDL-C level. Modification of the immunosuppressive regimen and use of cholesterol-lowering medications are often warranted.[41]

LO 9 **Immunosuppressive Regimen Modifications** Tacrolimus has shown the propensity to cause less severe hyperlipidemia when compared with cyclosporine. Conversion from cyclosporine-based immunosuppression to tacrolimus-based immunosuppression may be one way to counteract this disease in transplant recipients. Also, the ToR inhibitors have been associated with significant changes in lipids and triglycerides; therefore, conversion from a ToR inhibitor to a CNI or belatacept may be warranted in patients receiving ToR inhibitor therapy with resistant dyslipidemia.[41]

LO 9 **Cholesterol-Lowering Agents** 3-Hydroxy-3-methylglutaryl coenzyme A (HMG-CoA) reductase inhibitors, or statins, are considered first-line therapy for hyperlipidemia in the general population.[41] However, there is some uncertainty about the pathogenesis of cardiovascular disease in transplant recipients and whether statin therapy will have similar effectiveness in organ transplant recipients. Statins have shown definite advantages when used in heart transplantation, including a reduction in LDL-C and major adverse cardiac events (MACE), as well as an apparent cardioprotective effect. In renal transplant recipients, statins lower LDL-C levels and reduce the incidence of some cardiac events; however, the ability to lower MACE has not been seen in this population. Despite these mixed results, statins are still considered the primary therapeutic option for hyperlipidemia in organ transplant recipients.[41] When choosing a statin for management of hyperlipidemia in the transplant patient, a focus on potential DDIs is warranted. It is recommended that doses of atorvastatin not exceed 10 mg daily when taken with cyclosporine due to an increased risk of myopathy and rhabdomyolysis. Use of cyclosporine in conjunction with simvastatin is considered a contraindication due to the risk of skeletal muscle effects.[41]

LO 9 Fibric acid derivatives are an excellent choice for lowering triglycerides, but are not as effective as statins at lowering LDL-C.[41] These agents play a role in conjunction with statins in patients with both elevated cholesterol and triglycerides. Nicotinic acid is very effective at improving the lipid panel, with excellent results in lowering LDL-C, as well as increasing high-density lipoprotein cholesterol (HDL-C). However, patient tolerability is a concern with this agent. The bile acid sequestrants should be avoided in transplant recipients due to their high incidence of GI adverse events, as well as their propensity for pharmacokinetic DDIs with MPA. Ezetimibe has proven safe and effective in lowering LDL-C in renal transplant recipients. Future studies are needed to establish ideal regimens involving antihyperlipidemic and immunosuppressive medications to decrease morbidity and mortality and ultimately prevent cardiovascular events.[41]

▶ *New-Onset DM after Transplantation*

LO 9 KEY CONCEPT New-onset DM after transplantation (NODAT) is a serious complication that is often underestimated by transplant practitioners.[44] Kasiske and colleagues attempted to quantify the cumulative incidence of NODAT in renal transplant recipients and found that 8.3% of patients developed NODAT at 3 months posttransplant, 12.9% at 12 months, and 22.3% at 36 months.[45] Even more alarming is that recent studies have revealed an overwhelming prevalence of impaired glucose tolerance, which is also accepted as a risk factor for long-term morbidity and mortality. NODAT is associated with a 22% higher risk of mortality. Patients with NODAT are also more likely to suffer acute rejection episodes and infectious complications.[44]

LO 9 **Prevention** KEY CONCEPT NODAT prevention mainly consists of identifying patients at risk before transplant and controlling modifiable risk factors both before and after transplantation.[44] The major modifiable risk factors are choice of immunosuppressive therapy and body mass index (BMI). For example:

- Immunosuppressive medications: Steroid minimization and possibly withdrawal are effective strategies for preventing NODAT. Also, patients with worsening blood glucose who are receiving tacrolimus may benefit from conversion to cyclosporine or belatacept.[44]
- BMI: A reduction in body weight is recommended in obese patients prior to transplant to lower their NODAT risks.[44]

LO 9 **Treatment** KEY CONCEPT Lifestyle modifications are recommended in patients who have developed or those who are at increased risk of developing NODAT.[44] Insulin therapy and oral hypoglycemic agents are often utilized in those patients in whom lifestyle modifications alone have not controlled blood glucose. Refer to Chapter 43, Diabetes Mellitus, for proper instruction on choosing the appropriate treatment regimens in patients with DM.

▶ *Neoplasia*

Cancer Screening in Transplant Patients Transplant recipients are at increased risk for malignancies (Table 55–8).[46,47] The risk of developing Kaposi sarcoma following transplantation is over 200 times that in the general population. In addition, the risk of nonmelanocytic and melanocytic skin cancer is 10 to 20 times higher compared with the nontransplanted population. Transplant recipients are at greatest risk for the types of cancers associated with viral infections, such as PTLD, cervical, and vulvovaginal cancers. Solid organ tumors like colorectal and lung cancers are two to three times higher in transplant recipients when compared with the general population. The American Cancer Society and American Transplant Society recommend cancer screening for most adults who have undergone transplantation

Table 55–8

Overall Risk of Different Types of Cancer in Transplant Patients[46,48]

Cancer	Cumulative Incidence (per 100,000)	Male	Female
Kaposi sarcoma	140	17.4	62
Kidney/ureter	1010	14.1	14.6
Lymphoma	80	6.9	29.1
Bladder	126	1.6	3.6
Esophagus	70	2.4	2.8
Cervix	180	–	5.7
Liver	220	4.2	4.5
Melanoma	320	6.9	5.2
Lung/bronchus/trachea	690	2.3	3.6
Colorectal	510	1.6	2.8
Breast	1050	4	1.1
Prostate	1740	1.6	–

Table 55–9

Cancer Screening Recommendations in Transplant Patients[46,48]

Cancer Type	General Populations	Transplant Populations
Breast	Mammography every 1–2 years for all women ≥ 50 years old Clinical breast examination every 3 years in women 20–39 years old, yearly after age 40 Monthly self-examination	Mammography every 1–2 years for all women ≥ 50 years old May undergo screening between 40 and 49 years old but no evidence for or against screening in this age group
Cervical	Annual Pap smear and pelvic examination once sexually active; after three or more tests with normal results, may decrease frequency of examinations	Annual Pap smear and pelvic examination once sexually active
Colorectal	Annual FOBT plus flexible sigmoidoscopy every 5 years for all patients ≥ 50 years old or colonoscopy and DRE every 10 years	Annual FOBT plus flexible sigmoidoscopy every 5 years for all transplant patients ≥ 50 years old
Prostate	Annual DRE and PSA for men ≥ 50 years old with 10-year life expectancy or younger men at high risk	Annual DRE and PSA measurement in all males ≥ 50 years old
Hepatocellular	Not recommended for average-risk individuals α-Fetoprotein and ultrasound every 6 months in high-risk patients (no firm supporting data)	α-Fetoprotein and ultrasound every 6 months in high-risk patients (no firm supporting data)
Skin	Skin examination every 3 years between ages 20 and 40, annually thereafter	Monthly self-examination Total body skin examination every 6–12 months by dermatologists
Renal	Insufficient evidence to support routine screening	No firm recommendations Regular ultrasound of native kidneys
Lung	Insufficient evidence to support routine screening	No firm recommendations
Ovarian	Insufficient evidence to support routine screening	No firm recommendations
Testicular	Insufficient evidence to support routine screening	No firm recommendations
Endometrial	Insufficient evidence to support routine screening	No firm recommendations

DRE, digital rectal examination; FOBT, fecal occult blood test; PSA, prostate-specific antigen.

(Table 55–9).[46,47] Although clinical research has not yet proven that potential benefits of testing outweigh the harms of testing in transplant recipients, most believe that transplant recipients should be tested and screened very closely.[46]

LO 9

Skin Cancer Skin cancer remains the most common malignancy after transplantation. The incidence of these types of cancers increases with time posttransplant, with one study showing a prevalence rate of 35% among patients within 10 years after transplant. Also, skin cancers in transplant recipients tend to grow more rapidly and are more likely to metastasize.[46]

The most common risk factors for skin cancer development after transplant include increased age; excessive ultraviolet (UV) light exposure; high degree of immunosuppression; Fitzpatrick skin types I, II, and III; history of skin cancers; and infection by human papillomavirus.[46] KEY CONCEPT Many believe that ToR inhibitors in place of CNIs in transplant recipients can reduce the risk of nonmelanoma skin carcinomas.[48]

Transplant practitioners must be vigilant about educating their patients about excessive exposure to the sun.[46] Patients should be warned about the risk of skin cancer and be advised on simple methods to limit risk:

- Wear protective clothing (ie, long-sleeved shirts, pants, dark-colored clothing)
- Use of sunscreen, sun protection factor (SPF) 30 or higher, daily to all sun-exposed skin

► *Posttransplant Lymphoproliferative Disorders*

KEY CONCEPT PTLDs are a major complication following organ transplantation.[46] Large series of case reports have demonstrated that the incidence of PTLD is 1% for renal patients, 1.8% for cardiac patients, 2.2% for liver patients, and 9.4% for heart–lung patients. The risk of developing non-Hodgkin lymphoma is nearly 50-fold higher in organ transplant recipients compared with the general population. Another risk factor is the presence of EBV. Lymphomas are the most common form of PTLD.[46,47]

Disease incidence depends on certain factors including the type of organ transplanted, age of the transplant recipient, type and degree of immunosuppression, and exposure to EBV. The mortality rate in these patients is 50%, with most dying shortly after diagnosis. It has also been demonstrated that risk of developing PTLD is greater in EBV seronegative patients.[46,47] Belatacept has a black box warning outlining an increased risk of PTLD, especially of the CNS. Patients who are EBV seronegative or have an unknown immunity to EBV should not receive belatacept. Also, immunosuppressive regimens utilizing the ALAs have been proven to increase the risk of PTLD.[46,47]

LO 9

Treatment KEY CONCEPT Treatment for PTLD is still controversial; however, the most common treatment options include reduction of immunosuppression, chemotherapy, and anti–B-cell monoclonal antibodies.[46,47] PTLD continues to be a long-term complication of prolonged immunosuppression. Current treatment options are all associated with certain risks. Prevention is the most effective treatment for PTLD. A better understanding of the disease process and risk factors involved will aid in prophylaxis and treatment of this disorder.[46,47]

► *Pregnancy*

Females of childbearing age who do not wish to become pregnant after transplantation require adequate education on preferred forms of birth control.[49] The optimal method of birth control in this patient population is the barrier method (eg, condom, diaphragm). Use of intrauterine devices and progestin-based oral contraceptives is controversial, and associated risks must

be considered prior to initiating therapy. Intrauterine devices may be less effective in the setting of immunosuppression and predispose patients to an increased risk of infection. Progestin-based contraceptives are considered a less effective form of birth control, but may be a safe option in those patients without hypertension.[49]

LO 9

Female patients considering pregnancy after transplantation should be educated extensively regarding the potential impact of pregnancy on renal function and the risks that transplantation and medical immunosuppression may present to a fetus.[49] Risks to the infant include premature birth (50%) and intrauterine growth restriction (20%), which may result in death or long-term complications, including cerebral palsy, blindness, deafness, and learning deficiencies. Patients hoping to become pregnant should wait at least 1 year after transplantation to ensure reconstitution of gonadal function posttransplant, as well as demonstrate a 1-year freedom from acute rejection.[49]

Understanding the associated risk of immunosuppressives while pregnant is paramount considering their ability to cross the placenta as well as enter breast milk.[49] Tacrolimus and cyclosporine, both pregnancy category C, are the backbone of immunosuppressive therapy and have been used safely and effectively in pregnancy posttransplant for decades. Side effects associated with CNIs such as hypertension, diabetes, and nephrotoxicity should be monitored closely in the pregnant population. The ToR inhibitors are also pregnancy category C and have not been associated with fetal malformation but should be used cautiously in pregnant patients. Corticosteroids, pregnancy category B, are recognized to be relatively safe and have been used extensively in pregnancy after transplantation. However, they carry a risk of premature membrane rupture and newborn adrenal insufficiency. More common side effects associated with corticosteroids that may cause complications in pregnancy include hypertension, diabetes, weight gain, and poor wound healing. Due to teratogenic effects in animal studies, azathioprine is considered pregnancy category D; however, it has been used extensively as an antimetabolite in pregnant transplant patients without extensive evidence of harm to the fetus. 6-Mercaptopurine has not been shown to cross the placental barrier.[49]

Currently, the MPA derivatives, both pregnancy category D, are not considered optimal immunosuppressive agents for patients who become pregnant, and alternative therapies should be pursued.[49] These agents have a FDA-approved risk evaluation and minimization strategy to help minimize fetal exposure to MPA, prevent unplanned pregnancies in patients using MPA, collect data on MPA use in pregnancy via the Mycophenolate Pregnancy Registry, and educate patients about the risks associated with the use of this medication. A less teratogenic antimetabolite, azathioprine, should be substituted for mycophenolate mofetil or enteric-coated MPA in patients who plan on becoming pregnant. The safety of ALAs and rituximab in transplantation has yet to be fully determined; however, IVIG has been widely used without any documented adverse events. Newly available immunosuppressives, belatacept and everolimus, are pregnancy category C but are not recommended for use in pregnant patients due to inadequate human data.[49]

▶ *Immunosuppressant Therapy Adherence*

Transplant recipients require strict adherence to their medication regimens to ensure optimal outcomes. Nonadherence in this population can be attributed to the complexity of the regimens coupled with the variability in drug dosing, need for therapeutic drug monitoring, avoidance of potential DDIs, infectious risks, and drug toxicities. The incidence of nonadherence to immunosuppressant therapy in the first year posttransplant has been estimated to be as high as 23%.[50] This is especially alarming when one considers that 35% of all graft failures can be directly attributed to nonadherence. Risk factors associated with immunosuppressant therapy nonadherence include a history of substance abuse, personality disorders, and lack of social support. The role of the pharmacist in educating patients on the importance of their medication regimens and stressing the need for adherence is paramount in optimizing both patient and allograft survival after transplantation. Previous reports have suggested that intervention by a pharmacist posttransplant improves adherence.[50]

LO 10

Patient Encounter Part 4

The patient continues to have his posttransplant care at your renal transplant ambulatory care clinic. He returns to your clinic 1 month after the transplant.

Labs:

Na: 142 mEq/L (mmol/L)

K: 4.9 mEq/L (mmol/L)

Cl: 197 mEq/L (mmol/L)

CO_2: 19 mEq/L (mmol/L)

BUN: 24 mg/dL (8.6 mmol/L)

SCr: 0.9 mg/dL (80 µmol/L)

Glucose: 86 mg/dL (4.8 mmol/L)

Lipid panel: total cholesterol = 341 mg/dL (8.82 mmol/L); LDL-C = 179 mg/dL (4.63 mmol/L); HDL-C = 47 mg/dL (1.22 mmol/L); triglycerides = 575 mg/dL (6.50 mmol/L)

Uric Acid: 8.6 mg/dL (512 µmol/L)

Tacrolimus: 10.9 ng/mL (mcg/L; 13.5 nmol/L)

Vitals: BP = 164/95 mm Hg (162/88 mm Hg repeated); HR = 87

Medications:

- Tacrolimus 6 mg by mouth twice a day
- Mycophenolate mofetil 1000 mg by mouth twice a day
- Prednisone 10 mg by mouth once a day
- Atovaquone 1500 mg by mouth once a day
- Valganciclovir 900 mg by mouth once a day
- Metoprolol XL 100 mg by mouth once a day
- Amlodipine 10 mg by mouth once a day
- Zolpidem 10 mg by mouth once a day at bedtime

Identify why the patient is taking each agent listed.

What are some treatment options for the patient's elevated blood pressure?

What are some treatment options for the patient's elevated cholesterol?

What are some treatment options for the patient's elevated uric acid?

Design a monitoring plan for the patient's therapy.

OUTCOME EVALUATION

- Successful outcomes in solid-organ transplantation are generally measured in terms of several separate end points: (a) preventing rejection, (b) preventing immunosuppressive drug complications, and (c) improving long-term survival.
- Short-term goals revolve around reducing the incidence of acute rejection episodes and attaining a high graft survival rate. By accomplishing these goals, transplant clinicians hope to attain good allograft function to allow for an improved quality of life. These goals can be achieved through the appropriate use of medical immunosuppression and scrutinizing over the therapeutic and toxic monitoring parameters associated with each medication employed. In addition, transplant recipients should be monitored for adverse drug reactions, DDIs, and adherence with their therapeutic regimen.
- Long-term goals after organ transplant are to maximize the functionality of the allograft and prevent the complications of immunosuppression, which lead to improved patient survival. Clinicians must play multiple roles in the long-term care of transplant recipients, as not only must the patient be followed from an immunologic perspective, but practitioners must be focused on identifying and treating the adverse sequelae associated with lifelong immunosuppression including cardiovascular disease, malignancy, infection, and osteoporosis, among others. Again, limiting drug misadventures and ensuring adherence with the therapeutic regimen are important and should be stressed.

Patient Care Process

Collect Information:

- Perform a pretransplant evaluation, including taking a medication history for use of prescription, nonprescription, and complementary and alternative medications. Identify allergies to medications and other substances.
- Review all available diagnostic and laboratory data, and patient history and comorbidities to evaluate patient for transplant.
- Speak with the patient and review records to identify lifestyle habits, preferences and beliefs, health goals, and socioeconomic factors that affect medication access and other aspects of care.

Assess the Information:

- Document current medications that should be addressed prior to a surgical procedure (eg, anticoagulation, antiplatelet therapies).
- Identify comorbidities and how they may impact patient and allograft survival, and medication adherence.
- Review relevant laboratory tests (eg, DSA, PRA, infectious serologies of the recipient and donor [if known]).
- Evaluate current medications that will be continued posttransplant such as drugs to treat concomitant disease states (eg, hypertension, DM, dyslipidemia).
- For medications likely to be continued posttransplant, assess efficacy, safety, adherence, and any significant drug interactions with potential immunosuppressants or other medications following transplant. Are there any financial issues surrounding medications or access?
- Determine whether patient is taking any substance that could adversely affect transplant outcomes.
- Based on allergy history, determine whether the patient has compelling reasons to avoid center-specific immunosuppressants (eg, macrolide antibiotic allergy and tacrolimus) or antimicrobial prophylaxis (eg, sulfa allergy and SMZ-TMP).

Develop a Care Plan:

- Develop patient-specific short-term and long-term therapeutic goals.
- Propose an immunosuppressive regimen following transplantation, including:
  - Induction therapy (see Table 55–2):
    - Determine if the patient requires induction therapy based on type of organ being transplanted, recipient's history, and donor characteristics.
    - If induction therapy is warranted, assess for appropriate drug choice, dose, and duration of therapy.
  - Maintenance immunosuppressive agents (see Tables 55–2, 55–3, 55–4, and 55–5, and Figure 55–2):
    - Assess for appropriate choice, dose, and duration of therapy.
    - Assess for eligibility to utilize a steroid withdrawal regimen, or a CNI-sparing regimen.
    - Assess the need for therapeutic drug monitoring.
  - Antimicrobial prophylaxis (see Table 55–6):
    - Assess suitability of chosen prophylactic agents (eg, drug allergies, CMV donor and recipient serostatus, need for antifungal prophylaxis).
  - Medications used for comorbidities:
    - Assess appropriate selection of medications for pharmacokinetic and pharmacodynamic DDIs, need, efficacy, and side effects.
    - Determine if patient has insurance coverage and what agents are on formulary.

Implement the Care Plan:

- Educate the patient about the organ transplant, complications associated with transplantation, need for lifestyle modifications to reduce risk of complications (eg, wear sunscreen, low-sodium diet), drug therapy (including importance of adherence to therapeutic regimen and insurance/payer information), changes in drug therapy, medication administration, potential adverse effects, and how to manage and report adverse effects that occur.
- Address patient concerns about management of comorbidities, including medication adherence and lifestyle modifications.

(*Continued*)

Patient Care Process (*Continued*)

- Determine whether the patient has insurance coverage or whether recommended agents are included on the institution's formulary.

Follow-up: Monitor and Evaluate:

- General therapeutic monitoring parameters based on organ transplanted and toxic monitoring parameters for medications prescribed.
- Continually evaluate the patient for presence of adverse drug reactions, drug allergies, or DDIs.
- In outpatient transplant clinic:
  - Monitor therapeutic parameters based on organ transplanted.
  - Obtain a thorough history of prescription, nonprescription, and complementary and alternative medication use.
  - Monitor the patient's maintenance immunosuppression, including adherence.
  - Assess for appropriate dose, duration of therapy, and toxic monitoring parameters for all prescribed medications.
  - Assess for new or worsening comorbid disease.
  - Antimicrobial prophylaxis:
    - Does the patient need continued prophylaxis therapy?
    - When do you stop prophylaxis?
  - Medications used for comorbidities:
    - Assess appropriate selection of medications for pharmacokinetic and pharmacodynamic DDIs, need, and efficacy.
    - Assess whether new medications are needed for existing comorbidities or new diagnoses.
  - Reassess patient-specific short-term and long-term therapeutic goals.
  - Continue with patient education regarding complications associated with transplantation, need for lifestyle modifications to reduce risk of complications (eg, wear sunscreen, low-sodium diet), and drug therapy.
  - Reemphasize the importance of adherence with therapeutic regimen.
  - Assess improvement in quality-of-life measures such as physical, psychological, and social functioning, and well-being.
  - Review physical examination, lab tests, and results of other diagnostic tests to assess changes in clinical status or organ function.

Abbreviations Introduced in This Chapter

6-MP	6-Mercaptopurine
ACE	Angiotensin-converting enzyme
aHUS	Atypical hemolytic uremic syndrome
ALA	Antilymphocyte antibodies
AMR	Antibody-mediated rejection
APC	Antigen-presenting cell
ARB	Angiotensin receptor blocker
ATG	Antithymocyte globulin
AUC	Area under the curve
BKV	BK virus
BMI	Body mass index
BUN	Blood urea nitrogen
C_0	Trough concentration
C_2	Drug concentration 2 hours postdose
CCB	Calcium channel blocker
$CD4^+$	Helper T-cells
$CD8^+$	Cytotoxic T-cells
CKD	Chronic kidney disease
CMV	Cytomegalovirus
CNI	Calcineurin inhibitor
CNS	Central nervous system
CXR	Chest x-ray
CYP	Cytochrome P-450
DC	Dendritic cell
DDI	Drug–drug interaction
DM	Diabetes mellitus
DOE	Dyspnea on exertion
DRE	Digital rectal examination
DS	Double strength
DSA	Donor-specific antibody
e-ATG	Antithymocyte globulin equine
EBV	Epstein-Barr virus
ESRD	End-stage renal disease
FBS	Fasting blood sugar
FDA	Food and Drug Administration
FEV	Forced expiratory volume
FOBT	Fecal occult blood test
FSGS	Focal segmental glomerulosclerosis
G6PD	Glucose-6-phosphate-dehydrogenase
GFR	Glomerular filtration rate
GI	Gastrointestinal
HDL-C	High-density lipoprotein cholesterol
HLA	Human leukocyte antigen
HMG-CoA	3-Hydroxy-3-methylglutaryl coenzyme A
IgG	Immunoglobulin G
IL-2	Interleukin-2
IV	Intravenous
IVIG	Intravenous immunoglobulin
LC-MS/MS	Liquid chromatography coupled to tandem mass spectrometry
LDL-C	Low-density lipoprotein cholesterol
LFT	Liver function test
MAC	Membrane attack complex
MACE	Major adverse cardiac events
MHC	Major histocompatibility complex
MPA	Mycophenolic acid
MPAG	MPA-glucurinide
NK	Natural killer
NODAT	New-onset diabetes mellitus after transplantation
NYHA	New York Heart Association
P-gp	P-glycoprotein
PRA	Panel-reactive antibodies
PSA	prostate-specific antigen
PTLD	Posttransplant lymphoproliferative disorders
PyVAN	Polyomavirus-associated nephropathy

r-ATG (RATG)	Antithymocyte globulin rabbit
SCr	Serum creatinine
SL	Sublingual
SMZ-TMP	Sulfamethoxazole-trimethoprim
SOB	Shortness of breath
SOT	Solid organ transplant
SPF	Sun protection factor
SPK	Simultaneous pancreas-kidney
SS	Single strength
TCR	T-cell receptor
TDaP	Tetanus, diphtheria, and pertussis
ToR	Target of rapamycin
TPMT	Thiopurine methyltransferase
UV	Ultraviolet

56 Osteoporosis

Beth Bryles Phillips and Elizabeth A. Price

LEARNING OBJECTIVES

LO

Upon completion of the chapter, the reader will be able to:

1. Explain the association between osteoporosis and morbidity and mortality.
2. Identify risk factors that predispose patients to osteoporosis.
3. Describe the pathogenesis of fractures in patients with osteoporosis.
4. List the criteria for diagnosis of osteoporosis.
5. Recommend appropriate lifestyle modifications to prevent bone loss.
6. Compare and contrast the effect of available treatment options on reduction of fracture risk.
7. Recommend an appropriate treatment regimen for a patient with osteoporosis and develop a monitoring plan for the selected regimen.
8. Educate patients on osteoporosis and drug treatment, including appropriate use, administration, and adverse effects.

INTRODUCTION

Osteoporosis is a common and often silent disorder causing significant morbidity and mortality and reduced quality of life. It is characterized by low bone density and loss of strength in bone tissue resulting in an increased risk and rate of bone fracture. Osteoporosis is responsible for more than 2 million fractures in the United States annually. Approximately 10 million Americans have osteoporosis, and an additional 43 million are classified as having low bone density.[1,2] The cost of care is expected to rise to $25.3 billion by 2025. It is estimated that postmenopausal white women have a 50% lifetime chance of developing an osteoporosis-related fracture, whereas men have a 20% lifetime chance.[1] Common sites of fracture include the spine, hip, and wrist, although almost all sites can be affected.

The fractures associated with osteoporosis have an enormous impact on individual patients, not only causing initial pain, but also chronic pain, loss of mobility, depression, nursing home placement, and death. Patients with vertebral fractures may also experience height loss, **kyphosis**, and decreased mobility due to limitations in bending and reaching. These patients are also at greater risk of having a future vertebral fracture. Multiple vertebral fractures may lead to restrictive lung disease and altered abdominal anatomy, while patients with hip fractures have added risks associated with surgical intervention to repair the fracture. More than 50% of patients never fully recover or regain preinjury independence, and death may occur in up to 20% of patients within 2 years after fracture.[2]

EPIDEMIOLOGY AND ETIOLOGY

Osteoporosis is the most common skeletal disorder, but only a fraction of patients are evaluated and diagnosed, and less than one in four receives treatment after a fracture.[2,3] Osteoporosis can be classified as either primary (no known cause) or secondary (caused by drugs or other diseases). Primary osteoporosis is most often found in postmenopausal women and aging men, but it can occur in other age groups as well.[1,2]

The prevalence of osteoporosis varies by age, gender, and race/ethnicity and increases exponentially after age 50.[4] As a group, African Americans have the highest BMD, while Asian Americans have the lowest.[4] Most hip fractures occur in postmenopausal white women, who also have the highest incidence of fracture when adjusted for age. The frequency of fracture in African American and Hispanic women trail far behind that of Caucasians, although hip fracture-related mortality may be higher.[5] Although both men and women lose bone as they age, postmenopausal women have accelerated bone loss due to loss of estrogen. Men have some protection from osteoporosis due to their larger initial bone mass and size and lack of accelerated bone loss associated with menopause.[6] Secondary causes of osteoporosis, such as **hypogonadism**, are found more commonly in men with **fragility fractures**.[6]

PATHOPHYSIOLOGY

The human skeleton contains both cortical and trabecular bone. Cortical bone comprises approximately 80% of the skeleton, and its density and compactness account for much of bone strength. It is generally found on the surfaces of long and flat bones. Trabecular (or cancellous) bone has a sponge-like appearance and is found along the inner surfaces of long bones and throughout the vertebrae, pelvis, and ribs. This type of bone is more susceptible to osteoporotic fractures.

Under normal circumstances, the skeleton undergoes a dynamic and constant process of bone remodeling, responding to stress and injury through continuous replacement and repair. This process is completed by the basic multicellular unit, including both osteoblasts and osteoclasts. Osteoclasts are involved with resorption or breakdown of bone and continuously create microscopic cavities in bone tissue. Osteoblasts are involved in bone formation and continuously mineralize new bone in the

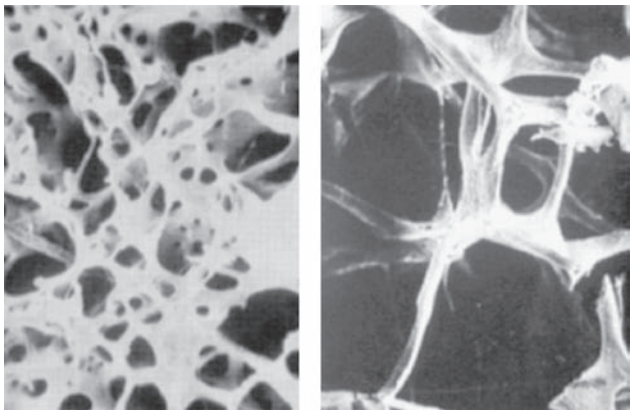

FIGURE 56–1. Normal trabecular bone (*left*) compared with trabecular bone from a patient with osteoporosis (*right*). The loss of mass in osteoporosis leaves bones more susceptible to breakage. (From Barrett KE, Barman SM, Boitano S. Brooks H. Ganong's Review of Medical Physiology, 25th ed. New York: McGraw-Hill; 2016: Figure 21–11; with permission. http://www.accesspharmacy.com.)

cavities created by osteoclasts. Until peak bone mass is achieved between the ages of 25 and 35, bone formation exceeds bone resorption for an overall increase in bone mass. Figure 56–1 illustrates the difference between normal and osteoporotic bone.

In osteoporosis, an imbalance in bone remodeling occurs. Most commonly, osteoclastic activity is enhanced, resulting in overall bone loss. However, a reduction in osteoblastic activity and bone formation also occurs in certain types of osteoporosis. Due to a decrease in endogenous estrogen, bone remodeling accelerates during menopause, and a substantial amount of bone is lost during the first 5 years after menopause. After this initial decline, bone loss continues to occur at a slower rate. The resultant bone loss and change in bone quality predispose patients to low-impact or fragility fractures.

CLINICAL PRESENTATION AND DIAGNOSIS

See accompanying text box for the clinical presentation of osteoporosis.

KEY CONCEPT The National Osteoporosis Foundation (NOF) recommends evaluating all postmenopausal women and men older than 50 years for osteoporosis risk and need for further diagnostic assessment. Many risk factors for osteoporosis and osteoporotic fractures are predictors of low bone mineral density (BMD) (Table 56–1). The risk for osteoporosis generally increases as the number of risk factors increases, and the risk of fractures increases as BMD decreases. Because osteoporosis is commonly caused by secondary factors (Table 56–2), medical history, medication history, and laboratory values should be evaluated to determine if further workup is needed.

Clinical Presentation of Osteoporosis

General

Many patients with osteoporosis are asymptomatic unless they experience a fragility fracture.

Symptoms of Fragility Fracture

Pain at the site of the fracture or immobility.

Signs

Height loss (> 2 cm), spinal kyphosis ("dowager's hump"), fragility fracture especially of the hip or spine.

Table 56–1

Risk Factors for Osteoporosis and Osteoporotic Fractures[1,2]

Risk Factors for Osteoporosis	Risk Factors for Falling and Fractures
Low bone mineral density[a]	Poor health/frailty
Female sex[a]	Impaired gait or balance
Age over 65[a]	Recent falls
Race/ethnicity[a]	Cognitive impairment
History of previous low trauma (fragility) fracture as an adult[a]	Impaired vision
Osteoporotic fracture in a first-degree relative (especially parental hip fracture)[a]	Environmental factors (eg, stairs, throw rugs, pets, poor lighting)
Low BMI or body weight (under 57.6 kg)[a]	Medications (eg, opioids, psychotropics, anticonvulsants)
Premature menopause (before 45 years old)[b]	
Secondary osteoporosis[b] (especially rheumatoid arthritis)[a]	
Oral glucocorticoid therapy[a]	
Current cigarette smoking[a]	
Alcohol intake (three or more drinks daily)[a]	
Low calcium intake	
Low physical activity	
Minimal sun exposure	

[a]Major risk factors used in the World Health Organization (WHO) fracture risk model.

[b]Secondary causes in the FRAX tool: type 1 diabetes, adult osteogenesis imperfecta, longstanding untreated hyperthyroidism, hypogonadism, premature menopause (before age 45), chronic malnutrition, malabsorption, and chronic liver disease.

BMI, body mass index.

Diagnostic Assessment

The diagnostic assessment for osteoporosis may include an assessment of BMD, vertebral imaging, laboratory workup, and other factors for secondary causes of osteoporosis, and biochemical markers of bone turnover. KEY CONCEPT Osteoporosis may be diagnosed by low bone density as determined by BMD or established history of low-trauma hip or vertebral fracture in adulthood.[1]

▶ *Measurement of Bone Mineral Density*

Osteoporosis is characterized by weakened bone tissue, and BMD is the best measure of bone strength, predicting approximately 70% of bone strength.[7] Low BMD is associated with an increased risk of fractures. BMD can be measured at various sites throughout the skeletal system and by various methods. Dual-energy x-ray absorptiometry (DXA) can be used to measure

Table 56–2[1,2]

Medical Conditions and Drugs Associated with Osteoporosis or Low Bone Mass

Medical Conditions	Drugs
Alcoholism	Anticoagulants (heparin, warfarin)
Chronic kidney disease	Anticonvulsants (phenytoin, phenobarbital)
Chronic obstructive pulmonary disease	Aromatase inhibitors (anastrozole, exemestane, letrozole)
Cushing syndrome	Cytotoxic drugs (eg, methotrexate, cisplatin)
Cystic fibrosis	Glucocorticoids (5 mg or more of prednisone daily or equivalent for at least 3 months)
Diabetes mellitus	Gonadotropin-releasing hormone analogs (leuprolide acetate, nafarelin, goserelin)
Eating disorders	Immunosuppressants (eg, tacrolimus)
GI disorders (eg, gastrectomy, malabsorption syndromes)	Lithium
Hematologic disorders (eg, hemophilia)	Medroxyprogesterone acetate
Hyperparathyroidism	Proton pump inhibitors
Hyperthyroidism	Selective serotonin reuptake inhibitors
Hypogonadal states	Thiazolidinediones
Organ transplantation	Thyroid supplements (due to over-replacement)
Skeletal cancer (eg, myeloma)	Total parenteral nutrition
Vitamin D deficiency	

central (hip and/or spine) and peripheral (heel, forearm, or hand) sites. Quantitative ultrasound, peripheral quantitative computed tomography, radiographic absorptiometry, and single-energy x-ray absorptiometry are used to measure peripheral sites.

The World Health Organization (WHO) recommends a standardized approach to measuring BMD for diagnosis of osteoporosis using central measurement of BMD by DXA.[2] Preferred sites for central measurement include the total hip, femoral neck, and lumbar spine. Some instruments used for peripheral bone densitometry are portable, allowing bone density to be measured in pharmacies and health-fair screening booths. In addition to accessibility, peripheral measurement of BMD is generally less expensive than central DXA, making it an attractive option for many patients. Peripheral BMD testing is useful in identifying patients who are candidates for central DXA and who are at increased risk of fracture, but it should not be used for diagnosis.

Once the BMD report is available, *T*-scores and *Z*-scores are used to interpret the data. The *T*-score is the number of standard deviations from the mean BMD in healthy, young, white women. Osteoporosis is defined as a *T*-score more than –2.5 standard deviations below the mean BMD in young adults (Table 56–3). Osteopenia, or low bone mass that may eventually lead to osteoporosis, is defined as a *T*-score between –2.5 and –1.0. The *Z*-score, defined as the number of standard deviations from the mean BMD of age- and sex-matched controls, is similar to the *T*-score but is corrected for both age and sex of the patient. *Z*-scores may be more clinically relevant in evaluating BMD in premenopausal women, men younger than the age of 50, and patients who may have secondary causes for low BMD.

▶ *Screening and Risk Factor Assessment*

The NOF recommends BMD measurements in the following groups: women age 65 and older, men age 70 and older, perimenopausal women and men age 50 to 69 with risk factors,

Table 56–3

World Health Organization (WHO) Definition of Osteoporosis

Classification	*T*-Score[a]
Normal	–1 or greater
Osteopenia	Between –1 to –2.5
Osteoporosis	Less than –2.5

[a]*T*-score is the number of standard deviations above or below the mean bone mineral density in young adults.

anyone with a fracture after age 50, and adults with a secondary cause for osteoporosis.[1]

FRAX (see *www.shef.ac.uk/FRAX*) is an additional tool developed by the WHO to evaluate an individual's 10-year probability of developing hip and major osteoporotic fractures based on femoral neck BMD *T*-score, age, and other risk factors.[1] The intended use is for men and women older than 40 years. The FRAX tool has not been validated for patients with previous or current use of pharmacotherapy to treat osteoporosis. Although the *T*-score is helpful in calculating risk of fracture with FRAX, fracture risk may be calculated without it.

▶ *Vertebral Imaging*

Vertebral fractures cause significant morbidity and mortality among patients with osteoporosis. They are often clinically silent, widespread, frequently recur, and commonly go undiagnosed. For these reasons, vertebral imaging is recommended in high-risk patients: (a) central *T*-score less than –1.0 in women age 70 and older and men age 80 and older; (b) central *T*-score less than –1.5 in women age 65 to 69 or men age 70 to 79; and (c) postmenopausal women and men age 50 and older who have had a fragility fracture in adulthood, reported decrease in height of 4 or more centimeters, documented reduction in height of 2 or more centimeters, or long-term glucocorticoid therapy.[1] Patients may receive vertebral imaging through traditional x-ray or lateral vertebral fracture assessment (VFA) available on some DXA machines.

▶ *Laboratory Evaluation*

Laboratory assessment has little value in diagnosing osteoporosis but can be beneficial in identifying or excluding secondary causes of bone loss, or for monitoring drug therapy. Screening laboratory tests for the most common causes of secondary osteoporosis include complete blood cell count, serum chemistries (electrolytes with calcium, phosphorus, and liver enzymes), vitamin D, and urinalysis. Bone turnover markers (BTMs), such as serum C-terminal telopeptide (S-CTX) and serum carboxy-terminal propeptide of type I collagen (PINP), measure skeletal activity and may play a role in monitoring efficacy of drug therapy. For example, a decrease in S-CTX suggests fracture risk reduction and effective treatment with antiresorptive therapy. Due to high assay variability, measuring BTMs for drug absorption, adherence, or efficacy should only be considered for patients in whom treatment decisions may be dependent on response to therapy or identifying nonresponders to therapy.[2]

TREATMENT

Desired Outcomes

KEY CONCEPT Treatment goals for osteoporosis include: (a) preventing fractures; (b) maintaining or increasing BMD; (c) preventing secondary causes of bone loss; and (d) reducing morbidity and

Patient Encounter Part 1: Patient History

HPI: A 76-year-old white woman presents to the clinic with her daughter for follow-up on her bone mineral density test results. She takes no prescription medication to prevent osteoporotic fracture. She takes calcium carbonate (Tums) approximately once a week for heartburn, in addition to omeprazole daily. Milk upsets her stomach, so she usually drinks tea, diet soda, or occasionally fruit juice. She is unable to eat much cheese or dairy products. She reports occasional gardening for exercise. Her diabetes has been well controlled with diet and metformin. She is motivated to keep her diabetes under control because she states she would be unable to self-administer daily insulin injections. She has thought about quitting smoking but is not ready to do so at this time. She reports tolerating her medications well and reports no problems. She lives alone in her own home in a rural community. She no longer drives and is dependent on her daughter who lives 2 hours away to take her to medical appointments. She does not like coming to the doctor because her daughter has difficulty getting time off work to take her to appointments. Her daughter comes to visit approximately once a month.

PMH: DM type 2, HTN, hyperlipidemia, GERD, lactose intolerance, osteoarthritis.

FH: Father died at age 76 with Alzheimer disease; mother died at age 92 with history of breast cancer and osteoporotic fracture of the hip; sister alive and well at age 69.

SH: Homemaker; smoked two packs a day for 40 years, now smokes 1/2 pack daily; denies alcohol use.

Meds: Acetaminophen 1000 mg TID as needed for joint pain, metformin 500 mg twice daily; lisinopril 10 mg daily; atorvastatin 40 mg daily, omeprazole 20 mg daily; calcium carbonate (Tums) 500 mg as needed.

Do any symptoms suggest the presence of osteoporosis?

What risk factors for osteoporosis does this patient have as defined by the World Health Organization?

What diseases or medications could contribute to osteoporosis in this patient?

What are her recommended daily intakes for calcium and vitamin D?

How could she incorporate more calcium into her diet?

mortality associated with osteoporosis. Strategies to prevent fractures include maximizing peak bone mass, reducing bone loss, and using precautions to prevent falls leading to fragility fractures.

Nonpharmacologic Therapy

▶ *Modification of Risk Factors*

Some osteoporosis risk factors (see Tables 56–1 and 56–2) are nonmodifiable, including family history, age, ethnicity, gender, and concomitant disease states. Other risk factors for bone loss may be minimized by early intervention, including smoking, low calcium intake, poor nutrition, inactivity, heavy alcohol use, and vitamin D deficiency. To avoid certain risk factors and maximize peak bone mass, efforts must be directed toward osteoporosis prevention at an early age.

▶ *Nutrition*

A healthy diet is essential to ensure sufficient nutrient intake and appropriate weight maintenance. Dietary calcium intake is important for achieving peak bone mass and maintaining bone density. Good dietary sources of calcium include dairy products, fortified juice, cruciferous vegetables (eg, broccoli, kale), salmon, and sardines (Table 56–4). Dietary intake generally provides 600 to 700 mg/day of calcium for men and women 50 and older. Supplementation to achieve recommended intake not attained by diet alone is important for primary prevention, as well as for those with a diagnosis of osteoporosis.

Adequate dietary intake of vitamin D is essential for calcium absorption. The most common source of vitamin D comes from exposure to sunlight. Ultraviolet rays from the sun promote synthesis of vitamin D_3 (cholecalciferol) in the skin, generally occurring within 15 minutes of direct sunlight exposure to bare skin without sunscreen. However, during the winter months, patients living in northern latitudes are not able to obtain the type of exposure that results in vitamin D synthesis.[2] It is recommended that individuals receive twice weekly sun exposure to ensure optimal synthesis. Vitamin D may also be found in some dietary sources, including fortified milk, egg yolks, salt-water fish, and liver.

▶ *Exercise*

Exercise can help prevent fragility fractures. Weight-bearing exercise such as walking, jogging, dancing, and climbing stairs can help build and maintain bone strength. Muscle-strengthening or resistance exercises can help improve and maintain strength, agility, and balance, which can reduce falls.[1] It is important to develop and maintain a lifelong routine of weight-bearing and resistance exercise, because the benefits on bone can be lost after cessation of the exercise program.[1]

Table 56–4

Foods Containing Approximately 300 mg of Elemental Calcium

1 cup[a] skim milk
1 cup soy milk (calcium-fortified)
1 cup yogurt
1½ oz[b] cheddar cheese
1½ oz jack cheese
1½ oz Swiss cheese
1½ oz part-skim mozzarella
4 tablespoonfuls[c] grated Parmesan cheese
8 oz tofu
1 cup greens (collards, kale)
2 cups broccoli
4 oz almonds
2 cups low-fat cottage cheese
3 oz sardines with bones
5 oz canned salmon
1 cup orange juice (calcium-fortified)

[a]One cup = 240 mL.

[b]One ounce (1 oz) = 28 g.

[c]One tablespoon ≈ 15 mL.

▶ *Falls Prevention*

The threshold at which individual patients develop a fracture varies, and other factors, such as fall risk, may play a role in fracture susceptibility. For this reason, fall history and evaluation of risk factors for falling should also be included in the initial evaluation. Patients with frailty, poor vision, hearing loss, or those taking medications affecting balance are at higher risk for falling and subsequent fragility fractures.[1,2]

A number of medications have been associated with an increased risk of falling, including drugs affecting mental status such as antipsychotics, benzodiazepines, tricyclic antidepressants, sedative/hypnotics, anticholinergics, and corticosteroids. Some cardiovascular and antihypertensive drugs can also contribute to falls, especially those causing orthostatic hypotension.[1] Efforts to decrease the risk of falling include balance training, muscle strengthening, removal of hazards in the home, installation of fall reduction measures such as handrails, and discontinuation of predisposing medications.[1,2] Patients with underlying physical and functional deficits may also benefit from physical and occupational therapy intervention to augment fall prevention strategies.[1,2]

Pharmacologic Treatment (Figure 56–2)

KEY CONCEPT The NOF recommends that all men and women older than 50 years be considered for pharmacologic treatment if they meet **any** of the following criteria: (a) history of hip or vertebral fracture, (b) *T*-score –2.5 or less at femoral neck or spine, or (c) osteopenia and at least a 3% 10-year probability of hip fracture or at least a 20% 10-year probability of major osteoporosis-related fracture as determined by FRAX.[1]

▶ *Calcium and Vitamin D*

KEY CONCEPT Calcium and vitamin D supplements to meet requirements should be added to all drug therapy regimens for osteoporosis to increase BMD and decrease the risk of hip and vertebral fractures.

Calcium plays an important role in maximizing peak bone mass and decreasing bone turnover, thereby slowing bone loss. When the calcium supply is insufficient, calcium is taken from bone stores to maintain the serum calcium level. Adequate calcium consumption is essential to prevent this from occurring and may also correct secondary hyperparathyroidism in elderly patients.

The NOF recommends a daily calcium intake of 1000 mg for men between the ages of 51 to 70 and a higher intake of 1200 mg for women older than 51 and men older than 71.[1] When these requirements cannot be achieved by diet alone, appropriate calcium supplementation is recommended. Intakes over 1200 to 1500 mg/day may increase the risk of developing kidney stones,[1] and supplementation greater than 2500 mg/day may lead to hypercalciuria and hypercalcemia. Additionally, excessive calcium supplementation may be associated with an increased risk of cardiovascular events.[8,9]

Calcium supplements are available in a variety of calcium salts and dosage forms. Daily calcium requirements are reported as elemental calcium. However, many product labels list calcium content in the salt form, so the percentage of elemental calcium must be known to calculate the elemental calcium content per tablet. A number of factors, including a single large intake of calcium, can limit calcium absorption, and special consideration must be given to calcium dosing to maximize absorption. Supplement doses should be limited to 500 to 600 mg of elemental calcium per dose, and absorption parameters, elemental calcium content, and adherence should be considered when choosing an appropriate supplement. Similar to other over-the-counter (OTC) products, various formulations may be included under the same general brand name (eg, Tums®), so product labeling is very important in determining the amount of calcium contained in the product. Table 56–5 lists several common OTC products with their calcium and vitamin D content.

Calcium carbonate should be taken with food to maximize absorption. Elderly patients or patients receiving proton pump inhibitors or H_2-receptor antagonists may have difficulty absorbing calcium supplements due to reduced stomach acidity. Calcium citrate may be better absorbed in these situations because an acid environment is not needed for absorption; it may be taken with or without food.

Common adverse effects include constipation, bloating, cramps, and flatulence, especially with calcium carbonate. Changing to a different salt form may alleviate symptoms for some patients. Calcium salts may reduce the absorption of iron and some antibiotics, such as tetracycline and fluoroquinolones. To mitigate absorption issues, calcium supplements should be administered 2 hours prior to or four hours after antibiotic or iron therapy.

Vitamin D is crucial for bone health. It is needed for calcium absorption and may aid in balance and reduce fall risk, enhance bisphosphonate efficacy, improve BMD, and reduce fracture risk.[2] The NOF recommends a daily vitamin D intake of 800 to 1000 IU daily for all adults age 50 and older.[1]

Vitamin D is available as a single entity, in combination with varying amounts of calcium salts, and in many multivitamin preparations. To avoid hypercalciuria and hypercalcemia, the maximum recommended dose for chronic use in most patients is 4000 IU/day.[10] High-dose ergocalciferol (vitamin D_2), 50,000 IU, is available by prescription only and is generally reserved for patients with vitamin D deficiency, whereas cholecalciferol (vitamin D_3) is available over-the-counter.

Patients at risk for vitamin D deficiency include elderly patients with malabsorption syndromes, chronic renal insufficiency, other chronic diseases, and those with limited sun exposure.[1] Frail, older patients in particular are at increased risk of deficiency due to decreased exposure to sunlight and subsequent decreased vitamin D synthesis in the skin, decreased GI absorption of vitamin D, and reduction in vitamin D_3 synthesis.

Many adults have low vitamin D levels, and vitamin D deficiency is an important secondary cause of osteoporosis.[2] Although vitamin levels should only be drawn in patients at risk for deficiency, patients with osteoporosis meet this criterion.[11] Laboratory determination of 25-hydroxyvitamin D levels should occur prior to the start of pharmacotherapy to determine whether supplementation is adequate or whether treatment of deficiency is needed. The Endocrine Society Vitamin D Deficiency clinical practice guideline recommends treatment with ergocalciferol 50,000 IU once weekly (or cholecalciferol equivalent of 6000 IU daily) for 8 to 12 weeks.[11] After 25-hydroxyvitamin D levels have risen above 30 ng/mL (75 nmol/L), cholecalciferol doses of 1500 to 2000 IU or more may be needed to maintain 25-hydroxyvitamin D levels between 30 and 60 ng/mL (75 and 150 nmol/L).[2,11]

▶ *Bisphosphonates*

KEY CONCEPT Bisphosphonates are first-line therapy for osteoporosis in both men and women due to established efficacy in preventing hip and vertebral fractures. They decrease bone resorption by rapidly binding to the bone matrix and inhibiting osteoclast activity. Once attached to bone tissue, bisphosphonates are released very slowly over several years. Alendronate, risedronate, and zoledronic acid are approved for use in men and women, whereas ibandronate is only approved for postmenopausal

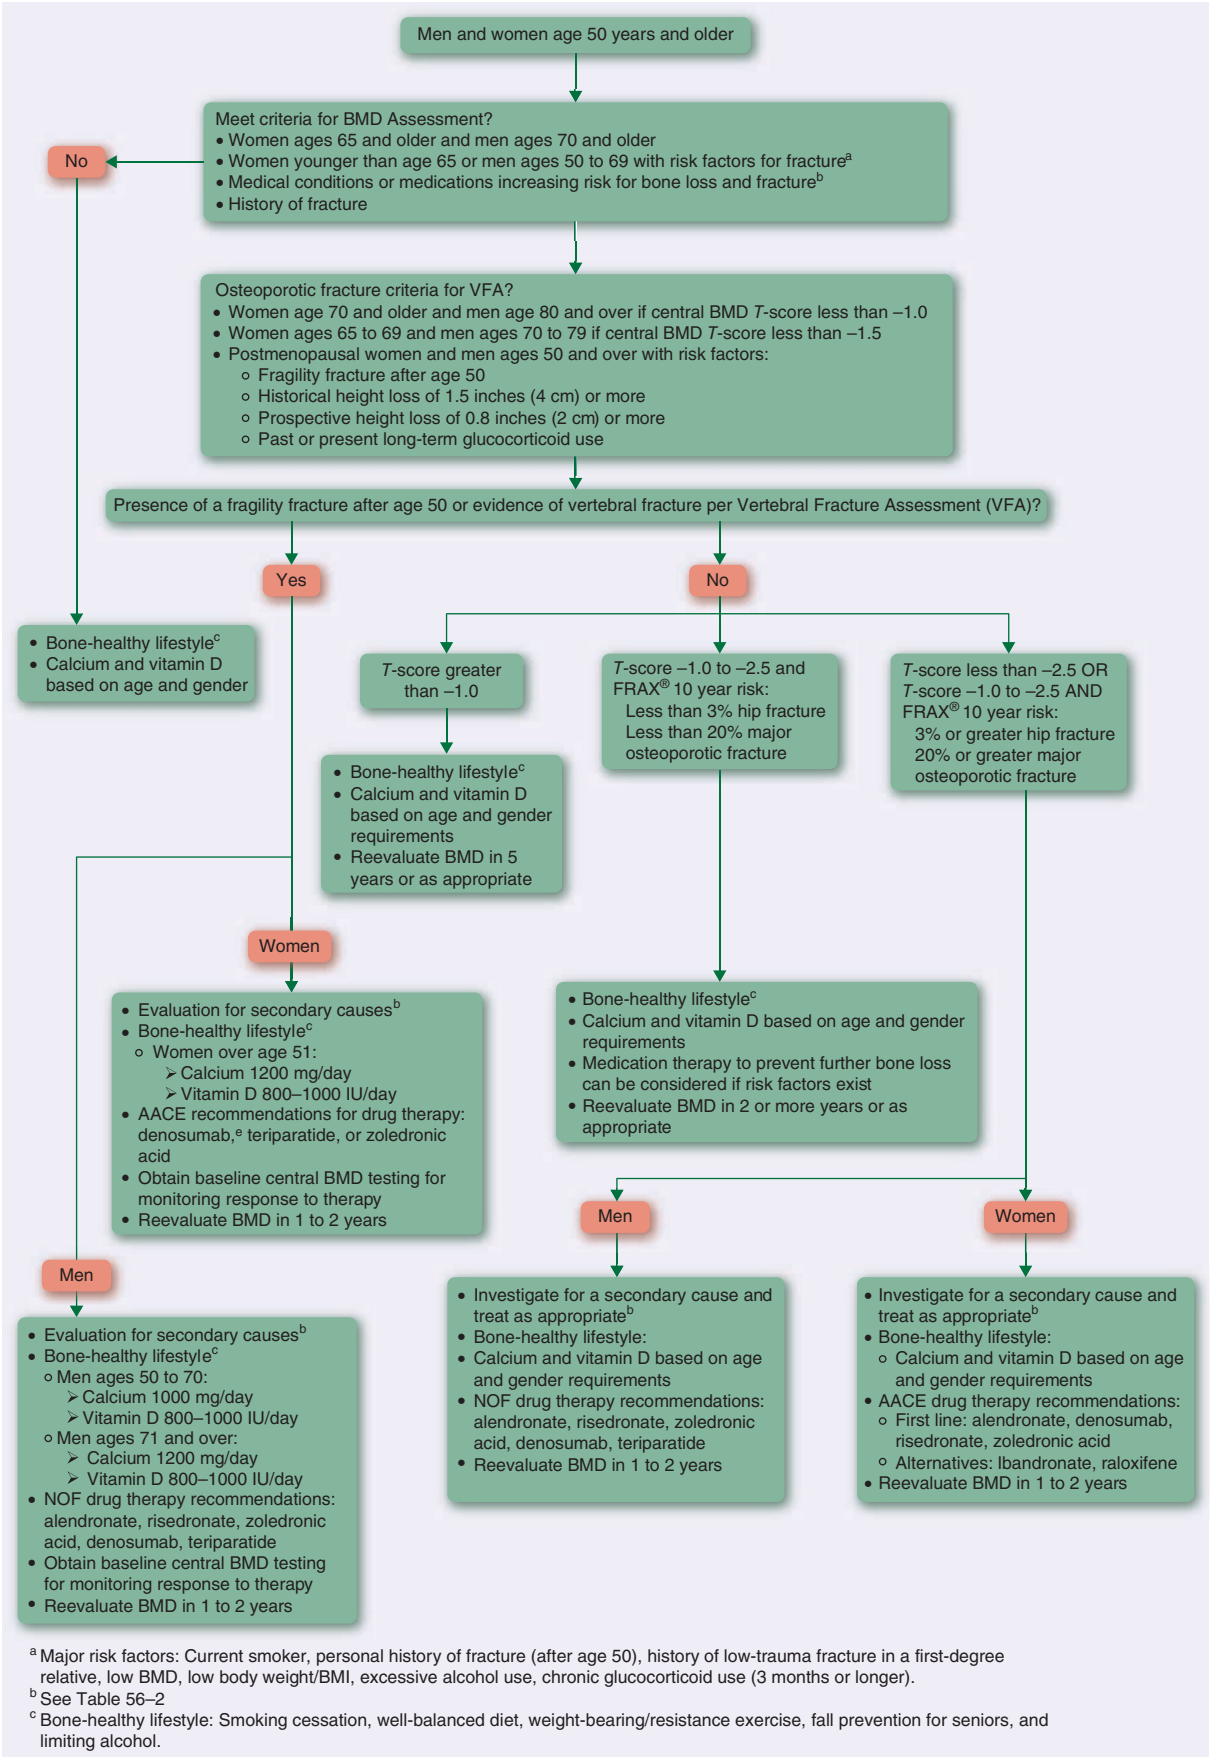

FIGURE 56–2. Algorithm for the management of osteoporosis in postmenopausal women and men ages 50 and older. (Adapted from O'Connell M, Borhert JS. osteoporosis. Ibandronate is generally considered a second-line bisphosphonate due to lack of documented efficacy in nonvertebral fractures in prospective trials.[2,12] Table 56–6 contains comparative dosing for the bisphosphonates. Although some bisphosphonates were approved for prevention doses at the time of initial data submission to the Food and Drug Administration (FDA) for approval, patients who meet criteria for drug treatment of osteoporosis should be given treatment doses.

Bisphosphonates can increase BMD by up to 5% to 8% in the lumbar spine and up to 3% to 6% in the hip.[13,14] BMD continues to increase with long-term bisphosphonate therapy of 7 to 10 years.[15,16] Although increases in BMD have been reported at other sites, most of the clinically significant increases occur in the hip or spine and are an important marker of treatment effects. Bisphosphonate therapy can also prevent vertebral and nonvertebral fractures, decreasing the vertebral fracture risk by as much as 40% to 50% with oral bisphosphonates and up to 70% with zoledronic acid.[1,17] IV zoledronic acid has also shown a 28% decrease in mortality associated with hip fracture.[18] Upon discontinuation of therapy, clinical trials with alendronate and zoledronic acid have shown sustained benefits in fracture risk reduction up to 5 years after therapy is stopped.[2] Long-term administration of bisphosphonates is considered beneficial in patients at high risk for fracture. However, for women who must discontinue bisphosphonate therapy due to intolerance or adverse events, improvements in BMD may be sustained.[16]

Patients may experience bone, muscle, or joint pain that resolves upon bisphosphonate discontinuation. Upper GI adverse effects occur in up to 20% of patients receiving oral bisphosphonates and are often related to inappropriate administration. These adverse effects range from relatively mild nausea, vomiting, and diarrhea to more severe esophageal irritation and esophagitis. Other common adverse reactions include dyspepsia, abdominal pain, nausea, and esophageal reflux. Esophageal ulceration, erosions with bleeding, perforation, stricture, and esophagitis may also occur. Advanced age, previous upper GI tract disease, and use of nonsteroidal anti-inflammatory drugs also increase the risk for GI adverse events, whereas once-weekly administration of oral bisphosphonates may decrease the risk.

IV zoledronic acid is associated with acute-phase reactions (flu-like symptoms) that can last for days, such as headache, arthralgia, myalgia, and fever.[1,2,18] Pretreatment with acetaminophen may prevent these symptoms.[2] Patients with moderate to severe renal impairment, severe dehydration, or taking concomitant diuretics or nephrotoxic drugs may be at higher risk of developing acute renal failure with zoledronic acid. Laboratory monitoring, including serum creatinine, alkaline phosphatase, phosphate, magnesium, and calcium, is recommended prior to administration of each zoledronic acid dose.

Serious but rare adverse events associated with long-term bisphosphonate use include **osteonecrosis** of the jaw (ONJ),[19,20] **subtrochanteric** fractures,[19] and nonvertebral atraumatic fractures.[20] These events may be related to oversuppression of bone turnover causing weakening of bone structure related to inhibition of osteoclastic activity.[21,22] ONJ is less common in patients receiving bisphosphonates for osteoporosis than other indications. Patients should complete major dental work prior to initiation of bisphosphonate therapy.[23,24] The rate of subtrochanteric fractures also increases with more than 5 years of use, and the risk appears to decline upon discontinuation of therapy.[23,25,26] Patients may experience thigh or groin pain prior to the fracture. The American Association of Clinical Endocrinologists (AACE) recommends a drug holiday after 5 years of oral bisphosphonate use and 3 to 6 years of IV bisphosphonate use for lower risk patients.[2] Esophageal cancer has also been reported with long-term therapy, but data are currently inconclusive.[2]

Oral bisphosphonates are poorly absorbed, and administration with food or calcium supplementation further reduces absorption. Proper drug administration is important for optimal absorption and prevention of adverse effects. See Table 56–6 for recommended administration.

Contraindications to bisphosphonates include hypersensitivity, hypocalcemia, pregnancy and renal impairment (creatinine clearance < 30 to 35 mL/min [0.50–0.58 mL/s]), or failure. Patients with esophageal abnormalities delaying swallowing (eg, **achalasia**, **stricture**), GI malabsorption (eg, celiac disease, Crohn disease, or gastric bypass), or who cannot remain upright for 30 minutes should avoid oral bisphosphonates; consider IV bisphosphonates for these patients.

▶ *Denosumab*

Denosumab is the first human monoclonal antibody FDA approved for treatment of postmenopausal osteoporosis. It is first-line therapy for women and men, and it can also be considered in patients unable to tolerate bisphosphonates due to GI contraindications or side effects and for patients with malabsorption or adherence issues.[2] Denosumab reduces nuclear factor-kappa B ligand (RANKL) action, which leads to selective inhibition of osteoclast formation, function, and survival. In contrast to bisphosphonates, the antiresorptive effects of denosumab are reversible, and beneficial effects on BMD may be lost within 2 years of discontinuation of therapy.[2]

Denosumab has been shown to increase BMD in the hip and spine by up to 6% and 9%, respectively; and decrease hip, vertebral, and nonvertebral fracture risk by up to 40%, 68%, and 20%, respectively.[27] Use of denosumab for up to 8 years has been associated with continued increases in BMD of up to 16.5% in

Table 56–6

Drug	Product Size	Indication/Usual Dose	Administration
Bisphosphonates			
Alendronate (Fosamax)	5-, 10-, 35-, 70-mg tablets; 70-mg with cholecalciferol 2800 IU; 70-mg with cholecalciferol 5600 IU; 70-mg oral solution	Prevention of PM osteoporosis: 5 mg orally daily or 35 mg orally once weekly Osteoporosis (men and women): 10 mg orally once daily or 70 mg orally once weekly Glucocorticoid-induced osteoporosis: 10 mg once daily Avoid when CrCl < 35 mL/min (0.58 mL/s)	Take after an overnight fast with 6–8 oz (180–240 mL) plain water while sitting or standing upright at least 30 minutes prior to morning meal. Do not lie down for 30 minutes after administration. Do not take with other medications or fluids. Do not crush, chew, or suck on the tablet.
Ibandronate (Boniva)	150-mg tablets; 3-mg/3 mL injection	PM osteoporosis: 150 mg orally once monthly; 3 mg IV push over 15–30 seconds every 3 months Avoid when CrCl < 30 mL/min (0.5 mL/s)	Same as alendronate except administer at least 1 hour prior to morning meal and refrain from lying down for 1 hour after administration.
Risedronate (Actonel, Atelvia)	5-, 30-, 35-, 75-, 150-mg tablets; 35-mg delayed release tablets	PM osteoporosis: 5 mg orally daily, 35 mg orally once weekly, 75 mg on 2 consecutive days each month, or 150 mg once monthly Male osteoporosis: 35 mg orally weekly or 150 mg orally monthly Glucocorticoid-induced osteoporosis: 5 mg orally daily Avoid when CrCl < 30 mL/min (0.50 mL/s)	Same as alendronate. Delayed release tablets may be taken with food.
Zoledronic acid (Reclast)	5 mg/100 mL IV infusion	Prevention of PM osteoporosis: 5 mg infused IV over 15 minutes or longer every 24 months Treatment of osteoporosis (men and women), glucocorticoid-induced osteoporosis: 5 mg infused IV over 15 minutes or longer every 12 months Avoid when CrCl < 35 mL/min (0.58 mL/s)	Infuse over at least 15 minutes. May premedicate with acetaminophen.
Monoclonal Antibody			
Denosumab (Prolia)	60 mg/mL SC prefilled syringe	PM or male osteoporosis, glucocorticoid-induced osteoporosis: 60 mg SC every 6 months	Inject in the upper arm, upper thigh, or abdomen. Keep refrigerated.
Osteoanabolic Agents			
Abaloparatide (Tymlos)	3120 mcg/1.56 mL pen injector (30 doses)	PM osteoporosis: 80 mcg SC daily	Inject into abdomen. Keep refrigerated.
Teriparatide (Forteo)	250 mcg/mL, 2.4-mL prefilled pen	Osteoporosis (men and women), glucocorticoid-induced osteoporosis: 20 mcg SC daily	Inject into thigh or abdominal wall. Keep pen refrigerated.
Estrogen Agonists/Antagonists			
Raloxifene (Evista)	60-mg tablets	PM osteoporosis: 60 mg daily	May be taken with or without food.
Bazedoxifene/ conjugated estrogens (Duavee)	20 mg/0.45 mg	PM osteoporosis + menopausal symptoms: one tablet daily	Only for short duration.
Calcitonin			
Calcitonin salmon (Miacalcin)	200 IU/0.9 mL, 3.7-mL nasal spray	PM osteoporosis: Nasal spray: 200 IU daily	Nasal spray: Alternate nostrils on a daily basis.

CrCl, creatinine clearance; PM, postmenopausal; SC, subcutaneously.

the lumbar spine and 6.8% in the hip without additional safety concerns.[28] Sustained reductions in fracture risk have also been shown with 6 years of use.[29]

Common adverse effects include back pain, arthralgias, fatigue, headache, dermatologic reactions, diarrhea, and nausea. Serious adverse reactions, including hypophosphatemia, hypocalcemia, dyspnea, and skin and other infections, can also occur. Patients should seek medical attention if they experience any symptoms of infection. Denosumab can worsen hypocalcemia in predisposed patients, such as those with severe kidney disease, and preexisting hypocalcemia should be corrected before initiating therapy. Suppression of bone turnover has been associated with denosumab therapy, and ONJ has also been reported.[2] Drug holidays are not recommended for denosumab therapy because, unlike the bisphosphonates, the beneficial effects on bone and fracture risk are lost once the drug is discontinued.[2]

Denosumab has a Risk Evaluation and Mitigation Strategy (REMS) program, in which the manufacturer is required by

Patient Encounter Part 2: Physical Examination and Diagnostic Tests

ROS: 4-cm height loss since middle age; (+) back and knee pain; weight decrease of 7 lbs in last 6 months with unintended weight loss

PE:

Gen: Well-developed white female in no acute distress

VS: BP 134/76 mm Hg, P 76 beats/min, RR 18 breaths/min, T 36.3°C (97.3°F), Wt 55 kg (121 lb), Ht 64 in (163 cm), BMI 20.8 kg/m^2

Chest: No crackles or rhonchi

CV: RRR, normal S_1, S_2; no murmurs, rubs, or gallops

Spine: Mild kyphosis present, nontender

Abd: Soft, nontender, nondistended; normal bowel sounds, no hepatosplenomegaly

Ext: No clubbing, cyanosis, or edema

Labs: Na 139 mEq/L (mmol/L); K 4.0 mEq/L (mmol/L); SCr 0.9 mg/dL (80 µmol/L); A1C 6.3% (0.063; 45 mmol/mol hemoglobin); 25(OH)D 21 ng/mL (52 nmol/L)

Bone Densitometry by DXA

- BMD of femoral neck: *T*-score = –1.8
- BMD of lumbar spine: *T*-score = –2.4

Vertebral Fracture Assessment: L1 wedge compression fracture present

What additional risk factors and signs of osteoporosis are present in this patient?

What are the goals of pharmacologic and nonpharmacologic therapy?

List at least three nonpharmacologic interventions important in her treatment plan.

What factors support pharmacotherapy for osteoporosis in this patient?

What type of supplement(s) would you recommend for this patient to meet her calcium and vitamin D requirements? Why?

the FDA to inform patients and health care providers of the risks associated with its use.[30] Denosumab is administered as a subcutaneous injection once every 6 months by a health care provider and should be stored in the refrigerator until administration. Once at room temperature, the vial or prefilled syringe must be used within 14 days.

▶ *Osteoanabolic Therapy*

Abaloparatide and teriparatide are osteoanabolic therapies that exert beneficial effects on bone through stimulation of the parathyroid hormone (PTH) type 1 receptor. Activation of this receptor promotes osteoblastic activity and bone formation but may also enhance bone resorption.[31] The overall net effect is an increase in BMD. These drugs should be reserved for patients with a high fracture risk or those in whom other therapies have been ineffective.[2,32] Both agents are available for self-injection as prefilled pens and administered as daily subcutaneous injections.

Teriparatide, recombinant human PTH (1–34), is FDA-approved for treatment of postmenopausal and male osteoporosis. Teriparatide increases BMD in the spine and hip by 9% and 3%, respectively; and reduces vertebral and nonvertebral fracture risk by 65% and 53%, respectively.[33]

Abaloparatide, a synthetic analog of PTH-related protein (PTHrP), was approved in 2017 for treatment of postmenopausal women at high risk of fracture based on the results of clinical trials in this population.[34] Abaloparatide increases BMD in the femoral neck and lumbar spine by up to 3.6% and 11.2%, respectively; it reduces vertebral and nonvertebral fractures by 86% and 43%, respectively, in high-risk women.[34,35]

Common adverse effects of both drugs include nausea, headache, leg cramps, dizziness, orthostatic hypotension, injection site discomfort, hypercalciuria, and hypercalcemia.[2,32] Abaloparatide may also be associated with palpitations.[35] Neither drug should be used in patients with preexisting hypercalcemia. Observations of osteosarcoma in animal studies led to the inclusion of a "black box warning" in product labeling for both drugs, but the risk has not been confirmed in humans.[2]

Patient-related concerns include cost of therapy and need for daily subcutaneous injections. Treatment is not recommended beyond 2 years, and BMD declines once treatment is stopped although sustained benefits in fracture reduction may be seen for 1 to 2 years after discontinuation.[2] The AACE recommends initiating treatment with alendronate or another bisphosphonate following osteoanabolic therapy (known as sequential therapy) to prevent these losses and maintain or provide further reduction in fracture risk.[2]

▶ *Estrogen Agonists/Antagonists*

Raloxifene has estrogen-like activity on bones and cholesterol metabolism, and estrogen antagonist activity in breast and endometrium. It reduces bone resorption and decreases overall bone turnover. It is recommended as alternative therapy after bisphosphonates, denosumab, or osteoanabolic therapies.[2]

Raloxifene has been shown to increase BMD in the vertebrae (2%–3%) and hips (1%–2%), and reduce vertebral fracture rates by as much as 55%.[36] Significant decreases in nonvertebral fractures have not been demonstrated.[2] Raloxifene has been shown to decrease the incidence of breast cancer in high-risk women. It also decreases total and low-density lipoprotein (LDL) cholesterol, which generated initial enthusiasm for additional cardiovascular benefits. However, mixed results have been seen on cardiovascular disease, stroke, and noncardiovascular mortality.[37,38]

Adverse effects of raloxifene include hot flushes, leg cramps, and increased risk of venous thromboembolism.[37] A previous history of venous thromboembolism is a contraindication to therapy. Hot flushes are very common and may be intolerable in postmenopausal women who are already predisposed to experiencing them.

Bazedoxifene, a third-generation estrogen agonist/antagonist, has similar effects to raloxifene. It is currently available only as a combination product with conjugated estrogens (Duavee) for treatment of moderate to severe vasomotor symptoms associated with menopause and for prevention of postmenopausal osteoporosis.[1] Other therapies should be considered for women who meet criteria for osteoporosis treatment.

▶ *Calcitonin*

Calcitonin is a naturally occurring mammalian hormone that plays a major role in regulating calcium levels. It inhibits bone resorption by binding to osteoclast receptors. Calcitonin is considered a last-line agent for the treatment of osteoporosis due to limited fracture prevention data.[2] Calcitonin produces a modest increase in BMD at the spine of 1% to 3% and reduces vertebral fracture risk by up to 30%.[39] However, no benefit has been demonstrated in reducing nonvertebral fractures.[2] Calcitonin is generally reserved for patients unable to tolerate or take other agents. However, it is sometimes used for relief of back pain from vertebral fractures due to data suggesting benefit for this purpose.[2]

Although salmon calcitonin is approved and available in injectable and intranasal formulations, only the intranasal formulation has documented benefit in clinical trials for management of osteoporosis. Adverse effects associated with the intranasal formulation include rhinitis, nasal irritation, and dryness. Hypersensitivity can develop with either formulation and should be considered before administering to patients with suspected risk.[2]

▶ *Hormone Therapy*

Estrogen, either alone or in combination with a progestin as hormone replacement therapy (HRT), has a long history as an effective treatment of osteoporosis. The Women's Health Initiative (WHI) trial found a 34% reduction in both vertebral and hip fractures and a 23% reduction in other fractures in postmenopausal women receiving conjugated estrogens and medroxyprogesterone.[40] However, significant risks associated with long-term HRT, including breast cancer and venous thromboembolism, have limited its use in osteoporosis.[40,41]

▶ *Combination Therapy*

Combination therapy is based on the premise that two more antiresorptive therapies with different mechanisms of action may provide more benefit on bone than monotherapy. However, this practice is currently not recommended for most patients due to high cost and lack of long-term safety and efficacy data. Combination therapy with a bisphosphonate, denosumab, or an osteoanabolic agent may be considered in cases when indications exist for raloxifene to reduce breast cancer risk or HRT to treat menopausal symptoms.[2]

▶ *Investigational Therapy*

Romosozumab, a monoclonal antisclerostin antibody administered by subcutaneous injection, has shown promising results in clinical trials.[42,43] It promotes bone formation and reduces resorption by binding to and inhibiting sclerostin, resulting in significant decreases in vertebral and nonvertebral fractures. Early adverse effects include injection site reactions, arthralgias, and skin-related hypersensitivity reactions. ONJ and atypical femur fracture were also noted. Additionally, recent clinical trials have reported mixed data on the risk of cardiovascular events.[43,44] This prompted the FDA to initially deny approval of romosozumab in 2017 and to ask for more data.[45]

Treatment of Special Populations

▶ *Glucocorticoid-Induced Osteoporosis*

Glucocorticoids (eg, prednisone, hydrocortisone, methylprednisolone, and dexamethasone) play a significant role in bone remodeling, including increasing bone resorption, inhibiting bone formation, and changing bone quality. They promote bone resorption through reduced calcium absorption from the GI tract and increased renal calcium excretion. Bone formation is reduced through inhibition of osteoblasts and decreased estrogen and testosterone production.[46] Up to 40% of patients receiving long-term oral glucocorticoids have evidence of vertebral fracture.[47] Most bone mass is lost during the initial 3 to 6 months of therapy and continues to decline slowly thereafter.[47] Fracture risk is affected by other osteoporotic risk factors, and this risk is largely reversible once glucocorticoids are discontinued.

Patient Encounter Part 3: Development of a Treatment Plan

Considering all of the information presented, develop a treatment plan for this patient. Include the following information:

Recommendations for patient-specific drug therapy including dose and frequency.

Patient education about the chosen regimen, including administration directions.

Monitoring plan for efficacy and adverse effects.

Consideration of alternate therapies if the initial therapy fails or is intolerable.

KEY CONCEPT The American College of Rheumatology (ACR) recommends oral bisphosphonate therapy for all patients age 40 and over at moderate to high risk of fracture receiving glucocorticoids (prednisone 2.5 mg or more daily or equivalent) for 3 months or longer. Nonpharmacologic therapy and optimal calcium and vitamin D intake are also recommended. For patients unable to take oral bisphosphonates, alternative therapy recommendations include IV bisphosphonates, teriparatide, denosumab, and raloxifene in that order.[47] Frequent clinical fracture risk assessment with BMD testing every 1 to 3 years is recommended while receiving glucocorticoids.[47]

OUTCOME EVALUATION

- Evaluate patients for progression of osteoporosis, including signs and symptoms of new fragility fracture (eg, localized pain), loss of height, and physical deformity (eg, kyphosis). Assess patients on an annual basis or more often if new symptoms present
- Monitor for beneficial effects on bone density. The NOF recommends a follow-up DXA scan every 2 years to monitor the effects of therapy
- Assess patients for adverse effects of therapy:
  - Oral bisphosphonates: Dyspepsia, esophageal reflux, esophageal pain, or burning, ONJ (rare), subtrochanteric fracture (rare)
  - Injectable zoledronic acid: Influenza-type symptoms related to infusion, ONJ (rare), subtrochanteric fracture (rare)
  - Denosumab: Arthralgias, dermatologic reactions, and hypocalcemia, ONJ (rare)
  - Abaloparatide and teriparatide: Nausea, headache, leg cramps, hypercalcemia, and orthostatic hypotension; also palpitations with abaloparatide
  - Raloxifene: Hot flushes, signs, or symptoms of thromboembolic disease (eg, pain, redness, or swelling in one extremity, chest pain, and shortness of breath)
  - Calcitonin salmon: Nasal irritation or burning

Patient Care Process

Collect Information:

- Perform a thorough medication history, including prescription, over-the-counter, and alternative therapies.
- Determine the patient's average daily intake of calcium and sources of vitamin D; frequency, duration and type of physical activity; and history of smoking and/or alcohol consumption.
- Review past medical and family history, recent laboratory and procedure reports, and medication allergies/intolerances.
- Test bone densitometry in patients at risk for having low bone mass or bone loss. If *T*-score is between –1.0 and –2.5, use FRAX to estimate fracture risk.
- If the patient is already receiving pharmacotherapy, assess efficacy, safety, and patient adherence. How long has the patient been on each agent? Was the patient previously treated with other agents?

Assess the Information:

- Assess risk factors for osteoporosis and the presence of secondary causes of osteoporosis.
- Assess nonpharmacologic interventions for preventing osteoporotic fractures, including nutrition and weight-bearing and muscle-strengthening exercise regimens. What is the patient's fall risk? What medications is the patient taking that could increase fall risk?
- Determine the feasible options available for the patient. Does the patient have prescription coverage? What agents are recommended on the formulary? Are there any contraindications to available treatment options?

Develop a Care Plan:

- Select therapy (including agent and dose) likely to be safe and effective for the patient (see Table 56–6).

Implement the Care Plan:

- If pharmacologic therapy is indicated, discuss therapeutic goals and expectations (eg, changes in individual *T*-scores may not necessarily correlate with benefit in fracture risk reduction).
- Educate the patient on drug therapy selected, including drug name, dose, route and method of administration, common or serious adverse reactions, adherence, and monitoring.
- Educate the patient about nonpharmacologic measures to prevent osteoporotic fractures.

Follow up: Monitor and Evaluate:

- Annually review the need for continued medication. Assess appropriate drug administration and adherence efficacy, adverse effects, and nonpharmacologic measures to prevent fractures.
- Reassess BMD every 2 years in patients on pharmacologic agents to treat osteoporosis. Vertebral imaging is appropriate if there is a documented loss in height of 2 cm or greater.

Abbreviations Introduced in This Chapter

AACE	American Association of Clinical Endocrinologists
ACR	American College of Rheumatology
BMD	Bone mineral density
BMI	Body mass index

57 Rheumatoid Arthritis

Susan P. Bruce

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

LO

1. Identify risk factors for developing adult rheumatoid arthritis (RA) or juvenile idiopathic arthritis (JIA).
2. Describe the pathophysiology of RA, with emphasis on the specific immunologic components.
3. Discuss the comorbidities associated with RA.
4. Recognize the typical clinical presentation of RA or JIA.
5. Create treatment goals for a patient with RA or JIA.
6. Compare the available pharmacotherapeutic options, selecting the most appropriate regimen for a given patient.
7. Propose a patient education plan that includes nonpharmacologic and pharmacologic treatment measures.
8. Formulate a monitoring plan to evaluate the safety and efficacy of a therapeutic regimen designed for an individual patient with RA or JIA.

INTRODUCTION

Rheumatoid arthritis (RA) is a complex systemic inflammatory condition manifesting initially as symmetric swollen and tender joints of the hands and/or feet. Some patients may experience low disease activity, whereas others may present with high disease activity and/or extraarticular manifestations. The systemic inflammation of RA leads to joint destruction, disability, and premature death. Juvenile idiopathic arthritis (JIA) is the most common form of arthritis in children.

EPIDEMIOLOGY AND ETIOLOGY

RA has a prevalence of 0.5% to 1%.[1,2] Patients with RA have a 50% increased risk of premature death and a decreased life expectancy of 3 to 10 years compared with individuals without RA.[3] The underlying causes of increased mortality are unclear. RA arises from an immunologic reaction, perhaps in response to a genetic or infectious antigen. Risk factors associated with the development of RA include the following:

LO 1

- Female gender (3:1 females to males)
- Increasing age (peak onset 35–50 years of age)
- Current tobacco smoking.[4] Tobacco users are more likely to have extraarticular manifestations and to experience treatment nonresponsiveness. This risk is reduced when a patient has remained tobacco-free for at least 10 years.
- Family history of RA. Genetic studies demonstrate a strong correlation between RA and the presence of major histocompatibility complex class II **human leukocyte antigens** (HLA), specifically HLA-DRB1 haplotypes.[5] HLA is a molecule associated with the presentation of antigens to T lymphocytes.
- Emerging evidence suggests that stress may influence RA onset and disease activity. It appears that individual major stressful life events do not play a significant role. Instead, chronic presence of minor stressors (daily hassles, work and relationship stress, financial pressures) may affect the immune response and RA disease activity.[6]
- The prevalence of JIA is approximately 1 in 1000 children.[7] There are no known risk factors for JIA.

PATHOPHYSIOLOGY

LO 2

The characteristics of a **synovium** affected by RA are: (a) the presence of a thickened, inflamed membrane lining called **pannus**; (b) development of new blood vessels; and (c) influx of inflammatory cells in the synovial fluid, predominantly T lymphocytes. The pathogenesis of RA is driven by T lymphocytes, but the initial catalyst causing this response is unknown. Understanding specific components of the immune system and their involvement in the pathogenesis of RA will facilitate understanding of current and emerging treatment options for RA. The components of most significance are T lymphocytes, cytokines, B lymphocytes, and kinases.[5,8]

T Lymphocytes

The development and activation of T lymphocytes are important to maintain protection from infection without causing harm to the host. Activation of mature T lymphocytes requires two signals. The first is the presentation of an antigen by antigen-presenting cells to the T-lymphocyte receptor. Second, a ligand-receptor complex (ie, CD80/CD86) on antigen-presenting cells binds to CD28 receptors on T lymphocytes.[5]

Table 57–1

Cytokines Involved in the Pathogenesis of RA[5,8,9]

Cytokine	Source	Activity
Proinflammatory		
TNF-α	Macrophages, monocytes, B lymphocytes, T lymphocytes, fibroblasts	Induces IL-1, IL-6, IL-8, GM-CSF; stimulates fibroblasts to release adhesion molecules
IL-1	Macrophages, monocytes, endothelial cells, B lymphocytes, activated T lymphocytes	Stimulates fibroblasts and chondrocytes to release matrix metalloproteinases
IL-6	T lymphocytes, monocytes, macrophages, synovial fibroblasts	Activates T lymphocytes, induces acute-phase response, stimulates growth and differentiation of hematopoietic precursor cells; stimulates synovial fibroblasts
IL-17	T lymphocytes in synovium	Synergistic effect with IL-1 and TNF leading to increased production of proinflammatory cytokines
Anti-Inflammatory		
IL-4	CD4+ type 2 helper T lymphocytes	Inhibits activation of type 1 helper T lymphocytes, decreases production of IL-1, TNF-α, IL-6, IL-8
IL-10	Monocytes, macrophages, B lymphocytes, T lymphocytes	Inhibits production of IL-1, TNF-α, and proliferation of T lymphocytes

LO 2 Once a cell successfully passes through both stages, the inflammatory cascade is activated. Activation of T lymphocytes: (a) stimulates the release of macrophages or monocytes, which subsequently causes the release of inflammatory cytokines; (b) activates osteoclasts; (c) activates release of matrix metalloproteinases or enzymes responsible for the degradation of connective tissue; and (d) stimulates B lymphocytes and the production of antibodies.[5,8,9]

Cytokines

LO 2 Cytokines are proteins secreted by cells that serve as intercellular mediators (Table 57–1). An imbalance of proinflammatory and anti-inflammatory cytokines in the synovium leads to inflammation and joint destruction. Some of the proinflammatory cytokines are interleukin 1 (IL-1), tumor necrosis factor-α (TNF-α), IL-6, and IL-17. These proinflammatory cytokines cause activation of other cytokines and adhesion molecules responsible for recruitment of lymphocytes to the site of inflammation. Anti-inflammatory cytokines and mediators (IL-4, IL-10, and IL-1 receptor antagonist) are present in the synovium, although concentrations are not high enough to overcome the effects of the proinflammatory cytokines.[5,8,9]

B Lymphocytes

LO 2 In addition to serving as antigen-presenting cells to T lymphocytes, B lymphocytes may produce proinflammatory cytokines and antibodies.[8] Antibodies of significance in RA are **rheumatoid factors** (antibodies reactive with the Fc region of IgG) and **anticitrullinated protein antibodies** (ACPA). Rheumatoid factors are not present in all patients with RA, but their presence is indicative of disease severity and structural progression. ACPA are produced early in the course of disease. High levels of ACPA are indicative of aggressive disease and a greater likelihood of poor outcomes. Monitoring RF and ACPA may be useful to match the intensity of treatment appropriately.[10]

Kinases

LO 2 Kinases are enzymes involved in communication or signaling activities within and between cells. Activated kinases lead to cell activation and proliferation. Examples include Janus-associated kinases (JAKs) and spleen tyrosine kinase. Research is ongoing to identify additional therapeutic targets to interrupt signaling and thereby halt the inflammatory process.[11]

Comorbidities Associated with RA

LO 3 RA reduces a patient's average life expectancy, but RA alone rarely causes death. Instead, specific **comorbidities** contribute to premature death independent of safety issues surrounding the use of immunomodulating medications. KEY CONCEPT The comorbidities with the greatest impact on morbidity and mortality associated with RA are: (a) cardiovascular disease, (b) infections, (c) malignancy, and (d) osteoporosis.

▶ *Cardiovascular Disease*

More than half of all deaths in RA patients are cardiovascular related. Because a patient with RA experiences inflammation and swelling in joints, it is likely that there is inflammation elsewhere, such as in the blood vessels, termed **vasculitis**. C-reactive protein (CRP), a nonspecific marker of inflammation, is associated with an increased risk of cardiovascular disease; CRP is elevated in patients with RA. Traditional cardiovascular risk factors alone cannot explain the increased cardiovascular mortality in patients with RA. Increasing evidence suggests that the presence of RA is a cardiovascular risk similar to diabetes. Aggressive management of systemic inflammation and traditional cardiovascular risk factors (eg, blood pressure, cholesterol, tobacco use) may reduce cardiovascular mortality in this population.[12-14]

▶ *Infections*

Patients with RA have an increased risk of infections due to the underlying disease process. Older age, disease activity, and concomitant conditions (ie, renal failure, lung disease) may increase risk of infection. Additionally, prolonged glucocorticoid use may contribute to infection risk. Patients and clinicians must pay close attention to signs and symptoms of infection.[15]

▶ *Malignancy*

Cancer is the second most common cause of death in RA patients. There is an overall increased risk of malignancy and an increased risk of developing **lymphoproliferative** malignancy (eg, lymphoma, leukemia, multiple myeloma), melanoma, and lung cancer but decreased risk of developing cancer of the cervix, prostate, and digestive tract. Research is underway to understand

Table 57–2

Comparison of RA and Osteoarthritis

Characteristic	RA	Osteoarthritis
Speed of onset	Rapid (weeks to months)	Slow (years)
Gender prevalence (women:men)	3:1	1:1
Usual age of onset	Juvenile or adult (35–50 years)	Greater than 50 years
Most common joints affected	Small joints of hands (MCPs, PIPs), feet	Hands (DIPs), large weight-bearing joints (hips, knees)
Joint symptoms	Pain, swelling, warmth, stiffness	Pain, bony enlargement
Presence of inflammation	Local and systemic	None or mild, local
Duration of morning joint stiffness	Usually 60 minutes or longer	Usually less than 30 minutes
Joint pattern	Symmetric	Symmetric or asymmetric
ESR	Elevated	Normal
Synovial fluid	Leukocytosis, slightly cloudy	Mild leukocytosis
Systemic manifestations	Yes	No

DIPs, distal interphalangeal joints; ESR, erythrocyte sedimentation rate; MCPs, metacarpophalangeal joints; PIPs, proximal interphalangeal joints.

the mechanisms that increase or decrease risk of specific cancers, and how medication use independently contributes to individual risk.[15,16]

▶ *Osteoporosis*

Cytokines involved in the inflammatory process directly stimulate **osteoclast** and inhibit **osteoblast** activity. Additionally, arthritis medications can lead to increased bone loss. Bone mineral density should be evaluated at baseline and routinely using dual-energy x-ray absorptiometry.

CLINICAL PRESENTATION AND DIAGNOSIS

See the box on next page for the clinical presentation of RA.

Diagnosis

Both osteoarthritis and RA are prevalent in the US population, but they differ in presentation (Table 57–2). Because management of the two conditions differs significantly, early evaluation and diagnosis are essential to maximize an individual's care.

In 2010, The American College of Rheumatology (ACR) and European League Against Rheumatism (EULAR) released classification criteria for RA (Table 57–3).[1] The goal was to identify a subset of patients with undifferentiated synovitis who were at high risk for chronic and erosive disease. The criteria are intended to help identify patients earlier in the course of disease. This will allow researchers to determine whether earlier introduction of medications alters the disease process. The criteria were developed as a tool for research purposes, but they are also helpful to guide clinical diagnosis. Patients with at least one joint with definite clinical synovitis that is not explained by another disease should be evaluated for RA.

Certain clinical features of RA are considered in diagnosis and treatment decisions because they may be related to rapid disease progression. KEY CONCEPT The most clinically important features associated with poor long-term outcomes include: (a) high disease activity, (b) positive autoantibodies (RF or ACPA), and (c) early presence of bony erosions by radiography.[18]

▶ *Diagnosis of Juvenile Idiopathic Arthritis*

Diagnostic criteria for JIA include: (a) age less than 16 years at disease onset, (b) arthritis in one or more joints for more than 6 weeks, and (c) exclusion of other types of arthritis. JIA can be divided into three main types:

1. *Systemic (4%–17% of cases)*: Occurs equally in girls and boys. There are characteristic fever spikes twice daily (> 38.3°C or 101°F) and the presence of a pale, pink, transient rash. The peak onset is between ages 1 and 6 years.
2. *Polyarticular (approximately 40% of cases)*: More likely to affect girls than boys (3:1). Arthritis is present in five or more joints. The disorder resembles adult RA more than the other types of JIA.

Table 57–3

ACR/EULAR 2010 Classification Criteria for Rheumatoid Arthritis[1]

Criteria	Score
Joint involvement	
1 large joint (hips, knees, ankles, elbows, shoulders)	0
2–10 large joints	1
1–3 small joints (MCPs, PIPs, MTPs, wrists)	2
4–10 small joints	3
More than 10 joints (at least one small joint)	5
Serology (need at least one result for classification)	
Negative RF and negative ACPA	0
Low-positive RF or low-positive ACPA	2
High-positive RF or high-positive ACPA	3
Acute-phase reactants (need at least one result for classification)	
Normal CRP and normal ESR	0
Abnormal CRP or abnormal ESR	1
Duration of symptoms	
Less than 6 weeks	0
More than 6 weeks	1
TOTAL:	6 or greater indicates definite RA

ACPA, anticitrullinated protein antibodies; ACR, American College of Rheumatology; CRP, C-reactive protein; ESR, erythrocyte sedimentation rate; EULAR, European League Against Rheumatism; MCPs, metacarpophalangeal joints; MTPs, metatarsophalangeal joints; PIPs, proximal interphalangeal joints; RA, rheumatoid arthritis; RF, rheumatoid factor.

LO 4

Clinical Presentation of RA

General

- About 60% of patients develop symptoms gradually over several weeks to months.
- Patients may present with systemic findings, joint findings, or both.

Symptoms

- Nonspecific systemic symptoms may include fatigue, weakness, anorexia, and diffuse musculoskeletal pain.
- Patients complain of pain in involved joints and prolonged morning joint stiffness.

Signs

- The metacarpophalangeal (MCP), proximal interphalangeal (PIP), metatarsophalangeal (MTP), and wrist joints are involved frequently.
- Joint involvement is usually symmetric.
- There is often limited joint function.
- Swan neck and/or boutonniere deformities may be present (see Figure 57–1).
- Signs of joint inflammation are present (tenderness, warmth, swelling, and erythema).
- Low-grade fever may be present.
- Extraarticular manifestations:
  - *Skin:* Subcutaneous nodules
  - *Ocular:* Keratoconjunctivitis sicca, scleritis
  - *Pulmonary:* Interstitial fibrosis, pulmonary nodules, pleuritis, pleural effusions
  - *Vasculitis:* Ischemic ulcers, skin lesions, leukocytoclastic vasculitis
  - *Neurologic:* Peripheral neuropathy, Felty syndrome
  - *Hematologic:* Anemia, thrombocytosis

Laboratory Tests

- Positive rheumatoid factor (RF) (the test is negative in up to 30% of patients)
- Elevated ESR (Westergren ESR: > 20 mm/hour in men; > 30 mm/hour in women)
- Elevated C-reactive protein (CRP) (> 0.7 mg/dL or 7 mg/L)
- Complete blood count: Slight elevation in WBC count with a normal differential; slight anemia; thrombocytosis
- Positive anticitrullinated protein antibodies (ACPA)

Other Diagnostic Tests

- *Synovial fluid analysis:* Straw colored, slightly cloudy, WBC 5–25 × 10^3/mm^3 (10^9/L), no bacterial growth if cultured
- *Joint x-rays:* To establish baseline and evaluate joint damage
- *MRI:* May detect erosions earlier in the course of disease than x-rays but is not required for diagnosis

Assessing Disease Activity

- Common tools to assess disease activity include Patient Activity Scale, Clinical Disease Activity Index, Simplified Disease Activity Index, and Disease Activity in 28 joints (DAS-28).[17] Components involved in calculating a DAS-28 score are the number of swollen and tender joints, ESR or CRP, and a subjective measure of the patient's general health. A DAS-28 score of 3.2 or less indicates low disease activity, between 3.2 and 5.1 is considered moderate activity, and 5.1 or more is considered to be high activity. Remission as defined by DAS-28 is a score of less than 2.6.[17] An online DAS-28 calculator is available at www.4s-dawn.com/DAS28/.

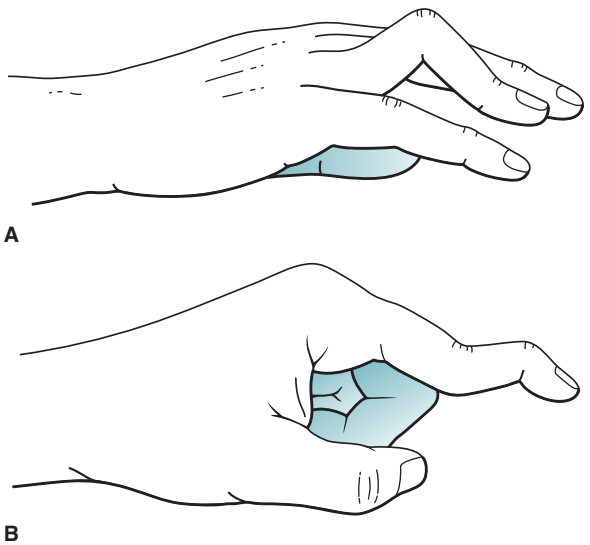

FIGURE 57–1. Boutonnière **(A)** and swan-neck **(B)** deformities. (Reproduced with permission from: Toy EC, Patlan Jr JT, Warner MT. Case Files: Internal Medicine 5e; 2017. http://accessmedicine.mhmedical.com/ViewLarge.aspx?figid=140919481.)

Patient Encounter Part 1

A 47-year-old woman presents to her rheumatologist for routine follow-up. She was diagnosed with RF-positive RA 10 years ago and presents today with concerns of increased morning stiffness (average 90 minutes daily) and symmetrical tenderness/swelling in her hands. She wishes to improve function as soon as possible. She maintains a stressful career in the banking industry. She tries to eat healthy, although she travels frequently and relies on many fast food meals. She smokes one pack per day and consumes alcohol socially. She has been taking medications for RA since diagnosis, although she admits to missing doses often because of her busy lifestyle.

What additional information do you need to assess disease activity?

What variables in this scenario may inhibit optimal patient care?

Which features suggest that the patient is experiencing symptoms of RA rather than OA?

What additional information do you need before creating a care plan for this patient?

3. *Oligoarticular (about 50% of cases)*: More likely to affect girls than boys (5:1). Uveitis is more likely to be present. Arthritis is present in four or fewer joints. The peak onset is between ages 1 and 3 years.

TREATMENT

Desired Outcomes

LO 5

KEY CONCEPT The goals of treatment in RA are to: (a) reduce or eliminate pain, (b) reduce disease activity to the lowest possible level, ideally remission, as soon as possible, (c) protect articular structures and function, (d) control systemic complications, and (e) improve/maintain quality of life. The goals for JIA are the same, with the added goals of maintaining normal growth, development, and activity level.[19,20] It is a common misconception that patients with JIA grow out of the disease. Many children with JIA become adults with JIA. Knowing this, it is essential that early, aggressive treatment is initiated to achieve the goals of therapy.

General Approach to Treatment

LO 6

The clinician must evaluate patient-specific factors and select appropriate treatment to maximize the care of each patient. Joint damage accumulates over time; therefore, early diagnosis and early aggressive treatment are necessary to reduce disease progression and prevent joint damage. Aggressive treatment is defined as one or more disease-modifying antirheumatic drugs (DMARDs) at effective doses. Delaying treatment will result in more destructive disease that is very difficult to delay or reverse to preserve joint function.

KEY CONCEPT It is imperative that one or more DMARDs be initiated in all patients as soon as possible to reduce disease activity. DMARDs are the mainstay of RA treatment because modifying the disease process can prevent or reduce joint damage. The umbrella term DMARD includes traditional nonbiologic DMARDs, biologic DMARDs, and Janus-kinase inhibitors. The drugs in these classes modify the underlying disease process rather than merely providing symptomatic relief. In addition to safety and efficacy data, the initial DMARD choice depends on disease severity, patient characteristics (ie, comorbidities, likelihood of adherence), cost, and clinician experience with the medication.[7,17] Methotrexate alone or in combination therapy is the initial treatment of choice.

Depending on disease severity, combination therapy may be initiated at the time of diagnosis or after an adequate trial of DMARD monotherapy. If a patient has evidence of rapid disease progression (eg, worsening radiographic erosions), a more aggressive treatment plan may be warranted with more frequent follow-up to achieve the goal of remission or low disease activity.

Nonsteroidal anti-inflammatory drugs (NSAIDs) and glucocorticoids also have specific roles in the treatment of RA, as discussed below. Agents such as azathioprine, cyclosporine, minocycline, gold salts, and anakinra are used rarely today.[17]

Figures 57–2 and 57–3 outline the course of treatment for adult RA according to the ACR 2015 Recommendations.[17] The recommendations are based on the disease activity level and duration of disease activity (early vs established). Figure 57–2 applies to patients with early RA (defined as < 6 months). Nonbiologic DMARD monotherapy includes methotrexate (preferred), hydroxychloroquine, leflunomide, or sulfasalazine. Examples of combination nonbiologic DMARD therapy include methotrexate/sulfasalazine, methotrexate/hydroxychloroquine, or methotrexate/sulfasalazine/hydroxychloroquine.

Figure 57–3 outlines the course of treatment for patients with established RA (disease duration 6 months or longer). Combination biologic DMARDs should be avoided because of the increased risk of infection due to excessive immunosuppression. There is no evidence that the benefits of combination biologic DMARD therapy outweigh the potential risks, especially the increased risk of infections.

Sarilumab does not appear in either figure because it was not FDA approved until after the guidelines were published. Anakinra does not appear in the 2015 treatment guidelines due to limited efficacy and infrequent use in RA.

Nonpharmacologic Therapy

All patients should receive education about the nonpharmacologic and pharmacologic measures to help manage RA and JIA. Empowered patients take an active role in care by participating in therapy-related decisions. Certain forms of nonpharmacologic therapy benefit all levels of severity, whereas others (ie, surgery) are reserved for severe cases only.

Occupational and physical therapy may help patients preserve joint function, extend joint range of motion, and strengthen joints and muscles through strengthening exercises. Patients with joint deformities may benefit from the use of mobility or assistive devices that help to minimize disability and allow continued activities of daily living. When appropriate, patients should also be counseled about stress management. In situations where the disease has progressed to a severe form with extensive joint erosions, surgery to replace or reconstruct the joint may be necessary.

Pharmacologic Therapy

LO 7

► *Bridge Therapy/Symptomatic Relief*

The current standard of care for RA treatment is to initiate disease-modifying therapy immediately. While this step is critical to control the underlying disease activity, it may take weeks to months for the patient to experience relief. It is acceptable to initiate "bridge therapy" or short-term use of certain medications to provide symptomatic relief until the disease modifying drug reaches its therapeutic effect. The most common classes used for bridge therapy are NSAIDs and glucocorticoids.

NSAIDs These agents provide analgesic and anti-inflammatory benefits for joint pain and swelling. However, they do not prevent joint damage or change the underlying disease. Selecting an NSAID depends on multiple patient-specific factors, including cardiovascular risk, potential for GI-related adverse events, adherence to medication regimens, and insurance coverage or lack thereof. NSAID monotherapy is recommended as initial treatment in children with JIA without prior treatment for a duration of 1 month.[19] Clinicians must carefully evaluate the potential risks of NSAID therapy against the potential benefits. See Chapter 58 for additional discussion of NSAID therapy.

Glucocorticoids In contrast to NSAIDs, low-dose glucocorticoid treatment (equivalent to prednisone 10 mg/day or less) effectively reduces inflammation through inhibition of cytokines and inflammatory mediators and prevents disease progression.[21] However, due to the adverse effect profile, the goal of glucocorticoid use is to keep doses low and use the drugs as infrequently as possible. For the purposes of bridge therapy, the recommended duration is 3 months or less. Patients taking more than 2.5 mg/day of prednisone or equivalent are at increased risk for clinically significant adverse reactions, especially bone loss leading to osteoporosis. Other glucocorticoid-related adverse reactions include Cushing syndrome, peptic ulcer disease,

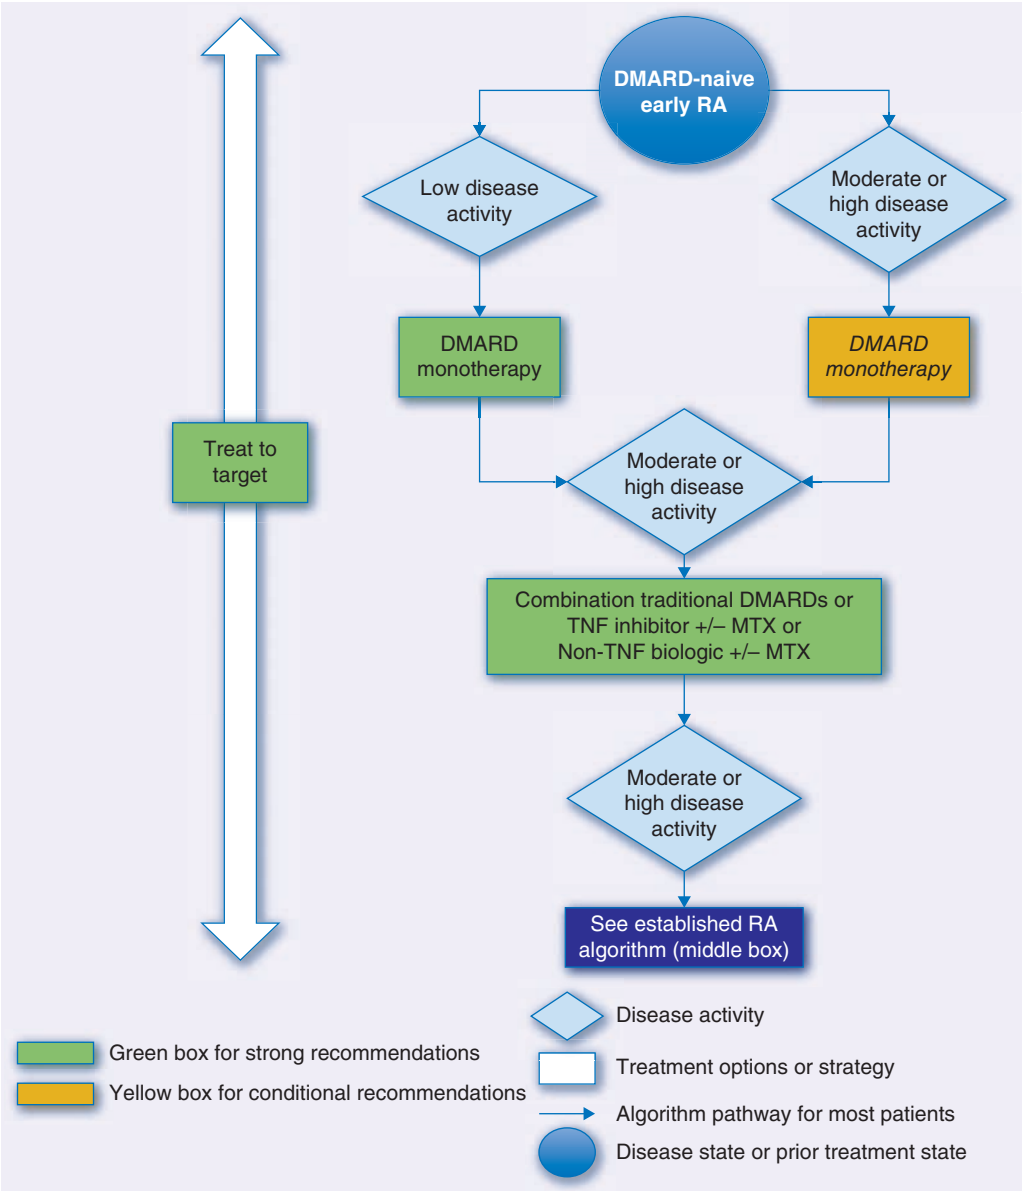

FIGURE 57–2. 2015 American College of Rheumatology recommendations for the treatment of the treatment of early RA (disease duration < 6 months). (Reproduced, with permission, from Singh JA, Saag KG, Bridges SL, et al. 2015 American College of Rheumatology guideline for the treatment of rheumatoid arthritis. Arthritis Care Res. 2016;68:1–25.)

hypertension, weight gain, infection, mood changes, cataracts, dyslipidemia, and hyperglycemia.[21] Intraarticular administration of glucocorticoids may be considered in RA for rapid control of inflammation if a limited number of joints are affected. Intraarticular glucocorticoid injections are recommended as initial treatment of JIA for disease affecting four or fewer joints.[19]

▶ *Nonbiologic DMARDs*

Methotrexate KEY CONCEPT Methotrexate is the nonbiologic DMARD of choice in RA because of its documented efficacy and safety profile when monitored appropriately. Methotrexate exerts its anti-inflammatory effect through inhibition of dihydrofolate reductase, which causes inhibition of purines and thymidylic acid, and by inhibiting production of certain cytokines. Unless the patient has contraindications to methotrexate or takes other medications that should be used with caution or avoided in combination with methotrexate, once-weekly doses should be initiated and increased steadily until the patient has symptomatic improvement or a maximum dose of 20 mg/week is reached. It is important to emphasize to patients and health care providers that the dosing is once weekly (not once daily) to avoid medication errors resulting in serious complications from profound myelosuppression (eg, infections, bleeding). If monotherapy does not produce complete resolution of symptoms, methotrexate may be used in combination with other nonbiologic or biologic DMARDs. If a patient experiences intolerable gastrointestinal effects, switching to subcutaneous methotrexate will reduce those effects. Concomitant folic acid is given routinely to reduce the risk of folate-depleting reactions induced by methotrexate therapy (eg, **stomatitis**, diarrhea, nausea, **alopecia**, **myelosuppression**, and elevated liver function tests).

Methotrexate is recommended as initial treatment for JIA in patients with more than four active joints.[19] There are insufficient published data to assess the risk of serious toxicity in children

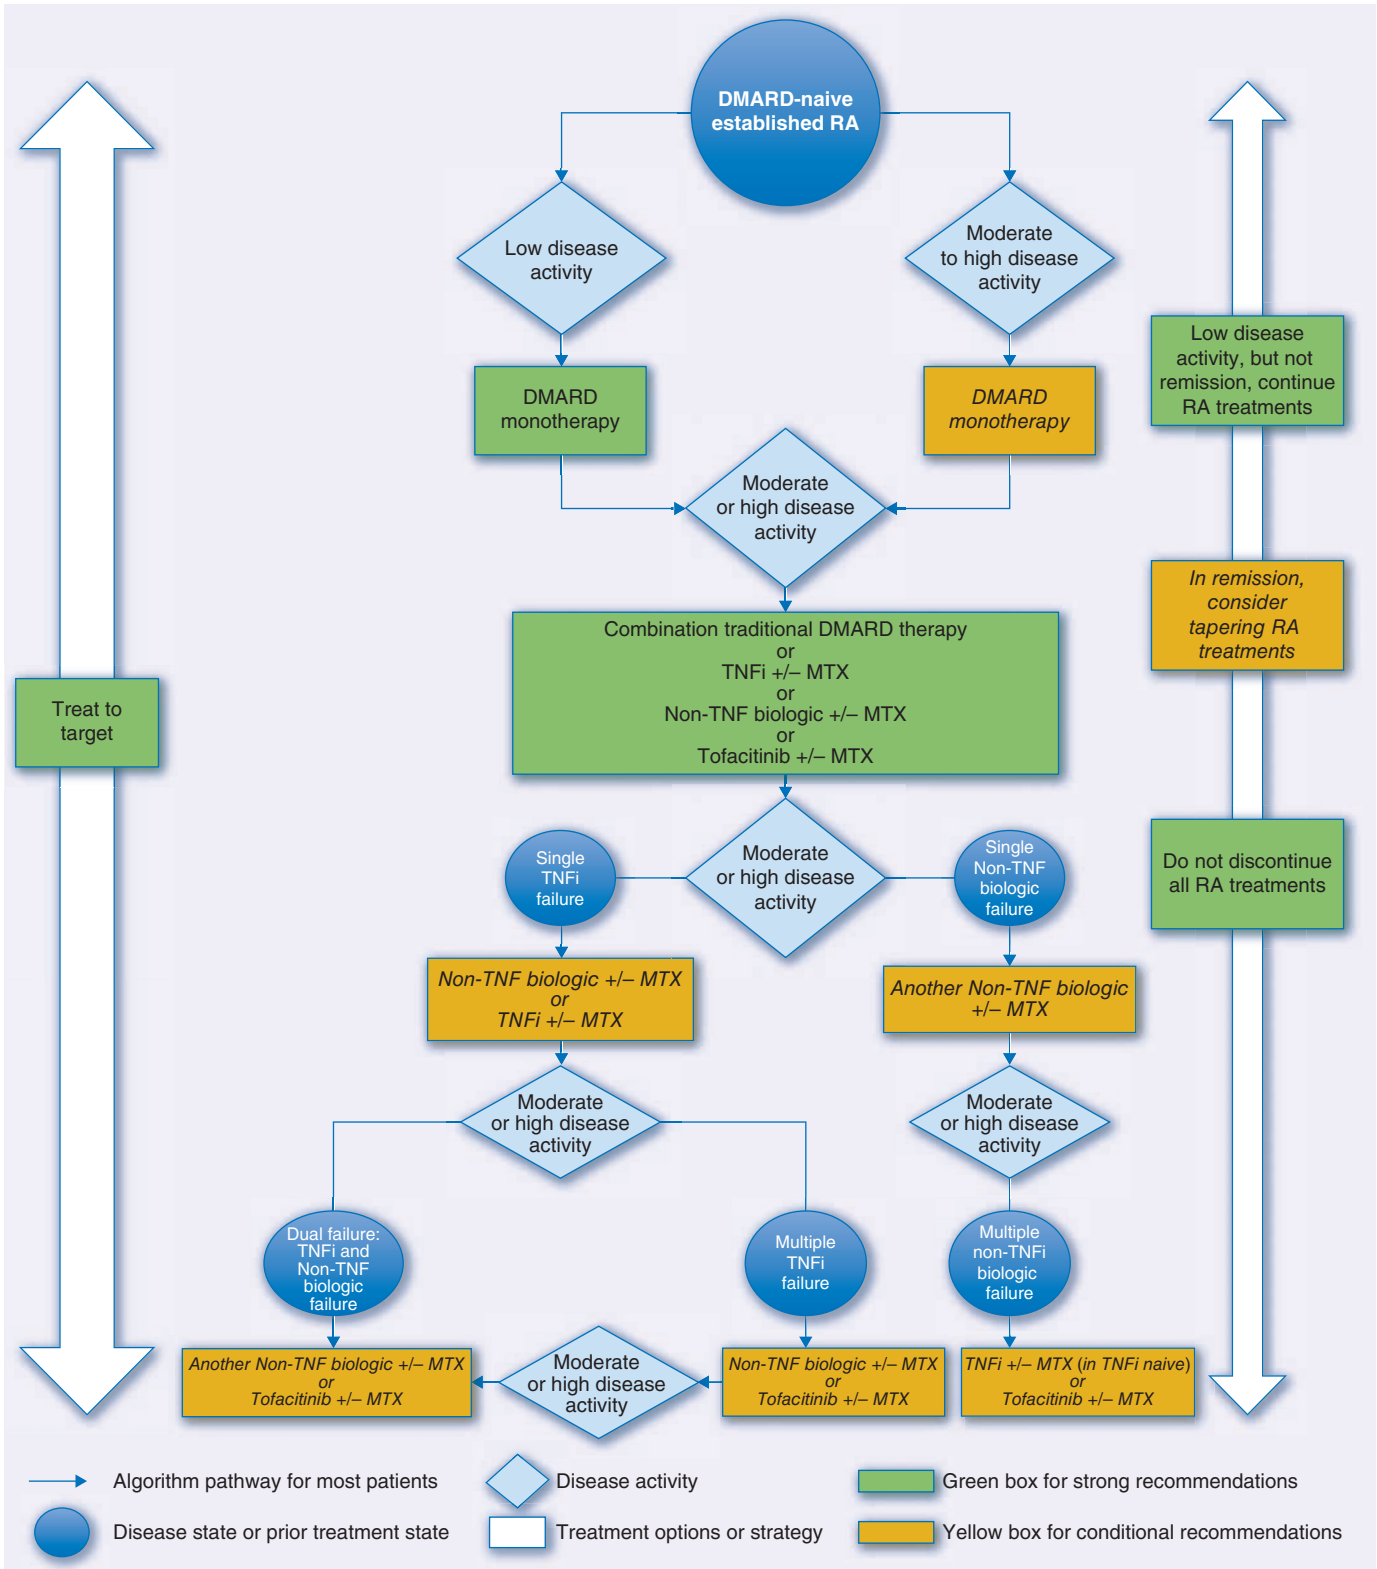

FIGURE 57–3. 2015 American College of Rheumatology recommendations for the treatment of established RA (disease duration 6 month or longer). (Reproduced, with permission, from Singh JA, Saag KG, Bridges SL, et al. 2015 American College of Rheumatology guideline for the treatment of rheumatoid arthritis. Arthritis Care Res. 2016;68:1–25.)

receiving doses greater than 20 mg/m^2/week. Methotrexate therapy in children should be monitored the same way that is recommended in adults.

Hydroxychloroquine and Sulfasalazine The exact mechanism of action of these drugs is unknown, but both agents are fairly well tolerated. Because of their slow onset of action, each drug must be given at therapeutic doses for at least 6 months before it can be deemed a treatment failure. If a patient does not respond to methotrexate monotherapy, adding one of these two drugs may provide the benefit necessary to reduce symptoms satisfactorily and ideally induce remission.[17]

Hydroxychloroquine is not associated with renal, hepatic, or bone marrow suppression and therefore may be an acceptable treatment option for patients with contraindications to other DMARDs because of their toxicities.

Starting sulfasalazine at low doses and titrating slowly will minimize the nausea and abdominal discomfort caused by the drug. Patients with a sulfa allergy should not receive sulfasalazine.

In patients with JIA, sulfasalazine is recommended only for patients with the **enthesitis**-related category. Enthesitis-related arthritis is a less common form of JIA that affects boys more than girls and is characterized by lower extremity joint involvement, including heel pain and enthesitis. Hydroxychloroquine is not recommended in JIA patients with active arthritis.[17,22]

Leflunomide This drug inhibits dihydroorotate dehydrogenase, an enzyme within mitochondria that supplies T lymphocytes with the necessary components to respond to cytokine stimulation. Thus, leflunomide inhibits the T-lymphocyte response to various stimuli and halts the cell cycle. Its efficacy is similar to that of moderate doses of methotrexate or sulfasalazine. Because of its extended half-life, leflunomide therapy begins with a loading dose followed by a maintenance dose. Leflunomide may be used in combination with methotrexate, but the added efficacy comes with a dramatic rise in the risk of hepatotoxicity. If therapy requires abrupt discontinuation (eg, due to toxicity or pregnancy), administering cholestyramine will accelerate leflunomide removal from the body.[22]

Leflunomide is recommended as an alternative to methotrexate in patients with JIA experiencing disease activity in five or more joints.[21] However, leflunomide does not have an FDA-approved indication for this use.

▶ *Biologic DMARDs and Associated Biosimilars*

Biologic DMARDs are indicated in patients who have received an adequate trial of nonbiologic DMARD monotherapy or combination therapy but have failed to achieve treatment goals. These agents may be added to nonbiologic DMARD monotherapy (eg, methotrexate), replace ineffective nonbiologic DMARD therapy, or even be considered for initial therapy, based on current guidelines.

"Biosimilars" are highly similar to an FDA-approved biologic agent (called the reference product) and have been shown to have no clinically meaningful differences in efficacy or adverse effects from the reference product. They are not completely identical to the originator compound because of molecular complexity and production using recombinant DNA techniques in living organ systems. The FDA will approve a biosimilar product only if it has the same mechanism of action, route of administration, dosage form, and strength as the reference product. Also, a biosimilar can only be approved for indications that were previously approved for the reference product. Biosimilars have a nonproprietary name plus an FDA-designated suffix consisting of four lower-case letters that have no intended meaning. Five biosimilars are now approved for use in RA: etanercept-szzs, infliximab-dyyb, infliximab-abda, adalimumab-adbm, and adalimumab-atto. Biosimilars are not considered to be interchangeable with the reference product unless the manufacturer fulfills additional requirements for interchangeability.

Patients with concomitant serious infections, lymphoproliferative disorders, hepatitis, history of malignancy, or heart failure should be evaluated thoroughly to determine if or which biologic DMARD is appropriate, preferred, or contraindicated in their treatment regimen. The 2015 treatment guidelines provide recommendations for those scenarios based on available evidence.[17]

Tumor Necrosis Factor (TNF) Antagonists There are currently five reference TNF antagonists approved for the treatment of RA: etanercept, adalimumab, infliximab, golimumab, and certolizumab.

Etanercept is a recombinant form of human T receptor. Etanercept provides a therapeutic effect by binding to soluble TNF and preventing its binding with TNF receptors. Etanercept is very effective as monotherapy or in combination with other nonbiologic DMARDs. Etanercept has an FDA-approved indication for treatment of JIA.

Adalimumab is a recombinant human IgG1 monoclonal antibody specific for human TNF. Adalimumab binds to soluble and bound TNF-α. It can be administered in combination with methotrexate or other DMARDs. Adalimumab has an FDA-approved indication for JIA.

Infliximab is a **chimeric** IgG1 monoclonal antibody that binds to soluble and bound TNF-α. Methotrexate is given with it to suppress antibody production against the mouse-derived portion of the molecule. Qualified health care personnel must be present during the infliximab infusion to respond to infusion-related reactions, if they occur (rash, urticaria, flushing, headache, fever, chills, nausea, tachycardia, dyspnea). These reactions may be treated by: (a) temporarily discontinuing the infusion, (b) slowing the infusion rate, or (c) administering corticosteroids or antihistamines. Patients may be pretreated with corticosteroids or antihistamines if they continue to experience infusion reactions. Infliximab was shown in clinical trials to be effective for treatment of JIA, but it has not yet received FDA approval for this indication.

Golimumab is a human monoclonal antibody that binds to membrane-bound and soluble TNF. Golimumab can be administered in combination with methotrexate in patients with moderate to severe RA. One advantage of this agent over others in the class may be the once-monthly SC dosing or every-other-month IV dosing. Golimumab is not FDA approved for use in JIA.

Certolizumab is a humanized antibody Fab fragment conjugated to polyethylene glycol, which delays its metabolism and elimination. Certolizumab can be administered alone or in combination with methotrexate in patients with moderate to severe RA. Certolizumab is not FDA approved for use in JIA.[23]

Interleukin-1 Antagonists Anakinra is a recombinant form of human IL-1 receptor antagonist. Anakinra inhibits the activity of IL-1 by binding to it and preventing cell signaling. It is indicated for adults with RA who have failed one or more nonbiologic DMARDs. Regarding treatment of JIA, anakinra is recommended in the ACR treatment guidelines for patients with systemic arthritis with continued disease activity following an adequate trial of glucocorticoids or NSAIDs.[18] Anakinra is not FDA approved for the treatment of JIA.[23]

Canakinumab is a human monoclonal antibody that binds to IL-1 and blocks binding with the IL-1 receptor, thereby neutralizing

its activity. Canakinumab is not indicated for treatment of adult RA. Canakinumab is indicated for the treatment of systemic JIA in patients 2 years and older. The recommended dose is 4 mg/kg (maximum 300 mg) subcutaneously every 4 weeks.[24]

Costimulation Modulators Abatacept interferes with T-cell signaling, ultimately blocking T-cell activation and leading to anergy, or lack of response to an antigen. Abatacept is indicated as monotherapy or in combination with nonbiologic DMARDs following inadequate response to methotrexate or anti-TNF agents. Abatacept is FDA approved for the treatment of moderate to severe JIA; it is recommended as an option for patients who did not respond to an adequate trial of methotrexate, leflunomide, or anakinra.[19,23]

Anti-CD20 Monoclonal Antibody Rituximab is a genetically engineered chimeric anti-CD20 monoclonal antibody that causes B-lymphocyte depletion in bone marrow and synovial tissue. Rituximab is indicated for patients with moderate to severe RA and a history of inadequate response to one or more TNF antagonist therapies. Patients with RF-positive RA tend to respond more favorably to rituximab than patients with RF-negative disease. Rituximab carries a black-box warning of fatal infusion reactions, severe mucocutaneous reactions, hepatitis B reactivation, and progressive multifocal leukoencephalopathy. The benefits of rituximab must be tempered against the safety concerns reported with use of rituximab in the oncology setting. The role of rituximab in JIA is unclear, and the medication is not FDA approved for this purpose.[19,23]

Interleukin-6 Antagonists Interleukin-6 (IL-6) production is increased in patients with RA. High levels are indicative of joint damage and disease activity. In addition, IL-6 plays a significant role in the pathogenesis of anemia associated with RA. Tocilizumab, an anti–IL-6 receptor monoclonal antibody, inhibits the binding of IL-6 to the IL-6 receptor.[25] Tocilizumab is FDA approved for the treatment of moderate to severe RA and JIA. In JIA, it is recommended for patients with inadequate response to glucocorticoid monotherapy, methotrexate, leflunomide, or anakinra.[19]

Sarilumab is an IL-6 receptor antagonist that binds to soluble and membrane-bound IL-6 receptors. It is indicated for treatment of moderate to severe RA following inadequate response or intolerance to one or more DMARDs. It is not FDA approved for JIA.[24]

▶ *Janus-Kinase (JAK) Inhibitors*

Tofacitinib selectively inhibits Janus kinases, with greatest affinity for JAK3.[26] Tofacitinib is indicated for the treatment of moderate to severe RA as monotherapy or in combination with nonbiologic DMARDs. Combination administration with biologic DMARDs is inappropriate due to increased immunosuppression and subsequent increased infection risk. One distinct advantage of tofacitinib over biologic DMARDs is that it is given orally because it is a synthetic small molecule rather than a large protein produced by recombinant DNA techniques. It may be initiated if a patient does not have an adequate response to or is otherwise unable to receive nonbiologic or biologic DMARDs.[26] Baricitinib is an inhibitor of JAK 1 and 2 undergoing review by the FDA for treatment of RA.

▶ *Selecting Disease-Modifying Therapy*

The decision to select a particular agent generally is based on the prescriber's comfort level with monitoring medication safety and efficacy, severity of disease activity, presence of factors suggestive of poor prognosis, the frequency and route of administration, the patient's comfort level or manual dexterity to self-administer subcutaneous injections, the cost, and the availability of insurance coverage. Table 57–4 highlights dosing, safety, monitoring, and patient counseling information for DMARDs used in the treatment of RA. Together, Figures 57–2 and 57–3 and Table 57–4 can be used to build an individualized treatment plan. While monotherapy is preferred, combination therapy may be necessary to achieve the target of low disease activity or remission. When selecting a treatment plan, cost should also be considered. The expense of biologic DMARDs can limit their use in patients without adequate insurance or other means of covering the drug cost. Cost analyses indicate that the increased expenses associated with biologic DMARDs may be offset by the costs avoided for treatment of advanced RA. It is anticipated that introduction of biosimilars will reduce RA treatment costs because they are expected to be less costly than the reference products.

KEY CONCEPT The risk of infection in patients treated with biologic DMARDs must be considered when selecting and monitoring therapy.[17,27] Influencing the immune response to reduce symptoms of RA may influence the body's response to pathogens. Of particular concern is use of TNF antagonists in patients with a history of tuberculosis exposure. TNF is important in the formation of granulomas that wall off tuberculosis infection. In theory, if TNF is inhibited, patients with latent tuberculosis may have a reactivated infection. Patients receiving any biologic DMARD should be screened for tuberculosis and other infections (hepatitis B, hepatitis C). Antituberculosis therapy should be initiated in patients with active or latent tuberculosis.[17] Patients with active tuberculosis should receive the full course of antituberculosis treatment prior to initiating biologic DMARDs. If there is latent infection, biologic DMARD therapy may be initiated after at least 1 month of antituberculosis treatment. Biologic DMARDs should not be initiated and should be discontinued temporarily during an acute, serious infection. Biologic DMARD therapy can be continued during nonserious infections.[28] Concomitant use of two biologic DMARDs or use of a biologic DMARD in combination with a JAK inhibitor is contraindicated due to increased infection risk.

▶ *Vaccinations*

Initiation of biologic DMARD therapy suppresses the immune system and reduces the body's ability to mount a response to a pathogen or a vaccine. Prior to initiation of an immunosuppressant, a patient's immunization status should be determined, and recommended vaccines should be administered. Specifically, administration of killed vaccines (pneumococcal, influenza, hepatitis B), recombinant vaccines (human papillomavirus, recombinant zoster vaccine [Shingrix]), and live attenuated vaccines (zoster vaccine live [Zostavax]) should be considered prior to and reevaluated during treatment with DMARDs. Herpes zoster status should be determined prior to initiation of biologic DMARDs or tofacitinib and the vaccine administered, if appropriate. In October 2017, the CDC Advisory Committee on Immunization Practices (ACIP) preferentially recommended Shingrix over Zostavax for prevention of herpes zoster and related complications in immunocompetent adults aged 50 years or more. Live vaccines (eg, Zostavax) should be avoided in patients already taking biologic DMARDs or tofacitinib because they may result in disseminated varicella-zoster virus disease, including fatal outcomes.[17] At the time of this writing, the CDC ACIP had not made recommendations about use of the newer recombinant zoster vaccine (Shingrix) in immunocompromised persons and

Table 57–4

FDA-Approved DMARDs for Treatment of RA[1,2,20,23,24]

Drug	Dose[a]	Time to Effect (weeks)	ADRs	Dosing in Hepatic Impairment	Dosing in Renal Impairment	Monitoring	Counseling Points
Nonbiologic DMARDs							
Methotrexate	Adults: 7.5–20 mg orally, SC or IM once weekly Polyarticular-course JIA: Recommended starting dose: 10 mg/m^2 oral, IM, or SC once weekly; usual max dose: 20 mg/m^2 once weekly	4–8	N, D, hepatotoxicity, alopecia, new-onset cough or SOB, MYL	Contraindicated	CrCl (mL/min)[b]: 61–80: 75% of dose 51–60: 70% of dose 10–50: 50% of dose Less than 10: Avoid use	CBC, creatinine, LFTs every 4–8 weeks; monitor for signs of infection	Use of folic acid concomitantly Avoid alcohol Use contraception if childbearing potential
Hydroxychloroquine	Adults: 200 mg orally twice daily or 400 mg once daily	8–24	N, D, HA, vision changes, skin pigmentation	Use with caution	No change	Specialized retinal eye examination every 5 years	
Sulfasalazine	Adults: 1000 mg orally two to three times daily Polyarticular-course JIA: Initial: 10 mg/kg/day orally; increase weekly by 10 mg/kg/day; usual dose: 30–50 mg/kg/day orally in two divided doses; max 2 g/day	8–12	N, D, rash, yellow-orange discoloration, photosensitivity, MYL	Avoid use	CrCl (mL/min)[b]: 10–30: Give twice daily Less than 10: Give once daily	CBC, LFTs, creatinine every 2–4 weeks for 3 months, then every 8–12 weeks	Sunscreen use
Leflunomide (Arava)	Adults: 100 mg orally daily for 3 days; then 20 mg daily	4–12	Hepatotoxicity, D, N, HTN, rash, HA, abdominal pain	Avoid use	Guidelines not available	CBC, LFTs, creatinine every 2–4 weeks for 3 months, then every 8–12 weeks Monitor for signs of infection	Avoid alcohol Use contraception if childbearing potential
Biologic DMARDs and Associated Biosimilars							
Etanercept (Enbrel) Biosimilar: Etanercept-szzs (Erelzi)	Adults: 25 mg SC twice weekly or 50 mg SC once weekly Children ages 2–17: 0.8 mg/kg SC once weekly; max 50 mg/week	1–4	ISR	No change	No change	Monitor for infection	ISR—topical corticosteroids, antipruritics, analgesics, rotate injection sites Screen for tuberculosis, Hepatitis B
Infliximab (Remicade) Biosimilars: Infliximab-dyyb (Inflectra) Influximab-abda (Renflexis)	Adults: 3–10 mg/kg by IV infusion at 0, 2, and 6 weeks; then every 8 weeks	1–4	IR (rash, urticaria, flushing, HA, fever, chills, nausea, tachycardia, dyspnea)	No change	No change	Monitor for infection	Screen for tuberculosis, Hepatitis B
Adalimumab (Humira) Biosimilar: Adalimumab-atto (Amjevita) Adalimumab-adbm (Cyltezo)	Adults: 40 mg SC every other week Children older than 4 years and weighing 15–29 kg: 20 mg SC every other week Children weighing 30 kg or more: 40 mg SC every other week	1–4	ISR	No change	No change	Monitor for infection	Screen for tuberculosis, Hepatitis B

Golimumab (Simponi)	Adults: 50 mg SC once monthly 2 mg/kg IV infusion at weeks 0, 4, then every 8 weeks	1–4	ISR, IR	No change	No change	Monitor for infection	Screen for tuberculosis, Hepatitis B
Certolizumab (Cimzia)	Adults: 400 mg SC initially, at 2 weeks, 4 weeks, then every 4 weeks thereafter	1–4	ISR	No change	No change	Monitor for infection	Screen for tuberculosis, Hepatitis B
Anakinra (Kineret)	Adults: 100 mg SC daily	2–4	HA, N, V, D, ISR	No data available	CrCl < 30 mL/min[b]: consider 100 mg every other day	Monitor for infection	
Abatacept (Orencia)	Adult IV infusion: < 60 kg, 500 mg; 60–100 kg, 750 mg; > 100 kg, 1000 mg IV on days 1, 15 and every 28 days thereafter SC Injection: Weight-based loading dose, then 125 mg SC within 1 day, 125 mg SC once weekly; or 125 mg once weekly in patients unable to receive IV. JIA (> 6 years of age): < 75 kg: 10 mg/kg; 75–100 kg: 750 mg; > 100 kg: 1000 mg IV infusion on days 1, 15, 28 and every 28 days thereafter	2	HA, infection, IR, ISR	No change	No change	Monitor for infection	
Rituximab (Rituxan)	Adults: Two 1000-mg IV infusions separated by 2 weeks; timing of the third dose is based on patient symptoms (no earlier than 16 weeks)	4	IR	No change	No change	Monitor for infection	
Tocilizumab (Actemra)	Adults: 8 mg/kg IV infusion every 4 weeks SC: if > 100 kg, 162 every week; if < 100 kg, 162 every other week JIA (2 years and older): < 30 kg: 12 mg/kg IV infusion every 2 weeks; > 30 kg: 8 mg/kg every 2 weeks		Elevated LFTs, total cholesterol, triglycerides, and high-density lipoprotein; nasopharyngitis, infection	No data available	No data available	Monitor for infection; LFTs	
Sarilumab (Kevzara)	Adults: 200 mg SC every 2 weeks		ISR, elevated LFTs, neutropenia	Not recommended in patients with hepatic impairment	CrCl < 30 mL/min[b]: no data available	Monitor for infection, LFTs, lipids	Screen for tuberculosis
Janus-Kinase Inhibitors							
Tofacitinib (Xeljanz) Tofacitinib extended-release (Xeljanz-XR)	Adults: 5 mg orally twice daily Adults: 11 mg orally once daily		Infection, headache, HTN, elevated LFTs, D, worsening lipid profile	Mild impairment: no adjustment Moderate: 5 mg once daily Severe: Use not recommended	Mild: no adjustment; Moderate/severe: 5 mg once daily	CBC, Hgb, lipids, LFTs, monitor for infection	

[a]Geriatric patients should receive the usual adult dose unless renal or hepatic impairment is present. Pediatric doses are provided for drugs that have FDA-approved indications for juvenile idiopathic arthritis (JIA).

[b]To convert to SI units of mL/s, multiply by 0.0167.

CBC, complete blood count; D, diarrhea; HA, headache; Hgb, hemoglobin; HTN, hypertension; IR, infusion reactions; ISR, injection site reactions; LFTs, liver function tests; MYL, myelosuppression (watch for fever, symptoms of infection, easy bruisability, and bleeding); N, nausea; SC, subcutaneous injection; SOB, shortness of breath.

those on moderate to high doses of immunosuppressive therapy because these patients were excluded from the efficacy studies. Additional vaccine information is available on the Centers for Disease Control and Prevention website (www.cdc.gov).

▶ *Fertility, Pregnancy, and Fetal Development*

Women of childbearing potential should be counseled about the impact of antirheumatic drugs on fertility, pregnancy, fetal development, and lactation. Some women may experience a reduction in disease symptoms during pregnancy; however, many agents used to treat RA are known teratogens. In addition, some women may present with signs and symptoms of RA for the first time during the postpartum period. Women desiring motherhood must consult with their physicians to carefully plan for the pregnancy and reduce risks to the developing fetus.[29,30]

Treatment plans must also consider the potential effects on breastfeeding babies. Low-dose corticosteroids, certain NSAIDs, hydroxychloroquine, sulfasalazine, and certain biologic DMARDs described below may be considered during pregnancy. Health care providers and patients are encouraged to visit MotherToBaby (https://mothertobaby.org) for educational information regarding medication use in pregnancy and ongoing studies designed to learn more about medication exposure during pregnancy.

Methotrexate use is associated with spontaneous abortion, fetal myelosuppression, limb defects, and CNS abnormalities; therefore, pregnancy must be avoided. Methotrexate should be discontinued 3 months prior to attempting conception.[30] Patients of childbearing potential receiving methotrexate should be counseled on the importance of effective contraception (ie, oral contraceptives, condoms plus spermicidal foam). If pregnancy occurs, the patient should notify their health care providers immediately. Leflunomide is teratogenic in animal studies, and discontinuation prior to conception is recommended.[30]

Although data on safety of biologic DMARD use in pregnant women are limited, TNF antagonists are considered safe in the first trimester. Etanercept and certolizumab may be continued throughout the pregnancy because the transfer of medication across the placenta is very low. Rituximab should be discontinued 1 year prior to planned conception. Abatacept should be discontinued 10 weeks prior to planned conception. Insufficient data exist regarding use of tocilizumab and tofacitinib during pregnancy.[29,30]

Male patients with RA must receive counseling about the effects of certain medications on their fertility and potential harm to the fetus. It is difficult to establish causality between use of a medication by a male and the effect on fertility or fetal development; therefore, a conservative approach must be taken. KEY CONCEPT Women of childbearing potential and their partners must be counseled to: (a) use proper birth control while undergoing treatment for RA, and (b) involve health care providers in discussions regarding family planning to carefully consider all treatment options.[29,30]

OUTCOME EVALUATION

- Rheumatologists rely on standardized criteria to assess treatment interventions through measurement of disease activity. The ACR uses criteria for improvement based on percentage improvement in tender and swollen joint count, and the presence of at least three or more of the following measures: (a) pain, (b) patient global assessment, (c) physician global assessment, (d) self-assessed physical disability, and (e) acute-phase reactants.[32] ACR20, ACR50, and ACR70 are common efficacy endpoints in clinical trials. The number corresponds with the percentage improvement. As drug development continues to evolve, the acceptable criteria for 20% improvement may be too low.
- Physical disability from RA can be measured through the Stanford Health Assessment Questionnaire (HAQ).[33,34] This patient self-assessment tool was developed to evaluate patient outcomes in five dimensions of chronic conditions: (a) disability, (b) discomfort, (c) drug adverse effects, (d) dollar costs, and (e) death. Clinicians and clinical studies in rheumatology use the HAQ to assess longitudinal changes that influence the patient's quality of life.[33,34]

Patient Encounter Part 2: Medical History, Physical Examination, and Laboratory Tests

PMH: Hypertension (15 years), depression (5 years), rheumatoid arthritis (10 years)

FH: Mother died age 65 from lung cancer; father died age 82 from lymphoma

Allergies: Sulfa

Meds: Metoprolol 50 mg once daily, lisinopril 20 mg once daily; hydrochlorothiazide 25 mg once daily; citalopram 40 mg once daily; methotrexate 20 mg orally once weekly; abatacept 125 mg SC once weekly (initiated 1 year ago); folic acid 1 mg daily; prednisone 5 mg every morning

Previous Meds: Etanercept, infliximab

ROS: (+) Fatigue, (–) N/V/D, HA, SOB, chest pain, cough

PE:

VS: BP 174/86 mm Hg, P 78 beats/min, RR 18 breaths/min, T 38.0°C (100.4°F); Ht 5'7" (170 cm), Wt 87 kg (192 lb)

Skin: Warm, dry

HEENT: NC/AT, PERRLA, TMs intact

CV: RRR, normal S_1 and S_2, no m/r/g

Chest: CTA

Abd: Soft, NT/ND

Neuro: A&O × 3; CN II to XII intact

Ext: Bilateral tender and swollen PIPs and MCPs

Labs: ESR 58 mm/hour, RF (+), ACPA (high +)

Synovial fluid analysis: Yellow, cloudy, decreased viscosity

Hand x-rays: Soft-tissue swelling, joint space narrowing, evidence of erosions

Disease Activity Score 28 (DAS-28): 4.85

How would you categorize this patient's disease activity—low, moderate, or high? Why? How does this affect your treatment plan?

What nonpharmacologic and pharmacologic alternatives are appropriate for this patient?

Patient Encounter Part 3: Creating a Care Plan

Based on the information available, create a care plan for this patient's RA. The plan should include the following:

(a) A statement of the drug-related needs and/or problems

(b) A patient-specific detailed care plan (including specific medications and associated doses)

(c) Monitoring parameters to assess safety and efficacy

(d) Key patient education topics

Patient Encounter Part 4: Patient Counseling

While meeting with the patient, she admits that she forgets to administer the abatacept 2 to 3 times a month due to her busy schedule. Also, the prednisone was initiated about 5 years ago. She rarely forgets to take it in the morning.

How does this information change your care plan?

Patient Care Process

Collect Information:

- Perform a medication history to determine current prescription, nonprescription, and dietary supplements. Inquire about previous medications for RA and reasons why they were discontinued. Ask about allergies (and the associated reaction) and immunizations.
- Determine whether physical examination findings and patient-reported symptoms are consistent with RA. Evaluate the duration of symptoms and impact on daily living.
- Review the medical history. Determine if comorbidities are present.

Assess the Information:

- Determine if any of the patient's medications are causing the signs or symptoms.
- Review laboratory test results to establish baseline renal and hepatic function and blood cell status. Review other findings specific to RA (RF, ACPA, etc.).
- Determine disease severity.
- If the patient is already receiving pharmacotherapy for RA, assess efficacy, safety, and patient adherence.
- Review immunization history and determine if vaccinations are necessary prior to initiating new medications.

Develop a Care Plan:

LO 6

- If newly diagnosed with RA, make sure the patient receives DMARD therapy immediately to minimize disease progression and joint destruction.
- Consider bridge therapy with an NSAID or glucocorticoid to provide symptomatic relief until the DMARD reaches its time to effect (Table 57–4).
- Review current medications to proactively identify potential drug interactions with the addition of one more DMARDs.
- Select DMARD therapy that is likely to be safe and effective (see Figures 57–2 and 57–3).
- Ensure that drug doses are optimal (see Table 57–4).
- Incorporate measures to control the increased risk of present comorbidities.
  - *Cardiovascular*: Keep doses of NSAIDs and glucocorticoids low; consider initiating folic acid, low-dose aspirin, hypertensive and/or lipid therapy; encourage tobacco cessation, physical activity and a healthy diet.[13,14] Screen and aggressively treat elevated blood pressure and lipids.
  - *Infection*: Inform the patient to wash hands routinely, limit contact with individuals who are ill, and report signs and symptoms of infection immediately (eg, fever, weight loss, and night sweats).
  - *Malignancy*: Have the patient report new signs and symptoms (eg, fever, chills, anorexia, and night sweats) immediately.
  - *Osteoporosis*: Encourage the patient to ingest adequate amounts of calcium and vitamin D; consider initiating medications for prevention/treatment of osteoporosis if the patient is taking glucocorticoids chronically or has evidence of low bone mineral density.[30] Review glucocorticoid-induced osteoporosis guidelines.[31]

Implement the Care Plan:

LO 7

- Educate the patient on pharmacologic and nonpharmacologic measures, including medication administration.
- Screen for tuberculosis if initiation of a biologic DMARD or tofacitinib is under consideration.
- Stress the importance of adherence with medications and laboratory monitoring.
- Determine whether the patient has prescription coverage. If not, determine if the patient is eligible for prescription assistance programs.

Follow-up: Monitor and Evaluate:

LO 8

- Assess the patient's response to initiation of DMARD therapy after allowing adequate time for the medication to achieve its therapeutic effect.
- Determine whether any adverse reactions to medications are present.
- Reevaluate need for bridge therapy and discontinue if possible.
- Monitor laboratory parameters to ensure patient safety and reduce the risk of adverse reactions.
- Longitudinally evaluate the patient's clinical response to therapy and the impact on quality of life and mobility.
- Assess patient understanding of RA and their medications. Provide additional education where appropriate.

- Before starting treatment for RA, assess the subjective and objective evidence of disease. For joint findings, this includes the number of tender and swollen joints, pain, limitations on use, duration of morning stiffness, and presence of joint erosions. Systemic findings may include fatigue and the presence of extraarticular manifestations. Obtain laboratory measurements of CRP and ESR. The impact of the disease on quality of life and functional status is also important.
- At follow-up visits, compare the patient's status to baseline or previous visits using standardized criteria for improvement of disease activity (ie, DAS-28) and the influence on quality of life.
- KEY CONCEPT In addition to designing an individualized therapeutic regimen to control the progression of RA, the clinician must evaluate the presence of comorbidities and implement measures to control the increased risk.

Abbreviations Introduced in This Chapter

ACPA	Anticitrullinated protein antibodies
ACR	American College of Rheumatology
CRP	C-reactive protein
DAS	Disease Activity Score
DMARD	Disease-modifying antirheumatic drug
ESR	Erythrocyte sedimentation rate
EULAR	European League against Rheumatism
HAQ	Health Assessment Questionnaire
HLA	Human leukocyte antigen
IL	Interleukin
JIA	Juvenile idiopathic arthritis
MCP	Metacarpophalangeal joint
MTP	Metatarsophalangeal joint
NSAID	Nonsteroidal anti-inflammatory drug
PIP	Proximal interphalangeal joint
RA	Rheumatoid arthritis
TNF	Tumor necrosis factor

58 Osteoarthritis

Scott G. Garland, Nicholas W. Carris, and Steven M. Smith

LEARNING OBJECTIVES

LO

Upon completion of the chapter, the reader will be able to:

1. Explain the pathophysiologic mechanisms involved in the development of osteoarthritis (OA).
2. Identify risk factors associated with OA.
3. Recognize the clinical presentation of OA.
4. Determine the goals of therapy for individual patients with OA.
5. Formulate a rational nonpharmacologic plan for patients with OA.
6. Recommend a pharmacologic plan for treating OA, taking into consideration patient-specific factors.
7. Develop monitoring parameters to assess effectiveness and adverse effects of pharmacotherapy for OA.
8. Modify an unsuccessful treatment strategy for OA.
9. Deliver effective patient counseling, including lifestyle modifications and drug therapy, to facilitate effective and safe management of OA.

INTRODUCTION

KEY CONCEPT

Osteoarthritis is the most common form of arthritis and is strongly related to age. Weight-bearing joints (eg, hips, knees) are most susceptible, but non–weight-bearing joints, especially hands, may be involved. OA causes tremendous morbidity and financial burden because of its high prevalence and effect on joints critical for daily functioning.[1] OA is the leading cause of chronic mobility disability and the most common reason for total-hip and total-knee replacement.[2]

EPIDEMIOLOGY AND ETIOLOGY

Approximately 27 million Americans have signs and symptoms of OA.[3] OA is more common in females and older persons, affecting an estimated 10% of men and 18% of women over age 60 years. Approximately 7% of Americans experience daily symptomatic hand OA, 6% experience daily symptomatic knee OA, and 3% experience daily symptomatic hip OA.[3] Hip OA occurs more frequently in men.[4] However, women tend to have more generalized disease and joint inflammation. Some patients can develop bony enlargements of the hands, called **Bouchard nodes** or **Heberden nodes**, in the absence of inflammation. The prevalence of OA in African Americans is similar to whites, but African Americans often experience more severe and disabling disease.

PATHOPHYSIOLOGY

LO 1

OA is characterized by damage to **diarthrodial joints** and joint structures (**Figure 58–1**). The pathophysiology is multifactorial and typified by progressive destruction of joint cartilage, erratic new bone formation, thickening of **subchondral** bone and the joint capsule, bony remodeling, development of **osteophytes**, variable degrees of mild **synovitis**, and other changes.[5]

The earliest stages of OA are characterized by increasing water content and softening of cartilage in weight-bearing joints. As the disease progresses, **proteoglycan** content of cartilage declines, and eventually, cartilage becomes hypocellular. Procatabolic and proinflammatory changes precede cartilage degradation and are thought to play important roles in OA development and progression.[6]

Subchondral bone undergoes metabolic changes, including increased bone turnover, that appear to be precursors to tissue destruction. The normally contiguous bony surface becomes fissured. Persistent use of the joint eventually results in loss of cartilage, permitting bone-to-bone contact that ultimately promotes thickening and **eburnation** of exposed bone. Microfractures may appear in subchondral bone, and **osteonecrosis** may develop beneath the surface, especially in advanced disease.

New bone is formed haphazardly, creating osteophytes that extend into the joint capsule and ligament attachments and may encroach on joint space. Progressive loss of joint cartilage, subchondral damage, joint space narrowing, and changes in underlying bone and soft tissue may culminate in deformed, painful joints.

Classification

OA is classified as primary (idiopathic) or secondary. *Primary OA* is the predominant form, occurring in the absence of a known precipitating event. Primary OA may be localized, generalized, or erosive. Localized OA is distinguished from generalized disease by the number of sites involved. Erosive disease—typically in hand or foot joints—is characterized by erosive bone destruction and in some cases bony proliferations. Secondary OA results from congenital or developmental disorders or inflammatory, metabolic, or endocrine diseases.

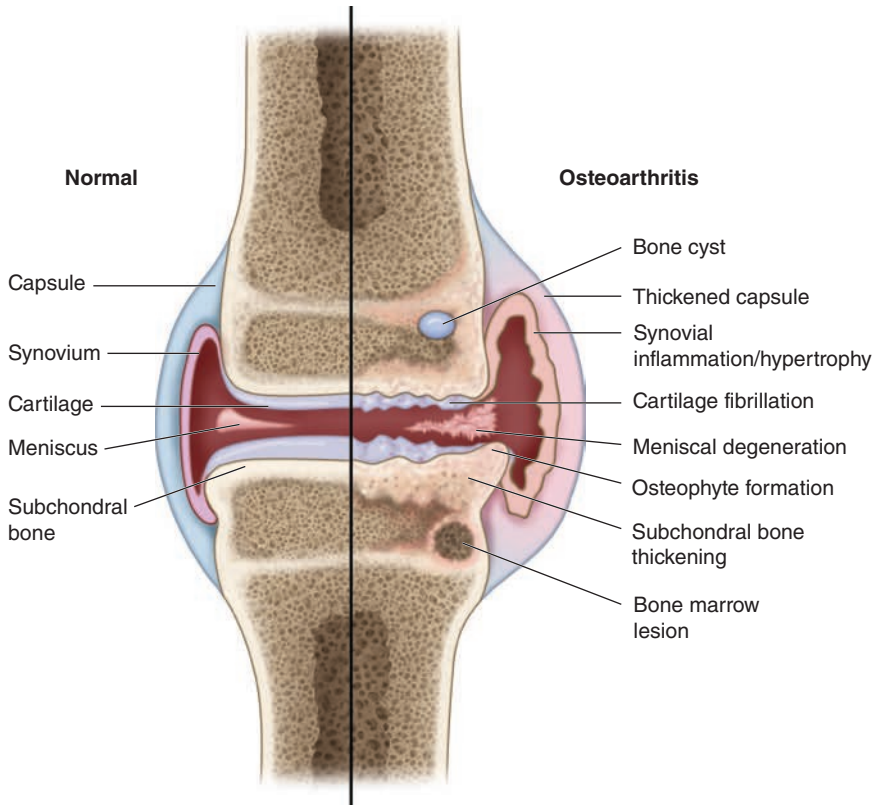

FIGURE 58–1. Characteristics of osteoarthritis in the diarthrodial joint. (From DiPiro JT, Talbert RL, Yee GC, et al., [eds.] Pharmacotherapy: A Pathophysiologic Approach, 10th ed. New York: McGraw-Hill; 2017:1601, Fig. 90–2; with permission.)

Risk Factors

LO 2

OA develops when systemic factors and biomechanical vulnerabilities combine. Systemic factors include increased age, female sex, genetic predisposition, and nutritional status. Age is the strongest predictor of OA, although advanced age alone is insufficient to cause OA.

Joints exposed to biomechanical factors are at increased risk. Occupational and recreational activities involving repetitive motion or injury can provoke OA, although most daily activities do not produce enough joint trauma to cause OA. However, daily activities may lead to OA if a joint is susceptible because of previous injury, joint deformity, muscle weakness, or systemic

Clinical Presentation of OA

General

- Patients usually are more than 50 years old.
- Presentation may range from asymptomatic to severe joint pain and stiffness with functional limitations.
- Joint involvement has an asymmetric local distribution without systemic manifestations.
- Unlike some other arthritic conditions (eg, rheumatoid arthritis, gout), inflammation is usually absent or mild and localized.

Symptoms

LO 3

- KEY CONCEPT The most common symptoms are joint pain, reduced range of motion, and brief joint stiffness after inactivity.
- The cardinal symptoms are use-related joint pain, typically described as deep and aching in character, and stiffness. In advanced cases, pain may occur continuously and at rest.
- Joint stiffness ("gelling") abates with motion and recurs with rest.
- Joint stiffness generally lasts fewer than 30 minutes after extended periods of inactivity, limits the range of joint motion, impairs daily activities, and may be related to weather.
- Weight-bearing joints may be unstable.

Signs

- One or more joints may be involved, usually in an asymmetric pattern.
- The following sites are most often involved in primary OA:
  - Distal interphalangeal finger joints (Heberden nodes)
  - Proximal interphalangeal finger joints (Bouchard nodes)
  - First carpometacarpal joint
  - Knees, hips, and cervicolumbar spine
  - Metatarsophalangeal joint of the great toe
- Joint examination may reveal local tenderness, bony prominence, soft tissue swelling, crepitus, muscle atrophy, limited motion with passive/active movement, and effusion.

factors. Heavy physical activity is a stronger predictor of OA than light-to-moderate activities, especially for older individuals, in whom joint structures are less capable of coping with highly stressful activities.[7] Obesity increases load-bearing stress on hip and knee joints. OA risk increases by 10% for each kilogram above ideal body weight.[8]

CLINICAL PRESENTATION AND DIAGNOSIS

OA is diagnosed clinically from symptoms and physical examination of the joint(s), sometimes supported by radiographic evidence (see Clinical Presentation of OA). Radiographic changes are often absent in early OA. As OA progresses, joint space narrowing, subchondral bone sclerosis, and osteophytes may develop. Laboratory tests are not helpful for diagnosing OA but may rule out related diseases. The erythrocyte sedimentation rate (ESR) and the hematologic and chemistry panels are usually unremarkable in OA. Synovial fluid aspirated from an affected joint should be sterile, without crystals, and with a WBC count less than $1.5 \times 10^3/mm^3$ ($1.5 \times 10^9/L$). Gross joint deformity and joint effusions may occur in late severe OA.

TREATMENT

Desired Outcomes

LO 4

KEY CONCEPT Goals of therapy include: (a) educating the patient and caregivers, (b) relieving pain, (c) maintaining or restoring mobility, (d) minimizing functional impairment and associated adverse outcomes (eg, falls), (e) preserving joint integrity, and (f) improving quality of life.

General Approach to Treatment

Treatment is individualized considering medical history, physical examination, radiographic findings, distribution and severity of joint involvement, and response to previous treatment. Comorbid diseases, concomitant medications, and allergies are integrated into a holistic treatment approach.

Patient Encounter Part 1

A 68-year-old obese white woman presents to her primary care physician with left hip pain that has significantly worsened over the past several years. She describes the pain as dull and achy, and it is most severe in the morning after awakening until she "loosens up" 10 to 15 minutes later. She believes the morning stiffness is worse when it is overcast or raining. She has tried heating pads without relief. She also reports feeling "down" because she is no longer able to go on walks with her grandchildren when they come to visit. She is a retired store clerk in a position that required her to be on her feet for long hours in addition to lifting heavy boxes.

What information is suggestive of osteoarthritis (OA)?

What risk factors for OA does this patient have?

What other information will you need to differentiate OA from rheumatoid arthritis?

What potential comorbidities should be considered in this patient?

What other information will be required before formulating a treatment plan?

As shown in Figure 58–2, nonpharmacologic treatment is integral to achieving optimal outcomes. Pharmacologic therapy is an adjunctive measure to relieve pain; available medications do not substantially modify the disease course. Surgical intervention generally is reserved for patients with advanced disease complicated by unremitting pain or severely compromised function.

Nonpharmacologic Therapy

LO 5

KEY CONCEPT Nonpharmacologic therapy is the cornerstone of treatment: education, exercise, weight loss, and cognitive behavioral intervention are integral components.

Educational programs are designed to improve health behaviors and health status, thereby slowing OA progression. The goal is to increase patient knowledge and self-confidence in adjusting daily activities in the face of evolving symptoms. Effective programs produce positive behavioral changes, decrease pain and disability, and improve functioning and psychological outcomes (eg, depression, self-efficacy, life satisfaction). Patients can be referred to the Arthritis Foundation (www.arthritis.org) for educational materials and information on support groups.

Lifestyle modification should be encouraged for all patients at risk for, or with established OA. Low-impact exercise is advisable for most patients, especially with knee or hip OA. Aerobic exercise and strength-training programs improve functional capacity in older adults. Stretching and strengthening exercises should target affected and vulnerable joints. Isokinetic and isotonic exercises performed at least three to four times weekly improve physical functioning and decrease disability, pain, and analgesic use.

The association between body weight and OA onset and progression make weight loss a pivotal goal in overweight and obese patients. Women who reduce body weight by 5 kg (11 lb) can halve their risk of developing OA. Weight loss improves symptoms and quality of life in patients with knee OA. Weight loss should be pursued through diet modification and increased physical activity (see Chapter 102, Overweight and Obesity). Knee braces may delay the progression of knee OA. Clinicians should consider the patient's physical capabilities when implementing any exercise program. Application of heat or cold to involved joints improves range of motion, reduces pain, and decreases muscle spasms. Applications of heat include warm baths or warm water soaks. Heating pads should be used cautiously, especially in older persons, and patients must be warned of the potential for burns if used inappropriately.

Referral to a physical or occupational therapist may be helpful, particularly in patients with functional disabilities. Physical therapy is tailored to the patient and may include assessment of muscle strength, joint stability, and mobility; use of heat (especially prior to increased activity); structured exercise regimens; and assistive devices such as canes, crutches, and walkers. Occupational therapists advise on optimal joint protection and function, energy conservation, and use of splints and other assistive devices.

Pharmacologic Therapy

Simple analgesics such as acetaminophen and nonsteroidal anti-inflammatory drugs (NSAIDs) are first-line agents for treating OA (Table 58–1).

▶ *Acetaminophen*

Acetaminophen is a centrally acting analgesic that inhibits prostaglandin production in the brain and spinal cord.

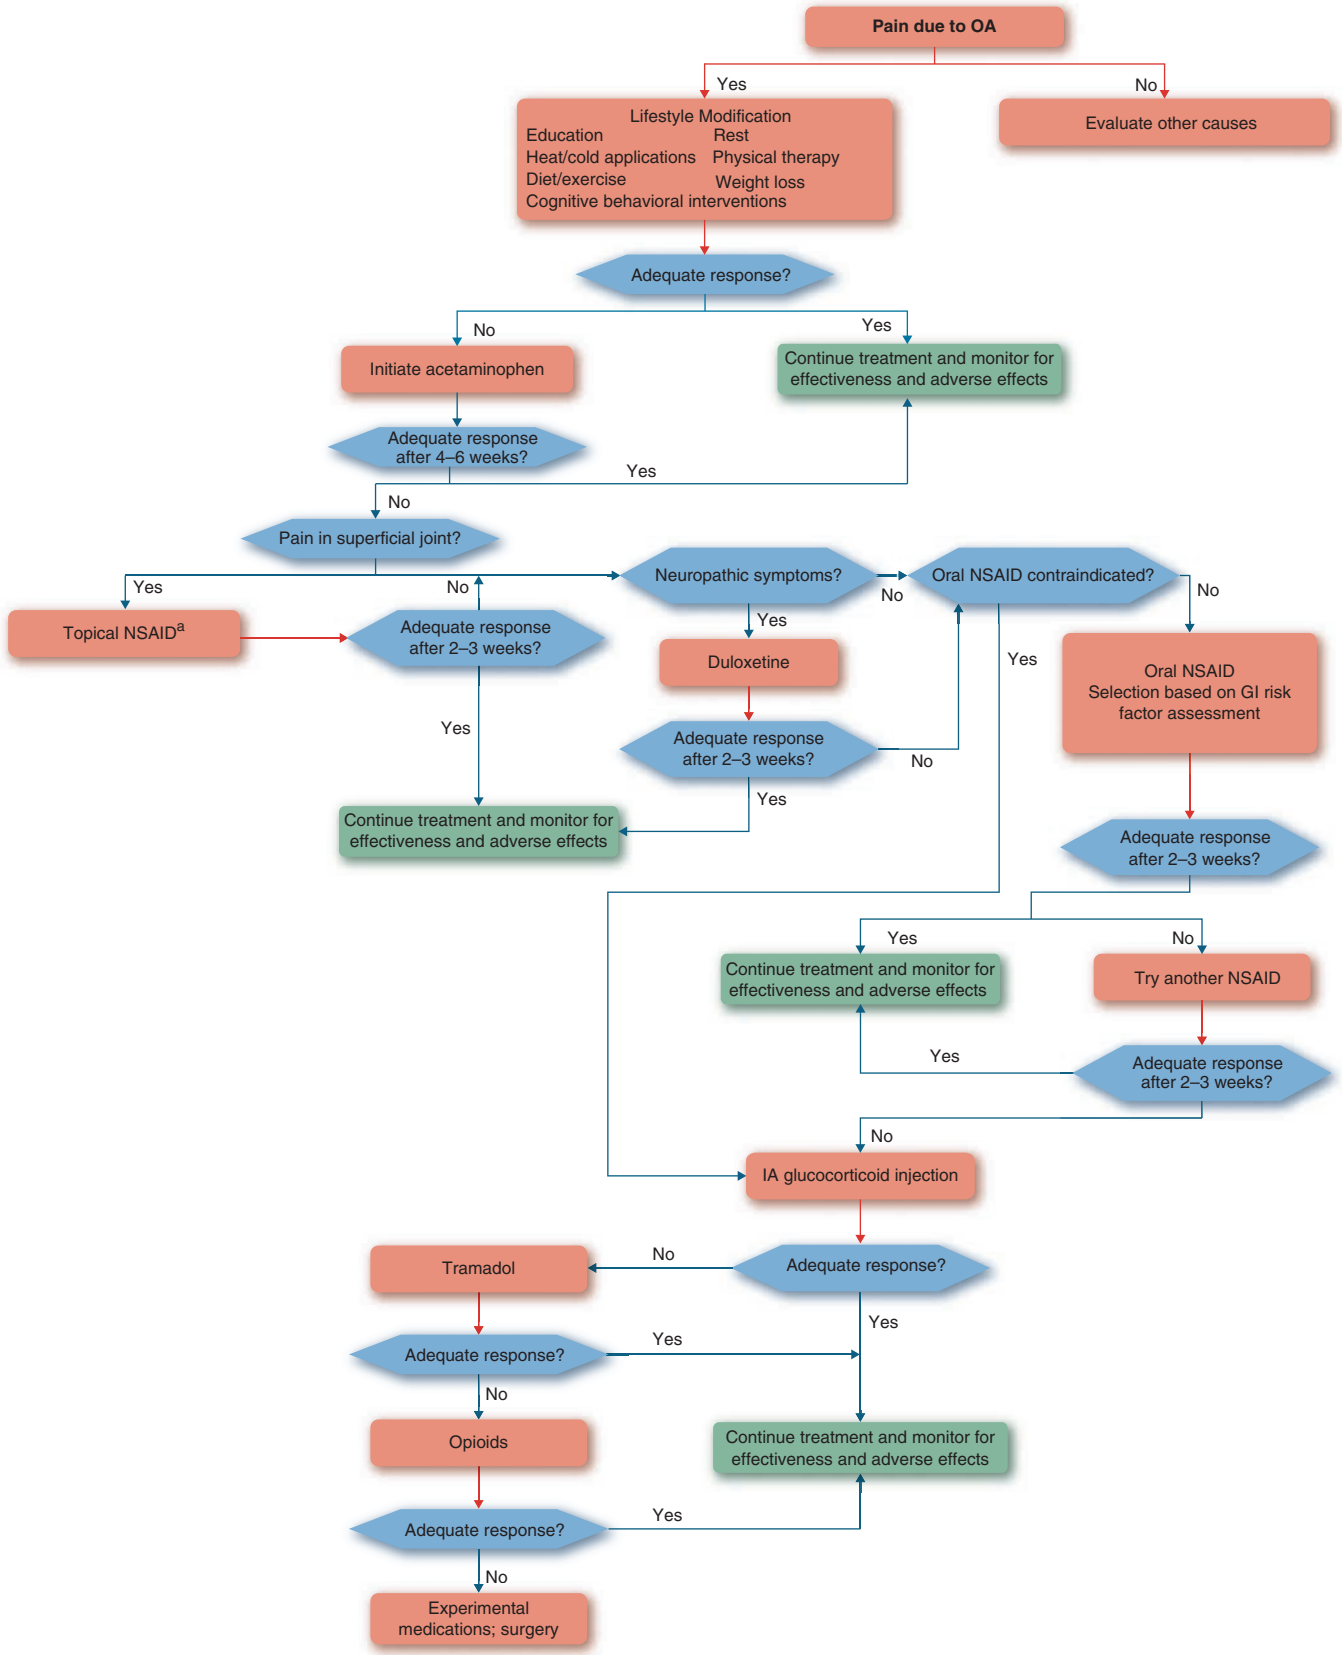

FIGURE 58–2. Treatment of osteoarthritis. (OA, osteoarthritis; CV, cardiovascular; IA, intraarticular; NSAID, nonsteroidal anti-inflammatory drug.)

[a]Topical NSAIDs can be considered before acetaminophen for superficial joints due to their favorable side effect profile and their potentially greater effect than acetaminophen.

Table 58–1

Dosing Parameters of Select Agents Used to Treat OA

Medication	Dosage and Frequency
Oral Analgesics	
Acetaminophen	325 mg every 4–6 hours or 1000 mg every 6–8 hours; max 4000 mg/day (from all sources)
Tramadol	50–100 mg every 4–6 hours; max 400 mg/day (300 mg in elderly) CrCl < 30 mL/min (0.50 mL/s): 50–100 mg every 12 hours; max 200 mg/day
Oxycodone	5–15 mg every 4–6 hours (initial dose for opioid naïve); dose depends on degree of opioid tolerance and patient response
Serotonin-Norepinephrine Reuptake Inhibitors	
Duloxetine	30–60 mg once daily; max 60 mg/day
Intraarticular Corticosteroid Injection	
Triamcinolone acetonide	2.5–15 mg for single injection; doses can be adjusted to 20–40 mg; administered not more often than every 3 months
Triamcinolone acetonide extended-release	32 mg for a single knee injection
Methylprednisolone acetate	Small joints 4–10 mg; medium joints 10–40 mg; large joints 20–80 mg; administered no more often than every 3 months
Intraarticular Hyaluronic Acid Injection	
Hyaluronic Acid	16–30 mg injected into the affected knee every week for a total of 3–5 weeks, depending on the product (see text)
Oral NSAIDs by Chemical Class	
Carboxylic acid (salicylates)	
Aspirin	325–650 mg every 4–6 hours; max 3600 mg/day
Salsalate	500–1000 mg two to three times daily; max 3000 mg/day
Acetic acid	
Etodolac	300–600 mg twice daily; max 1200 mg/day 400–1000 mg once daily (extended-release)
Diclofenac	50 mg two to three times daily 75 mg twice daily (delayed-release tablets) 100 mg once daily (extended-release tablets) 35 mg three times daily (submicron particle capsules) Max 150 mg/day from any formulation
Indomethacin	25 mg two to three times daily 75 mg one to two times daily (sustained-release) Max 200 mg/day from any formulation
Nabumetone	500–1000 mg one to two times daily; max 2000 mg/day
Propionic acid	
Ibuprofen	400–800 mg three to four times daily; max 3200 mg/day
Naproxen	250–500 mg two times daily 750–1000 mg once daily (controlled-release) 275–550 mg two times daily (naproxen sodium) Max 1650 mg/day from any formulation
Enolic acid	
Meloxicam	7.5–15 mg once daily; max 15 mg/day
Piroxicam[c]	20 mg once daily; max 20 mg/day
Coxibs	
Celecoxib[c]	100 mg twice daily or 200 mg once daily; max 200 mg/day
Topical Analgesics	
Capsaicin 0.025% or 0.075% cream	Apply to affected joint every 6–8 hours
Diclofenac sodium 1% gel	Upper extremity joints: 2 g four times daily; max 8 g[b] per upper extremity joint per day Lower extremity joints: 4 g four times daily; max 16 g[b] per joint per day
Diclofenac sodium 1.5% solution	40 drops per affected knee, four times per day; max 160 drops per day per knee
Diclofenac sodium 2% solution	40 mg (2 pump actuations) on each painful knee, two times a day; max 80 mg per day per knee
Dietary Supplements	
Glucosamine sulfate	500 mg three times daily or 1500 mg once daily
Chondroitin	400–800 mg up to three times daily with glucosamine

[a]Serum salicylate levels should be monitored for doses greater than 3 g/day.

[b]Total daily dose of diclofenac 1% gel should not exceed 32 g for all affected joints.

[c]Substrate for CYP2C9, consider a 50% reduction in the initial dose in known or suspected poor metabolizers.

CrCl, creatinine clearance.

KEY CONCEPT Acetaminophen is an inexpensive analgesic with a favorable risk–benefit profile. Although less effective than NSAIDs, acetaminophen may be tried initially at an adequate dose and duration in patients with mild-to-moderate pain, before considering an oral NSAID.[9-12]

Acetaminophen should be administered initially on an as-needed basis in divided doses up to 4 g daily. Single doses should not exceed 1 g. Some patients may require scheduled dosing to achieve adequate pain relief. Periodic assessment of pain control should be performed to maintain the lowest effective dose. Insufficient acetaminophen dose or duration are common reasons for inadequate response. A sufficient trial is defined as up to 4 g daily in divided doses for 4 to 6 weeks.

Despite being among the safest analgesics, acetaminophen can cause significant adverse effects, including hepatic and renal toxicity.[13] Acetaminophen overdose, both intentional and unintentional, is the leading cause of acute liver injury in the United States.[14] Doses greater than 4 g are associated with increased risk of hepatotoxicity. Total daily doses of 4 g have been associated with significant liver enzyme elevations, but such elevations do not necessarily portend hepatotoxicity.[15] Concomitant use of alcohol may increase risk of hepatic injury; a maximum acetaminophen dose of 2.5 g daily is recommended in patients who consume more than 2 to 3 alcoholic beverages daily. Acetaminophen does not appear to exacerbate stable, chronic liver disease, but liver function should be monitored regularly in this population.[13] Careful inventory should be taken of all concomitant prescription and over-the-counter (OTC) products to minimize the risk of inadvertent acetaminophen overdose.

Acetaminophen may worsen kidney function and increase blood pressure.[16,17] Nevertheless, acetaminophen remains the preferred oral analgesic for mild-to-moderate pain in patients with hypertension or kidney disease because of the greater risks associated with systemic NSAIDs.[18] Monitoring specifically for these adverse effects generally is unnecessary.

▶ *Nonsteroidal Anti-inflammatory Drugs*

Prostaglandins play an important role in the function of several organ systems. These compounds are synthesized via the interaction of two isoforms of the **cyclooxygenase** enzyme (COX-1 and COX-2) with their substrate, arachidonic acid.

The COX-1 enzyme is expressed constitutively in various body tissues (eg, gastric mucosa, kidney, platelets). Prostaglandins produced by the actions of the COX-1 enzyme in the gastrointestinal (GI) tract preserve GI mucosal integrity by increasing mucous and bicarbonate secretion, maintaining mucosal blood flow, and decreasing gastric acid secretion. Prostaglandins associated with COX-1 also promote normal platelet activity and function. In the kidney, COX-1–mediated prostaglandins dilate the afferent arteriole, thereby maintaining intraglomerular pressure and glomerular filtration rate when renal blood flow is reduced.

In contrast, the COX-2 enzyme is normally undetectable in most tissues, but its expression can be induced rapidly in the presence of inflammation and local tissue injury. This change leads to the synthesis of prostaglandins involved in pain and inflammation. Consequently, blocking the COX-2 enzyme is thought to result in analgesic and anti-inflammatory effects. All NSAIDs inhibit both the COX-1 and COX-2 enzyme isoforms, but nonselective NSAIDs (eg, ibuprofen, naproxen) are not particularly selective for one isoform, whereas COX-2 inhibitors (ie, celecoxib) preferentially inhibit COX-2.

KEY CONCEPT NSAIDs are a reasonable first-line therapy in patients with moderate-to-severe OA or as adjunctive or alternative therapy when acetaminophen fails to provide an acceptable analgesic response. NSAIDs reduce pain and improve functioning in patients with OA, although individual responses vary widely. Pooled analyses suggest that NSAIDs improve OA pain more than acetaminophen, although direct comparisons have yielded mixed results.[10] Consensus guidelines support the use of NSAIDs as an alternative to acetaminophen if clinical features of peripheral inflammation or severe pain are present.[9] The route of administration (ie, oral or topical) should be based on affected joint(s), patient preference, ability to administer, and an assessment of risk for adverse effects of systemic NSAIDs.

Topical NSAID administration minimizes systemic exposure while providing pain relief comparable to oral NSAIDs. Consequently, topical NSAIDs may be an acceptable alternative first-line treatment to acetaminophen for patients with OA in a superficial joint, including hands, wrists, elbows, knees, ankles, and feet. Currently, the only commercially available topical NSAID in the United States is diclofenac, which is marketed in a variety of preparations (ie, solution, gel, topical patch). These products decrease pain and improve joint function without demonstrated superiority for any one product.[19,20] Systemic absorption of topical diclofenac is significantly less than that of oral diclofenac. Thus, with proper administration, GI, cardiovascular, and renal adverse effects are rare and similar in incidence to placebo.[19,20] The most common adverse effects are application site dermatitis, pruritus, and phototoxicity.

For patients with OA affecting deeper joints (ie, hip, shoulder, spine), or who have not achieved adequate response to topical NSAIDs, an oral NSAID should be considered. KEY CONCEPT At equipotent doses, the analgesic and anti-inflammatory activities of all oral NSAIDs, including COX-2–selective inhibitors, are similar. The selection of a specific oral NSAID should be based on patient preference, previous response, tolerability, side-effect profile, dosing frequency, cost, and underlying GI risk. Pain relief occurs rapidly (within hours), but anti-inflammatory response occurs after 2 to 3 weeks of continuous therapy. This latter period is the minimal duration that should be considered an adequate NSAID trial. If an insufficient response is achieved with one oral NSAID, another oral agent should be tried.

KEY CONCEPT All systemic NSAIDs are associated with adverse GI, renal, hepatic, cardiovascular, central nervous system (CNS), and hypertensive effects, particularly in older individuals. Inhibition of the COX-1 enzyme is thought to be responsible primarily for the adverse effects on the gastric mucosa, kidney, and platelets. Direct irritant effects also may contribute to adverse GI events. Minor GI complaints, including nausea, dyspepsia, anorexia, abdominal pain, flatulence, and diarrhea, are reported by 10% to 60% of patients treated with oral nonselective NSAIDs. Asymptomatic gastric and duodenal mucosal ulceration can be detected in 15% to 45% of patients.[21] Perforation, gastric outlet obstruction, and GI bleeding are the most severe complications and occur in 1.5% to 4% of patients annually.[21]

KEY CONCEPT COX-2 inhibitors are preferred for patients at high risk for GI complications.[22] Several risk factors predict a greater likelihood of GI complications in NSAID-treated patients (see Chapter 18, Peptic Ulcer Disease). Identifying at-risk patients based on symptoms alone is impractical because the presence of symptoms and actual gastroduodenal damage are poorly correlated. For patients at particularly high GI risk (eg, previous history of NSAID-induced GI bleed), a selective

COX-2 inhibitor combined with a proton pump inhibitor reduces risk for GI bleeds more than a COX-2 inhibitor alone, which in turn has lower GI bleed risk than a nonselective NSAID combined with a proton pump inhibitor.[23–26] See Chapter 17 (Gastroesophageal Reflux Disease) for more information on proton pump inhibitors.

COX-2 inhibitors have historically been associated with a greater risk of MI than nonselective NSAIDs, which led to removal of rofecoxib and valdecoxib from the market.[27] However, direct comparison of naproxen, ibuprofen, and celecoxib suggests similar cardiovascular risk between these agents.[28] Nevertheless, all NSAIDs, except low-dose aspirin, increase cardiovascular risk.[29] Accordingly, NSAIDs should be used at the lowest effective dose for the shortest duration, consistent with individual patient treatment goals, to limit risk. All oral NSAIDs can increase blood pressure, and patients with hypertension should be monitored within the first 2 to 4 weeks of initiation and periodically thereafter.[30]

All NSAIDs can cause adverse renal effects. Patients who are particularly susceptible include older persons and patients with chronic renal insufficiency, left ventricular dysfunction, and those taking diuretics or drugs that interfere with the renin–angiotensin system. These effects include decreased glomerular filtration, hyperkalemia, and sodium and water retention. Therefore, both nonselective NSAIDs and selective COX-2 inhibitors should be used with caution in patients with hypertension, heart failure, or chronic renal insufficiency. NSAIDs rarely cause **tubulointerstitial** nephropathy and renal papillary necrosis.

Like most medications, NSAIDs should be avoided if possible during pregnancy due to potential risks to the fetus. However, all NSAIDs should be strictly avoided starting at 30 weeks gestation to prevent premature closure of the ductus arteriosus in the fetus.

Nonselective NSAIDs and selective COX-2 inhibitors are prone to drug interactions due to high protein binding, detrimental renal effects, and antiplatelet activity. Interactions are encountered frequently with aspirin, warfarin, oral hypoglycemics, antihypertensives, and lithium. When potential interactions are present, vigilant monitoring is warranted for therapeutic efficacy (eg, NSAIDs blunt the antihypertensive efficacy of diuretics) and adverse effects (eg, NSAIDs increase the risk of bleeding in anticoagulated patients).

▶ *Tramadol*

Tramadol is an oral, centrally acting synthetic opioid analgesic that also weakly inhibits serotonin and norepinephrine reuptake. Tramadol has been shown to relieve OA pain (albeit minimally), and is a reasonable option for patients with contraindications to NSAIDs or in those who have failed to respond to other oral therapies.[31,32] The addition of tramadol to NSAIDs or acetaminophen may augment the analgesic effects of a failing regimen and provide sufficient pain relief in some patients.[32] Moreover, concomitant tramadol may permit lower NSAID doses. However, the increased side effect risk associated with tramadol may offset these benefits.[31]

Common adverse events include dizziness, vertigo, nausea, vomiting, constipation, and lethargy. These effects are more pronounced for several days after initiation or a dose increase. Seizures have been reported rarely; the risk is dose-related and appears to increase with concomitant use of antidepressants, such as tricyclics or selective serotonin reuptake inhibitors. Tramadol should be avoided in patients receiving monoamine oxidase inhibitors due to the potential for serotonin syndrome.

▶ *Other Opioid Analgesics*

Opioid analgesics other than tramadol are reserved for patients experiencing pain severe enough to require opioid treatment for which alternative options are inadequate or contraindicated (eg, renal failure, heart failure, anticoagulation). Opioids may decrease pain, improve sleep patterns, and increase functioning in patients with OA who are unresponsive to nonpharmacologic therapy and nonopioid analgesics. However, opioids also increase the risk for addiction and other serious adverse effects that limit their use in most patients.[32] Small improvement in OA pain has been demonstrated with oxycodone, oxymorphone, morphine, hydromorphone, codeine, buprenorphine, and transdermal fentanyl, but with significant increased risk of serious side effects.[33]

Opioids should be initiated with short-acting agents at low doses and titrated to the lowest effective dose to minimize adverse events. When feasible, opioids should be combined with acetaminophen or NSAIDs to reduce the opioid requirement. However, adverse effects from opioids are common even with the lowest effective doses.[33] Common or serious adverse effects include nausea, constipation, sedation, and respiratory depression. Use of combination opioid-acetaminophen products should be accompanied by clear instructions to limit additional use of OTC acetaminophen to avoid unintentional overdose.

Clinicians should establish realistic pain and function goals for all patients before starting opioid therapy. The Centers for Disease Control and Prevention recommends taking a detailed history, providing information regarding treatment expectations, and developing a management plan with goals and safeguards, including how opioid therapy will be discontinued if benefits do not outweigh risks (see Chapter 34, Pain Management). Additional recommendations to mitigate the risk of opioid therapy misuse include frequent follow-up, urine drug testing initially and at least yearly thereafter to assess use of prescribed medications or other illicit substances, and use of prescription drug monitoring programs to identify filling of opioid prescriptions from other providers. Patient response to opioid therapy should be assessed within 1 to 4 weeks of initiation or dose increase and every 3 months thereafter. Clinicians should use both nonopioid analgesics and nondrug therapies, as appropriate, to lower opioid doses or taper to opioid discontinuation.[32]

▶ *Duloxetine*

Duloxetine, a serotonin and norepinephrine reuptake inhibitor, is an effective adjunctive therapy for knee OA in patients achieving a suboptimal response to acetaminophen or oral NSAIDs alone.[34] Benefits typically are observed only after several weeks of therapy with moderate doses (ie, 60 mg/day); larger doses do not provide additional benefit.[35] Duloxetine may be the preferred adjunctive treatment in patients experiencing concurrent neuropathic and musculoskeletal pain. The most common adverse events are nausea, dry mouth, somnolence, constipation, decreased appetite, and hyperhidrosis.[35] Concomitant use with tramadol should be pursued cautiously owing to an increased risk of serotonin syndrome. For more duloxetine information, see Chapters 38 (Major Depressive Disorder) and 39 (Bipolar Disorder).

▶ *Intraarticular Therapy*

Intraarticular (IA) therapy is an alternative to oral and topical agents for joint pain treatment. Two IA therapies, corticosteroids and hyaluronic acid, have been used as second-line therapy in OA. However, the ideal injection agent is still debated.[36]

IA injection, per se, appears to be remarkably effective, at least for knee OA, where IA placebo injections have similar efficacy to oral NSAIDs.[36] Whether injection of specific agents improve on the substantial placebo effect remains a subject of debate. Nevertheless, these injections are used to improve symptoms but do not reverse disease progression.[4] Therefore, IA injections are usually reserved for patients unresponsive to other treatments because they are more invasive, have a small infection risk, and the procedure may be expensive.

Corticosteroids KEY CONCEPT Current evidence suggests limited benefit of intraarticular corticosteroids over placebo in the general OA population.[37] However, IA corticosteroids may still play a role in the subset of patients with significant inflammation or effusion. Corticosteroids with reduced solubility, such as methylprednisolone and triamcinolone, are usually preferred. The affected joint can be aspirated and subsequently injected with the corticosteroid. The aspirate should be examined for the presence of crystal formation and infection. Pain relief begins within days after the injection but may wane beyond 3 weeks for most agents. The triamcinolone acetonide extended-release product may provide pain relief for up to 12 weeks. Corticosteroid injections should be administered as infrequently as possible to avoid joint damage. Specifically, a single joint should not be treated more than 3 to 5 times per year to reduce the risk of corticosteroid-induced cartilage and joint damage. Because the recommended dosing interval exceeds the typical duration of benefit for most agents, IA corticosteroids are usually ineffective as monotherapy for chronic OA treatment.

The crystalline nature of corticosteroid suspensions can provoke a postinjection flare that mimics the flare of arthritis and inflammation that accompanies infection. Cold compresses and analgesics are recommended to treat symptoms in affected patients.

Hyaluronic Acid The mechanism of action of hyaluronic acid is not fully understood. Healthy cartilage and synovial fluid are replete with hyaluronic acid, a viscous substance believed to facilitate lubrication and shock absorbency under varying load-bearing conditions. Patients with OA demonstrate an absolute and functional decline in hyaluronic acid; thus, exogenous administration is referred to as viscosupplementation.

Pain and joint function following IA hyaluronic acid injections have been evaluated frequently in clinical trials, most of which were of low quality. Evidence is conflicting, but hyaluronic acid appears to offer no substantial benefit over placebo injections, and treatment courses are relatively expensive. Hyaluronic acid is not recommended in current treatment guidelines.[9]

Several hyaluronic acid formulations are available in the United States for knee OA:

- Euflexxa: 20 mg (2 mL) injected every week for a total of 3 weeks
- Hyalgan: 20 mg (2 mL) injected every week for a total of 5 injections
- Orthovisc: 30 mg (2 mL) injected every week for a total of 3 to 4 weeks
- Synvisc: 16 mg (2 mL) injected every week for a total of 3 weeks
- Synvisc-One: 48 mg (6 mL) for a single injection

Injections are generally well tolerated, although patients may report local reactions. Rarely, postinjection flares or anaphylaxis has been reported. Patients should be counseled to minimize activity and stress on the joint for several days after each injection.

▶ *Over-the-Counter Agents*

Glucosamine and Chondroitin Glucosamine is believed to function as a "chondroprotective" agent, stimulating the cartilage matrix and protecting against oxidative chemical damage. Chondroitin, often administered with glucosamine, is thought to inhibit degradative enzymes and serve as a substrate for proteoglycan production. Previous high-quality evidence suggested no clinically important benefit with the combination of chondroitin-glucosamine compared to placebo in patients with knee OA.[38] However, recent evidence suggests that monotherapy with chondroitin may improve knee OA symptoms similarly to celecoxib.[39] If used, these agents should be adjuncts to traditional nonpharmacologic and pharmacologic therapies and discontinued after 3 to 6 months if no benefit is achieved.[9]

Patients with shellfish allergies should be warned of the potential for severe anaphylactic reactions with the use of glucosamine products (derived from crab, lobster, or shrimp shells). Because the allergic reaction is caused by shellfish proteins rather than the animal shell, most products pose little risk.[40,41] However, patients should be aware that products may be contaminated with shellfish proteins given that these agents are loosely regulated in the United States as dietary supplements, product standards are inconsistent, and the constituents are not validated by any regulatory agency. Additionally, glucosamine may alter cellular glucose uptake, thus elevating blood glucose levels in patients with diabetes.[42] Because the clinical significance of this is unclear, blood glucose levels in diabetic patients should be monitored closely after glucosamine initiation or dosage adjustments.

Other Topical Agents Limited data support use of salicylate-containing **rubefacients** (eg, methyl salicylate, trolamine salicylate) or other **counterirritants** (eg, menthol, camphor, methyl nicotinate) in OA.[43] See Chapter 60 (Musculoskeletal Disorders) for more information on these products.

Capsaicin relieves pain by depleting substance P from spinal sensory neurons, thereby decreasing pain transmission. Capsaicin is not effective for acute pain; it may take up to 2 weeks of daily administration to relieve pain. As with other topical products, capsaicin is best suited for treating superficial joints (eg, hand OA). The lower concentration (0.025%) is better tolerated, but most patients experience a localized burning sensation. The discomfort usually does not result in discontinuation and often abates within the first week with regular use. Contact with eyes or mucous membranes should be avoided and patients should be counseled to wash their hands after application.

Surgery

Surgery generally is reserved for patients who fail medical therapy and have progressive limitations in activities of daily living. In joint replacement surgery (arthroplasty), the damaged joint surfaces are replaced with metal or plastic prostheses. Hip and knee joints are most commonly replaced, but arthroplasty may also be performed on shoulders, elbows, fingers, and ankles. Total knee arthroplasty combined with physical and medical therapy improves knee OA symptoms more than physical and medical therapy alone.[44] Most patients achieve significant pain relief and functional restoration after arthroplasty, and it is a reasonable option in carefully selected patients.

Surgical debridement may be performed arthroscopically. With this procedure, a tiny video camera is inserted into the affected joint through a small incision, and the surgeon removes

torn cartilage or other debris from the joint. The long-term benefits of arthroscopic surgery for OA are unclear, and it may be no better than optimized physical and medical therapy.[45]

OUTCOME EVALUATION

- At baseline, quantify pain using a visual analog scale, assess range of motion of affected joints, and identify activities of daily living that are impaired.
- In patients treated with acetaminophen or oral NSAIDs, assess pain control after 2 to 3 weeks. Full anti-inflammatory effects of NSAIDs may take longer to occur.
- Incorporate other measures to track disease progress. Use radiography to assess severity of joint destruction, determine 50-ft (~15-m) walking time and grip strength, and administer the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) and the Stanford Health Assessment Questionnaire, where appropriate, to assess activities of daily living.
- If pain control is adequate, continue the current therapy at the lowest effective dose. If pain is improving but still inadequate, titrate to maximum therapeutic dose or consider adjunctive agents. If the patient has no improvement after 2 weeks, assess medication adherence and consider switching therapy.
- Ask patients if they are experiencing side effects or other problems with their medications and respond with more specific questions.
- Educate patients to not exceed maximum daily doses of medications.

Patient Encounter Part 3: Creating a Care Plan

Based on the available information, create a care plan for this patient's OA. The plan should include:

(a) A statement of the drug-related needs and/or problems

(b) An individualized, detailed therapeutic plan

(c) A plan for follow-up monitoring to document the patient's response and identify adverse reactions

- Consider baseline liver function tests in patients being prescribed acetaminophen who are at high risk for hepatoxicity.
- Assess acetaminophen exposure from all sources, including OTC products.
- In patients with hypertension, who are taking oral NSAIDs, monitor blood pressure at baseline, every 2 to 4 weeks for 1 to 2 months, and then periodically thereafter.
- For patients prescribed NSAIDs, monitor for weight gain, edema, and skin rash, and inquire about CNS adverse effects such as headaches and drowsiness at baseline and at least every 6 to 12 months.
- Evaluate serum creatinine, complete blood count, and serum transaminases at baseline and at every 6 to 12 months in patients treated with oral NSAIDs or acetaminophen.
- Perform stool guaiac in patients taking oral NSAIDs when clinically indicated.
- Monitor for drug interactions, including with alcohol, at every visit.

Patient Encounter Part 2: Medical History, Physical Examination, and Diagnostic Tests

PMH: Obesity (BMI 32 kg/m^2), HTN for 24 years, dyslipidemia, coronary artery disease, COPD

PSH: Hysterectomy 12 years ago

FH: Father had OA of the hip and knee; mother died of MI at age 68

SH: Retired clerk. Consumes one glass of wine per day; denies illicit drug use; smoked one pack of cigarettes per day for 35 years but quit 3 years ago

Allergies: NKDA; shellfish allergy (hives)

Meds: Losartan 50 mg once daily; rosuvastatin 20 mg once daily; enteric-coated aspirin 81 mg once daily; tiotropium 18 mcg by inhalation once daily; albuterol 1 to 2 puffs as needed for wheezing/shortness of breath; acetaminophen 500 mg, one tablet 2 to 4 times per day as needed for pain

ROS: (+) SOB on exertion, left hip pain 6 out of 10 with movement

PE:

VS: BP 138/85 mm Hg, Pulse 70 beats/min, RR 13 breaths/min, T 98.6°F (37.0°C)

Skin: Warm, dry, cracked skin on feet bilaterally

HEENT: NC/AT, PERRLA, TMs intact

CV: RRR, normal S_1 and S_2, no m/r/g

Chest: CTA

Abd: Soft, NT/ND

Neuro: A&O × 3; CN II to XII intact

Ext: No edema, swelling, or tenderness of the soft tissue surrounding left hip. Noticeable crepitus and decreased range of motion of the left hip. No other joint involvement.

Labs: ESR 12 mm/hour; basic metabolic panel within normal limits

Hip x-rays: Left hip shows joint space narrowing, minor osteophyte formation, and subchondral bone sclerosis

What clinical parameters are consistent with a diagnosis of OA?

What are the treatment goals for this patient?

What nondrug options are available to treat this patient?

What pharmacologic options are available to treat this patient?

What factors are important to consider when selecting medications for this patient?

Pharmacist's Patient Care Process

Collect Information:

- Obtain a thorough history of previous device and drug use, including prescription drugs, OTC drugs, and dietary supplements.
- Ask the patient about known allergies to medications and other substances, including type and severity of reaction.
- Determine lifestyle habits, preferences and beliefs, health goals, and socioeconomic factors that affect overall patient care.
- Consider obtaining laboratory tests depending on degree of clinical suspicion for inflammatory etiology (eg, ESR, C-reactive protein [CRP], rheumatoid factor [RF], antinuclear antibodies [ANA]).

Assess the Information:

- Determine whether the patient's symptoms are consistent with OA. Review the medical history to determine whether other rheumatic diseases may be involved.
- Assess symptoms to determine whether pain warrants additional attention. Does the pain affect quality of life or interfere with activities of daily living?
- Assess radiographs for diagnosis and disease severity (joint-space narrowing, subchondral bone sclerosis, osteophyte formation, joint deformity, joint effusion).

Develop a Care Plan:

- At baseline, quantify pain using a visual analog scale, assess range of motion of affected joints, and identify activities of daily living that are impaired.
- Evaluate the effectiveness of current or previous pharmacotherapy, including dose, frequency, and duration to determine whether an adequate trial was given.
- Establish realistic treatment goals with the patient, including acceptable levels of pain and function.
- Formulate a plan for lifestyle modifications and alteration/addition of pharmacotherapy that considers risks, benefits, and patient preference, given the patient's medical history, concomitant medications, and previous response to OA therapies.

Implement the Care Plan:

- Discuss with the patient any modifications to nondrug or pharmacological treatment plans and how to implement the new care plan.
- Address patient concerns related to OA and its treatment, with special focus on the expected benefits and potential adverse effects of medications.
- Emphasize the value of adherence to medication regimens and lifestyle modifications.
- Facilitate adherence by implementing medication regimens and lifestyle plans that are simple and consistent with the patient's lifestyle.

Follow-up: Monitor and Evaluate:

- Schedule follow-up within 1 to 2 weeks to assess the effectiveness of therapy and associated adverse effects; the specific time frame depends on patient factors and the treatment regimen chosen.
- If laboratory tests (eg, renal function for NSAIDs) are appropriate for monitoring drug therapy, provide the patient with an order for the laboratory test(s) and instructions to complete them before the follow-up appointment.
- If the patient has hypertension and is taking an oral NSAID, monitor blood pressure at each follow-up visit within 2 to 4 weeks of initiating therapy and then every 1 to 2 months.
- Document whether the patient has had improvements in pain, quality of life measures, mobility and functioning, ability to perform activities of daily living, and well-being.
- If pain control is adequate, continue the current therapy at the lowest effective dose. If pain is improving but still inadequate, titrate as needed to the maximum therapeutic dose or consider adjunctive agents. If the patient has no improvement after 2 weeks, assess medication adherence and consider switching therapy.
- Ascertain new OTC medication use; for patients prescribed acetaminophen or oral NSAIDs, pay particular attention to OTC sources of these drugs.
- Evaluate for the presence of adverse drug reactions, drug hypersensitivity, and potential drug interactions.

Abbreviations Introduced in This Chapter

ANA	Antinuclear antibodies
BMI	Body mass index
CNS	Central nervous system
COX	Cyclooxygenase
CRP	C-reactive protein
CYP	Cytochrome P450
ESR	Erythrocyte sedimentation rate
GI	Gastrointestinal
IA	Intraarticular
NSAID	Nonsteroidal anti-inflammatory drug
OA	Osteoarthritis
OTC	Over-the-counter
RF	Rheumatoid factor

59 Gout and Hyperuricemia

Maria Miller Thurston

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

LO

1. Explain the pathophysiologic mechanisms underlying gout and hyperuricemia.
2. Recognize major risk factors for developing gout in a given person.
3. Assess the signs and symptoms of an acute gout attack.
4. List the treatment goals for a patient with gout.
5. Develop a pharmacotherapeutic plan for a patient with acute gouty arthritis that includes individualized drug selection and monitoring for efficacy and safety.
6. Identify patients for whom prophylactic urate-lowering therapy for gout and hyperuricemia is warranted.
7. Formulate appropriate educational information for a patient on lifestyle modifications to help prevent gouty arthritis attacks.
8. Select an appropriate drug to reduce serum uric acid (SUA) levels in patients with gout, and outline a plan for monitoring efficacy and toxicity.

INTRODUCTION

KEY CONCEPT Gout is an inflammatory condition of the arthritis-type that results from deposition of uric acid crystals in joint spaces or surrounding tissues, leading to an inflammatory reaction that causes intense pain, erythema, and joint swelling. It is associated with hyperuricemia, defined as a SUA level of 6.8 mg/dL (404 μmol/L) or greater, but not all patients with hyperuricemia demonstrate symptoms.[1] Four organizations publish guidelines that provide recommendations for the diagnosis and/or management of gout.[2-9] There is much similarity in the recommendations, and this chapter focuses primarily on the consensus expert panel recommendations of the American College of Rheumatology (ACR).[5,6] However, the American College of Physicians (ACP) guideline includes updated clinical trial data and some distinct and controversial differences.[8-10]

EPIDEMIOLOGY AND ETIOLOGY

Gout is the most common inflammatory arthritis in men, with a male:female incidence of about 4:1; it affects over 3% of US adults.[1,11] The National Health and Nutrition Examination Survey (NHANES) 2007–2008 estimated the prevalence of gout among US adults to be 8.3 million.[12] The incidence increases with age and is rising in part due to a larger number of patients with risk factors for gout.[13] There is also a significant economic cost and humanistic burden associated with gout, which increases with worsening disease severity.[14]

In order to lessen the incidence and disease severity of gout, it is important to be mindful of risk factors and pharmacologic agents that can influence the disease. Dietary risk factors involve ingestion of animal purines, fructose, and alcohol (especially beer). Patients experiencing frequent attacks and those with poorly controlled advanced disease should be educated to avoid sweetbreads (organ meats such as thymus and pancreas), liver, and kidney meat; high-fructose corn syrup; and alcohol use.[5] Other risk factors include male sex, obesity, hypertension, dyslipidemia, and the metabolic syndrome.[11] Gout also occurs frequently in patients with type 2 diabetes mellitus, chronic kidney disease (CKD), and coronary artery disease.[15] Prospective data indicate that gout is an independent risk factor for coronary heart disease,[16] and the cardiovascular impact of urate-lowering therapy continues to be investigated.[17-19] Uric acid excretion is reduced in patients with CKD, putting them at risk for hyperuricemia.

LO 2

KEY CONCEPT Some drugs can cause hyperuricemia and precipitate gout, such as thiazide and loop diuretics, niacin, pyrazinamide, calcineurin inhibitors, and aspirin. In most cases, these drugs block uric acid secretion in the kidney. The effect of aspirin on uric acid is dose-dependent. Aspirin in high analgesic doses (600–2400 mg/day) blocks uric acid reabsorption by the kidneys, increasing uric acid excretion. Aspirin doses below 600 mg/day inhibit uric acid excretion and can elevate serum uric acid levels.[4] However, patients with hyperuricemia or gout and cardiovascular risk factors should continue low-dose aspirin (eg, 81–325 mg/day) for myocardial infarction or stroke prevention because the cardiovascular benefit outweighs the minimal effect on serum urate.[5]

PATHOPHYSIOLOGY

LO 1

Gout is caused by an abnormality in uric acid metabolism. Uric acid is a waste product of purine breakdown contained in the DNA of degraded body cells and dietary protein. It is water soluble and excreted primarily by the kidneys, although some is broken down by colonic bacteria and excreted via the

gastrointestinal (GI) tract. Uric acid solubility is dependent on concentration and temperature. At high serum concentrations, lower body temperature causes the precipitation of **monosodium urate** (MSU) crystals. Collections of these crystals (called microtophi) can form in joint spaces in distal extremities as well as soft tissues such as tendons and ligaments. Larger **tophi** may take 10 years or longer to develop. LO1

Free urate crystals can activate neutrophils and macrophages, which release proinflammatory mediators, including tumor necrosis factor α (TNF-α), interleukin 1 (IL-1), and IL-8. This signals chemotactic movement of neutrophils into the joint space that phagocytize MSU crystals. These neutrophils are then lysed, releasing proteolytic enzymes that trigger the clinical manifestations of an acute gout attack, such as pain and swelling. Inflammatory mechanisms in gout, especially in untreated disease, can lead to cartilage and joint destruction. LO1

The increased SUA involves either the underexcretion of uric acid (90% of patients) or its overproduction. The cause of overproduction or underexcretion of uric acid in most gout patients is unknown; this is referred to as primary gout.[1] The reference range for SUA is 3.6 to 6.8 mg/dL (214–404 μmol/L). The risk of gout increases as the SUA concentration increases. Uric acid **nephrolithiasis** can occur in patients with persistently acidic urine and hyperuricemia. In severe cases, uric acid stones can cause nephropathy and renal failure. LO1 LO2

KEY CONCEPT Long-term consequences of gout and hyperuricemia include joint destruction, tophi, nephrolithiasis, and nephropathy.

CLINICAL PRESENTATION AND DIAGNOSIS

Refer to the accompanying box for the clinical presentation of acute gouty arthritis.

Diagnosis

A presumptive diagnosis is often based on presenting symptoms and may be confirmed later with laboratory and other diagnostic tests. However, in younger patients (< 25 years of age) with evidence of clinical disease, screening for uric acid overproduction is recommended.[5] Severe joint pain, swelling, tenderness, and erythema that rapidly peak are highly suggestive of, but not specific for, gout. Gout is a reasonably accurate clinical diagnosis in patients with recurrent **podagra** and hyperuricemia.[1] While gout classification criteria are available to identify patients potentially suitable for clinical trial enrollment, the point-based system should not be used clinically to diagnose gout.[20] Rather, severity of symptoms and proper categorization as delineated in the ACR guidelines should be assessed.[5,6] LO3

The SUA level is often elevated but may be normal during an acute attack; an elevated SUA alone is not diagnostic for gout. The peripheral white blood cell (WBC) count may be only mildly elevated. Other laboratory markers of inflammation (eg, increased erythrocyte sedimentation rate) are often present. Although difficult to perform, aspiration of affected joint fluid or a tophus is essential for a definitive diagnosis.[8] Needle-shaped negatively birefringent MSU crystals in the aspirate confirm the diagnosis (**Figure 59–1**). Joint fluid may also have an elevated WBC count with neutrophils predominating.[2]

Radiographs of affected joints may have characteristic cystic changes, punched-out lytic lesions with overhanging bony edges, and soft-tissue calcified masses. These signs may also appear in other arthropathies and are generally not apparent with the first acute gout attack.[21] Therefore, radiographs are often reserved for patients with long-standing disease.

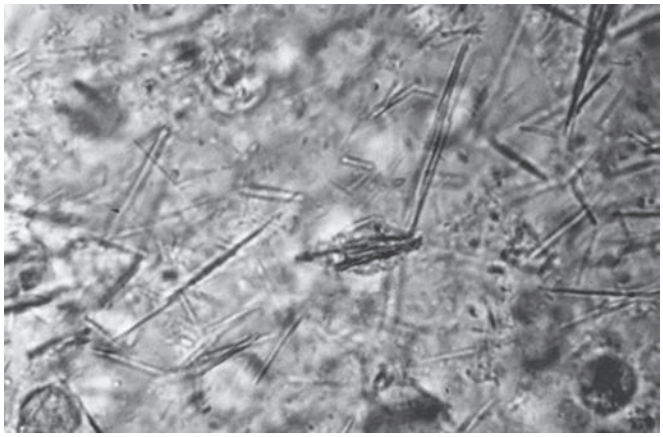

FIGURE 59–1. Synovial fluid containing extracellular and intracellular needle-like, negative birefringent monosodium urate crystals. (Reprinted with permission from: Schumacher HR, Chen LX. Chapter 395. Gout and Other Crystal-Associated Arthropathies. In: Kasper DL, Fauci AS, Hauser SL et al., eds. Harrison's Principles of Internal Medicine, 19th ed. New York, NY: McGraw-Hill; 2015. http://accesspharmacy.com)

A 24-hour urine collection can determine whether the patient is an overproducer or an underexcretor of uric acid. Individuals who excrete more than 800 mg (4.8 mmol) of uric acid are overproducers. Patients with hyperuricemia who excrete less than 600 mg/day (3.6 mmol/day) are classified as underexcretors. However, this approach is not often used because the urine collection is inconvenient for patients and clinicians and does not identify patients who may be both overproducers and underexcretors.

TREATMENT OF ACUTE GOUTY ARTHRITIS

KEY CONCEPT Treatment of gout involves: (a) acute relief of a gouty arthritis attack with topical application of ice and drug therapy commonly including NSAIDs, colchicine, corticosteroids, or

Clinical Presentation of Acute Gouty Arthritis

General

- Acute inflammatory monoarthritis.
- Patients are usually in acute distress.

Symptoms

- There is severe pain and swelling in the affected joint(s).
- Symptoms reach maximal intensity within 6 to 12 hours.
- The attack is usually monoarticular; the most common site is the metatarsophalangeal joint.
- In older patients, gouty attacks may be atypical with insidious and polyarticular onset, often involving hand or wrist joints.

Signs

- Affected joint(s) are warm, erythematous, and swollen.
- Mild fever may be present.
- Tophi (usually on hands, wrists, elbows, or knees) may be present in chronic, severe disease.

Patient Encounter Part 1

A 62-year-old Korean woman presents to the charitable rheumatology clinic with complaints of excruciating pain in her right wrist that has progressed quickly since onset late yesterday afternoon. She is a poor historian but reports no recent injuries and states that these symptoms "happen every couple of months in my ankle, toe, and wrist and I take whatever strong pain medicine I can get because the other stuff makes me break out." On examination, she can barely move her wrist due to pain and it is red, swollen, tender, and warm to the touch. She also has multiple small, firm nodules under the skin on her right hand. She is unemployed, homeless, and has difficulty reading and completing clinic intake paperwork due to limited English. She is concerned that she cannot carry her personal items between shelters with this reoccurring pain.

What information is suggestive of acute gouty arthritis?

What additional information is necessary to differentiate gout from other joint abnormalities?

What additional information do you need before creating a treatment plan for this patient?

What are aspects to consider when providing care for a patient who speaks limited English and has socioeconomic difficulties?

a combination thereof, and (b) in some patients, long-term prophylactic treatment with urate-lowering therapy (ULT) to prevent subsequent attacks.

Desired Outcomes

LO 4 Treatment goals for an acute attack are to: (a) achieve rapid and effective pain relief, (b) maintain joint function, (c) prevent disease complications, (d) avoid treatment-related adverse effects, (e) provide cost-effective therapy, and (f) improve quality of life.[3] Infrequent gouty arthritis is a self-limited disease, and treatment usually focuses on symptomatic relief.

Nonpharmacologic Therapy

Nondrug modalities play an adjunctive role and usually are not effective when used alone. Immobilization of the affected extremity speeds resolution of the attack. Applying ice packs to the joint is most effective in decreasing pain and swelling.[6]

Pharmacologic Therapy

LO 5 KEY CONCEPT Nonsteroidal anti-inflammatory drugs (NSAIDs), colchicine, and corticosteroids are considered first-line monotherapy options for acute attacks.[6] Selection depends on number of joints affected, presence/absence of infection, clinician/patient preference, prior response, and patient factors such as comorbidities and renal function (Figure 59–2). Each drug class has a unique safety and efficacy profile in gout that should be considered carefully before choosing a specific agent (Table 59–1). Generally, the earlier in the course of the arthritic attack these agents are employed (ie, within 24 hours), the better the outcome.[6] Therefore, fully informed patients are encouraged to self-medicate at the first sign of an attack.[7] Corticotropin (adrenocorticotropic hormone, ACTH) and IL-1 inhibitors are alternatives in select cases.[6] Opioid analgesics have little to no role in acute gout, which results from overwhelming inflammation.

▶ *Nonsteroidal Anti-inflammatory Drugs*

NSAIDs, which reduce the pain and inflammation associated with an acute attack, have largely supplanted colchicine as the treatment of choice (see Chapter 58, Osteoarthritis, for more detailed information on NSAIDs). These agents are most LO 5 effective when given within the first 24 hours of the onset of pain. Most studies have shown similar results among agents, and no one NSAID is preferred over another. Doses at the higher LO 5 end of the therapeutic range are often needed.[6] NSAIDs are usually continued at full doses until 24 hours after symptoms subside. Clinicians may consider tapering the dose if a patient has multiple comorbidities, including hepatic or renal failure.

Only naproxen, indomethacin, and sulindac are FDA approved for treatment of acute gout. Although indomethacin has been used traditionally, its relative cyclooxygenase-1 (COX-1) selectivity increases its gastropathy risk. Studies comparing indomethacin to other NSAIDs consistently show similar efficacy with higher side effects with indomethacin; thus, other generic NSAIDs may be preferred. The patient's overall clinical status should LO 5 be evaluated prior to NSAID initiation because adverse effects include gastropathy (primarily peptic ulcers), renal dysfunction, and fluid retention.[6] In general, NSAIDs should be avoided in patients at risk for peptic ulcers; those taking anticoagulants; and those with renal insufficiency, uncontrolled hypertension, or heart failure. Gastroprotective agents such as proton pump inhibitors may protect against ulcer development in patients receiving NSAIDs for acute gout.

Cyclooxygenase-2 (COX-2)–selective inhibitors produce results comparable to those of traditional NSAIDs, with celecoxib being the only available product in the US market currently.[22] However, the need for large COX-2 inhibitor doses during an acute gouty attack (ie, celecoxib 800 mg daily), cardiovascular safety concerns, and high cost make the risk-benefit ratio unclear for this disorder.

▶ *Colchicine*

Colchicine has a long history of successful use and was the treatment of choice for many years. It is used less commonly today because of its low therapeutic index and more recently, increased cost. Colchicine is thought to exert its anti-inflammatory effects by interfering with the function of mitotic spindles in neutrophils by binding of tubulin dimers; this inhibits phagocytic activity.[23] Colchicine is not considered to be an analgesic.

About two-thirds of patients with acute gout respond favorably LO 5 if colchicine is given within the first 24 hours of symptom onset.[24] Presently, colchicine is only indicated if given within 36 hours of attack onset.[6] Gastrointestinal effects (eg, nausea, vomiting, diarrhea, and abdominal pain) are most common and are considered a forerunner of more serious systemic toxicity, including myopathy and bone marrow suppression (usually neutropenia). However, systemic colchicine toxicity can occur without prior GI effects, especially with renal insufficiency. In the presence of severe renal impairment (creatinine clearance [CrCl] < 30 mL/min [0.5 mL/s]), dosing should be repeated no more than once every 2 weeks. Dose reductions are required when coadministered with p-glycoprotein or strong CYP3A4 inhibitors (eg, clarithromycin, verapamil, ritonavir, cyclosporine, ranolazine).[23] Because of these problems, colchicine may be reserved for patients who are at risk for NSAID-induced gastropathy or who have failed NSAID therapy.

Until recently, Colcrys was the only single-ingredient oral colchicine product FDA approved for treatment of acute gout attacks. For many years prior to its release, generic colchicine

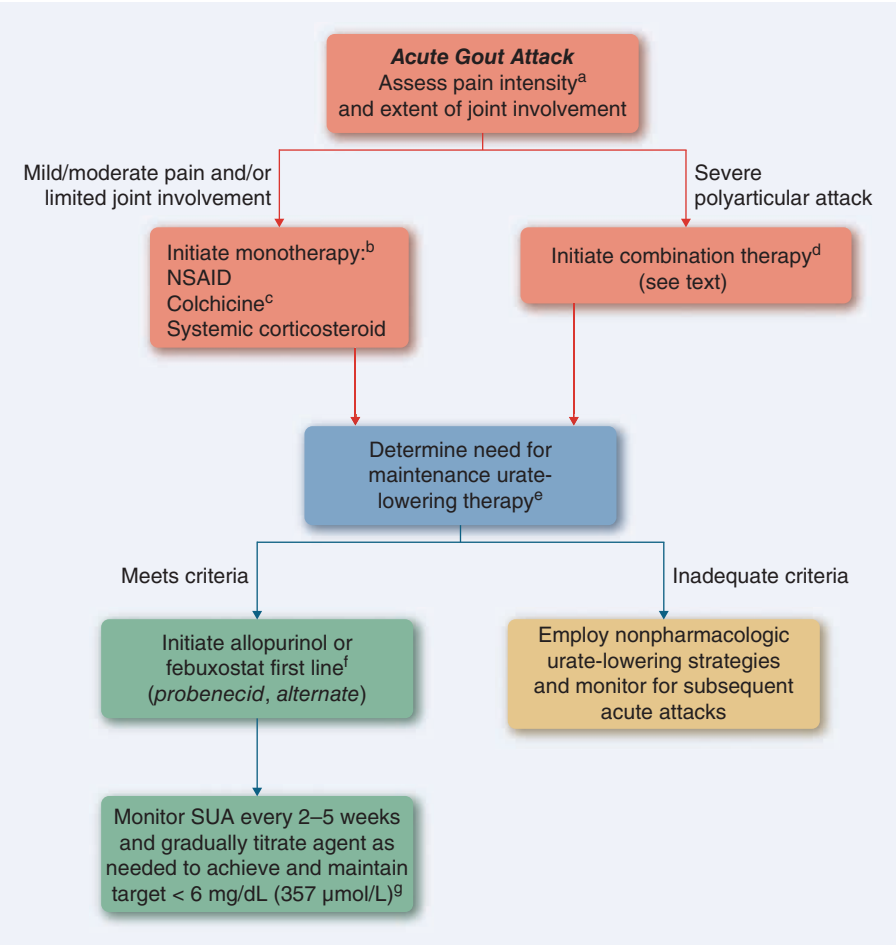

FIGURE 59–2. Treatment algorithm for hyperuricemia in gout. (NSAID, nonsteroidal anti-inflammatory drug; SUA, serum uric acid.)

[a]Self-reported pain score using a visual analog scale of 6 or less is considered mild/moderate pain and 7 or more is considered severe pain.

[b]May consider switch to alternate monotherapy, add-on combination therapy, or off-label therapy for inadequate response (< 20% improvement in pain score within 24 hours or < 50% at 24 hours or longer).

[c]Colchicine recommended only if started within 36 hours of symptom onset.

[d]Intraarticular corticosteroids may be used in combination when only one or two large joints are affected.

[e]Criteria for ult initiation include: Recurrent attacks (2 or more per year), evidence of tophus or tophi, chronic kidney disease stage 2 or worse, or past urolithiasis.

[f]Initiate concomitant anti-inflammatory prophylaxis and continue for indicated duration.

[g]May add on uricosuric therapy if unable to achieve target SUA on maximally dosed xanthine oxidase inhibitor therapy; addition of lesinurad only recommended with febuxostat (40 or 80 mg) or allopurinol doses above 200–300 mg based on renal function; switch to pegloticase for refractory cases.

products were available without FDA approval, but the FDA mandated their discontinuation in 2010. Colcrys is significantly more expensive than the generic compounds it replaced but has evidence-based labeling and safety data. In 2015, a generic form of colchicine was approved for use, helping to enhance affordability.

As part of the Colcrys approval process, a dosing study showed that one dose initially and a single additional dose after 1 hour was just as effective as and less toxic than continued hourly colchicine dosing.[25] Thus, the approved dosage regimen is 1.2 mg (two 0.6-mg tablets) at the onset of an acute flare, followed by 0.6 mg 1 hour later.[23] The ACR guidelines suggest it can then be continued starting 12 hours later at a dose of 0.6 mg once or twice daily (prophylaxis dosing) until the gout attack is resolved.[6] This is not part of the FDA-approved labeling but is an off-label recommendation based on pharmacokinetic data.[25] Dose adjustment is required for renal insufficiency.

Colchicine should not be used for an acute attack if the patient is currently prescribed colchicine for prophylaxis and was previously treated with colchicine for an acute attack within the last 14 days. Intravenous colchicine (no longer commercially available) should never be used in gout management.[6]

► *Corticosteroids*

It is important to determine the number of joints affected when considering a corticosteroid for first-line therapy. Systemic corticosteroids are a useful option in patients with contraindications to NSAIDs or colchicine (primarily renal impairment) or polyarticular attacks, especially in older patients. Furthermore, corticosteroids and NSAIDs have been shown equally effective in acute gout treatment.[26,27] The ACR recommends initiating oral prednisone or prednisolone at a dose of at least 0.5 mg/kg daily for 5 to 10 days, followed by abrupt

Table 59–1

Pharmacotherapy Regimens for Acute Gout Treatment

Drug	Usual Dosage Range
NSAIDs	
Etodolac	300–500 mg po two times daily
Fenoprofen	400–600 mg po three to four times daily
Ibuprofen	400–800 mg po three to four times daily
Indomethacin[a]	50 mg po three times daily initially until pain is tolerable, then quickly taper to discontinue
Ketoprofen	50 mg po four times daily or 75 mg po three times daily
Naproxen[a]	750 mg po initially, then 250 mg po every 8 hours
Piroxicam	20 mg po once daily or 10 mg po twice daily
Sulindac[a]	150–200 mg po two times daily for 7–10 days
Celecoxib	800 mg po followed by 400 mg po on day 1, then 400 mg po twice daily for 1 week
Colchicine[b]	1.2 mg po at the onset of attack, then 0.6 mg po 1 hour later
Corticosteroids	
Local corticosteroid	
Triamcinolone acetonide	10–40 mg (large joint), 5–20 mg (small joint) for one dose by intraarticular injection
Systemic corticosteroid	
Prednisone (example)	30–60 mg po once daily for 3–5 days, then taper to discontinue by 5 mg decrements over 10–14 days
Triamcinolone acetonide	60 mg by IM injection for one dose[c]
Methylprednisolone	100–150 mg by IM injection once daily for 1–2 days
Corticotropin[d]	40–80 units IM or SC every 24–72 hours
Interleukin-1 Inhibitors[d]	
Anakinra	100 mg SC once daily for 3 days
Canakinumab	150 mg SC for 1 dose

[a]This drug has FDA approval for the treatment of acute gout.

[b]Dose reduction recommended for renal impairment.

[c]Administration of IM triamcinolone should be followed by oral prednisone or prednisolone.

[d]Not FDA approved for this indication.

Drug regimens derived from various sources.

IM, intramuscular; NSAIDs, nonsteroidal anti-inflammatory drugs; po, by mouth; SC, subcutaneous.

discontinuation, or full dose therapy for 2 to 5 days with a 7- to 10-day taper to discontinue.[6] Oral methylprednisolone (ie, the 6-day dose pack consisting of a 21-tablet taper of 4 mg tablets, starting with 6 tablets on day 1 [divided into three separate doses] and ending with one tablet on day 6) and naproxen have been shown to be equivalent in treating acute gout attacks.[28]

When only one or two large joints are affected, an **intraarticular** corticosteroid injection can provide rapid relief with a relatively low incidence of side effects, and it may be used in combination with either an NSAID, colchicine, or oral corticosteroid. Joint fluid obtained by **arthrocentesis** should be examined for evidence of joint space infection and crystal identification. If uric acid crystals are present and there is no infection, intraarticular injection can proceed. Finally, an alternative regimen consisting of a single intramuscular injection of a long-acting corticosteroid such as triamcinolone acetonide, followed by oral prednisone or prednisolone, may also be used.[6]

LOS

Adverse effects from systemic corticosteroids include fluid retention, hyperglycemia, CNS stimulation, weight gain, GI upset, and increased risk of infection. Patients with diabetes should have blood glucose levels monitored carefully during the corticosteroid course, and caution should be exercised when treating patients with a history of peptic ulcer disease.

▶ *Corticotropin (Adrenocorticotropic Hormone)*

Exogenous administration of intramuscular adrenocorticotropic hormone (ACTH) stimulates production of cortisol and corticosterone by the adrenal cortex. Clinical studies have shown efficacy similar to other agents for acute gout. Although not a first-line option (or FDA approved for this use), the ACR supports its use for patients unable to take medications orally.[6] The product is available in the United States only through specialty pharmacy distribution.

▶ *Interleukin-1 Inhibitors*

Several small clinical trials have demonstrated efficacy of IL-1 inhibitors in inhibiting inflammation associated with acute gout attacks. While their role is unclear and the available products (anakinra and canakinumab) are not FDA approved for this purpose, the ACR guidelines include off-label use as an option for severe acute attacks or for patients refractory to other agents.[6]

▶ *Combination Therapy*

In severe polyarticular attacks, particularly attacks involving multiple large joints, colchicine may be used in combination with an NSAID or oral corticosteroid. Intraarticular corticosteroid injections may be used in combination with any other first-line agent (NSAID, colchicine, oral corticosteroid).[6]

URATE-LOWERING THERAPY FOR GOUT PROPHYLAXIS

Gout is an episodic disease, and the number of attacks varies widely among patients. Thus, the benefit of long-term acute attack prophylaxis must be weighed against the cost and potential toxicity of therapy that may not be necessary in all patients.

The benefits of long-term use (> 12 months) in patients with single or infrequent gout attacks have not been evaluated, and the time at which therapy could be discontinued is unclear.[9] KEY CONCEPT Asymptomatic hyperuricemia generally does not require treatment.

Nonpharmacologic Therapy

LO 7

Historically, lifestyle modifications alone have been insufficient for lowering SUA levels, and low purine diets are not well tolerated. Patients should be educated on general nutrition principles and advised to engage in regular exercise to lose weight if obese, strictly limit or discontinue ethanol consumption, maintain hydration, and manage other comorbidities (eg, hypertension, diabetes). Evidence suggests that men who follow the Dietary Approaches to Stop Hypertension (DASH) diet have a reduced risk for gout compared to those who eat a Western diet.[29] While the ACR guidelines encourage patients to consume low/non-fat dairy products and vegetables, they also cite a lack of specific evidence[5] (similar to the ACP guidelines) that judge the available evidence insufficient to recommend specific dietary changes.[9] Complementary therapies are considered to be inappropriate for gout due to insufficient evidence of benefit, such as cherry juice/extract, flaxseed, and celery root.[6,11] Drugs that may cause or aggravate hyperuricemia should be discontinued if clinically appropriate. Clinical experience indicates that few patients adhere to lifestyle modifications long-term, and pharmacologic therapy usually is needed to treat hyperuricemia adequately.

Pharmacologic Therapy

LO 6

KEY CONCEPT Patients with recurrent attacks (2 or more per year), evidence of tophus or tophi, CKD stage 2 or worse, or past urolithiasis are candidates for *prophylactic* therapy with allopurinol, febuxostat, lesinurad, probenecid, and/or pegloticase to lower SUA levels (see Figure 59–2).[5] However, ULT may be considered sooner in patients younger than 40 years, those with comorbidities, or SUA levels above 8 mg/dL (480 µmol/L).[7] Because hyperuricemia is the strongest modifiable risk factor for acute gout, prophylactic therapy commonly involves either decreasing uric acid production or increasing excretion (Table 59–2). The goal of therapy is to decrease SUA levels significantly, leaving less uric acid available for conversion to MSU crystals.[3] KEY CONCEPT ULT may be started during an acute attack if anti-inflammatory treatment has been initiated. Similarly, ULT should be continued during acute flares.

LO 4

Ideally, the selection of long-term prophylactic therapy involves determining the cause of hyperuricemia (primarily by analyzing a 24-hour urine collection for uric acid) and tailoring therapy appropriately. Drugs used to increase uric acid excretion (**uricosuric** agents) generally are not as well tolerated as drugs that decrease production, and uricosurics increase the risk of uric acid nephrolithiasis.

LO 8

Because allopurinol (which reduces uric acid production) is effective in both overproducers and underexcretors and is generally well tolerated, many clinicians forego the 24-hour urine collection and treat patients empirically with it. Both allopurinol and febuxostat are xanthine oxidase inhibitors (XOIs) and are first-line ULT agents.[5] Probenecid, a uricosuric agent, is an alternative first-line option. Combination therapy with an XOI and probenecid or lesinurad may be used if single-agent XOI therapy is insufficient. Pegloticase, a recombinant urate oxidase, is reserved for refractory cases.[5]

Table 59–2

Pharmacotherapy Regimens for Urate Lowering

Drug	Usual Dosage Range
Xanthine Oxidase Inhibitors	
Allopurinol[a]	100 mg po initially, then titrate to achieve SUA level < 6 mg/dL (357 µmol/L); maximum 800 mg po daily
Febuxostat	40 mg po once daily initially, then increase to 80 mg po once daily if SUA does not decline to 6 mg/dL (357 µmol/L) or lower after 2 weeks of treatment
Uricosurics	
Probenecid	250 mg po two times daily for 1 week, then 500 mg po twice daily; may increase by 500 mg every 4 weeks to achieve SUA level < 6 mg/dL (357 µmol/L); maximum 2 g po daily
Lesinurad[b]	200 mg po once daily in combination with a xanthine oxidase inhibitor
Other	
Pegloticase	8 mg given as an IV infusion over at least 2 hours once every 2 weeks, optimal duration unknown

[a]Initial dose reduction recommended for renal impairment.

[b]Not recommended if patient is taking less than 300 mg of allopurinol (or 200 mg if creatinine clearance is less than 60 mL/min [(1 mL/s]).

Drug regimens derived from various sources.

po, by mouth; SUA, serum uric acid.

▶ *Allopurinol*

Most patients in the United States are treated with allopurinol, which usually is effective if the dosage is titrated appropriately. The drug and its primary active metabolite, oxypurinol, reduce SUA concentrations by inhibiting the enzyme xanthine oxidase, thereby blocking the two-phase oxidation of hypoxanthine and xanthine to uric acid.[3]

Allopurinol is well absorbed, with a short half-life of 2 to 3 hours. The half-life of oxypurinol approaches 24 hours, allowing allopurinol to be dosed once daily. Oxypurinol is primarily renally cleared and can accumulate in patients with reduced kidney function.

Allopurinol may be started during an acute gout attack only if anti-inflammatory treatment is also initiated, because sudden shifts in SUA levels from mobilization of tissue urate stores may precipitate or exacerbate gouty arthritis. Thus most clinicians provide anti-inflammatory prophylaxis during initiation of ULT with colchicine (0.6 mg once or twice daily or 0.3 mg daily if severe renal impairment) or a low-dose NSAID (eg, naproxen 250 mg twice daily) with acid-suppressing therapy (eg, omeprazole 20 mg once daily). If a patient is being treated with colchicine for an acute attack, the prophylactic colchicine dose may be administered 12 hours after the last treatment dose. This approach, with colchicine having a stronger evidence grade, is supported by the ACR guidelines. Guidelines recommend that all acute gout patients receive prophylaxis when ULT is started with continuation of therapy for at least 6 months or up to 3 to 6 months after no clinical evidence of gout activity and the target SUA has been achieved.[6] Patients receiving colchicine for prophylaxis should be screened for drug–drug interactions (via the cytochrome p-450 system) that may increase the risk of colchicine adverse effects. Low-dose prednisone or

prednisolone (< 10 mg/day) is an alternative for patients unable to take colchicine or NSAIDs. The IL-1 inhibitors have also been investigated off-label as potential alternatives.

The initial dose of allopurinol is based on the patient's renal function. If renal function is normal, an initial dose no greater than 100 mg daily is recommended. The initial dose should be reduced to 50 mg daily in patients with a CrCl less than 30 mL/min (0.5 mL/s).[6] The relationship between allopurinol dose and its most severe side effects, including allopurinol hypersensitivity syndrome (AHS), is controversial.[30] Patients should be screened for AHS risk factors (female sex, age above 60 years, renal or cardiovascular disease, treatment of asymptomatic hyperuricemia, or an initiation dose of allopurinol greater than 100 mg daily.)[31] However, the dose can be adjusted upward every 2 to 5 weeks as needed and tolerated to the SUA target, even in patients with renal insufficiency provided that they are monitored and educated appropriately.[5,32]

LO 8 SUA levels must be monitored every 2 to 5 weeks during titration, then every 6 months after the target SUA is achieved. The target SUA level is less than 6 mg/dL (357 μmol/L) in all cases and perhaps even less than 5 mg/dL (297 μmol/L) in more severe disease involving tophi.[5] It is not recommended to have a SUA level less than 3 mg/dL (178 μmol/L) long-term.[7] The allopurinol dose should be titrated upward (to a maximum of 800 mg/day) or downward as these levels dictate.[5] However, the ACP guideline does not support the ACR's proactive "treat-to-target" approach due to a lack of adequate supporting evidence; rather the ACP recommends "treating-to-avoid-symptoms."[9] Nevertheless, most clinicians likely follow the ACR recommendations and strategies at this time. The typical allopurinol dose prescribed is 300 mg/day in patients with normal renal function, but this dose often fails to achieve the target SUA level.[5]

LO 8 Allopurinol is typically well tolerated; nausea and diarrhea occur uncommonly. A generalized, maculopapular rash occurs in about 2% of patients. Although usually mild, this can progress to severe skin reactions such as Stevens-Johnson syndrome. The most serious side effect is AHS, which may involve severe desquamating skin lesions, high fever (usually greater than 39.0°C [102.2°F]), hepatic dysfunction, leukocytosis with predominant eosinophilia, and renal failure. The risk appears to be highest in the first few months of therapy, and although rare, this severe reaction has a 20% to 25% mortality rate.[5,33,34] Prior to initiating allopurinol, pharmacogenomic screening via human leukocyte antigen (HLA)-B*5801 testing is recommended for patients at an elevated risk for AHS (eg, Koreans with stage 3 or worse CKD and all individuals of Han Chinese and Thai descent). If results are positive, the patient should be provided with an alternative to allopurinol. Patients with a history of AHS should never again receive allopurinol (including desensitization) or oxypurinol (available outside the United States). Patients with a mild skin rash who require allopurinol can be desensitized to it using published protocols or be switched to febuxostat.[35]

There are several important drug–drug interactions with allopurinol. The effects of both theophylline and warfarin may be potentiated by allopurinol. Azathioprine and 6-mercaptopurine are purines whose metabolism is inhibited by concomitant allopurinol therapy; the dose of these drugs must be reduced by 75% with allopurinol cotherapy. Patients taking allopurinol who receive ampicillin are at increased risk of skin rashes.

▶ *Febuxostat*

Febuxostat is a nonpurine XOI structurally distinct from allopurinol that is FDA approved for chronic hyperuricemia associated with gout. The initial dose is 40 mg orally once daily. The dose may be increased to 80 mg orally once daily if the SUA does not decrease to 6 mg/dL (357 μmol/L) or less after 2 weeks of treatment. No dosage adjustment is necessary in patients with mild or moderate renal impairment (CrCl 30–89 mL/min [0.5–1.48 mL/s]); however, febuxostat is not recommended in severe renal insufficiency (CrCl < 30 mL/min [0.5 mL/s]).[36,37] Because of its potency and rapid reduction of SUA levels, anti-inflammatory prophylaxis with low-dose colchicine or an NSAID is also recommended during initiation and titration of therapy and for at least 6 months as previously discussed for allopurinol.

LO 8 Adverse effects of febuxostat include nausea, arthralgias, rash, transient elevation of hepatic transaminases, and cardiovascular events. Therefore, periodic liver function tests are recommended (eg, at baseline, 2 and 4 months after starting therapy, and then periodically thereafter). Additionally, preliminary results from a safety clinical trial demonstrated an increased risk of heart-related deaths and death from all causes with febuxostat compared to allopurinol.[38] Due to differences in chemical structure, febuxostat would not be expected to cross-react in patients with a history of AHS.

Due to cost concerns, febuxostat should generally be reserved for patients who do not tolerate allopurinol and those who cannot achieve SUA levels of 6 mg/dL (357 μmol/L) or less despite maximal allopurinol therapy.[1]

▶ *Probenecid*

Probenecid is a uricosuric agent that blocks the tubular reabsorption of uric acid, increasing its excretion. Because of its mechanism of action, probenecid is not recommended for urate overproducers and is contraindicated in patients with a history of urolithiasis or urate nephropathy. Probenecid loses its effectiveness as renal function declines and should be avoided when the CrCl is 50 mL/min (0.83 mL/s) or less.[39] Probenecid is

LO 8 an alternate first-line agent if XOI therapy is either not tolerated or contraindicated. It may also be added to XOI therapy that has been titrated to the maximum dose without attainment of the target SUA level.[6]

Although generally well tolerated, probenecid can cause GI side effects (nausea), as well as fever, rash, and rarely, hepatic toxicity.[39] Patients should maintain adequate fluid intake and urine output to decrease the risk of uric acid stone formation. Some experts advocate alkalinizing the urine to decrease this risk, but no specific recommendations are provided.

▶ *Escalating Urate-Lowering Therapy*

If the target SUA level is not achieved with single-agent XOI therapy (allopurinol or febuxostat) titrated to the maximum appropriate dose, a uricosuric (eg, probenecid) may be added and also titrated to the appropriate dose.[5] Other medications with mild uricosuric effects may be appropriate adjunctive therapy in some patients. Losartan increases both uric acid excretion and urine pH and may be an option in hypertensive patients with gout. Fenofibrate is also uricosuric and may be appropriate in select dyslipidemic patients with gout.[40] Either one of these agents may be combined with a XOI in patients who fail to achieve

LO 8 the target SUA level on maximized therapy.[5] Another option for patients failing to achieve the target SUA level with

Patient Encounter Part 2

PMH: Stage 3 chronic kidney disease, hypertension, dyslipidemia, asthma, prediabetes mellitus (type 2)

FH: Unknown—adopted as child. No siblings.

SH: Unemployed with "off and on" side jobs. She drinks soda during the day to stay awake and a 12-pack of beer on the weekends. She denies use of tobacco products, but buys illicit opioids occasionally for joint pain. She admits to a poor diet consisting of packaged and canned food donations and eats candy from the convenience store if she is unable to find a meal.

Allergies: NSAIDs (anaphylaxis), simvastatin (myopathy), allopurinol (severe rash)

Meds: Chlorthalidone 25 mg once daily, niacin ER 1000 mg at bedtime, aspirin 325 mg TID PRN pain, albuterol HFA MDI 1-2 puffs every 6 hours PRN

ROS: Aside from pain in her wrist, she reports occasional shortness of breath. No fatigue, N/V/D, chest pain, or cough.

PE:

VS: 155/92, P 79, RR 19, T 37.3°C (99.1°F), Ht 69 inches (175 cm), Wt 77.5 kg

Skin: Warm, dry with excessive warmth surrounding right wrist

HEENT: NC/AT, PERRLA, TMs intact

CV: RRR, normal S1 and S2, no m/r/g

Chest: CTA

Abd: Slightly overweight, but soft, NT/ND. Normal bowel sounds in all quadrants.

Ext: No c/c. Trace edema in both ankles. Erythematous, edematous right wrist joint. Joint is warm to the touch and extremely painful (9/10 on the pain scale). Signs of tophi on right hand. No swelling of other joints.

Neuro: A&O × 3, CN II to XII intact

Labs: Serum creatinine 1.4 mg/dL (124 µmol/L), SUA 13.4 mg/dL (797 µmol/L), WBC + diff WNL. AST/ALT WNL.

Other: 24-hour urine collection not performed. Joint aspirate from wrist tap: > 50 WBC/HPF, containing negatively birefringent monosodium urate crystals. Wrist and hand radiographs negative for break or trauma, but indicate cystic changes and calcified masses. (+) for HLA-B*5801.

What risk factors promote gout and hyperuricemia in this patient?

Given this additional information, what is your assessment of the patient's condition?

Identify your gout treatment goals for this patient.

What nonpharmacologic and pharmacologic alternatives are available for this patient's acute gouty attack?

What alternatives are available for urate-lowering therapy for gout prophylaxis in this patient?

an appropriately dosed XOI is to combine the XOI with the uricosuric lesinurad.[41]

► *Lesinurad*

Lesinurad is a uric acid transporter 1 (URAT1) inhibitor that increases renal excretion of SUA and is approved for co-administration with a XOI (allopurinol or febuxostat) in patients who fail to meet their SUA target on a XOI alone.[41] Its place in therapy was determined by recent clinical trials.[42-44] Lesinurad should never be used as monotherapy due to the boxed warning of acute renal failure when given alone. Lesinurad is recommended at a dose of 200 mg once daily in the morning with food and water. It is also available in a dual-mechanism combination product that contains lesinurad 200 mg plus allopurinol 200 or 300 mg.[45] Additional URAT1 inhibitors are still in development.[46]

LO 8 Common adverse events include headache, influenza, blood creatinine increase, and gastroesophageal reflux disease; cardiovascular events were also observed. Interactions with aspirin in doses above 325 mg daily, hormonal contraceptives, inhibitors of epoxide hydrolase, moderate CYP2C9 inhibitors and inducers, and CYP3A4 substrates are possible. Renal function should be monitored at initiation and during therapy, avoiding initiation and discontinuing the product if CrCl is below 45 mL/min (0.75 mL/s). Contraindications include **tumor lysis syndrome** (TLS) and **Lesch-Nyhan syndrome**. Patients should be instructed to stay well hydrated, and gout flare prophylaxis is also recommended when starting lesinurad.[41]

Patient Encounter Part 3

The charitable clinic stocks only brand name medications donated by pharmaceutical companies to dispense to patients without charge. Older generic medications are unavailable. Based on all the information provided, create a care plan for this patient's gout. The plan should include: (a) a statement of the drug-related needs and/or problems, (b) a patient-specific detailed therapeutic plan, and (c) monitoring parameters to assess efficacy and safety.

► *Pegloticase*

Gout does not occur in most nonprimate mammals because these species produce the enzyme uricase, which catalyzes oxidation of uric acid into the more soluble compound allantoin, which is readily excreted. Humans lack this enzyme, which allows uric acid to accumulate, leading to gout in some individuals.

Pegloticase is a recombinant form of uricase (also known as urate oxidase) conjugated to polyethylene glycol. It is FDA approved for treatment of chronic gout refractory to other therapies. The approved dose of 8 mg by IV infusion over at least 2 hours every 2 weeks rapidly (within 6 hours) decreased SUA in subjects in published trials.[47] However, pegloticase should be limited to patients with severe gout with tophi or nephropathy that has not responded to other agents because of significant adverse effects, including gout flares, infusion reactions, anaphylaxis (in up to 5% of patients) that mandates pretreatment with antihistamines and corticosteroids, the inconvenience of IV therapy, and its high cost. Pegloticase is contraindicated in patients with G6PD deficiency due to the risk of hemolysis and methemoglobinemia; therefore, patients should be screened prior to initiation of therapy.

LO 8

Patient Care Process

Collect Information:

- Perform allergy assessment and medication history for prescription, nonprescription, and dietary supplement use.
- Review medical history for contributing lifestyle factors (ie, alcohol use) and comorbidities including CKD that may exacerbate hyperuricemia or help guide therapy.
- Review physical assessment findings and patient symptoms to determine time of attack onset, joint(s) affected, pain level, and observe signs (joint warmth, swelling, redness).
- Identify patient preferences, beliefs, health goals, and socioeconomic factors that affect medication access and other aspects of care.

Assess the Information:

- Identify risk factors and comorbidities associated with gout.
- Determine whether patient is taking products such as diuretic therapy that may contribute to hyperuricemia.
- Determine whether patient is experiencing signs/symptoms of an acute gout flare or long-term complications of hyperuricemia.
- If patient is currently receiving pharmacotherapy, assess efficacy (ie, frequency/severity of attacks), safety/adverse reactions, adherence, and potential drug interactions.
- Evaluate SUA level to confirm presence of hyperuricemia and document the level.
- If a gout diagnosis has not been confirmed previously, assess feasibility of aspirating the affected joint to identify uric acid crystals.

Develop a Care Plan: (Figure 59–2)

- Select a regimen for treatment of the acute attack, considering the patient's past response (if any) and comorbidities.
- Ensure patient has met criteria for ULT if already prescribed.
- Select appropriate lifestyle modifications and therapy based on comorbidities and potential safety/efficacy.
- Determine need for continuous ULT (Table 59–2). Use patient factors such as comorbidities to select an agent.
- Choose adjunctive therapy with low-dose colchicine or NSAID during initiation or titration of ULT to prevent rebound flare.
- Initiate ULT during acute attack only in conjunction with effective anti-inflammatory therapy.

Implement the Care Plan:

- Initiate therapy to treat acute gout attack within 24 hours (Table 59–1).
- Educate patient on hyperuricemia/gout, drug therapy, importance of adherence, and lifestyle modifications that may improve symptoms (eg, weight loss, alcohol avoidance).
- Address patient concerns about hyperuricemia/gout and its management.
- Determine if patient has prescription insurance and whether recommended agents (eg, colchicine) are included on formulary.
- Discontinue nonessential urate-elevating medications.

Follow-up: Monitor and Evaluate:

- Follow-up every 2 to 5 weeks to assess effectiveness, safety, and titrate ULT or add alternate agent to achieve target SUA; monitor SUA concentration during ULT titration and periodically thereafter.
- Review physical examination, lab tests, and results of other diagnostic tests to assess changes in clinical status.
- Once gout symptoms are controlled, monitor patient and SUA every 6 months; reinforce adherence with regimen to prevent future gout attacks and long-term complications (ie, development of tophi or nephrolithiasis).

OUTCOME EVALUATION

Acute Gout

- Monitor the patient for pain relief and decreased swelling of the affected joint(s). Both parameters improve significantly within 48 hours of starting therapy.
- Assess the patient's complaints and objective information for adverse effects:
  - NSAIDs: Be alert for new-onset epigastric pain, dark or tarry stools, blood in vomitus, dizziness or lightheadedness, development of edema, decreased urine output, or shortness of breath.
  - Colchicine: Monitor for nausea or vomiting, diarrhea, easy bruising, cold or flu-like symptoms, lightheadedness, muscle weakness, or pain. Advise the patient to inform you of any new medications started or stopped while taking colchicine.
  - Systemic corticosteroids: Assess for mental status changes, fluid retention, increased blood glucose, muscle weakness, or development of new infections.
  - Intraarticular corticosteroid injections: Monitor for increased swelling or pain at the injection site.

Urate-Lowering Therapy

- Monitor the SUA level every 2 to 5 weeks during ULT initiation and titration. Adjust the dose of ULT to achieve a target SUA level of less than 6 mg/dL (357 µmol/L) or optionally less than 5 mg/dL (297 µmol/L) in more severe disease. Then continue measurements every 6 months thereafter and evaluate need for additional therapy.
- Concomitantly initiate anti-inflammatory prophylaxis and continue for the greater of 6 months or 3 to 6 months after achieving target SUA level with no gout signs/symptoms.
- Assess for new gouty arthritis attacks or development of tophi.
- Evaluate patients for adverse medication effects:
  - Allopurinol: Assess for development of rash, nausea, or new fever. These symptoms usually appear within the first 3 months of therapy but can occur anytime.

- Febuxostat: Monitor for presence of nausea, arthralgias, rash, transient elevation of hepatic transaminases, and cardiovascular events.
- Lesinurad: Monitor for headache, influenza, serum creatinine increase, gastroesophageal reflux disease, and cardiovascular events.
- Probenecid: Assess for fever, nausea, or skin rash. Reevaluate therapy if a significant decrease in urine output occurs.
- Pegloticase: Monitor SUA levels before each 2-week IV infusion. Also evaluate patients on pegloticase for development of gouty flares and infusion reactions, which may include anaphylaxis. The manufacturer recommends giving an antihistamine and perhaps low-dose methylprednisolone before the infusion to minimize reactions.

60 Musculoskeletal Disorders

Jill S. Borchert and Lisa M. Palmisano

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

LO

1. Describe the pathophysiologic principles of tissue injury and inflammation.
2. Identify the desired therapeutic outcomes for a patient with musculoskeletal injury or pain.
3. Identify the factors that guide selection of an analgesic or counterirritant for a particular patient.
4. Recommend appropriate nonpharmacologic and pharmacologic therapy for a patient with musculoskeletal injury or pain.
5. Design a patient education plan, including nonpharmacologic therapy and preventative strategies.
6. Develop a monitoring plan to assess treatment of a patient with a musculoskeletal disorder.

INTRODUCTION

The musculoskeletal system consists of muscles, bones, joints, tendons, and ligaments. Disorders related to the musculoskeletal system often are classified by etiology. Acute soft-tissue injuries include strains and sprains of muscles and ligaments.[1] Repeated movements in sports, exercise, work, or activities of daily living can lead to repetitive strain injury, where cumulative damage occurs to the muscles, ligaments, or tendons.[2] Although tendonitis and bursitis can arise from acute injury, more commonly these conditions occur as a result of chronic stress.[2,3] Other forms of chronic musculoskeletal pain, such as pain from rheumatoid arthritis (see Chapter 57) or osteoarthritis (see Chapter 58), are discussed elsewhere in this textbook.

EPIDEMIOLOGY AND ETIOLOGY

Musculoskeletal disorders are commonly self-treated, so true estimates of the incidence of both acute and chronic injury are difficult to obtain. In the United States, over 65 million musculoskeletal injuries occur each year, with 62% of episodes treated in ambulatory care offices.[4] These disorders account for a large portion of medical care expenditures and are a leading cause of work absenteeism and disability, resulting in a substantial economic burden from lost productivity and lost wages.

Some musculoskeletal disorders arise from workplace injuries, including those induced by trauma or an acute overexertion and those induced by repetition and cumulative trauma.[4] The most common sites of injury include the upper extremities (eg, hand, shoulder, and wrist), back, and lower extremity (eg, ankle, knee).

In older adults, musculoskeletal injuries may not be related to work but to daily life. Half of all musculoskeletal injuries occur in the home with falls being the most common cause for those aged 65 and older.[4] In children and adolescents, fractures are more common than muscle and tendon injuries because growth spurts cause bones to weaken while the muscle–tendon unit tightens.[2]

Muscle injuries comprise the majority of sports-related injuries, and roughly half are related to overuse.[4,5] The ankle is the most common site of sports injury.[6] Activities that require rapid acceleration or pivoting at high speeds, such as basketball and soccer, pose the greatest risk of muscle sprain and acute injury.[5,7]

Overuse musculoskeletal injury is the phrase used to describe disorders arising from repetitive motion.[5] This injury is common in activities such as running, particularly during periods of increased intensity or duration of training. It also can occur in the workplace with repeated, unvaried motion.[8]

PATHOPHYSIOLOGY

Skeletal muscle consists of muscle fibers linked together by connective tissue. Tendons and ligaments are composed of collagenous fibers that have a restricted capability to stretch. Tendons connect muscle to bone, whereas ligaments connect bone to bone.

Muscle Strains and Sprains

A sprain is an overstretching of supporting ligaments that results in a partial or complete tear of the ligament.[1] Although a strain also arises from an overstretching of the muscle–tendon unit, it is marked by damage to the muscle fibers or tendon without tearing of the ligament. The key difference is that a sprain involves damage to ligaments, whereas a strain involves damage primarily to muscle.

Overloading the muscle and connective tissue results in complete or partial tears of the skeletal muscle, tendons, or ligaments.[7,9] This usually occurs when the muscle is activated in an *eccentric contraction*, defined as a contraction in which the muscle is being lengthened.[9] Examples of this type of contraction include putting down a large, heavy object or lowering oneself from a chin-up bar. Small tears can occur in the muscle because it is lengthening while also trying to contract to support the load. This leads to rupture of blood vessels at the site of the injury, resulting in formation of a hematoma.[7,9] During the inflammatory stage, macrophages remove necrotic fibers. Activated neutrophils then release growth factors that activate myocytes for regeneration. Finally, capillaries grow into the area, and muscle fibers regenerate during the repair and remodeling phases of healing.

LO 1

Bursitis and Tendonitis

Bursitis is an inflammation of the bursa, the fluid-filled sac near the joint where the tendons and muscles pass over the bone.[3] Overuse of a joint can result in an inflamed bursa. Bursitis causes stiffness and pain because the bursa serves to reduce friction within the joint space.

Tendonitis (or *tendinitis*) refers to inflammation of the tendon that follows incomplete tendon degeneration.[2] Repetitive overuse of a tendon can cause cellular changes in the tissues. Specifically, collagenous tendon tissue is replaced with tissue that lacks the organized collagen arrangement of a normal tendon. Many patients diagnosed with chronic tendonitis may not have inflammation but instead have **tendinosis**, a condition marked by these degenerative changes. As a result of the cellular changes, the tendon progressively loses elasticity and its ability to handle stress or weight. This makes the tendon vulnerable to rupture or inflammation.

Inflammation and Peripheral Pain Sensation

LO 1

Inflammation is a common pathway in soft-tissue injury of musculoskeletal disorders. Inflammatory processes lead to two outcomes: swelling and pain. They are considered to be a necessary part of the remodeling process because inflammatory cells remove damaged tissue.[10,11] However, inflammation also contributes to continued pain and swelling that limits range of motion.

The initial injury exposes membrane phospholipids to phospholipase A_2, leading to the formation of arachidonic acid.[11] Next, arachidonic acid is transformed by cyclooxygenase (COX) to thromboxanes and prostaglandins (PGs), including prostaglandin E_2 (PGE_2). PGE_2 is the most potent inflammatory mediator; it increases vascular permeability, leading to redness, warmth, and swelling of the affected area. The increased permeability also increases proteolysis, or the breakdown of proteins in the tissue.

Neutrophils, lymphocytes, and monocytes are attracted to the area, and monocytes are converted to macrophages, which then stimulate additional PG production.[11] Phagocytic cells release cytokines, including interleukins, interferon, and tumor necrosis factor.

In addition to increasing vascular permeability, PGs also induce pain by sensitizing pain receptors to other substances such as bradykinin. Bradykinin, PGs, leukotrienes, and other inflammatory mediators lower the pain threshold through peripheral pain sensitization.[12] These substances make nerve endings more excitable, and the nerve fibers are more reactive to serotonin, heat, and mechanical stimuli. The increased sensitization in the damaged tissue causes tenderness, soreness, **hyperalgesia**, and production of additional PGs. In a cyclic fashion, the PGs then sensitize the nerves to bradykinin action.

Without interruption, the neurochemicals ultimately lead to a firing of the unmyelinated or thinly myelinated afferent neurons. This sends messages along the pain pathway in the periphery and communicates the pain message to the central nervous system (CNS). Interruption of this cycle may occur via the effects of anti-inflammatory agents such as aspirin and nonsteroidal anti-inflammatory drugs (NSAIDs).

Nerve receptors, or **nociceptors**, release substance P and other peptides when they are activated.[12] Substance P mediates the production and release of inflammatory mediators and acts as a potent vasodilator. This receptor activation also increases the sensitivity of nociceptors to painful stimuli. Capsaicin relieves pain by stimulating the release of substance P from sensory nerve fibers, ultimately depleting stores of substance P.[13]

CLINICAL PRESENTATION AND DIAGNOSIS

See next page for information on the clinical presentation and diagnosis of musculoskeletal disorders.

TREATMENT

Desired Outcomes

LO 2

KEY CONCEPT The primary goals of treating musculoskeletal disorders are to: (a) relieve pain, (b) maintain functionality, and (c) prevent or minimize overuse injury. This is accomplished by decreasing the severity and duration of pain, shortening the recovery period, and preventing the acute injury from becoming an overuse injury. If these goals are achieved, functional limitations are decreased. Ideally, a patient should be able to continue to perform activities of daily living and maintain normal functions. Children ideally should be able to maintain usual play activities and sports schedules.

Further goals include a return to usual activity, prevention of future injury, and allowing for full emotional recovery. It is also important to minimize the potential for adverse events from nonpharmacologic and pharmacologic therapies.

General Approach to Treatment

LO 4

Treatment of musculoskeletal injury involves three phases: (a) nonpharmacologic therapy of an acute injury (eg, using the rest, ice, compression, and elevation [RICE] principle); (b) pain relief using oral or topical agents; and (c) lifestyle and behavioral modifications for rehabilitation and to prevent recurrent injury, overuse injury, or disability (**Figure 60–1**).

The approach to treatment for low back pain with nonpharmacologic and pharmacologic therapies is stratified by duration of pain. In acute or subacute low back pain, nonpharmacologic therapy (eg, superficial heat) is preferred, whereas for chronic low back pain pharmacologic therapy may be warranted after failure of nonpharmacologic measures.

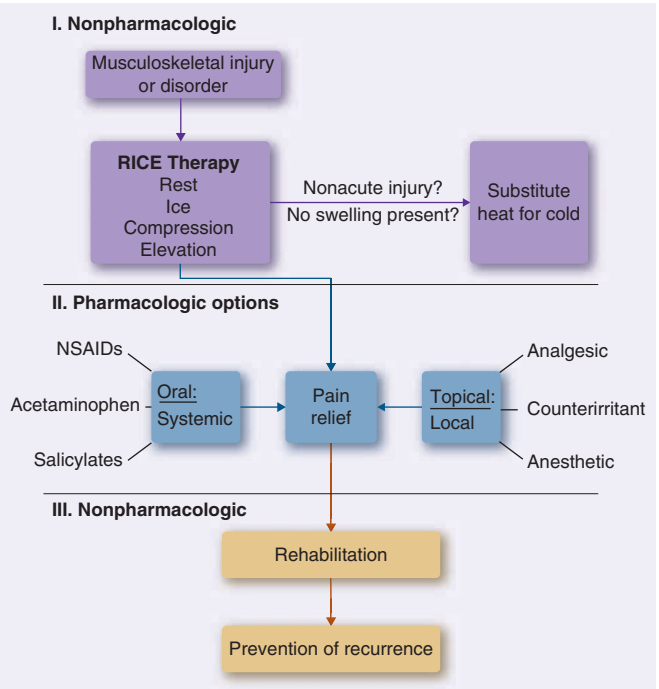

FIGURE 60–1. Treatment plan for musculoskeletal injury or disorder.

Clinical Presentation and Diagnosis of Musculoskeletal Disorders

General[2,3,5]

- Clinical presentation varies based on etiology of the disorder.
- Repetitive strain or overuse injuries may have a gradual onset.
- Disorders due to acute injury may be associated with other signs of injury such as abrasion.

Signs and Symptoms of Acute Soft-Tissue Injury (Strains, Sprains)[1,6]

- Discomfort ranging from tenderness to pain may occur at rest or with motion
- Swelling and inflammation of the affected area
- Bruising
- Loss of motion
- Mechanical instability

Signs and Symptoms of Repetitive Strain or Overuse Injury (Tendonitis, Bursitis)[2,3,5,14]

- Pain and stiffness that occur either at rest or with motion
- Localized tenderness on palpation
- Mild swelling of the affected area
- Decreased range of motion
- Muscle atrophy

Low Back Pain[15,16]

- Low back pain is often chronic, but other cases may present acutely.
- Pain is often nonspecific and may be accompanied by stiffness upon waking.
- Lifting, twisting, or bending may worsen pain.
- In some cases, pain may radiate to the hip or thigh.

Other Diagnostic Tests and Assessments[6]

- *Radiograph (x-ray)*: Evaluates bony structures to rule out fracture, malalignment, or joint erosion as the primary cause of pain.
- *MRI*: Soft-tissue imaging to evaluate for tendon or ligament tears.
- *Ultrasound*: Superficial soft-tissue imaging to evaluate for tears in tendons or ligaments. Ultrasound does not penetrate bone, so it is of limited usefulness for assessing tendons or ligaments deep within joints.
- *Electromyogram*: Evaluates electrical activity in muscles and may be used when low back pain is accompanied by leg pain or sciatica to rule out other causes of the pain.
- *Pain scale*: Patient self-rating on a pain scale. For example, a numeric pain scale with zero (no pain) to 10 (worst possible pain) or a visual analog scale. Used to assess pain both at rest and with movement. Determined at baseline and to assess response to therapy.

LO 6

Acute pain typically improves within 1 to 5 days of therapy. Further evaluation may be warranted if acute pain persists longer than 7 to 10 days with treatment, symptoms worsen or subside and then return, or there are signs of a more serious condition.[6,9,17,18] Some warning signs of more serious conditions that may warrant immediate emergency care include joint deformity, dislocation, immobility, or paralysis. Some red flags specifically for low back pain include fracture, infection, urinary or bowel incontinence, or foot drop syndrome.[15,16]

LO 3

In children and adolescents, treatment practices are similar to the approach in adults with a focus on nonpharmacologic therapy and oral analgesics. Children younger than 2 years, older adults, and pregnant women also may need special care.[19]

Patient Encounter 1, Part 1

A 48-year-old man presents with right wrist pain. He was playing flag football with his friends earlier today and twisted his wrist when he fell. The pain occurs at rest and is worsened with pressure or weight on the wrist and with rotation or movement. There is moderate swelling and bruising of the right wrist. Abrasions across his hand and wrist are noted.

What information is suggestive of a musculoskeletal disorder?

What is your assessment of the patient's wrist pain?

What additional information do you need to formulate a treatment plan?

Nonpharmacologic Therapy: RICE

LO 4

KEY CONCEPT The cornerstone of nonpharmacologic therapy for acute injury in the first 24 to 72 hours is known by the acronym RICE: rest, ice, compression, and elevation.[7,9,18,20] These four methods initially minimize bleeding from broken blood vessels followed by anti-inflammatory and analgesic actions to allow for appropriate healing at the site of injury. See Table 60–1.

Rest eases pressure on the affected area, promotes pain control during the acute inflammatory phase (the first 1–5 days after injury), and prevents additional injury to the affected area.[7,9,20] During acute injury, the ability of muscles and tendons to stretch is limited. Movement in the injured tissue can cause further retraction of the ruptured muscle and increase the size of the gap in the muscle to be healed. For simple injuries, immobilization should not exceed 1 week, with low impact, isometric, and passive stretching or exercise modalities started 3 to 4 days after injury while minimizing pain.[9,20-22] Mobilization too early after injury predisposes a patient to further injury, but prolonged inactivity can lengthen recovery times and delay healing. Longer immobilization may sometimes be warranted for more severe injuries (eg, extensive muscle tears or fractures) and may require additional support devices (eg, crutches).

The benefits of cryotherapy (modalities that act to lower tissue temperatures) following acute musculoskeletal injury are well documented.[7,10,23] Cold causes vasoconstriction, assisting in prevention of a large hematoma and providing analgesia by slowing nerve impulses. Immediately after injury, ice also helps to reduce metabolic rate and oxygen demand, thereby reducing tissue damage from hypoxia.[7,9,23] Types of cryotherapy include

Table 60–1

RICE Therapy[6,7,9,18,21-23]

Therapy	General Guidelines	Therapeutic Benefit
*R*est	Rest the affected area	Analgesia
	Use supports such as slings and crutches as necessary	Anti-inflammatory
	Employ during the acute inflammatory phase, 1–5 days after injury	Prevent further injury
*I*ce	Cool the affected area by submersion in cool water (13°C [55°F]) or by application of crushed ice in a plastic bag covered with a thin cloth	Analgesia Anti-inflammatory
	Cool the affected area for 15–20 minutes; repeat every 2 hours for the first 48 hours	
*C*ompression	Compress the affected area with an elastic bandage or support	Anti-inflammatory
	Begin wrapping the bandage at the point most distal to the injury (eg, at the toes for an ankle injury); bind firmly but not tightly	Adjunctive analgesia
	If the area distal to the injury (eg, fingers, toes) throbs or turns cold or blue, the bandage is too tight and should be loosened	
*E*levation	Elevate the area (especially the extremities) above heart level	Anti-inflammatory

(1) crushed ice (preferred over large ice pieces to provide more even cooling), (2) single-use cold packs, or (3) reusable ice packs. Patients should wrap the injured surface with a thin moist towel and then apply the ice therapy to the injured site for no longer than 20 minutes. Applying ice directly to the affected area or for longer than recommended can cause tissue damage, and any ice application should be stopped if the area becomes white or blue.[23] Recommend ice application every other 20 minutes for approximately 2 hours, followed by 2 hours of no cryotherapy. This process should then be repeated for at least the first 48 hours after injury.[18,23] If swelling is present, cryotherapy can be continued throughout the recovery process, but the duration may be shortened as pain and swelling is lessened.[21,23] Alternatively, soaking the area for 20 minutes in a cool bath (13°C [55°F]) provides effective cooling.[7,23] For small areas, direct ice massage for 15 to 20 minutes can cool the area and add relief.[23] However, there is little evidence for the effectiveness of cryotherapy in relieving low back pain, regardless of presentation.[24]

LO 4 KEY CONCEPT Heat should not be applied during the acute injury phase (when edema is present) because it promotes swelling and inflammation.[23] After the acute inflammatory phase, many patients find that heat decreases pain and eases muscle stiffness. A heating pad, heat wrap, or warm bath can be used as long as no edema is present and no swelling develops after heat is applied. Application time should not exceed 20 minutes to minimize tissue injury.[23] Patients should avoid sleeping with or sitting or lying on heating pads because this can result in burns. Low-level heat, such as that supplied by therapeutic heat wraps (eg, ThermaCare), may provide a safer means of heat application. However, the risk of burns increases with age, and older adults should be cautioned about this risk.

In the presence of acute or subacute low back pain, superficial heat application provides effective pain relief and reduces disability after 4 to 5 days of application.[24] For chronic low back pain, there is insufficient evidence to support the effectiveness of superficial heat for reduction of pain or disability (Table 60–2).

Compression and elevation are important steps in the initial treatment of an acute injury. Compression, achieved by wrapping the area with an elastic bandage, massage, or intermittent pressure devices, also reduces the size of the developing hematoma and swelling.[25] Preventing hematoma formation is important because a large hematoma can limit mobility and range of motion. Alternating compression with cryotherapy provides more swelling reduction than use of either method alone.[25] Elevating the injured area is most critical within the first 24 to 48 hours, but elevation should continue as long as swelling is present. Elevation, ideally above the heart level, decreases blood flow and reduces fluid accumulation at the injured site.[7,9]

Pharmacologic Therapy

LO 3 KEY CONCEPT There are two main approaches to pharmacologic intervention for pain relief: oral (systemic) and topical agents. In many cases, musculoskeletal disorders are self-treated with over-the-counter (OTC) oral or topical agents. The choice between systemic or topical options is often guided by patient preference. The extent of musculoskeletal pain also guides treatment choice. KEY CONCEPT Localized pain may be treated effectively with local topical therapy, whereas generalized pain is best treated with systemic agents. Factors such as alcohol use, liver function, renal function, allergies, age, and comorbid conditions should be considered when choosing among therapeutic options.

▶ *Oral Analgesics*

Nonopioid analgesics, including acetaminophen, aspirin, and NSAIDs, are used commonly for musculoskeletal disorders. These agents all provide analgesia, but aspirin and NSAIDs also work peripherally by inhibiting the enzyme COX

Table 60–2

Treatment for Low Back Pain[24]

Low Back Pain Type by Duration	Acute (< 4 weeks) or Subacute (4 to 12 weeks)	Chronic (> 12 weeks)
Nonpharmacologic therapy[a]	Superficial heat application, spinal manipulation, massage, acupuncture, exercise	Exercise, multidisciplinary rehabilitation, acupuncture, massage, psychological stress reduction, spinal manipulation
Pharmacologic therapy	NSAIDs or muscle relaxants	NSAIDs, duloxetine[b], tramadol[b], opioids[b]

[a]Evidence supporting use ranges from low to moderate.

[b]Refer to Chapter 34 (Pain Management) for further drug review.

to decrease production of PGE_2, the principal mediator of acute inflammation.[12,21] Although the mechanism of action of acetaminophen is less clear, it appears that acetaminophen acts as a weak inhibitor of PG production via COX-2 inhibition and exerts only a mild anti-inflammatory effect.[13,26]

LO 4 **Acetaminophen** KEY CONCEPT Acetaminophen is the drug of choice for mild-to-moderate regional musculoskeletal pain without inflammation.[13,27] However, acetaminophen does not provide adequate analgesia for patients with any low back pain.[24] Comparative trials between acetaminophen and oral NSAIDs demonstrate equivalent analgesia in some situations, but NSAIDs may be preferred in others. Therefore, if adequate analgesia is not achieved with acetaminophen, switching to an NSAID is a reasonable alternative. Acetaminophen offers the advantage of less gastrointestinal (GI) toxicity than NSAIDs. Although tolerability of acetaminophen is high at therapeutic doses, hepatotoxicity has been reported after overdose and at therapeutic doses, especially in combination with other factors.[13,26] Patients should not exceed 4 g/day of acetaminophen to minimize the risk of liver injury. Acetaminophen should be used with caution in patients who have liver disease or consume alcohol because of the risk of hepatotoxicity. Due to concern over liver injury, many nonprescription products are now labeled with a maximum recommended dose of 3 g/day. In addition, oral prescription combination products are limited by the US Food and Drug Administration (FDA) to 325 mg acetaminophen per dosage unit.[28] Acetaminophen can be used safely in infants, children, adolescents, and older adults.

LO 5 LO 3 LO 3

LO 4 **Salicylates** KEY CONCEPT Aspirin is not more effective than acetaminophen, and it is not recommended for initial treatment of acute musculoskeletal pain because its adverse effects may be more common and severe.[13] Gastric irritation is more common with aspirin, and bleeding risk is increased because aspirin irreversibly inhibits platelet aggregation. Patients with aspirin-induced asthma should avoid aspirin and other salicylates. Due to the risk of Reye syndrome, aspirin should be avoided in persons younger than age 19 during episodes of fever-causing illnesses.

LO 3

Some salicylates are specifically marketed for musculoskeletal back pain, such as magnesium salicylate. However, use of salicylates is not supported given the limited evidence showing benefit in treating acute pain.[29] Magnesium salicylate should be used with caution in patients with renal impairment due to risk of hypermagnesemia and should be avoided in patients 19 years old and younger due to risk of Reye syndrome.[30]

LO 3 LO 3

NSAIDs Oral NSAIDs are used commonly for musculoskeletal pain because of their availability without a prescription and anti-inflammatory effects.[12,27] KEY CONCEPT NSAIDs are a preferred choice over acetaminophen in musculoskeletal disorders in which inflammation is the primary problem.[27] As a result, NSAIDs are particularly beneficial for chronic overuse injury, in which inflammation is central to the pain and loss of motion.[21] Although NSAIDs may be helpful in relieving pain and inflammation in tendonitis, many tendinopathies are not associated with inflammation. Therefore, use of acetaminophen may relieve pain adequately.[2] For patients with low back pain, NSAIDs are first-line pharmacotherapy given the evidence demonstrating efficacy.[24] There has been some debate that early NSAID use in severe injuries such as fractures or extensive muscle tears may impede healing by reducing collagen formation, causing further chronic instability.[21,31] However, use of NSAIDs for less severe injury has shown beneficial effects in the recovery and healing process.[21]

LO 4

The analgesic effects of NSAIDs are attributed to inhibition of the COX-2 enzyme, whereas the negative GI effects are due to inhibition of COX-1.[13,27] Patients taking oral anticoagulants, those with a history of peptic ulcer disease, or others at high risk for GI complications may be considered candidates for a COX-2 inhibitor (eg, celecoxib) or a combination of a nonselective NSAID with a gastroprotective agent such as a proton pump inhibitor (see Chapter 58). Combination of any NSAID, including COX-2 inhibitors, with alcohol can increase GI adverse effects.[13]

LO 3

Both nonselective NSAIDs and COX-2 inhibitors are associated with nephrotoxicity.[13,21] Furthermore, NSAIDs, including selective COX-2 inhibitors, may increase the risk of myocardial infarction. See Chapter 58 (Osteoarthritis) for discussion of the relative risks of nonselective NSAIDs and COX-2 inhibitors, treatment options based on an individual patient's cardiovascular and GI risk profile, and maximum dosing recommendations. Refer to the drug package labeling for children and adolescents to ensure correct dosing and safe use. For example, ibuprofen is approved for use in infants 6 months and older, whereas naproxen is approved for individuals age 12 years and older.

LO 3

▶ *Topical (External) Analgesics*

Topically (or externally) applied drugs that exert a local analgesic, anesthetic, or antipruritic effect by either suppressing cutaneous sensory receptors or by stimulating these receptors in a counterirritant fashion.[13] These medications are applied directly to the affected area to create high local concentrations of the drug and exert action locally in the nerves or tissues. Negligible systemic concentrations are achieved with intact skin, minimizing systemic adverse effects.[13] Formulations include gel, cream, lotion, patch, liquid, liniment, or aerosol spray. Topical delivery should not be confused with transdermal delivery, in which drug absorption into the bloodstream produces a systemic effect. Musculoskeletal disorders often are treated with topical (not transdermal) medications.

After application, the topical medication penetrates the skin to the soft tissue and peripheral nerves.[13] Topical analgesics suppress the sensitization of pain receptors at the site, thereby reducing pain and burning. Examples include topical NSAIDs and local anesthetics. In contrast, *counterirritant* products are external analgesics that stimulate cutaneous sensory receptors, producing a burning, warming, or cooling sensation that masks the underlying pain. In effect, the irritation or inflammation caused by the counterirritant distracts from the underlying pain.

External analgesics are useful adjuvants to nonpharmacologic therapy and systemic analgesic therapy to provide additional relief. These agents are also an option in patients who cannot tolerate systemic analgesics. Because these products are not in pill form and many are available without a prescription, they may be overused or misused. Clinicians should advise patients to read and follow directions on the labels of OTC products.

Topical NSAIDs In acute soft-tissue injury such as strains and sprains, efficacy of topical NSAIDs is superior to that of placebo and similar to that of oral NSAIDs.[32] Tissue concentrations of topical NSAIDs are high enough to produce anti-inflammatory effects, but systemic concentrations after application remain low.

Diclofenac is the only topical NSAID commercially available in the United States.[13] Topical diclofenac solution (Pennsaid) and gel (Voltaren) are only indicated for treatment of osteoarthritis (see Chapter 58).[33-35] The diclofenac patch (Flector Patch) is indicated specifically for topical treatment of acute pain from minor sprains and strains in adults.[36] One patch is applied to

the most painful area twice daily to intact skin only.[13,36] Patients should be instructed to wash hands before and after application, discard the patch after use, avoid wearing the patch while bathing or showering, and to tape the patch in place if it begins to peel off.

Theoretically, the risk of serious GI adverse events should be less than with oral NSAIDs, but long-term studies evaluating these events are lacking.[21] Like oral NSAIDs, topical NSAIDs should be used with caution in patients with a history of GI bleeding or ulcer.[13] Use of topical NSAIDs with oral NSAIDs is not recommended given the potential for increased systemic adverse effects. See Chapter 58 (Osteoarthritis) for further review of NSAID-related adverse effects. Studies comparing topical NSAIDs with other topical products, including counterirritants, are also needed. Local cutaneous adverse reactions (eg, erythema, rash, pruritus, and irritation) are reported and may be due in part to the vehicle used.[13]

LO 3

Local Anesthetics Nonprescription topical anesthetics such as lidocaine and benzocaine are available in many types of products. Local anesthetics decrease discharges in superficial somatic nerves and cause numbness on the skin surface but do not penetrate deeper structures such as muscle where the pain often lies.[37] Although these topical anesthetics are not effective in direct treatment of musculoskeletal pain, they are helpful when abrasion accompanies the injury. Anesthetics are often formulated in combination with an antibiotic for OTC use; the anesthetic provides soothing relief to the abrasion site while the antibiotic promotes healing of abrasions and prevents soft-tissue infection.

Prescription topical anesthetic agents are not approved for the treatment of acute musculoskeletal pain.[13] Agents include topical lidocaine patch (Lidoderm) and heated lidocaine/tetracaine patch (Synera). The patches deliver lidocaine to local tissues to reduce neuronal impulse, induce an anesthetic effect, and reduce inflammation. The heated lidocaine/tetracaine patch provides a similar mechanism of action but also is formulated with an oxygen-activated heating component to enhance local anesthetic delivery. These agents may be considered for off-label treatment of musculoskeletal and low back pain when other first-line or approved therapies have not provided adequate pain relief.

LO 4

Counterirritants Counterirritants are indicated for the temporary relief of minor aches and pains related to muscles and joints.[17] These symptoms may be associated with arthritis, strains, or sprains. Many are available as combination products with ingredients from different counterirritant groups. Active ingredients in marketed products sometimes change; clinicians should be aware of the current ingredients before recommending a product. These products are applied multiple times a day (ranging from 3 to 4 applications daily) for up to 7 days; if pain relief is not achieved by that time, the patient should follow-up with the provider to further evaluate the acute musculoskeletal pain.

LO 4

Nonprescription counterirritants are categorized by the FDA into four groups (groups A through D) based on their primary actions (Table 60–3).[17] They produce a feeling of redness, cooling, warmth, or irritation that diverts sensation from the pain. Because these irritant effects are central to the beneficial

Table 60–3

Nonprescription Counterirritant External Analgesics[17]

Group and Effect	Agents and Concentration	Example Products (If Applicable)	Comments
Group A			
Rubefacients: Produce redness	Allyl isothiocyanate 0.5%–5%		Mustard derivative; pungent odor; avoid inhalation
	Ammonia water 1%–2.5%		More concentrated solutions are highly caustic; avoid inhalation
	Methyl salicylate 10%–60%	BenGay Ultra Strength,[a] Flexall Plus,[a] Icy Hot Stick[a]	Caution in aspirin sensitivity May produce systemic concentrations May increase INR with warfarin Use in adults and children > 12 years old
Group B			
Produce cooling	Camphor 3%–11% Menthol 1.25%–16%	JointFlex BenGay Patch, Icy Hot Patch, Mineral Ice[c]	Medicinal odor Sensation of heat follows cooling Mild anesthetic effects at low concentrations Use in adults and children > 12 years old[d]
Group C			
Produce vasodilation	Methyl nicotinate 0.25%–1%	Arth Arrest[b]	May produce systemic vasodilation Use in adults and children > 2 years old
Group D			
Irritate without redness	Capsaicin 0.025%–0.25% Capsicum oleoresin 0.025%–0.25%	Capzasin-HP, Zostrix	Must use regularly Burning effect subsides with regular use Use in adults only (ages > 18 years old)

[a]Combination products that also contain menthol and/or camphor.

[b]Combination product that also contains capsaicin.

[c]May be used in adults and children age 2 years old and older.

[d]Federal Register recommends to avoid in children less than 2 years old.

INR, international normalized ratio.

Table 60–4

Patient Education for Counterirritants[17]

Apply up to three to four times daily to affected area.
Only for external use on the skin; do not ingest.
Do not apply to broken or damaged skin or cover large areas.
Wash hands immediately after application.
Avoid contact with the eyes and mouth.
Do not use with heating pads or other methods of heat application, because burning or blistering can occur.
Do not wrap or bandage the area tightly after application.
Discontinue product if excessive skin irritation or rash occurs.
Consult a physician if:
- Symptoms worsen
- Symptoms persist for more than 7 days[a] for acute pain
- Symptoms resolve but then recur

[a]Capsaicin is used for chronic pain, and efficacy is evaluated after 2 weeks.

actions, counterirritants should not be combined with topical anesthetics or topical analgesics. KEY CONCEPT Patient education on proper use of counterirritants is essential to therapeutic success (Table 60–4).[17] LO 5

Rubefacients (group A) are counterirritants that produce redness on application. Evidence from clinical trials and a systematic review showed rubefacients to be ineffective for relieving acute pain from strains, sprains, and sports injuries, and for chronic musculoskeletal pain.[29] However, topical rubefacients containing salicylates (eg, methyl salicylate) are still used commonly if a patient does not tolerate or has contraindications to other therapy or prefers an alternative route of administration for acute pain.

Application of methyl salicylate can lead to systemic effects similar to aspirin therapy, especially if the product is applied liberally.[38] Repeated application and occlusion with a wrap or bandage also can increase systemic concentrations. Salicylate-containing products should be used with caution in patients in whom systemic salicylates are contraindicated, such as patients with severe asthma or aspirin allergy.[38] Topical salicylates have been reported to increase prothrombin time in patients on warfarin and should be used with caution in patients on oral anticoagulants. Methyl salicylate, including oil of wintergreen, is a common source of pediatric poisonings.[39,40] LO 3

The group B counterirritants menthol and camphor exert a sensation of cooling through direct action on sensory nerve endings, followed by a sensation of warmth.[38,40] The agents cause a burning sensation by stimulating cutaneous nociceptors.[40] For topical analgesic use, menthol is available in creams, lotions, ointment, and patches. The patches can be trimmed to fit the affected area. Despite limits on the concentration of available products, camphor can be toxic to children even in small amounts, posing a seizure risk.[41]

The group C counterirritants methyl nicotinate and histamine dihydrochloride produce vasodilation.[17] Methyl nicotinate produces PG-mediated vasodilation.[42] NSAIDs and aspirin block the production of PGs and decrease methyl nicotinate–induced vasodilation. Application over a large area has been reported to cause systemic symptoms and syncope, possibly due to vasodilation and a decrease in blood pressure.[43] Patients should be educated to apply only scant amounts to the affected area. LO 5

The primary counterirritant in group D is capsaicin, a natural substance found in red chili peppers.[13,40] Capsaicin stimulates the release of substance P from local sensory nerve fibers, depleting substance P stores over time. A period of reduced sensitivity to painful stimuli follows, and transmission of pain impulses to the CNS is reduced.

As with other counterirritants, capsaicin and its derivatives (capsicum and capsicum oleoresin) exert a warming or burning sensation.[13,40] With repeated application, desensitization occurs, and the burning sensation subsides within the first 1 to 2 weeks. Pain relief is usually noted within 2 to 6 weeks.[13] After discontinuation, resensitization occurs gradually over several weeks for autonomic nerves and 4 to 5 months for sensory nerves.[40]

Because of the lag time between initiation and effect, capsaicin is not used for treatment of acute pain from injury. Topical capsaicin is used for chronic pain from musculoskeletal and neuropathic disorders. Capsaicin preparations have been studied for treatment of pain from diabetic neuropathy, osteoarthritis, postherpetic neuralgia, and other disorders.[13] It is often used as an adjuvant to systemic analgesics in these chronic pain conditions. LO 4

Although systemic adverse effects to capsaicin are rare, local adverse effects are expected and common.[13,40] Patient education regarding consistent use of capsaicin products is essential to achieving desired outcomes. Product should be applied in a thin layer and rubbed into the skin thoroughly until little remains on the surface. KEY CONCEPT Patients using capsaicin should be advised to apply it regularly and consistently three to four times daily and that full effect may take 2 weeks or longer. Patients should be assured that the burning effects will diminish with repeated application. Adherence to therapy is essential because the burning sensation persists if applications are less frequent than recommended. Because the burning sensation is enhanced with heat, patients should avoid hot showers or baths immediately before or after application. Wearing nitrile gloves during application and washing hands immediately after application can decrease the potential for unintended contact with eyes or mucous membranes. Dried product residue has been reported to cause respiratory effects on inhalation (eg, coughing), and caution should be used in patients with asthma or other respiratory illnesses. Transient increases in blood pressure have been noted upon initial application, so it is important to evaluate the patient's cardiovascular status before initiation.[40] LO 5 LO 3

▶ *Oral Muscle Relaxants*

Oral muscle relaxants are a useful adjunct to therapy when pain is worsened by muscle spasm.[13] Antispasmodic agents are preferred over antispastic agents for musculoskeletal pain because antispasmodics exert their effect directly on skeletal muscle fibers, polysynaptic reflexes, and/or descending facilitatory systems; whereas antispastic agents mostly target upper motor neuron conditions. Examples of antispasmodic agents include baclofen, tizanidine, carisoprodol, metaxalone, and cyclobenzaprine. Muscle relaxants decrease spasm and stiffness associated with either acute or chronic musculoskeletal disorders. For low back pain, a systematic review demonstrated that muscle relaxants provide significant acute or subacute pain relief but are not effective in treating chronic low back pain.[24,44] These agents should be used with caution because they all may cause sedation, especially in combination with alcohol or opioid analgesics. Many produce anticholinergic effects, such as xerostomia and blurred vision, and have potential for abuse; therefore, patient-specific factors should be reviewed before recommending muscle relaxants. Sudden discontinuation should be avoided because it may lead to withdrawal symptoms. LO 3

▶ *Opioid Analgesics*

Opioid analgesics may be considered in acute pain management if nonopioid analgesics are already optimized and the patient is still experiencing moderate to severe pain.[21,27] Opioids may be used in combination with nonopioids such as acetaminophen or NSAIDs, but not to exceed the recommended daily dose of the respective nonopioid agent(s). Opioids are not recommended as initial therapy for acute or subacute low back pain, given the low level of evidence of effectiveness in reducing pain. Patients presenting with chronic low back pain, having inadequate response to NSAIDs, duloxetine, or tramadol, may benefit from opioid medications.[24] Given the concern for abuse potential and adverse events with opioids, a full patient medical history is recommended before prescribing. See Chapter 34 (Pain Management) for more information on use of duloxetine, tramadol, and opioids.

▶ *Complementary and Alternative Medicine for Pain Relief*

Various complementary and alternative modalities are available for patients seeking additional or alternative treatments for pain relief.[13] Integrative practices include manipulation therapy, acupuncture, massage therapy, yoga, electrical stimulating currents, low-power laser, hyperbaric oxygen therapy, and ultrasound therapy.[7,9,10,13]

Massage therapy, spinal manipulation, and acupuncture have shown potential benefit in relieving acute or subacute low back pain.[24] Acupuncture and cognitive behavioral therapy have demonstrated moderate benefit in reducing chronic low back pain, whereas massage therapy and spinal manipulation have shown minimal benefit.

Dietary supplements that have been shown to potentially reduce pain and/or inflammation include devil's claw, willow bark extract, aspen or goldenrod, marijuana, and turmeric.[13] Given the mechanisms of action and metabolism of these supplements, it is highly recommended to review potential adverse events, drug interactions, and a patient's current medical history before recommending any of these supplements.[45] Overall evidence of benefit may be limited or conflicting, and patients should be educated on the benefits and risks of these therapies before initiation as additional treatment.[45]

Lifestyle and Behavioral Modifications

After treatment of an acute injury, repetitive strain injury, or low back pain with nonpharmacologic and pharmacologic therapy, the final phase of therapy is rehabilitation and prevention of future injury. For most injuries, prolonged immobilization can lengthen the recovery time by causing wasting of the healthy muscle fibers and increased scarring.[9,21] Rehabilitation starts with decreasing inflammation, then increasing range of motion and flexibility via stretching exercises. The patient should warm the muscle first with light activity or moderate heat. Warmth produces relaxation and increases elasticity. Next, the patient may start general strengthening exercises. The focus of the rehabilitation may not be the injured muscle itself but nearby muscles to assist with stability. End goals of rehabilitation are specific to each patient and may range from return to activities of daily living to a rigorous sports schedule.

After rehabilitation, the patient should be educated about behavior changes to prevent reinjury.[21] The strength and flexibility exercises learned in the rehabilitation phase should be continued. For overuse injury, correction of biomechanical abnormalities with proper footwear and changes in technique may correct misalignments and imbalances.[2,5] Repetitive trauma can be decreased with proper training (eg, a gradual increase in mileage in a running plan).

In the workplace, repetitive motion can be decreased through proper ergonomic design and diversification of job tasks.[8] In pain of the back or lower extremity, weight loss in overweight or obese patients can help to prevent reinjury or repetitive strain injuries.[3,16]

OUTCOME EVALUATION

LO 6

- Use a pain scale to monitor treatment interventions to ensure that pain relief is achieved. Ask the patient to rate pain on a scale of zero (no pain) to 10 (worst possible pain) both at rest and with movement. Compare the results with baseline pain assessment to monitor the response to therapy. In pediatric patients, use a visual pain scale with facial expressions depicting various degrees of pain.

Patient Encounter 1, Part 2: Medical History, Physical Examination, and Diagnostic Tests

PMH/PSH: Appendectomy 10 years ago

SH: Smokes 2 to 3 cigarettes per week socially; drinks 2 to 3 beers Friday and Saturday

Meds: Multivitamin one tablet by mouth daily, fish oil 1000 mg daily

Allergies: Sulfa drugs (rash)

Intolerances: None

Preferences: No preference to topical or oral medications at this time

Diagnostic Tests: Radiographs of right wrist show no evidence of fracture

Pain (numerical rating scale): 5 out of 10

What are your treatment goals and desired outcomes?

What nonpharmacologic and pharmacologic treatment options are available? Are there treatment options that should be avoided? If so, which options and why?

Patient Encounter 1, Part 3: Creating a Care Plan

Based on the information presented, create a care plan to treat this patient's wrist injury. Your plan should include the following:

(a) The goals of therapy and desired outcomes

(b) A patient-specific therapeutic plan, including nonpharmacologic therapy

(c) A plan to monitor the outcome of therapy to determine whether goals of therapy have been met and adverse effects avoided

Patient Encounter 2

A 26-year-old woman presents with left ankle pain. Upon questioning, you find she is an avid runner for the past 4 years, running several marathons, and trains by running at least 6 continuous miles daily every morning. She reports gradual onset of pain over the last few months. When she wakes in the morning, she has minimal pain after resting overnight, but the pain begins to intensify during the middle of her morning run and lasts throughout the day. She denies any swelling. She reports a decreased range of motion compared to her right ankle. She has no significant past medical history and only takes a daily prenatal multivitamin.

Given this information, what is your assessment of the patient's ankle pain? What is the likely etiology of the pain?

What nonpharmacologic and pharmacologic treatment options should be considered?

Based on the information presented, create a care plan for this patient's ankle injury. Your plan should include the following:

(a) The goals of therapy and desired outcomes

(b) A patient-specific therapeutic plan, including nonpharmacologic therapy

(c) A monitoring plan to determine whether goals of therapy have been met and adverse effects avoided

- Assess range of motion at baseline and after treatment by comparing movement with the unaffected limb and functionality before the injury. Assess functionality by asking patients if they are able to perform activities of daily living or participate in exercise as desired.
- If pain from acute injury does not decrease greatly within 7 to 10 days, further diagnostic evaluation is warranted.
- In patients with chronic low back pain, periodically assess the patient for new signs and symptoms that may warrant further workup.
- Assess adherence to recommended treatments for therapeutic benefit. For all products except capsaicin, assess for acute pain relief within 7 days. For topical capsaicin, assess chronic pain control in 2 weeks.
- Assess medication adverse effects on a regular basis. When NSAIDs and aspirin are used, ask about GI tolerability, bruising, and bleeding. Inquire about local adverse effects, such as burning, when topical counterirritants are used for treatment. When oral muscle relaxants are used, inquire about anticholinergic effects such as xerostomia and blurred vision. Refer to Chapter 34 (Pain Management) for opioid side effects.
- Evaluate adherence to preventative rehabilitation measures such as proper footwear, warm-up before activity, strength training, and proper lifting technique.

Patient Care Process

Collect Information:

- Establish the timing of injury (if applicable), duration, type and degree of pain, and exacerbating factors. Ask about interference with usual activities or range of motion.
- Ask the patient about exacerbating or alleviating factors. Inquire if the patient has tried any successful or unsuccessful nonpharmacologic or pharmacologic treatments for the current complaint or for this condition in the past.
- Obtain a complete medication history, including prescription and nonprescription drugs and dietary supplement use. Gather patient history, including social history and alcohol use. Inquire about drug allergies and chronic health problems such as asthma. Collect physical assessment and laboratory data when available.
- Inquire about patient preference for systemic (oral) or local (topical) therapy including acceptability of topical medication with frequent application and/or a medicinal odor. Identify the patient's goals, beliefs, lifestyle habits, and socioeconomic factors relevant to development of care plan.

Assess the Information:

- Assess the efficacy, safety, and patient adherence of any nonprescription or prescription medications currently being used for the condition and consider alignment with patient preferences for therapy.
- Based on review of symptoms and timing, assess whether empirical care or diagnostic evaluation is appropriate and whether pharmacologic therapy is warranted.

Develop a Care Plan:

- Develop goals of therapy in collaboration with the patient.
- Determine if referral to another health care provider on the team is warranted based on the symptoms provided.
- Recommend nonpharmacologic and pharmacologic therapy appropriate for the specific patient (Tables 60–1, 60-2, and 60–3; Figure 60–1).

Implement the Care Plan:

- Educate the patient on nonpharmacologic therapy for the presenting pain type when appropriate (Tables 60–1 and 60–2).
- Educate on proper use of oral or topical agents selected (Table 60–4). If a counterirritant is recommended, counsel patients on the irritant effect of the product and recommend washing hands immediately after use and to avoid heating pads. For patients using a capsaicin product, emphasize adherence.
- Coordinate any referrals, when applicable.

Follow-up: Monitor and Evaluate:

- If pain is from an acute injury, assess effectiveness within 7 to 10 days. For chronic pain treated with capsaicin, begin to assess pain control in 2 weeks.
- Evaluate for adherence, adverse effects (systemic or local), and drug interactions.

Patient Encounter 3

A 67-year-old man presents with left shoulder pain. He states he was at his daughter's house yesterday and tripped on one of his grandson's toys. As he fell, his weight was placed on his left arm and shoulder. He reports decreased range of motion compared to his right shoulder and mild swelling.

PMH/PSH: Hypertension, dyslipidemia

SH: Nonsmoker, 1 glass of wine on holidays

Meds: Lisinopril 10 mg one tablet orally daily, atorvastatin 10 mg one tablet orally daily, aspirin 81 mg one tablet orally daily, multivitamin one tablet orally daily

Allergies: NKDA

Intolerances: NSAIDs, stomach upset

Preferences: Prefers topical medications

Vital signs: BP 160/92 today

Diagnostic Tests: None

Pain (numerical rating scale): 3 out of 10. Pain worsens to 4 out of 10 with weight or lifting.

Given this information, what is your assessment of the patient's shoulder pain? What is the likely etiology of the pain?

What nonpharmacologic and pharmacologic treatment options should be considered?

Based on the information presented, create a care plan for this patient's shoulder injury. Your plan should include:

(a) Goals of therapy and desired outcomes

(b) Patient-specific therapeutic plan, including nonpharmacologic therapy

(c) A plan to monitor the outcome of therapy to determine whether goals of therapy have been met and adverse effects avoided

Abbreviations Introduced in This Chapter

CNS	Central nervous system
COX	Cyclooxygenase
FDA	Food and Drug Administration
GI	Gastrointestinal
NSAIDs	Nonsteroidal anti-inflammatory drugs
OTC	Over-the-counter
PG	Prostaglandin
RICE	Rest, ice, compression, and elevation

61 Glaucoma

Mikael D. Jones

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

LO

1. Identify risk factors for the development of primary open-angle glaucoma (POAG) and acute angle-closure glaucoma.
2. Recommend a frequency for glaucoma screening based on patient-specific risk factors.
3. Compare and contrast the pathophysiologic mechanisms responsible for open-angle glaucoma and acute angle-closure glaucoma.
4. Outline the clinical presentation of chronic open-angle glaucoma and acute angle-closure glaucoma.
5. List the goals of managing patients with POAG suspect, POAG, and acute angle-closure glaucoma.
6. Choose the most appropriate therapy based on patient-specific data for open-angle glaucoma, glaucoma suspect, and acute angle-closure glaucoma.
7. Develop a monitoring plan for patients on specific pharmacologic regimens.
8. Counsel patients about glaucoma, drug therapy options, ophthalmic administration techniques, and the importance of adherence to the prescribed regimen.

INTRODUCTION

Glaucoma refers to a spectrum of ophthalmic disorders characterized by neuropathy of the optic nerve and loss of retinal ganglion cells, which typically leads to permanent deterioration of the visual field (peripheral vision) initially and potentially total vision loss (including central vision). It is often, but not always, eye pressure related.[1-3] Table 61–1 describes the general classification of glaucoma. *Glaucoma Suspects* are patients with a higher than average risk of developing glaucoma because of the presence of certain clinical findings, risk factors, family history, or racial background. Glaucoma suspects can be further classified as open-angle glaucoma suspects or angle-closure glaucoma suspects.

Primary Open-Angle Glaucoma (POAG) and Primary Angle-Closure Glaucoma (PACG) represent the most common types of glaucoma and therefore are the focus of this chapter. PACG can present clinically as acute angle-closure crisis (AACC). AACC is the sudden obstruction of the trabecular meshwork, which leads to a rapid increases in IOP resulting in pressure-induced optic neuropathy if untreated.[1-4] KEY CONCEPT In contrast, patients with POAG typically have a slow, insidious loss of vision which is often asymptomatic until the latter stage of the disease process. This is contrasted by the course of AACC, which can lead to rapid and painful vision loss that develops over hours to days.

EPIDEMIOLOGY AND ETIOLOGY

LO 1

It is estimated that almost 65 million people had glaucoma in 2013, making it the second leading cause of blindness after cataracts. By 2040 this number may increase to greater than 110 million people worldwide.[5] In North America it is estimated that almost 3 million people are affected by POAG, and by 2040 this number will increase to 4.2 million.[5] The prevalence varies with race and ethnicity, and it is three to five times more prevalent in African Americans than white Americans.[6] The prevalence of POAG increases with age and is rarely seen in patients younger than 40 years.[6,7] The prevalence of POAG suspects is difficult to estimate at this time, but it is expected that 3.5% to 4.5% of white and Hispanic patients older than 40 years have ocular hypertension.[2]

Approximately 20 million people were estimated to have angle-closure glaucoma in 2013, and this is projected to increase to 32 million people by 2040.[5] The prevalence of angle-closure glaucoma is lower than POAG and varies significantly by race and ethnicity. The prevalence is lower in patients of European ancestry (0.4%) but higher in patients of Asian ancestry (1.2%).[5] PACG is also more prevalent with increasing age and among females.[4]

PATHOPHYSIOLOGY

The pathophysiology of glaucomatous neurodegeneration has not been completely elucidated, but appears to be caused by both IOP-dependent and IOP-independent factors. Elevated IOP is clearly associated with damage and eventual death of optic nerves; however, optic neuropathy can occur in patients without elevated IOP which indicates the presence of independent factors that contribute to ganglion cell death.[8,9] The key to understanding the pathophysiology and treatment of glaucoma relies on an understanding of aqueous humor dynamics, IOP, and optic nerve anatomy and physiology.

Aqueous Humor and Intraocular Pressure

Intraocular pressure (IOP) maintains the curvature of the cornea which is important for the refractive properties of the eye.[10] The distribution of IOP in the general population is 10 to 21 mm Hg (1.3–2.8 kPa) and is slightly skewed toward higher values. However, caution should be used in assigning this as the "normal range" for IOP because some patients may have

Table 61–1

Glaucoma Classifications[3,4]

Classification	Description
Primary glaucoma	Glaucoma that cannot be attributed to a preexisting ocular or systemic disease
Secondary glaucoma	Glaucoma that can be attributed to preexisting ocular or systemic disease. Examples include pigment dispersion syndrome, neovascular glaucoma, and pseudoexfoliative syndrome.
Open-angle glaucoma	Glaucoma characterized by normal anterior-chamber angles and glaucomatous changes of the optic disc. Can be further classified as primary or secondary.
Angle-closure glaucoma	Glaucoma characterized by the obstruction of the anterior chamber angle resulting in either intermittent or progressive elevated IOP with subsequent damage to the optic nerve. Can be further classified as primary or secondary.

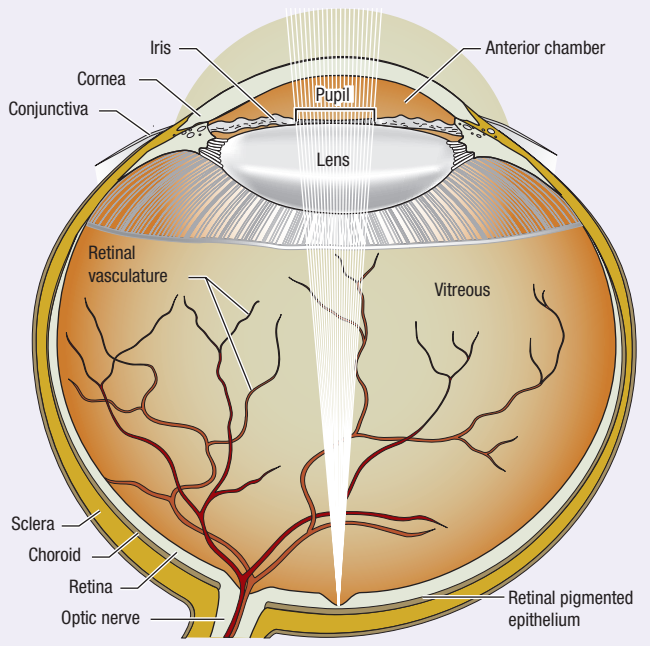

FIGURE 61–1. Anatomy of the eye. (From Fiscella RG, Lesar TS, Owaidhah OA, et al. Glaucoma In: Dipiro JT, Talbert RL, Yee GC, et al, eds. Pharmacotherapy: A Pathophysiologic Approach. 10th ed. New York, NY: McGraw-Hill; 2017: Figure 94–1; with permission.)

optic neuropathy in the "normal range" while for other patients optic neuropathy may be absent at higher IOPs. Elevated IOP is generally considered greater than 21 mm Hg (2.8 kPa).[11]

Aqueous humor is an optically neutral fluid that provides oxygen and nutrition to the avascular lens and cornea. IOP is dependent on the balance between aqueous humor production and outflow from the anterior segment (Figures 61–1 and 61–2). The anterior segment of the eye is separated by the iris into the posterior and anterior chambers. The ciliary body is a ring-like structure that surrounds and supports the lens. It also produces aqueous humor through the diffusion and ultrafiltration of plasma. The nonpigmented epithelium of the ciliary body secretes the aqueous humor into the posterior chamber. Aqueous humor production can be modified pharmacologically through the α- and β-adrenoceptors, carbonic anhydrase, and sodium and potassium adenosine triphosphatase of the nonpigmented ciliary epithelium.[12,13]

After secretion, the aqueous humor flows from the posterior chamber through the pupil into the anterior chamber. From the

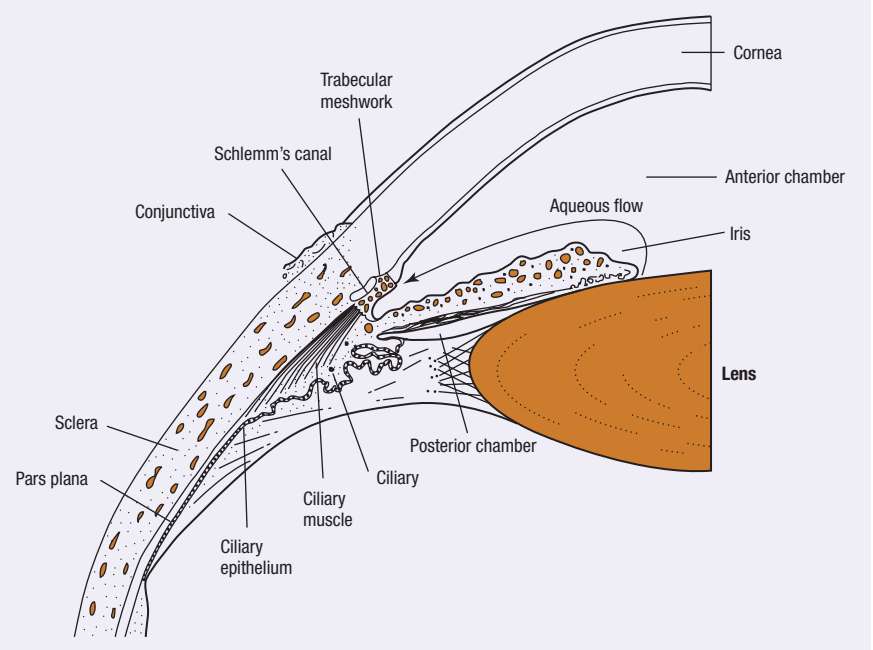

FIGURE 61–2. Anterior chamber of the eye and aqueous humor flow. (From Fiscella RG, Lesar TS, Owaidhah OA, et al. Glaucoma In: Dipiro JT, Talbert RL, Yee GC, et al, eds. Pharmacotherapy: A Pathophysiologic Approach. 10th ed. New York, NY: McGraw-Hill; 2017: Figure 94–2; with permission.)

anterior chamber, approximately 80% of aqueous humor then exits through the trabecular meshwork while the remaining 20% exits through the uveoscleral pathway.[12,13]

The trabecular meshwork is a lattice of connective tissue that surrounds peripheral edge of the anterior chamber located in the inside intersection of the edge of the cornea and the iris insertion. The size of the trabecular meshwork can be altered by the contraction or the relaxation of the ciliary muscle. Stimulation of muscarinic receptors on the ciliary muscle causes contraction, which in turn causes the pores of the trabecular meshwork to open, increasing aqueous humor outflow into Schlemm canal and the episcleral venous system.[12] The contraction can also be decreased by inhibiting Rho Kinases which are involved in the regulation of the contractile tone of the trabecular meshwork tissue.[13]

In the uveoscleral pathway, aqueous humor exits the anterior chamber through the iris root and through spaces in the ciliary muscles, which then drain into the suprachoroidal space. Uveoscleral outflow can be pharmacologically modulated by adrenoceptors, prostanoid receptors, and prostamide receptors.[10,14]

Optic Nerve

In the posterior segment of the eye, retinal ganglion cells are responsible for transmitting visual signaling from the retina to the brain. The axons of the retinal ganglion cells converge at the retinal nerve fiber layer to form the optic nerve. The optic nerve head (also called the optic disc) is the portion of the optic nerve that is visible on funduscopic examination. The optic nerve head is vertically oval and pink to pale yellow with a depression in the center of the optic nerve, called a physiologic cup, which is formed as the axons converge and exit the eye as a bundle through the **lamina cribrosa** (**Figure 61–3**). The optic nerve synapses at the lateral **geniculate nucleus** in the brain.[8,9,15,16]

Pathophysiology of Open-Angle Glaucoma

LO 3

In patients with POAG, the cause of elevated IOP is not obvious, as obstruction in aqueous humor outflow is not clinically discernible. Possible causes of this increased IOP may be related to an increase in outflow resistance in the trabecular meshwork.[8,9,13,15]

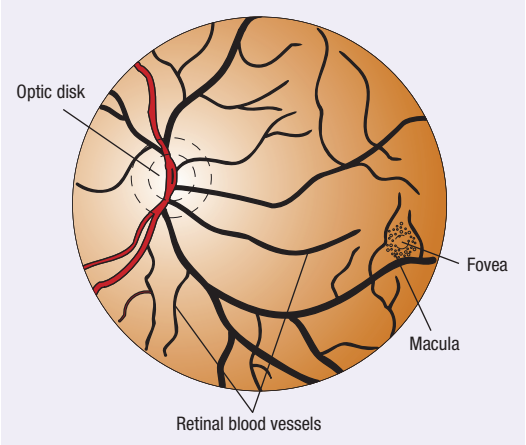

FIGURE 61–3. Normal fundus of the eye and optic disk and cup. (From Fiscella RG, Lesar TS, Owaidhah OA, et al. Glaucoma In: Dipiro JT, Talbert RL, Yee GC, et al, eds. Pharmacotherapy: A Pathophysiologic Approach. 10th ed. New York, NY: McGraw-Hill; 2017: Figure 94–3; with permission.)

LO 3

Glaucomatous optic neuropathy may also occur independent of increased IOP. Pressure independent causes of optic neuropathy include abnormal ocular perfusion, oxidative stress, and inflammation.[8,9,11,15]

Regardless of the underlying cause, elevated IOP initiates several detrimental changes to glial cells, the lamina cribrosa, and retinal ganglion cells. The increase in IOP can lead to alterations in retinal blood flow and axonal transport of neurotrophic factors, resulting in cellular stress of the retinal ganglion cells. This stress activates the glial cells in a manner that leads to inappropriate remodeling of the extracellular matrix. Elevated IOP deforms the lamina cribrosa, which places mechanical strain on the retinal ganglion cells. Chronic elevation of IOP ultimately causes the retinal ganglion cells to undergo apoptosis.[8,9,15,17,18]

Current glaucoma therapies fail to target IOP-independent glaucoma pathophysiologic factors. However, IOP reduction may still be beneficial, as the rate of visual field progression is decreased in many patients who exhibit IOP reduction via medical or surgical modalities.[3,8]

Pathophysiology of Angle-Closure Glaucoma

LO 3

PACG involves a mechanical obstruction of aqueous humor outflow through the trabecular meshwork by the peripheral iris. Two major mechanisms of trabecular meshwork obstruction by the peripheral iris include pupillary block and an abnormality of the iris called *iris plateau*. Pupillary block is the more common mechanism of obstruction and results from a complete or functional apposition of the central iris to the anterior lens and is associated with mid-dilation of the pupil. The trapped aqueous humor in the posterior chamber increases pressure behind the iris, causing the peripheral iris to bow forward and obstruct the trabecular meshwork. Plateau iris refers to an anterior displacement of the peripheral iris caused by anteriorly positioned ciliary processes. In this configuration, the peripheral iris bunches as the eye dilates. Both of these mechanisms result in the occlusion of aqueous humor outflow, causing IOP elevation at extreme levels that can lead to vision loss in hours to days.[4,8,19] The degree of iridotrabecular contact (angle closure) can be assessed by visualizing the anatomy of the iridocorneal angle by an examination technique called **gonioscopy**.

Patient Encounter Part 1

LN, a 65-year-old Hispanic female with a history of asthma and hypertension, presents to your clinic for her yearly checkup. She states that she is concerned about losing her eyesight because her older sister has started losing her vision from glaucoma. She denies any changes in her vision.

Meds: Budesonide 160 mcg/formoterol 4.5 mcg meter dose inhaler two inhalations twice daily, Albuterol HFA MDI 1-2 puffs every 4 to 6 hours as needed, and Ramipril 5 mg orally twice daily.

Based on the patient's medical and family history, what risk factors does this patient have for glaucoma?

What objective assessments should be gathered in order to fully evaluate her risk factors for glaucoma?

How often would you recommend that this patient receive a comprehensive eye evaluation?

Table 61–2

Recommended Frequency of Comprehensive Adult Medical Eye Evaluation[21]

Age (Years)	With Risk Factors for Glaucoma	No Known Risk Factors for Ocular Disease
65 or above	1–2 years	1–2 years
55–64	1–2 years	1–3 years
40–54	1–3 years	2–4 years
Under 40	1–2 years	5–10 years

Data from Feder RS, Olsen TW, Prum BE, Jr., et al. Comprehensive Adult Medical Eye Evaluation Preferred Practice Pattern® Guidelines. Ophthalmol. 2016;123(1):P209–P236.

Table 61–3

Risk Factors for Glaucoma[3,4]

POAG	PACG
Elevated IOP	Advancing age
African or Hispanic descent	Asian or Eskimo ethnicity
Family history of glaucoma	Female sex
Older age	Hyperopia
Thinner CCT	Shallow anterior chamber
Type 2 diabetes	Family history of angle-closure glaucoma
Low ocular perfusion pressures	
Myopia	

CCT, central corneal thickness; IOP, intraocular pressure; PACG, primary angle-closure glaucoma; POAG, primary open-angle glaucoma.

CLINICAL PRESENTATION AND DIAGNOSIS

Risk Factor Evaluation

For POAG, only 4% to 8% of patients may progress to legal blindness. Vision loss does not occur until there has been significant loss of the retinal ganglion cells. It may take 13 to 16 years for a patient to go blind from glaucoma. A patient's quality of life may not be affected until significant visual field loss is present and the patient can no longer perform the activities of daily living.[20] KEY CONCEPT Practitioners can play an important role in eye care by assessing patients for risk factors and referring to an eye care specialist for appropriate screening and evaluation. Risk factor evaluation is essential in determining the frequency of comprehensive eye examinations for patients (Table 61–2).[21] Glaucoma risk factors are also useful in deciding when to start therapy and determining the sequence of pharmacotherapeutic or surgical treatment modalities.[2-4] Table 61–3 lists the major risk factors associated with POAG and PACG.

LO 4

The development of PACG is associated with several anatomical risk factors that lead to shallow anterior chambers. PACG patients may have a thick, anteriorly displaced lens that results from continued growth of the lens and/or cataractous changes. The anterior chamber depth is typically shallower in many individuals with PACG, which predisposes these eyes to anatomically narrower iridocorneal inlets that are a set-up for developing critically narrow angles more susceptible to closure (from an enlarging cataractous lens or other insults).[4,19]

Patients with PACG are characterized by at least 180 degrees of iridotrabecular contact, elevated IOP, and ophthalmic examination characteristic of glaucomatous changes. Recurrent attacks or a prolonged acute attack can lead to the development of peripheral anterior synechia, which partially obstructs the flow of aqueous humor through the trabecular meshwork.[4,19]

TREATMENT

Primary Open-Angle Glaucoma

► *Desired Outcomes and Goals*

LO 5

KEY CONCEPT The goals of therapy are to prevent further loss of visual function; minimize adverse effects of therapy and impact on the patient's vision, general health, and quality of life; maintain IOP at or below a pressure at which further optic nerve damage

Clinical Presentation and Diagnosis of POAG

General

- Adult onset (usually > 40 years of age)
- Patients may be unaware that they have glaucoma and may be diagnosed during routine eye evaluation
- POAG is usually bilateral with asymmetric disease progression

Symptoms

- Patients with severe disease progression may report loss of peripheral vision ("tunnel vision") and may describe the presence of paracentral, nasal, and arcuate scotoma (blind spots) in their field of vision

Signs

Ophthalmoscopic examination may reveal:

- Optic nerve head (optic disc) cupping
- Large cup-to-disc ratio
- Diffuse thinning, focal narrowing, or notching of the optic nerve head rim
- Splinter hemorrhages
- Optic nerve head/nerve fiber layer changes occur before visual field changes can be detected

Diagnostic Tests

- Gonioscopy—anterior-chamber angles are to be open.
- Applanation tonometry—elevated IOP (> 21 mm Hg [2.8 kPa]) may be present. However, patient can have signs of optic neuropathy without elevated IOP.
- Pachymetry—measures central corneal thickness. Thin corneas (< 540 µm) are considered a glaucoma risk factor.
- Automated static threshold perimetry—evaluates visual fields. Can detect defects in the visual field before a patient may notice.
- Other diagnostic tests—scanning laser polarimetry, confocal scanning laser ophthalmoscopy, and optical coherence tomography.

is unlikely to occur; and educate and involve the patient in the management of their disease. KEY CONCEPT Current therapy is directed at altering the flow and production of aqueous humor, which is the major determinant of IOP.

▶ General Approach

KEY CONCEPT Because POAG is a chronic, often asymptomatic condition, the decision of when and how to treat patients is difficult, as the treatment modalities are often expensive and have potential adverse effects or complications. Currently lowering IOP is the best method to reduce the risk of visual field loss.[1,22] The clinician should evaluate the potential effectiveness, toxicity, and the likelihood of patient adherence for each therapeutic modality. The ideal therapeutic regimen should have maximal effectiveness and patient tolerance to achieve the desired therapeutic response. The American Academy of Ophthalmology (AAO) publishes Preferred Practice Patterns for POAG and POAG Suspect.[2,3]

Before the selection of a therapeutic modality, the target IOP should be determined for each patient. The target IOP ideally represents an IOP range that will slow the progression of optic neuropathy and not simply obtain an IOP in the range of 10 to 21 mm Hg (1.3–2.8 kPa). Currently, the initial target IOP is an estimate, but it should be modified based on the progression of the disease at each follow-up visit (treatment is individualized).

LO 6 KEY CONCEPT The AAO recommends an initial target IOP to be set at least 25% lower than the patient's baseline IOP. The target IOP can be set lower (30%–50% of baseline IOP) for patients who already have severe disease, risk factors for disease progression, or have normal-tension glaucoma (NTG).[3,23] Risk factors for progression include high IOP, older age, hemorrhage of the optic disc, large cup-to-disc ratio, thinner CCT (central corneal thickness), and established glaucomatous progression (velocity of disease progression is nonlinear).

LO 6 Initial IOP control can be achieved by medical, laser, surgical, or combination of these therapies. The AAO guidelines[3] do not provide a specific recommendation on which therapeutic modality should be selected first, but patients in the early stages

LO 6 of glaucoma should receive treatment. In general, medical and laser trabeculoplasty are preferred as early treatment options over surgical as surgical interventions are not without potential intraoperative or postoperative complications.[22] The ophthalmologist will individualize therapy based on the risk and benefits for a specific patient. Table 61–4 describes nonpharmacologic treatment modalities for POAG.[3]

LO 6 Medical treatment is the most commonly selected therapeutic modality. A well-tolerated ocular antihypertensive, at the lowest concentration, should be selected as the initial mediation (Table 61–5). The ocular hypotensive lipids are preferred first-line agents since they are the most effective at lowering at IOP of both peak and trough measurements by at least 25% of baseline IOP.[24-28] Additionally, these agents lack systemic side effects and are dosed once-daily. If monotherapy alone lowers IOP but does not reach target pressure or there is evidence of progression, then combination therapy or switching to another agent is appropriate. The addition of a second agent from another class generally has an additive effect

LO 6 on IOP reduction. The ocular hypotensive lipids, timolol, carbonic anhydrase inhibitors, or brimonidine are reasonable choices for addition as a second agent.[3,8,11] Combination eye-drops reduce the number of drops that need to be administered. Increasing the concentration or dose frequency can also be tried when possible. Adverse effects can be caused by an eye drop's therapeutic agent or inactive excipients, such as preservatives. Benzalkonium chloride is a common eye drop preservative that has been associated with superficial punctate keratitis, corneal erosion, and conjunctival allergy. Intolerances to preservatives can be resolved by changing to a preservative-free eye drop.[29] Figure 61–4 presents an algorithm to select and optimize POAG treatment.

A uniocular trial can be used to assess the safety and effectiveness of a topical medication before initiation in both eyes; however, uniocular drug trials do not always predict the IOP response of the second eye. Ideally, the effectiveness of a medication should be assessed independently using baseline IOP measurements.

Table 61–4

Select Nonpharmacologic Treatment Options for POAG[3,4,14]

Treatment Option	Description
Laser trabeculoplasty	Laser energy aimed at trabecular meshwork Improves aqueous humor outflow
Trabeculectomy	Surgical removal of a portion of the trabecular meshwork Improves aqueous humor outflow Mitomycin C and fluorouracil are used to decrease scarring
Cyclodestructive surgery	Trans-scleral laser reduces rate of aqueous humor production Reserved for patients who have failed other options
Aqueous shunts	Drainage device that redirects the outflow of aqueous humor through a small tube into an outlet chamber placed underneath the conjunctiva

▶ Treatment Considerations for POAG Suspects

LO 6 POAG suspects should be considered for topical medication therapy if they are at high risk for developing POAG or have a high IOP in which glaucomatous nerve damage is likely to occur. POAG suspects that develop evidence of glaucomatous damage or visual field defect have developed POAG and should be treated accordingly.[2] The Ocular Hypertension Treatment Study (OHTS) demonstrated that a 20% decrease in IOP can reduce the progression from ocular hypertension to POAG over a 5-year period. The incidence of progression to POAG in the treatment (4.4%) and control (9.5%) groups was small, which underscores the importance of selecting patients at high risk of progressing

LO 6 to POAG.[30] When medical therapy is indicated, a well-tolerated agent should be selected and optimized following the POAG treatment algorithm (Figure 61–4). The benefit of therapy should be reassessed in patients who may require third- or fourth-line agents to control IOP. Surgical or laser intervention are not indicated in the treatment of glaucoma suspects.[2]

Primary Angle-Closure Glaucoma

▶ Desired Outcomes and Goals

LO 5 Therapeutic modalities for PACG are targeted at decreasing IOP. The goals of therapy are to preserve visual function by controlling the elevation in IOP, prevent damage to the optic nerve, and manage or prevent an acute attack of angle closure.[4]

▶ General Approach

LO 6 KEY CONCEPT Acute angle-closure crisis is a medical emergency and requires urgent laser or surgical intervention. The treatment of choice for PACG is peripheral laser iridotomy. Laser iridotomy

TABLE 61–5

Pharmacologic Treatment Options for Primary Open Angle Glaucoma

Drug	Pharmacologic Properties	Common Brand Names	Dose Form	Strength (%)	Usual Dose[a]	Mechanism of Action
β-Adrenergic Blocking Agents						
Betaxolol	Relative β_1-selective	Generic	Solution	0.5	One drop twice a day	All reduce aqueous production of ciliary body
		Betoptic-S	Suspension	0.25	One drop twice a day	
Carteolol	Nonselective, intrinsic sympathomimetic activity	Generic	Solution	1	One drop twice a day	
Levobunolol	Nonselective	Betagan	Solution	0.25, 0.5	One drop twice a day	
Metipranolol	Nonselective	OptiPranolol	Solution	0.3	One drop twice a day	
Timolol	Nonselective	Timoptic, Betimol, Istalol	Solution	0.25, 0.5	One drop every day—one to two times a day	
		Timoptic-XE	Gelling solution	0.25, 0.5	One drop every day[a]	
Adrenergic Agonists						
Nonspecific Adrenergic Agent						
Dipivefrin[b]	Epinephrine prodrug	Propine	Solution	0.1	One drop twice a day	Increased aqueous humor outflow
α_2-Adrenergic Agonists						
Apraclonidine	Specific α_2-agonists	Iopidine	Solution	0.5 (U.D.), 1	One drop two to three times a day	Both reduce aqueous humor production; brimonidine known to also increase uveoscleral outflow; only brimonidine has primary indication
Brimonidine		Alphagan P	Solution	0.2 (generic) 0.15 (brand/generic), 0.1	One drop two to three times a day	
Cholinergic Agonists Direct Acting						
Carbachol[b]	Irreversible	Carboptic, Isopto Carbachol	Solution	1.5, 3	One drop two to three times a day	All increase aqueous humor outflow through trabecular meshwork
Pilocarpine	Irreversible	Isopto Carpine, Pilocar	Solution	0.5, 1, 2, 4, 6	One drop two to three times a day One drop four times a day	
		Pilopine HS[b]	Gel	4	Every 24 hours at bedtime	
Cholinesterase Inhibitors						
Echothiophate[b]		Phospholine Iodide	Solution	0.125	Once or twice a day	
Carbonic Anhydrase Inhibitors						
Topical						
Brinzolamide	All carbonic anhydrase inhibition	Azopt	Suspension	1	Two to three times a day	All reduce aqueous humor production of ciliary body
Dorzolamide		Trusopt Generic	Solution	2	Two to three times a day	

(*Continued*)

TABLE 61–5

Pharmacologic Treatment Options for Primary Open Angle Glaucoma (*Continued*)

Drug	Pharmacologic Properties	Common Brand Names	Dose Form	Strength (%)	Usual Dose[a]	Mechanism of Action
Systemic						
Acetazolamide		Generic	Tablet	125 mg, 250 mg	125-250 mg two to four times a day	
			Injection	500 mg/vial	250-500 mg	
		Diamox Sequels	Capsule	500 mg	500 mg twice a day	
Methazolamide		Generic	Tablet	25 mg, 50 mg	25-50 mg two to three times a day	
Prostaglandin Analogs						
Latanoprost	Prostanoid agonist	Xalatan	Solution	0.005	One drop every night	Increases aqueous uveoscleral outflow and to a lesser extent trabecular outflow
Bimatoprost	Prostamide agonist	Lumigan	Solution	0.01, 0.03	One drop every night	
Travoprost	Prostanoid agonist	Travatan Z	Solution	0.004	One drop every night	
Tafluprost	Prostanoid agonist	Zioptan	Preservative free solution	0.0015	One drop every night	
Combinations						
Timolol–dorzolamide		Cosopt Generic	Solution	Timolol 0.5 dorzolamide 2	One drop twice daily	Reduce aqueous production

[a]Use of eyelid closure (ELC) technique for 5 minutes will increase the drug availability and reduce potential for local and systemic side effects.

[b]Often used as fourth-line agents; limited or no commerical availability.

[c]Not available in the United States.

Adapted from Fiscella RG, Lesar TS, Owaidhah OA, et al. Glaucoma In: Dipiro JT, Talbert RL, Yee GC, et al, eds. Pharmacotherapy: A Pathophysiologic Approach. 10th ed. New York, NY: McGraw-Hill; 2017: Table 94–4; with permission.

uses laser energy to cut a hole into the iris to alleviate the aqueous humor buildup behind the iris, resulting in reversal of appositional angle closure. Patients currently experiencing an acute angle-closure crisis should receive medical therapy to lower IOP, reduce pain, and reverse corneal edema before the iridotomy. IOP should first be lowered with topical β-blockers, topical α-agonist, prostaglandin $F_{2\alpha}$ analog, systemic carbonic anhydrase inhibitors, or hyperosmotic agents. Once the IOP has been controlled, miotics (ie, pilocarpine) can be used to break the pupillary block. A topical IOP-lowering agent should be continued to control IOP until laser iridotomy can be performed. Corneal indentation with a cotton-tipped applicator or gonioscopic lens may break pupillary block. If laser iridotomy cannot be performed, then surgical incisional iridectomy is used. Incisional iridectomy is the surgical removal of a small portion of the peripheral iris to allow flow of aqueous humor trapped in the posterior chamber to migrate to the anterior chamber (bypassing the normal flow pattern through the pupil). Topical corticosteroid may be employed to decrease inflammation postoperatively. The fellow eye is at high risk to develop an acute attack and should receive prophylactic iridotomy within a reasonable interval of time. Lens extraction surgery may be another treatment modality as it increases the anterior chamber depth. PACG patients may require chronic medical therapy if the patient has PACG

Clinical Presentation and Diagnosis of Acute Angle-Closure Crisis

General
- Medical emergency due to high risk of vision loss
- Unilateral in presentation, but fellow eye is at risk

Symptoms
- Ocular pain
- Red eye
- Blurry vision
- Halos around lights
- Systemic symptoms may develop
  - Nausea/vomiting
  - Abdominal pain
  - Headache
  - Diaphoresis

Signs
- Cloudy cornea caused by corneal edema
- Conjunctival hyperemia
- Pupil semidilated and fixed to light
- Eye will be harder on palpation through closed eye

Diagnostic Tests
- Gonioscopy—anterior-chamber angles will be closed. Peripheral anterior synechiae may be present.
- Applanation tonometry—elevated IOP (> 21 mm Hg [2.8 kPa], but when symptoms are present, IOP may be > 30 mm Hg [4.0 kPa])
- Slit-lamp biomicroscopy—reveals shallow anterior-chamber depth. Signs of previous attacks include peripheral anterior synechiae, iris atrophy, and pupillary dysfunction

superimposed on preexisting POAG or if synechia formation causes reduced outflow with a continued increase in IOP.[4,8,19]

Pharmacologic Therapy

▶ *Ocular Hypotensive Lipids*

LO 6

The ocular hypotensive lipids in typical ophthalmology practice are considered first-line agents along with β-blockers because of their superior efficacy and safety profiles. Many clinicians may choose to use the ocular hypotensive lipids as first line, especially in patients who have an initial requirement to lower IOP by greater than 25%.[27,28,31,32] All four of the available agents currently have an FDA indication for both POAG and ocular hypertension. Latanoprost and travoprost have dosing aids that help patients administer each medication. Travoprost and tafluprost are available as benzalkonium chloride–free solutions.

Latanoprost, travoprost, tafluprost are analogs of prostaglandin $F_{2\alpha}$ and are agonists of the prostanoid FP receptor, which appears to lower IOP by increasing aqueous humor outflow through the uveoscleral pathway. Bimatoprost is a prostamide analog and appears to lower IOP by activating prostamide receptors in the uveoscleral pathway and possibly through increasing outflow through the trabecular meshwork. The exact mechanism of how uveoscleral outflow is increased is still unclear, but stimulation of prostanoid FP receptors and prostamide receptors in the ciliary body cause remodeling of the extracellular matrix, making it more permeable to aqueous humor, thus increasing aqueous humor outflow through the ciliary muscles.[31,33,34]

The ocular hypotensive lipids are administered once daily at bedtime and should not be increased to twice daily, as this may decrease effectiveness. The ocular hypotensive lipids can provide a consistent reduction in IOP over a 24-hour period.[32] For patients nonresponsive to latanoprost, switching to IOP goal, presumably because of the proposed difference in the site of action of each drug.[35,36]

The ocular hypotensive lipids are well tolerated and rarely cause systemic side effects (headache has been reported). Local effects include conjunctival hyperemia, stinging on instillation, increase in iris pigmentation, deepening of the upper eyelid sulcus, hypertrichosis, and darkening of the eyelashes. Increases in iris pigmentation occur most commonly in patients with multicolored irides on long-term prostaglandin analog therapy. The mechanism of this effect is by its action on melanocytes of the iris, in which the irides become darker because of increased production of melanin in the iris.[29] Increased iris pigmentation appears to be only a cosmetic effect but may affect your product selection, especially when choosing monocular therapy. Conjunctival hyperemia or engorgement of conjunctival blood vessels is a common adverse effect caused by a vasodilatory effect on scleral blood vessels. It is most prominent early in therapy and usually subsides over time. Although generally a benign adverse effect, patients may have a concern if it affects their cosmetic appearance.[29,31]

The ocular hypotensive lipids should be used with caution in patients, since they may worsen anterior uveitis and herpetic keratitis. Cystoid macular edema has been reported during treatment with the ocular hypotensive lipids; therefore, use caution in patients with intraocular inflammation, aphakic patients, pseudophakic patients with a history of intraoperative complications (eg, torn posterior lens capsule), or in patients with risk factors for macular edema.[29]

LO 8

Patients prescribed ocular hypotensive lipids should be counseled on potential adverse effects and appropriate administration. Patients receiving latanoprost or tafluprost should be instructed to refrigerate unopened medication. Once open latanoprost can be stored at room temperature for 6 weeks. Tafluprost single-use containers can be stored at room temperature for up to 28 days.

▶ *β-Adrenergic Antagonists*

LO 6

Topical β-adrenergic antagonists (β-blockers) are now considered a second-line agent after the prostaglandin analogues for the treatment of POAG unless contraindications are present.[3,8] Topical β-blockers decrease IOP by reducing the formation of aqueous humor made by the ciliary body, which results in a 20% to 35% reduction in IOP.[27,28,31,32] Timolol, levobunolol, metipranolol, and carteolol are nonselective for β_1- and β_2-adrenergic receptors, whereas betaxolol has β_1-selective properties.[31,32] Betaxolol reduces IOP to a lesser extent than the nonselective β-blockers,

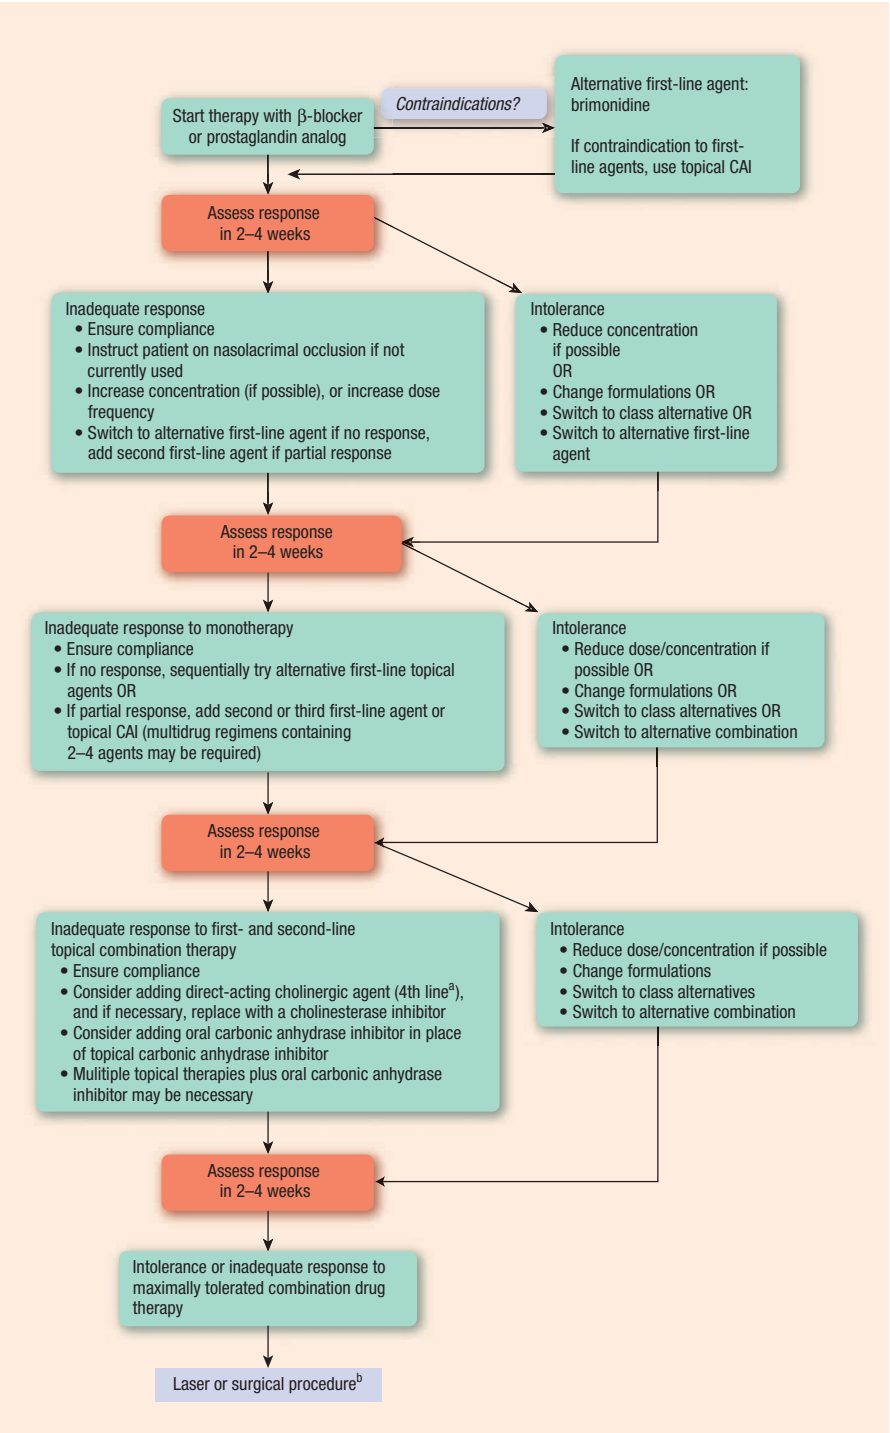

FIGURE 61–4. Algorithm for the pharmacotherapy of open-angle glaucoma. [a]Fourth-line agents not commonly used any longer or commercially unavailable. [b]Most clinicians believe the laser procedure should be performed earlier (eg, after three-drug maximum, poorly adherent patient). (CAI, carbonic anhydrase inhibitor.) (From Fiscella RG, Lesar TS, Owaidhah OA, et al. Glaucoma In: Dipiro JT, Talbert RL, Yee GC, et al, eds. Pharmacotherapy: A Pathophysiologic Approach. 10th ed. New York, NY: McGraw-Hill; 2017: Figure 94–4; with permission.)

but part of its efficacy may be related to a neuroprotective mechanism independent of IOP reduction.[37]

LO 6

Topical β-blockers are typically administered twice daily. A gel-forming solution of timolol (Timoptic-XE) can be administered once daily. Tachyphylaxis may occur in 20% to 50% of patients on monotherapy with a β-blocker, resulting in the need for a different agent or combination therapy. Patients on concurrent systemic β-blockers may experience less IOP reduction than patients on only topical β-blockers.[31,32]

β-Blockers can cause significant systemic adverse effects through nasolacrimal drainage and subsequent systemic absorption in the mucus membranes in the nasal-pharyngeal cavity. This route bypasses first-pass hepatic metabolism resulting in pharmacologically significant serum drug concentrations.[38]

Bronchospasm is the most common pulmonary effect of topical β-blockers. Pulmonary edema, status asthmaticus, and respiratory arrest have been reported with β-blockers as well. Cardiovascular effects include bradycardia, hypotension, and congestive heart failure exacerbation. As with systemic β-blockers, topical β-blockers have also been reported to cause depression and hyperlipidemia and mask symptoms of hypoglycemia. The β_1-selective properties of betaxolol may cause less exacerbation of pulmonary disease. Despite the intrinsic sympathomimetic activity demonstrated by carteolol, this does not translate to a clinically significant decrease in pulmonary or cardiovascular adverse effects. Topical β-blockers are generally contraindicated in patients with asthma, chronic obstructive pulmonary disease (COPD), sinus bradycardia, second- or third-degree heart block, cardiac failure, and hypersensitivity to the product.[29,32,38]

Stinging of the eyes upon instillation is the most common adverse effect. Other local adverse effects include conjunctivitis, keratitis, dry eyes, and **uveitis**.[29,31]

LO 8 Patients prescribed topical β-blockers should be counseled on the nasolacrimal occlusion technique to decrease systemic absorption.

▶ α_2-Adrenergic Agonists

LO 6 Brimonidine and apraclonidine are α_2-adrenergic agonists that decrease IOP by reducing aqueous humor production. Brimonidine has a higher selectivity to the α_2-receptor than apraclonidine and has a dual mechanism of action by increasing uveoscleral outflow.[31,32] LO 6 Apraclonidine is often used for the prevention and treatment of postsurgical IOP elevations and is no longer commonly used for long-term treatment of POAG because of tachyphylaxis and high rate of blepharoconjunctivitis. Brimonidine lowers IOP by 14% to 25%. Peak IOP-lowering effect is similar to that of timolol, but the trough IOP-lowering effect is less than that of timolol.[26,27] Brimonidine may exhibit a neuroprotective effect and has been shown to delay visual field progression compared with timolol but there is insufficient evidence it prevents retinal ganglion cell death.[39]

LO 6 Brimonidine is typically used as an adjunctive agent in combination with other agents and is usually administered every 8 hours. A 12-hour dosing schedule may be employed when used in combination therapy. Brimonidine-purite 0.1% and 0.15% solution (Alphagan-P) has similar efficacy compared with the brimonidine 0.2% solution, because the purite solution's higher pH allows for more drug to penetrate the cornea.[31,32] Brimonidine cause both local and systemic effects. Local effects include blepharoconjunctivitis, conjunctivitis, and ocular allergy. Systemic effects include headache, dry mouth, and fatigue.[29,31,32]

The frequency of dosing and local adverse effects may lead to nonadherence in some patients. LO 8 Patients prescribed brimonidine should be counseled on the nasolacrimal occlusion technique to reduce systemic adverse effects and to improve efficacy.[31,32]

▶ Carbonic Anhydrase Inhibitors

Carbonic anhydrase inhibitors decrease aqueous humor production by inhibition of the carbonic anhydrase isoenzyme II located in the ciliary body. In the eye, carbonic anhydrase catalyzes the conversion of H_2O and CO_2 to HCO_3^- and H^+, which is a significant step in aqueous humor production. Carbonic anhydrase inhibitors are available in systemic and topical preparations.[31,32]

LO 6 **Topical Carbonic Anhydrase Inhibitors** Dorzolamide and brinzolamide are the only topical carbonic anhydrase inhibitors available on the market. Both medications are administered every 8 hours and are used as adjunctive therapy or as monotherapy for patients who cannot tolerate first-line therapies. Nasolacrimal occlusion may allow for an every-12-hour dosing interval. They lower peak and trough IOP by 17% to 20%.[27,28,31,32]

Local side effects include burning, stinging, itching, foreign body sensation, dry eyes, and conjunctivitis. Brinzolamide may have fewer incidences of these side effects since the drug is in a neutral pH solution. Dorzolamide has been reported to cause irreversible corneal decompensation. Taste abnormalities have been reported with each agent. Both topical carbonic anhydrase inhibitors are sulfonamides and are contraindicated in patients with history of sulfonamide hypersensitivity.[29,31,32]

LO 6 **Systemic Carbonic Anhydrase Inhibitors** There are three systemic carbonic anhydrase inhibitors: acetazolamide, dichlorphenamide, and methazolamide. These agents effectively lower IOP by 20% to 30% but are reserved as third-line to fourth-line agents because of their significant adverse effects. They are typically used as bridge therapy from maximal medical therapy to laser or surgical intervention or to control IOP in the perioperative period following a laser or surgical ocular procedure. The systemic carbonic anhydrase inhibitors can also be used to lower IOP in acute angle-closure glaucoma. Acetazolamide has an IV formulation that can be used in patients who are experiencing nausea due to the angle-closure attack. Acetazolamide and methazolamide are the best tolerated of the three agents.[4,31,32]

The systemic carbonic anhydrase inhibitors are associated with significant adverse effects that include paresthesias of the hands and feet, nausea, vomiting, and weight loss. Patients can develop systemic acidosis, hypokalemia, hyponatremia, and nephrolithiasis due to the inhibition of renal carbonic anhydrase. Sulfonamide allergy, renal failure, hepatic insufficiency, COPD, and decreased serum potassium and sodium levels are all contraindications of systemic carbonic anhydrase inhibitor therapy. Blood dyscrasias from bone marrow suppression have been reported and include agranulocytosis, aplastic anemia, neutropenia, and thrombocytopenia.[31,32]

▶ Cholinergic Agents

Cholinergic agents (also called parasympathomimetics or miotics) were the first class of agents to treat glaucoma. The class can be divided into direct-acting cholinergic agents and indirect-acting cholinergic agents.

LO 6 **Direct-Acting Cholinergic Agents** Pilocarpine directly stimulates the muscarinic (M_3) receptors of the ciliary body, which causes contraction of the ciliary muscle. This results in the widening of spaces in the trabecular meshwork, which causes an increase in aqueous humor outflow and reduces IOP by 20% to 30%.

Patient Encounter Part 2

LN was referred to an ophthalmologist for a comprehensive eye evaluation. The ophthalmology report reveals the patient has an IOP (as assessed by applanation tonometry) of 22 mm Hg (2.9 kPa) in the right eye and 24 mm Hg (3.2 kPa) in the left eye. Gonioscopic examination reveals open anterior angles in both eyes. Ophthalmoscopy reveals cupping of the optic discs in both eyes. Visual field examination reveals a nerve fiber bundle defect consistent with glaucoma in the right eye.

What is your assessment of this patient's glaucoma type?

What pharmacologic and nonpharmacologic treatment modalities are available for this patient?

Pilocarpine requires administration four times daily, since the IOP-lowering effect lasts only 6 hours. Pilocarpine is available in 1%, 2%, and 4% concentrations. Higher concentrations may be needed for patients with dark irides to obtain adequate IOP reduction. A pilocarpine 4% gel is available and allows for once-daily dosing at bedtime.[31] Pilocarpine is considered a fourth-line agent for POAG. In the treatment of PACG, it is important to delay use until IOP has been controlled, because pilocarpine could worsen angle closure by causing anterior displacement of the lens. Once IOP is controlled, pilocarpine can be given to break pupillary block by instilling one drop applied twice in an hour.

The adverse effects of pilocarpine are caused by the induction of miosis. The contraction of the ciliary muscle causes the lens to displace forward, which can lead to accommodation spasm and myopia, and can lead to brow ache. Pupillary constriction can also affect night vision. Pilocarpine should be avoided in patients with severe myopia as it increases the risk of developing retinal detachment. Systemic effects may occur at higher concentrations and include nausea, vomiting and diarrhea, and bradycardia.[29]

Carbachol stimulates the same muscarinic receptor as pilocarpine and also inhibits acetylcholinesterase, the enzyme that metabolizes acetylcholine. Carbachol is more potent than pilocarpine, but it causes more accommodation spasm and brow ache and may also cause anterior uveitis. Other reported side effects include corneal clouding, persistent bullous keratopathy, and retinal detachment. Carbachol is rarely used today because of the side effect profile.[29,31]

Indirect-Acting Cholinergic Agents Echothiophate iodide and demecarium bromide inhibit acetylcholinesterase. Inhibition of this enzyme increases the availability of acetylcholine at the nerve junction, thus increasing the stimulation of the muscarinic (M_3) receptors of the ciliary body. These products are given twice daily and have similar efficacy to pilocarpine in the degree of IOP reduction. The side effect profile is similar to that of pilocarpine; however, they can deplete systemic cholinesterases and pseudocholinesterases and may cause the formation of cataracts. These agents should be discontinued at least 1 week before general surgical procedures. Succinylcholine and some local anesthetics are metabolized by pseudocholinesterases; therefore, depletion of this enzyme by echothiophate or demecarium may lead to toxic effects. These agents are typically used when other topical agents have failed and are limited to patients who have had their lenses removed or who have artificial lenses.[31]

▶ *Hyperosmotics*

Glycerin, isosorbide, and mannitol are hyperosmotic agents that increase the osmolality of blood. These agents create an osmotic gradient that draws water from the vitreous humor, thus decreasing IOP. The resulting dehydration of the vitreous humor may cause posterior movement of the lens, which then causes the anterior chamber to deepen, thus opening the anterior angle. If the patient is not vomiting, glycerin (1–1.5 g/kg of a 50%) solution and isosorbide (1.5–2 g/kg) can be given orally. Isosorbide is preferred in patients with diabetes because it is not metabolized into glucose. If the patient has nausea or vomiting, mannitol (20%) can be given IV at a dose of 1 to 2 g/kg over 45 minutes. The hyperosmotic agents are rapid acting, reaching peak effect in 30 to 60 minutes. Headache and thirst are common complaints. Patients who are already dehydrated are at risk of developing CNS dehydration, which can lead to coma. These agents should be used with caution in patients with renal or cardiovascular disease, as extracellular water is increased.[32,40]

Nonselective Adrenergic Agonists Epinephrine and its prodrug, dipivefrin, are rarely used for the treatment of glaucoma and are considered last-line agents because of their systemic side effect profile. Dipivefrin increases the corneal penetration. Once it is absorbed through the cornea, it is enzymatically cleaved to epinephrine. Epinephrine has α- and β-agonist activity and is thought to increase the outflow of aqueous humor through the trabecular meshwork and the uveoscleral pathway. Both products are instilled twice daily and reduce IOP by 15% to 25%. Local adverse effects include mydriasis, conjunctival hyperemia, and ocular irritation. Aphakic patients should not use these medications because they cause a reversible cystoid macular edema. Epinephrine and dipivefrin should not be used in patients with narrow angles since these agents can cause acute angle closure. Systemic side effects include palpitations, increased blood pressure, and arrhythmia, and therefore, these drugs should be used with caution in patients with cardiovascular disease, cerebrovascular disease, and hyperthyroidism. Using the nasolacrimal technique may decrease systemic effects.[31]

SPECIAL CONSIDERATIONS: DRUG-INDUCED GLAUCOMAS

Medications have the potential to cause or exacerbate both POAG and PACG; however, PACG is more likely to be exacerbated by medications than POAG. The use of medications with anticholinergic or sympathomimetic properties can precipitate angle closure. Medications with anticholinergic properties include first-generation antihistamines, tricyclic antidepressants, and antipsychotics. Medications with sympathomimetic properties include phenylephrine and pseudoephedrine. PACG patients who have been treated with laser iridotomy can usually use these agents without causing an exacerbation. Sulfa-based drugs, such as topiramate, acetazolamide, and hydrochlorothiazide, cause swelling of the ciliary body, which causes an anterior displacement of the lens, resulting in a decrease in anterior-chamber depth. Patients with open or closed anterior angles can experience elevated IOP from these drugs. Controlled POAG is rarely exacerbated by anticholinergics and sympathomimetics unless the patient is concomitantly at risk for angle closure. For uncontrolled or untreated POAG, the risk–benefit ratio should be considered before employing these agents. POAG can be exacerbated by any administrated form of corticosteroids. Corticosteroids increase IOP by causing obstruction of the trabecular meshwork with extracellular material. The increase in IOP appears to increase with potency and intraocular penetration. Ophthalmic corticosteroid preparations carry the highest risk of increasing IOP. However, all administrated routes have been shown to raise IOP in some patients. The onset and extent of IOP elevation is dependent on the specific corticosteroid, dose, route, and frequency. Generally, corticosteroid-induced IOP elevation typically occurs within a few weeks of beginning steroid therapy. In most cases, the IOP lowers

Patient Encounter Part 3

The practitioner and LN agree to start medication therapy.

Develop a patient-specific care plan.

Address the patient's (a) drug-related needs, (b) goals of therapy, (c) potential pharmacologic therapies, and (d) plan for follow-up of therapy.

List the monitoring parameters for effectiveness and safety for the chosen therapy.

Explain how you would counsel the patient on the chosen therapy, including the administration of an ophthalmic preparation.

spontaneously to the baseline within a few weeks to months upon stopping the steroid. In rare instances, the IOP remains elevated. Some patients exhibit clinically significant and dangerously high IOP as a result of steroid use.[41]

OUTCOME EVALUATION

Primary Open-Angle Glaucoma

LO 7 Evaluate patients 2 to 4 weeks after the initiation or alteration of medical therapy. The clinician should elicit the status of ocular health since the last visit, systemic medical history, medication history, and presence of local and ocular adverse effects of medications. IOP measurement, visual acuity assessment, and slit-lamp biomicroscopy at every POAG follow-up visit are necessary. The frequency of visual fields and optic nerve evaluation depends on whether IOP is controlled, the length of time IOP has been controlled, and whether there is progression of the disease. Patients who are at target IOP and have no disease progression should have optic nerve head evaluation and visual field testing every 6 to 12 months. Patients with disease progression and/or who are not at target IOP should receive follow-up evaluation every 1 to 6 months. Assess the patient's ability to use topical eye drops.[3] (See Application of Ophthalmic Solutions or Suspensions textbox.) Finally, evaluate the patient's adherence to their medical regimen. Nonadherence among patients on topical medical therapy ranges from 5% to 80%. Suspect nonadherence in patients who have visual field and optic nerve progression despite a low-IOP measurement, as patients may be more adherent to their medical regimen before their visit. Pharmacy refill histories may be useful in assessing adherence but do not confirm that the patient is actually taking the regimen as prescribed.[42] Specific patient factors related to the risk of nonadherence may include health literacy, medication cost, complicated medication regimens, adverse effects, and ethnicity.[43] Using adherence aids, prescribing the least complex regimen, and educating patients about their glaucoma are ways to reduce nonadherence.[44] Consider providing an eye drop instillation aid for patients that have dexterity and/or coordination problems.[45]

LO 7 KEY CONCEPT Target IOP should be revised based on the course of the disease and rate of progression. Adjust therapy if the patient fails to reach his or her target IOP. Patients who have achieved target IOP yet have progressive damage of the optic nerve or who have worsening of their visual fields should have further adjustment of their therapy. Evaluate these patients further for possible reasons of continued disease progression. Consider determining the diurnal pattern of IOP and looking for signs of poor ocular perfusion pressure. Establish a lower target IOP. Adjust therapy in patients who are intolerant, are nonadherent, or develop contraindications to their drug therapy regimen. Consider increasing the target IOP and reducing drug therapy for patients who have stable disease and who have maintained a low IOP; closely follow these patients to assess their response.[3]

Primary Angle-Closure Glaucoma

LO 7 Follow-up of acute angle-closure crisis occurs in the postoperative period. Evaluate the patency of the iridotomy and IOP in the postoperative period. Perform gonioscopy and optic nerve head evaluation if not already performed. Stable patients with PACG should be evaluated at least annually, specifically for the presence

LO 8 Application of Ophthalmic Solutions or Suspensions

1. Clean hands with soap and water.
2. Avoid touching the dropper tip with your fingers or against your eye to maintain sterility of product; shake dropper bottle if product is a suspension.
3. Tilt head back; pull down the lower eyelid with index finger.
4. Hold the dropper bottle with the other hand as close as possible without touching the eye. The dropper should be pointing toward the eye with remaining fingers bracing against the face.
5. Gently squeeze the bottle so that one drop is placed into the pocket.
6. Close your eye for 2 to 3 minutes to allow for the maximum corneal penetration of drug.
7. Use a tissue to wipe away any excess liquid.
8. Replace and retighten the cap to the dropper bottle.
9. Wait at least 5 minutes before instilling another ophthalmic drug preparation.
10. Application of some ophthalmic preparations (suspension and gels) may cause blurring of vision.

Patient Care Process

Collect Information:

- Obtain the patient's medical history. Inquire about previous and current medical problems with eyes.
- Obtain a complete medication history for use of prescription, nonprescription, and dietary supplements.
- Review the medical record for ophthalmologic examination findings (IOP, visual acuity, gonioscopy, visual fields, optic nerve evaluation, and so on).
- Interview the patient and review records to identify socioeconomic factors and health beliefs that affect access to medical care and medications.
- Have patient demonstrate or explain how they instill their ophthalmic medications.

Assess the Information:

- Determine whether the patient is experiencing difficulty with vision.
- Determine the patient's risk factors for glaucoma.
- Review patient's prescription, nonprescription, and natural product use; determine if the patient uses any medications that could exacerbate glaucoma or interact with any glaucoma medications.

(*Continued*)

Patient Care Process (*Continued*)

- Determine if the patient is experiencing ocular or systemic adverse effects from glaucoma medications.
- Based on ophthalmic examination findings, determine if patient has achieved their goal IOP and if there is evidence of disease progression.
- Determine if there are barriers to adherence with the use of eye drops such as low health literacy, or socioeconomic and physical limitations.

Develop a Care Plan:

- Select medication therapy that will likely achieve goal IOP with minimal adverse effects.
- Use combination glaucoma eye drops when possible to improve adherence.
- When possible, discontinue or minimize the use of medications that could increase IOP.

Implement the Care Plan:

- Educate patient about changes in ophthalmic medication regimen.
- Address patient concerns about glaucoma and its treatment.
- Educate patient on importance of medication adherence. Instruct patient on how to instill eye drops and have them demonstrate their technique.
- Educate the patient on potential adverse effects. Reinforce proper instillation technique as a strategy to minimize local and systemic adverse effects.

Follow-up: Monitor and Evaluate:

- Follow-up in 2 to 4 weeks to reassess patient for progression in glaucomatous damage, achievement of target IOP, adherence, and presence of adverse effects to medication therapy.
- Review interval medical history.
- Perform/Review ophthalmic examination findings.
- Once disease progression is controlled, follow-up interval can be extended.

of peripheral anterior synechia and optic neuropathy. Treat patients according to POAG guidelines if they have underlying POAG or areas of peripheral anterior synechia with the presence of optic neuropathy.[4]

Abbreviations Introduced in This Chapter

POAG	Primary open-angle glaucoma
PACG	Primary angle-closure glaucoma
IOP	Intraocular pressure
CCT	Central corneal thickness
NTG	Normal-tension glaucoma
AAO	American Academy of Ophthalmology

62 Minor Ophthalmic and Otic Disorders

Lauren R. Biehle and Michelle L. Hilaire

LEARNING OBJECTIVES

LO **Upon completion of the chapter, the reader will be able to:**

1. Differentiate between the various ophthalmic disorders based on patient-specific information.
2. Choose an appropriate treatment regimen for an ophthalmic disorder.
3. Discuss the product differences that direct the selection of ophthalmic medications.
4. Assess when further treatment is required based on patient-specific information.
5. Recommend an ophthalmic monitoring plan given patient-specific information, a diagnosis, and a treatment regimen.
6. Educate patients about ophthalmic disease states and appropriate drug and nondrug therapies.
7. Review common otic disorders and appropriate drug and nondrug therapies.

This chapter provides an overview of common ophthalmic and otic disorders and their treatments. KEY CONCEPT Many ophthalmic disorders are benign or self-limited, but the clinician must be able to distinguish conditions that lead to serious morbidity, including blindness. Preserving both visual function and cosmetic appearance is the goal.[1] The clinician must understand when referral is appropriate and the proper time frame for follow-up, based on the patient-specific condition. Health care professionals should also be aware of common otic disorders that may be encountered.

OCULAR INJURIES

Etiology and Epidemiology

Ophthalmic problems encompass 3% of all emergency department visits.[2] Corneal abrasions are the most common eye injury in children. Scratches, objects, and aggressive eye rubbing may damage the cornea.[3] Health care practitioners must know the proper treatment for ocular emergencies and the time frame for follow-up in order to prevent further morbidity (Table 62–1).

CORNEAL ABRASIONS

Treatment

▶ *Desired Outcomes*

- Complete healing of the corneal abrasion with no scarring or vision impairment
- Prevent infection and pain
- Prevent corneal loss or corneal transplant

▶ *General Approach to Treatment*

The five layers of the cornea contain no blood vessels but are nourished by tears, oxygen, and aqueous humor. Minor corneal abrasions, also called corneal epithelial defects, heal quickly—typically within 24 hours.[4] Moderate abrasions take 24 to 72 hours to heal. Deep abrasions may scar the cornea. This rarely results in sufficient visual impairment to require corneal transplant. Patients should be instructed not to rub the eye if a corneal abrasion is present. Do not use eye patches to treat uncomplicated corneal abrasion.[3]

▶ *Corneal Abrasion Prevention*[3]

- Wear eye protection during sports
- Wear industrial safety lenses
- Carefully fit and place contact lenses

▶ *Pharmacologic Therapy*

LO 2 **Topical NSAIDs** Topical nonsteroidal anti-inflammatory drugs (NSAIDs) decrease pain from corneal abrasion. In a Cochrane review of nine trials (n = 637), topical NSAIDs were associated with a reduced need for oral analgesics. However, strong evidence was not available to support their use in the management of corneal abrasions.[4] Available ocular NSAIDs are diclofenac,

Table 62–1

Ophthalmic Emergencies: Time to Follow-Up by Ophthalmologist

Immediate Consult Required	Within 24 Hours
Foreign body in eye	Acute angle-closure glaucoma
Acute, painless loss of vision	Orbital cellulitis
Acute chemical burn	Blood in the eye (hyphema)
Blunt trauma to eye	Macular edema
	Retinal detachment
	Sudden congestive proptosis (bulging of eye forward)
	Corneal ulcer

Adapted from Handler JA, Ghezzi KT. General ophthalmologic examination. Emerg Med Clin North Am. 1995;13:521–538.

Clinical Presentation and Diagnosis of Corneal Abrasions[3]

Symptoms

- Photophobia
- Pain with eye or eyelid movement
- Foreign body sensation (or gritty feeling)
- Recent ocular trauma

Signs

- Excessive tearing
- Blepharospasm
- Blurred vision
- Conjunctival injection ("red eye")

Diagnostic Test

Use sterile fluorescein dye strips and visualize the cornea under a cobalt-blue filtered light; abrasions appear green; ensure that no foreign body remains in the eye or under eyelid.

ketorolac, nepafenac, and bromfenac. The usual dose for diclofenac and ketorolac is one drop four times daily; nepafenac is dosed one to three times daily, and bromfenac is dosed once or twice daily. Use topical NSAIDs with caution in patients with clotting disorders or those who are on systemic NSAIDs or warfarin therapy. Adverse effects typically include discomfort upon administration and conjunctival hyperemia or itching.[4]

LO3 **Topical Antibiotics** Infection slows the healing of a corneal abrasion; therefore, prophylactic antibiotics are often used. However, antibiotic-steroid ophthalmic products are not recommended as the steroid may slow healing of the abrasion. Patients should be asked if any contaminated matter could have entered the eye as this can lead to bacterial keratitis. Discontinue the use of contact lenses until the abrasion is healed and the antibiotic course complete. KEY CONCEPT In patients who do not wear contacts, antibiotics active against *Staphylococcus*, such as erythromycin ointment or trimethoprim-polymyxin B solution, are appropriate choices. In contact lens wearers, choose an ophthalmic antibiotic that covers *Pseudomonas aeruginosa*, like gentamicin or a fluoroquinolone.[3]

► *Outcome Evaluation*

LO5
1. Reevaluate patients in 24 hours.
2. If symptoms worsen, recheck for foreign bodies.
3. Refer to ophthalmologist if:[3]
   - Contact lens wearers
   - Decreased vision
   - Lack of improvement or worsening symptoms

OTHER OCULAR INJURIES: TREATMENT

Traumatic Injuries

Attempt to remove loose foreign bodies by gentle irrigation with artificial tears or sterile saline. If removal is successful, a topical broad-spectrum antibiotic, such as erythromycin, will prevent infection. If irrigation is unsuccessful, only ophthalmologists should complete mechanical removal of foreign objects. Protect the eye from further injury with a metal eye shield or a paper cup taped over the eye while awaiting the ophthalmologist.[2]

Splash Injuries and Chemical Exposure

LO6 LO4 Instruct patients to immediately irrigate the eye with water or saline continuously for at least 15 minutes before seeking a clinician. Irrigation dilutes and removes the chemical agent and is the best way to decrease ocular tissue damage. Patients should then seek immediate care from an ophthalmologist or emergency facility.[5]

Loss of Vision

LO1 A variety of disorders may lead to rapid, painless, monocular, or binocular vision loss. These include central retinal artery occlusion, acute narrow-angle glaucoma, trauma, and others.[6] The differential diagnosis is complex and should be undertaken by an emergency department or ophthalmologist.

CONJUNCTIVITIS

Etiology

Conjunctivitis, also known as red eye, is one of the most common ophthalmic complaints seen by clinicians. An inflamed conjunctiva is the most common cause of red eye.[7] Conjunctivitis cases are most commonly viral in nature. Both viral and bacterial conjunctivitis are highly contagious. The most common symptoms indicating bacterial conjunctivitis rather than viral are adherence of the eyelids upon waking and presence of mucopurulent discharge. The most common symptom differentiating allergic conjunctivitis from bacterial or viral is itching.[8] Use the differential diagnosis algorithm shown in Figure 62–1 to determine the proper treatment or need for referral.

BACTERIAL CONJUNCTIVITIS

Etiology and Pathophysiology

The primary causes of acute bacterial conjunctivitis (ABC) are gram-positive organisms, *Staphylococcus aureus, Streptococcus pneumoniae,* and gram-negative *Haemophilus influenzae.*[6] *S. aureus* is a more common cause in adults, while *S. pneumoniae* and *H. influenzae* are more common in children.[7] KEY CONCEPT The pathogens are rarely cultured unless the case is unresponsive to treatment.[6] Patients with bacterial conjunctivitis lasting 4 weeks or more should be referred to an ophthalmologist.[8]

Hyperacute bacterial conjunctivitis is associated with gonococcal (*Neisseria gonorrhoeae*) infections in sexually active patients. Prompt workup and treatment is required, as corneal perforation can occur.[6,7]

Treatment

► *Desired Outcomes*

- Complete resolution of the bacterial conjunctivitis
- Prevent adverse consequences of the infection
- Preserve functionality of the eye

► *General Approach to Treatment*

LO2 ABC may be treated with broad-spectrum antibiotics. Although the condition is usually self-limiting, antibiotic treatment decreases the spread of disease to others and prevents extraocular infection. Additionally, treatment may help decrease the risk of corneal ulceration or other complications that affect sight. Finally, treatment speeds recovery.[6,7]

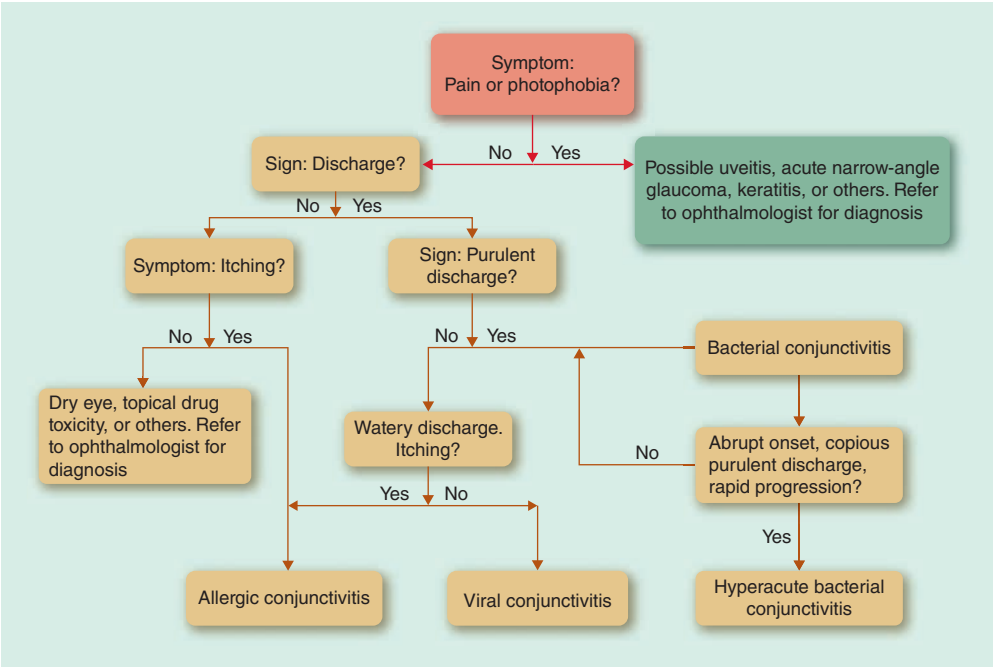

FIGURE 62–1. Differential diagnosis for red eye.

▶ *Pharmacologic Therapy*

LO 3

The choice of an antibiotic agent for ABC is largely empiric. The initial treatment needs to include *Staphylococcus* coverage, and cost and side-effect profile may be pertinent.[6] In general, ointments are a good dosage form for children. Adults may prefer drops because they do not interfere with vision.

Many broad-spectrum topical antibiotics are approved to treat ABC (Tables 62–2 and 62–3).

LO 2

- First-line treatments include polymyxin B/trimethoprim solution, polymyxin B with bacitracin ointment, or erythromycin ointment as these provide activity against *S. aureus*.
- The aminoglycosides (tobramycin and gentamicin) are alternatives but have incomplete gram-positive coverage and can cause corneal epithelial toxicity.[7]
- Sulfacetamide has significant resistance.

Table 62–2

Adult Bacterial Conjunctivitis Dosing Guidelines for Topical Ophthalmic Antibiotics

Azithromycin 1% solution	Days 1 and 2: 1 drop twice daily Days 3–7: 1 drop once daily
Ciprofloxacin 3.5 mg/mL solution	Days 1 and 2: 1–2 drops every 2 hours while awake Days 3–7: 1–2 drops every 4 hours while awake
Ciprofloxacin 0.3% ointment	Apply a ½ in (~1 cm) ribbon of ointment 3 times daily for 2 days, then twice daily for next 5 days
Erythromycin 0.5% ointment	Apply a ½ in (~1 cm) ribbon of ointment up to 6 times daily
Gatifloxacin 0.5% solution	Days 1 and 2: 1 drop every 2 hours while awake up to 8 times daily Days 3–7: 1 drop 4 times per day while awake
Gentamicin 0.3% solution	1–2 drops every 4 hours. In severe infections, may use up to 2 drops every hour
Gentamicin 0.3% ointment	Apply a ½ in (~1 cm) ribbon of ointment 2–3 times daily
Levofloxacin 0.5% solution	Days 1 and 2: 1–2 drops every 2 hours while awake, up to 8 times per day Days 3–7: 1–2 drops every 4 hours while awake, up to 4 times daily
Moxifloxacin 0.5% solution	1 drop 2 times a day for 7 days 1 drop 3 times a day for 7 days
Ofloxacin 0.3% solution	Days 1 and 2: 1–2 drops every 2–4 hours while awake Days 3–7: 1–2 drops 4 times daily
Polymyxin B with bacitracin ointment	Apply a ½ in (~1 cm) ribbon of ointment every 3–4 hours, or 2–3 times per day for 7–10 days
Polymyxin B/trimethoprim solution	1 drop every 3 hours for 7–10 days
Sulfacetamide 10% ointment	Apply a ½ in (~1 cm) ribbon of ointment every 3–4 hours and at bedtime
Sulfacetamide 10% solution	1–2 drops every 2–3 hours for 7–10 days
Sulfacetamide 10% ointment	Apply a ½ in (~1 cm) ribbon of ointment every 3–4 hours and at bedtime
Tobramycin 0.3% ointment	Mild-to-moderate infections: Apply a ½ in (~1 cm) ribbon of ointment 2–3 times daily. Severe infections: Apply every 3–4 hours
Tobramycin 0.3% solution	Mild-to-moderate infections: 1–2 drops every 2–4 hours Severe infections: initially, 2 drops every hour

Table 62–3

Pediatric Bacterial Conjunctivitis Dosing Guidelines for Topical Ophthalmic Antibiotics

Azithromycin 1% solution	Children 1 year of age or older: Days 1 and 2: 1 drop twice daily, 8–12 hours apart Days 3–7: 1 drop once daily
Ciprofloxacin 3.5 mg/mL solution	Children 1 year of age or older: Days 1 and 2: 1–2 drops every 2 hours while awake Days 3–7: 1–2 drops every 4 hours while awake
Ciprofloxacin 0.3% ointment	Children 2 years of age or older: Apply a ½ in (~1 cm) ribbon of ointment 3 times daily for 2 days, then twice daily for next 5 days
Erythromycin 0.5% ointment	Apply a ½ in (1 cm) ribbon of ointment up to 6 times daily
Gatifloxacin 0.3% solution	Children 1 year of age or older: Days 1 and 2: 1 drop every 2 hours while awake up to 8 times daily Days 3–7: 1 drop every 4 hours while awake
Gentamicin 0.3% solution	1–2 drops every 4 hours. In severe infections, may use up to 2 drops every hour
Gentamicin 0.3% ointment	Apply a ½ in (~1 cm) ribbon of ointment 2–3 times daily; up to every 3–4 hours
Levofloxacin 0.5% solution	Children 1 year of age or older: Days 1 and 2: 1–2 drops every 2 hours while awake, up to 8 times daily Days 3–7: 1–2 drops every 4 hours while awake, up to 4 times daily
Moxifloxacin 0.5% solution	Children 4 months of age or older: 1 drop 2 times per day for 7 days Children 1 year of age or older: 1 drop 3 times a day for 7 days
Ofloxacin 0.3% solution	Children 1 year of age or older: Days 1 and 2: 1–2 drops every 2–4 hours while awake Days 3–7: 1–2 drops 4 times daily
Polymyxin B with bacitracin ointment	Apply a ½ in (~1 cm) ribbon of ointment every 3–4 hours for 7–10 days
Polymyxin B/trimethoprim solution	Infants and children 2 months of age or older: 1 drop every 3 hours for 7–10 days
Sulfacetamide 10% ointment	Apply a ½ in (~1 cm) ribbon of ointment every 3–4 hours and at bedtime
Sulfacetamide 10% solution	1–2 drops every 2–3 hours for 7–10 days
Tobramycin 0.3% ointment	Infants and children 2 months of age or older: Mild-to-moderate infections: Apply an approximately ½ in (~1 cm) ribbon 2–3 times daily Severe infections: Apply every 3–4 hours
Tobramycin 0.3% solution	Infants and children 2 months of age or older: Mild-to-moderate infections: 1–2 drops every 4 hours Severe infections: initially, 2 drops every hour

Data from Lexi-Drugs Online™. Lexi-Comp Online™. Hudson (OH): Lexi-Comp, Inc.; 2017. Available from: http://online.lexi.com. Accessed: August 30, 2017.

Patient Encounter 1

This morning, a mother brings in her 13-year-old son who has been complaining of irritation, redness, and "goop" coming out of his right eye for the past 13 hours. He woke up terrified this morning because his right eye seemed glued shut. At first, the mother was concerned because his younger sister had "pink-eye" 2 weeks ago. A warm washcloth was used to ease the eye open, and upon examination, the right eye was red and revealed a whitish discharge, whereas the left eye was just red.

What is the probable diagnosis?

Please differentiate between bacterial, hyperacute bacterial, viral, and allergic causes based on physical assessment.

What organisms should be suspected, and what are reasonable treatment regimens?

If the child would have been diagnosed with viral conjunctivitis, what nonpharmacologic measures should be employed to prevent spreading?

- If infection recurs or is severe, use a topical fluoroquinolone.[7] Moxifloxacin has been shown to have similar efficacy when compared to polymyxin B ointment.[9]
- Treat hyperacute bacterial conjunctivitis with a single dose of intramuscular ceftriaxone in combination with topical antibiotics and refer the patient to an ophthalmologist.[7]
- If concurrent blepharitis is present, add a lid hygiene regimen to antibiotic treatment.[6]

Outcome Evaluation

LOS

Significant improvement of ABC should be seen within 1 week.[7]

VIRAL CONJUNCTIVITIS

Etiology

Viral conjunctivitis is commonly caused by adenovirus and is often called "pink-eye."[7] Adenovirus is easily spread through swimming pools, camps, and contaminated fingers and medical instruments.[8] Patients often present with an upper respiratory tract infection or recent exposure to viral conjunctivitis.[7] KEY CONCEPT Viral conjunctivitis is usually self-limiting, resolving within 2 weeks.[7]

Treatment

▶ *Desired Outcomes*

- Complete resolution of the viral conjunctivitis
- Prevent adverse consequences of the infection
- Avoid spreading infection to others

▶ *Nonpharmacologic Therapy*

KEY CONCEPT Nonpharmacologic measures are critical to prevent the spread of viral conjunctivitis. Cold compresses may relieve symptoms.[6,7] Patients should not share towels or other contaminated objects, should avoid close contact with other people, and avoid swimming for 2 weeks.[7,8] Current contact lenses in the infected eyes and their lens case should be discarded. Take care in the medical setting to thoroughly decontaminate instruments and wash hands.[7,8]

LO 6

▶ *Pharmacologic Therapy*

Patients may obtain further symptomatic relief by using artificial tears.[7,8] If artificial tear solutions sting, recommend a preservative-free formula.

LO 3

Topical antivirals are not used to treat adenovirus conjunctivitis. Topical antibiotics are unnecessary and should not be used for a viral infection and to help prevent the development of antibiotic resistance.[8]

LO 1

Patients with severe subepithelial infiltration may require a topical steroid. However, topical steroids may cause serious ocular complications, increase the period of viral shedding, and may worsen herpetic conjunctivitis, which has similar symptoms as viral conjunctivitis.[8] Only ophthalmologists should prescribe topical steroids.[7]

LO 4

Outcome Evaluation

Refer patients who do not see improvement within 7 to 10 days or with visual loss to an ophthalmologist to rule out herpetic and other infectious processes.[7,8]

ALLERGIC CONJUNCTIVITIS

Etiology and Clinical Presentation

LO 1

Ocular allergy is a broad term that includes several diseases with the hallmark symptom of itching, often accompanied by tearing, conjunctival swelling, photophobia, and stringy or sticky mucoid discharge.[10] Allergic conjunctivitis affects up to 40% of patients.[11] Seasonal ocular allergy is the most common type of allergic conjunctivitis. Often, the patient's history is positive for atopic conditions including allergic rhinitis, asthma, or eczema.[7] Perennial allergic conjunctivitis has similar but less severe symptoms and may not be tied to a specific time of year. Finally, **conjunctivitis medicamentosa** is a drug-induced form of allergic conjunctivitis caused by overuse of topical vasoconstricting agents and sometimes polypharmacy from use of multiple topical glaucoma eyedrops.[10]

LO 1

Pathophysiology

The conjunctiva of the eye is often the initial site of contact with an environmental allergen. Mast cell degranulation occurs, and the earliest mediator is histamine, which causes itching, redness, and swelling.[11] Leukotrienes and prostaglandins cause cellular infiltration and increased mucus secretion along with chemosis, resulting in conjunctival vasodilation.

Table 62–4

Mechanisms of Action of Ocular Allergy Drugs

Drug	Mechanisms
Azelastine	H_1-receptor antagonist
Cromolyn sodium	Mast cell stabilizer
Emedastine	H_1-receptor antagonist
Epinastine	H_1- and H_2-receptor antagonist, mast cell stabilizer
Ketorolac	Inhibitors prostaglandin synthesis
Ketotifen	H_1-receptor antagonist, mast cell stabilizer, eosinophil inhibitor
Lodoxamide	Mast cell stabilizer
Loteprednol	Corticosteroid
Nedocromil	Mast cell stabilizer, eosinophil inhibitor
Olopatadine	H_1-receptor antagonist, mast cell stabilizer
Pemirolast	Mast cell stabilizer

Adapted from McEvoy GK, ed. AHFS Drug Information 2014. Bethesda, MD: American Society of Health-System Pharmacists Inc., 2018.

Treatment of ocular allergy is aimed at slowing or stopping these processes. Antihistamines block the histamine receptors, prevent histamine release from the mast cells and stop eosinophil activity.[11] Mast cell stabilizers inhibit the degranulation of mast cells, preventing mediator release. Some topical agents have multiple mechanisms of action, combining antihistaminic, mast cell stabilization, and anti-inflammatory properties (Tables 62–4 and 62–5).[11]

Treatment

▶ *Desired Outcomes*

- Relief of current allergic symptoms
- Prevention of future allergic symptoms
- No adverse effects from treatment

▶ *Nonpharmacologic Therapy*

LO 2

The primary treatment for ocular allergy is removal and avoidance of the allergen.[7,8] For conjunctivitis medicamentosa, discontinue the offending medication. Patients should be instructed to avoid rubbing their eyes. Apply cold compresses several times daily to reduce redness and itching and to provide symptomatic relief.[10]

LO 6

▶ *Pharmacologic Therapy*

KEY CONCEPT Use a step-care approach for the treatment of allergic conjunctivitis.

LO 2

- Step 1: nonmedicated, artificial tears solution. The solution dilutes or removes the allergen, providing relief while lubricating the eye. The artificial tear solutions may be refrigerated to provide additional topical relief.[12] Solutions are applied two to four times daily as needed. Ointments may be used in the evenings to further moisturize the surface of the eye. Preservative-free formulations may be tried if other products sting or burn, or if the artificial tears need to be used frequently throughout the day.

LO 3

- Step 2: topical antihistamine or antihistamine/decongestant combination. The antihistamine/decongestant combination is more effective than either agent alone. Decongestants are vasoconstrictors that reduce redness and seem to have a small synergistic effect with the antihistamine. Topical

Table 62–5

Pediatric and Adult Dosing and Common Side Effects of Ocular Allergy Drugs

Drug	Dosing	Common Side Effects
Azelastine 0.05%	Children 3 years of age or older and adults: 1 drop in affected eye(s) twice daily	Ocular stinging, bitter taste, headache
Cromolyn sodium 4%	Children 4 years of age or older and adults: 1–2 drops in each eye 4–6 times daily	Ocular stinging
Emedastine 0.05%	Children 3 years of age or older and adults: 1 drop in affected eye up to 4 times daily	Ocular stinging, blurred vision, headache
Epinastine 0.05%	Children 3 years of age or older and adults: 1 drop in each eye twice daily	Ocular burning, ocular itching, cold symptoms
Ketorolac 0.5%	Children 3 years of age or older and adults: 1 drop 4 times a day	Ocular stinging, irritation
Ketotifen 0.025%	Children 3 years of age or older and adults: 1 drop in affected eye(s) twice daily	Red eyes, headache, rhinitis
Lodoxamide 0.1%	Children 2 years of age or older and adults: 1–2 drops in affected eye(s) 4 times daily, for up to 3 months	Ocular stinging, discomfort, foreign body sensation
Loteprednol 0.2%	Adults only: 1 drop in affected eye(s) 4 times daily	Elevated intraocular pressure, cataracts, secondary ocular infections, systemic side effects possible
Nedocromil 2%	Children 3 years of age or older and adults: 1–2 drops in each eye twice daily	Headache, ocular stinging, unpleasant taste, nasal congestion
Olopatadine 0.1%; 0.2%	Children 3 years of age or older and adults (0.1%): 1 drop in affected eye(s) 2 times daily with minimum 6- to 8-hour interval between doses Children 2 years of age or older: and adults (0.2%): 1 drop in affected eye(s) once daily	Headache, blurred vision, ocular stinging
Pemirolast 0.1%	Children 3 years of age or older and adults: 1–2 drops in affected eye(s) 4 times daily	Headache, cold symptoms

Adapted from McEvoy GK, ed. AHFS Drug Information 2014. Bethesda, MD: American Society of Health-System Pharmacists Inc., 2018.

Alomide (lodoxamide tromethamine) solution/drops 0.1%. Fort Worth (TX): Alcon Laboratories, Inc., 2003.

decongestants used in combination products include naphazoline and tetrahydrozoline. Topical decongestants burn and sting on instillation and commonly cause mydriasis, especially in patients with lighter-colored eyes. Topical decongestant use should be limited to less than 10 days to avoid rebound congestion.

LO 3
- Step 3: a mast cell stabilizer or a multiple-action (antihistamine-mast cell stabilizer) agent. Use mast cell stabilizers, including cromolyn or nedocromil, prophylactically throughout the allergy season-they are not used for acute relief of symptoms. Full response may take 4 to 6 weeks.

LO 4
- Step 4: short-term topical corticosteroids and immunotherapy.[10,11]

LO 3 Topical antihistamine-mast cell stabilizers are recommended before oral agents in step therapy due to the increased risk of systemic side effects with oral drugs. Topical antihistamines provide faster relief of ocular symptoms. Topical antihistamine-mast cell stabilizers include alcaftadine, bepotastine, emedastine, epinastine, ketotifen, and olopatadine. Topical NSAID ketorolac tromethamine is approved for ocular itching, though it is used less commonly than topical antihistamines.[11]

Outcome Evaluation

LO 5 Monitor patients for relief of symptoms. Ensure an adequate trial of each agent. Refer severe cases that do not respond to an ophthalmologist.

Patient Encounter 2

TS is a 63-year-old female who presents with eye complaints. She states her eyes are watering off and on and feel like they have sand in them. She has been wearing her glasses, rather than her usual contact lens use. She is able to look up at the light on the ceiling and denies eye pain or itching. She denies any discharge from the eye, except the feeling that they water occasionally. She states now that the spring temperatures have increased, she has recently turned on the fans in her apartment.

Past medical history:
- GERD
- Migraines
- Insomnia

Social history:
- Alcohol use: denies
- Tobacco: 1 pack per day
- Illicit drug use: denies

Medications:
- Amitriptyline 25 mg at bedtime
- Ibuprofen 400 mg PRN headaches
- Pantoprazole 40 mg Q AM

Which symptoms would distinguish dry eye from conjunctivitis?

Which environmental or medication risk factors may contribute to TS's dry eye?

What nonpharmacologic therapies should be recommended for this patient?

What pharmacologic therapies should be recommended for this patient?

Which dosage forms should be recommended for this patient?

How should the patient be monitored?

BACTERIAL KERATITIS

Epidemiology

Thirty thousand cases of microbial keratitis occur annually in the United States.[13] Microbial keratitis encompasses bacterial, fungal, and *Acanthamoeba* keratitis.[13] Only bacterial keratitis, the most common form, is discussed here.

Pathophysiology

Bacterial keratitis is a broad term for a bacterial infection of the cornea including corneal ulcers and corneal abscesses. The cornea in a healthy eye has natural resistance to infection, making bacterial keratitis rare. However, many factors may predispose a patient to bacterial infection by compromising the defense mechanisms of the eye (Table 62–6).[13]

The most common pathogens in bacterial keratitis are *Pseudomonas* (including *Pseudomonas aeruginosa*) and other gram-negative rods, *Staphylococci*, and *Streptococci*.[13] If the keratitis is related to the use of contacts, *Pseudomonas* and *Serratia marcescens* are the most common pathogens.[13] KEY CONCEPT Untreated bacterial keratitis can result in corneal scarring and potential loss of vision. Corneal perforation may occur which may require emergent corneal transplant, and the patient could lose the eye.[13] In virulent organisms, this destruction may occur within 24 hours.[13] Central corneal scarring may result in vision loss even after successful eradication of the organism.[13]

Table 62–6

Risk Factors for Bacterial Keratitis

Exogenous Factors	
	Contact lenses
	Loose sutures from ocular surgeries
	Previous corneal surgery
	Previous ocular or eyelid surgery
	Trauma, including foreign bodies, chemical and thermal injuries, and local irradiation
Ocular Surface Disease	
	Abnormal lid anatomy or function
	Misdirection of eyelashes
	Ocular infection (eg, conjunctivitis, blepharitis)
	Tear film deficiencies
Systemic Conditions	
	Atopic dermatitis
	Connective tissue disease
	Diabetes mellitus
	Gonococcal infection
	Immunocompromised
	Stevens-Johnson syndrome
	Substance abuse
	Vitamin A deficiency
Ocular Medications	
	Anesthetics
	Antimicrobials
	Contaminated ocular medications
	Glaucoma medications
	Preservatives
	Steroids
	Topical NSAIDs
Corneal Epithelial Abnormalities	
	Corneal epithelial edema
	Predisposition to recurrent erosion of the cornea
	Viral keratitis (eg, herpes simplex or zoster keratitis)

Data from American Academy of Ophthalmology Cornea/External Disease Panel. Preferred Practice Pattern® Guidelines. Bacterial Keratitis [Internet]. San Francisco, CA: American Academy of Ophthalmology, 2013 [cited 2017 Aug 30]. Available from: www.aao.org/ppp.

Clinical Presentation and Diagnosis of Bacterial Keratitis[7,13]

General

The rate of progression of signs and symptoms varies depending on the infecting organism. A differential diagnosis for keratitis must include viral, fungal, and nematodal infections in addition to bacterial causes.

Symptoms

- Photophobia
- Rapid onset of ocular pain

Signs

- Red eye
- Conjunctival discharge
- Decreased vision

Laboratory Tests

Culture if keratitis is severe or sight-threatening, chronic or unresponsive to broad-spectrum antimicrobial therapy.

Treatment

▶ *Desired Outcomes*[13]

- Resolution of infection and corneal inflammation
- Reduced corneal pain
- Restored corneal integrity with minimal scarring
- Restored visual function

▶ *General Approach to Treatment*

LO 4 All cases of suspected bacterial keratitis require prompt ophthalmology consultation to prevent permanent vision loss.[7]

▶ *Pharmacologic Therapy*

LO 3 **Dosage Considerations** Topical antibiotic drops are preferred. Consider subconjunctival antibiotics if compliance is a concern. Systemic therapy is useful in cases of systemic infection (eg, gonorrhea) or if the sclera is infected. Reserve ointments for minor cases or adjunctive nighttime therapy.[13]

LO 2 **Drug Choice** Start topical broad-spectrum antibiotics empirically. Use a loading dose for severe keratitis (Table 62–7). Single-drug therapy with a fluoroquinolone is as effective as combination therapy. Resistance is seen with some fluoroquinolones, LO 4 choose moxifloxacin or gatifloxacin in severe keratitis cases.[13] Antibacterials should be continued until positive response, then tapered. Fortified antibiotic therapy is an option for severe or unresponsive cases, but may increase toxicity to the corned and surrounding tissues. Fortified antibiotics are compounded products that are a higher concentration than the commercially available formulations.

Table 62–7

Pharmacologic Therapies for Bacterial Keratitis

Organism	Drug
Unknown or multiple types of organisms	Cefazolin 50 mg/mL *and* tobramycin/gentamicin 9–14 mg/mL *or* Fluoroquinolones various strengths
Gram-positive cocci	Cefazolin 50 mg/mL *or* Vancomycin[a] 15–50 mg/mL *or* Bacitracin[a] 10,000 international unit *or* Moxifloxacin or gatifloxacin various strengths
Gram-negative rods	Tobramycin 9–14 mg/mL *or* Gentamicin 9–14 mg/mL *or* Ceftazidime 50 mg/mL *or* Fluoroquinolones various strengths
Gram-negative cocci	Ceftriaxone 50 mg/mL *or* Ceftazidime 50 mg/mL *or* Fluoroquinolones various strengths
Nontuberculous mycobacteria	Amikacin 20–40 mg/mL *or* Oral clarithromycin, adults: 500 mg every 12 hours Fluoroquinolones various strengths
Nocardia	Amikacin 20–40 mg/mL *or* Trimethoprim 16 mg/mL *and* sulfamethoxazole 80 mg/mL
Adult Topical Dosing	
Severe keratitis: loading dose every 5–15 minutes for the first hour, then every 15 minutes to 1 hour around the clock. Less severe keratitis may use less frequent dosing	

[a]Use for resistant *Enterococcus* and *Staphylococcus* species and penicillin allergy. Due to the absence of gram-negative activity, do not use vancomycin or bacitracin for single-agent empiric therapy in bacterial keratitis.

Data from American Academy of Ophthalmology Cornea/External Disease Panel. Preferred Practice Pattern Guidelines. Bacterial Keratitis [Internet]. San Francisco, CA: American Academy of Ophthalmology, 2013 [cited 2017 Aug 30]. Available from: www.aao.org/ppp.

LO 3 Topical corticosteroids are employed in some cases of bacterial keratitis. The suppression of inflammation may reduce corneal scarring. However, local immunosuppression, increased ocular pressure, and reappearance of the infection are disadvantages to their use. Topical steroids may be beneficial in bacterial keratitis if initiated early (within 72 hours of antibiotic therapy), but may lead to worse outcomes in keratitis caused by fungi or *Acanthamoeba*.[14]

Outcome Evaluation[13]

LO 5
- Symptomatic improvement is indicative of therapeutic efficacy.
- Adjust treatment based on culture and sensitivity reports.
- Modify the treatment regimen if the patient does not show improvement within 48 hours.
- Gram-negative keratitis will have increased inflammation in the first 24 to 48 hours, even on appropriate therapy.
- Taper therapy based on clinical response.
- Reculture if negative clinical response; discontinue antibiotics 12 to 24 hours before culturing for best results.
- Contact lenses–wearers should be educated about the increased risk of infection overnight and continuous wear and the importance of adherence to contact lens hygiene.

Table 62–8

Risk Factors for Dry Eye

Androgen deficiency
Antihistamine use
Connective-tissue disease
Estrogen replacement therapy
Female gender
Hematopoietic stem cell transplantation
Hepatitis C infection
LASIK and refractive excimer laser surgery
Low dietary intake of omega-3 fatty acids
Older age
Radiation therapy
Vitamin A deficiency

Data from American Academy of Ophthalmology Cornea/External Disease Panel. Preferred Practice Pattern Guidelines. Dry Eye Syndrome [Internet]. San Francisco, CA: American Academy of Ophthalmology, 2013 [cited 2017 Aug 30]. Available at: www.aao.org/ppp.

DRY EYE

Epidemiology and Etiology

Dry eye is a frequent cause of eye irritation. The lack of a single diagnostic test for the condition limits the available epidemiologic data. Reports of the prevalence of dry eye range from 5% to 30%, being more frequent in elderly patients.[15] The risk factors for dry eye are listed in Table 62–8. Dry eye that is left untreated can cause loss of vision, structural damage, an increased risk for infection, and compromised efficacy of ocular surgery.[16]

Pathophysiology

The surface of the eye and the tear-secreting glands work together as an integrated unit that refreshes the tear supply and clears away used tears. Dry eye may be caused by impaired tear secretion and/or increased tear evaporation.[16] It has been suggested that dry eye be called "dysfunctional tear syndrome," as all of the predisposing factors cause some disruption of the tear.[15]

Dysfunction may be caused by aging, systemic inflammatory diseases, a decrease in androgen hormones, surgery, ocular surface diseases, systemic diseases, or medications that affect the efferent cholinergic nerves. Dysfunctional tear film may result in an inflammatory response on the ocular surface called keratoconjunctivitis sicca.[16]

Environmental causes (Table 62–9) and an abnormal blink reflex are common causes of increased evaporative loss of tears and worsening of dry eye.[16]

Treatment

▶ *Desired Outcomes[16]*

- Relief of the symptoms of dry eye
- Maintain or improve visual acuity
- Prevention of long-term adverse effects from dry eye

▶ *General Approach to Treatment*

KEY CONCEPT Dry eye is a chronic condition. Symptoms can be improved with treatment, but unless dry eye is secondary to a disease, it is not usually curable. Because of this, patient education is important, and a periodic reassessment of the efficacy of the treatment is appropriate. If the patient is unresponsive to treatment, refer to an ophthalmologist for additional options. LO 6

Table 62–9

Associated Conditions That Cause or Worsen Dry Eye

Ocular Conditions	Environmental Factors
Blepharitis	Air travel
Eyelid malposition	Air conditioning or heating
Lagophthalmos	Contact lenses
Meibomian gland dysfunction	Exogenous irritants or allergens
Systemic Diseases	Prolonged use of computer or reading
Amyloidosis	Reduced humidity
Bell palsy	Smoke exposure
Epstein-Barr virus	Wind and/or use of fans
Graft-versus-host disease	**Local Trauma**
Hemochromatosis	Injury/scarring
Hepatitis C infection	Orbital surgery
Human immunodeficiency virus infection	Radiation
Lymphoma	**Medications**
Neuromuscular diseases	Anticholinergics
Ocular mucous membrane pemphigoid	Antidepressants
Parkinson disease	Antihistamines
Rosacea	Beta-blockers
Rheumatoid arthritis	Diuretics
Sarcoidosis	Hormone therapy
Scleroderma	Systemic retinoids
Sjögren syndrome	Frequent administration of ophthalmic medication
Stevens-Johnson syndrome	
Systemic lupus erythematosus	

Data from American Academy of Ophthalmology Cornea/External Disease Panel. Preferred Practice Pattern Guidelines. Dry Eye Syndrome [Internet]. San Francisco, CA: American Academy of Ophthalmology, 2013 [cited 2017 Aug 30]. Available at: www.aao.org/ppp.

If the dry eye is secondary to a systemic disease, the disease should be managed by the appropriate medical specialist.[16]

► *Nonpharmacologic Therapy*

LO 6 Behavioral and environmental modifications may significantly improve dry eye, especially in mild cases. Patients should be counseled to increase their frequency of blinking, use eyelid hygiene and warm compresses, and stop smoking. Reduce air drafts and consider adding a humidifier in low-humidity areas. Schedule regular breaks from computer work, other electronic screens, or reading. These activities promote decreased blinking and can increase dry eye symptoms. Lower the computer screen to below eye level to decrease lid aperture. Evaluate medication profile and therapeutically substitute medications that do not exacerbate dry eye. Spectacle side shields or goggles may reduce tear evaporation.[15,16]

LO 4 If pharmacologic and other therapies are not sufficient, punctal occlusion or lateral tarsorrhaphy may be an option for more severe cases.[15,16] Punctal occlusion is the plugging of the punctal drainage sites with collagen or silicone plugs. Lateral tarsorrhaphy sutures portions of the lid margins together to decrease evaporative tear loss.

► *Pharmacologic Therapy*

LO 2 The mainstay of treatment for dry eye is artificial tears. Artificial tears augment the tear film topically by increasing viscosity and provide symptom relief. If a patient uses artificial tears more than four times daily, or develops an allergy to ophthalmic preservatives, recommend a preservative-free formulation.

LO 1 Clinical Presentation and Diagnosis of Dry Eye[15,16]

General

Many other ocular diseases have similar symptoms. Patients with suggestive symptoms without signs should be placed on a treatment trial. Repeated observations may be required for a clinical diagnosis.

Symptoms

- Dry or foreign body sensation
- Mild itching
- Burning or stinging
- Photophobia
- Ocular irritation or soreness
- Blurry vision and/or variable vision
- Contact lens intolerance
- Diurnal fluctuation or symptoms worsening later in the day

Signs

- Redness
- Mucus discharge
- Increased blink frequency
- Intermittent tearing

Other Diagnostic Tests

- The tear break-up time test assesses the stability of precorneal tear film. Break-up times of less than 10 seconds are considered abnormal.
- Ocular surface dye staining assesses the ocular surface and will show blotchy areas in the dry eye.
- Schirmer test evaluates aqueous tear production but is not diagnostic. Results of 5 mm or less are considered abnormal.
- Assess corneal sensation if trigeminal nerve dysfunction is suspected.
- Consider an autoimmune disorder if significant dry eyes, other signs and symptoms, or family history are present.

Artificial tears are available in gel, ointment, and emulsion forms that provide a longer duration of relief. Ointment use is appropriate at bedtime as it may cause blurry vision.[15]

LO 2 Preliminary data suggest dietary or supplemental intake of omega-3 fatty acids may be beneficial.[7,15,16] Omega-3 fatty acids may block the production of inflammatory cytokines and proinflammatory mediators.[15]

LO 3 Anti-inflammatory agents may be used in conjunction with artificial tears. The first approved agent was cyclosporine emulsion. Cyclosporine emulsion increases tear production in some patients. Fifteen minutes should elapse after instillation of cyclosporine before artificial tears are instilled.[17] Cyclosporine emulsion may require several months for full results, so it should not be used for acute relief.

An additional treatment for the signs and symptoms of dry eye is twice daily lifitegrast 5% ophthalmic solution. Lifitegrast is a lymphocyte function associated antigen-1 (LFA-1) antagonist. LFA-1 is a protein that interacts with an intracellular adhesion

molecule (ICAM-1). ICAM-1 may be overexpressed in patients with dry eye disease and can promote inflammation of the ocular surface. By blocking the interaction of LFA-1 to ICAM-1, lifitegrast may reduce ocular surface inflammation. The duration of therapy in clinical trials was 12 weeks. The most common adverse effects of lifitegrast include eye irritation, distortion of taste, and reduced visual acuity.[18,19] Use of topical corticosteroids for short periods (2 weeks) may suppress inflammation and ocular irritation symptoms, but should be used with caution[16] (Table 62–10).

LO 2

Outcome Evaluation[16]

- Monitor patient for relief of symptoms and ocular damage.
- Periodically reassess the patient's compliance with therapy and understanding of the disease.
- Cyclosporine therapy may take up to 3 months for full improvement.

Table 62–10

Pharmacologic Therapies for Dry Eye

Drug	Dosing
Cyclosporine ophthalmic emulsion 0.05%	1 drop in each eye twice daily
Lifitegrast 5% ophthalmic solution	1 drop in each eye twice daily
Loteprednol etabonate suspension 0.5%	1–2 drop(s) in affected eye(s) 4 times daily; short-term use only
Cevimeline capsule	30 mg orally 3 times daily

Adapted from American Academy of Ophthalmology Cornea/External Disease Panel. Preferred Practice Pattern® Guidelines. Dry Eye Syndrome [Internet]. San Francisco, CA: American Academy of Ophthalmology, 2013 [cited 2017 Aug 30]. Available at: www.aao.org/ppp.

Patient Care Process: Dry Eye

Collect Information:

- Collect relevant information about medical history of dry eye.
- Collect information about the patient's signs and symptoms related to dry eye.
- Collect relevant information about the patient's behaviors, such as smoking, and environmental risk factors for dry eye.
- Collect an updated medication list including prescription medications, nonprescription medications, herbal products, and dietary supplements.

Assess the Information:

- Assess the patient's signs and symptoms of dry eye for potential need for referral.
- Assess the patient's reported behaviors and environmental risk factors for potential intervention.
- Assess each medication in the patient's medication list for appropriateness and risk of exacerbation of dry eye.

Develop a Care Plan:

- Address the patient's risk factors for dry eye, including potential nonpharmacologic interventions related to smoking and other environmental risk factors.
- Address the patient's medication-related problems and optimize the patient's medication therapy by recommending alternatives to medications that can exacerbate symptoms of dry eye.
- Determine an appropriate care plan based on the patient's frequency of symptoms. The care plan may include treatment options such as over-the-counter formulations of artificial tears, omega-3 fatty acids, or prescription therapies such as cyclosporine or lifitegrast.
- Plan to counsel the patient on appropriate use of ophthalmic solutions that may be utilized as part of the recommended therapy for dry eye.

Implement the Care Plan:

- Engage the patient in discussion about his/her risk factors for dry eye, including potential nonpharmacologic interventions related to smoking and other environmental risk factors.
- Recommend alternatives to medications that can exacerbate symptoms of dry eye.
- Initiate an appropriate care plan based on the patient's frequency of symptoms. The care plan may include treatment options such as over-the-counter formulations of artificial tears, omega-3 fatty acids, or prescription therapies such as cyclosporine or lifitegrast.
- Counsel the patient on appropriate use of ophthalmic solutions with the steps below:
  - Wash hands before and after instilling medication(s) into the eye.
  - Contact lenses should be removed prior to instilling eye medication, and the patient should wait 10 minutes before reinserting contact lenses.
  - Do not touch the tip of the container with anything.
  - Use of nasolacrimal occlusion decreases systemic absorption up to 60% and may increase ocular bioavailability of the drug. After instilling the eye drop, the patient should close the eye and press a finger gently against the nasolacrimal duct (tear duct) for 2 to 3 minutes.[20]
  - Contribute to the coordination of care by referring the patient to an ophthalmologist if self-care is not appropriate.

Follow-up: Monitor and Evaluate:

- Monitor patient for relief of symptoms and ocular damage.
- Assess adherence and recommend alternative formulations of artificial tears if necessary.
- Periodically reassess the patient's compliance with therapy and understanding of the disease.

- If a patient presents with vision loss, moderate or severe pain, corneal ulceration, or a lack of response to therapy, refer the patient to an ophthalmologist for prompt evaluation.

DRUG-INDUCED OCULAR DISORDERS

Many systemic medications can cause ocular adverse effects. Patients presenting with ocular complaints should have their medication profile evaluated.

OTIC DISORDERS

OTITIS EXTERNA

Epidemiology and Etiology

KEY CONCEPT Acute otitis externa (AOE), or what is commonly referred to as swimmer's ear, is an infection of the external auditory canal which potentially involves diffuse inflammation that may extend distally to the pinna and proximally to the tympanic membrane.[21,22] Otitis externa has a lifetime prevalence of approximately 10% and can be considered chronic rather than acute if it lasts 3 months or longer.[21]

A diffuse acute otitis media is diagnosed by a rapid onset, generally within 48 hours, in the past 3 weeks of symptoms and signs of inflammation such as intense or disproportionate tenderness of the tragus, pinna, or both.[22] Patients with a nonintact tympanic membrane, tympanostomy tube, diabetes, immunocompromised state, or prior radiotherapy are at risk for more serious infections and are not treated the same as an uncomplicated AOE.

Pathophysiology

In North America, the vast majority of AOE cases are bacterial caused by pathogens such as *Pseudomonas aeruginosa* and *Staphylococcus aureus*.[21,22] Otitis externa can be polymicrobial, and it should be treated with topical antibiotics if uncomplicated.[22]

Otitis externa can be caused by a variety of different factors such as water exposure, self-cleaning, soapy deposits, alkaline eardrops, dermatologic conditions, trauma, sweating, allergies, genetics, climate, and stress.[22]

Treatment

▶ *Desired Outcomes*

- Relief of the symptoms of otitis externa
- Prevention of long-term adverse effects from otitis externa

▶ *General Approach to Treatment/Nonpharmacologic Therapy*

LO 7 Removing obstructing cerumen; using acidifying ear drops shortly before swimming, after swimming, at bedtime, or all three; drying the ear canal with a hair dryer; using ear plugs while swimming; and avoiding trauma to the external auditory canal are recommended by the guidelines as therapy options for preventing otitis externa.[22]

▶ *Pharmacologic Therapy*

An otitis externa in a patient with a perforated tympanic membrane needs to be treated with medications that are not ototoxic as compared to an uncomplicated case. There are not significant differences in efficacy of the topical agents; therefore, patient and provider preferences, cost, adherence, and adverse effects are priority.[22] Refer to Table 62–11 for common otic preparations.

LO 7

Table 62–11

Pharmacologic Therapies for Otitis Externa

Drug	Considerations
Acetic acid 2.0% solution (Acetic acid otic)	Pain and irritation, may be less effective beyond a week of treatment; not with perforated tympanic membrane
Acetic acid 2.0%, hydrocortisone 1.0 (Acetasol HC)	Pain and irritation; not with perforated tympanic membrane
Ciprofloxacin 0.2%, hydrocortisone 1.0% (Cipro HC)	Twice daily adequate
Ciprofloxacin 0.3%, dexamethasone 0.1% (Ciprodex)	Twice daily adequate
Neomycin, polymyxin B, hydrocortisone (Cortisporin Otic)	Ototoxic; four times daily; not with perforated tympanic membrane
Ofloxacin 0.3% (Floxin Otic)	Twice daily adequate, potentially daily

Adapted from Schaefer P, Baugh RF. Acute otitis externa: An update. Am Fam Physician. 2012 Dec 1;86(11):1055–1061.

Data from Rosenfeld RM, Schwartz SR, Cannon CR, et al. Clinical practice guideline: acute otitis externa. Otolaryngol Head Neck Surg. 2014 Feb;150(1 suppl):S1–S24.

Cortisporin (bacitracin, neomycin, polymyxin B, hydrocortisone) is typically used first in patients with an intact tympanic membrane. Ofloxacin and ciprofloxacin/dexamethasone (Ciprodex) are used with a perforated tympanic membrane or if it cannot be visualized. A total of 7 to 10 days of topical therapy is recommended.[22] Also, pain is very common with otitis media, and it needs to be managed accordingly. Anesthetic otic drops are not recommended for pain management. If there is no improvement with the drops within 48 to 72 hours, then the diagnosis of otitis externa should be reviewed.

LO 7

Patient Encounter 3

NL, a 25-year-old white female, presents with an irritation to her left ear that started about 24 hours ago. She has recently started swimming at a local pool for exercise.

PMH: Hypertension

PE:

BP 142/82, P 68, R 14, Ht. 5'6" (168 cm), Wt. 132 lbs (60 kg)

Medications:

Lisinopril 10 mg daily

Multivitamin daily

Does NL have any potential risk factors for acute otitis externa?

What pharmacologic options are available?

What nonpharmacologic therapies could NL do to decrease the likelihood of this happening again?

Outcome Evaluation

- Monitor patient for relief of symptoms and otic damage.

CERUMEN IMPACTION

Epidemiology and Etiology

One of the most common reasons for patients seeking care for auditory problems is obstruction of the ear. Ear canal obstruction is most commonly caused by cerumen. Twelve million people in the United States annually seek care for cerumen impaction, 8 million cerumen removal procedures occur annually, and "… one in 10 children, 1 in 20 adults and more than one-third of the geriatric and developmentally delayed populations…" have excessive or impacted cerumen.[23]

Pathophysiology

Obstruction can lead to more serious problems including hearing loss, tinnitus, fullness, itching, otalgia, discharge, odor, and cough. Hearing loss can range from 5 to 40 dB depending on the degree of occlusion of the canal with cerumen.[23] Cerumen impaction can also prevent a provider from viewing the external auditory canal and/or tympanic membrane and performing auditory diagnostic tests that are vital components of any physical examination. Common symptoms include pain, itching, sensation of fullness, tinnitus, odor, drainage, and cough.

Treatment

▶ *Desired Outcomes*

- Relief of the symptoms of Cerumen impaction

▶ *General Approach to Treatment*

Prevention of cerumen impaction includes education in proper ear hygiene. Proper ear hygiene does not include using cotton-tipped swabs to clean ears. Cotton-tipped swabs have been implicated in increasing cerumen impaction.[23] Alcohol or hydrogen peroxide drops or irrigation, topical earwax-softening agents, and irrigation are all potential options for secondary prevention of impacted cerumen.[23]

Only patients who are symptomatic should receive treatment.[1] Patients with cerumen that prevent assessment of the ear should also be treated. Treatment for cerumen impaction may include cerumenolytic agents, irrigation, or manual removal.[23] Cerumenolytics work by thinning the cerumen to decrease the need for irrigation and manual removal. All cerumenolytic agents have been shown to be equally efficacious including water. The different cerumenolytic agents available include water-based, oil-based, and nonwater- and nonoil-based. Water-based agents work by breaking up the cerumen while oil-based preparations soften without breaking up the cerumen. Irrigation uses a jet of warm water to flush out the cerumen. A curette, probe, hook, forceps, or suction may be used for manual removal. All treatment regimens have been shown to be efficacious and none are preferred over another.

Side effects, although rare, can occur with treatment for cerumen impaction. Some side effects include tympanic membrane perforation, ear canal laceration, infection of the ear, bleeding, or hearing loss. The number of side effects from cerumen impaction treatment that occur in the United States is around 8000 yearly.[23]

Outcome Evaluation

- Monitor patient for relief of symptoms from excess cerumen.

Abbreviations Introduced in This Chapter

ABC	Acute bacterial conjunctivitis
AOE	Acute otitis externa
ICAM	Intracellular adhesion molecule
LFA	Lymphocyte function associated antigen
NSAID	Nonsteroidal anti-inflammatory drug

63 Allergic Rhinitis

Hanna Phan and Michael Daines

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

LO

1. Describe the basic pathophysiology of allergic rhinitis (AR).
2. Define mild versus moderate/severe AR, persistent versus episodic, and differentiate between seasonal, perennial, and episodic AR.
3. Differentiate the categories of pharmacotherapy choices for treatment of AR based on mechanism, efficacy on symptom type (eg, ocular, nasal congestion), and side effect profile.
4. Identify situations in which a referral to an allergy specialist is needed.
5. Describe an approach for treatment and monitoring for treatment of mild and moderate–severe AR based on patient specific factors.
6. Identify the differences in approach to the treatment of AR for children, pregnant women, and the elderly compared with the routine approach in adults.

INTRODUCTION

Rhinitis is inflammation of the lining of the nose and contiguous parts of the upper respiratory tract.[1–4] Allergy is only one of numerous causes of rhinitis.[1–5] The most common causes of nonallergic rhinitis (NAR) are shown in Table 63–1.[1-5] Some patients suffer concurrently from both allergic rhinitis (AR) and one or more types of NAR. This is sometimes called mixed rhinitis (MR).[1,3] AR will be emphasized in this chapter, but some mention will be made of NAR. Because ocular symptoms (eg, itching and/or redness of eyes, tearing) frequently occur in association with AR, some sources use the term allergic rhinoconjunctivitis. This acknowledges involvement of the bulbar and palpebral conjunctivae in the allergic process.

KEY CONCEPT AR is an allergen-induced, immunoglobulin E (IgE)-mediated inflammatory condition of the lining of the nose and upper respiratory tract.[1,6–9] This pathophysiologic feature differentiates AR from NAR. AR has traditionally been categorized as either seasonal or perennial.[7,8] Seasonal allergic rhinitis (SAR) is attributed to inhaled allergens (aeroallergens) that have a seasonal variation. These allergens are usually encountered outdoors and are most often grass, tree, or weed pollens and substances from molds and fungi. Length of seasonal exposure depends on geographic location and climatic conditions.[7,8] Perennial allergic rhinitis (PAR) is attributed to aeroallergens that are present in the patient's environment year-round and are usually encountered indoors. Common perennial allergens are the house dust mite, indoor molds and fungi, insects (especially cockroaches), and companion animals (pets).[7,8] Some patients are affected by AR year-round, but have seasonal exacerbations. These people are probably allergic to both seasonal and perennial aeroallergens. Other patients have only episodic manifestations. These people are probably allergic to aeroallergens that are only episodically encountered (eg, cat at a friend's house).[7,8]

LO 2

Because these traditional categories of seasonal and perennial AR are imperfect and help little with therapeutic management decisions, another system for categorizing AR has been suggested by guidelines.[8,9,10] This alternative system categorizes the manifestations by a combination of frequency and severity. There are two divisions of frequency: intermittent and persistent. Intermittent frequency is defined as AR manifestations occurring less often than 4 days per week or for fewer than 4 consecutive weeks. Persistent frequency is defined as AR manifestations occurring for 4 or more days per week *and* for 4 or more consecutive weeks. Severity is categorized as either mild or moderate–severe based on presence of the following symptoms: sleep disturbance, impairment of daily activity (including leisure and/or sports), impairment of work/school, and troublesome symptoms. Mild manifestations are those of which none of the listed symptoms are present. Moderate–severe severity includes those patients with manifestations of AR with at least one of the listed symptoms present. Additionally, AR impact on comorbidities such as asthma and sinus disease which can also be considered when evaluating a patient's AR severity. See Table 63–2 for a summary of these categories of AR.

EPIDEMIOLOGY AND ETIOLOGY

AR affects up to 40% of adults and 25% of children in the United States.[8,9] The direct health care expenditures of AR in the United States were estimated to be between 2 to 5 billion dollars, annually.[8] Indirectly, as much as 4 billion dollars in work and school loss has been reported annually.[8]

Etiology of AR is multifaceted, both genetic and environmental in nature. Some studies have suggested that in addition to possible genetic predisposition, inadequate environmental exposure (eg, to animals) in early life may increase risk for AR.[11] The major risk factors for AR are: a family history of atopy (AR, asthma, eczema or food allergies); elevated serum IgE levels (especially before the age of 6 years); higher socioeconomic class; positive skin test results; exposure to particulate air pollution; maternal smoking;

Table 63–1

Types of Rhinitis

Allergic (see Table 63–2 for details)

Nonallergic

Vasomotor (also known as perennial nonallergic, idiopathic, and autonomic rhinitis) (triggered by irritants, cold air, exercise/running, or unidentified factors)
Food/meal related (gustatory)
Infectious
NARES (nonallergic rhinitis with eosinophilia syndrome)
Occupational (caused by protein allergens [IgE-mediated] or by irritants [probably non–IgE-mediated])
Hormonally related (hypothyroidism, pregnancy, menstrual cycle related, and some drugs [see below])
Drug-induced
- Angiotensin-converting enzyme inhibitors (ACEIs)
- α_1-blockers (used for treatment of BPH and HTN)
- Phosphodiesterase-5 inhibitors (used for treatment of ED)
- Aspirin and other NSAIDs (as an isolated side effect of AERD)
- Oral contraceptives and hormone replacement therapy
- Miscellaneous agents have been implicated (calcium channel blockers, some diuretics, centrally acting alpha-2 agonists, risperidone, gabapentin)

Atrophic rhinitis
Rhinitis associated with inflammatory or immunologic diseases (eg, granulomatous infections, SLE, Wegener granulomatosis, sarcoidosis, Churg–Strauss syndrome)
Malignancy

Mixed

Combination of allergic and nonallergic manifestations

AERD, aspirin-exacerbated respiratory disease; BPH, benign prostatic hyperplasia/hypertrophy; ED, erectile dysfunction; HTN, hypertension; NSAIDs, nonsteroidal anti-inflammatory drugs; SLE, systemic lupus erythematosus.

From Refs. 1–5.

Table 63–2

Categories of Allergic Rhinitis

Based on Etiologic Category

Seasonal—symptoms due to seasonal aeroallergens; present only during specific portions of the year, with length of exposure dependent on geographic location and climate conditions
Perennial—symptoms present throughout the year due to environmental aeroallergens,such as indoor allergens (eg, dust mites)
Episodic—symptoms present only during intermittent exposure to allergen trigger (eg, exposure to a friend's pet)

Based on ARIA 2016 Update

Symptoms: sleep disturbance, interference with daily activities (including leisure or sport), impairment of school/work, and troublesome symptoms
Mild versus moderate–severe
- Mild—none of the above symptoms present
- Moderate–severe—presence of any one of the above symptoms

Intermittent versus persistent
- Intermittent—symptoms are present for less than 4 days/week, or for less than 4 consecutive weeks
- Persistent—symptoms are present for 4 or more days/week and for more than 4 consecutive weeks
- Any one of the four possibilities of these variables can occur: mild intermittent, mild persistent, moderate–severe intermittent, and moderate–severe persistent

From Refs. 8, 9, and 10.

firstborn status; and emigration into a Western industrialized environment.[5,7,9,10,12,13] Certain disorders commonly occur with AR. The most important example is asthma. While different percentages are reported, most patients with asthma have rhinitis symptoms (many of which are AR), and only somewhat fewer with AR have asthma.[5,13] In fact, there is evidence that AR can predispose to the development and/or worsening of asthma.[1,5,13] Other conditions that can occur with AR include allergic conjunctivitis, eczema, sinusitis, sleep disorders, otitis media with effusion, and the oral food allergy syndrome.[5,10]

PATHOPHYSIOLOGY

LO 1

AR is an IgE-mediated disorder of people who are allergy prone. Initial contact is required to sensitize the patient to subsequent exposures. Patients with an inherited tendency to allergic disorders produce T-helper lymphocyte type 2 (Th-2)-directed responses, including production of specific IgE antibodies, to one or more allergens. Many types of cells, mediators, and intermediate substances (including cytokines) are involved. In response to subsequent exposures to the trigger antigen(s), there is an early-phase and often a late-phase allergic response. This distinction has therapeutic implications.[1,5,6-10]

During the early phase, the trigger allergen becomes bound to IgE that is fixed to mast cells in the nasal mucosa. This occurs within minutes of subsequent exposure to the antigen. Mast cells degranulate and release preformed mediators, the most important of which is histamine. This stimulates more mast cells, as well as macrophages, eosinophils, and basophils to produce more substances, including cysteine leukotrienes and prostaglandin D_2. These mediators bind to receptors in the nose and facilitate many of the manifestations of AR. The resultant vasodilation, mucosal edema, and hypertrophy all contribute to nasal congestion. Clear, watery, and often profuse rhinorrhea is also characteristic in this early phase, a result of mucous secretion and increased vascular permeability. Sneezing and nasal itch are other prominent features of the early phase. Many patients also have ocular symptoms.[1,5,6-10]

The late phase occurs in about 50% of AR sufferers. It can begin as soon as 2 hours after the early phase and usually peaks between 6 and 12 hours. The late phase involves a second release of many of the mediators of the early phase. In addition, the late phase is characterized by an inflammatory component caused by infiltration of several cell types into the nasal mucosa. The most significant manifestation during the late phase is nasal congestion that is often severe and long lasting.[1,5,6–10]

A phenomenon known as the priming response or nasal hyperresponsiveness is also of importance. This means that prolonged and/or repeated allergen exposure makes it easier to stimulate mediator release and symptoms. A vicious cycle results in which smaller doses of allergen can create symptoms (ie, the threshold is lowered). Thus, even when pollen exposure is decreased, symptoms may continue. In some patients, the threshold is lowered to the degree that even irritant substances (eg, formaldehyde, tobacco smoke, perfumes, automobile exhaust, and other environmental pollutants) may cause symptoms, on a nonallergic basis.[1,5,6–10]

TREATMENT

General Approach and Desired Outcomes

Guideline documents have been published on AR.[7–10] They provide some of the basis for the sections that follow. Although guideline documents are highly regarded by many, the patients enrolled

Clinical Presentation and Diagnosis of Allergic Rhinitis[1–3,6,7,13,14]

Typical Symptoms

- Rhinorrhea (usually clear and bilateral; primarily anterior but may be posterior [postnasal drip])
- Sneezing
- Itching (mostly nasal, but also palate, throat, eyes, ears)
- Nasal congestion (not in all patients, but when present, usually the most troublesome symptom)

Other Symptoms

- Ocular manifestations (itch, redness, tearing, chemosis, periorbital edema)
- Sleep disturbances often with fatigue, asthenia, malaise, and irritability
- Presenteeism (impaired performance at work or school)
- Absenteeism from work or school
- Quality of life impairment (including social function)
- Headache, mild facial or ear pain or fullness
- Cough (especially in those with concurrent asthma)
- Children (especially): snorting, sniffling, clearing the throat, learning or attention problems, poor appetite

Signs (Especially Common in Children)

- Pale, boggy nasal mucosa
- Rubbing the nose upward (allergic salute; may create horizontal crease just above tip of nose)
- Rubbing/scratching of eyes
- Mouth breathing
- Dark circles under the eyes (allergic shiners)
- Dennie-Morgan lines or folds under the eyes

Diagnosis

- Typical symptoms, confirmatory signs, especially in association with exposure to allergen triggers
- Other diagnostic testing usually optional, but may be necessary to rule out nonallergic causes or if immunotherapy is considered (appropriate physical examination, specific IgE antibody testing by either skin testing or in vitro serum testing, other specialized testing)
- Several sources particularly good for differential diagnosis of nonallergic rhinitis[3,13,15]
- Vasomotor rhinitis—sneezing and itch less common than AR; anosmia more common
- Unilateral symptoms—refer for possible obstruction, anatomic abnormality, tumor, cerebrospinal fluid (CSF) leak
- Atrophic rhinitis—older adults, history of nasal surgery

in the randomized clinical trials that are a major basis for their conclusions and recommendations are not always representative of patients in a primary practice population.[15] KEY CONCEPT The general approach for treatment of AR is fourfold: avoidance of allergen triggers, pharmacotherapy, immunotherapy, and patient/caregiver education.[8–10] Recommended approaches to AR management begin with allergen avoidance and patient/family education. If allergen avoidance is not sufficient and/or symptoms necessitate treatment, pharmacotherapy is utilized. Failure to respond to first-line over-the-counter (OTC) or prescription AR medication may warrant referral to an allergy specialist for further assessment. Based on assessment by a specialist, immunotherapy may also be an option in selected patients.

LO 4

Patient Encounter 1, Part 1

Mr. Z, a regular customer in your community pharmacy, asks your advice about helping his 5-year-old daughter, Kim. She has a diagnosis of "mild" asthma that is primarily exercise-induced but is well controlled on fluticasone 44 mcg 1 puff twice a day and has an albuterol metered-dose inhaler for use before exercise and as needed for shortness of breath. Kim has recent had frequent trouble with runny nose, sneezing, and watery and itchy eyes, as well as "throat" itching.

What information is suggestive of AR? What additional information is needed in order to make a recommendation in treatment?

Education of the patient and the patient's support system is essential.[7] All parties need to understand the potential seriousness of AR (including complications such as asthma) and the chronic, recurrent nature of AR. All should be told about the treatment options, including their relative advantages and disadvantages. Proper understanding and use of current medication in the patient's regimen should be assured. A better educated patient and support system will result in a better relationship with health care providers and hopefully will optimize patient outcomes.

KEY CONCEPT The goals of treatment of AR are to minimize the frequency and severity of symptoms, prevent comorbid disorders and complications, improve the patient's quality of life, improve work attendance and productivity and/or school attendance and performance, and minimize adverse effects of therapy. Until a cure is established, these are the only realistic goals.

Nonpharmacologic Therapy

Avoidance of allergen triggers is a core component of nonpharmacologic therapy of AR. Patient and caregiver education is fundamental in reducing preventable allergen exposure. Avoidance of allergen triggers, to the extent they have been identified and to the extent such avoidance is possible, underlies the treatment for all patients with AR (see Table 63–3).[7–10]

▶ *Saline*

Nasal administration of saline is an alternative and often used as an adjunctive, nonpharmacological treatment of AR.[5,7,16,17] This therapy may benefit any patient with rhinitis, including those with vasomotor rhinitis.[5] Saline may be administered as drops or a spray, but the irrigation mode of administration is popularly known by several terms, including neti pot, nasal wash, nasal douche, nose bidet, and as nasal irrigation. Although

Table 63–3

Allergen Avoidance Measures

Allergen avoidance underlies all other treatments of AR

There are several limitations to allergen avoidance:

- Allergen(s) must be identified.
- Literature support for a clinically significant improvement in symptoms from allergen avoidance is meager.
- Quality of life may be negatively impacted by forced removal of a pet from the household.

Outdoor plant pollen and mold/fungi parts:

- Limit outdoor exposure, especially during high pollen conditions (warm sunny days with wind and low humidity) and during mold/fungi spore release (shortly after rains).
- Wear a face mask during activities that disturb soil and decaying vegetation.
- Keep windows and doors closed.
- Use air conditioning, but maintain clean equipment.

Indoor allergens (house dust mite, mold/fungi, cockroaches, and pets):

- Use air-conditioning, as above.
- Maintain humidity below 50%, and maintain clean equipment.
- Clean frequently to prevent mold growth (dilute bleach with detergent).
- Avoid exposed food and garbage to deter insects.
- Clean kitchen frequently.
- Use roach traps that facilitate their removal.
- Vacuum frequently, and use a high-efficiency particulate air (HEPA) filter.
- Minimize carpeting, fabric covered furniture, and fabric wall/window coverings.
- Cover bedding (pillows, mattresses, box springs) with allergen-proof, zippered cases.
- Launder bedding frequently, in hot water (> 130°F or 54°C) to kill mite ova.
- Consider acaricide (eg, benzyl benzoate) treatment of carpets to kill mites and ova.
- Put items that cannot be laundered (eg, soft toys) in a plastic bag and freeze.
- Keep pets out of bedroom and bathe cats weekly, if possible.

Irritants:

- Avoid, as possible, all exposure to smoke, chlorine fumes, formaldehyde fumes, and other substances identified as irritant triggers (eg, perfumes, newspaper ink).

From Refs. 7–10.

Table 63–4

Intranasal and Oral Medications for AR

Corticosteroids
Intranasal[a] (budesonide [OTC], beclomethasone, ciclesonide, flunisolide, fluticasone [propionate and furoate] [OTC], mometasone, triamcinolone [OTC])
Oral (rarely used, eg, prednisone)

Antihistamines
Intranasal[a] (azelastine, olopatadine)
Oral[b]

- First generation/sedating (cautious use in selected patients) (most OTC depending on strength: diphenhydramine, chlorpheniramine, clemastine, and others)
- Second generation/low- or nonsedating[a]: loratadine (OTC), cetirizine (OTC), fexofenadine (OTC), levocetirizine (OTC), desloratadine,

Combination Antihistamine/Corticosteroid
Intranasal (azelastine and fluticasone propionate)

Mast cell stabilizer/cromone
Intranasal (cromolyn [OTC])

LTRA
Oral (montelukast)

Antimuscarinic
Intranasal (ipratropium)

Decongestant
Intranasal (short-term use) (tetrahydrozoline, phenylephrine [OTC], naphazoline [OTC], oxymetazoline [OTC])
Oral[b] (phenylephrine [OTC]; pseudoephedrine [BTC[c]])

[a]First-line choices.

[b]Some products combine an antihistamine with a decongestant, sometimes with other ingredients.

[c]Behind the counter (OTC plus other requirements necessary; see the Decongestants section of text).

Note: All products are prescription unless indicated as OTC.

From Refs. 7–10 and 18–20.

less effective than intranasal corticosteroids (INCSs), it has been shown to improve sneezing and nasal congestion. It can be used either alone or as add-on therapy. The formula provided by the American Academy of Allergy, Asthma and Immunology (AAAAI) should be followed for those making their own saline nasal irrigation solution.[17] Iodized salt is not recommended as it may be irritating. Hypertonic saline seems to have no advantage over 0.9% sodium chloride. Administration can be accomplished while the patient is in the shower or leaning over a sink. The head is bent forward and downward, then tilted to the side opposite the treated nostril. Then, with a bulb syringe or similar device, slowly introduce about 4 oz (118 mL) of the warm saline solution into one nostril. Soon, the solution will run out of the opposite nostril. The position of the head should be adjusted as necessary to avoid the solution running into the ears or down the throat.

Nasal irrigation is one delivery method, although the optimal method (spray, drops, nebulizer, or irrigation) is not known. Optimal frequency of administration is also not known. Nasal irrigation is usually given twice daily, but use of smaller volumes as spray products may be given up to four times daily. Side effects are usually limited to minor local nasal irritation, but nausea has been reported.

Pharmacologic Therapy

LO 3

KEY CONCEPT Routine first-line agents for the treatment of AR are INCSs and oral (or possibly intranasal) antihistamines. Secondary agents, each of which may have a first-line role in selected patients, include oral (and rarely intranasal) decongestants, the intranasal mast cell stabilizer (cromolyn), the oral leukotriene receptor antagonist (LTRA) (montelukast), the intranasal antimuscarinic (ipratropium), and intranasal saline irrigation. See Table 63–4 for intranasal and oral medications for the treatment of AR. Treatment selection, among common medications for AR, can vary based on best available evidence (ie, guidelines, clinical trials, etc) for a given medication in addition to the severity of AR of a given patient. See Figure 63–1. In all cases, therapy must be individualized, in cooperation with the patient. Considerations include frequency and severity of specific symptoms, realistic avoidance measures, patient age, patient preferences for route of administration, tolerance of side effects, adherence issues, comorbid disorders, and concurrent therapy.

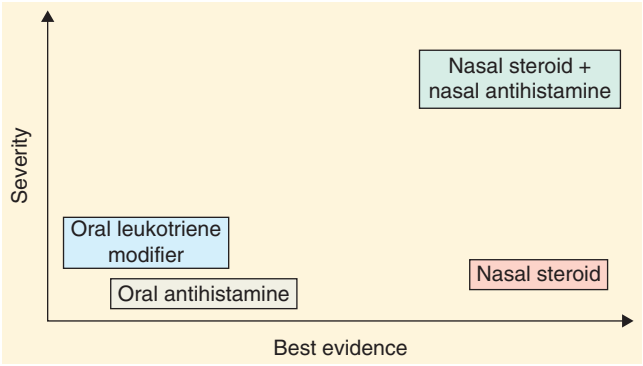

FIGURE 63–1. Evidence-based treatment options for AR based on current guidelines. (From Refs. 7–10.)

Some clinicians may elect to use an action plan for AR with their patients, similar to that used for asthma.[7] Some patients may benefit from having an AR action plan, depending on their AR severity and complexity of therapy.

▶ *First-Line Agents*

Corticosteroids. Corticosteroids are usually administered by the intranasal route for the treatment of AR. Occasionally, a short course of oral therapy (eg, prednisone burst and taper) is necessary. Oral corticosteroids may be used to overcome severe nasal congestion, particularly that due to rhinitis medicamentosa (see the section on Decongestants). Parenteral administration of corticosteroids for AR is discouraged due to side effects.[5,7,10]

INCSs provide very good relief for sneezing, itching, and rhinorrhea, and even nasal congestion and ocular symptoms. Nasal congestion is often the most bothersome symptom of AR, and the most difficult to control. This is probably because it results from inflammation that predominates in the late phase of the allergic response. KEY CONCEPT INCSs are the most effective therapy for AR, especially for nasal congestion. Their anti-inflammatory mechanism of action probably contributes to this superiority.[5,6,13] The majority of contemporary literature suggests that INCSs are superior to intranasal antihistamines, to oral antihistamines even when combined with a leukotriene antagonist, and to a leukotriene antagonist alone.[5,8–10] In recent guidelines by the American Academy of Allergy, Asthma, and Immunology (AAAAI) and American College of Allergy, Asthma, and Immunology (ACAAI), INCSs are recommended as monotherapy versus in combination with an oral antihistamine for initial treatment of nasal symptoms of seasonal allergic rhintitis in patients ages 12 years and older. Additionally, in patients ages 15 years and older with moderate to severe SAR, INCSs are recommended over an LTRA such as montelukast.[7]

There are currently eight INCS products available in the United States, including two different salt forms of fluticasone. Most (budesonide, ciclesonide, fluticasone furoate, mometasone, and triamcinolone) are used once daily. However, fluticasone propionate may be given either once or twice daily, beclomethasone is usually given twice daily, and flunisolide is given two or three times daily. There is no good evidence that any single product is superior in efficacy. INCSs are best given regularly, as the onset of action usually takes up to 12 hours and the maximum effects may be delayed up to 14 days.[5,7–10,18] In some people the onset is within 3 to 4 hours, so these agents may even be used on an as-needed basis.[7,19] When nasal congestion is severe, intranasal administration may not be effective due to limited exposure to the nasal mucosa. Short-term use of intranasal decongestants may facilitate better exposure. Two agents are formulated as hydrofluoroalkane (HFA) metered-dose aerosols: beclomethasone (Qnasl) and ciclesonide (Zetonna), which may be better tolerated.[19,20] There is also a fixed dose intranasal combination of fluticasone propionate with azelastine (an antihistamine).[19,20] See Table 63–5 for INCS products.

The correct technique for administration of intranasal medication is important for optimum efficacy. Consult the individual product labeling for specific instructions. Also see Table 63–6 for general instructions for the optimal administration of intranasal solutions. The technique described maximizes exposure of the drug to the nasal mucosa to optimize efficacy and minimizes both exposure to the nasal septum and loss of medication down the esophagus.

Most patients tolerate INCSs very well. Local side effects include nasal burning, irritation, and dryness, which may occur in 2% to 10% of patients.[5,8,20] Also, 2% to 8% of patients may experience mild epistaxis.[5,8] This may be partly due to administration technique. Perforation of the nasal septum is very rare. This can be minimized by proper administration technique (see Table 63–6), specifically, directing the spray laterally and away from the (medial) nasal septum.[5,8,19,20]

The older INCSs (beclomethasone, flunisolide, and budesonide) have significant absorption, whereas, among the newer products, fluticasone, ciclesonide, and mometasone have bioavailability of less than 1% to 2%.[22] The decreased absorption minimizes systemic side effects. However, there is still some concern for hypothalamic–pituitary–adrenal (HPA) axis suppression (growth suppression), osteoporosis, and ocular effects (glaucoma, cataracts).[5,22,23] There is no confirmation that INCSs *cause* posterior subcapsular cataracts, increased intraocular pressure, or decreased bone density; however, those with risk factors for these conditions should be monitored carefully for their development.[5,22,23] Additionally, clinicians should examine total corticosteroid exposure (ie, from all sources, inhaled, oral, etc) in assessing potential risk for adverse effects from systemic exposure.[22,23] Ultimately, patient preference for a specific INCS may be determined more by cost, availability, and formulation differences that affect odor and aftertaste.

Antihistamines. Antihistamines used for AR treatment are administered by either the oral or the intranasal route. These agents interact with the histamine type 1 (H_1) receptor. They are technically inverse agonists, not competitive antagonists; however, there may be little clinical significance to the difference.[24] These drugs bind H_1 receptors, keeping them in the inactive state. This downregulation of H_1 receptor activity results in a decrease in end organ effects.

Activation of H_1 receptors in the nose, upper airway mucosa, and the eye produce the common manifestations of AR (sneezing, itching, rhinorrhea, nasal congestion, and ocular symptoms). The antihistamines are very effective for the sneezing, itching, and rhinorrhea. There is some improvement of nasal congestion, but less so than for the other symptoms. There is also benefit for the ocular symptoms (eg, itching, redness, tearing). Intranasal administration is more effective than oral administration for the nasal congestion, but less effective for the ocular symptoms. The onset of action by oral administration is usually within 1 to 2 hours, and for intranasal administration within 15 minutes.[5,6,19,20] Antihistamines probably provide better relief when used continuously during symptomatic periods, but they are also effectively used only when needed for mild and/or intermittent or episodic AR.

Table 63–5

Intranasal Corticosteroids

Generic (Brand) Name	mcg/dose	Adult Dosages (each nostril)	Pediatric Dosages (each nostril)[a]
Beclomethasone dipropionate (Beconase AQ)	42	1–2 sprays twice daily	6 yo and older: 1–2 sprays twice daily, once symptoms controlled decrease dose to 1 spray twice daily 12 yo and older: 1–2 sprays twice daily
Beclmethasone dipropionate (Qnasl [HFA MDP])	40 80	— 2 sprays once daily	4–11 years: 1 spray once daily 12 yo and older: 2 sprays once daily
Budesonide (Rhinocort Aqua)	32	1–4 sprays once daily	6–11 yo or older: 1–2 sprays once daily 12 yo and older: see adult dosing
Ciclesonide (Omnaris)	50	2 sprays once daily	2–11 yo: 1–2 sprays once daily (perennial AR) 6 yo and older: 2 sprays once daily (seasonal AR)
Ciclesonide (Zetonna [HFA MDP])	37	1 spray once daily	12 yo and older: 2 sprays once daily (perennial AR) 12 yo and older: 1 spray once daily (seasonal AR)
Flunisolide	25	2 sprays two or three times daily	6–14 yo or older: 1 spray three times daily or 2 sprays twice daily 15 yo and older: 2 sprays two or three times daily
Fluticasone furoate (Veramyst)	27.5	2 sprays once daily	2–11 yo or older: 1–2 sprays once daily 12 yo and older: 2 sprays once daily
Fluticasone propionate (Flonase)	50	1–2 sprays once daily or 1 spray twice daily	4–11 yo or older: 1 spray once daily
Mometasone (Nasonex)	50	2 sprays once daily	2–11 yo or older: 1 spray once daily 12 yo and older: 2 sprays once daily
Triamcinolone acetonide (Nasacort AQ)[b]	55	2 sprays once daily	2–5 yo: 1 spray once daily 6–12 yo: 1–2 sprays once daily

[a]Includes off-label dosing from Ref. 19,20.

[b]Available OTC.

Note: All products are FDA pregnancy category C except budesonide, which is B.

mcg, micrograms; yo, years old; HFA, hydrofluoroalkane (propellant); MDP, metered-dose pump.

From Refs. 7–10 and 18–20.

The oral agents are divided into first- and second-generation drugs. The first-generation agents are distributed among six chemical classes, including the more sedating ethanolamine class (eg, diphenhydramine) and the least sedating alkylamine class (eg, chlorpheniramine). Most sources now discourage the routine use of the first-generation agents for AR. This is due to their central nervous system (CNS) and antimuscarinic side effects. The CNS effects are primarily sedation and impairment of cognitive function and performance of tasks. Decision-making and driving or work/school performance can be impaired even when the patient is unaware of any overt effects.[6,7] The major antimuscarinic effects include blurred vision, dry mouth, urinary retention, and constipation. The only possible advantage of the antimuscarinic properties is an additional effect to decrease rhinorrhea. Another

Table 63–6

Administration Instructions for Intranasal Solution Medications (not HFA MDP products)

1. Clear the nose of mucus and debris.
2. Consult product labeling for preadministration instructions (eg, shaking the container, priming the spray pump).
3. Do not tilt head backward. This increases drug lost down the esophagus. This decreases efficacy and increases the potential for systemic absorption and thus systemic side effects.
4. Bend the head forward (flex the chin onto the chest) so that the nose is the lowest portion of the head. This is best for nasal sprays. If possible, lie down with the stomach on a flat surface or kneel down. Then, flex chin onto neck, so that the open nostrils are pointing upward, toward the ceiling. This position may be best for nose drops (more volume than sprays). An alternate position is to lie supine on a flat surface, then bend the neck backward (extend the head), so that the open nostrils point upward toward the ceiling.
5. Use the contralateral hand to insert the spray nozzle or dropper into one nostril (ie, the left hand for right nostril).
6. Use the other hand to occlude the opposite nostril (the one not being medicated).
7. Aim the spray or drops toward the outer (lateral) inside surface of each nostril and away from the nasal septum.
8. Breath in slowly but deeply through the medicated nostril.
9. Repeat this procedure to apply medication to the other nostril.
10. Consult the product labeling for instructions on cleaning the device.
11. See the text for information about preparation and use of saline irrigation.

HFA, hydrofluoroalkane (propellant); MDP, metered-dose pump.

From Refs. 8 and 21.

disadvantage of the first-generation antihistamines is that most are administered three to four times daily due to shorter half-life. Patients who take other sedative substances may have an additive effect from the antihistamine. Those taking any other medications with antimuscarinic properties may experience additive effects from the antihistamine. The elderly are, in general, more sensitive to both types of adverse effects.

Currently available oral second-generation H_1 antihistamines are cetirizine, loratadine, and acrivastine. All except acrivastine are available as a single agent, and some are marketed in combination with the decongestant pseudoephedrine. As these agents are active metabolites of preceding agents, fexofenadine (preceding agent was terfenadine, removed from marked due to cardiac toxicity), levocetirizine, and desloratadine are informally labeled as "third generation" antihistamines, but sometimes classified as "second generation" antihistamines. As of August 2014, cetirizine, loratadine, and fexofenadine are available OTC. The second-generation antihistamines have less antimuscarinic activity than the first-generation agents. Based on current literature, no single H_1 antihistamine (first- or second-generation) is clearly superior in efficacy; however, very few head-to-head comparative studies have been conducted. Individual variation is likely, and patients may need to try more than one product to realize optimal benefit. The oral second-generation antihistamines are effective for the sneezing, itching, and rhinorrhea of AR, but less effective for the nasal congestion. They also improve ocular symptoms. Intranasal antihistamines are somewhat better for nasal congestion.

Fexofenadine has virtually no sedative effects, even at doses higher than recommended. Loratadine and desloratadine are not sedative at recommended doses, but can be at higher doses. Cetirizine, levocetirizine, and acrivastine have some sedative effects, even at recommended doses. All the oral second-generation agents require some dosage reduction with impaired renal function, but specific recommendations vary with creatinine clearance.[25,26] Most of the oral second-generation antihistamines can be administered once daily (except for the lower dosage forms of fexofenadine and the acrivastine combination product).

There are only two intranasal antihistamine products available in the US market as of July 2017, azelastine and olopatadine. These are considered second-generation agents, although they also have anti-inflammatory effects.[27] Both are available only by prescription. The most common side effect of these products is a bitter taste. This is more common with the original formulation of azelastine (Astelin) and less common with olopatadine.[7,19] A specific formulation of azelastine (Astepro) has less bitter taste.[20,27] There is also an available combination product with azelastine and fluticasone propionate.[28] There is enough systemic absorption to cause sedation in some patients using azelastine (about 10%) and perhaps somewhat fewer on olopatadine.[7,20] See Table 63–7 for the single-agent second-generation antihistamine products.

Table 63–7

Single-Agent Second-Generation Antihistamine Products (Oral and Intranasal)

Oral Dosage Forms

Generic (Brand) Name	Formulation	Usual Adult Dosage	Usual Pediatric Dosage
Cetirizine[a,b] (Zyrtec, generic)	5, 10 mg tabs/chew tabs; capsule 5 mg/5 mL syrup	5–10 mg once daily	6–11 mo; 2.5 mg once daily 12–23 mo; 2.5 mg once or twice daily 2–5 yo; 2.5–5 mg once daily or 2.5 mg twice daily
Desloratadine[b] (Clarinex)	5 mg tabs; 2.5 mg/5 mL syrup 2.5, 5 mg orally disintegrating tabs	5 mg once daily	6–11 mo; 1 mg once daily 1–5 yo; 1.25 mg once daily 6–11 yo; 2.5 mg once daily
Fexofenadine[a,b] (Allegra, generic)	60, 180 mg tabs, 6 mg/mL suspension 30 mg orally disintegrating tabs	60 mg twice daily or 180 mg once daily	2–11 yo; 30 mg twice daily
Levocetirizine (Xyzal)	5 mg tabs 2.5 mg/5 mL solution	5 mg once daily	6 mo–5 yo; 1.25 mg once daily 6–11 yo; 2.5 mg once daily
Loratadine[a,b] (Claritin; Alavert, generic)	10 mg tabs and cap; 5 mg/5 mL syrup and susp; 10 mg disintegrating tabs; 5 mg chewable tab	10 mg once daily	2–5 yo; 5 mg once daily

Intranasal Sprays

Generic (Brand) Name	mcg/spray	Usual Adult Dosage (Each Nostril)	Usual Pediatric Dosage (Each Nostril)
Azelastine (Astelin, Astepro)	137	1–2 sprays twice daily	5–11 yo; 1 spray twice daily
Azelastine/fluticasone propionate (Dymista, Triclast)	137 (azelastine); 50 (fluticasone propionate)	1 spray twice daily	6–11 yo: 1 spray twice daily
Olopatadine (Patanase)	665	2 sprays twice daily	6–11 yo: 1 spray twice daily

[a]Available OTC.

[b]Available in combination with pseudoephedrine (consult labeling for pediatric dosage).

Note: Acrivastine is available only with pseudoephedrine and so is not included in this table.

mo, months old; yo, years old.

From Refs. 7–10, 19, 20, and 28.

Patient Encounter 1, Part 2

Additional history from both Mr. Z and Kim reveals the following information. Kim's symptoms began about a week ago after they moved into a new home that is older with quite a bit of dust. Both Mr. Z and his wife have seasonal allergies and are treated with oral antihistamines. Kim's symptoms have become problematic in that she had to miss school today due to her inability to stop itching her eyes and the constant runny nose. She has also not slept well for the past few days due to her symptoms. Mr. Z states that she was not recently sick (ie, no fever, aches) and is not congested. Her nasal secretions are clear. The family also recently visited a horse farm a month back while on spring vacation, where she had some itchy eyes after the visit. Kim was given an over-the-counter medication that made her "super hyper" and has not since been given medication for her symptoms.

How would you classify Kim's presumed allergic rhinitis? Why?

What OTC-specific treatment options are there for initial management of Kim's presumed AR?

KEY CONCEPT Second-generation antihistamines are often effective alone, specifically for mild or intermittent AR. They are preferred over first-generation antihistamines because of fewer side effects. Although effective for most symptoms of AR, they are less effective than INCSs for nasal congestion. Intranasal administration is more effective than oral administration for nasal congestion. Most patients can use oral second-generation products. Others may prefer the intranasal route of administration, but they require a prescription. If nasal congestion is not relieved, addition of a decongestant is reasonable, either alone or as a combination product (see Decongestant section). Perhaps even the combination of an oral with an intranasal antihistamine is reasonable for some patients, depending on their preferences. Other pharmacologic agents can be combined with oral and/or intranasal antihistamines, as necessary for optimal control of symptoms. The intranasal combination product of azelastine and fluticasone (Dymista, Triclast) may be appropriate for some patients.[28] In recent guidelines by the AAAAI and ACAAI, for patients age 12 years and older for initial management of moderate to severe SAR, use of both INCS and intranasal anthistamine may be considered.[7]

▶ *Adjunctive or Secondary Choice Agents*

Decongestants. Decongestant drugs are useful only for nasal congestion.[7–10] This results from their α_1 adrenergic agonist activity, which causes vasoconstriction in the nasal mucosa. They provide no benefit for the sneezing, itching, rhinorrhea, or the ocular manifestations. Decongestants can be given alone, either by the oral or by the intranasal route. Also, numerous combination products are available, consisting of a decongestant with an antihistamine (and sometimes other ingredients). There are some special considerations for use of decongestants in pediatric and pregnant patients (see the Special Populations section).

Oral decongestant products are currently limited to pseudoephedrine and phenylephrine.[5,19] Pseudoephedrine has been changed from truly OTC to a more controlled "behind-the-counter" (BTC) status because it is an ingredient in the illicit manufacture of methamphetamine. Some manufacturers changed the ingredients of their products by replacing pseudoephedrine with phenylephrine to maintain shelf presence in the OTC area. However, much controversy surrounds the efficacy of oral phenylephrine. Most contemporary literature suggests that the currently recommended adult dose is minimally effective as a nasal decongestant, even compared to placebo in SAR.[5,29]

The side effects of orally administered decongestants most often affect cardiovascular function or the CNS. The side effects are primarily due to sympathetic stimulation and are usually dose-related. Some elevation of blood pressure may occur, but in normotensive and well-controlled hypertensive patients, the elevation is usually small. It is not of clinical significance in most situations, especially considering that these drugs are most appropriately used only briefly or intermittently. Insomnia, nervousness, irritability, and anxiety are relatively common CNS side effects. Some patients may have decreased appetite, tremors, headache, and even hallucinations. Men with benign prostatic hyperplasia (BPH) and other patients with disorders causing bladder outlet obstruction may have increased urinary retention due to α_1 stimulation of the urethral sphincter.

The intranasal agents currently available in the United States include the OTC products phenylephrine, oxymetazoline, and naphazoline. Intranasal application of decongestants provides rapid and effective relief of nasal congestion. This therapy may provide relief for nasal congestion, even for those patients already on INCSs.[30,31] However, the continuous use of intranasal decongestants often causes a paradoxical rebound phenomenon of persistent nasal congestion, called rhinitis medicamentosa.[5,30,31] Although some patients do not develop rhinitis medicamentosa, even after several weeks of continuous use of intranasal decongestants, the usual recommendation is to use them for no more than 3 consecutive days.[7] Intranasal decongestants can cause local side effects, including stinging, burning, dryness, and even sneezing. These are usually mild and well tolerated. Due to very limited absorption, the intranasal route rarely causes systemic side effects.[5,7] Administration technique should be optimized as described in Table 63–6. Should rhinitis medicamentosa occur, the best management is first to discontinue the decongestant, possibly with a taper to minimize worsening the situation. However, the response to withdrawal is often delayed for days. Therefore, it may be necessary to start INCSs and/or begin a short course of oral corticosteroid.[30,31]

KEY CONCEPT Whenever possible, intranasal decongestants in AR should be limited to short term use to overcome severe nasal congestion and to facilitate improved efficacy of other intranasal agents. The intranasal administration of decongestants should usually not exceed 3 consecutive days. Despite the usual good tolerance of recommended doses of oral decongestants, caution is warranted when they are used in patients with cardiac disease (dysrhythmias, angina pectoris, heart failure), hypertension, cerebrovascular disease, bladder outlet obstruction (including BPH), glaucoma (especially closed angle), hyperthyroidism, and possibly diabetes.[5,19,20] The choice between the two routes of administration is based on several considerations, including cost, convenience, patient preference, speed of onset (within 30 minutes orally, within 5 to 10 minutes intranasally), and side effects.[7,11]

Mast Cell Stabilizer. Cromolyn is available as an OTC intranasal product. The mechanism of action in AR is mast cell stabilization. The drug binds to mast cells and prevents

release of the mediators of AR that would otherwise result from allergen exposure. The drug is moderately effective, but less so than both INCSs and oral or intranasal antihistamines. It does have effects on both early and late phases of AR.[5,7] Its effects begin within 4 to 7 days of use, but may not be maximal for up to 2 weeks.[7] However, it can be used effectively on an as-needed basis for episodic exposures to allergen.[7,20] Cromolyn is very well-tolerated. The most common side effects are mild local stinging and/or burning, sneezing, unpleasant taste, and possibly nose bleed. A disadvantage is the frequency of administration. At least initially, it should be used four times daily. Some patients may need only two or three daily doses when used continuously after the first few weeks at four times daily. It is most useful for patients with mild or intermittent symptoms, especially in the pediatric population and in pregnant women.

Leukotriene Receptor Antagonist. Leukotrienes are involved in the pathophysiology of AR and in particular contribute to the nasal congestion in the late phase.[1,5,7–10] There is some difference of opinion about benefits of LTRAs. LTRAs are recommended by some guidelines in the case of PAR (not SAR) over oral antihistamines.[9] Most sources indicate good benefit for nasal congestion and rhinorrhea, some benefit for ocular symptoms, but less for nasal itch and sneezing compared to INCSs and antihistamines.[5,20] Montelukast is the only LTRA approved for treatment of AR. It is marketed as oral granules and as both chewable and regular tablets. The combination of montelukast with an oral antihistamine may have improved efficacy over either agent alone, according to some sources; however, even the combination is probably not better than INCSs.[5,7,9] The onset of action of montelukast is delayed for a day or more.[6] The drug is usually considered to be very well-tolerated. However, there are postmarketing reports of neuropsychiatric events, including sleep disturbances, depression and suicidal ideation, as well as headache, gastrointestinal (GI) disturbances, skin rash, and Churg–Strauss syndrome.[7,19,32] It is administered once daily, considered safe (Food and Drug Administration [FDA] pregnancy category B and indicated for children as young as 6 months of age), and particularly well-suited to those patients who also have asthma.[19,20]

Antimuscarinic Agent. Ipratropium is currently the only antimuscarinic agent indicated for treatment of AR. Systemic absorption is minimal. It is available by prescription as an intranasal spray. Its use is limited to those patients whose rhinorrhea has not been controlled by other therapy (antihistamines and/or INCSs).[5,7,13] There are two strengths available, 0.03% and 0.06%. The 0.03% product is approved for AR in children as young as 6 years of age. This agent may be particularly helpful for patients who have vasomotor (idiopathic, autonomic) rhinitis, or those who may have a mixed etiology.[5] Local side effects are usually limited to nasal and oral dryness, throat irritation, and mild epistaxis.[19,20]

Omalizumab. Omalizumab is a monoclonal antibody that binds to IgE. The product is approved for moderate to severe persistent asthma with a positive skin test or in vitro reactivity to a perennial aeroallergen and symptoms that are inadequately controlled with inhaled corticosteroids in patients ages 6 years and older. It is not approved for treatment of AR as of October 2017. It is administered by subcutaneous injection. Dosage is determined by the patient's circulating IgE levels. The cost is high compared with that of other modes of therapy. Investigational use has demonstrated efficacy in AR, although relative efficacy is unknown. Its use is best limited to those with concurrent asthma and AR until further data is known.[7,33]

Complementary and Alternative Medicine (CAM) Therapy. Complementary and alternative therapy for AR has been reviewed.[34] For example, capsaicin (Capsicum annum), once regarded as CAM, in the form of a nasal spray is being investigated as a possible agent in treatment of AR.[35] Previous data behind this compound was inconclusive, citing the need for future studies.[36] Consistent evidence for efficacy has not been established, and there are some safety concerns.

Patient Encounter 1, Part 3

About 6 months later, Kim and Mr. Z come back to speak with you. Kim is getting nose bleeds occasionally and stopped wanting to use any nasal product and only uses the OTC antihistamine you originally recommended. She is due to see her pulmonologist for a follow-up visit. She still has nasal symptoms (rhinorrhea, some congestion) and eye itching. Her allergies are now beginning to affect her asthma with some additional use of her albuterol over the last couple of weeks (ie, used 1 time each week at night, with relief of symptoms).

What suggestions would you offer for control of Kim's symptoms, now? What should be monitored?

Immunotherapy

Immunotherapy could be considered a type of pharmacotherapy. Allergen-specific immunotherapy (SIT) involves repetitive dosing of allergen(s). This approach to treatment can be considered for patients with moderate–severe AR, especially those who have limited response to usual therapy (eg, intranasal steroid, antihistamine) and limiting environmental exposure.[37–39] Immunotherapy is almost always initiated by an allergist or otolaryngologist, after referral for specific allergen testing to determine individualized therapy. This type of therapy is intended for patients with IgE-mediated AR by history and confirmed with specific allergen testing.[8] Historically, immunotherapy was considered for patients in three categories.[5] The first were those with severe, complicated or worsening rhinitis. This was partly for additional diagnostic testing to rule out nonallergic causes of rhinitis. The second were those patients with AR who did not tolerate or responded poorly to appropriate pharmacotherapy. The third were those patients who had a single, or one major allergen identified, for which there was an immunotherapy product available for treatment. In addition, some patients requested immunotherapy, on the basis of superior and durable effectiveness.

Currently, the role of any other health care provider is limited to referral of appropriate candidates to allergy specialists.[35]

Currently, SIT can be done via subcutaneous immunotherapy (SCIT) or sublingual immunotherapy (SLIT). The major advantage of SLIT over SCIT is ease of administration. Possible adverse effects of SLIT include oral or ear pruritis, throat irritation, tongue pruritis, and mouth edema, with decrease in occurrence and severity of such events in subsequent years of treatment. Potential adverse effects of SCIT include local injection reactions, systemic reactions, and rare, allergic, anaphylaxis reactions. The first dose of immunotherapy is given

Patient Encounter 2, Part 1

Jane D is 30 years old, married, with two children. She works full time as a museum curator for the local museum and has moved to the area about a year ago. Both her children, ages 6 and 10 years, are in school. She has allergies, which she jokingly states that she's "allergic to her work" as it is the dust from artifacts and displays that make her sneeze and have itchy, watery eyes. She is currently on cetirizine 10 mg daily and mometasone nasal spray. She has found that she is sleepier since starting cetirizine about a month ago. Prior to cetirizine, she was on loratadine. She tried taking the cetirizine at night but she still feels quite drowsy in the morning.

What additional information do you need to better evaluate Jane D?

What preliminary suggestions would you make?

in the prescriber's office, for purposes of safety. Subsequent doses are self-administered by the patient. SCIT is always done under medical supervision, requiring regular clinic visits and observation after SCIT administration.[8,40,41] Potential risk factors for SLIT-associated anaphylaxis include previous systemic reaction to SCIT, severe or uncontrolled asthma, acute infection, interruption of dose regimen, and oral lesions.[37]

As of July 2017, four products have been FDA approved for administration as SLIT. There are currently two products for grass pollen, Oralair and Grastek. Oralair contains a mixure of pollens from Sweet Vernal, Orchard, Perennial Rye, Timothy, and Kentucky Blue Grass, and is approved for adults and children ages 10 years and older.[42] Grastek, which contains only Timothy grass pollen, is approved for adults and children ages 5 years and older.[43] Ragwitek is a SLIT for short ragweed pollen, approved for adults ages 18 to 65 years.[44] Odactra, the SLIT for house dust mites, is approved for adults ages 18 to 65 years.[45]

Special Populations

▶ *Children*

LO 6

KEY CONCEPT Generally speaking, the treatment of AR in children is the same as it is for adults. There are, however, limitations in terms of FDA-approved products for different age groups. Also, depending on the age of the patient, there may be administration issues with some products. Most children affected by AR are more than 2 years old, because usually, several years of antigen exposure is required to establish sensitization. Children who have rhinitis before the age of 2 should be evaluated for other etiologies.[7,46]

There has been concern about use of combination cough and cold products (many contain an antihistamine and a decongestant) in children due to side effects. Most negative outcomes have resulted from inadvertent overdosage, often by giving the same drug from more than one product concurrently. These products are discouraged in children less than 4 years old.[47]

First-generation H_1 antihistamines are discouraged for children as they are for adults, due to the possible detrimental effects on school performance and learning. They may also cause paradoxical CNS stimulation in the very young (< 2 years old).[20,46]

Second-generation (less sedating) H_1 antihistamines (primarily for mild or intermittent symptoms) or INCSs (for moderate–severe or persistent manifestations) are first-line modes of therapy. Antihistamines may need to be used even for more severe and/or persistent symptoms in those children who have difficulty with use of intranasal products. If necessary, these two classes can be combined.[46] See Table 63–7 for dosages of second-generation antihistamines by age groups for which they are indicated. Special care should be given to avoid administration of the same medication from different (especially combination) products. The side effects of second-generation antihistamines in children are similar to those for adults.

See Table 63–5 for dosages of INCSs by age groups. The consensus of opinion about INCSs and systemic side effects, especially delay in growth, is that most products are safe. Three INCSs, mometasone, fluticasone furoate, and triamcinolone, are FDA approved for children as young as 2 years of age.[18] The local side effects of INCSs are the same in children as for adults.

Other therapy options may be worth consideration for some pediatric patients. Montelukast provides an oral alternative, especially for those who are too young to cooperate with intranasal administration of corticosteroids.[7–10,46] It may be used in combination with an oral antihistamine for additional efficacy.[7–10] Another option for mild or intermittent symptoms is intranasal cromolyn, primarily due to its excellent safety.[46] This OTC product is labeled for use in children 2 years of age and older.[17,46] Intranasal ipratropium is indicated for patients 6 years of age or older and may benefit unresponsive rhinorrhea.[46]

▶ *Pregnant Women*

LO 6

Women who have AR may suffer an exacerbation of symptoms during pregnancy.[5,48] However, only minor changes in the routine approach to therapy are necessary as a result of the pregnancy. Nasal saline irrigations are safe, effective, and improve the response to most other modes of therapy. They can be the foundation of AR therapy for pregnant patients.[5,48] Physical exercise increases vasoconstriction of the nasal mucosa, decreasing congestion and rhinorrhea.[38] External adhesive strips can be used to help keep the nares open, especially during sleep.[48] Second-generation antihistamines are generally considered safe, based on an increasing number of studies and experience.[5,48] While budesonide is the only product which is FDA pregnancy category B, data is somewhat lacking regarding fetal harm from either INCSs or inhaled corticosteroids.[20,49,50] Cromolyn is also FDA pregnancy category B and is considered safe.[20,47] The disadvantages are frequent administration and less efficacy than antihistamines and INCSs. Montelukast is also FDA pregnancy category B, but some recommend it primarily in those with concurrent asthma or who have demonstrated a good response prior to pregnancy.[7,19] Ipratropium is FDA pregnancy category B, and is useful for troublesome rhinorrhea.[10,19] Oral decongestants are best avoided, especially in the first trimester. If nasal congestion is severe enough to warrant a decongestant, the intranasal route of administration is preferable, due to decreased systemic exposure.[7,48] Limiting the duration of use to 2 to 3 days is wise.[7,48]

▶ *Breast-Feeding Women*

LO 6

There is available information about the relative safety of AR medication use in breast feeding women.[19,51] Budesonide is probably the safest INCS and loratadine is probably the safest antihistamine. Intranasal cromolyn is also considered safe. Nasal

Table 63–8

Intraocular Medications

Category	Generic (Brand) Name	Formulation	Frequency	Age
Decongestant/vasoconstrictor	Naphazoline[a] (Naphcon, Privine, others)	0.012% + 0.025%	Four times daily	Adult
Decongestant/vasoconstrictor + antihistamine	Naphazoline + pheniramine[a] (Visine A)	0.025%/0.3%	Four times daily	6 yo or more
Antihistamine	Emedastine (Emadine)	0.05%	Four times daily	3 yo or more
	Alcaftadine (Lastacaft)	0.25%	Once daily	2 yo or more
Mast cell stabilizer	Cromolyn (generic)	4%	Every 4–6 hours	4 yo or more
	Lodoxamide (Alomide)	0.1%	Four times daily	2 yo or more
	Nedocromil (Alocril)	2%	Twice daily	3 yo or more
	Pemirolast (Alamast)	0.1%	Four times daily	3 yo or more
Antihistamine + mast cell stabilizer	Azelastine (Optivar)	0.05%	Twice daily	3 yo or more
	Epinastine (Elestat)	0.05%	Twice daily	2 yo or more
	Ketotifen[a] (Zaditor, Alaway, Claritin, Zyrtec, generic)	0.025%	Every 8–12 hours	3 yo or more
	Olopatadine (Patanol/Pataday)	0.1%/0.2%	Twice daily/once daily	3 yo or more
	Bepotastine (Bepreve)	1.5%	Twice daily	2 yo or more
NSAIDs	Ketorolac (Acular)	0.5%	Four times daily	3 yo or more
Corticosteroid	Loteprednol (Alrex)	0.2%	Four times daily	Adult

[a]Available OTC.

Also, see Chapter 62, Ophthalmic Disorders, for more details.

NSAID, nonsteroidal anti-inflammatory drug; yo, years old.

From Refs. 7, 19, and 20.

saline irrigation could also be considered as a safe alternative in breast-feeding women.

▶ *Elderly*

LO 6

AR in elderly patients is treated generally as it is in younger adults; however, consideration of increased risk for certain side effects (eg, antimuscarinic) should weigh into therapy choices. Therefore, first-line agents are primarily INCSs and second-generation oral or possibly intranasal antihistamines.[5,7] Older patients may also have a component of atrophy of nasal tissues that can result in more nasal congestion. Most will benefit from regular nasal saline irrigation.[5] The elderly are more sensitive to the sedative and antimuscarinic effects of (especially first-generation) antihistamines and to the cardiovascular and CNS stimulant effects of decongestants. These drugs should be used cautiously if at all. An increase in cholinergic activity may result in more rhinorrhea. This may respond well to ipratropium.

Patient Encounter 2, Part 2

Jane D returns months later after having taken your advice. She is now noticing symptoms no matter where she is, especially when outdoors. She was prescribed a combination nasal corticosterioid and antihistamine by her primary care physician, but it does not seem to be helping much with her symptoms. She does saline nasal rinses several times a week with limited relief. She has missed work several times in the last few months due to unbearable congestion in addition to her nasal and ocular itching. One of her friends, who has asthma, told her about an injectable medication for asthma that has helped her asthma and allergy symptoms. She asks you, "Would this be something I can take? Would it help me with my allergies?"

What is your explanation to Jane D about her inquiry and what is your recommendation at this time?

Ocular Symptoms

Several products are available for instillation directly into the eyes for those patients with predominant or unresponsive ocular manifestations. They may be appropriate for occasional moderate–severe flares or episodic AR when other modes of therapy are not optimally effective. The combination (antihistamine and mast cell stabilizing) agents may be the most effective, and they have the advantages of rapid onset of action and (usually) only twice daily administration.[5,19,20] Ketotifen is in this category and because it is available OTC, it can be an appropriate initial agent. See Table 63–8 for these products.

Summary of Treatment

LO 5

Once an agent appropriate for initial therapy is chosen, ongoing management requires repeated checks to ascertain response and freedom from intolerable or adherence limiting side effects. Either "step-up" or "step-down" therapy may be appropriate, depending on individual response. See Table 63–9 for a summary of the approach to treatment of AR. Table 63–10 attempts to rank the relative effectiveness of the classes of agents for treatment of AR by specific symptoms.

OUTCOME EVALUATION

- Confirm the patient's understanding of the disorder (see Clinical Presentation and Diagnosis of Allergic Rhinitis).
- Confirm the patient's understanding about allergen avoidance measures (see Table 63–3).

Table 63–9

Routine Approach to Therapy of AR

All patients should practice avoidance of identified allergens

Mild Intermittent

First line:
Oral antihistamine (OTC, initially; preferably second generation)

Adjunctive/secondary (may use more than one; no specific order intended):
- Add nasal saline (eg, as irrigation)
- Consider intranasal cromolyn, especially preexposure for episodic AR
- Consider OTC INCS for refractory symptoms
- Consider intraocular medications, as needed for ocular symptoms (see Table 63–8)
- Consider OTC oral decongestant for nasal congestion
- Consider OTC intranasal decongestant for refractory nasal congestion (not more than 3 days)
- Consider prescription therapy for inadequate response (see below)

Possibly consider referral for immunotherapy

Persistent or Moderate–Severe

First line:
Intranasal corticosteroid
Add oral antihistamine (preferably second generation) for possible additional benefit if necessary

Adjunctive/secondary (may use more than one):
- Add nasal saline (eg, as irrigation)
- Consider intranasal antihistamine
- Consider combination intranasal antihistamine with corticosteroid
- Consider intraocular medications, as needed for ocular symptoms (see Table 63–8)
- Consider OTC oral decongestant for nasal congestion
- Consider short-term intranasal decongestant for refractory nasal congestion
- Consider montelukast
- Consider intranasal ipratropium for inadequately controlled rhinorrhea

Consider referral for immunotherapy

Episodic (no order of preference intended)
Oral antihistamine (OTC, initially; preferably second generation)
Consider addition of or replacement with intranasal cromolyn (OTC) or intranasal antihistamine or intranasal corticosteroid

Special Situations (children, pregnant women, elderly, ocular symptoms)
See Special Populations section of text

From Refs. 6–10, 46, and 48.

Table 63–10

Relative Efficacy (Semiquantitative) by Classes of Agents for Specific Symptoms of Allergic Rhinitis

Drug Class	Nasal Congestion	Sneezing	Rhinorrhea	Nasal Itch	Ocular Symptoms
Intranasal corticosteroids[a]	+++	+++	+++	+++	+
Oral antihistamines[a]	+	++	++	++	++
Intranasal antihistamines	++	++	++	++	+
Oral decongestants[a]	++	0	0	0	0
Intranasal decongestants[a,b]	+++	0	0	0	0
Oral leukotriene antagonist	++	+	++	+	++
Intranasal mast cell stabilizer[a]	++	++	++	++	++
Intranasal antimuscarinic	0	0	++	0	0

[a]Some products in these classes are available OTC.

[b]Intranasal decongestants are best used for severe, unresponsive nasal congestion, or to facilitate mucosal contact of other intranasal medications, but in either case, should usually be limited to no more than 3 days.

Note: There are different opinions about some of the rankings, partly due to inadequate study. Individual variation may create different relative efficacy in some patients. +++ = greatest relative efficacy, 0 = no relative efficacy.

From Refs. 8, 9, and 10.

Patient Encounter 2, Part 3

It is now several years later. Jane D's AR is under control after seeing the allergy specialist. She has not needed to see the specialist for over a year now, but comes to you with a question about medications and family planning. She has read that women sometimes have increased allergy symptoms in pregnancy and given her history, feared this would be something she will face. She asks which OTC allergy medications are safest while she is trying to become pregnant and once she is pregnant.

What do you recommend and why?

- Assess the patient's symptom response, tolerance, and adherence.
- Assess the patient's administration technique with intranasal products.
- Recommend second-generation oral antihistamine therapy for most patients with mild or intermittent symptoms (see Clinical Presentation and Diagnosis of Allergic Rhinitis and Table 63–9).
- Recommend INCS therapy for moderate–severe or persistent symptoms. Suggest additional therapy for those with incomplete control (see Clinical Presentation and Diagnosis of Allergic Rhinitis and Table 63–9).
- Consider step-up therapy for exacerbations or incomplete response.
- Consider step-down therapy if symptoms are minimal or stable for several months.
- Consider referral to rule out nonallergic causes of rhinitis in nonresponding patients or those with an atypical presentation (see Clinical Presentation and Diagnosis of Allergic Rhinitis).
- Consider referral for patients who request immunotherapy.
- Consider referral for patients with comorbid conditions, especially asthma.

Patient Care Process

Collect Information:

- Collect information from the history of present illness (HPI), past medical history (PMHx), and physical assessment. HPI includes location, onset, quality, quantity, setting, associated symptoms, and modifying factors (see Clinical Presentation and Diagnosis of Allergic Rhinitis). PMHx should include conditions associated with AR and its complications (see Epidemiology section). Physical assessment includes observation of patient and examination of nasal mucosa (see Clinical Presentation and Diagnosis of Allergic Rhinitis).
- Identify therapies attempted and their efficacy.
- Determine additional considerations in treatment (eg, pregnancy, lactation, child or elderly; see Selected Populations section).

Assess the Information:

- Rule out nonallergic type of rhinitis (see Table 63–1).
- Determine extent and severity of patient's assessing frequency and severity of AR symptoms (see Clinical Presentation and Diagnosis of Allergic Rhinitis and Table 63–2).
- Determine the patient's understanding of AR.
- Assess response to past and current AR treatment. If clinical response is inadequate assess adherence and technique. See Table 63–6. If nonadherence and poor technique do not explain suboptimal response, consider alternative treatments or specialist referral. See Table 63–9.

Develop a Care Plan:

- Advise allergen avoidance. See Table 63–3.
- Review optimal administration technique and adherence.
- Base therapy recommendations on symptoms and response to current and past treatment.

Implement the Care Plan:

- For mild AR where OTC agents can be used, provide patient with recommended therapy including drug name, dose, and dosing frequency. Educate on appropriate administration, expected outcomes, and possible side effects.
- For moderate to severe AR where physician management is likely needed, communicate recommendations to primary care provider and assist with follow-up if needed by monitoring patient symptoms control and treatment of side effects.

Follow up: Monitor and Evaluate:

- Follow up weekly at first, especially during worse times/seasons for change in symptoms and possible side effects.
- When optimal control is approached, increase duration between follow-up visits (eg, monthly, every 2–3 months, or less frequently).

ACKNOWLEDGMENT

The authors would like to acknowledge the contributions of David A. Apgar, who was the author of this chapter in previous editions.

Abbreviations Introduced in This Chapter

AAAAI	American Academy of Allergy, Asthma, and Immunology
ACAAI	American College of Allergy, Asthma, and Immunology
ACEI	Angiotensin-converting enzyme inhibitor
AERD	Aspirin-exacerbated respiratory disease
AR	Allergic rhinitis
ARIA	Allergic rhinitis and its impact on asthma
BPH	Benign prostatic hyperplasia/hypertrophy
BTC	Behind-the-counter
CHPA	Consumer Health Protection Agency
H_1	Histamine type 1 (receptor)
HEPA	High-efficiency particulate air (filter)

HFA	Hydrofluoroalkane ("green" propellant for metered-dose INCSs)
HPA	Hypothalamic–pituitary–adrenal (axis)
HPI	History of present illness
HTN	(essential or primary) hypertension
IAR	Intermittent allergic rhinitis (ARIA system)
IgE	Immunoglobulin E
INCS(s)	Intranasal corticosteroid(s)
LTRA	Leukotriene receptor antagonist
MDP	metered-dose pump
NARES	Nonallergic rhinitis with eosinophilia [on nasal smear] syndrome
NSAID	Nonsteroidal anti-inflammatory drug
OTC	Over-the-counter
PAR	Perennial allergic rhinitis (AAAAI/ACAAI system)
PDE-5	Phosphodiesterase (isoenzyme)-5
PER	Persistent allergic rhinitis (ARIA system)
PMHx	Past medical history
QT	Interval between the Q and T waves in an ECG
SAR	Seasonal allergic rhinitis (AAAAI/ACAAI system)
SCIT	Subcutaneous immunotherapy
SIT	Allergen-specific immunotherapy
SLIT	Sublingual immunotherapy

64 Psoriasis

Amy Kennedy

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

1. Discuss the etiology of, and risk factors for, psoriasis.
2. Describe the pathophysiology and clinical presentations of psoriasis.
3. Delineate treatment goals for each patient.
4. Develop an appropriate treatment and care plan for psoriasis patients.
5. Recommend nonpharmacologic and pharmacologic treatments for psoriasis.
6. Recommend appropriate monitoring parameters for a patient diagnosed with psoriasis.
7. Provide patient education for patients and caregivers as part of the care plan.

INTRODUCTION

KEY CONCEPT Psoriasis is a chronic inflammatory condition that exhibits a cyclical pattern of relapse and remission. There is currently no cure for the disease and treatment is designed to manage signs and symptoms associated with the disease.[1] Remission may last for years in some patients, whereas, in others, exacerbations may occur as frequently as every few months. Patient factors known to exacerbate the condition are stress, environmental factors including seasonal changes, and certain medications.[2] Depression, alcohol-related problems, cardiovascular diseases, metabolic syndrome, irritable bowel disease (Crohn disease and ulcerative colitis), and skin cancers are select comorbidities associated with the severe form of psoriasis.[1] The severity of the condition ranges from mild to severely disabling. Thus management of patients with psoriasis is lifelong and treatment approaches may change according to the severity of illness at the time. Treatment modalities should be individualized to meet patient needs. The disease may result in emotional distress that requires empathy, a caring attitude, and consideration when weighing treatment approaches.

EPIDEMIOLOGY AND ETIOLOGY

Psoriasis is a common chronic inflammatory skin disorder with a population prevalence of 2% to 3% worldwide. The prevalence found in the United States is approximately 2.1%, while African, African American, and Asian populations have an estimated 0.4% to 0.7% prevalence of the disease.[3] This difference may be attributed to genetic variations of the disease. While the overall incidence rate does not differ between men and women, male patients tend to die at least 3.5 years earlier and females 4.5 years earlier than nonpsoriasis patients normalized for differences in mortality by gender.[3] The disease may present at any age, but new diagnoses peak between ages 15 and 30 and again from 50 to 60 years.[3] Psoriasis can manifest as several different types including **plaque**, **flexural** (aka inverse or intertriginous), **erythrodermic**, **pustular**, **guttate**, **nail**, and **psoriatic arthritis (PsA)**. Eighty to ninety percent of patients diagnosed with psoriasis present with plaque psoriasis. Plaque psoriasis presents with red-pink lesions of varying sizes covered with silvery-white scales (**Figure 64–1**).[2] Up to 42% of patients with psoriasis have co-occurring PsA.[1,4] PsA is limited to joints, ligaments, and tendons, and clinical presentation includes pain, stiffness, swelling, and/or tenderness in the affected area. PsA progresses from mild symptoms to the destruction of joints, negatively impacting quality of life for patients.

Recent research has shown that psoriatic patients have an increased risk of cardiovascular disease, especially myocardial infarction (MI).[4-6] Risk is present in both mild and severe disease, with the highest risk in younger patients with severe psoriatic disease.[6] These findings persist even when corrected for other cardiovascular risk factors.[5-7]

In 2012, the first gene directly linked to psoriasis was identified. Through the use of the National Psoriasis Foundation biobank, researchers identified that a mutation in the CARD14 gene, when activated by an environmental trigger, led to plaque psoriasis.[8] Up to 36 additional gene loci are suspected to be involved in the manifestation of psoriasis and the histocompatibility complex region of chromosome 6 (HLA-Cw*06) has been suspected in the disease.[9] KEY CONCEPT While genetic variations have a significant role, modifiable risk factors greatly impact the likelihood of developing or exacerbating existing psoriasis. These include stress, skin injury (including trauma), medications, infection, obesity, tobacco, and cold, dry weather. First-degree relatives with psoriasis can increase risk of presentation, affecting males more than females. Women exposed to tobacco smoke have a higher risk of developing psoriasis than their male counterparts with the same exposure. Risk is also found to be higher in urban settings versus rural settings. Additional factors exacerbating psoriasis include drugs such as lithium, nonsteroidal anti-inflammatory drugs (NSAIDs), antimalarials, β-adrenergic blockers, and corticosteroid withdrawal.[10]

PATHOPHYSIOLOGY

The pathogenesis of psoriasis involves multiple components of the immune system. Cytokines such as interleukins and tumor necrosis factor-α (TNF-α), T cells, and keratinocytes are

FIGURE 64–1. Chronic plaque psoriasis located at typical sites. Note marked symmetry of lesions. (From Goldsmith LA, Katz SI, Gilchrest BA, Paller AS, Leffell DJ, Wolff K, eds. Fitzpatrick's Dermatology in General Medicine. 8th ed. New York, NY: McGraw-Hill; 2012. Photos used with permission from Dr. Johann Gudjonsson and Mr. Harrold Carter.)

central to the inflammatory process associated with psoriasis. Additionally, it has been found that when keratinocytes are disturbed, the release of antimicrobial peptide LL-37 takes place. This peptide binds with DNA and RNA. This complex potentially leads to the activation of plasmacytoid and myeloid dendritic cells. These activated dendritic cells secrete interleukin (IL)-12 and IL-13. The production of these two interleukins eventually results in IL-17 and T helper cell type 1 differentiation.[2] The T cells then release IL-17A, IL-17F, IL-22, and IL-23 as mediators which then subsequently activate keratinocytes. This process then generates a complex cascade including proinflammatory cytokines such as TNF-α, interferon (IFN-α and IFN-γ), and interleukin (IL-1β and IL-6). The entire process then leads to alteration of the immune system and chronic inflammation that manifests in the skin causing vascular changes and formation of psoriatic lesions.[2] Hyperkeratosis that results from immune derangements causes the characteristic thick, scaly skin lesions seen in patients with psoriasis. The pathologic pathway of PsA is the same, except that the changes that occur as a result of T-cell mediators happen in the synovial fluid within the joints. Osteoclast activation, osteolysis, and bone resorption produce the damage that occurs within the joints.[2]

LO 2

LO 2

CLINICAL PRESENTATION AND DIAGNOSIS

KEY CONCEPT Diagnosis of psoriasis is usually based on recognition of the characteristic plaque lesion and is not based on lab tests.

The severity of the disease is classified as mild/limited disease, moderate, or severe disease based on body surface area (BSA) involvement (Table 64–1). Additionally, classification may be based on assessment tools used such as the Psoriasis Area and Severity Index (PASI) and the Dermatology Life Quality Index (DLQI).[11,12]

Table 64–1

Disease Severity Classification[11,12]

Mild or limited disease	Less than or equal to 5% BSA involvement
Moderate disease	PASI greater than or equal to 8 (higher in trials of biologics)
Severe disease	The Rule of Tens: PASI ≥ 10 or DLQI ≥ 10 or BSA ≥ 10% (in some phototherapy trials, BSA ≥ 20% is used as the lower limit)

BSA, body surface area; DLQI, Dermatology Life Quality Index; PASI, Psoriasis Area and Severity Index.

Clinical Presentation and Diagnosis of Plaque Psoriasis

General Characteristics

Small, discrete lesions to generalized confluent lesions over a large body surface area (BSA)

Symptoms

Severe itching (some patients will not experience)

Signs

- Raised lesion red to violet in color (commonly known as plaques)
- Sharply demarcated borders lesions, except where confluent
- Lesions are loosely covered with silvery-white scales, which, if lifted off, show small pinpoints of bleeding (Auspitz sign).
- Plaques appear on the elbows, knees, scalp, umbilicus, and lumbar areas, and often extend to involve the trunk, arms, legs, face, ears, palms, soles, and nails.
- Nail involvement presents as pitting, discoloration ("oil spots"), crumbling, splinter hemorrhages, growth arrest lines, or tissue buildup around the nails.

Patient Encounter Part 1

GG is a 32-year-old woman who has noticed red lesions that flake covering her elbows, back of knees, and scalp. When questioned, the patient says her skin has been relatively clear, until about 3 months ago. Since then, the lesions have been becoming more noticeable, increasing in size. She is feeling self-conscious about what is happening and does not know what to do.

FH: Mother has psoriasis and rosacea. Father has hypertension. Younger brother has depression and Type 1 diabetes.

SH: GG is in a same sex partnership with 2 children: ages 5 and 3. She works for the city parks department and routinely forgets to wear sunscreen. She does not drink and admits to smoking on her lunch breaks.

Meds: Multivitamin daily

PE:

Gen: She appears very distressed about the lesions.

VS: BP 124/77 mm Hg, P 98 beats/min, RR 20 breaths/min, T 37.0°C (98.6°F), Ht 5'3" (160 cm), Wt 175 lb (79.5 kg)

Abd: Soft, NTND; (+) bowel sounds

Exts: Within normal limits; no joint pains; lesions covering both elbows

Skin: Red lesions with silvery scale on elbows, knees, and scalp (BSA 4%)

Labs: All within normal limits, including lipids, renal function tests, and LFTs

What type of psoriasis is GG experiencing?

What risk factors does she have for psoriasis?

TREATMENT

Desired Outcomes and Goals

KEY CONCEPT Given its manifestations, inflammation, involvement of multiple areas of the affected skin, and the chronic nature of psoriasis, treatment goals must be individualized to each patient. The goals of treatment must be set based on clinical presentation, disease-related comorbidities, treatment-related morbidity, mortality, quality of life, staging of the disease, and remission status of the disease at any given point in time.[4,11-13] It is imperative to remember that no cure currently exists for any type of psoriatic disease. However, evidence shows that current treatment options increase remission periods and reduce severity of the disease.[13] The treatment goals should include the following:

LO 3

- Minimize or eliminate, when possible, the signs of psoriasis, such as plaques and scales.
- Alleviate pruritus and minimize excoriations when present.
- Extend remission cycles.
- Ensure appropriate management of associated comorbidities such as PsA, cardiovascular disorders, Crohn disease, or clinical depression.
- Avoid or minimize adverse effects from treatments.
- Provide cost-effective therapy.
- Provide counseling as needed (eg, stress-reduction techniques).
- Maintain or improve the patient's quality of life.

Clinical Presentation and Diagnosis of Other Types of Psoriasis

- Flexural psoriasis:
  - Appears in intertriginous areas
  - Scaling is minimal
- Guttate psoriasis:
  - Sudden eruption of small, disseminated erythematosquamous papules and plaques
  - Often preceded by a streptococcal infection 2 to 3 weeks prior
- Pustular psoriasis:
  - May be localized or generalized
  - May be an acute emergency requiring systemic therapy due to loss of skin integrity
- Generalized pustular psoriasis:
  - Disseminated deep-red erythematous areas and pustules
  - May merge to become "lakes of pus"
- Erythrodermic psoriasis: generalized, life-threatening condition
  - Erythema, desquamation, and edema
  - May require life support measures as well as systemic therapy

General Approach to Treatment

LO 4

The management of the disease should target the type of psoriasis that the patient presents with. General treatment considerations must include disease severity, location, the extent

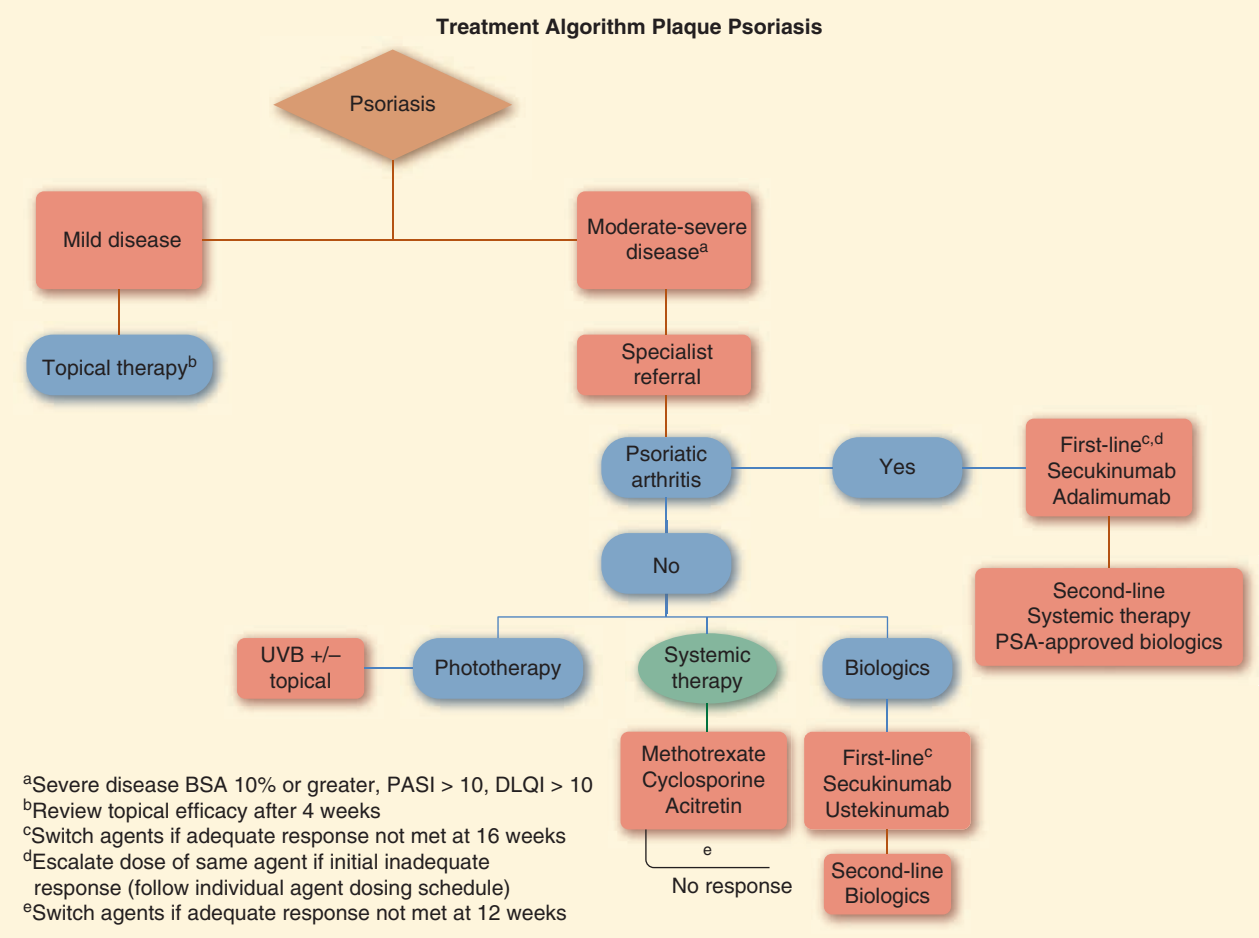

FIGURE 64–2. Treatment algorithm for plaque psoriasis.[4,6,7,15,16,21,28]

of BSA involvement, and pertinent lifestyle modifications.[11] The psychological impact of psoriasis may not correlate with the severity of the skin presentation, and it is important to continually evaluate the psychosocial effects of psoriasis on each patient.[6,7]

LO 4 For PsA the goal of treatment is to reduce pain and swelling, slow down or minimize joint damage, and maintain joint function.[2,4,6,7] KEY CONCEPT Effective psoriasis treatment should include both pharmacologic and nonpharmacologic approaches.[11] See Figure 64–2.

Nonpharmacologic Management

KEY CONCEPT Several effective nonpharmacologic options are available to patients with psoriasis. However, considering the inflammatory nature of the disease, these treatments should be used as adjunctive treatments to therapeutic agents when appropriate.[12]

LO 5 Stress reduction techniques such as psychotherapy, guided imagery, and relaxation techniques have been shown to reduce the extent and severity of psoriasis.[14] Oatmeal baths in tepid water may help soothe the itching associated with psoriasis. Nonmedicated moisturizers (occlusive agents, humectants, and/or emollients) help the skin retain moisture and reduce the silvery-white scaling of skin lesions. Emollients can be applied multiple times during the day to prevent skin dryness. Patients with skin sensitivities should consider the use of fragrance-free products to prevent flareups.[15] Harsh soaps, detergents, and other skin irritants should be avoided as they may worsen symptoms. Skin cleansing is appropriate; however, it should be done with lipid-free cleansers and tepid water when possible. Trauma to the skin must always be avoided as damage to skin integrity can precipitate a flare. Sunburn is one of the most frequent skin traumas that can result in a flare. Consequently, the use of sunscreen with sun protection factor (SPF) of 30 is recommended. Loose-fitting clothes are desired to help reduce skin irritation.[15]

LO 5

Pharmacologic Therapy

The pathogenesis of the disease involves a complex mechanism that disturbs the immune system, causes vascular changes, and results in the development of skin lesions.[2] It is paramount that therapeutic agents that oppose these processes are well represented in the treatment of psoriasis. KEY CONCEPT These agents are anti-inflammatory, anti-cytokines, and biologic therapies. They are classified into topical, phototherapy, conventional systemic therapy, and biologics.[2,11] Several factors must be taken into consideration in identifying the right therapy for a patient with psoriasis. Some of these factors are the affected area of the disease, cost, availability of medication, and the preferred lifestyle of the patient. Full patient history including allergies must be collected to make the chosen therapeutic approach a success. Topical agents are recommended for mild to moderate disease due to their affordability and fewer adverse effects. Low potency corticosteroids are used as first line for mild conditions.

If the condition persists, it is recommended to switch to a very high potency steroid in combination with vitamin D analogue or topical retinoids. In general, a patient disease surface area should be less than 5% to qualify for topical therapy alone. A general recommendation after unsuccessful treatment with topical agents is to add phototherapy. Psoralen and ultraviolet A (PUVA) was found to be more effective than ultraviolet B (UVB) in the treatment of patients with moderate to severe psoriasis.[16] The traditional systemic agents can be used for patients with severe disease and these are often combined with topical therapy to improve effectiveness in these patients. Clinical trials indicate that immunosuppressants are more effective than oral retinoids. Biological agents may be the drug of choice for severe disease depending on patient comorbidities, those intolerant to, or that fail traditional systemic agents. The choice of biologic agents depends on the patient's preference and comorbidities.[17] Psoriasis affecting more than 5% of the BSA should be the justification for initiating systemic/biologic therapy. For patients with liver disease, kidney dysfunction, and skin cancer, it is recommended to avoid methotrexate, cyclosporine, and PUVA treatment, respectively.[18]

► *Topical Treatment*

These agents are first-line treatment for mild to moderate psoriasis (Tables 64–2 and 64–3). They are specifically known for their anti-inflammatory, antiproliferative, and anti-immunologic properties. They are classified as corticosteroids, vitamin D analogues, retinoids, calcineurin inhibitors, coal tar, anthralin, and salicylic acid derivatives. Different dosage forms are available such as creams, lotions, gels, foams, ointments, shampoos, oil solutions, tapes, and sprays. KEY CONCEPT The choice of specific dosage form or vehicle is dependent on several factors including the surface area involved, location, thickness of the lesions, and the appearance of the plaques.[19] Ointments are recommended for dry and thick lesions to enhance absorption and reduce loss of skin moisture. Creams are indicated for acute, but moist appearing, lesions that do not require ointment-based products. Solutions/shampoos and gels are recommended for scalp lesions and foams and sprays are usually used for lesions in genital areas.[15,19]

LO 5

Vehicle selection is an important consideration as it can impact topical efficacy and may vary from one body part to another. Ointments and tapes provide occlusion, enhancing drug penetration to improve efficacy. Shampoos incorporating coal tar distillates or salicylic acid with corticosteroids are useful for scalp psoriasis. Coal tar and salicylic acid are rarely used as lone agents due to tolerability issues related to staining and irritation, respectively. Pastes, such as Lassar's paste, have an inherent stiffness, minimizing the spread of medication, and are useful for incorporating drugs such as anthralin, which, especially in higher concentrations used in short-contact methods, may cause skin irritation and burning if in contact with normal skin. It is important to remember that changing to a different vehicle may significantly alter drug potency. Ultimately, the optimal vehicle may be the vehicle that the patient is willing to use. Occlusive ointments may be too greasy and cosmetically unappealing, resulting in poor adherence. Sometimes using a cream formulation during the day and an ointment at night may be the best option.[18]

LO 5

KEY CONCEPT Corticosteroids are the topical first-line treatment for mild to moderate psoriasis. They exert anti-inflammatory and immunosuppressive effects resulting in reduced scaling and overall plaque size. Additionally, topical corticosteroids can be combined with other topicals or systemic/biologic agents to enhance therapy. Adverse effects include skin atrophy with prolonged use (especially if used with an occlusive agent), hypopigmentation, and striae. More than 2 weeks of continuous use should be avoided to prevent these complications.[13]

LO 5

Phototherapy for Psoriasis Phototherapy and photochemotherapy are generally used in the management of moderate to severe disease.[11,12]

Phototherapy is traditionally done by using narrowband UVB (NB-UVB) radiation. It can be used as monotherapy or in combination with topical or systemic agents. The UVB disrupts the synthesis of proteins and nucleic acids in skin, which reduces epidermal keratin proliferation. Education should be provided to all patients and include information about the importance of wearing goggles for eye protection when undergoing phototherapy. Phototherapy may be administered during pregnancy and is considered a first-line therapy for those patients.[21]

LO 5

Photochemotherapy is the administration of phototherapy together with topical or systemic agents.[11,15,18] UVA has a long wavelength, and therapy with UVA is always combined with psoralens (eg, methoxsalen or trioxsalen), which are used as photosensitizers to increase efficacy. The use of PUVA for psoriasis causes two types of reactions: (a) an anoxic reaction that affects cellular deoxyribonucleic acid (DNA) that inhibits the proliferation of epidermal cells and induces cell death (apoptosis), and (b) an oxygen-dependent reaction that gives rise to the formation of free radicals and reactive oxygen that may damage membranes by lipid peroxidation.[22]

PUVA therapy applies to a group of therapies utilizing psoralens to sensitize cells to UVA light.[21] Bath PUVA, topical PUVA, and oral PUVA regimens are available.[11,21] Bath topical PUVA uses psoralens directly on the skin, followed by UVA therapy.[21] Psoralens act much more on cells that are actively dividing than on resting cells. Their action on actively dividing or activated immune cells, especially on T cells, explains their action in immune mediated diseases like psoriasis.

► *Systemic Therapy*

LO 5

Systemic therapies are used for patients with moderate to severe disease. To minimize drug toxicities or increase efficacy, systemic therapies are sometimes used in conjunction with topical or phototherapy.[4,11,12,17,23] These oral agents are classified into immunosuppressants, oral retinoids, T-cell activation inhibitors, cytokine modulators, TNF-α inhibitors, and IL-12 and IL-23 blockers.[1] See Tables 64–4 and 64–5.

Acitretin is an oral retinoid that is likely safer, but less effective, than methotrexate or cyclosporine since potentially serious adverse effects can usually be minimized by appropriate

Patient Encounter Part 2

The diagnosis is that the patient has plaque psoriasis. Patient expresses to you at this time that she "does not have the best insurance," but she wants something that will take care of her psoriasis.

What nonpharmacologic alternatives are appropriate for this patient?

What pharmacologic agents are appropriate for this patient?

Table 64–2

Topical Medications[2,12,20,24]

Actions and Effects	Selected Agents	Criteria	Approach to Therapy	Efficacy Assessment (PGA) Scores	Dosage Form/ Strength	Place in Therapy
Corticosteroids						
Anti-inflammatory Vasoconstriction Immunosuppression Antiproliferative	**Very High Potency** • Bethamethasone • Clobetasol • Diflorasone	Mild to moderate	Monotherapy for acute episode	41%–92% with increase in potency	Ointment, creams, lotions, gel, foams, solutions, shampoo, spray, and tape	First-line
	High Potency • Amcinoride • Betamethasone dipropionate and valerate • Desoximetasone		Monotherapy for acute episode			
	Intermediate Potency • Betamethasone • Desoximetasone		Monotherapy for acute episode			
	Low Potency • Alclometasone • Desonide • Hydrocortisone		Monotherapy for acute episode			
Vitamin D Analogues						
Not well known Vitamin D receptor binding is proposed Keratinocytes proliferation is attenuated	Calcipotriene	Mild to moderate	Mono- or steroid sparing adjunctive therapy. First consideration with steroid when rapid lesion eradication is desired	60%–70%	Cream Scalp solution	First-line with or without steroid
	Calcipotriol			60%–70%	Ointment	
Retinoids						
Not well known Modifies gene transcription Decrease inflammation and proliferation due to its retinoid acid receptors binding	Tazarotene	Mild to moderate	Mono- or adjunctive therapy with steroid. More effective with high potency steroids	63%	Gel	Second-line with or without steroid
Calcineurin Inhibitors						
Decrease lymphokines activity by phosphatase inhibition Act as immunomodulators	Tacrolimus (Protopic)	Mild to moderate	Monotherapy for more sensitive areas such as face	65%–70%	Ointment strengths: 0.03% and 0.1%	Third-line with or without steroid
	Pimecrolimus (Elidel)	Mild to moderate	Monotherapy for more sensitive areas of the skin such as face	56%–62%	Cream strength: 1%

Table 64–2

Topical Medications[2,12,20,24] (*Continued*)

		Other Agents				
Actions and Effects	**Selected Agents**	**Mild to Moderate**	**Approach to Therapy**	**Partly Indicated**	**Various**	**Place in Therapy**
Moisturizers						
Unknown	Nonmedicated moisturizers	Mild to moderate	Commonly used throughout the day	31%	Creams and ointments	
Salicylates						
Act as keratolytic agents and reduce lesion scaling to improve absorption of applied medications	Salicylic acid	Mild to moderate	More effective when used as an adjunctive therapy to other topical agents	Unknown	Creams, foams ointments, shampoos Strengths: 1.8%–2.5% and 3%	Adjunct therapy for scalp psoriasis used with steroids to increase efficacy (breaks down keratin)
Anthralin						
Inhibition of T-Cell proliferation and migration of neutrophils Keratolytic agent	Anthralin	Mild to moderate	Use infrequently due to irritation	Unknown	Creams, shampoos Strengths: 1%–1.2%	Adjunct therapy often used in conjunction with steroids in a paste
Coal Tar						
Inhibition of cell proliferation Acts as keratoplastic agent	Coal tar, crude coal tar, combinations (Polytar and Sebutone)	Mild to moderate	Use infrequently due to skin irritation	Unknown	Creams, gels, shampoo, solutions, lotions, oil Strengths: 0.5%–3%	Adjunct therapy with steroids to increase efficacy

PGA, Physician Global Assessment score.

patient selection, careful dosing, and monitoring.[24] Acitretin given concurrently with phototherapy, acitretin + ultraviolet B (ReUVB) or oral retinoid + PUVA (RePUVA), has a synergistic treatment effect. Acitretin monotherapy is usually given for 14 days before instituting UVB or PUVA.[13] ReUVB and RePUVA are well-established treatment regimens for psoriasis.[4,6,7,11,21,23] Pregnancy and blood donation must be avoided during treatment and for 3 years after discontinuation of therapy.[6,7,12,23] Acitretin can transform spontaneously or be converted by ethanol (transesterification) into etretinate, which may take up to 3 years to completely clear the body. Due to this, abstinence from alcoholic beverages should be observed during therapy and for at least 2 months after acitretin is discontinued.

Methotrexate is a folic acid antagonist that interferes with purine synthesis and thus inhibits DNA synthesis and cell replication. In addition to the antimitotic effect, it suppresses T-cell effects, and, in low doses, anti-inflammatory and antiproliferative effects. Compared with cyclosporine, methotrexate has a more modest effect but can be used continuously for years, with persistent benefits.[11] Folic acid is added to the treatment with methotrexate to reduce gastrointestinal symptoms and bone marrow toxicity. It may take up to 4 weeks to see a clinical response after a dose increase.[23]

Cyclosporine is an immunosuppressant that specifically inhibits helper T cells and keratinocyte activation and proliferation. Cyclosporine is efficacious in both inducing and maintaining remission for patients with moderate to severe plaque psoriasis and is also effective in treating pustular, erythrodermic, and nail psoriasis.[11,12]

Mycophenolate mofetil may be useful in resistant cases of moderate to severe psoriasis and in patients with cyclosporine-induced nephrotoxicity as a switch-over agent. Although PASI increased, patients' renal function improved.[24] As adjunctive or monotherapy, there are a few studies in relatively small groups of patients with moderate to severe psoriasis that showed some benefit (at least a 50% reduction in PASI).[23]

LO 5

Biologic Response Modifiers Biologic response modifiers (BRMs) and their biosimilars are currently recommended for consideration as first-line therapies alongside traditional systemic agents for moderate to severe disease.[11] These are agents employed in the treatment of psoriasis that act by inhibiting various molecular signaling steps of the immunological signaling cascade that are key determinants of the pathogenesis of psoriasis.

LO 5

The following agents are available for the treatment of chronic plaque psoriasis[25]:

1. Inhibitors of TNF-α, which includes biologic agents such as etanercept, adalimumab, infliximab, and golimumab
2. Inhibitors of interleukin which includes ustekinumab, ixekizumab, brodalumab and secukinumab

Table 64–3

Topical Medications[2,12,20,24]

Drug Class	Dosing and Application	Administration Guidelines	Cautions and Side Effects
Corticosteroid	• Mostly once or twice daily • Every other day or weekends only application may be suitable for chronic conditions • Treatment is recommended for 2–3 weeks • Low and intermediate potency can be used up to 3 months	• Intermediate and low potency agents are indicated for acute and mild lesions and tapering is recommended with the lowest dose when the condition improves • Low potency agents are suitable for lesions in infants due to large body surface area and elderly for the sensitive and thin layer of the skin • High and very high potency agents are indicated for chronic and severe lesions • Palms and soles of the skin require high and very high potency agents to maximize absorption and penetration due to the thickness of the skin	• Skin irritation • Dryness • Withdrawal effects
Vitamin D analogues	Mostly once or twice daily for a maximum of 2 months for effective results	• Recommended to be used with topical steroids to speed up the healing process • Considered less toxic than topical steroids • Combination therapy with steroids has shown to be more effective than the single agent • Onset of action is slow • Avoid calcipotriene use with salicylic acid due to instability of calcipotriene	• Pruritus • Skin irritation on facial area and skin folds • Skin irritation is less with calcitriol • Skin rashes • Burning • Changes in systemic vitamin D levels
Retinoids	Preferred as once daily at bedtime	• Best used to achieve better efficacy results with high-potent steroids or UVB phototherapy	• Skin irritation • Pruritus • Dryness • Photosensitivity
Calcineurin inhibitors	Mostly once or twice daily depending on the product until effective result is observed	• Comparison data to other agents or in combination is lacking • Use with salicylic acid for 8 weeks showed efficacy improvement in facial lesions	• Skin irritation • Pruritus • Photosensitivity • Risk of malignancy
Other agents: • Salicylic acid • Coal tar • Anthralin	As directed	• Decreases the scaling of the skin lesion to allow application of other agents • Infrequent use of tars and anthralins due to irritation and staining	• Skin irritation • Potential salicylic acid toxicity manifesting as nausea and ringing in ears

Their safety profile in comparison with other systemic agents and relatively good acceptability by patients are all positive factors.[10] However, given that immunosuppression is an adverse effect of many of these agents, clinicians should ensure that appropriate vaccinations are administered and tuberculosis skin testing performed prior to initiation of therapy. Additionally, clinicians should monitor for signs/symptoms of infection throughout therapy. Primary response success with BRMs is defined as a 50% or greater reduction in baseline disease severity. Patients should be switched to an alternative therapy if the primary response is not achieved or if the psoriasis initially responds but then loses its response.

Oral apremilast is one of a class of "small molecule" systemic BRMs specifically approved for PsA. It inhibits phosphodiesterase 4 (PDE4) which controls part of the inflammatory actions within cells via cyclic adenosine monophosphate (cAMP) to decrease nitric oxide synthase, TNF-α and IL-23 and increase IL-10. Many other BRMs may be used when PsA is present, but certolizumab (TNF-α inhibitor), guselkumab (interleukin inhibitor), and abatacept (T-cell inhibitor) can only be used for PsA and not severe psoriasis.

OUTCOME EVALUATION

LO 6

- Monitor for clearance of skin lesions. Depending on the agent(s) used and site of lesions, it may take 2–6 weeks or longer to see a response. Complete clearance may not be achieved for all patients. A BSA of 3% or less or a BSA improvement of 50% or more from baseline is considered an acceptable response.
- Beginning 3 months after the start of new therapies (important to wait at least 90 days since it can take up to 16 weeks to effect [induction phase]):
  - A BSA of 1% or less is recommended for target therapy
- During maintenance or remission, monitor every 6 months.
  - A BSA of 1% or less is the target response at every 6 months during maintenance evaluation.
- In Europe, successful treatment is defined as a decrease in the PASI score of 75% or greater. The PASI is a scoring instrument that ranges from 0 (absence of disease) to 72 (most severe form of the disease).[17]

Table 64–4

Systemic Agents[26,27]

Drug	Mechanism of Action	Doses and Administration	Dosage Forms	Adverse Effects	Therapeutic Efficacy on PASI 75	Therapeutic Application	Therapeutic Monitoring
Immunosuppressants							
Cyclosporine	An immunosuppressive agent that specifically inhibits helper T cell and keratinocyte activation and proliferation	2.5 mg/kg/day in two divided doses for at least 4 weeks This dose may be subsequently titrated and increased by 0.5 mg/kg/day Q 2 weeks until there is control of plaques (maximum dose of 4 mg/kg /day)	Oral and IV solution	Nephrotoxicity, lowering of seizure threshold, tremor, gingival hyperplasia, hypertension, squamous cell carcinoma (cutaneous)	~41%–71%	First-line agent Used in psoriasis only (children only as last line therapy)	LFTs (Baseline and routine) SCR, BUN CBC Uric acid Blood pressure Drug interaction with cytochrome p450 substrate and inhibitors Pregnancy
Methotrexate	Folic acid antagonist Acts by interfering with purine synthesis, thus inhibit DNA synthesis and cell replication	-7.5 to 10 mg weekly (max of 25 mg) -2.5 mg Q 12 hours times 3 doses	Oral and injectable	Nausea, vomiting, stomatitis, fatigue, hepatotoxicity, bone marrow suppression, pulmonary fibrosis	24%–60%	First-line agent Used in psoriasis and psoriatic arthritis (adults and children)	CBC SCR, BUN LFTs (baseline and Q 4 weeks), avoid in cirrhosis and alcohol use disorders Pregnancy category X
Oral Retinoids							
Acitretin	Stimulates differentiation and normalizes epidermal cell proliferation	10–50 mg/day	Oral capsule	Myalgia, hair loss, hepatotoxicity, pancreatitis, hypervitaminosis A, hyperlipidemia	70%–75%	Second-line agent Used in psoriasis only (adults and children)	Lipids CBC SCR, BUN (baseline and Q 3 months) Pregnancy category X CYP450 medications

BUN, blood urea nitrogen; CBC, complete blood count; CYP450, cytochrome P450; LFT, liver function test; Q, every; SCR, serum creatinine.

Table 64–5

Biological Therapy[28–33] (*Continued*)

Medication	Mechanism of Action	Dose and Administration	Dosage Forms	Adverse Effects	Therapeutic effects on PASI	Place in Therapy	Therapeutic Monitoring
Cytokine Modulators-Tumor Necrosis Factors							
Etanercept	Fusion protein that binds to both TNF-α and TNF-β	50 mg SC twice weekly for 12 weeks then 50 mg SC weekly	SC solution Biosimilar available: Etanercept-szzs	Upper respiratory tract infection, nausea, vomiting, headaches; injection site reaction	47%–59% at weeks 12 and 24	Second-line agent Used in psoriasis (people > 4 years old) and psoriatic arthritis (adults)	CBC LFTs PPD (tuberculosis)
Abatacept	Blocks T-cell activation	125 mg once weekly	SC self-injection, IV infusion	HA, upper respiratory infection, cold-flu-like symptoms		Used in psoriatic arthritis only (adults)	Signs of infection (especially when used with a TNF inhibitor) PPD prior to starting therapy (TB testing)
Adalimumab	Human monoclonal antibody that targets TNF-α	80 mg SC, first dose then 40 mg SC on week 2, then 40 mg SC Q 2 weeks	SC solution Biosimilars available: adalimumab-adbm, adalimumab-atto	Upper respiratory tract infection, pharyngitis, nausea, dyspepsia, fatigue, headaches; injection site reaction	53%–80% at weeks 12 and 16	First-line Used in psoriasis and psoriatic arthritis (adults)	CBC LFTs PPD (tuberculosis)
Certolizumab	Blocks TNF-α	400 mg (2 injections of 200 mg each) weeks 0, 2, and 4 then every other week	SC injection	Upper respiratory infection, rash, UTI, serious allergic reaction, Lupus-like syndrome		Used in psoriatic arthritis only (adults)	CBC LFTs Signs and symptoms of infection
Infliximab	Chimeric monoclonal antibody that targets TNF-α	5 mg/kg IV on weeks 0, 2, 6 and then 5 mg Q 8 weeks (10 mg/kg dosing is reserved for IBD)	IV and SC solutions Biosimilars available: infliximab-abda, infliximab-dyyb, infliximab-qbtx	Upper respiratory tract infection, pharyngitis, diarrhea, fatigue, hypersensitivity reaction	76%–82% at weeks 10 and 24	Second-line Used in psoriasis and psoriatic arthritis (adults)	PPD (tuberculosis)
Golimumab	Human monoclonal antibody that binds to both soluble and transmembrane bioactive forms of human TNF-α (a cytokine protein), resulting in inhibition of TNF-α biological activity by preventing the binding of TNF-α to its receptors	50 mg SC once monthly	SC solution	Hypertension, injection site reaction, rash, ALT/SGPT level raised, AST/SGOT level raised, dizziness, paresthesia, bronchitis, sinusitis, upper respiratory infection, new or worsening heart failure		Used in psoriatic arthritis only (adults) alone or with methotrexate	LFTs Infection Edema

Cytokine Modulators: Interleukin Inhibitors							
Ustekinumab	Human monoclonal antibody that targets IL-12/23 p40	45–90 mg SC on week 0 and 4, then every 12 weeks	SC solution	Headache, upper respiratory tract infection, pharyngitis, abdominal pain	66%–78% at weeks 12 and 28	First-line Used in psoriasis (people > 12 years) and psoriatic arthritis (adults)	PPD (TB testing), signs of serious infection
Secukinumab	Human monoclonal antibody that antagonizes IL-17A	300 mg SC at weeks 0, 1, 2, 3, and 4 then 300 mg every 4 weeks	SC solution	Nasopharyngitis, diarrhea, upper respiratory tract infection	82%–86% at week 12	First-line Used in psoriasis and psoriatic arthritis (adults)	PPD (tuberculosis), inflammatory bowel disease, caution in patients with chronic or recurrent infection
Ixekizumab	Human monoclonal antibody that inhibits the release of proinflammatory cytokines and chemokines by selectively binding with IL-17A cytokine	160 mg (two 80 mg injections) SC at week 0, followed by 80 mg SC at weeks 2, 4, 6, 8, 10, and 12, then 80 mg SC every 4 weeks	SC solution	Injection site reaction, neutropenia, upper respiratory infection, hypersensitivity reaction	71%–100% at week 12	Second-line Used in psoriasis and psoriatic arthritis (adults)	PPD (uberculosis), caution in patients with chronic or recurrent infection, Inflammatory bowel disease
Brodalumab	Human monoclonal IgG2 antibody that blocks the release of proinflammatory cytokines and chemokines by selectively binding to human IL17 receptor A (IL-17RA) and inhibiting its interactions with cytokines IL-17A, IL-17F, IL-17C, and IL-17A/F heterodimer and IL-25	210 mg SC on weeks 0, 1, and 2, then every 2 weeks thereafter	SC solution	Diarrhea, mycosis, arthralgia, headache, pain in throat, fatigue, neutropenia, cryptococcal meningitis, suicidal thoughts	83%–86% at week 12	Second-line Used in psoriasis only (adults)	PPD (tuberculosis), caution in patients with chronic or recurrent infection
Guselkumab	Blocks IL-23	100 mg weeks 0 and 4, then every 8 weeks	Subcutaneous self-injection	Upper respiratory infection, HA, joint pain, diarrhea		Used in psoriasis only (adults)	Signs of infection PPD prior to starting therapy (TB testing)

(*Continued*)

Table 64–5

Biological Therapy[28–33] (*Continued*)

Medication	Mechanism of Action	Dose and Administration	Dosage Forms	Adverse Effects	Therapeutic effects on PASI	Place in Therapy	Therapeutic Monitoring
PDE 4 Inhibitors							
Apremilast	Phosphodiesterase 4 (PDE4) inhibitor, with specificity for cyclic adenosine monophosphate (cAMP) that results in increased intracellular cAMP levels	Initial titration over 5 days: Day 1, 10 mg orally in the morning Day 2, 10 mg twice daily Day 3, 10 mg in the morning, 20 mg in the evening Day 4, 20 mg twice daily Day 5, 20 mg in the morning, 30 mg in the evening Maintenance: Day 6 and thereafter, 30 mg orally twice daily	Oral tablet	Diarrhea, nausea, headache, tension-type headache, weight decreased, depression, suicidal behavior, suicidal thoughts		Used in psoriasis and psoriatic arthritis (adults)	Coadministration with strong CYP450 inducers (eg, rifampin, phenobarbital, carbamazepine, and phenytoin) is not recommended
Janus Kinase (JAK) Inhibitors							
Tofacitinib	Inhibits janus kinase which are intracellular enzymes, and modulates a signaling pathway that influences the cellular processes of hemopoiesis and immune cell function	Immediate release: 5 mg twice daily Extended release: 11 mg once daily	Oral tablet (immediate and extended release)	URI, headache, diarrhea, cold or flu-like symptoms		Second-line Used in psoriatic arthritis only (adults) (in combination with nonbioologic DMARDs)	Serious infection, malignancies, GI perforations, changes in CBC, LFTs, or lipids, caution with administration of live vaccines when switching from IR to ER give ER tablet day after last IR dose

ALT, alanine transaminase; AST, aspartate transaminase; BUN, blood urea nitrogen; cAMP, cyclic adenosine monophosphate; CBC, complete blood count; CYP450, cytochrome p450; DMARDs, disease-modifying antirheumatic drugs; ER, extended release formulation; GI, gastrointestinal; IBD, inflammatory bowel disease; IgG, immunoglobulin G; IL, interleukin; IR, immediate release formulation; IV, intravenous; LFT, liver function test; PDE, phosphodiesterase 4; PPD, purified protein derivative; Q, every; SC, subcutaneous; SCR, serum creatinine; SGOT, serum glutamic oxaloacetic transaminase; SGPT, serum glutamic pyruvic transaminase; TB, tuberculosis; TNF-α, tumor necrosis factor-α; tumor necrosis factor-α; TNF-β, tumor necrosis factor-β; URI, upper respiratory infection; UTI, urinary tract infection.

- Treatment failure is defined as a decrease in the PASI score of less than 50% necessitating a new treatment.

LO 6

- Monitor for improvement of symptoms and control of comorbid conditions. Incomplete clearance of lesions, but improvement in these metrics can be considered at least partial treatment success. The National Institute for Health and Care Excellence (NICE) clinical guidelines on psoriasis outline other qualitative measures to be used in assessing the holistic approach to disease management.[1] It emphasizes evaluating the physical, psychological, and social impact of the disease on the patients' quality of life. The impact of psoriasis on the patients' daily living activities should be assessed. Depending on how the patient is coping, advice and support may be needed in the overall treatment plan for the patient. Efficacy achievement alone may not have the overall desired effect on patients wellbeing.[1,19] Dermatology Quality of Life Scales, DLQI, Dermatology Specific Quality of Life Instrument, and Skindex-29 are validated instruments that are used to measure these quality outcomes in patients with psoriasis by specialists.[12,19]

LO 6

- Monitor for specific adverse effects and drug interactions, depending on agent(s) used.

Patient Encounter Part 3

The patient was started on clobetasol 0.1% ointment and has been doing well for 18 months. She reports that her condition was well controlled during this time, but recently, she lost her spouse and she has noticed the lesions have reappeared. She continued her clobetasol, but her lesions have now spread to her back (BSA 11%).

Current Meds: Nonmedicated moisturizer after bathing and as needed; clobetasol 0.1% ointment twice daily

What is your main treatment goal for this patient?

What pharmacologic treatments would be appropriate for this patient at this time?

What are the monitoring parameters of your proposed treatment?

- Total clearance of skin disease is not impossible during periods of remission; remissions may be days, months, years, and even decades in length, with patients being weaned from their medications entirely or have them reduced to a low maintenance dose.

Patient Care Process

Collect Information:

- Perform a medication history for use of prescription and nonprescription medications and dietary supplements. Identify allergies to medications and other substances.
- Review the medical history and physical assessment findings (eg, BMI, BSA % covered in plaques).
- Speak with the patient and review records to identify lifestyle habits (take note of tobacco use), preferences and beliefs, health goals, and socioeconomic factors that affect medication access and other aspects of care.
- Identify any sources of stress that could worsen psoriasis.

Assess the Information:

- Determine whether the patient is taking any substance that could adversely affect psoriasis control or interact with prescribed medications.
- Based on the medical history, determine whether the patient has any contraindications to therapy.
- Document pertinent family medical history (eg, heart disease, stroke, diabetes, dyslipidemia).
- Based on physical examination and review of systems, determine the severity of psoriasis.
- Identify comorbidities associated with psoriasis.
- Document location and BSA % covered by plaques.
- Assess the efficacy, safety, and patient adherence of current pharmacotherapy.
- Identify any significant adverse drug effects or interactions.

Develop a Care Plan:

- If patient is not at the desired level of remission, determine which pharmacologic treatment is indicated (Figure 64–2).
- Select lifestyle modifications that are likely to be effective, safe, and applicable to the individual patient.
- Choose medications and doses that are optimal for the patient (Tables 64–2, 64–3, 64–4, and 64–5). Use combination therapy when appropriate to take advantage of complementary mechanisms of action and to reduce side effects.

Implement the Care Plan:

- Educate the patient about changes in drug therapy, medication administration, potential new adverse effects, and how to manage and report adverse effects that occur.
- Address any patient concerns about psoriasis and its management.
- Discuss importance of medication adherence and lifestyle modifications to prolong remission.
- Determine whether the patient has insurance coverage or whether recommended agents are included on the institution's formulary.
- Educate patient about the involvement of dermatologists (eg, when biologic therapy is warranted).

Follow-up: Monitor and Evaluate:

- Follow up at 6–12 week intervals to assess effectiveness and safety of therapy until remission is achieved.
- Review medication adherence and BSA % covered measurements, evaluating the degree of control.
- Once psoriasis is in remission, monitor patient twice yearly to assess psoriasis control and pertinent lab monitoring. Determine whether the patient is experiencing any adverse reactions or drug interactions.

SUMMARY

It should be recognized that psoriasis is a chronic disease with no current cure but requires lifelong management of the disease state. No two cases of psoriasis are identical and treatment modalities must be tailored to the patient with the help of a dermatologist. The disease can severely impact the patients' quality of life by affecting their physical, psychological, and social well-being. The NICE guidelines recommend a holistic approach in assessing all areas of life in caring for patients that live with this disease.

ACKNOWLEDGMENTS

The authors and editors wish to acknowledge and thank Dr. Rebecca Law, the primary author of this chapter in the third edition of this book, and Dr. Miriam Ansong, Dr. Samson Amos, and Dr. Victor Padron, the authors of this chapter in the fourth edition of this book.

Abbreviations Introduced in This Chapter

BRM	Biologic response modifier
BSA	Body surface area
cAMP	Cyclic adenosine monophosphate
IFN-γ	Interferon-γ
IL-2	Interleukin-2
IL-10	Interleukin-10
IL-12/23	Interleukin-12 and interleukin-23
LFT	Liver function test
MI	Myocardial infarction
NB-UVB	Narrowband ultraviolet B
NSAIDs	Nonsteroidal anti-inflammatory drugs
PASI	Psoriasis Area and Severity Index
PPD	Purified protein derivative
PsA	Psoriatic arthritis
PUVA	Psoralen and ultraviolet A
RePUVA	Oral retinoid + PUVA
ReUVB	Acitretin + ultraviolet B
TNF	Tumor necrosis factor
UVB	Ultraviolet B

65 Common Skin Disorders

Laura A. Perry and Lori J. Ernsthausen

LEARNING OBJECTIVES

LO

Upon completion of the chapter, the reader will be able to:

1. Describe the pathophysiology of common skin disorders.
2. Assess the signs and symptoms of common skin disorders in a presenting patient.
3. List the goals of treatment for patients with common skin disorders.
4. Select appropriate nonpharmacologic and pharmacologic treatment regimens for patients presenting with common skin disorders.
5. Identify adverse effects that may result from pharmacologic agents used in the treatment of common skin disorders.
6. Develop a monitoring plan that will assess the safety and efficacy of the overall disease state management of common skin disorders.
7. Create educational information for patients about common skin disorders, including appropriate self-management, available drug treatment options, and anticipated therapeutic responses.

INTRODUCTION

Several thousand skin disorders are currently documented, and many patients seek the assistance of a health care provider when a complication with their skin develops. Others will utilize self-care to effectively treat their symptoms.

This chapter discusses acne vulgaris, contact dermatitis (irritant and allergic), and diaper dermatitis; other common skin and soft tissue infections and superficial fungal infections are discussed in Chapters 73 and 83, respectively. Providing patients with appropriate therapy options, as well as patient education on treatment and prevention, will assist the successful management of many common skin disorders.

ACNE VULGARIS

Acne vulgaris is an inflammatory skin disorder of the pilosebaceous units of the skin. Although most commonly seen on the face, acne can also present on the chest, back, neck, and shoulders (Figure 65–1).[1] Acne is not just a self-limiting disorder of teenagers. The clinical course of acne can be prolonged or recur, resulting in long-term physical complications, such as extensive scarring and psychological distress.[2]

Epidemiology and Etiology

With an estimated 40 to 50 million people affected, acne vulgaris is the number one skin disease in the United States.[3] Acne affects approximately 85% of adolescents and adults aged 12 to 25 years, with severity of acne correlating with pubertal maturity.[3,4] Additionally, acne may persist beyond puberty and has been found to affect 64% and 43% of individuals into the 20s and 30s, respectively. Acne is more likely to occur in males during adolescence and females during adulthood. Individuals with a positive family history of acne have been shown to develop more severe cases of acne at an earlier age. Prevalence of acne among ethnic groups is similar.[4]

The link between diet and acne has continued to be controversial, with emerging evidence suggesting a link to foods with high glycemic indexes as well as dairy products (ie, skim milk); however, no specific dietary changes are recommended in the management of acne.[5-7] Local irritation from occlusive clothing or athletic equipment, oil-based cosmetics or beauty products, prolonged sweating or environments of high humidity, and a variety of medications may also worsen acne.[8]

Pathophysiology

LO 3

KEY CONCEPT The development of acne lesions results from four pathogenic factors: excess sebum production, **keratinization**, bacterial growth, and inflammation.[1,2,7]

The **pilosebaceous unit** of the skin consists of a hair follicle and the surrounding sebaceous glands. Sebum is released by the sebaceous glands and naturally maintains hair and skin hydration. Increased androgen levels, especially during puberty, can cause an increased size of the sebaceous gland and production of abnormally high levels of sebum within those glands. Keratinization, the sloughing of epithelial cells in the hair follicle, is also a natural process. In acne, however, *hyper*keratinization occurs resulting in an increased adhesiveness of the sloughed cells.

An initial acne lesion invisible to the naked eye, called a microcomedo, forms as a result of the increased cell division and cohesiveness. Sub-clinical microcomedo formation is a precursor for noninflammatory acne lesions called comedos. A **closed comedo** or "whitehead" appears when accumulation of epithelial cells and sebum partially obstruct the follicular opening. If the follicular opening is dilated, the keratin build-up can darken and form an **open comedo** or "blackhead."

FIGURE 65–1. Twenty-year-old man. In this case of papulopustular acne, some inflammatory papules become nodular and thus represent early stages of nodulocystic acne. (From Wolff K, Johnson RA. Disorders of sebaceous and apocrine glands. Fitzpatrick's Color Atlas & Synopsis of Clinical Dermatology, 6th ed. New York: McGraw-Hill; 2009:3.)

Propionibacterium acnes (*P. acnes*), an anaerobic organism, is also found in the normal flora of the skin. This bacteria proliferates in the mixture of sebum and keratinocytes and can result in an inflammatory response producing more severe acne lesions such as papules, pustules, and nodules. Inflammatory lesions may result in scarring if treated inadequately.

Treatment

▶ *Desired Outcomes and Goals*

LO 3

Although traditionally thought of as a self-limiting disorder, acne can have patterns of recurrence. Because acne cannot be cured, proper treatment must involve both short-term and long-term strategies. KEY CONCEPT Goals of therapy are to (1) reduce the number and severity of existing lesions, (2) prevent the development of new lesions and recurrence, and (3) prevent long-term disfigurement and permanent scarring.[7] Acne can cause psychological symptoms of stress, anxiety, frustration, embarrassment, and even depression.[2,5,7] Evaluating both physical and psychological aspects of acne is imperative.

General Approach to Treatment

LO 4

KEY CONCEPT Acne treatment regimens should be based on acne severity and type of acne lesion. Other factors such as response to previous treatment, patient preference, cost, and adherence should also be considered. Topical therapy is considered first-line for mild acne with oral therapies added to topical therapy in moderate to severe acne. Using multiple topical agents that target different aspects of acne pathogenesis is more effective, reduces adverse effects, and minimizes treatment resistance.[2,5,12] Topical therapies should be applied to the entire area affected by acne to prevent new lesions from developing.[2,7]

Optimal management includes aggressive induction treatment and maintenance therapy to prevent recurrence. Improvement of symptoms following induction therapy occurs gradually, sometimes taking 6 to 8 weeks for results to be physically apparent. Patients need to be educated on continual treatment compliance during this time and should not get discouraged if acne lesions appear to worsen before getting better. Maintenance therapy should begin after 12 weeks of induction therapy and it

Clinical Presentation and Diagnosis of Acne

LO 2

Acne lesions are most often seen on the face, but can also present on the chest, back, neck, and shoulders and are described as either noninflammatory or inflammatory. Severe inflammatory lesions may lead to scarring and hyperpigmentation.

Noninflammatory Lesions

Closed comedo or "whitehead": A partially plugged follicle containing sebum, keratinocytes, and bacteria that remains beneath the surface of the skin. Closed comedos usually appear as small white bumps about 1 to 2 mm in diameter.

Open comedo or "blackhead": A partially plugged, dilated follicle containing sebum, keratinocytes, and bacteria approximately 2–5 mm in diameter that protrudes from the surface of the skin and appears black or brown in color. Although dark in color, blackheads do not indicate the presence of dirt, but rather, an accumulation of melanin.

Inflammatory Lesions

Papules: Solid, elevated lesion less than 0.5 cm in diameter

Pustules: Vesicles filled with purulent fluid less than 0.5 cm in diameter

Nodules: Warm, tender, firm lesions greater than 0.5 cm in both width and depth

Cysts: Nodules that harden into larger, pus-filled lesions

Scars

Inflammatory acne can result in permanent scarring that ranges from small, depressed pits to large elevated blemishes.

Hyperpigmentation

Inflammatory acne may result in hyperpigmentation of the skin that can last for weeks to months.

Diagnosis

The diagnosis of acne vulgaris is clinical. Lesion cultures may be warranted when treatment regimens fail to rule out Gram negative folliculitis and other skin infections. Endocrinological laboratory evaluation is only recommended for patients who have acne and additional signs of androgen excess.[5]

Assessment

No standard acne grading scale has been identified. While several grading scales exist,[2,5,7,11,12] most clinicians describe acne as mild (noninflammatory lesions), moderate (many inflammatory lesions), or severe (numerous severe inflammatory lesions and evidence of scarring).

was continued for 3 to 4 months in most clinical trials. Due to frequent acne recurrences, clinical experience indicates that a longer duration of maintenance therapy may be beneficial for most patients.[2,5,7]

Nonpharmacologic Therapy

LO 4

There is significant variance in the clinical benefit of many nonpharmacologic interventions for acne vulgaris. Patients should be counseled to avoid aggressive skin washing and to use a mild, noncomedogenic facial soap twice daily. Excessive washing or use of harsh or abrasive cleansers can disrupt the skin barrier and promote comedones and bacterial colonization. Manipulating or squeezing lesions should also be avoided to minimize scarring. Use of an oil-free, noncomedogenic moisturizer daily may improve the tolerability of topical drug therapy.[8,9,10]

▶ *Pharmacologic Therapy*

Topical Agents

LO 4

Retinoids Topical retinoids are the foundation of first-line therapy for induction and maintenance regimens in all forms of acne. Although success is seen with monotherapy in comedonal acne, using topical retinoids in combination with benzoyl peroxide, topical antibacterial agents, or oral antibacterial agents is preferred for inflammatory acne lesions.[2,5,12]

Retinoids normalize epithelial cell turnover, which in turn promotes clearing of obstructed follicles and prevents microcomedo formation. Retinoids also exhibit anti-inflammatory properties through the inhibition of neutrophil and monocyte chemotaxis.[13,14]

Available topical retinoids include tretinoin, adapalene, and tazarotene. Adapalene, available by prescription and over-the-counter, is considered the drug of first choice because it has similar efficacy and a lower incidence of adverse effects.[5,8,12–14] Newer topical retinoid formulations using a microsphere gel (Retin-A Micro) or a prepolyolprepolymer-2 gel or cream (Avita) gradually release the active ingredient over time and may also cause less initial skin discomfort.[13] Table 65–1 describes available products and adverse effects of topical retinoids.

Topical retinoids should be applied once daily at bedtime, beginning with a low-potency formulation. Increased strengths are then initiated according to treatment results and tolerance. Patients should be advised that a worsening of acne symptoms generally occurs in the first few weeks of therapy, with lesion improvement occurring in 3 to 4 months.[14,15] The safety and efficacy of topical retinoids in children younger than 12 years of age and in pregnant women is not well established.[9,13]

LO 4

Benzoyl Peroxide Benzoyl peroxide is easy to use and is recommended as an alternative to, or in combination with, topical retinoids, topical antibacterial agents, or oral antibacterial agents in the treatment of acne of all severities.[2,5,12] Benzoyl peroxide has a **comedolytic** effect that increases the rate of epithelial cell turnover and helps to unclog blocked pores. It also has antibacterial activity against *P. acnes*, which appears to be the main reason for its effectiveness.[16,17]

Benzoyl peroxide is available with or without a prescription and remains the most commonly purchased over-the-counter topical treatment for acne.[8,10] Some data suggest that lower strengths offer similar efficacy to higher strengths. Beginning benzoyl peroxide treatment regimen with the lowest strength and titrating to higher effective strengths over several weeks, if needed, will reduce the incidence of localized adverse effects. Newer formulations of benzoyl peroxide are combined with moisturizers to help decrease skin redness and irritation.[9,16,17]

A typical regimen for benzoyl peroxide is to apply the product to clean and dry skin no more than two times a day. The strength and dosage form selected may vary from patient to patient depending on acne severity and the sensitivity of the patient's skin. Gel preparations are the most potent dosage form. Patients with dry or overly sensitive skin should try a cream, lotion, or facial wash first.[5,7] If severe irritation or an allergic reaction develops, benzoyl peroxide should be discontinued. Table 65–1 describes available products and adverse effects.

LO 5

LO 4

Antibacterials Topical antibacterials directly suppress *P. acnes* and are first-line agents used in combination with benzoyl peroxide, topical retinoids, or azelaic acid for the treatment of mild to moderate inflammatory acne. To reduce the likelihood of bacterial resistance, topical antibiotics should never be used as monotherapy or as long-term maintenance therapy.[2,5,12]

Clindamycin is currently the preferred topical antibiotic for acne therapy due to increased bacterial resistance to erythromycin preparations.[5] Applied once or twice daily for 3 months, these agents are available in various formulations and combinations with benzoyl peroxide and topical retinoids.[2,5,12] Table 65–1 describes the strengths, formulations, and adverse effects of the available antimicrobial agents.

LO 4

Azelaic Acid With antibacterial and anti-inflammatory properties, and the ability to stabilize keratinization, azelaic acid is an effective alternative in the treatment of mild to moderate acne in patients who cannot tolerate benzoyl peroxide or topical retinoids.[2,12,15] It can also even out skin tone and may prove effective in patients who are prone to postinflammatory hyperpigmentation resulting from acne.[5,15,18] Azelaic acid 20% cream should be applied twice daily, with improvement of symptoms seen within 4 weeks.[15]

LO 4

Dapsone Dapsone gel, a sulfone drug, has antimicrobial and anti-inflammatory properties.[19] Dapsone gel may be used as an alternative agent for inflammatory acne as monotherapy or in combination with topical or oral agents. Topical dapsone gel has been shown to be more effective in adult females than in males or adolescents.[5]

Dapsone 5% is a gritty gel that should be applied in a thin layer to the affected areas twice daily.[19,20] When administered concomitantly with benzoyl peroxide, topical dapsone may become oxidized, causing orange-brown coloration of the skin which can be brushed or washed off. If no improvement is seen after 12 weeks, treatment should be reevaluated.[5,20]

LO 4

Keratolytics Sulfur, resorcinol, and salicylic acid have limited evidence available to support efficacy, but can be used as second-line therapies in the treatment of mild to moderate acne.[2,5]

Although these agents may cause less skin irritation than benzoyl peroxide or the topical retinoids, several disadvantages exist. Sulfur preparations produce an unpleasant odor when applied to the skin, whereas resorcinol may cause brown scaling. And although rare, the possibility of salicylism exists with continual salicylic acid use.[8,10,15]

Oral Agents

LO 4

Antibacterials Oral antibiotics are indicated for use in patients with moderate to severe acne and forms of inflammatory acne that are resistant to topical therapy. When used, oral antibiotics should be combined with a topical retinoid and/or benzoyl peroxide.[2,5,12] Because of the ability to decrease *P. acnes* colonization, oral antibiotics can prevent acne lesions from developing. Use of

Table 65–1

Topical Agents Used in the Treatment of Acne

Drug	Brand	Dosage Form	Adverse Reactions	Comments
Retinoids				
Tretinoin	Atralin	0.05% gel 0.025% cream 0.025% gel	Erythema, dryness, scaling, stinging/burning, pruritus, initially may worsen acne	Local adverse reactions most likely occur in first 2–4 weeks of use and will usually lessen with continued use
	Avita	0.025%, 0.05%, 0.1% cream	Possibly teratogenic	Category C
	Retin-A	0.01%, 0.025% gel	Photosensitivity	Minimize exposure to sun light and sun lamps
	Retin-A Micro	0.04%, 0.1% gel		Sunscreen use and protective clothing recommended
	Tretin-X	0.038%, 0.075% cream		
Tazarotene	Tazorac	0.05%, 0.1% cream 0.05%, 0.1% gel	Erythema, dryness, scaling, stinging/burning, pruritus, initially may worsen acne	Local adverse reactions most likely occur in first 2–4 weeks of use and will usually lessen with continued use
	Fabior	0.1% foam	Teratogenic	Category X. Use in pregnancy is contraindicated
			Photosensitivity	Minimize exposure to sun light and sun lamps
				Sunscreen use and protective clothing recommended
Adapalene	Differin	0.1% cream; 0.1%, 0.3% gel; 0.1% lotion	Erythema, dryness, scaling, stinging/burning, pruritus, initially may worsen acne	Local adverse reactions most likely occur in first 2–4 weeks of use and will usually lessen with continued use
	Differin Gel (over the counter)	0.1% gel		Less irritation compared to other retinoids
	Epiduo	0.1%–2.5% and 0.3%–2.5% benzoyl peroxide combination gel	Photosensitivity	Minimize exposure to sun light and sun lamps
				Sunscreen use and protective clothing recommended
				Pregnancy category C
Other Topical Agents				
Benzoyl peroxide	2.5%–10%, various over-the-counter and prescription products	Lotion, gel, foam, pads, liquid wash, bar	Excessive drying, peeling, erythema, allergic contact sensitization/dermatitis	Local reactions are dose-dependent Gradually increase dose as tolerance develops
			Bleaching of hair and colored fabric	Minimize exposure to sun light and sun lamps
			Body odor on clothes/ bedding	Sunscreen use and protective clothing recommended
			Photosensitivity	Pregnancy category C
Azelaic acid	Azelex	20% cream	Erythema, skin irritation	Alternative to benzoyl peroxide Pregnancy category B
Clindamycin	Cleocin T	1% solution, lotion, gel, swab	Burning, itching, dryness, erythema, peeling	Rare cases of colitis have been observed with topical use. Discontinue immediately and seek medical attention if diarrhea occurs
	Clindagel	1% gel	Diarrhea, colitis (pseudomembranous colitis)	Should be combined with topical benzoyl peroxide
	ClindaMax	1% gel, lotion		Pregnancy category B (C when combined with benzoyl peroxide or tretinoin)
	Evoclin	1% foam		
	BenzaClin	1%–5% benzoyl peroxide combination gel		
	Duac	1.2%–5% benzoyl peroxide combination gel		
	Veltin, Ziana	0.025%–1.2% tretinoin combination gel		
Erythromycin	ERYGEL	2% gel	Burning, peeling, dryness, pruritus, erythema	Should be combined with topical benzoyl peroxide
	Ery	2% pad		Pregnancy category B (C when combined with benzoyl peroxide)
	Benzamycin	5%–3% benzoyl peroxide combination gel		
Dapsone	Aczone	5% gel	Dryness, erythema, oiliness, and peeling	Does not have a risk of phototoxicity Pregnancy category C

Data from (1) Lexicomp [Internet]. Hudson (OH): Wolters Kluwer Health, Inc. 1978–2017 [cited 2017 June 13]. Available from: http://online.lexi.com/lco/action/home/switch. oral antibiotics should be limited to short periods of time, ideally 3 to 4 months, or less.[5] Assessment of response to oral antibiotics after 6 to 8 weeks of therapy is recommended.[2] After inflammatory lesions have stopped emerging, oral antibiotics should be discontinued and replaced with topical retinoid or benzoyl peroxide containing maintenance regimens.[5,9] As with topical antibiotics, oral antibiotics should never be used as monotherapy or as long-term maintenance therapy. Additionally, the use of topical antibiotics in combination with oral antibiotics should be avoided due to increased risk of bacterial resistance.[2,5,12]

Tetracycline, doxycycline, and minocycline are the most commonly prescribed oral antibiotics for acne. Doxycycline and minocycline are more effective than tetracycline, but neither is superior to each other.[5] Erythromycin, azithromycin, and trimethoprim (± sulfamethoxazole) are appropriate second-line agents for use when patients cannot tolerate or have developed resistance to tetracycline or its derivatives. Although effectiveness is similar to the tetracyclines, erythromycin use is often limited due to potential adverse outcomes and increased bacterial resistance.[5,21] (See Table 65–2 for antibiotic dosing guidelines and adverse effects.)

Isotretinoin. Isotretinoin works on the four pathogenic factors that contribute to acne development and can produce acne remission rates of up to several years. Oral isotretinoin is Food and Drug Administration (FDA)-approved for patients with severe recalcitrant nodular acne unresponsive to other topical and oral treatment regimens.[5,12] Although studies are lacking, expert clinicians suggest that oral isotretinoin may be useful in treatment resistant moderate acne or acne that is producing physical scarring or psychosocial distress.[2,5,12] Contrary to some expert clinicians, the 2012 European Guidelines suggest that oral isotretinoin therapy may be used as first-line therapy in patients with severe nodular acne due to clinical effectiveness, prevention of scarring, and quick improvements in patient's quality of life.[12]

LO 4

Adverse effects with the use of isotretinoin are frequent and generally dose related. Table 65–2 lists common isotretinoin adverse effects and management strategies for those symptoms.

LO 5

Because isotretinoin is teratogenic and classified as pregnancy category X, the FDA mandates an online registry program called iPLEDGE to ensure that females do not become pregnant while taking isotretinoin. Wholesalers, pharmacies, doctors, and patients must be registered in the iPLEDGE computer-based system in order to control the distribution, prescribing, and dispensing of isotretinoin. Two negative pregnancy tests prior to initiating therapy and one negative pregnancy test each month thereafter must be obtained and confirmed in the system before a prescription can be dispensed to female patients of child-bearing potential. These patients must also commit to using two effective forms of birth control 1 month prior, during, and at least 1 month after discontinuation of isotretinoin therapy. Contact the program at their website https://www.ipledgeprogram.com/ for further details.

Initial dose for treatment of severe acne is typically 0.5 mg/kg daily in two divided doses, then increasing to 1 mg/kg daily, as tolerated, with goal cumulative doses of 120 to 150 mg/kg. Increasing the total daily dose to 1 mg/kg daily resulted in a significantly lower relapse and retreatment rate.[5,9,12] For patients with treatment resistant moderate acne, low-dose isotretinoin (0.25–0.4 mg/kg/day) has comparable efficacy to conventional dosing with decreased adverse effects and improved tolerability. Intermittent dosing of isotretinoin is not recommended due to lack of efficacy and increased relapse rates.[5] Treatment with oral isotretinoin should be continued for 4 to 6 months, but may be extended for patients with an insufficient response.[5,12]

LO 4

Hormonal Agents Oral contraceptives and anti-androgens are valuable second-line treatment options for moderate to severe inflammatory acne in female patients.[5,12,22] Hormonal agents primarily work by decreasing androgen production resulting in reduced sebum formation. Because sebum production occurs early in the pathogenesis of acne, several months to see the full effect of hormonal agents.[5]

Although many contraceptives are effective, agents containing ethinyl estradiol/norgestimate, ethinyl estradiol/norethindrone acetate/ferrous fumarate, and ethinyl estradiol/drospirenone have been FDA-approved for the treatment of acne.[5] While not FDA-approved, spironolactone, at higher doses, is effective for acne through anti-androgenic properties.[5,12] (See Table 65–2 for hormonal agent dosing guidelines and adverse effects.)

Other Agents. Although use is infrequent, several other agents are available as second- or third-line treatment options for acne when first-line therapies fail:[2,5,12]

- Corticosteroids
- Chemical peels
- Surgical extraction
- Phototherapy/photodynamic therapy
- Laser treatments

Figure 65–2 shows useful algorithms for the effective treatment of the various stages of acne.

OUTCOME EVALUATION

LO 6

KEY CONCEPT Depending on severity, complete resolution of acne lesions may take weeks to months. Monitor patients every 4 to 8 weeks during pharmacologic therapy to assess for efficacy.[5,9]

- Decreased number of lesions
- Decreased severity of lesions
- Relief of pain/irritation
- Presence of scarring or pigmentation
- Psychological effects
- Medication adherence

If no improvement is reported after 6 weeks of drug therapy or if symptoms have worsened, patients should be reevaluated and a change to an alternative drug regimen may be necessary (Figure 65–2).

Educate patients on potential adverse effects of drug therapy (Tables 65–1 and 65–2). Consider changing therapy if a patient experiences effects that are not tolerated or are a compromise to their health.

CONTACT DERMATITIS

Contact dermatitis is a condition in which exposure to an offending substance produces inflammation, erythema, and pruritus of the skin.[23,24] More specifically, contact dermatitis can be divided into either irritant or allergic forms.[25,26] KEY CONCEPT Irritant contact dermatitis (ICD) results from first-time exposure to irritating substances such as soaps, plants, cleaning solutions, or solvents. Allergic contact dermatitis (ACD) is a delayed hypersensitivity reaction that occurs after an initial exposure to an allergen results in sensitization. With additional exposure, activation of the immune system results in dermatitis. Allergens that commonly

Table 65–2

Oral Agents Used in the Treatment of Acne

Drug	Dosage Form (mg)	Dosing Regimen	Adverse Reactions	Comments
Oral Antibiotics				
Tetracycline	250, 500 capsule	250–500 mg twice daily	GI upset, headache, blurry vision, vaginal candidiasis, possible teratogenic risk, tooth discoloration in children Vaginal candidiasis Photosensitivity Drug–food interactions	Avoid use in children < 8 years. Pregnancy category D. Avoid use in pregnancy. Minimize exposure to sun light and sun lamps. Sunscreen use and protective clothing recommended. Take 1 hour before or 2 hours after dairy products, antacids, vitamins, or iron supplements.
Doxycycline	50, 75, 100 tablets and capsules	100 mg twice daily on day 1, then 100 mg once daily	GI upset, headache, blurry vision, possible teratogenic risk, tooth discoloration in children Vaginal candidiasis Photosensitivity Drug–food interactions	Avoid use in children < 8 years. Pregnancy category D. Avoid use in pregnancy. Minimize exposure to sunlight and sun lamps. Sunscreen use and protective clothing recommended. Take 1 hour before or 2 hours after dairy products, antacids, vitamins, or iron supplements.
Minocycline	50, 75, 100 immediate release tablets 45, 55, 65, 80, 90, 105, 115, 135 extended release tablets 50, 75, 100 immediate release capsules	Immediate release: 50–100 mg twice daily Extended release: 1 mg/kg daily for 12 weeks.	GI upset, headache, blurry vision, lupus-like syndrome, hepatitis, exfoliative dermatitis, possible teratogenic risk, tooth discoloration in children Vaginal candidiasis Photosensitivity Drug–food interactions	Avoid use in children < 8 years. Pregnancy category D. Avoid use in pregnancy. Minimize exposure to sunlight and sun lamps. Sunscreen use and protective clothing recommended. Take 1 hour before or 2 hours after dairy products, antacids, vitamins, or iron supplements.
Erythromycin	250, 500 tablets	250–500 mg twice daily	GI upset, rash, hearing loss, hypersensitivity reactions Vaginal candidiasis	Highest incidence of GI intolerance and increasing bacterial resistance. Possible drug interactions: CYP3A4 substrate and p-glycoprotein inhibitor. Alternative to tetracyclines Pregnancy category B. Drug of choice in pregnant women and children < 8 years.
Azithromycin	500 tablet	Dosing regimens used in clinical trials have varied greatly, using pulse dose regimens (eg, 500 mg once daily for 4 consecutive days per month for 3 consecutive months)	GI upset, rash, headache, drowsiness	Alternative if other antibiotics cannot be used. Pregnancy category B
Trimethoprim	100 mg tablet	100 mg three times daily or 300 mg twice daily	GI upset, allergic rash, Stevens-Johnson syndrome Photosensitivity	Alternative if other antibiotics cannot be used. Pregnancy category C. Minimize exposure to sunlight and sun lamps. Sunscreen use and protective clothing recommended.
Sulfamethoxazole + trimethoprim	400/80, 800/160 tablets	400–800/80–160 mg one to two times daily	GI upset, allergic rash, urticaria, Stevens-Johnson syndrome, possible teratogenicity Photosensitivity	Alternative if other antibiotics cannot be used. Pregnancy category D. Avoid use in pregnancy. Minimize exposure to sunlight and sun lamps. Sunscreen use and protective clothing recommended

Table 65–2

Oral Agents Used in the Treatment of Acne (*Continued*)

Drug	Dosage Form (mg)	Dosing Regimen	Adverse Reactions	Comments
Hormonal Agents				
Oral contraceptives	Norgestimate/ethinyl estradiol (Ortho Tri-Cyclen) Norethindrone acetate/ethinyl estradiol (Estrostep)	One tablet daily	Nausea, headache, weight gain, breast tenderness, break through bleeding, venous thromboembolism	Not for treatment of acne in men. Use only in adolescent girls ≥ 15 years of age. Pregnancy category X.
Spironolactone	25, 50, 100	50–200 mg daily	Menstrual irregularities, breast tenderness, nausea, dizziness, headache, transient diuretic effect, hyperkalemia	Not recommended for treatment of acne in men. Monitor serum creatinine and potassium. Pregnancy category C.
Oral Etinoid				
Isotretinoin	10, 20, 30, 40 tablets	0.5–1 mg/kg/day in two divided doses with food	Cheilitis, dryness of the nose, eyes, and mouth, peeling, pruritus, and drying of the face and skin, alopecia, acne flair up at start of therapy Teratogenicity Depression/suicidality Musculoskeletal pain Increased serum lipids, creatine phosphokinase, and blood glucose Photosensitivity	Nasal sprays, lip moisturizers, and hard candy may help to reduce drying of mucous membranes. Apply oil-free moisturizers to face to relieve drying of skin. Contraindicated in pregnancy category X. Monitor patient closely for changes in mood. May use nonsteroidal anti-inflammatory drugs to relieve pain Monitor lipid panel, liver function tests, and blood glucose. Minimize exposure to sunlight and sun lamps. Sunscreen use and protective clothing recommended

GI, gastrointestinal; CYP, cytochrome.

Data from (1) Lexicomp [Internet]. Hudson (OH): Wolters Kluwer Health, Inc.1978-2017 [cited 2017 June 13].Available from: http://online.lexi.com/lco/action/home/switch. (2) Facts & Comparisons eAnswers. St. Louis (MO) 2017: Wolters Kluwer health, Inc. 2017 [cited 2017 June 13]. Available from: http://fco.factsandcomparisons.com/lco/action/home

Patient Care Process: Acne

Collect Information:

- Perform dermatologic examination and note the number and type of acne lesions: open and closed comedos, papules, pustules, nodules, cysts.
- Obtain age of onset and family history of acne, including severity.
- Determine patient's current skin care routine, including use of cosmetics, facial washes, moisturizers, and other possible exacerbating factors.
- Review patient preferences and beliefs, health goals, and socioeconomic factors.
- Conduct a medication history (nonprescription, prescription, and herbal medications). Identify previous acne treatment regimens.
- Note allergies to medications or other substances.

Assess the Information:

- Assess patient symptoms and acne lesions to determine acne severity: mild, moderate, or severe.
- Determine if any medications or behaviors may be exacerbating acne.
- If patient is already receiving pharmacotherapy, assess whether active and/or previously tried therapies were effective, safe, and used as directed.

Develop a Care Plan:

- If acne is not well controlled, determine appropriate pharmacotherapy options for the patient's acne severity (Figure 65–2).
- Determine whether patient has prescription medication coverage to identify possible recommendations included in the plan formulary.

(*Continued*)

Patient Care Process (*Continued*)

- Select nondrug and drug therapy likely to be effective and safe and determine drug, dose, route, and frequency of administration/application. Use combination products as appropriate to improve adherence and reduce adverse effects (Tables 65–1 and 65–2).
- Choose appropriate changes to lifestyle.

Implement the Care Plan:

- Provide patient education on acne:
  - What is acne and how does it develop?
  - Physical and psychological complications that can result from acne.
- Educate patient on proper use, adverse effects, and expectations of acne drug therapy.
- Inform the patient of recommended changes, deletions, and additions to acne drug regimen.
- Review drug, dose, route/proper administration technique, and duration of therapy. Topical acne therapy should be applied to entire acne-prone area and existing lesions.
- Review possible side effects of drug therapy.
- Inform patient of possible initial worsening of acne and/or delay of therapeutic effectiveness of acne drug therapy.
- Emphasize medication compliance and adherence to lifestyle modifications for treating existing acne lesions and preventing recurrence.
- Address any patient concerns.

Follow-up: Monitor and Evaluate:

- Follow-up every 1 to 2 months to assess effectiveness and safety of nondrug and drug therapy (Tables 65–1 and 65–2).
- If acne lesions do not respond after 3 months of drug therapy, consider an alternative acne regimen (Figure 65–2).
- If the patient experiences resolution of acne symptoms, transition to maintenance drug therapy.

cause ACD include poison ivy, latex, and certain types of metal[27,28] (Figures 65–3 and 65–4). Table 65–3 lists agents commonly responsible for irritant and ACD. Although generally occurring on the exposed skin, such as the hands and face, contact dermatitis can appear anywhere on the body.[25]

Epidemiology and Etiology

Contact dermatitis is the most common occupation-related skin disease.[29] Although most often seen in adults, contact dermatitis can affect all age groups, with females at slightly greater risk than males due to increased risk of exposure.[28]

	Mild	Moderate	Severe
1st Line Treatment	Benzoyl Peroxide (BP) or Topical Retinoid -or- Topical Combination Therapy** BP + Antibiotic or Retinoid + BP or Retinoid + BP + Antibiotic	Topical Combination Therapy** BP + Antibiotic or Retinoid + BP or Retinoid + BP + Antibiotic -or- Oral Antibiotic + Topical Retinoid + BP -or- Oral Antibiotic + Topical Retinoid + BP + Topical Antibiotic	Oral Antibiotic + Topical Combination Therapy** BP + Antibiotic or Retinoid + BP or Retinoid + BP + Antibiotic -or- Oral Isotretinoin
Alternative Treatment	Add Topical Retinoid or BP (if not on already) -or- Consider Alternate Retinoid -or- Consider Topical Dapsone	Consider Alternate Combination Therapy -or- Consider Change in Oral Antibiotic -or- Add Combined Oral Contraceptive or Oral Spironolactone (Females) -or- Consider Oral Isotretinoin	Consider Change in Oral Antibiotic -or- Add Combined Oral Contraceptive or Oral Spironolactone (Females) -or- Consider Oral Isotretinoin

FIGURE 65–2. Algorithms for acne treatment. The double asterisks (**) indicate that the drug may be prescribed as a fixed combination product or as separate component. (BP, benzoyl peroxide.) (From Zaenglein AL, Pathy AL, Schlosser BJ, et al. Guidelines of care for the management of acne vulgaris. J Am Acad Dermatol. 2016;74:945–973.)

Patient Encounter 1

A 22-year-old woman complains of uncontrollable acne. She has experienced acne off and on since she was 12 years old. Her acne has been very mild for the past several years, but recently worsened. She expresses... "I thought I would have grown out of acne by this age." She has always been embarrassed by her acne, and is very self-conscious. Engaged to be married in roughly 4 months, she is anxious that her acne will negatively affect her image on her wedding day. Visual examination reveals numerous noninflammatory lesions, a few papules and pustules adjacent to her nose and on her chin, and one nodule noted on her cheek. Her skin is also very dry and irritated. A month ago, she was evaluated by her primary care physician who prescribed Retin-A 0.05% cream at bedtime. She reports that she has been applying her acne cream directly to each lesion daily, but continues to break out. She washes her face at least twice a day with an over-the-counter face wash containing salicylic acid with warming action to "get the dirt out of her blackheads." She is very adamant about adjusting her acne regimen to ensure her acne is cleared up prior to her wedding. She is very frustrated because her current regimen is not improving her complexion and is making her skin very dry and irritated. She has never seen a dermatologist. The patient appears to be in good physical health.

What reported symptoms support the diagnosis of acne?

What other information would you obtain from this patient before determining a treatment plan for her?

Describe your treatment goals for this patient.

What nonpharmacologic treatment options and lifestyle modifications would you suggest to this patient?

What pharmacologic treatment options are available for this patient?

Given the information presented, develop a treatment regimen for this patient that includes (a) a statement of the drug-related needs and/or problem, (b) a patient-specific therapeutic plan, and (c) monitoring parameters to assess efficacy and safety.

Pathophysiology

LO 1

ICD is not the result of an immunologic process, but rather occurs from direct injury to the skin. An irritating agent comes into contact with the skin, damages the protective layers of the epidermis, and can cause erythema, the formation of vesicles and pruritus.[23,25,26] Symptoms occur within minutes to hours of exposure and begin to heal soon after removal of the offending substance.

LO 1

ACD is a type IV hypersensitivity reaction.[27] Upon initial exposure, a substance penetrates the skin, is processed by antigen presenting cells, and subsequently activate allergen-specific T cells. Subsequent exposures to that substance will elicit a response by circulating memory T cells, resulting in an allergic reaction.[23,25,26,27] Symptoms of ACD are similar to those of the irritant type, but may take several hours to several days to develop following reexposure.[23,30]

FIGURE 65–3. Acute irritant contact dermatitis on the hand due to an industrial solvent. There is massive blistering on the palm. (From Wolff K, Johnson RA. Eczema/dermatitis. Fitzpatrick's Color Atlas & Synopsis of Clinical Dermatology, 6th ed. New York: McGraw-Hill; 2009:23.)

FIGURE 65–4. Allergic contact dermatitis of the hand: chromates. Confluent papules, vesicles, erosions, and crusts on the dorsum of the left hand in a construction worker who was allergic to chromates. (From Wolff K, Johnson RA. Eczema/dermatitis. Fitzpatrick's Color Atlas & Synopsis of Clinical Dermatology, 6th ed. New York: McGraw-Hill; 2009:27.)

Common Agents Causing Contact Dermatitis

Irritant Contact Dermatitis
Soaps
Detergents
Cosmetics
Solvents
Acid, mild or strong
Alkali, mild or strong

Allergic Contact Dermatitis
Plant resins, poison ivy, poison oak, sumac
Metals (nickel or gold in jewelry)
Latex and rubber
Cigarette smoke
Local anesthetics (lidocaine, benzocaine)

Treatment

▶ *Desired Outcomes and Goals*

LO 4 KEY CONCEPT Identifying the causative substance and eliminating its exposure is the initial treatment goal for contact dermatitis. Although physical symptoms can develop almost immediately after contact, removal of the offending agent will improve existing symptoms and prevent further complications.[5] Removing the offending agent includes washing the skin and any clothing or objects that may have come into contact with the agent to prevent reexposure. LO 2 KEY CONCEPT The second treatment goal is symptom relief. Since inflammation and pruritus, as well as lesion formation, are likely to result from contact dermatitis, appropriate selection of nonpharmacologic and pharmacologic agents for these symptoms is necessary.[31]

Clinical Presentation and Diagnosis of Contact Dermatitis

Contact dermatitis is generally confined to the area of contact, but, in a highly sensitive person, a widespread or even generalized eruption may occur. Contact dermatitis is divided into two forms—irritant and allergic. Both forms may include, but are not limited to:

- Erythema
- Pruritus
- Vesicles
- Papules
- Crusts
- Burning
- Pain

Irritant Form

The irritant form usually presents within hours of exposure and the rash is often localized. Irritant contact dermatitis may also result in fissuring and scaling.

Allergic Form

The allergic form can take several days to present and the condition may extend beyond the borders of the region exposed. Allergic contact dermatitis may cause intense itching and include oozing pustules and skin erosion.

Diagnosis

Contact dermatitis may be suspected based on clinical presentation, especially if the causative agent is known; however, patch testing may be necessary to confirm the diagnosis.[30]

▶ *Nonpharmacologic Therapy*

In many cases, contact dermatitis may not require medical treatment. Nondrug therapy for contact dermatitis is aimed at relieving pruritus and maintaining skin hydration.[27] Effective agents used for this include the following[23,33]:

LO 4
- Colloidal oatmeal baths
- Cool or tepid soapless showers
- Cool, moist compresses applied to the area for 20–30 minutes as often as needed
- Emollients applied to the area after bathing

Preventative measures to prevent additional exposure should be considered including gloves, protective clothing, barrier creams, and skin conditioning products.

▶ *Pharmacologic Therapy*

LO 4 **Topical Steroids** Erythema, inflammation, pain, and itching caused by ACD can be effectively treated with topically applied corticosteroids. The use of topical corticosteroids for the management of ICD is controversial, as patients with ACD generally respond better to therapy than those with ICD.[31] With such a wide range of products and potencies, appropriate steroid selection is based on severity and location of lesions (see Table 65–4 for a list of topical steroids and potencies). Higher potency preparations are used in areas where penetration is poor, such as the elbows and knees. Lower potency products should be reserved for areas of higher penetration, such as the face, axillae, and groin. Low-potency steroids are also recommended for the treatment of infants and children.[31–33] The use of topical corticosteroids for prolonged periods of time should be avoided.

LO 5 Adverse effects from topical steroids are usually related to the potency of the steroid, frequency of application, duration of therapy, and the site of application. Skin atrophy, hypopigmentation, striae, and steroid-induced acne are all possible side effects associated with long-term use.[26] Ointments, because of their occlusive properties, should be avoided on weeping lesions.[23,34]

Topical steroids are typically applied two to four times daily. As improvement begins, maintenance therapy should be limited to the lowest strength steroid that continues to control the condition. Once symptoms are completely resolved, use should be discontinued and should not exceed 1 to 2 weeks.[35]

LO 4 **Antihistamines** Whether due to their antihistaminic activity or their sedative side effects, pruritus caused by contact dermatitis can be relieved with the use of sedating oral antihistamines, such as diphenhydramine or hydroxyzine. Topical antihistamines are available, but use is limited due to their high-sensitizing potential.[23,36] In addition to sedation, many oral antihistamines can cause hypotension, dizziness, blurred vision, and confusion.

LO 4 **Astringents** The drying effect of astringents will decrease oozing from lesions and relieve itching.[23,30] Due to their ability to cause blood vessel constriction, astringents can also

Table 65–4

Topical Corticosteroid Potency Chart

Potency Rating	Topical Dosage Forms
Class 1: Superpotent	Betamethasone dipropionate 0.05% ointment (Diprolene and Diprosone ointment)
	Clobetasone propionate 0.05% lotion/spray/shampoo (Clobex lotion/spray/shampoo, OLUX foam)
	Clobetasone propionate 0.05% cream and ointment (Cormax, Temovate, Dermovate)
	Desoximetasone 0.25% spray (Topicort)
	Flucinonide 0.1% cream (Vanos)
	Halobetasol propionate 0.05% cream, lotion, ointment (Ultravate)
	Flurandrenolide tape 4 mcg/cm^2 (Cordran)
Class 2: Potent	Amcinonide 0.1% ointment (Cyclocort ointment)
	Betamethasone dipropionate 0.05% cream/gel (Diprolene cream, gel, and Diprosone cream)
	Desoximetasone 0.25% cream, oinment (Topicort)
	Diflorasone diacetate 0.05% (Florone, Psorcon)
	Fluocinonide 0.05% cream, gel, ointment (Lidex)
	Halcinonide 0.1% cream (Halog)
Class 3: Upper mid-strength	Amcinonide 0.1% cream (Cyclocort cream)
	Betamethasone valerate 0.1% ointment (Betnovate/Valisone ointment)
	Diflorasone diacetate 0.05% cream (Psorcon cream)
	Fluticasone propionate 0.005% ointment (Cutivate ointment)
	Mometasone furoate 0.1% ointment (Elocon ointment)
	Triamcinolone acetonide 0.5% cream and ointment (Aristocort)
Class 4: Mid-strength	Betamethasone valerate 0.12% foam (Luxiq)
	Clocortolone pivalate 0.1% cream (Cloderm)
	Desoximetasone 0.05% cream, ointment and gel (Topicort LP)
	Fluocinolone acetonide 0.025% ointment (Synalar ointment)
	Fluocinolone acetonide 0.2% cream (Synalar-HP)
	Flurandrenolide 0.05% ointment (Cordran)
	Hydrocortisone valerate 0.2% ointment (Westcort ointment)
	Mometasone furoate 0.1% cream (Elocon cream)
	Triamcinolone acetonide 0.1% ointment (Kenalog)
Class 5: Lower mid-strength	Betamethasone dipropionate 0.05% lotion (Diprosonelotion)
	Betamethasone valerate 0.1% cream and lotion (Betnovate/Valisone cream & lotion)
	Desonide 0.05% lotion (DesOwen)
	Fluocinolone acetonide 0.01% shampoo (Capex shampoo)
	Fluocinolone acetonide 0.025%, 0.03% cream (Synalar cream)
	Flurandrenolide 0.05% cream and lotion (Cordran)
	Fluticasone propionate 0.05% cream and lotion (Cutivate cream and lotion)
	Hydrocortisone butyrate 0.1% cream (Locoid)
	Hydrocortisone valerate 0.2% cream (Westcort cream)
	Prednicarbate 0.1% cream (Dermatop)
	Triamcinolone acetonide 0.1% cream and lotion (Kenalog cream and lotion)
Class 6: Mild	Alclometasone dipropionate 0.05% cream and ointment (Aclovate)
	Betamethasone valerate 0.05% cream and ointment
	Desonide 0.05% cream, ointment, gel (DesOwen, Desonate, Tridesilon)
	Desonide 0.05% foam (Verdeso)
	Fluocinonide acetonide 0.01% cream and solution (Synalar)
	Fluocinonide acetonide 0.01% FS oil (Derma-Smoothe)
Class 7: Least potent	Hydrocortisone 0.5%, 1%, 2%, 2.5% cream, lotion, spray, and ointment (various brands)

From Law RM, Gulliver WP. Psoriasis. In: DiPiro JT, Talbert RL, Yee GC, Matzke GR, Wells BG, Posey L, eds. Pharmacotherapy: A Pathophysiologic Approach, 10th ed. New York, NY: McGraw-Hill. http://accesspharmacy.mhmedical.com/content.aspx?bookid=1861&sectionid=146069987. Accessed September 4, 2017.

decrease inflammation. Aluminum acetate (Burow's solution), aluminum sulfate/calcium acetate solution (Domeboro), calamine lotion, colloidal oatmeal baths/soaks, and witch hazel are safe and effective.[23] Aluminum acetate or aluminum sulfate/calcium acetate may be applied as a compress for 30 minutes at least four times daily as needed. Colloidal oatmeal baths or soaks may be applied for 15–20 minutes at least twice daily.

LO 5

Adverse effects reported with these agents are minimal and include drying and tightening of the skin.

T-Cell Selective Inhibitors Topical T-cell selective inhibitors, such as tacrolimus and pimecrolimus are approved for the treatment of atopic dermatitis, but may also be effective in the treatment of ACD.[30,32,35]

Outcome Evaluation

LO 6

With adequate treatment, most cases of contact dermatitis should improve within 7 days. Complete resolution of symptoms may take up to 3 weeks.[23] If patients experience severe symptoms

Patient Care Process: Contact Dermatitis

Collect Information:

- Assess symptoms.
- Obtain a thorough patient history. Can the agent/exposure be identified? Has there been prior exposure to that agent? If so, what treatment regimens were used to alleviate symptoms?
- Obtain patient's allergy status.

Assess the Information:

- Determine whether the patient has ICD or ACD.
- Discuss testing needed to suggest or confirm the etiologic agent (patch testing).

Develop a Care Plan:

- Develop a treatment plan for ICD or ACD. In most cases, nondrug and nonprescription treatment options are most appropriate. If case is severe or if the patient has ACD, the plan may also include prescription therapy.

Implement the Care Plan:

- Provide patient education on ICD or ACD and treatment:
  - Possible adverse effects of drug therapy
  - Symptoms that warrant physician referral
  - Importance of treatment compliance
  - Educate on the recognition of agents that may cause contact dermatitis.

Follow-up: Monitor and Evaluate:

- Symptoms should improve within 2–3 days. If no improvement, the patient should be advised to follow-up with the provider.

associated with fever or difficulty breathing, they should be instructed to seek medical attention immediately. Furthermore, patients should return to their health care provider if any of the following occur:

- Rash has not improved (increased in size or spread to other locations) after several days of treatment.
- Patient is experiencing adverse effects from the treatment regimen.

DIAPER DERMATITIS

Epidemiology and Etiology

Diaper dermatitis, more commonly known as diaper rash, is a form of ICD that affects the buttocks, upper thighs, lower abdomen, and genitalia of an estimated 7% to 35% of all infants.[37] Onset of occurrence is usually between 3 weeks and 2 years of age, with the most cases reported between 9 and 12 months of age.[37] The use of diapers for incontinence in adults also increases the risk of developing diaper dermatitis.[37]

Pathophysiology

KEY CONCEPT Although many factors contribute to diaper rash, it is most likely the result of prolonged contact of the skin with urine and feces in the diaper. If a diaper is not changed soon after urination or defecation, the excessive hydration, friction of the diaper, and enzymes in the feces lead to breakdown in the protective layer of the skin making the area more susceptible to irritation and infection.[38,39] Although most mild cases of diaper rash present as erythema, moderate to severe cases can result in the formation of papules, vesicles, and even ulceration. If these cases are not effectively treated, the likelihood of secondary fungal or bacterial infections developing is greatly increased.[40]

LO 1

Treatment

▶ *Desired Outcomes and Goals*

KEY CONCEPT The primary goal in the treatment of diaper rash is prevention and is most often accomplished through frequent diaper changes. KEY CONCEPT When a diaper rash is already present,

LO 2

Patient Encounter 2

A 36-year-old man presents to your pharmacy with complaints of intense itching and shows you a red, raised rash with papules on his legs. The patient tells you that he recently spent the weekend hiking and camping with several friends. He states that he mostly wore T-shirts, shorts, and hiking boots, but occasionally went barefoot or wore sandals to let his "feet breathe." He does not think he saw any poison ivy on the trip, but his friend suggested that his rash looks like it may be caused by poison oak or poison ivy. The patient states he tried some kind of soap that said it would help treat poison ivy, but has not tried anything else to manage his symptoms, which are worsening. From the information he has presented, you conclude that he did likely come in contact with an agent while camping and that exposure caused an allergic contact dermatitis to develop.

What information supports the possibility of exposure to an allergic agent?

Describe the symptoms that support this diagnosis.

Determine what the patient has tried to relieve her symptoms.

Describe the differences between allergic and irritant contact dermatitis.

What are your treatment goals for this patient?

What nonpharmacologic and pharmacologic treatment options are available for this diagnosis?

Given the information presented, develop a treatment regimen for this patient that includes (a) a statement of the problem, (b) a patient-specific therapeutic plan, and (c) monitoring parameters to assess efficacy and safety.

Clinical Presentation and Diagnosis of Diaper Dermatitis

Typical Symptoms

- Erythema is the most common symptom presented with a diaper rash. The rash may begin as light to medium pink with poorly defined edges, but may become dark red and raised lesions with distinct edges.
- Rashes generally appear in the folds of the skin around the diaper area, thighs, genitals, and buttocks.
- Other typical symptoms include irritation and pruritus.

Atypical Symptoms

Patients presenting with the following symptoms may indicate the need for more aggressive antibiotic or antifungal therapy and should be referred to a physician for further evaluation:

- Rashes not responding to typical creams and concurrent nonpharmacologic treatment
- Rashes extending beyond the diaper region (upper abdomen, back)
- Formation of papules, bullae, ulceration
- Excessive oozing
- Presence of genital discharge
- Concurrent fever
- Rashes appearing when diapers have not been used or rashes that fail to improve upon discontinuing diaper usage for extended periods of time (several days or more)
- Bleeding or open skin

Diagnosis

- The diagnosis of diaper dermatitis is clinical. The presence of *Candida albicans* can be determined by KOH testing or culture, but is generally not necessary.

repairing the damaged skin, relieving discomfort, and preventing secondary infections from occurring are important factors to consider when developing an effective treatment regimen.[39]

▶ *Nonpharmacologic Therapy*

LO 4 Most mild cases of diaper rash can be resolved with the use of nonpharmacologic therapies. Keeping the diaper area clean and dry by changing diapers as soon as practically possible (at least every 2 hours or more frequently) is highly effective for treatment and prevention.[30,40] Other nondrug options include[31,39,41]:

- Washing the area with lukewarm water and mild soap and allowing to completely dry before applying a new diaper
- Using water and a cotton cloth or commercial "baby wipes" without coloring, fragrances, or other additives
- Keeping diapers loose and well ventilated
- Avoiding plastic pants over diapers
- Allowing infants to take naps on an open diaper or absorbent pad to promote drying and healing

▶ *Pharmacologic Therapy*

LO 4 **Protectants** Protectants form an occlusive barrier between the skin and moisture from the diaper. Cream and ointment preparations are effective in providing a sufficient barrier in mild, irritant, and noninfected diaper rashes. For more severe cases, a paste is the topical agent of choice. Pastes are thicker and often contain additional ingredients (petrolatum, moisturizers) to decrease discomfort and promote healing.[39] Zinc oxide is one of the most commonly used topical protectants. In addition to forming an effective barrier against moisture, it has astringent and antiseptic properties that provide added symptom relief.[39]

Protectants are generally applied to the affected area after every diaper change and can be discontinued when the rash resolves. Other available protectants that can be used alone or in combination for the safe and effective treatment of diaper rash include white petrolatum, vitamins A and D, lanolin, and topical cornstarch. Many agents contain a combination of occlusive and protective agents such as Triple Paste and Calmoseptine.

Topical Steroids Because of the increased permeability of their skin, infants are at risk for excessive absorption and toxicity from the use of topical steroids. Although effective in decreasing inflammation and relieving pruritus, steroid use in infants for the treatment of diaper dermatitis should be limited to only low-potency preparations.[41]

LO 7 A thin layer of hydrocortisone cream (0.25% to 1%) applied twice a day for no more than 2 weeks is an appropriate regimen. Use of higher potency steroids or use extending beyond 2 weeks should be at the discretion of a physician only.

LO 4 **Antifungals** Diaper rashes lasting longer than 48 to 72 hours are at increased risk for the development of fungal infections. These complications are most frequently caused by *C. albicans* and will require treatment with a topical antifungal[42] (Figure 65–5).

FIGURE 65–5. Candidiasis: diaper dermatitis. Confluent erosions, marginal scaling, and "satellite pustules" in the area covered by a diaper in an infant. (From Wolff K, Johnson RA. Cutaneous fungal infections. Fitzpatrick's Color Atlas & Synopsis of Clinical Dermatology, 6th ed. New York: McGraw-Hill; 2009:723.)

Patient Encounter 3

A woman presents to a community pharmacy inquiring about a product to purchase for her 3-month-old daughter who recently developed diaper rash. The rash has been present on the infant's buttocks for 3 to 4 days and has increasingly worsened from light pink to bright red. The mother reports that her daughter cries during each diaper change, especially when she cleans the areas with diaper wipes. She tells you that she has been trying to wash the area more frequently. She has tried using A & D ointment a few times and is now concerned about the risk of infection.

What reported symptoms support the diagnosis of diaper rash?

What additional information would aid in your assessment of this patient?

What are your treatment goals for this patient?

What nonpharmacologic and pharmacologic treatment options are available for this diagnosis?

Given the information presented, develop a treatment regimen for this patient that includes (a) a statement of the problem, (b) a patient-specific therapeutic plan, and (c) monitoring parameters to assess efficacy and safety.

LO 5 Adverse events with the use of topical antifungals are generally limited to local irritation at the site of application.

Nystatin, clotrimazole, and miconazole creams or ointments applied two to four times daily with diaper changes have all shown to be effective in the treatment of candidal diaper rash.[43] LO 7 Although some of these products are available over the counter, parents and caregivers should be advised to initiate treatment with antifungal agents only after physician's recommendation.

Antibacterials If conventional treatment fails, unresolved diaper rash can also lead to secondary bacterial infections. *Staphylococcus aureus* and *Streptococcus* are the most likely pathogens responsible for these infections and require treatment with systemic antibiotics.[38,40] While topical protectants may be used as an adjunct in treatment, suspected bacterial infections should always be referred to a physician for accurate diagnosis and the selection of an appropriate antibacterial regimen.[38] Figure 65–6 shows a useful algorithm for the effective treatment of diaper dermatitis.

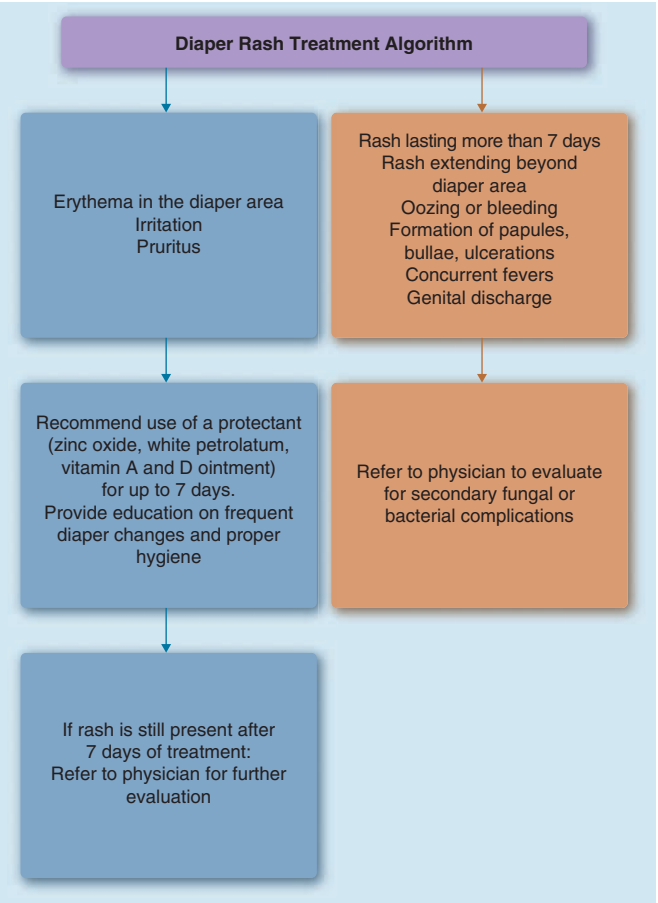

FIGURE 65–6. Diaper dermatitis treatment algorithm.

Patient Care Process: Diaper Dermatitis

Collect Information:

- Gather information related to rash symptoms, characteristics, location, and onset.
- Inquire about the patient's history, including similar rashes in the past, and any previous treatment.
- Obtain patient's allergy status.

Assess the Information:

- Determine the level of severity—is there a possibility of a secondary fungal or bacterial infection?
- Identify any signs and symptoms that require immediate physician referral.
- Determine what treatment options, if any, have been tried and if they were successful.
- Discuss labs that may be necessary if a secondary infection is suspected (cultures, biopsies).

Develop a Care Plan:

- Discuss available barrier treatment options with the caregiver.
- Identify appropriate preventative and treatment measures.

Implement the Care Plan:

- Provide caregiver education that includes proper usage instructions and potential side effects.
- Educate the caregiver on the importance of frequent diaper changes and proper hygiene.
- Emphasize importance of treatment compliance and use of preventative measures.

Follow-up: Monitor and Evaluate:

- Discuss symptoms to report to a physician (blistering, oozing, bleeding, changes in rash, or no improvement in symptoms within 2–3 days).

Outcome Evaluation

LO 6

KEY CONCEPT Most diaper rashes can be effectively treated in less than 1 week. If symptoms do not resolve or begin to worsen, advise caregivers to seek medical attention to determine the presence of secondary fungal or bacterial infections. In addition, provide educational information on proper diaper hygiene techniques in order to prevent the development of future diaper rashes.

Abbreviations Introduced in This Chapter

ACD	Allergic contact dermatitis
FDA	Food and Drug Administration
ICD	Irritant contact dermatitis

66 Anemia

Maribel A. Pereiras

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

1. Discuss common causes of anemia.
2. Identify common signs and symptoms of anemia.
3. Describe diagnostic evaluation required to determine the etiology of anemia.
4. Develop a treatment regimen considering the underlying cause and patient-specific variables.
5. Compare and contrast oral and parenteral iron preparations.
6. Explain the optimal use of folic acid and vitamin B_{12} in patients with macrocytic anemia.
7. Evaluate the proper use of epoetin and darbepoetin in patients with anemia caused by cancer chemotherapy or chronic kidney disease.
8. Develop a plan to monitor the outcomes of pharmacotherapy for the treatment of anemia.

INTRODUCTION

KEY CONCEPT

Anemia is a deficiency of erythrocytes with a corresponding reduction in the concentration of hemoglobin (Hgb) that results in reduced oxygen-carrying capacity of the blood. Some patients with anemia may be asymptomatic initially, but eventually, the lack of oxygen to tissues results in fatigue, lethargy, shortness of breath, headache, edema, and tachycardia. Common causes include blood loss, decreased functional red blood cell (RBC) production, and increased RBC destruction. Determination of the underlying cause of anemia is essential for successful management.

LO 1 LO 2

EPIDEMIOLOGY AND ETIOLOGY

Anemia is a common diagnosis with a prevalence that varies widely based on age, gender, and race/ethnicity (Table 66–1).[1,2] Patients with specific comorbidities such as cancer and chronic kidney disease (CKD) have significantly higher rates of anemia. The incidence of anemia in cancer patients ranges from 30% to 90%. Contributing factors include the underlying malignancy and myelosuppressive antineoplastic therapy.[3] The prevalence of anemia in patients with CKD ranges from 15% to 20% in patients with CKD stages 1 through 3 and up to 70% in patients with stage 5.[4]

LO 1

A decrease in erythrocyte production can be multifactorial. Nutritional deficiencies (iron, vitamin B_{12}, and folic acid) are common causes and often easily treatable. Patients with cancer or CKD are at risk for developing anemia caused by dysregulation of iron and erythropoietin (EPO) hemostasis. Patients with chronic immune-related diseases such as rheumatoid arthritis and systemic lupus erythematosus are also at increased risk to develop anemia as a complication of their disease. Anemia related to chronic inflammatory conditions is termed anemia of chronic disease (ACD).[5]

Drug therapy is the mainstay of treatment for anemias caused by reduced RBC production and is the focus of this chapter. Anemia due to the destruction of erythrocytes, such as with blood loss or hemolytic anemia, will not be discussed.[6]

PATHOPHYSIOLOGY

Erythropoiesis

Erythropoiesis begins with a pluripotent stem cell in the bone marrow undergoing differentiation and ends with the appearance of RBCs in peripheral blood. The production of RBCs is stimulated by EPO, a hormone secreted by the kidney in response to cellular hypoxia. EPO stimulates RBC production by inducing differentiation of RBC precursors in the bone marrow to become reticulocytes (Figure 66–1). Reticulocytes become erythrocytes after 1 to 2 days in the bloodstream.[7]

Decreased-Production Anemias

▶ *Nutritional Deficiencies*

Deficiencies in folic acid and vitamin B_{12} may hinder the process of erythrocyte maturation. Folic acid and vitamin B_{12} are required for the formation of DNA. Significant decreases in the amount of either folic acid or B_{12} inhibit DNA synthesis and consequently RBC production.[7,8] Poor diet can contribute to folic acid and vitamin B_{12} deficiencies. Pernicious anemia describes a severe anemia caused by the malabsorption of vitamin B_{12} due to the absence of intrinsic factor, a glycoprotein produced by gastric parietal cells that binds to vitamin B_{12} and facilitates its absorption in the ileum. This condition results in B_{12} deficiency despite adequate dietary B_{12} intake.[9]

Iron is also essential for RBC production. It is required in the formation of Hgb. Lack of iron leads to a decrease in Hgb synthesis and decreased RBC production. Normal homeostasis of iron transport and metabolism is depicted in Figure 66–2.[10]

Table 66–1

Prevalence of Anemia[1,2]

Children (1–5 years)	43%
Males (17–84 years)	29%
Males (85+ years)	26%
Females (15–49 years, pregnant)	38%
Females (15–49 years, nonpregnant)	29%
Females (85+ years)	20%

Approximately 1 to 2 mg of iron is absorbed through the duodenum daily, and the same amount is lost via blood loss, desquamation of mucosal cells, or menstruation.

Iron-deficiency anemia (IDA) typically occurs because of inadequate absorption of iron or excessive blood loss. Inadequate absorption may occur in patients who have congenital or acquired intestinal conditions, such as inflammatory bowel disease, celiac disease, or bowel resection. Achlorhydria and diets poor in iron may also contribute to iron-deficient states. Iron deficiency may also occur following excessive iron loss. Common etiologies include excessive menstruation, ulcers, neoplastic lesions, and excessive bleeding following surgery or trauma.[10,11]

▶ *Dysregulation of Iron Homeostasis and Impaired Marrow Production*

Chronic diseases associated with ACD include infection, autoimmune disease, CKD, and cancer. A major contributing factor for development of ACD is disturbance of iron homeostasis related to activation of the immune system. Hepcidin is an acute-phase protein expressed in response to the upregulation of inflammatory cytokines. Increased expression of hepcidin causes decreased iron absorption from the gastrointestinal (GI) tract and inhibition of iron release from macrophages. In addition, immune activation can cause upregulation of cytokines that impair the proliferation and differentiation of erythroid precursors. Decreased production and blunted responsiveness to EPO can also contribute to ACD; this is best documented in patients with CKD. Finally, disruption of erythropoiesis secondary to infiltration of the bone marrow by cancer can lead to anemia.[3,5,10–12]

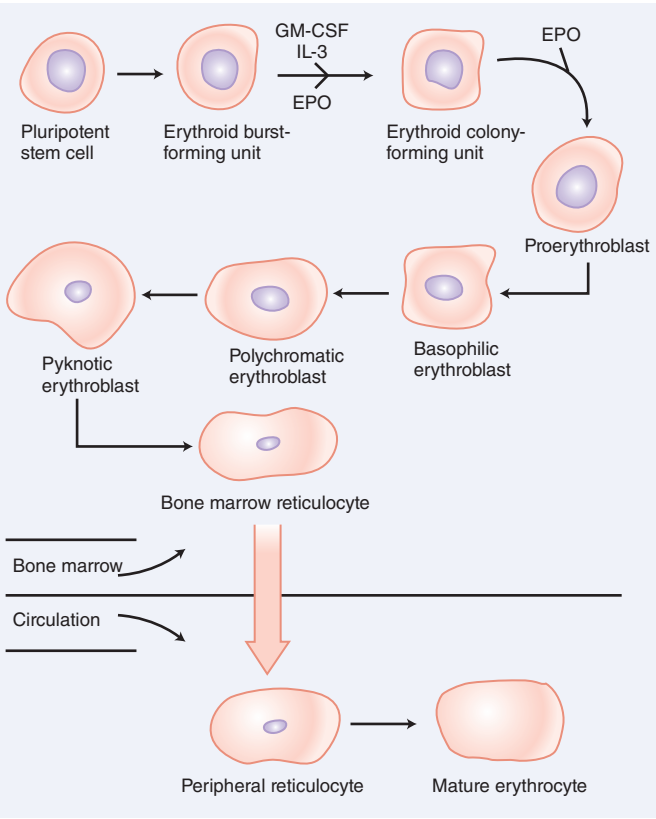

FIGURE 66–1. The process of erythropoiesis.

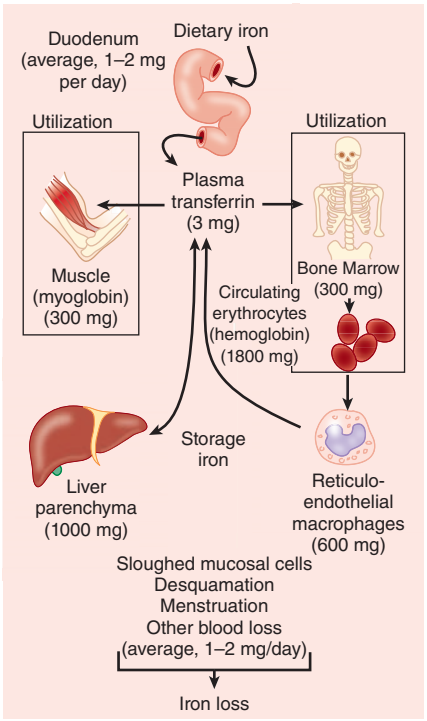

FIGURE 66–2. The distribution of iron use in adults. (From Andrews NC. Disorders of iron metabolism. N Engl J Med. 1999;341:1986–1995.)

TREATMENT

Desired Outcomes

KEY CONCEPT The goal of anemia therapy is to increase Hgb to levels that improve red cell oxygen-carrying capacity, alleviate symptoms, and prevent complications from anemia. Normal Hgb values are 14.0 to 17.5 g/dL (140–175 g/L or 8.69–10.9 mmol/L) for males and 12.3 to 15.3 g/dL (123–153 g/L or 7.63–9.50 mmol/L) for females. It is important to note that continuation of therapy should be assessed primarily by resolution of clinical symptoms. Patients who experience a resolution in their symptoms (eg, shortness of breath, tachycardia, fatigue, dizziness,) may not require aggressive therapy to maintain their Hgb values within normal limits. Hypoxia and cardiovascular sequelae due to anemia can be avoided if Hgb levels are greater than 7.0 g/dL (70 g/L or 4.34 mmol/L).[11]

General Approach to the Anemic Patient

KEY CONCEPT The underlying cause of anemia must be determined and used to guide therapy. A complete blood count (CBC) is the laboratory evaluation that provides objective characteristics of RBCs useful in determining etiology and appropriate treatment. The mean corpuscular volume and determination of iron, ferritin, folate, and vitamin B_{12} levels are required to correctly diagnose a

Patient Encounter 1, Part 1

A 58-year-old African American man was admitted to the emergency department secondary to dyspnea and fatigue or asthenia. He has also been having some paresthesias in his hands for the past 2 months. No other significant past medical history. Past surgical history includes gastric bypass surgery, 3 years ago.

What aspects of this patient's history suggest he may be anemic?

What laboratory assessments are required to make an appropriate diagnosis and therapeutic plan?

How would the requested laboratory parameter(s) aid your decision making?

patient's anemia. Figure 66–3 and Table 66–2 illustrate how laboratory test results determine the correct diagnosis.

Nonpharmacologic Therapy

The primary nonpharmacologic treatment of anemia is transfusion of RBCs. Safety concerns, cost, and the limited availability of this therapy support efforts to establish the "optimum" threshold for administering RBC transfusions. A Cochrane review concluded it is appropriate to use "restrictive transfusion triggers in patients free of serious cardiac disease." The authors concluded a reasonable "trigger for transfusion" for patients without significant cardiovascular disease is 7.0 g/dL (70 g/L or 4.34 mmol/L).[13] The Transfusion Requirements In Critical Care trial reported no significant differences in in-hospital mortality between patients randomly assigned to maintain Hgb levels of 7.0 to 9.0 g/dL (70–90 g/L or 4.34–5.59 mmol/L) and

Clinical Presentation and Diagnosis of Anemia

LO 2

Signs and Symptoms

Generally, the signs and symptoms of anemia are nonspecific and may include the following:

- Fatigue, lethargy, dizziness
- Shortness of breath
- Headache
- Edema
- Tachycardia

Other findings that may be present in some patients include:

- Dry skin, chapped lips
- Nail brittleness
- Hunger for ice, starch, or clay (termed pica)

Past Medical History

Inquire about the following conditions:

- History of blood loss, such as hemorrhoids, melena, or menorrhagia (IDA)
- Malnourished or recent weight loss (vitamin B_{12} or folate deficiency)
- Alcoholism (folate deficiency)
- Cancer or CKD
- Chronic autoimmune disorders or infections, such as HIV infection or rheumatoid arthritis (anemia of chronic disease)

Physical Examination

These findings aid the clinician in determining the severity of the anemia:

- Orthostatic hypotension and tachycardia secondary to volume depletion
- Cutaneous changes such as pallor, jaundice, and nail brittleness

LO 3

Laboratory Evaluation

Table 66–2 describes common tests used to determine the etiology of anemia. A diagnostic and treatment algorithm for anemia is outlined in Figure 66–3.

1. A CBC is a necessary first step in evaluating a patient with anemia. If the Hgb and Hct are less than the normal range, the patient is anemic. Subsequent evaluations of RBC indices and the peripheral smear often are necessary to determine the etiology (and ultimately, the treatment) of the anemia.
2. Evaluating the mean corpuscular volume (MCV) is the next step in an anemia workup. It is classified as microcytic, normocytic, or macrocytic if the MCV is below, within, or above the normal range of 80 to 96 fL/cell, respectively.

Microcytic Anemia and Iron Evaluation

Iron studies (see Table 66–2) should be evaluated in the setting of a low MCV. These include:

- Serum iron
- Serum ferritin—the best indirect determinant of body iron stores. It is commonly decreased in patients with IDA
- Total iron-binding capacity (TIBC)—quantifies the iron-binding capacity of transferrin and is increased in IDA
- Transferrin saturation (serum iron/TIBC)—indicates the amount of transferrin that is bound with iron; it is lower in IDA

Macrocytic Anemia

- Evaluate folic acid and vitamin B_{12} levels in the setting of an elevated MCV
- Further investigation by administering radiolabeled B_{12} (ie, Schilling test) to determine if lack of intrinsic factor

Normocytic Anemia

- Evaluate reticulocytes and CBC
- High reticulocyte counts may indicate RBCs loss via acute blood loss, hemolysis, or splenic sequestration
- Low serum iron with normal to increased ferritin consistent with ACD

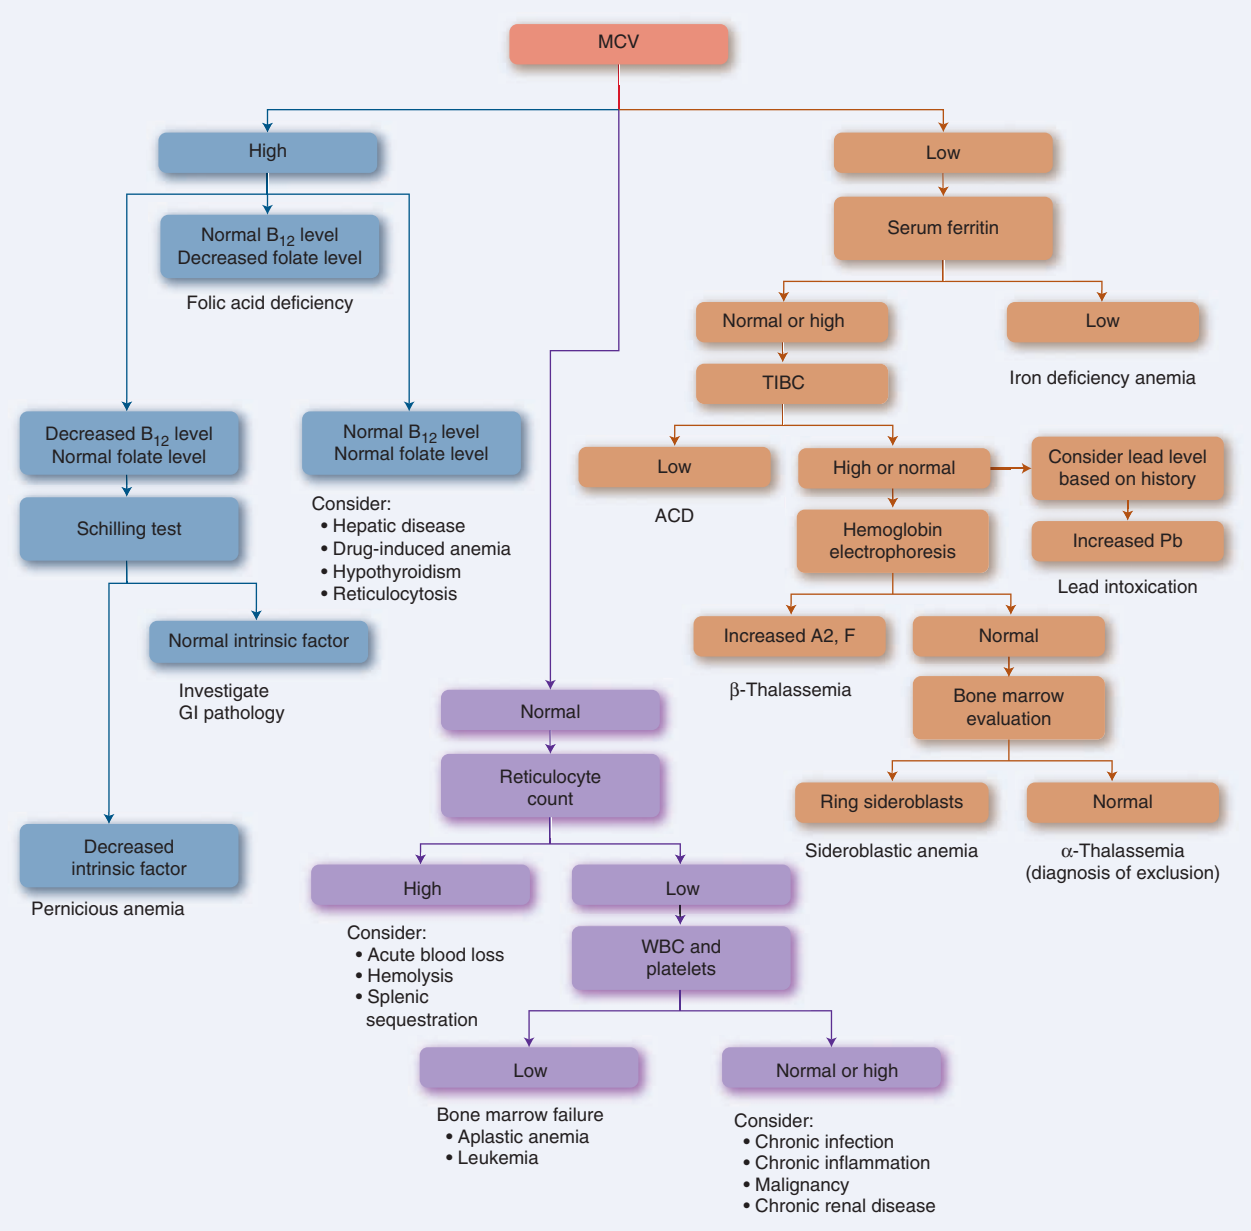

FIGURE 66–3. The anemia evaluation process. (ACD, anemia of chronic disease; A2, hemoglobin A2 type; F, hemoglobin F type; MCV, mean corpuscular volume; Pb, lead; TIBC, total iron-binding capacity.)

10.0 to 12.0 g/dL (100–120 g/L or 6.21–7.45 mmol/L).[14] Typically, only patients with acute symptoms (ie, dyspnea, chest pain) and Hgb concentrations in the range of 7.0 to 9.0 g/dL (70–90 g/L or 4.34–5.59 mmol/L) require blood transfusions.

Anemia can be attributed to diets poor in iron, folic acid, or vitamin B_{12}. However, in the United States, nutrient-poor diets rarely cause anemia. Therefore, ingesting a diet that is rich in iron, folic acid, or vitamin B_{12} should be encouraged, but is rarely the sole modality of treatment. Food sources of iron, folic acid, and vitamin B_{12} are listed in Table 66–3.

Pharmacologic Therapy

▶ *Iron-Deficiency Anemia*

KEY CONCEPT The gold standard treatment of IDA is oral iron therapy that provides 150 to 200 mg of elemental iron daily in divided doses. Many different iron products and salt forms are available.

LO 5

Typically, iron sulfate is the most commonly used formulation. Table 66–4 lists commonly prescribed oral iron products and the amount of elemental iron provided by each.

Iron supplementation resolves anemia by replenishing iron stores to levels necessary for RBC production and maturation. Reticulocytosis should occur in 7 to 10 days, and Hgb values should rise by about 1.0 g/dL (10 g/L or 0.62 mmol/L) per week. Patients should be reassessed if Hgb does not increase by 2.0 g/dL (20 g/L or 1.24 mmol/L) in 3 weeks.[15]

The preferred regimen for oral iron is 50 to 65 mg of elemental iron two to three doses daily on an empty stomach. Administration on an empty stomach (1 hour before or 2 hours after a meal) is preferred for maximal absorption. If patients develop intolerable GI side effects (ie, heartburn, nausea, bloating) after taking iron on an empty stomach, they should be advised to take it with meals. After absorption, iron binds to transferrin in

Table 66–2

Pertinent Laboratory Tests in the Evaluation of Anemia

Test Name	Normal Range	Description/Significance
CBC		
Hgb	Males: 14.0–17.5 g/dL (140–175 g/L or 8.69–10.9 mmol/L) Females: 12.3–15.3 g/dL (123–153 g/L or 7.63–9.50 mmol/L)	Amount of Hgb in the blood; signifies oxygen-carrying capacity of the blood and determines whether a patient is anemic
Hct	Males: 40.7%–50.3% (0.407–0.503) Females: 36.1%–44.3% (0.361–0.44.3)	The percent of blood that the erythrocytes encompass; also indicates anemia; the Hgb is measured, and the Hct is calculated
RBC	Males: 4.5–5.9 × 10^6 cells/μL (4.5–5.9 × 10^{12} cells/L) Females: 4.1–5.1 × 10^6 cells/μL (4.1–5.1 × 10^{12} cells/L)	The number of erythrocytes in a volume of blood; also indicates anemia, but seldom used
RBC Indices		
MCV	80–97.6 μm^3/cell (80–97.6 fL/cell)	A widely used laboratory value to measure RBC "size"; higher values indicate macrocytosis and lower values indicate microcytosis
MCH	27–33 pg/cell	Amount of Hgb per RBC; may be decreased in IDA
MCHC	32–36 g/dL (320–360 g/L)	Hgb divided by the Hct; also low in IDA
Iron Studies		
Serum iron		
Males	45–160 mcg/dL (8.1–28.6 μmol/L)	Measures amount of iron bound to transferrin; low in IDA
Females	30–160 mcg/dL (5.4–28.6 μmol/L)	
Serum ferritin		
Males	20–250 ng/mL (20–250 mcg/L; 45–562 pmol/L)	Ferritin is the protein–iron complex found in macrophages used for iron storage; low in IDA
Females	10–150 ng/mL (10–150 mcg/L; 22–337 pmol/L)	
TIBC	220–420 mcg/dL (39.4–75.2 μmol/L)	Measures the capacity of transferrin to bind iron; high in IDA
TSAT	15%–50% (0.15–0.50)	TSAT (%) = (serum iron/TIBC) × 100; a saturation of less than 15% (0.15) is common in IDA
Other Tests		
RBC distribution width (RDW)	11.5%–14.5% (0.115–0.145)	A higher value means the presence of many different sizes of RBCs; the MCV is therefore less reliable when RDW is larger
Reticulocyte count (Erythrocyte precursors)		Should be elevated in patients who are responding to treatment
Males	0.5%–1.5% of RBCs (0.005–0.015)	
Females	0.5%–2.5% of RBCs (0.005–0.025)	
Folic acid (plasma)	3.1–12.4 ng/mL or mcg/L (7.0–28.1 nmol/L)	Used to determine folic acid deficiency
Folic acid (RBC)	125–600 ng/mL (283–1360 nmol/L)	Used to determine folic acid deficiency
Vitamin B_{12}	180–1000 pg/mL (133–738 pmol/L)	Used to determine vitamin B_{12} deficiency
EPO level	2–25 mIU/mL (2–25 IU/L)	Patients may benefit from EPO therapy if they are anemic and EPO levels are normal or mildly elevated

EPO, erythropoietin; Hct, hematocrit; Hgb, hemoglobin; IDA, iron-deficiency anemia; MCH, mean cell hemoglobin; MCHC, mean cell hemoglobin concentration; MCV, mean cell volume; RDW, RBC distribution width; TIBC, total iron-binding capacity; TSAT, transferrin saturation.

the plasma and is transported to the muscles (for myoglobin), liver (for storage), or bone marrow (for red cell production). Common toxicities associated with oral iron include abdominal pain, nausea, heartburn, constipation, and dark stools.[16] New data is emerging regarding the optimal dosing schema for iron supplementation based on additional information regarding iron absorption and the effect on hepcidin. A study by Motretti and colleagues suggests that lower doses and less frequent dosing may improve the amount of iron absorbed. This data requires further evaluation but may offer a more convenient dosing schedule while minimizing side effects.[17,18]

Potentially clinically significant drug–drug interactions involving iron products include fluoroquinolones, tetracyclines, eltrombopag, and mycophenolate mofetil. Iron decreases the absorption of these drugs. The absorption of iron is influenced by gastric acidity. Limited data support drugs that decrease gastric acidity (antacids, proton pump inhibitors, and H_2-receptor antagonists) may impair the absorption of iron. If concurrent administration cannot be avoided, to minimize this interaction, oral iron should be administered at least several hours before or after the affected drug. The absorption can also be affected by certain disease states that may limit the absorption, such as celiac disease, inflammatory bowel disease or patients who have had gastric surgeries.[11]

Table 66–3

Food Sources of Iron, Folic Acid, or Vitamin B_{12}[41]

Nutrient	Food Sources
Iron	Red meat, organ meats, wheat germ, egg yolks, oysters
Folic acid	Green vegetables, liver, fruits, fortified cereals, chickpeas, enriched pasta
Vitamin B_{12}	Animal by-products, milk, yogurt

Patient Encounter 1, Part 2

Laboratory parameters are ordered, and the following is reported

CBC

- WBC: 6.50 × 10^3/μL (6.50 × 10^9/L)
- Hgb: 8.3 g/dL (83 g/L; 5.15 mmol/L)
- Hct: 24.8% (0.248)
- Plt: 121 × 10^3/μL (121 × 10^9/L)

Red Blood Cell Indices

- MCV: 120.4 μm^3 (120.4 fL)
- MCH: 28.4 pg/cell
- MCHC: 35.3 g/dL (353 g/L; 21.9 mmol/L)

Others

- RBC count: 3.6 × 10^6/μL (3.6 × 10^{12}/L)
- RDW: 22% (0.22)

Iron Studies

- Serum iron: 100 mcg/dL (17.9 μmol/L)
- Serum ferritin: 123 ng/L (123 mcg/L; 276 pmol/L)
- TIBC: 300 mcg/dL (53.7 μmol/L)
- Transferrin saturation: 36% (0.36)

B_{12} and Folate

- Serum folate: 5.3 ng/mL (12.0 nmol/L)
- Serum B_{12}: 127 pg/mL (93.7 pmol/L)

Is this a macrocytic or microcytic anemia?

Specifically, what is the etiology of the anemia?

Recommend the most appropriate drug regimen (drug, dosage form, and schedule).

Parenteral iron therapy is indicated when patients cannot tolerate oral formulations, have decreased intestinal absorption or are noncompliant. Five parenteral iron formulations are available in the United States.[19–24] Table 66–5[20–24] provides details pertinent to the use of these products. Iron dextran was available in two formulations, as a high and low molecular weight iron product. Dexferrum (the high-molecular-weight [HMW] product) is associated with a much higher incidence of life-threatening adverse effects, typically anaphylactic-like reactions, and this formulation has been discontinued.[25] Although total dose infusion (TDI), where the total replacement dose of iron is administered in one dose is not an approved method of administration in the United States, low-molecular-weight ID is approved for TDI in Europe. TDI administration achieves similar patient outcomes while lowering costs. Sodium ferric gluconate complex, iron sucrose, ferumoxytol, and ferric carboxymaltose received FDA labeling for the treatment of patients with anemia and CKD in the last decade.[19–24] Although the occurrence of life-threatening adverse events caused by parenteral iron is extremely low, the absolute rate of life-threatening events is substantially higher for HMW ID.[21]

The dose of iron dextran is calculated by the following equation: dose (mL) = 0.0442 (desired Hgb – observed Hgb) × body weight + (0.26 × body weight). The body weight that should be used is lean body weight for adults and children weighing more than 15 kg and actual body weight for children weighing 5 to 15 kg. Hemoglobin should be expressed in units of g/dL (hemoglobin expressed in g/L × 0.10, or mmol/L × 1.61). The dose in milligrams can be calculated based on a standard concentration of 50 mg of elemental iron per milliliter.[19] Prescribing information recommends administering iron dextran in 100-mg aliquots daily until the total dose is achieved. However, anecdotal evidence reports that the total calculated dose can be administered safely over 4 to 6 hours on 1 day. Because of the risk of anaphylaxis, a test dose of iron dextran (0.5 mL over at least 30 seconds) must be administered to patients before their first dose of iron dextran. Patients should be monitored for signs of anaphylaxis for at least 1 hour before administering the remaining total dose. Other adverse effects include arthralgias, arrhythmias, hypotension, flushing, and pruritus.[19]

▶ *Vitamin B_{12} and Folic Acid Anemia*

KEY CONCEPT Anemia from vitamin B_{12} (also known as pernicious anemia) or folic acid deficiency is treated by replacing the missing nutrient. Both folic acid and vitamin B_{12} are essential for erythrocyte production and maturation.

Table 66–4

Oral Iron Products and Elemental Iron Content[37–40]

Salt Form	Brand Name(s)	Percent of Elemental Iron	Formulation types
Ferrous sulfate	FeroSul Fer-In-Sol Slow Fe	~20	Elixir, liquid, solution Tablet—slow and extended release
Ferrous sulfate, anhydrous	N/A	~30	Tablet
Ferrous gluconate	Ferate	~12	Tablets
Ferrous fumarate	Ferretts Ferrimin Hemocyte	33	Tablets
Polysaccharide–iron complex	Niferex Ferrex NovaFerrum	Dose expressed as elemental iron	Liquid Capsule

Table 66–5

Data from Auerbach M, Adamson JW. How we diagnose and treat iron deficiency anemia. Am J Hematol. 2016;91:31–38.

LO 6

Oral and parenteral vitamin B_{12} (cyanocobalamin) replacement therapies are equally effective in patients able to absorb B_{12}. Vitamin B_{12} is absorbed completely following parenteral administration, whereas oral vitamin B_{12} is absorbed poorly via the GI tract. Consequently, cyanocobalamin is commonly administered as an intramuscular or subcutaneous injection of 1000 mcg/day for 1 week, followed by 1000 mcg/week for a month or until the Hgb normalizes. Life-long maintenance therapy (1000 mcg/month) is required for patients with pernicious anemia or surgical resection of the terminal ileum. If the etiology was a dietary deficiency or reversible malabsorption syndrome, treatment can be discontinued after the underlying cause is corrected and vitamin B_{12} stores normalized. A common oral dosing regimen is from 1000 to 2000 mcg/day. If parenteral cyanocobalamin is used initially, oral vitamin B_{12} can be useful as maintenance therapy. Typically, resolution of neurologic symptoms, disappearance of megaloblastic RBCs, and increased Hgb levels occur within a week of therapy.[26] Vitamin B_{12} is well tolerated. Reported adverse effects include injection-site pain, pruritus, and rash.[27]

LO 6

The effective dose of folic acid is 1 mg/day by mouth. Absorption of folic acid is rapid and complete. However, patients with malabsorption syndromes may require doses up to 5 mg/day. Reticulocytosis occurs within days of commencing therapy. Typically, a patient's Hgb will start to rise after 2 weeks of therapy and normalize after 2 to 4 months of therapy. Folic acid is well tolerated. Nonspecific adverse effects include allergic reactions, flushing, and rash. A small study evaluating the effect of folic acid doses of 10 mg/day on phenytoin levels reported decreased phenytoin levels in 3 of 4 subjects. However, the occurrence of this interaction at folic acid doses of 1 mg/day has not been reported.[27]

Patient Encounter 1, Part 3

The patient is diagnosed with vitamin B_{12} deficiency anemia and is started on parenteral cyanocobalamin for 1 month followed by 1000 mcg of oral cobalamin taken daily. At his first weekly visit the patient reports no shortness of breath and feels better overall. A follow-up CBC 2 months later reveals a Hgb of 10 g/dL (100 g/L or 6.2 mmol/L), previously 8.3 g/dL (83 g/L or 5.15 mmol/L). He states he has noticed improvement in his paresthesias and he occasionally misses doses due to his hectic days.

What hemoglobin level would constitute a therapeutic response in this patient?

How can compliance be improved in this patient?

▶ *Anemia of Chronic Disease*

KEY CONCEPT Decreased RBC transfusion requirements is a goal of therapy in patients with ACD treated with the erythropoietin stimulating agent (ESAs). However, in 2007, the FDA product labeling for epoetin and darbepoetin were revised to include new data documenting safety concerns. Subsequently, the Centers for Medicare and Medicaid Services (CMS) implemented more restrictive ESA coverage determination guidelines. In 2010, the FDA implemented a risk evaluation and mitigation strategy (REMS) for ESAs administered to treat patients with cancer who are undergoing chemotherapy but in 2017 the FDA decided the REMS program was no longer needed.[28] Table 66–6 summarizes the FDA-labeled dosing regimens for patients whose anemia is related to cancer chemotherapy, CKD, or zidovudine treatment.

Anemia Due to Chemotherapy in Patients with Cancer Epoetin, a recombinant human EPO, and darbepoetin, a synthetic EPO analog, bind to the EPO receptors on RBC precursor cells in the bone marrow and result in increased RBC production. Darbepoetin differs from epoetin in that it is a glycosylated protein and exhibits a longer half-life, allowing for a longer dosing interval. Clinical practice guidelines consider epoetin and darbepoetin to be therapeutic equivalents.[3,29]

LO 7

KEY CONCEPT ESAs should only be used to prevent a transfusion and should not be initiated unless the hemoglobin is less than 10.0 g/dL (100 g/L, 6.21 mmol/L) and chemotherapy is planned for a minimum of two additional months. ESA-labeled dosing regimens for treatment of patients receiving chemotherapy are summarized in Table 66–6.

Postmarketing outcome data documented that cancer patients administered ESAs had an increased risk of thrombotic events, shorter progression-free and overall survival.[30] ESAs increased mortality of patients while on study (combined hazard ratio [cHR] 1.17; 95% confidence interval [CI] 1.06–1.30)

Table 66–6

ESA Products and Usual Doses for Anemia from Cancer/Chemotherapy, CKD, and Zidovudine/HIV Infection in Adult Patients[a]

	Epoetin-α (Epogen, Procrit)	Darbepoetin-α (Aranesp)
Cancer/chemotherapy dosing regimens	150 units/kg SC or IV three times per week 40,000 units SC or IV once every week	2.25 mcg/kg SC or IV once every week 500 mcg SC or IV fixed dose every 3 weeks
CKD dosing regimens	50–100 units/kg SC or IV three times per week	0.45 mcg/kg SC or IV once every week[b] 0.75 mcg/kg SC or IV once every 2 weeks[b] 0.45 mcg/kg SC or IV once every 4 weeks[c]
Zidovudine/HIV dosing regimen[d]	100 units/kg IV or SC three times per week	Not recommended

[a]Indications and dosage regimens per FDA product labeling.

[b]For patients on dialysis.

[c]For patients not on dialysis.

[d]FDA labeled indication for Procrit (epoetin-α), not Epogen (epoetin-α) or darbepoetin.

and worsened overall survival (cHR 1.06; 95% CI 1.00–1.12). This corresponds to a 17% increased risk of mortality for patients treated with ESAs while on study and a 6% increase of mortality overall. Based on these data, the FDA revised ESA product labeling, restricting their administration to patients with chemotherapy-induced anemia without curative intent. The 2010 update of the American Society of Clinical Oncology/American Society of Hematology clinical practice guideline on the use of ESAs in patients with cancer adopted FDA recommendations for more restrictive use of ESA in patients with cancer.[29]

In 2008, CMS published more restrictive coverage criteria for ESA treatment of chemotherapy-associated anemia. Patients should be monitored every 4 weeks. If Hgb has not increased by 1.0 g/dL (10 g/L, 0.62 mmol/L) after 4 weeks and remains less than 10.0 g/dL (100 g/L, 6.21 mmol/L), a one-time dose escalation of 25% is appropriate. If Hgb increases by more than 1.0 g/dL (10 g/L, 0.62 mmol/L), or is more than 10.0 g/dL (100 g/L, 6.21 mmol/L), the ESA should be discontinued. At 8 weeks if Hgb has increased by 1 g/dL (10 g/L, 0.62 mmol/L) but remains less than 10.0 g/dL(100 g/L, 6.21 mmol/L), continued ESA administration is covered. However, if after 8 weeks Hgb fails to increase by 1 g/dL (10 g/L, 0.62 mmol/L), CMS payment of therapy is not covered. CMS covers ESA therapy for up to 8 weeks after completion of chemotherapy for patients achieving respones.[3,31]

Patient Encounter 2, Part 1

A 4-year-old girl, along with her mother, presents to her pediatrician complaining of lack of energy that has become more noticeable over the past month. The daughter is also very "moody" throughout the day. She has also been exhibiting strange behaviors, such as eating dirt when playing in the yard. Her physical examination was notable for pallor. Past medical history is negative. Patient was born at 33 weeks 5 days via emergent cesarean, spent 44 days in NICU and suffered from necrotizing enterocolitis and underwent a small bowel surgical procedure. Mother states that her child is a very "picky" eater.

What aspects of this patient's history suggest she may be anemic?

What laboratory assessments are required to make an appropriate diagnosis and therapeutic plan?

Patient Encounter 2, Part 2

Laboratory results:

CBC

- WBC: 6.7 × 10^3/mm^3 (6.7 × 109/L)
- Hgb: 6.2 g/dL (62 g/L; 3.84 mmol/L)
- Hct: 20.8% (0.208)
- Plt: 210 × 103/μL (210 × 109/L)

Red Blood Cell Indices

- MCV: 71 μm^3 (71 fL)
- MCH: 23 pg/cell
- MCHC: 28.3 g/dL (283 g/L; 17.6 mmol/L)

Iron Studies

- Serum iron: 27 mcg/dL (4.8 μmol/L)
- Serum ferritin: 6.9 ng/mL (6.9 mcg/L; 16 pmol/L)
- TIBC: 459 mcg/dL (82.2 μmol/L)
- Transferrin saturation: 11% (0.11)

B_{12} and Folate

- Serum B_{12}: 707 pg/mL (522 pmol/L)
- Serum folate: 10 ng/mL (22.7 nmol/L)

Is this a macrocytic or microcytic anemia?

Specifically, what is the etiology of the anemia?

What would be the preferred drug regimen (drug, dosage form, and schedule)?

Patient Encounter 2, Part 3

The patient is diagnosed with iron-deficiency anemia (IDA) and is started on FeroSul (liquid iron sulfater) 2.5 mL (44 mg Fe/220 mg/5 mL) orally three times daily to be taken on an empty stomach. Follow-up CBC 1 month later reveals Hgb of 9.5 g/dL (95 g/L; 5.89 mmol/L), previously 6.2 g/dL (62 g/L; 3.84 mmol/L). The mother reports an improvement in mood and more energy. Pica has also decreased significantly. However, the mother struggles to give the medication three times a day explaining that her child is not fond of the taste and has developed constipation.

What hemoglobin level would constitute a therapeutic response in this patient?

What recommendation would you make regarding the compliance and to help with constipation?

"Functional" iron deficiency exists when total iron stores are normal or increased but disruption of iron homeostasis prevents utilization of the stored iron for erythropoiesis. "Functional" iron deficiency has been described in patients with ACD. Therefore, it is imperative that patients starting ESA therapy have laboratory studies performed to assess iron stores. If results document that a patient has suboptimal iron stores, iron replacement therapy is indicated prior to initiation of ESA therapy.

Anemia Due to CKD Anemia is common in patients with CKD. Early treatment of anemia in patients with CKD on dialysis has been associated with slower disease progression and lower risk of death. It is essential to evaluate and treat anemia in patients before they progress to stage 5 CKD (glomerular filtration rate [GFR] of less than 15 mL/min/1.73 m^2 [0.14 mL/s/m^2]).[32]

Patients with CKD typically develop normocytic, normochromic anemia as a result of EPO deficiency. However, a thorough workup of anemia should be performed to rule out other etiologies.[32] The 2012 KDIGO Clinical Practice Guideline for Anemia in Chronic Kidney Disease recommends that ESA therapy be started when the hemoglobin is between 9.0 and 10.0 g/dL (90–100 g/L) in dialysis patients. For those CKD patients not on dialysis, the guidelines recommend that ESAs be started when the Hgb is less than 10.0 g/dL (10 g/L) and should also be based on patient specific scenarios—if the rate of Hgb decline predicts the need for an RBC transfusion and if a goal of therapy is to either reduce the risk of RBC transfusion-related risks or reduce the chance of alloim-munization.[32,33] This dosing strategy was adopted to decrease the risk of serious adverse cardiovascular events. ESA-labeled dosing regimens for patients with CKD are summarized in Table 66–6.[34–36]

LO 7

Although EPO deficiency is the primary cause of CKD anemia, iron deficiency may also exist. Iron stores in patients with CKD should be maintained so that transferrin saturation is greater than 20% (0.20) and serum ferritin is greater than 100 ng/mL (100 mcg/L or 225 pmol/L). If iron stores are not maintained appropriately, epoetin or darbepoetin will not be effective. Most CKD patients will require iron supplementation.[32]

Anemia Due to Zidovudine in HIV-Infected Patients Early clinical trials evaluating the efficacy of zidovudine in patients with HIV documented that nearly 50% of patients treated with zidovudine developed anemia requiring RBC transfusions. Subsequently, results from numerous clinical trials reported that epoetin resulted in statistically significant decreases in transfusion requirements for patients with HIV who have serum EPO levels less than 500 mUnits/mL (500 U/L). Currently, epoetin has a labeled indication for the treatment of anemia in patients with EPO levels less than 500 mUnits/mL (500 U/L) and administered zidovudine doses less than 4200 mg/week.[34]

OUTCOME EVALUATION

KEY CONCEPT Patients should be monitored for Hgb response, symptom resolution, and adverse effects at appropriate intervals, and treatment regimens adjusted accordingly. The goal of anemia therapy is to correct the underlying etiology of the anemia, normalize the Hgb, and alleviate associated symptoms.

LO 4

- To ensure response for patients with IDA, monitor CBC with special attention to occurrence of reticulocytosis and iron studies.
- A 1.0-g/dL (10 g/L or 0.62 mmol/L) per week increase in Hgb is desirable in patients with IDA. Reevaluate patients with increases less than 2.0 g/dL (20 g/L or 1.24 mmol/L) in 3 weeks.
- For patients with folic acid deficiency, monitor Hgb periodically and reevaluate patients who fail to normalize Hgb levels after 2 months of therapy.
- For patients with vitamin B_{12} deficiency, monitor for resolution of neurologic symptoms (ie, confusion and paresthesias), if applicable, and Hgb levels weekly until the levels normalize.
- For cancer patients treated with chemotherapy without curative intent, initiate ESA treatment when Hgb levels are less than 10.0 g/dL (100 g/L or 6.21 mmol/L) and monitor Hgb levels weekly. If Hgb increases exceed 1.0 g/dL (10 g/L or 0.62 mmol/L) or if Hgb levels exceed 10.0 g/dL (100 g/L or 6.21 mmol/L), hold therapy until the Hgb level drops below 10.0 g/dL (100 g/L or 6.21 mmol/L). Restart the ESA at the lowest dose sufficient to reduce transfusions.
- For patients with CKD on dialysis, initiate ESA treatment when Hgb levels are less than 10.0 g/dL (100 g/L or 6.21 mmol/L) and monitor Hgb levels weekly. If Hgb levels approach or exceed 11.0 g/dL (110 g/L or 6.83 mmol/L), reduce or hold further doses until the level drops below 10.0 g/dL (100 g/L or 6.21 mmol/L). Restart the ESA at the lowest dose sufficient to reduce transfusions.
- For patients with CKD not on dialysis, initiate ESA treatment when Hgb levels are less than 10.0 g/dL (100 g/L or 6.21 mmol/L) and when the following additional criteria apply:
  - The rate of hemoglobin decline indicates the likelihood of a transfusion AND
  - Reducing the risk of alloimmunization and/or RBC transfusion-related risks are/is a goal. Monitor Hgb levels weekly. If Hgb levels exceed 10.0 g/dL (100 g/L or 6.21 mmol/L), reduce or hold further doses until the level drops below 10.0 g/dL (100 g/L or 6.21 mmol/L). Restart the ESA at the lowest dose sufficient to reduce transfusions.

Patient Care Process

Collect Information:

- Review the medical and surgical history in conjunction with any physical assessment findings
- Speak with the patient/family member to evaluate lifestyle habits, particularly dietary preferences, beliefs, health goals, and socioeconomic factors

Assess the Information:

- Based on physical examination and review of systems, determine if the patient exhibits signs or symptoms of anemia
- Review current medications and assess if they could be contributing to anemia
- Evaluate CBC, if anemia is present, assess RBC indices to determine if the anemia is microcytic, normocytic, or macrocytic
- Assess iron, folic acid, and vitamin B_{12} studies to determine etiology of anemia

Develop a Care Plan:

- Determine whether a transfusion or pharmacotherapy is indicated. If pharmacotherapy is needed, decide whether oral or intravenous therapy is indicated
- When initiating ESAs, assess the patient's iron status
- Discuss the importance of medication adherence with oral therapy
- Choose oral medications and doses that are optimal for the patient
- Select lifestyle and diet modifications that are likely to be effective and safe for the patient

Implement the Care Plan:

- Educate the patient on medication administration, potential new adverse effects, and how to report adverse effects
- Review signs and symptoms of anemia with the patient and address any concerns about anemia and its management
- Determine whether the patient has insurance coverage or whether recommended agents are included on the institution's formulary

LO 8

Follow-up: Monitor and Evaluate:

- Follow-up monthly to assess efficacy and tolerance of therapy until resolution of symptoms and Hgb goal achieved
- Monitor for resolution of symptoms such as fatigue, shortness of breath, lethargy, headache, edema, and tachycardia
- Monitor the CBC monthly
- Monitor compliance of prescribed therapy and for side effects, such as:
  - Oral iron: nausea, vomiting, abdominal pain, heartburn, constipation, and dark stools
  - Parenteral iron: anaphylaxis (test dose required for iron dextran and observe for 1 hour after), injection-site pain/irritation, arthralgias, myalgias, flushing, malaise, and fever
  - Folic acid: bad taste, nausea, rash, and allergic reactions
  - Vitamin B_{12}: pain and erythema at injection site
  - ESAs: hypertension (monitor blood pressure), thrombosis (eg, deep vein thrombosis/pulmonary embolism, myocardial infarction, cerebrovascular accident, and transient ischemic attack), arthralgias, and headache

Abbreviations Introduced in This Chapter

CKD	Chronic kidney disease
EPO	Erythropoietin
ESA	Erythropoietin stimulating agent
GFR	Glomerular filtration rate
Hct	Hematocrit
Hgb	Hemoglobin
IDA	Iron-deficiency anemia
MCV	Mean corpuscular volume
MCH	Mean corpuscular hemoglobin
TIBC	Total iron-binding capacity

67 Coagulation and Platelet Disorders

Anastasia Rivkin, Sandeep Vansal, and Anna Dushenkov

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

1. Describe the basics of the regulation of hemostasis and thrombosis.
2. Select appropriate nonpharmacological and pharmacological therapy for a patient with hemophilia in a given clinical situation.
3. Calculate an appropriate factor-concentrate dose for a product, given the percentage correction desired based on clinical situation.
4. List possible complications from hemophilia bleeding episodes.
5. Choose an appropriate treatment strategy for patients with factor VIII or IX inhibitors.
6. Devise a treatment plan for a patient with a specific variant of von Willebrand disease.
7. Describe various recessively inherited coagulation disorders (RICDs) and role of specific factor replacement in RICD management.
8. Recommend first-line and second-line treatment approaches for immune thrombocytopenia (ITP).
9. Identify basic clinical features, causes, and management of select thrombotic microangiopathies (TMAs).

INTRODUCTION

Components of the Hemostatic System

Following endothelial injury, vessel-wall response involves vasoconstriction, platelet plug formation, coagulation, and fibrinolysis regulation. In normal circumstances, platelets circulate in the blood in an inactive form. After injury, platelets undergo activation, which consists of (a) adhesion to the subendothelium, (b) secretion of granules containing chemical mediators (eg, adenosine diphosphate, thromboxane A2, thrombin, etc), and (c) aggregation. Chemical factors released from the injured tissue and platelets stimulate the coagulation cascade and thrombin formation. In turn, thrombin catalyzes the conversion of fibrinogen to fibrin and its subsequent incorporation into the platelet plug.

The coagulation system consists of intrinsic and extrinsic pathways. Both pathways are composed of a series of enzymatic reactions that ultimately produce thrombin, fibrin, and a stable clot. In parallel with the coagulation, the fibrinolytic system is activated locally. Plasminogen is converted to plasmin, which dissolves the fibrin mesh (Figure 67–1).[1]

INHERITED COAGULATION DISORDERS

HEMOPHILIA

Epidemiology and Etiology

Hemophilia A and B are coagulation disorders that result from defects in the genes encoding for plasma coagulation proteins. Hemophilia A (classic hemophilia) is caused by the deficiency of factor VIII, and hemophilia B (Christmas disease) is caused by the deficiency of factor IX. The incidences of hemophilia A and B are estimated at 1 in 5000 and 1 in 30,000 male births, respectively. Both types of hemophilia are evenly distributed across all ethnic and racial groups.[1]

Pathophysiology

The pathophysiology of hemophilia is based on the deficiency of factor VIII or IX resulting in inadequate thrombin generation and an impaired intrinsic pathway coagulation cascade (see Figure 67–1). Factor VIII and IX genes are located on the X-chromosome. Hemophilias are recessive X-linked diseases. Generally, affected males carrying a defective allele for either factor VIII or IX on their X-chromosome do not transmit the gene to their sons. However, their daughters are obligate carriers. More than 1000 mutations in factor VIII and IX genes have been identified to cause clinical hemophilia.[2] Consequently, hemophilia is not a result of a single genetic mutation. However, inversion at intron 22 of the factor VIII gene accounts for 40% of severe hemophilia A cases and this mutation is assessed during carrier and prenatal testing.[3]

Complications of Hemophilia

The severity of bleeding associated with hemophilia correlates with the degree of factor VIII or factor IX deficiency as measured against the normal plasma standard. Table 67–1 summarizes the age at onset and laboratory and clinical manifestations of hemophilia A and B.[4]

Treatment

▶ *Desired Outcomes*

Currently, there is no cure for hemophilia A or B. The life expectancy of hemophiliacs was only 8 to 11 years in the

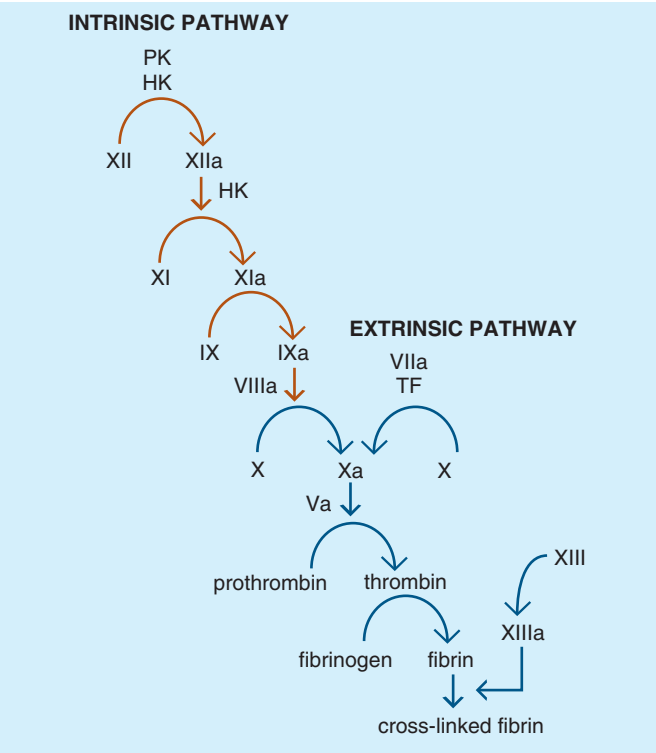

FIGURE 67–1. Cascade model of coagulation demonstrates activation via the intrinsic or extrinsic pathway. This model shows successive activation of coagulation factors proceeding from the top to the bottom where thrombin and fibrin are generated. (PK, prekallikrein; HK, high–molecular weight kininogen; TF, tissue factor.) (From Roberts HR et al. Molecular biology and biochemistry of the coagulation factors and pathways of hemostasis. In: Lichtman MA, Beutler E, Coller BS et al, eds. Williams Hematology, 7th ed. New York, NY: McGraw-Hill, 2006:1665–1694.)

1920s and 1930s. With the development of effective treatment strategies, life expectancy is currently about 63 to 75 years, or nearly that of the normal population.[5]

The short-term goals of hemophilia treatment include the following:

- Decrease the number of bleeding episodes per year or bleeding frequency
- Normalize or improve clotting factor concentrate levels

The long-term goals of hemophilia treatment include the following:

- Maintain clinical joint function
- Normalize orthopedic joint score
- Normalize radiologic joint score
- Maintain quality-of-life measurements

▶ *General Approach to Treatment*

KEY CONCEPT Intravenous factor replacement with recombinant or plasma-derived products to treat or prevent bleeding is the primary treatment of hemophilia. Primary prophylaxis is defined as the regular administration of factor concentrates in the absence of documented joint disease and initiated before the age of 3.[6] Primary prophylaxis is recommended for individuals who have not had a bleeding episode but have severe factor deficiency (factor VIII or IX activity levels < 1%) as it is efficacious in preventing bleeding and associated complications.[7]

Several studies have shown the benefit of prophylaxis in reducing morbidity in severe hemophilia A and B in both children and adults.[8]

▶ *Nonpharmacologic Therapy*

LO 2 **Supportive Care** Rest, ice, compression, elevation (RICE) can be used during the bleeding episode, following with casts, splints, and crutches after the bleeding has been controlled.

LO 2 **Surgery** Surgical arthroscopic synovectomy reduces replacement therapy–resistant disease and repetitive hemarthrosis of a single joint. This procedure removes inflamed joint tissue. Patients may have decreased range of motion after the surgery.

LO 2 **Orthotics** Joint prostheses do not deal with the deformities directly. Orthotics in hemophilia serves as an important supportive measure before or after surgery.

▶ *Pharmacologic Therapy*

Hemophilia A

LO 2 ***DDAVP*** Primary therapy is based on disease severity and type of hemorrhage.[9] Most patients with mild to moderate disease and a minor bleeding episode can be treated with 1-desamino-8-D-arginine vasopressin (desmopressin acetate [DDAVP]), a synthetic analogue of the antidiuretic hormone, vasopressin. DDAVP causes

Table 67–1

Laboratory and Clinical Manifestations of Hemophilia

	Severe (< 0.01 IU/mL [10 IU/L])[a]	Moderate (0.01–0.05 IU/mL [10–50 IU/L])[a]	Mild (> 0.05 IU/mL [50 IU/L])[a]
Age at onset	1 year or younger	1–2 years	2 years–adult
Neonatal symptoms			
PCB	Usual	Usual	Rare
ICH	Occasional	Uncommon	Rare
Muscle/joint hemorrhage	Spontaneous	Minor trauma	Minor trauma
CNS hemorrhage	High risk	Moderate risk	Rare
Postsurgical hemorrhage (without prophylaxis)	Frank bleeding, severe	Wound bleeding, common	Wound bleeding
Oral hemorrhage following trauma, tooth extraction	Usual	Common	Common

[a]0.01 IU/mL = 10 IU/L; 0.05 IU/mL = 50 IU/L; 0.5 IU/mL = 500 IU/L; 1 unit/mL = 1 IU/mL = 1000 IU/L; 1.5 IU/mL = 1500 IU/L.

CNS, central nervous system; ICH, intracranial hemorrhage; PCB, postcircumcisional bleeding.

Normal range of factor VIII/IX activity level is 0.5–1.5 IU/mL (50–150 IU/L). 1 IU/mL (1000 IU/L) corresponds to 100% of the factor found in 1 mL of normal plasma.

Clinical Presentation and Diagnosis of Hemophilia A and B

Hemophilia A and B are clinically indistinguishable.

Symptoms

- Ecchymoses
- Hemarthrosis—bleeding into joint spaces[a] (especially knee, elbow, and ankle)
  - Joint pain, swelling, and erythema
  - Cutaneous warmth
  - Decreased range of motion
- Muscle hemorrhage
  - Swelling
  - Pain with motion of affected muscle
  - Signs of nerve compression
  - Potential life-threatening blood loss, especially with thigh bleeding
- Mouth bleeding with dental extractions or trauma
- Genitourinary bleeding
- Gastrointestinal (GI) bleeding
- Hematuria
- Intracranial hemorrhage (spontaneous or following trauma), with headache, vomiting, change in mental status, and focal neurologic signs
- Excessive bleeding with surgery

Diagnostic Parameters/Laboratory Testing

- Family history
- Normal prothrombin time (PT)
- Normal platelet count
- Prolonged activated partial thromboplastin time (aPTT)
- Low factor VIII level (hemophilia A)
- Low factor IX level (hemophilia B)

[a]Hallmark of hemophilia; recurrent inadequately managed hemarthrosis leads to deformity and chronic pain (hemophilic arthropathy).

release of von Willebrand factor (vWF) and factor VIII from endothelial storage sites. DDAVP increases plasma factor VIII levels by twofold to fourfold within 60 minutes after an infusion or 90 minutes after an intranasal dose.[10] The recommended dose is 0.3 mcg/kg IV (infused over 15–30 minutes) or subcutaneously (if < 1.5 mL) or 150 mcg (in patients weighing < 50 kg) to 300 mcg (in patients weighing > 50 kg) intranasally via concentrated nasal spray, may repeat after 24 hours.[9] Desmopressin infusion may be administered daily for up to 2 to 3 days. Facial flushing, hypertension or hypotension, gastrointestinal upset, and headache are common side effects of desmopressin. Water retention and hyponatremia may occur; patients should be instructed to limit water intake while taking desmopressin. Serious side effects include seizures related to hyponatremia and myocardial infarction. Due to higher incidence of hyponatremia-related seizures in patients less than 2 years old, use of desmopressin is not recommended in this population. Tachyphylaxis, an attenuated response with repeated administration, may occur after several doses.[11] DDAVP should not be used in severe life-threatening bleeding because the response is delayed and the increase in factor VIII may not be sufficient for proper clotting. It is usually used to treat mild hemophilia A.

According to the manufacturer, use of DDAVP is contraindicated in patients with creatinine clearance less than 50 mL/min (0.83 mL/s); however, it has been used off label in patients with impaired renal function.

LO 2

Antifibrinolytic Therapy Aminocaproic acid and tranexamic acid are antifibrinolytic agents that reduce plasminogen activity leading to inhibition of clot lysis and clot stabilization. These agents are usually used as adjuncts in dental procedures or in difficult-to-control and menorrhagia episodes and have to be administered with appropriate factor concentrates to form a clot.[9]

LO 2

Factor VIII Replacement Patients with severe hemophilia may receive primary (before the first major bleed) or secondary (after the first major bleed) prophylaxis. All hemophiliacs with a major bleed require factor VIII replacement.[12] The therapy may include recombinant (produced via transfection of mammalian cells with the human factor VIII gene) or plasma-derived (concentrate from pooled plasma) factor VIII (Table 67–2). The choice of product and dose is based on the overall clinical scenario because the efficacy of various preparations does not differ significantly.[13] Newer generation plasma-derived coagulation factor concentrates are considerably safer owing to advancements in viral testing and inactivation technology. New-generation recombinant factor VIII products are stabilized with sucrose or produced in human cell lines, eliminating the concern for viral transmission.[9]

The severity of hemorrhage and its location are major determinants of percentage correction to target, as well as duration of therapy (Table 67–3). The normal range of factor VIII activity level is 1 IU/mL (1000 IU/L), which corresponds to 100% of the factor found in 1 mL of normal plasma. Minor bleeding may be treated with a goal of 25% to 30% (0.25–0.30 IU/mL [250–300 IU/L]) of normal activity, whereas serious or life-threatening bleeding requires greater than 80% of normal activity. Factor VIII is a large molecule that remains in the intravascular space, and its estimated volume of distribution is approximately 50 mL/kg. Generally, factor VIII levels increase by 2% (0.02 IU/mL [20 IU/L]) for every 1 unit/kg of factor VIII concentrate infused. To calculate factor VIII replacement dose, the following equation can be used:

LO 3

$$\text{Dose of factor VIII (units)} = \text{weight (kg)} \times \text{(desired percentage increase)} \times 0.5$$

Thus, to increase factor VIII levels by 50% (eg, from 0% to 50%) in a 70-kg (154-lb) patient, an IV dose of 1750 units is required. The median half-life of factor VIII ranges from 9.4 hours (in 1–6 year olds) to 10.4 hours (in 10–65 year olds).[14,15] Half the initial dose is given every half-life (every 8–12 hours) to maintain the desired factor VIII level. Although intermittent bolus infusions of factor VIII concentrates have been used successfully, continuous-infusion protocols can be used in patients requiring prolonged treatment of acute hemorrhage to avoid dangerously low trough levels and decrease the overall cost of therapy. Factor VIII can be administered as a continuous infusion at 2 to 4 units/kg/hour with daily factor level monitoring to ensure appropriate rate of infusion.[16,17]

Table 67–2

Factor Concentrates

Brand Name	Half-life	Other Contents
Factor VIII Concentrates		
Recombinant		
Advate	12.0 ± 4.2	Mannitol, trehalose
Adynovate	14.69 ± 3.79	Mannitol, trehalose
Afstyla	14.2 (26)	Sucrose
Eloctate	19.7 (17.4, 22.0)	Sucrose
Helixate FS	14.6 ± 4.38	Sucrose
Kogenate FS	14.6 ± 4.38	Sucrose
Kovaltry	14.3 ± 3.7	Sucrose
NovoEight	12.0 ± 9.3	Sucrose
Nuwiq	17.1 ± 11.2	Sucrose
Obizur		Sucrose
Recombinate	14.6 ± 4.9	Albumin
Xyntha	11.2 ± 5.0	Sucrose
Plasma-derived		
Alphanate	17.9 ± 9.6	Albumin, heparin, vWF
Hemofil M	14.7 ± 5.1	Albumin
Humate-P	11 (median)	Albumin, vWF
Koāte-DVI	16.12	Albumin, vWF
Monoclate-P	17.5	Albumin
Wilate	15.8 ± 11.0	Sucrose, vWF
Factor IX Concentrates		
Recombinant		
Alprolix	86.52 (37.2)	Sucrose, mannitol
Benefix	18.8 ± 5.4	Sucrose
Idelvion	104 (25)	Sucrose, mannitol
Ixinity	24 ± 7	Mannitol, Trehalose
Rixubis	26.7 ± 9.6	Sucrose, mannitol
Plasma-derived		
AlphaNine SD	21	Heparin
Mononine	25.3	
APCC		
Feiba VH or NF		II, VIIa, IX, X, factor VIII coagulant antigen
PCC		
Bebulin		Heparin, II, IX, X
Profilnine		II, VII, IX, X
Proplex T		Heparin, II, VII, IX, X
Other		
NovoSeven RT	3.54	Sucrose, mannitol

APCC, activated prothrombin complex concentrate; PCC, prothrombin complex concentrate; vWF, von Willebrand factor.

Table 67–3

Guidelines for Replacement Dosing with Factor VIII and Factor IX

Type of Hemorrhage	Desired Plasma Factor VIII Level (% of Normal)	Desired Plasma Factor XI Level (% of Normal)
CNS, intracranial, retropharyngeal, retroperitoneal, surgical prophylaxis	80–100	80–100
Mild hemarthrosis, mucosal (eg, epistaxis), superficial hematoma	30	20–30

Hemophilia B

LO 5

Factor IX Replacement Hemophilia B therapy may include recombinant (produced via transfection of mammalian cells with the human factor IX gene) or plasma-derived (concentrate from pooled plasma) factor IX (see Table 67–2). Guidelines for choosing the factor-concentrate formulation for hemophilia B are similar to the guidelines for hemophilia A. However, older generation factor IX concentrates containing other vitamin K–dependent proteins, called prothrombin complex concentrates (PCCs), have been associated with thrombogenic side effects and these products are not first-line treatment for hemophilia B. Because it is a small protein, the factor IX molecule passes into both the intravascular and the extravascular spaces. Therefore, the volume of distribution of recombinant factor IX is twice that of factor VIII. Consequently, 1 unit of factor IX administered per kilogram of body weight yields a 1% rise in the plasma factor IX level (0.01 IU/mL [10 IU/L]). To calculate the factor IX replacement dose, the following equation can be used:

LO 3

$$\text{Dose of factor IX (units)} = \text{weight (kg)} \times \text{(desired percentage increase)} \times F$$

where F = 1 for human plasma-derived products; F = 1.1 for Rixubis; F = 1.4 for Benefix in adults and 1.2 in children.

Thus, to increase factor IX levels by 50% (eg, from 0% to 50%) in a 70-kg (154-lb) patient, the required dose of factor IX is 4900 units IV (using Benefix). The half-life of factor IX ranges from 16 to 17 hours; therefore, doses are given every 18 to 24 hours. Factor IX fusion protein can be given every 1 to 2 weeks.[18]

Gene therapy for the treatment of hemophilia is currently under investigation. A recent clinical trial has shown long-term therapeutic levels of factor IX in ten subjects with severe hemophilia B receiving a single infusion of a factor IX transgene vector.[19,20]

► *Treatment of Patients with Factor VIII or IX Inhibitors*

Factor VIII and IX inhibitors are antibodies that develop in approximately 30% and 5% of hemophilia A and hemophilia B patients, respectively, in response to replacement therapy. There is no difference between plasma-derived and recombinant products in their potential for inhibitor development. These antibodies bind to and neutralize the activity of infused factor concentrates. Other complications include anaphylaxis.[21] Although the inhibitors do not increase hemorrhage frequency, their existence challenges the treatment of bleeding episodes. Titers of inhibitors are measured and reported in Bethesda units (BU), and this measurement is used to guide therapy (Figure 67–2). Management options for acute bleeding in patients with factor inhibitors include the administration of factor VIII concentrates, PCCs, aPCC, recombinant factor VIIa (rFVIIa), and recombinant porcine factor VIII (Obizur).[22] Immune tolerance induction can be attempted to prevent future bleeding episodes.

LO 5

Factor VIII concentrates can be used in patients with low inhibitor levels to control acute bleeding episodes. The dose of factor VIII is determined based on clinical response (see Figure 67–2).

PCCs contain the vitamin K–dependent factors II, VII, IX, and X. These agents bypass factor VIII at which the antibody is directed (see Figure 67–2). However, PCCs carry the risk of serious thrombotic complications. The only aPCC agent available, FEIBA® (Factor Eight Inhibitor Bypassing Activity), has a higher concentration of activated factors.

Factor VIIa (rFVIIa) is a bypassing agent designed to generate thrombin only at tissue injury sites, where it binds tissue factor.

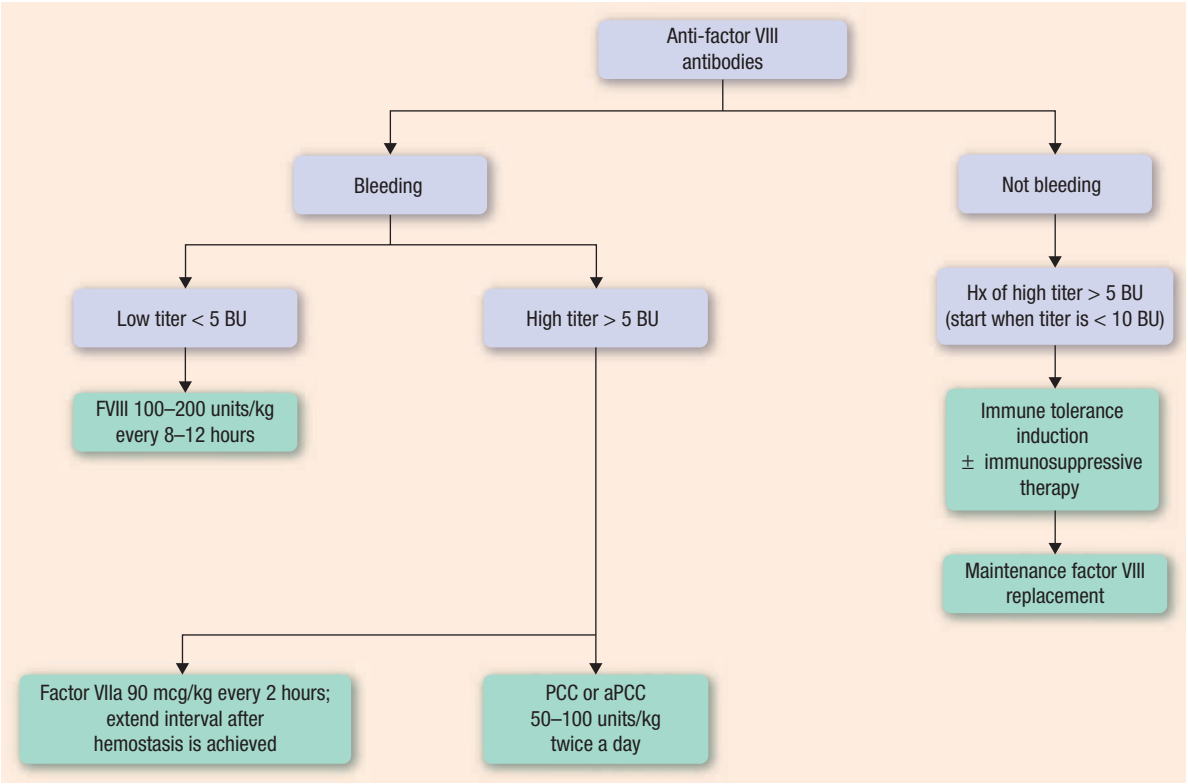

FIGURE 67–2. Treatment algorithm for the management of patients with hemophilia A and factor VIII antibodies. (aPCC, activated prothrombin complex concentrate; BU, Bethesda unit.) (From Trinkman H, Beam D, Hagemann T. In: DiPiro JT, Talbert RL, Yee GC, et al., eds. Pharmacotherapy: A Pathophysiologic Approach. 10th ed. New York, NY: McGraw-Hill; 2017, Figure 101–1.)

Due to its local action, rFVIIa is associated with fewer systemic thrombotic events than PCC. rFVIIa is used effectively in surgeries and spontaneous bleeds.[23]

Recombinant porcine factor VIII serves as a third-line agent (only after factor VIIa and aPCC have failed) due to the relatively high incidence of cross-reactivity with factor VIII inhibitors.

Induction of immune tolerance, which is often performed with the goal of eliminating the inhibitor, is accomplished by the administration of repetitive doses of factor VIII or IX with or without immunosuppressive therapy. It is effective in 70% of patients with hemophilia A and 30% of patients with hemophilia B.

Pain Associated with Hemophilia

Pain commonly occurs in patients with hemophilia. Acute bleeding episodes and long-term joint destruction are common sources of pain. Acetaminophen and opioid analgesics are recommended to control mild to moderate and severe pain, respectively. Nonsteroidal anti-inflammatory drugs and aspirin should be avoided if possible, because these drugs bind to platelets and increase the risk of bleeding episodes. Cyclooxygenase-2 (COX-2) inhibitors can be used with caution.[24]

Outcome Evaluation

The main goal of hemophilia treatment is to prevent bleeding episodes and their long-term complications. Clinicians should evaluate patients for the following:

- Musculoskeletal status, including joint range of motion and radiologic assessment, as indicated.
- Number and type of bleeding episodes to assess adequacy of prophylactic treatment and home therapy.
- Use of clotting-factor concentrates to check for the development of inhibitors, especially in patients with severe disease and poor treatment responders.
- Age-appropriate immunizations following standard vaccination schedules are recommended in all hemophiliacs without evidence of immunity.

VON WILLEBRAND DISEASE

Epidemiology and Etiology

Von Willebrand disease (vWD) is the most common inherited bleeding disorder caused by a deficiency or dysfunction of vWF. It is classified based on the quantitative deficiency of vWF or qualitative abnormalities of vWF. Based on population studies, the prevalence of vWD is 0.6% to 1.3%. In contrast to hemophilia, the majority of vWD cases are inherited as an autosomal dominant disorder, suggesting equal frequency in males and females.[25,26]

Pathophysiology

vWF is a large multimeric glycoprotein with two main functions in hemostasis: to aid platelet adhesion to injured blood vessel walls and to carry and stabilize factor VIII in plasma. Table 67–4 represents three main vWD phenotypes, their frequency, and genetic transmission.[27]

Treatment

▶ *Desired Outcomes*

Unlike hemophilia, the bleeding tendency in vWD is less frequent and generally less severe. Consequently, chronic prophylaxis

Patient Encounter 1, Part 1: vWD

A 15-year-old girl without significant past medical history is referred to hematology clinic with a complaint of having heavy menstrual bleeds with normal menstrual cycle but with clots, size of about a quarter and soaking through a pad within an hour. The bleeds usually last for 10 days. Her mother reports history of spontaneous nosebleeds and easy bruising in male and female members of the family.

What are this patient's risk factors for vWD?

What additional information for developing a treatment plan do you need to collect?

is usually unwarranted. The goal of two mainstay therapeutic options in vWD is:

- To stop spontaneous bleeding as necessary
- To prevent surgical and postpartum bleeding

▶ *Nonpharmacologic Therapy*

Local measures, including pressure and ice, may be used to control superficial bleeding.

▶ *Pharmacologic Therapy*

Systemic therapy is used to prevent bleeding associated with surgery, childbirth, and dental extractions and to treat bleeding that cannot be controlled with local measures. The two systemic approaches involve using desmopressin, which stimulates the release of endogenous vWF, or administering products that contain vWF. The general approach to the treatment of vWD is depicted in Figure 67–3. In 2008, The National Heart, Lung, and Blood Institute issued comprehensive evidence-based guidelines for the diagnosis and management of vWD.[26]

LO 6

DDAVP Most patients with type 1 vWD (functionally normal vWF) and a minor bleeding episode can be treated successfully with desmopressin, which induces release of factor VIII and vWF from endothelial cells through interaction with vasopressin V2 receptors. The recommended dose is the same as that used to treat mild factor VIII deficiency (0.3 mcg/kg IV infused over 15–30 min or 150–300 mcg intranasally via concentrated nasal spray, may repeat after 24 hours). This therapy is generally ineffective in type 2A patients, who secrete abnormal vWF. It is recommended in type 2B patients who respond to it. DDAVP may increase the risk of postinfusion thrombocytopenia, in which case a concomitant platelet infusion is administered. Type 3 vWD patients who lack releasable stores of vWF do not respond to DDAVP therapy.[28]

The individual responsiveness to desmopressin is consistent, and a test dose administered at the time of diagnosis or prior to therapy is the best predictor of response. Generally, DDAVP is more effective in vWD than in hemophilia patients, with an average twofold to fivefold increase in vWF and factor VIII levels over baseline. In patients with an adequate response, desmopressin is first-line therapy because it allows for once-daily administration (elevates plasma levels for 8–10 hours), does not pose a threat in terms of viral transmission, and costs substantially less than the plasma-derived products.

Antifibrinolytic Therapy Fibrinolysis inhibitors and oral contraceptives are used successfully in the management of epistaxis and menorrhagia or as adjuvant treatments.[29] Fibrinolysis inhibitors include aminocaproic acid (25–60 mg/kg orally or IV [or 4–5 g] every 4–6 hours, to a maximum dose of 24 g/day) and tranexamic acid (10 mg/kg IV every 8 hours). Oral tranexamic acid recently received FDA approval for the treatment of cyclic heavy menstrual bleeding; its use is currently not approved for vWD patients. The IV form of tranexamic acid given as swish and swallow or spit every 6 to 8 hours has been used as bleeding prophylaxis in dental surgery. Both aminocaproic acid and tranexamic acid are dose adjusted for patients with renal insufficiency.

Replacement Therapy KEY CONCEPT Type 1 vWD patients unresponsive to desmopressin, patients with types 2 and 3 vWD, and major surgery patients require replacement therapy with plasma-derived, intermediate- and high-purity virus-inactivated factor VIII concentrates containing vWF.

Table 67–5 provides typical dosing guidelines and target levels of replacement therapy–concentrates to control various types of hemorrhage. Ultra-high-purity (monoclonal) plasma-derived and recombinant factor VIII concentrates do not contain vWF and should not be used in the treatment of vWD.

Outcome Evaluation

The main goal of vWF treatment is to prevent bleeding with surgery or dental procedures. Clinicians should evaluate patients every 6 to 12 months for the following:

- Number and type of bleeding episodes to assess the need for prophylactic treatment.

Table 67–4

Classification of vWD

Phenotype	Mechanism of Disease	Percentage of Cases	Genetic Transmission
Type 1 vWD	Partial (mild to moderate) quantitative deficiency of vWF and factor VIII	70–80	Autosomal dominant
Type 2 vWD	Qualitative abnormalities of vWF	10–30	
2A	Decreased platelet-dependent vWF function owing to lack of larger multimers	10–20	Autosomal dominant (or recessive)
2B	Decreased platelet-dependent vWF function owing to lack of larger multimers	5	Autosomal dominant
2M	Defective platelet-dependent vWF functions not associated with multimer defects	Uncommon	Autosomal dominant (or recessive)
2N	Defective vWF binding to factor VIII	Uncommon	Autosomal recessive
Type 3 vWD	Severe quantitative deficiency of vWF	Rare	Autosomal recessive

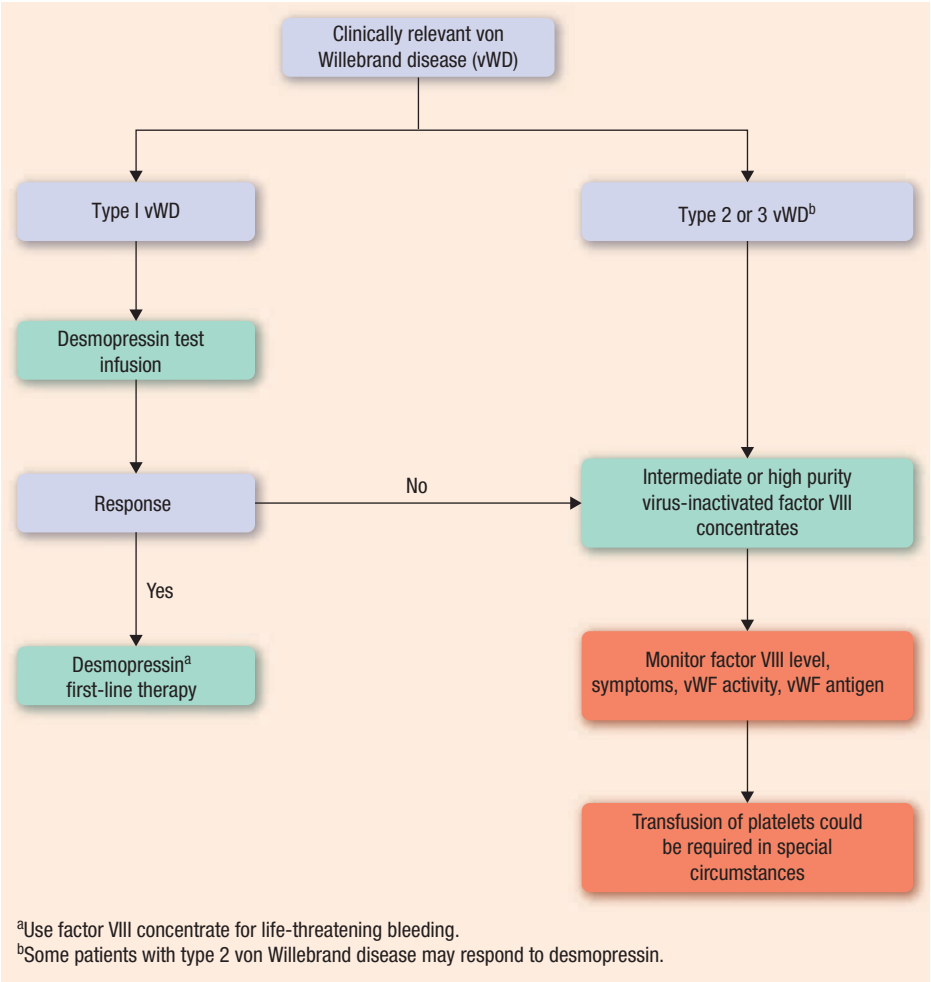

FIGURE 67–3. Guidelines for the treatment of vWD. (From Trinkman H, Beam D, Hagemann T. In: DiPiro JT, Talbert RL, Yee GC, et al., eds. Pharmacotherapy: A Pathophysiologic Approach. 10th ed. New York, NY: McGraw-Hill; 2017, Figure 101–2.)

- Ensure adequate levels of vWF and factor VIII prior to minor and major surgical procedures and for the treatment of bleeding.
- Vaccination against hepatitis A and B is recommended in all patients with vWF deficiency with no evidence of immunity.

OTHER CLOTTING FACTOR DEFICIENCIES

Etiology and Epidemiology

LO 7

Recessively inherited coagulation disorders (RICDs) refer to relatively rare deficiencies in factors II, V, VII, and X to XIII resulting in either decreased clotting factor production or production of a dysfunctional molecule with reduced activity.[30]

Clinical Presentation and Diagnosis of vWD

Clinical manifestations vary depending on the subtype. Patients with mild disease may be asymptomatic into adulthood.

Symptoms

- Bruising
- Mucocutaneous bleeding
- Epistaxis
- Oral cavity bleeding
- Menorrhagia
- GI bleeding
- Joint and deep tissue bleeding
- Postoperative bleeding

Laboratory Testing

- Low or normal vWF antigen concentration in plasma (vWF:Ag)
- Low or normal factor VIII coagulation assay (FVIII:C)[a]
- Low ristocetin cofactor activity (vWF:RCo)[b]

[a]Factor VIII coagulation assay measures the ability of vWF to bind and maintain adequate levels of factor VIII.

[b]Ristocetin cofactor activity (vWF:RCo) assay measures the ability of vWF to interact with intact platelets (normal 50–200 IU/dL [500–2000 IU/L]).

Table 67–5

Replacement Therapy in vWD

Condition	Therapy	Recommended Dosage
Major surgery	Maintain vWF:RCo and factor VIII levels at least 100 IU/dL (1000 IU/L) followed by 50 IU/dL (500 IU/L) for 7–14 days To minimize risk of thrombosis: vWF:RCo levels should not exceed 200 IU/dL (2000 IU/L), and factor VIII levels should not exceed 250 IU/dL (2500 IU/L)	40–60 units/kg[a] loading dose, followed by 20–40 units/kg every 12–24 hours DDAVP may be added after a few days
Minor surgery	Prophylaxis: maintain vWF:RCo and factor VIII levels at least 30 IU/dL (300 IU/L) (preferably > 50 IU/dL [> 500 IU/L]) Minor surgery: maintain vWF:RCo and factor VIII levels at least 30 IU/dL (300 IU/L) (preferably > 50 IU/dL [> 500 IU/L]) for 3–5 days	30–60 units/kg loading dose, followed by 20–40 units/kg every 12–48 hours DDAVP may be added after a few days

[a]vWF concentrates are dosed based on vWF:RCo units concentration in the preparation to achieve the desired vWF:RCo levels.

LO 7 The clinical severity of bleeding varies and generally is poorly correlated with the factor blood levels. Table 67–6 illustrates these clotting factor deficiencies and some of their characteristics.

Pathophysiology

The RICDs are rare genetic disorders. Mutations in the genes responsible for the respective clotting factors result in impaired functionality or production of the factor.

Treatment

▶ *Desired Outcomes*

LO 7 Therapeutic interventions for RICDs improve hemostasis via replacement of deficient blood coagulation factors while minimizing the development of immune tolerance.[31]

Hemostatic levels should be maintained for the following conditions:

- Spontaneous bleeding—until bleeding stops
- Minor surgery—for 2 to 3 days
- Major surgery—until incision site has healed

▶ *Nonpharmacologic Therapy*

Transfusional Therapies KEY CONCEPT The primary treatment of RICDs is single-donor fresh-frozen plasma (FFP) that contains all coagulation factors. Disadvantages of FFP treatment include the risk of the patient becoming volume overloaded, especially when repeated infusions are administered to improve and maintain hemostasis; risk of infections; and risk of inhibitor development. PCCs licensed for the treatment of hemophilia B also contain significant levels of vitamin K–dependent factors and may be used for treatment of RICD. Table 67–7 lists the recommended RICD treatment schedules in different clinical scenarios.

▶ *Pharmacologic Therapy*

Less severe hemorrhages may be treated successfully with antifibrinolytic amino acids alone or in combination with factor replacement therapy. Tranexamic acid and aminocaproic acid may be administered IV or orally (for doses, see vWD, Pharmacologic Therapy mentioned earlier).

Table 67–6

Clotting Factor Deficiency Characteristics

Factor Deficient	Inheritance Pattern	Estimated Incidence	Laboratory Abnormalities	Severity and Site of Bleeding
II	Autosomal dominant or recessive	Extremely rare	Prolonged PT and aPTT	Mild to moderate umbilical cord, joint, and mucosal tract
V	Autosomal recessive	1:1,000,000	Prolonged PT and aPTT	Mild to moderate mucosal tract
VII	Autosomal recessive	1:500,000	Prolonged PT	Mild to severe mucosal tract and joint
X	Autosomal recessive	1:1,000,000	Prolonged PT and aPTT	Mild to severe umbilical cord, joint, and muscle
XI	Autosomal recessive	4% of Ashkenazi Jews: otherwise rare	Prolonged aPTT	Mild to moderate posttraumatic bleeding
XII	Unknown	Unknown	Prolonged aPTT	No bleeding
XIII	Autosomal recessive	< 1:2,000,000	Normal PT and aPTT	Moderate to severe umbilical cord, intracranial, and joint bleeding; recurrent miscarriages, impaired wound healing

aPTT, activated partial thromboplastin time; PT, prothrombin time.

Table 67–7

Treatment of Factor Deficiencies

Factor Deficient	Major Surgery	Spontaneous Bleeding
II	1. PCC: 20–30 units/kg 2. FFP: 15–20 mL/kg	1. FFP: 15–20 mL/kg
V	1. FFP: 15–20 mL/kg	1. FFP: 15–20 mL/kg
VII	1. rFVIIa: 15–30 mcg/kg every 4–6 hours	1. rFVIIa: 15–30 mcg/kg every 4–6 hours
X	1. PCC: 20–30 units/kg 2. FFP: 15–20 mL/kg	1. PCC: 20–30 units/kg 2. FFP: 15–20 mL/kg
XI	1. FFP: 15–20 mL/kg	1. FFP: 15–20 mL/kg
XIII	1. Pasteurized plasma concentrate: 10–20 units/kg 2. FFP: 15–20 mL/kg 3. Cryoprecipitate (1 bag per 10 kg)	1. FFP: 3–5 mL/kg

Numbers indicate lines of therapy.

FFP, fresh-frozen plasma; PCC, prothrombin complex concentrates.

PLATELET DISORDERS

Platelets, in combination with several other factors such as blood vessel wall and coagulation factors, play key role in hemostasis. Normal platelet count is 150–450 × 10^3/mm^3 (150–450 × 10^9/L). Thrombopoietin, a hormone synthesized in the liver, regulates platelet production. Several congenital and iatrogenic disorders may result in low platelet count; among them, drug-induced thrombocytopenia, infection-induced thrombocytopenia, disseminated intravascular coagulation (DIC), congenital thrombocytopenia, and idiopathic immune thrombocytopenia (ITP). Two types of thrombocytopenic disorders and their treatments are discussed below.

Patient Encounter 1, Part 2: vWD

Medications: None

Allergies: NKA

PE/ROS:

Well-nourished, well-developed (WNWD) female, otherwise healthy. Wt 52 kg.

Labs:

Platelet count: 205 × 10^3/mm^3 (205 × 10^9/L) (normal 140–440 × 10^3/mm^3 [140–440 × 10^9/L])

aPTT: 40 seconds (normal 25–40 seconds)

PT: 14 seconds (normal 11–15 seconds)

FVIII-C: 51% (normal 50%–150%)

vWF: RCo: 25 IU/dL or 250 IU/L (normal 50–200 IU/dL or 500–2000 IU/L)

vWF-Ag: 28 IU/dL or 280 IU/L (normal 50–200 IU/dL or 500–2000 IU/L)

Given this additional information, is this patient's presentation consistent with vWD?

Define treatment goals for this patient.

Patient Care Process: Hemophilia A/B, vWD, and RICD

Collect Information:

- Obtain a complete medical and medication history.
- Evaluate CBC, vital signs, and coagulation studies. If a bleeding disorder is diagnosed, evaluate specific coagulation assays to determine the etiology of the bleeding disorder.

Assess the Information:

- Identify appropriate goals of therapy based on patient's presentation.
- Based on patient data, determine if patient has contraindications to any potential therapeutic options.

Develop a Care Plan:

- Institute nonpharmacological therapy to minimize minor bleeding.
- Depending on the specific diagnosis and disease severity, select appropriate therapy with desmopressin, antifibrinolytic medications, and/or disease-specific factor replacement therapies.
- Recommend prophylactic therapies before major and minor surgical procedures based on bleeding risk assessment.
- Evaluate pain and treat if necessary, selecting medications that do not increase the risk of bleeding.

Implement the Care Plan:

- Educate the patient and/or patient's caregivers about coagulation disorder, efficacy/safety of replacement therapies, and medication/activities to avoid.
- Address any patient concerns about coagulation disorder and its management.
- Discuss importance of medication adherence and follow-up monitoring to achieve optimal outcomes. Determine whether there are any barriers to adherence.
- Review vaccination history and recommend appropriate vaccinations.
- Determine patient's ability to afford prescribed pharmacotherapy.

Follow-up: Monitor and Evaluate:

- If clotting factor replacement is utilized, continuously evaluate its efficacy and test for inhibitors development if loss of efficacy is observed.
- Monitor number/severity of bleeding episodes, joint count/joint destruction, and pain associated with some coagulation/bleeding disorders.
- Determine whether the patient is experiencing any adverse reactions or drug interactions.

Patient Encounter 1, Part 3: vWD: Creating a Care Plan

Based on the information presented, create a care plan for this patient.

What additional pharmacologic interventions can be considered for this patient if first line fails?

IMMUNE THROMBOCYTOPENIA

Epidemiology and Etiology

ITP is one of the most common causes of acquired thrombocytopenia. The estimated incidence is 1.9 to 6.4 cases per 100,000 persons in children and 3.3 cases per 100,000 in adults.[32] ITP is an acquired disorder caused by immune-mediated destruction of platelets, resulting in shortened platelet life span.

Childhood-onset and adult-onset ITP present very differently. Adult-onset ITP is generally chronic (> 6 months) and affects women two to three times more often than men. By contrast, childhood-onset ITP is acute in onset and usually follows an infectious illness, and both sexes are equally affected. Childhood ITP typically resolves on its own within 4 to 6 weeks without major sequelae. ITP occurs in about 1 of every 1000 pregnancies. In pregnant women with preexisting ITP, both maternal and fetal complications may occur, requiring separate management.

Clinical Presentation and Diagnosis of ITP

General

The typical patient is well with the exception of bleeding.

Symptoms

- Petechiae
- Purpura, wet purpura
- Ecchymoses
- Cutaneous bleeding
- Mucosal site bleeding
- Epistaxis
- Gingival bleeding
- Hematuria
- Menorrhagia
- Intracranial hemorrhage (rare)

Diagnostic Criteria

- Platelet count less than $100 \times 10^3/mm^3$ ($100 \times 10^9/L$)
- Otherwise normal complete blood count with differential
- Normal reticulocyte count
- Normal peripheral blood smear (no hemolysis or blast cells)
- History and physical examination ruling out other possible causes of thrombocytopenia[30]

Other Laboratory Testing

Laboratory testing to evaluate other courses of that can lead to secondary ITP, such as HCV, HIV, *H. pylori*.

Pathophysiology

ITP can be primary or secondary. Primary ITP can occur due to formation of autoimmune IgG antibodies directed at patient's platelets' surface glycoproteins, GPIIb/IIIa and GP1b/IX/V; abnormal production of megakaryocytes in the bone marrow; or T-cell defects that lead to destruction of platelets. The majority of adult ITP cases are due to primary causes.

Secondary ITP occurs due to an underlying disorder, such as autoimmune (eg, rheumatoid arthritis, systemic lupus erythematosus [SLE]) or infections diseases (eg, human immunodeficiency virus [HIV], hepatitis C virus [HCV], or *Helicobacter pylori* infections).[33] Platelet survival time is significantly shorter in patients with ITP (from minutes to 2–3 days compared with normal 7–10 days). Sequestration in spleen, liver, and bone marrow is partially responsible for decreased platelet survival.

Treatment

▶ *Desired Outcomes*

In children, the main goal of ITP treatment is to maintain the platelet count associated with sufficient hemostasis, while awaiting spontaneous or treatment-induced remission. In adults, the main goal is to maintain platelet count greater than $30 \times 10^3/mm^3$ ($30 \times 10^9/L$), because below this count, the incidence of bleeding is increased.[34]

▶ *General Approach to Treatment*

KEY CONCEPT The treatment of ITP is determined by the presence of bleeding and platelet count. In some cases, no therapy is needed (Table 67–8). The initial treatment of children with ITP is controversial because greater than 75% to 80% of cases resolve spontaneously irrespective of pharmacologic intervention, although children with severe hemorrhage should be treated. Therapy may be considered in children meeting one of the following criteria: platelet counts less than $10 \times 10^3/mm^3$

Table 67–8

Guidelines for the Management of Adult ITP

Greater than 30×10^3 platelets/mm^3 (30×10^9/L), no bleeding	No treatment
First line therapies	
Less than 30×10^3 platelets/mm^3 (30×10^9/L), bleeding symptoms	Prednisone (1 mg/kg/day) or high-dose dexamethasone Anti-D immune globulin (50–75 mcg/kg/day, × one dose) if corticosteroids contraindicated IVIg (1 g/kg/day × one dose, repeat as necessary) if corticosteroids contraindicated
Second line therapies	
Reserved for patients with bleeding symptoms and platelets < 30×10^3 platelets/mm^3 (30×10^9/L) after an adequate trial of first-line agents	Splenectomy Rituximab (375 mg/m^2 once weekly for four doses) Eltrombopag (25–75 mg daily) Romiplostim (1–10 mcg/kg) Immunosuppressants
Hemorrhage	Platelet transfusion IVIg (1 g/kg/day × one dose, repeat as necessary) Methylprednisolone (1 g/day for 3 days)

Patient Encounter 2, Part 1: ITP

A 23-year-old female with history of a short respiratory illness presented with gingival bleeding, requiring swishing with icy water and nonitchy ecchymotic rash on her left forearm. Patient denied any history of hematemesis, epistaxis, hemoptysis, hematuria, melena, or trauma.

What patient information is suggestive of ITP?

What additional information for developing a treatment plan do you need to collect?

(10 × 10^9/L) and mucocutaneous bleeding; platelet counts less than 30 × 10^3/mm^3 (30 × 10^9/L) and moderate systemic or mucosal bleeding; or factors that may increase the risk of bleeding (such as participation in active contact sports increasing risk of head injury).[35] In adults, treatment is indicated when platelet counts are less than 30 × 10^3/mm^3 (30 × 10^9/L) or severe bleeding is present.[34]

▶ *Nonpharmacologic Therapy*

LO 8

Splenectomy In adults, splenectomy is generally considered after 3 to 6 months if the patient continues to require 10 to 20 mg/day of prednisone to maintain the platelet count greater than 30 × 10^3/mm^3 (30 × 10^9/L). Splenectomy may also be considered for urgent treatment of neurologic symptoms or for managing relapse despite an adequate trial of corticosteroids, IV immunoglobulin (IVIg), or anti-Rh(D). Even though individual patient response cannot be predicted, the majority (66%–88%) of refractory adult patients have a favorable response to splenectomy within several days; however, some patients will have no response or will experience a relapse sometime after splenectomy.

In children, splenectomy is usually reserved due to the self-limited nature of ITP and fear of infectious complications following splenectomy. However, splenectomy is recommended in children with ITP duration greater than 1 year with significant bleeding symptoms and unresponsive or intolerant of pharmacological therapies. Between 70% and 80% of children attain complete remission following splenectomy. Laparoscopic splenectomy is preferable to open splenectomy because it speeds the recovery and shortens the duration of hospitalization. The major drawback of splenectomy is bacterial sepsis, occurring at incidence rates of approximately 1%. Immunizations with *Haemophilus influenzae* type b, pneumococcal, and meningococcal vaccines are indicated in all patients 2 weeks prior to splenectomy.[36] Additional complications include thrombosis and pulmonary hypertension.

Platelet Transfusions Platelet transfusions are indicated if a patient has severe life-threatening bleeding, such as intracranial hemorrhage. In such situations, platelet transfusions are administered along with IVIg and glucocorticoids (discussed later).[35]

Additional Consideratons Patients with severe thrombocytopenia may need to restrict their participation in extreme contact sports. Medications that inhibit platelet aggregation (eg, nonsteroidal anti-inflammatory drugs [NSAIDs]) should be avoided.

▶ *Pharmacologic Therapy*

The general approach to management of ITP in adults is summarized in Table 67–8.

Patient Encounter 2, Part 2: ITP

PE/ROS:

Wt 60 kg; vital signs within normal limits.

Skin: round, macular, bluish in color, ecchymotic rash, 4 cm in diameter, located on left forearm. Oral cavity: bleeding gingival surfaces noted.

The rest of the examination is unremarkable.

Medications: None

Allergies: NKA

Labs:

WBC: 5.8 × 10^3/mm^3 (5.8 × 10^9/L) (normal 3.5–10.5 × 10^3/mm^3 [3.5–10.5 × 10^9/L])

Platelet count: 9 × 10^3/mm^3 (9 × 10^9/L); manual count: 15 × 10^3/mm^3 (15 × 10^9/L) (normal 140–440 × 10^3/mm^3 [140–440 × 10^9/L])

Platelet count 2 months prior: 240 × 10^3/mm^3 (240 × 10^9/L)

aPTT: 35 seconds (normal 25–40 seconds)

PT: 11 seconds (normal 10–12 seconds)

Hgb: 12.1 g/dL (121 g/L or 7.5 mmol/L) (normal 12.0–15.5 g/dL or 120–155 g/L or 7.50–9.61 mmol/L)

Hct: 35% (normal 34.9%–44.5%)

Peripheral blood smear:

WBC: few activated lymphocytes and neutrophils with left shift

RBC: normocytic and normochromic

Platelets: giant platelets seen

Disseminated intravascular coagulation ruled out based on laboratory test and blood film

HCV: negative

HIV: negative

H. pylori antibody: negative

Pregnancy: negative

Given this additional information, is this patient's presentation consistent with ITP?

Define treatment goals for this patient.

Glucocorticoids Glucocorticoids may decrease splenic sequestration of antibody-coated platelets, diminish antibody generation, and increase platelet output by the bone marrow. In adults, the response rate to oral prednisone (1 mg/kg/day) is 50% to 75%, with patients usually responding within the first 1 to 2 weeks. The duration of therapy depends on the platelet count response; guidelines advocate for a longer course of prednisone therapy (21 days), followed by a taper. High-dose dexamethasone (40 mg orally or intravenously daily) administered for 4 days in 14- to 28-day cycles has also been used successfully and may be superior to prednisone.[37] In children, oral or parenteral corticosteroids (prednisone, dexamethasone, methylprednisolone) can be used; various dosage regimens have been studied with no specific drug or dosage regimen showing superiority.[34]

LO 8

LO 8

IV Immunoglobulin (IVIg) IVIg impairs the clearance of platelets coated with IgG by activating inhibitory receptor

FcRγIIb. Roughly 80% of adults will respond to IVIg, but remission usually is not sustained. In adults, use of IVIg (1 g/kg/day given as a single dose, repeated if necessary) is reserved for situations in which rapid increase in platelet count is necessary, such as life-threatening bleeding and very low platelet count, or for patients who have contraindications to glucocorticoids. If treatment is indicated in children, a single dose of IVIg (0.8–1 g/kg) is usually effective. IVIg use is complicated by many serious adverse effects and high cost.

LO 8

Anti-Rh(D) Anti-Rh(D) can be used only in Rh(D)-positive patients who have not had splenectomy. It is as efficacious as IVIg and is generally less expensive. The indications for use of anti-Rh(D) are identical to those for IVIg. Anti-Rh(D) is a desirable form of treatment in chronic ITP when the goal is to circumvent long-term exposure to corticosteroids. Initial dose is 50 mcg/kg intravenously, with dosage adjustment recommended based on hemoglobin levels. Administration of anti-Rh(D) may increase the platelet count in about 70% to 80% of children with ITP. Response to anti-Rh(D) lasts about 3 to 5 weeks, and substantial numbers of patients treated repetitively with anti-Rh(D) can postpone or avoid splenectomy. Rare fatal intravascular hemolysis has been reported with use of anti-Rh(D); close monitoring for 8 hours after drug administration is recommended.

LO 8

Immunosuppressants Immunosuppressant therapy is generally utilized for patients who are refractory to or intolerant of all other ITP treatments. Rituximab, an anti-CD20 antibody, at a dose of 375 mg/m^2 once weekly for four doses, can induce long-term response in 21% to 27% of patients.[34] Progressive multifocal leukoencephalopathy (PML) has been rarely reported with rituximab use. Rituximab can be considered as a second- or third-line therapy in patients who have experienced treatment failure with corticosteroids, IVIg, or splenectomy. Screening for hepatitis B infection is required prior to rituximab initiation.

Azathioprine and cyclophosphamide produce response rates of 20% to 40% in adult patients who are treated for 2 to 6 months. Other medications used in ITP include vincristine, vinblastine, cyclosporine, danazol, and mycophenolate mofetil; due to major toxicities and lack of adequate evidence-based recommendations, their use is reserved for refractory ITP. All immunizations should be up to date prior initiating immunosuppressant therapy because these medications increase susceptibility to infections.

Thrombopoietic Growth Factors Additional treatment options for ITP include a thrombopoiesis-stimulating protein and a small-molecule thrombopoietin (TPO) receptor agonist. These agents stimulate the bone marrow to make enough platelets to overcome the body's premature destruction of platelets. Romiplostim and eltrombopag are two TPO mimetics that have been approved by the FDA for the treatment of thrombocytopenia in patients with chronic ITP who have had an insufficient response to corticosteroids, immunoglobulins, or splenectomy. Eltrombopag is approved for managing of childhood ITP.

LO 8

Romiplostim is a TPO peptide mimetic that binds to and activates the human TPO receptor. Romiplostim works by stimulating megakaryopoiesis, which results in enhanced platelet production. Initial dose of romiplostim is 1 mcg/kg subcutaneously once weekly based on the actual body weight. Dose can be adjusted weekly by increments of 1 mcg/kg until the patient achieves a platelet count greater than or equal to 50×10^3/mm^3 (50×10^9/L) as necessary to reduce the risk for bleeding. The maximum dose is 10 mcg/kg/week. Studies demonstrate long-term efficacy of romiplostim over treatment periods of 5 years.[38]

Eltrombopag is a nonpeptide thrombopoietin receptor agonist with a low immunogenic potential that stimulates megakaryocyte proliferation and differentiation. Eltrombopag has been shown to increase platelet counts and decrease bleeding eposides in patients with ITP.[39] The usual daily dose is 50 mg by mouth once daily; it is subsequently adjusted to a maximum dose of 75 mg daily in order to achieve and maintain a platelet count greater than or equal to 50×10^3/mm^3 (50×10^9/L) in order to reduce the risk for bleeding. Studies demonstrate long-term efficacy over treatment periods of 3 years.[38,40]

Both agents need to be discontinued if platelet counts do not increase after 4 weeks at a maximum dose.

Romiplostim and eltrombopag are effective in increasing platelet counts in patients with ITP and can be used in combination with therapies that inhibit platelet destruction. Although usually well tolerated, a number of rare but serious risks have been reported, including changes in the bone marrow, worsened thrombocytopenia and the risk of bleeding after cessation of the medication, thrombotic/thromboembolic complications (including portal vein thrombosis with eltrombopag), and worsening of blood cancers. Eltrombopag carries a "black box warning" regarding increased risk of hepatotoxicity. Monitoring of hepatic enzymes every 2 weeks initially, followed by every 4 weeks thereafter, is recommended. In patients with hepatitis C treated with interferon and ribavirin, eltrombopag increases the risk of hepatic decompensation. It is also associated with development of cataracts and has several significant drug–drug interactions.

TPO-mimetic agents are expensive. Their use is generally reserved for patients who have treatment-resistant ITP after trying splenectomy and rituximab. These agents can also be tried in patients intolerant to other therapies, or in combination with other therapies.

Fostamatinib is a tyrosine kinase inhibitor that received FDA approval for ITP in adults who have insufficient response to a previous treatment (approved April 2018). Place in therapy for this new medication remains to be determined.

Outcome Evaluation

- Monitor platelet counts as indicated clinically.
- In adults, the goal of therapy is to maintain platelet count greater than or equal to 30×10^3/mm^3 (30×10^9/L).
- Monitor for signs and symptoms of bleeding.

THROMBOTIC MICROANGIOPATHIES

Epidemiology and Etiology

TMAs include a diverse variety of disorders with different pathophysiological features. Typical presentation includes small vessel (microangiopathic) hemolytic anemia with thrombocytopenia. Microvascular thrombosis occurs due to defects in the endothelium of small vessels, such as arterioles and capillaries.[41]

Patient Encounter 2, Part 3: ITP: Creating a Care Plan

Based on the information presented, create a care plan for this patient. If pharmacologic therapy is indicated, list first-line and alternative therapies.

Patient Care Process ITP

Collect Information:

- Conduct physical examination evaluating sites of bleeding. Obtain a complete medical and medication history.
- Evaluate CBC, peripheral blood smear, and Rh(D) status; order tests to rule out other diseases commonly associated with thrombocytopenia.

Assess the Information:

- Determine whether ITP is likely due to primary or secondary causes (this may change treatment focus).
- Evaluate platelet count, occupational risks of bleeding, and actual bleeding severity to determine the initial treatment approach.
- Identify relevant goals of therapy based on patient's platelet counts and presence or absence of bleeding.
- Based on patient data, determine if patient has contraindications to any potential ITP therapeutic options.

Develop a Care Plan:

- Choose medications and doses that are optimal for the patient.
- First-line treatment for patients meeting criteria for pharmacotherapy is corticosteroids for up to 21 days. Anti-Rh(D) or IVIg can be considered if corticosteroids are contraindicated or rapid rise in platelet count is necessary. Alternatives to first-line agents include immunosuppressants and TPO mimetics, which are reserved for patients failing to respond after adequate trial of first-line agents. Surgical splenectomy is reserved for refractory ITP.

Implement the Care Plan:

- Educate the patient about new medications in their regimen, discuss drug administration and side effects, especially focusing on serious effects and their management.
- Address any patient concerns about ITP and its management.
- Discuss importance of medication adherence and follow-up monitoring to achieve optimal outcomes. Determine whether there are any barriers to adherence. Educate patient's caregivers, if applicable.
- Review vaccination history and recommend appropriate vaccinations.
- Determine patient's ability to afford prescribed pharmacotherapy.

Follow-up: Monitor and Evaluate:

- Adhere to prescriber's recommendations on appropriate frequency of follow-up (depends on severity at presentation and pharmacotherapy chosen).
- Review platelet response and bleeding to assess changes in clinical status and evaluate pharmacotherapy for efficacy and safety. In adults, once response is achieved, monitor regularly to ensure platelet counts stay above $30 \times 10^3/mm^3$ ($30 \times 10^9/L$).
- Determine whether the patient is experiencing any adverse reactions or drug interactions.

LO 9

Primary TMAs include thrombotic thrombocytopenic purpura (TTP), shiga toxin-mediated hemolytic uremic syndrome (ST-HUS), immune or dose-related drug-induced TMA, complement-mediated TMA, metabolism-mediated TMA, and coagulation-mediated TMA. Classification and causes of primary TMA are summarized in Table 67–9. Here, we will focus on TTP and complement-mediated TMAs.

Table 67–9

Thrombotic Microangiopathy Syndromes

Name	Notes
TTP (ADAMTS13 deficiency)	Hereditary presents in children, acquired usually presents in adults.
Shiga toxin-mediated hemolytic uremic syndrome (ST-HUS)	Triggered by *Shigella dysenteriae* or *Escherichia coli* Shiga-toxin producing infection.
Drug-induced	Can be mediated by immune reaction (eg, quinine) or related to the increased dose (eg, bevacizumab, sunitinib).
Complement-mediated	Mutations in complement factor H (CFH), CD46, complement factors I (CFI), B (CBF).
Coagulation-mediated	Genetic abnormalities in proteins mediating coagulation (eg, thrombomodulin gene [THBD], diacylglycerol kinase epsilon [DGKE]).

Thrombotic Thrombocytopenic Purpura

TTP is a severe systemic disorder characterized by thrombi formation within the circulation that results in the platelet consumption and subsequent thrombocytopenia.[41] TTP can occur in all ages, and can be hereditary or acquired. Both types of TTP are very rare; the estimated annual incidence of acquired TTP is three cases per million adults.[42]

▶ *Pathophysiology*

LO 9

Endothelial cells normally synthesize vWF in the form of a high-molecular-weight multimer composed of smaller identical monomers. Each monomer is able to bind platelets, and the number of monomers on the vWF multimer is directly proportional to its platelet-binding capacity. Consequently, particularly adherent ultra-large molecules of vWF (ULvWF) are broken down to smaller size by vWF-cleaving proteases such as ADAMTS13 (a disintegrin and metalloprotease with thrombospondin type 1 repeats) to avoid undesired clot formation. TTP results from inherited deficiency in the vWF-cleaving protease ADAMTS13 activity, or development of autoimmune inhibitors to ADAMTS13. This, in turn, elevates circulating levels of ULvWF, leading to inappropriate platelet agglutination. Thrombocytopenia develops because the rate of aggregated platelet consumption is faster than megakaryocyte bone marrow production. Microangiopathic hemolytic anemia generally follows as a consequence of red blood cell damage by platelet clumps occluding the microcirculation. Occlusive ischemia of the brain or GI tract

is common. TTP is distiguished from other TMAs for rarely causing renal abnormalities.

▶ *Desired Outcomes*

The main goal of TTP treatment is to prevent end-organ damage.

▶ *Nonpharmacologic Therapy*

LO 9 KEY CONCEPT The present standard of treatment for hereditary TTP is plasma infusion containing ADAMTS13 protease. For acquired TTP, urgent plasma exchange (PEX) is needed to remove ADAMTS13 inhibitor. If PEX is unavailable, treatment with plasma infusion and glucocorticoids is indicated until PEX is available.[43]

LO 9 **Plasma Exchange** The procedure involves removal of the patient's plasma and its substitution with donor plasma. In this manner, circulating antibody inhibitor to ADAMTS13 is removed and enzyme is replenished. PEX involves placement of two IV lines (cannulae) into two separate veins. Blood removed through one cannula is centrifuged to separate the blood cells from the plasma. The blood cells are mixed subsequently with donor plasma and returned to the patient via the second cannula. The goal is to exchange 1 to 1.5 plasma volumes (40–60 mL/kg). The procedure generally is repeated daily until neurologic symptoms resolve and normal lactate dehydrogenase (LDH) and platelet counts are maintained for several days. After complete remission is achieved, PEX frequency can be reduced to every other day for an additional few days, with subsequent PEX discontinuation and close patient follow-up. When PEX is started immediately upon diagnosis, remission and survival rates at 6 months are approximately 80%. Although generally considered safe, complications from catheter insertion or catheter infection may occur and include hemorrhage, pneumothorax, sepsis, and thrombosis. Allergic reactions to plasma can cause severe hypotension and hypoxia.[44]

LO 9 **Splenectomy** Splenectomy is reserved for patients with frequently relapsing disease who are refractory to PEX or immunosuppressive therapy.

▶ *Pharmacologic Therapy*

LO 9 **Glucocorticoids** Glucocorticoids can be used for their immunosuppressive effect in combination with PEX; however, they are not as efficacious as monotherapy in TTP. The most commonly used agents are methylprednisolone 250 mg/day IV for or prednisone 1 mg/kg/day orally for the duration of PEX therapy and 1 to 2 weeks after normalized platelet counts are maintained.

LO 9 **Immunosuppressants** TTP that fails to respond adequately to PEX can be treated with immunosuppressive agents. Cytotoxic immunosuppressive therapies with the most potential benefit in refractory TTP include cyclosporine and rituximab. Other agents that had been used include bortezomib, vincristine, cyclophosphamide, azathioprine, and mycophenolate mofetil.[43]

Complement-Mediated TMA

LO 9 This type of TMA results from a genetic mutations of various factors responsible for alternative pathway of complement activation. Generally thought to be triggered by an infectious episode in predisposed patients, uncontrolled complement activation leads to formation of membrane attack complexes that cause endothelial damage, TMA, and renal failure.[45]

▶ *Nonpharmacologic Therapy*

LO 9 Supportive therapy may include blood or platelet transfusions, maintenance of fluid balance to support adequate end-organ perfusion, and dialysis therapy. Liver-kidney transplantation provides cure for this type of TMA, but is associated with significant complications.

▶ *Pharmacologic Therapy*

LO 9 Eculizumab is a humanized monoclonal antibody that binds to complement component C5, thus preventing formation of C5b and subsequent formation of C5b-9 (membrane attack complex).[46] Complement genetic studies may be helpful in determining whether a patient is a good candidate to receive eculizumab (eg, patients with C5 mutations may not be best candidates). For best results, treatment should be started within 48 hours of presentation; the usual adult dose is 900 mg intravenous infusion once weekly for 4 doses, followed by 1200 mg on week 5 and

Clinical Presentation and Diagnosis of Thrombotic Microangiopathies[a]

Onset and typical features will vary depending on precipitating cause.

1. Thrombocytopenia
   - Thrombocytopenic purpura
   - Bleeding
2. Fever (sometimes)
3. Microangiopathic hemolytic anemia
4. Neurologic symptoms (sometimes)
   - Headache, confusion, difficulty speaking, transient paralysis, numbness
5. Renal abnormalities (rare with TTP, common with other TMA types)
   - Proteinuria, hematuria, mild or severe renal insufficiency

Laboratory Testing

- Decreased ADAMTS 13 activity (< 10% or normal)—TTP
- Decreased hemoglobin, hematocrit, and platelets
- Peripheral blood smear showing schistocytes
- Decreased serum haptoglobin
- Elevated LDH
- Elevated indirect bilirubin level
- Elevated reticulocyte count
- Normal PT and aPTT
- Elevated urine protein, red blood cells, and/or serum creatinine, decreased urine output

[a]Thrombotic microangiopathies diagnosis can be based on the presence of thrombocytopenia and microangiopathic hemolytic anemia in the absence of other possible causes.

Patient Encounter 3, Part 1: TTP

A 21-year-old African female was seen in the emergency room for severe headache, confusion, chills, nausea and vomiting, and purplish pin-point nonitchy rash and petechiae on the abdomen. Patient has no history of gingival bleeding, hematemesis, melena, hematochezia, or autoimmune diseases including SLE and is otherwise healthy.

What patient information is suggestive of TTP?

What additional information for developing a treatment plan do you need to collect?

Patient Encounter 3, Part 2: TTP

PE/ROS:

Young WNWD female in no distress

Wt 70 kg, T 101.3°F (38.5°C), BP 128/75 mm Hg, HR 80 beats/min, RR 18 breaths/min

Neuro: patient appears confused but oriented × 3

Skin: disseminated purplish pin-point nonitchy rash and bruises on the abdomen

The rest of the examination is unremarkable

No familial history of hematologic disorders

Medications: none

Allergies: NKA

Labs:

- Platelet count: $8 \times 10^3/mm^3$ ($8 \times 10^9/L$) (normal 140–440 × $10^3/mm^3$ [140–440 × $10^9/L$])
- aPTT: 35 seconds (normal 25–40 seconds)
- PT: 11 seconds (normal 10–12 seconds)
- Haptoglobin: 10 mg/dL (100 mg/L) (normal 30–200 mg/dL or 300–2000 mg/L)
- LDH: 1057 U/L (17.62 µkat/L) (normal 100–250 U/L, or 1.67–4.17 µkat/L)
- Hgb: 7.1 g/dL (71 g/L; 4.34 mmol/L) (normal 12.0–15.5 g/dL or 120–155 g/L or 7.50–9.61 mmol/L)
- Hct: 22% (normal 34.9%–44.5%)
- Blood peripheral smear: numerous schistocytes (10–15 per high power field)
- SCr: 0.8 mg/dL (71 µmol/L) (normal 0.6–1.2 mg/dL [53–106 µmol/L])
- ADAMTS13 activity: < 5% (normal ≥ 60%)
- Anti-ADAMTS13 IgG: 3.2 units/mL [normal ≤ 0.4 units/mL]
- Imaging studies: CT-scan head–unremarkable
- Pregnancy test: negative

Given this additional information, is this patient's presentation consistent with TTP?

What is the likely etiology of this patient's TTP?

Define treatment goals for this patient.

Patient Encounter 3, Part 3: TTP: Creating a Care Plan

Based on the information presented, create a care plan for this patient.

Patient Care Process for Thrombotic Microangiopathy

Collect Information:

- Obtain a complete medical and medication history.
- Evaluate CBC, vital signs, neurologic symptoms, chemistry 7 panel, and urinalysis for presence of thrombocytopenia, fever, anemia, and renal abnormalities. Evaluate neurologic symptoms and peripheral blood smear.

Assess the Information:

- Identify the primary cause of TMA to evaluate appropriate targeted treatment selection.
- Identify appropriate goals of therapy based on patient's presentation.
- Based on patient data, determine if patient has contraindications to any potential therapeutic options.

Develop a Care Plan:

- Choose medication and doses (if applicable) that are optimal for the patient.
- If patient meets clinical criteria for diagnosis of acquired TTP, start daily PEX as soon as possible. Glucocorticoids and other adjunctive therapies may be considered.

Implement the Care Plan:

- Educate the patient about new medications in their regimen, discuss drug administration and side effects, especially focusing on serious effects and their management.
- Address any patient concerns about specific TMA and its management.
- Discuss importance of medication adherence and follow-up monitoring to achieve optimal outcomes. Determine whether there are any barriers to adherence. Educate patient's caregivers, if applicable.
- Review vaccination history and recommend appropriate vaccinations.
- Determine patient's ability to afford prescribed pharmacotherapy.

Follow-up: Monitor and Evaluate:

- Adhere to prescriber's recommendations on appropriate frequency of follow-up (depends on severity at presentation and pharmacotherapy chosen). When platelet counts stay above $150 \times 10^3/mm^3$ ($150 \times 10^9/L$) for 2 days, PEX may be discontinued; glucocorticoids may be continued for additional 1 to 2 weeks.
- Determine whether the patient is experiencing any adverse reactions or drug interactions.
- Follow patients indefinitely with periodic CBC/LDH measurements to screen for possible relapse.

1200 mg every 2 weeks thereafter. All immunizations should be up to date in patients considered for this therapy, as it can increase the risk of serious infections, including meningiococcal infection. PEX or plasma infusion are alternative therapies, since eculizumab therapy is very expensive.

Abbreviations Introduced in This Chapter

ADAMTS13	A disintegrin and metalloprotease with thrombospondin type 1 repeats (vWF-cleaving metalloprotease)
BU	Bethesda units
DDAVP	1-Desamino-8-D-arginine vasopressin (desmopressin acetate)
DIC	Disseminated intravascular coagulation
FFP	Fresh-frozen plasma
HCV	Hepatitis C virus
ICH	Intracranial hemorrhage
ITP	Immune thrombocytopenia
IVIg	IV immunoglobulin
PCC	Prothrombin complex concentrate
PEX	Plasma exchange
rFVIIa	Recombinant factor VIIa
RICD	Recessively inherited coagulation disorder
TTP	Thrombotic thrombocytopenic purpura
ULvWF	Ultra-large molecules of vWF
vWD	von Willebrand disease
vWF	von Willebrand factor

68 Sickle Cell Disease

Tracy M. Hagemann and Teresa V. Lewis

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

1. Explain the underlying causes of sickle cell disease (SCD) and their relationship to patient signs and symptoms.
2. Identify the typical characteristics of SCD as well as symptoms that indicate complicated disease.
3. Identify the desired therapeutic outcomes for patients with SCD.
4. Recommend appropriate pharmacotherapy and nonpharmacotherapy interventions for patients with SCD.
5. Recognize when chronic maintenance therapy is indicated for a patient with SCD.
6. Describe the components of a monitoring plan to assess effectiveness and adverse effects of pharmacotherapy for SCD.
7. Educate patients about the disease state, appropriate therapy, and drug therapy required for effective treatment and prevention of complications.

INTRODUCTION

KEY CONCEPT "Sickle cell syndrome" refers to a collection of autosomal recessive genetic disorders that are characterized by the presence of at least one sickle hemoglobin (HbS) gene.[1,2]

Sickle cell disease (SCD) is a chronic illness that is associated with frequent crisis episodes. Acute complications are unpredictable and potentially fatal. Common symptoms include excruciating musculoskeletal pain, life-threatening pneumonia-like illness, cerebrovascular accidents, and splenic and renal dysfunction.[2] As the disease progresses, patients may develop organ damage from the combination of hemolysis and infarction. Because of the complexity and severity of SCD, it is imperative that patients have access to comprehensive care with providers who have a good understanding of the countless clinical presentations and the management options of this disorder.

EPIDEMIOLOGY AND ETIOLOGY

LO 1 Sickle cell trait (SCT) is the heterozygous form (HbAS) of SCD in which a person inherits one normal adult hemoglobin (*HbA*) gene and one sickle hemoglobin (*HbS*) gene. These individuals are carriers of the SCT and are usually asymptomatic.[2] About 1 in 13 African American babies is born with SCT.[3] Symptomatic disease is seen in homozygous and compound heterozygous genotypes of SCD. Sickle cell anemia (SCA) is the homozygous (HbSS) state of SCD.[2] It is the most common and severe form of SCD. SCD affects both males and females equally because it is not a sex-linked disease.

KEY CONCEPT Around 100,000 Americans have SCD and it occurs in approximately 1 out of every 365 African American births.[3] HbSS (~75%) is the most common genotype, followed by HbSC (~18%), HbSβ^+-thalassemia (~5%), and HbSβ^0-thalassemia (~2%). Other variants account for fewer than 1% of patients.[2,4] For every infant diagnosed with SCD, 50 are identified as carriers.[4]

Having the *HbS* gene protects heterozygous carriers from succumbing to *Plasmodium falciparum* (malaria) infection.[1] The microorganism cannot parasitize abnormal red blood cells (RBCs) as easily as normal RBCs. Consequently, persons with heterozygous sickle gene (*SCT*) have a selective advantage in tropical regions where malaria is endemic.

The highest incidence of SCD is seen in those with African heritage, but SCD also affects persons of Indian, Saudi Arabian, Mediterranean, South and Central American, and Caribbean ancestry.[4]

Normal HbA is composed of two α-chains and two β-chains (α2β2).[1] A single substitution of the amino acid valine for glutamic acid at position 6 of the β-polypeptide chain is responsible for the production of a defective form of hemoglobin called HbS.[1] Different genetic mutations encode for other hemoglobin variants such as hemoglobin C (HbC).[1] The α-chains of HbS, HbA, and HbC are structurally identical. The chemical differences in the β-chain are responsible for RBC sickling and its associated sequelae.

The HbSS state of SCD occurs when individuals inherit the mutant *HbS* gene from both parents. The progeny of two carriers will have a 25% probability of having SCD and a 50% risk of being a carrier. β-Thalassemia can be found in conjunction with HbS. Patients with HbSS and HbSβ^0-thalassemia do not have normal β-globulin production and usually have a more severe course than those with HbSC and HbSβ^+-thalassemia.

LO 1 Impaired circulation, destruction of RBCs, and vascular stasis are three known problems that are primarily responsible for the clinical manifestations of SCD (Figure 68–1).

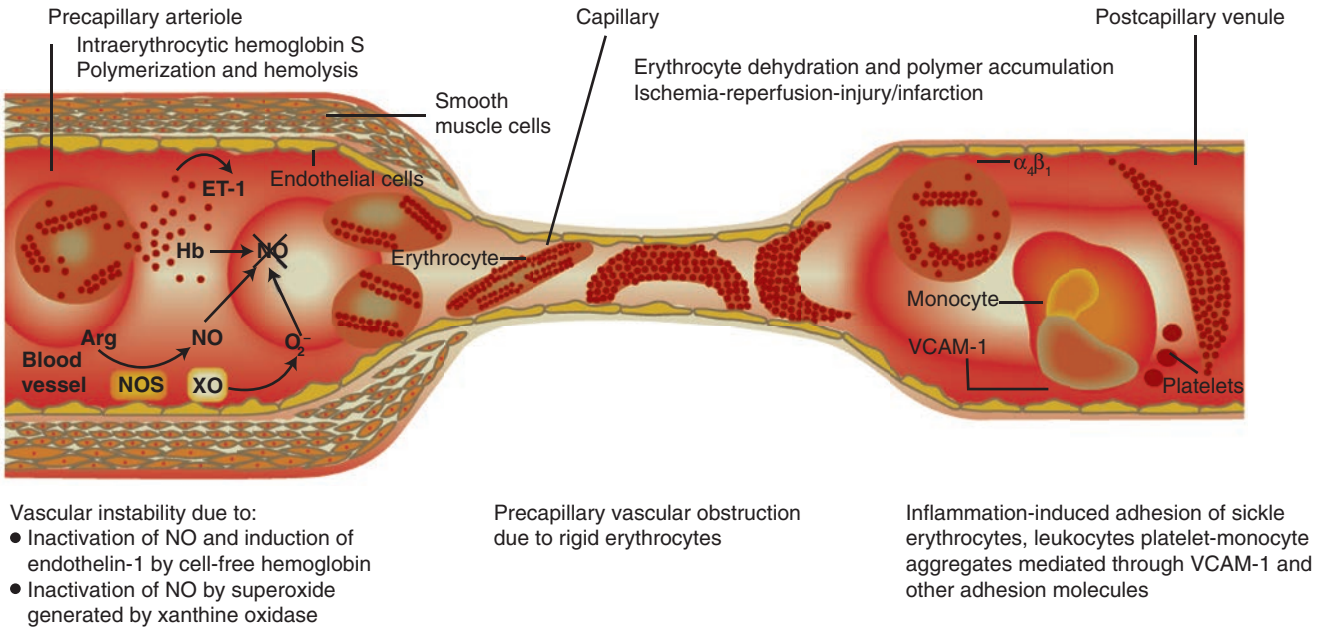

FIGURE 68–1. Pathophysiology of SCD. (Arg, arginine; ET-1, endothelin-1; Hb, hemoglobin; NO, nitric oxide; NOS, nitrous oxide synthase; VCAM-1, vascular cell adhesion molecule 1; XO, xanthine oxidase.) (From Kato GJ, Gladwin MT. Sickle cell disease. In: Hall JB, Schmidt GA, Wood LDH, eds. Principles of Critical Care, 3rd ed. New York, NY: McGraw-Hill; 2005:1658.)

PATHOPHYSIOLOGY

KEY CONCEPT SCD involves multiple organ systems, and its clinical manifestations vary greatly between and among genotypes.

Sickle Hemoglobin Polymerization

The primary event in the molecular pathogenesis of SCD involves polymerization of deoxygenated HbS. HbS carries oxygen normally, and when oxygenated, the solubility of HbS and HbA are the same. Once the oxygen is unloaded to the tissues, HbS solubility decreases. This promotes hydrophobic interactions between the hemoglobin molecules and polymerization, which leads to the distortion of the RBC into the characteristic crescent or sickle shape.[1]

Viscosity of Erythrocytes and Sickle Cell Adhesion

LO 2

When HbS becomes reoxygenated, the polymers within the RBCs disappear, and the cells eventually return to normal shape. Vasoocclussion is caused by a combination of factors. Repeated assaults on RBCs from sickling and unsickling can lead to cell membrane damage, loss of membrane flexibility, and rearrangement of surface phospholipids. The life span of sickled RBCs is markedly shorter (10–20 days) than that of normal RBCs (100–120 days). As intracellular membrane viscosity of HbS-containing RBCs increases, blood viscosity increases, which further contributes to vasoocclusion.[5] There is also increasing evidence that suggest sickle cells adhere to vascular endothelium.[1,5] The combined effects of decreased RBC deformability, slow transit through microcirculation, and adhesion to vascular endothelium contribute to obstruction of small and sometimes large blood vessels. The resulting local tissue hypoxia can accentuate the pathologic process of SCD.

Protective Hemoglobin Types

Fetal hemoglobin (HbF) binds oxygen more tightly than HbA, and it has a decreased propensity to sickling. HbA2 also possesses this characteristic but to a lesser extent. RBCs that contain HbF sickle less readily than cells without. HbF is composed of two α chains and two γ chains; therefore, it is not affected by point mutations on β chains. Irreversibly sickled cells (ISCs) are found to have low HbF concentrations. In some patients, higher HbF may ameliorate the disease.

Other Pathophysiologic Effects

LO 2

Other factors may be responsible for the pathogenesis of some of the clinical features of SCD. Sickle cells can obstruct blood flow to the spleen leading to functional asplenia. Impaired splenic function can increase the propensity to infection by encapsulated organisms, particularly *Streptococcus pneumoniae*.[1] Additionally, coagulation abnormalities are not uncommon since almost every component of hemostasis is altered in SCD.

Clinical Presentation and Diagnosis of SCT

General

- Generally asymptomatic

Symptoms

- Females may have frequent urinary tract infections

Signs

- Microscopic hematuria occurs rarely
- Gross hematuria may occur spontaneously or with heavy-intensity exercise

Laboratory Tests

- Normal Hgb values

Clinical Presentation and Diagnosis of SCD

General

- Identified by neonatal screening before 2 months of age in the United States

Symptoms

- Painful vasoocclusive crises are the hallmark of SCD
- Dactylitis (hand–foot syndrome) before age 1 year
- May develop infarction of the spleen, liver, bone marrow, kidney, brain, and lungs
- Gallstones
- Priapism in males
- Slow-healing lower extremity ulcers after trauma or infection
- Weakness, fatigue

Signs

- Chronic hemolytic anemia is common
- Enlargement of spleen and heart
- Scleral icterus

Laboratory Tests

- Hgb 7.0 to 10.0 g/dL (70–100 g/L or 4.34–.21 mmol/L)
- Low HgF and increased reticulocytes, platelets, and white blood cells (WBCs)
- Presence of sickled cells on blood smear
- Neonatal screening: hemoglobin electrophoresis, isoelectric focusing, or DNA analysis

TREATMENT

Desired Outcomes

LO 3 Multidisciplinary, regularly scheduled care is required over the lifetime of the SCD patient, with the goal of reduction of complications and hospitalizations. Comprehensive care should include medical, educational, and psychosocial aspects as well as genetic and medication counseling.

LO 3 Therapeutic interventions for SCD should be targeted at preventing and/or minimizing the symptoms related to the disease and its complications. The goals of treatment are to reduce or eliminate the patient's symptoms; decrease the frequency of sickle crises, including vasoocclusive pain crises; prevent the development of complications; and maintain or improve the quality of life through decreased hospitalizations and decreased morbidity. Specific therapeutic options may:

- Maintain or increase the hemoglobin level to the patient's baseline
- Increase the HbF concentration
- Decrease the HbS concentration
- Prevent infectious complications
- Prevent or effectively manage pain
- Prevent central nervous system (CNS) damage, including stroke

General Approach to Treatment

Patients should be educated to recognize the signs and symptoms of complications that would require urgent evaluation. Patients and parents of children with SCD should be educated to seek immediate medical care when a fever develops or signs of infection occur. With acute illnesses, prompt evaluation is important, as deterioration may occur rapidly. Fluid status should be monitored to avoid dehydration or overhydration, both of which may worsen complications of SCD. Patients in acute distress should maintain oxygen saturation at 92% (0.92) or at their baseline. Any supplemental oxygen requirements should be evaluated.[4]

Nonpharmacologic Therapy

LO 4 Patients should avoid smoking and excessive alcohol intake. Patients with SCD should maintain adequate hydration in order to help decrease blood viscosity and should be educated to avoid extreme temperature changes and to dress properly in hot and cold weather. Physical exertion that leads to complications should be avoided.[4] Regular examinations, including ophthalmic, dental, renal, pulmonary, and cardiac function, are required to monitor for organ damage. A treatment overview is shown in Table 68–1.

Pharmacologic Therapy

▶ *Health Maintenance*

Immunizations Children with SCD should receive the required immunizations as recommended by the American Academy of Pediatrics and the Advisory Committee on Immunization Practices, including vaccination for meningococcal disease.[6] Additionally, influenza vaccine should be administered yearly to SCD patients 6 months of age and older, including adult patients. All adult patients with SCD should also receive the vaccine for meningococcal disease as well as a one-time dose of *Haemophilus influenzae* type b vaccine. The quadrivalent conjugate meningococcal vaccine should be administered in two doses at least 2 months apart and should be revaccinated every 5 years.[7] In addition, adults should be vaccinated with the serogroup B meningococcal vaccine with either a 2-dose series of MenB-4C at least 1 month apart, or a 3-dose series of MenB-FHbp at 0, 1–2, and 6 months.[7]

Because patients with SCD have impaired splenic function, they are less adequately protected against encapsulated organisms such as *S. pneumoniae*, *H. influenzae,* and *Salmonella*. KEY CONCEPT

LO 4 The use of pneumococcal vaccine in combination with penicillin prophylaxis in SCD patients has dramatically decreased the rates of morbidity and mortality; however, there are still groups of SCD children who continue to have high rates of invasive pneumococcal infections.[8,9] Infection is the leading cause of death in children with SCD younger than 3 years of age.[9] Two pneumococcal vaccines are available. The 13-valent pneumococcal conjugate vaccine (PCV 13: Prevnar) is routinely administered to infants and children and provides good protection against the 13 most common isolates seen in this age range. Administer the first dose of PCV 13 between 6 weeks and 6 months of age, followed by two additional doses at 2-month intervals and a fourth dose at 12 to 15 months of age. The 23-valent polysaccharide vaccine (PPSV 23: Pneumovax 23) is indicated for children older than 2 years and adults. Because PPSV 23 is a polysaccharide vaccine, children younger than 2 years do not respond well. PPV 23 contains the 23 most common isolates of *S. pneumoniae* seen in older children and adults. Because of the different serotypes seen in the two vaccines, it is recommended that children with SCD receive both vaccines, with a dose of PPSV 23 administered after the child turns 2 years of age. The dose of PPSV 23 should be separated from the last dose of PCV 13 by at least 2 months.

Table 68–1

Management of SCD

Options and Comments	
Health Maintenance	
Infection prophylaxis	• Pneumococcal vaccines (PCV 13 and PPV 23) • Penicillin prophylaxis for children younger than 5 years of age • Annual influenza vaccine
Induction of fetal hemoglobin	• Hydroxyurea is the primary agent • Other agents are butyrates (arginine butyrate and sodium phenylbutyrate), decitabine, clotrimazole, and erythropoietin • Combination HbF inducers have been proposed
Chronic transfusion therapy	• Primary indication: stroke prevention in pediatric patients • May also reduce pain crisis and acute chest syndrome • Goal: maintain HbS < 30% (0.30)
Future Prospects	
Transplantation	• May potentially cure the disease • Most experience is with HLA-matched donors; umbilical cord blood transplantation is being evaluated
L-Glutamine	• Decreases complications • FDA approved 2017
Crises and Complications	
Fever and infection	• Broad-spectrum antibiotic: cefotaxime or ceftriaxone (clindamycin for cephalosporin allergy); vancomycin for staphylococcal and resistant pneumococcal organisms • Fluids • Acetaminophen or ibuprofen for fever
Stroke	• Exchange transfusion • Initiate chronic transfusion therapy to prevent recurrent strokes
Acute chest syndrome	• Broad-spectrum antibiotics (include Mycoplasma coverage) • Bronchodilator if wheezing or history of reactive airway disease • Fluids • Pain management • Transfusion
Pain crisis	• Hydration • Analgesics

An additional dose of PPSV 23 should be given to children 3 to 5 years of age to ensure antibody response. This second dose should be administered 5 years after the first PPSV 23 dose. All adults with SCD should be vaccinated with both PCV 13 as well as PPSV 23. Adults and children who have not previously received PCV13 or PPSV 23 should receive one dose of PCV 13 followed by a single dose of PPSV 23 at a minimum of 8 weeks later.[7] If an adult or child with SCD has already received at least one dose of PPSV 23, they should additionally receive one dose of PCV 13 at least 1 year after the dose of PPSV 23. When both vaccines are indicated in an unvaccinated patient with SCD, PCV 13 should be administered first, followed by a dose of PPSV 23 at least 8 weeks later.[7] A one-time revaccination with PPSV 23 should occur 5 years after the first dose of PPSV 23.[7] Because some children fall behind on their childhood vaccinations, a catch-up schedule is presented in Table 68–2.[6]

LO 4 LO 5 **Penicillin** KEY CONCEPT Children with SCD should receive prophylactic penicillin until at least the age of 5 years, even if they have been appropriately immunized against pneumococcal infections. Penicillin V potassium is typically initiated at age 2 months, with a dose of 125 mg orally twice daily until age 3 years, then 250 mg orally twice daily until 5 years of age. Amoxicillin 20 mg/kg/day divided every 12 hours (maximum of 250 mg/dose) can also be used. The intramuscular use of benzathine penicillin 600,000 units every 4 weeks from age 6 months to 6 years is also an option for nonadherent patients. Penicillin-allergic patients may receive erythromycin 10 mg/kg twice daily. Penicillin prophylaxis usually is not continued in children older than 6 years, but may be considered in patients with a history of invasive pneumococcal infection or surgical splenectomy.[4,10]

LO 4 **Folic Acid** Folic acid supplementation with 1 mg daily is generally recommended in adult SCD patients, women considering pregnancy, and any SCD patient with chronic hemolysis.[4] Because of accelerated erythropoiesis, these patients have an increased need for folic acid. There are conflicting studies in the SCD population, especially among infants and children, but if the child has chronic hemolysis, supplementation is recommended.[11]

Fetal Hemoglobin Inducers HbF induction in patients with SCD, especially those with frequent crises, has been shown to decrease RBC sickling and RBC adhesion. A direct relationship between HbF concentrations and the severity of disease has been demonstrated in studies.[2]

Hydroxyurea Hydroxyurea is a ribonucleotide reductase inhibitor that prevents DNA synthesis and traditionally has been used in chemotherapy regimens. Studies in the 1990s found that hydroxyurea increases HbF levels as well as increasing the number of HbF-containing reticulocytes and intracellular HbF. Other beneficial effects of hydroxyurea include antioxidant properties, reduction of neutrophils and monocytes, increased intracellular water content leading to increased red cell

Table 68–2

Pneumococcal Immunization for Children with SCD[6,8]

	Recommended Schedule
Previously Unvaccinated	
Age 2–6 months	PCV 13 (Prevnar): three doses 8 weeks apart; then one dose at 12–15 months
Age 7–11 months	PCV 13 (Prevnar): two doses 8 weeks apart; then one dose at 12–15 months
Age 12–23 months	PCV 13 (Prevnar): two doses 8 weeks apart
Age 24–71 months	PCV 13 (Prevnar): two doses 8 weeks apart PPV 23 (Pneumovax): two doses; first dose at least 8 weeks after last PCV 13 dose; second dose 5 years after the first PPV 23 dose
Age 5 years or older	PCV 13 (Prevnar): one dose PPV 23 (Pneumovax): one dose at least 8 weeks after last PCV 13 dose; second dose 5 years after the first PPV 23 dose
Previously Vaccinated	
Age 12–23 months, incomplete PCV 13 series	PCV 13 (Prevnar): two doses 8 weeks apart
Age 24–71 months, any incomplete schedule or completed less than three doses with PCV 13	PCV 13 (Prevnar): two doses 8 weeks apart PPV 23 (Pneumovax): two doses; first dose at least 6–8 weeks after last PCV 13 dose; second dose 5 years after the first PPV 23
Age 24–71 months, any incomplete schedule of three doses or four doses of PCV 13	PCV 13 (Prevnar): one dose at least 8 weeks after the most recent dose PPV 23 (Pneumovax): two doses; first dose at least 6–8 weeks after last PCV 13 dose; second dose 5 years after the first PPV 23
Age 24–71 months, one dose PPV 23 given	PCV 13 (Prevnar): one dose at least 8 weeks after PPV 23 dose
Age 5–18 years, received one dose PPV 23	PPV 23 (Pneumovax): second dose 5 years after first PPV 23 PCV 13 (Prevnar): one dose at least 8 weeks after PPV 23 If only received one dose of PPV 23 (Pneumovax): second dose 5 years after the first PPV 23 dose

deformability, decreased red cell adhesion to endothelium, and increased levels of nitric oxide, which is a regulator involved in physiologic disturbances.[12]

KEY CONCEPT Hydroxyurea reduced the frequency of hospitalizations and the incidences of pain, acute chest syndrome (ACS), and blood transfusions by almost 50% in a landmark trial in adult SCD patients with moderate to severe disease. Hemoglobin and HbF concentrations increased and hemolysis decreased.[12] A follow-up study demonstrated a 40% reduction in mortality over a 9-year period in patients continuing to receive hydroxyurea.[13] Not all patients responded equally; therefore, hydroxyurea may not be the best option for all patients.

The use of hydroxyurea in children and adolescents with SCD has been investigated, and similar results were reported as in adult trials, with no adverse effects on growth and development.[4,14,15] LO 4 Hydroxyurea is recommended as an option for children with moderate to severe SCD and can be used in children as young as 6 months of age.[16]

The most common adverse effect of hydroxyurea is myelosuppression. Long-term adverse effects are unknown, but myelodysplasia, acute leukemia, and chronic opportunistic infections have been reported.[12] Hydroxyurea is teratogenic in high doses in animal studies and this is a concern, which should be addressed with patients. Normal pregnancies with no birth defects have been reported in some women receiving hydroxyurea, but close monitoring and weighing risk versus benefit to the patient are vitally important. Hydroxyurea is excreted in breast milk and should be avoided in lactating mothers.[12]

LO 5 Hydroxyurea should be considered in SCD with frequent vasoocclusive crises, severe symptomatic anemia, repeated history of ACS, or other history of severe vasoocclusive crisis (VOC) complications.[4] The prevention of organ damage or reversal of previous damage has not been shown to occur with chronic use of hydroxyurea.[13] However, hydroxyurea treatment LO 5 should be considered in all infants 9 months of age and older, as well as children and adolescents with SCD regardless of their clinical severity, in order to reduce complications related to SCD.[17] The goals of therapy with hydroxyurea are to decrease the acute complications of SCD, improve quality of life, and reduce the number and severity of pain crises.

Hydroxyurea is available in 200-, 300-, 400-, and 500-mg capsules. Extemporaneous liquid preparations can be prepared for children who cannot swallow capsules. Doses should start at 10 to 15 mg/kg daily in a single oral dose, which can be increased after 8 to 12 weeks if blood counts are stable and there are no

Patient Encounter 1

A 3-year-old boy with SCD is currently taking penicillin V potassium 125 mg orally twice daily, acetaminophen as needed for pain, and a gummy multivitamin daily. He fully completed all his routine childhood vaccinations, including PCV 13 and is up to date. His only past hospitalization was at 9 months for dactylitis.

What are the general prophylaxis recommendations for children with SCD?

What interventions do you want to make today to his medication/immunization regimens?

Design an infection prevention plan for this patient.

Table 68–3

Dosage Adjustments for Renal and Hepatic Dysfunction

Medication	Renal Adjustment	Hepatic Adjustment
Decitabine (Decagon)	For Scr ≥ 2 mg/dL (177 μmol/L): hold therapy until values return to baseline	For serum alanine transaminase (ALT), serum glutamic pyruvic transaminase (SGPT), or total bilirubin values more than two times the upper limit of normal: hold therapy until values return to baseline
Deferoxamine (Desferal)	Cl_{cr} 10–50 mL/min (0.17–0.83 mL/s): administer 25%–50% of usual dose	No adjustment recommended
Deferasirox	Cl_{cr} < 10 mL/min (0.17 mL/s): do not use	Severe or persistent elevations in liver function tests: decrease the daily dose or discontinue therapy
Children	Greater than 33% increase in Scr (on two consecutive readings) and above the age-appropriate upper limits of normal: decrease daily dose by 10 mg/kg (Exjade) or 7 mg/kg (Jadenu) Scr ≥ 2 times age-appropriate upper limits of normal: discontinue treatment	
Adults	Greater than 33% increase in Scr above pretreatment values on two consecutive readings: decrease daily dose by 10 mg/kg (Exjade) or 7 mg/kg (Jadenu) CL < 40 mL/min (0.38 mL/s): discontinue treatment	Severe or persistent elevations in liver function tests: decrease the daily dose or discontinue therapy
Deferiprone	No adjustment necessary	No adjustment necessary
Folic acid	No adjustment necessary	No adjustment necessary
Hydroxyurea	Cl_{cr} < 60 mL/min (1.00 mL/s): initial dose of 7.5 mg/kg/day Cl_{cr} 10–50 mL/min (0.17–0.83 mL/s): reduce the daily dose by 50% Cl_{cr} < 10 mL/min (0.17 mL/s): administer 20% of the usual dose Hemodialysis: 7.5 mg/kg/day given after dialysis	Monitor patient for bone marrow toxicity

Data from Refs. 18–24.

LO 6 side effects. Individualize the dosage based on the patient's response and the toxicity seen. With close monitoring, doses can be increased 5 mg/kg/day up to 35 mg/kg daily.[12] In patients with renal failure, dosing of hydroxyurea will need to be adjusted according to the creatinine clearance, as shown in Table 68–3.

LO 6 Closely monitor patients for efficacy and toxicity while they are receiving hydroxyurea. Monitor mean corpuscular volume (MCV), since it typically increases as the level of HbF increases. If the MCV does not increase with hydroxyurea use, the marrow may be unable to respond, the dose may not be adequate, or the patient may be nonadherent.[12] However, lack of increase in MCV or in HbF is not an indication to discontinue therapy; the clinical response to therapy may take 3 to 6 months. A 6-month trial on the maximum tolerated dose is required prior to consideration of discontinuation due to treatment failure, whether secondary to lack of adherence or failure to respond to therapy. HbF levels can also be monitored to assess response LO 6 with a goal of increasing HbF to 15% to 20% (0.15–0.20). Assess blood counts every 2 weeks during dose titration and then every 4 to 6 weeks once the dose is stabilized. Temporary discontinuation of therapy is warranted if hemoglobin level is less than 4.5 g/dL (45 g/L or 2.79 mmol/L), absolute neutrophil count is less than $2 \times 10^3/mm^3$ ($2 \times 10^9/L$), platelets are less than $80 \times 10^3/mm^3$ ($80 \times 10^9/L$), or the reticulocytes are less than $80 \times 10^3/mm^3$ ($80 \times 10^9/L$). Monitor for increases in serum creatinine and transaminases. Once the patient's blood counts have returned to baseline, hydroxyurea may be restarted with a dose that is 2.5 to 5 mg/kg less than the dose associated with the patient's toxicity. Doses may then be increased by 2.5 to 5 mg/kg daily after 12 weeks with no toxicity.

Administer prophylactic folic acid supplementation to SCD patients receiving hydroxyurea, because folate deficiency may be masked by the use of hydroxyurea.

5-Aza-2′-Deoxycytine (Decitabine) For patients who do not respond to hydroxyurea, or cannot tolerate the side effects of hydroyurea, 5-azacytidine and 5-aza-2′-deoxycytidine (decitabine) may be useful. Both induce HbF by inhibiting methylation of DNA, preventing the switch from γ- to β-globin production. Decitabine appears to be safer and more potent than 5-azacytadine. In a small study in adults refractory to hydroxyurea, decitabine 0.2 mg/kg subcutaneously one to three times weekly was associated with an increase in HbF in all patients. Additionally, RBC adhesion was reduced. Neutropenia was the only significant toxicity reported.[25]

LO 4 **L-Glutamine Therapy** Recently FDA approved to reduce acute complications of SCD in adults and children 5 years of age and older, L-glutamine is available as an oral powder that is administered twice daily based on body weight. The dose should be mixed immediately prior to administration with 8 oz of cold or room temperature water, milk or apple juice, or can be mixed into 4 to 6 oz of soft food, such as applesause or yogurt. Clinical studies demonstrated significant decreases in the number of pain crises, vaso-occlusive crises hospitalizations, hospitalizations, ACS and time to first sickle cell crisis. Adverse effects seen in studies included constipation, nausea, headache, and abdominal pain. A majority of the patients in clinical trials were also receiving hydroxyurea.[26,27]

LO 5 **Chronic Transfusion Therapy** Chronic transfusion therapy is warranted to prevent serious complications from SCD, including stroke prevention and recurrence. KEY CONCEPT Especially in children, chronic transfusions have been shown to decrease stroke recurrence from approximately 50% to 10% over 3 years. Without chronic transfusions, approximately 70% of ischemic stroke patients will have another stroke. Chronic transfusion therapy also may be used to prevent vasoocclusive pain and ACS, as well as prevent progression of organ damage.[4]

Patient Encounter 2, Part 1

A 25-year-old African American man with SCD is admitted to the hospital for progressive shoulder and chest pain that began 2 days ago. The patient denies injury. He complains of a nonproductive cough.

PMH: Sickle cell disease (HbSS); admitted for vasoocclusive crises three times over the past year; acute chest syndrome at age 8, 9, 12, 18, 22, and 24; multiple blood transfusions

PSH: Cholecystectomy, splenectomy

FH: Father with SCD. Mother with SC trait.

Allergies: NKDA

SH: Occasional alcohol. Is sexually active

Home Meds: Hydrocodone/acetaminophen 7.5/325 mg, two tablets every 6 hours as needed for pain; folic acid 1 mg daily by mouth, hydroxyurea 2 gm orally once daily.

PE:

VS: T 39.1°C (102.4°F), BP 113/66 mm Hg, P 78 beats/min, RR 26 breaths/min, O_2 Sat 97% (0.97) on 2 L nasal cannula, Ht 173 cm (5′8″), Wt 71 kg (160 lb)

Gen: Awake, alert × 3, in some distress, and obviously in pain

HEENT: Normocephalic, atraumatic. PERRLA. No lymphadenopathy

Chest: Normal to inspection and palpation. Mild rales and wheezes

CV: RRR, no m/g/r

Abd: Soft, NT/ND

Ext: No clubbing, cyanosis, or edema. Shoulder pain with palpation

Neuro: Cranial nerves II through XII are grossly intact. Nonfocal

Labs: Hgb 7.3 g/dL (73 g/L or 4.53 mmol/L), Hct 23.1% (0.231 fraction), WBC 16 × 10^3/μL (16 × 10^9/L), BMP WNL

Chest x-ray shows pulmonary infiltrates.

What is your assessment of this patient's condition?

List treatment goals for this patient.

Devise a detailed therapeutic plan for this patient's hospital management.

The goal of chronic transfusion therapy is to maintain the HbS level at less than 30% (0.30) of total hemoglobin concentration. Transfusions are usually administered every 3 to 4 weeks depending on the HbS concentration. For secondary stroke prevention, current studies have indicated that lifelong transfusion may be required, with increased incidence of recurrence once transfusions are stopped.[4,17]

The benefits of transfusion should be weighed with the risks. Risks associated with transfusions include alloimmunization (sensitization to the blood received), hyperviscosity, viral transmission, volume overload, iron overload, and transfusion reactions. Although the risk of contracting AIDS has decreased dramatically, hepatitis C remains a concern. All SCD patients should be vaccinated for hepatitis A and B and should be serially monitored for hepatitis C and other infections. Parvovirus occurs in 1 of every 40,000 units of RBCs and can be associated with acute anemia and multiple sickle cell complications.[4] Iron overload is a risk for patients maintained on chronic transfusions for more than 1 year. Counsel patients to avoid excessive dietary iron, and monitor serum ferritin regularly. Chelation therapy with deferoxamine, deferasirox, or deferiprone should be considered when the serum ferritin level is greater than 1500 to 2000 ng/mL (1500–2000 mcg/L; 3400–4500 pmol/L).

LO6 LO7 LO4 LO6

Patient Encounter 2, Part 2

The patient recovers from his hospitalization and comes to clinic for follow-up 2 weeks after discharge. He was discharged on his home medications. He has been feeling pretty well, but routine laboratory tests indicate that his Cl_{Cr} is now 40 mL/min/1.73 m^2 (0.38 mL/s/m^2).

How should his medications be adjusted?

Deferoxamine should be initiated at 20 to 40 mg/kg daily (to a maximum of 1–2 g/day) over 8 to 12 hours subcutaneously and has been associated with growth failure.[4] Monitor children receiving deferoxamine for adequate growth and development on a regular basis. Additionally, patients receiving deferoxamine should receive supplemental ascorbic acid starting 1 month after deferoxamine initiation; the ascorbic acid will increase the availability of iron for chelation. Patients with preexisting cardiac conditions should not receive ascorbic acid supplementation. Deferasirox is available in three dosage forms: a tablet (Exjade) that should be dispersed in water, orange juice, or apple juice and taken orally 30 minutes before food, a tablet (Jadenu) that can be swallowed whole and granules (Jadenu Sprinkle) which are sprinkled on soft food.[28] Exjade should be initiated at 20 mg/kg once daily and titrated every 3 to 6 months by 5 to 10 mg/kg/day up to a maximum dose of 40 mg/kg/day. Jadenu and Jadenu Sprinkle should be initated at 14 mg/kg once daily and titrated every 3 to 6 months by 3.5 or 7 mg/kg/day to a maximum dose of 28 mg/kg/day. Exjade and Jadenu are not bioequivalent on an mg to mg basis because of bioavailability differences: when converting from one dosage form to the other, the dose for Jadenu should be about 30% less than the Exjade dose. For both products, the dose should be rounded to the whole tablet dosage form available. Exjade is available in 125 mg, 250 mg, and 500 mg dispersible tablets. Jadenu and Jadenue Sprinkles are available in 90 mg, 180 mg, and 360 mg tablets and packets. Deferiprone is approved for use in adults with thalassemia syndromes who have not responded adequately to other chelation therapies.[29] It is administered three times daily as an oral dosage form. Some recent studies have evaluated combination therapy for treatment of transfusion-associated iron overload. A synergistic effect has been demonstrated with the concomitant use of deferoxamine and deferiprone.[30] Monitor all chelation patients for auditory and ocular changes on a yearly basis. Exchange transfusions may also be helpful in cases of iron overload.

LO6

Sickle cell hemolytic transfusion reaction syndrome is a unique problem in SCD patients. Due to alloimmunization, an acute or delayed transfusion reaction may occur 5 to 20 days posttransfusion. Patients may develop symptoms suggestive of a pain crisis or worsening symptoms if they are already in crisis. A severe anemia after transfusion also may occur due to a rapid decrease in hemoglobin and hematocrit, along with a suppression of erythropoiesis. Further transfusions may worsen the clinical picture due to autoimmune antibodies. Recovery may occur only after ceasing all transfusions and is evidenced by a gradual increase in hemoglobin with reticulocytosis, which indicates the patient is now making their own RBCs.[4]

LO 4 **Allogeneic Hematopoietic Stem Cell Transplant** Allogeneic hematopoietic stem-cell transplantation (HSCT) is the only potential cure for SCD. The best candidates are children with SCD who are younger than 16 years of age with severe complications, who have an identical human leukocyte antigen (HLA)-matched donor, usually a sibling. The transplant-related mortality rate is between 5% and 10%, and graft rejection is approximately 10%. In a recent review, the overall survival rate was 95% and the event-free survival was 92% in children with SCD who received a transplant from an HLA-matched sibling.[31] Other risks include secondary malignancies, development of seizures or intracranial bleeding, and infection in the immediate posttransplant period.[4,32]

Experience with HSCT in adult patients with SCD is still somewhat limited. The use of less intense preparative regimens has made HSCT more available for the older patient with SCD. The best results have been seen in the use of progenitor cells (from bone marrow, cord blood, or peripheral blood stem cells) from matched sibling or related donors. The largest published trial to date in adults undergoing nonmyeloablative transplant involved 30 patients with an 87% rate of disease-free survival.[32]

► *Acute Complications*

LO 4 **Transfusions for Acute Complications** Red cell transfusion is indicated in patients with acute exacerbations of baseline anemia; in cases of severe vasoocclusive episodes, including ACS, stroke, and acute multiorgan failure; and in preparation for procedures that will require the use of general anesthesia or ionic contrast products. Transfusions also may be useful in patients with complicated obstetric problems, refractory leg ulcers, refractory and prolonged pain crises, or severe priapism. Hyperviscosity may occur if the hemoglobin level is increased to greater than 10.0 to 11.0 g/dL (100–110 g/L or 6.21–6.83 mmol/L). Volume overload leading to congestive heart failure is more likely to occur if the anemia is corrected too rapidly in patients with severe anemia and should be avoided.[4]

Infection and Fever KEY CONCEPT Any fever greater than 38.5°C (101.3°F) in an SCD patient should be immediately evaluated, and the patient should have a blood culture drawn and be started on antibiotics that provide empirical coverage for encapsulated organisms.[4]

Patients who should be hospitalized include the following:

- Infants younger than 1 year of age
- Patients with a previous sepsis or bacteremia episode
- Patients with temperatures in excess of 40°C (104°F)
- Patients with WBC counts greater than $30 \times 10^3/mm^3$ ($30 \times 10^9/L$) or less than $0.5 \times 10^3/mm^3$ ($0.5 \times 10^9/L$) and/or platelets less than $100 \times 10^3/mm^3$ ($100 \times 10^9/L$) with evidence of other acute complications
- Acutely ill-appearing individuals

LO 4 Broad IV antibiotic coverage for the encapsulated organisms can include ceftriaxone or cefotaxime. For patients with true cephalosporin allergy, clindamycin may be used. If staphylococcal infection is suspected due to previous history or the patient appears acutely ill, vancomycin should be initiated. Macrolide antibiotics, such as erythromycin or azithromycin, may be initiated if mycoplasma pneumonia is suspected. While the patient is receiving broad-spectrum antibiotics, their regular use of penicillin for prophylaxis can be suspended. Fever should be controlled with acetaminophen or ibuprofen. Because of the risk of dehydration during infection with fever, increased fluid may be needed.[1,4]

Bone infarcts or sickling in the periosteum usually is indicated by pain and swelling over an extremity. Osteomyelitis should also be considered. *Salmonella* species are the most common cause of osteomyelitis in children with SCD, followed by *Staphylococcus aureus*.[1] Select an appropriate antibiotic to cover the suspected organisms empirically.

LO 6 **Cerebrovascular Accidents** Acute neurologic events, such as stroke, will require hospitalization and close monitoring. Patients should have physical and neurologic examinations every 2 hours.[4] Acute treatment may include exchange transfusion or simple transfusion to maintain hemoglobin at approximately 10.0 g/dL (100 g/L or 6.21 mmol/L) and HbS concentration at less than 30% (0.30). Patients with a history of seizure may need anticonvulsants, and interventions for increased intracranial pressure should be initiated if necessary. Children with history of stroke should be initiated on chronic transfusion therapy.[4]

LO 6 Early detection of ischemic stroke can be done with the use of transcranial Doppler ultrasonography. In the Stroke Prevention Trial in Sickle Cell Anemia (STOP) study, screening with this method followed by chronic transfusion therapy significantly reduced the incidence of stroke.[33-35] Screening is recommended in all patients older than 2 years.

Acute Chest Syndrome ACS will require hospitalization for appropriate management of symptoms and to avoid complications. Patients should be encouraged to use incentive spirometry at least every 2 hours. Incentive spirometry helps the patient take long, slow breaths to increase lung expansion. Appropriate management of pain is important, but analgesic-induced hypoventilation should be avoided. Patients should maintain appropriate fluid balance because overhydration can lead to pulmonary edema and respiratory distress. Infection with gram-negative, gram-positive, or atypical bacteria is common in ACS, and early use of broad-spectrum antibiotics, including a macrolide, quinolone, or cephalosporin is recommended. Fat emboli, from infarction of the long bones, may lead to ACS. Oxygen therapy should be utilized in any patient presenting with respiratory distress or hypoxia. Oxygen saturations, measured by pulse oximeter, should be maintained at 92% (0.92) or above. Exchanges transfusions are often indicated when there is a rapid progression of ACS symptoms, such as increased needs for supplemental oxygen, increased respiratory distress, or progression of pulmonary infiltrates, and patients who present with wheezing may require inhaled bronchodilators.[4,36]

LO 4

The use of corticosteroids is controversial. Although they may decrease the inflammation and endothelial cell adhesion seen with ACS, their use has also been associated with higher readmission rates for other complications.

Priapism By age 18, approximately 90% of males with SCD will have had at least one episode of priapism. Stuttering priapism, where erection episodes last anywhere from a few minutes to

Clinical Presentation and Diagnosis of ACS in SCD

General
- Occurs in 15% to 43% of patients and is responsible for 25% of deaths
- Risk factors include young age, low HbF level, high Hgb and WBCs, winter seasons, reactive airway disease
- Recurrences are up to 80% and can lead to chronic lung disease

Symptoms
- Patients may complain of cough, fever, dyspnea, chest pain

Signs
- Temperature greater than 38.5°C (101.3°F)
- Hypoxia
- New infiltrate on chest x-ray

Laboratory Tests
- CBC with reticulocyte count
- Blood gases
- Oxygen saturation
- Cultures (blood and sputum)

Other
- Closely monitor pulmonary status

less than 2 hours, resolves spontaneously. Erections lasting more than 2 hours should be evaluated promptly. Goals of therapy are to provide pain relief, reduce anxiety, provide detumescence, and preserve testicular function and fertility. Initial treatment should include aggressive hydration and analgesia. Transfusion may or may not be helpful, but should be considered in anemic patients. Avoid the use of ice packs due to the risk of tissue damage.[4]

LO 4

Both vasoconstrictors and vasodilators have been used in the treatment of priapism. Vasoconstrictors are thought to work by forcing blood out of the cavernosum and into the venous return. Aspiration of the penile blood followed by intracavernous irrigation with epinephrine (1:1,000,000 solution) has been effective with minimal complications.[37] In severe cases, surgical intervention to place penile shunts has been used, but there is a high failure rate, and the risk of complications, from skin sloughing to fistulas, limits its use.

LO 4

Pseudoephedrine dosed at 30 to 60 mg daily taken at bedtime has been used to prevent or decrease the number of episodes of priapism.[4] Terbutaline 5 mg has been used orally to prevent priapism, with mixed results.[37,38] Leuprolide, a gonadotropin-releasing hormone, also has been used for this indication. Hydroxyurea may be helpful in some patients.[37,39] The use of antiandrogens is under investigation.[4]

LO 4

▶ *Treatment of Acute Complications*

Aplastic Crisis Most patients in aplastic crisis will recover spontaneously and therefore treatment is supportive. If anemia is severe or symptomatic, transfusion may be indicated. Infection with human parvovirus B19 is the most common cause of aplastic crisis. Isolate infected patients because parvovirus is highly contagious. Pregnant individuals should avoid contact with infected patients because midtrimester infection with parvovirus may cause hydrops fetalis and still birth.[1,4]

Clinical Presentation and Diagnosis of Priapism in SCD

General
- Mean age of initial episode is 12 years of age
- Most males with SCD will have one episode by age 20
- Repeated episodes can lead to fibrosis and impotence

Symptoms
- Patients may complain of painful and unwanted erection lasting anywhere from less than 2 hours (stuttering type) to more than 2 hours (prolonged type)

Signs
- Urinary obstruction

Laboratory Tests
- CBC with reticulocyte count

Other
- Monitor for duration of episode
- Prolonged episodes should be considered medical emergencies

Sequestration Crisis RBC sequestration in the spleen in young children may lead to a rapid drop in hematocrit, resulting in hypovolemia, shock, and death. Treatment is RBC transfusion to

Clinical Presentation and Diagnosis of Acute Aplastic Crisis in SCD

General
- Transient suppression of RBC production in response to bacterial or viral infection
- Most commonly due to infection with parvovirus B19

Symptoms
- Patients may complain of headache, fatigue, dyspnea, pallor, or fever
- Patients may also complain of upper respiratory or GI infection symptoms

Signs
- Temperature greater than 38.5°C (101.3°F) may occur
- Hypoxia
- Tachycardia
- Acute decrease in Hgb with decreased reticulocyte count

Laboratory Tests
- CBC with reticulocyte count
- Chest x-ray
- Parvovirus titers
- Cultures (blood, urine, and throat)

Clinical Presentation and Diagnosis of Sequestration Crisis in SCD

General
- Acute exacerbation of anemia due to sequestration of large blood volume by the spleen
- More common in patients with functioning spleens
- Onset often associated with viral or bacterial infections
- Recurrence is common and can be fatal

Symptoms
- Sudden onset of fatigue, dyspnea, and distended abdomen
- Patients may present with vomiting and abdominal pain

Signs
- Rapid decrease in Hgb and Hct with elevated reticulocyte count
- Splenomegaly
- May exhibit hypotension and shock

Evaluation
- Vital signs
- Spleen size changes
- Oxygen saturations
- CBC with reticulocyte count
- Cultures (blood, urine, throat)

Clinical Presentation and Diagnosis of Vasoocclusive Crisis in SCD

General
- Most often involves the bones, liver, spleen, brain, lungs, and penis
- Precipitating factors include infection, extreme weather conditions, dehydration, and stresses
- Recurrent acute crises result in bone, joint, and organ damage and chronic pain

Symptoms
- Patients may complain of deep throbbing pain, local tenderness

Signs
- Erythema and swelling of painful area
- Dactylitis in young infants
- Temperature greater than 38.5°C (101.3°F)
- Leukocytosis

Laboratory tests
- CBC with reticulocyte count
- Urinalysis
- Abdominal studies (if symptoms exist)
- Cultures (blood and urine)
- Liver function tests and bilirubin
- Chest x-ray

correct the hypovolemia, as well as broad-spectrum antibiotics, because infections may precipitate the crisis.[1,4]

LO 4 Recurrent episodes are common and can be managed with chronic transfusion and splenectomy. Observation is used commonly in adults because their episodes are milder. Splenectomy is usually delayed until after 2 years of age to lessen the risk of postsplenectomy septicemia. Patients with chronic hypersplenism should be considered for splenectomy.[4,40]

LO 4 **Vasoocclusive Pain Crisis** The mainstay of treatment for vasoocclusive crisis includes hydration and analgesia (Table 68–4). Pain may involve the extremities, back, chest, and abdomen. KEY CONCEPT Patients with mild pain crisis may be treated as outpatients with rest, warm compresses to the affected (painful) area, increased fluid intake, and oral analgesia. Patients with moderate to severe crises should be hospitalized. Infection should be ruled out because it may trigger a pain crisis, and any patient presenting with fever or critical illness should be started on empirical broad-spectrum antibiotics. Patients who are anemic should be transfused to their baseline. IV or oral fluids at 1.5 times maintenance are recommended. Close monitoring of the patient's fluid status is important to avoid overhydration, which can lead to ACS, volume overload, or heart failure.[4]

LO 6 Aggressive pain management is required in patients presenting in pain crisis. Assess pain on a regular basis (every 2–4 hours), and individualize management to the patient. The use of pain scales may help with quantifying the pain rating. Obtain a good medication history of what has worked well for the patient in the past. Use acetaminophen or a nonsteroidal anti-inflammatory drug (NSAID) for treatment of mild to moderate pain. Patients with bone or joint pain who require IV medications may be helped by the use of ketorolac, an injectable NSAID. Because of the concern for side effects, including GI bleeding, ketorolac should be used only for a maximum of 5 consecutive days.

LO 6 Monitor for the total amount of acetaminophen given daily, because many products contain acetaminophen. Maximum daily dose of acetaminophen for adults is 3 g/day, and for children, five doses over a 24-hour period.[41] Add an opioid if pain persists or if pain is moderate to severe in nature. Combining an opioid with an NSAID can enhance the analgesic effects without increasing adverse effects.[42-45]

LO 4 Severe pain should be treated with an opioid such as morphine, hydromorphone, methadone, or fentanyl. Moderate pain can be effectively treated in most cases with a weak opioid such as codeine or hydrocodone, usually in combination with acetaminophen. Meperidine should be avoided because of its relatively short analgesic effect and its toxic metabolite, normeperidine. Normeperidine may accumulate with repeated dosing and can lead to CNS side effects including seizures.

IV opioids are recommended for use in treatment of severe pain because of their rapid onset of action and ease in titration. Intramuscular injection should be avoided. Analgesia should be individualized and titrated to effect, either by scheduled around-the-clock doses or continuous infusion. The use of continuous infusion will avoid the fluctuations in blood levels between doses that are seen with bolus dosing. As-needed dosing of analgesia is only appropriate for breakthrough pain or uncontrolled pain. Patient-controlled analgesia (PCA) is commonly used and allows the patient to have control over his or her analgesic breakthrough dosing. As the pain crisis resolves, the pain medications can be

Table 68–4

Management of Acute Pain of SCD

Principles

Treat underlying precipitating factors.
- Avoid delays in analgesia administration.
- Use pain scale to assess severity.
- Choice of initial analgesic should be based on previous pain crisis pattern, history of response, current status, and other medical conditions.
- Schedule pain medication; avoid as-needed dosing.
- Provide rescue dose for breakthrough pain.
- If adequate pain relief can be achieved with one or two doses of morphine, consider outpatient management with a weak opioid; otherwise hospitalization is needed for parenteral analgesics.
- Frequently assess to evaluate pain severity and side effects; titrate dose as needed.
- Treating adverse effects of opioids is part of pain management.
- Consider nonpharmacologic intervention.
- Transition to oral analgesics as the patient improves; choose an oral agent based on previous history, anticipated duration, and ability to swallow tablets; if sustained-release products are used, a fast-release product is also needed for breakthrough pain.

Analgesic Regimens

Mild to moderate pain:

Hydrocodone + acetaminophen:
- Dose based on hydrocodone—children: 0.2 mg/kg per dose every 6 hours; adults: 5–10 mg/dose

Anti-inflammatory agents:
- Use with caution in patients with renal failure (dehydration) and bleeding
- Ibuprofen (oral): children: 10 mg/kg every 6–8 hours; adults: 200–400 mg/dose
- Naproxen: 5 mg/kg every 12 hours; adults: 250–500 mg/dose
- Ibuprofen + hydrocodone: Each tablet contains 200 mg ibuprofen and 7.5 mg hydrocodone per tablet; only for older children who can swallow tablets

Moderate to severe pain:

Morphine—children:
- 0.1–0.15 mg/kg per dose every 3–4 hours; adults: 5–10 mg/dose
- Continuous infusion: 0.04–0.05 mg/kg/hour; titrate to effect

Hydromorphone—children:
- 0.015 mg/kg per dose every 3–4 hours; adults: 1.5–2 mg/dose
- Continuous infusion: 0.004 mg/kg/hour; titrate to effect

IV anti-inflammatory agents:
- Ketorolac: 0.5 mg/kg up to 30 mg/dose every 6 hours

Patient-controlled analgesics:
- Morphine: 0.01–0.03 mg/kg/hour basal; demand 0.01–0.03 mg/kg every 6–10 minutes; 4 hours lockout 0.04–0.06 mg/kg
- Hydromorphone: 0.003–0.005 mg/kg/hour basal; demand 0.003–0.05 mg/kg every 6–10 minutes; 4 hours lock out 0.4–0.6 mg/kg

tapered. Physical therapy and relaxation therapy can be helpful adjuvants to analgesia.[42–45]

Tolerance to opioids is seen when patients have had continuous long-term use of the medications and can be managed during acute crises by using a different potent opioid or using a larger dose of the same medication. Adverse effects associated with the use of opioids include respiratory depression, itching, nausea and vomiting, constipation, and drowsiness. Patients on continuous infusions of opioids should be on continuous pulse oximeter to assess oxygen saturations. Monitor the patient for oxygen saturations less than 92% (0.92). Oxygen should be administered as needed to keep the saturations above 92% (0.92). Itching can be managed with an antihistamine such as diphenhydramine. Nausea and vomiting can be treated and managed with the administration of antiemetics such as promethazine or the 5HT3 antagonists, but the use of promethazine is contraindicated in children younger than 2 years of age. Assess stool frequency in all patients on a continuous opioid, and start stool softeners or laxatives as needed. Excessive sedation is difficult to control, and the concurrent use of an opioid with diphenhydramine or other sedative medications can exacerbate the drowsiness, leading to hypoxemia. A continuous very low dose of naloxone, an opioid antagonist, has been used successfully when the adverse effects such as itching are unbearable.[46]

LO 6

As patients age and their SCD advances, most will present with some level of chronic pain, which should be treated with the lowest dose of oral analgesic, typically a combination of hydrocodone and acetaminophen on an as-needed basis. Neuropathic pain can result from repeated vaso-occlusive crises, and may require the regular use of medications such as gabapentin, amitriptyline, or pregabalin.

OUTCOME EVALUATION

SCD treatment and prevention are considered successful when complications are minimized. The major outcome parameters are a decrease in morbidity and mortality, measured by the number of hospitalizations, and the extent of end-organ damage seen over time. Today, with longer survival for SCD, chronic manifestations of the disease contribute to the morbidity later in life (Table 68–5). Thirty years ago, complications from SCD contributed to high mortality. It was estimated that approximately 50% of patients with SCD did not survive to reach adulthood.[1] Since that time, data suggest improvement in mortality rates for patients with SCD. The survival age for individuals with HbSS has increased to at least the fifth decade of life. Recent reports suggest 85% survival by 18 years of age.[4] SCD is a chronic disease and cannot be cured, except in some patients with transplant.

Table 68–5

Chronic Complications of SCD

System	Complications
Auditory	Sensorineural hearing loss due to sickling in cochlear vasculature with hair cell damage
Cardiovascular	Cardiomegaly, myocardial ischemia, murmurs, and abnormal ECG; patients with SCD have lower BP than the normal population; normal BP values for SCD should be used for diagnosis of hypertension ("relative" hypertension); heart failure usually is related to fluid overload
Dermatologic	Painful leg ulcers; failure to heal occurs in 50% of patients; recurrences are common
Genitourinary	Renal papillary necrosis, hematuria, hyposthenuria, proteinuria, nephrotic syndrome, tubular dysfunction, chronic renal failure, impotence, priapism
Growth and development	Delay in growth (weight and height) and sexual development; decreased fertility; increased complications during pregnancy; depression may be more prevalent than in general population, especially in patients with unstable disease
Hepatic and biliary	Cholelithiasis, biliary sludge, acute and chronic cholecystitis, and cholestasis (can be progressive and life-threatening)
Neurologic	"Silent" brain lesions on MRI are associated with poor cognitive and fine motor functions; pseudotumor cerebri (rare)
Ocular	Retinal or vitreous hemorrhage, retinal detachment, transient or permanent visual loss; central retinal vein occlusion
Pulmonary	Pulmonary fibrosis, pulmonary hypertension, cor pulmonale
Renal	Hematuria, hyposthenuria (inability to concentrate urine maximally), tubular dysfunction, enuresis during early childhood, acute renal failure can also occur
Skeletal	Aseptic necrosis of ball-and-socket joints (shoulder and hip); prostheses may be needed due to permanent damage; bone marrow hyperplasia resulting in growth disturbances of maxilla and vertebrae
Spleen	Asplenia (autosplenectomy or surgical splenectomy)

LO 7

Starting with birth, SCD patients should have regularly scheduled health assessments and interventions when necessary. Obtain a urine analysis, complete blood count, liver function tests, ferritin or serum iron level and total iron-binding capacity, blood urea nitrogen (BUN), and creatinine on at least a yearly basis and more often for children younger than 5 years of age to monitor for complications. All SCD patients should have regular screening of their hearing and vision.

All patients and parents of children with SCD should have a plan for what to do in the event of symptoms of infection or pain. Obtain a medication history when patients are admitted to the hospital. Assess adherence with prophylactic penicillin and childhood immunization schedules in all pediatric SCD patients.

Patient Care Process

Collect Information:

- Perform a medication history for use of prescription and nonprescription medications and dietary supplements. Identify allergies to medications and other substances.
- Review the medical history and physical assessment findings.
- Speak with the patient and review records to identify lifestyle habits, preferences and beliefs, health goals, and socioeconomic factors that affect medication access and other aspects of care.
- Review available laboratory tests.

Assess the Information:

- Based on physical examination and review of systems, determine whether the patient is experiencing any signs or symptoms of an acute or chronic SCD complication (Tables 68–1 and 68–5).
- Assess the safety, efficacy, and patient adherence of current pharmacotherapy.
- Identify any significant adverse drug effects or interactions.
- Assess the patient's medication history. Does the patient take any medications routinely for SCD? Which analgesics have been helpful to the patient in the past? Are they taking appropriate doses to achieve the desired effect? If not, why?
- Determine if the patient is up to date on their immunizations. Have they received their annual influenza vaccine? Are they missing any vaccines?

Develop a Care Plan:

- Choose medications and doses that are optimal for the patient.
- Select lifestyle modifications that are likely to be effective and safe for the patient.
- Determine whether drug doses are optimal.
- If the patient is having an acute complication of SCD, arrange for referral and/or admission to the hospital.

Implement the Care Plan:

- Educate the patient about changes in drug therapy, medication administration, potential new adverse effects, and how to manage and report adverse effects that occur.

(*Continued*)

Patient Care Process (*Continued*)

- Address any patient concerns about SCD and its management.
- Discuss the importance of medication adherence and lifestyle modifications to prevent complications of SCD.
- Determine if the patient has prescription coverage or whether recommended agents are included on the institution's formulary.
- Arrange for vaccination if the patient is not up to date with recommendations.
- Review medication history and physical examination findings, laboratory tests, and results of other diagnostic tests.
- Assess for adverse effects from medications that the patient is taking.
- Stress the importance of adherence with the therapeutic regimen. Adjust therapeutic regimens as needed based on patient response and adverse effects.

Follow-up: Montor and Evaluate:

- Follow-up at monthly intervals or more frequently to assess effectiveness and safety of therapy, to avoid complications from SCD and to improve quality of life for the patient.

Abbreviations Introduced in This Chapter

ACS	Acute chest syndrome
CNS	Central nervous system
HbA	Normal adult hemoglobin
HbAS	One normal and one sickle hemoglobin gene
HbC	Hemoglobin C
HbF	Fetal hemoglobin
HbS	Sickle hemoglobin
HbSβ^0-thalassemia	One sickle hemoglobin and one β^0-thalassemia gene
HbSβ$^+$-thalassemia	One sickle hemoglobin and one β$^+$-thalassemia gene
HbSC	One sickle hemoglobin and one hemoglobin C gene
HbSS	Homozygous sickle hemoglobin
Hgb	Hemoglobin
HLA	Human leukocyte antigen
HSCT	Hematopoietic stem-cell transplantation
ISC	Irreversibly sickled cell
MCV	Mean corpuscular volume
NSAID	Nonsteroidal anti-inflammatory drug
PCA	Patient-controlled analgesia
PCV 13	13-Valent pneumococcal conjugate vaccine
PPV 23	23-Valent pneumococcal polysaccharide vaccine
SCA	Sickle cell anemia
SCD	Sickle cell disease
SCT	Sickle cell trait
STOP	Stroke Prevention Trial in Sickle Cell Anemia
VOC	Vasoocclusive crisis
WBC	White blood cell

69 Antimicrobial Regimen Selection

Catherine M. Oliphant

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

1. Recognize that antimicrobial resistance is an inevitable consequence of antimicrobial therapy.
2. Describe how antimicrobials differ from other drug classes in terms of their effects on individual patients as well as on society as a whole.
3. Identify two guiding principles to consider when treating patients with antimicrobials, and apply these principles in patient care.
4. Differentiate between microbial colonization and infection based on patient history, physical examination, and laboratory and culture results.
5. Evaluate and apply at least six major drug-specific considerations when selecting antimicrobial therapy.
6. Evaluate and apply at least seven major patient-specific considerations when selecting antimicrobial therapy.
7. Select empirical antimicrobial therapy based on spectrum-of-activity considerations that provide a measured response proportional to the severity of illness. Provide a rationale for why a measured response in antimicrobial selection is appropriate.
8. Identify and apply five major principles of patient education and monitoring response to antimicrobial therapy.
9. Discuss two common causes of patients failing to improve while on antimicrobials, and recognize other less common but potential reasons for antimicrobial failure.
10. Define antimicrobial stewardship and describe the purpose of such a program.

INTRODUCTION

The CDC's Antibiotic Resistance Threats in the United States 2013 estimates more than 2 million patients per year are infected with resistant pathogens resulting in approximately 23,000 deaths.[1] For several decades, infectious disease–related mortality in the United States has increased, in part owing to increases in antimicrobial resistance. The discovery of virtually every new class of antimicrobials has occurred in response to the development of bacterial resistance and loss of clinical effectiveness of existing antimicrobials. KEY CONCEPT An inevitable consequence of exposing microbes to antimicrobials is that some organisms will develop resistance to the antimicrobial. Today, there are many antimicrobial classes and antimicrobials available for clinical use. However, in many cases, differences in mechanisms of action between antimicrobials are minor, and the microbiologic properties of the agents are similar. KEY CONCEPT Antimicrobials are different from other classes of pharmaceuticals because they exert their action on bacteria infecting the host as opposed to acting directly on the host. Because antimicrobial use in one patient affects not only that patient but also other patients if they become infected with resistant bacteria, correct selection, use, and monitoring of clinical response are paramount.

KEY CONCEPT There are two guiding principles to consider when treating patients with antimicrobials: (a) make the correct diagnosis and (b) do no harm! Patients with infections frequently present with signs and symptoms that are nonspecific and may be confused with other noninfectious diseases. Not only is it important to determine whether a disease process is of infectious origin, but it is also important to determine the specific causative pathogen of the infection. Antimicrobials vary in their spectrum of activity, the ability to inhibit or kill different species of bacteria. Antimicrobials that kill many different species of bacteria are called *broad-spectrum antimicrobials*, whereas antimicrobials that kill only a few species of bacteria are called *narrow-spectrum antimicrobials*. One might argue that treating everybody with broad-spectrum antimicrobials will increase the likelihood that a patient will get better even without knowing the bacteria causing infection. However, counter to this argument is the principle of "Do no harm!" Broad antimicrobial coverage does increase the likelihood of empirically killing a causative pathogen; unfortunately, the development of secondary infections can be caused by selection of antimicrobial-resistant nontargeted pathogens. In addition, adverse events are thought to complicate up to 10% of all antimicrobial therapy, and for select agents, the adverse-event rates are similar to high-risk medications such as warfarin, digoxin, or insulin.[2] Therefore, the overall goal of antimicrobial therapy should be to cure the patient's infection; limit harm by minimizing patient risk for adverse effects, including secondary infections; and limit societal risk from antimicrobial-resistant bacteria.

EPIDEMIOLOGY AND ETIOLOGY

Infectious disease–related illnesses, particularly respiratory tract infections, are among the most common reasons patients seek medical care.[3] Antimicrobial prescribing has been associated with inappropriate use of antimicrobial agents. Recent trends in prescribing suggest a modest reduction in antimicrobial use for these infections, suggesting an increased recognition of the negative consequences of antimicrobial use.[4,5] However, it is estimated that at least 30% of outpatient antibiotic prescriptions are unnecessary with the majority prescribed for acute respiratory tract infections.[6] Up to one-half of all patients receive at least one antimicrobial during hospitalization with a trend toward increased use of broad-spectrum antimicrobials.[7] In 2016, the CDC reported that there were reductions in central line–associated bloodstream infections, surgical site infections, and hospital-onset MRSA bloodstream infection.[8] Nosocomial infections tend to be associated with antimicrobial-resistant strains of bacteria. However, there has been a shift in the etiology of some community-acquired infections. Increasingly, infections caused by antimicrobial-resistant pathogens, traditionally nosocomial in origin, are being identified in ambulatory care settings. Reasons for this change include an aging population, improvement in the management of chronic comorbid conditions including immunosuppressive conditions, and increases in outpatient management of more debilitated patients. The majority of infections caused by antimicrobial-resistant pathogens in the ambulatory care setting occur in patients who have had recent exposure to the health care system. The converging bacterial etiologies and increasing resistance in all health care environments emphasize the need to "make the diagnosis."

PATHOPHYSIOLOGY

Microbiome and Endogenous Infection

Many areas of the human body are colonized with microbes—this is known as the microbiome. Infections often arise from one's own normal flora (called an *endogenous infection*). Endogenous infection may occur when there are alterations in the normal flora (eg, recent antimicrobial use may allow for overgrowth of other normal flora) or disruption of host defenses (eg, a break or entry in the skin). Knowing what organisms reside where can help guide empirical antimicrobial therapy (Figure 69–1 describes common human pathogens). In addition, it is beneficial to know what anatomic sites are normally sterile. These include the cerebrospinal fluid, blood, and urine.

Determining Colonization versus Infection

LO 4

Infection refers to the presence of bacteria that are causing disease (eg, organisms found in normally sterile anatomic sites or in nonsterile sites with signs/symptoms of infection). *Colonization* refers to the presence of bacteria that are not causing disease. KEY CONCEPT Only bacteria that cause disease should be targeted with antimicrobial therapy, and non–disease-producing colonizing flora should be left intact. It is important to differentiate infection from colonization because antimicrobial therapy targeting colonization is inappropriate and may lead to the emergence of resistant bacteria.

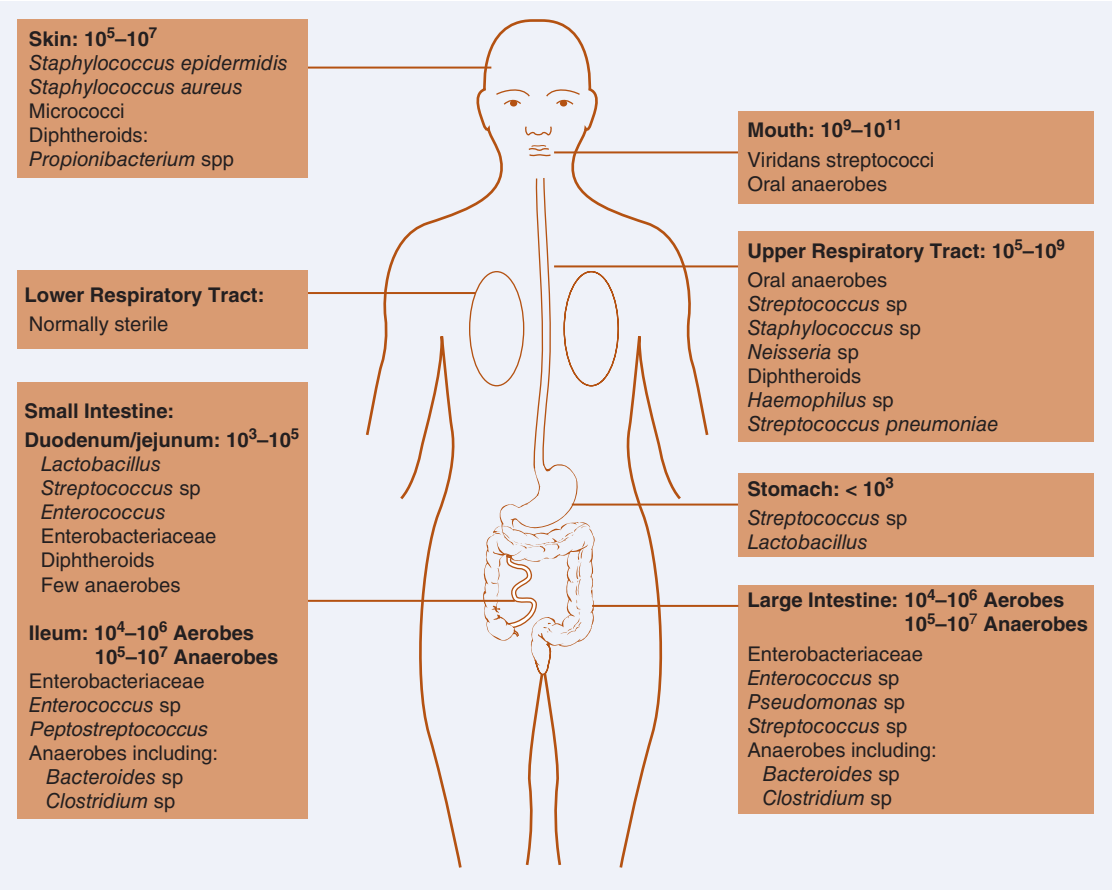

FIGURE 69–1. Normal flora and concentrations of bacteria (organisms per milliliter).

Exogenously Acquired Bacterial Infections

Infections acquired from an external source are referred to as *exogenous infections*. These infections may occur as a result of human-to-human transmission, contact with exogenous bacterial populations in the environment, and animal contact. Resistant pathogens such as methicillin-resistant *Staphylococcus aureus* (MRSA) and vancomycin-resistant *Enterococcus* spp (VRE) may colonize hospitalized patients or patients who access the health care system frequently. It is important to know which patients have acquired these organisms because patients generally become colonized prior to developing infection, and colonized patients should be placed in isolation to minimize transmission.

Contrasting Bacterial Virulence and Resistance

Virulence refers to the pathogenicity or disease severity produced by an organism. Bacteria may produce toxins or possess characteristics that contribute to their pathogenicity. Some virulence factors allow the organism to avoid the host immune response and cause significant disease. Virulence and resistance are different microbial characteristics. For example, *Streptococcus pyogenes*, a common cause of skin infections, produces toxins that can cause severe disease, yet it is very susceptible to penicillin. *Enterococcus faecium* is a highly resistant organism but is frequently a colonizing flora that causes disease primarily in the immunocompromised.

CLINICAL PRESENTATION AND DIAGNOSIS

Physical Examination

Findings on physical examination, along with the clinical presentation, can help identify the anatomic location of the infection. Once the anatomic site is identified, the most probable pathogens associated with disease can be determined based on likely endogenous or exogenous flora.

Fever often accompanies infection and is defined as a rise in body temperature above the normal 37°C (98.6°F). Oral and axillary temperatures may underestimate core temperature by at least 0.6°C (1°F), whereas rectal temperatures best approximate core temperatures. Fever is a host response to bacterial toxins. However, bacterial infections are not the sole cause of fever. Fever also may be caused by other infections (eg, fungal or viral), medications (eg, penicillins, cephalosporins, salicylates, and phenytoin), trauma, or other medical conditions (eg, autoimmune disease, malignancy, pulmonary embolism, and hyperthyroidism). Some patients with infections may present with hypothermia (eg, patients with overwhelming infection). Elderly patients may be afebrile, as may those with localized infections (eg, urinary tract infection [UTI]).[9] For others, fever may be the only indication of infection. Neutropenic patients may not have the ability to mount normal immune responses to infection (eg, infiltrate on chest x-ray, pyuria on urinalysis, or erythema or induration around catheter site), and the only finding may be fever.

Imaging Studies

Imaging studies also may help to identify anatomic localization of the infection. These studies usually are performed in conjunction with other tests to establish or rule out the presence of an infection. Radiographs are performed commonly to establish the diagnosis of pneumonia, as well as to determine the severity of disease. Computed tomography (CT) or magnetic resonance imaging (MRI) may also be obtained.

Clinical Presentation

- Review of symptoms consistent with an infectious etiology.
- Signs and symptoms may be nonspecific (eg, fever) or specific.
- Specific signs and symptoms are beyond the scope of this chapter (see disease state–specific chapters for these findings).

Patient History

- History of present illness (HPI)
- Comorbidities
- Current medications
- Allergies
- Previous antibiotic exposure (may provide clues regarding colonization or infection with new specific pathogens or pathogens that may be resistant to certain antimicrobials)
- Previous hospitalization or health care utilization (also a key determinant in selecting therapy because the patient may be at risk for specific pathogens and/or resistant pathogens)
- Travel history
- Social history
- Pet/animal exposure
- Occupational exposure
- Environmental exposure

Physical Findings

- Findings consistent with an infectious etiology
- Vital signs
- Body system abnormalities (eg, rales, altered mental status, localized inflammation, erythema, warmth, edema, pain, and pus)

Diagnostic Imaging

- Radiographs (x-rays)
- CT scans
- MRI
- Labeled leukocyte scans

Nonmicrobiologic Laboratory Studies

- White blood cell count (WBC) with differential
- Erythrocyte sedimentation rate (ESR)
- C-reactive protein
- Procalcitonin

Microbiologic Studies

- Gram stain
- Culture and susceptibility testing

Nonmicrobiologic Laboratory Studies

Nonmicrobiological laboratory tests include the white blood cell count (WBC) and differential, erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), and procalcitonin levels. In most cases, the WBC count is elevated in response to infection, but it may be decreased owing to overwhelming or long-standing infection. The differential is the percentage of each type of WBC (Table 69–1). In response to physiologic stress, neutrophils leave the bloodstream and enter the tissue to "fight" against the offending pathogens (ie, leukocytosis). It is important to recognize that leukocytosis is nonspecific for infection and may temporarily occur in response to noninfectious conditions such as acute myocardial infarction. During an infection, immature neutrophils (eg, bands) are released at an increased rate to help fight infection, leading to what is known as a "bandemia" or "left shift". Therefore, a WBC count differential is key to determining whether an infection is present. Some patients may present with a normal total WBC with a left shift (eg, the elderly). ESR and CRP are nonspecific markers of inflammation that increase as a result of the acute-phase reactant response, which is a response to inflammatory stimuli such as infection or tissue injury. These tests may be used as markers of infectious disease response because they are elevated when the disease is acutely active and usually fall in response to successful treatment. Clinicians may use these tests to monitor a patient's response to therapy in osteomyelitis and infective endocarditis. These tests should not be used to diagnose infection because they may be elevated in noninfectious inflammatory conditions. In contrast, procalcitonin, a prohormone of calcitonin, is rapidly produced in response to bacterial infection. Procalcitonin serum levels in conjunction with clinical findings are increasingly being utilized to assess both the need to initiate antibiotic therapy as well as determine when antibiotic therapy may be safely discontinued.[10,11]

Table 69–1

WBC and Differential

Type of Cell	Normal Value % (or Fraction)	Function	Abnormalities
Neutrophil	Segs 40–60 (0.40–0.60) Bands 3–5 (0.03–0.05)	Phagocytic	Leukocytosis • Bacterial infections • Fungal infections • Physiologic stress • Tissue injury (eg, myocardial Infarction) • Medications (eg, corticosteroids) Leukopenia • Long-standing infection • Cancer • Medications (eg, chemotherapy)
Lymphocyte	20–40 (0.20–0.40)	T cells (cell-mediated immunity) B cells (humoral antibody response)	Lymphocytosis • Viral infections (eg, mononucleosis) • Tuberculosis • Fungal infections Lymphopenia • HIV
Monocyte	2–8 (0.02–0.08)	Phagocytic precursor to macrophage	Monocytosis • Tuberculosis • Protozoal infections • Leukemia
Eosinophil	1–4 (0.01–0.04)	Antigen-antibody reactions	Eosinophilia • Hypersensitivity reactions, including medications • Parasitic infections
Basophil	< 1 (0.01)		Hypersensitivity reactions

Patient Encounter 1

HPI: SC is a 76-year-old man who has been in the intensive care unit (ICU) for 6 days s/p myocardial infarction. He has been unresponsive since his MI and has required mechanical ventilation for 6 days. On day 6, SC becomes hypotensive, tachycardic, tachypneic, and febrile. His oxygen requirements have increased significantly overnight. SC also has increased secretions coming from his endotracheal tube.

Allergies: Sulfa

Meds:

Metoprolol 2.5 mg IV Q6hours

Insulin glargine 20 u QPM

Insulin lispro as needed

Aspirin 81 mg daily

Enoxaparin 40 mg SQ daily

Pantoprazole 40 mg IV daily

Enalaprilat 2.5 mg IV Q6hours

Ipratropium Q6hours

Albuterol Q6hours and prn

What information in the history supports an infectious etiology?

Is this patient at risk for resistant pathogens? Why?

Microbiologic Studies

Microbiologic studies that allow for direct examination of a specimen (eg, sputum, blood, or urine) may aid in a presumptive diagnosis and give an indication of the characteristics of the infecting organism. Generally, microbial cultures are obtained with a Gram stain of the cultured material.

A Gram stain of collected specimens can give rapid information that can be applied immediately to patient care. A Gram stain may identify whether bacteria are present and determine bacterial morphologic characteristics (eg, gram-positive or gram-negative and shape—cocci, bacilli). Certain specimens do not stain well or at all and must be identified by alternative staining techniques (*Mycoplasma* spp., *Legionella* spp., *Mycobacterium* spp.). Figure 69–2 identifies bacterial pathogens classified by Gram stain and morphologic characteristics. The presence of WBCs on a Gram stain

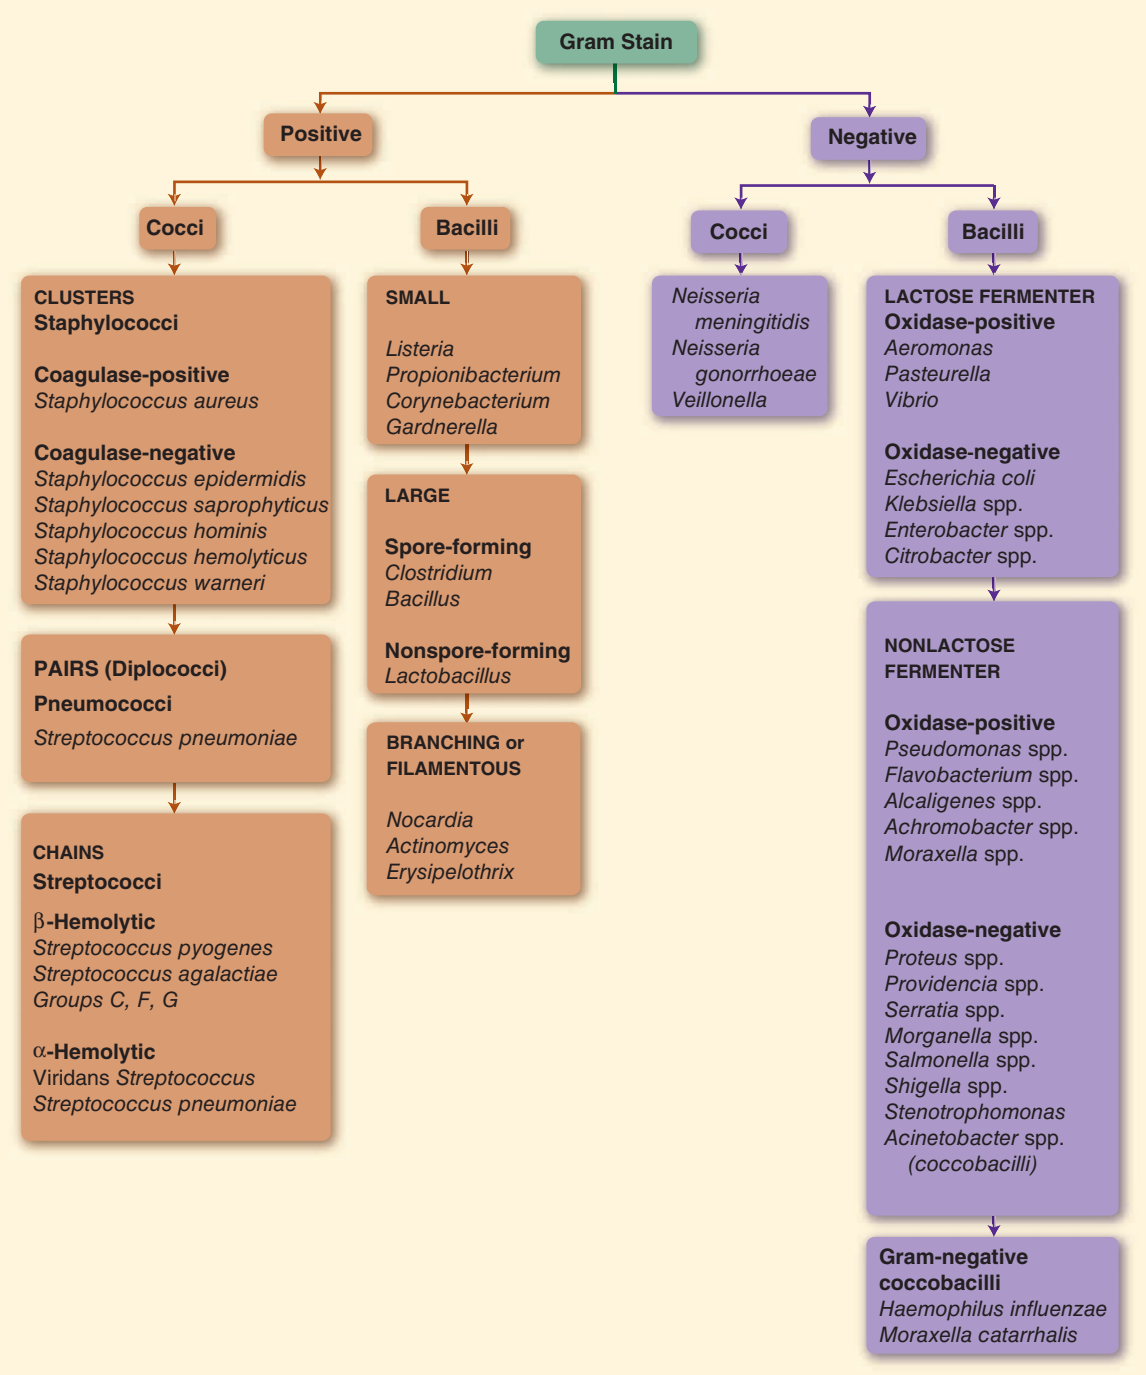

FIGURE 69–2. Important bacterial pathogens classified according to Gram stain and morphologic characteristics. (From Rybak MJ, Aeschlimann JR. Laboratory tests to direct antimicrobial pharmacotherapy. In: DiPiro JT, Talbert RL, Yee GC, et al, eds. Pharmacotherapy: A Pathophysiologic Approach, 9th ed. New York, NY: McGraw-Hill; 2014.)

indicates inflammation and suggests that the identified bacteria are pathogenic. The Gram stain may be useful in evaluating a sputum specimen's adequacy (eg, the presence of epithelial cells on sputum Gram stain suggests that the specimen is either poorly collected or contaminated). A poor specimen can give misleading information regarding the underlying pathogen and may result in inappropriate antimicrobial use.

Culture and susceptibility testing provides additional information to the clinician to select appropriate therapy. Specimens are placed in or on culture media that provide proper growth conditions. Once the bacteria grow on culture media, they can be identified through biochemical tests. When a pathogen is identified, susceptibility tests can be performed to various antimicrobial agents. The minimum inhibitory concentration (MIC) is a standard susceptibility test. The MIC is the lowest concentration of antimicrobial that inhibits visible bacterial growth after approximately 24 hours (Figure 69–3). **Breakpoint** and MIC values determine whether the organism is susceptible (S), intermediate (I), or resistant (R) to an antimicrobial. If the MIC is below the breakpoint, the organism is considered to be

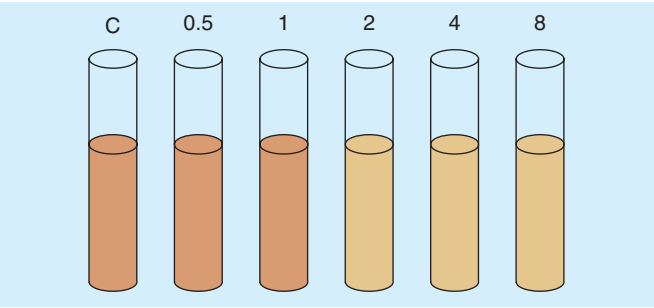

FIGURE 69–3. Macrotube minimal inhibitory concentration (MIC) determination. The growth control (C), 0.5 mg/L, and 1 mg/L tubes are visibly turgid, indicating bacterial growth. The MIC is read as the first clear test tube (2 mg/L). (From Rybak MJ, Aeschlimann JR. Laboratory tests to direct antimicrobial pharmacotherapy. In: DiPiro JT, Talbert RL, Yee GC, et al, eds. Pharmacotherapy: A Pathophysiologic Approach, 9th ed. New York, NY: McGraw-Hill; 2014.)

susceptible to that agent. If the MIC is above the breakpoint, the organism is said to be resistant. Reported culture and susceptibility results may not provide MIC values but generally report the S, I, and R results.

KEY CONCEPT In general, bacterial cultures should be obtained prior to initiating antimicrobial therapy in patients with a systemic inflammatory response, risk factors for antimicrobial resistance, or infections where diagnosis or antimicrobial susceptibility is uncertain. The decision to collect a specimen for culture depends on the physical and diagnostic findings, and whether or not the pathogens are readily predictable. Culture and susceptibility testing usually is not warranted in a young, otherwise healthy woman who presents with signs and symptoms consistent with a UTI because the primary pathogen, *Escherichia coli*, is readily predictable. Cultures and susceptibility testing are routine for sterile-site specimens (eg, blood and spinal fluid), as well as for material presumed to be infected (eg, material obtained from joints and abscesses). Cultures need to be interpreted with caution. Poor specimen collection technique and processing speed can result in misleading information and inappropriate use of antimicrobials.

TREATMENT

General Approach to Treatment, Including Nonantimicrobial Treatment

While antimicrobial therapy selection may be a major consideration in treating infectious diseases, it may not be the only therapeutic intervention. Other important therapies may include hydration, ventilatory support, and supportive medications. In addition, antimicrobials are unlikely to be effective if the source that leads to the infection is not controlled. **Source control** refers to this process and may involve removal of prosthetic materials such as catheters and infected tissue or drainage of an abscess. Source control considerations should be a fundamental component of any infectious diseases treatment. It is also important to recognize that there may be many different antimicrobial regimens that may cure the patient. While the following therapy sections provide factors to consider when selecting antimicrobial regimens, excellent and more in-depth resources for selecting antimicrobial regimens for a variety of infectious diseases are the Infectious Diseases Society of America Guidelines.[12]

Antimicrobial Considerations in Selecting Therapy

LOS KEY CONCEPT Drug-specific considerations in antimicrobial selection include spectrum of activity, effects on nontargeted microbial flora, appropriate dose, pharmacokinetic and pharmacodynamic properties, adverse-effect and drug-interaction profile, and cost (Table 69–2).

▶ *Spectrum of Activity and Effects on Nontargeted Flora*

Most initial antimicrobial therapy is empirical because cultures have not had sufficient time for identification of a pathogen. KEY CONCEPT Empirical therapy should be based on patient- and antimicrobial-specific factors such as the anatomic location of the infection, the likely pathogens associated with the presentation, the potential for adverse effects in a given patient, and the antimicrobial spectrum of activity. Prompt initiation of appropriate therapy is paramount in hospitalized patients who are critically ill. Patients who receive appropriate initial antimicrobial therapy survive at twice the rate of patients who receive inadequate therapy.[13] Empirical selection of antimicrobial spectrum of activity should be based on the pathogens most likely causing the infection as well as the severity of the illness. Generally, acutely ill patients require broader-spectrum antimicrobial coverage, whereas less ill patients may

Patient Encounter 2: Review of Symptoms, Physical Examination, and Laboratory Data

ROS: Elderly gentleman who is intubated and unable to answer questions.

PE:

- VS: BP 90/50 mm Hg, P 120 beats/min, RR 30 breaths/min, T 38.9°C, FiO_2 0.7 (increased from 0.4), PEEP 10 cm H_2O, Ht 5′10″ (178 cm), Wt 78 kg
- Chest: Rhonchi with decreased breath sounds
- CV: Tachycardic with regular rate and rhythm

Labs:

- WBC 18.5 × 10^3/mm^3 (16.5 × 10^9/L), segs 76% (0.76), bands 17% (0.17), lymphs 7% (0.07)
- SCr 1.8 mg/dL (159 µmol/L)
- Glucose 242 mg/dL (13.4 mmol/L)
- Procalcitonin 1.0 µg/L
- Sputum gram-stain: < 10 epis/lpf, > 25 WBCs/lpf, gram-negative bacilli
- Sputum Culture: Pending
- Blood Cultures: Pending

Chest radiography: bilateral lower lobe infiltrates.

What findings on physical examination are suggestive of an infectious process?

What laboratory findings and/or diagnostic studies have been performed to help establish the presence of an infection?

Are the findings of these laboratory and diagnostic studies suggestive of an infection?

What is your working diagnosis based on this patient encounter?

Table 69–2

Considerations for Selecting Antimicrobial Regimens

Drug Specific	Patient Specific
Spectrum of activity and effects on nontargeted flora	Anatomic location of infection
Dosing	Antimicrobial history
Pharmacokinetic properties	Drug allergy history
Pharmacodynamic properties	Renal and hepatic function
Adverse-effect potential	Concomitant medications
Drug-interaction potential	Pregnancy or lactation
Cost	Compliance potential

be managed initially with narrow-spectrum therapy. Either approach should ensure that the selected antimicrobial therapy covers the most likely pathogens causing the infection. While a detailed description of antimicrobial pathogen-specific spectrum of activity is beyond the scope of this chapter, this information can be obtained readily from a number of sources.[14,15]

Collateral damage is defined as the development of resistance occurring in a patient's nontargeted flora that can cause secondary infections. *Clostridium difficile* infection (CDI) is an example of a disease that occurs secondary to collateral damage. Antibiotics, especially high-risk agents such as fluoroquinolones, can increase the risk of CDI by suppressing normal intestinal flora, resulting in overgrowth of the nonsusceptible *C. difficile* bacteria.[16] If several different antimicrobials possess activity against a targeted pathogen, the antimicrobial that is least likely to be associated with collateral damage may be preferred.

▶ *Single versus Combination Therapy*

A common debate involves the need for empiric coverage with two antimicrobials for serious infections. Proponents state that double coverage may be synergistic, prevent the emergence of resistance, and improve outcome by ensuring activity against the infecting pathogen. However, there are few clinical examples in the literature to support these assertions. Examples where double coverage is considered superior are limited to infections associated with large bacterial loads and in species that are known to readily develop resistance such as active tuberculosis or enterococcal endocarditis.[17,18] Double antimicrobial coverage with two agents of similar spectra of activity may be beneficial for selected infections associated with high bacterial loads or for initial empirical coverage of critically ill patients in whom antimicrobial-resistant organisms are suspected. In these cases, monotherapy usually is satisfactory once antimicrobial susceptibilities are established.[19]

▶ *Antimicrobial Dose*

Clinicians should be aware that antimicrobial dosage regimens may be different depending on the infectious process. For example, ciprofloxacin, a fluoroquinolone, has various dosage regimens based on site of infection. The dosing for uncomplicated UTIs is 250 mg twice daily for 3 days. For pyelonephritis, the dose is 500 mg twice daily for 7 to 14 days. Severe complicated pneumonia may require a dosage regimen of 750 mg twice daily for 7 to 14 days. Clinicians are encouraged to use dosing regimens designed for treatment of the diagnosed infection because they have demonstrated proven efficacy and are most likely to minimize harm.

▶ *Pharmacokinetic Properties*

Pharmacokinetic properties of an antimicrobial may be important in antimicrobial regimens. Pharmacokinetics refers to a mathematical method of describing a patient's drug exposure in vivo in terms of absorption, distribution, metabolism, and elimination. Bioavailability refers to the amount of antimicrobial that is absorbed orally relative to an equivalent IV dose administered. Drug-related factors that may affect oral bioavailability include the formulation of the antimicrobial, dosage form, and stability of the drug in the gastrointestinal (GI) tract. Patients with systemic signs of infection such as hypotension should receive intravenous antimicrobials to ensure drug delivery as absorption is affected by GI blood flow. In cases where patients have a functioning GI tract and are not hypotensive, antimicrobials with almost complete bioavailability (> 80%) such as the fluoroquinolones, fluconazole, and linezolid may be given orally. With antimicrobials with modest bioavailability (eg, many β-lactams), the decision to choose an oral product will depend more on the severity of the illness and the anatomic location of the infection. In sequestered infections, where higher systemic concentrations of antimicrobial may be necessary to reach the infected source (eg, meningitis) or for antimicrobials with poor bioavailability, IV formulations should be used.

Some antimicrobials may be bound to proteins in serum. Only unbound drug is biologically active and distributes freely between tissues. Protein binding is clinically relevant in highly protein-bound antimicrobials (> 50%) as the agents may not be able to penetrate sequestered compartments, such as cerebral spinal fluid, resulting in insufficient concentrations to inhibit bacteria. In addition, some drugs may not achieve sufficient concentrations in specific compartments based on distribution characteristics. For example, *Legionella pneumophila*, an organism that causes severe pneumonia, is known to survive and reside inside pulmonary macrophages. Treatment with an antibiotic that inhibits bacterial cell wall synthesis, such as a cephalosporin, will be ineffective because it only distributes into extracellular host tissues. However, macrolide, tetracycline, or fluoroquinolone antimicrobials, which concentrate in human pulmonary macrophages, are highly effective against this organism.

Many antimicrobials undergo some degree of metabolism once ingested. Metabolism may occur via hepatic, renal, or non-organ-specific enzymatic processes. The route of elimination of the metabolic pathway may be exploited for infections associated with tissues related to the metabolic pathways. For example, many fluoroquinolone antimicrobials have renal elimination. Urinary concentrations of active drug are many times those achieved in the systemic circulation, making these agents good choices for complicated UTIs.

▶ *Pharmacodynamic Properties*

Pharmacodynamics describes the relationship between drug exposure and pharmacologic effect of antibacterial activity or human toxicology. Antimicrobials are categorized based on their concentration-related effects on bacteria. Concentration-dependent activity occurs where higher drug concentrations are associated with greater rates and extents of bacterial killing. Concentration-dependent antimicrobial activity is maximized when peak antimicrobial concentrations are high. In contrast, concentration-independent (or time-dependent) activity refers to a minimal increase in the rate or extent of bacterial killing with an increase in antimicrobial dose. Concentration-independent antimicrobial activity is maximized when these antimicrobials are dosed to maintain blood and/or tissue

concentrations above the MIC in a time-dependent manner. Fluoroquinolones, aminoglycosides, and metronidazole are examples of antimicrobials that exhibit concentration-dependent activity, whereas β-lactam and glycopeptide antimicrobials exhibit concentration-independent activity. Pharmacodynamic properties have been optimized to develop new dosing strategies for older antimicrobials. Examples include single-daily-dose aminoglycoside or β-lactam therapy administered by continuous or extended infusion.

Antimicrobials also can be classified as possessing bactericidal or bacteriostatic activity in vitro. Bactericidal antibiotics reduce the bacterial population by greater than or equal to a 3 log reduction, whereas bacteriostatic antibiotics possess antimicrobial activity but reduce bacterial load by less than 3 logs. Clinically, bactericidal antibiotics may be necessary to achieve success in infections such as endocarditis or meningitis. A full discussion of the application of antimicrobial pharmacodynamics is beyond the scope of this chapter, but excellent sources of information are available.[20]

▶ *Adverse-Effect and Drug-Interaction Properties*

A major concern when selecting antimicrobial regimens should be the propensity for the regimen to cause adverse effects and the potential for drug interactions. In general, if several different antimicrobial options are available, antimicrobials with a low propensity to cause adverse events should be selected, particularly for patients with risk factors for a particular complication. Risk factors for adverse events may include the coadministration of other drugs that are associated with a similar type of adverse event. For example, coadministration of the known nephrotoxin gentamicin with vancomycin increases the risk for nephrotoxicity compared with administration of either drug alone.[21] Other drug interactions may predispose the patient to dose-related toxicity through inhibition of drug metabolism. For example, macrolides have the potential to prolong cardiac QT intervals in a dose-dependent manner, potentially increasing the risk for sudden cardiac death.[22]

▶ *Antimicrobial Cost*

A final consideration in selecting antimicrobial therapy relates to cost. The least expensive antimicrobial is not necessarily the most cost-effective antimicrobial. Antimicrobial costs constitute a relatively small portion of the overall cost of care. Careful consideration of antimicrobial microbiologic, pharmacologic, and patient-related factors such as adherence and a variety of clinical outcomes is necessary to establish the cost versus benefit of an antimicrobial in a given patient. If there is no difference or a small difference in these factors, the least costly antimicrobial may be the best choice.

Patient Considerations in Antimicrobial Selection

LO 6

KEY CONCEPT Key patient-specific considerations in antimicrobial selection include recent antimicrobial exposures, identification of the anatomic location of infection through physical examination and diagnostic imaging, history of drug allergies, pregnancy or breast-feeding status, organ dysfunction that may affect drug clearance, immunosuppression, compliance, and the severity of illness (see Table 69–2).

▶ *Host Factors*

Host factors can help to ensure selection of the most appropriate antimicrobial agent. Age is an important factor in antimicrobial selection. Populations with diminished renal function include neonates and the elderly. Hepatic function in the neonate is not fully developed, and drugs that are metabolized or eliminated by this route may produce adverse effects. For example, sulfonamides and ceftriaxone may compete with bilirubin for binding sites and may result in hyperbilirubinemia and kernicterus. Gastric acidity also depends on age; the elderly and children younger than 3 years tend to be achlorhydric. Drugs that need an acidic environment (eg, ketoconazole) are not well absorbed, and those whose absorption is enhanced in an alkaline environment will have increased concentrations (eg, penicillin).

Disruption of host defenses due to IV or indwelling Foley catheters, burns, trauma, surgery, and increased gastric pH may place patients at higher risk for infection. Breaks in skin integrity provide a route for infection because the natural barrier of the skin is disrupted. Increased gastric pH can allow for bacterial overgrowth and has been associated with an increased risk of pneumonia.[23]

Recognizing the presumed site of infection and most common pathogens associated with the infectious source should guide antimicrobial choice, dose, and route of administration. For example, community-acquired pneumonia is caused most commonly by *Streptococcus pneumoniae*, *E. coli* is the primary cause of uncomplicated UTIs, and staphylococci and streptococci are implicated most frequently in skin and skin-structure infections (eg, cellulitis).

Patients with a history of recent antimicrobial use may have an altered microbiome or harbor resistant organisms. These patients should receive a different antimicrobial agent than was recently used. If a patient develops a new infection while on therapy or fails therapy, it is reasonable to prescribe either a different class of antimicrobial or alternative agent directed at the most likely pathogens. Failure may not be related to the antimicrobial agent but to poor source control. Previous hospitalization or health care utilization (eg, residing in a nursing home, hemodialysis, and outpatient antimicrobial therapy) are risk factors for the acquisition of nosocomial pathogens, which are often resistant organisms.

Antimicrobial allergies are some of the most common drug-related allergies reported and have significant potential to cause adverse events. In particular, reported penicillin-related allergy is common and can be problematic as this contributes to the unnecessary or inappropriate use of other antimicrobial agents.

Patient Encounter 3: Empirical Selection of Antibiotics

Based on the information presented, select an empirical antimicrobial regimen for this patient. Your plan should include:

(a) A tentative infectious diagnosis or source, including likely pathogens or resistant organisms;

(b) A specific antimicrobial regimen, including drug(s), dose, and route of administration;

(c) Description of any ancillary treatments;

(d) A rationale for your empirical antimicrobial selection based on drug- and patient-specific considerations.

A patient's medical history should be reviewed to determine the offending β-lactam and nature of the allergic reaction. Patients with mild or certain nonimmunologic reactions to penicillins may receive a β-lactam antimicrobial. Non-IgE- mediated findings such as Stevens-Johnson syndrome, toxic epidermal necrolysis, or interstitial nephritis, should not be rechallenged with the offending agent, desensitized to penicillin, or undergo penicillin allergy skin testing. Previously it was thought that patients with a history of findings consistent with IgE-mediated reactions (type I) such as anaphylaxis, urticaria, or bronchospasm should not be administered any type of β-lactam antimicrobial. However, newer data suggests that β-lactam antimicrobials may be safely administered. Data demonstrate that the actual cross-reactivity between penicillins and cephalosporins is likely less than 1% and slightly lower with carbapenems. Penicillins, cephalosporins, and carbapenems have the β-lactam ring in common; however, it is more likely that the allergy cross-reactivity between penicillins and cephalosporins is secondary to side chain groups (R_1 and R_2). Therefore, in the majority of patients with a penicillin allergy, cephalosporins with dissimilar side chains, carbapenems, and monobactams may be safely administered.[24,25] Structural side chain similarities among β-lactam agents may be found in the literature (reference 24 contains a chart).

Renal and/or hepatic function should be considered prior to initiation of antimicrobial therapy. Most antimicrobials undergo renal elimination and dosing adjustments are frequently necessary and recommendations for adjustment are available in the literature.[26] In contrast, dosing adjustments for antimicrobials that undergo nonrenal elimination are less well documented. Failure to adjust the antimicrobial dose or interval may result in drug accumulation and adverse effects.

Concomitant administration of other medications may influence the selection of the antimicrobial, dose, and monitoring. Medications that commonly interact with antibiotics include, but are not limited to, warfarin, rifampin, phenytoin, digoxin, theophylline, multivalent cations (eg, calcium, magnesium, and zinc), and sucralfate. Drug interactions between antimicrobials and other medications may occur via the cytochrome P-450 system, protein-binding displacement, and alteration of vitamin K–producing bacteria. Interactions may result in increased concentrations of one or both agents, increasing the risk of adverse effects or additive toxicity. A key consideration in selecting antimicrobial regimens starts with obtaining a good patient medical and drug history, recognizing drug-specific adverse-event characteristics, and anticipating potential problems proactively. If it is necessary to use an antimicrobial with a relatively high frequency of adverse effects, informing patients of the risks and benefits of therapy, as well as what to do if an adverse effect occurs, may improve patient compliance and safety.

Antimicrobial agents must be used with caution in pregnant and nursing women. Some agents pose potential threats to the fetus or infant (eg, quinolones, tetracyclines, and sulfonamides). For some agents, avoidance during a specific trimester of pregnancy is warranted (eg, the first trimester with trimethoprim/sulfamethoxazole). Pharmacokinetic variables also are altered during pregnancy. Both the clearance and volume of distribution are increased during pregnancy. As a result, increased dosages and/or more frequent administration of certain drugs may be required to achieve adequate concentrations. This information can be obtained from a number of sources.[27]

Adherence is essential to ensure efficacy. Patients may stop taking their antibiotics once the symptoms subside and save them for a "future" infection. Self-medication with saved antibiotics may be harmful, leading to overtreatment, which may further contribute to antibiotic resistance. Poor adherence may be due to adverse effects, tolerability, cost, and lack of patient education.

OUTCOME EVALUATION

LO 7 Figure 69–4 provides an overview of patient- and antimicrobial agent-specific factors to consider when selecting an antimicrobial regimen. It further delineates monitoring of therapy and actions to take depending on the response to therapy. Duration of therapy depends on patient response and type of infection being treated.

After selection and initiation of an antimicrobial regimen, there are additional patient care and monitoring considerations that should be addressed to improve the likelihood of a successful outcome. LO 8 KEY CONCEPT Patient education, de-escalation of antimicrobial therapy based on culture results, monitoring for clinical response and adverse effects, and appropriate duration of therapy are important.

Modifying Empirical Therapy Based on Cultures and Clinical Response

If a successful clinical response occurs and culture results are available, therapy should be de-escalated. Antibiotic de-escalation generally refers to the discontinuation of antibiotics that are providing a spectrum of activity greater than necessary to treat the infection, discontinuation of duplicative spectrum antibiotics, or switching to a narrower spectrum antibiotic once a patient is clinically stable. De-escalation of empirical therapy may also include discontinuing antibiotics based on clinical criteria and negative culture results, such as the absence of antibiotic-resistant pathogens.[28] The purpose of de-escalation therapy is to prevent problematic effects such as adverse events and to minimize the risk of *C. difficile* infections and development of resistance. In cases in which a specific organism is recovered that has a known preferred antimicrobial treatment of choice, therapy might be changed to that specific agent. For example, antistaphylococcal penicillins and first-generation cephalosporins (ie, cefazolin) are considered to be the agents of choice for methicillin-susceptible *S. aureus* owing to their bactericidal activity and narrow-spectrum activity and may be preferable to other antibiotic regimens. In other cases, empirical coverage might be discontinued if a specific suspected pathogen is excluded by culture or an alternative, noninfectious diagnosis is established. In addition, IV antimicrobials frequently are more expensive than oral therapy. Therefore, it is usually desirable to convert to oral antimicrobials with a comparable antimicrobial spectrum or specific pathogen sensitivity as soon as the patient improves clinically.[29]

Failure of Antimicrobial Therapy

While many infections respond readily to antimicrobials, some infections do not. A common question when a patient fails to improve relates to whether the antimicrobial therapy has failed. Changing antimicrobials generally is one of the easiest interventions relative to other options. However, it is important to remember that antimicrobial therapy comprises only a portion of the overall disease treatment, and there may be many factors that contribute to a lack of improvement. LO 9 KEY CONCEPT In general,

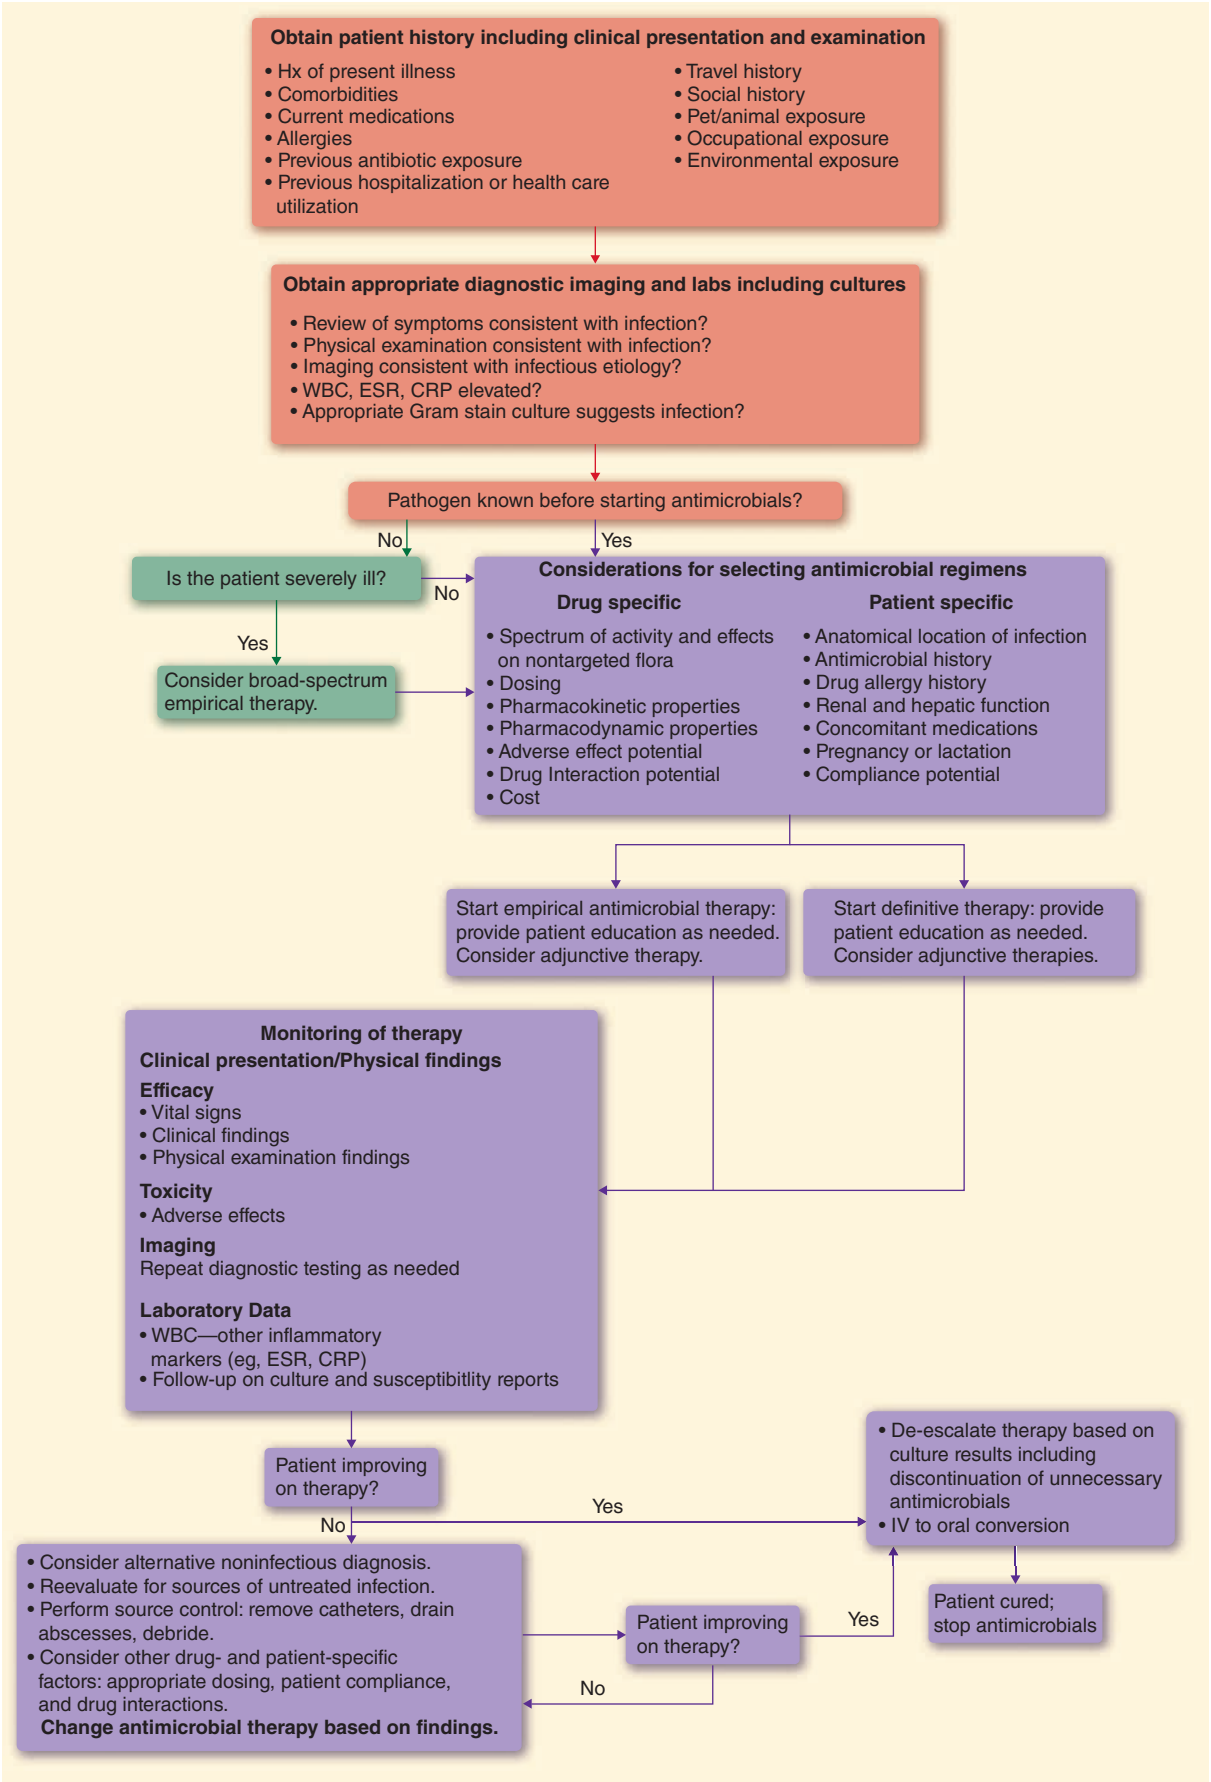

FIGURE 69–4. Approach to selection of antimicrobial therapy.

inadequate diagnosis resulting in poor initial antimicrobial or other nonantibiotic drug selection, poor source control, or the development of a new infection with a resistant organism are relatively common causes of antimicrobial failure. An infection-related diagnosis may be difficult to establish and generally has two components: (a) differentiating infection from noninfectious disease and (b) providing adequate empirical spectrum of activity if the cause is infectious. Failure of improvement in a patient's condition should warrant broadening the differential diagnosis to include noninfectious causes, as well as considering other potential infectious sources and/or pathogenic organisms. Another common cause of failure is poor source control. A diagnostic search for unknown sources of infection and removal of indwelling devices in the infected environment or surgical drainage of abscesses should be undertaken if the patient's condition is not improving. Less common causes of therapeutic failure include the development of secondary infections. In this case, the patient generally improves, but then develops a new infection caused by an antimicrobial-resistant pathogen and relapses. The emergence of resistance to a targeted pathogen while on antimicrobial therapy can be associated with clinical failure but usually is limited to tuberculosis, pseudomonads, or other gram-negative enterics. Drug- and patient-specific factors such as appropriate dosing, patient compliance, and drug interactions can be associated with therapeutic failure and also should be considered. A common assumption is that the correct diagnosis was made, but the patient was not treated long enough with antimicrobials. There are certain types of infections (eg, endocarditis or osteomyelitis) where the standard of care is to treat for prolonged periods of time (ie, weeks or months). However, the optimal duration of therapy for many infectious diseases is somewhat subjective. Studies of several infectious processes have suggested that shorter durations of therapy can result in similar clinical outcomes as longer durations of therapy, frequently with fewer complications or secondary infections.[30,31] In this period of extensive antimicrobial resistance, clinicians should keep abreast of changing recommendations emphasizing shorter durations of therapy.

Tracking/reporting antimicrobial use and outcomes
Education

ANTIBIOTIC STEWARDSHIP

LO 10

KEY CONCEPT Antibiotic stewardship promotes the optimal use of antimicrobial agents to reduce the emergence of resistant pathogens, improve the quality of patient care and safety, and reduce costs. Optimal use of antimicrobial agents includes appropriate selection, dose, route, and duration of therapy. Antibiotic stewardship programs have been implemented in many acute care institutions. As of January 1, 2017, the Joint Commission's Antimicrobial Stewardship Standard became effective for hospitals, critical access hospitals and nursing care centers. See Table 69–3.

Program leaders are often a physician trained in infectious diseases and a pharmacist. Other key personnel/support include clinicians, infection prevention, quality improvement, microbiology laboratory, information technology, and nursing. The goal is to support optimal antimicrobial use through various interventions and measures. Readers are encouraged to view the IDSA guidelines on implementing an antibiotic stewardship program and the CDC's Get Smart Campaign for further information.[4,28]

Patient Encounter 4: Patient Care and Monitoring

Update: Vancomycin, piperacillin/tazobactam, and levofloxacin were initiated.

After 48 hours of therapy, the following parameters are obtained:

PE:

- VS: BP 130/70 mm Hg, P 70 beats/min, RR 22 breaths/min, T 37.2°C (98.9°F), FiO_2 0.3, PEEP 5 cm H_2O

Labs:

- WBC 9.2 × 10^3/mm^3 (9.2 × 10^9/L)/differential 85% segs, 10% lymphs, 5% monos
- SCr 1.1 mg/dL (97.2 µmol/L)
- Glucose 126 mg/dL (6.9 mmol/L)
- Blood cultures × 2: No growth
- Sputum culture: *Pseudomonas aeruginosa*

Susceptibility Report:

Cefepime susceptible (MIC > 16 mg/L)

Ceftazidime susceptible (MIC < 16 mg/L)

Piperacillin/tazobactam susceptible (MIC ≤ 16 mg/L)

Meropenem susceptible (MIC ≤ 1 mg/L)

Gentamicin susceptible (MIC ≤ 4 mg/L)

Tobramycin susceptible (MIC < 4 mg/L)

Ciprofloxacin resistant (MIC > 4 mg/L)

Levofloxacin resistant (MIC > 4 mg/L)

What information suggests improvement in the patient's condition?

Do any of the antimicrobial doses need to be adjusted for changes in organ function?

Should antimicrobial therapy be modified based on the culture results?

Can the antimicrobial therapy be converted from IV to oral therapy?

Patient Care Process

Collect Information:

- Review pertinent patient medical history including significant comorbid conditions
- Determine patient allergy histories (including reactions and timing)
- Determine and document recent antibiotic exposure

Assess the Information:

- Review patient labs, including labs obtained for specific infectious syndromes and vital signs
- Determine if patient may have any potential sources for infection (eg, central venous catheter, urinary catheter)
- Assess the severity of illness
- Assess patient-specific risk factors based on infection type to aid in determining appropriate empirical therapy
- Review local antibiotic susceptibility patterns including hospital antibiograms

Develop a Care Plan:

- Based on proposed infectious diagnosis combined with above data assessed, select empirical antibiotic regimen
- Consider additional diagnostics and culture and susceptibility reports

Implement the Care Plan:

- Timely antibiotics are required, especially in critically ill patients, including those with sepsis

Follow-up: Monitor and Evaluate:

- Follow-up on culture and susceptibility reports to determine opportunities to streamline antibiotic therapy
- Some antibiotics may require therapeutic drug monitoring (eg, vancomycin) to evaluate for safety and effectiveness
- Duration of therapy should be determined based on several factors including but not limited to infection type, culture results, host immune status, and source control (eg, removal of a central venous catheter)

Abbreviations Introduced in This Chapter

CDC	Centers for Disease Control and Prevention
CRP	C-reactive protein
ESR	Erythrocyte sedimentation rate
HPI	History of present illness
MIC	Minimum inhibitory concentration
MRSA	Methicillin-resistant *Staphylococcus aureus*
PMH	Past medical history
UTI	Urinary tract infection
VRE	Vancomycin-resistant *Enterococcus*
WBC	White blood cell count

70 Central Nervous System Infections

April Miller Quidley and P. Brandon Bookstaver

LEARNING OBJECTIVES

LO

Upon completion of the chapter, the reader will be able to:

1. Discuss the pathophysiology of central nervous system (CNS) infections and the impact on antimicrobial treatment regimens (including antimicrobial dosing and CNS penetration).
2. Describe the signs, symptoms, and clinical presentation of CNS infections.
3. List the most common pathogens causing CNS infections and identify risk factors for infection with each pathogen.
4. State the goals of therapy for CNS infections.
5. Outline the initial management strategies for CNS infections.
6. Design appropriate empirical antimicrobial regimens for patients suspected of having CNS infections (taking age, vaccine history, and other patient-specific information into account) caused by each of the following pathogens, and analyze the impact of antimicrobial resistance on both empirical and definitive therapy: *Neisseria meningitidis* meningitis, *Haemophilus influenzae* meningitis, *Listeria monocytogenes* meningitis, group B *Streptococcus* meningitis, gram-negative bacillary meningitis, postneurosurgical infection, CNS shunt infection, herpes simplex encephalitis.
7. Modify empirical antimicrobial regimens based on laboratory data and other diagnostic criteria.
8. Discuss the management of close contacts of patients diagnosed with CNS infections.
9. Identify candidates for vaccines and other prophylactic therapies to prevent CNS infections.
10. Describe the role of adjunctive agents (eg, dexamethasone) in the management of CNS infections.

INTRODUCTION

The term *central nervous system (CNS) infections* describes a variety of infections involving the brain and spinal cord and associated tissues, fluids, and membranes, including meningitis, encephalitis, brain abscess, cerebrospinal fluid (CSF) shunt infections, and postoperative infections. KEY CONCEPT CNS infections, such as meningitis, are considered neurologic emergencies that require prompt recognition, diagnosis, and management to prevent death and residual neurologic deficits. Improperly treated, CNS infections are associated with high rates of morbidity and mortality. Despite advances in care, the overall mortality of bacterial meningitis in the United States remains at approximately 15%, and at least 10% to 30% of survivors are afflicted with neurologic impairment, including hearing loss, hemiparesis, and learning disabilities.[1,2] Antimicrobial therapy and preventive vaccines have revolutionized management and improved outcomes of bacterial meningitis and other CNS infections dramatically.

EPIDEMIOLOGY AND ETIOLOGY

CNS infections are uncommon and declining in incidence, with a rate of 0.8 per 100,000 persons between 1997 and 2010.[3] However, the severity of these infections demands prompt medical intervention and treatment. CNS infections can be caused by bacteria, fungi, mycobacteria, viruses, parasites, and spirochetes.

Bacterial meningitis is the most common cause of CNS infections. While vaccination has reduced the incidence of disease by many common pathogens, *Streptococcus pneumoniae* (pneumococcus) was the most common pathogen for bacterial meningitis (0.306 cases per 100,000), followed by *Neisseria meningitidis* (meningococcus, 0.123 cases per 100,000).[3] Staphylococcal species and gram-negative bacteria account for 0.114 and 0.127 cases per 100,000 persons, respectively in the United States.[3] Group B *Streptococcus* (GBS) and *Listeria monocytogenes* remain important causes, but current data on their incidence are lacking.[2] Vaccines directed against bacteria causing meningitis and related infections (eg, pneumonia and ear infections) have reduced the risk of infections due to *S. pneumoniae*, *N. meningitidis*, and *H. influenzae* type B (Hib) dramatically.[2,3] Prior to the availability of Hib conjugate vaccines, Hib meningitis or other invasive disease was documented in one in 200 children by the age of 5 years and due to widespread use, its incidence has decreased such that it is no longer a leading pathogen.[3] Historically, a 7-valent conjugate pneumococcal vaccine (PCV7) was administered, but despite use of the PCV7, *S. pneumoniae* remained the most common pathogen for pediatric bacterial meningitis. In 2010, a 13-valent conjugate pneumococcal vaccine was licensed for use in the

United States; however, its impact on the epidemiology of disease in the United States is still unknown. In France, the 13-valent vaccine reduced the incidence of pneumococcal meningitis by 27.4% and similar reductions were seen in Canada with strains found in the vaccine.[4,5]

Encephalitis may result from viral, bacterial, parasitic, or other noninfectious causes. Herpes simplex virus (HSV) is the most common cause of encephalitis in the United States, accounting for 10% of all cases.[6] The annual incidence of viral encephalitis is 3.5 to 7.4 infections per 100,000 persons.[6] Other pathogens including common bacterial meningitis causes, *Rickettsia* species, enteroviruses, arboviruses, varicella-zoster virus, rotavirus, coronavirus, influenza viruses A and B, West Nile virus, and Epstein-Barr virus may be associated with a meningoencephalopathic presentation.[7] Approximately 20,000 hospitalizations each year are secondary to encephalitis, accounting for $650 million in health care costs.[8] Over the past 10 to 20 years, mortality secondary to encephalitis has remained constant, correlating with the increased number of people living with human immunodeficiency virus (HIV) and acquired immune deficiency syndrome (AIDS).

Neurosurgical procedures may place patients at risk for meningitis due to bacteria acquired at the time of surgery or in the postoperative period, including *Staphylococcus aureus*, coagulase-negative staphylococci, and gram-negative bacilli. In addition to bacteria, other pathogens may cause meningitis in at-risk patients. Immunocompromised patients, such as solid-organ transplant patients and patients living with HIV infection, are at risk for fungal meningitis with *Cryptococcus neoformans* and encephalitis secondary to *Toxoplasma gondii* and JC virus. Tuberculosis can spread from pulmonary sites to cause clinical disease in the CNS. Life-threatening viral encephalitis and meningitis can occur in otherwise healthy, young individuals, as well as in patients immunocompromised by age or other factors.

Risk factors for CNS infections can be classified as follows:

- *Environmental:* Recent exposures (eg, close contact with meningitis or respiratory tract infection, contaminated foods), active or passive exposure to cigarette smoke, close living conditions
- *Recent infection in the patient:* Respiratory infection, otitis media, sinusitis, mastoiditis
- *Immunosuppression:* Anatomic or functional asplenia, sickle cell disease, alcoholism, cirrhosis, immunoglobulin or complement deficiency, cancer, HIV/AIDS, uncontrolled diabetes mellitus, debilitated state of health
- *Surgery, trauma:* Neurosurgery, head trauma, CSF shunt, cochlear implant
- Noninfectious causes of meningitis include malignancy, medications (eg, sulfonamides, nonsteroidal anti-inflammatory drugs [NSAIDs], IV immunoglobulin), autoimmune disease (eg, lupus), and trauma.[6,7]
- The most common pathogens causing bacterial meningitis, by age group and other risk factors, are found in Table 70–1.

Table 70–1

Most Likely Pathogens and Recommended Empirical Therapy, by Risk Factor, for Bacterial Meningitis[2,24,25]

Predisposing Factor	Most Likely Pathogens	Recommended Empirical Antibiotic Therapy
Age		
Less than 3 months	Group B *Streptococcus* *Escherichia coli* *Klebsiella pneumoniae* *Listeria monocytogenes*	Ampicillin *plus* cefotaxime *or* aminoglycoside
3 months to less than 18 years	*Streptococcus pneumoniae* *Neisseria meningitidis*	Cefotaxime *or* ceftriaxone *plus* vancomycin
18 years to less than 60 years	*S. pneumoniae* *N. meningitidis*	Cefotaxime *or* ceftriaxone *plus* vancomycin
60 years *or* older	*S. pneumoniae* Gram-negative bacilli *L. monocytogenes*	Cefotaxime *or* ceftriaxone *plus* vancomycin *plus* ampicillin
Immunocompromised	*S. pneumoniae* *N. meningitidis* *L. monocytogenes* Gram-negative bacilli (including *Pseudomonas aeruginosa*)	Cefotaxime *or* ceftriaxone *plus* vancomycin *plus* ampicillin (consider double antibiotic coverage against *Pseudomonas* spp. if suspected)
Surgery, Trauma		
Postneurosurgical infection	*S. aureus* (including MRSA) Coagulase-negative *Staphylococcus* (including MRSE) Gram-negative bacilli (including *P. aeruginosa*)	Vancomycin *or* linezolid *plus* cefepime or ceftazidime *or* meropenem (consider empiric use of two active antibiotics against *Pseudomonas* spp. if suspected)
Penetrating head trauma	*S. aureus* (including MRSA) coagulase-negative *Staphylococcus* Gram-negative bacilli (including *P. aeruginosa*)	Vancomycin *or* linezolid *plus* cefepime or ceftazidime *or* meropenem (consider empiric use of two active antibiotics against *Pseudomonas* spp. if suspected)
CSF shunt	Coagulase-negative *Staphylococcus* (including MRSE) *S. aureus* (including MRSA) Gram-negative bacilli (including *P. aeruginosa*)	Vancomycin *or* linezolid *plus* cefepime or ceftazidime or meropenem (consider empiric use of two active antibiotics against *Pseudomonas* spp. if suspected)

MRSA, methicillin-resistant *Staphylococcus aureus*; MRSE, methicillin-resistant *Staphylococcus epidermidis*.

Patient Encounter 1, Part 1

NB is a 10-year-old, 35 kg boy without a significant past medical history. He is active in sports and recently returned from a baseball tournament where he lived in shared housing with his teammates. He now presents to the emergency department with a 2-day history of headache, fever, and confusion. Physical findings and laboratory values include temperature of 38.9°C (102°F) and WBC of 18.7 × 10^3/mm^3 (18.7 × 10^9/L), with 73% (0.73) polymorphonuclear cells (PMNs). Examination reveals nuchal rigidity and altered mental status. He is up to date on his vaccinations.

What signs and symptoms consistent with meningitis are present in NB?

What causative pathogens should be suspected in NB?

What empiric antimicrobials should be started?

PATHOPHYSIOLOGY

Meningitis is an inflammation of the membranes of the brain and spinal cord (**meninges**) and the CSF in contact with these membranes, whereas encephalitis is an inflammation of the brain tissue. CSF produced in the brain ventricles flows through the subarachnoid space and downward through the spinal cord, insulating and protecting delicate CNS tissue.

To initiate a CNS infection, pathogens must gain entry into the CNS by **contiguous** spread, **hematogenous** seeding, direct inoculation, or reactivation of latent infection. Contiguous spread occurs when infections in adjacent structures (eg, sinus cavities or the middle ear) invade directly through the blood–brain barrier. Hematogenous seeding occurs when a remote infection causes bacteremia that seeds the CSF, such as pneumococcal pneumonia. Reactivation of latent infection results from dormant viral, fungal, or mycobacterial pathogens in the spine, brain, or nerve tracts. Direct inoculation of bacteria into the CNS is the result of trauma, congenital malformations, or complications of neurosurgery.

Once through the blood–brain barrier, pathogens replicate due to limited host defenses in the CNS. **Figure 70–1** depicts the pathophysiologic changes associated with meningitis. Neurologic tissue damage is the result of the host's immune reaction to bacterial cellular components, which trigger cytokine production, particularly tumor necrosis factor alpha (TNF-α) and interleukin 1 (IL-1), and other inflammatory mediators.[9] Bacteriolysis resulting from antibiotic therapy further contributes to the inflammatory process. Cytokines increase permeability of the blood–brain barrier, allowing influx of neutrophils and other host defense cells that contribute to the development of cerebral edema and increased intracranial pressure characteristic of meningitis.[10] The increase in intracranial pressure is responsible for the hallmark clinical signs and symptoms of meningitis: headache, neck stiffness, altered mental status, photophobia, and seizures. Untreated, these pathophysiologic changes may result in cerebral ischemia and death.

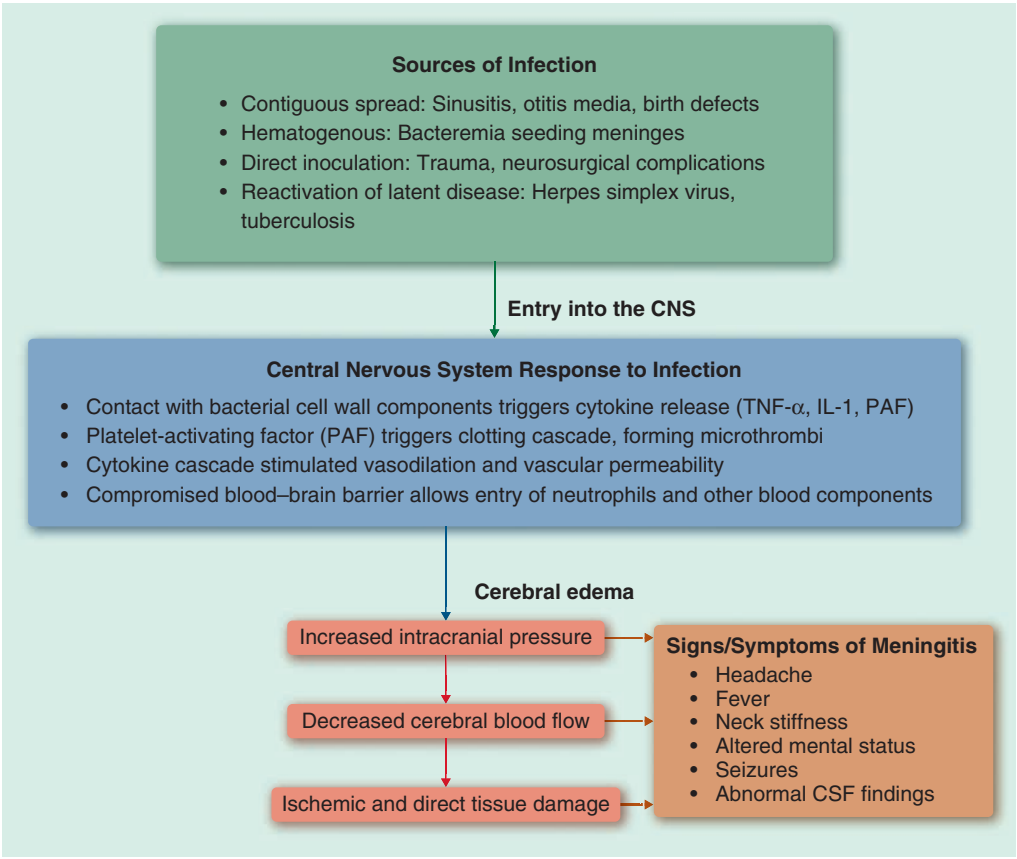

FIGURE 70–1. Pathophysiology of bacterial meningitis.

Table 70–2

CNS Response to Infection (CSF Findings)

	Normal CSF	Bacterial Infection	Viral Infection	Fungal Infection	Tuberculosis
WBC ($\times 10^3$/mm^3 *or* $\times 10^9$/L)	< 0.005	1.0–greater than 5.0	0.1–1	0.1–0.4	50–500
WBC differential (% or fraction in brackets, predominant cell type)	> 85% (0.85) monocytes	At least 80% (0.80) PMNs	50% (0.50) lymphocytes (PMN early)	> 50% (0.50) lymphocytes	> 80% (0.80) lymphocytes (PMNs early)
Protein (mg/dL, mg/L)	20–45 (200–450)	> 100 (> 1000)	50–100 (500–1000)	100–200 (1000–2000)	40–150 (400–1500)
Glucose (mg/dL, mmol/L)	45–80 (2.5–4.4)	5–40 (0.3–2.2)	30–70 (1. 7–3. 9)	< 30–70 (< 1. 7–3. 9)	< 30–70 (< 1. 7–3. 9)
CSF: serum glucose ratio	At least 0.6 serum glucose	< 0.4 serum glucose	At least 0.6 serum glucose	< 0.4 serum glucose	< 0.4 serum glucose
CSF stain	Negative	Positive Gram stain (60%–90%)	Negative	Positive India ink stain (Cryptococcus)	Positive acid-fast bacilli stain
Opening pressure	< 20 mm Hg	> 20 mm Hg	< 20 mm Hg	> 20 mm Hg	> 20 mm Hg

CSF, cerebrospinal fluid; PMNs, polymorphonuclear neutrophils.

From Refs. 5 and 11.

LO 5

The CNS response to infection is cellular and chemical changes in the CSF. KEY CONCEPT Ideally, lumbar puncture (LP) to obtain CSF for direct examination and laboratory analysis, as well as blood cultures and other relevant cultures, should be obtained before initiation of antimicrobial therapy. However, initiation of antimicrobial therapy should not be delayed if a pretreatment LP cannot be performed.

Normal CSF has a characteristic composition in terms of protein and glucose content, as well as cell count. Table 70–2 lists CSF findings normally observed and in the setting of meningitis.

CLINICAL PRESENTATION AND DIAGNOSIS

A high index of suspicion should be maintained for patients at risk for CNS infections. Prompt recognition and diagnosis are essential so that antimicrobial therapy can be initiated as quickly as possible. A medical history (including risk factors for infection and history of possible recent exposures) and physical examination yield important information to help guide the diagnosis and treatment of meningitis. Common signs and symptoms include fever, headache, **nuchal rigidity**, and photophobia. Infants present with nonspecific signs and symptoms, including excessive irritability or crying, vomiting or diarrhea, tachypnea, altered sleep pattern, and poor eating. Depending on involved pathogens and disease severity, patients may also present with altered mental status, stupor, and seizures.

TREATMENT

Goals of Therapy

Prior to antibiotic therapy and vaccination bacterial meningitis was almost universally fatal, with survivors suffering from debilitating residual neurologic deficits, such as permanent hearing loss.[1,2] Although significant improvements have been made, the fatality rate of meningitis remains above 15% in adults, likely due to its occurrence in debilitated patient populations.[2]

KEY CONCEPT The treatment goals for CNS infections are to prevent death and residual neurologic deficits, eradicate or control causative micro-organisms, ameliorate clinical signs and symptoms, and implement vaccination and suppressive measures to prevent future infections. Surgical debridement should be employed, if appropriate (as in postneurosurgical infections and brain abscess). Supportive care, consisting of hydration, electrolyte replacement, antipyretics, antiemetics, analgesics, antiepileptic drugs, and wound care (for surgical wounds), is an important adjunct to antimicrobial therapy, particularly early in the treatment course.

LO 4

Treatment Principles

KEY CONCEPT Prompt initiation of IV high-dose bactericidal antimicrobial therapy directed at the most likely pathogen(s) is essential due to the high morbidity and mortality associated with CNS infections. Although there are no prospective studies that relate timing of antibiotic administration to clinical outcome in bacterial meningitis, a longer duration of symptoms and more advanced disease before treatment initiation increase the risk of a poor outcome.[2,11] Initiation of antibiotic therapy as soon as possible after bacterial meningitis is suspected or proven (even before hospitalization) reduces mortality and neurologic sequelae.[11-13]

LO 5

High-dose parenteral bactericidal antibiotic therapy is required to achieve CSF antibiotic concentrations adequate to rapidly sterilize the CSF and reduce the risk of complications. Data from animal studies and patients demonstrate better outcomes when bactericidal antibiotic therapy (vs bacteriostatic therapy) is used to sterilize the CSF.[14] However, successful treatment of meningitis has been reported with bacteriostatic agents. The presence of infection in the CSF reduces the activity of some classes of antibiotics. For example, the decreased pH of CSF associated with meningitis significantly reduces the activity of aminoglycoside antibiotics.[15]

Antimicrobial pharmacokinetics and pharmacodynamics must be considered when designing treatment regimens for CNS infections. The key of treatment success is the ability of antibiotics to reach and achieve effective concentrations at the infection site. In experimental models of meningitis, maximum bactericidal activity is achieved when CSF concentrations exceed the minimum bactericidal concentration (MBC) of the infecting pathogen by 10- to 30-fold.[16] In general, low-molecular-weight

Clinical Presentation and Diagnosis of CNS Infections

General

- Evaluate patient risk factors and recent exposures
- Evaluate other possible causes: space-occupying lesion (which may *or* may not be malignant), drug-induced CNS pathology autoimmune disease, and trauma[12,13]

Signs and Symptoms[2]

- 95% of patients with bacterial meningitis have two of the following: headache, fever, neck stiffness, and altered mental status
- Headache (87%)
- Nuchal rigidity (stiff neck) (83%)
- Fever (77%)
- Nausea (74%)
- Altered mental status (ie, confusion, lethargy, and obtundation) (69%)
- Focal neurologic defects (including positive Brudzinski sign and Kernig sign) (33%)
- Seizures
- Malaise, restlessness
- Photophobia
- Skin lesions (diffuse petechial rash observed in 50% of patients with meningococcal meningitis)
- Signs and symptoms in neonates, infants, and young children: nonspecific findings, such as altered feeding and sleep patterns, vomiting, irritability, lethargy, bulging fontanel, seizures, respiratory distress, and petechial/purpuric rash[17]
- Predictors of an unfavorable outcome: seizures, focal neurologic findings, altered mental status, papilledema, hypotension, septic shock, and pneumococcal meningitis[4]

Laboratory Tests[5,18,44]

- CSF examination via lumbar puncture (LP, spinal tap); contraindicated in patients with cardiorespiratory compromise, increased intracranial pressure and papilledema, focal neurologic signs, seizures, bleeding disorders, abnormal level of consciousness, and possible brain herniation (a CT scan should be performed before LP if there is a question of a CNS mass to avoid potential for brain herniation) (see Table 70–2 for specific CSF findings)
- Elevated opening pressure (may be decreased in neonates, infants, and children)
- Cloudy CSF
- Decreased glucose
- Elevated protein
- Elevated WBC (differential provides clues to offending pathogen)
- Gram stain (adequate for diagnosis in 60%–90% of patients with bacterial meningitis)
- Culture and sensitivity (positive in 70%–85% without prior antibiotic therapy, likelihood of positivity reduced by 20% in those who have had prior therapy)
- If CSF Gram stain and/or culture is negative, rapid diagnostic tests (such as latex agglutination) may be useful; these tests are positive even if bacteria are dead
- Polymerase chain reaction (PCR; DNA amplification of the most common bacterial meningitis pathogens) may be useful to help exclude bacterial meningitis
- Elevated CSF lactate and C-reactive protein
- Blood cultures (at least two cultures, one set; positive in 66%)
- Scraping of skin lesions (eg, rash) for direct microscopic examination and culture
- Other cultures should be obtained as clinically indicated (eg, sputum)
- WBC with differential
- Fungal meningitis: CSF culture, CSF and serum cryptococcal antigen titers, microscopic examination of CSF specimens
- Tuberculous meningitis: CSF culture, PCR evaluation (preferred), and acid-fast stain

Patient Encounter 1, Part 2

NB, the 10-year-old patient with signs and symptoms of meningitis underwent lumbar puncture. Initial results from CSF studies are WBC 2×10^3/mm^3 (2×10^9/L) with 85% (0.85) PMNs and 39% (0.39) monocytes, protein 182 mg/dL (1820 mg/L), glucose 18 mg/dL (1.0 mmol/L). Gram stain shows gram-positive cocci. Vital signs remain stable in the ED. First doses of antimicrobial therapy are initiated in the ED, and NB is admitted to a pediatric medicine ward for continued treatment and confirmation of final diagnosis. Culture results confirm *Streptococcus pneumoniae* with a penicillin MIC of 1 mg/L and ceftriaxone/cefotaxime susceptibility. Antimicrobials are streamlined and continued for the full duration.

What clues in the CSF results are suggestive of bacterial meningitis?

Would adjunctive steroids offer additional benefit in this patient?

How can his antibiotic regimen be streamlined at this time?

Patient Encounter 1, Part 3

NB has clinically improved on hospital day 3 and would like to be discharged home to continue therapy, but would prefer oral therapy if available. As his teammate's parents learn of his illness, they are concerned about the possibility of their children getting sick and begin to follow-up with their own primary care providers. They wonder about medications and vaccinations to prevent the disease.

How long should therapy be continued in NB?

What oral options are viable options for continuation as an outpatient in this case?

Who should receive antimicrobial prophylaxis for Streptococcus pneumoniae?

lipophilic antibiotics that are nonionized at physiologic pH and not highly protein bound penetrate best into CSF and other body tissues and fluids.[15,17] In addition to drug characteristics, integrity of the blood–brain barrier determines antibiotic penetration into CSF. The CSF penetration of most, but not all, antibiotics is enhanced by the presence of infection and inflammation. Sulfonamides, trimethoprim, chloramphenicol, rifampin, and most antitubercular drugs achieve therapeutic CSF levels even without meningeal inflammation.[7] Most β-lactams and related antibiotics (ie, carbapenems and monobactams), vancomycin, quinolones, acyclovir, linezolid, daptomycin, and colistin achieve therapeutic CSF levels in the presence of meningeal inflammation.[7] Aminoglycosides, first-generation cephalosporins, second-generation cephalosporins (except cefuroxime), clindamycin, and amphotericin do not achieve therapeutic CSF levels, even with inflammation, but clindamycin does achieve therapeutic brain tissue levels.[7]

An adequate duration of therapy is required to treat meningitis successfully (Table 70–3). KEY CONCEPT Parenteral (IV) therapy is administered for the full course of therapy for CNS infections to ensure adequate CSF penetration throughout the course of treatment. Antibiotic treatment (and dexamethasone, if used as a treatment adjunct) reduces the inflammation associated with meningitis, which, in turn, reduces the penetration of some antibiotics into the CSF, and parenteral therapy must be used throughout the entire treatment course to ensure adequate concentrations. Carefully selected patients who have close medical monitoring and follow-up may be able to receive a portion of their parenteral meningitis treatment on an outpatient basis.[11,18] A management algorithm for adults with suspected bacterial meningitis, as recommended by the Infectious Diseases Society of America (IDSA), is summarized in Figure 70–2.

Empirical Antimicrobial Therapy

After diagnosis, prompt and aggressive antimicrobial therapy with an appropriate empirical treatment is of the utmost importance in patients with suspected CNS infections. In most patients, a diagnostic LP will be performed before beginning antibiotics, but this should never delay initiation of antimicrobials. Antibiotic pretreatment may alter the CSF profile and complicate interpretation. KEY CONCEPT Empirical therapy should be directed at the most likely pathogen(s) for a specific patient, taking into account age, risk factors for infection (including underlying disease and immune dysfunction, vaccine history, and recent exposures), CSF Gram stain results, CSF antibiotic penetration, and local antimicrobial resistance patterns. Results of the CSF Gram stain may be used to help narrow empirical therapy for bacterial meningitis. In the absence of a positive Gram stain, empirical therapy should be continued for at least 48 to 72 hours, when meningitis may, in most cases, be ruled out by CSF findings inconsistent with bacterial meningitis, negative CSF culture, and negative polymerase chain reaction (PCR) evaluations. A repeat LP may be useful in the absence of other findings. Table 70–1 outlines recommendations for empirical antibiotic therapy for bacterial meningitis by most likely pathogen(s) and patient risk factors.

Impact of Antimicrobial Resistance on Treatment Regimens for Meningitis

Development of resistance to β-lactam antibiotics, including penicillins and cephalosporins, has significantly impacted the management of bacterial meningitis with one-fifth of CSF isolates resistant to penicillin and 3.5% of isolates resistant to cephalosporins.[19] The Clinical and Laboratory Standards Institute (CLSI) has set a lower ceftriaxone susceptibility breakpoint for pneumococcal CSF isolates (1 mg/L) than for isolates from non-CNS sites (2 mg/L). Empirical treatment regimens now include the combination of a third-generation cephalosporin plus vancomycin. Recognition of relative and high-level resistance to *N. meningitidis* in the laboratory, as well as in clinical treatment failures, has led to greater use of third-generation cephalosporins for empirical therapy of meningococcal meningitis.[3,11] Treatment of suspected or proven β-lactamase-mediated Hib meningitis also requires a third-generation cephalosporin. Increasing rates of methicillin-resistant *S. aureus* (about one-third of staphylococcal CSF isolates) and coagulase-negative staphylococci require the use of vancomycin for empirical therapy when these staphylococcal pathogens are suspected.[11,18]

The emergence and continued rise of multidrug-resistant strains of gram-negative organisms such as *Pseudomonas aeruginosa*, *Acinetobacter* species, AmpC, and extended-spectrum β-lactamase (ESBL) producing strains of Enterobacteriaceae have become a recognized threat nationally, and broad-spectrum therapy taking into account local resistance patterns should be used.

Pathogen-Directed Antimicrobial Therapy

KEY CONCEPT Empirical antimicrobial therapy should be modified on the basis of laboratory data and clinical response. If cultures, CSF Gram stain, or antigen/antibody testing indicate a specific pathogen, therapy should be adjusted quickly as needed to ensure adequate coverage for the offending pathogen(s). Table 70–3 outlines recommended definitive pathogen-directed treatment regimens, recommended treatment duration, and key adverse effects that should be monitored during antibiotic therapy for meningitis. Table 70–4 provides pediatric doses of selected agents used in bacterial meningitis treatment.

▶ *Neisseria meningitidis* Meningitis

N. meningitidis CNS infections most commonly occur in children and young adults. From 11% to 19% of survivors of meningococcal meningitis experience long-term sequelae, including hearing loss, limb loss, and neurologic deficits.[20] Nearly all meningococcal disease is caused by five serogroups: A, B, C, Y, and W-135. In the United States, serotypes B, C, and Y each are responsible for approximately 30% of cases.[3,4]

Meningococcal meningitis is observed most commonly in individuals living in close quarters (eg, college students, military personnel). Infants younger than 1 year are at highest risk, possibly because pneumococcal vaccination reduces bactericidal antibodies.[21] However, nearly 60% of cases occur in patients over 11 years of age.[20,22] *N. meningitidis* colonizes the nasopharynx and usually is transmitted via inhaled respiratory droplets from patients or asymptomatic carriers. A subclinical bacteremia typically ensues, seeding the meninges. Meningococcal disease is often (approximately 50%) associated with a diffuse petechial rash, and patients may experience behavioral changes. Patients may develop fulminant meningococcal sepsis, characterized by shock, disseminated intravascular coagulation (DIC), and multiorgan failure.[23] Meningococcal sepsis has a poor prognosis and carries a mortality rate of up to 80%, whereas the mortality rate with meningococcal meningitis alone is 13%.[23,24] Patients with suspected meningococcal infection should be kept on respiratory isolation for the first 24 hours of treatment.[20]

Increasing penicillin resistance requires that third-generation cephalosporins now be used for empirical treatment until *in vitro* susceptibilities are known.[11,15] Patients with a history of type I penicillin allergy or cephalosporin allergy may be treated with

Table 70–3

Pathogen-Based Definitive Treatment for CNS Infections[11,24]

Pathogen	Recommended and Alternative Antimicrobial Therapy (Adult Doses)	Adverse Effects/Safety Monitoring	Renal and Hepatic Dose Adjustment	Duration (Days)
Neisseria meningitidis[a]	*Standard Therapy*			
Penicillin MIC < 0.1 mg/L	Penicillin G 4 million units IV every 4 hours *or*	Hypersensitivity (rash, anaphylaxis), diarrhea	*Renal*: CrCl < 50 mL/min (0.83 mL/s): 3 million units IV every 4 hours; CrCl < 10 mL/min (0.17 mL/s): 2 million units IV every 4 hours *Hepatic*: No dose adjustment	7
	Ampicillin 2 g IV every 4 hours	Hypersensitivity (rash, anaphylaxis), diarrhea	*Renal*: CrCl < 50 mL/min (0.83 mL/s): 2 g IV every 8 hours; CrCl < 30 mL/min (0.50 mL/s): 2 g IV every 12 hours; CrCl < 10 mL/min (0.17 mL/s): 2 g IV every 24 hours *Hepatic*: No dose adjustment	
	Alternative Therapies			
	Ceftriaxone 2 g IV every 12 hours *or*	LFT elevation, cholecystitis	*Renal*: No dose adjustment *Hepatic:* Caution in severe hepatic impairment	
	Cefotaxime 2 g IV every 4 hours	Pseudocholelithiasis	*Renal*: CrCl < 80 mL/min (1.34 mL/s): 2 g IV every 6–8 hours; CrCl < 50 mL/min (0.83 mL/s): 2 g IV every 8–12 hours; CrCl < 30 mL/min (0.50 mL/s): 2 g IV every 12 hours; CrCl < 10 mL/min (0.17 mL/s): 2 g IV every 24 hours *Hepatic:* No dose adjustment	
Penicillin MIC 0.1–1 mg/L	*Standard Therapy*			
	Ceftriaxone *or* cefotaxime			
	Alternative Therapies			
	Moxifloxacin 400 mg IV every 24 hours *or*	Nausea/vomiting/diarrhea, dizziness, headache, QT prolongation	*Renal*: No dose adjustment *Hepatic*: Caution in severe hepatic impairment	
	Meropenem 2 g IV every 8 hours *or*	Rash, hypersensitivity, diarrhea, decreased seizure threshold	*Renal*: CrCl < 50 mL/min (0.83 mL/s): 2 g IV every 12 hours; CrCl < 30 mL/min (0.50 mL/s): 500 mg to 1 g IV every 12 hours; CrCl < 10 mL/min (0.17 mL/s): 500 mg to 1 g IV every 24 hours *Hepatic*: No dose adjustment	
	Chloramphenicol 1–1.5 g IV every 6 hours	Rash, diarrhea, seizures, anemia, gray baby syndrome, hypersensitivity, neurotoxicity (last choice due to toxicities)	*Renal*: No dose adjustment *Hepatic*: Reduce dose in moderate to severe impairment; consider serum drug monitoring	
Streptococcus pneumoniae				
Penicillin MIC < 0.1 mg/L	*Standard Therapy*			10–14
	Penicillin G *or* ampicillin			
	Alternative Therapies			
	Ceftriaxone *or* cefotaxime *or* chloramphenicol			
Penicillin MIC 0.1–1 mg/L (ceftriaxone/cefotaxime-sensitive strains)	*Standard Therapy* Ceftriaxone *or* cefotaxime

Pathogen-Based Definitive Treatment for CNS Infections[11,24] (*Continued*)

Pathogen	Recommended and Alternative Antimicrobial Therapy (Adult Doses)	Adverse Effects/Safety Monitoring	Renal and Hepatic Dose Adjustment	Duration (Days)
	Alternative Therapy Foscarnet 120–200 mg/kg IV per day in divided doses every 8–12 hours	Nephrotoxicity, electrolyte imbalances, nausea/vomiting, headache, penile ulceration, thrombophlebitis, seizures	*Renal*: CrCl: 1.0–1.4 mL/min/kg (0.017–0.023 mL/s/kg): 70 mg/kg IV every 12 hours; CrCl: 0.8–1.0 mL/min/kg (0.013–0.017 mL/s/kg): 50 mg/kg IV every 12 hours; CrCl: 0.6–0.8 mL/min/kg (0.010–0.013 mL/s/kg): 80 mg/kg IV every 24 hours; CrCl: 0.5–0.6 mL/min/kg (0.008–0.010 mL/s/kg): 60 mg/kg IV every 24 hours; CrCl: 0.4–0.5 mL/min/kg (0.007–0.008 mL/s/kg): 50 mg/kg IV every 24 hours; CrCl < 0.4 mL/min/kg (0.007 mL/s/kg) *or* < 20 mL/min (0.33 mL/s) not recommended *Hepatic*: No dose adjustment	
Cryptococcus neoformans	Amphotericin B 0.7mg/kg IV daily *plus* flucytosine 100–150 mg/kg/day in divided doses every 6 hours (induction) Fluconazole 400–800 mg (maintenance) Fluconazole 200 mg (secondary prophylaxis)	Amphotericin: nephrotoxicity, electrolyte imbalances Flucytosine: bone marrow suppression, rash Fluconazole: transaminitis; QTc prolongation	*Renal*: Caution in severe renal dysfunction; consider alternative dosing strategy or change to lipid formulation *Hepatic*: No dose adjustment Flucytosine: *Renal*: CrCl 25–50 mL/min (0.42–0.83 mL/s): every 12 hours; CrCl 10–25 mL/min (0.17–0.42 mL/s) every 24 hours; CrCl < 10 mL/min (0.17 mL/s) 12.5 mg/kg every 24 hours *Hepatic*: No dose adjustment Fluconazole *Renal*: CrCl < 50 mL/min (0.83 mL/s) decrease dose by 50% *Hepatic*: Consider 50% reduction in mild-moderate hepatic insufficiency; risk-benefit in severe hepatic dysfunction	
Toxoplasmosis gondii	Pyrimethamine 200 mg po x 1, then 50 mg (< 60 kg) to 75 mg (≥ 60 kg) daily *plus* sulfadiazine 1000 mg (< 60 kg) to 1500 mg (≥ 60 kg) po every 6 hours plus leucovorin 10–25 mg po daily	Pyrimethamine: bone marrow suppression, high-risk for anemia Sulfadiazine: nephrotoxicity, bone marrow suppression, rash, SJS	*Renal*: No dose adjustment *Hepatic*: No dose adjustment *Renal*: CrCL 25–50 mL/min (0.42–0.83 mL/s): every 12 hours; CrCl 10–25 mL/min (0.17–0.42 mL/s) every 24 hours; CrCl less than 10ml/min (< 0.17 mL/s) caution use due to high risk of crystalluria *Hepatic*: No dose adjustment	

[a]Empiric therapy with a third-generation cephalosporin should be used until in vitro susceptibility data are known.

LFTs, liver function tests; MIC, minimum inhibitory concentration; SJS, Stevens-Johnson syndrome.

vancomycin. Treatment should be continued for 7 days, after which no further treatment is necessary.

Prevention of meningococcal disease by vaccination is a key to reducing the incidence of meningococcal meningitis. Routine vaccination should be administered between ages 11 and 12 years with a booster dose at age 16 with quadrivalent vaccine that provides protection against serogroups A, C, Y, and W.[20] Additional vaccination against serogroup B can be considered in all patients and is recommended in those with immunocompromising conditions. In addition, individuals aged 2 through 54 years who are immunocompromised (including those with complement deficiencies, who have HIV, or who have asplenia) or those with recent disease exposure during community outbreaks should receive the quadrivalent vaccine and the vaccine against Serogroup B is also recommended for immunocompromised individuals and during outbreaks.[20] Additionally, children less than 2 years may also need quadrivalent vaccine and serogroup B vaccine, depending on risk factors. The quadrivalent conjugate

meningococcal vaccine protects against four of the five serotypes causing invasive disease (A, C, Y, and W-135). A separate vaccine product confers protection against serogroup B. Meningococcal vaccines can be used in outbreak situations, with protective antibodies measurable within 7 to 10 days. KEY CONCEPT Close contacts of patients with meningococcal infections should be evaluated for antimicrobial prophylaxis. Close contacts include members of the same household, individuals who share sleeping quarters, daycare contacts, and individuals exposed to oral secretions of meningitis patients. After consultation with the local health department, close contacts should receive prophylactic antibiotics to eradicate nasopharyngeal carriage of the organism. Household contacts of patients with meningococcal meningitis have a 400- to 800-fold increased risk of developing meningitis.[23] Prophylactic antibiotics should be started as soon as possible, preferably within 24 hours of exposure and within 14 days. Recommended regimens, all of which are 90% to 95% effective, for adults include rifampin 600 mg orally every 12 hours for 2 days, ciprofloxacin 500 mg orally for one dose, or ceftriaxone 250 mg intramuscularly for one dose. Regimens for children include rifampin 5 mg/kg orally every 12 hours for 2 days (< 1 month of age), rifampin 10 mg/kg orally every 12 hours for 2 days (> 1 month of age), or ceftriaxone 125 mg intramuscularly for one dose (< 12 years of age).[11,23] It is not known whether close contacts who have been vaccinated will benefit from prophylaxis. Patients with meningococcal meningitis who are treated with antibiotics other than third-generation cephalosporins also should be considered for prophylaxis to eradicate the nasopharyngeal carrier state.[22]

LO 8

▶ *Streptococcus pneumoniae Meningitis*

S. pneumoniae is the most common cause of meningitis in adults and in children younger than 2 years of age. Pneumococcus is associated with the highest mortality observed with bacterial meningitis in adults (14%–18%), and coma and seizures are more common in pneumococcal meningitis.[1-3] Patients at high risk for pneumococcal meningitis include the elderly, alcoholics, splenectomized patients, patients with sickle cell disease, and patients with cochlear implants. At least 50% of pneumococcal meningitis cases are due to a primary infection of the ears, sinuses, or lungs.

Due to increases in pneumococcal resistance to high-dose penicillin G, the preferred empirical treatment now includes a third-generation cephalosporin in combination with vancomycin.[11] All CSF isolates should be tested for penicillin and cephalosporin resistance by methods endorsed by the CLSI. Once *in vitro* sensitivity results are known, therapy may be tailored (see Table 70–3). Patients with a history of type I penicillin or cephalosporin allergy may be treated with vancomycin. Treatment should be continued for 10 to 14 days, after which no further maintenance therapy is required. Antimicrobial prophylaxis is not indicated for close contacts.

Administration of vaccines to high-risk individuals is a key strategy to reduce the risk of invasive pneumococcal disease. However, 2013 reports note only 82% of children aged 35 months completed the full series of the pneumococcal conjugate vaccine.[25] The 23-valent pneumococcal vaccine targets serotypes that account for more than 90% of invasive disease in high-risk patients. However, the 23-valent vaccine does not produce a reliable immunologic response in children younger than 2 years, nor does it reduce pneumococcal carriage. The 7-valent pneumococcal protein-polysaccharide conjugate vaccine used between 2000 and 2010 targeted the seven most common serotypes in children and provided protection (94% reduction) against invasive pneumococcal disease (such as sepsis and meningitis) in children younger than 5 years.[4,26,27] Widespread administration of the 7-valent conjugate vaccine to children has also contributed to a 28% reduction in invasive pneumococcal disease in adults.[4] PCV13, a 13-valent vaccine introduced in 2010, confers protection against serotypes 1, 3, 4, 5, 6A, 6B, 7F, 9V, 14, 18C, 19A, 19F, and 23F. It is intended for use in children younger than 18 years in the same schedule as the 7-valent conjugate vaccine.[27] PCV13 is specifically recommended for immunocompromised children aged 6 to 18 years.[28] Based on additional data, newer recommendations also recommend vaccination with PCV13 in addition to PPSV23 in adults older than age 65 and aged 18 to 64 with immunocompromising conditions. Additionally, immunization schedules provided by Centers for Disease Control and Prevention (CDC) are updated at least annually and should be consulted for more details.

▶ *Haemophilus influenzae Meningitis*

Prior to the introduction of the Hib conjugate vaccine, *H. influenzae* type B was the most common cause of bacterial meningitis in the United States.[3,4] Routine inoculation of pediatric patients against Hib has significantly reduced the incidence of Hib meningitis between 1998 and 2007.[3,4] The Hib vaccine is also recommended for patients undergoing splenectomy. Hib meningeal disease is often associated with a parameningeal focus such as a sinus or middle ear infection. Due to β-lactamase–mediated resistance, the empirical treatment of choice is third-generation cephalosporins (eg, ceftriaxone and cefotaxime). Treatment should be continued for 7 days, after which no further maintenance therapy is required.

KEY CONCEPT Close contacts of patients with H. influenzae type B meningitis should be evaluated for antimicrobial prophylaxis. The risk of Hib meningitis in close contacts may be up to 200- to 1000-fold higher than in the general population.[7] Invasive Hib disease, including meningitis, should be reported to the local health department and the CDC. Prophylaxis to eliminate nasal and oropharyngeal carriage of Hib in exposed individuals should be initiated after consultation with local health officials. Rifampin (600 mg/day for adults; 20 mg/kg/day for children, maximum of 600 mg/day) is administered for 4 days.[11,16] Rifampin prophylaxis is not necessary for individuals who have received the full Hib vaccine series. Exposed, unvaccinated children between 12 and 48 months of age should receive one dose of vaccine, and

Patient Encounter 2, Part 1

BB is an 18-year-old college freshman who is brought to the ED with a 1-day history of extreme fatigue and fever. Her roommate brought her to ED because of confusion and vomiting. Vital signs and laboratory values include a rectal temperature of 38.6°C (101.5°F), respirations 24 per minute, heart rate 119 beats/min, and peripheral WBC of 22.1 × 10^3/mm^3 (22.1 × 10^9/L), with 72% (0.72) PMNs. Physical examination reveals an unresponsive patient with nuchal rigidity.

What signs and symptoms consistent with meningitis are present in BB?

What clues to causative pathogen are present in BB?

What empiric antimicrobial regimen should be started?

Patient Encounter 2, Part 2

BB underwent lumbar puncture. Initial results from CSF studies are WBC 1.82 × 10^3/mm^3 (1.82 × 10^9/L) with 76% (0.76) PMNs, protein 255 mg/dL (2550 mg/L), glucose 30 mg/dL (1.7 mmol/L), with a concurrent serum glucose of 110 mg/dL (6.1 mmol/L). Gram stain shows gram-positive diplococci and culture results identify *Neisseria* infection with a penicillin MIC of 1 mg/L. The patient is admitted to an acute care unit and remains clinically stable.

What complications is BB at risk for acutely? What potential long-term complications may result?

How can her antibiotic regimen be streamlined at this time?

How long should the antibiotics be continued?

unvaccinated children 2 to 11 months of age should receive three doses of vaccine, as well as rifampin prophylaxis.[11,16] According to the CDC, up to 18% of children at 35 months have not completed the Hib vaccine series.[25]

▶ *Listeria monocytogenes* Meningitis

L. monocytogenes is an intracellular gram-positive bacillus that contaminates foods, such as soft cheese, unpasteurized milk, raw meats and fish, processed meats, and raw vegetables. Bacteria from contaminated foods colonize the GI tract, pass into the bloodstream, and overcome natural cellular immune responses to cause infection. *L. monocytogenes* meningitis, usually observed in patients at extremes of age and in immunocompromised patients with depressed cellular immunity (including patients with leukemia, solid-organ transplants, and HIV/AIDS) has an overall mortality rate of up to 30% and is associated with miscarriage when infection occurs during pregnancy.[29,30]

Only a limited number of antibiotics show bactericidal activity against *L. monocytogenes*. The combination of high-dose ampicillin or penicillin G and an aminoglycoside is synergistic and bactericidal against *L. monocytogenes*. A total treatment course of at least 3 weeks is required. Because of concerns about the risk of nephrotoxicity with an extended treatment course of aminoglycosides, patients are treated with combination therapy for 10 days and may finish out the remainder of their treatment with ampicillin or penicillin alone.[30] In penicillin-allergic patients, trimethoprim-sulfamethoxazole is the agent of choice due to documented *in vitro* bactericidal activity against *L. monocytogenes*, as well as good CNS penetration. Vancomycin and cephalosporins are not effective treatments for *L. monocytogenes* meningitis. Prophylaxis is not needed for close contacts, nor is suppressive therapy indicated. Patients with severe depression of cell-mediated immunity should be advised to avoid foods that may be contaminated with *L. monocytogenes.*

▶ Group B Streptococcus Meningitis

Infection with GBS (eg, *S. agalactiae*) is the most common cause of neonatal sepsis and meningitis. Around 15% to 35% of pregnant women are a carrier of GBS in the vagina or rectum. Group B streptococci can be acquired during childbirth after exposure to infected secretions from the mother's birth canal or rectum. Neonates born to women who are carriers are at very high risk (1 of every 100–200 babies) of developing invasive group B streptococcal disease.[31] Neonatal meningitis is associated with significant morbidity and mortality. Synergistic treatment with penicillin or ampicillin, plus gentamicin, for 14 to 21 days is recommended for group B streptococcal meningitis.[11]

To reduce the risk of clinical group B streptococcal disease in neonates, pregnant women should be screened at 35 to 37 weeks' gestation to determine whether they are carriers of group B streptococci.[31] Intrapartum antibiotics (eg, penicillin or ampicillin) are recommended for pregnant women with the following characteristics: group B streptococcal carrier state detected at screening, history of group B streptococcal bacteriuria at any time during pregnancy, and history of delivery of infant with invasive group B streptococcal disease.[31]

▶ Gram-Negative Bacillary Meningitis

Meningitis caused by enteric gram-negative bacilli is an important cause of morbidity and mortality in populations at risk, including those with diabetes, malignancy, cirrhosis, immunosuppression, advanced age, parameningeal infection, and/or a defect allowing communication from skin to CNS (eg, neurosurgery, congenital defects, cranial trauma).[7]

The optimal treatment for gram-negative bacillary meningitis is not well defined. The introduction of extended-spectrum cephalosporins has improved patient outcomes significantly. Although the third-generation cephalosporins ceftriaxone and cefotaxime provide good coverage for most Enterobacteriaceae, these antibiotics are not active against *P. aeruginosa*. Ceftazidime, cefepime, and carbapenems are effective in pseudomonal meningitis.[15,17] Addition of an aminoglycoside may improve treatment results; however, CNS penetration of aminoglycosides is extremely poor, even in the setting of inflamed meninges. Intrathecal or intraventricular administration of aminoglycosides may be useful, but intraventricular antibiotics have been associated with increased mortality in neonates.[15,32] Intrathecal therapy is accomplished by administering the antibiotic into the CSF via LP, whereas intraventricular therapy is usually administered into a reservoir implanted in the ventricles of the brain.

Initial therapy of suspected or documented pseudomonal meningitis should include an antipseudomonal β-lactam (eg, cefepime, meropenem) plus an aminoglycoside (eg, tobramycin, amikacin). Although the carbapenem imipenem-cilastatin has similar activity to these β-lactams, its use is not recommended in meningitis because of the risk of seizures. Aztreonam, high-dose ciprofloxacin, and colistin are alternative treatments for pseudomonal meningitis, although local susceptibility rates should be considered before initiating alternative therapy. Local therapy (ie, intrathecal or intraventricular therapy) may be indicated in patients with multidrug-resistant gram-negative bacillary meningitis or in patients who fail to improve on IV antibiotics alone. In cases of multidrug-resistant pathogens, alternative pharmacodynamic dosing strategies such as continuous or extended infusion of β-lactam antimicrobials may be considered to optimize target attainment (time greater than minimum inhibitory concentration [MIC]). Given the differences in local hospital resistance patterns, administration of pathogen-directed treatment is very important after microbiology results become available. Therapy for gram-negative bacillary meningitis should be continued for at least 21 days.

▶ Postoperative Infections in the Neurosurgical Patient and Shunt Infections

Patients who undergo neurosurgical procedures or have invasive or implanted foreign devices (eg, CSF shunts, intraspinal pumps or catheters, epidural catheters) are at risk for CNS infections. Key pathogens in postneurosurgical infections

include coagulase-negative staphylococci, *S. aureus*, streptococci, propionibacteria, and gram-negative bacilli, including *P. aeruginosa*. Clinical signs and symptoms may be similar to those of other CNS infections, and there also may be evidence of malfunction of implanted hardware or visible signs of a postoperative wound infection.

Empirical therapy for postoperative infections in neurosurgical patients (including patients with CSF shunts) should include vancomycin in combination with either cefepime, ceftazidime, or meropenem. Linezolid reaches adequate CSF concentrations and resolves cases of meningitis refractory to vancomycin.[30,33] However, data with linezolid are limited. The addition of rifampin may be considered for treatment of shunt infections. Removal of infected devices is desirable; aggressive antibiotic therapy (including high-dose IV antibiotic therapy plus intraventricular vancomycin and/or tobramycin) may be effective for patients in whom hardware removal is not possible.[34] If methicillin-resistant *S. aureus* is identified as the causative organism, daptomycin may be considered an alternative therapy.[35]

The use of prophylactic antibiotics against meningitis postcraniotomy remains controversial.[36,37] One meta-analysis suggests that prophylaxis reduces rates of postoperative meningitis by nearly one-half.[36] Breakthrough meningitis that does occur may be a result of drug-resistant pathogens.[37]

Brain abscesses are localized collections of pus within the cranium. These infections are difficult to treat due to the presence of walled-off infections in the brain tissue reducing antibiotic penetration. In addition to appropriate antimicrobial therapy (a discussion of which is beyond the scope of this chapter), surgical debridement is often required as an adjunctive measure. Surgical debridement may also be required in the management of neurosurgical postoperative infections.

► *Viral Encephalitis and Meningitis*

Viral encephalitis and meningitis may mimic bacterial meningitis on clinical presentation but often can be differentiated by CSF findings (see Table 70–2). The most common viral pathogens are enteroviruses, which cause approximately 85% of cases of viral CNS infections.[7] Other viruses that may cause CNS infections include arboviruses, HSV, cytomegalovirus, varicella-zoster virus, rotavirus, coronavirus, influenza viruses A and B, West Nile virus, and Epstein-Barr virus. Viral CNS infections are acquired through hematogenous or neuronal spread.[7] Most cases of enteroviral meningitis or encephalitis are self-limiting with supportive treatment.[38] However, arbovirus, West Nile virus, and Eastern equine virus infections are associated with a less favorable prognosis.

In contrast to other viral encephalitides, HSV type 1 and 2 encephalitis are treatable. Although rare (one case per 250,000 population per year in the United States), HSV encephalitis is a serious, life-threatening infection.[39] More than 90% of HSV encephalitis in adults is due to HSV type 1, whereas HSV type 2 predominates in neonatal HSV encephalitis (> 70%).[40] HSV encephalitis is the result of reactivation of a latent infection (two-thirds of cases) or a severe case of primary infection (one-third). Without effective treatment, the mortality rate may be as high as 85%, and survivors often have significant residual neurologic deficits. In accordance with 2008 IDSA guidelines, high-dose IV acyclovir is the drug of choice, given for 2 to 3 weeks at a dose of 10 mg/kg IV every 8 hours in adults, based on ideal body weight, and for 3 weeks at a dose of 20 mg/kg IV every 8 hours in neonates.[41] Patients receiving acyclovir should maintain adequate hydration (consider continuous IV hydration) to help prevent acute kidney injury secondary to crystal nephropathy.[41] Foscarnet 120 to 200 mg/kg/day divided every 8 to 12 hours for 2 to 3 weeks is the treatment of choice for acyclovir-resistant HSV.[41]

► *Opportunistic CNS Infections*

Cerebral Toxoplasmosis Across the globe, cerebral toxoplasmosis represents the most common focal brain infection in HIV-infected patients. Infection rates in the United States vary but are reported to be approximately 15% among patients with AIDS.[42] The majority of cases occur in patients with $CD4^+$ cell counts less than 100 cells/mm^3 (100×10^6/L). Potent antiretroviral therapy and primary prophylaxis (first-line option is sulfamethoxazole-trimethoprim) in IgG-positive patients has greatly reduced the disease burden.[43] First-line therapy in toxoplasmosis encephalitis is pyrimethamine plus sulfadiazine, given concomitantly with leucovorin to prevent severe hematologic adverse effects secondary to pyrimethamine (see tables for dosing).[43] Clindamycin may be substituted for sulfadiazine in cases of contraindications to sulfa-based therapy. Sulfamethoxazole-trimethoprim may also be an option, specifically in patients unable to take oral therapy. Adjunctive corticosteroids and anticonvulsant therapy should be considered to reduce sequelae from the inflammatory process and control active seizures, respectively.[43]

Cryptococcal Meningitis CNS disease secondary to *Cryptococcus neoformans* is primarily observed in severely immunocompromised hosts, such as those with HIV infection. Potent antiretroviral therapy has significantly reduced the disease burden from preantiretroviral therapy rates of 5% to 8% in developed countries. The majority of disease occurs in patients with $CD4^+$ cell counts less than 50 cells/mm^3 (50×10^6/L). First-line therapy is considered amphotericin B deoxycholate 0.7 mg/kg IV daily plus flucytosine 100 mg/kg/day orally in four divided doses for a minimum of 2 weeks.[43] Therapeutic drug monitoring may be considered for flucytosine to help reduce the risk of adverse effects. Development of renal dysfunction as a result of disease and/or drug toxicity should be closely monitored and may prompt dose reduction or possible switch to alternative lipid formulations of amphotericin, which may be less nephrotoxic. High-dose fluconazole is considered an alternative first-line therapy, especially in resource-limited areas. Secondary prophylaxis with fluconazole for an indefinite period is recommended following the completion of at least 2 weeks of induction therapy and 8 weeks of maintenance therapy with fluconazole.[43]

► *Adjunctive Dexamethasone Therapy*

The adjunctive agent dexamethasone improves outcomes in selected patient populations with bacterial meningitis. Dexamethasone inhibits the release of proinflammatory cytokines and limits the CNS inflammatory response stimulated by infection and antibiotic therapy.

Clinical benefit in reducing neurologic deficits (primarily by reducing hearing loss) has been observed in infants and children, if dexamethasone is initiated prior to antibiotic therapy.[1,44] The American Academy of Pediatrics recommends dexamethasone (0.15 mg/kg IV every 6 hours for 2 to 4 days) for infants and children at least 6 weeks of age with Hib meningitis and consideration of dexamethasone in pneumococcal meningitis.[11,45] In contrast to this recommendation, a large multicenter cohort study failed to show any mortality benefit of adjunctive dexamethasone therapy regardless of age or responsible pathogen

(*S. pneumoniae* or *N. meningitidis*).[46] Dexamethasone should be initiated 10 to 20 minutes before or no later than the time of initiation of antibiotic therapy; it is not recommended for infants and children who have already received antibiotic therapy because it is unlikely to improve treatment outcome in these patients. There are insufficient data to make a recommendation regarding the use of adjunctive dexamethasone therapy in neonatal meningitis.

In adults, a significant benefit was observed with dexamethasone in reducing meningitis complications, including death, particularly in patients with pneumococcal meningitis.[47] The IDSA recommends dexamethasone 0.15 mg/kg IV every 6 hours for 2 to 4 days (with the first dose administered 10–20 minutes before or with the first dose of antibiotics) in adults with suspected or proven pneumococcal meningitis.[11] Dexamethasone is not recommended for adults who have already received antibiotic therapy. Some clinicians would administer dexamethasone to all adults with meningitis pending results of laboratory tests. Benefit of dexamethasone in bacterial meningitis in an HIV-positive population has not been clearly established.[48]

There is controversy regarding the administration of dexamethasone to patients requiring vancomycin for pneumococcal meningitis. Animal models indicate that concurrent steroid use reduces vancomycin penetration into the CSF by 42% to 77% and delays CSF sterilization.[15] A prospective evaluation in patients with pneumococcal meningitis receiving vancomycin and adjunctive dexamethasone demonstrated that adequate concentrations of vancomycin (nearly 30% of serum concentrations) were achievable in the CSF, provided appropriate vancomycin dosage was utilized.[49] Treatment failures have been reported in adults with resistant pneumococcal meningitis who were treated with dexamethasone, but the risk–benefit of using dexamethasone in these patients cannot be defined at this time. Animal models indicate a benefit of adding rifampin in patients with resistant pneumococcal meningitis whenever dexamethasone is used.[15,17]

OUTCOME EVALUATION

Monitor patients with CNS infections continuously throughout their treatment course to evaluate their progress toward achieving treatment goals, including relief of symptoms, eradication of infection, and reduction of inflammation to prevent death and the development of neurologic deficits. These treatment goals are best achieved by appropriate parenteral antimicrobial therapy, including empirical therapy to cover the most likely pathogens, followed by directed therapy after culture and sensitivity results are known. KEY CONCEPT Components of a monitoring plan to assess efficacy and safety of antimicrobial therapy of CNS infections include clinical signs and symptoms and laboratory data (eg, CSF findings, culture, sensitivity data).

During the patient's treatment course, monitor clinical signs and symptoms at least three times daily. Trends are more important than one-time assessments. Expect fever, headache, nausea and vomiting, and malaise to begin to improve within 24 to 48 hours of initiation of antimicrobial therapy and supportive care. Evaluate the patient for resolution of neurologic signs and symptoms, such as altered mental status and nuchal rigidity, as the infection is eradicated and inflammation is reduced within the CNS. Expect improvement and subsequent resolution of signs and symptoms as the treatment course continues. At the time of hospital discharge, arrange outpatient follow-up for several weeks to months depending on the causative pathogen, clinical treatment course, and patient's underlying comorbidities.

Patient Encounter 2, Part 3

Upon review of her records, BB did not receive vaccination against *Neisseria meningitis* prior to college. In addition, her roommates are concerned about getting sick and inquire about measures to help prevent disease.

Who should receive antimicrobial prophylaxis for Neisseria?

Who should receive vaccination against meningococcal disease?

Patient Care Process

Collect Information:

- Obtain a complete patient allergy history, including details on the severity of reactions, and obtain a medication history
- Determine if patient has received recent antibiotics that may influence LP results or treatment decisions
- Review laboratory values, past medical history, and vaccination history

Assess the Information:

- Analyze CSF findings to determine the likely etiology of meningitis
- Assess the patient history for possible risk factors for specific etiologies of meningitis
- Determine from a medication history if any medicines may be associated with drug-induced aseptic meningitis

Develop a Care Plan:

- Based on patient-specific factors and local susceptibility patterns, determine appropriate empirical antimicrobial treatment plan
- Assess LP results, results of antigenic testing, and culture and susceptibility for additional data to help streamline therapy

Implement the Care Plan:

- Collaborate with treatment team to ensure timely administration of antibiotic in relation to performing LP and obtaining blood cultures
- Collaborate with treatment team to determine appropriate administration of adjunctive corticosteroid therapy

Follow-up: Monitor and Evaluate:

- Monitor patient for any antimicrobial-related adverse events. Provide recommendations for necessary prophylaxis based on causative pathogen and exposure history
- Determine appropriate length of therapy for diagnosed CNS infection
- Provide recommendations for outpatient parenteral therapy as needed upon discharge from acute care facility

Monitoring of laboratory tests is important in patients receiving treatment for CNS infections. Monitor CSF and blood cultures so that antimicrobial therapy can be tailored to the etiologic organisms. Follow-up cultures may be obtained to prove eradication of the organism(s) or treatment failure. Although repeat LP generally is not performed, consider repeat LP for patients who do not respond clinically after 48 hours of appropriate antimicrobial therapy, especially those with resistant pneumococcus who receive dexamethasone.[11] Other candidates for repeat LP include those with infection with gram-negative bacilli, prolonged fever, and recurrent meningitis. Repeat the LP in neonates to determine the duration of therapy. Repeat LP also may be performed to relieve elevated intracranial pressure. Expect repeat blood cultures to become negative quickly during therapy and the serum WBC count to improve and normalize with appropriate antimicrobial therapy.

Evaluate antimicrobial dosing regimens to ensure efficacy of the treatment regimen. Trough vancomycin concentrations of 15 to 20 mg/L (10–14 μmol/L) are recommended for the treatment of CNS infections.[44] Monitor patients for drug adverse effects, drug allergies, and drug interactions. The specific safety monitoring plan will depend on the antibiotic(s) used (Table 70–3). Pay close attention to concomitant medications in patients on rifampin for treatment or prophylaxis. Rifampin is a potent inducer of hepatic metabolism and may reduce the efficacy of other drugs metabolized by the cytochrome P-450 enzyme pathway.

Abbreviations Introduced in This Chapter

CDC	Centers for Disease Control and Prevention
CLSI	Clinical and Laboratory Standards Institute
CNS	Central nervous system
CSF	Cerebrospinal fluid
DIC	Disseminated intravascular coagulation
ESBL	Extended spectrum β-lactamase
GBS	Group B *Streptococcus*
Hib	*Haemophilus influenzae* type B
HSV	Herpes simplex virus
IDSA	Infectious Diseases Society of America
IL-1	Interleukin 1
LP	Lumbar puncture
MBC	Minimum bactericidal concentration
MIC	Minimum inhibitory concentration
MRSA	Methicillin-resistant *Staphylococcus aureus*
MRSE	Methicillin-resistant *Staphylococcus epidermidis*
NSAIDs	Nonsteroidal anti-inflammatory drugs
PCR	Polymerase chain reaction
PMN	Polymorphonuclear cell
SJS	Stevens-Johnson Syndrome
TNF-α	Tumor necrosis factor-alpha

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

LO

1. List the common pathogens that cause community-acquired pneumonia (CAP), aspiration pneumonia, ventilator-associated pneumonia (VAP), and hospital-associated pneumonia (HAP).
2. Explain the pathophysiology of pneumonia and associated host defenses.
3. List the signs and symptoms associated with CAP and VAP.
4. Identify patient and organism factors required to guide the selection of a specific antimicrobial regimen for an individual patient.
5. Design an appropriate empirical antimicrobial regimen based on patient-specific data for an individual with CAP, aspiration pneumonia, HAP, and VAP.
6. Design an appropriate antimicrobial regimen based on both patient- and organism-specific data.
7. Develop a monitoring plan based on patient-specific information for a patient with one of the four categories of pneumonia.
8. Apply the complete Patient Care Process to caring for patients with any type of pneumonia.
9. Formulate appropriate educational information to be provided to a patient with pneumonia.
10. Explain prevention of pneumonia via immunization and include who the appropriate patient groups are for receiving the various vaccines.

INTRODUCTION

Pneumonia is inflammation of the lung with consolidation. The cause of the inflammation is infection, which can be caused by a wide range of organisms. KEY CONCEPT There are four classifications of pneumonia: community-acquired, aspiration, hospital-acquired, and ventilator-associated. Patients who develop pneumonia in the outpatient setting and have not been in any health care facilities, which include wound care and hemodialysis clinics, have community-acquired pneumonia (CAP). Pneumonia can be caused by aspiration of either oropharyngeal or gastrointestinal contents. Hospital-acquired pneumonia (HAP) is defined as pneumonia that occurs 48 hours or more after admission.[1] Ventilator-associated pneumonia (VAP) requires endotracheal intubation for at least 48 hours before the onset of pneumonia.[1] Health care–associated pneumonia was addressed in the 2005 VAP and HAP guidelines but was eliminated in the 2016 guidelines due to the lack of resistant organisms associated as the cause.[2] The CAP guidelines might address health care–associated pneumonia; however, the updated guidelines will not be available until summer 2018 which is after the printing of this edition.

LO 1

EPIDEMIOLOGY AND ETIOLOGY

Etiology and Mortality Rates

KEY CONCEPT The etiology of bacterial pneumonia varies in accordance with the type of pneumonia. Table 71–1 lists the more common pathogens associated with the various types or classifications of pneumonia. *Streptococcus pneumoniae* colonizes the nasopharyngeal flora in up to 50% of healthy adults and may colonize the lower airways in individuals with chronic bronchitis.[2,3] It possesses many virulence factors, enhancing its ability to cause infection in the respiratory tract. KEY CONCEPT Therefore, it is not surprising that *S. pneumoniae* is the predominant bacterial pathogen associated with CAP. The second most common pathogen is one of the atypical organisms, *Mycoplasma pneumoniae*. Nontypeable *Haemophilus influenzae* intermittently colonizes about 80% of the population, and the incidence of permanent colonization increases in chronic obstructive pulmonary disease (COPD) patients and those with cystic fibrosis. Therefore, the likelihood of nontypeable *H. influenzae* causing pneumonia increases in COPD patients. *Moraxella catarrhalis* is a more common cause of pneumonia in the very young and the very old. *Chlamydophila pneumoniae* and *Legionella pneumophila* are less frequent causes than the other bacterial and atypical organisms. Community-acquired methicillin-resistant *Staphylococcus aureus* (CA-MRSA) is associated with necrotizing and severe pneumonia in healthy children and young adults. Less than 2% of all CA-MRSA infections are pneumonia (most are skin and soft tissue); however, the number of case reports of pneumonia are increasing.[4,5]

LO 1

LO 1

Viruses are a common cause of CAP in children (about 65%) and in adults ranging from 12% to 29%.[5-7] Mixed infections of viruses and bacteria have been increasingly identified in 11% to 56% of cases.[5-8] Viruses most often associated with pneumonia in adults include influenza A and B and rhinoviruses, but

Table 71–1

Common Pathogens by Type of Pneumonia

Type of Pneumonia	Common Pathogens
Community	Aerobic bacteria: *S. pneumoniae, H. influenzae, M. catarrhalis* Atypical: *M. pneumoniae, C. pneumoniae, L. pneumophila,* respiratory viruses (rhinoviruses and influenza most common)
Aspiration	Oral contents: Anaerobes, *Viridans* streptococci GI contents with pH increase Enteric gram-negative bacilli
Hospital	*S. pneumoniae,* MSSA, *E. coli, K. pneumoniae* (*M. pneumoniae, C. pneumoniae* are rare) (MDR pathogen risk factors present; MRSA, *P. aeruginosa*, extended-spectrum β-lactamase-producing gram-negative bacilli, carbapenemase-producing gram-negative bacilli)
Ventilator	MRSA, extended-spectrum β-lactamase-producing gram-negative bacilli, *P. aeruginosa, Acinetobacter* spp., carbapenemase-producing gram-negative bacilli

MDR, multi-drug resistant; MRSA, methicillin-resistant *Staphylococcus aureus*; MSSA, methicillin-susceptible *S. aureus.*

can be caused by adenoviruses, enteroviruses, cytomegalovirus, varicella-zoster virus, herpes simplex virus, and others. In children, viral pneumonia is more commonly caused by respiratory syncytial virus, influenza A, and parainfluenza, and less commonly by those listed previously for adults. Influenza is associated with seasonal local outbreaks (epidemics) and global outbreaks (pandemics). Influenza viruses are characterized and named for the hemagglutinin (H) and neuraminidase (N) proteins on the surface of the viruses. There are 16 hemagglutinin and 9 neuraminidase subtypes of influenza A, and H1–3 and N1 and 2 are the principal antigenic types found in humans.[9]

Mortality associated with CAP is dependent on the severity of the illness and the age of the patient. In elderly patients admitted to the hospital with severe pneumonia, the mortality rate is up to 40%.[10-13] In the outpatient setting (mild to moderate disease), the mortality rate is less than 5%.[14] Mortality among case reports of CA-MRSA necrotizing pneumonia is 42%.[4] Pneumonia owing to aspiration of oral contents is caused by a variety of anaerobes (*Bacteroides* spp., *Fusobacterium* spp., *Prevotella* spp., and anaerobic gram-positive cocci) as well as *Streptococcus* spp. *Moraxella catarrhalis* and *Eikenella corrodens* may be involved but much less frequently.[15,16] When gastric contents are aspirated, enteric gram-negative bacilli and *Staphylococcus aureus* are more commonly the pathogens.[16]

HAP and VAP may be caused by a wide spectrum of organisms. HAP and VAP pathogens are influenced by risk factors for multidrug-resistant (MDR) bacteria. These factors include: intravenous antibiotic use within the past 90 days, septic shock at the time of HAP or VAP, ARDS preceding VAP, five or more days of hospitalization, and acute renal replacement therapy.[1] MDR organisms include extended spectrum β-lactamase and/or carbapenemase-producing enteric gram-negative bacilli, *Pseudomonas aeruginosa*, *Acinetobacter* spp., or MRSA. The number of infections caused by MDR bacteria is increasing significantly in hospitalized patients.[1,5,13,17-19]

PATHOPHYSIOLOGY

Local Host Defenses

Local host defenses of both the upper and lower respiratory tract along with the anatomy of the airways are important in preventing infection. Upper respiratory defenses include the mucociliary apparatus of the nasopharynx, nasal hair, normal bacterial flora, IgA, and complement. Local host defenses of the lower respiratory tract include cough, mucociliary apparatus of the trachea and bronchi, antibodies (IgA, IgM, and IgG), complement, and alveolar macrophages. Mucous lines the cells of the respiratory tract, forming a protective barrier for the cells. This minimizes the ability of organisms to attach to the cells and initiate the infectious process. The squamous epithelial cells of the upper respiratory tract are not ciliated, but those of the columnar epithelial cells of the lower tract are. The cilia beat in a uniform fashion upward, moving particles up and out of the lower respiratory tract.

Particles greater than 10 microns (μm) are efficiently trapped by mechanisms of the upper airway and are removed from the nasopharynx either by swallowing or by expulsion. The mucociliary apparatus of the trachea and bronchi along with the sharp angles of the bronchi often are effective at trapping and eliminating particles that are 2 to 10 μm in size. Particles in the range of 0.5 to 1 μm may consistently reach the alveolar sacs of the lung. Microorganisms fall within this size range, and if they reach the alveolar sacs, then infection may result if alveolar macrophages and other defenses cannot contain the organisms.

Aspiration

Aspiration of the oropharyngeal or gastric contents may lead to aspiration pneumonia or chemical (acid) pneumonitis. Risk factors for aspiration include dysphagia, change in oropharyngeal colonization, gastroesophageal reflux (GER), and decreased host defenses.

Dysphagia can be caused by stroke or other neurologic disorders, seizures, alcoholism, and aging.[15] Oropharyngeal colonization may be altered by oral/dental disease, poor oral hygiene, tube feedings, or medications. This could result in a higher number of anaerobic organisms in the oral cavity or colonization with enteric gram-negative bacilli.[15] Acid suppression is an important factor in the treatment of GER disease, which may allow enteric gram-negative bacilli to colonize the gastric contents. Finally, impaired mucous production or cilia function, decreased immunoglobulin in secretions, and altered cough reflex may increase the likelihood of infection following an aspiration. The infection can result in a necrotizing pneumonia or lung abscess.

Inflammatory Response

Once breakdown of the local host defenses occurs and organisms invade the lung tissue, an inflammatory response is generated either by the organisms causing tissue damage or by the immune response to the presence of the organisms. This inflammatory

Patient Encounter 1

A 68-year-old woman, who only speaks Spanish, presents to your ED with difficulty breathing, coughing, and shortness of breath. It is late October and she collapsed in her front yard while raking leaves, her neighbors immediately called 911. Her physical examination reveals that she is easily confused and oriented name and place (×2), has decreased breath sounds on the right and left sides, and has rales and crackles in both lower lobes. Her temperature is 38.9°C (102.0°F), respiratory rate is 20 breaths/min, oxygen saturation 87% on room air, and blood pressure is 120/80 mm Hg. She is coughing up greenish sputum. The hospital interpreter is called to the ED to translate for this patient.

What are her signs and symptoms of pneumonia?

What are the top two bacterial organisms that could be causing the pneumonia?

What is the top atypical organism, as well as the top two viruses that could be causing the pneumonia?

What are the advantages and disadvantages of having a hospital employed interpreter for the patient?

response either can remain localized in the infected tissue or can become systemic. The role of the alveolar macrophages is twofold. First, to engulf the organisms to contain the infection, and second, to process the antigens for presentation in regional lymph nodes in order to generate a specific immune response by either the cell-mediated or humoral system, or both. The macrophages release cytokines in the area of the infection, which result in increased mucous production, constricting the local vasculature, and lymphatic vessels and attraction of other immune cells to the site. The increase in mucus is associated with symptoms such as cough and sputum production. If tumor necrosis factor alpha (TNF-α) and interleukins-1 and -6 are released systemically, then the symptoms become more severe and include hypotension, organ dysfunction, and/or a septic or septic-shock clinical presentation.

Patient Encounter 2

A 52-year-old man was admitted to the hospital for abdominal surgery. He developed complications postoperatively and was intubated 6 days ago. The nurses note an increase in the amount and purulence of his sputum. Attempts yesterday and today to wean the patient off the ventilator have failed. He is sedated but does respond to commands. His temperature is 38.4°C (101.1°F), blood pressure is 120/84 mm Hg, and white blood cell (WBC) 20.4 × 10^3/mm^3 (20.4 × 10^9/L) with a cell differential of 75% (0.75) neutrophils, 7% (0.07) bands, 15% (0.15) lymphocytes, and 3% (0.03) monocytes. The chest x-ray revealed left middle lobe infiltrates.

What are his signs and symptoms of pneumonia?

What are the top three bacterial organisms that could be causing the pneumonia?

CLINICAL PRESENTATION AND DIAGNOSIS

Several scoring systems are available for assessing the severity of the pneumonia: the Pneumonia Severity Index (PSI); confusion, uremia, respiratory rate, blood pressure (CURB); CURB-65 (for those ≥ 65 years of age), and systolic BP, oxygenation, age, and respiratory rate (SOAR).[10,13] These models are used to help determine the severity of illness, prognosis (mortality risk), and the need for hospitalization and then to help guide in the selection of antimicrobial therapy, along with the use of published guidelines.[10,13,14] For example, PSI or CURB-65 scores less than or equal to 70 and less than 2, respectively, correlate with mild disease that should be treated in the outpatient setting.

TREATMENT

LO 5

KEY CONCEPT The goal of antibiotic therapy is to eliminate the patient's symptoms, minimize or prevent complications, and decrease mortality. Potential complications secondary to pneumonia include further decline in pulmonary function in patients with underlying pulmonary disease, prolonged mechanical ventilation, bacteremia/sepsis/septic shock, and death. Use of an antimicrobial agent with the narrowest spectrum of activity that covers the suspected pathogen(s) without having activity against organisms not involved in the infection is preferred to minimize the development of resistance and secondary infections such as *Clostridium difficile* diarrhea/colitis.

General Approach to Treatment

Designing a therapeutic regimen for any patient with any type of pneumonia begins with three general categories of consideration:

1. Patient-specific factors that will impact therapy.
2. The top two to three organisms likely causing the infection and resistance issues associated with each organism.
3. The antimicrobials that will cover these organisms. Local resistance patterns, which can be obtained from hospital or clinic antibiograms, will influence the choice of antimicrobial. The spectrum should not be too broad or narrow; they should penetrate into the site of infection and be the most cost effective.

Patient factors that need to be considered include age, renal function, drug allergies and/or drug intolerances, immune status (diabetes, neutropenia, or immunocompromised host), cardiopulmonary disease, pregnancy, medical insurance and prescription coverage, exposure to resistant organisms, and prior antibiotic exposure(s).

- The most common pathogens vary with the type of pneumonia, and they are listed in Table 71–1. *M. pneumoniae* lack a cell wall; therefore, β-lactam drugs have no activity against this organism. The atypical organisms have not changed in recent years with respect to antibiotic resistance. β-Lactamase production in *H. influenzae* has remained relatively steady over the last 5 to 10 years, and the rate is approximately 25%.[20] *S. pneumoniae* has developed resistance mechanisms against many classes of antimicrobials, and the mechanisms include the following:
  - Alteration of the penicillin-binding proteins (PBPs), inactivating β-lactams

Clinical Presentation of CAP or Aspiration Pneumonia

General

Patients may experience nonrespiratory symptoms in addition to respiratory symptoms. With increasing age, both respiratory and nonrespiratory symptoms decrease in frequency.

LO 3

KEY CONCEPT **Symptoms**

- Respiratory—cough (productive or nonproductive), shortness of breath, and difficulty breathing
- Nonrespiratory—fever, fatigue, sweats, headache, myalgias, mental status changes

LO 3

KEY CONCEPT **Signs**

- Temperature may increase or decrease from baseline, but most often it is elevated. The temperature may be sustained or intermittent.
- Respiratory rate is often increased. Cyanosis, increased respiratory rate, and use of accessory muscles of respiration are suggestive of severe respiratory compromise.
- Breath sounds may be diminished. Rales or rhonchi may be heard.
- Confusion, lethargy, and disorientation are relatively common in elderly patients.

Diagnostic Tests

- Chest x-ray should reveal single or multiple infiltrates.
- Oxygen saturation on room air should be more than 90% (0.90), as determined by pulse oximetry.
- Arterial blood gases are beneficial primarily in patients with severe pneumonia.

Laboratory Tests

- The WBC may or may not be elevated. In elderly patients, a drop in WBCs also can be a sign of infection. The differential should show a predominance of neutrophils if a bacterial infection is present. The presence of bands also could be an indicator of bacterial infection. Elevated lymphocytes are an indication of viral infection.
- Blood urea nitrogen (BUN) and serum creatinine are needed to dose antibiotics appropriately and to minimize or prevent drug toxicity (especially in the elderly patient).

Microbiology Tests

- Sputum Gram stain should demonstrate the presence of WBCs and the absence of squamous epithelial cells. It may or may not show a predominance of one type of organism.
- Sputum culture and susceptibility are not obtained in the outpatient setting. The value of culturing is debated owing to the rapidity in which *S. pneumoniae* dies in transport media and the inability to reliably or routinely culture atypical organisms.
- Bronchoscopy may be performed to improve the ability to diagnose pneumonia. Tracheal secretions often are better specimens than sputum owing to the lack of oral contamination.
- Serology (IgM and IgG) is useful in determining the presence of atypical organisms such as *Mycoplasma* and *Chlamydia*.
- Urinary Legionella antigen is often used to diagnose *L. pneumophila*.
- Polymerase chain reaction (PCR) is being used more frequently to detect the DNA of respiratory pathogens.
- Blood cultures should be obtained in all patients admitted to the ICU with pneumonia. Positive blood cultures are present in about 1% to 20% of patients with CAP.

Clinical Presentation of Severe CAP or Aspiration Pneumonia

General

In approximately 10% of patients, CAP will be severe enough to require intensive care or mechanical ventilation.

LO 3

KEY CONCEPT **Symptoms**

Respiratory—cough (productive or nonproductive), shortness of breath, difficulty breathing

- Nonrespiratory—fever, fatigue, sweats, headache, myalgias, mental status changes

Signs

- Temperature may increase or decrease from baseline, but most often it is elevated. The temperature may be sustained or intermittent.
- Respiratory rate greater than 30 breaths/min, cyanosis and use of accessory muscles of respiration are suggestive of severe respiratory compromise.
- Hypotension (systolic blood pressure < 90 mm Hg or diastolic blood pressure < 60 mm Hg).
- Requirement for vasopressors.
- Breath sounds may be diminished. Rales or rhonchi may be heard.
- Urine output less than 20 mL/hour or less than 80 mL over 4 hours.
- Confusion, lethargy, and disorientation are relatively common in elderly patients.

Diagnostic Tests

As stated in the clinical presentation of community-acquired or aspiration pneumonia. Nasal swab MRSA PCR testing has a strong negative predictive value for MRSA pneumonia.

Laboratory Tests

As stated in the clinical presentation of community-acquired or aspiration pneumonia.

Microbiology Tests

As stated in the clinical presentation of community-acquired or aspiration pneumonia.

Diagnosis of VAP

Clinical Strategy

- Chest x-ray should reveal a new infiltrate *plus* two of the following:
  - Temperature greater than 38.0°C (100.4°F)
  - Leukocytosis or leukopenia
  - Purulent secretions
  - Semiquantitative cultures obtained identify the pathogen(s)
- Tracheal aspirates grow more organisms than invasive quantitative cultures and often result in overuse of antibiotics

- Efflux or methylation of the ribosome-inactivating macrolides
- Ribosome protection (tetM gene) inactivating tetracyclines
- Alteration of DNA gyrase or topoisomerase IV inactivating fluoroquinolones

S. pneumoniae resistance to commonly prescribed antimicrobials such as the penicillins and macrolides/azalides dramatically increased in the late 1980s through the mid- to late-1990s and has remained relatively flat in the 2000s. Resistance information collected nationally along with susceptibility testing for new antimicrobials demonstrates that average national rates of resistance to penicillin and macrolides were approximately 13% and 38%, respectively.[21,22] Resistance to trimethoprim/sulfamethoxazole is approximately 25%, and fluoroquinolone resistance remains less than 0.5%.[22]

For HAP, and VAP, the risk of infection from an MDR pathogen is relatively high. The number and type of organisms that are MDR vary from hospital to hospital, making it more difficult to generate guidelines for treatment. Therefore, the treatment recommendations may be too broad or too narrow for any given institution and local antibiogram data should influence the choice of therapeutic regimens. Risk factors for developing infection caused by a resistant pathogen are as follows:

- intravenous antibiotic use within the past 90 days
- septic shock at the time of HAP or VAP
- ARDS preceding VAP
- five or more days of hospitalization
- acute renal replacement therapy

The patient- and drug-related categories are common to all types of pneumonia, but the organisms vary with the type of pneumonia. Guidelines have been generated by experts in the field for all types of pneumonia. These guidelines were generated to provide practitioners with evidence-based therapeutic options for the management of patients with pneumonia.

Pharmacologic Therapy for CAP

LOS

KEY CONCEPT Treatment of CAP is predominantly empiric, that is, treatment is started without knowing the causative pathogen. The most recent guidelines are the result of collaboration between the Infectious Diseases Society of America (IDSA) and the American Thoracic Society (ATS).[23] The approach to patient care is based on the classification of patients into two broad categories, outpatient and inpatient, and then further dividing the groups by comorbid conditions and location in the hospital, respectively. These guidelines use patient-specific data along with predominant pathogen information to design appropriate empirical antimicrobial regimens. Table 71–2 summarizes these therapeutic options.

Patient Encounter 1, Part 2: Medical History, Physical Examination, and Diagnostic Tests

A 68-year-old woman, who only speaks Spanish, presents to your ED with difficulty breathing, coughing, and shortness of breath

PMH: Hypertension for 18 years, noninsulin dependent diabetes for 5 years, currently controlled

FH: Father died of lung cancer at the age of 68 years; mother died of natural causes

SH: Denies alcohol and tobacco use. Lives alone and has two children. She is 5′4″ (162.6 cm) and weighs 190 lb (86.4 kg)

Allergies: sulfa—hives, red-burning skin

Meds: Lisinopril 10 mg orally once daily; metformin ER 1000 mg orally twice daily

ROS: (+) difficulty breathing and shortness of breath; (–) chest pain, N/V/D, change in appetite

PE:

VS: BP 120/80 mm Hg, P 82 beats/min, RR 20 breaths/min, T 38.9°C (102.0°F)

CV: RRR, normal S_1, S_2; no murmurs, rubs, or gallops

Lungs: Decreased breath sounds on both sides, rales and crackles in both lower lobes, greenish sputum production

Abd: Soft, nontender, nondistended; (+) bowel sounds, no hepatosplenomegaly, heme (–) stool

Neuro: Oriented to name and place, confused

Diagnostic Tests: Chest x-ray: left and right lower lobe infiltrates; oxygen saturation 87% (0.87) on room air

Labs: WBCs 18.6 × 10^3/mm^3 (18.6 × 10^9/L) with a cell differential of 70% (0.70) neutrophils, 2% (0.02) bands, 20% (0.20) lymphocytes, and 8% (0.08) monocytes; BUN 10 mg/dL (3.57 mmol/L), SCr 0.8 mg/dL (70.74 µmol/L), fasting glucose 110 mg/dL (6.1 mmol/L); sputum Gram stain: moderate gram-positive diplococci, few gram-negative bacilli, rare squamous epithelial cells, many WBCs; sputum culture is pending

Given this additional information, what is your assessment of the patient's condition?

Identify your treatment goals for the patient.

What organisms should you include in your list of potential pathogens?

What pharmacologic agents are available for treating this patient?

Table 71–2

Summary of CAP Treatment

Adult outpatient otherwise healthy	*Monotherapy*
Empirical coverage against *S. pneumoniae, M. pneumoniae, C. pneumoniae,* and *H. influenzae*	Azithromycin, clarithromycin, erythromycin, doxycycline
Adult outpatient comorbidities	*Combination therapy*
Empirical coverage against *S. pneumoniae, M. pneumoniae, C. pneumoniae,* and *H. influenzae*	High-dose amoxicillin, or high-dose amoxicillin-clavulanate (alternatives are cefpodoxime, or cefuroxime, or ceftriaxone) *plus* azithromycin, or clarithromycin or, doxycycline
	Monotherapy
	Gemifloxacin, levofloxacin, moxifloxacin
Adult inpatient (non-ICU)	*Combination therapy*
Empirical coverage against *S. pneumoniae, H. influenzae, M. pneumoniae,* and *C. pneumoniae*	Cefotaxime, or ceftriaxone, or ampicillin-sulbactam, or ertapenem *plus* azithromycin, or clarithromycin, or doxycycline
	Monotherapy
	Gemifloxacin, levofloxacin, moxifloxacin
Adult inpatient ICU (*no* Pseudomonas)	*Combination therapy*
Empirical coverage against *S. pneumoniae, L. pneumophila, H. influenzae,* enteric GNB, and *S. aureus*	Cefotaxime or ceftriaxone *plus* azithromycin, or levofloxacin, or moxifloxacin
Adult inpatient ICU (Pseudomonas is a concern)	*Combination therapy*
Empirical coverage against *P. aeruginosa, S. pneumoniae, L. pneumophila, H. influenzae,* enteric GNB, and *S. aureus*	Cefepime, or ceftazidime, or piperacillin-tazobactam, or imipenem, or meropenem *plus* or ciprofloxacin or levofloxacin or an aminoglycoside
	If an aminoglycoside is chosen, then add azithromycin or levofloxacin or moxifloxacin
Adult inpatient non-ICU or ICU (MRSA is a concern)	
Empirical coverage against *S. pneumoniae, L. pneumophila, H. influenzae,* enteric GNB, and *S. aureus (Pseudomonas* if ICU)	Add vancomycin or linezolid to the regimens listed above
Pediatric outpatient	*Monotherapy*
Empirical coverage against *S. pneumoniae, M. pneumoniae,* and *C. pneumoniae*	High-dose amoxicillin, or high-dose amoxicillin-clavulanate, or intramuscular ceftriaxone, or azithromycin, or clarithromycin
Pediatric inpatient (non-ICU)	*Monotherapy*
Empirical coverage against *S. pneumoniae*	Fully immunized child—ampicillin or penicillin G
	Partially immunized child—ceftriaxone or cefotaxime
	Combination therapy
Empirical coverage against *S. pneumoniae, H. influenzae, M. pneumoniae,* and *C. pneumoniae*	IV cefuroxime, or cefotaxime, or ceftriaxone, or ampicillin-sulbactam plus azithromycin, or clarithromycin
Pediatric inpatient ICU	*Combination therapy*
Empirical coverage against *S. pneumoniae, L. pneumophila, H. influenzae,* enteric GNB, and *S. aureus*	Cefotaxime, or ceftriaxone plus azithromycin, or clarithromycin

CA-MRSA, community-acquired methicillin-resistant *Staphylococcus aureus;* GNB, gram-negative bacteria; ICU, intensive care unit.

Patient Encounter 2, Part 2: Medical History, Physical Examination, and Diagnostic Tests

A 52-year-old man was admitted to the hospital for abdominal surgery. He developed complications postoperatively and was intubated 6 days ago. The nurses note an increase in the amount and purulence of his sputum. Attempts yesterday and today to wean the patient off the ventilator have failed.

PMH: Hypertension for 15 years, currently controlled.

FH: Father and mother deceased from natural causes. Both had hypertension, mother had hypothyroidism.

SH: Smokes half a pack per day for 22 years, social alcohol two to three beers or liquor per week. He lives with his wife; truck driver. He is 5'11" (180.3 cm) and weighs 86.4 kg (190 lb).

Allergies: Penicillin—hives

Meds: Losartan 50 mg orally once daily

PE:

VS: BP 120/84 mm Hg, P 78 beats/min, T 38.4°C (101.1°F).

CV: RRR, normal S_1, S_2; no murmurs, rubs, or gallops.

Abd: Soft, nontender, nondistended; (+) bowel sounds, no hepatosplenomegaly.

Diagnostic Tests: Chest x-ray: left middle lobe infiltrate; oxygen saturation 98% (0.98) on ventilator.

Labs: WBC is $20.4 \times 10^3/mm^3$ ($20.4 \times 10^9/L$) with a cell differential of 75% (0.75) neutrophils, 7% (0.07) bands, 15% (0.15) lymphocytes, and 3% (0.03) monocytes; BUN 10 mg/dL (3.6 mmol/L), SCr 0.9 mg/dL (80 µmol/L); sputum Gram stain: many gram-negative bacilli, moderate gram-positive cocci in clusters, many WBCs; culture is pending.

Given this additional information, what is your assessment of the patient's condition?

Identify your treatment goals for the patient.

What pharmacologic agents are available for treating this patient?

▶ Adult Outpatient Previously Healthy

First-line therapeutic options for treating previously healthy adults include use of a macrolide (erythromycin, clarithromycin) or an azalide (azithromycin) or doxycycline.[23] If a patient has failed therapy with a macrolide, azalide, or doxycycline, one has to consider why the patient failed. The most common reasons are either medication adherence issues or the presence of resistant organisms. If a resistant organism is suspected, then use of one of the respiratory fluoroquinolones active against *S. pneumoniae* (gemifloxacin, levofloxacin, or moxifloxacin) is warranted.

▶ Adult Outpatient with Comorbid Conditions

The comorbid conditions that can impact therapy and outcomes in patients with CAP include diabetes mellitus, COPD, chronic heart, liver, or renal disease, alcoholism, malignancy, asplenia, and immunosuppressive condition or use of immunosuppressive drugs.[23] If the patient did not receive antibiotics in the last 3 months, then either a respiratory fluoroquinolone alone or a combination of an oral β-lactam agent plus a macrolide or azalide is recommended. If the patient received an antibiotic in the last 3 months, the recommendation is to use an agent from a different class. Doxycycline is an acceptable alternative to a macrolide or azalide. The preferred β-lactam antimicrobial agents are high-dose (3 g daily) amoxicillin or high-dose (4 g daily) amoxicillin-clavulanate. Alternative β-lactams are second- and third-generation cephalosporins such as cefuroxime, cefpodoxime, or ceftriaxone intramuscular.

▶ Adult Inpatient Not in the ICU

For patients admitted to the hospital with CAP, the severity of illness is generally increased (caused either by the organism itself or underlying comorbidities in the patient), and the pathogens are essentially the same as in the outpatient setting. Recommendations are to use either a respiratory fluoroquinolone alone or a combination of an IV β-lactam antimicrobial agent plus an advanced macrolide/azalide (clarithromycin/azithromycin) or doxycycline. The recommended β-lactams include cefotaxime, ceftriaxone, ampicillin-sulbactam, or ertapenem.[23] The first antibiotic dose should be administered within the first 24 hours of admission. Conversion to oral therapy should occur when the patient is hemodynamically stable, improving clinically, and able to take oral medications, which often is within 48 to 72 hours for most patients. Discharge from the hospital should be as soon as the patient is stable and without other medical complications. The need to observe the patient in the hospital on their oral antibiotic is not necessary.[23]

▶ Adult Inpatient in the ICU

Patients admitted to the ICU have severe pneumonia, and the likely etiology includes *S. pneumoniae* and *H. influenzae* as in the other categories; however, the incidence of *L. pneumophila* increases in this setting and should be considered a potential pathogen. In addition, enteric gram-negative bacilli and *S. aureus* are more frequently the cause of the pneumonia in these patients. The recommendations are to treat with an IV β-lactam plus either azithromycin or a respiratory fluoroquinolone. These combination therapies minimize the risk of treatment failure due to a resistant pathogen as well as provide broad coverage.[23] The β-lactams are the same as for inpatient non-ICU treatment. If the patient is allergic to β-lactams, then aztreonam plus a respiratory fluoroquinolone are preferred.

If *P. aeruginosa* is suspected, then the antimicrobial treatment must be broadened to cover *Pseudomonas* as well as the organisms listed previously. Owing to the high resistance rates observed with *Pseudomonas*, the recommended regimens empirically double cover the *Pseudomonas* to ensure at least one of the antibiotics is active against it. The regimens include the use of an antipneumococcal, antipseudomonal β-lactam (cefepime, ceftazidime, piperacillin/tazobactam, imipenem, or meropenem), plus either ciprofloxacin or levofloxacin or an aminoglycoside. If the aminoglycoside is chosen, then either IV azithromycin or a respiratory fluoroquinolone should be added to cover the atypical bacterial organisms.[23]

If CA-MRSA is suspected in the patient (refer to Clinical Presentation of Severe CAP or Aspiration Pneumonia), then the addition of vancomycin or linezolid to the preceding regimen should be considered. Daptomycin cannot be used because surfactant in the lung inactivates the drug, thus rendering it ineffective for pneumonia. CA-MRSA can cause a necrotizing pneumonia, and the cause is believed to be due to its many virulence factors, including the Panton-Valentine leukocidin toxin.[4] In these patients the use of an agent that decreases toxin production may be beneficial. Linezolid decreases toxin production; the other recommended agents to decrease toxin production and added to vancomycin therapy are clindamycin or a respiratory fluoroquinolone.[23]

▶ Influenza

Influenza viruses A and B can cause pneumonia in pediatric and adult patients. Amantadine and rimantadine are available oral agents with activity against influenza virus type A. If started within 48 hours of the onset of the first symptoms, they reduce the duration of the illness by about 1.3 days. However, resistance to the adamantanes is over 90%.[24] Oseltamivir and zanamivir are oral agents active against both type A and B influenza that reduce the duration of the illness by about 1.3 days if initiated within 40 to 48 hours of the first symptoms.[25] Peramivir is an intravenous neuraminidase inhibitor approved as a single dose for adults with uncomplicated influenza. It may be used in hospitalized patients in whom oral therapy is contraindicated or not tolerated.[26] For active infection beyond the first 48 hours, none of these agents are effective in treating infection, and supportive care is the best treatment for these patients. Neuraminidase resistance rates in influenza A strains prevalent prior to 2009 were high and rates in strains prevalent after 2009 are low.[24] Seasonal information on resistance patterns and treatment recommendations should be evaluated.

▶ Aspiration

Anaerobes and *Streptococcus* spp. are the primary pathogens if a patient aspirates their oral contents and develops pneumonia. Antibiotics active against these organisms include penicillin G, ampicillin/sulbactam, metronidazole, and clindamycin. If the patient aspirates oral and gastric contents, then anaerobes and gram-negative bacilli are the primary pathogens. The preferred

Patient Encounter 1, Part 3: Creating a Care Plan

A 68-year-old woman, who only speaks Spanish, presents to your ED with difficulty breathing, coughing, and shortness of breath.

Based on the information presented, create a care plan for this patient's pneumonia. Your plan should include: (a) a statement of drug-related needs and/or problems; (b) a patient-specific detailed therapeutic plan; and (c) monitoring parameters to assess efficacy and safety.

Patient Encounter 2, Part 3: Creating a Care Plan

A 52-year-old man was admitted to the hospital for abdominal surgery. He developed complications postoperatively and was intubated 6 days ago. The nurses note an increase in the amount and purulence of his sputum. Attempts yesterday and today to wean the patient off the ventilator have failed. Your hospital antibiogram for gram-negative organisms is below; values are percentage of isolates susceptible to the antibiotic. Boxes without values indicate you should not use that antibiotic for that organism.

	Total # tested	Amikacin	Ampicillin	Amp/Sulbactam	Cefazolin	Cefepime	Ceftriaxone	Ciprofloxacin	Gentamicin	Imipenem/ Meropenem	Levofloxacin	Piperacillin/ Tazobactam	TMX/SMX	Tobramycin	Nitrofurantoin

Pseudomonas aeruginosa	132	88				88		45	50	70	45	90		63	

Based on the information presented, create a care plan for this patient's pneumonia. Your plan should include: (a) a statement of drug-related needs and/or problems; (b) a patient-specific detailed therapeutic plan; and (c) monitoring parameters to assess efficacy and safety.

treatment regimen is a β-lactam/β-lactamase inhibitor combination (ampicillin/sulbactam, amoxicillin/clavulanate, piperacillin/tazobactam, or ticarcillin/clavulanate).[23]

▶ *Pediatric Outpatient*

Guidelines have been published for treating CAP in children. The most predominant pathogens in preschool children in the outpatient setting are viruses, and often supportive therapy (maintaining hydration, antipyretics) is all that is needed.[27] For appropriately immunized infants, children, and adolescents with mild-to-moderate pneumonia in an area lacking high-level penicillin-resistant pneumococcus, high-dose amoxicillin is the recommended first-line therapy. If atypical organisms are considered likely, then a macrolide is recommended. If moderate to severe CAP is diagnosed and it is during influenza season, then treatment with oseltamivir, zanamivir (Relenza), amantadine, or rimantadine is recommended; however, seasonal resistance rates need to be evaluated.[27] Fluoroquinolones and tetracyclines should not be used in children younger than 5 years. Dosing of antibiotics for pediatric patients is presented in Table 71–3.

▶ *Pediatric Inpatient*

If the infant or child is fully immunized, then the guidelines recommend the use of IV penicillin G or ampicillin. Alternative β-lactams include IV cefotaxime or ceftriaxone. If the infant or child is not fully immunized, then the third-generation cephalosporins (cefotaxime or ceftriaxone) should be administered.[27] If atypical organisms are suspected, add azithromycin to the β-lactam. If community-acquired MRSA is suspected, then vancomycin or clindamycin should be added to the regimen.[27]

Pharmacologic Therapy for HAP/VAP

Nosocomial pneumonia has since been replaced by the terms *hospital-associated pneumonia*, and *ventilator-associated pneumonia*. KEY CONCEPT Empirical selection of antimicrobial therapy for ventilator- and hospital-associated pneumonia is broad spectrum; however, once culture and susceptibility information is available, the therapy should be narrowed (de-escalation) to cover the identified pathogen(s). Three factors important to the empirical selection of antibiotics for these types of pneumonia are risk of mortality, MRSA risk factors, and intravenous use of antibiotics in the prior 90 days.[1] MDR organisms that need to be considered include *P. aeruginosa*, extended-spectrum β-lactamase–producing *K. pneumoniae*, *Acinetobacter* spp., and MRSA. Empirical antibiotic selection must cover *P. aeruginosa*, which often then covers the other gram-negative pathogens. Empirical therapy for HAP and VAP is listed in Table 71–4 and is stratified by these three factors. If there is low risk of mortality and no MRSA

LOS

Table 71–3

CAP Antimicrobial Dosing in Pediatric Patients

	Body Weight < 2000 g		Body Weight > 2000 g		
Drug (Route)	**0–7 Days Old**	**7–28 Days Old**	**0–7 Days Old**	**7–28 Days Old**	**> 28 Days Old**
Amoxicillin (po)				15 mg/kg every 12 hours	17 mg/kg every 8 hours
Amoxicillin-clavulanate (po)			15 mg/kg every 12 hours	15 mg/kg every 12 hours	45 mg/kg every 12 hours
Cefotaxime (IV)	50 mg/kg every 12 hours	50 mg/kg every 8 hours	50 mg/kg every 12 hours	50 mg/kg every 8 hours	50 mg/kg every 8 hours
Ceftriaxone (IM/IV)	25 mg/kg every 24 hours	50 mg/kg every 24 hours	25 mg/kg every 24 hours	50 mg/kg every 24 hours	50 mg/kg every 24 hours
Cefuroxime (po)					15 mg/kg every 12 hours
Azithromycin (po/IV)	5 mg/kg every 24 hours	10 mg/kg every 24 hours	5 mg/kg every 24 hours	10 mg/kg every 24 hours	10 mg/kg every 24 hours
Clarithromycin (po)					7.5 mg/kg every 12 hours

risk factors then recommended antibiotics include cefepime, piperacillin/tazobactam, or levofloxacin. If risk of mortality is high or intravenous antibiotics have been used in the prior 90 days then double coverage for gram-negative bacilli including *P. aeruginosa* is recommended. If MRSA is suspected, then either vancomycin or linezolid should be added to the regimen.[1]

Currently there is debate over whether or not double coverage for *Pseudomonas* is required. In vitro studies have shown that aminoglycosides exhibit synergistic killing against gram-negative bacilli when combined with β-lactams. Dosing of the aminoglycosides is dependent on the patient's renal function. A high-dose once-daily regimen (eg, 4–7 mg/kg gentamicin or tobramycin or 15–20 mg/kg amikacin) can be utilized in patients with good renal function. Most of the studies enrolled patients with estimated creatinine clearances of at least 70 mL/min (1.17 mL/s). Meta-analyses have shown high-dose once-daily regimens to be as efficacious as and less toxic than divided daily dosing.[28-32] Divided daily dosing (eg, 1–2 mg/kg gentamicin or tobramycin or 7.5 mg/kg amikacin) has been utilized since the 1970s, and the dosing interval is based on the patient's renal

Table 71–4

[a]Choose one agent for MRSA coverage PLUS one β-lactam antibiotic PLUS one non-β-lactam antibiotic.

[b]The hospital antibiogram or intensive care unit specific antibiogram should influence the selection from each column.

[c]Target area under the curve (AUC) > 400 (400–650) or target trough concentration of 15–20 mcg/mL.

[d]Extended infusions can be utilized.

[e]Trough concentrations ideally should be nondetectable; < 1 mcg/mL for gentamicin and tobramycin (1 mg/L; 2 µmol/L) and < 4–5 mcg/mL (4–5 mg/L; 7–9 µmol/L) for amikacin.

[f]Aztreonam should be reserved for a patient with a severe β-lactam allergy.

function to achieve a trough concentration of less than 2 mcg/mL (2 mg/L; 4 µmol/L) for gentamicin and tobramycin and less than 5 mcg/mL (5 mg/L; 9 µmol/L) for amikacin.

In addition to obtaining a synergistic effect, the primary reason for double coverage when treating VAP, or HAP is to broaden the coverage empirically to increase the likelihood of covering the majority of resistant pathogens. VAP is the most studied of these types of pneumonias and is often the most severe. There is an increase in mortality when inadequate therapy is initiated for VAP. Crude mortality ranges are quite large (35%–92%) compared with estimates of attributable mortality (approximately 9%); however, attributable mortality studies are limited by the large sample size needed to accurately measure this outcome.[33-35]

KEY CONCEPT Once a pathogen or pathogens have been identified, therapy should be narrowed (de-escalated) to cover only those pathogens. Use of broad-spectrum antibiotics for prolonged durations increases the risk of colonization with MDR pathogens.

LO 6

Duration of Antimicrobial Therapy

KEY CONCEPT The duration of therapy for pneumonia should be kept as short as possible and depends on several factors: type of pneumonia, inpatient or outpatient status, patient comorbidities, bacteremia/sepsis, and the antibiotic chosen. If the duration of therapy is too prolonged, then it can have a negative impact on the patient's normal flora in the respiratory and gastrointestinal tracts, vaginal tract of women, and on the skin. This can result in colonization with resistant pathogens, *Clostridium difficile* colitis, or overgrowth of yeast. In addition, the longer antibiotics are administered, the greater the chance for toxicity from the agent, as well as an increase in cost.

LO 6

The IDSA recommends treatment for CAP for a minimum of 5 days, and if the patient has been afebrile for 48 to 72 hours and has no more than 1 CAP-associated sign of instability (heart rate ≤ 100 beats/minute, respiratory rate ≤ 24 breaths/minute, systolic blood pressure ≥ 90 mm Hg, oxygen saturation ≥ 90% on room air, tolerating oral intake or normal mental status) then treatment can be discontinued.[23] For treatment of CAP in adult patients admitted to the hospital, the duration is dependent on whether or not blood cultures were positive. In the absence of positive blood cultures, the criteria for the 5-day duration of therapy listed above was validated for hospitalized patients and demonstrated similar clinical success as compared to longer durations of therapy.[36] If blood cultures were positive, the duration of therapy should be 2 weeks from the day blood cultures first became negative. The duration of therapy in pediatric patients is 10 days for uncomplicated CAP, with the exception of azithromycin, which is approved for 5 days.[27]

The duration of therapy cited in the literature for HAP or VAP ranges from 10 to 21 days. The ATS and IDSA guidelines (Table 71–5) recommend a shortened duration of therapy from the traditional 14 to 21 days to 7 days.[1] The ratings for the recommendations is a strong recommendation with moderate quality of evidence for VAP and a strong recommendation with very low quality of evidence for HAP.[1] Shorter or longer durations of therapy could be appropriate and should be based on the rate of improvement of clinical, radiological, and laboratory parameters. Shortening the duration of therapy was found to be beneficial with regard to secondary infections, colonization, toxicity, and cost issues. Several studies evaluated mortality, clinical success, recurrence, or the development of resistance with shorter courses of therapy for VAP and found no differences when compared with longer courses of therapy.[34,37]

OUTCOME EVALUATION

For CAP, outcomes include preventing hospitalization, shortening the duration of hospitalization, and minimizing mortality. Improvement of symptoms should occur within 24 to 72 hours after initiation of therapy for most patients with CAP. Response to therapy could be slowed in patients with underlying pulmonary disease such as moderate to severe asthma, COPD, or emphysema. In patients not responding to therapy consider patient comorbid conditions, other infectious and noninfectious reasons, and a drug-resistant pathogen as a causative agent. Noninfectious reasons to

consider include pulmonary embolus, congestive heart failure, carcinoma, lymphoma, intrapulmonary hemorrhage, and certain inflammatory lung diseases.

Outcome parameters for VAP and HAP are similar to those with CAP. Clinical improvement should occur within 48 to 72 hours of the start of therapy. If a patient is not responding to therapy, then, again, consider infectious and noninfectious reasons. Infectious explanations are the same as for CAP stated above, but noninfectious are not. They include atelectasis, acute respiratory distress syndrome (ARDS), pulmonary embolism or hemorrhage, cancer, empyema, or lung abscess.

PREVENTION

KEY CONCEPT Prevention of both pneumococcal and influenza pneumonia by use of vaccination is a national goal. Vaccination is used to prevent or minimize the severity of pneumonia caused by *S. pneumoniae* or the influenza virus. Further information on vaccination can be found in Chapter 86.

LO 10

The influenza vaccine is available in two forms: trivalent and quadrivalent. The trivalent vaccines are injectable, and inactivated consisting of 2 type A and 1 type B influenza viruses. There are several different formulations of the trivalent vaccine: standard dose, high dose, recombinant, and adjuvanted. Each manufacturer has different age approvals and should be evaluated prior to use in pediatric patients.[38] The high-dose influenza and standard dose adjuvanted vaccines are recommended for those 65 years of age and older.

The quadrivalent vaccines contain 2 type A and 2 type B influenza viruses. Each manufacturer has different age approvals and should be evaluated prior to use in pediatric patients.[37] Fluzone Quadrivalent is approved for use in people older than 6 months of age, including healthy people and people with chronic medical conditions. The quadrivalent nasal-spray influenza vaccine is made with live-attenuated influenza viruses that do not cause the influenza and is approved for use in healthy people 2 to 49 years of age who are not pregnant. The ability of influenza vaccine to protect a person depends on two key factors: the age and health status of the person getting the vaccine, and the similarity or "match" between the virus strains in the vaccine and those in circulation. Protective antibodies are detected approximately 2 weeks after vaccination. The Centers for Disease Control and Prevention (CDC) adopted a universal influenza vaccination policy, thus recommending all persons 6 months of age and older to be vaccinated annually prior to the start of during influenza season. Annual vaccination is recommended for individuals who are allergic to eggs. All licensed, age-appropriate vaccines can be used and it is no longer required to monitor the person for 30 minutes after the injection. If the person has a severe reaction to eggs, it is recommended they be vaccinated in a medical setting and supervised by a health care provider who can manage severe allergic reactions and conditions.[38]

Pneumococcal conjugate vaccine (PCV) is comprised of 13 serotypes and is recommended for all babies and children younger than 2 years old, all adults 65 years or older, and people 2 through 64 years old with certain medical conditions. Pneumococcal polysaccharide vaccine (PSV) is comprised of 23 serotypes and is recommended for all adults 65 years or older, people 2 through 64 years old who are at increased risk for disease due to certain medical conditions, and adults 19 through 64 years old who smoke cigarettes. The serotypes in the PCV13 are the most common disease-causing strains of pneumococcus.[39,40] A reliable immunologic response to the PCV13 has been demonstrated, along with a favorable safety profile.[40,41] One dose of PCV13 is recommended for children 6 through 18 years old and adults 19 through 64 years old with the following medical conditions that put them at increased risk for pneumococcal disease: cerebrospinal fluid (CSF) leaks (leak in fluid around the brain and spine), cochlear implant(s) (electronic medical device that replaces the function of a damaged inner ear), sickle cell disease and other hemoglobinopathies (blood disorders), functional or anatomic asplenia (a spleen that is damaged or removed), congenital or acquired immunodeficiencies, HIV infection, chronic renal failure, nephrotic syndrome, leukemia, Hodgkin disease, generalized malignancy, long-term immunosuppressive therapy, solid organ transplant, or multiple myeloma.[42] The 23 capsular types in the PPSV23 represent at least 85% to 90% of the serotypes that cause invasive pneumococcal infections among children and adults in the United States. Ten years after vaccination, a sample of elderly individuals demonstrated significant quantity of protective antibodies.[43] Individuals aged 2 to 64 years of age with one of the above disorders should receive 1 dose of the PCV13 and 5 years later receive the PSV23. Individuals 65 years and older should receive the PSV23 vaccine every 5 years for a maximum of three doses.[42] Additional information on these vaccines is available on the CDC website, Advisory Committee on Immunization Practices (ACIP; https://www.cdc.gov/vaccines/acip/index.html).

Patient Care Process

KEY CONCEPT Monitoring response to therapy is essential for determining efficacy, identifying adverse reactions, and determining the duration of therapy.

Collect Information:

- Perform a medication history for use of prescription and nonprescription medications and dietary supplements.
- Identify allergies to medications, including the reaction.
- Review the medical history and physical assessment findings.
- Speak with the patient (except for VAP patients) to identify lifestyle habits, preferences and beliefs, health goals, and socioeconomic factors that affect medication access and other aspects of care.

Assess the Information:

- Evaluate the symptoms, and status (ie, inpatient, outpatient, or intubated) to determine the type of pneumonia.
- Identify comorbid conditions of asthma, COPD, or emphysema, smoking history to determine if there are factors that could slow or alter the rate of response to therapy due to bronchial or lung damage or impact the pathogen list.
- Review chest x-ray, pulse oximetry, laboratory values, microbiology data, and vital signs available.
- Assess allergies and drug intolerances, noting the severity of the reaction.
- Identify any significant drug interactions or adverse drug effects.

(*Continued*)

Patient Care Process (*Continued*)

Develop a Care Plan:

- Determine the top two to three organisms associated with the type of pneumonia for the patient (Table 71–1).
- Select an appropriate empirical antibiotic regimen for the patient and type of pneumonia, ensuring that the doses are correct for renal function and medication allergies or intolerances (see Tables 71–2 and 71–3).

Implement the Care Plan:

- Educate the patient on the importance of completing their antibiotic therapy, medication adverse effects, and drug interactions.
- Address any patient concerns regarding their pneumonia and its management.
- Determine whether the patient has insurance coverage or if the recommended agent(s) are included on the institution's formulary.

Follow-up: Monitor and Evaluate:

- Assess the effectiveness of the antibiotic therapy after 24 to 72 hours looking for improvement in signs and symptoms.
- If the patient responds to therapy within the first 72 hours, consider a 5- to 7-day course of therapy for CAP and HAP/VAP, respectively. If inpatient status, assess the patient for conversion from IV to oral therapy.
- If the patient is not improving, then reevaluate the diagnosis and pathogen list, and make appropriate changes to therapy.
- Assess the patient for the presence of adverse drug reactions, drug allergies, and drug interactions.
- Discuss with the patient the value of vaccination against *S. pneumoniae* and/or influenza. Recommend and administer vaccinations annually during the season for influenza and as appropriate for the patient for *S. pneumoniae*.

Abbreviations Introduced in This Chapter

ARDS	Acute respiratory distress syndrome
ATS	American Thoracic Society
BUN	Blood urea nitrogen
CA-MRSA	Community-acquired methicillin-resistant *Staphylococcus aureus*
CAP	Community-acquired pneumonia
CDC	Centers for Disease Control and Prevention
COPD	Chronic obstructive pulmonary disease
DFA	Direct fluorescence antigen
GER(D)	Gastroesophageal reflux (disease)
H	Hemagglutinin
HAP	Hospital-acquired pneumonia
IDSA	Infectious Diseases Society of America
MDR	Multidrug resistant
MRSA	Methicillin-resistant *Staphylococcus aureus*
MSSA	Methicillin-susceptible *Staphylococcus aureus*
N	Neuraminidase
PBP	Penicillin-binding protein
PCR	Polymerase chain reaction
PCV13	Pneumococcal 13-valent conjugated vaccine
PPSV23	Purified-capsular polysaccharide 23 antigen vaccine
TNF-α	Tumor necrosis factor alpha
VAP	Ventilator-associated pneumonia

72 Upper Respiratory Tract Infections

Heather L. Girand

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

1. List common bacteria that cause acute otitis media (AOM), acute bacterial rhinosinusitis (ABRS), and acute pharyngitis.
2. Explain the pathophysiology of and risk factors for AOM, ABRS, and streptococcal pharyngitis.
3. Identify clinical signs and symptoms associated with AOM, ABRS, streptococcal pharyngitis, and the common cold.
4. List treatment goals for AOM, ABRS, streptococcal pharyngitis, and the common cold.
5. Develop a treatment plan for a patient with an upper respiratory tract infection (URI) based on patient-specific information.
6. Create a monitoring plan for a patient with a URI based on patient-specific information and the treatment regimen.
7. Formulate appropriate educational information for patients about URIs and proper antibiotic use.

INTRODUCTION

Upper respiratory tract infection (URI) is a comprehensive term for upper airway infections, including otitis media, sinusitis, pharyngitis, laryngitis, and the common cold. Over 1 billion URIs occur annually in the United States, triggering millions of antibiotic prescriptions each year, of which up to 50% are considered inappropriate for use for acute respiratory conditions.[1] KEY CONCEPT Most URIs are caused by viruses, have nonspecific symptoms, and resolve spontaneously.[2] Antibiotics are not effective for viral URIs, and their excessive use has contributed to resistance, which has prompted development of clinical guidelines and national campaigns to reduce inappropriate prescribing.[3-7] This chapter focuses on acute otitis media (AOM), sinusitis, and pharyngitis, which are frequently caused by viruses but may be caused by bacteria. Proper management of the common cold is also reviewed.

OTITIS MEDIA

Otitis media, or middle ear inflammation, is the most common childhood illness treated with antibiotics. It usually results from a nasopharyngeal viral infection and can be subclassified as AOM or otitis media with effusion (OME). AOM is a rapid, symptomatic infection with effusion, or fluid, in the middle ear. OME is not an acute illness but is characterized by noninfectious middle ear effusion. Antibiotics are only useful for the treatment of AOM.

Epidemiology and Etiology

LO 2

AOM occurs in all ages but is most common between 6 and 18 months of age. By 3 years of age, about 60% of children have had at least one episode of AOM and nearly 25% have had at least 3 episodes of AOM.[8] Many risk factors (Table 72–1) predispose children to otitis media.[8,9] While the use of antibiotics for otitis media has declined since the mid-1990s, the proportion of health care visits resulting in antibiotic prescriptions for AOM remains high between 60% and 80%.[1,10]

LO 1

Although AOM occurs frequently with viral URIs, bacteria are isolated from middle ear fluid in 70% to 90% of children with AOM.[3,8] Historically, *Streptococcus pneumoniae* was the most common organism, responsible for up to half of bacterial cases.[3,8] *Haemophilus influenzae* and *Moraxella catarrhalis* caused up to 30% and 20% of cases, respectively. Routine childhood pneumococcal vaccination has altered the microbiology such that *H. influenzae* is now responsible for up to 60% of bacterial cases.[8,11] Viruses are isolated from middle ear fluid with or without concomitant bacteria in up to 70% of cases.[12] Lack of improvement with antibiotics is usually a result of viral infection and subsequent inflammation rather than antibiotic resistance.

Antibiotic resistance heavily influences the treatment options for AOM. Penicillin-resistant *S. pneumoniae* (PRSP) exhibit intermediate resistance (minimum inhibitory concentrations [MIC] between 0.12 and 1.0 mcg/mL [0.12 and 1.0 mg/L]) or high-level resistance (MIC of 2.0 mcg/mL [2.0 mg/L] and higher). Altered penicillin-binding proteins cause resistance in 35% to 44% of pneumococci with up to half of these strains exhibiting high-level resistance.[8,13,14] Recent data show that the prevalence of high-level penicillin resistance is less than 5% in pneumococci obtained from children.[14] Amoxicillin resistance is less common than penicillin resistance, occurring in 2% to 19% of pneumococci.[13,15] PRSP are frequently resistant to other drug classes, including sulfonamides, macrolides, and clindamycin, but are usually susceptible to levofloxacin. Treatment should be aimed at *S. pneumoniae* because pneumococcal AOM is unlikely to resolve spontaneously and commonly results in more ear pain and fever.[3,11] β-Lactamase production occurs in 20% to 45% of *H. influenzae* and 90% to 100% of *M. catarrhalis* strains.[8,11] Although

Table 72–1

Risk Factors for Otitis Media[8,9]

Atopy	Pacifier use
Craniofacial defects	Positive family history/genetic predisposition
Daycare attendance	Siblings
Gastroesophageal reflux	Tobacco smoke exposure
Immunodeficiency	Viral respiratory tract infection/winter season
Lack of breast-feeding	Young age at first diagnosis
Male sex	
Non-Hispanic white race	

infections caused by these organisms are more likely to resolve without treatment, they should be considered when failure occurs or when there is recurrent disease.[3,11]

Pathophysiology

LO 2

AOM is caused by an interplay of factors. Viral URIs impair eustachian tube function and cause mucosal inflammation, impairing mucociliary clearance and promoting bacterial proliferation and infection. Children are predisposed because they have shorter, more flaccid, and more horizontal eustachian tubes than adults, which are less functional for middle ear drainage and protection. Clinical manifestations of AOM result from host immune response and cellular damage from inflammatory mediators released by bacteria.

LO 2

Viscous effusions caused by allergy or irritant exposure contribute to impaired mucociliary clearance and AOM in susceptible individuals. Effusions can persist for up to 6 months after an episode of AOM. Atopic children experience chronic OME that may require tympanostomy tube placement to reduce complications such as hearing and speech impairment and recurrent AOM.

Patient Encounter 1, Part 1

A 12-month-old girl presents to the pediatrician's office with 36 hours of fever (maximum temperature of 39.1°C [102.4°F]) and fussiness and 2 to 3 days of rhinorrhea. Her mother reports that she was rubbing both of her ears throughout the day yesterday. She states that her daughter is irritable and was crying intermittently throughout last night. She has not eaten well today. She attends daycare 5 days a week.

What information is suggestive of acute otitis media (AOM)?

What risk factors does this child have for AOM?

Is there any additional information you need to know before recommending a treatment plan?

Treatment

LO 4

The goals of treatment are to alleviate ear pain and fever, if present; eradicate infection; prevent complications; and avoid unnecessary antibiotic use.

▶ *General Approach to Treatment*

Most uncomplicated cases of AOM do not require antibiotic treatment and will resolve spontaneously. Untreated AOM improves in over 80% of children between days 2 and 3 of illness without increasing complications.[16] Antibiotics improve otalgia in only 5% of children between days 2 and 7 of therapy while *increasing* the risk of adverse events by 38%.[16] Antibiotics significantly improve recovery in children younger than 2 years with bilateral AOM and in those with AOM and otorrhea.[16] Children younger than 2 years have a higher incidence of PRSP infections, and children between 6 months and 3 years have

Clinical Presentation and Diagnosis of AOM

Patients with AOM usually have cold symptoms, including rhinorrhea, cough, or nasal congestion, before or at diagnosis.

Symptoms

- Young children: ear tugging or rubbing, irritable, poor sleeping and eating
- Older patients: ear pain, ear fullness, hearing impairment

Signs[3]

- Fever: not common in older children; often in younger children
- Middle ear effusion
- Otorrhea with tympanic membrane perforation
- Bulging tympanic membrane
- Limited or absent mobility of tympanic membrane
- Distinct erythema of tympanic membrane
- Opaque tympanic membrane that obscures middle ear visibility

Laboratory Tests

- Gram stain, culture, and sensitivities of ear fluid if draining spontaneously or obtained via tympanocentesis (not performed routinely in practice)

Complications

- Infectious: mastoiditis, meningitis, osteomyelitis, intracranial abscess
- Structural: perforated eardrum, cholesteatoma
- Hearing and/or speech impairment

Diagnosis[3]

AOM should be diagnosed if any of the following is met:

- Moderate to severe bulging of tympanic membrane (usually with impaired mobility as assessed by pneumatic otoscopy)
- Mild bulging of tympanic membrane *and* recent onset (< 48 hours) of otalgia (or ear rubbing/tugging in nonverbal child) or intense erythema of tympanic membrane
- New onset otorrhea not caused by acute otitis externa
- Severe AOM: Moderate to severe otalgia or otalgia for at least 48 hours *or* temperature of 39.0°C (102.2°F) or greater

higher clinical and bacteriologic failure rates and complications without initial antibiotic treatment as compared with older children.[3,17] Patients with severe AOM have lower spontaneous recovery rates than those with less severe disease, particularly in children less than 2 years.[3,18] KEY CONCEPT Therefore, antibiotics should be reserved for patients most likely to benefit, which is dependent on proper diagnosis, patient age, and illness severity. Current guidelines stratify patients using these criteria in order to identify those most likely to benefit from antibiotics.[3]

▶ *Nonpharmacologic Therapy*

Watchful waiting and "safety-net" antibiotic prescriptions (prescription given to the patient but only filled if symptoms persist or worsen within 48–72 hours after diagnosis) are approaches used to attenuate microbial resistance and avoid unnecessary antibiotic adverse events and costs. Initial observation and use of delayed prescriptions in older children and those with less severe disease can reduce antibiotic use by 60% without increasing complications.[16,19] These approaches should only be considered in otherwise healthy children (Figure 72–1) as a joint decision between the clinician and the parent/caregiver and only if close follow-up and good communication exist.[3]

Children with recurrent AOM or chronic OME with impaired hearing or speech may benefit from surgery (tympanostomy tube placement with or without adenoidectomy).

▶ *Pharmacologic Therapy*

Adjunctive Therapy Pain is a central feature of AOM but it is often overlooked. Analgesics provide relief within 24 hours and should be used regardless of antibiotic therapy.[3] Acetaminophen and ibuprofen are commonly used for mild to moderate pain. Ibuprofen provides longer relief than acetaminophen but should be avoided in children younger than 6 months because of increased toxicity concerns. Alternating ibuprofen with acetaminophen is not recommended because of the potential for dosing error in ambulatory settings and a lack of safety and efficacy data. Myringotomy provides immediate relief but is rarely performed. Decongestants, antihistamines, and corticosteroids have no role in AOM treatment and can prolong effusion duration.[3,20] Data are lacking on the safety and efficacy of complementary and alternative treatments.

Antibiotic Therapy When antibiotics are necessary, clinicians must consider drug factors (eg, antimicrobial spectrum, likelihood of response, middle ear fluid penetration, side effects, drug interactions, cost) and patient factors (eg, risk factors for resistance, allergies, regimen complexity, medication palatability, and presence of other medical conditions). Studies in uncomplicated AOM have not revealed significant differences between antibiotics in clinical response rates, but most were confounded by spontaneous resolution in children likely to have had viral URIs. Bacteriologic response varies among antibiotics and does not always correlate well with clinical response but is considered important when selecting therapy.[3]

The American Academy of Pediatrics (AAP) developed clinical guidelines for healthy children between 6 months and 12 years of age with uncomplicated AOM (Figure 72–2).[3] KEY CONCEPT Amoxicillin is the drug of choice in most patients because of its proven effectiveness, high middle ear concentrations, excellent safety profile, low cost, palatable suspension, and relatively narrow spectrum (Table 72–2). High-dose amoxicillin (80–90 mg/kg/day) is preferred over conventional doses (40–45 mg/kg/day) because higher middle ear fluid concentrations can overcome pneumococcal penicillin resistance without substantially increasing adverse effects.[3,21] High dose amoxicillin-clavulanate is preferred for children who received amoxicillin in the previous 30 days, have concurrent purulent conjunctivitis, have a history of recurrent AOM unresponsive to amoxicillin, and when coverage for β-lactamase-producing organisms is desired. Despite reported high rates of penicillin allergies, only those with immunologic penicillin or amoxicillin allergies, such as hives, require alternative therapy

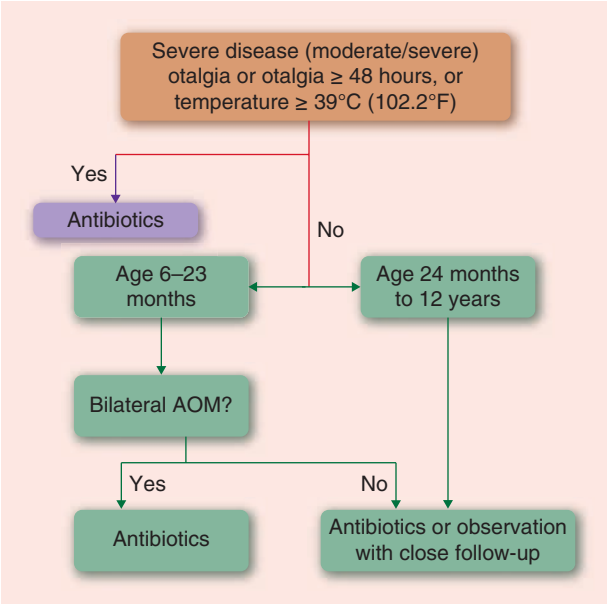

FIGURE 72–1. Treatment algorithm for initial antibiotics or observation in children 6 months to 12 years of age with uncomplicated AOM. (Data from Lieberthal AS, Carroll AE, Chonmaitree T, et al. The diagnosis and management of acute otitis media. Pediatrics. 2013;131(3):e964–e999.)

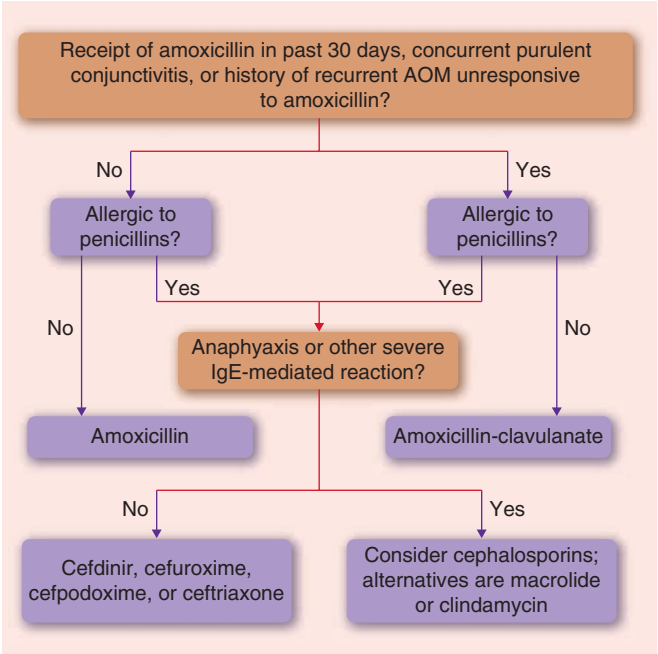

FIGURE 72–2. Treatment algorithm for uncomplicated AOM in children 6 months to 12 years of age. (Data from Lieberthal AS, Carroll AE, Chonmaitree T, et al. The diagnosis and management of acute otitis media. Pediatrics. 2013;131(3):e964–e999.)

Table 72–2

Antibiotics[a] for the Treatment of Acute Otitis Media

Drug	Usual Dose and Schedule	Common Adverse Effects	Relative Cost[b]	Comments
Amoxicillin	80–90 mg/kg/day divided in two doses (adult: 875 mg twice daily)	Nausea, vomiting, diarrhea, rash	$	Drug of choice for AOM; experts recommend high dose to overcome penicillin resistance
Amoxicillin-clavulanate	90 mg/kg/day divided in two doses (adult: 875 mg twice daily)	Nausea, vomiting, diarrhea, rash, diaper rash	$$–$$$	More diarrhea than amoxicillin; amoxicillin:clavulanate ratio of 14:1 preferred because of lower daily clavulanate component
Cefdinir	14 mg/kg/day divided in one to two doses (adult: 300 mg twice daily or 600 mg once daily)	Diarrhea, rash, vomiting, diaper rash, yeast infections	$$–$$$	Preferred oral cephalosporin (pleasant taste); separate from Fe supplements by 3 hours
Cefpodoxime proxetil	10 mg/kg/day divided in two doses (adult: 200 mg twice daily)	Diarrhea, diaper rash, vomiting, rash, yeast infections	$$$–$$$$	Suspension is bitter tasting
Ceftriaxone	50 mg/kg IM or IV for 1 or 3 days (max 1 g/dose)	Injection site pain, swelling, or erythema; diarrhea, rash	$$$–$$$$	3-day regimen preferred for PRSP
Cefuroxime axetil	30 mg/kg/day divided in two doses (adult: 250 mg twice daily)	Nausea, vomiting, diarrhea, rash, diaper rash	$$–$$$	Suspension is no longer available in the United States

[a]Other FDA-approved antibiotics for AOM not recommended in AAP guidelines: azithromycin, cefaclor, cefixime, cefprozil, ceftibuten, cephalexin, clarithromycin, erythromycin-sulfisoxazole, and trimethoprim-sulfamethoxazole.

[b]Approximate cost per course: $ (under $25), $$ ($25–$50), $$$ ($50–$100), $$$$ (over $100).

AAP, American Academy of Pediatrics AOM, acute otitis media; Fe, iron; IM, intramuscular; IV, intravenous; PRSP, penicillin-resistant *S. pneumoniae.*

Data from Lieberthal AS, Carroll AE, Chonmaitree T, et al. The diagnosis and management of acute otitis media. Pediatrics. 2013;131(3):e964–e999.

(see Figure 72–2). There is limited cross-reactivity between penicillins and newer cephalosporins, which supports AAP recommendations to use cephalosporins in penicillin-allergic patients because they are more effective than alternatives.[3,22] Trimethoprim-sulfamethoxazole and macrolides are less active against *S. pneumoniae* and *H. influenzae* than the preferred cephalosporins, making them less appropriate for most penicillin-allergic patients.[3,14,23] Single-dose intramuscular ceftriaxone is effective for children who cannot tolerate oral medications, but a 3-day course may be preferred to prevent recurrence caused by resistant pneumococci and because of reported treatment failures with single doses.[3] Ototopical antibiotic and glucocorticoid combinations are more effective than systemic antibiotics for patients with acute otorrhea and tympanostomy tubes.[24]

If there is no improvement or worsening with initial therapy during the first 48 to 72 hours, proper diagnosis and antibiotic selection must be reassessed.[3] Tympanocentesis can assist with guiding therapy in difficult cases.

Duration of antimicrobial therapy depends on antibiotic selection, patient characteristics, and acceptability of failure if a short treatment course is used. The risk of treatment failure within 1 month is modestly higher with short-course therapy (3–5 day regimens) than standard-course therapy (minimum 7 days), but failure rates with short-course therapy are significantly higher in children with perforated eardrums.[25] Failure with short-course amoxicillin-clavulanate is also significantly more common in children 6 to 23 months of age as compared to 10 days of therapy.[26] Short-course regimens have not been proven to reduce the rates of adverse events or emergence of microbial resistance.[24,25] Standard 10-day regimens are recommended for all severe infections and for children younger than 2 years.[3] Seven-day regimens and five- to seven-day regimens can be considered for mild to moderate AOM in children 2 to 5 years and children 6 years and older, respectively.[3]

Prevention

Influenza vaccines and pneumococcal conjugate vaccines may prevent AOM in certain patients, but their benefits are small and they should not be administered solely for this purpose.[27,28] Antibiotic prophylaxis is not recommended because of selection pressure on microbial resistance. Exclusive breast-feeding for the first 6 months of life and avoidance of tobacco smoke are advised, but the effects of these interventions remain unproven.

Outcome Evaluation

Improvement of signs and symptoms (ie, pain, fever, and tympanic membrane inflammation) should be evident by 72 hours of proper therapy. Children can appear clinically worse during the first 24 hours but often stabilize during the second day. If symptoms persist or worsen, reevaluate the patient for the proper diagnosis and treatment. Counsel patients and caregivers regarding common antibiotic adverse effects such as rash, diarrhea, and vomiting that may prompt additional medical attention.

Presence of middle ear effusion in the absence of symptoms is not an indicator of treatment failure. Evaluate hearing in children who are otherwise healthy and have persistent effusion lasting 3 months in duration. Preschool-aged and younger children or those at risk for developmental difficulties may need reexamination earlier because speech and hearing impairment is more difficult to assess in these populations.

Patient Care Process for Upper Respiratory Tract Infections

Collect Information:

- Perform a medication history including prescription and nonprescription medications or therapies and dietary supplements. Identify allergies and adverse reactions to medications or other substances and document reaction(s) that occurred. Gather information on immunization history from the patient or patient's parent or caregiver and medical records including immunization registry, if applicable.
- Review the medical history and physical examination findings.
- Speak with the patient or patient's parent or caregiver to identify lifestyle habits, preferences and beliefs, health goals, and socioeconomic factors that affect medication access and other aspects of care.

Assess the Information:

- Based on patient history and physical examination findings, determine if the patient has a bacterial infection and, if present, whether it is severe and/or recurrent.
- Determine if antibiotic therapy is indicated.
- Determine if the patient is current or behind on recommended immunizations.
- Determine if modifiable risk factors are present, such as exposure to tobacco smoke.
- Assess the effectiveness, safety, and patient adherence of current pharmacotherapy, where applicable.
- Identify comorbidities or conditions that may complicate the treatment plan or prompt referral to a specialist.

Develop a Care Plan:

- Select appropriate analgesic therapy that will provide optimal pain relief and appropriate adjunctive therapies to relieve symptoms.
- If appropriate, select antibiotic therapy that is likely to be effective and safe.
- Select an optimal antibiotic dose and an appropriate duration of treatment based on patient age and illness severity.

Implement the Care Plan:

- Discuss expectations for improvement of signs and symptoms with the patient, parent, or caregiver.
- Discuss importance of medication adherence to treat symptoms and infection.
- Discuss potential medication adverse effects and how to manage them.
- When appropriate, recommend and/or administer influenza and pneumococcal conjugate vaccinations to reduce risk for future infections.

Follow-up: Monitor and Evaluate:

- Reevaluate patient if symptoms persist or worsen at any time.

Patient Encounter 1, Part 2

On further questioning, her mother states that she is "allergic" to amoxicillin-clavulanate. She was treated for a skin infection 3 months ago and experienced diarrhea while taking this antibiotic. She has not received antibiotics since that time, and this is her second ear infection. The first episode was diagnosed at 8 months of age.

Immunizations: Up-to-date

Meds: Ibuprofen 75 mg orally every 6 to 8 hours as needed for fever

ROS: (+) rhinorrhea and fever, (–) vomiting, diarrhea, or cough

PE:

Gen: Irritable child but consolable

VS: BP 90/55 mm Hg, P 140 beats/min, RR 24 breaths/min, T 38.6°C (101.5°F), Weight 9.5 kg

HEENT: Erythema, moderate bulging, and limited mobility of the left and right tympanic membranes

Identify your treatment goals for this child.

Given this information, what nonpharmacologic and pharmacologic therapy do you recommend?

Patient Care Process for Acute Otitis Media

See Patient Care Process for Upper Respiratory Tract Infections.

Assess the Information:

- Determine if antibiotic therapy is indicated or if observation can be employed (see Figure 72–1).

Develop a Care Plan:

- If appropriate, select an antibiotic (see Figure 72–2) and optimal dose and duration (see Table 72–2).

Implement the Care Plan:

- Educate parents or caregivers that pain, fever, and/or other symptoms should improve but may not resolve completely within 48 to 72 hours and can be present for up to 7 days or longer in some patients.
- After joint decision with parent or caregiver, refer children with recurrent AOM (three distinct episodes within 6 months or four episodes within 12 months with at least one episode in preceding 6 months) and/or chronic OME to an otolaryngologist for surgical evaluation and treatment.

Follow-up: Monitor and Evaluate:

- Reevaluate patient within 48 to 72 hours if symptoms persist or worsen at any time.
- Monitor for middle ear effusion resolution at an appropriate interval based on age and presence of conditions that interfere with recognition of hearing impairment.
- Evaluate hearing if middle ear effusion is present for 3 months in healthy children and earlier in children who are at risk for speech, language, or learning problems.

SINUSITIS

Sinusitis, or paranasal sinus inflammation, is often described as rhinosinusitis because it involves contiguous nasal mucosa and occurs in nearly all viral URIs. Acute rhinosinusitis is characterized by symptoms that persist for up to 4 weeks, whereas chronic rhinosinusitis lasts for more than 12 weeks. Acute bacterial rhinosinusitis (ABRS) refers to an acute bacterial sinus infection that occurs independently of or is superimposed on chronic sinusitis. This section will focus on ABRS.

Epidemiology and Etiology

Rhinosinusitis affects 12% of adults annually in the United States.[4] It is caused mainly by respiratory viruses but can also be triggered by allergies or environmental irritants. Viral rhinosinusitis is complicated by secondary bacterial infection in 0.2% to 2% of adults and 5% to 7% of children.[5,6] Sinusitis is the most common diagnosis associated with antibiotic prescriptions; they are used in 70% to 85% of cases, of which up to half are considered inappropriate.[1] URIs of less than 7 to 10 days' duration are usually viral, whereas more prolonged or severe symptoms are often caused by bacteria. Common risk factors for ABRS include prior viral URI, allergic rhinitis, and dental infections or procedures (Table 72–3).[6,29,30]

LO 2

LO 1

Bacteria that cause sinusitis are similar to those in AOM. *S. pneumoniae* and *H. influenzae* cause more than half of ABRS cases, with an additional 8% to 16% of cases caused by *M. catarrhalis*.[4-6] Similar to AOM, an increased prevalence of *H. influenzae* has been reported in ABRS, and certain factors predict the presence of drug-resistant pathogens.[4-6]

Pathophysiology

LO 2

Rhinosinusitis is typically caused by mucosal inflammation and mucociliary dysfunction from viral infection or allergy. Increased mucous production and reduced clearance lead to blockage of the sinus ostia. This environment is ideal for bacterial growth and promotes a cycle of local inflammation and mucosal injury characterized by increased concentrations of interleukins, interferons, and tumor necrosis factor.[31] Damage to the host defense system perpetuates bacterial overgrowth and persistence of infection.

Treatment

LO 4

The goals of treatment are to relieve symptoms; promote sinus drainage; avoid unnecessary antibiotic use or, when appropriate, use safe and effective antibiotics to eradicate bacterial infection and minimize resistance development; and prevent development of chronic disease or complications.

Table 72–3

Risk Factors for Acute Bacterial Rhinosinusitis[6,29,30]

Allergic or nonallergic rhinitis	Intranasal medications or illicit drugs
Anatomic defects (eg, septal deviation)	Mechanical ventilation
Aspirin allergy, nasal polyps, and asthma	Nasogastric tubes
Cystic fibrosis or ciliary dyskinesia	Swimming or diving
Dental infections or procedures	Tobacco smoke exposure
Immunodeficiency	Trauma or barotrauma
	Viral respiratory tract infection
	Winter season

Clinical Presentation and Diagnosis of Acute Bacterial Rhinosinusitis

Signs and Symptoms[4-6]

- *Adults:* Purulent nasal and/or postnasal discharge *plus* nasal congestion/obstruction and/or facial pain, pressure, or fullness; diminished sense of smell; fever; cough; maxillary tooth pain; fatigue; ear fullness, pressure, or pain
- *Children:* Persistent nasal or postnasal drainage; nasal congestion and mouth breathing; persistent cough (particularly at night) or throat clearing; fever; pharyngitis; ear discomfort; halitosis; morning periorbital edema or facial swelling; fatigue; facial or tooth pain

Laboratory Tests

- *Laboratory studies/nasopharyngeal cultures:* not recommended
- *Radiographic studies:* Useful for assessing presence of complications
- *Paranasal sinus puncture:* "Gold standard"; not routine but can be useful in complicated or chronic cases

Complications

- Orbital cellulitis or abscess, periorbital cellulitis, meningitis, cavernous sinus thrombosis, ethmoid or frontal sinus erosion, chronic sinusitis, and exacerbation of asthma or bronchitis

Diagnosis[4-6]

- *Clinical diagnosis:* Most common method; signs and symptoms that persist *without evidence of improvement* for at least 10 days *or* that worsen after initial improvement, *or* severe symptoms (fever ≥ 39.0°C [102.2°F] and purulent nasal discharge) for at least 3 to 4 days at illness onset. Respiratory secretion color is unreliable for diagnosis because neutrophil presence causes color and is found in viral sinusitis.[4]

▶ *General Approach to Treatment*

Initial management should focus on symptom relief and identification of patients with ABRS who are most likely to benefit from antibiotics. KEY CONCEPT Antibiotics should be prescribed only when ABRS is most likely and when the benefits of treatment outweigh the potential harms. ABRS is more likely than viral sinusitis in instances where symptoms persist without evidence of improvement for at least 10 days after the onset of illness; when symptoms suddenly worsen within 10 days after initial improvement; or when symptoms are severe in the first 3 to 4 days of illness onset.[4-6]

▶ *Nonpharmacologic Therapy*

Humidifiers, nasal saline sprays or drops, and nasal saline irrigation devices moisturize the nasal canal, impair crusting of secretions, and promote mucociliary clearance. Although many patients report benefit from these therapies, few controlled studies exist to support their efficacy in acute sinusitis.[32] Nasal irrigation with isotonic or hypertonic saline may reduce medication use and improve symptoms, especially in patients with allergic rhinitis and recurrent or chronic sinusitis, and it has a low risk of adverse reactions.[33,34]

▶ *Pharmacologic Therapy*

Adjunctive Therapy Medications that target rhinosinusitis symptoms are commonly used despite a lack of published evidence supporting their efficacy.[4] Analgesics/antipyretics may be used to treat facial pain and fever. Oral decongestants relieve congestion but should be avoided in children younger than 4 years and patients with ischemic heart disease or uncontrolled hypertension. Intranasal decongestants can be used for severe congestion in patients 6 years of age or older, but use should be limited to 3 to 5 days to avoid rebound nasal congestion. Avoid antihistamines because they thicken mucus and impair clearance, but they may be useful in patients with allergic rhinitis or chronic sinusitis.[29] Similarly, intranasal corticosteroids usually are reserved for patients with allergies or chronic sinusitis, but they may be beneficial as monotherapy or with antibiotics in ABRS if the clinician and patient agree that their modest benefits after 15 to 21 days of use outweigh their cost and minor adverse events (epistaxis, nasal itching, headache).[4,5,35] There is no evidence to support the use of guaifenesin in ABRS.

Antibiotic Therapy Because diagnosis is usually based on clinical presentation, clinicians must differentiate ABRS from viral rhinosinusitis in order to minimize inappropriate antibiotic use. In addition, recent evidence suggests that ABRS resolves spontaneously in many cases. Studies in adults with clinically diagnosed nonsevere sinusitis report cure rates of 50% to 90% by 7 to 15 days with no statistical differences between antibiotics and placebo, but there are significantly more adverse effects with antibiotics (27%) as compared to placebo (15%).[4,36] Studies in children with persistent nasal discharge for at least 10 days report modest benefits with antibiotic therapy.[37] In some studies, antibiotics led to faster symptom resolution with lower failure rates compared with no treatment, particularly with more severe infection.[5,6]

Treatment guidelines outline management approaches that include watchful waiting with close follow-up for uncomplicated infections (eg, those that do not extend beyond the sinuses or nasal cavity) or the use of antibiotics, depending on patient characteristics and illness presentation.[4-6] In adults, some experts recommend the use of watchful waiting for up to 7 days after ABRS is diagnosed, but only through shared decision making with patients and only if follow-up is available during this timeframe.[4] If symptoms worsen or fail to improve by 7 days post diagnosis, reevaluation should occur and antibiotics should be initiated (either with a repeat office visit or via use of a safety-net antibiotic prescription). Alternatively, antibiotics may be prescribed at the time of diagnosis for adults who are willing to accept the risk of adverse effects and cost of therapy in exchange for the small benefit that antibiotics provide. Other experts recommend prompt antibiotic therapy in all patients when the diagnosis of ABRS is confirmed with use of strict diagnostic criteria.[5] In children, 3 days of watchful waiting with close follow-up is an alternative approach for patients with persistent illness without symptom improvement for at least 10 days.[6] Severe or complicated infections should be treated in conjunction with specialists such as otolaryngologists or infectious diseases physicians.

When antibiotics are prescribed, empiric selection of an agent that is likely to result in favorable clinical and bacteriologic outcomes is recommended (Figure 72–3). Antibiotics (Table 72–4) should target *S. pneumoniae* and *H. influenzae*, but consideration must also be given to local resistance patterns and other bacteria.

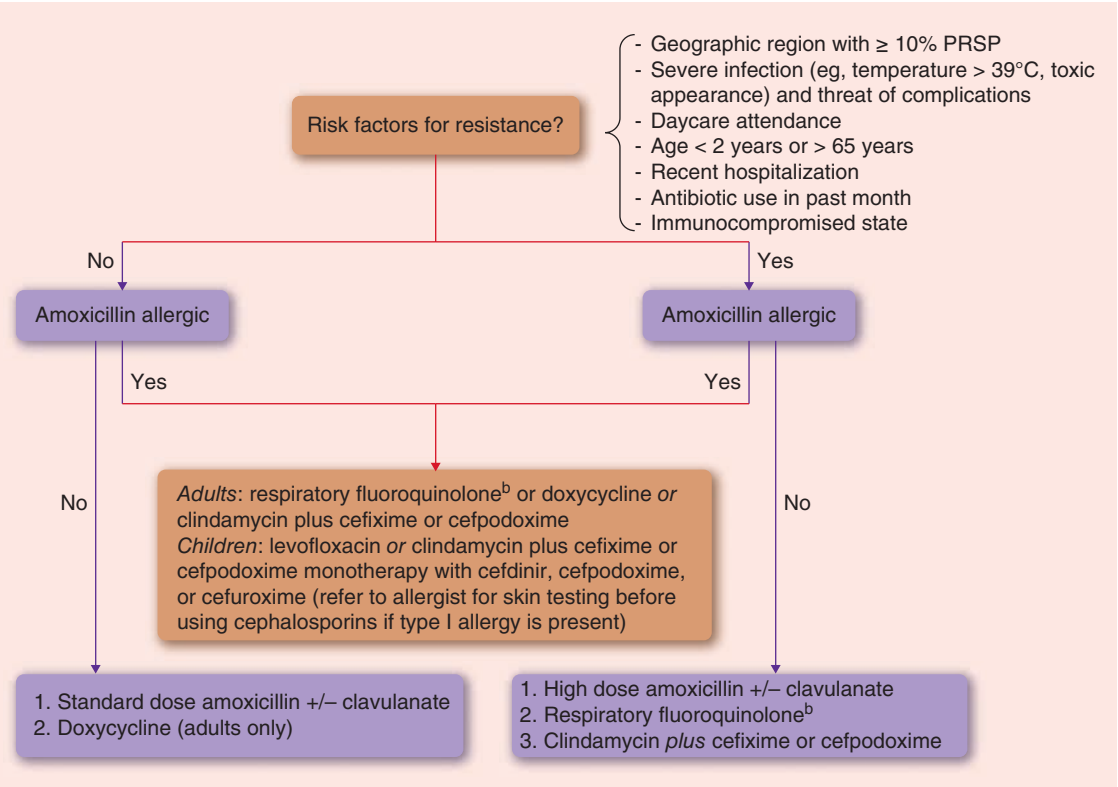

FIGURE 72–3. Treatment algorithm[a] for ABRS. [a]Antibiotics are listed in order of preference based on predicted clinical and bacteriologic efficacy rates, clinical studies, safety, and tolerability. Doses can be found in Table 72–4. [b]Respiratory fluoroquinolone = levofloxacin, moxifloxacin.[4-6]

Table 72–4

Antibiotics[a] for the Treatment of Acute Bacterial Rhinosinusitis[4-6]

Drug	Adult Dose	Pediatric Dose[b]	Relative Cost[c]	Comments
Amoxicillin	1.5–4 g/day divided in two to three doses	45–90 mg/kg/day divided in two doses	$	Lacks coverage against β-lactamase producers
Amoxicillin-clavulanate	1.5–4 g/day divided in two to three doses	45–90 mg/kg/day divided in two doses	$$–$$$	Broad coverage particularly with high doses; Augmentin XR (2 g every 12 hours) targeted toward PRSP
Cefdinir	600 mg/day divided in one to two doses	14 mg/kg/day divided in one to two doses	$$–$$$	Preferred oral liquid cephalosporin owing to good palatability
Cefixime	200 mg twice daily	8 mg/kg/day divided in two doses	$$$$	IDSA recommends use only in combination with clindamycin
Cefpodoxime proxetil	200 mg twice daily	10 mg/kg/day divided in two doses	$$$–$$$$	IDSA recommends use only in combination with clindamycin
Cefuroxime axetil	250–500 mg twice daily	15–30 mg/kg/day divided in two doses	$$–$$$	Only included as an option in AAP guideline
Ceftriaxone	1 g IM/IV every 24 hours	50 mg/kg IM/IV every 24 hours	$$$$	Experts recommend a 5-day treatment course; useful for patients who are vomiting and cannot tolerate oral therapy
Doxycycline	100 mg twice daily	Avoid in children < 8 years	$–$$$	Can cause photosensitivity, GI problems, tooth staining in young children; many drug–drug interactions (antacids, iron, calcium)
Levofloxacin	500–750 mg once daily (750 mg × 5 days)	10 mg/kg/dose every 12–24 hours	$–$$$$	Common fluoroquinolone side effects are nausea, vaginitis, diarrhea, dizziness; many drug–drug interactions (antacids, iron, calcium); tendon rupture, photosensitivity, QT prolongation possible
Moxifloxacin	400 mg once daily	Not available	$$$–$$$$	
Clindamycin	300–450 mg three times daily	30–40 mg/kg/day divided in three doses	$–$$$	No Gram-negative coverage; use only in combination with cephalosporin

[a]Refer to Table 72–2 for more information on antibiotics. Other FDA-approved antibiotics for ABRS not included in the Infectious Diseases Society of America, American Academy of Pediatrics, or American Academy of Otolaryngology-Head and Neck Surgery Foundation guidelines: azithromycin, cefaclor, cefprozil, clarithromycin, ciprofloxacin, erythromycin, and trimethoprim-sulfamethoxazole.

[b]Maximum dose not to exceed adult dose.

[c]Approximate cost per course: $ (under $25), $$ ($25–$50), $$$ ($50–$100), $$$$ (over $100).

AAP, American Academy of Pediatrics; ABRS, acute bacterial rhinosinusitis; IDSA, Infectious Diseases Society of America; IM, intramuscular; PRSP, penicillin-resistant *S. pneumoniae*.

Patient Encounter 2

A 45-year-old woman presents to her primary care physician with purulent postnasal discharge, nasal congestion, headache, and fatigue. She reports that her symptoms began 12 days ago and have worsened over the past 2 days. She states that her headache gets worse when she bends forward and she noticed that her upper molars ache when she eats or brushes her teeth. She tried acetaminophen and phenylephrine but received little to no relief. She has sinus infections every 3 to 4 years. Her last course of antibiotics was 2 years ago when she received amoxicillin for streptococcal pharyngitis. She has two daughters (12 years and 16 years of age).

Immunizations: Up-to-date; she has received the influenza vaccine this season

Allergies: Dust mites; cat and dog dander

Meds: Cetirizine 10 mg orally once daily; intranasal fluticasone one spray each nostril twice daily; acetaminophen 500 mg orally every 6 hours as needed; phenylephrine 10 mg orally every 4 hours as needed

PE:

Gen: Tired-appearing, moderate distress, appears uncomfortable

VS: BP 105/68 mm Hg, P 62 beats/min, RR 14 breaths/min, T 38.0°C (100.4°F), Wt 54.1 kg (119 lb)

HEENT: Thick, purulent brown/green postnasal discharge; nasal mucosal edema; bilateral maxillary facial pain and upper molar hypersensitivity upon tapping; no oral lesions; erythematous pharynx with no tonsillar hypertrophy

What information is suggestive of acute bacterial rhinosinusitis (ABRS)?

What risk factors are present?

What other diagnostic studies, if any, should be performed?

What are the treatment goals for this patient?

Create a care plan for this patient that includes nonpharmacologic and pharmacologic therapies and a monitoring plan.

KEY CONCEPT Standard dose amoxicillin or amoxicillin-clavulanate is recommended for most patients.[4-6] Amoxicillin is effective for most infections and is less expensive and better tolerated than amoxicillin-clavulanate, which provides expanded coverage against β-lactamase–producers. Amoxicillin-clavulanate should be considered in patients who are at risk for infection with an amoxicillin-resistant organism, such as recent antibiotic use in the previous month. High-dose amoxicillin or amoxicillin-clavulanate is recommended for patients who are at high risk for infection from resistant bacteria, such as those who attend daycare, have moderate to severe illness, and when PRSP and other resistant bacteria are frequent in a community (see Figure 72–3). Patients with penicillin allergies can be treated with an appropriate cephalosporin, doxycycline, or a respiratory fluoroquinolone depending on age and allergy severity. Cephalosporin monotherapy is less desirable because of increased pneumococcal resistance, so combination therapy may be required to optimize coverage for PRSP and β-lactamase producers, especially in moderate to severe illness.[4-6] Macrolides and trimethoprim-sulfamethoxazole are not recommended because of high pneumococcal and *H. influenzae* resistance. For uncomplicated infections, treatment duration ranges from 5 to 10 days in adults and 10 to 14 days in children.[4-6] While short-course therapy with some fluoroquinolones and β-lactams are as effective as longer courses in adults with uncomplicated ABRS, data are lacking to support shorter courses in more severe infections or in children.[38]

Failure to improve within 7 days of therapy or worsening at any time requires reevaluation to confirm the diagnosis, consider changing antibiotics, and examine for complications.[4]

Outcome Evaluation

Clinical improvement (eg, defervescence, reduced nasal congestion and discharge, improvements in pain or facial pressure) should be evident within 7 days of therapy. Monitor for common adverse effects and refer to a specialist if clinical response is not obtained with first- or second-line therapy. Referral is also important for severe, recurrent, or chronic infection. Surgery may be indicated in complicated cases.

Patient Care Process for Acute Bacterial Rhinosinusitis

See Patient Care Process for Upper Respiratory Tract Infections.

Develop a Care Plan:

- If appropriate, select an antibiotic (see Figure 72–3) and optimal dose and duration (see Table 72–4).

Implement the Care Plan:

- Educate patient or patient's parent or caregiver that symptoms may resolve slowly and can be present for up to 7 days (or longer) after diagnosis, even if antibiotics are initiated.
- Manage patients with severe infection or complications in conjunction with otolaryngologists and/or infectious diseases physicians.

Follow-up: Monitor and Evaluate:

- Reevaluate patient if symptoms persist beyond 7 days or worsen at any time.
- If patient does not respond to first- or second-line therapy, refer to an otolaryngologist or infectious diseases physician.
- If recurrent infections or chronic sinusitis develop, refer to an otolaryngologist.

PHARYNGITIS

Pharyngitis is an inflammation of the throat often caused by infection. Most infections are viral and self-limited, but antibiotics are frequently prescribed because of difficulty in clinically distinguishing between viral and bacterial infection and the fear of untreated streptococcal illness.

Epidemiology and Etiology

LO 1 LO 2 Pharyngitis is a common manifestation of viral URIs. *Streptococcus pyogenes* (Group A streptococci) is the most common bacterial cause, responsible for 20% to 30% of cases in children and 5% to 15% of adult infections.[7,39] It is most common in late winter and early spring and spreads easily through direct contact with contaminated secretions. Children between 5 and 15 years have the highest incidence of streptococcal pharyngitis. Clusters of infection are common within families, classrooms, and other crowded settings.

Pathophysiology

LO 2 Group A streptococcal pharyngeal colonization occurs in up to 20% of children and is a risk factor for developing pharyngitis if there is disruption in mucosal integrity.[7] Symptoms of streptococcal pharyngitis usually are self-limited and resolve within a few days of onset *without* antibiotic treatment.[7] Historically, untreated or inappropriately treated infection caused acute rheumatic fever, heart valve damage, and other infectious complications. Antibiotic therapy given up to 9 days after symptom onset can prevent these sequelae. Proper diagnosis of streptococcal pharyngitis is important to minimize inappropriate antibiotic use for viral infections and prevent complications of untreated streptococcal infection.[7,39]

Treatment

LO 4 KEY CONCEPT The goals of therapy for streptococcal pharyngitis are to shorten the disease course, reduce spread, and prevent complications. Certain immune-mediated complications such as glomerulonephritis and reactive arthritis are not impacted by antibiotics.[7]

▶ *Nonpharmacologic Therapy*

Pain and throat irritation are key features of pharyngitis. Consumption of warm fluids, such as tea or soup, or cold items, such as ice chips or popsicles, can soothe dry throat tissue and provide hydration. Food items that coat the throat, such as honey or hard candies, can provide temporary relief of throat pain. Environmental approaches, such as adjusting room humidity to avoid a dry environment and avoiding smoke exposure, and warm saline gargles can also relieve throat irritation.

▶ *Pharmacologic Therapy*

Adjunctive Therapy Oral analgesics provide pain relief within 1 to 2 hours and can allow patients to maintain normal eating and drinking habits. Topical therapies, including medicated lozenges or sprays, provide quicker but temporary relief of throat pain and can be used in conjunction with oral analgesics. There is no evidence to support enhanced efficacy of one type of lozenge

Clinical Presentation and Diagnosis of Streptococcal Pharyngitis

Signs and Symptoms of Streptococcal Pharyngitis[7,39]

- Sudden sore throat with severe pain while swallowing
- Fever
- Headache, abdominal pain, nausea, or vomiting (especially children)
- Tonsillopharyngeal erythema with or without exudates
- Tender, anterior cervical lymphadenitis
- Swollen erythematous uvula
- Halitosis
- Soft palate petechiae
- Scarlatiniform rash
- Absence of conjunctivitis, hoarseness, cough, rhinorrhea, discrete ulcerations, and diarrhea (suggestive of viral etiology)
- Centor criteria: tonsillar exudates; tender anterior cervical adenopathy; fever; absence of cough

Complications

- Nonsuppurative: acute rheumatic fever, scarlet fever, streptococcal toxic shock syndrome, poststreptococcal glomerulonephritis or reactive arthritis, pediatric autoimmune neuropsychiatric disorder associated with group A streptococci (PANDAS)
- Suppurative: peritonsillar or retropharyngeal abscesses, cervical lymphadenitis, otitis media, sinusitis, necrotizing fasciitis

Diagnosis[7,39]

- Tests should be performed *only* when there is clinical suspicion for streptococcal pharyngitis. The likelihood of having streptococcal infection increases with the number of Centor criteria that are present. Centor criteria are most useful for identifying patients for whom testing and antimicrobial therapy are unnecessary (ie, fewer than three criteria). Pharyngeal streptococcal carriage occurs in up to 20% of healthy children.
- Rapid antigen detection test (RADT): 70% to 90% sensitivity; results available within minutes.
- Throat culture: "gold standard"; results available within 24 to 48 hours. Should be performed after all negative RADTs in children and adolescents, and adults with significant pediatric contact. Also recommended in outbreaks and to monitor for resistance.

or spray over another; however, benzocaine should be avoided because of rare but serious reports of **methemoglobinemia** associated with benzocaine sprays.

Antibiotic Therapy KEY CONCEPT Antibiotics should be used only in cases of laboratory-confirmed streptococcal pharyngitis with associated clinical symptoms (Figure 72–4).[7,39] Effective therapy (Table 72–5) reduces the infectious period from approximately 10 days to 24 hours and results in clinical improvement in 1 to 2 days.[2,7,39] KEY CONCEPT Penicillin is the drug of choice because of its narrow spectrum, documented safety and efficacy in nasopharyngeal streptococcal eradication, and low cost.[7,39] Amoxicillin is an alternative agent, particularly for children

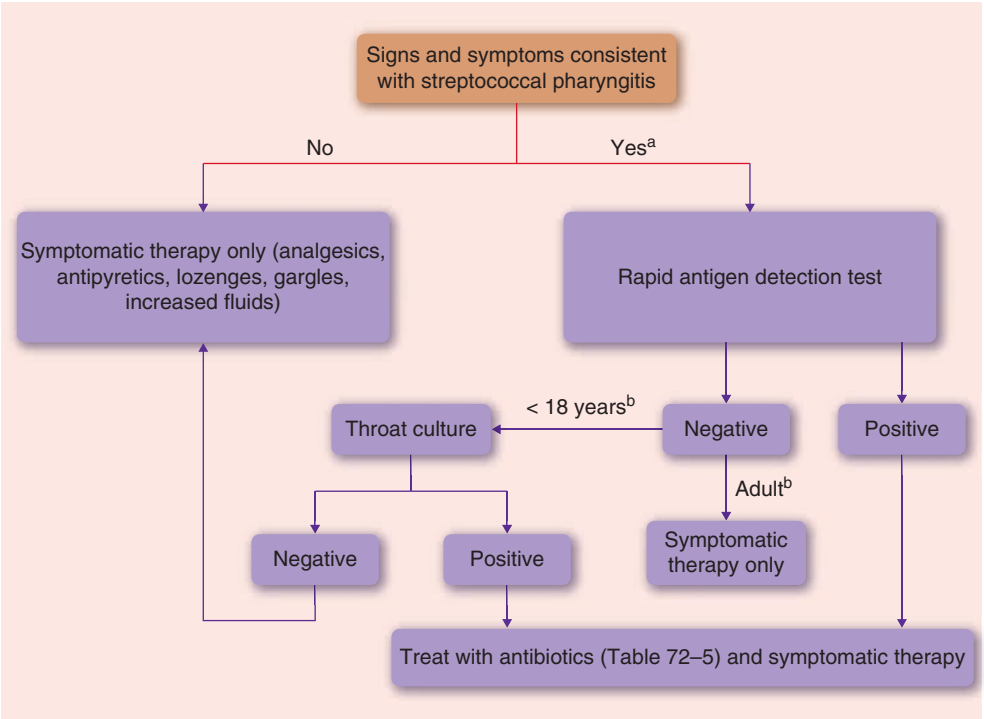

FIGURE 72–4. Treatment algorithm for management of pharyngitis in children and adults. [a]Rapid antigen detection tests (RADTs) are preferred if the test sensitivity exceeds 80%. [b]It is the clinician's discretion to perform a throat culture in adults who have a negative RADT.[7,39]

Table 72–5

Antibiotics[a] for the Treatment of Streptococcal Pharyngitis[7,39]

Drug	Adult Dose	Pediatric Dose[b]	Duration	Relative Cost[c]	Comments
Penicillin V	500 mg two to three times daily	250 mg two to three times daily (if ≤ 27 kg), 500 mg two to three times daily (if > 27 kg)	10 days	$	Drug of choice but increasing reports of treatment failures
Penicillin G benzathine	1.2 million units	600,000 units (if ≤ 27 kg); 1.2 million units (if > 27 kg)	1 IM dose	$$$$	Useful for patients with poor adherence or emesis; painful injection but pain can be reduced if warmed to room temperature prior to administration
Amoxicillin	775 mg to 1 g once daily[d]	50 mg/kg once daily; max 1 g	10 days	$ ($$$$[d])	Preferred drug for young children because of improved palatability and once daily dosing
Cephalexin	500 mg twice daily	25–50 mg/kg/day divided in two doses	10 days	$–$$	Recommended in non–type I penicillin allergy
Cefadroxil	1 g once daily	30 mg/kg once daily	10 days	$–$$	Recommended in non–type I penicillin allergy
Cefuroxime axetil	250 mg twice daily	20 mg/kg/day divided in two doses	10 days	$$–$$$	
Cefdinir	300 mg twice daily or 600 mg once daily	14 mg/kg/day divided in one to two doses	5–10 days	$$–$$$	Broad spectrum; expensive
Azithromycin	500 mg once daily	12 mg/kg once daily	5 days	$–$$	Recommended in immediate-type penicillin hypersensitivity; increasing resistance
Clindamycin	300 mg 3 times daily	20 mg/kg/day divided in three doses	10 days	$–$$$	Recommended in immediate-type penicillin hypersensitivity; useful for recurrent infections

[a]Other FDA-approved agents include amoxicillin-clavulanate, cefixime, cefaclor, cefprozil, cefpodoxime, erythromycin, clarithromycin, and others.

[b]Maximum dose not to exceed adult dose.

[c]Approximate cost per course: $ (under $25), $$ ($25–$50), $$$ ($50–$100), $$$$ (over $100).

[d]Moxatag 775 mg is a time-released formulation given once daily for patients 12 years of age and older

IM, intramuscular.

because of its improved taste and its enhanced adherence with once-daily dosing.[7,39] Cephalosporins may be more effective than penicillin for relapse prevention and nasopharyngeal eradication, particularly in asymptomatic carriers and adults.[39,40] Usual duration of therapy is 10 days, but shorter courses (5 days) of some cephalosporins, such as cefpodoxime and cefdinir, are as effective for streptococcal eradication and clinical improvement in children as 10 days of penicillin.[41]

Resistance plays a smaller role in pharyngitis treatment compared with other URIs. KEY CONCEPT Penicillin resistance is extremely rare in group A streptococci, but resistance and clinical failures occur more frequently with tetracyclines, trimethoprim-sulfamethoxazole, and to a lesser degree macrolides. Patients with penicillin allergies should be treated with a first-generation cephalosporin (if non–type I allergy), a macrolide/azalide, or clindamycin.[7,39] Recurrent infections or treatment failures can be retreated with the same initial antibiotic or treated with amoxicillin-clavulanate, a first-generation cephalosporin, clindamycin, or penicillin G benzathine.[7,39]

Outcome Evaluation

Antibiotics relieve symptoms of streptococcal pharyngitis within 3 to 5 days, and patients can return to work or school if improved after the first 24 hours of therapy. Lack of improvement or worsening after 72 hours of therapy requires reevaluation. Follow-up throat cultures are not recommended unless symptoms persist or recur. Recurrent symptoms following an appropriate treatment course should prompt reevaluation for possible retreatment.

Patient Encounter 3

A 9-year-old boy presents to the pediatrician with a sore throat and fever of 38.7°C (101.7°F) that has worsened over the past 24 hours. He says his "throat burns" when swallowing, so he is not able to eat or drink like usual. He also complains of a "tummy ache." He has no other symptoms and takes no medications. He is allergic to sulfonamides (rash). His mother reports that his 6-year-old sister had "strep throat" earlier in the week. Physical examination reveals pharyngeal and tonsillar erythema with exudates, swollen red uvula, soft palate petechiae, and tender cervical lymphadenopathy.

Does this child have streptococcal pharyngitis?

Is antibiotic therapy indicated? If so, what agent should be initiated and for how long?

What education should be provided to his mother regarding treatment?

Patient Care Process for Streptococcal Pharyngitis

See Patient Care Process for Upper Respiratory Tract Infections.

Assess the Information:

- If streptococcal pharyngitis is likely, perform an RADT and follow-up throat culture (if necessary) to confirm the diagnosis.
- Determine if antibiotic therapy is indicated based on diagnostic testing (see Figure 72–4).

Develop a Care Plan:

- If streptococcal pharyngitis is confirmed with laboratory testing, select antibiotic therapy that is likely to be effective and safe (Table 72–5).

Implement the Care Plan:

- Educate patient or patient's parent or caregiver that symptoms should improve within 1 to 2 days and resolve completely within 3 to 5 days with appropriate antibiotic therapy (if streptococcal pharyngitis is confirmed).
- Discuss the need to avoid close contact with others for 24 hours to minimize spread.
- Discuss importance of medication adherence to treat infection, minimize spread, and reduce chances of recurrence.

Follow-up: Monitor and Evaluate:

- Reevaluate patient if symptoms persist after 72 hours or worsen at any time.
- Reevaluate patient if symptoms recur after completion of therapy.

COMMON COLD

The common cold is a viral URI associated with significant health care resource utilization, including physician office and emergency department visits and nearly universal use of cough and cold medication for treatment or prevention.[42,43] Clinicians must be aware of evidence regarding the use of cough and cold products in order to make appropriate recommendations for this commonly encountered condition.

Epidemiology and Etiology

Many viruses cause the common cold, including rhinoviruses (most common), coronaviruses, parainfluenza viruses, respiratory syncytial virus, and adenoviruses. Infection rates increase during the fall through spring seasons and are highest in the winter months. Adults experience 2 to 3 colds each year, whereas children have about 6 colds per year.[43] Colds usually resolve over 10 to 14 days but can be complicated by bacterial superinfections, including AOM and ABRS. Factors associated with an increased incidence of colds are young age, daycare attendance, contact with school-age children, crowded conditions and poorly ventilated areas, and cigarette smoking. Children are more likely than adults to transmit viruses because of poorer hand hygiene, closer casual contacts, and sharing of toys. Viral antigenic drifts and host immune system evasion contribute to the persistence of URIs in the community.

Pathophysiology

Viruses enter the respiratory tract mucosa via inhalation of aerosols or infected droplets or direct contact with contaminated secretions. After cell entry, viral replication and shedding occur for several days to weeks. Symptoms arise from epithelial cell damage, inflammation, vasodilation, local tissue edema, increased mucous production, and impaired mucociliary clearance. Tracheobronchial inflammation and irritation induce cough via afferent nerve impulse transmission to the medulla. Antibody production halts viral replication and inflammation as symptoms diminish.

Treatment

LO 4

The treatment goal is to minimize discomfort from symptoms to allow patients to function as normally as possible. Preventative measures are also important to limit the spread of infection. Antibiotics are not effective, but they are often prescribed to patients with viral URIs and purulent secretions, which have contributed to increased resistance.[1,2] Treatment should focus on symptom relief.

▶ *Nonpharmacologic Therapy*

Supportive measures include air humidification, intranasal saline drops or sprays with or without bulb suctioning, nasal saline irrigation, increased fluid intake, throat lozenges or saline gargles, and rest. Nasal strips may relieve congestion by lifting the nares and opening the anterior nasal passages. These nondrug measures are particularly important for children younger than 6 years and pregnant women, for whom medication safety is a significant concern. Although studies proving their benefits are lacking, these nondrug treatments are safe.

Clinical Presentation and Diagnosis of the Common Cold

Symptoms begin 24 to 72 hours after infectious contact. They peak at day 3 to 4, begin to wane by day 7, and resolve by day 10 to 14.

Signs and Symptoms[42,43]

- *Onset:* Malaise, fatigue, headache, pharyngitis, mildly elevated temperature (can be higher in infants and children)
- *Secondary:* Nasal and/or postnasal drainage (often clear at onset, but can become thick and purulent); congestion; cough and/or throat clearing; sneezing; conjunctivitis; irritability; impaired smell or taste

Complications

- AOM, ABRS, chronic bronchitis, bronchiolitis (in infants and children < 2 years), pneumonia, asthma exacerbation

Diagnosis

- *Clinical diagnosis:* Most common method; based on history, presence of symptoms, and physical examination
- *Radiographic studies:* Useful for assessing complications such as pneumonia
- *Laboratory studies:* Rapid viral antigen tests and nasopharyngeal cultures helpful for epidemiology and diagnosis in acutely ill young infants

▶ *Pharmacologic Therapy*

Nonprescription cough and cold preparations are used frequently despite a lack of evidence to support their safety and efficacy. Reports of serious adverse events and deaths led to efforts to eliminate use of these medications in young children.[44] Manufacturers have removed product labeling for all children younger than 4 years. Hundreds of products are available to manage cold symptoms. KEY CONCEPT Choice of therapy is influenced by patient age, presence of comorbid conditions, and balance of effectiveness and safety. Single-ingredient agents are preferred to target only symptoms that are present and to minimize toxicity that can result from confusion and lack of knowledge about active ingredients in multiple ingredient formulations. Cautious use of nonprescription products is warranted in certain patient populations: pregnant or lactating women, children, elderly, and patients with cardiovascular disease, diabetes, or glaucoma. Table 72–6 summarizes some of the available agents used for cold symptoms. Antipyretics

Table 72–6

Select Nonprescription Medications for the Common Cold for Patients 6 Years of Age and Older[42–44]

Class/Drug	Adults and Children > 12 Years of Age	Children 6–12 Years of Age[a]	Comments
Analgesics/Antipyretics			
Acetaminophen[b,c]	650 mg every 4–6 hours or 1000 mg every 6 hours as needed (max 3.25g/day or 4 g/day if directed by health care provider); extended-release 1300 mg every 8 hours as needed (max 3.9 g/day)	10–15 mg/kg/dose every 4–6 hours as needed (max 5 doses/day)	Use with caution in preexisting liver disease; monitor acetaminophen dose from all sources (prescription, nonprescription, and combination products)
Ibuprofen[d]	200–400 mg every 6–8 hours as needed (max 1200 mg/day)	5–10 mg/kg/dose every 6–8 hours as needed (max 4 doses/day)	Use with caution in cardiovascular disease and those with history of peptic ulcer disease or GI bleeding; avoid use in elderly, renal impairment, and heart failure; avoid in third trimester of pregnancy
Decongestants			
Intranasal:			
Oxymetazoline 0.05%[c]	Two to three sprays every 12 hours as needed (max 2 doses/24 hours)	One to two sprays every 12 hours as needed (max 2 doses/24 hours)	Limit use of intranasal decongestants to 3–5 days to minimize risk of rebound congestion; use with caution in patients with cardiovascular disease
Phenylephrine 0.25%, 0.5%, 1%	Two to three sprays no more than every 4 hours as needed	Two to three sprays no more than every 4 hours as needed (0.25% only)	
Systemic:			
Pseudoephedrine	60 mg every 4–6 hours as needed; extended release 120 mg every 12 hours or 240 mg every 24 hours as needed (max 240 mg/day)	30 mg every 4–6 hours as needed (max 120 mg/day)	Avoid use in patients with cardiovascular disease; children and elderly have increased risk of adverse effects (cardiovascular or CNS stimulation); use with caution in patients with diabetes, hyperthyroidism, prostatic hypertrophy; avoid in first trimester of pregnancy
Phenylephrine	10 mg every 4 hours as needed (max 60 mg/day)	5 mg every 4 hours as needed (max 30 mg/day)	
Cough Suppressants			
Dextromethorphan[c]	10–20 mg every 4 hours or 20–30 mg every 6–8 hours as needed; extended release 60 mg twice daily as needed (max 120 mg/day)	5–10 mg every 4 hours or 15 mg every 6–8 hours as needed; extended release 30 mg twice daily as needed (max 60 mg/day)	Increased adverse effects in children and poor metabolizers (5%–10% of white patients); can cause dysphoria and serotonin syndrome; use caution in those taking psychotropic medications
Expectorants			
Guaifenesin	200–400 mg every 4 hours as needed; extended release 600–1200 mg every 12 hours as needed (max 2.4 g/day)	100–200 mg every 4 hours as needed (max 1.2 g/day)	May cause nausea and abdominal pain, particularly in higher doses
Anticholinergics			
Intranasal ipratropium 0.06%[c]	Two sprays three to four times/day	Two sprays three times/day	Used for rhinorrhea only; does not improve congestion, postnasal drip, or sneezing; can cause epistaxis and nose/mouth dryness

[a]Maximum dose not to exceed adult dose.

[b]Preferred antipyretic/analgesic for children; can be used in newborns.

[c]Safe to use in pregnancy.

[d]Can be used in children older than 6 months of age.

and analgesics are used for fever, pain, and discomfort. Local anesthetics (eg, phenol, dyclonine) temporarily relieve throat pain and are available in lozenges and sprays. Decongestants cause vasoconstriction that can improve congestion, but use of intranasal products should be limited to 3 to 5 days to avoid rebound congestion.

Antihistamines should generally be avoided: first-generation agents may dry secretions through their anticholinergic effects, but they impair mucociliary clearance of thick mucus, which can worsen congestion, and there is not a clear benefit for cough or cold symptoms when these agents are used alone.[42,43] When used in combination with decongestants, antihistamines may provide some improvement in symptoms in adults and older children only but not in young children.[45] Cough suppressant use is not supported by strong evidence showing benefit.[46] They can cause significant neurologic adverse effects and have been linked to abuse by teens for their euphoric effects in high doses. Guaifenesin, an expectorant, may reduce sputum thickness in adults, but it has been poorly studied in children.[46] Regular high-dose vitamin C (> 200 mg/day) supplementation may result in mild reductions in cold severity or duration, but it is most useful for preventing colds in patients exposed to severe physical exercise or cold stress.[47] Echinacea has limited benefit for treatment in adults, and its use is discouraged for prevention and in all children because of adverse effects including gastrointestinal distress and rash.[48] Zinc lozenges are not consistently effective, but when used within 24 hours of symptom onset, they may slightly reduce the duration and severity of cold symptoms.[42,43]

Prevention

Prevention of the common cold is best achieved by minimizing contact with infected people and secretions. Frequent handwashing with soap and water or use of alcohol-based products is vital. Coughing and sneezing into the arm sleeve should be taught rather than using tissues or covering the mouth and nose with hands. Other methods that are advocated for preventing the spread include smoking cessation, maintenance of a healthy lifestyle through diet and exercise, and minimizing stress.

Outcome Evaluation

Most colds resolve within 7 to 10 days. Monitor patients for persistent symptoms lasting longer than 10 to 14 days, worsening symptoms, and complications such as wheezing, difficulty breathing, significant facial or ear pain, and high fevers. If complications are suspected, refer to a clinician for evaluation.

Patient Encounter 4

A 32-year-old man presents to his primary care provider's office with a "sinus infection." Four days ago, he developed a sore throat and a "runny nose." His throat pain has improved, but today his nasal discharge is thicker and yellow in color and he is congested. He took pseudoephedrine 60 mg this morning, which provided some relief. He has mild intermittent asthma and has had two sinus infections in the past (none for over 5 years). He is married with one daughter (2 years of age); both his wife and his daughter are ill with similar symptoms.

Immunizations: Up-to-date; needs influenza vaccine this season

Allergies: Amoxicillin (rash)

Meds: Albuterol inhaler as needed (hasn't used it for a few months)

PE:

Gen: No apparent distress

VS: BP 120/74 mm Hg, P 64 beats/min, RR 14 breaths/min, T 37.1°C (98.8°F), Wt 84.1 kg (185 lb)

HEENT: Conjunctiva clear; no photophobia; yellow nasal and postnasal discharge with swollen nasal mucosa; erythematous pharynx; no facial pain upon palpation; tympanic membranes normal appearing

Lungs: Clear to auscultation; no crackles

What signs and symptoms are suggestive of the common cold? Which are suggestive of ABRS?

What diagnostic studies should be performed?

Create a care plan that includes nonpharmacologic and pharmacologic therapies and a monitoring plan. Include preventative measures in your plan.

Patient Care Process for Common Cold

See Patient Care Process for Upper Respiratory Tract Infections

Assess the Information:

- Based on patient history, review of systems, and physical examination, determine if the presentation is consistent with the common cold.
- Determine if pharmacologic therapy is indicated or if nonpharmacologic measures alone can be employed.

Develop a Care Plan:

- Select nonpharmacologic and/or nonprescription therapies that will provide optimal relief of symptoms and that are safe for the patient.

Implement the Care Plan:

- Educate patient or patient's parent or caregiver that symptoms may resolve slowly and can be present for up to 10 to 14 days. If symptoms persist without improvement for longer than 10 days or worsen, refer the patient for medical evaluation.
- Discuss preventative measures for minimizing spread and future illnesses.

Follow-up: Monitor and Evaluate:

- Reevaluate patient if symptoms persist beyond 10 to 14 days or worsen at any time.
- If complications develop such as wheezing, difficulty breathing, significant facial or ear pain, or high fevers, refer to a clinician for evaluation.

Abbreviations Introduced in This Chapter

ABRS	Acute bacterial rhinosinusitis
AOM	Acute otitis media
OME	Otitis media with effusion
PRSP	Penicillin-resistant *S. pneumoniae*
RADT	Rapid antigen detection test
URI	Upper respiratory tract infection

73 Skin and Skin Structure Infections

Jaime R. Hornecker and Lauren R. Biehle

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

1. Discuss skin structure and function responsible for preventing infection.
2. Describe the epidemiology, etiology, pathogenesis, diagnostic criteria, and clinical manifestations associated with acute bacterial skin and skin structure infections (ABSSSIs).
3. Identify goals of therapy associated with clinical response in patients with ABSSSI.
4. Recommend effective empiric and definitive antimicrobial regimens when given a diagnosis, patient history, physical examination, and laboratory findings.
5. Monitor chosen antimicrobial therapy for safety and efficacy.

INTRODUCTION

Skin and skin structure infections (SSSIs), also known as acute bacterial skin and skin structure infections (ABSSIs), are frequently encountered in both acute and ambulatory care settings, with outpatient visits and hospitalizations increasing annually.[1] ABSSSIs range in severity from mild, superficial, and self-limiting, to life-threatening deep tissue infections requiring intensive care, surgical intervention, and intravenous (IV) broad-spectrum antibiotics. Gram-positive pathogens, primarily *Staphylococcus aureus* and *Streptococcus* species, are the most common causative bacteria.[2-5] Polymicrobial infections are more likely in complicated or deeper infections and in persons with immune suppression, diabetes, vascular insufficiency, or recent surgery.[2,5]

The role of methicillin-resistant *S. aureus* (MRSA), particularly community-acquired methicillin-resistant *S. aureus* (CA-MRSA), in ABSSSI is of increasing importance. In many US cities, MRSA is the most frequently isolated pathogen from patients presenting to emergency departments with ABSSSI, and antimicrobial prescribing has largely shifted toward empiric use of MRSA-active agents.[3,6] Historically, MRSA infections were associated with health care exposure or defined populations such as injection drug users or athletes;[5,7] however, increasing MRSA prevalence in the community and its identification in otherwise healthy individuals means that risk stratification may be more difficult to perform. In areas with high rates of CA-MRSA, and in those with recurrent infections or infections that persist despite appropriate antimicrobial therapy, empiric therapy including antibiotics active against MRSA must be considered.[2,8] The general management of ABSSSIs is discussed throughout this chapter.

LO 1

Intact skin generally is resistant to infection. In addition to providing a mechanical barrier, its relative dryness, slightly acidic pH, colonizing bacteria, frequent desquamation, and production of various antimicrobial defense chemicals, including sweat (which contains IgG and IgA), prevent invasion by various microorganisms.[9] Conditions predisposing patients to ABSSSIs include: (a) high bacterial load (> 10^5 microorganisms); (b) excessive skin moisture; (c) decreased skin perfusion; (d) availability of bacterial nutrients; and (e) damage to the corneal layer of the skin.[10]

IMPETIGO

EPIDEMIOLOGY AND ETIOLOGY

KEY CONCEPT Impetigo is a common skin infection that can occur in any age group, but most frequently affects children between 2 and 5 years.[11] β-Hemolytic streptococci (*Streptococcus pyogenes* or Group A *Streptococcus* [GAS]) and *S. aureus* are the most common pathogens.[5] Impetigo is a superficial infection and spreads easily, especially in settings of poor hygiene and crowding, and particularly during summer months. The offending microorganisms colonize the skin surface and invade through abrasions, insect bites, or trauma. The crusty eruption of impetigo ensues. These lesions may occur anywhere on the body, but are most common on the face and extremities.[12]

LO 2

CLINICAL PRESENTATION AND DIAGNOSIS

Impetigo lesions are numerous, well localized, and erythematous. KEY CONCEPT They begin as small, thin-walled blisters that quickly evolve into ruptured lesions, with the dried discharge forming a honey-colored crust reminiscent of cornflakes.[5] Impetigo lesions are rarely painful, but are pruritic. Scratching the lesions can spread the infection to other areas of the body. Scarring is rarely problematic, unless ulceration occurs, as in ecthyma.[5]

LO 2

In order to avoid further spread and complications, antibiotic therapy is usually indicated. Sequelae of impetigo are uncommon. Rare manifestations of disease include transformation into cellulitis, progression to sepsis requiring hospitalization, or development of glomerulonephritis secondary to GAS.[5]

TREATMENT

LO 3

The primary goals of impetigo therapy include preventing infection spread within the patient and to others, infection resolution, and preventing recurrence. Secondarily, symptom relief (eg, itching) and improving cosmetic appearance are important. Prevention of the rare, but serious complications of impetigo is an alternative goal.[13]

Nonpharmacologic Treatment

Because impetigo is rarely painful, there is often a delay in seeking medical attention. Lesions may improve with time and increased hygiene along with soaking and cleansing lesions with mild soap and water. The use of skin emollients to dry skin areas may reduce spread and urge to scratch itchy lesions.[13]

Pharmacologic Treatment

LO 4

Antibiotic therapy is recommended to prevent spread of infection and complications. Although GAS historically has been the primary causative organism and penicillin is recommended when cultures yield streptococci alone, KEY CONCEPT the incidence of *S. aureus* impetigo is common, and oral penicillinase-stable penicillins (such as *dicloxacillin*) or first-generation cephalosporins (such as *cephalexin*) are preferred. In skin cultures of children with impetigo, MRSA rates have only ranged from 7% to 10% of cases (other cases were due to GAS or Methicillin-sensitive *S. aureus* [MSSA]). Clindamycin, sulfamethoxazole-trimethoprim, or doxycycline is preferred for the treatment of MRSA impetigo. These are also alternative choices when penicillin allergy is a concern; however, tetracyclines should be avoided in children younger than 8 years. KEY CONCEPT Topical mupirocin or retapamulin twice daily for 5 days may be used alone in mild cases with few lesions or in individual outbreaks.[5,8]

FOLLICULITIS, FURUNCLES, AND CARBUNCLES

See Table 73–1 for summary.

CELLULITIS AND ERYSIPELAS

EPIDEMIOLOGY AND ETIOLOGY

Cellulitis and erysipelas are common bacterial infections involving the skin, with over 14 million cases annually.[14] KEY CONCEPT Cellulitis is an infection of the dermis and subcutaneous tissue, whereas erysipelas is a more superficial infection of the upper dermis and superficial lymphatics. Although both can occur on any part of the body, many infections involve the leg.[16,17] These infections develop after a break in skin integrity, resulting from trauma, surgery, ulceration, burns, tinea infection, or other skin disorder. However, they may occur after an inapparent break in the skin. In rare cases, cellulitis develops from bloodborne or contiguous spread of pathogens.[5,17]

Etiologic microorganisms vary according to the area involved, host factors, and exposures. KEY CONCEPT The predominant pathogens associated with cellulitis are streptococci, mainly group A, and less frequently *S. aureus*, including methicillin-resistant strains. Persons who are immunocompromised, have diabetes or vascular insufficiency, or use injection drugs are at risk for polymicrobial cellulitis.[5]

CLINICAL PRESENTATION AND DIAGNOSIS

LO 2

The manifestations of nonpurulent infections are compared to purulent infections in Table 73–2.

With early diagnosis and appropriate therapy, the prognoses for cellulitis and erysipelas are excellent. Severe or repeated episodes can cause lymphedema. Blood cultures are often obtained, though the rates of bacteremia range widely from 2% to 18.5% in patients with cellulitis.[18,19] Patients at higher risk for bacteremia from cellulitis include those with malignancy, signs of systemic infection (such as fever), animal bites, and the immunocompromised. Rare complications include the spread of infection to deeper skin and soft tissue layers and sepsis.[5]

Annual recurrence rates, especially for cellulitis of the leg, can be as high as 20%,[5] and over 50% within 3 years from the initial infection.[16] Cases often recur at the same site as previous infections. Vascular and lymphatic insufficiencies increase the risk of recurrences; obesity, tobacco use, history of cancer, and homelessness also increase risk.[5]

TREATMENT

LO 3

The goals of therapy for cellulitis and erysipelas are rapid and successful eradication of the infection and prevention of related complications.

Nonpharmacologic Treatment

Nonpharmacologic treatment includes elevating the involved limb to decrease swelling. Sterile saline dressings may be placed on open lesions to cleanse them of purulent materials. Surgical debridement may be indicated for severe infection and to assess for necrotizing infection. Incision and drainage of abscesses is imperative to achieving clinical cure and may be the only treatment necessary if abscesses are small (< 5 cm) with limited cellulitis.[5,17] The choice to treat with antibiotics after incision and drainage of an uncomplicated abscess is controversial.

Pharmacologic Treatment

Most patients with erysipelas or cellulitis are effectively treated with outpatient therapy. Hospitalization and treatment with IV antibiotics is recommended in the presence of systemic inflammatory response syndrome (SIRS) (eg, temperature > 38°C or < 36°C, tachypnea > 24 breaths/min, tachycardia > 90 beats/min, or white blood cell count > 12×10^3/mm^3 [12×10^9/L] or < 400/mm^3 [0.4×10^9/L]), altered mental status, or hemodynamic instability. Patients presenting with sepsis based on the Sepsis-3 definition and Sequential [Sepsis-related] Organ Failure Assessment (SOFA) should also be candidates for hospitalization and broad spectrum antimicrobials.[20] Further, inpatient therapy should be considered when suspecting deep or necrotizing infections, severely immunocompromised patients, failure of outpatient therapy, or poor adherence to therapy.[5]

Antibiotic choices for nonpurulent cellulitis should have activity against streptococci, and include penicillin, amoxicillin, amoxicillin-clavulanate, dicloxacillin, cephalexin, or clindamycin. In uncomplicated cases, a 5-day course is as effective as a 10-day course.[5] Monotherapy with a β-lactam is appropriate in uncomplicated cases.[21,22] As an example, when trimethoprim-sulfamethoxazole (TMP-SMX) was combined with cephalexin and compared to cephalexin monotherapy, a higher rate of clinical resolution was not seen in uncomplicated cellulitis.[22] TMP-SMX was also compared to clindamycin for uncomplicated cellulitis or abscess and found to have no significant difference in efficacy.[23] However, when purulent drainage, abscess, or ulcer is present, or in cases of penetrating trauma, particularly IV drug use, coverage for MRSA should be initiated.

Table 73–1

Folliculitis, Furuncles, and Carbuncles

	Folliculitis	Furuncles	Carbuncles
Epidemiology/ etiology	KEY CONCEPT Folliculitis is a superficial inflammatory reaction involving the hair follicle. The most familiar form of folliculitis is acne. It can be infectious, caused by microorganisms such as *S. aureus, Pseudomonas* spp., and *Candida* spp.	Also known as boils, furuncles might be described as a deep form of folliculitis. A furuncle is a bacterial infection that has spread into the subcutaneous skin layers but still only involves individual follicles. Furuncles occur primarily in young men. Diabetes and obesity are other predisposing factors. Staphylococci are the most common cause.	Carbuncles share all the characteristics of furuncles. However, a carbuncle is larger and involves several adjacent follicles and may extend into the subcutaneous fat. Carbuncles are more likely to occur in patients with diabetes and tend to form on the back of the neck.
Presentation and diagnosis	Folliculitis presents as small, pruritic, erythematous papules. Location of the lesions and patient history are often all that are required in the diagnosis of folliculitis. Although Gram stain and culture of the papules may be considered, they are not generally required as folliculitis typically resolves spontaneously.	Furuncles most commonly develop on the face, neck, axilla, and buttock. A furuncle typically starts as a small, red, tender nodule. Within a few days, the nodule becomes painful and pustular. Typically, a furuncle will spontaneously discharge pus, heal, and leave a small scar.	Carbuncles are similar to furuncles; only they are larger and exquisitely painful.
Desired outcomes	The goals of therapy for folliculitis, furuncles, and carbuncles are resolution of infection with no or minimal scarring. A secondary goal of therapy for larger furuncles and all carbuncles is to minimize the risk of endocarditis or osteomyelitis by reducing bloodstream invasion.		
Nonpharmacologic treatment	KEY CONCEPT Warm compresses are generally sufficient.	Moist heat is indicated to facilitate drainage. Large furuncles require incision and drainage.	Incision and drainage are indicated.
Pharmacologic treatment	KEY CONCEPT Often resolves spontaneously. A topical antibiotic or antifungal may be used to control the spread of infection but generally is unnecessary. For staphylococcal or streptococcal folliculitis, antibiotic ointments such as mupirocin might be administered. Antifungal shampoo can be used for dermatophytes.	Carbuncles and furuncles that are purulent with signs of infection (ie, fever) should be treated systemically with an antibiotic that will cover *S. aureus*, such as dicloxacillin or cephalexin. Trimethoprim-sulfamethoxazole or doxycycline is preferred if CA-MRSA is suspected or if the patient has a severe allergy to penicillin. Treatment should continue until acute inflammation has resolved, usually a 5- to 10-day course. Immunocompromised patients and severe infections or abscesses in patients who fail incision and drainage plus oral antibiotics should be treated empirically with vancomycin, daptomycin, linezolid, or ceftaroline. Prevention for recurrent episodes may be warranted, including adequate skin hygiene with the use of soap and water, and handwashing after contact with lesions. Proper care of clothing and dressings is also recommended to prevent autoinoculation.	

Data from Refs. 5, 12, and 14.

Patient Encounter 1, Part 1: Cellulitis

A 54-year-old man presents to the emergency department with a 5-day history of progressively worsening pain and swelling of his left lower extremity. Upon examination, you notice that in addition to the patient's complaints, the area is visibly erythematous. He has multiple purulent, weeping wounds along the left lower extremity. The left lower extremity also seems to have significant lymphedema when compared to the right lower extremity. When questioned, he indicates that he recently stepped on a shard of glass while barefoot inside his home. He reports using several rolls of paper towels to wrap and attempt to control the purulent discharge from his wounds. He reports running a low-grade fever and some feelings of fatigue, but otherwise feels fine. He has not seen a provider in over 10 years. His vital signs in the emergency department reveal a temperature of 38.8°C, pulse 98 beats/min, blood pressure 128/89 mm Hg, and respiratory rate 18 breaths/min. The physician diagnoses the patient with cellulitis and he is admitted to the inpatient care team.

What subjective and objective clinical manifestations are suggestive of cellulitis?

What additional information do you need before developing a therapeutic plan for this patient?

Table 73–2

Characteristics of Nonpurulent and Purulent ABSSSI

	Nonpurulent	Purulent
Clinical manifestation	Cellulitis, erysipelas	Abscess, carbuncle, furuncle
Initial presentation	Diffuse redness, edema, warmth, and tenderness	Painful and tender localized lesion
Microbiology	Often unable to obtain culture from infected area Blood cultures considered in complicated or severe cases	Often able to obtain culture data from localized lesion Blood cultures considered in complicated or severe cases
Nonpharmacologic management	Incision and drainage not recommended	Incision and drainage recommended
Common causative pathogens	*Streptococcus pyogenes*	*Staphylococcus aureus,* including MRSA

Data from Refs. 5 and 15.

Vancomycin continues to be the drug of choice for severe cellulitis due to MRSA because of its efficacy, safety, and low cost. Daptomycin, linezolid, or ceftaroline are also acceptable and should be considered over vancomycin when the isolated organism has a minimum inhibitory concentration (MIC) of greater than 2 mcg/mL (> 2 mg/L) (eg, vancomycin-intermediate *S. aureus* [VISA] or vancomycin-resistant *S. aureus* [VRSA]).[8] Newer agents for ABSSSI, including tedizolid, dalbavancin, and oritavancin, may have advantages over traditional therapy in terms of duration of activity and administration.[24,25] For less severe, uncomplicated infections, many CA-MRSA strains can be treated with clindamycin (isolates resistant to erythromycin should be evaluated with a **D-test**), doxycycline, or trimethoprim-sulfamethoxazole.[5,8] Trimethoprim-sulfamethoxazole and doxycycline should be empirically combined with a β-lactam if GAS is also a suspected causative organism, since the activity of these agents against β-hemolytic streptococci is unknown.[5] Linezolid is an additional oral option approved for ABSSI with activity against MRSA and Streptococci. It is available in both intravenous and oral formulations. It should be avoided in combination with medications that have serotonin or monoamine oxidase activity as it can precipitate serotonin syndrome.[26]

KEY CONCEPT In addition to coverage for staphylococcal and streptococcal ABSSSI, patients with severe infections should receive treatment for gram-negative bacilli such as *Escherichia coli* and *Pseudomonas aeruginosa*, with or without **anaerobic** coverage. Empiric broad-spectrum antimicrobial coverage, including coverage for resistant organisms such as health care–associated MRSA (HA-MRSA) and *P. aeruginosa*, is appropriate for severe ABSSSI and/or severe systemic illness. Broad spectrum antimicrobials, including activity against gram-negative bacteria, can also be considered in individuals who are neutropenic, receiving chemotherapy, or have an immunodeficiency.[5] Vancomycin with an antipseudomonal beta-lactam (ie, piperacillin-tazobactam, cefepime, meropenem) is recommended in these cases. Empiric therapy continuation is recommended in polymicrobial infections, whereas more defined therapy is recommended when a causative pathogen is isolated.[5]

LO 4

Patient Encounter 1, Part 2: Cellulitis: Medical History, Physical Examination, and Diagnostic Tests

PMH: Hypertension, obstructive sleep apnea.

FH: Father family history unknown. Mother passed away at 81 years of age due to complications of chronic obstructive pulmonary disease (COPD).

SH: Denies alcohol or tobacco use. Daily use of marijuana. Lives alone, works as a writer.

Meds: Lisinopril 20 mg daily; HCTZ 25 mg daily.

Allergies: No known drug allergies.

ROS: (+) chills, fatigue, rash, and swelling of lower extremity; (–) headache, chest pain, shortness of breath, cough, nausea, vomiting, diarrhea, and weight loss.

PE:

Gen: Patient is alert, awake, oriented. Wt 159 kg (350 lb); Ht 5′7″ (170 cm).

Chest: Lungs bilaterally clear to auscultation.

CV: Regular rate, rhythm. No murmurs/rubs/gallops.

Ext: Left lower extremity with significant lymphedema and approximately 3× larger than right lower extremity. Left lower extremity warm to touch and tender to palpation. He has sensation to light touch in bilateral lower extremity and is able to move toes bilaterally. Multiple actively weeping wounds with erythema present from above knee to toes. Right lower extremity within normal limits.

Imaging:

Foot x-ray of left lower extremity: Diffuse soft tissue swelling of the foot and ankle. No subcutaneous gas or foreign body. No fracture or arthritic change.

Tibia fibula x-ray of left lower extremity: No definitive fracture or other bone abnormalities identified.

Labs: WBC 15.8 × 10^3/mm^3 (15.8 × 10^9/L), serum creatinine 0.8 mg/dL (71 µmol/L).

What are the most likely causative organisms in this case of cellulitis?

What subjective or objective clinical criteria would be concerning for necrotizing fasciitis in this patient's presentation rather than the diagnosis of cellulitis?

What are the goals of therapy for this patient?

What nonpharmacologic interventions would you recommend for him?

What antimicrobial therapy would you recommend? Include drug, dosage, route, interval, and duration of therapy.

How would you monitor your selected regimen for safety and efficacy?

Table 73–3

Empiric Antimicrobial Therapy for Cellulitis

Host Factors	Probable Etiologic Bacteria	Mild Infection or Step-Down Therapy[a] (Oral Antibiotic Therapy)	Moderate–Severe Infection[a] (IV Antibiotic Therapy)
Previously healthy	MSSA GAS CA-MRSA	Dicloxacillin 500 mg every 6 hours Cephalexin 500 mg every 6 hours Clindamycin 300–450 mg q 6 hrs CA-MRSA suspected or allergy to PCNs: Clindamycin[b] 300–450 mg q 6 hrs Trimethoprim-sulfamethoxazole DS[c] one to two tablets every 12 hours Doxycycline[c] 100 mg every 12 hours Linezolid 600 mg every 12 hours	Nafcillin 1–2 g every 4 hours Cefazolin 1–2 g every 8 hours Clindamycin 600–900 mg every 8 hours CA-MRSA suspected or allergy to PCNs: Vancomycin 15–20 mg/kg every 8–12 hours (individualize dose to achieve a trough of 15–20 mcg/mL) Linezolid 600 mg every 12 hours Daptomycin 4 mg/kg every 24 hours Ceftaroline[f] 600 mg every 12 hours
Immunocompromise, diabetes mellitus, vascular insufficiency, pressure ulcer infection, or other polymicrobial infection suspected	MSSA HA-MRSA[g] CA-MRSA[g] Enterobacteriaceae *P. aeruginosa* Anaerobes	Amoxicillin-clavulanate[d,f] 875 mg every 12 hours Levofloxacin[e] 750 mg every 24 hours + clindamycin 300–600 mg every 6 hours Moxifloxacin[d] 400 mg every 24 hours	Vancomycin, daptomycin, or linezolid, in combination with one of the following choices: Piperacillin-tazobactam[e,f] 4.5 g every 6 hours Ampicillin-sulbactam[f] 3 g every 6 hours Imipenem-cilastatin[e,f] 500 mg every 6 hours Ertapenem[f] 1 g every 24 hours Meropenem[e,f] 1 g every 8 hours Cefepime[e,f] 2 g every 8 hours ± metronidazole 500 mg every 8 hours Ceftazidime[e,f] 2 g every 8 hours + clindamycin 600–900 mg every 8 hours OR Ceftaroline[f] 600 mg every 12 hours + clindamycin 600–900 mg every 8 hours or metronidazole 500 mg every 8 hours

[a]Doses given are for adults with normal renal function. IV therapy can be switched to oral therapy (as for mild infection) when the patient is afebrile and signs of infection are resolving. Extended infusion of beta-lactams can be considered per protocol of individual institution.

[b]CA-MRSA isolates resistant to erythromycin should be evaluated for inducible clindamycin resistance via a D-test.

[c]Limited clinical data exist for the treatment of MRSA infections. Poor activity against GAS; consider using in combination with clindamycin or cephalexin if empiric coverage for GAS is desired.

[d]If CA-MRSA suspected, clindamycin, trimethoprim-sulfamethoxazole, or doxycycline must be added to this regimen.

[e]*P. aeruginosa* generally is susceptible to this agent.

[f]Use caution in patients with known hypersensitivity to β-lactam antibiotics.

[g]MRSA coverage indicated for patients with severe cellulitis or systemic illness, who have risk factors for HA-MRSA or CA-MRSA infection, or reside in areas with high CA-MRSA prevalence. Otherwise, the broad-spectrum regimens listed in the table, without MRSA coverage, are appropriate.

Data from Refs. 5, 12, and 17.

LO 4

Table 73–3 lists some recommended antibiotic regimens for the treatment of ABSSSI. Because antimicrobial susceptibilities vary considerably between geographic locations, clinicians should select empiric treatment based on the antibiograms at their respective institutions. To decrease spread of resistance, antibiotic therapy should be narrowed based on culture and sensitivity results whenever possible. The duration of therapy for uncomplicated cellulitis typically ranges from 5 to 10 days. For complicated cellulitis, therapy with IV antibiotics is generally initiated, and a switch to oral therapy can be made once the patient is afebrile and skin findings begin to resolve. Typically, this is done after 3 to 5 days. The complete duration of therapy may extend beyond 10 days if the patient's infection has a slower clinical response within the first 5 days.[5]

Recurrent cellulitis can be problematic, and reducing risk factors, such as obesity, edema, or toe abnormalities, may help with prevention, especially in the lower extremities. For patients with recurrent abscesses due to *S. aureus*, decolonization regimens can be considered. These include intranasal mupirocin, chlorhexidine

Patient Encounter 1, Part 3: Cellulitis: Clinical Course

During the patient's hospitalization, his wound culture grows methicillin-sensitive *Staphylococcus aureus*. On day four of the patient's hospital stay, his cellulitis has significantly improved. The interdisciplinary team of clinicians is preparing the patient for discharge.

What would you suggest for modification of his antimicrobial regimen to an oral regimen?

What is the appropriate duration of his antibiotic course of therapy for his cellulitis?

How would you monitor his new regimen for safety and efficacy?

What are the patient's risk factors for recurrence of his cellulitis?

What strategies would you recommend to prevent recurrence of cellulitis?

rinses, and decontamination of towels or sheets. Efficacy of decolonization has not been consistently proven to reduce rates of ABSSSIs.[5] Low-dose antibiotic prophylaxis with penicillin or erythromycin for up to 1 year may reduce recurrences, but the benefit subsides when therapy is discontinued.[5,16]

NECROTIZING FASCIITIS

EPIDEMIOLOGY AND ETIOLOGY

LO 2

Necrotizing fasciitis (NF) is a rapidly progressive, life-threatening infection causing necrosis of subcutaneous tissue and fascia. When due to GAS infection, its associated mortality rate approaches 25%.[27] NF can affect any age group. Although the risk of NF is higher in injection drug users and in patients with diabetes or vascular insufficiency, healthy hosts can become infected as well.[5]

NF typically erupts after an initial trauma, which can range from a small abrasion to a deep penetrating wound. The infection begins in the fascia, where bacteria replicate and release toxins facilitating spread.[5]

NF may be monomicrobial, most often involving *S. pyogenes, S. aureus, Vibrio vulnificus, Aeromonas hydrophilia*, or anaerobic streptococci (*Peptostreptococcus*). Polymicrobial NF develops in the following clinical settings: after surgery or deep penetrating wounds involving the bowel; from decubitus ulcer, perianal, or vulvovaginal infection; or from the injection site in an IV drug user.[5]

CLINICAL PRESENTATION AND DIAGNOSIS

Patient outcomes rely on the clinician's ability to recognize NF early in the course of disease. This is often difficult because early disease tends to be indistinguishable from cellulitis. The clinical presentation of NF is presented in Table 73–4.

Table 73–4

Presentation of Necrotizing Fasciitis

Symptoms
- Early: Severe pain that is disproportionate to clinical signs and extends beyond the margins of the infected area.
- Late: Area may become numb secondary to muscle and nerve involvement.

Signs
- Early: Skin is erythematous, edematous, and warm; the clinical presentation is similar to that of cellulitis.
- Intermediate (within 24–48 hours): Blisters and bullae indicate severe skin and tissue ischemia.
- Late: The skin becomes violaceous and progressively gangrenous, and subcutaneous tissues have wooden-hard induration; hemorrhagic bullae may be present. Systemic signs may include fever, tachycardia, hypotension, and shock.

Laboratory Tests
- White blood count, serum creatinine, and C-reactive protein may be elevated.
- Deep tissue specimens obtained during surgical irrigation and debridement should be sent for Gram stain, culture, and sensitivity.

Imaging Studies
- MRI and CT scans may reveal fluid and gas along fascial planes.
- Typically, imaging studies are avoided when making a diagnosis because they may delay surgical intervention and increase mortality.

Data from Refs. 5 and 28.

NF is perhaps the most devastating ABSSSI. Left untreated, it can invade the muscles and circulation, resulting in myonecrosis and septic shock, respectively. Half of the cases caused by GAS are accompanied by GAS toxic shock–like syndrome. The syndrome is endotoxin mediated, manifested by hypotension and multiorgan dysfunction, and highly lethal.[28] Amputation is common in patients with extremity infections. Once the patient recovers from acute NF, he or she often requires skin and/or muscle grafting and consequent physical rehabilitation depending on the amount and types of tissues removed during surgical intervention and the duration of hospital stay.[29]

TREATMENT

LO 3

The goals of therapy for NF include eradication of infection and reduction of related morbidity and mortality.

Nonpharmacologic Treatment

LO 4

KEY CONCEPT *After resuscitation and hemodynamic stabilization*, prompt surgical intervention is key in the treatment of NF. Delayed operative debridement increases mortality, and most patients should return to the operating room frequently until debridement is no longer indicated.[5,29]

Pharmacologic Treatment

As an adjunct to surgery, high-dose, broad-spectrum IV antibiotic therapy should be initiated immediately in patients with NF until the patient has improved clinically and is afebrile for 48 to 72 hours, and no further need for debridement exists. Piperacillin-tazobactam, a carbapenem, ceftriaxone plus metronidazole, or a fluoroquinolone plus metronidazole is appropriate for empiric therapy. These agents should be used in combination with vancomycin, daptomycin, or linezolid until MRSA infection is ruled out.[5] Protein synthesis inhibitors, clindamycin or linezolid, are often utilized to decrease bacterial toxin production, thereby limiting tissue damage. This is particularly beneficial in streptococcal or clostridial infections.[28]

IV immunoglobulin (IVIG) dosed at 2 g/kg may also be a useful adjunctive treatment in patients with GAS NF who present with shock. Anecdotal evidence and data from small studies strongly support its use in improving 30-day survival and reducing mortality, although additional evidence is needed for a definitive recommendation.[5]

DIABETIC FOOT INFECTIONS

EPIDEMIOLOGY AND ETIOLOGY

LO 2

Foot ulcers and related infections are among the most common, severe, and costly complications of diabetes mellitus. For the approximately 25 million patients with diabetes in the United States, the lifetime risk of developing at least one foot ulcer is estimated at 25%.[30] In addition to significant morbidity, the health care costs associated with treating infected foot ulcers are enormous.

Infected diabetic foot ulcers typically contain a multitude of microorganisms. KEY CONCEPT Aerobic gram-positive cocci, such as *S. aureus* and β-hemolytic streptococci, are the predominant pathogens in acutely infected diabetic foot ulcers. However, severe, or more extensive chronically infected wounds are subject to polymicrobial infection. Clinicians should suspect gram-negative (such as *P. aeruginosa*) and possibly low-virulence pathogens (including enterococci and *S. epidermidis*) in polymicrobial infections. Foul-smelling, necrotic, or gangrenous wounds are also commonly infected with anaerobic bacteria.

LO 4

Patient Encounter 2, Part 1: Diabetic Foot Infection

A 69-year-old man presents to the emergency department with complaints of pain, redness, and swelling of his left foot. He has difficulty ambulating to the examination table because his foot is so sore. Upon examination, you see a purulent lesion on the plantar aspect of his left great toe approximately 3 cm (1.2 in) in diameter, and a smaller, more superficial ulcer near the heel. His foot is erythematous, warm, and foul-smelling, and cellulitis and lymphangitic streaking extend beyond his ankle. The patient has poorly controlled type 2 diabetes mellitus, and has not seen his primary care provider in over a year. Because of obesity, the patient admits that it is difficult for him to perform proper foot care at home. The patient is afebrile, and other vital signs are within normal limits.

What signs and symptoms present in this patient are indicative of a diabetic foot infection?

Based on presentation, classify this patient's diabetic foot infection using the PEDIS grading scale.

What additional information do you need before developing a therapeutic plan for this patient?

Patients recently hospitalized or treated with broad-spectrum antibiotics, or those with a previous history of MRSA infection are at risk for MRSA as a causative agent.[31]

PATHOPHYSIOLOGY

KEY CONCEPT The pathogenesis of diabetic foot infection stems from two key factors: peripheral neuropathy and ischemia from peripheral vascular disease.[30] Neuropathy, the most prominent risk factor for diabetic foot ulcers, develops when continuously high blood glucose levels damage motor, autonomic, and sensory nerves. Damage to motor neurons that supply the small intrinsic muscles of the foot causes deformation, resulting in altered muscular balance, abnormal areas of pressure on tissues and bone, and repetitive injuries. Damage to autonomic neurons results in the shunting of blood through direct arteriole-venous communications, thereby decreasing capillary flow. The secretion of sweat and oil is also diminished, producing dry, cracked skin that is more prone to infection. Finally, damage to sensory neurons produces a loss of protective sensation so that the patient becomes unaware of injury or ulceration.[30]

Dysfunction of the endothelial cells and abnormalities of the smooth muscles of the peripheral vessels is also the result of high blood glucose concentrations. Vasoconstriction can occur due to decreased levels of endothelium-derived vasodilators, as well as in the presence of other risk factors, including hypertension, dyslipidemia, and smoking. Together, ischemia and skin breakdown can occur as a cumulative result.[30]

Finally, persons with diabetes have altered immune function that predisposes them to infection. Leukocyte function, and cell-mediated and humoral immunity are compromised in poorly controlled disease.[31] Achieving and maintaining controlled blood glucose levels should be a component of the prevention and management of diabetic foot infections.

CLINICAL PRESENTATION AND DIAGNOSIS

Not all diabetic foot ulcers are infected. However, infection is often difficult to detect when perfusion and the inflammatory response are limited in the patient with diabetes. The common signs and symptoms (ie, pain, erythema, and edema) of infection may be absent.[32] Still, the diagnosis of diabetic foot infection depends mostly on clinical evaluation.

Patient Encounter 2, Part 2: Diabetic Foot Infection: Medical History, Physical Examination, and Diagnostic Tests

PMH: Type 2 diabetes mellitus × 14 years, hypertension, dyslipidemia, obesity, and GERD.

FH: Father died of lung cancer at age 70; mother (age 89) is living with type 2 diabetes mellitus, hypertension, and COPD. One sister alive with hypertension.

SH: Married, no children. Retired rancher. Denies alcohol and tobacco use.

Meds: Lantus 56 units at bedtime, metformin 1000 mg BID, lisinopril 20 mg daily, amlodipine 10 mg daily, atorvastatin 40 mg daily, omeprazole 20 mg daily, and aspirin 81 mg daily.

Allergies: penicillin (hives).

ROS: (+) left foot findings per HPI; (–) headache, chest pain, shortness of breath, cough, nausea, vomiting, diarrhea, and weight loss.

PE:

Gen: Patient is in no acute distress. Wt 154.3 kg (339.46 lb); Ht 6'1" in (185 cm).

Chest: CTAB.

CV: RRR. No murmurs/rubs/gallops.

Ext: 3-cm purulent, erythematous lesion present on the plantar aspect of the left great toe. 2+ edema in the left foot; diminished sensation bilaterally. Lymphangitic streaking present; wound probe 1.5 cm deep.

Labs: Most recent labs were drawn at last visit 8 months ago: BUN 13 mg/dL, SCr 1.1 mg/dL, Glu 239 mg/dL, A_{1C} 12.4%.

The patient is diagnosed with a diabetic foot infection and is admitted to the local hospital.

Explain the role of neuropathy, ischemia, and immunopathy in the development of this patient's diabetic foot infection.

What are the best preventative strategies for diabetic foot infections and complications such as lower extremity amputation?

Antimicrobial therapy for this patient's infection should provide coverage for which microorganisms?

What antimicrobial therapy would you recommend? Include drug, dosage, route, interval, and duration of therapy.

How would you monitor your selected regimen for safety and efficacy?

Purulent drainage from the ulcer is indicative of infection. When pus and inflammatory symptoms are not present, the clinician must be astute to more subtle findings. These include delayed healing, increase in lesion size, prolonged exudate production, malodor, and tissue friability. Abnormal granulation tissue also may be present, as evidenced by color change (from bright red to dark red, brown, or gray) and increased bleeding. The ability to probe the ulcer to the underlying bone is highly indicative of osteomyelitis.[32]

Diabetic foot infections are classified into four categories based on clinical presentation using the PEDIS scale (perfusion, extent/size, depth/tissue loss, infection, sensation). Grade 1 signifies no infection; grade 2, involvement of skin and subcutaneous tissue only; grade 3, extensive cellulitis or deeper infection; and grade 4, presence of SIRS.[31] Table 73–5 provides detailed information regarding these grades.

Imaging studies, such as x-ray and magnetic resonance imaging (MRI), can identify osteomyelitis. Blood cultures should be obtained from all patients with signs and symptoms of systemic illness. Deep tissue cultures may help to direct therapy. Bone also may be sent for culture in cases of osteomyelitis, as osteomyelitis is present in up to half of diabetic foot infections.[33] Superficial cultures of ulcers are unreliable and should be avoided.[31]

Spreading soft tissue infection and osteomyelitis are often the first complications that develop from diabetic foot infection. Some patients develop bacteremia and sepsis.

The most feared complication of infected diabetic foot ulcers is lower extremity amputation. More than 80% of all nontraumatic lower extremity amputations performed each year in the United States are linked to diabetic foot infections, about half of which could be potentially avoided.[30]

Table 73–5

Clinical Classification of a Diabetic Foot Infection

Infection Severity	PEDIS Grade	Clinical Manifestations of Infection
Uninfected	1	Wound lacking purulence or any manifestations of inflammation
Mild	2	Presence of at least two manifestations of inflammation (purulence or erythema, pain, tenderness, warmth, or induration), but any cellulitis/erythema extends no more than 2 cm around the ulcer, and infection is limited to the skin or superficial subcutaneous tissues; no other local complications or systemic illness
Moderate	3	Infection (as above) in a patient who is systemically well and metabolically stable but who has at least one of the following characteristics: cellulitis extending > 2 cm, lymphangitic streaking, spread beneath the superficial fascia, deep tissue abscess, gangrene, and involvement of muscle, tendon, joint, or bone
Severe	4	Infection in a patient with systemic toxicity or metabolic instability (eg, fever, chills, tachycardia, hypotension, confusion, vomiting, leukocytosis, acidosis, severe hyperglycemia, or azotemia)

From Lipsky BA, Berendt AR, Cornia PB, et al. 2012 Infectious Diseases Society of America clinical practice guideline for the diagnosis and treatment of diabetic foot infections. Clin Infect Dis. 2012;54(12)132–173.

Patient Encounter 2, Part 3: Diabetic Foot Infection: Clinical Course

The patient received the empiric therapy you recommended for his diabetic foot infection. Two days later, deep wound cultures were reported positive for *P. aeruginosa*. Blood cultures revealed no growth. The patient remained hospitalized for an additional week, during which time his cellulitis improved on directed antimicrobial therapy. He was discharged to complete his antibiotic therapy and to follow-up as an outpatient in 1 week.

What modifications would you make to this patient's antimicrobial regimen knowing that the causative agent is P. aeruginosa?

What individualized foot care strategies can you suggest to this patient to prevent further infections?

TREATMENT

LO 3

The goals of therapy for diabetic foot infection are eradication of the infection and avoidance of soft tissue loss and amputation.

Prevention

Comprehensive foot care programs and the utilization of multidisciplinary care teams can improve outcomes and decrease amputation rates.[31] Periodic foot examinations with monofilament testing and patient education regarding proper foot care, optimal glycemic control, and smoking cessation are key preventative strategies.

Nonpharmacologic Treatment

The nonpharmacologic treatment of diabetic foot ulcers may include debridement of necrotic or nonviable tissue, wound dressings, vascular or orthopedic surgery, and off-loading pressure from the wound.[31]

Pharmacologic Treatment

The severity of a patient's infection, based on the PEDIS scale, can help guide the selection of empiric antimicrobial therapy. Although most patients with grade 2 diabetic foot infections can be treated as outpatients with oral antimicrobial agents, all grade 4 and many grade 3 infections require hospitalization, stabilization of the patient, and broad-spectrum IV antibiotic therapy.[31]

LO 4

Multiple antibiotic options exist for the treatment of diabetic wound infections. Table 73–6 provides both general treatment strategies and specific, although not all-inclusive, antibiotic recommendations. The duration of therapy correlates with infection severity. Antibiotics should be continued until the infection has resolved, but not necessarily until the ulcer has healed. Milder infections generally require 7 to 14 days of therapy; more severe infections may necessitate treatment durations of 2 to 3 weeks, or longer with bone involvement. Patients with osteomyelitis may require weeks to months of antibiotic therapy depending on whether infected and necrotic bone is surgically debrided or amputated.[31]

Table 73–6

Empiric Pharmacologic Treatment of Diabetic Foot Infection

Infection Severity	PEDIS Grade	General Approach to Empiric Pharmacologic Treatment	Examples of Appropriate Empiric Antibiotics[a]
Uninfected	1	None. Avoid treating uninfected diabetic foot ulcers.	Not applicable
Mild	2	Oral, narrow-spectrum antibiotic therapy with activity against *S. aureus* and streptococcal species. Include coverage for MRSA according to patient history and resistance patterns in the area. Duration of antibiotics: 1–2 weeks, may extend to 4 weeks if slow resolution	MRSA not suspected: cephalexin, dicloxacillin, clindamycin, amoxicillin-clavulanate, levofloxacin MRSA suspected: clindamycin,[b] trimethoprim-sulfamethoxazole,[c] doxycycline,[c] or linezolid
Moderate	3	Difficult to define a general approach. In many patients, highly bioavailable oral therapy is appropriate. IV therapy should be initiated in patients with more extensive or chronic infections, or those with abscess, deep tissue or bone involvement, or gangrene. Duration of antibiotics: 1–3 weeks	Options for grade 3 infections: amoxicillin-clavulanate or ampicillin-sulbactam, cefoxitin, ceftriaxone, ertapenem, levofloxacin[d] + clindamycin, or moxifloxacin MRSA suspected: clindamycin,[b] doxycycline,[c] linezolid, daptomycin, trimethoprim-sulfamethoxazole,[c] or vancomycin
Severe	4	Parenteral, broad-spectrum antibiotic therapy should be initiated. Ideally, drugs with activity against gram-positive, gram-negative, and anaerobic bacteria (especially if wound is malodorous) should be selected. Include coverage for MRSA. Duration of antibiotics: 2–4 weeks	IV options for grade 3–4 infection: gram-negative/anaerobic activity: ampicillin-sulbactam, aztreonam, cefepime, ceftazidime, ceftriaxone, ertapenem, imipenem-cilastatin,[d] piperacillin-tazobactam, meropenem, moxifloxacin, levofloxacin[d] + clindamycin MRSA activity: vancomycin, daptomycin, or linezolid

[a]Please refer to Table 73–3 for dosing in adults with normal renal function.

[b]CA-MRSA isolates resistant to erythromycin should be evaluated for inducible clindamycin resistance via a D-test.

[c]Poor activity against GAS; consider using in combination with clindamycin or cephalexin if empiric coverage for GAS is desired.

[d]*P. aeruginosa* generally is susceptible to this agent.

Data from Williams DT, Hilton JR, Harding KG. Diagnosing foot infection in diabetes. Clin Infect Dis. 2004;39(2):S83–S86.

INFECTED BITE WOUNDS

EPIDEMIOLOGY AND ETIOLOGY

LO 2

Approximately 1 in 2 Americans will be bitten by an animal at least once during their lifetimes.[34] Bite wounds account for 5% of traumatic wounds in emergency departments and 1% of all emergency department visits.[34,35] Although most of these injuries are minor, some will require medical treatment.

Dogs cause most animal bites, typically open lacerations, of which approximately 20% become infected. Cat bites are the second most common animal bite, most often puncture wounds involving the hand. Because cat bites are deep and penetrating, up to 80% may become infected.[36]

Human bites are the third most common and the most serious. Before the availability of antibiotics, up to 20% resulted in amputation. Currently, human bite–associated amputation rates remain at 5%, secondary to vascular compromise and infectious complications.[37]

There are two types of human bite injuries. Occlusal injuries are inflicted by actual biting, whereas clenched-fist injuries are sustained when a person's closed fist hits another's teeth. Of the two, clenched-fist injuries typically are more prone to infectious complications.[36,37]

KEY CONCEPT Bite wound infections generally are polymicrobial.[5]

LO 4

Both the normal flora of the biter's mouth and that of the bite recipient's skin can be implicated. The bacteriology of the cat and dog mouth is quite similar. *Pasteurella multocida,* a gram-negative aerobe, is one of the predominant pathogens. Viridans streptococci are the most frequently cultured bacteria from human bite wounds, although empiric treatment should also provide coverage for *Eikenella corrodens*.[5,37] Table 73–7 provides a comprehensive list of cat-, dog-, and human bite-wound pathogens.

CLINICAL PRESENTATION AND DIAGNOSIS

The clinical presentation of infected bite wounds is presented in Table 73–7.

Table 73–7

Etiology and Presentation of Infected Bite Wounds

Bacterial Pathogens

- Dog and cat: *Pasteurella multocida,* staphylococci, streptococci *Moraxella* spp., *Eikenella corrodens, Capnocytophaga canimorsus, Actinomyces, Fusobacterium, Prevotella,* and *Porphyromonas* spp.
- Human: Viridans streptococci, *S. aureus, E. corrodens, Haemophilus influenzae,* and β-lactamase–producing anaerobic bacteria.

Signs and Symptoms

- The onset of infectious symptomatology is typically 12–24 hours after the bite.
- Pain at the wound site is common.
- Erythema, edema, and purulent or malodorous drainage at the wound site are manifestations of infected wounds. The patient may be febrile.
- Limited range of motion may be present, especially if the hand is bitten.

Laboratory Tests

- Leukocytosis may be present.
- The clinician should obtain anaerobic and aerobic wound cultures only if the wound appears clinically infected.

Imaging Studies

- Radiographs should be obtained if the bite is on the hand, could have damaged bone or joints, or if an embedded object or tooth fragment is suspected.

Data from Refs. 5 and 37.

Complications of infected bite wounds include lymphangitis, abscess, septic arthritis, tenosynovitis, and osteomyelitis. Bites to the hand are particularly complication-prone.[37]

TREATMENT

LO 3

The goals of therapy for an infected bite wound are rapid and successful eradication of infection and prevention of related complications.

Nonpharmacologic Treatment

LO 4

Thorough irrigation with normal saline is the first step in the care of an infected bite wound. The wound should be elevated and immobilized. Surgical closure may be advocated, especially for facial wounds. Wounds that are infected, at higher risk for infection, or older than 24 hours should be left open because premature closure can lead to disastrous infectious complications.[37]

Pharmacologic Treatment

Most bite wounds require antibiotic therapy only when clinical infection is present. *However, prophylactic therapy is recommended for wounds at higher risk for infection and bites requiring surgical repair.*[37] Bites to the hand or face and human bites may benefit the most from prophylaxis.[36] Other indications include immunocompromised state, asplenia, advanced liver disease, edema in the affected area, or injuries to the joint capsule.[5]

The most effective agent for the treatment (and prophylaxis) of human and animal bite-wound infections is amoxicillin-clavulanate. Alternatives include second-generation cephalosporins, such as cefuroxime, plus coverage for anaerobes, such as clindamycin or metronidazole. Moxifloxacin, doxycycline, or a carbapenem may also be used. The durations of prophylaxis and treatment are generally 3 to 5 days.[5] Consider rabies prophylaxis as appropriate, based on recommendations from the Centers for Disease Control and local health department.

If the wound is associated with significant cellulitis and edema, systemic signs of infection, or possible joint or bone involvement, hospitalization and IV antibiotics (typically ampicillin-sulbactam 3 g IV every 6 hours) should be initiated. Bone and joint infections will require longer durations of therapy of up to 6 weeks.[5,37]

OUTCOME EVALUATION

Education of the patient, caregivers, and household members is important to limit further spread of infection and is a key component in ABSSSI case management. Table 73–8 lists several key prevention messages for patients with ABSSSIs.

Table 73–8

Prevention Education for Patients with ABSSSIs

1. Draining wounds should be covered with clean, dry bandages.
2. Hands should be cleaned regularly with soap and water (or with alcohol-based hand gel if not visibly soiled) and immediately after touching infected skin or any item directly contacting a draining wound.
3. General hygiene should be maintained with regular bathing.
4. Items that may become contaminated with wound drainage or that directly touch the skin should not be shared.
5. Wash and dry thoroughly any clothing that has come in contact with wound drainage after each use.
6. If the wound is unable to be covered with a clean, dry bandage at all times, avoid activities with skin-to-skin contact until the wound is healed.
7. Equipment and environmental surfaces with bare skin contact should be cleaned with *S. aureus*—active detergents or disinfectants.

From Gorwitz RF, Jernigan DB, Powers JH, et al. Strategies for clinical management of MRSA in the community: summary of an experts' meeting convened by the Centers for Disease Control and Prevention [online]. 2006. [cited 2017 Sept 1]. http://www.cdc.gov/ncidod/dhqp/ar_mrsa_ca.html.

LO 5

Patients receiving antibiotic therapy for ABSSSIs require monitoring for efficacy and safety. Efficacy typically is manifested by reductions in temperature, white blood cell count, erythema, edema, and pain. Initially, signs and symptoms of infection may worsen owing to toxin release from certain organisms (ie, GAS); however, they should begin to resolve within 48 to 72 hours of treatment initiation. If no response or worsening infection is noted after the first 3 days of antibiotics, reevaluate the patient.[5] Lack of response may be due to a noninfectious or nonbacterial diagnosis, a pathogen not covered by or resistant to current antibiotic therapy, poor patient adherence, drug or disease interactions causing decreased antibiotic absorption or increased clearance, immunodeficiency, or the need for surgical intervention. To ensure the safety of the regimen, dose antibiotics according to renal and hepatic function as appropriate, and monitor for or minimize adverse drug reactions, allergic reactions, and drug interactions.

Patient Care Process

Collect Information:

- Review the medical history and physical assessment findings.
- Perform a medication history for use of prescription and nonprescription medications and dietary supplements. Identify allergies to medications and other substances.
- Speak with the patient and review records to identify lifestyle habits, preferences and beliefs, health goals, and socioeconomic factors that affect medication access and other aspects of care.

Assess the Information:

- Based on physical examination and review of systems, determine whether the patient is experiencing signs or symptoms of an ABSSSI and if so, its severity.
- Based on the history and presentation, determine the most likely causative microorganism of the patient's infection to select treatment.
- Document current temperature, blood pressure, and heart rate.

(*Continued*)

Patient Care Process (*Continued*)

- Review relevant laboratory tests (eg, complete blood count, renal function, basic metabolic profile, and culture and sensitivity report).
- Identify any significant adverse drug effects or interactions with current drug therapy.

Develop a Care Plan:

- Determine the most appropriate nonpharmacologic or pharmacologic treatment option(s) for the patient's infection based on presentation and history.
- Select the most appropriate antibiotic therapy that is likely to be effective and safe.
- Choose medications, doses, routes, and treatment durations that are optimal for the patient and will result in resolution of infection. In pediatric patients especially, consider method and ease of administration, and palatability and tolerability of oral formulations.

Implement the Care Plan:

- Educate the patient about their drug therapy, medication administration, potential adverse effects, and how to manage and report adverse effects that occur.
- Address any patient concerns about SSSI and its management.
- Discuss importance of medication adherence to improve resolution of infection and reduce antimicrobial resistance.
- Determine whether the patient has insurance coverage or whether recommended agents are included on the institution's formulary.
- Abide by antimicrobial stewardship practices at the institution.

Follow-up: Monitor and Evaluate:

- Follow-up at an appropriate interval to ensure resolution of infection.
- Review physical examination, vital signs, and lab tests to assess changes in clinical status and resolution of infection.
- Narrow antibiotic coverage when possible with the use of culture and sensitivity data.
- Reinforce proper infection prevention strategies.

Abbreviations Introduced in This Chapter

ABSSSI	Acute bacterial skin and skin structure infection
CA-MRSA	Community-acquired methicillin-resistant *S. aureus*
GAS	Group A *Streptococcus* (also known as *Streptococcus pyogenes*, one of the β-hemolytic streptococci)
GERD	Gastroesophageal reflux disease
HA-MRSA	Health care–associated methicillin-resistant *S. aureus*
IVIG	Intravenous immunoglobulin
MIC	Minimum inhibitory concentration
MRI	Magnetic resonance imaging
MRSA	Methicillin-resistant *S. aureus*
MSSA	Methicillin-sensitive *S. aureus*
NF	Necrotizing fasciitis
SIRS	Systemic inflammatory response syndrome
SSSI	Skin and skin structure infection
VISA	Vancomycin-intermediate *S. aureus*
VRSA	Vancomycin-resistant *S. aureus*

74 Infective Endocarditis

Ronda L. Akins

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

LO

1. Differentiate the causes and development of infective endocarditis (IE).
2. Identify the clinical presentation and laboratory evaluation for IE.
3. Assess diagnostic criteria used to evaluate a patient suspected of having IE.
4. Describe the most likely causative pathogens of IE, particularly in specific patient populations.
5. Develop appropriate pharmacologic treatment recommendations for patients with IE.
6. Define appropriate patient populations requiring prophylactic treatment, and differentiate appropriate drug regimens.
7. Devise a monitoring plan for patients with IE to determine treatment efficacy and discern any adverse effects.

INTRODUCTION

Infective endocarditis (IE) is a serious infection affecting the lining and valves of the heart. Although this disease is mostly associated with infection of the heart valves, septal defects may become involved in some cases. Infections also occur in patients with prosthetic or mechanical devices or who are intravenous drug users (IVDUs). Bacteria are the primary cause of IE; however, fungi and atypical organisms may also be responsible pathogens.

Typically, IE is classified into two categories: acute or subacute. Differences between the two categories are based on the progression and severity of the disease. Acute disease is more aggressive, characterized by high fevers, leukocytosis, and systemic toxicity, with death occurring within a few days to weeks. This type of IE is often caused by more virulent organisms, particularly *Staphylococcus aureus*. Subacute disease is often caused by less virulent organisms, such as viridans group streptococci, producing a slower and more subtle presentation. It is characterized by nonspecific symptoms including fatigue, low-grade fever, and weight loss, with death occurring in several months.

Successful management of patients with IE is based on proper diagnosis, treatment with appropriate therapy, and monitoring for complications, adverse events, or development of resistance. The treatment and management of IE are best determined through identification of the causative organism. IE has varied clinical presentations; therefore, patients with this infection may be found in any medical subspecialty (ie, medicine, surgery, critical care, etc).

EPIDEMIOLOGY AND ETIOLOGY

Despite IE being a fairly uncommon infection, in the United States, there are about 10,000 to 15,000 new cases annually, accounting for an incidence of approximately three to seven cases per 100,000 persons-years.[1,2] Although the exact number of cases is often difficult to determine, owing to the diagnostic criteria and reporting methods for this disease, its incidence remains similar overall but is increasing in older patients, those with prosthetic valves, and infections due to *S. aureus*. IE is now considered the fourth leading cause of serious infectious diseases syndromes following sepsis, pneumonia, and intraabdominal abscess.[3] Although IE occurs at any age, more than 50% of cases occur in patients older than 50 years.[1,2] IE in children continues to be uncommon and is mainly associated with underlying structural defects, surgical repair of the defects, or nosocomial catheter-related bacteremia.[1] With the increased use of mechanical valves, prosthetic-valve endocarditis (PVE) now accounts for approximately 10% to 33%.[1,4] Patients who are IVDUs are typically younger patients and also at an increased risk for IE, with 150 to 2000 cases per 100,000 persons per year accounting for 5% to 15% of infection-related hospital admissions.[1,5] Additionally, others at high risk for IE include patients with any congenital or structural cardiac defects, including valvular disease; long-term hemodialysis; diabetes mellitus; poor oral hygiene; major dental treatment; previous endocarditis; hypertrophic cardiomyopathy; and mitral valve prolapse with regurgitation.[3,6,7]

Although almost any type of microorganism is capable of causing IE, the majority of cases are caused by gram-positive bacteria. These consist primarily of streptococci, staphylococci, and enterococci. Consideration of gram-negative, fungal, and other atypical organisms must be taken into account in select patient populations. In Table 74–1, approximate percentages are given for each organism based on the type of IE, including native valve (community-acquired vs health care–associated), prosthetic valve (grouped by months postsurgery), and IVDUs.

PATHOPHYSIOLOGY

LO 1

KEY CONCEPT For IE to develop, the occurrence of several factors is required. Typically, there must be an alteration of the endothelial

Table 74–1

Etiologic Organisms of Infective Endocarditis

	Percentage of Cases							
	Native-Valve IE		PVE at Indicated Onset (Months) after Valve Surgery			IE in IVDU		
	Community-Acquired	Health Care–Associated	< 2	2–12	> 12	Right-sided	Left-sided	Total
Streptococci[a]	40	13	1	9	31	5	15	12
Pneumococci	2	—	—	—	—	—	—	—
Enterococci[b]	9	16	8	12	11	2	24	9
Staphylococcus aureus	28	52[c]	22	12	18	77	23	57
CoNS	5	11	33	32	11	—	—	—
HACEK group	3	—	—	—	6	—	—	—
Gram-negative bacilli	1	1	13	3	6	5	13	7
Fungi (*Candida* spp.)	< 1	1	8	12	1	—	12	4
Polymicrobial/ miscellaneous	3	3	3	6	5	8	10	7
Diphtheroids	—	< 1	6	—	3	—	—	0.1
Culture-negative	9	3	5	6	8	3	3	3

[a]Includes viridans group streptococci; *S. gallolyticus* (formerly *S. bovis*); other nongroup A, groupable streptococci; and *Abiotrophia* and *Granulicatella* spp. (nutritionally variant streptococci).

[b]Primarily *E. faecalis* or nonspeciated isolates, occasionally *E. faecium*.

[c]Methicillin resistance is common among these *S. aureus* strains.

CoNS, coagulase-negative staphylococci; HACEK, *Haemophilus* spp. (primarily *H. paraphrophilus, H. parainfluenzae*, and *H. aphrophilus*), *Aggregatibacter actinomycetemcomitans, Cardiobacterium hominis, Eikenella corrodens*, and *Kingella kingae*.

Modified from Karchmer AW. Infective endocarditis. In: Kasper D, Fauci A, Hauser S, Longo D, Jameson J, Loscalzo J, eds. Harrison's Principles of Internal Medicine, 19th ed. New York: McGraw Hill; 2014: Chap. 155.

surfaces of the heart valves to allow for organism attachment and colonization. These alterations may be produced by an inflammatory process such as rheumatic heart disease or by injury from turbulent blood flow. Platelets and fibrin are then capable of depositing on the damaged valves, forming a **nonbacterial thrombotic endocarditis** (NBTE). At this point, bacteria, through hematogenous spread (ie, bacteremia), adhere to and colonize the **nidus**, forming a **vegetation**. Further deposits of platelets and fibrin cover the bacteria, providing a protective coating that allows for development of a suitable environment for continued organism and vegetation progression, often producing an organism density of 10^9 to 10^{10} **colony-forming units** (CFU) per gram.

Acquisition of PVE differs in early stages, where direct inoculation may occur during surgery rather than through hematogenous seeding. In addition, causative organisms in early PVE are typically nosocomial, with increased likelihood of being drug-resistant.[7,8] The prosthetic valve also has a greater propensity for organism colonization than native valves.[8] However, in late PVE, the process of colonization and vegetation formation is similar to that of native-valve IE, as described earlier.[7,8] Differentiation of native versus prosthetic valve IE is important in determining empiric therapy as well as impacting the risk of disease complications (discussed later).

Typically, vegetations are located on the line along valve closure on the atrial surface of the atrioventricular valves (tricuspid and mitral) or on the ventricular surface of the semilunar valves (pulmonary and aortic). The vegetations can vary significantly in size, ranging from millimeters to several centimeters and may be single or multiple masses. Often, destruction of underlying tissue occurs and may cause perforation of the valve leaflet or rupture of the chordae tendineae, interventricular septum, or papillary muscle. Valve ring abscesses may occur, resulting in fistulas penetrating into the myocardium or pericardial sac, particularly with staphylococcal endocarditis.

Patient Encounter Part 1

A 48-year-old woman with a history of Crohn disease, breast cancer, CHF, and HTN is brought to the emergency department after developing fever, chills, nausea, and vomiting. The patient was recently discharged (approximately 1 month ago) after a prolonged hospital stay with a complicated intraabdominal infection secondary to a perforated colon (blood cultures *E. coli* and urine culture *E. faecalis*). Postoperatively for a colon resection she received approximately 3 weeks of therapy, initially consisting of vancomycin, cefepime and metronidazole then narrowed down to oral ciprofloxacin once discharged. She reports losing about 10 pounds over the past few weeks and denies any use of alcohol or tobacco.

Does the patient have any specific presenting signs or symptoms that would make you suspect IE?

What, if any, risk factors does the patient have for developing IE?

Based on presentation, which causative organism(s) should be considered to empirically treat?

Is there any other information you would like to know before deciding on an empirical treatment for this patient?

Embolic events are also common. Embolization occurs as portions of the friable vegetation break loose and enter the bloodstream. These infected pieces are called **septic emboli**. Pulmonary abscesses are commonly formed as a result of septic emboli from right-sided IE (tricuspid and pulmonary valves). However, left-sided IE (mitral and aortic valves) is more likely to have an embolus travel to any organ, especially kidneys, spleen, and brain. Along with emboli, immune complex deposition may occur in organ systems, causing extracardiac manifestations of the disease. This commonly occurs in the kidneys, producing abscesses, infarction, or glomerulonephritis. Immune complexes or emboli may also produce skin manifestations of the disease, as seen with petechiae, Osler nodes, and Janeway lesions, or within the eye (eg, Roth spots).

CLINICAL PRESENTATION AND DIAGNOSIS

The clinical presentation for IE is quite variable and often nonspecific. KEY CONCEPT A fever is the most frequent and persistent symptom in patients but may be blunted with previous antibiotic use, congestive heart failure, chronic liver or renal failure, or infection caused by a less virulent organism (ie, subacute disease).[1,4] Other symptoms may include chills, weakness, night sweats, dyspnea, weight loss, and myalgias/arthralgias.

Historically, heart murmurs were frequently heard on auscultation (> 85% of cases), but recent data indicates that a new murmur or change/worsening in murmurs was only found in 48% or 20%, respectively.[1,9] Over 90% of patients with a new murmur will develop congestive heart failure, which is a major cause of morbidity and mortality. Splenomegaly and mycotic aneurysms are also noted in many cases of IE.

Peripheral manifestations may be found in up to one-half of adult patients with IE, although recently the prevalence of these findings has been decreasing and is rarely seen in children.[1,3,9]

- **Skin:** *Petechiae* are very small (usually < 3 mm), pinpoint, flat, red spots beneath the skin surface caused by microhemorrhaging. They occur in 10% to 40% of patients with chronic IE and are often found on the buccal mucosa, conjunctivae (Figure 74–1A), and extremities.[1,4] *Splinter hemorrhages* appear as small dark streaks beneath the fingernails or toenails and occur most commonly proximally with IE, typically as a result of local vasculitis or microemboli in about 5% to 15% of patients (Figure 74–1B). *Osler nodes* are small (usually 2–15 mm), painful, tender, subcutaneous nodules located on the pads of the fingers and toes (Figure 74–1D) caused primarily by either septic emboli or vasculitis. These nodes are rare in acute disease but are also nonspecific for IE despite occurring in 3% to 10% of all patients.[1,4] *Janeway lesions* are small, painless, hemorrhagic macular plaques on the palms of the hands or soles of the feet due to septic emboli (in ~5%–10% of patients) and more commonly associated with acute *S. aureus* IE (Figure 74–1E).
- **Extremities:** *Clubbing* of the finger tips typically occurs in long-standing illness and is present in approximately 10% to 20% of patients (Figure 74–1C).[1]
- **Eye:** *Roth spots* occur rarely (< 5% of IE cases) and are oval-shaped retinal hemorrhages with a pale center near the optic disc (Figure 74–1F).

Laboratory Studies

KEY CONCEPT Blood cultures are the essential laboratory test for the diagnosis and treatment of IE. Typically, patients with IE have a low-grade consistent bacteremia.[1] Blood culture results are critical for determining the causative organism, thus aids in selection of the most appropriate therapy. Three blood culture sets from different venipuncture sites should be drawn within 24 hours of initial evaluation to determine the etiologic organism. Approximately 90% of the first two cultures will yield a positive result. If a positive blood culture is not obtained from a patient with suspected IE, the microbiology laboratory should be notified to monitor cultures for growth of fastidious organisms (eg, HACEK) for up to 1 month if these organisms are suspected.

KEY CONCEPT Another important tool aiding in the diagnosis of IE is the echocardiogram. This imaging tool is used to visualize the heart valves to assess the presence of vegetations. Two methods of the echocardiogram are used: the **transthoracic echocardiogram** (TTE) and the **transesophageal echocardiogram** (TEE). The TTE has been used since the 1970s; however, it is less sensitive (historically 40%–60%, newer imaging for native-valve 82%) than

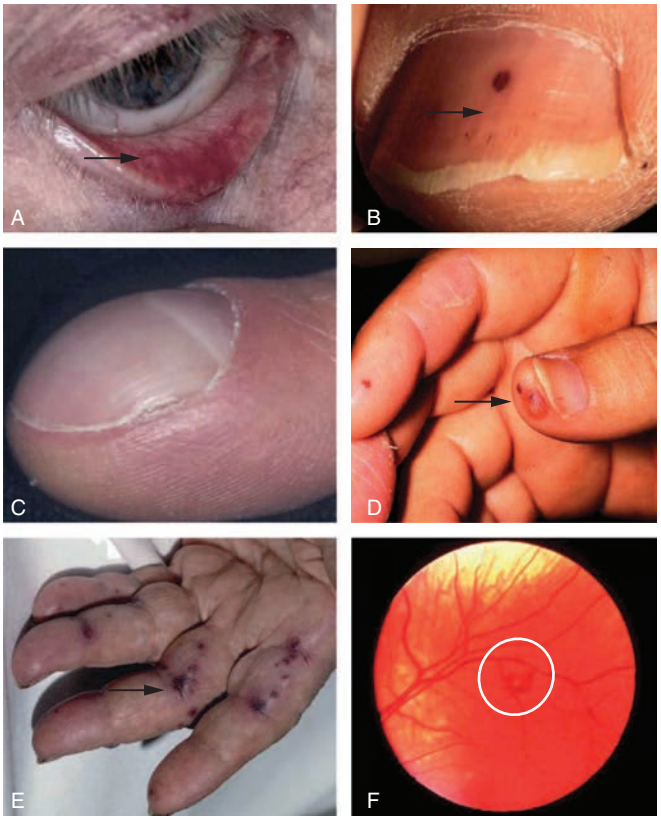

FIGURE 74–1. **(A)** Conjunctival petechiae. (From Wolff K, Johnson R, Saavedra AP, Roh EK. In: Fitzpatrick's Color Atlas & Synopsis of Clinical Dermatology, 8th ed. New York: McGraw Hill. (From Wolff K, Johnson R, Saavedra AP, Roh EK. In: Fitzpatrick's Color Atlas & Synopsis of Clinical Dermatology, 8th ed. New York: McGraw Hill. Copyright 2016.) **(F)** Roth spots. (From Effron D, Forcier BC, Wyszynski RE. In: Atlas of Emergency Medicine, 4th ed. New York: McGraw Hill. Copyright 2016.)

the TEE (80%–95%).[4] Despite the TEE being more sensitive, use of the TTE for patients with suspected native-valve IE is usually sufficient for diagnosis.[10] The TEE may be used as a secondary test for patients whose TTE was negative in the setting of high clinical suspicion of IE and is often preferred in patients with complicated disease, including left-sided IE, prosthetic valves, or perivalvular extension of the vegetation.[10,11] Echocardiograms may also be employed to assess the need for surgical intervention or to determine the possible source of emboli.[10]

Additional nonspecific tests for IE may be performed. These include hematologic parameters to determine whether the patient is anemic (normochromic, normocytic), which occurs in the majority of patients. The white blood cells (WBCs) may be elevated in acute disease, but potentially normal in a subacute infection. Other nonspecific tests may also result in an increased **erythrocyte sedimentation rate** (ESR) or C-reactive protein, abnormal urinalysis (proteinuria or microscopic hematuria), or thrombocytopenia.

Diagnostic Criteria

A definitive pathological diagnosis of IE consists of invasive testing such as a biopsy or culture directly from specimens of the endocardium. Instead, the clinical diagnosis of IE relies on patient's presentation as well as laboratory and echocardiographic results. LO 3 To guide the clinical diagnosis of IE, major and minor criteria have been established (Table 74–2A).[12] The number of major or minor

Table 74–2

Modified Duke Criteria for IE

2A. Definitions of Modified Duke Criteria

Major Criteria

Blood culture positive for IE:

Typical microorganisms consistent with IE from two separate blood cultures:

Viridans streptococci, *S. bovis*, HACEK group, *S. aureus,* or community-acquired enterococci in the absence of a primary focus, or

Microorganisms consistent with IE from persistently positive blood cultures, defined as follows:

At least two positive cultures of blood samples drawn > 12 hours apart, or

All of three or a majority of four separate cultures of blood (with first and last sample drawn at least 1 hour apart)

Single positive blood culture for *C. burnetii* or antiphase I IgG antibody titer > 1:800

Evidence of endocardial involvement:

Echocardiogram positive for IE (TEE recommended in patients with prosthetic valves, rated at least "possible IE" by clinical criteria, or complicated IE [paravalvular abscess]; TTE as first test in other patients), defined as follows:

Oscillating intracardiac mass on valve or supporting structures, in the path of regurgitant, or on implanted material in the absence of an alternative anatomic explanation, or

Abscess, or

New partial dehiscence of prosthetic valve

New valvular regurgitation (worsening or changing of preexisting murmur not sufficient)

Minor Criteria

Predisposition: predisposing heart condition or injection drug use

Fever: temperature > 38°C (100.4°F)

Vascular phenomena: major arterial emboli, septic pulmonary infarcts, mycotic aneurysm, intracranial hemorrhage, conjunctival hemorrhages, and Janeway lesions

Immunologic phenomena: glomerulonephritis, Osler nodes, Roth spots, and rheumatoid factor

Microbiologic evidence: positive blood culture but does not meet a major criterion as noted above[a] or serologic evidence of active infection with organism consistent with IE

2B. Modified Duke Criteria for the Diagnosis of IE

Definite IE

Pathologic criteria:

(1) Microorganisms demonstrated by culture or histologic examination of a vegetation that has embolized, or an intracardiac abscess specimen, or

(2) Pathologic lesions; vegetation or intracardiac abscess confirmed by histologic examination showing active endocarditis

Clinical criteria[b]:

(1) Two major criteria, or

(2) One major criterion and three minor criteria, or

(3) Five minor criteria

Possible IE

(1) One major criterion and one minor criterion, or

(2) Three minor criteria

Rejected

(1) Firm alternate diagnosis explaining evidence of IE, or

(2) Resolution of IE syndrome with antibiotic therapy for less than or equal to 4 days, or

(3) No pathologic evidence of IE at surgery or autopsy, with antibiotic therapy for ≤ 4 days, or

(4) Does not meet criteria for possible IE, as above

[a]Excludes single positive cultures for CNS and organisms that do not cause endocarditis.

[b]See above for definitions of major and minor criteria.

TEE, transesophageal echocardiography; TTE, transthoracic echocardiography.

Data from Li JS, Sexton DJ, Mick N, et al. Proposed modifications to the Duke criteria for the diagnosis of infective endocarditis. Clin Infect Dis. 2000;30:633–638; by permission of Oxford University Press, 2000 by the Infectious Diseases Society of America.

criteria demonstrated by a specific patient leads to a classification of definite, possible, or rejected diagnosis of IE (Table 74–2B).

Causative Organisms

LO 4

Gram-positive bacteria are the most common causative organisms in IE. Streptococci and staphylococci species account for the majority of cases at more than 80% to 90%.[1,7] Viridans group streptococci are primary pathogens in community-acquired native-valve and pediatric IE. However, staphylococci are now considered the dominant causative organisms, with *S. aureus* being the most common in developed countries (see Table 74–1).[3,9,12] Other gram-positive, gram-negative, atypical, and fungal organisms are less common, but still must be considered in certain patient populations. General recommendations also encourage obtaining an infectious diseases consult to aid in selection of empirical regimen, diagnosis, treatment duration, and management regardless of organism or disease severity.

▶ *Streptococci*

Streptococci causing IE are typically a group of species called viridans group streptococci. The most common of this group are *Streptococcus salivarius, Streptococcus mutans, Streptococcus mitis/oralis*, and *Streptococcus sanguinis* (formerly *sanguis*). This group of bacteria is α-hemolytic and considered normal flora in the human mouth, with most clinical microbiology laboratories not differentiating to the exact species. These organisms may cause bacteremia after dental procedures, which can lead to the development of IE in at-risk patients. Viridans group streptococci are also a predominant pathogen of IE associated with mitral valve prolapse, IE of native valves, and in children.[1,13] Another streptococcal species commonly associated with IE is *Streptococcus gallolyticus* (formerly *bovis*), classified as group D streptococci which is frequently found in the gastrointestinal (GI) tract. However, owing to the similarities of these streptococci, including microbiologic susceptibility, treatment is similar regardless of species. Other streptococcal species (eg, *Streptococcus pneumoniae*, beta-hemolytic streptococci) are a rare cause of IE and would be treated based on susceptibility.

IE caused by these streptococci typically has a subacute clinical course. The current cure rate is often greater than 90% unless complications arise, which do occur in more than 30% of patients.[1,13] The majority of viridans group streptococci remain very susceptible to penicillin, with most strains having a *minimum inhibitory concentration* (MIC) of less than 0.12 mcg/mL (0.12 mg/L).[1,13] However, isolation of organisms with reduced penicillin susceptibilities is increasing. Therefore, antibiotic susceptibilities need to be assessed in order to determine the most appropriate treatment regimen.

▶ *Staphylococci*

Staphylococcal endocarditis continues to increase in prevalence, causing 30% or more of all cases of IE, with the majority (80%–90%) being due to *S. aureus* (coagulase-positive staphylococci).[1,3–5] This increase in staphylococci has been primarily attributed to expanded use of venous catheters, more frequent valve replacement, and increased IVDU.[1,3–5] Coagulase-negative staphylococci (CoNS) is also a cause IE. However, these organisms most frequently infect prosthetic valves over native valves or foreign material such as indwelling catheters, thus is the predominate causative pathogen in PVE.[1,8]

Patients with *S. aureus* bacteremia are at an increased risk of developing IE. *S. aureus* may infect "normal" heart valves (no prior detected valvular disease) in one-third of cases.[1,3] Therefore, it is imperative to assess these patients adequately for the presence of vegetations. Any heart valve may be affected; however, the mitral or aortic valve is most commonly involved, often resulting in extensive infection with a mortality rate of approximately 40%.[1,14] When treating *S. aureus* IE, one must consider whether the isolate displays methicillin-resistance, the location of infection (right or left side), presence of prosthetic valves, and history of IVDU. Despite significantly decreased activity of penicillinase-resistant penicillins (eg, methicillin and nafcillin), most isolates remain susceptible to vancomycin. However, there is an increasing incidence of *S. aureus* with an elevated vancomycin MIC of 2 mcg/mL (2 mg/L) which may require use of an alternative agent, such as daptomycin.[3,15] Additionally, strains with intermediate or fully resistant MICs to vancomycin have been rarely reported.[16,17] Fortunately, these strains are not widespread enough to affect empirical antibiotic selection. Susceptibility reports along with clinical response should be assessed to ensure appropriate antimicrobial coverage.

The predominant coagulase-negative organism causing IE has been *S. epidermidis*. However, there has been an increase in isolation of another coagulase-negative species, *S. lugdunensis*.[18] Typically, coagulase-negative staphylococcal IE has a subacute course with numerous complications. Treatment (with or without surgical intervention) is usually successful. On the other hand, *S. lugdunensis* produces a more virulent infection which is more comparable to that of *S. aureus* and, despite similar antibiotic susceptibilities to other CoNS, has a much higher mortality rate.[18]

▶ *Enterococci*

Enterococci are normal flora of the human GI tract and sometimes found in the anterior urethra. Affected patients are typically older males who have undergone genitourinary manipulations or younger females who have had obstetric procedures. Although enterococci are a less common cause of IE, there are two predominant species: *Enterococcus faecium* and *Enterococcus faecalis*. *E. faecalis* is the most common and more susceptible of the strains. However, enterococcal IE represents one of the most problematic gram-positive bacterial infections to treat and cure. Enterococci, especially *E. faecium*, frequently display intrinsic and acquired resistance to multiple antibiotics, including penicillins, vancomycin, aminoglycosides, linezolid, and daptomycin.[19]

▶ *Gram-Negative Bacteria*

Gram-negative bacterial IE is much less common (~2%), but is typically much more difficult to treat than gram-positive bacterial infections.[1,20] Fastidious organisms, such as the HACEK group, tend to predominate, causing approximately 3% of all native valve IE.[1,21,22] HACEK organisms consist of *Haemophilus* spp. (primarily *H. paraphrophilus, H. parainfluenzae*, and *H. aphrophilus*), *Aggregatibacter actinomycetemcomitans, Cardiobacterium hominis, Eikenella corrodens*, and *Kingella kingae*. The clinical presentation of IE by these organisms is subacute, with approximately 50% of patients developing complications. These complications are primarily due to the presence of large, friable vegetations and numerous emboli along with development of acute congestive heart failure often requiring valve replacement.[21,23] Traditionally, it was important to allow cultures sufficient incubation time (often 2–3 weeks) in order to isolate these organisms. Newer media and current automated incubation systems are now favored for recovery. Despite improvement in isolating these organisms, they may still not be isolated on culture and, thus, may present as culture-negative IE.

Other gram-negative organisms, such as *Pseudomonas* spp., can cause IE, especially in IVDUs, health care exposure, and in

patients with prosthetic valves. Additionally, IE may be caused by *Salmonella* spp., *Escherichia coli, Citrobacter* spp., *Klebsiella* spp., *Enterobacter* spp., *Serratia marcescens, Proteus* spp., and *Providencia* spp.[1,20]

Historically, gram-negative IE typically had a poor prognosis with high mortality rates. However, as nondrug therapy advances to include cardiac surgery in more than half of patients, in-hospital mortality has improved to 24%.[1,20] Treatment usually consists of high-dose combination antimicrobial therapy, with valve replacement often necessary in many patients.

▶ *Culture-Negative IE*

Negative blood cultures are reported in approximately 5% of confirmed IE cases, often resulting in delayed diagnosis and treatment.[1,4,24] Cultures that do not grow bacteria may be the result of previous antibiotic use, subacute right-sided disease, slow growth of fastidious organisms, nonbacterial endocarditis (eg, fungal or intracellular parasitic infections), noninfective endocarditis, or improper collection of blood cultures. If nonbacterial or fastidious organisms are suspected, additional testing is essential. The choice of treatment regimen depends on patient history and risk factors.

▶ *Other Organisms*

Numerous other bacteria, including gram-positive bacilli, unusual gram-negative bacteria, atypical bacteria, and anaerobes, as well as spirochetes, are rare causes of IE.[25] Some of the more common organisms include *Legionella, Coxiella burnetii* (Q fever), and *Brucella*. These rare organisms occur primarily in at-risk patients such as those with prosthetic valves or IVDUs. A comprehensive discussion of these organisms is not feasible for this chapter; for further information, other references (particularly references 1–4 and 8 at the end of this chapter) should be examined. Identification and treatment of these organisms is difficult, and cure rates are low. Therefore, consulting an infectious diseases specialist is warranted.

▶ *Fungi*

Fungal endocarditis is quite uncommon, but has significant mortality and typically affects patients with a history of cardiovascular surgery, total parenteral nutrition (TPN), prolonged courses of broad-spectrum antibiotics, long-term catheter placement, immunocompromised, or IVDU.[4,26] Survival rates were historically poor at approximately 15%, but improved survival rates of ~40% have been reported owing to advances in diagnosis and treatment.[26] Poor prognosis has been attributed to large vegetations, propensity for organism invasion into the myocardium, extensive septic emboli, poor antifungal penetration into vegetations, and low toxic-to-therapeutic ratio and lack of cidal activity of certain antifungals.[21,26] The two most commonly associated organisms are *Candida* spp. and *Aspergillus* spp. Lack of clinical studies makes treatment decisions difficult. Typically, combination and/or high-dose therapy in conjunction with surgery is required.

TREATMENT

General Approaches/Therapeutic Considerations

Treatment of IE often is complicated and difficult. Numerous factors involving vegetations influence the effectiveness of antimicrobial agents. The fibrin matrix of vegetations provides an environment where organisms are relatively free to replicate unimpeded, allowing the microbial density to reach very high concentrations (10^9–10^{10} CFU/g). Once organism density has reached this level, the majority of organisms are in a static growth phase. These factors hinder host defenses, as well as the ability of antimicrobials to produce sufficient kill. This is often seen with β-lactams and glycopeptides as their effectiveness can be significantly diminished with increased bacterial inoculum and stationary growth phase of the bacteria.

KEY CONCEPT Selection of an appropriate antimicrobial agent must combine characteristics such as the ability to penetrate into the vegetation, the ability to achieve adequate drug concentrations, and the ability to be minimally affected by high bacterial inoculum in order to achieve adequate kill rates.

KEY CONCEPT To accomplish this, antimicrobials typically have to be given parenterally at high doses, with an extended treatment course of 4 to 6 weeks (in most cases). Other desirable drug characteristics include bactericidal and synergistic activity.

Patient Encounter Part 2: Medical History, Physical Examination, and Diagnostic Tests

PMH: Crohn disease, breast cancer, CHF and HTN, perforated colon

Surgical History: Bilateral mastectomy (age 35), colon resection (age 48)

FH: Mother had diabetes and kidney disease, died at age 62; father had a history of HTN, dyslipidemia, and BPH, died at age 75

SH: Currently at a rehab facility, but prior to previous admission lived at home. She denied alcohol or tobacco usage.

Meds: Lisinopril 20 mg daily, furosemide 80 mg twice daily, carvedilol 12.5 mg twice daily, infliximab 400 mg every 8 weeks

Allergies: Clindamycin

ROS: Weakness, recent weight loss ~10 pounds (4.55 kg), nausea, vomiting, chills, shortness of breath

PE:

VS: BP 110/60 mm Hg, P 115 beats/min, RR 22 breaths/min, T 38.8°C

Cardiovascular: Tachycardia, worsening murmur than on previous admission

Abd: Obese, soft, tender, guarded, nondistended; (–) bowel sounds

Labs: Within normal limits, except WBC = 16.2 × 10^3/μL (16.2 × 10^9/L), Neutrophils = 72%, Bands = 21%, SCr = 2.9 mg/dL (256.4 μmol/L), BUN 68 mg/dL (24.3 mmol/L urea), BNP 680 pg/mL (196.5 pmol/L), ALT 124 U/L (2.1 μKat/L)

Given this additional information, what is your assessment of the patient's condition?

Do you have any other concerns based on the patient's presenting signs/symptoms?

What do you recommend for empiric treatment for this patient?

What other information would be beneficial?

Empiric Pharmacological Therapy

KEY CONCEPT The overall goal of therapy is to eradicate the infection and minimize/prevent any complications. Patients with suspected IE should be evaluated for risk factors that may provide some indication of the most likely causative organism. If no risk factors can be determined, empirical therapy should primarily cover gram-positive bacterial organisms, specifically *S. aureus*, viridans group streptococci, and enterococci. Thus, vancomycin is a reasonable empiric therapy unless decreased local susceptibilities (mainly for enterococci) or patient concerns in which daptomycin would be more appropriate. If risk factors for other organisms are present, broaden coverage based on suspected pathogens. It is important to monitor the patient's response to therapy closely until cultures and susceptibilities are determined to ensure treatment is appropriately tailored to maximize patient outcome.

Specific Therapy

LO 5

The American Heart Association (AHA) has published guidelines for the management of IE, including specific treatment recommendations.[3] A summary of recommended treatment regimens for the most common organisms (streptococci, staphylococci, and enterococci) is provided in Tables 74–3

Table 74–3

Therapy of Native-Valve Endocarditis Caused by Highly Penicillin-Susceptible Viridans Group Streptococci and *S. gallolyticus (bovis)*

Regimen	Dosage[a] and Route	Duration (weeks)	Strength of Recommendation[b]	Comments
Aqueous crystalline penicillin G sodium[c] *OR*	12–18 million units/24 hour IV either continuously or in four or six equally divided doses	4	Class IIa, Level of Evidence B	Preferred in most patients ≥ 65 years of age or patients with impairment of eighth cranial nerve function or renal function
Ceftriaxone sodium	2 g/24 hour IV/IM in one dose	4	Class IIa, Level of Evidence B	
Aqueous crystalline penicillin G sodium *OR*	12–18 million units/24 hour IV either continuously or in six equally divided doses	2	Class IIa, Level of Evidence B	2-week regimen not intended for patients with cardiac or extracardiac abscess or for those with creatinine clearance of < 20 mL/min/1.73m^2 (0.19 mL/s/m^2), impaired eighth cranial nerve function, or *Abiotrophia, Granulicatella, or Gemella* spp. infection; gentamicin dosage should be adjusted to achieve peak serum concentration of 3–4 mcg/mL (3–4 mg/L; 6.3–8.4 µmol/L) and trough serum concentration of < 1 mcg/mL (1 mg/L; 2.1 µmol/L) when three divided doses are used; there is no optimal drug concentrations for single daily dosing[e]
Ceftriaxone plus	2 g/24 hour IV/IM in one dose	2	Class IIa, Level of Evidence B	
gentamicin sulfate[d] *OR*	3 mg/kg/24 hour IV/IM in one dose	2		
Vancomycin hydrochloride[f]	30 mg/kg/24 hour IV in two equally divided doses	4	Class IIa, Level of Evidence B	Vancomycin therapy is reasonable only for patients unable to tolerate penicillin or ceftriaxone; vancomycin dose should be adjusted to a trough concentration range of 10–15 mcg/mL (10–15 mg/L; 6.9–10.4 µmol/L)

[a]Doses recommended are for patients with normal renal function.

[b]Class IIA—benefit > > risk, level of evidence B—limited populations evaluated; recommendations in favor of treatment or procedure being useful/effective, although some conflicting evidence from single randomized trial or nonrandomized studies.

[c]Ampicillin 2 g IV every 4 hours is a reasonable alternative to penicillin if a penicillin shortage exists.

[d]Other potentially nephrotoxic drugs (eg, nonsteroidal anti-inflammatory drugs) should be used with caution in patients receiving gentamicin therapy. Although it is preferred that gentamicin (3 mg/kg) be given as a single dose to adult patients with endocarditis caused by viridans group streptococci, as a second option, gentamicin can be administered daily in three equally divided doses.

[e]Data for once-daily dosing of aminoglycosides for children exist, but no data for treatment of IE exist.

[f]Vancomycin dosages should be infused during course of at least 1 hour to reduce risk of histamine-release "red man" syndrome.

IM, intramuscular; IV, intravenous; highly penicillin-susceptible is defined as an MIC is less than or equal to 0.12 mcg/mL (0.12 mg/L).

Table 74–4

Therapy for Native-Valve Endocarditis Caused by Staphylococci

Regimen	Dosage[a] and Route	Duration (weeks)	Strength of Recommendation[b]	Comments
Oxacillin-Susceptible Strains				
Nafcillin or oxacillin	12 g/24 hour IV in four to six equally divided doses	6	Class I, level of evidence C	For complicated right-sided IE and for left-sided IE, 6-week treatment; for uncomplicated right-sided IE, 2-week treatment
For penicillin-allergic (nonanaphylactoid type) patients			Class I, level of evidence B	Consider skin testing for oxacillin-susceptible staphylococci and questionable history of immediate-type hypersensitivity to penicillin
Cefazolin	6 g/24 hour IV in three equally divided doses	6		Cephalosporins should be avoided in patients with anaphylactoid-type hypersensitivity to β-lactams; vancomycin should be used in these cases
Oxacillin-Resistant Strains				
Vancomycin hydrochloride[c]	30 mg/kg/24 hour IV in two equally divided doses	6	Class I, level of evidence C	Adjust vancomycin dosage to achieve trough concentration of 10–20 mcg/mL (10–20 mg/L; 6.9–13.8 μmol/L) (see text for vancomycin alternatives)
Daptomycin	≥ 8 mg/kg/dose	6	Class IIb, level of evidence B	Await additional study data to define optimal dosing

[a]Doses recommended are for patients with normal renal function.

[b]Class I—benefit > > > risk, Class IIb—benefit > or equal to risk; level of evidence B—limited populations evaluated, recommendations that treatment or procedure is useful/effective, evidence from single randomized trial or nonrandomized studies, level of evidence C—limited populations evaluated, recommendations that treatment or procedure is useful/effective, only expert opinion, case series or standard of care.

[c]For specific dosing adjustment and issues concerning vancomycin, see Table 74–3 footnotes.

IV, intravenous.

through 74–6. However, for more detailed information, refer to the complete guidelines.[3]

▶ *Streptococci*

Most isolates are highly susceptible to penicillin; therefore, penicillin G or ceftriaxone remain the preferred agents unless patients are unable to tolerate β-lactams or penicillin resistance is suspected. Typically, length of treatment is 4 weeks and remains the most common duration. However, a shorter course (ie, 2 weeks) may be employed for a patient with uncomplicated IE due to highly penicillin-susceptible strains with no extracardiac infection or whose creatinine clearance is greater than 20 mL/min/1.73 m^2 (0.19 mL/s/m^2). If the shorter length of therapy is chosen, gentamicin should be added to the previous regimens for the entire course (ie, 2 weeks). Recommended therapies for highly penicillin-susceptible viridans streptococci are summarized in Table 74–3.

When penicillin MICs for viridans group streptococci are greater than 0.12 mcg/mL (0.12 mg/L) but less than or equal to 0.5 mcg/mL [0.5 mg/L], antimicrobial duration should be increased to 4 weeks of penicillin G (ceftriaxone or ampicillin remain alternatives). In addition, combination therapy with gentamicin is recommended during the first 2 weeks if utilizing penicillin G or ampicillin. In patients who are allergic or intolerant to β-lactams, vancomycin monotherapy is an alternative treatment option. In patients with resistant strains of viridans group streptococci (MIC > 0.5 mcg/mL [0.5 mg/L]), treatment should include antimicrobial agents utilized for enterococcal IE (precise agents determined by the susceptibility report) such as high-dose penicillin G, or ampicillin combined with gentamicin. If susceptible, ceftriaxone plus gentamicin may be an alternative.

Table 74–5

Therapy for PVE or Other Prosthetic Material Caused by Staphylococci

Regimen	Dosage[a] and Route	Duration (weeks)	Strength of Recommendation[b]	Comments
Oxacillin-Susceptible Strains				
Nafcillin or oxacillin *plus* Rifampin *plus* Gentamicin sulfate[c]	12 g/24 hour IV in six equally divided doses 900 mg/24 hour IV/orally in three equally divided doses 3 mg/kg/24 hour IV/IM in two or three equally divided doses	6 weeks or longer 6 weeks or longer 2	Class I, level of evidence B	Vancomycin should be used in patients with immediate-type hypersensitivity reactions to β-lactam antibiotics (see Table 74–3 for dosing guidelines); cefazolin may be substituted for nafcillin or oxacillin in patients with non–immediate-type hypersensitivity reactions to penicillins.
Oxacillin-Resistant Strains				
Vancomycin hydrochloride *plus* Rifampin *plus* Gentamicin sulfate[c]	30 mg/kg/24 hour IV in two equally divided doses 900 mg/24 hour IV/oral in three equally divided doses 3 mg/kg/24 hour IV/IM in two or three equally divided doses	6 weeks or longer 6 weeks or longer 2	Class I, level of evidence B	Adjust vancomycin to a trough concentration of 10–20 mcg/mL (10–20 mg/L; 6.9–13.8 μmol/L)

[a]Dosages recommended are for patients with normal renal function.

[b]Class I—benefit > > > risk; level of evidence B—limited populations evaluated, recommendations that treatment or procedure is useful/effective, evidence from single randomized trial or nonrandomized studies.

[c]Gentamicin should be administered in close proximity to vancomycin, nafcillin, or oxacillin dosing. See Table 74–3 for appropriate dose of gentamicin.

IM, intramuscular; IV, intravenous

Reprinted with permission from Baddour LM, Wilson W, Bayer A, et al. Infective Endocarditis in Adults: Diagnosis, Antimicrobial Therapy, and Management of Complications. Circulation 2015;132:1435–1486. ©2015, American Heart Association, Inc.

Vancomycin alone may be used for patients unable to tolerate β-lactams.

Patients with PVE caused by penicillin-susceptible strains of viridans streptococci require treatment for 6 weeks with penicillin G or ceftriaxone with or without gentamicin during the initial 2 weeks of therapy. However, if the organism demonstrates less susceptibility to penicillin (MIC > 0.12 mcg/mL [0.12 mg/L]), combination therapy with penicillin G or ceftriaxone plus gentamicin should be given for the entire 6 weeks. Vancomycin remains the primary alternative for β-lactam (eg, penicillins, cephalosporins) allergic patients.

▶ *Staphylococci*

It is important to determine (a) whether the isolate is methicillin-susceptible versus methicillin-resistant and (b) whether the patient has a native versus prosthetic valve. For patients with native-valve IE, methicillin-susceptible staphylococcal treatment should consist of a penicillinase-resistant penicillin (eg, nafcillin or oxacillin) or cefazolin, and for methicillin-resistant strains, therapy should consist of vancomycin or daptomycin (see Table 74–4). Duration for all therapies should be for 6 weeks. In patients with central nervous system (CNS) involvement (ie, brain abscess), use of penicillinase-resistant penicillin or vancomycin is recommended. If use of daptomycin is needed, consult with infectious diseases is recommended to assist in optimal dosing.

For staphylococcal PVE, treatment length increases significantly, typically requiring a minimum of 6 weeks (see Table 74–5). For methicillin-sensitive staphylococci, a

Patient Encounter, Part 3: Additional Laboratory and Diagnostic Tests

Blood Cultures: 2 out of 3 sets taken on admission are positive for gram-positive cocci in pairs and chains; presumptive report enterococcal species

Labs: CBC with differential and BMP obtained on day 3, all within normal limits excluding WBC 17.1 × 10^3/μL (17.1 × 10^9/L), Neutrophils 78%, Bands = 18%, SCr = 2.3 mg/dL (203.3 μmol/L), BUN 35 mg/dL (12.5 mmol/L urea)

Echo: TTE was inconclusive secondary to difficulty in visualizing the valves.

Given this additional information, would you make any changes in the assessment of your patient?

Would you adjust therapy at this time based on these new data?

Are you now able to determine treatment goals, including length of treatment?

What other information would you like to obtain?

Table 74–6

Therapy for Endocarditis Involving a Native-Valve or Prosthetic-Valve or Other Prosthetic Material Resulting from Enterococcus Species Caused by Strains Susceptible to Penicillin (in patients who can tolerate β-lactam therapy), Gentamicin, and Vancomycin (in patients unable to tolerate β-lactam therapy)

Regimen	Dosage[a] and Route	Duration (weeks)	Strength of Recommendation[b]	Comments
Able to Tolerate β-lactam Therapy				
EITHER				
Ampicillin sodium	12 g/24 hour IV in six divided doses	4–6	Class IIa, level of evidence B	Native valve: 4-week therapy recommended for patients with symptoms of illness ≤ 3 months; 6-week therapy recommended for patients with symptoms > 3 months and for patients with prosthetic valve or prosthetic material. Recommended for patients with creatinine clearance > 50 mL/min/1.73m^2 (0.48 mL/s/m^2).
OR				
Aqueous crystalline penicillin G sodium	18–30 million units/24 hour IV either continuously or in six equally divided doses	4–6	Class IIa, level of evidence B	
plus				
Gentamicin sulfate[c]	3 mg/kg ideal body weight IV in two to three equally divided doses	4–6		
OR				
Combination *β-lactam* Ampicillin	2 g IV every 4 hours	6	Class IIa, level of evidence B	Recommended for patients with initial creatinine clearance < 50 mL/min/1.73m^2 (0.48 mL/s/m^2) or who develop creatinine clearance < 50 mL/min/1.73m^2 (0.48 mL/s/m^2) during therapy with gentamicin-containing regimen.
plus				
Ceftriaxone	2 g IV every 12 hours	6		
Penicillin Resistance or Unable to Tolerate β-lactams				
Vancomycin hydrochloride[d]	30 mg/kg/24 hour IV in two equally divided doses	6	Class IIa, level of evidence B	For patients unable to tolerate β-lactams.
plus			Class IIb; level of evidence C	For patients with penicillin resistance; intrinsic or β-lactamase producer.
Gentamicin sulfate[c]	3 mg/kg/24 hour IV/IM in three equally divided doses	6		For β-lactamase-producing strains, if able to tolerate a β-lactam antibiotic, ampicillin-sulbactam[e] plus aminoglycoside therapy may be used.

[a]Dosages recommended are for patients with normal renal function.

[b]Class IIA—benefit > > risk, level of evidence B—limited populations evaluated; recommendations in favor of treatment or procedure being useful/effective, although some conflicting evidence from single randomized trial or nonrandomized studies; Class IIb—benefit > or equal to risk, Level of evidence C—limited populations evaluated, recommendations that treatment or procedure is useful/effective, only expert opinion, case series or standard of care.

[c]Dosage of gentamicin should be adjusted to achieve a peak serum concentration of 3 to 4 mcg/mL (3–4 mg/L; 6.3–8.4 µmol/L) and a trough concentration of less than 1 mcg/mL (1 mg/L; 2.1 µmol/L).

[d]Dose of vancomycin should be adjusted to obtain a serum trough concentration of 10 to 20 mcg/mL (10–20 mg/L; 6.9–13.8 µmol/L)

[e]Ampicillin-sulbactam dosing is 3 g IV every 6 hours.

IV, intravenous.

Data from Baddour LM, Wilson W, Bayer A, et al. Infective Endocarditis in Adults: Diagnosis, Antimicrobial Therapy, and Management of Complications. Circulation 2015;132:1435–1486. ©2015, American Heart Association, Inc.

penicillinase-resistant penicillin (ie, nafcillin or oxacillin) should still be used, as well as vancomycin for methicillin-resistant staphylococci. Duration of therapy should be at least 6 weeks. However, with either regimen, addition of gentamicin for first 2 weeks and rifampin for the entire length of treatment is recommended. Infectious diseases consultation is recommended for all patients with *S. aureus* IE, irrespective of methicillin-susceptibility, due to an observed reduction in mortality associated with expert consultation in this patient population.

Increasing resistance of staphylococci necessitates the expanded use of alternative therapies. Secondary to studies in patients with staphylococcal IE in which daptomycin demonstrated similar efficacy when compared to standard

therapy (ie, penicillinase-resistant penicillin for methicillin-sensitive *S. aureus* [MSSA] or vancomycin for methicillin-resistant *S. aureus* [MRSA]), the Food and Drug Administration (FDA) approved the agent for treatment of right-sided IE or bacteremia caused by *S. aureus*.[27] The recommended daptomycin dosing for these indications is 6 mg/kg/day (unless renal adjustments are necessary); however, several studies and current AHA IE guidelines recommend higher dosages of greater than or equal to 8 mg/kg in IE.[3,15,29] Daptomycin, even at higher dosages, has been shown to be safe and well tolerated.[27–29] Additionally, other antibiotics, such as ceftaroline, linezolid, tedizolid, quinupristin/dalfopristin, telavancin, long-acting lipoglycopeptides, and tigecycline alone or in combination, have been used in patients with variable response rates.[30–35] These therapies often are reserved for patients who have been unresponsive to traditional therapy or for multidrug-resistant organisms.

▶ *Enterococci*

For enterococci, it is imperative to determine the specific species given significant differences in antibiotic susceptibility patterns between the two most common organisms (*E. faecalis* vs *E. faecium*). If the organism is susceptible to penicillin, ampicillin, and vancomycin, treatment may consist of high-dose penicillin G, ampicillin, or vancomycin (for β-lactam allergy) plus an aminoglycoside (gentamicin [see Table 74–6] or streptomycin for gentamicin-resistant strains). Treatment length is usually 4 to 6 weeks, with the aminoglycoside used over the entire course if the patient does not develop toxicities. However, 6 weeks of combination β-lactam therapy is recommended as an alternative for patients unable to tolerate aminoglycoside therapy or aminoglycoside resistance, particularly for *E. faecalis*.[3] As resistance develops to penicillin and ampicillin, vancomycin remains a viable treatment option. If the isolate becomes resistant to vancomycin, daptomycin or linezolid are currently the most appropriate/viable treatment options.

Treatment options for vancomycin-resistant enterococci (VRE) have not been well established. However, current recommendations for treating vancomycin-resistant enterococcal isolates include linezolid or daptomycin for a minimum of 6 weeks. The most likely species to develop vancomycin resistance is *E. faecium*, as *E. faecalis* infrequently develops multidrug resistance and ampicillin susceptibility is typically retained in this latter species. Per AHA IE guidelines, dosing for the recommended therapy is daptomycin 10 to 12 mg/kg per dose and linezolid 600 mg IV or orally every 12 hours. However, use of either agent has concerns. Linezolid is a bacteriostatic agent with potential for resistance development and/or increased likelihood of significant hematological side effects over a prolonged treatment course. Daptomycin is considered a bacteriocidal agent, but development of resistance is increasing; thus combination therapy with a beta-lactam (eg, ampicillin or ceftaroline) has been shown to enhanced activity even for daptomycin nonsusceptible organisms. Synergistic combinations with gentamicin, rifampin, or tigecycline have also been utilized with variable results. Other potential agents include long-acting lipoglycopeptides (insufficient data at this point) or quinupristin/dalfopristin (rarely used secondary to side effects and intrinsic resistance to *E. faecalis*).[36] Even with agents displaying susceptibility, combination therapy is often warranted; therefore, consultation with an infectious diseases specialist is recommended if VRE is identified.

Patient Encounter Part 4: Additional Laboratory

Susceptibility Report: *Enterococcus faecium*

Drug	MIC (mg/L)
Ampicillin	≥ 16
Vancomycin	≥ 32
Linezolid	≤ 2
Daptomycin	≤ 2
Gentamicin synergy	> 500

Repeat blood cultures: Preliminary blood cultures from day 3—presumed enterococci

Echo: TEE shows 0.5 × 0.8 cm vegetation on the aortic valve

VS Day 5: BP 118/68 mm Hg, P 108 beats/min, RR 20 breaths/min, T 38.5°C

Labs: CBC with differential and BMP obtained on day 5, all within normal limits excluding WBC 16.1 × 10^3/μL (16.1 × 10^9/L), Neutrophils 76%, Bands = 15%, SCr = 2.1mg/dL (185.6 μmol/L), BUN 32 mg/dL (11.4 mmol/L urea)

Given this additional information, are there any changes in your assessment of the patient?

Do you need to adjust your treatment regimen based on these data?

What are your treatment goals, including nonpharmacologic therapy and length of treatment?

▶ *Gram-Negative Bacteria*

Identification of the exact pathogen is crucial in gram-negative bacterial IE as treatment decisions depend on which organism is isolated. Therapy is usually targeted to the most susceptible antibiotics. Combination therapy is commonly used, usually with the addition of an aminoglycoside or fluoroquinolone. For example, *Pseudomonas* spp. are treated with an antipseudomonal β-lactam (eg, piperacillin/tazobactam, cefepime, imipenem/cilastatin) plus high-dose aminoglycoside (typically tobramycin 8 mg/kg/day).[1] However, exact dosing of antibiotics depends on the organism isolated. Length of treatment is usually a minimum of 6 to 8 weeks and often includes surgical intervention. Consultation with an infectious diseases specialist is recommended.

▶ *HACEK Group*

The HACEK group bacteria are difficult to isolate, often leading to culture-negative IE. If one of these organisms is suspected, it is important to initiate appropriate empirical treatment. The preferred regimen is ceftriaxone (or another third- or fourth-generation cephalosporin), followed by ampicillin-sulbactam due to the increased occurrence of β-lactamase–producing strains. However, for patients who are intolerant of these treatments, fluoroquinolones may be used. The length of treatment for these organisms is typically 4 weeks (native-valve) or 6 weeks (prosthetic-valve).

▶ *Culture-Negative IE*

Treatment for culture-negative IE presents a significant dilemma. As outlined above, therapeutic regimens are usually guided

by isolated organisms. When cultures fail to identify a specific organism, decisions regarding empiric treatment should cover the most common causative pathogens. Patient characteristics and risk factors aid in defining additional organisms requiring coverage (refer to AHA guidelines for specific etiologic features).[3] If the patient is unresponsive to initial treatment, additional coverage for less common organisms becomes warranted. An infectious diseases specialist should be consulted for the management of culture-negative IE.

▶ *Fungi*

Treatment of fungal IE is exceptionally difficult. There is a significant lack of evidence to identify the most appropriate therapy. Currently, amphotericin B is the most common treatment. However, valve replacement surgery is often considered a necessary adjunctive therapy in the majority of cases. Intravenous antifungal therapy requires high doses for a minimum of 6 weeks of treatment, often followed by life-long oral suppression therapy (ie, oral triazoles). Newer antifungals may be effective options, including echinocandins (eg, caspofungin) and voriconazole, depending on the organism and susceptibilities.[26]

Surgery

Surgical intervention has become an integral therapy in combination with pharmacologic management of IE. Valve replacement is the predominant intervention, and is used in almost one-half of all cases of IE.[1] Surgery may be indicated if the patient has unresolved infection, ineffective antimicrobial therapy, more than one episode of serious emboli, refractory congestive heart failure, significant valvular dysfunction, mycotic aneurysm requiring resection, local complications (perivalvular or myocardial abscesses), or prosthetic-valve infection associated with a pathogen demonstrating higher antimicrobial resistance.[37,38] Often a patient's hemodynamic status (eg, blood pressure, heart rate, pulmonary artery pressure) is used to determine when surgical intervention is warranted.[1] Despite appropriate medical management and cure, a significant number of people who develop native-valve endocarditis require valve replacement surgery. Involvement of the aorta or development of IE complications is considered an indication for surgery in the majority of patients with PVE.[39,40]

Antimicrobial Dosing Considerations

The majority of antibiotic and antifungal agents used for the treatment of IE require dosing modifications based on renal or hepatic function. However, the most closely monitored are vancomycin and aminoglycosides. This is due in part because (a) therapeutic drug monitoring of serum concentrations is normally utilized to guide therapy, and (b) there is an increased likelihood of toxicity (ie, nephrotoxicity, ototoxicity) if the drug concentration is too high or adverse outcomes (ie, clinical failure or resistance development) if level is too low. General dosing considerations are included in Table 74–7 for the most common drugs used in the treatment of IE. However, specific dosing adjustments for individual patients should be determined by referring to an appropriate drug dosing reference.

Prophylaxis

KEY CONCEPT Certain conditions have been associated more commonly with IE due to preexisting cardiac disease in the presence of a transient bacteremia. In an effort to prevent the development of IE, prophylactic treatment is generally considered appropriate for these at-risk patients. Although there are no well-controlled clinical studies of these recommendations, it is thought that if antibiotics are given just prior to a procedure, the number of bacteria may be decreased in the bloodstream and prevent the bacteria from adhering to the valves.

Cardiac conditions in which prophylaxis is reasonable include presence of prosthetic valves or material, prior IE, select forms of congenital heart disease, and cardiac transplant patients with cardiac valvulopathy (Table 74–8).[6] Although many patients have other cardiac dysfunction, only patients with these conditions are considered to be at a high risk of developing IE. No prophylaxis is advised in other patients.

Transient bacteremia may occur due to many types of dental and surgical procedures. However, the AHA guidelines significantly limit the types of procedures where prophylaxis is appropriate. Only dental procedures involving manipulation of gingival tissue or periapical region of teeth or perforation of the oral mucosa are considered to increase the likelihood that high-risk patients will develop IE.[6] Viridans group streptococci are the primary bacteria targeted for prophylaxis in this circumstance. On the other hand, prophylaxis for GI or genitourinary surgeries primarily targets enterococci.

LO 6

The AHA guidelines include suggested antibiotic regimens for dental procedures for which prophylaxis is warranted.[6] Recommended regimens are summarized in Table 74–9. Therapy consists of a penicillin for most patients, a cephalosporin for penicillin-allergic patients who have not had an anaphylactic reaction, and clindamycin or a macrolide for penicillin-allergic patients. These guidelines recommend a single oral or intramuscular/intravenous dose initiated shortly before the procedure. A second prophylactic dose is not recommended. However, if an infection develops at the procedure site, additional antibiotics (ie, a therapeutic course) may be required.

Antimicrobial Stewardship in IE

Antimicrobial stewardship efforts in relation to IE should focus on recommendations which optimize antimicrobial management, including but not limited to: appropriate selection of empiric and definitive antimicrobial regimens, suggestion for infectious diseases consultation, and ensuring adequate dosages for selected therapy. Once culture and susceptibility data is (if) available, the stewardship team can work with clinicians to tailor and maximize treatment of the patient. Patients with IE will require a prolonged treatment course (often 4 weeks or more); the stewardship team can

Patient Encounter Part 5: Create a Care Plan

Based on this patient's information, create a care plan for the management of her IE. Be sure to include:

(a) A statement regarding treatment requirements and/or possible problems

(b) Goals of therapy

(c) A patient-specific plan, including preventive plans

(d) A follow-up plan to assess whether the goals have been met and to determine whether the patient experienced any adverse effects

Table 74–7

Dosage Considerations for Common Antibiotics for Treatment of IE[a]

Drug	Renal Adjustment	Hepatic Adjustment	Comments
Penicillin G	Required	None	Extension of dosing interval primarily used for adjustment
Ampicillin	Required	None	Seizures most common AE if dosing not adjusted
Nafcillin	None	If severe (see comment)	Adjustments necessary ONLY in patients with severe hepatic AND renal impairment
Oxacillin	If severe (see comment)	None	For CrCl < 10 mL/min/1.73m^2 (0.1 mL/s/m^2), adjust to lower range of normal dose
Cefazolin	Required	None	Dose and/or dosing interval require adjustment. Based on patient's CrCl
Ceftriaxone	If severe (see comment)	None	Do not exceed 2 g/day if patient has BOTH severe renal AND hepatic impairment
Vancomycin	Required	None	Monitor therapeutic concentrations to guide dosage adjustments (see treatment guidelines for target ranges)
Daptomycin	Required	None	Adjust dosing interval for CrCl < 30 mL/min/1.73m^2 (0.48 mL/s/m^2) CPK should be monitored prior to and during therapy (at least weekly, and more frequently if increasing or on concomitant medications associated with muscle toxicity, particularly statins)
Linezolid	None	None	Metabolites may accumulate in severe renal impairment Monitor for hematologic AE, particularly severe thrombocytopenia Use in severe hepatic impairment not established
Gentamicin	Required	None	Dosing should be based on ideal body weight; however, if significantly obese, use of adjusted body weight may be required to achieve target levels (listed below). Monitor therapeutic concentrations to guide dosage adjustments, and target concentrations vary based on indication Only used as synergy (combination therapy) for gram-positive bacteria. Target concentrations for synergy: peak 3–4 mcg/mL (3–4 mg/L; 6.3–8.4 µmol/L) and trough < 1 mcg/mL (1 mg/L; 2.1 µmol/L) Gentamicin (or tobramycin or amikacin) can be used as treatment for non-HACEK gram-negative bacteria (target concentrations not shown but dependent upon selected aminoglycoside and organism susceptibility)
Rifampin	None	Required	Adjustment based on hepatic dysfunction
Newer and Salvage Drugs			
Ceftaroline	Required	None	Adjustments in dose (33%–67% reduction) are based on patient's CrCl. Suggested dosages for off-label use in IE are higher than standard dosing (ie, 600 mg every 8 hours)
Quinupristin/dalfopristin	None	Possibly	Rarely used secondary to side effects. Adjustments suggested based on pharmacokinetic data. However, no specific recommendations are described
Telavancin	Required	None	Decrease daily dose by 25% if CrCl 30–50 mL/min/1.73 m^2 (0.29–0.48 mL/s/m^2) or if CrCl < 30 mL/min (0.29 mL/s/m^2)—extend interval to every 48 hours
Tigecycline	None	If severe (see comment)	In severe hepatic impairment (Child-Pugh class C)—decrease maintenance dose 50%
Streptomycin	Required	None	Only used as synergy (combination therapy) for gram-positive bacteria. Therapeutic concentrations vary for gram-negative bacteria Monitor therapeutic concentrations to guide dosage adjustments Target concentrations for synergy: peak 20–35 mcg/mL (20–35 mg/L; 34–60 µmol/L) and trough < 10 mcg/mL (10 mg/L; 17 µmol/L)

[a]Gram-negative bacteria, fungal, or atypical treatments are not listed. It is suggested that an infectious diseases consult be obtained if a patient has IE caused by one of these organisms due to the complexity and difficulty in managing these patients.

AE, adverse event; CPK, creatinine phosphokinase; CrCl, creatinine clearance.

Table 74–8

Cardiac Conditions Associated with the Highest Risk of Adverse Outcome from Endocarditis for Which Prophylaxis with Dental Procedures Is Reasonable[a]

- Prosthetic cardiac valve or prosthetic material used for cardiac-valve repair
- Previous IE
- Congenital heart disease (CHD)[b]
  - Unrepaired cyanotic CHD, including palliative shunts and conduits
  - Completely repaired congenital heart defect with prosthetic material or device, whether placed by surgery or by catheter intervention, during the first 6 months after the procedure[c]
  - Repaired CHD with residual defects at the site or adjacent to the site of a prosthetic patch or prosthetic device (which inhibit endothelialization)
- Cardiac transplantation recipients who develop cardiac valvulopathy

[a]*All dental procedures* involving manipulation of gingival tissue or the periapical region of teeth or perforation of the oral mucosa are reasonable indications for prophylaxis in patients with the conditions listed above.

[b]Except for the conditions listed above, antibiotic prophylaxis is no longer recommended for any other form of CHD.

[c]Prophylaxis is reasonable because endothelialization of prosthetic material occurs within 6 months after the procedure.

Data from Wilson W, Taubert KA, Gewitz M, et al. Prevention of infective endocarditis: guidelines from the American Heart Association. Circulation. 2007;116:1736–1754. ©2007, American Heart Association, Inc.

provide or assist in monitoring serum antibiotic concentrations (if patient is receiving vancomycin or an aminoglycoside) and pertinent laboratory values associated with side effects (such as creatine kinase increase with daptomycin, decreased platelets with linezolid, etc). Additionally, the stewardship team should be aware of potential patients requiring prophylaxis and provide guidance/recommendations for antimicrobial coverage prior to procedures as indicated in the IE prevention guidelines.

OUTCOME EVALUATION

KEY CONCEPT Monitoring for successful therapy is critical for this serious infection to prevent complications, prevent development of resistance, and decrease mortality. Routine assessment of clinical signs and symptoms, as well as laboratory tests (ie, repeat blood cultures), microbiologic testing, and serum drug concentrations (if appropriate), must be performed.

Resolution of signs and symptoms typically occurs within a few days to a week in most cases. Monitor the patient's temperature daily for febrile episodes, as well as other vital signs, with expected normalization of values within 2 to 3 days of antimicrobial therapy initiation.[1] Persistent signs or symptoms could be indicative of inadequate treatment and/or development of resistance.

Blood cultures are the primary laboratory evaluation to assess response to therapy. Collect and monitor blood cultures every 24 to 48 hours until bacteremia is cleared; with appropriate treatment, they should become negative within 3 to 7 days. Perform additional blood cultures if the patient appears unresponsive to current therapy or upon treatment completion to confirm eradication of infection. Evaluate all susceptibility testing reports to assess appropriateness of antimicrobial therapy.

Monitor the patient for potential development of side effects based on selected therapy. For patients receiving vancomycin, collect and assess serum concentrations based on the causative organism, adjusting the dosage regimen if necessary. For patients receiving an aminoglycoside, collect and assess serum concentrations. Refer to treatment Tables 74–3 through 74–6 for target concentrations.

Educate patients on the necessity of prophylactic antibiotics prior to major dental treatments in order to prevent recurrent infections. This is critical in patients with risk factors that predispose them to developing IE, such as prosthetic heart valves, other valvular defects, or previous IE.

Develop a follow-up plan to determine whether the patient has achieved a cure, which includes a clinical evaluation of signs/symptoms, repeat blood cultures, and possibly a repeat echocardiogram. Assess the patient for any adverse events throughout treatment course and at follow-up. Perform follow-up visit within a few weeks after the completion of therapy.

Table 74–9

Prophylactic Regimens for Dental Procedure

		Regimen: Single Dose 30–60 Minutes Before Procedure	
Situation	**Agent**	**Adults**	**Children**
Oral	Amoxicillin	2 g	50 mg/kg
Unable to take oral medications	Ampicillin or Cefazolin or Ceftriaxone	2 g IM or IV	50 mg/kg IM or IV
Allergic to penicillins or ampicillin—oral	Cephalexin[a,b] or Clindamycin or	2 g	50 mg/kg
	Azithromycin or Clarithromycin	600 mg	20 mg/kg
		500 mg	15 mg/kg
Allergic to penicillins or ampicillin and unable to take oral medications	Cefazolin or Ceftriaxone[b] or Clindamycin	1 g IM or IV	50 mg/kg IM or IV
		600 mg IM or IV	20 mg/kg IM or IV

[a]Or other first- or second-generation oral cephalosporin in equivalent adult or pediatric dosage.

[b]Cephalosporins should not be used in an individual with a history of anaphylaxis, angioedema, or urticaria with penicillins or ampicillin.

IM, intramuscular.

Patient Care Process

Collect Information:

- Perform a medication history review for prescription and nonprescription medications and herbal or dietary supplements.
- Determine allergies, including reaction, to medications, food, or material.
- Review past medical and surgical history and findings of physical assessment.
- Review medical records and communicate with the patient to ascertain lifestyle habits, preferences and beliefs, goals for health and function, and socioeconomic factors affecting access to medication or other components of therapy.

Assess the Information:

- Determine whether patient has any risk factors for the development of IE utilizing modified Duke criteria (see Table 74–2).
- Review and document pertinent patient social, medical, and surgical history associated with development or identification of causative organisms of IE.
- Review physical examination and vital signs, relevant laboratory tests (eg, white blood cell count, differential, blood cultures), and diagnostic imaging (echocardiogram) as indicators of diagnosis and severity of the IE infection.
- Assess the empirical pharmacologic regimen for appropriate coverage of likely causative organisms, patient allergies, and potential adverse effects (eg, nephrotoxicity).
- Determine whether selected regimen is on institution's formulary. If not, is there a formulary alternative? If no alternative, is there anything specific to institution to utilize nonformulary agent?
- Determine appropriate duration of therapy based on first negative blood culture.

Develop a Care Plan:

- Once blood culture identification/susceptibility is reported, determine if patient is on appropriate antimicrobial therapy.
- Recommend change in therapy if pathogen is not susceptible to current antimicrobial(s) or if patient is not improving on current therapy (ie, persistent bacteremia, persistent fevers, increasing white blood cell count, etc).
- Determine whether drug doses are optimal for treatment but minimize development of adverse effects.
- Determine appropriate duration of treatment.
- Determine if lifestyle modifications are appropriate.

Implement the Care Plan:

- Educate the patients about the selected antimicrobial therapy and dosing, expected duration, possible adverse effects, and how to self-monitor for worsening of infection and adverse effects.
- Address any patient concerns about IE and its management.
- Discuss importance of lifestyle modifications if applicable.
- Determine if outpatient therapy is required and choose appropriate alternative if in-patient therapy is not feasible based on frequency of dosages, lack of monitoring, or cost/insurance limitations.

Follow-up: Monitor and Evaluate:

- Review medication efficacy and safety. Is the infection resolving? Is patient experiencing any adverse effects from their antimicrobial(s)? Are there any potential drug–drug interactions from this medication?
- Follow up with blood cultures and physical examination. Review medical history and any other pertinent laboratory tests and results of other diagnostic tests.
- Monitor vital signs/symptoms for return to baseline during each clinic follow-up over the duration of therapy. If continued to be abnormal, reassessment of therapy/other diagnostic testing is necessary.
- Once the infection has resolved, educate the patient on importance of preventative antibiotics prior to future invasive dental procedures and to inform all health care providers including dentists of history of having IE.

Abbreviations Introduced in This Chapter

AHA	American Heart Association
CFU	Colony-forming units
CoNS	Coagulase-negative staphylococci
CNS	Central Nervous System
ESR	Erythrocyte sedimentation rate
FDA	Food and Drug Administration
IE	Infective endocarditis
IVDUs	Intravenous drug users
MIC	Minimum inhibitory concentration
MRSA	Methicillin-resistant *S. aureus*
MSSA	Methicillin-sensitive *S. aureus*
NBTE	Nonbacterial thrombotic endocarditis
PVE	Prosthetic-valve endocarditis
TEE	Transesophageal echocardiogram
TPN	Total parenteral nutrition
TTE	Transthoracic echocardiogram
VRE	Vancomycin-resistant enterococci
WBC	White blood cell

75 Tuberculosis

Rocsanna Namdar and Charles Peloquin

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

1. Compare the risk for active tuberculosis (TB) disease among patients based on their age, immune status, place of birth, and time since exposure to an active case.
2. Design an appropriate therapeutic plan for a patient with active TB disease.
3. Distinguish among the diagnostic tests used for patients potentially infected with TB.
4. Assess the effectiveness of therapy in TB patients.
5. Describe the common and important adverse drug effects caused by TB drugs.
6. Select patients for whom therapeutic drug monitoring (TDM) may be valuable and identify the necessary laboratory monitoring parameters for patients on antituberculosis medications.
7. Design appropriate antimicrobial regimens for the treatment of latent TB infection.

INTRODUCTION

Tuberculosis (TB) remains one of the leading infectious causes of death worldwide. In 2015, there were about 10.4 million new cases of TB worldwide and an estimated 1.4 million people died from the disease.[1] Most deaths are preventable if access to health care for diagnosis and correct treatment are provided.

EPIDEMIOLOGY AND ETIOLOGY

KEY CONCEPT Roughly one-third of the world's population is infected and drug resistance is increasing in many areas.[1] The majority of cases worldwide are found in South-East Asia and Africa. In the United States, about 13 million people have latent TB infection (LTBI), evidenced by a positive skin test (**purified protein derivative** [PPD]) but no signs or symptoms of disease. The PPD is the antigen derived from *Mycobacterium tuberculosis* used to determine the presence of an immune response in patients with previous exposure. Patients testing positive have roughly a 1 in 10 chance of active disease during their lives, with the greatest risk in the first 2 years after infection. In 2016, 9287 new TB cases were reported in the United States; a 2.7% decline from 2015.[2]

The most recent data from the Centers for Disease Control and Prevention (CDC) indicate that TB deaths in the United States have decreased from 2013 by 11.2% to 493 in 2014.[3] (For details, visit the CDC website at www.cdc.gov/nchstp/tb.)

Risk Factors for Infection

LO 1

▶ *Location and Place of Birth*

California, New York, Florida, and Texas accounted for approximately 50% of all TB cases in 2015.[2] These higher numbers may reflect the high-immigration rates into these states.[2] Mexico, the Philippines, Vietnam, India, and China account for the largest numbers of these immigrants.[2] TB is most prevalent in large urban areas and is exacerbated by crowded living conditions.[2] Those in close contact with patients with active pulmonary TB are most likely to become infected.[2,3]

▶ *Race, Ethnicity, Age, and Gender*

In 2016, Asians accounted for approximately 27% of new foreign born TB cases, followed by non-Hispanic blacks (22%), Hispanics (10%), whereas foreign born non-Hispanic whites accounted for 4% of new TB cases in the United States.[3] Among the US born populations in 2016, the highest incidence of TB occurred in Native Hawaiin/Pacific Islander (9.2%) followed by American Indian/Alaska Native (5%).[3] TB is most common among people 25 to 44 years of age, and those 45 to 64 years of age.[3]

Risk Factors for Disease

Once infected, a person's lifetime risk of active TB is about 10%, with about half this risk during the first 2 years.[2–4] Young children, the elderly, and immunocompromised patients have greater risks. KEY CONCEPT HIV is the most important risk factor for active TB because the immune deficit prevents patients from containing the initial infection.[1–4] HIV-infected patients with *M. tuberculosis* infection are roughly 100 times more likely to develop active TB than normal hosts.[1,3,4]

TB is caused by *M. tuberculosis*, a rod-shaped thin aerobic bacterium. It presents either as LTBI or as progressive active disease.[4] The latter typically causes progressive destruction of the lungs, leading to death in most patients who do not receive treatment. *M. tuberculosis* are acid-fast bacilli (AFB). Acid-fast organisms are characterized by wax-like nearly impermeable cells walls which often do not stain with Gram stain and cannot be decolorized by acid alcohol. The cell wall contains a high amount of mycolic acids, long-chain fatty acids, and cell wall lipids which make the wall difficult to attack with conventional antibiotics. The acid-fast stain is a differential stain used to identify acid-fast organisms.

Culture and Susceptibility Testing

KEY CONCEPT Microscopic examination of infected material ("sputum smear" of material on a glass slide) is the most rapid and readily available test to detect AFB in clinical specimens. Three sputum specimens should be collected in patients suspected of pulmonary TB to increase the likelihood of finding AFB. *The sensitivity of the sputum smear is only about 40%, so culture-based TB diagnosis is the current gold standard.*[4–6] Unfortunately, culture is much slower due to the roughly 20-hour doubling time of the bacilli. Furthermore, microscopic examination for AFB through sputum smear alone cannot determine which of over 100 mycobacterial species is present. Depending on the presence of epidemiological risk factors, the usual practice is to isolate the patient and treat empirically until presence of *M. tuberculosis* is confirmed by genetic probe or positive culture.

Antimicrobial susceptibility testing is essential for directing proper treatment. The most common method utilizing solid growth media, known as the *proportion method*, takes 3 to 8 weeks to produce results. Growth in liquid media is faster and can detect live mycobacteria in about 2 weeks.[5,6] Rapid-identification tests include nucleic acid amplification tests utilizing the polymerase chain reaction (PCR).[7–9] Three nucleic acid amplification tests have been approved for use in the United States to detect *M. tuberculosis* in respiratory secretions. These tests are highly sensitive and specific for smear positive patients and somewhat less sensitive in smear negative patients, but only need as few as 1 to 10 organisms/mL (10^3–10^4/L) to give a positive result.[8–10] The Cepheid MTB/RIF Assay performed on the Xpert System is a qualitative test designed for rapid detection of *M. tuberculosis* and rifampin resistance.[11]

Patient Encounter Part 1

HPI: CG is a 46-year-old man who presents to the medical clinic complaining of a 2-month history of a persistent cough that has become productive over the past 3 weeks. He also complains of fever, malaise, and a 6-kg (13-lb) weight loss over the past 2 months.

PMH: Type 2 diabetes mellitus (noninsulin-dependent diabetes mellitus, NIDDM)—not well controlled; hypertension (HTN) × 5 years—not controlled.

FH: Mother, age 82, alive and well, lives with CG. Father died of alcoholic liver disease10 years ago. One brother, age 53, lives with the patient, currently undergoing chemotherapy treatment for lung cancer.

SH: Born and raised in India until the age of 19 when he moved to Los Angeles, California. Single, one daughter. He had a 20-year history of alcohol abuse but has been sober for 5 years. He owns his own import/export business and travels internationally to India and parts of China.

Meds: Lisinopril 20 mg daily; amlodipine 5 mg daily; metformin 500 mg twice daily. Patient reports that he tries to be compliant with his therapies and takes them regularly except when he travels he often forgets; over the past 2 months, he has only gone 3 to 4 days without medication.

What information is suggestive of TB?

What factors place this patient at increased risk for acquiring TB?

New tests looking for specific mutations such as the katG gene associated with isoniazid resistance may facilitate rapid drug therapy decisions in the future. Nitrate reductase assays and porous ceramic support systems are among other rapid drug susceptibility testing techniques currently being investigated.[12] DNA fingerprinting is performed to assist surveillance programs and contact investigations. Various techniques are employed including restriction fragment length polymorphism (RFLP) analysis, spoligotyping, and mycobacterial interspersed repeat units. These techniques exploit conserved fragments in the TB genome that change gradually over time and allow investigators to determine if strains are related to one another. Strains that are related to one another are referred to as clusters. Clusters generally indicate recent transmission and are then targeted for interventions by TB programs.[13]

PATHOPHYSIOLOGY

Primary Infection

KEY CONCEPT *M. tuberculosis* is transmitted from person to person by coughing or any other aerosol producing activities such as sneezing.[4,14] This produces small particles known as droplet nuclei that float in the air for long periods of time. Primary infection usually results from inhaling droplet nuclei that contain *M. tuberculosis*.[4,14] The progression to clinical disease depends on three factors: (1) the number of *M. tuberculosis* organisms inhaled (infecting dose), (2) the virulence of these organisms, and (3) the host's cell-mediated immune response.[4,14] If pulmonary macrophages inhibit or kill the bacilli, the infection is aborted.[14] If not, *M. tuberculosis* eventually spreads throughout the body through the bloodstream.[4,14] *M. tuberculosis* most commonly infects the posterior apical region of the lungs, where conditions are most favorable for its survival.

T lymphocytes become activated over the course of 3 to 4 weeks, producing interferon-γ (IFN-γ) and other cytokines. These stimulate microbicidal macrophages to surround the tuberculous foci and form granulomas to prevent further extension.[14] A granuloma is a nodular aggregation of mononuclear inflammatory cells formed when the immune system attempts to wall off foreign substances. At this point, the infection is largely under control, and bacillary replication falls off dramatically. Any remaining mycobacteria are believed to reside primarily within granulomas or within macrophages that have avoided detection and lysis. Over 1 to 3 months, tissue hypersensitivity occurs, resulting in a positive PPD.[4,14] Approximately 95% of individuals with an intact immune system will enter into this latent phase. KEY CONCEPT Progressive primary disease occurs in roughly 5% of patients, especially children, the elderly, and immunocompromised patients.[15,16] This presents as a progressive pneumonia and frequently spreads, leading to meningitis and other severe forms of TB, often before patients develop positive (PPD) or interferon-γ release assays.[15]

Reactivation Disease

About 10% of infected patients develop reactivation TB, with half occurring in the first 2 years after infection.[4,9] Reactivation TB results when a previously "dormant" focus is reactivated and causes disease. Progression involves the development of caseating granulomas as a result of a vigorous immune response. Liquefaction leads to local spread and a pulmonary cavity results. This provides a portal to the airways and subsequently ambient air that enhances person-to-person spread. Bacterial counts in the cavities can be as high as 10^8/mL (10^{11}/L) of cavitary

fluid.[4,14] Prior to the chemotherapy era, pulmonary TB usually was associated with hypoxia, respiratory acidosis, and eventually death related to asphyxia; a fate that remains all too common in poor countries where patients do not have access to effective therapy.

Extrapulmonary and Miliary Tuberculosis

Caseating granulomas, regardless of location, can spread tubercle bacilli and cause symptoms.[4] Because of muted or altered symptoms, the diagnosis of TB is difficult and often delayed in immunocompromised hosts.[4,14] HIV-infected patients may present with only extrapulmonary TB, which is uncommon in HIV-negative persons. A widely disseminated form of the disease called *miliary TB* can occur, particularly in children and immunocompromised hosts. It can be rapidly fatal and immediate treatment is required.[14]

Influence of HIV Infection on Pathogenesis

HIV infection is the strongest known risk factor for active TB.[14] As $CD4^+$ lymphocytes multiply in response to the mycobacterial infection, HIV multiplies within these cells and selectively destroys them, gradually eliminating the TB-fighting lymphocytes.[16,17] HIV-positive patients often have negative PPD and fail to produce **cavitary lesions**, and fever may be absent. Cavitary lesions are present in a wide variety of pathological processes involving the lung and are observed radiographically as gas or fluid filled areas of the lung in the center of a nodule. Approximately 5% of HIV-infected patients with pulmonary TB who are not being treated effectively with antiretroviral medications will have positive results on acid-fast staining, yet have a normal chest radiograph. Patients coinfected with HIV and TB have a substantially higher risk of early mortality compared with HIV-negative patients with TB.[18]

CLINICAL PRESENTATION AND DIAGNOSIS

Fever, night sweats, weight loss, fatigue, and a productive cough are the classic symptoms of TB.[4,14] Onset may be gradual, and the diagnosis is easily missed if the symptoms are muted.[4,14] Progressive pulmonary disease leads to cavitary lesions visible on x-ray. Physical examination is nonspecific but may be consistent with pneumonia. Dullness to chest percussion, rales, and increased vocal **fremitus** may be observed on examination. Laboratory data often are uninformative, but a modest increase in the white blood cell (WBC) count with a lymphocytic predominance can be seen. Frequently, however, the physical examination is largely unremarkable.

Atypical presentations are common in patients coinfected with HIV.[4,14,18] Symptoms for these patients range from classic pulmonary to muted and nonspecific. Extrapulmonary TB typically presents either as a slowly progressive decline in the effected organ's function or commonly as a mass lesion. Lymphadenopathy is relatively common.[14,15] Abnormal behavior, headaches, or convulsions suggest tuberculous meningitis, although other acute central nervous system (CNS) infections must be excluded.[4,14]

Multidrug resistant TB remains a public health concern. The WHO estimated 600,000 new cases with resistance to rifampicin, of which 490,000 had multidrug-resistant tuberculosis (MDR-TB). There are a number of laboratory tools available for diagnosis of MDR-TB, including phenotypic culture-based drug susceptibility testing as well as molecular methods.[19] The FDA has not yet approved any molecular test for use in the United States, but several validated tests (line-probe assays, molecular beacons, and DNA sequencing) are being used. Molecular testing may be useful in patients with high risk of having MDR-TB, very ill patients who are not improving with standard first line therapy, and outbreak investigations.[20]

The Elderly

Positive PPD test, fevers, night sweats, sputum production, or hemoptysis may be absent, making TB hard to distinguish from other bacterial or viral infections or chronic lung diseases.[4,19] In contrast, mental status changes are twice as common in the elderly, and CNS disease must be considered when TB is entertained. Mortality is six times higher in the elderly, in part owing to delays in diagnosis.[4,19,21]

Children

TB in children may present as atypical bacterial pneumonia, and often involves the lower and middle lobes.[4,15,22] Extrapulmonary TB is more common in children. The Bacille Calmette-Guérin (BCG) is a vaccine made from strains of tubercle bacilli and is used to produce immunity against human TB. It is administered in countries where TB remains common and appears to stimulate children's immune systems to ward off the most serious forms of the disease. In fact, BCG is most effective in reducing infant mortality from TB meningitis and miliary disease. BCG does not block infection, and these same children often experience reactivation TB as young adults.[22]

Skin Testing

TB skin testing with PPD (commercially available as Tubersol or Aplisol) is one of the oldest diagnostic tests still in clinical use.[4,15,17] Also known as the tuberculin skin test, the product is injected into the skin (not subcutaneously) with a fine (27-gauge) needle, a technique referred to as the Mantoux method, and produces a small, raised, blanched wheal to be read by an experienced professional in 48 to 72 hours. The chance of a false-negative result is increased when the patient is immunosuppressed. The CDC does not recommend the routine use of anergy panels to determine if a patient's T-cell immune system reacts to common antigens.[17,23]

Criteria for interpretation are listed in **Table 75–1**.[15]

The "booster effect" occurs in patients who do not respond to an initial PPD test but show a positive reaction if retested 1 to 3 weeks later.[15,20,23] In order to reduce the likelihood that a boosted reaction is misinterpreted as a new infection, the two-step method is recommended at the time of initial testing for individuals such as health care workers or nursing home residents who may be tested periodically. If the first PPD test is negative, repeat the test in 1 to 3 weeks. If the second test is positive, it is most likely a boosted reaction, and the person should be classified as previously infected.

LO 3 Newer Diagnostic Tests

Newer technology has led to the development of blood tests or interferon-γ release assays (IGRAs) that have replaced the PPD test in the United States for individuals 5 years and older who meet the following criteria: likely to be infected with *M. tuberculosis*; low or intermediate risk of disease progression; testing for LTBI is warranted; and have history of BCG vaccine or unlikely to return to have PPD read.[15,23] These newer methods measure the release of interferon-γ in blood in response to TB antigens. The two TB blood tests approved in the United States are: the QuantiFERON®-TB Gold In-Tube test (QFT-GIT) and

Table 75–1

Criteria for Tuberculin Positivity, by Risk Group

Reaction ≥ 5 mm of Induration	Reaction ≥ 10 mm of Induration	Reaction ≥ 15 mm of Induration
HIV-infected persons	Recent immigrants (ie, within the last 5 years) from high-prevalence countries	Persons with no risk factors for TB
A recent contact of a person with TB disease	Injection drug users	
Fibrotic changes on chest radiograph consistent with prior TB	Residents and employees[a] of the following high-risk congregate settings: prisons and jails, nursing homes and other long-term facilities for the elderly, hospitals and other health care facilities, residential facilities for patients with AIDS, and homeless shelters	
Patients with organ transplants and other immunosuppressed patients (receiving the equivalent of 15 mg/day or more of prednisone for 1 month or longer, taking TNF-α antagonists)[b]	Mycobacteriology laboratory personnel, persons with the following clinical conditions that place them at high risk: silicosis, diabetes mellitus, chronic renal failure, some hematologic disorders, other specific malignancies, gastrectomy, and jejunoileal bypass	
	Children younger than 5 years of age or infants, children, and adolescents exposed to adults at high risk	

Interpretation of IGRA Results

The interpretation of IGRAs is based on the amount of IFN-γ, in T-SPOT®.TB. Laboratories should provide both the qualitative and quantitative results.

- Qualitative results are reported positive, negative, indeterminate, or borderline.
- Quantitative results are reported as numerical values that include a response to the TB antigen and 2 controls, nil and mitogen. Quantitative results may be useful for clinical decision making in individual cases, in combination with risk factors.

[a]For persons who are otherwise at low risk and are tested at the start of employment, a reaction of 15 mm or more of induration is considered positive.

[b]Risk of TB in patients treated with corticosteroids increases with higher dose and longer duration.

the T-SPOT® TB test (T-Spot).[23] The sensitivity of IGRAs ranges from 80% to 90%, and specificity of 95% for diagnosis of latent TB. Recent evidence suggests that prior placement of PPD can boost an IGRA. The boosting effect may wane after several months.[17,23] The IGRAs do not cause the booster phenomenon and are unaffected by BCG, or infection by most nontuberculosis mycobacteria. Results of the IGRAs are available in less than 24 hours, versus the 3 days required for the traditional PPD test. Data are limited for use of IGRAs in children younger than 5 years of age, persons recently exposed to TB, health care workers, and immunodeficient patients.[23] KEY CONCEPT The CDC has endorsed the use of IGRA tests in all circumstances where the PPD is used. IGRAs are approved for the diagnosis of LTBI in HIV-infected patients, but sensitivity is diminished.[23] Testing with both PPD and IGRA generally is not recommended, but may be useful in certain situations (eg, if the initial PPD test is negative and the risk for infection, clinical suspicion, or the risk for poor outcome is high; or if the initial PPD test is positive and additional evidence of infection is required; or the patient has a low risk of infection or progression).[23,24] IGRAs, and for that matter the PPD, should not be used to rule in or rule out the diagnosis of active TB disease.[24]

TREATMENT

General Approaches to Treatment

The primary treatment approach is the use of antimicrobials active against *M. tuberculosis*. Monotherapy can be used only for patients with LTBI, as evidenced by a positive PPD test or positive IGRA in the absence of signs or symptoms of disease. Once active disease is present, typically *three or four drugs* must be used simultaneously from the outset of treatment.[4,14,17,23] The shortest duration of treatment is 4 months in the unusual case of smear and culture negative clinical cases of pulmonary TB, and up to 2 years of treatment may be necessary for advanced cases of MDR-TB.[23,25] **Directly observed treatment** (DOT) is a method used to ensure adherence in which patients are directly observed by a health care worker while taking their antituberculosis medication.[26] Case management interventions such as patient education, counseling, home visits, integration, and coordination of care with specialists and incentives and enableers during treatment of patients wth TB disease are also encouraged. This also is a cost-effective way to ensure completion of treatment.

Desired Outcomes

Steps should be taken to (a) prevent the spread of TB (respiratory isolation); (b) find where TB has already spread (contact investigation); and (c) return the patient to a state of normal weight and well-being. Items (a) and (b) are performed by public health departments. Clinicians involved in the treatment of TB should verify that the local health department has been notified of all new cases of TB. In rare instances, surgery may be needed.[17]

Pharmacologic Therapy

LO 7

► *Treating LTBI*

KEY CONCEPT Isoniazid is used for treating LTBI. Typically, isoniazid 300 mg daily (5–10 mg/kg of body weight) is given alone for 9 months. Lower doses usually are less effective.[17] In some instances, a 6-month duration of treatment with isoniazid alone is an acceptable alternative. Pyridoxine (25–50 mg/day in adults) can reduce the risk of peripheral neuropathy.[17,27] Treatment of LTBI reduces a person's lifetime risk of active TB from about 10%

to about 1%.[17,24] Rifampin 600 mg daily for 4 months can be used when isoniazid resistance is suspected or when the patient cannot tolerate isoniazid.[17,27] Rifabutin 300 mg daily might be substituted for rifampin in patients at high risk of drug interactions.[28] The combination of pyrazinamide and rifampin is no longer recommended.[28,29] Once-weekly doses of isoniazid 900 mg and rifapentine 900 mg given as DOT for 3 months are as effective as 9 months of self-administered isoniazid 300 mg daily.[30] When resistance to isoniazid and rifampin is suspected, there is no regimen proven to be effective (Table 75–2).[27] Note that patients with LTBI are not infectious and there is no isolate on which to perform susceptibility testing. Susceptibility patterns must be inferred based on the most likely source of infection.

LO 2

▶ *Treating Active Disease*

In the United States, TB patients can receive free treatment through the local health department. Treating active TB disease requires combination chemotherapy. KEY CONCEPT Generally, four drugs are started. In particular, isoniazid and rifampin should be included because they are the best drugs available for preventing drug resistance.[17,27] Drug susceptibility testing should be done on the initial isolate for all patients.[17,27] Susceptibility testing is repeated if the patient remains culture-positive 8 weeks or more into therapy.[25]

The standard TB treatment regimen for susceptible TB is isoniazid, rifampin, pyrazinamide, and ethambutol for 2 months, followed by isoniazid and rifampin for 4 months, for a total of

CXR: Bilateral upper lobe infiltrates with cavitary lesions on left; small left pneumothorax

Clinical Course: The patient was admitted and placed on respiratory isolation. Three separate sputum AFB stain specimens were reported to contain 3+ AFB. IFN-γ was sent and a PPD tuberculin skin test was placed. Sputum samples were sent for AFB, fungi, and bacterial cultures and sensitivities. After 48 hours, the PPD skin test was read as a 7-mm area of induration

Assessment: Active pulmonary TB; pneumothorax; hypertension; type 2 diabetes mellitus

Which signs, symptoms, and other findings are consistent with active TB infection?

Table 75–2

Choosing the Most Effective LTBI Treatment Regimen

Drug	Duration	Dose	Frequency	Comments
Isoniazid	9 months	Adult: 5 mg/kg Children: 10–20 mg/kg	Daily	In HIV-infected patients, isoniazid may be administered concurrently with nucleoside reverse transcriptase inhibitors (NRTIs), protease inhibitors, or non-NRTIs (NNRTIs) Preferred regimen in children 2–11 years
	9 months	Adult: 15 mg/kg Children: 20–40 mg/kg	Twice weely	Directly observed treatment (DOT) must be used with twice-weekly dosing
	6 months	Adult: 5 mg/kg Children: Not recommended	Daily	Treatment for LTBI for 6 months rather than 9 months may be more cost-effective and result in greater adherence by patients
	6 months	Adult: 15 mg/kg Children: Not recommended	Twice weekly	Directly observed treatment (DOT) must be used with twice-weekly dosing
Isoniazid and Rifapentine	3 months	Adults and Children 12 years of age and over: INH: 15 mg/kg rounded up to the nearest 50 or 100 mg RPT: 10.0–14.0 kg 300 mg 14.1–25.0 kg 450 mg 25.1–32.0 kg 600 mg 32.1–49.9 kg 750 mg ≥ 50.0 kg	Once weekly	Equal alternative to 9 months of daily isoniazid for otherwise healthy patients age > 12 years DOT is recommended Not recommended for children < 2 years; HIV-infected patients taking antiretroviral therapy, presumed resistance, pregnant women or women expecting to become pregnant during the treatment period
Rifampin	4 months	Adult: 10 mg/kg[a]	Daily	For persons who are contacts of patients with isoniazid-resistant rifampin-susceptible Can be considered for persons who cannot tolerate INH or who have been exposed to INH-resistant TB RIF should not be used to treate HIV-infected person taking some combinations of ART.

[a]In the United States, the recommended regimen for treatment of LTBI in children is a 9-month course of INH. For the treatment of LTBI in infants, children, and adolescents when INH could not be tolerated or the child has had contact with a case patient infected with an isoniazid-resistant but rifamycin-susceptible organism the American Academy of Pediatrics recommends 6 months of daily rifampin (RIF) (180 doses) at a dosage of 10–20 mg/kg.

Adapted from: Latent tuberculosis infection: a guide for primary health care providers 2013. Atlanta, GA: US Department of Health and Human Services; CDC; 2013.

6 months of treatment.[17,27] Extending treatment to 9 months of isoniazid and rifampin treatment is recommended for patients at greater risk of failure and relapse, including those with cavitary lesions on initial chest radiograph and positive cultures at the completion of the initial 2-month phase of treatment, as well as for patients treated initially without pyrazinamide. Ideally, treatment should be continued for at least 6 months from the time that patients convert to a negative culture.[17,27] When the patients' sputum smears convert to negative, the risk of infecting others is greatly reduced, but it is not zero.[11,27] Such patients can be removed from respiratory isolation if they are responding clinically. The decision to discontinue isolation should be done by medical providers experienced in TB control. Table 75–3 shows the recommended treatment regimens. Daily dosing rather than intermittent dosing is preferred; but intermittent dosing can be considered in patients with low risk of relapse and negative HIV test results. When intermittent therapy is used, DOT is essential. Doses missed during an intermittent TB regimen decrease the efficacy of the regimen and increase the relapse rate.

Adjustments to the regimen should be based on susceptibility data.[9,27] Drug resistance should be suspected in patients who have been treated previously for TB. If adjustments are needed, two or more drugs with in vitro activity against the patient's isolate and that were not used previously should be added to the regimen.[9,27] When isoniazid and rifampin cannot be used, either because of drug resistance or intolerance, treatment durations typically become 2 years or more, regardless of immune status.[9,27,31] TB specialists should be consulted regarding cases of drug-resistant TB, or whenever treatment is uncertain.[9,27] Therapeutic drug monitoring (TDM) can direct dosing for such patients. One of the proven reasons for treatment failure is malabsorption of orally administered drugs.[27,31,32] KEY CONCEPT Due to the risk of further drug resistance, it is critical to avoid adding only a single drug to a failing regimen.[9,27]

Special Populations

Treatment for extrapulmonary TB is the same as for pulmonary disease. Unless drug resistance is suspected, corticosteroid treatment should also be added to the treatment regimen of TB meningitis and pericarditis. Patients with CNS TB usually are treated for 12 months.[9,27] Isoniazid and pyrazinamide cross the blood–brain barrier well, but rifampin, ethambutol, and streptomycin can penetrate inflamed meninges. TB osteomyelitis typically is treated for 9 months, occasionally with surgical débridement.[9,27] TB of the soft

Table 75–3

Drug Regimens for Microbiologically Confirmed Pulmonary Tuberculosis Caused by Drug-Susceptible Organisms

	Initial Phase		Continuation Phase		
Regimen	Drugs	Interval and Doses[a] (Minimal Duration)	Drugs[b]	Interval and Doses[b] (Minimal Duration)	Comments[c,d]
1	Isoniazid Rifampin Pyrazinamide Ethambutol	7 days per week for 56 doses (8 weeks) or 5 days per week for 40 doses (8 weeks)[c]	Isoniazid/Rifampin	7 days per week for 126 doses (18 weeks) or 5 days per week for 90 doses (18 weeks)[c]	This is the preferred regimen for patient with newly diagnosed pulmonary tuberculosis
2	Isoniazid Rifampin Pyrazinamide Ethambutol	7 days per week for 56 doses or 5 days per week for 40 doses	Isoniazid/Rifampin	Three times weekly for 54 doses (18 weeks)[d]	Preferred alternative regimen in situations in which more frequent DOT during continuation phase is difficult to achieve
3	Isoniazid Rifampin Pyrazinamide Ethambutol	3 times weekly for 24 doses (8 weeks)	Isoniazid/Rifampin	Three times weekly for 54 doses (18 weeks)	Use regimen with caution in patients with HIV and/or cavitary disease. Missed doses can lead to treatment failure, relapse, and acquired drug resistance
4	Isoniazid Rifampin Ethambutol Pyrazinamide	7 days per week for 14 doses then twice weekly for 12 doses[e]	Isoniazid/Rifampin	Twice weekly for 36 doses (18 weeks)	Do not use twice weekly regimens in HIV-infected patients or patients with smear positive and/or cavitary disease. If doses are missed, then therapy is equivalent to once weekly, which in inferior

[a]Other combinations may be appropriate in certain circumstances; additional details are provided in the section "Recommended Treatment Regimens."

[b]When DOT is used, drugs may be given 5 days per week and the necessary number of doses adjusted accordingly. Although there are no studies that compare 5 with 7 daily doses, extensive experience indicates this would be an effective practice. DOT should be used when drugs are administered < 7 days per week.

[c]Based on expert opinion, patients with cavitation on initial chest radiograph and positive cultures at completion of 2 months of therapy should receive a 7-month (31-week) continuation phase.

[d]Pyridoxine (vitamin B6), 25–50 mg/day, is given with INH to all persons at risk of neuropathy (eg, pregnant women; breastfeeding infants; persons with HIV; patients with diabetes, alcoholism, malnutrition, or chronic renal failure; or patients with advanced age). For patients with peripheral neuropathy, experts recommend increasing pyridoxine dose to 100 mg/day.

[e]Alternatively, some US tuberculosis control programs have administered intensive-phase regimens 5 days per week for 15 doses (3 weeks), then twice weekly for 12 dose.

DOT, directly observed therapy; EMB, ethambutol; HIV, human immunodeficiency virus; INH, isoniazid; PZA, pyrazinamide; RIF, rifampin.

Centers for Disease Control and Prevention. Treatment of Tuberculosis, American Thoracic Society, CDC, and Infectious Diseases Society of America. CID. 2016:63;853–867.

tissues can be treated with conventional regimens.[9,27] Patients with diabetes mellitus have been shown to have low 2-hour peak serum concentrations of antimicrobials. TDM can be considered to optimize treatment response.[33] TB in children may be treated with regimens similar to those used in adults, although some physicians extend treatment to 9 months.[9,15-17,27] Pediatric doses of isoniazid and rifampin on a milligram per kilogram basis are higher than those used in adults (Table 75–4).[27]

Pregnant women receive the usual treatment of isoniazid, rifampin, and ethambutol for 9 months.[24] Pyrazinamide has not been studied in large numbers of pregnant women, but anecdotal data suggest that it may be safe.[27,34] The clinician should always determine risk versus benefit and determine if a drug is safe to administer in pregnancy.

▶ *Human Immunodeficiency Virus*

HIV-infected adults may receive a 6-month total treatment regimen with isoniazid, a rifamycin, pyrazinamide, and ethambutol for the first 2 months followed by isoniazid and a rifamycin for 4 months.[9,27,35] Some clinicians recommend extending treatment to 9 months. Rifabutin is used to reduce drug interactions with protease inhibitors and some nonnucleoside reverse transcriptase inhibitors. Integrated antiretroviral therapy (ART) is superior to sequential ART in the treatment of naïve HIV seropositive patients with TB.[36] The optimal timing of integrated HIV and TB therapy is influenced by the patient's immune status.[36] It is recommended to start integrated ART therapy 2 to 12 weeks after initiating anti-TB therapy in patients with CD4 cell counts less than 50/mm^3.[34] TB-HIV experts should manage such patients. Highly intermittent regimens (twice or once weekly) are not recommended for HIV-positive TB patients.[27,35] Some patients with acquired immunodeficiency syndrome (AIDS) malabsorb their oral medications, and drug interactions are common, so TDM can be useful.[27,31,32]

For complete recommendations on management of TB and HIV visit the CDC website: www.cdc.gov/tb/publications/guidelines/HIV_AIDS.htm.

Table 75–4

Antituberculosis Drugs for Adults and Children

Drug	Daily Doses[a,b,c]	Adverse Effects	Monitoring
Isoniazid	*Adults*: 5 mg/kg (300 mg) *Children*: 10–15 mg/kg (300 mg)	Asymptomatic elevation of aminotransferases, clinical hepatitis, fatal hepatitis, peripheral neurotoxicity, CNS system effects, lupus-like syndrome, hypersensitivity, monoamine poisoning, diarrhea	LFT monthly in patients who have preexisting liver disease or who develop abnormal liver function that does not require discontinuation of drug Dosage adjustments may be necessary in patients receiving anticonvulsants or warfarin
Rifampin[d]	*Adults*: 10 mg/kg (600 mg) *Children*: 10–20 mg/kg (600 mg)	Cutaneous reactions, GI reactions (nausea, anorexia, abdominal pain), flu-like syndrome, hepatotoxicity, severe immunologic reactions, orange discoloration of bodily fluids (sputum, urine, sweat, tears), drug interactions owing to induction of hepatic microsomal enzymes	Rifampin causes many drug interactions. For a complete list of drug interactions and effects, refer to CDC website: www.cdc.gov/nchstp/tb/tb
Rifabutin[d]	*Adults*: 5 mg/kg (300 mg) *Children*: Appropriate dosing unknown	Hematologic toxicity, uveitis, GI symptoms, polyarthralgias, hepatotoxicity, pseudojaundice (skin discoloration with normal bilirubin), rash, flu-like syndrome, orange discoloration of bodily fluids (sputum, urine, sweat, tears)	Drug interactions are less problematic than rifampin
Rifapentine[d]	*Adults*: 10 mg/kg (continuation phase) (600 mg) dosed weekly *Children*: The drug is not approved for use in children	Similar to those associated with rifampin	Drug interactions are being investigated and are likely similar to rifampin
Pyrazinamide	*Adults*: Based on IBW: 40–55 kg: 1000 mg; 56–75 kg: 1500 mg; 76–90 kg: 2000 mg *Children*: 15–30 mg/kg	Hepatotoxicity, GI symptoms (nausea, vomiting), nongouty polyarthralgia, asymptomatic hyperuricemia, acute gouty arthritis, transient morbilliform rash, dermatitis	Serum uric acid can serve as a surrogate marker for compliance LFTs in patients with underlying liver disease
Ethambutol[e]	*Adults*: Based on IBW: 40–55 kg: 800 mg; 56–75 kg: 1200 mg; 76–90 kg: 1600 mg *Children*[c]: 15–20 mg/kg daily	Retrobulbar neuritis, peripheral neuritis, cutaneous reactions	Baseline visual acuity testing and testing of color discrimination Monthly testing of visual acuity and color discrimination in patients taking > 15–20 mg/kg, renal insufficiency, or receiving the drug for > 2 months
Cycloserine[f]	*Adults*: 10–15 mg/kg/day, usually 500–750 mg/day in two doses *Children*: 10–15 mg/kg/day	CNS effects	Monthly assessments of neuropsychiatric status Serum concentration may be necessary until appropriate dose is established
Ethionamide[g]	*Adults*: 15–20 mg/kg/day, usually 500–750 mg/day in a single daily dose or two divided doses *Children*: 15–20 mg/kg/day	GI effects, hepatotoxicity, neurotoxicity, endocrine effects	Baseline LFTs Monthly LFTs if underlying liver disease is present TSH at baseline and monthly intervals
Streptomycin	*Adults*[h] *Children*: 20–40 mg/kg/day	Ototoxicity, neurotoxicity, nephrotoxicity	Baseline audiogram, vestibular testing, Romberg testing and SCr Monthly assessments of renal function and auditory or vestibular symptoms
Amikacin/ kanamycin	*Adults*[h] *Children*: 15–30 mg/kg/day IV or intramuscular as a single daily dose	Ototoxicity, nephrotoxicity	Baseline audiogram, vestibular testing, Romberg testing and SCr Monthly assessments of renal function and auditory or vestibular symptoms
Capreomycin	*Adults*[h] *Children*: 15–30 mg/kg/day as a single daily dose	Nephrotoxicity, ototoxicity	Baseline audiogram, vestibular testing, Romberg testing and SCr Monthly assessments of renal function and auditory or vestibular symptoms Baseline and monthly serum K^+ and Mg^{2+}
p-Aminosalicylic acid (PAS)	*Adults*: 8–12 g/day in two or three doses *Children*: 200–300 mg/kg/day in two to four divided doses	Hepatotoxicity, GI distress, malabsorption syndrome, hypothyroidism, coagulopathy	Baseline LFTs and TSH TSH every 3 months
Levofloxacin	Adults: 500–1000 mg daily *Children*[i]: Not recommended	GI disturbance, neurologic effects	No specific monitoring recommended

(*Continued*)

Table 75–4

Antituberculosis Drugs for Adults and Children (*Continued*)

Drug	Daily Doses[a,b,c]	Adverse Effects	Monitoring
Moxifloxacin	*Adults*: 400 mg daily *Children*[j]: Not recommended		
Bedaquiline	*Adults:* Weeks 1–2: 400 mg daily Weeks 3–24: 200 mg three times weekly *Children:* Not recommended	GI disturbances, dizziness, headache, rash, arthralgia	Serum K, Ca, Mg ECG at baseline, weeks 2, 12, 24 Weekly ECG for persons taking other QTc prolonging drugs, history of arrhythmias, hypothyroidism, uncompensated heart failure, or have serum K, Ca, or Mg below normal limits

[a]Dose per weight is based on ideal body weight. Children weighing more than 40 kg should be dosed as adults.

[b]For purposes of this document adult dosing begins at age 15 years.

[c]The authors of this chapter do not agree with the use of maximum doses, since this arbitrarily caps doses for patients who otherwise might need larger doses. These maximum doses were not based on prospective studies in large or overweight individuals, and do not consider patients with documented malabsorption of their medications. Clinical judgment should be used in such circumstances.

[d]Higher doses of rifampin and rifapentine are being studied. Rifabutin dose may need to be adjusted when there is concomitant use of protease inhibitors or nonnucleoside reverse transcriptase inhibitors.

[e]The drug can likely be used safely in older children but should be used with caution in children less than 5 years of age, in whom visual acuity cannot be monitored. In younger children, ethambutol at the dose of 15 mg/kg/day can be used if there is suspected or proven resistance to isoniazid or rifampin.

[f]It should be noted that, although this is the dose recommended generally, most clinicians with experience using cycloserine indicate that it is unusual for patients to be able to tolerate this amount. Serum concentration measurements are often useful in determining the optimal dose for a given patient.

[g]The single daily dose can be given at bedtime or with the main meal.

[h]Dose: 15 mg/kg/day (1 g), and 10 mg/kg in persons older than 59 years of age (750 mg). Usual dose: 750–1000 mg administered intramuscularly or intravenously, given as a single dose 5–7 days/week and reduced to two or three times per week after the first 2 to 4 months or after culture conversion, depending on the efficacy of the other drugs in the regimen.

[i]The long-term (more than several weeks) use of levofloxacin in children and adolescents has not been approved because of concerns about effects on bone and cartilage growth. However, most experts agree that the drug should be considered for children with tuberculosis caused by organisms resistant to both isoniazid and rifampin. The optimal dose is not known.

[j]The long-term (more than several weeks) use of moxifloxacin in children and adolescents has not been approved because of concerns about effects on bone and cartilage growth. The optimal dose is not known.

Data from Centers for Disease Control and Prevention. Treatment of tuberculosis. MMWR 2003;52(RR-11).

► *Multidrug-Resistant TB*

MDR-TB is caused by *M. tuberculosis* that is resistant to at lease isoniazid and rifampin. If drug-resistant TB is suspected, the empiric regimen should be modified based on patterns of suspected resistance. Once susceptibilities are confirmed, regimens can be modified appropriately. Patients with MDR-TB are at high risk of failure and should be treated by specialists or centers with experience treating drug resistant TB. Effective treatement of MDR-TB requires administration, for 18 to 24 months, of four to six drugs to which the infecting organism is susceptible, including second line drugs.

► *Renal Failure*

Isoniazid and rifampin usually do not require dose modification in renal failure.[30,37] Pyrazinamide and ethambutol typically are reduced to three times weekly to avoid accumulation of the parent drug (ethambutol) or metabolites (pyrazinamide).[31,32] Renally cleared TB drugs include the aminoglycosides, ethambutol, cycloserine, and levofloxacin.[31,32] With renal impairment, dosing intervals need to be extended for these drugs. TB drugs should be administered after hemodialysis; three times weekly regimens may be more convenient. Serum concentration monitoring should be performed for cycloserine and ethambutol to avoid dose-related toxicities in renal failure patients.[32,37,38]

► *Hepatic Failure*

Hepatically cleared TB drugs include isoniazid, rifampin, pyrazinamide, ethionamide, and *p*-aminosalicylic acid.[25] Ciprofloxacin and moxifloxacin are about 50% cleared by the liver. Isoniazid, rifampin, pyrazinamide, and to a lesser degree

Patient Encounter Part 3

Based on the information provided, what are the goals of therapy for this patient?

Select and recommend a therapeutic plan for treatment of this patient's TB infection. What drugs, dose, schedule, and duration of therapy are best for this patient?

Who else should be tested? How should any contacts infected by this patient be evaluated and treated?

ethionamide, *p*-aminosalicylic acid, and rarely ethambutol may cause hepatotoxicity.[29,31] These patients require close monitoring, and serum concentration monitoring may be the most accurate way to dose them.[32]

TB Drugs

Detailed information regarding TB drugs can be accessed at the following references.[25,27,31,32] A summary is provided in Table 75–4.[26] Isoniazid, rifampin, and pyrazinamide are the key drugs. Other drugs are used in selected circumstances. Quinolones eventually may be used as first-line drugs, but currently are not.[39,40] In 2012, the Food and Drug Administration approved bedaquiline for the treatment of MDR-TB.[41] Bedaquiline may be used in adults with confirmed pulmonary MDR-TB when an effective treatment regimen cannot otherwise be provided.[42]

It should be used with three or more drugs that are active against the patient's isolate. Bedaquiline carries a black-box warning due to prolongation of QTc interval. Baseline and follow-up electrocardiograms are recommended. Other new therapies include investigational vaccines, and investigational drugs such as pretomanid, delamanid, and SQ109, which are in clinical trials.[43]

OUTCOME EVALUATION

LO 4

Effectiveness of TB therapy is determined by AFB smears and cultures. Send sputum samples for AFB staining and microscopic examination (sputum smears) every 1 to 2 weeks until two consecutive smears are negative. This provides early evidence of a response to treatment.[27] Once on maintenance therapy, *sputum cultures* can be performed monthly until two consecutive cultures are negative, which generally occurs over 2 to 3 months. If sputum cultures continue to be positive after 2 months, repeat drug susceptibility testing and check serum concentrations of the drugs.

KEY CONCEPT The most serious problem with TB therapy is patient nonadherence.[27,44] There is no reliable way to identify such patients a priori, therefore DOT should be used.[9,27,44] DOT also provides increased opportunities to observe the patient for any apparent toxicities, thus improving overall care.[44]

LO 5

Check serum chemistries, including blood urea nitrogen (BUN), creatinine, aspartate transaminase (AST), and alanine transaminase (ALT) and a complete blood count with platelets at baseline and periodically thereafter depending on the presence of other factors that may increase the likelihood of toxicity (eg, advanced age, alcohol abuse, pregnancy).[27] Suspect hepatotoxicity in patients whose transaminases exceed five times the upper limit of normal (ULN) or whose total bilirubin exceeds 3 mg/dL (51 µmol/L), and in patients with symptoms such as nausea, vomiting, and jaundice with liver enzyme elevations of more than three times ULN. At this point, discontinue the offending agents. Typically, all TB drugs are stopped, followed by the sequential reintroduction of the drugs, along with frequent testing of liver enzymes. This usually is successful in identifying the offending agent; other agents may be continued (see Table 75–4).[27]

Patient Encounter Part 4

Based on the information provided, which clinical and laboratory parameters should be monitored in this patient to determine efficacy and avoid toxicity?

Is this patient a candidate for therapeutic drug monitoring? Why or why not?

Therapeutic Drug Monitoring

LO 6

TDM is the use of serum drug concentrations to optimize therapy.[27,31,32] Patients with uncomplicated, drug-susceptible TB generally do well. Pharmacokinetic variability of anti-TB drugs can contribute to poor outcomes despite adherence. TDM can be used to shorten the time to response and to treatment completion. The evidence to support the use of TDM in the treatment of TB is growing.[32] TDM can assist in patients failing appropriate DOT (no clinical improvement after 2–4 weeks or smear-positive after 4–6 weeks). Patients with AIDS, diabetes, and various GI disorders often fail to absorb these drugs properly and also are candidates for TDM. Drug concentrations in patients with hepatic or renal disease should be monitored, given their potential for toxicities. In the treatment of MDR-TB, TDM may be particularly useful.[25] Finally, TDM of the TB and HIV drugs is perhaps the most logical way to untangle the complex drug interactions that take place.

For a complete list of drug interactions, visit the CDC website: www.cdc.gov/tb/publications/guidelines/TB_HIV_DRUGS/default.htm.[45] In particular, interactions between the rifamycins (eg, rifampin, rifapentine, rifabutin) and the HIV protease inhibitors and nonnucleoside reverse transcriptase inhibitors are common and require dose and frequency modifications in many cases. Because these are constantly being updated, the preceding link is an excellent way to keep current.

Patient Care Process

Collect Information:

- Obtain a thorough medical and medication history.
- Obtain necessary laboratory tests, cultures, and radiology to determine active infection. (Collect appropriate samples for smears and cultures.)
- Review physical assessment findings.
- Speak with the patient obtain risk factors for infection and risk factors for developing active TB (travel, living conditions, immune status, etc).

Assess the Information:

- Assess the patient's risk factors and signs and symptoms to determine whether the patient might be infected with TB.
- Based on physical examination, medical history, laboratory tests and cultures, and X-rays, determine whether the patient has an active TB infection.
- Assess the efficacy, safety, and patient adherence of required pharmacotherapy.
- Identify any significant adverse drug effects or interactions.

Develop a Care Plan:

- Isolate the patient with active disease to prevent the spread of the disease.
- Select and recommend appropriate antituberculosis treatment. Consider susceptibility, HIV status, drug interations, type of TB infection, etc.
- Choose medication doses that are optimal for the patient. Consider renal function, liver function, etc.

(*Continued*)

Patient Care Process (*Continued*)

- Consider DOT.
- Identify the index case that infected the patient, identify all persons infected by both the index case and the new case of TB, and the complete appropriate treatments for those individuals.

Implement the Care Plan:

- Review drugs, duration, dose, frequency, and side effects of selected medications.
- Educate the patient about the importance of compliance with the regimen and the risks of noncompliance.
- Ensure adherence to the treatment regimen by the patient.

Follow-up: Monitor and Evaluate:

- Follow-up at required intervals to obtain AFB stains to evaluate the effectiveness of treatment.
- Review susceptibilities when available and modify treatment regimen as determined by susceptibility results.
- Continue treatment for at least 6 months from the time that the patient converts to a negative culture.
- Consider TDM if no clinical improvement.

Abbreviations Introduced in This Chapter

AFB	Acid-fast bacilli
AIDS	Acquired immunodeficiency syndrome
ALT	Alanine transaminase
ART	antiretroviral therapy
AST	Aspartate transaminase
BCG	Bacille Calmette-Guérin
CDC	Centers for Disease Control and Prevention
CNS	Central nervous system
DOT	Directly observed therapy
HIV	Human immunodeficiency virus
HTN	Hypertension
IGRA	Interferon-γ release assay
INF	Interferon
LTBI	Latent tuberculosis infection
MDR-TB	Multidrug-resistant tuberculosis
NIDDM	Noninsulin-dependent diabetes mellitus
PCR	Polymerase chain reaction
PPD	Purified protein derivative
RFLP	Restriction fragment length polymorphism
TB	Tuberculosis
TDM	Therapeutic drug monitoring
ULN	Upper limit of normal
WBC	White blood cell

76 Gastrointestinal Infections

Bradley W. Shinn and Sharon Ternullo

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

LO

1. Describe the epidemiology and clinical presentation of commonly encountered gastrointestinal (GI) infections.
2. Summarize common risk factors associated with the development of a GI infection.
3. Given a patient with a GI infection, develop an individualized treatment plan.
4. Outline the impact of widespread antimicrobial resistance on current treatment recommendations for GI infections.
5. Discuss the effect of host immunosuppression on the risk of disease complications and treatment strategies associated with GI infections.
6. Educate patients on appropriate prevention measures of GI infections.
7. Describe the role of antimicrobial prophylaxis and/or vaccination for GI infections.

INTRODUCTION

One of the primary concerns related to gastrointestinal (GI) infection, regardless of the cause, is dehydration, which is the second leading cause of worldwide morbidity and mortality.[1] Dehydration is especially problematic for children younger than age 5; however, the highest rate of death in the United States occurs among the elderly.[1] KEY CONCEPT Rehydration is the foundation of therapy for GI infections, and oral rehydration therapy (ORT) is usually preferred (Table 76–1).[2] Single-dose oral ondansetron should be considered the first-line antiemetic in children who are dehydrated with significant vomiting.[3] In nonimmunocompromised hospitalized pediatric patients, *Lactobacillus* supplementation may reduce the length of hospitalization.[4]

LO 1

In the United States, each year 31 major pathogens cause about 9 million episodes of food-borne illness, almost 56,000 hospitalizations, and 1350 deaths. Most illnesses are caused by norovirus, nontyphoidal *Salmonella* (NTS), *Clostridium perfringens*, and *Campylobacter*.[5] KEY CONCEPT The indiscriminate use of proton-pump inhibitor (PPI) therapy leads to changes in gut microbiome and increased susceptibility to enteric bacterial infections.[6] The Centers for Disease Control and Prevention (CDC) and World Health Organization (WHO) actively track food-borne illnesses via surveillance systems that offer excellent epidemiological information.

BACTERIAL INFECTIONS

SHIGELLOSIS

Epidemiology

Shigella causes bacillary dysentery, which refers to diarrheal stool containing pus and blood. Shigellosis is endemic in most developing countries and is the most important cause of bloody diarrhea worldwide. It is estimated to cause at least 80 million cases and 700,000 deaths each year, the majority of which occur in children less than 5 years old.[7] There are approximately 500,000 infections each year in the United States; it is a particular problem in daycare centers and in areas with crowded living conditions or poor sanitation. Most cases of shigellosis are transmitted through the fecal–oral route. Activities that may lead to shigellosis include handling diapers, ingesting pool water, or consuming vegetables from a sewage-contaminated field. *Shigella* transmission from contaminated food and water, although less common, is associated with large outbreaks.

Pathogenesis

LO 2

Shigella organisms are nonmotile, nonlactose-fermenting, gram-negative rods and are members of the Enterobacteriaceae family. *S. sonnei* (serogroup D) is responsible for most shigellosis cases in the United States. Infection with Shigella occurs after ingestion of as few as 10 to 100 organisms, which may explain the ease of person-to-person spread. Symptoms develop about 1 to 2 days after contracting the bacteria.[8]

Shigella strains invade intestinal epithelial cells, with subsequent multiplication, inflammation, and destruction. This organism only rarely invades the bloodstream; but, bacteremia can occur in malnourished children and immunocompromised patients and is associated with a mortality rate as high as 20%.[9]

Treatment and Monitoring

In April 2017, the CDC issued a health advisory describing the emergence of *Shigella* strains with elevated MIC values for ciprofloxacin. Within this advisory, the CDC outlined new recommendations for the clinical diagnosis and management of this infection as well as new recommendations for laboratories

Table 76–1

Clinical Assessment of Degree of Dehydration in Children Based on Percentage of Body Weight Loss

Variable	Mild (3%–5%)	Moderate (6%–9%)	Severe (10% or More)
Blood pressure	Normal	Normal	Normal to reduced
Quality of pulses	Normal	Normal to slightly decreased	Moderately decreased
Heart rate	Normal	Increased	Increased (bradycardia in severe cases)
Skin turgor	Normal	Decreased	Decreased
Fontanelle	Normal	Sunken	Sunken
Mucous membranes	Slightly dry	Dry	Dry
Eyes	Normal	Sunken orbits/decreased tears	Deeply sunken orbits/decreased tears
Extremities	Warm, normal capillary refill	Delayed capillary refill	Cool, mottled
Mental status	Normal	Normal to listless	Normal to lethargic to comatose
Urine output	Slightly decreased	< 1 mL/kg/hour	< 1 mL/kg/hour
Thirst	Slightly increased	Moderately increased	Very thirsty
Fluid replacement	ORT 50 mL/kg over 2–4 hours	ORT 100 mL/kg over 2–4 hours	Lactated Ringer 40 mL/kg in 15–30 minutes, then 20–40 mL/kg if skin turgor, alertness, and pulse have not returned to normal *or* Lactated Ringer or normal saline 20 mL/kg, repeat if necessary, and then replace water and electrolyte deficits over 1–2 days, followed by ORT 100 mL/kg over 4 hours

From Martin S, Jung R. Gastrointestinal infections and enterotoxigenic poisonings. In: DiPiro JT, Talbert RL, Yee GC, et al, eds. Pharmacotherapy: A Pathophysiologic Approach, 9th ed. New York: McGraw-Hill; 2014:1951–1967.

and public health officials. It is now recommended that stool cultures and antimicrobial susceptibility testing be obtained in patients suspected of having a *Shigella* infection. The CDC now recommends that antibiotics not be routinely prescribed for Shigella infections. Antibiotic therapy should be reserved for patients who are immunocompromised or who develop severe illness or when public health officials advise treatment in an outbreak situation.[10] Although treatment can shorten the duration of symptoms by 1 to 2 days, shigellosis is generally a self-limited infection and unnecessary treatment with antibiotics promotes further resistance. Fluoroquinolones, which have generally been considered the first-line drug for the treatment of shigellosis in adults, should not be prescribed if the ciprofloxacin MIC is 0.12 mcg/mL or higher, even if identified by the laboratory as susceptible. In these cases, an infectious disease specialist should be consulted to identify an appropriate antibiotic. In children, oral azithromycin or parenteral ceftriaxone is considered preferable to fluoroquinolones for first-line therapy. All shigellosis cases should be reported to the local health department.[10]

SALMONELLOSIS

Epidemiology

Salmonella are gram-negative facultative rods that cause a wide variety of disease manifestations. *Salmonella enterica* (serotypes Typhi and Paratyphi A and B) cause typhoid (or enteric) fever. Although typhoid fever is now a rare disease in the United States with approximately 400 clinical cases reported per year, these infections cause an estimated 30 million cases and 215,000 deaths annually worldwide.[11] Typhoid fever is most commonly acquired from water or food contaminated by feces from an infected person. The incubation period is 6 to 30 days; illness onset is insidious with gradually increasing fatigue and fever. Nontyphoidal *Salmonella* (NTS) are important causes of reportable food-borne infection. There are an estimated 1.4 million cases of NTS illness annually in the United States, and almost 94 million worldwide.[12] The highest incidence is in those younger than 1 year of age, older than 65 years of age, or in those with HIV/AIDS. Foods commonly associated with infection include raw meat, poultry, eggs, tuna,

Clinical Presentation and Diagnosis of Shigellosis

- Biphasic illness
  - Early—high fever, watery diarrhea without blood
  - Later—after approximately 48 hours, colitis develops with urgency, tenesmus, and dysentery
  - Low-grade fever
  - More frequent small-volume stools ("fractional stools")
  - Vomiting (35%)
- Complications of shigellosis
  - Proctitis or rectal prolapse—more common in infants and young children
  - Intestinal obstruction
  - Colonic perforation
  - Bacteremia—more common in children
  - Metabolic disturbances
  - Neurologic disease—most commonly seizures (approximately 10% of patients)
  - Hemolytic-uremic syndrome (HUS)
- Microscopic examination of stool is extremely useful and reveals multiple polymorphonuclear leukocytes and red blood cells (RBCs). Diagnosis is usually confirmed by stool culture

Patient Encounter 1

A mother carrying a 1-year-old infant comes to you with a prescription for Augmentin® suspension 200 mg/5 mL, 1 teaspoonful q12h for an ear infection. You check the child's prescription record and note that this is the second course of antibiotics over the last 2 months (previously, ampicillin 250 mg po q6h). In addition, the child is on omeprazole suspension 5 mg once daily for GE reflux.

This child is at high risk for what type of gastrointestinal infection?

What risk factors are present to develop this disease in this child?

What are the symptoms of this infection that you could counsel this mother to watch for? How is this different from the normal side effects of Augmentin®?

What antibiotics are less likely to result in an overgrowth of C. difficile *than those listed above, which could still treat the child's otitis media in some circumstances?*

and unwashed food and vegetables. Exotic pets, especially reptiles, are an increasing source of human salmonellosis. NTS strains may also result in bacteremia and focal disease, such as endovascular infections, osteomyelitis, meningitis, and septic arthritis. Antimicrobial-resistant strains are associated with excess bloodstream infections and hospitalizations.[13] Recurrent *Salmonella* bacteremia is an AIDS-defining illness.

LO 2

Risk factors for salmonellosis include extremes of age; alteration of endogenous GI flora due to antimicrobial therapy, surgery, or acid-suppressive therapy[6]; diabetes; malignancy; rheumatologic disorders; HIV infection; and therapeutic immunosuppression. Proper food handling and storage can help prevent *Salmonella* gastroenteritis. Effective handwashing is important, especially when handling eggs and poultry.

Treatment and Monitoring

▶ *Gastroenteritis*

LO 3

Salmonella gastroenteritis is usually self-limited, and antibiotics have no proven value. Patients respond well to ORT. Symptoms typically diminish in 3 to 7 days without sequelae. Antibiotic use may result in a higher rate of chronic carriage and relapse. Antimicrobial use should be limited to preemptive therapy among patients at higher risk for extraintestinal spread or invasive disease (Table 76–2). Antimotility agents should not be used.

Table 76–2

Antimicrobial Indications for Nontyphoidal Salmonellosis (NTS)

Age 3 months or less or 65 years or more
Fever and systemic toxicity
HIV/AIDS
Other immunodeficiency (eg, steroid use, organ transplantation)
Uremia or hemodialysis or renal transplant
Malignancy
Sickle cell anemia or hemoglobinopathy
Inflammatory bowel disease
Aortic aneurysm, prosthetic heart valve, vascular or orthopedic prosthesis

Clinical Presentation and Diagnosis of Salmonellosis

Gastroenteritis

- Onset 8 to 48 hours after ingestion of contaminated food.
- Fever, diarrhea, and cramping.
- Stools are loose, of moderate volume, and without blood.
- Headache, myalgias, and other systemic symptoms can occur.
- Certain underlying conditions (eg, AIDS, inflammatory bowel disease, and prior gastric surgery) predispose the patient to more severe disease.

Enteric Fever

- Febrile illness 5 to 21 days after ingestion of contaminated food or water, which may be persistent and high-grade. A relative bradycardia may be noted at the fever peak.
- Chills, diaphoresis, headache, anorexia, cough, weakness, sore throat, dizziness, muscle pain, and diarrhea may be present before onset of fever.
- Rose spots, a coated tongue, and/or hepatosplenomegaly may be noted.
- Intestinal hemorrhage or perforation, leukopenia, anemia, and subclinical disseminated intravascular coagulopathy may occur.
- Culture of stool, blood, or bone marrow for *Salmonella* species is helpful.

▶ *Enteric Fever*

The current drug of choice for typhoid fever in adults is a fluoroquinolone, such as ciprofloxacin. Azithromycin or ceftriaxone are preferred in children. The recommended adult dose of ciprofloxacin for uncomplicated typhoid fever is 500 mg orally twice daily for 5 to 7 days; however, decreased susceptibility to ciprofloxacin is a significant problem in many parts of the world. In the United States, *Salmonella* spp. with decreased ciprofloxacin susceptibility are associated with travel to the Indian subcontinent.[14] If ciprofloxacin resistance is present, ceftriaxone may be used; however, this agent may be less suitable in some low- and middle-income countries due to cost and route of administration. Azithromycin is an effective alternative for uncomplicated typhoid fever.[15]

Two typhoid vaccines are available for use in the United States; however, neither is licensed by the FDA for the prevention of paratyphoid fever. Immunization is recommended for travelers going to endemic areas such as Latin America, Asia, and Africa; household contacts of chronic carriers; and laboratory personnel who frequently work with *Salmonella* serotype Typhi.[16] Vaccination is increasingly important for travelers to consider since the growth of multidrug-resistant strains of *Salmonella* serotype Typhi have become common in many regions.

▶ *Bacteremia and Focal Infections*

Treatment of *Salmonella* bacteremia should be initiated with either a fluoroquinolone (eg, levofloxacin, ciprofloxacin) or a third-generation cephalosporin (eg, ceftriaxone). Given increasing antimicrobial resistance, life-threatening infections should be treated with both agents until susceptibilities are

available.[12] If there is no evidence of an endovascular infection, therapy for bacteremia should continue for 10 to 14 days. For patients with suspected meningitis, high-dose ceftriaxone is preferred because of its optimal penetration of the blood–CSF barrier. Osteomyelitis and joint infections, often associated with sickle-cell anemia, are difficult to eradicate and require longer durations of antimicrobial therapy (at least 4–6 weeks), as do patients who are infected with HIV.[12]

▶ *Chronic Carrier State*

A chronic carrier state, defined as positive stool or urine cultures for more than 12 months, develops in 1% to 4% of adults with typhoid fever. Effective agents for eradication of chronic carriage include amoxicillin (3 g orally divided three times a day in adults for 3 months), trimethoprim-sulfamethoxazole (one double-strength tablet orally twice a day for 3 months), or ciprofloxacin (750 mg orally twice daily for 4 weeks). Surgery in combination with antibiotic therapy is indicated in patients with biliary tract abnormalities.

CAMPYLOBACTERIOSIS

Epidemiology

Campylobacter jejuni is the most commonly identified cause of bacterial gastroenteritis worldwide. In the United States, this organism accounts for an estimated 1.4 million infections, 13,000 hospitalizations, and 100 deaths annually.[17] Risk factors for *Campylobacter* infection include consumption of contaminated foods of animal origin, especially undercooked poultry or other foods that are cross-contaminated by raw poultry meat during food preparation; unpasteurized milk; contaminated water; foreign travel; contact with farm animals and pets; and the use of antimicrobial therapy.[18] People should be instructed to wash their hands after contact with raw meats and animals.

In developed countries, there are two distinct age peaks for Campylobacter infection: younger than 1 year of age and 15 to 44 years of age, with a mild male predominance. In developing countries, *Campylobacter*–associated diarrhea is primarily a pediatric disease.

Patient Encounter 2

A 55-year-old male, who was diagnosed with nonsmall cell lung cancer (NSCLC) about 6 months, has now completed three courses of cytotoxic chemotherapy, completing the third course about 10 days ago. He now presents to his local emergency department (ED) with a 3-day history of nausea, several episodes of vomiting, abdominal pain, and non-bloody diarrhea. He also complains of episodes of chills and nightsweats over the past 2 days. The patient states that he first noticed these symptoms following a church picnic that took place on a hot summer day. He and his wife had arrived at the picnic a bit late after the others had started eating. The patient states that he did wonder how long some of the food had been sitting out in the sun. STAT blood cultures are positive for nontyphoidal *Salmonella* (NTS).

What risk factors are present in this patient that may have predisposed him to developing Salmonella *bacteremia?*

What treatment strategy would you recommend? Are there any special considerations given this patient's immunosuppression?

Clinical Presentation and Diagnosis of Campylobacteriosis

- Incubation period of 1 to 7 days.
- A brief prodrome of fever, headache, and myalgias is followed by crampy abdominal pain, a high fever, and several bowel movements per day, which may be watery or bloody.
- The abdominal pain and tenderness may be localized, and pain in the right lower quadrant may mimic acute appendicitis. Abdominal pain is more prevalent in *Campylobacter* infection than in either *Shigella* or *Salmonella* infections.
- Tenesmus occurs in approximately 25% of patients.
- Fecal leukocytes and red blood cells (RBCs) are detected in the stools of 75% of infected individuals. Diagnosis of *Campylobacter* is established by stool culture.

Pathophysiology

Campylobacter spp. are gram-negative bacilli that have a curved or spiral shape. *Campylobacter* are sensitive to stomach acidity; as a result, diseases or medications that buffer gastric acidity may increase the risk of infection. The infectious inoculum for *C. jejuni* is low, similar to that for *Salmonella* spp. After an incubation period, infection is established in the jejunum, ileum, colon, and rectum.

Treatment

LO 3 Effective fluid and electrolyte replacement is the cornerstone of therapy for patients with *Campylobacter* infection. In most cases, this can be accomplished with the use of oral glucose–electrolyte solutions. Antibiotic therapy should be considered in patients with high fevers, bloody stools, symptoms lasting longer than 1 week, pregnancy, infection with HIV, and other immunocompromising conditions.

LO 4 Azithromycin is the recommended first-line drug (500 mg orally daily for 1–3 days) for the treatment of *Campylobacter* infections.[19] A fluoroquinolone or a tetracycline are alternatives; however, the widespread use of these agents in food animals has resulted in fluoroquinolone resistant *Campylobacter* strains worldwide.[18] *Campylobacter fetus* is the most commonly identified species in patients with bacteremia, which primarily occurs in patients who are elderly or immunocompromised. In addition, focal infections such as cellulitis, vascular infections, meningitis, and abscesses may be present. *C. fetus* has a predilection for the vascular endothelium and implanted medical devices.[20] For these serious infections, treatment with a third-generation cephalosporin, gentamicin, ampicillin, or a carbapenem is recommended.[19] LO 6 Antimotility agents should be avoided because they may prolong the duration of symptoms and have been associated with worse outcomes. Postinfectious complications associated with *Campylobacter* infection include reactive arthritis (1%) and Guillain-Barré syndrome (0.1%).

ENTEROHEMORRHAGIC *ESCHERICHIA COLI*

Epidemiology

KEY CONCEPT Blood in the stool indicates the possibility of inflammatory mucosal disease of the colon such as enterohemorrhagic Escherchia coli (EHEC), a pathogenic subgroup of shiga toxin-producing E. coli (STEC) and an

LO 1

Clinical Presentation and Diagnosis of EHEC

- Incubation period of 3 to 5 days.
- Bloody stools.
- Leukocytosis is often present; fever is frequently absent.
- Abdominal tenderness.
- HUS in 2% to 10% of patients (especially children 1–5 years of age and the elderly in nursing homes); develops on average 1 week after the onset of diarrhea.
- EHEC belonging to serotype 0157:H7 characteristically do not ferment sorbitol, whereas more than 70% of intestinal microbiome *E. coli* do. To properly screen EHEC strains in cases of diarrhea, stool should be placed on special sorbitol-MacConkey agar. In addition, stool should be tested directly for the presence of Stx I and II by enzyme immunoassay (EIA).

important cause of bloody diarrhea in the United States. Acute hemorrhagic colitis has been primarily associated with the O157:H7 serotype. This serotype is responsible for large outbreaks of infection, has higher rates of complications, and appears to be more pathogenic than non-EHEC STEC strains. The spectrum of disease associated with *E. coli* O157:H7 includes bloody diarrhea, which is seen in up to 95% of patients; nonbloody diarrhea; hemolytic-uremic syndrome (HUS); and thrombotic thrombocytopenic purpura (TTP).[21]

An estimated 265,000 STEC infections occur each year in the United States. Serotype O157:H7 causes about one-third of these infections. Very young children and the elderly are more likely to develop severe illness and HUS; however, healthy older children and young adults can also become seriously ill.[22] Outbreaks of diarrhea due to *E. coli* O157:H7 and other STECs have occurred following ingestion of contaminated beef, unpasteurized milk, vegetables (eg, alfalfa sprouts, coleslaw, and lettuce), and apple juice. The most important reservoir for *E. coli* O157:H7 is the GI tract of cattle. Person-to-person transmission also occurs, and swimming in infant pools or contaminated lakes or drinking contaminated municipal water are additional risk factors. The incidence of diagnosed *E. coli* O157:H7 infections in the United States is greater among rural populations and usually occur in summer and autumn months.

Pathophysiology

The infectious inoculum of EHEC is very low, between 1 and 100 colony-forming units (CFUs). The major virulence factor for EHEC is the production of two Shiga-like cytotoxins (Shiga toxin [Stx] I and II), which are responsible for vascular damage and systemic effects such as HUS. Adhesion mediates initial attachment of EHEC to intestinal epithelial cells. Following attachment, these organisms produce lesions on individual intestinal epithelial cells in the small or large intestine resulting in diarrhea.

Treatment

The only recommended treatment of EHEC infection is supportive, including fluid and electrolyte replacement, usually in the form of ORT. Most illnesses resolve in 5 to 7 days. Patients should be monitored for the development of HUS.[21] Antibiotics are currently contraindicated because they can induce the expression and release of toxin. Antimotility agents should be avoided because they delay clearance of the pathogen and toxin, which increases the risk of systemic complications. The incidence of HUS has declined in recent years and nonsteroidal anti-inflammatory drugs (NSAIDs) are increasingly recognized as an important contributor to acute kidney injury in infected children, especially if volume depleted.[23]

LO 6

Prevention of EHEC infection is especially important because no therapeutic interventions are available to lessen the risk of the development of HUS. Hamburgers should be cooked thoroughly until the temperature of the thickest part of the patty is 72°C. All surfaces and utensils that contact raw meat should be washed thoroughly before reuse. Fruits and vegetables should be washed thoroughly, especially those that will not be cooked. Handwashing is also very important and should include the supervision of handwashing by children in daycare centers.

CHOLERA

Epidemiology

Cholera is an intestinal infection that is caused by the bacterium *Vibrio cholerae* that leads to a massive loss of fluid through the GI tract and often results in life-threatening dehydration and shock. The biotypes of *V. cholerae* responsible for pandemics are serogroups O1 (El Tor) and O139. Worldwide this infection affects 3 to 5 million people and causes about 100,000 deaths per year, almost entirely in developing countries. Cholera can be transmitted by water or by food tainted with contaminated water, particularly undercooked seafood. Infants and young toddlers who are not breastfed at the time of exposure are at increased risk of infection.[24]

Pathophysiology

V. cholerae are gram-negative bacilli that pass through the stomach to colonize the upper small intestine. They possess filamentous protein extensions that attach to receptors on the intestinal mucosa, and their motility assists with penetration of the mucus layer. The cholera enterotoxin consists of two subunits, one of which (subunit A) is transported into the cells and causes an increase in cyclic adenosine monophosphate (cAMP), which leads to the secretion of fluid into the small intestine. This large volume of GI fluid results in the watery diarrhea that is characteristic of cholera and leads to stools made up of an electrolyte-rich isotonic fluid that is highly infectious. Low gastric acid levels have been associated with more severe disease.

Patient Encounter 3

A 26-year-old man is travelling to Mexico with his new bride for a 2-week honeymoon. On the fifth day of their trip, he notices an acute onset of very watery diarrhea following a buffet-style meal at his hotel. He also states that he enjoyed several mixed alcoholic drinks during the evening. He denies noting blood or pus in his stools, nor does he complain of any abdominal cramping. He is also noted to be afebrile.

What is the most likely organism infecting this patient?

Would loperamide be appropriate for the treatment of this patient?

If this patient had been prescribed an antibiotic before departing on this trip for empiric use, if needed, should he begin taking them at this time?

Is this patient at increased risk of developing hemolytic uremic syndrome (HUS)?

Clinical Presentation and Diagnosis of Cholera

- Incubation period of 18 hours to 5 days.
- Abrupt, painless onset of watery diarrhea and vomiting. The diarrheal fluid is usually clear and may be as much as 10 to 20 liters per day.
- Large volumes of rice-water stools, which may have fishy odor.
- Dehydration is often severe and puts patients at risk for death within hours of disease onset. Symptoms of severe dehydration include low blood pressure, poor skin turgor, sunken eyes, and rapid pulse.
- Severe muscle cramps in extremities are due to electrolyte imbalances caused by fluid loss. These cramps should resolve with treatment.
- Metabolic acidosis.

Treatment

LO4 LO5

The cornerstone of cholera treatment is fluid replacement. Without treatment, the case-fatality rate for severe cholera is approximately 50%. For cholera, rice-based ORT is better than glucose-based ORT because it reduces the number of stools. Antibiotic prophylaxis is not warranted. The current WHO treatment protocol recommends antibiotics for only "severe" symptoms; however, this is controversial and some expert groups argue that antibiotics should be used more liberally in significant outbreaks.[25] With effective antibiotic therapy, the illness is shortened by about 50%, and the duration of excretion of *V. cholerae* in the stool is shortened to 1 or 2 days.[26] Antibiotic treatment should be dictated by local antimicrobial susceptibility profiles. Azithromycin and ciprofloxacin are commonly used; doxycycline may be recommended in areas of low tetracycline resistance. Azithromycin may be more effective than ciprofloxacin in terms of shortened duration of diarrhea, reduced stool volume, and cessation of fecal excretion of cholera vibrios.[24] Azithromycin is preferred in children younger than 8 years old and pregnant women.

Primary preventive strategies include ensuring a safe water supply and safe food preparation, improving sanitation, and patient education. In 2016, the FDA approved the first and only vaccine in the United States for the prevention of cholera (Vaxchora®) due to serogroup 01. It is indicated for adults (age 18–64) travelling to an area of active *V. cholerae* 01 transmission who have risk factors for poor outcomes if infected. This is a live vaccine that is administered as a single dose a minimum of 10 days before potential exposure.

TRAVELER DIARRHEA

Epidemiology

Traveler's diarrhea (TD) commonly occurs when visitors from developed countries travel to developing countries. More than 50 million people are at risk for TD each year; the incidence of one episode of TD during a 2-week trip is 10% to 40%. These infections arise following the consumption of food or water contaminated with bacteria, viruses, or parasites. KEY CONCEPT Bacteria such as *Shigella*, *Salmonella*, *Campylobacter*, and enterotoxigenic *E. coli* (ETEC) are responsible for 60% to 85% of TD cases. Noroviruses are increasingly recognized as a significant cause of TD as well. Most of these illnesses occur during the first 2 weeks of travel and last about 4 days without therapy. Protozoans are an uncommon cause but should be suspected if diarrhea lasts for more than 2 weeks.[27]

Food and water contaminated with fecal matter are the main sources of pathogens that lead to TD. Particularly problematic foods and beverages include salads, unpeeled fruits, raw or poorly cooked meats and seafood, unpasteurized dairy products, and tap water (including ice). Food from street vendors and buffet-style meals are particularly risky. The consumption of more than five alcoholic drinks per day is a risk factor for TD, especially in males.

Clinical Presentation and Diagnosis of Traveler Diarrhea

- Frequent, loose stools
- Nausea and vomiting
- Abdominal pain
- Fecal urgency
- Dysentery
- Signs and symptoms related to specific causative pathogen

Pathophysiology

Enterotoxigenic *E. coli*, which is responsible for up to 70% of TD cases in Mexico, produces both heat-labile enterotoxins (LT) and heat-stable enterotoxins (ST). Both toxins demonstrate cellular mechanisms similar to those of cholera toxins and lead to a great increase in both fluid and electrolyte secretion. These *E. coli* strains are not invasive, as are the Shiga-toxin–producing EHEC strains. These organisms lead to a profuse, watery diarrhea without blood, leukocytes, or abdominal cramping.

Treatment

The goal of treatment is to maintain hydration and functional status and to prevent disruption of travel plans. For travelers with mild cases of diarrhea, oral rehydration salts can prevent and treat dehydration and may be particularly important for children and the elderly. Loperamide (to a maximum dose of 16 mg/day) may be used for milder diarrhea; however, this agent is not recommended for use alone if bloody diarrhea or fever is present. Antibiotics are effective at reducing the duration of illness to 1 or 2 days. Providing the traveler with a means for empiric self-treatment is an effective method of treating this illness without promoting the inappropriate use of antibiotics. Therapy should be initiated after the first episode of diarrhea that is uncomfortable or interferes with activities.[27] In general, levofloxacin or ciprofloxacin are recommended as first-line agents for travel to most parts of the world.[19,28] Azithromycin is an alternative and is preferred in areas where quinolone-resistant *Campylobacter* is prevalent (eg, Thailand, India). Azithromycin can also be used in pregnant women and children (10 mg/kg/day orally for 3 days).[28] Rifaximin, a nonabsorbed oral antibiotic, is approved for treatment of TD caused by ETEC in persons at least 12 years old and has been used off-label in younger children at a dose of 20 to 40 mg/kg/day for 4 days. This agent may be a good choice for persons traveling to destinations where ETEC is the predominant pathogen, such as Mexico. Many clinicians will recommend the use of loperamide in dysentery if it is combined with an antibiotic.[27]

KEY CONCEPT The education of travelers about high-risk food and beverages is an important component for travelers to at-risk regions. Slogans such as "peel it, boil it, cook it, or forget it" can help to remind travelers of the foods that may be contaminated; however, reduction in the incidence of TD is often more related to the level of santitation at the destination than specific interventions made by the traveler.[27] Antibiotic prophylaxis is not recommended by the CDC because it can lead to drug-resistant organisms, including extended-spectrum beta-lactamase (ESBL)-producing strains,[29] and may give travelers a false sense of security. However, some health care professionals do prescribe prophylactic antibiotics for those who are at high risk of developing TD (eg, immunocompromised persons, patients with impaired gastric acid production) or for those who cannot risk temporary incapacitation (eg, athletes, diplomats, business people). A fluoroquinolone antibiotic, such as levofloxacin or ciprofloxacin, is usually used first line for this purpose at a dose of one tablet daily during travel and for 2 days following return.[28] Although not approved for prophylaxis, rifaximin may be an option for travelers to Mexico because it is not absorbed and should be less likely to select out resistant organisms than are the fluoroquinolones. Bismuth subsalicylate (Pepto-Bismol; 525 mg orally four times daily for up to 3 weeks) provides a rate of protection of about 60% against TD in adults and children 12 years and older. It should be avoided in persons taking anticoagulants or other salicylates. The data supporting the use of synbiotics, prebiotics, and probiotics to minimize TD are not consistently strong and are not recommended for this purpose.[27] No effective vaccines are available for TD.

CLOSTRIDIUM DIFFICILE INFECTION

Epidemiology

C. difficile is the primary cause of hospital-acquired infectious diarrhea in hospitalized patients, including children. Both the incidence and severity of *C. difficile* infection (CDI) have been increasing in the United States.[30] The incidence of CDI has increased from 4.5 per 1000 adult discharges in 2001 to 8.2 per 1000 discharges in 2010. Annual attributable costs associated with CDI exceed $1.5 billion in the United States.[31] In 2011, an estimated 500,000 people suffered from CDI in the United States and 29,000 died within 30 days of CDI diagnosis. An increasing proportion of CDI patients have a community-acquired infection. These patients are often younger, lack traditional risk factors, and generally have less severe disease compared with those with hospital-acquired infections.[30] A primary risk factor in both adults and children for these community-acquired infections appears to be therapeutic gastric acid suppression.[32,33] In February, 2012, the FDA issued a warning that the use of PPIs may be associated with a higher risk for CDI. Common risk factors for hospital-acquired CDI include increasing age, severe underlying illness, intensive care unit admission, gastric acid suppression, and exposure to antimicrobials, especially broad-spectrum, multiple-drug regimens. KEY CONCEPT Nosocomial Clostridium difficile-associated diarrhea (CDAD) is almost always associated with antimicrobial use; therefore, unnecessary and inappropriate antibiotic therapy should be avoided. Clindamycin, fluoroquinolones, cephalosporins, and penicillins are antibiotics most commonly associated with CDAD, but almost all antibiotics except aminoglycosides have been implicated.[31]

Pathophysiology

C. difficile, a gram-positive, spore-forming anaerobe, is spread by the fecal–oral route, and patient-to-patient spread is an important mode of transmission within the hospital. The organism is ingested either as the vegetative form or spores, which can survive for long periods in the environment and can traverse the acidic stomach. In the small intestine, spores germinate into the vegetative form. Once the GI tract is colonized with spores, disruption of the gut flora, which occurs with antibiotic therapy, allows *C. difficile* to proliferate. Toxin production is essential for the disease to occur and is responsible for the inflammation, fluid and mucus secretion, and mucosal damage that lead to diarrhea or colitis.

Treatment

Patients who develop CDI while receiving an antibiotic should have the antibiotic discontinued, if possible. The use of concurrent antibiotics during CDI therapy, or soon thereafter, lowers the chances of a clinical cure and increases the risk of recurrence.[34] If antimicrobial therapy must continue, an attempt should be made to switch the patient to an agent with a lower risk of CDI.[31] Clinical practice guidelines recommend that initial antimicrobial therapy should be based on the severity of illness.[35]

Metronidazole (500 mg orally three times daily for 7–14 days; or, 30 mg/kg/day divided into four daily doses for children) is the recommended first-line drug for initial treatment of mild-to-moderate CDI. Oral vancomycin (125 mg four times daily for 7–14 days; or, 40–50 mg/kg/day divided into four daily doses for children) is the recommended first-line drug therapy for initial treatment of severe CDI,[35] which is usually defined as a serum creatinine increase to more than 1.5 times baseline or a white blood cell count greater than 15,000 cells/mm^3 (15 × 10^9/L). Other risk factors for severe disease include age more than 65 years, hypoalbuminemia, immunosuppression, and severe underlying disease. For the treatment of severe, complicated CDI (refractory hypotension, ileus, and/or toxic megacolon), a higher dose of vancomycin (500 mg orally four times daily) may be combined with IV metronidazole (500 mg every 8 hours). Vancomycin may be given as a retention enema (500 mg in 100 mL of normal saline every 6 hours) if a complete ileus is present.[35] The use of antimotility agents should be avoided because they may precipitate toxic megacolon. Surgical intervention may be lifesaving, particularly in cases complicated by toxic megacolon or colonic perforation. Antimicrobial stewardship programs can decrease the incidence of CDIs and better assure appropriate initial therapy.[36]

Fidaxomicin, a drug that is minimally absorbed, has no activity against organisms other than clostridia, and allows for preservation of normal gut flora, is also approved for the treatment of CDI. The recommended dose is 200 mg orally twice daily for 10 days. In clinical trials, there were fewer recurrences in patients treated with fidaxomicin compared with vancomycin.[37] Fidaxomicin is costly, but may be considered for recurrent CDI or where the risk of recurrence is high. One hospital that used fidaxomicin as first-line therapy for many patients with CDI noted a decreased readmission rate and overall decreased hospital costs versus vancomycin.[38]

The recurrence rate after an initial episode of CDI is approximately 20% to 25%, with the highest risk within the first 2 weeks.[39] This rate is independent of the initial antibiotic choice. Continuous use of acid suppression therapies increases the risk of CDI recurrences.[40] Treatment of the first recurrence of CDI is usually treated with the same regimen used for the initial episode; however, this choice should also depend on the clinical condition of the patient, as recommended for the initial therapy choice. Metronidazole should not be used beyond the first recurrence or for long-term chronic treatment due to the risk of neurotoxicity. The treatment of second or later recurrences of CDI should be undertaken with vancomycin using a tapered

Clinical Presentation and Diagnosis of CDAD

- Symptoms can start as early as the first day of antimicrobial therapy or several weeks after antibiotic therapy is completed.
- Asymptomatic carriage.
- Diarrhea:
  - Acute watery diarrhea with lower abdominal pain, low-grade fever, and mild or absent leukocytosis.
  - Mild, with only three or four loose watery stools per day.
  - *C. difficile* toxins are present in stool, but sigmoidoscopic examination is normal.
- Colitis:
  - Profuse, watery diarrhea with 5 to 15 bowel movements per day, abdominal pain, abdominal distention, nausea, and anorexia.
  - Left or right lower quadrant abdominal pain and cramps that are relieved by passage of diarrhea.
  - Dehydration and low-grade fever.
  - Sigmoidoscopic examination may reveal a nonspecific diffuse or patchy erythematous colitis with or without pseudomembranes.
- Toxic megacolon: Suggested by acute dilation of the colon to a diameter greater than 6 cm, associated systemic toxicity, and the absence of mechanical obstruction. It carries a high mortality rate.
- Fulminant colitis: Acute abdomen and systemic symptoms such as fever, tachycardia, dehydration, and hypotension. Some patients have marked leukocytosis (up to 40×10^3 white blood cells/mm^3 [40×10^9/L]). Diarrhea is usually prominent but may not occur in patients with paralytic ileus and toxic megacolon.
- Recurrent disease:
  - Risk factors include increased age, recent abdominal surgery, increased number of *C. difficile* diarrheal episodes, and leukocytosis.
  - 20% to 25% of patients develop a second episode of CDAD within 2 months of the initial diagnosis.
- In most cases, *C. difficile* toxin testing of a single unformed stool specimen effectively establishes the diagnosis. Stool culture is the most sensitive test, but it is not clinically practical due to slow turnaround time. Enzyme immunoassay (EIA) testing for toxin A and B is rapid, but less sensitive, and repeat testing may be necessary if the initial test is negative. Many labs now use newer tests, such as EIA detection of glutamate dehydrogenase (GDH) and polymerase chain reaction (PCR) technology. Leukocytosis, hypoalbuminemia, and fecal leukocytes are nonspecific but suggestive of *C. difficile* infection.
- In selected patients, sigmoidoscopy, colonoscopy, or abdominal CT scan can provide useful diagnostic information.

and/or pulse regimen.[35] Fidaxomicin may be superior to vancomycin at preventing CDAD recurrences secondary to non-NAP1/B1/027 strains.[37] Rifaximin, administered directly following a course of metronidazole or vancomycin, may be an option for the prevention of recurrent episodes of CDI in some patients. In 2016, the FDA approved bezlotoxumab, a human monoclonal antibody that binds to *C. difficile* toxin B, to reduce recurrence of CDI in patients at high risk for recurrence. This drug is administered as a single infusion (10 mg/kg); but, it is important to note it is not an antibacterial drug and must be used in conjunction with antibacterial drug treatment.[41] Fecal microbiota transplantation (FMT) has a reported efficacy of about 90% in preventing recurrent CDI and this therapy is emerging as a first-line option for patients with multiple recurrent episodes of CDI.[42]

Strict infection control measures, including contact precautions, should be instituted for all patients with CDAD. Environmental

Patient Encounter 4

A 56-year-old woman with a history of stage III COPD presents to her local medical hospital complaining of acute onset shortness-of-breath and a worsening and more productive cough. She is admitted to the general medicine floor of the hospital with a presumed community-acquired pneumonia and COPD exacerbation. Upon admission, this patient also complains of a bothersome case of diarrhea that has been present for about the past week. She thought it may be due to "something she ate," but it has begun to concern her because it does not seem to be going away. Upon chart review, you note that this patient was in the hospital 3 weeks ago, at which time she was treated for pneumonia for 10 days with cefepime and levofloxacin. She also received pantoprazole at that time for SRMD prophylaxis and was continued on it at discharge with an outpatient prescription. Upon this admission, she is noted to be afebrile, her white blood cell count is 11,800/μL (11,800/10^9/L) and her serum creatinine is 1.3 mg/dL (99.2 μmol/L), which is stable upon comparison with her previous hospital admission. A chest x-ray is negative for infiltrates or any acute changes since the last admission. Due to her recent history of antibiotic use and new-onset diarrhea, a stool sample is sent to the microbiology lab for a *C. difficile* toxin determination.

Should this patient be prescribed diphenoxylate/atropine (Lomotil®) to decrease her diarrhea while the C. difficile *toxin lab is pending?*

What antimicrobial therapy should you recommend for this patient? Should an antimicrobial agent be started prior to receiving the C. difficile *toxin lab result?*

The C. difficile *toxin report comes back from the lab and is positive. What should you recommend regarding the antibiotics (ceftriaxone and azithromycin) that were started on admission to treat this patient's presumed pneumonia?*

Assuming this patient is successfully treated for her CDI, what is the risk of the infection recurring? If it does recur, what antimicrobial agent should be recommended to treat the first recurrence?

cleaning with chlorine-containing agents should be used to eliminate *C. difficile* spores. Because alcohol is ineffective in killing spores, it is essential that health care workers wash their hands with soap and water rather than using alcohol-based hand sanitizers. Meticulous handwashing is the single most important strategy to decrease the patient-to-patient transmission of *C. difficile*. Although some systematic reviews have concluded that the use of probiotics may help prevent CDIs,[43] randomized controlled trials (RCTs) have failed to do so.[44] Probiotics should not be recommended for the prevention of CDI in hospitalized patients without additional evidence from RCTs.

CRYPTOSPORIDIOSIS

Epidemiology

Cryptosporidiosis has been recognized as a human disease since the 1970s, with increasing importance in the 1980s and 1990s because of its relationship with HIV/AIDS. *Cryptosporidium* is now recognized as a major cause of diarrhea in children, especially those less than 2 years old,[45] and has been linked with childhood malnutrition and death in low resource settings. Studies using PCR and antigen detection have identified Cryptosporidium in 15% to 25% of children with diarrhea, which is often prolonged (7–14 days) or persistent (> 14 days).[46] Incident rates have also increased in the United States, which is partially attributed to recreational water outbreaks and likely reflects increased use of communal swimming venues (eg, lakes, swimming pools, and water parks) by young children.[47]

Cryptosporidiosis is spread person-to-person, usually via the fecal–oral route; by animals, particularly cattle and sheep; and through the environment, especially water.

Pathophysiology

Cryptosporidium is an intracellular protozoan parasite that is capable of completing its entire life cycle within one host. Humans become infected upon ingestion of the oocysts, and autoinfection and persistent infections are possible owing to repeated life cycles within the GI tract. As few as 10 to 100 oocysts can cause infection.

Treatment

In general, immunocompetent persons and those with asymptomatic infection do not require antimicrobial therapy. In patients with HIV/AIDS, the optimal therapy is restoration of immune function through use of antiretroviral therapy (ART). For persons in whom antimicrobial therapy is deemed necessary or in HIV/AIDS patients in whom ART is ineffective, a combination of an antimicrobial and an antidiarrheal agent is recommended.[46]

Clinical Presentation and Diagnosis of Cryptosporidiosis

General

- 7- to 10-day incubation period.
- Profuse, watery diarrhea with mucus but not blood or leukocytes that lasts for approximately 2 weeks.
- Nausea, vomiting, fever, and abdominal cramps may accompany the diarrhea.
- Simplest method of diagnosis is detection of oocysts by modified acid-fast staining of a stool specimen. Standard ova and parasite test does not include *Cryptosporidium*.

Immunocompetent

- May manifest as asymptomatic disease, acute diarrhea, or persistent diarrhea lasting for several weeks.
- Usually self-limiting.

Immunocompromised

- May manifest as asymptomatic disease, chronic diarrhea lasting at least 2 months, or fulminant infection with at least 2 L of watery stool per day.
- In HIV-infected individuals, asymptomatic disease is more common in those with a $CD4^+$ cell count greater than 200 cells/mm^3 (200 × 10^6/L), and fulminant infection is more common in those with a $CD4^+$ cell count of less than 50 cells/mm^3 (50 × 10^6/L).

Nitazoxanide is the only FDA-approved agent for the treatment of cryptosporidiosis in adults and children 1 year and older. This agent has demonstrated efficacy in cryptosporidiosis in immunocompetent persons, malnourished children, and HIV/AIDS patients. Patients who are infected with both HIV and *Cryptosporidium* usually require longer therapy durations and higher doses than immunocompetent patients. Alternative agents include paromomycin, azithromycin, and clarithromycin.[46]

VIRAL GASTROENTERITIS

KEY CONCEPT Viruses are the most common cause of diarrheal illness in the world and, in the United States, account for 450,000 illnesses and 160,000 hospitalizations for adults and children, respectively, and more than 4000 deaths. Many viruses may cause gastroenteritis, including rotaviruses, noroviruses, astroviruses, enteric adenoviruses, and coronaviruses (Table 76–3). This chapter focuses on rotaviruses.

Table 76–3

Agents Responsible for Acute Viral Gastroenteritis and Diarrhea

Virus	Peak Age	Peak Time	Duration	Transmission	Symptoms
Rotavirus	6 months–2 years	Winter	3–8 days	Fecal–oral, water, food	Diarrhea, vomiting, fever, abdominal pain
Enteric adenovirus	< 2 years	Year-round	7–9 days	Fecal–oral	Diarrhea, respiratory symptoms, vomiting, fever
Astrovirus	< 7 years	Winter	1–4 days	Fecal–oral, water, shellfish	Vomiting, diarrhea, fever, abdominal pain
Noroviruses	> 5 years	Variable	12–24 hours	Fecal–oral, food, aerosol	Nausea, vomiting, diarrhea, abdominal cramps, headache, fever, chills, myalgia

Modified from Martin S, Jung R. Gastrointestinal infections and enterotoxigenic poisonings. In: DiPiro JT, Talbert RL, Yee GC, et al, eds. Pharmacotherapy: A Pathophysiologic Approach, 8th ed. New York: McGraw-Hill; 2011:1951–1967.

Clinical Presentation and Diagnosis of Rotavirus Infection

- Incubation period of 2 days.
- 2- to 3-day prodrome of fever and vomiting.
- Profuse diarrhea without blood or leukocytes (up to 10–20 stools per day).
- Severe dehydration.
- Anorexia.
- Fever may be present.
- Presentation in adults may vary from asymptomatic to nonspecific symptoms of headache, malaise, and chills to severe diarrhea, nausea, and vomiting.
- Diagnosis can be made by polymerase chain reaction (PCR) of the stool.

Patient Encounter 5

A young woman comes into your pharmacy to pick up a pediatric oral electrolyte solution recommended by her child's doctor for her 3-year-old child's mild dehydration. Her child has been ill with a gastroenteritis for the last 3 days and she vocalizes that unfortunately her child has contracted some sort of GI bug 3 to 4 times a year since he has been a young infant. He had not been able to receive the preventative vaccine the child's doctor had recommended because it contains cow proteins and she and her husband are devout Hindus. She is also concerned about the mercury content in vaccines and has been very careful about what vaccines she has allowed herself and her family to receive. She has also heard that the rotavirus vaccine can cause an intestinal blockage in infants. You note she looks about ready to deliver and when you ask her, she indicates that her due date is in 2 weeks.

What scientific findings could you discuss with this mother to persuade her to get her soon-to-be newborn immunized for rotavirus?

ROTAVIRUS

Rotavirus causes between 600,000 and 875,000 deaths each year, with the highest rates in the very young and in developing countries. Rotavirus is the leading cause of childhood gastroenteritis and death worldwide. Most infections occur in children between 6 months and 2 years of age, typically during the winter season, but adults may be infected as well. Worldwide, rotavirus causes more than 2 million hospitalizations and 600,000 deaths per year in children younger than 5 years of age and approximately 60,000 hospitalizations in the United States each year. Almost all children will experience at least one episode of rotavirus infection before 5 years of age. Person-to-person transmission occurs through the fecal–oral route.

The mechanism of diarrhea has not been clearly elucidated, but theories include a reduction in the absorptive surface along with impaired absorption owing to cellular damage, enterotoxigenic effects of a rotavirus protein, and stimulation of the enteric nervous system.

The cornerstone of rotavirus treatment is supportive care and rehydration with ORT or IV fluids. Antimotility and antisecretory agents should not be used owing to their potential side effects in children and the self-limited nature of the disease. KEY CONCEPT Two oral rotavirus vaccines are currently approved by the FDA and, since their introduction, these vaccines have reduced diarrhea-related health care use in children by as much as 94% and have conferred protection on unvaccinated children (herd immunity). This reduction in health care usage has saved an estimated $1 billion over a 4-year period.[48,49] The CDC Advisory Committee on Immunization Practices recommends vaccination at 2, 4, and 6 months for *RotaTeq* and 2 and 4 months for *Rotarix*. There is a small risk of intussusception from rotavirus vaccination within a week or two of the first 2 doses. This risk is estimated to be between 1 in 20,000 and 1 in 100,000 infants who receive the vaccine.[50]

LO 7

FOOD POISONING

Each year in the United States, approximately 76 million food-borne illnesses occur, leading to 325,000 hospitalizations and more than 5000 deaths. Many bacterial and viral pathogens that have been discussed previously in this chapter (eg, *Salmonella, Shigella, Campylobacter, E. coli*, and noroviruses) can cause food poisoning. Other bacteria that can cause food-borne illness include *Staphylococcus aureus, C. perfringens, Clostridium botulinum,* and *Bacillus cereus* (Table 76–4). Food poisoning should be suspected if at least two individuals present with similar symptoms after the ingestion of a common food in the prior 72 hours.

Table 76–4

Food Poisonings

Organism	Onset (Hours)	Associated Foods	Duration	Symptoms	Treatment
Staphylococcus aureus	1–6	Salad, pastries, ham, poultry	12 hours	Nausea, vomiting	Supportive
Bacillus cereus—emetic	0.5–6	Rice, noodles, pasta, pastries	24 hours	Vomiting	Supportive
Bacillus cereus—diarrheal	8–16	Meats, vegetables, soups, sauces, milk products	24 hours	Diarrhea, abdominal pain	Supportive
Clostridium perfringens (type A)	8–12	Meats, poultry	24 hours	Nausea; abdominal cramps; profuse, watery diarrhea	Supportive
Clostridium botulinum	18–24	Canned fruits, vegetables, meats, honey, salsa, relish	Weeks	Acute GI symptoms followed by symmetric, descending, flaccid paralysis; death is possible	Supportive (including mechanical ventilation); trivalent antitoxin

Patient Care Process

Collect Information:

- Perform a medication history for use of prescription and nonprescription medications and dietary supplements.
- Identify allergies or rashes to medications and other substances.
- Review the medical history and physical assessment findings. In a child the growth curves and immunization records are especially important.
- Speak with the patient's parents to identify feeding and food preferences, any cultural beliefs, health goals, or socioeconomic factors that affect medication access, vaccination compliance, and other aspects of care.

Assess the Information:

- Determine if the patient is taking any substance that could interact with prescription medications (eg, vitamins, iron drops, probiotics).
- Based on medical history, determine if the patient has risk factors for GI disorders, such as diarrhea, *C. difficile* colitis, etc.
- Based on physical examination and review of systems, identify signs or symptoms associated with diarrhea or possible *C. difficile* infection.
- Determine the child's growth history from growth curve or parents and determine if weight loss has occurred.
- Determine the cause of any weight loss (eg, anorexia, dehydration, insufficient calories).
- Determine adherence to current medication regimen.
- Identify potential adverse drug events or drug interactions with medication regimen.

Develop a Care Plan:

- Determine if the child is currently showing symptoms of reflux (spitting up, regurgitation of feedings, vomiting) and whether omeprazole is still needed.
- Determine whether treatment of otitis meets current guidelines.
- Determine whether immunizations are needed in the near future.

Implement the Care Plan:

- Determine if the patient has insurance coverage and if recommended agents are included in the health system's formulary.
- Educate the patient's parents about changes in drug therapy, the administration of liquid medications, potential adverse effects associated with the new antibiotic, and how to manage and report adverse effects that may occur.
- Dialogue with parents about concerns or past problems administering liquid medications; suggest possible solutions.
- Indicate what actions to take if the child vomits the dose or the parents forget to administer a dose.
- Counsel parents on recognition of symptoms of *C. difficile* infection, serious diarrhea, and dehydration and actions to take if these occur, including notification of the child's primary care physician.
- Discuss importance of completing the full antibiotic course and routine vaccinations.

Follow-up: Monitor and Evaluate:

- Offer assistance for follow-up for parents who have problems administering medications or who need help with choosing an oral rehydration solution.
- Follow-up assessing for symptoms of chronic diarrhea.
- Follow-up the child's weight gain using a child-specific growth curve.

Abbreviations Introduced in This Chapter

CDAD	*Clostridium difficile*-associated diarrhea
CDC	Centers for Disease Control and Prevention
CDI	*Clostridium difficile* infection
CFUs	Colony-forming units
EHEC	Enterohemorrhagic *Escherichia coli*
ESBL	Extended-spectrum beta-lactamase
FMT	Fecal microbiota transplantation
HUS	Hemolytic-uremic syndrome
ORT	Oral rehydration therapy
MIC	Minimum inhibitory concentration
NSAID	Nonsteroidal anti-inflammatory drug
NTS	Nontyphoidal *Salmonella*
PPI	Proton-pump inhibitor
STEC	Shiga toxin-producing *E. coli*
TTP	Thrombotic thrombocytopenic purpura
WHO	World Health Organization

77 Intraabdominal Infections

Joseph E. Mazur and Melanie N. Smith

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

1. Define and differentiate between primary and secondary intraabdominal infections (IAIs).
2. Describe the microbiology typically seen with primary and secondary IAIs.
3. Describe the clinical presentation typically seen with primary and secondary IAIs.
4. Describe the role of culture and susceptibility information for diagnosis and treatment of IAIs.
5. Recommend the most appropriate drug and nondrug measures to treat IAIs.
6. Recommend an appropriate antimicrobial regimen for treatment of primary and secondary IAIs.
7. Describe the patient-assessment process during the treatment of IAIs.
8. Introduce the concepts of antimicrobial stewardship programs (ASPs) and antimicrobial de-escalation as it pertains to the treatment of IAIs.

INTRODUCTION

Intraabdominal infections (IAIs) are those contained within the peritoneal cavity or retroperitoneal space. The peritoneal cavity extends from the undersurface of the diaphragm to the floor of the pelvis and contains the stomach, small bowel, large bowel, liver, gallbladder, and spleen. The duodenum, pancreas, kidneys, adrenal glands, great vessels (aorta and vena cava), and most mesenteric vascular structures reside in the retroperitoneum, which is the anatomical space in the abdominal cavity behind the peritoneum. IAIs may be generalized or localized. They may be contained within visceral structures, such as the liver, gallbladder, spleen, pancreas, kidney, or female reproductive organs. Two general types of IAI are discussed throughout this chapter: peritonitis and abscess. **Peritonitis** is defined as the acute inflammatory response of the peritoneal lining to microorganisms, chemicals, irradiation, or foreign-body injury.

An **abscess** is a purulent collection of fluid separated from surrounding tissue by a wall consisting of inflammatory cells and adjacent organs. It usually contains necrotic debris, bacteria, and inflammatory cells. Peritonitis and abscess differ considerably in presentation and approach to treatment.

EPIDEMIOLOGY AND ETIOLOGY

LO 1

Peritonitis may be classified as primary, secondary, or tertiary. Primary peritonitis, also called spontaneous bacterial peritonitis, is an infection of the peritoneal cavity without an evident source of bacteria from the abdomen.[1,2] In secondary peritonitis, a focal disease process is evident within the abdomen. Secondary peritonitis may involve perforation of the gastrointestinal (GI) tract (possibly because of ulceration, ischemia, or obstruction), postoperative peritonitis, or posttraumatic peritonitis (eg, blunt or penetrating trauma). Tertiary peritonitis occurs in critically ill patients, and it is an infection that persists or recurs at least 48 hours after apparently adequate management of primary or secondary peritonitis. Factors related to the development of tertiary peritonitis are not well described although it is more often associated with opportunistic and nosocomial pathogens.

KEY CONCEPT Most IAIs are secondary infections that are caused by a defect in the GI tract that must be treated by surgical drainage, resection, and/or repair. The prevalence of primary peritonitis is 10% to 30% in hospitalized patients with alcoholic cirrhosis.[3] Patients undergoing continuous ambulatory peritoneal dialysis (CAPD) average one episode of peritonitis every 2 years.[4] The majority of these are related directly to the peritoneal dialysis (PD) rather than nondialysis-related intraabdominal or systemic processes. Secondary peritonitis may be caused by perforation of a peptic ulcer; traumatic perforation of the stomach, small or large bowel, uterus, or urinary bladder; appendicitis; pancreatitis; diverticulitis; bowel infarction; inflammatory bowel disease; cholecystitis; operative contamination of the peritoneum; or diseases of the female genital tract such as septic abortion, postoperative uterine infection, endometritis, or salpingitis. Appendicitis is one of the most common causes of IAI.[5]

Primary peritonitis in adults occurs most commonly in association with alcoholic cirrhosis, especially in the end stage, or with ascites caused by postnecrotic cirrhosis, chronic active hepatitis, acute viral hepatitis, congestive heart failure, malignancy, systemic lupus erythematosus, and nephrotic syndrome. It also may result from the use of a peritoneal catheter for dialysis with renal failure or central nervous system (CNS) ventriculoperitoneal shunting for hydrocephalus. Abscesses are the result of chronic inflammation and may occur without preceding generalized peritonitis. They may be located within the peritoneal cavity or in a visceral organ and may vary in size, taking a few weeks to years to form.

Patient Encounter 1, Part 1

A 56-year-old woman with a history of epilepsy presents to the surgery clinic with chief complaints of abdominal pain. She had a cholecystectomy 2 weeks ago and had an uneventful course. Her current medications are oxycodone 10 mg orally every 6 hours, acetaminophen 500 mg orally every 6 hours as needed, and divalproex sodium ER 250 mg orally every day. On the previous hospital course, she was treated with a 2-day course of ceftriaxone.

PMH: Epilepsy and CKD, stage 3

Meds: Oxycodone 10 mg orally every 6 hours, acetaminophen 500 mg orally every 6 hours as needed, divalproex sodium ER 250 mg daily

SOC: Single, no alcohol, smoking, or illicit drugs

PE:

Tender, hard, distended abdomen, negative bowel sounds. Rest of the physical examination is noncontributory.

VS: T 100.4°F (38.0°C), BP 100/70 mm Hg, P 124 beats/min, RR 22 breaths/min, Wt 140 lb (63.6 kg), Ht 5′5″ (165 cm)

Labs: Hct 15.0% (0.150), Hgb 5.1 g/dL (51 g/L; 3.17 mmol/L), WBC 14 × 10^3/mm^3 (14 × 10^9/L), serum creatinine 3.2 mg/dL (283 µmol/L), BUN 30 mg/dL (10.7 mmol/L), Na 140 mEq/L (140 mmol/L), K 4.9 mEq/L (4.9 mmol/L), Cl 95 mEq/L (95 mmol/L), CO_2 20 mEq/L (20 mmol/L), total bilirubin 1.8 mg/dL (30.8 µmol/L), aPTT 32.0 seconds

Comment on the diagnostic approach which should be taken in this patient in order to determine a diagnosis.

What are the top two diagnoses that could be made for this patient?

Based on your assessment of her medication history, are there any of her medications that could be potentiating her clinical condition?

What pharmacotherapeutic treatments should the pharmacy clinician focus on?

Patient Encounter 2, Part 1

A 65-year-old man with a history of hypertension, diabetes, and ESRD on CAPD presents to the emergency room with a 3-day history of fevers and abdominal pain. His surgical history comprises an appendectomy (3 years ago) and PD catheter placement (2 years ago). He has had three cases of bacterial peritonitis in the past 2 years with the last case being polymicrobial including *Pseudomonas aeruginosa* with increasing patterns of resistance. His lab values are as follows:

PMH: Hypertension, diabetes, and ESRD with residual renal function of 50 mL/day

Meds: Lisinopril 20 mg orally daily, metformin 1000 mg orally twice daily, aspirin 81 mg daily

SOC: Single, no alcohol, smoking, or illicit drugs

PE:

The patient is tender to palpation and winces in pain.

VS: T 101°F (38.3°C), BP 110/75 mm Hg, P 99 beats/min, RR 12 breaths/min, Wt 250 lb (dry weight on admission [114 kg]), Ht 6′2″ (188 cm)

Labs: Na 142 mEq/L (142 mmol/L), K 4.5 mEq/L (4.5 mmol/L), Cl 95 mEq/L (95 mmol/L), CO_2 22 mEq/L (22 mmol/L), glucose 250 mg/dL (13.9 mmol/L), BUN 42 mg/dL (15.0 mmol/L), serum creatinine 4.2 mg/dL (371 µmol/L), total bilirubin 1.2 mg/dL (20.5 µmol/L), lactate 4.0 mg/dL (0.44 mmol/L), Hct 30% (0.30), Hgb 10 g/dL (100 g/L; 6.21 mmol/L), WBC 14.5 × 10^3/mm^3 (14.5 × 10^9/L).

What test(s) or lab(s) should be done to ascertain the cause of his continued fevers and abdominal pain?

Which monitoring parameters should be monitored in the next 24 to 48 hours?

What pharmacological treatment (fluids, antibiotics, and doses)? What potential toxicities exist?

List the most likely organisms and resistance patterns that can result from overuse of antimicrobials for intraabdominal processes.

PATHOPHYSIOLOGY

IAI results from bacterial entry into the peritoneal or retroperitoneal spaces or from bacterial collections within intraabdominal organs. In primary peritonitis, bacteria may enter the abdomen via the bloodstream or the lymphatic system by transmigration through the bowel wall, through an indwelling PD catheter, a ventriculoperitoneal catheter, or via the fallopian tubes in females. Hematogenous bacterial spread (through the bloodstream) occurs more frequently with tuberculosis peritonitis or peritonitis associated with cirrhotic ascites. When peritonitis results from PD, skin-surface flora are introduced via the peritoneal catheter. In secondary peritonitis, bacteria most often enter the peritoneum or retroperitoneum as a result of perforation of the GI or female genital tracts caused by diseases or traumatic injuries.

If bacteria that enter the abdomen are not contained by cellular and humoral defense mechanisms, bacterial dissemination occurs throughout the peritoneal cavity, resulting in peritonitis. This is more likely to occur in the presence of a foreign body, hematoma, necrotic tissue, large bacterial inoculum, continuing bacterial contamination, and contamination involving a mixture of synergistic organisms.

The fluid and protein shift into the abdomen (called **third spacing**) may be so dramatic that circulating blood volume is decreased, which causes decreased cardiac output and hypovolemic shock. Fluid shifts into the peritoneum occur secondary to inflammatory processes and leaky capillaries, as well as sepsis. Accompanying fever, vomiting, or diarrhea may worsen the fluid imbalance. A reflex sympathetic response, manifested by sweating, tachycardia, and vasoconstriction, may be evident. With an inflamed peritoneum, bacteria and endotoxins are absorbed easily into the bloodstream (**translocation**), and this may result in septic shock.[1] Other foreign substances present in the peritoneal cavity potentiate peritonitis, notably feces, dead tissue, barium from medical imaging procedures, mucus, bile, and blood.

Many of the manifestations of IAIs, particularly peritonitis, result from cytokine activity. Inflammatory cytokines are produced by macrophages and neutrophils in response to

bacteria and bacterial products or to tissue injury, resulting from the surgical incision.[1] The outer membrane components of gram-negative and gram-positive organisms contribute to the cascade of proinflammatory cytokines, ultimately leading to end-organ dysfunction (lungs, heart, kidneys) and septic shock.[6] Peritonitis may result in death because of the effects on major organ systems.

An abscess occurs if peritoneal contamination is localized but bacterial elimination is incomplete. The location of the abscess often is related to the site of primary disease. For example, abscesses resulting from appendicitis tend to appear in the right lower quadrant or the pelvis; those resulting from diverticulitis tend to appear in the left lower quadrant or pelvis. A mature abscess may have a fibrinous capsule that isolates bacteria and the liquid core from antimicrobials and immunologic defenses. In such cases, surgical drainage is the only effective therapy.

Microbiology of Intraabdominal Infection

LO 2

KEY CONCEPT Primary bacterial peritonitis is often caused by a single organism. In children, the pathogen is usually *Streptococcus pneumoniae* or a group A *Streptococcus*, *Escherichia coli*, or *Bacteroides* species.[4,7] When peritonitis occurs in association with cirrhotic ascites, *E. coli* and *Klebsiella* are isolated most frequently.[8] Other potential pathogens are *Haemophilus pneumoniae*, *Pseudomonas*, anaerobes, and *S. pneumoniae*.[9] Occasionally, primary peritonitis may be caused by *Mycobacterium tuberculosis*. Peritonitis in patients undergoing PD is caused most often by common skin organisms ranging from *Staphylococcus aureus* to *Staphylococcus epidermidis*.[10]

KEY CONCEPT Because of the diverse bacteria present in the GI tract, secondary intraabdominal infections are often polymicrobial.[2,11]

Bacterial Synergism and Other Factors

A combination of aerobic and anaerobic organisms appears to increase the severity of infection (synergism). Facultative bacteria (eg, *E. coli*) may provide an environment conducive to the growth of anaerobic bacteria.[2] Although many bacteria isolated in mixed infections are nonpathogenic by themselves, their presence may be essential for the pathogenicity of the bacterial mixture.[3]

Complicating the clinical picture for treatment are polymicrobial IAIs with certain bacterial species being isolated such as enterococci or *P. aeruginosa*. Depending on the patient's immune system (immunocompromised host), targeting these organisms may be necessary to avoid treatment failure or mortality.[12]

CLINICAL PRESENTATION AND DIAGNOSIS

IAIs have a wide spectrum of clinical features. Peritonitis usually is easily recognized, but intraabdominal abscess often may continue unrecognized for long periods of time. Patients with primary and secondary peritonitis present quite differently.

Clinical Presentation of Primary Peritonitis

LO 3

General

Patients may not be in acute distress, particularly with peritoneal dialysis (PD)-related peritonitis.

Symptoms

Patients may complain of nausea, vomiting (sometimes with diarrhea), and abdominal tenderness.

Signs

- Temperature may range from only mildly elevated to significantly elevated. In patients undergoing PD, temperature may not be elevated.
- Bowel sounds may be hypoactive.
- Cirrhotic patients may have worsening encephalopathy.
- There may be cloudy dialysate fluid with PD.

Laboratory Tests

- The WBC may range from mildly elevated to significantly elevated.
- Ascitic fluid usually contains more than $0.25 \times 10^3/mm^3$ ($0.25 \times 10^9/L$) leukocytes, and bacteria may be evident on gram stain of a centrifuged specimen.

Other Diagnostic Tests

Culture of peritoneal dialysate or ascitic fluid should be positive.

TREATMENT

The primary goals of treatment are correction of the intraabdominal disease processes or injuries that have caused infection and drainage of collections (source control) of purulent material (abscess). A secondary objective is to resolve the infection without major organ system complications (eg, pulmonary, hepatic, cardiovascular, or renal failure) or adverse drug effects. Ideally, the patient should be discharged from the hospital with full function for self-care and routine daily activities.

General Approach to Treatment

The treatment of IAI most often requires the coordinated use of four major modalities: (a) prompt drainage, (b) support of vital functions, (c) appropriate antimicrobial therapy to treatinfection not eradicated by surgery,[13] and (d) antimicrobial stewardship principles.[14,15] Antimicrobials are an important adjunct to drainage procedures in the treatment of secondary IAIs; however, the use of antimicrobial agents without surgical intervention, especially in secondary peritonitis, usually is inadequate. For most cases of primary peritonitis, drainage procedures may not be required, and antimicrobial agents become the mainstay of therapy.

KEY CONCEPT In the early phase of serious IAIs, attention should be given to preserving major organ system function. With generalized peritonitis, large volumes of intravenous (IV) fluids are required to maintain intravascular volume, to improve cardiovascular function, and to ensure adequate tissue perfusion and oxygenation. Adequate urine output should be maintained to ensure appropriate fluid resuscitation and to preserve renal function. A common cause of early death is hypovolemic shock caused by inadequate intravascular volume expansion and tissue perfusion.

An additional important component of therapy is nutrition. IAIs often involve the GI tract directly or disrupt its function (paralytic ileus). The return of GI motility may take days, weeks, and occasionally, months. In the interim, enteral or parenteral

LO 3

Clinical Presentation of Secondary Peritonitis

General

Patients may be in acute distress.

Symptoms

- Patients may complain of nausea, vomiting, and generalized abdominal pain.
- Patients may demonstrate abdominal guarding and rigidity.

Signs

- Sweating, tachypnea, and tachycardia are present.
- Temperature is normal initially, then may increase to 100°F to 102°F (37.8–38.9°C) within the first few hours, and may continue to rise for the next several hours.
- Hypotension and shock may develop if intravascular volume is not restored.
- Decreased urine output may develop secondary to dehydration or intravascular volume depletion.
- Bowel sounds are faint initially and eventually cease.

Laboratory Tests

- The WBC count is typically high (WBCs 15–20 × 10^3/mm^3 [15–20 × 10^9/L]), with neutrophils predominating and an elevated percentage of immature neutrophils (bands).
- The hematocrit and blood urea nitrogen increase because of dehydration.
- Hyperventilation and vomiting result in early alkalosis, which changes to acidosis and lactic academia due to reduced intravascular volume and diminished tissue perfusion.

Other Diagnostic Tests

Abdominal radiographs may be useful because free air in the abdomen (indicating intestinal perforation) or distension of the small or large bowel is often evident.

nutrition as indicated facilitates improved immune function and wound healing to ensure recovery.

Nonpharmacologic Therapy

▶ *Drainage Procedures*

Primary peritonitis is treated with antimicrobials and rarely requires drainage. Secondary peritonitis requires surgical removal of the inflamed or gangrenous tissue to prevent further bacterial contamination. If the surgical procedure is suboptimal, attempts are made to provide drainage of the infected or gangrenous structures.

The drainage of purulent material is the critical component of management of an intraabdominal abscess. This may be performed surgically or with percutaneous image-guided techniques.[16] Without adequate drainage of the abscess, antimicrobial therapy and fluid resuscitation can be expected to fail. In addition, the most valuable microbiologic information may be obtained at the time of percutaneous or operative abscess drainage.

LO 4

▶ *Fluid Therapy*

LO 5

In patients with peritonitis, hypovolemia is often accompanied by acidosis, and large volumes of an IV solution such as lactated Ringer's may be required initially to restore intravascular volume. Maintenance fluids should be instituted (after intravascular volume is restored) with 0.9% sodium chloride and potassium chloride (20 mEq/L [20 mmol/L]) or 5% dextrose and 0.45% sodium chloride with potassium chloride (20 mEq/L [20 mmol/L]). The administration rate should be based on estimated daily fluid loss through urine and nasogastric suction, including 0.5 to 1.0 L for insensible fluid loss. Aggressive fluid therapy often must be continued in the postoperative period because fluid will continue to sequester in the peritoneal cavity, bowel wall, and lumen.

Pharmacologic Therapy

▶ *Antimicrobial Therapy*

The goals of antimicrobial therapy are as follows:

- To control bacteremia and prevent the establishment of metastatic foci of infection
- To reduce suppurative complications after bacterial contamination
- To prevent local spread of existing infection
- To de-escalate antimicrobials as soon as pathogens are identified and culture and sensitivity data are reported

KEY CONCEPT An empirical antimicrobial regimen should be started as soon as the presence of IAI is suspected and before identification of the infecting organisms is complete. Therapy must be initiated based on the likely pathogens, which vary

Patient Encounter 1, Part 2: Physical Examination and Diagnostic Tests

PE:

The patient is experiencing more pain (8/10 pain scale) and the attending physician decides to perform an invasive test.

Ascitic fluid analysis is reported as following: hazy yellow color with 3225/mm^3 (3.225 × 10^9/L) WBC, (40% [0.40] neutrophils, 5% [0.05] lymphocytes, 55% [0.55] macrophages). Urinalysis is not significant because the patient is oliguric. Other physical examination findings are nonsignificant.

VS: As noted previously

Labs: As noted previously

Serum: As noted previously

KUB: Negative findings

DPL (diagnostic peritoneal lavage): 3225/mm^3 (3225 × 10^9/L)

Microbiological cultures: 2/2 bottles from the blood positive for gram-positive pairs in chains and gram-negative bacilli.

Discuss the most appropriate pharmacologic course of treatment, outlining medications, dosing, and monitoring parameters.

List the goals of treatment and follow-up plan that should be developed by the clinician to ensure positive patient outcomes.

Patient Encounter 2, Part 2

The patient's clinical status grows worse over the next couple of hours despite the efforts of the team. He is now placed on vasopressor therapy combined with fluids, and antibiotics are begun emergently. He is intubated for respiratory failure and he is now anuric.

What are your next steps in terms of a care plan as well as monitoring parameters for this patient?

If the patient's cultures reveal carbapenem resistant Klebsiella pneumoniae, *what are two new agents that could be used and what treatment duration should you use?*

What is the overall goal of treatment in patients with intraabdominal infections?

How do the pharmacologic and nonpharmacologic goals compare in this patient?

depending on the site of IAI, the underlying disease process, and individual history of previous organisms. Cultures of metastatic IAI sites generally are not useful for directing antimicrobial therapy. Table 77–1 lists the likely pathogens against which antimicrobial agents should be directed.

Table 77–1

Likely Intraabdominal Pathogens

Type of Infection	Aerobes	Anaerobes
Primary (Spontaneous) Bacterial Peritonitis		
Children	Group A *Streptococcus*, *E. coli*, pneumococci	—
Cirrhosis	*E. coli*, *Klebsiella*, pneumococci (many others)	—
Peritoneal dialysis	*Staphylococcus*, *Streptococcus*, *E. coli*, *Klebsiella*, *Pseudomonas*	—
Secondary Bacterial Peritonitis		
Gastroduodenal	*Streptococcus*, *E. coli*	—
Biliary tract	*E. coli*, *Klebsiella*, enterococci	*Clostridium* or *Bacteroides* (infrequent)
Small or large bowel	*E. coli*, *Klebsiella*, *Proteus*	*B. fragilis* and other *Bacteroides*, *Clostridium*
Appendicitis	*E. coli*, *Pseudomonas*	*Bacteroides*
Abscesses	*E. coli*, *Klebsiella*, *Streptococcus*, enterococci	*B. fragilis* and other *Bacteroides*, *Clostridium*, anaerobic cocci
Liver	*E. coli*, *Klebsiella*, *Streptococcus*, enterococci, *Staphylococcus*, amoeba	*Bacteroides* (infrequent)
Spleen	*Staphylococcus*, *Streptococcus*, *E. coli*, *Salmonella*	

▶ *Antimicrobial Experience*

Important findings from clinical trials regarding selection of antimicrobials for IAIs are as follows:

- Antimicrobial regimens for secondary IAIs should cover a broad spectrum of aerobic and anaerobic bacteria from the GI tract. It is believed that the overuse of antimicrobials has contributed to the development of IAIs with carbapenem-resistant *Enterobacteriaceae* (CRE), *Pseudomonas* and *Acinetobacter* spp., as well as greater prevalence of methicillin-resistant *S. aureus* (MRSA), *Candida* spp., and *Enterococcus* IAIs. This has made drug selection a challenge.[17,18]
- Single-agent regimens (such as antianaerobic cephalosporins, extended-spectrum penicillins with β-lactamase inhibitors, or carbapenems) are as effective with fewer adverse effects as combinations of aminoglycosides (more adverse reactions) or fluoroquinolones (more incidences of *Clostridium difficile*) with antianaerobic agents. This is also true for antimicrobial treatment of acute bacterial contamination from penetrating abdominal trauma.
- LO 8 Antimicrobial stewardship efforts in the treatment of IAIs show promise to curb antimicrobial overuse that contributes to multidrug-resistant (MDR) organisms, without affecting positive outcomes.[19] Strategies utilized by antimicrobial stewardship programs (ASPs) are impactful on antimicrobial use when they incorporate institution-specific antibiograms, utilize national guidelines for treatment, and routinely proactively target adherence with prescribers for IAIs.[17]
- Metronidazole in combination with either certain cephalosporins for mild-moderate infections, and high-risk or high-severity infections or ciprofloxacin/levofloxacin (for the aforementioned infections) is considered effective empiric antimicrobial regimens.
- Oral alternatives such as moxifloxacin; the combination of levofloxacin or ciprofloxacin plus metronidazole; or amoxicillin-clavulanate can be considered if patients can be transitioned (after susceptibility results and clinical improvements are noted).
- Results from recent trials suggest that a 4-day duration of therapy is acceptable for most patients with IAIs with adequate source control.[20,21]
- New agents for the treatment of MDR gram-negative bacilli for complicated IAIs have recently been approved. Ceftolazone is a novel cephalosporin with the β-lactamase inhibitor tazobactam which both confers enhanced activity against *Pseudomonas aeruginosa* and MDR gram-negative bacilli. Ceftazidime-avibactam is another combination antibiotic (β-lactam/β-lactamase inhibitor) and treatment option in complicated IAIs (*Klebsiella pneumonia* CRE). Both new antibiotics have been studied in combination with metronidazole. ASPs will need to ensure proper use of these agents to limit resistance as much as possible.[22–26]
- IAIs present in many different ways and with a wide spectrum of severity. The antibiotic regimen employed and duration of treatment depend on the specific clinical circumstances (ie, the nature of the underlying disease process and the condition of the patient).

Recommendations

LO 6 KEY CONCEPT For most IAIs, the antimicrobial regimen should be effective against both aerobic and anaerobic bacteria.[15] Although

Table 77–2

Recommended Agents for the Treatment of Community-Acquired Complicated Intraabdominal Infections in Adults

Agents Recommended for Mild-to-Moderate Infections	Agents Recommended for High-Risk or High-Severity Infections
Single Agent	
Cefoxitin[a]	Piperacillin–tazobactam
Moxifloxacin[b]	Imipenem–cilastatin,[c]
Ertapenem[c]	Meropenem,[c] doripenem[c]
Combination Regimens	
Cefazolin,[a] cefuroxime,[a] ceftriaxone, cefotaxime each in combination with metronidazole	Cefepime or ceftazidime each in combination with metronidazole
Ciprofloxacin[b] or levofloxacin[b] each in combination with metronidazole	Ciprofloxacin[b] or levofloxacin[b] each in combination with metronidazole

[a]Empiric first- and second-generation cephalosporin use should be avoided unless local antibiograms show > 80%–90% susceptibility of *E. coli* to these agents.

[b]Use of quinolones may be associated with treatment failure due to increasing resistance of enteric pathogens including *E. coli*. Empiric quinolone use should be avoided unless local antibiograms show > 80%–90% susceptibility of *E. coli* to quinolones.

[c]Carbapenems should typically be reserved for settings where there is a high risk of resistance to other agents.

Reproduced, with permission, from Gross AE, Olsen KM, DiPiro JT. Intra-Abdominal Infections. In: Dipiro JT, Talbert RL, Yee GC, et al, eds. Pharmacotherapy: A Pathophysiologic Approach. 10th ed. New York: McGraw-Hill; 2017.

it is impossible to provide antimicrobial activity against every possible pathogen, agents with activity against enteric gram-negative bacilli, such as *E. coli* and *Klebsiella*, and anaerobes, such as *B. fragilis* and *Clostridia* spp., should be administered.

Table 77–2 presents the recommended agents for treatment of community-acquired and complicated IAIs from the Infectious Diseases Society of America and the Surgical Infection Society.[27] These recommendations were formulated using an evidence-based approach. Most community-acquired infections are "mild to moderate," whereas health care–associated infections tend to be more severe and difficult to treat. Table 77–3 presents guidelines for treatment and alternative regimens for specific situations. These are general guidelines; there are many factors that cannot be incorporated into such a table.

Aminoglycosides (with nephrotoxicity being a concern) and clindamycin have been relegated to secondary or tertiary options for the treatment of IAIs. Metronidazole is the agent of first choice for *B. fragilis*; but others, such as antianaerobic cephalosporins (eg, cefoxitin, cefotetan, or ceftizoxime), and combinations of extended-spectrum penicillins with β-lactamase inhibitors would be suitable alternatives. Preemptive antifungal therapy may be indicated with either an azole antifungal (fluconazole) or an echinocandin (caspofungin or micafungin) in patients who are immunocompromised or postsurgical with recurrent infection. These patients are more likely to develop a fungus secondary to risk factors such as being on broad-spectrum antimicrobials, having central lines, and being on parenteral nutrition.

In immunocompromised patients or patients with valvular heart disease or a prosthetic heart valve, there is justification to provide specific antimicrobial activity against enterococci. Ampicillin or other penicillins are active against enterococci (eg, penicillin and piperacillin) and should be used in patients at high-risk, patients with persistent or recurrent IAI, or patients who are immunosuppressed, such as after organ transplantation. Ampicillin remains the drug of choice for this indication because it is most active in vitro against enterococci and is relatively inexpensive. Vancomycin is active against most enterococci; however, resistance is increasing.

Intraperitoneal (IP) administration of antibiotics is preferred over IV therapy in the treatment of peritonitis that occurs in patients undergoing CAPD.[29] The International Society of Peritoneal Dialysis guidelines for the diagnosis and pharmacotherapy of PD-associated infections provide dosing recommendations for intermittent and continuous therapy based on the modality of dialysis (CAPD or automated peritoneal dialysis [APD]) and the extent of the patient's residual renal function.[10]

KEY CONCEPT Antimicrobial agents effective against both gram-positive and gram-negative organisms should be used for initial IP empirical therapy for peritonitis in PD patients. The most important factors to take into consideration for initial antimicrobial selection are the dialysis center's and the patient's history of infecting organisms and their susceptibilities. The use of cefazolin (loading dose [LD] 500 mg/L, maintenance dose [MD] 125 mg/L) plus ceftazidime (LD 500 mg/L, MD 125 mg/L) or cefepime (LD 250–500 mg/L, MD 100–125 mg/L) or gentamicin (LD 8 mg/L, MD 4 mg/L) or tobramycin (LD-3 mg/kg, MD-0.3 mg/kg) is suitable for initial empirical therapy. If patients are allergic to cephalosporin antibiotics, vancomycin (LD 30 mg/kg, MD 1.5 mg/kg/bag) or an aminoglycoside should be substituted. Aztreonam (LD 1000 mg/L, MD 250 mg/L) is an alternative to ceftazidime or cefepime in this patient population. Another option is monotherapy with imipenem-cilastin (LD 250 mg/L, MD 50 mg/L) or cefepime. Antimicrobial doses should be increased empirically by 25% in patients with residual renal function (> 100 mL/day urine output).[10] Repeat dialysis effluent cell counts and cultures should be done after at least 3 to 5 days of antimicrobial therapy, which should continue for at least a 14- to 28-day treatment course dependent on the microorganism identified. The reader is referred to these guidelines for additional information.[10]

After acute bacterial contamination, such as with abdominal trauma where GI contents contaminate the peritoneum, combination antimicrobial regimens are not required. If the patient is seen soon after injury (within 2 hours) and surgical measures are instituted promptly, antianaerobic cephalosporins (eg, cefoxitin or cefotetan) or extended-spectrum penicillins are effective in preventing most infectious complications. Antimicrobials should be administered as soon as possible after injury.[29]

For appendicitis, the antimicrobial regimen used should depend on the appearance of the appendix at the time of operation, which may be normal, inflamed, gangrenous, or perforated. Because the condition of the appendix is unknown preoperatively, it is advisable to begin antimicrobial agents before the appendectomy is performed. Reasonable regimens would be antianaerobic cephalosporins or, if the patient is seriously ill, a carbapenem or β-lactam–β-lactamase-inhibitor combination which are more broad spectrum in their scope. If, at operation, the appendix were normal or inflamed, postoperative antimicrobials would not be required. If the appendix is gangrenous or perforated, a treatment course of 4 days with the agents listed in Table 77–2 is appropriate.

Table 77–3

Guidelines for Empiric Antimicrobial Agents for Intraabdominal Infections[10,27]

	Primary Agents	Alternatives
Primary (Spontaneous) Bacterial Peritonitis		
Cirrhosis	Ceftriaxone, cefotaxime	1. Piperacillin–tazobactam, carbapenems 2. Aztreonam combined with an agent active against *Streptococcus* spp. (eg, vancomycin) or quinolones with significant *Streptococcus* spp. activity (levofloxacin, moxifloxacin)
Peritoneal dialysis	Initial empiric regimens should be active against both gram-positive (including *S. aureus*) and gram-negative pathogens: gram-positive agent (first-generation cephalosporin or vancomycin) plus a gram-negative agent (third-generation cephalosporin or aminoglycoside)	1. Cefepime or carbapenems may be used alone. 2. Aztreonam or an aminoglycoside may be used in place of ceftazidime or cefepime as long as combined with a gram-positive agent. 3. Quinolones may be used in place of gram-negative agents if local susceptibilities allow.
	1. *Staphylococcus* spp.: oxacillin/nafcillin or first-generation cephalosporin	1. Vancomycin should be used if concern for methicillin-resistant *Staphylococcus* spp. 2. Add rifampin for 5–7 days with vancomycin to reduce the risk for relapsing or repeat methicillin-resistant *Staphylococcus aureus* peritonitis.
	2. *Streptococcus* or *Enterococcus*: ampicillin	1. An aminoglycoside may be added for *Enterococcus* spp. 2. Linezolid, daptomycin, or quinupristin/dalfopristin should be used to treat vancomycin-resistant *Enterococcus* spp. not susceptible to ampicillin.
	3. Aerobic gram-negative bacilli: ceftazidime or cefepime	1. The regimen should be based on in vitro sensitivity tests.
	4. *Pseudomonas aeruginosa*: two agents with differing mechanisms of action, such as an oral quinolone plus ceftazidime, cefepime, gentamicin, or a carbapenem	
Secondary Bacterial Peritonitis		
Perforated peptic ulcer	First-generation cephalosporins	1. Ceftriaxone, cefotaxime, or antianaerobic cephalosporins[a]
Other	Third- or fourth-generation cephalosporin with metronidazole, piperacillin–tazobactam or carbapenem	1. Ciprofloxacin[b] or levofloxacin[b] each with metronidazole or moxifloxacin[b] alone 2. Aztreonam with vancomycin and metronidazole 3. Antianaerobic cephalosporins[a]
Abscess		
General	Third- or fourth-generation cephalosporin with metronidazole, piperacillin–tazobactam	1. Imipenem–cilastatin, meropenem, doripenem, or ertapenem 2. Ciprofloxacin[b] or levofloxacin[b] each with metronidazole or moxifloxacin alone
Liver	As above	Use metronidazole if amoebic liver abscess is suspected
Spleen	Ceftriaxone or cefotaxime	Moxifloxacin[b] or levofloxacin[b]
Other Intraabdominal Infections		
Appendicitis	Same management as for community-acquired complicated intraabdominal infections as listed in Table 77–2	
Community-Acquired Acute Cholecystitis	Ceftriaxone or cefotaxime	Severe infection, piperacillin/tazobactam, antipseudomonal carbapenem, aztreonam with metronidazole
Cholangitis	Ceftriaxone or cefotaxime each with or without metronidazole	Vancomycin with aztreonam with or without metronidazole
Acute Contamination from Abdominal Trauma	Antianaerobic cephalosporins[a] or metronidazole with either ceftriaxone or cefotaxime	1. Piperacillin/tazobactam or a carbapenem 2. Ciprofloxacin[b] or levofloxacin[b] each with metronidazole or moxifloxacin alone

[a]Cefoxitin or cefotetan; these agents should be avoided empirically unless local antibiograms show > 80%–90% susceptibility of *E. coli* to these agents.

[b]Use of quinolones may be associated with treatment failure due to increasing resistance of enteric pathogens including *E. coli*. Empiric quinolone use should be avoided unless local antibiograms show > 80%–90% susceptibility of *E. coli* to quinolones.

KEY CONCEPT Acute intraabdominal contamination, such as after a traumatic injury, may be treated with a short course (24 hours) of antimicrobials if therapy is begun quickly.[29] For established infections (ie, peritonitis or intraabdominal abscess), an antimicrobial course limited to 4 days is justified. Under certain conditions, therapy for longer than 4 days would be justified (eg, poor response, resistant organism identified, or failure to control the source of infection). For some abscesses, such as pyogenic liver abscess, antimicrobials may be required for a month or longer because of resistance increasing after initial antimicrobial treatment.

OUTCOME EVALUATION

LO 7

Whether diagnosed with primary or secondary peritonitis, monitor the patient for relief of symptoms. Once antimicrobials are initiated and the other important therapies described earlier are used, most patients should improve within 2 to 3 days. Successful antimicrobial therapy with resolution of infection will result in decreased pain, manifested as resolution of abdominal guarding and decreased use of pain medications over time. The patient should not appear in distress, with the exception of recognized discomfort and pain from incisions, drains, and a nasogastric tube.

Monitor vital signs and WBC count with differential; each should normalize as the infection resolves. At 24 to 48 hours, aerobic bacterial culture results should be available. If a suspected pathogen is not susceptible to the antimicrobial agents being given, and the patient has not sufficiently improved, the regimen should be adjusted. If the isolated pathogen is susceptible to one antimicrobial and the patient is improving, therapy should be streamlined to a single agent.

With anaerobic culturing techniques and the slow growth of these organisms, anaerobes often are not identified until 4 to 7 days after culture, and sensitivity information is difficult to obtain. For this reason, anaerobic culture information generally is not helpful for selection of the antianaerobic component of the antimicrobial regimen.

Once the patient's temperature is normal for 48 to 72 hours and the patient is eating, consider changing the IV antibiotic to an oral regimen for the duration of antibiotic treatment. Monitor the serum creatinine level to evaluate for renal complications as well as potential drug toxicity. Bowel sounds should return to normal. Evaluate the patient daily for development of rash or other drug-related adverse effects such as antibiotic-associated diarrhea.

For patients with primary peritonitis, if peritoneal dialysate cultures were positive initially, repeat cultures should be negative. For patients with secondary peritonitis, monitor the amount of fluid draining if a drain was placed. The volume of drainage should lessen as the infection resolves. Repeat abdominal radiographs should return to normal.

If symptoms do not improve, the patient should be evaluated for persistent infection. There are many reasons for poor patient outcome with IAI; improper antimicrobial selection is only one. The patient may be immunocompromised, which decreases the likelihood of successful outcome with any regimen. It is impossible for antimicrobials to completely compensate for a nonfunctioning immune system. There may be surgical reasons for poor patient outcome. Failure to identify all intraabdominal foci of infection or leaks from a GI anastomosis may cause continued IAI. Even when IAI is controlled, accompanying organ system failure, most often renal or respiratory, may lead to patient demise.

KEY CONCEPT Health care–associated infections are becoming more commonly seen for IAIs with increasing prevalence of acute care hospital admissions or admissions from chronic care settings. The major pathogens include more resistant gram-negative flora, *Candida* infections causing peritonitis, and *Enterococcus* species.[30]

The outcome from IAI is not determined solely by what transpires in the abdomen. Unsatisfactory outcomes in patients with IAIs may result from complications that arise in other organ systems. Infectious complications commonly associated with mortality after IAI are urinary tract infections and pneumonia.[18] Reasons for antimicrobial failure may not always be apparent. Even when antimicrobial susceptibility tests indicate that an organism is susceptible to the antimicrobial agent, therapeutic failures may occur. There may be poor penetration of the antimicrobial agent into the focus of infection, or bacterial resistance may develop after initiation of antimicrobial therapy. Superinfection—a secondary infection resulting from the preferential killing of the primary pathogen—can be caused

Patient Care Process

Collect Information:

- You should do a thorough patient medication history at the time of admission to document all recent medication use, including nonprescription medications and use of complementary or alternative medicines. You should also document any drug allergies or intolerances for your patient. You should also search for all available patient information in the pertinent patient's medical record.

Assess the Information:

- Be cognizant for the initial antimicrobial regimen conforming to standard guidelines (unless an appropriate justification for an alternative regimen is evident). See Table 77–3.

Develop a Care Plan:

- You should review the dosages of all medications to be sure that they are appropriate for age, weight, and major organ function.
- You should also verify that the drugs selected are not contraindicated in the patient with allergies or drug–drug interactions.

Implement the Care Plan:

- You should select antimicrobials that are appropriate based on the susceptibility information, while reviewing the results of the cultures obtained both preoperatively or during the surgical procedure. Antimicrobials should be de-escalated when clinically appropriate. You should educate other practitioners on proper de-escalation technique.
- On the fifth day of antimicrobial treatment or when GI function returns, determine whether parenteral antimicrobial agents can be switched to oral agents to complete therapy. This again is part of a robust ASP best practice.
- Assess nutritional needs and recommend appropriate supplementation. When the patient is tolerating an oral diet, determine whether any parenteral medications can be switched to the oral route.

Follow-up: Monitor and Evaluate:

- You should monitor the patient for the development of potential complications of treatment such as delayed hypersensitivity reactions, antibiotic-induced diarrhea, pseudomembranous colitis, or fungal superinfections (eg, oral thrush).
- You should also educate the patient on the medications administered in the hospital as well as any new medications prescribed for use at home.
- You should also advise the patient to contact his or her doctor or pharmacist if he or she experiences any adverse effects from medications.

by *Candida*; however, Enterococci or opportunistic gram-negative bacilli such as *Pseudomonas* or ESBL-producing Enterobacteriaceae may also be involved.

Treatment regimens for IAI can be deemed successful if the patient recovers from the infection without recurrent peritonitis or intraabdominal abscess and without the need for additional antimicrobials. A regimen can be considered unsuccessful if a significant adverse drug reaction occurs, reoperation or percutaneous drainage is necessary, or improvement is delayed beyond 1 or 2 weeks.

Abbreviations Introduced in This Chapter

APD	Automated peritoneal dialysis
ASP	Antimicrobial stewardship program
CAPD	Continuous ambulatory peritoneal dialysis
CRE	Carbapenemase-resistant Enterobacteriacae
DPL	Diagnostic peritoneal lavage
ESBL	Extended-spectrum producing β-lactamase Enterobacteriacae
IAIs	Intraabdominal infections
IP	Intraperitoneal
KPC	Klebsiella pneumonia carbapenemase
LD	Loading dose
MD	Maintenance dose
MDR	Multidrug-resistant
MRSA	Methicillin-resistant *S. aureus*
PD	Peritoneal dialysis

78 Parasitic Diseases

Madeline A. King and Jason C. Gallagher

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

LO

1. Identify the primary reasons why some parasitic diseases may be more prevalent in the US population.
2. Describe the treatment algorithm for giardiasis and amebiasis.
3. List one effective therapy for nematodes and select the drugs of choice for strongyloidiasis and tapeworms.
4. List three major reasons why travelers are infected with malaria.
5. Describe the presenting signs and symptoms of malaria.
6. List some specific toxicities of mefloquine.
7. Identify the monitoring parameters for quinidine gluconate in severe malaria.
8. Define the major complications of falciparum malaria.
9. Discuss the cardiovascular complications of chronic South American trypanosomiasis.
10. Describe the steps to take to eradicate lice infestation and scabies.

INTRODUCTION

LO 1

Globalization, including international tourism, has lead to increases in the spread of various infectious diseases from endemic areas to areas new to these pathogens. Population shifts with refugees and new immigrant populations from other parts of the world have brought new parasitic infections to our shores. Migrant farm workers, the large and growing Central and South American immigrant population, and an increasing presence of immunosuppressed patients represent significant sources of parasitic infections in the United States.[1–4]

Parasitism is a relationship between organisms where one organism (the parasite) thrives at the expense of the host. Parasites have made metabolic and other defensive adaptations over time to increase their ability to survive host defenses and allow them to utilize the host's biochemical systems to synthesize necessary cellular components.

Although acquired immunity to some parasitic diseases may lower the level of infection, absolute immunity as seen in viral and some bacterial infections is seldom seen in parasitic diseases. Since parasitic infections produce a wide variety of antigens because of the many life cycle phases, it is more difficult for the immune system to identify a constant antigen against which specific antibodies are protective.[5] However, malaria remains a likely candidate for a vaccine and there are ongoing studies to develop one.[6] Additionally, a vaccine for hookworms may advance to clinical trials based off initial animal studies.[7]

For more detailed discussions of parasites and the human parasites not discussed here, readers are directed to resources on parasites and parasitic diseases.[8,9] Discussion in this chapter includes parasitic diseases more likely seen in the United States and includes gastrointestinal (GI) parasites (primarily giardiasis and amebiasis), protozoan infections (malaria and South American trypanosomiasis), some common helminthic diseases (specifically those caused by nematodes and cestodes), and ectoparasites (lice and scabies).

GIARDIASIS

Epidemiology and Etiology

Giardia lamblia (also called *G. intestinalis* and *G. duodenalis*) is the most common intestinal parasite responsible for diarrheal syndromes throughout the world and is the most frequently identified intestinal parasite in the United States, with over 16,000 reported cases from 2011 to 2012.[10] *G. lamblia* is often encountered in areas with poor sanitation, particularly contaminated water.

Patient Encounter 1: Giardiasis

PB is a 31-year-old US resident who recently traveled to Guatemala to visit a friend. Although the majority of his meals were from his friend's home or from restaurants, he had a craving for "street food" the day he left and tried grilled corn, tacos, and a fresh fruit drink. Two days after his return he developed severe nausea and diarrhea that alternated with constipation. When he is seen at the travel clinic at a local hospital, he reports nausea and crampy, watery diarrhea with foul-smelling, "light-colored" stools for 3 days.

Are his symptoms characteristic of parasite-associated diarrhea?

How would you differentiate giardiasis from an Escherichia coli*–induced diarrhea?*

Do you think he requires treatment? If so, with what agent?

G. lamblia has been identified as the first documented enteric pathogen in children in developing countries. Giardiasis rates in the United States have been decreasing in recent years.[8–10]

G. lamblia is found in the small intestine, the gallbladder, and in biliary drainage.[8,10] The distribution of giardiasis is worldwide, with children or persons living in close quarters being more susceptible.[10]

Pathophysiology

There are two stages in the life cycle of *G. lamblia*: trophozoite and cyst. Giardiasis is caused by ingestion of *G. lamblia* cysts in contaminated water or food, via person-to-person contact, or fecal-oral contact, and has an incubation period of approximately 12–20 days.[8,10] The protozoan excysts in low gastric pH to release the trophozoite. Colonization and multiplication of the trophozoite lead to mucosal invasion, localized edema, and flattening of intestinal villi, resulting in malabsorption states in the host. Achlorhydria, hypogammaglobulinemia, or deficiency in secretory immunoglobulin A (IgA) predispose to giardiasis.[8] Individuals with human immunodeficiency virus (HIV) infection and acquired immune deficiency syndrome (AIDS) may have higher carriage rates than the general population. Some patients may develop irritable bowel syndrome or lactose intolerance after chronic giardiasis.[11]

Pharmacologic Therapy

LO 2

KEY CONCEPT All symptomatic adults and children over the age of 8 years with giardiasis should be treated with metronidazole, tinidazole, or nitazoxanide. See Table 78–1 for treatment regimens.[12] Alternative drugs include furazolidone, paromomycin, quinacrine 100 mg, or albendazole. Paromomycin is preferred for pregnant patients. The pediatric dose of metronidazole is 15 mg/kg/day three times daily for 7 days. Pediatric patients can be treated with metronidazole, furazolidone, or quinacrine.[12] Quinacrine is available from specialized pharmacies.[12,13]

Table 78–1

Treatment Regimens for Giardiasis

	Giardiasis	
Drug	**Adult Dosing and Duration**	**Pediatric Dosing**
Primary:		
Metronidazole	250 mg po 3 times daily × 7 days	15 mg/kg/day divided in 3 doses
Tinidazole	2g po as one dose	
Nitazoxanide	500 mg twice daily × 3 days	
Alternatives:		
Furazolidone	100 mg 4 times daily × 7 days	6 mg/kg/day in 4 doses
Paromomycin	25–35 mg/kg/day in 3 divided doses × 7 days	
Quinacrine	100 mg 3 times daily × 5 days	5 mg/kg/day × 5–7 days
Albendazole	400 mg daily × 5 days	

Clinical Presentation and Diagnosis of Giardiasis[8,9]

Acute Onset

- Diarrhea, cramp-like abdominal pain, bloating, and flatulence
- Malaise, anorexia, nausea, and belching

Chronic Symptoms

- Diarrhea: Foul-smelling, copious, light-colored, and greasy stools
- Weight loss, steatorrhea, and vitamin B_{12} and fat-soluble vitamin deficiencies
- Constipation alternating with diarrhea

Diagnosis

- Diagnosis is made by examination of fresh stool or a preserved specimen during acute diarrheal phase
- Fresh stool may show trophozoites, whereas preserved specimens yield cysts. (*Note:* stool for ova may show the presence of other parasites [eg, *Cryptosporidium parvum, Entamoeba histolytica*, or *Entamoeba hartmanni*]; multiple stool samples may be needed.)
- Stool examination for ova and parasites is the major means of diagnosis; other diagnostic tests include an enzyme-linked immunosorbent assay (ELISA).

Patient Care Process: Giardiasis

Collect Information:

- Evaluate patient medical history, recent travel, signs, and symptoms.
- Conduct a medication history, review laboratory findings, and consider if stool for ova and parasites or other tests may be necessary for diagnosis of giardiasis.

Assess the Information:

- Evaluate available laboratory data in conjunction with symptoms to confirm the diagnosis.
  - Unlike toxigenic *Escherichia coli* or food poisoning, there is no blood, mucus, or cellular exudate in giardiasis.
- Differentiate chronic giardiasis from amebiasis or other intestinal infections.

Develop a Care Plan:

Choose the most appropriate medications based on adherence and cost.

Implement the Care Plan:

- Address patient concerns about the infection and the therapy.
- Counsel patient on proper use of medications and possible adverse effects.
- Recommend fluids and electrolyte replacement.

Follow-up: Monitor and Evaluate:

- Decide if patient should come back for follow-up.
- Inform patient about the need for repeat stool for ova and parasites or for reevaluation at the end of therapy if symptoms persist or worsen.

Metronidazole and tinidazole act by disrupting DNA and inhibiting nucleic acid synthesis. Paromomycin acts by binding to 30S ribosomal subunits, inhibiting protein synthesis. Nitazoxanide interferes with the pyruvate:ferredoxin oxioreductase enzyme-dependent electron transfer reaction which is needed for anaerobic metabolism. Furazolidone interferes with the microbial enzyme system to prevent acetylation of coenzyme A. Paromomycin, quinacrine, nitazoxanide, albendazole, and tinidazole should be taken with food.[13] See Table 78–6 for adverse reactions related to drugs.

Outcome Evaluation

Patients who fail initial therapy with metronidazole should receive a second course of therapy. Long-term infection can result in malnourishment due to malabsorption.[9] Giardiasis can be prevented by good hygiene and by using caution in food and drink consumption in endemic areas.

AMEBIASIS

Epidemiology and Etiology

Amebiasis remains one of the most important parasitic diseases because of its worldwide distribution and serious GI manifestations. The major causative agent in amebiasis is *E. histolytica*, which invades the colon and must be differentiated from *Entamoeba dispar*, which is associated with an asymptomatic carrier state and is considered nonpathogenic.[14,15] Invasive amebiasis is almost exclusively the result of ingesting *E. histolytica* cysts found in fecally contaminated food or water. Approximately 50 million cases of invasive disease result each year worldwide, leading to an excess of 100,000 deaths. In the general population, the highest incidence is found in institutionalized mentally disabled patients, sexually active homosexuals, patients with advanced HIV, Native Americans, and new immigrants from endemic areas (eg, Mexico, South and Southeast Asia, West and South Africa, and portions of Central and South America).[14,15]

Pathophysiology

E. histolytica cysts invade mucosal cells of colonic epithelium, producing the classic flask-shaped ulcer in the submucosa. The trophozoites are released and have a cytocidal effect on cells. If the trophozoite gets into the portal circulation, it will be carried to the liver, where it produces abscess and periportal fibrosis. Liver abscesses are more common in men than women and are rarely seen in children. Amebic ulcerations can affect the perineum and genitalia, and abscesses may occur in the lung and brain.[14,16]

Erosion of liver abscesses can result in peritonitis. Liver abscesses that are located in the right lobe can spread to the lungs and pleura. Pericardial infection, although rare, may be associated with extension of the amebic abscesses from the liver.

Patient Encounter 2: Amebiasis

BK is a 25-year-old student who, on returning from studying abroad Egypt, is seen in the emergency department with complaints of a 3-day history of severe diarrhea, cramps, and postprandial abdominal pain. The abdominal pain is over the right lower quadrant and associated with nausea and flatulence. BK indicates that he had some diarrhea, possibly with blood, the night after he celebrated the end of the semester at a local restaurant in Hurghada. The diarrhea subsided after treatment from a local physician with paromomycin. However, 5 days later after his return to the United States, his symptoms came back.

What specific findings in this patient suggest that he may have giardiasis, amebiasis, or an E. coli*–associated diarrhea?*

What specific laboratory or diagnostic test will confirm a diagnosis of amebiasis?

Describe some of the complications associated with amebiasis.

Clinical Presentation and Diagnosis of Amebiasis[17]

Intestinal Disease

- Vague abdominal discomfort
- Symptoms may range from malaise to severe abdominal cramps, flatulence, and nonbloody or bloody diarrhea (heme-positive in 100% of cases) with mucus
- May have low-grade fever
- Eosinophilia is usually absent, although mild leukocytosis is not unusual

Note: Fecal screening may show other intestinal parasites, including *Cryptosporidium* spp., *Balantidium coli, Dientamoeba fragilis, Isospora belli, G. lamblia,* or *Blastocystis hominis.*

Amebic Liver Abscess

- May present with high fever with significant leukocytosis with left shift, anemia, elevated alanine aminotransferase, and dull abdominal pain on palpation
- *Physical findings:* Right upper quadrant pain, hepatomegaly, and liver tenderness, with referred pain to the left or right shoulder (*Note:* erosion of liver abscesses may present as peritonitis)

KEY CONCEPT Diagnosis

- Three stool specimens should be used and a permanent stained smear should be used.
- Intestinal amebiasis is diagnosed by demonstrating *E. histolytica* cysts or trophozoites from ova and parasite exam.
- Microscopy may not differentiate between the pathogenic *E. histolytica* and the nonpathogenic (commensal) *E. dispar* or *Entamoeba moshkovskii* in stools.
- Sensitive techniques are available to detect *E. histolytica* in stool: antigen detection, antibody test (ELISA) and polymerase chain reaction (PCR).
- Endoscopy with scrapings or biopsy and stained slides (iron hematoxylin or trichrome) may provide more definitive diagnosis of amebiasis.
- Diagnosis for liver abscess includes serology and liver scans (using isotopes by ultrasound or computed tomography [CT]) or magnetic resonance imaging (MRI); however, none of these are specific for liver abcess. In rare instances, needle aspiration of hepatic abscess may be attempted using ultrasound guidance.

Extraintestinal infection can be seen in the liver, lungs, heart, brain, eyes, skin, or genitourinary organs.[14,16] Complications and death result from the ability of *E. histolytica* to lyse host cells and destroy host tissue.[13,14,16,17]

Pharmacologic Therapy

LO 2

For asymptomatic patients, treatment should be given due to the possibility of spreading disease to others or developing disease within the year.[18] Iodoquinol, diloxanide furoate, and paromomycin are nonabsorbed luminal agents that are recommended for asymptomatic or intraluminal infection. Metronidazole, tinidazole, or nitazoxanide are recommended for mild to moderate diarrheal infection, and except for nitazoxanide, are recommended for severe or extrahepatic disease. However, an agent that is effective in the GI lumen may not attain sufficient tissue concentrations to be effective. Paromomycin is the preferred agent in pregnant patients. See Table 78–2 for treatment regimens.[12,13] See Table 78–6 for adverse reactions related to drugs.

Patients with severe intestinal disease or liver abscess should receive metronidazole followed by the luminal agents indicated previously. Tinidazole is an alternative to metronidazole and can be crushed and added to cherry syrup for children if necessary.[12] If there is no prompt response to metronidazole or aspiration of the abscess, an antibiotic regimen should be added due to the potential for a bacterial infection. Patients who cannot tolerate oral metronidazole should receive intravenous (IV) metronidazole.[14,16]

Patient Care Process: Amebiasis

Collect Information:

- Ask the patient about specific symptoms, travel history, food and water intake, and if any other travelers experienced similar symptoms.
- Collect stool samples.
- Conduct a medication history and check for allergies.

Assess the Information:

- Based on physical examination, review of systems, and travel history, determine if these findings are consistent with amebiasis.
- Determine, based on the results of the diagnostic tests, whether this is amebic colitis or colitis with liver abscess.

Develop a Care Plan:

- Verify the availability of the drug or drugs you intend to use.
- Select pharmacotherapy and appropriate regimen and check for any potential drug interactions.

Implement the Care Plan:

- Address any patient concerns and discuss the need for medication adherence and dietary restrictions.

Follow-up: Monitor and Evaluate:

- Follow-up in 10 days and repeat tests to evaluate therapy.
- Monitor for efficacy and toxicity.

Table 78–2

Treatment Regimens for Amebiasis

	Amebiasis	
Drug	**Adult Dosing and Duration**	**Pediatric Dosing**
Paromomycin	25–35 mg/kg/day in 3 doses × 7 days	Same as adult
Iodoquinol		30–40 mg/kg daily in 3 doses (max 2g)
Metronidazole	650 mg 3 times daily × 20 days	50 mg/kg/day in 3 doses
Tinidazole	750 mg 3 times daily × 10 days	50 mg/kg/day
Diloxanide furoate	2 g daily × 3 days	20 mg/kg/day in 3 doses × 10 days

Outcome Evaluation

Follow-up in patients with amebiasis should include repeat stool examinations, serology, colonoscopy (in colitis), or CT scan a month after the end of therapy. Serial liver scans have demonstrated healing of liver abscesses over 4 to 8 months after adequate therapy.[16,19]

HELMINTHIC DISEASES

Helminthic infections include three groups of organisms: roundworms or nematodes, flukes (trematodes), and tapeworms (cestodes). Brief descriptions of some of the helminthic infections most commonly seen in North America and their treatments are provided here. Although helminthic infections may not produce clinical manifestations, they can cause significant pathology. One factor that determines the pathogenicity of helminthic infections is their population density; a high-density population ("worm burden") results in predictable disease presentation. In the United States, these infections are reported most frequently in recent immigrants from Southeast Asia, the Caribbean, Mexico, and Central America.[20–22] Populations at risk include institutionalized patients, preschool children in daycare centers, residents of Native American reservations, and homosexuals.[20,21] Certain conditions and drugs (anesthesia and corticosteroids) can cause atypical localization of worms. Immunocompromised patients can be overwhelmed by some helminthic infections, such as *Strongyloides stercoralis*.[23]

Nematodes

▶ *Hookworm Disease*

Hookworm infection is caused by two species of nematodes, *Ancylostoma duodenale,* which is worldwide, and *Necator americanus,* which is found in the southeastern United States.[20–22] Infective larvae enter the host in contaminated food or water or penetrate the skin and migrate to the small intestine. The adult worm attaches to GI mucosa and causes injury by lytic destruction of the tissue. Over time, the adult worm can cause anemia and hypoproteinemia in the host.[24–26]

▶ *Treatment*

KEY CONCEPT The goals of therpay are to both kill the worms and replace depleted iron. The drugs of choice are albendazole or

mebendazole, which is also active against ascariasis, enterobiasis, trichuriasis, and hookworm.[12,13] Mebendazole inhibits glucose uptake and microtubule assemply, resulting in immobilization and death of the worm. Diagnosis is by detection of eggs or larvae in stool. An alternative agent is pyrantel pamoate, which acts on nicotinic acetylcholine receptors as a neuromuscular blocking agent which causes worm paralysis. Stool examination for eggs and larvae should be repeated in 2 weeks and the patient retreated if necessary.[13]

Ascariasis

The causative agent in ascariasis is the giant roundworm *Ascaris lumbricoides,* which is found worldwide and is responsible for about 4 million infections in the United States annually, primarily affecting residents of the Appalachian mountain range and the Gulf Coast region.[20–22] Migration of the worm into the lungs usually produces pneumonitis, fever, cough, eosinophilia, and pulmonary infiltrates. *Ascaris* infection can also cause abdominal discomfort, intestinal obstruction, and appendicitis. Diagnosis is made by detection of the characteristic eggs in the stool or passed worms.[21]

▶ *Treatment*

In both adults and pediatric patients older than 2 years of age, albendazole or mebendazole is appropriate. Ivermectin or nitazoxanide are alternatives. The stool should be checked within 2 weeks and the patient retreated when warranted. Surgery or endoscopy may be indicated.[12,13]

Enterobiasis

Enterobiasis, or pinworm infection, is caused by *Enterobius vermicularis*. It is the most widely distributed helminthic infection in the world. There are approximately 42 million cases in the United States, primarily affecting children. It is transmitted person-to-person via the fecal to oral route (ie, direct contact with infected feces or handling infected items) or contact with water contaminated with *E. vermicularis* eggs. The most common manifestation of the infection is cutaneous irritation in the perianal region, resulting from the migrating female or the presence of eggs. The intense pruritus may lead to dermatitis and secondary bacterial infections. Diagnosis is made by the use of a perianal swab and cellophane tape sampling, which will aid in egg identification.[22]

▶ *Treatment*

The three agents that are administered for enterobiasis are pyrantel pamoate, mebendazole, and albendazole. Following treatment with one of these agents, all bedding and underclothing should be sterilized by steaming or washing in the hot cycle of the washing machine to eradicate the eggs.[12,13]

Strongyloidiasis

Strongyloidiasis is caused by *Strongyloides stercoralis,* which has a worldwide distribution and is predominantly prevalent in South America (Brazil and Columbia) and in Southeast Asia.[22] Strongyloidiasis is primarily seen among institutionalized populations (those in mental hospitals and children's hospitals) and immunocompromised individuals (those with HIV infection, AIDS, and patients with hematologic malignancies).[23,27,28] The worm is usually found in the upper intestine, where the eggs are deposited and hatch to form the rhabditiform larvae. The rhabditiform larvae (male and female) migrate to the bowel where they may be excreted in the feces. If excreted in the feces, the larva can evolve into either one of two forms after copulation: a free-living noninfectious rhabditiform larva, or parasitic, infectious filariform larva. The filariform larva can penetrate host skin and migrate to the lungs and produce progeny, a process called autoinfection. This can result in hyperinfection (ie, an increased number of larva in the intestine, lungs, and other internal organs), especially in an immunocompromised host.[29]

Patients with acute infection may develop a localized pruritic rash, but heavy infestations can produce eosinophilia (10%–15% eosinophils [0.10–0.15]), diarrhea, abdominal pain, and intestinal obstruction. Administration of corticosteroids or other immunosuppressive drugs to an infected individual can result in hyperinfections and disseminated strongyloidiasis.[23,28] KEY CONCEPT The symptoms appear in cutaneous, pulmonary, and finally intestinal phases. Diagnosis of strongyloidiasis is made by identification of the rhabditiform larva in stool, sputum, or duodenal fluid, or from small bowel biopsy specimens. Even though antigen testing (ELISA essay) remains the most sensitive method, stool examinations and other body fluids should also be utilized in the diagnosis.[23,27]

▶ *Treatment*

LO 3

KEY CONCEPT The drug of choice for strongyloidiasis is oral ivermectin or alternatively, albendazole.[12,13] Ivermectin may also be given with the two doses 2 weeks apart due to the auto-infection cycle taking 2 to 3 weeks.[13] Albendazole may be less effective than ivermectin. With hyperinfection or disseminated strongyloidiasis, immunosuppressive drugs should be discontinued and ivermectin should be given daily until all symptoms are resolved. Patients should be tested periodically to ensure the elimination of the larva. Individuals from an endemic area who are candidates for organ transplantation must be screened for *S. stercoralis*.[23] A veterinary drug, moxidectin, may be effective for *S. stercoralis* in humans as well, although clinical trials are still being conducted for its efficacy and safety.[30] Intravenous ivermectin is used in veterinary medicine also and may be selectively utilized in severely ill patients who cannot tolerate oral medication, if Food and Drug Administration (FDA) approval for the exception is obtained.[12]

Cestodiasis

Cestodiasis (tapeworm infection) is caused by species of the phylum Platyhelminthes (flatworms) and include, among others, the pork tapeworm (*Taenia solium*) and the beef tapeworm (*T. saginata*). *T. saginata* is the most common tapeworm and is endemic in Latin America, Africa, Central Asia, and the Middle East.[13] *T. solium* causes the most common infectious disease of the nervous system in humans and is the most common preventable cause of epilepsy in developing countries.[31]

The cestodes can be acquired by eating undercooked meat. The tapeworm attaches itself to the mucosal wall of the upper jejunum by the scolex (mouth parts) and by two to four cup-shaped suckers. *T. saginata* has a structure called a rostellum, which has hooks to help with its grip.[32] Since the parasite lacks a digestive system, it obtains all nutrients directly from the host. The scolex, proglottids (segments), and eggs are specific for each species and used for identification of tapeworms. Tapeworm infections are caused by ingestion of poorly cooked meat that contains the larva or cysticerci. Cysticerci, when released from the contaminated meat by host digestive juices, mature in the host jejunum. Cystericercosis is the term for systemic disease caused by the larva of *T. solium* (oncosphere or hexacanth), usually acquired by ingestion of eggs in contaminated food or

by autoinfection. During cysticercosis, the larvae penetrate the bowel and migrate through the bloodstream to infect different organs, including the central nervous system (CNS) (neurocysticercosis). Identification of both *T. saginata* and *T. solium* infections is accomplished by recovery of the gravid proglottids and the scolex in the stool. Newer diagnostic tools for neurocysticercosis include serum and cerebrospinal antigen and antibody testing. Spinal fluid may show eosinophilia, pleocytosis, and reactive lymphoid cells.[17,34]

▶ *Treatment*

KEY CONCEPT Pharmacological treatment of tapeworms kills adult worms but not eggs, which presents an issue for individuals with *T. solium*. Tapeworm infections are treated with praziquantel or albendazole.[12,34] Niclosamide is an alternative and may be obtained from a compounding pharmacy.[13] The doses of antihelmintic therapy can be repeated if necessary for both adults and children. The treatment for cysticercosis and neurocysticercosis may include surgery, anticonvulsants (neurocysticercosis can cause seizures), steroids, and anthelmintic therapy. See Table 78–3 for treatment regimens.[31] Steroids are used to treat inflammation caused by the invasion of brain tissue and prevent life-threatening complications of the disease caused by increased intracranial pressure. The inflammatory response as a result of parasite death after administration of anti-helminthics must be mediated. Dexamethasone 0.1 mg/kg per day, prednisolone 1 mg/kg per day, or prednisone 1 mg/kg per day may be used for 5 days up to 2 weeks. Steroids should be tapered rather than abruptly stopped to avoid worsening of symptoms.[13,31,35] See Table 78–6 for adverse reactions related to drugs.

LO 3

Outcome Evaluation

Morbidity and disease due to helminthic infections are related to the intensity of infection. The major adverse effects of helminthic infections are malnutrition, fatigue, and diminished work capacity. Unlike other helminthic infections, strongyloidiasis can cause autoinfection, and in the presence of immunosuppression, it can cause CNS and disseminated infections, which have high mortality.[23,28]

The most serious complication of cysticercosis is neurocysticercosis that can cause strokes and seizures.[31,36] Treatment of neurocysticercosis with anthelmintic treatment remains controversial, but should still be administered or prescribed when available. Patients should receive MRI follow-up to evaluate reduction in number of cysts.[36]

Table 78–3

Treatment Regimens for Helminthic Diseases

	Helminthic Diseases	
Drug	**Adult Dosing and Duration**	**Pediatric Dosing**
Hookworm, Ascariasis		
Primary:		
Albendazole	400 mg × 1 dose	Same as adult
Mebendazole	100 mg twice daily × 2 days	Same as adult
Alternative (Hookworm):		
Pyrantel pamoate	11 mg/kg/daily × 3 days	Same as adult
Alternative (Ascariasis):		
Ivermectin	150–200 mcg/kg × 1 dose	Same as adult
Enterobiasis		
Primary:		
Pyrantel pamoate	11 mg/kg (max 1g) × 1 dose	Same as adult
Mebendazole	100 mg × 1 dose	Same as adult
Albendazole	400 mg × 1 dose (may repeat doses in 2 weeks)	Same as adult
Strongyloidiasis		
Primary:		
Ivermectin	200 mcg/kg/day × 2 doses	Same as adult
Alternative:		
Albendazole	400 mg twice daily × 3–5 days	Same as adult
Cestodiasis		
Primary:		
Praziquantel	5–10 mg/kg × 1 dose	Same as adult
Alternative:		
Albendazole	15 mg/kg/day (max 800 mg) in 2 doses × 8–30 days	Same as adult
Nicolsamide	2g × 1 dose	50 mg/kg × 1 dose
Neurocysticercosis		
Albendazole	15 mg/kg/day (max 800 mg[a]) in 2 doses × 7–28 days	Same as adult
Praziquantel	100 mg/kg/day PO in 3 doses on day 1, then 50 mg/kg/day in 3 doses for 15–30 days	> 4 years, dose as adult

[a]Up to 1200 mg per day can be used for subarachnoid disease.

Patient Encounter 3, Part 1: Malaria

AR is a 52-year-old man who returned recently from building homes in Uganda. He started feeling unwell after returning, and he developed a temperature as high as 39.0°C (102.2°F), with anorexia, headache, chills, sweats, myalgias, and abdominal pain. AR comes to the emergency department with high fever (> 39.8°C [> 103.6°F]), headache, abdominal pain, nausea, stiffness of the neck, and back pain. AR indicates that he did not take antimalarial prophylaxis on this trip.

What are the symptoms in this patient that are consistent with malaria?

Why is this patient at risk for malaria?

Are there any additional information you like to have, to be able to develop a pharmacotherapy plan for this patient?

MALARIA

Malaria is a devastating parasitic disease. Nearly 200 million cases of malaria were reported in 2013 worldwide, with 0.3% resulting in death. Over 1700 cases were diagnosed in the United States that year and, mostly acquired in Africa, followed by Asia, the

LO 4 Carribbean and Americas, and Oceania. KEY CONCEPT The primary reasons for morbidity and death in malaria are failure to take recommended chemoprophylaxis, inappropriate chemoprophylaxis, delay in seeking medical care or in initiating therapy promptly, and misdiagnosis.[3] Evaluation of a patient should include specific travel history, details of chemoprophylaxis, and physical findings (eg, splenomegaly).

Malaria is transmitted by the bites of female *Anopheles* mosquitoes, which introduce into the bloodstream one of five species of sporozoites of the plasmodia (*Plasmodium falciparum, P. ovale, P. vivax, P. malariae,* and *P. knowlesi*). LO 5 Initial symptoms of malaria are nonspecific and may resemble influenza and include chills, headache, fatigue, muscle pain, rigors, and nausea. The onset of the symptoms is between 1 and 3 weeks following exposure. Fever may appear 2 to 3 days after initial symptoms and may follow a pattern and occur every 2 or 3 days (*P. vivax, P. ovale,* and *P. malariae*). *P. falciparum*, which is the most common cause of severe disease, may cause erratic fever that may not follow specific patterns. It is not unusual for patients to have concomitant infections with *P. vivax* and *P. falciparum*.[37,38] Falciparum malaria (or *P. knowlesi*) must always be regarded as a life-threatening medical emergency.[39]

Epidemiology and Etiology

The distribution of the various species of malaria is not strictly defined, but *P. vivax* is reported to be prevalent in the Indian subcontinent, Central America, North Africa, and the Middle East, whereas *P. falciparum* is predominantly in Africa (including sub-Saharan Africa), both East and West Africa, Haiti, the Dominican Republic, the Amazon region of South America, Southeast Asia, and New Guinea.[3,37,38] Most *P. ovale* infections occur in Africa, whereas the distribution of *P. malariae* is worldwide. Most infections in the United States are reported in American travelers, recent immigrants, or immigrants who have visited friends and family in an endemic area.[3,38] Placental transmission and blood transfusions are uncommon sources of malaria.[3]

Pathophysiology

Within minutes after the bite of the *Anopheles* mosquito, sporozoites begin to distribute to hepatocytes where they incvade and begin an asexual phase called schizonts (exoerythrocytic stage or schizogony). This asexual phase is about 48 hours for *P. falciparum, P. vivax,* and *P. ovale,* and 72 hours for *P. malariae*. The patient may be asymptomatic during this period. After a lapse of between 5 and 15 days (depending on the species), schizonts rupture to release daughter cells (merozoites) into the blood, which then invade erythrocytes. In erythrocytes, the merozoites undergo various forms: a ring form, trophozoite, schizont, and merozoite, which then invade new erythrocytes. The merozoites develop into gametocytes and undergo a sexual phase (sporogony). After a mosquito bite of an infected person and ingestion of blood containing gametocytes, the gametocytes undergo a number of stages: zygote, ookinete, and oocyst, and finally transform into sporozoites in the salivary glands, where they can infect the next host. Unlike *P. falciparum* and *P. malariae*, which only remain in the liver for about 3 weeks before invading erythrocytes, *P. ovale* and *P. vivax* can remain in the liver for extended periods in a latent stage (as hypnozoites); this can result in the recurrence of the infection after weeks or months.[17,37] Primaquine therapy is necessary to eradicate this stage of the infection.[12]

Clinical Presentation and Diagnosis

The clinical presentation of malaria can vary. Normally, the appearance of a prodrome with headache, abdominal pain, fatigue, fever, and chills, which coincides with the erythrocytic phase of malaria, occurs between 8 and 40 days after being exposed.[3,17,37,38] This phase causes extensive hemolysis, which results in anemia and splenomegaly. The most serious complications are caused by *P. falciparum* infections. Infants and children younger than 5 years and nonimmune pregnant women are at high risk for severe complications with falciparum infections.[37,38,40] The complications associated with falciparum malaria are related to two unique features of *P. falciparum*: (a) its ability to produce high parasitism (up to 80%) of red cells of all ages; and (b) the propensity to be sequestered in postcapillary venules of critical organs such as brain, liver, heart, lungs, and kidneys.[38,40] It has been postulated that tissue hypoxia from anemia, together with *P. falciparum*–parasitized red blood cell adherence to endothelial cells in capillaries, contributes to severe ischemia and metabolic derangements.[40] *P. malariae* is implicated in immune-mediated glomerulonephritis and nephrotic syndrome.[41]

Patient Encounter 3, Part 2: Falciparum Malaria

AR presents with fever, nausea, headache, myalgias, chills, and body aches including back pain.

PMH: Otherwise healthy 52-year-old man

FH: Father died of colon cancer at age 62 years; mother, who is 82-year-old, has osteoarthritis and lives with his sister

SH: Works for a nonprofit organization providing water filters to communities in India

Meds: Multivitamin

ROS: In addition to the complaints noted previously, he complains of severe nausea and fatigue

Gen: Patient is slightly agitated and febrile

VS: BP 132/86 mm Hg; P 120 beats/min, RR 36 breaths/min, T 40.1°C (104.2°F)

Skin: Warm and dry to touch

HEENT: Slightly dry oral mucosa

ABD: Splenomegaly

Rest of the systems were WNL.

Labs: Sodium 148 mEq/L (148 mmol/L), hemoglobin 10.2 g/dL (102 g/L or 6.33 mmol/L), potassium 4.1 mEq/L (4.1 mmol/L), hematocrit 31% (0.31), chloride 96 mEq/L (96 mmol/L), WBC $14.8 \times 10^3/mm^3$ ($14.8 \times 10^9/L$), BUN 28 mg/dL (10.0 mmol/L), total bilirubin 1.8 mg/dL (30.8 µmol/L), Scr 1.4 mg/dL (124 µmol/L), platelets $110 \times 10^3/mm^3$ ($110 \times 10^9/L$), glucose 77 mg/dL (4.3 mmol/L), aspartate aminotransferase 87 U/L (1.45 µkat/L), albumin 3.2 g/dL (32 g/L), alanine aminotransferase 94 U/L (1.57 µkat/L), blood smear (Giemsa stain): *P. falciparum*.

Based on the above findings, what is your approach in the management of AR?

Describe the specific steps one needs to take to ensure a good outcome and minimize the associated complications with P. falciparum *infection.*

Thick and thin blood smears should reveal malaria parasites with the Giemsa stain being preferred, and rapid diagnostic tests should be used if microscopy is not available. KEY CONCEPT One negative set of blood smears does not rule out malaria.[17,42] Malaria can also be detected with DNA or RNA probes by PCR and monoclonal antibody testing.[3,38,43]

Treatment

Prevention of malaria is key in those traveling to regions with endemic malaria. Prophylaxis must be started prior to travel and continued through 1 week after travel. Drug selection is based on resistance patterns in the region. The primary goal in the management of malaria is to rapidly eradicate the infection to prevent complications such as hypoglycemia, pulmonary edema, and renal failure.[3,37,40,44]

Rapid identification of the *Plasmodium* species by blood smears is important. Antimalarial therapy should be initiated promptly to eradicate the infection within 48 to 72 hours.

Pharmacologic Therapy

Treatment of malaria is based on the species and resistance patterns in the region from which it was acquired. See Table 78–4 for treatment regimens. See Table 78–6 for adverse reactions related to drugs.[12,13]

KEY CONCEPT In severe illness or falciparum malaria, patients should be admitted to an acute care unit, and quinidine gluconate should be started. KEY CONCEPT Patients often cannot tolerate quinidine due to QTc prolongation. Artesunate may be used in place of quinidine, followed by oral therapy. Artesunate is available from the Centers for Disease Control and Prevention [CDC] under an investigational new drug application (www.cdc.gov/malaria/features/artesunate_now available.htm).[12]

LO 6 Mefloquine is associated with sinus bradycardia, confusion, hallucinations, and psychosis and should be avoided in patients with a history of epilepsy, cardiovascular problems, or depression. IV quinidine gluconate followed by quinine plus doxycycline or clindamycin should be administered for severe illness as

Table 78–4

Treatment Regimens for Malaria

Drug	Adult Dosing	Pediatric Dosing
Oral (Uncomplicated/Mild)		
No chloroquine resistance		
Chloroquine phosphate	1 g (600 mg base[a]), followed by 500 mg at 6, 24, and 48 hours	10 mg/kg (base[a]), followed by 5 mg/kg at 6, 24, and 48 hours
Chloroquine-resistant* P. falciparum *or unidentified species		
• Atovaquone/proguanil	4 tablets (250 mg/100 mg) daily for 3 days	5–8 kg: 2 pediatric tablets (62.5 mg/25 mg) daily; 9–10 kg: 3 peds tabs daily; 11–20 kg: 1 adult tab daily; 21–30 kg: 2 adult tabs daily; 31–40 kg: 3 adult tabs daily; > 40 kg: adult dose (all for 3 days)
• Artemether/lumefantrine	4 tablets per dose at 0, 8, 24, 36, 48, 60 hours	Same as adult
• Quinine sulfate PLUS	650 mg every 8 hours for 3–7 days	30 mg/kg/day in 3 doses for 3–7 days
doxycycline	100 mg twice daily	4 mg/kg/day in 3 doses
OR tetracycline	250 mg 4 times daily	25 mg/kg/day in 4 doses
OR clindamycin	20 mg/kg/day in 3 doses (all for 7 days)	20 mg/kg/day in 3 doses (all for 7 days)
Alternative:		
• Mefloquine	750 mg followed by 500 mg 12 hours later	15 mg/kg followed by 10 mg/kg 12 hours later
***Chloroquine-resistant* P. vivax**		
• Quinine sulfate PLUS	Same dosing as above	Same dosing as above
• Doxycycline	Same dosing as above	Same dosing as above
Alternative:		
• Atovaquone/proguanil	Same dosing as above	Same dosing as above
• OR Mefloquine	Same dosing as above	Same dosing as above
EITHER PLUS		
• Primaquine phosphate	30 mg base/day for 14 days	0.5 mg/kg/day for 14 days
Parenteral (Severe)		
All* Plasmodium *species		
• Quinidine gluconate	10 mg/kg IV loading dose (max 600 mg) over 1–2 hours followed by 0.02 mg/kg/min until PO can be used	Same as adult
• OR quinine dihydrochloride	20 mg/kg IV loading dose over 4 hours followed by 10 mg/kg over 2–4 hours every 8 hours (max 1800 mg/day) until PO can be used	Same as adult
• OR artesunate PLUS an oral drug	2.4 mg/kg/dose for 3 days at 0, 12, 24, 48, and 72 hours	Same as adult

[a]Tablets available as 250 mg of chloroquine phosphate, which is equivalent to 150 mg of chloroquine base.

Clinical Presentation and Diagnosis of Malaria[37]

Initial Presentation

Take a careful travel history, physical findings, and details of antimalarial chemoprophylaxis.

Erythrocytic Phase

1. Prodrome: Headache, anorexia, malaise, fatigue, and myalgia.
2. Nonspecific complaints include abdominal pain, diarrhea, chest pain, and arthralgia.
3. Paroxysm: High fever, chills, and rigor.
4. Cold phase: Severe pallor, cyanosis of the lips and nail beds.
5. Hot phase: Fever between 40.5°C (104.9°F) and 41.0°C (105.8°F) (seen more frequently with *P. falciparum*).
6. Sweating phase: Follows the hot phase by 2 to 6 hours
7. When fever resolves, it is followed by marked fatigue and drowsiness, warm dry skin, tachycardia, cough, headache, nausea, vomiting, abdominal pain, diarrhea and delirium, anemia, and splenomegaly.

KEY CONCEPT *P. falciparum* malaria is a life-threatening emergency. Complications include hypoglycemia, acute renal failure, pulmonary edema, severe anemia (high parasitism), thrombocytopenia, heart failure, cerebral congestion, seizures, coma, and adult respiratory distress syndrome.

Diagnostic Procedures for Malaria

1. To ensure a positive diagnosis, blood smears (both thick and thin films) should be obtained every 12 to 24 hours for 3 consecutive days.
2. The presence of parasites in the blood 3 to 5 days after initiation of therapy suggests resistance to the drug regimen.

Patient Care Process: Malaria

Collect Information:

- Based on physical examination and review of systems, determine whether patient has acute malaria.
- Review all laboratory tests and take note of blood work that identifies species of *Plasmodium*.
- Conduct a **medical history review** to identify **travel history and medication allergies.**

Assess the Information:

- Determine, based on patient presentation, travel history, and use of prophylaxis, if acute malaria is chloroquine sensitive or resistant.

Develop a Care Plan:

- Use the CDC malaria website for recommendations.
- Develop regimen, considering the region the patient traveled to and therapeutic options, as well as drug interactions.

Implement the Care Plan:

- Inform patient of regimen (or begin regimen if critically ill), and counsel patient on adherence, drug interactions, or side effects.

Follow-up: Monitor and Evaluate:

- Monitor for efficacy and toxicity.
- Repeat smear if necessary to detect level of parasitemia and improvement.

LO 7 indicated previously. The IV quinidine regimen requires close monitoring of the ECG (QT-segment) and other vital signs (hypotension and hypoglycemia). An alternative oral treatment for *P. falciparum* infections in adults, especially those with history of seizures, psychiatric disorders, or cardiovascular problems, is the combination of atovaquone and proguanil.[13] KEY CONCEPT LO 8 Since falciparum malaria is associated with serious complications, including pulmonary edema, hypoglycemia, jaundice, renal failure, confusion, delirium, seizures, coma, and death, careful monitoring of fluid status and hemodynamic parameters is essential.

Outcome Evaluation

Acute *P. falciparum* malaria resistant to chloroquine should be treated with IV quinidine. The loading dose of quinidine should be omitted in patients who have received quinine or mefloquine. Hypoglycemia, associated with both *P. falciparum* and quinidine administration, should be assessed every 6 hours and corrected with dextrose when necessary. Quinidine infusions should be slowed or stopped if the QT interval is greater than 600 msecs, the increase in the QRS complex is greater than 25%, or if hypotension unresponsive to fluid challenge results. Quinidine levels should be maintained at 3 to 7 mg/dL (9.2–21.6 µmol/L).[44]

When advising potential travelers on prophylaxis for malaria, be aware of the incidence of chloroquine-resistant *P. falciparum* malaria and the countries where it is prevalent.[44] In patients who have *P. vivax* or *P. ovale* malaria (note that some patients can have *P. falciparum* and one of these species), following the treatment of the acute phase of malaria and screening for glucose-6-phosphate dehydrogenase deficiency, patients should receive a regimen of primaquine for 14 days to ensure eradication of the hypnozoite stage of *P. vivax* or *P. ovale*.[44] Malaria prophylaxis recommendations are available from the CDC Yellow Book based on region, which can be viewed at https://wwwnc.cdc.gov/travel/page/yellowbook-home. Vaccines for malaria are under investigation.[6]

AMERICAN TRYPANOSOMIASIS

Epidemiology and Etiology

Two distinct forms of the genus *Trypanosoma* occur in humans. One is associated with African trypanosomiasis (sleeping sickness) and the other with American trypanosomiasis (Chagas disease). *Trypanosoma brucei gambiense* and *Trypanosoma brucei rhodesiense* are the causative organisms for the East African and West African trypanosomiasis, respectively. *T. brucei rhodesiense* causes the acute disease and is the more virulent of the two species. Both East and West African trypanosomiasis are transmitted by various species of tsetse fly belonging to the genus *Glossina*. Further discussion of this subject will focus on American trypanosomiasis.

Trypanosoma cruzi is the agent that causes American trypanosomiasis. American trypanosomiasis is transmitted by different species of reduviid bugs (*Triatoma infestans* and *Rhodium prolixus*) that live in wall cracks of houses in rural areas of North, Central, and South America.[45–47]

Pathophysiology

The reduviid bug ("kissing bug") is infected by sucking blood from animals (eg, opossums, dogs, and cats) or humans infected with circulating trypomastigotes. Patients who are carriers of *T. cruzi* can transmit the parasite via blood or organ donation. Patients may be asymptomatic or experience mild symptoms such as local inflammation and fever. Less commonly, the disease may present as CNS infection in patients with AIDS or cause death due to arrhythmias or heart failure.[46,48,49] Diagnosis of trypanosomiasis depends on trypomastigotes in the blood, in addition to other signs, and may be undetectable in chronic disease.[17]

LO 9

▶ *Pharmacologic Therapy*

The drugs used for *T. cruzi* include nifurtimox and benznidazole. See Table 78–5 for treatment regimens. Nifurtimox is available from the CDC, but benzinidazole was FDA-approved in 2017 in the United States for treatment of Chagas Disease in children aged 2–12 years.[13,46,50] Benznidazole and nifurtimox both act by producing free radicals that damage parasitic DNA. Since children may tolerate the dose better than adults, the pediatric dose is higher.[12,13] Nifurtimox requires monitoring of liver function tests (LFTs), complete blood count (CBC), and chemistries.

Table 78–5

Treatment Regimens for Trypanosomiasis

Trypanosomiasis		
Drug	**Adult Dosing and Duration**	**Pediatric Dosing**
Nifurtimox	8–10 mg/kg/day in 3–4 doses × 90 days	1–10 years: 15–20 mg/kg/day in 3–4 doses 11–16 years: 12.5–15 mg/kg/day in 3–4 doses
Benznidazole	5–8 mg/kg/day in 2 doses × 60 days	Same as adults (children > 2 years)

Benznidazole requires CBC and chemistry monitoring.[12,13] Symptomatic treatment for heart failure associated with Chagas disease should be initiated. The GI complications may require surgical revisions and reconstruction.[45,46] See Table 78–6 for adverse reactions related to drugs.

Outcome Evaluation

Treatment of the acute phase of the disease (ie, fever, malaise, edema of the face, and hepatosplenomegaly) is nifurtimox. The congestive heart failure associated with cardiomyopathy of Chagas disease is treated the same way as cardiomyopathy from other causes.[46,47]

Clinical Presentation and Diagnosis of Trypanosomiasis[17,46]

Acute (2 weeks after infection, in 1% of patients)

- Unilateral orbital edema (Romana sign)
- Granuloma (chagoma)
- Fever, hepatosplenomegaly, lymphadenopathy, myocarditis, or CNS involvement

Intermediate Stage

- Resolution of acute illness after 4–8 weeks with detectable antibodies

KEY CONCEPT **Chronic (30% of patients)**

Cardiac: cardiomyopathy and heart failure

ECG: first-degree heart block, right bundle-branch block, and arrhythmias

GI: enlargement of the esophagus and colon ("mega" syndrome)

CNS: meningoencephalitis, strokes, seizures, and focal paralysis

Diagnosis

Positive history of exposure and use of serology: indirect hemagglutination test, ELISA, and complement fixation (CF) test. (*Note:* CF may produce false-positive reactions in those exposed to leishmaniasis, syphilis, and malaria. PCR may be more definitive for diagnosis.)

ECTOPARASITES

A parasite that lives outside the body of the host is called an ectoparasite. Approximately 6 to 12 million subjects become infested with pediculosis (lice infestation) yearly in the United States.

Patient Care Process: Trypanosomiasis (Chagas Disease)

Collect Information:

- Review medical history and laboratory tests including serology to establish the diagnosis for *T. cruzi*.
- Identify common complications associated with *T. cruzi*.

Assess the Information:

- Determine if patient needs to be treated for primary disease and any secondary complications.
- Assess efficacy, safety, and potential drug interactions.

Develop a Care Plan:

- Determine the doses and regimen for pharmacotherapy.

Implement the Care Plan:

- Educate patient on treatment and side effects.

Follow-up: Monitor and Evaluate:

- Review medical history, physical examination findings, and lab tests monthly.
- Determine, after assessing efficacy and toxicities of pharmacotherapy, if changes in regimen are necessary.

Table 78–6

Adverse Effects of Anti-Parasitic Agents

Drug[a]	Adverse Effects
Metronidazole	Gastrointestinal intolerance, metallic taste, disulfiram-like reaction with alcohol use (flushing, tachycardia, and hypotension)
Tinidazole	Gastrointestinal intolerance, metallic taste, disulfiram-like reaction with alcohol use
Nitazoxanide	Gastrointestinal intolerance, discoloration of eyes or urine
Furazolidone	Gastrointestinal intolerance, yellow/brown discoloration of urine, pulmonary infiltrate, headache, fever, hemolysis with G6PD deficiency, hypotension, polyneuropathy, hypoglycemia, agranulocytosis
Paromomycin	Gastrointestinal intolerance. If systemic absorption occurs, nephrotoxicity and ototoxicity can result
Quinacrine	Gastrointestinal intolerance, psychosis, headache, yellow staining of skin, hemolytic anemia, leukopenia, rash, disulfiram-like reaction. Contraindicated if history of psychosis or psoriasis
Albendazole	CNS related, gastrointestinal intolerance, leukopenia
Iodoquinol	CNS related, rash, thyroid enlargement, optic neuritis, peripheral neuropathy
Diloxanide furoate	Gastrointestinal intolerance
Mebendazole	Gastrointestinal intolerance
Pyrantel pamoate	Gastrointestinal intolerance, stool discoloration, rash, dizziness
Ivermectin	Fever, rash, pruritis, inflammatory reaction (due to death of worms), lymphadenopathy, headache
Praziquantel	Dizziness, drowsiness, gastrointestinal intolerance, rash, fever
Niclosamide	Anorexia, gastrointestinal intolerance
Chloroquine phosphate	QTc prolongation, anorexia, gastrointestinal intolerance, headache, dizziness, blurred vision, pruritis
Atovaquone/proguanil	Gastrointestinal intolerance, headache, dizziness, mild AST/ALT increase
Artemether/lumefantrine	Headache, anorexia, dizziness, arthralgia, myalgia
Quinine sulfate	Cinchonism, tinnitus, headache, gastrointestinal intolerance, blurred vision. Less common: blood dyscrasias, drug fever, asthma, hypoglycemia, transient blindness. Contraindicated if prolonged QTc, G6PD deficiency, myasthenia gravis, optic neuritis
Doxycycline	Gastrointestinal intolerance, chelation with cations (separate administration with dairy products, antacids), erosive esophagitis (should take with water), photosensitivity, onycholysis
Tetracycline	Discoloration of tooth enamel, photosensitivity, gastrointestinal intolerance, chelation with cations (separate administration with dairy products, antacids)
Clindamycin	Gastrointestinal intolerance (especially diarrhea, including C. difficile infection), neutropenia, thrombocytopenia, eosinophilia
Mefloquine	Black box warning for neuropsychiatric events (Medication Guide must be dispensed with prescription). Other AE include headache, irritability, insomnia, diarrhea, toxic psychosis, seizures. Less common: prolonged QTc and toxic epidermal necrolysis. Contraindicated with quinine and quinidine
Primaquine phosphate	Avoid in G6PD deficiency (risk of hemolytic anemia, methemoglobinemia). Other AE include nausea/abdominal pain if taken on empty stomach
Quinidine gluconate	Fatal hypotension with rapid IV bolus, hypoglycemia. Can reduce rate of infusion of IV quinidine to reduce QTc prolongation
Quinine dihydrochloride	Fatal hypotension with rapid IV bolus, hypoglycemia, cinchonism, blindness
Artesunate	Hemolysis (decline in hemoglobin after treatment), bradycardia, dizziness, gastrointestinal intolerance. Less common: seizure, cerebellar dysfunction
Nifurtimox	Gastrointestinal intolerance, CNS effects, polyneuropathy, rash. Leukopenia, hepatitis. Hemolysis if G6PD deficiency
Benznidazole	Rash, anorexia, gastrointestinal intolerance, CNS effects, increased AST/ALT, arthralgia

[a]Listed in order of appearance in the chapter.

ALT, alanine aminotransferase; AST, aspartate aminotransferase; CNS, central nervous system.

Pediculosis is usually associated with poor hygiene, though infections are then passed from person to person through social and sexual contact.[51]

Lice

The two species that belong to this group include *Pediculus humanus capitis* (head louse) and *Pediculus humanus corporis* (body louse). The eggs (or nits) remain firmly attached to the hair, and in about 10 days the lice hatch to form nymphs, which mature in 2 weeks. The lice become attached to the base of the hair follicle and feed on the blood of the host. Pubic or crab lice is found on the hairs around the genitals but may occur in other parts of the body (eg, eyelashes or axillae). Hypersensitivity to the secretions from lice can produce macular swellings and lead to secondary bacterial infections.[51]

► *Treatment*

LO 10

KEY CONCEPT The pharmacologic agent of choice for all three infections (body, head, and crab lice) is permethrin, but it is as important to comb hair with a fine tooth comb to remove eggs and dead lice. Permethrin 1% is available over-the-counter and has both pediculicidal and ovicidal activity against *P. humanus capitis*. Individuals with a history of hypersensitivity to ragweed or chrysanthemum may react to permethrin and should avoid this preparation. An alternative agent is oral ivermectin. Permethrin can cause itching, burning, stinging, and tingling with application. Because of the reports of resistance to permethrin, an alternative agent is 0.5% malathion, which should be applied to dry hair, and rinsed after 8 to 12 hours with shampoo. Two applications of malathion, 7 days apart, may be necessary to eradicate the infection.[12,13] Other alternatives for head lice include spinosad

0.9% or benzyl alcohol 5%, for which dosing varies by hair length. For the relief of pruritus, calamine lotion with 0.1% menthol or an equivalent agent may be used. Lindane is no longer recommended due to side effects. KEY CONCEPT All individuals, including immediate family members and sexual partners of the primary host, should be treated. All bedding and clothes should be cleaned in hot water.[13] See Table 78–6 for adverse events related to drugs.

LO 10

Scabies

KEY CONCEPT Scabies is caused by the mite *Sarcoptes scabiei* hominis, which affects both humans and animals. Infection usually affects the interdigital and popliteal folds, axillary folds, the umbilicus, and the scrotum. The infection causes severe itching and excoriations in the interdigital web spaces, buttocks, groin, and scalp. Scabies may also manifest as nodules or crusted scabies (Norwegian scabies), which is a more aggressive form of disease. Diagnosis is made by identifying the mite from skin scrapings on a wet mount.[52]

Treatment

LO 10

KEY CONCEPT The agent of choice for scabies is permethrin 5% cream.[12,13] Alternative agents are crotamiton 10% (Eurax) or oral ivermectin 200 mcg/kg as a single dose. Lindane is only indicated for classic (not crusted) scabies and is contraindicated in pregnant women or children. Before applying permethrin, the skin should be scrubbed in a warm soapy bath to remove the scabs. The permethrin lotion should then be applied to the whole body, avoiding the face, mucous membranes, and eyes, and left on for 8 to 14 hours before washing off. A single application eradicates 97% of scabies. However, in subjects with poor response, permethrin application can be combined with oral ivermectin therapy.[13] All close contacts should be treated appropriately. The pruritus associated with scabies may persist for 2 to 4 weeks because of the remnants of mite parts in the skin. Clothing and bedding must be washed in hot water.[12,13] See Table 78–6 for adverse events related to drugs.

LO 10

Patient Care Process: Ectoparasites

Collect Information:

- Ask the patient about specific symptoms and when they started, and if anyone in the household is experiencing the same symptoms.
- Obtain a travel, medical, and medication history.

Assess the Information:

- Determine if symptoms are consistent with an ectoparasitic infection (ie, specific identifiable rash, identifiable mites).
- Identify treatment options.

Develop a Care Plan:

- Consider if other family members need to be treated and the ability for all members to be treated and adhere to a regimen.

Implement the Care Plan:

- Explain the treatment choice to the patient and counsel them on proper hygiene (eg, washing clothing and linens) and administration of medication.
- Advise patient on possible side effects.

Follow-up: Monitor and Evaluate:

- Instruct patient to follow up at the end of therapy if symptoms are not gone.

Outcome Evaluation

Infections due to arthropods can be controlled by preventing their access to the host. Avoiding sharing common personal items like hats and hair brushes may minimize the spread of these arthropod-transmitted infections. Permethrin is an effective agent for all of them.

Abbreviations Introduced in This Chapter

CDC	Centers for Disease Control and Prevention
CF	Complement fixation
ELISA	Enzyme-linked immunosorbent assay
IgA	Immunoglobulin A
PCR	Polymerase chain reaction

79 Urinary Tract Infections and Prostatitis

Spencer H. Durham

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

LO

1. Determine the diagnostic criteria for significant bacteruria, urinary tract infections (UTIs), and catheter-associated UTIs.
2. Recognize the signs and symptoms of urinary tract infections (UTIs), and differentiate asympotomatic bacteriuria from acute cystitis and pyelonephritis, and acute prostatitis from chronic prostatitis.
3. Identify the pathogenic organisms most commonly implicated in different UTIs.
4. Assess the laboratory tests used in the diagnosis of UTIs.
5. Based on clinical signs, symptoms, and laboratory parameters, recommend appropriate empiric and targeted pharmacotherapy for the treatment of acute cystitis, pyelonephritis, and prostatitis, including drug, dose, and duration of therapy.
6. Formulate appropriate monitoring and education information for patients with UTIs.

INTRODUCTION

A urinary tract infection (UTI) is defined as the presence of pathogenic microorganisms in the genitourinary tract with associated signs and symptoms of infection. UTIs represent a diverse array of syndromes based on location within the urinary tract, including acute cystitis, pyelonephtritis, and prostatitis.[1–3] UTIs are one of the most common reasons for the prescribing of antimicrobial therapy.[4]

EPIDEMIOLOGY AND ETIOLOGY

The prevalence and type of UTIs generally vary according to age and gender.[5,6] In adults, bacteriuria is more common in young, nonpregnant women (range, 1%–3%), but uncommon in men (up to 0.1%).[7] Symptomatic UTIs occur most frequently in women of childbearing age. It is estimated that the lifetime risk of UTIs in women is as high as 60%, with 25% of those patients experiencing a recurrence within 1 year.[8] UTIs are much more common in women and men due to their inherently shorter urethra and location in the perineal area. However, older men may experience UTIs due to immunoscenesence and concomitant disease states, such as benign prostatic hypertrophy (BPH).

LO 2

KEY CONCEPT UTIs can be classified as either uncomplicated or complicated. Uncomplicated infections usually occur in women of childbearing age. Complicated UTIs usually occur in patients who have structural or functional abnormalities of the genitourinary tract, and may involve the bladder or the kidneys.[2] Male patients with UTIs are considered complicated, and most older adults will also meet this criterion. Although complicated infections are usually treated similar to uncomplicated infections, a longer treatment duration is typically warranted in complicated infections. UTIs can also be classified as upper and lower depending on their anatomical location. Lower UTIs usually refer to acute cystitis, whereas upper UTIs refer to pyelonephritis. It is important to note that an upper UTI does not necessarily imply complicated UTI, nor does a lower UTI imply uncomplicated UTI.

LO 3

The etiologic pathogens of most UTIs originate from the perirectal area. *Escherichia coli* is implicated in more than 80% of uncomplicated infections, with *Klebsiella pneumoniae* and *Proteus* species being less common.[9] Gram-positive organsisms, such as *Staphylococcus saprophyticus* and *Enterococcus* species, are uncommon but potential causes.[10,11] Although *E. coli* is still implicated in complicated UTIs, it causes less than 50% of these infections. The bacteria responsible for complicated infections can be more varied than with uncomplicated infections, and some complicated infections may be due to highly resistant organisms such as *Enterobacter* species and *Pseudomonas aeruginosa*.[12]

PATHOPHYSIOLOGY

There are three potential ways for bacteria to enter into the urinary tract and cause infection: the ascending, hematogenous, and lymphatic pathways. The most common route of infection is via the ascending pathway. KEY CONCEPT Due to the inherently short urethra and proximity to the perirectal area, bacteria often colonize the female urethra. The ascending pathway of infection involves ascention of colonized bacteria upward into the bladder, leading to acute cystitis[13] (Figure 79–1). Once in the bladder, bacteria may continue to ascend the urinary tract via the ureters and cause upper UTIs as well.

The hematogenous route involves the seeding of the urinary tract with pathogens carried through the blood from a distant site of infection. For example, *Staphylococcus aureus* bacteremia is known to cause UTIs and renal abscesses via the hematogenous route.[14] However, less than 5% of all UTIs are thought to be related to hematogenous spread. The lymphatic pathway is least understood because it is uncertain that bacterial transmission occurs in this manner.

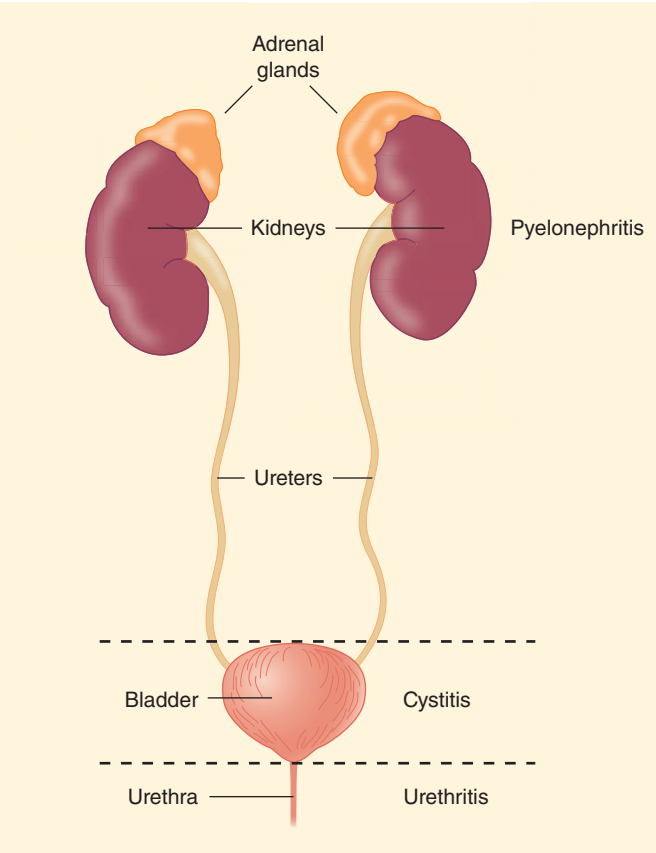

FIGURE 79–1. Anatomy and associated infection of the urinary tract. (From Sprandel KA, Lesch CA, Rodvold KA. Lower urinary tract infection. In: Schwinghammer TL (ed). 6th ed. New York: McGraw-Hill; 2005; 315; with permission.)

Host Defense Mechanisms and Risk Factors

Urine possesses numerous characteristics unsuitable for bacterial metabolism and growth, such as low pH, high urea concentration, and high osmolality. The presence of bacteria in the bladder stimulates an urge to urinate to void the bladder and release the bacteria. In addition, innate host response and adaptive immunity are defense mechanisms against bacterial infections, including UTIs.[15]

There are several risk factors for development of UTIs.[7] Common risk factors for uncomplicated infections in women include sexual intercourse, use of a cervical diaphragm or spermicidal jellies, diabetes, and pregnancy.[16–18] Risk factors in men include not being circumcised and, in older men, prostatic hyperplasia. In complicated infections, urinary tract obstruction is a common risk factor for both men and women. Vesicouretal reflux (VUR), which can result from obstruction or congenital abnormalities, results in urine being forced from the ureters into the kidneys, which can also predispose to infection.[19,20] Other risk factors common to both men and women include urologic instrumentation, urethral catheterization, renal transplantation, and neurogenic bladder.[21,22]

CLINICAL PRESENTATION AND DIAGNOSIS

Signs and symptoms of lower UTIs include increased urinary frequency, urgency, dysuria, nocturia, and supraputic heaviness. Systemic signs and symptoms are uncommon with lower UTIs. By contrast, patients with pyelonephritis often present with systemic signs and symptoms, such as fever, chills, flank pain, nausea and vomiting, and elevated white blood cell count. Older adults often do not present with traditional signs and symptoms of a UTI due to the naturally impaired ability of their immune systems to mount a typical reponse to infections. Instead, they may experience altered mental status, poor appetite, and incontinence.

Table 79–1

Quantitative Diagnostic Criteria for UTIs

Condition	Quantitative Measure
Asymptomatic bacteriuria	• 2 consecutive urine cultures with the same organism greater than or equal to 10^5 CFU/mL in asymptomatic patients
UTI	• ≥ 10^5 CFU/mL in a symptomatic woman[a] • ≥ 10^3 CFU/mL in a symptomatic man • Any growth of bacteria on suprapubic catheterization in a symptomatic patient
Catheter-associated UTI	• ≥ 10^3 CFU/mL of at least 1 pathogenic species in a symptomatic patient • ≥ 10^5 CFU/mL of at least 1 pathogenic species in any patient regardless of symptoms

[a]Some women may have signs and symptoms of a UTI but less organisms on culture results. Treatment is still indicated for these patients.

CFU, colony-forming unit; UTI, urinary tract infection.

The diagnosis of a UTI should generally be based on signs and symptoms in conjunction with laboratory tests to determine bacterial counts in the urine. Bacteriuria, defined as the presence of bacteria in the urine, does not always represent true infection. Asymptomatic bacteriuria is the isolation of a quantitative amount of bacteria from an appropriately collected urine specimen in a patient without signs and symptoms of a UTI.[23] While a full discussion of asymptomatic bacteriuria is beyond the scope of this chapter, it is important to note that it should only be treated with antimicrobial therapy in very selected circumstances, and not in premenopausal, nonpregnant women. To help diagnose true UTIs, quantitative diagnostic criteria have been developed based on the amount of bacteria present in the urine combined with the presence or abscense of infectious signs and symptoms (Table 79–1). A urinalysis is a microscopic examination of the urine and can be helpful to aid in diagnosis. Common abnormalities associated with UTIs seen on urinalysis can be seen in the Clinical Presentation and Diagnosis of UTIs textbox. In particular, the presence of white blood cells (pyuria) and leukocyte esterase (by-products of white blood cells) will almost always be seen in patients with UTIs. In addition, the presence of nitrites, which are formed by many of the etiologic gram-negative pathogens associated with UTIs, is usually seen. A urine culture is considered the gold standard for confirmatory diagnosis of a UTI in symptomatic patients.

TREATMENT

KEY CONCEPT The goals of treatment are to eradicate the causative pathogen, prevent or treat consequences of infection, administer appropriate empiric antimicrobial therapy or targeted therapy based on culture results, and prevent recurrence of infection.

Antimicrobial therapy is the cornerstone of treatment in symptomatic UTIs. Ideally, the selected antimicrobial should be well tolerated, require few total doses, achieve adequate concentrations in the urinary tract, possess few drug interactions, have wide therapeutic index, and have good oral bioavailability.

Clinical Presentation and Diagnosis of UTIs

General

- Most otherwise healthy women present with local signs and symptoms, such as dysuria and increased urgency and frequency.
- Patients with lower UTIs rarely present with systemic signs and symptoms, whereas those with upper UTIs usually do.
- Elderly patients are often asymptomatic or present with altered mental status.
- More than 95% of uncomplicated UTIs are caused by a single organism, most commonly *E. coli*.

KEY CONCEPT Signs and Symptoms of Lower UTIs

LO 2

- Dysuria, gross hematuria, suprapubic heaviness, nocturia, increased urinary frequency, and urgency

KEY CONCEPT Signs and Symptoms of Upper UTIs

LO 2

- Fever, chills, nausea/vomiting, malaise, and flank pain

Laboratory Tests

Urinalysis abnormalities include:

- Pyuria typically greater than 10 white blood cells/mm^3 urine (10×10^6/L)
- Bacteriuria, usually greater than 10^5 CFU organisms/mL (10^8 CFU/L)
- Presence of nitrites
- Presence of leukocyte esterase
- Bacterial urine culture
- Gold standard for diagnosis in a symptomatic patient

In addition, the empiric antimicrobial should be sufficiently narrow in antimicrobial spectrum to be unlikely to cause collateral damage (the ecological adverse effects of antimicrobial therapy).[1]

Nonpharmacologic Therapy

Several nonpharmacologic therapies have been proposed for prevention of UTIs with varying degrees of supportive evidence.

Patient Encounter Part 1

KB is a 32-year-old woman who presents to her primary care physician with complaints of a 3-day history of burning and pain upon urination and increased urinary frequency and urgency. She denies vomiting, fever, nausea, or flank pain. She has no significant past medical history. The physician orders a urinalysis to be done in the office.

What signs and symptoms are suggestive of a lower urinary tract infection (UTI)?

Would you classify this patient as noncomplicated or complicated UTI?

What additional patient information is required before creating an appropriate treatment plan for this patient?

Large volumes of cranberry juice have been associated with a decrease in the number of recurrent UTIs over a year period in small, randomized controlled trials, but efficacy is uncertain in the general population and with smaller intake volumes.[24–26] Probiotics such as *Lactobacillus* spp. lower urinary pH and may reduce the growth of pathogenic bacteria and show promise in preventing recurrent UTIs in women.[27] Although uncommonly used, topical estrogen replacement therapy has been shown to significantly decrease the incidence of UTIs in postmenopausal women as compared with placebo.[28] Methenamine hippurate and methenamine mandelate are hydrolyzed in acidic urine to the antimicrobial formaldehyde and are effective in preventing UTIs in patients without renal tract abnormalities.[29] Although several of these therapies show promise in the treatment of UTIs, their roles in therapy are currently unclear due to overall limited evidence.

Pharmacologic Therapy

Table 79–2 reviews oral and intravenous (IV) antibiotics frequently used to treat UTIs with comments on their use, and Table 79–3 reviews frequency, duration, and doses of oral antibiotics used commonly for outpatient treatment of UTIs.

Table 79–2

Commonly Used Antimicrobial Agents for the Treatment of UTIs

Agent	Comments
Oral Therapy	
Penicillins	
Amoxicillin Amoxicillin-clavulanic acid	Amoxicillin is no longer recommended for empiric therapy due to increasing *E. coli* resistance, but can be considered for targeted therapy. Amoxicillin-clavulanic acid can be considered for empiric therapy if a β-lactam must be used.
Pivmecillinam	Pivmecillinam is a prodrug of mecillinam and is recommended for treatment of acute cystitis. It should be avoided in patients with suspected pyelonephritis. Neither pivmecillinam nor mecillinam is currently approved for use by the US FDA.
Cephalosporins	
Cephalaexin Cefaclor Cefadroxil Cefixime Cefpodoxime Cefuroxime	Oral cephalosporins can be used as alternative therapies for the empiric treatments of UTIs, but they are less effective and have more adverse effects compared to nitrofurantoin and TMP/SMX. Concern also exists for use of these agents as a first-line option for uncomplicated cystitis therapy due to potential selection of cephalosporin-resistant organisms.

(Continued)

Table 79–2

Commonly Used Antimicrobial Agents for the Treatment of UTIs (*Continued*)

Agent	Comments
Fluoroquinolones	
Ciprofloxacin Levofloxacin	Fluoroquinolones are highly effective in the treatment of acute cystitis and pyelonephritis, but bacterial resistance is increasing. They should not be used empirically for acute cystitis due to the risk of collateral damage, unless a first-line agent cannot be used. They are first-line agents for pyelonephritis if *E. coli* resistance in the area is < 10%. Avoid in pregnancy and children. Moxifloxacin should not be used due to limited urinary excretion.
Miscellaneous	
Trimethoprim-sulfamethoxazole	Considered a first-line option for acute cystitis if *E. coli* resistance in the area is < 20%. A 3-day treatment regimen is recommended. It can also be used as prophylaxis for recurrent infections. Generally well tolerated and low cost but increasing resistance rates above 20% in certain regions. Its use may be precluded in patients with sulfa allergies.
Nitrofurantoin	Broad-spectrum agent with a low-risk of collateral damage. Does not penetrate renal tissue well, so should not be used for pyelonephritis. It is considered a first-line agent for acute cystitis and a 5-day treatment is recommended. This agent is effective in treatment and prophylaxis in patients with uncomplicated or recurrent lower tract UTIs. Traditionally, the Beers criteria recommended to avoid use in CrCl < 60 mL/min due to limited urine concentrations, but recent evidence suggests it is effective even with a CrCl as low as 30 mL/min.
Fosfomycin	First-line, single-dose therapy for uncomplicated cystitis. Has been recommended for empiric therapy since resistance rates are low but may have inferior efficacy when compared with short courses of other oral antibiotic agents. Possesses a broad-spectrum of activity, so is sometimes used to treat multidrug-resistant organisms, including ESBL-producing organisms.
Parenteral Therapy	
Aminoglycosides	
Amikacin Gentamicin Tobramycin	Gentamicin and tobramycin given as a consolidated 24-hour dose are recommended as a one-time dose for the treatment of outpatient pyelonephritis, followed by oral antimicrobials, when resistance rates preclude the empiric use of other agents. They can also be used for empiric inpatient treatment of pyelonephritis. Amikacin generally is reserved for multidrug-resistant bacteria.
Penicillins	
Ampicillin Ampicillin-sulbactam Piperacillin-tazobactam	These agents can be used for the treatment of pyelonephritis in the inpatient setting.
Cephalosporins	
Ceftriaxone Ceftazidime Cefepime	Ceftriaxone is recommended as an initial dose for the treatment of outpatient pyelonephritis when resistance rates preclude the empiric use of other agents. Ceftriaxone and other extended-spectrum cephalosporins can be used in the empiric treatment of pyelonephritis in the inpatient setting.
Carbapenems	
Doripenem Ertapenem Imipenem-cilastatin Meropenem	Broad-spectrum agents that can be used in the empiric treatment of pyelonephritis in the inpatient setting when multi-drug resistance is suspected.
Fluoroquinolones	
Ciprofloxacin Levofloxacin	IV dosage forms are considered first-line agents for pyelonephritis if *E. coli* resistance in the area is < 10%. These agents have broad-spectrum activity against both gram-negative and gram-positive bacteria. They provide high urine and tissue concentrations. Switch to oral therapy when possible due to excellent bioavailability. Resistance rates are increasing in the United States, so often cannot actually be used as a first-line therapy.

CrCl, creatinine clearance; ESBL, extended-spectrum β-lactamase; FDA, Food and Drug Administration; IV, intravenous; TMP/SMX, trimethoprim-sulfamethoxazole; UTI, urinary tract infection.

▶ *Uncomplicated UTIs*

Cystitis Because patients with uncomplicated acute cystitis rarely manifest systemic signs and symptoms of infection, treatment is generally provided in the outpatient setting.[1] Patients are subsequently monitored for resolution of signs and symptoms. LO 5 KEY CONCEPT Uncomplicated UTIs are usually managed with a short-course antimicrobial therapy involving one-dose, 3-day, or 5-day regimens depending on the clinical factors involved. Because urine culture results take several days for complete results, empiric treatment in the outpatient setting will often be complete prior to obtaining final culture results. Therefore, urine cultures are rarely obtained.[1,30]

For acute uncomplicated UTIs, there are three primary oral empiric treatment options: one dose of fosfomycin, a 3-day course of trimethoprim-sulfamethoxazole (TMP/SMX), or a 5-day course of nitrofurantoin.[1] Due to increasing antimicrobial resistance to TMP/SMX, empiric therapy with this agent should only be considered if local resistance rate to *E. coli* is less than 20%.[1,9,31] Fluoroquinolone (as 3-day regimens) and oral beta-lactam antimicrobials (3–7-day regimens) can also be used for empiric therapy, but should be relegated for use only when one of the three primary treatment options cannot be utilized. Fluoroquinolones are broad-spectrum antimicrobials and have a high propensity to cause collateral damage. Some β-lactams

Table 79–3

Overview of Outpatient, Oral Antimicrobial Therapy for Acute Cystitis, Pyelonephritis, and Prostatitis

Indications	Antibiotic	Adult Dose[a]	Frequency	Duration[b]
Acute Cystitis				
First-line options	Nitrofurantoin monohydrate/ macrocrystals	100 mg	Every 12 hours	5 days
Alternative options:	Trimethoprim-sulfamethoxazole	One DS[c] tablet	Every 12 hours	3 days
	Fosfomycin	3000 mg	One-time dose	1 day
	Pivmecillinam[d]	400 mg	Every 12 hours	3–7 days
	Ciprofloxacin	250 mg	Every 12 hours	3 days
	Levofloxacin	250 mg	Every 24 hours	3 days
	Amoxicillin-clavulanic acid	500 mg	Every 8 hours	3–7 days
	Cefdinir	100 mg	Every 12 hours	3–7 days
	Cefaclor	250–500 mg	Every 8 hours	3–7 days
	Cefpodoxime-proxetil	100 mg	Every 12 hours	3–7 days
Recurrent infections—continuous prophylaxis	Trimethoprim-sulfamethoxazole	½ SS[e] tablet	Every 24 hours	6 months
	Trimethoprim	100 mg	Every 24 hours	6 months
	Ciprofloxacin	125 mg	Every 24 hours	6 months
	Nitrofurantoin	50 *or* 100 mg	Every 24 hours	6 months
	Cefaclor	250 mg	Every 24 hours	6 months
	Cephalexin	125 mg	Every 24 hours	6 months
Pyelonephritis				
Outpatient treatment	Ciprofloxacin	500 mg	Every 12 hours	7 days
	Ciprofloxacin (extended release)	1000 mg	Every 24 hours	7 days
	Levofloxacin	750 mg	Every 24 hours	5 days
	Trimethoprim-sulfamethoxazole	One DS[c] tablet	Every 12 hours	14 days
Prostatitis	Ciprofloxacin	500 mg	Every 12 hours	2–4 weeks[f]
	Levofloxacin	500 mg *or* 750 mg	Once daily	2–4 weeks[f]
	Trimethoprim-sulfamethoxazole	One DS[c] tablet	Every 12 hours	2–4 weeks[f]

[a]Majority of listed antimicrobial agents require dosage adjustment in patients with significant renal dysfunction.

[b]Duration of therapy may be longer if treating complicated infections.

[c]DS, double strength (160 mg trimethoprim/800 mg sulfamethoxazole).

[d]Not approved for use by the US FDA.

[e]SS, single strength (80 mg trimethoprim/400 mg sulfamethoxazole).

[f]Treatment should be 6–12 weeks if treating chronic prostatitis.

are also broad-spectrum, but are also less efficacious and have a higher incidence of adverse effects compared to the three primary treatments. Ampicillin and amoxicillin should not be considered for empiric therapy due to low efficacy and high rates of resistance.[1]

▶ *Acute Pyelonephritis*

Patients experiencing acute pyelonephritis may be treated in either the outpatient or inpatient settings. In particular, patients who may be dehydrated due to poor fluid intake or severe nausea and vomiting, or those with unstable vital signs should receive inpatient treatment.

Unlike patient with acute cystitis, urine culture and susceptibility testing should always be performed in patients experiencing pyelonephritis. For patients who can be treated as outpatients, oral fluoroquinolones as a 5- or 7-day regimen are the mainstay of therapy if local *E. coli* resistance is less than 10% (see Table 79–3 for specific regimens). A one-time initial dose of IV ciprofloxacin (400 mg) can also be considered. For patients who reside in areas where resistance is greater than 10%, oral fluoroquinolones can still be utilized, but an initial dose of IV ceftriaxone (1 gram) or a consolidated 24-hour dose of an aminoglycoside should be given. The purpose of this initial IV dose is to provide long-acting empiric coverge while awaiting urine culture results. TMP/SMX can be used as a 14-day treatment, but only if susceptibility is confirmed. If TMP/SMX is used empirically, the initial IV dose of ceftriaxone or an aminoglycoside must be given. Another alternative regimen is an oral beta-lactam for 10 to 14 days given with the initial IV dose of ceftriaxone or an aminoglycoside. For patients who require empiric inpatient treatment, therapy with one of four general options is recommended: a fluoroquinolone alone; an aminoglycoside with or without ampicillin; an extended-spectrum penicillin or cephalosporin with or without an aminoglycoside; or a carbapenem. Local resistance patterns should be examined to determine appropriate empiric therapy in this case.[1,32,33]

Special Populations

▶ *Pregnant Women*

Pregnant women are predisposed to UTIs due to changes in the urinary tract, including alterations in amino acid and other nutrient concentrations in the urine and physiologic changes such as reduced bladder tone and dilation of the renal pelvis and ureters.[34,35]

UTIs during pregnancy can result in serious complications, such as fetal death, labor complications, mental retardation, and developmental delay.[36,37] Because of these risks, screening for UTIs during pregnancy is recommended, and patients should receive treatment regardless of symptoms.[16,38] Fluoroquinolones are pregnancy category C and should generally be avoided due to their ability to inhibit cartilage and bone development.

Patient Encounter Part 2: Medical History, Physical Examination, and Diagnostic Tests

PMH: Overweight (body mass index 28 kg/m^2)

FH: Mother living with hypertension; father living with chronic obstructive pulmonary disease, diabetes mellitus type 2, and dyslipidemia

SH: Unmarried, sexually active with two partners in last 6 months, occupation: elementary school teacher

Allergies: Bactrim (rash)

Meds: Norethindrone 0.5 mg/ethinyl estradiol daily

ROS: (+) dysuria, urinary frequency; (–) fever, nausea, vomiting, flank pain

PE:

VS: BP 122/74 mm Hg, P 78 beats/min, RR 16 breaths/min, T 37.2°C

CV: RRR, normal S1, S2; normal findings

Abd: Soft, nontender, nondistended; (+) bowel sounds, no hepatosplenomegaly, heme (–) stool

Lab: Within normal limits including blood glucose; (–) pregnancy test

Urinalysis: Greater than 200 white blood cells/mm^3 (200 × 10^6/L); urine nitrates positive; leukocyte esterase positive

Urine gram stain: Gram-negative rods, more than 10^5 CFU/mL (10^8 CFU/L)

Local resistance of *E. coli* to TMP/SMX and ciprofloxacin is 18% and 7%, respectively

Given this additional information, what is your assessment of the patient's condition?

Identify your treatment goals for the patient.

What nonpharmacologic and pharmacologic alternatives are available for the patient?

TMP/SMX is pregnancy category D and should also be avoided due to the potential for congenital malformations and an increased risk of neonatal kernicterus. Nitrofurantoin is category B and can be safely used during pregnancy except in the last 30 days, where it should be avoided due to an increased risk of neonatal jaundice. Most β-lactams are pregnancy category B and can be safely used, and are historically considered first-line options for pregnant patients. Fosfomycin is pregnancy category B and can be considered, but less clinical experience exists.[39] In pregnant patients who do experience UTIs, follow-up usually consists of a urine culture 1 to 2 weeks after completion of therapy, then subsequent monthly urine cultures until birth.

► *Catheterized Patients*

Catheter-associated urinary tract infections (CA-UTIs) are common in patient with an indwelling urinary catheter.[21,40] Bacteria may be introduced into the bladder via the catheter by colonization and direct introduction during catheterization. UTIs as a result of an indwelling catheter are common and occur at a rate of 3% to 8% for each day the catheter is present.[40]

The primary treatment of CA-UTIs is removal and discontinuation of the catheter if possible. In patients without signs and symptoms of infection, removal of the catheter is likely sufficient, and antimicrobials may be withheld. In patients who are symptomatic, antimicrobials should be administered. In all patients, if the catheter cannot be permanently discontinued, a new catheter should be inserted if the previous catheter has been in place for longer than 2 weeks. Empiric antimicrobial regimens for the treatment of CA-UTIs have not been well defined, and treatment should be based on local susceptibility patterns. Results from urinalyses are often difficult to interpret in patients with indwelling catheters as the white blood cell count is usually elevated due to the presence of a foreign material. Urine cultures should always be obtained in CA-UTIs to guide ultimate selection of antimicrobials. In general, treatment for 7 days is sufficient if symptoms promptly resolve, and 10 to 14 days if symptoms are slower to resolve.[40]

Patient Encounter Part 3: Creating a Care Plan

Based on the information presented, create a care plan for this patient's UTI. Your plan should include:

(a) a statement of the drug-related needs and/or problems,

(b) a patient-specific detailed therapeutic plan, and

(c) monitoring parameters to assess efficacy and safety.

► *UTIs in Men*

KEY CONCEPT UTIs occurring in men are usually due to a structural or functional abnormality of the urinary tract, and are therefore usually treated as a complicated infection.[41] For this reason, men should not generally be treated with a single dose or short course of therapy if diagnosed with a UTI. Antimicrobial therapy selection is similar to that used in otherwise healthy women, but men will usually receive 7 to 14 days of treatment.

LO 5

► *Prostatitis*

KEY CONCEPT Prostatitis is an inflammation of the prostate gland due to infection, usually from bacterial causes. Prostatitis can be acute or chronic, with acute being most common. It is uncommon in young men, but the incidence increases after the age of 30, and as many as half of all men will experience it at some point in their lifetimes. The pathogenesis of prostatitis is not completely understood, but likely involves the reflux of infected urine directly into the prostate gland.[42]

LO 2

Acute prostatitis differs from chronic in their respective signs and symptoms. KEY CONCEPT Patients with acute prostatitis present with fever, chills, localized rectal pain, dysuria, urinary straining, increased urinary frequency, and irritation. By contrast, patients with chronic prostatitis rarely present with these symptoms, but instead have difficulty urinating, perineal pain, recurrent UTIs, epididymitis, urethritis, or low back pain.[42] The pathogenic organisms responsible for prostatitis are similar to those that cause UTIs, with *E. coli* accounting for 75% of cases. *Klebsiella pneumoniae* and *Proteus mirabilis* can also be implicated, with other Enterobacteriaceae, such as *Pseudomonas*, being infrequent causes. *Staphylococcus* is a rare but possible cause as well. Some men may

LO 3

Table 79–4

Monitoring Parameters for Select Antibiotics Used in the Treatment of UTIs

Drug Class or Drug	What to Monitor	Frequency	Endpoint
Aminoglycosides	SCr, urine output	Every 24 hours	Prevention of nephrotoxicity manifested by a rise in SCr
	Aminoglycoside serum concentrations	Depends on duration of therapy. At least once weekly; more frequently if evidence of changing renal function	Trough serum concentrations < 2 mg/L or < 8 mg/L for amikacin, to decrease risk of nephrotoxicity and ototoxicity. Peak goal 5–6 mg/L. If using extended-interval dosing, monitoring should be based on the specific nomogram chosen
Nitrofurantoin	SCr	Only if renal function changing or unstable	Nitrofurantoin metabolites may accumulate in renal insufficiency and lead to neuropathy; avoid if CrCl < 30 mL/min
	Liver profile	Periodic monitoring	Prevention of cholestasis
Nitrofurantoin Tetracyclines Sulfonamides	SCr	Only if renal function changing or unstable	Decreases in glomerular filtrate rate can significantly decrease the urine concentration of these agents

CrCl, creatinine clearance; SCr, serum creatinine.

also experience prostatitis following infection with the sexually transmitted infections *Neisseria gonorrhoeae* and *Chlamydia trachomatis*. The organisms responsible for chronic prostatitis are the same as acute. Chronic prostatitis usually occurs after a patient experiences acute prostatitis when the infecting organsism is not completely removed from the prostate. Therefore, the same pathogens responsible for acute prostatitis also cause chronic.[43]

Acute prostatitis can be readily diagnosed based on symptoms and the presence of significant bacteriuria. The diagnosis of chronic prostatitis is more difficult due to the infrequent prostate symptoms. It is generally diagnosed when a male patient has a recurring UTI with the same organism each time.[42]

The pharmacologic treatment approach to the management of prostatitis is similar to that of UTIs. Antimicrobial penetration of the prostate must be taken under consideration as many antimicrobials do not penetrate well into prostatic tissue and fluids, although concentrations are improved through the inflammatory process in acute prostatitis. KEY CONCEPT Fluoroquinolones and TMP/SMX are considered the treatments of choice for prostatitis due to their activity against the most common organsims and their penetration into prostatic fluid. However, as discussed previously, bacterial resistance to these agents is increasing. Alternative agents to be considered include cephalosporins (such as cephalexin or cefuroxime) and penicillins (such as amoxicillin/clavulanate). Initial therapy with an IV agent may be necessary in some cases of acute prostatitis based on the clinical stability of the patient. Acute prostatitis should be treated for at least 2 weeks and can be extended to 4 weeks if patients are slow to improve. Chronic prostatitis is treated for a longer period of time, usually 6 weeks, but possibly up to 12 weeks.[42,44,45]

LO 5

Outcome Evaluation for UTIs

- Monitor the patient for resolution of symptoms with the goal of 48 to 72 hours to resolution after start of antimicrobial therapy.
- Follow up with urine culture results to deescalate antimicrobial therapy if possible.
- Repeat urine culture is necessary only if symptoms do not acutely abate, reinfection, or recurrence occurs. Resistance rates to *E. coli* are increasing to antibiotics commonly prescribed for UTI, and certain isolates are multidrug resistant.[46]
- Depending on the chosen antibiotic therapy, evaluate the patient based on drug therapy monitoring parameters including those presented in Table 79–4 to optimize therapy and decrease incidence of adverse events.

Patient Care Process

Collect Information:

- Based on physical examination, signs and symptoms, review of systems, and urinalysis, determine whether the patient is experiencing a UTI.
- Obtain the patient's medication history and risk factors for an antibiotic-resistant infection.
- Assess patient renal function and other laboratory tests for antibiotic dosing and systemic complications.
- Identify potential sources of infection, such as indwelling urinary catheters.

Assess the Information:

- Based on urinalysis and gram stain (if available), determine whether the empiric antibiotic selection is appropriate.
- Based on culture and susceptibility data (if available), determine whether any changes should be made from your initial empiric antimicrobial selection (ie, resistance to the regimen initially selected). Also, assess if the empiric antimicrobial selected can be deescalated to a lower-spectrum agent.

(*Continued*)

Patient Care Process (*Continued*)

- Evaluate the patient's symptoms to determine response to the antimicrobial regimen chosen.
- Evaluate the patient for the presence of adverse drug events, drug allergies, and potential drug interactions.

Develop a Care Plan:

- Determine the optimal antibiotic dose and duration of therapy based on the patient and infection type (complicated vs uncomplicated).
- Determine whether the patient may benefit from prophylactic therapy (ie, recurrent UTIs secondary to chronic urinary catheterization due to paraplegia).
- Identify lifestyle modifications as needed to minimize UTI recurrence.

Implement the Care Plan:

- Prescribe and dispense the optimal antibiotic at the correct dose and duration.
- Recommend lifestyle changes, if needed.

Follow-up: Monitor and Evaluate:

- Stress the importance of complying with the prescribed antimicrobial regimen and to follow up with the health care provider if signs and symptoms recur.

ACKNOWLEDGMENT

The authors and editors wish to acknowledge and thank Dr. Warren Rose, the primary author of this chapter in the third edition of this book.

Abbreviations Introduced in This Chapter

BPH	Benign prostatic hypertrophy
CA-UTI	Catheter-associated UTI
CFU	Colony-forming units
CrCl	Creatinine clearance
ESBL	Extended-spectrum β-lactamase
IV	Intravenous
SCr	Serum creatinine
TMP/SMX	Trimethoprim-sulfamethoxazole
UTI	Urinary tract infection
VUR	Vesicouretal reflux

80 Sexually Transmitted Infections

Marlon S. Honeywell and Evans Branch III

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

1. Analyze the behavioral considerations and assess the importance of contraception with regard to the contributing factors of sexually transmitted infections (STIs).
2. Apply the "patient-delivered partner therapy" method when recommending treatment for STIs.
3. Identify the patient populations that are typically affected by specific STIs.
4. Identify causative organisms for STIs.
5. Devise a list of the clinical signs and symptoms corresponding to each type of STI and classify patients based on recommended criteria.
6. Select appropriate diagnostic procedures for STIs.
7. Identify STI treatment regimens and recommend therapy when appropriate.
8. Design a patient care plan based on the monitoring parameters.

INTRODUCTION

Though we have made significant progress in science and medicine, longstanding problems of infectious disease continue to plague us.[1] Even with the discovery of newly improved antibiotics, sexually transmitted infections (STIs) have not been eradicated. Many have reemerged secondary to modern social trends of sexual activity, and some as a result of the human immunodeficiency virus (HIV) epidemic, socioeconomic concerns, and the global lack of preventive education. KEY CONCEPT Optimal detection and treatment of sexually transmitted diseases depend on counseling by a patient-friendly and knowledgeable clinician who can establish open communication with the patient.

LO 1 Since the correlation between risky sexual behavior and STIs is well documented,[2] most sexually active individuals will contract an infection at some point in their lives. Though inconsistent and incorrect condom use increases the probability of new STIs, counseling patients on the consistent use of condoms, spermicides, or diaphragms is an important component in reducing overall incidence.[3] Additionally, health care providers who manage persons at risk for STIs should counsel women in a timely fashion concerning the option for emergency contraception, when indicated. Mifepristone, misoprostol, oxytocin, and levonorgestrol have been employed in the United States for the prevention of unintended pregnancy.[4]

In addition to an increasing number of adolescents engaging in unsafe sexual practices, there is a high incidence of men who have sex with men (MSM) and women who have sex with women (WSW). Many MSM do not disclose their HIV status. In fact, MSM is documented as the risk group most severely affected by HIV in the United States. However, new infections within this group recently stabilized at approximately 26,000 new infections each year.[5] Although limited data are available with regard to STIs in WSW, transmission generally occurs through fisting, fingering, oral sex, or the use of sexual toys. Sharing penetrative items or employing practices involving digital vaginal or digital anal contact most likely represent the most common modes of transmission. This possibility is supported by reports of metronidazole-resistant trichomoniasis and genotype-specific HIV transmitted sexually between women who reported such behaviors and an increased prevalence of bacterial vaginosis (BV) among monogamous WSW.[6]

Sexual abuse in adolescents and children is becoming more ubiquitous in the United States. Children or adolescents with an STI should be evaluated for sexual abuse.[7] The identification of an STI in a child can have serious medical and legal implications; and is used to support the presence or allegation of abuse. In cases of abusive contact, commonly found infections include *Neisseria gonorrhoeae* or *Chlamydia trachomatis*. Abusive cases should be reported to Child Protective Services.

LO 3 Defined as a person who engages in the exchange of spouses for sexual activities, the emergence of "swingers" as a new category of at-risk patients has been seen in STI clinics throughout the world. In one Canadian clinic, swingers composed 40.8% of patients that rarely accessed STI health services.[8] Most swingers are likely to be diagnosed with HIV, herpes, chlamydia, or gonorrhea. To this end, although little data exists, swingers now represent a group with risky behaviors that must be identified and treated, when necessary.

LO 2 KEY CONCEPT Optimally, both sex partners should be treated simultaneously for an STI; however, this is difficult to accomplish. Clinics and health departments often proactively attempt dual treatment by providing a prescription for the partner to the index patient (the patient who is evaluated by a clinician), a practice commonly known as patient-delivered partner therapy. Medications or prescriptions should be accompanied by treatment instructions and appropriate warnings. Counseling regarding the appropriate use of condoms, cervical diaphragms, spermicides, and emergency contraception is also important to mitigate the occurrence of reinfection.

Accurate reporting of STIs is imperative to the evaluation of trends in sexual behaviors; reporting may be provider- or laboratory-based. State and local health departments may assist with the mechanism by which STI cases are reported in accordance with statutory requirements. Confidentiality should always be exercised in such cases.[9,10]

GONORRHEA

LO 4

A curable STI caused by the gram-negative diplococcus *Neisseria gonorrhoeae*, gonorrhea may be the second most commonly reported bacterial STI. Proper therapeutic management with antimicrobial agents is essential to eradicate this infection and prevent the development of associated sequelae such as a urethritis, cervicitis, or dysuria.

In the United States, over the past 5 years, an increase in the gonorrhea infections has been observed in both males and females; the increase was larger among males. The highest rate of gonococcal infection is seen within the 15- to 24-year-old age groups for both sexes; although more cases are reported in men. Approximately 700,000 new cases occur annually in the United States.[9,10] In 2015, approximately 3.95 cases per person were reported. Factors associated with an increased risk of infection include ethnicity, low socioeconomic status, illicit drug use, and age. Targeted screening of young women, less than 25 years of age, who are at an increased risk has been correlated to gonorrhea control in the United States.[9] In fact, the risk of a cervical infection after a single episode of vaginal intercourse is approximately 50% and increases with multiple exposure. Furthermore, rates of reinfection are significantly higher among ethnic minorities.

PATHOPHYSIOLOGY

Attachment to mucosal epithelium, mediated in part by pili and opa (outer membrane opacity proteins), is followed by penetration of *N. gonorrhoeae* through epithelial cells into the submucosal tissue within 24 to 48 hours. A vigorous response by neutrophils begins with sloughing of the epithelium, development of submucosal microabscesses, and exudation of pus. Stained smears usually reveal large numbers of gonococci within a few neutrophils, whereas most cells contain no organisms.[11]

DIAGNOSIS

LO 6

Several laboratory tests are available to aid in the diagnosis of gonorrhea and include Gram-stained smears, endocervical or vaginal specimens, culture, or the DNA hybridization probe.

Patient Encounter 1, Part 1

RT is a 58-year-old man who visits a clinic complaining of profuse urethral discharge, increased frequency of urination, a persistent sore throat, and swollen testicles for the past several days. The patient admits to having sexual intercourse with his wife and three other women without barrier contraception (condoms). He also admits to having sexual intercourse with one of the other women for more than 12 months.

What information is suggestive of gonorrhea?

What potential risk factors for STIs are present?

What other diagnostic tests should be ordered?

Clinical Presentation of Gonorrhea[9,10]

LO 5

General

- Purulent discharge
- Greater urinary frequency
- Persistent sore throat

Signs

- Painful or swollen testicles
- Tubal scarring

Symptoms

Men:

- May be asymptomatic, though acute urethritis is the predominant manifestation
- Urethral discharge and dysuria, usually without urinary frequency or urgency
- When compared with nongonococcal urethritis, the discharge in gonococcal urethritis is generally more profuse and purulent
- Pain during urination

Women:

- Cervicitis, urethritis, increased vaginal discharge, dysuria, and intermenstrual bleeding
- Pain during urination
- Abdominal pain

Patient Encounter 1, Part 2

PMH: Hypertension, diabetes, hyperlipidemia, asthma; no prior history of STIs; no drug allergies noted

Meds: Amlodipine 10 mg by mouth daily; furosemide 40 mg by mouth daily; metformin 500 mg by mouth three times daily; glipizide XL 5 mg by mouth daily; simvastatin 40 mg by mouth at bedtime; Advair HFA 250/50 2 inhalations by mouth twice daily

FH: Mother has diabetes and hypertension. Father is deceased.

SH: Admits to having unprotected sex with wife and another woman. Does not smoke; drinks alcohol occasionally

ROS: C/o urethral discharge and swollen testicles

PE:

VS: BP 150/88 mm Hg, post prandial glucose 132 mg/dL (7.3 mmol/L), total cholesterol 198 mg/dL (4.86 mmol/L), P 73 beats/min, T 37.0°C (98.6°F)

Lab: Urethral discharge swab revealed *N. gonorrhoeae*; rapid plasma reagin (RPR) test was positive

Given this additional information, what is your assessment of the patient's condition?

What consideration should be given to other STIs?

Identify your treatment goals for this patient.

What pharmacologic alternatives are available for this patient?

A gram stain of a male urethral specimen that demonstrates polymorphonuclear leukocytes with intracellular gram-negative diplococci may be considered diagnostic in symptomatic men. A gram-negative stain is insufficient for ruling out infection in asymptomatic men.[9] Additionally, gram stain of endocervical, pharyngeal, or rectal specimens are also insufficient to detect infections. All patients who test positive for gonorrhea should be tested for other STIs, including chlamydia, syphilis, and HIV.

TREATMENT

The desired outcome is complete eradication of *N. gonorrhoeae* and avoidance of sequelae.

Pharmacologic Therapy[4,9,12,13]

KEY CONCEPT Patients infected with gonorrhea are often coinfected with *C. trachomatis* and should receive concurrent therapy to eradicate both organisms. Treatment is now complicated by the development of resistance to *N. gonorrhoeae.* To mitigate the probability of resistance, the most recent guidelines recommend the combination of cephalosporins and azithromycin.[9] Use of azithromycin as the second antimicrobial is preferred to doxycycline because of the convenience and compliance advantages associated with single dose therapy; and the substantially higher resistance of gonococcus to tetracyclines. Ceftriaxone and azithromycin should be administered together on the same day to improve results. However, treatment failures involving cephalosporins have been noted in Hawaii and Asian countries. As such, clinicians should determine whether sexual activity may have occurred in these countries before recommending antibiotic therapy. Fluoroquinolones should not be prescribed for infections in MSM, in those with a history of recent foreign travel or for infections acquired in California, Hawaii, and Asian countries or for infections in other areas with increased gonococcal resistance.[14,15] First-line treatment for gonorrhea in most countries is third-generation cephalosporins, and in some cases, spectinomycin and azithromycin have been used.[16]

LO 7

Though unavailable in the United States, spectinomycin is expensive and has poor efficacy against pharyngeal infections. Doxycycline 100 mg orally (PO) twice daily for 7 days may be used in combination with ceftriaxone when an allergy to azithromycin is noted. The mechanism of resistance appears to be associated with a mosaic penicillin-binding protein in addition to other chromosomal mutations previously found to confer resistance to β-lactam antimicrobials. To reduce the prevalence of cephalosporin resistance, strong antimicrobial management programs, expanding surveillance networks and procedures, and STI control and prevention are warranted.

Oral hormonal contraception has been evaluated to determine if it deters the acquisition of gonococcal infections in women. Though transmission of *N. gonorrhoeae* is poorly understood, one study suggested that oral hormonal contraception may lessen the probability of infection.[17] More studies are required to support this theory as a viable option for prevention.

Treatment of gonorrhea may vary according to clinical presentation and is indicated as follows[9]:

Uncomplicated Gonococcal Infection of the Cervix, Urethra, and Rectum[a]: Ceftriaxone 250 mg intramuscularly (IM) *or* cefixime 400 mg PO *or* single-dose injectable cephalosporin regimens *plus* azithromycin 1 g PO *or* doxycycline 100 mg PO twice daily for 7 days. When ceftriaxone is unavailable, ceftizoxime 500 mg IM *or* cefoxitin 2 g IM with probenecid 1 g *or* Cefotaxime 500 mg IM have also been used.[15] Though several alternative agents possess notable activity, they should not be used if pharyngeal infection is suspected. Spectinomycin has also been prescribed.

Uncomplicated Gonococcal Infection of the Pharnyx: Ceftriaxone 250 mg IM plus azithromycin 1 g PO.

MSM or Heterosexuals with a History of Recent Travel[a]: Ceftriaxone 250 mg IM *or* cefixime 400 mg PO *plus* treatment for chlamydial infection, if it has not been ruled out.

Uncomplicated Gonococcal Infection of the Pharyngeal, Cervix, Urethra, or Rectum: Ceftriaxone 250 mg IM plus azithromycin 1 g PO or doxycycline 100 mg PO twice daily for 7 days. Single-dose injectable cephalosporins which are generally effective against uncomplicated urogenital and anorectal gonococcal infections include ceftizoxime 500 mg IM, cefoxitin 2 g IM with probenecid 1 g PO, and cefotaxime 500 mg IM. None of the aforesaid injectable cephalosporins offer any advantage over ceftriaxone.

Coverage for Coinfection with *C. trachomatis*: Azithromycin 1 g PO as a single dose *or* doxycycline 100 mg PO twice daily for 7 days. Since most gonococcal infections in the United States are susceptible to azithromycin and doxycycline, routine cotreatment might hinder the development of resistance.

Treatment of Gonorrhea in Special Situations

Uncomplicated infections of the cervix, urethra, and rectum can be treated with one of the following regimens in adults:

▶ *Recommendations During Pregnancy*

- Pregnant women should be treated with a recommended or alternative cephalosporin. For women who cannot tolerate a cephalosporin, azithromycin 2 g PO may be prescribed. For treatment of presumptive or diagnosed *C. trachomatis*, azithromycin or amoxicillin is recommended. When allergies or other issues preclude treatment, consultation with an infectious diseases specialist is recommended.

▶ *Allergy, Tolerance, or Adverse Reactions*

- When cephalosporin allergy is a consideration, single doses of PO or IM gemifloxacin 320 mg *plus* azithromycin 2 g may be used.
- Doxycycline and fluoroquinolones are contraindicated.

[a]Regimens are given for one dose only.

Patient Encounter 1, Part 3

Unprotected sex is a major risk factor for contracting STIs. Although the purulent discharge and pain during urination are consistent with gonorrhea infection, a positive urethral swab coupled with an incubation period consistent with gonorrhea confirms the diagnosis. A serologic test for HIV should be performed. Although gonorrhea has been confirmed in this patient, infection with *C. trachomatis* occurs commonly in this setting. The expedited partner treatment approach should be employed, and treatment should effectively cover gonorrhea and chlamydia.

If this patient has a true allergy to penicillin and cephalosporins, how would the therapeutic management of the identified problems change?

Recommendations for Disseminated Gonococcal Infection (Regimens Should Be Continued for 24–48 Hours): Ceftriaxone 1 g IM or intravenous (IV) every 24 hours *plus* azithromycin 1 g PO *or* cefotaxime 1 g IV every 8 hours *or* ceftizoxime 1 g IV every 8 hours plus azithromycin 1 g PO. Continue regimens for 24 to 48 hours after improvement is noted.

Uncomplicated Infections of the Cervix, Urethra, and Rectum in Children Less Than 45 kg: Ceftriaxone 250 mg IM as a single dose *or* spectinomycin 40 mg/kg IM as a single dose (not to exceed 2 g).

Gonococcal Conjunctivitis: Ceftriaxone 1 g IM once plus azithromycin 1 g PO for adults has demonstrated excellent response rates. Lavage of the infected eye(s) once with saline solution should also be considered. Since gonococcal conjunctivitis is uncommon and data is limited, consultation with an infectious-disease specialist should be considered.

Ophthalmia Neonatorum Prophylaxis: Erythromycin 0.5% ophthalmic ointment in each as a single application at birth. This medication should be instilled into both eyes, regardless of whether delivery is vaginal or cesarean. If erythromycin is unavailable, ceftriaxone may be used at a dose of 25–50 mg/kg IV or IM, not to exceed 125 mg in a single dose.

Gonococcal Scalp Access in Newborns: Ceftriaxone 25 to 50 mg/kg/day IV or IM in a single daily dose for 7 days or cefotaxime 25 mg/kg IV or IM every 12 hours for 7 days may be used. Both medications may be used for a duration of 10–14 days if meningitis is documented.

Outcome Evaluation

- Order diagnostic test for gonorrhea. If positive, recommend antibiotics that cover gonorrhea and chlamydia.
- Subsequent to treatment, expect the eradication of organisms responsible for gonorrhea and chlamydia.
- Monitoring is generally not required.

CHLAMYDIA

EPIDEMIOLOGY

LO4 LO3 Infection with *C. trachomatis* has increased dramatically in recent years. This bacterium is the most common cause of nongonococcal urethritis, accounting for as many as 40% of cases. In 2015, 1,526,658 cases of chlamydia were reported to the CDC; and an estimated 2.86 million infections occur annually. Many cases remain unreported because most people are asymptomatic and do not seek testing. Chlamydia is most common among young people. Almost two-thirds of new chlamydia infections occur among youth aged 15 to 24 years.

Substantial racial disparities in chlamydia infection exist, with a prevalence among non-Hispanic blacks 5.9 times the prevalence among non-Hispanic whites. Chlamydia is also common among MSM. Among MSM screened for rectal chlamydia infection, 3% to 10.5% were positive.

PATHOPHYSIOLOGY

C. trachomatis possesses characteristics resembling both bacteria and viruses. Its major membrane is comparable to that of gram-negative bacteria, although it lacks a peptidoglycan cell wall and requires cellular components from the host for replication. Chlamydia transmission risk is thought to be less than that of gonorrhea.

CLINICAL PRESENTATION AND DIAGNOSIS

LO6 Common tests used to diagnose *C. trachomatis* include the nucleic acid amplification test, culture, enzyme immunoassay, DNA hybridization probe, or the direct fluorescent monoclonal antibody test. Diagnosis has been confirmed in women through urine or swab specimen collected from the endocervix and in men using a urethral swab or urine specimen. Most women are asymptomatic; therefore, an annual screening or physical is necessary, as early detection may reduce rates of transmission.

TREATMENT[9,18]

Uncomplicated Genital

LO7 Azithromycin 1 g PO as a single dose *or* doxycycline 100 mg PO twice daily is suggested. Alternative recommendations include erythromycin 500 mg PO four times daily for 7 days *or* erythromycin ethylsuccinate 800 mg four times daily *or* levofloxacin 500 mg once daily for 7 days *or* ofloxacin 300 mg twice daily (or 600 mg once daily) for 7 days.

Anorectal Infection

Treatment for anorectal infection includes doxycycline 100 mg PO twice daily for 7 days or azithromycin 1 g PO as a single dose.

Chronic Reactive Arthritis

Doxycycline 100 mg PO twice daily plus rifampin 300 mg once daily for 6 months.

Uncomplicated Urethral, Endocervical, or Rectal Infection in Adults

The recommended adult regimen is azithromycin 1 g PO in a single dose *or* doxycycline 100 mg PO twice daily for 7 days. An alternate regimen *is* erythromycin ethylsuccinate 800 mg PO four times daily for 7 days *or* erythromycin base 500 mg PO four times daily for 7 days *or* levofloxacin 500 mg PO once daily for 7 days *or* ofloxacin 300 mg PO twice daily for 7 days.

The recommended regimen for pregnant patients is Azithromycin 1 g PO as a single dose *or* Amoxicillin 500 mg three times daily for 7 days *or* Erythromycin 500 mg four times daily for seven days *or* 250 mg four times daily for 14 days.

Alternate regimens include erythromycin base 500 mg PO four times daily for 7 days *or* 250 mg PO four times daily for 14 days *or* erythromycin ethylsuccinate 800 mg PO four times daily for 7 days *or* 400 mg PO four times daily for 14 days.

C. trachomatis Infection in Infants

Treatment of ophthalmia neonatorum or infant pneumonia should be with erythromycin base or ethylsuccinate 50 mg/kg/day PO divided into four doses daily for 14 days. An association between oral erythromycin and infantile hypertrophic pyloric stenosis (IHPS) has been reported in infants aged less than 6 weeks who were treated with this drug. Infants treated with erythromycin should be monitored for signs and symptoms of IHPS.

▶ *Infant Pneumonia Caused by* C. Trachomatis

Erythromycin base or ethylsuccinate 50 mg/kg/day PO divided into four doses daily for 14 days.

Clinical Presentation of Chlamydia[9,10,13]

General

- Asymptomatic

LO 5

Signs

- Beefy red cervix that bleeds easily (women)

Symptoms

- When present, the urethral discharge is watery and less purulent than that seen with acute gonococcal urethritis. Complications resulting from lack of treatment or inadequate treatment include: epididymitis (in males), and pelvic inflammatory disease (PID) including associated complications in women.

Other Diagnostic Tests

- Culture is usually positive for both chlamydia and gonorrhea.

Outcome Evaluation

- Order diagnostic test for chlamydia. If positive, recommend antibiotics that cover gonorrhea and chlamydia.
- Subsequent to treatment, expect the eradication of organisms responsible for gonorrhea and chlamydia.
- Monitoring is generally not required.

SYPHILIS

LO 4

Attributed to the spirochete *Treponema pallidum*, syphilis can have numerous and complex manifestations. Clinician familiarity, stage-specific diagnosis, and effective treatment are vital. Missed or inappropriately treated syphilis may result in cardiovascular complications, neurologic disease, or congenital syphilis.

EPIDEMIOLOGY AND ETIOLOGY

LO 3

Since the 1940s, the incidence of syphilis declined drastically following the introduction of penicillin; however, prevalence rose when HIV arrived from obscurity in the 1980s. In 2009, rates of primary and secondary syphilis increased for the tenth consecutive year, reaching the highest rate reported since 1995. Although increases have occurred mostly among men, in 2013, the rate of reported primary and secondary syphilis in the United States was 5.3 cases per 100,000 population. Additionally, from 2005 to 2015, the number of primary and secondary cases nearly doubled. The primary and secondary syphilis rate among black men was 5.2 times that among white men; the rate among black women was 13.3 times that among white women, emphasizing the need for enhanced preventive measures among blacks and MSM. The disparity among men and women has been observed across racial and ethnic groups and is highest in the South and among non-Hispanic blacks.[19]

PATHOPHYSIOLOGY

T. pallidum rapidly penetrates intact mucous membranes or microscopic dermal abrasions, and within a few hours, the organism enters the lymphatics and blood to produce systemic illness. During the secondary stage, examinations commonly demonstrate abnormal findings in the cerebrospinal fluid (CSF). As the infection progresses, the parenchyma of the brain and spinal cord may subsequently be damaged.

DIAGNOSIS AND CLINICAL PRESENTATION

Stages of Syphilis

▶ *Primary Syphilis*

LO 5 LO 6

Usually manifests as a solitary, painless chancre. Primary syphilis develops at the site of infection approximately 3 weeks after exposure to *T. pallidum*; the chancre is highly infectious.[9,20]

▶ *Secondary Syphilis*

Without appropriate treatment, primary syphilis will advance to secondary syphilis—a stage usually apparent from its clinical symptomatology. Symptoms include fatigue, diffuse rash, fever, lymphadenopathy, and genital or perineal condyloma latum. Additionally, the skin is most often affected, and a rash may present as macular, macropapular, or pustular lesions or may involve skin surfaces including the palms of the hands and soles of the feet.

▶ *Latent Syphilis*

Early Latent Usually occurs during the first year after infection and may be established in patients who have seroconverted, who had symptoms of primary or secondary syphilis, or who had sex with a partner with primary, secondary, or latent syphilis.

Late Latent Patients should be considered to have late latent syphilis if the aforementioned criteria (early latent) are not met. In both stages, patients are usually asymptomatic and the lesions noted in the primary and secondary phase usually resolve; however, individuals are still seropositive for *T. pallidum*.

Tertiary Syphilis Develops years after the initial infection and may involve any organ in the body.

Congenital Syphilis

Congenital syphilis is a condition in which the fetus is infected with *T. pallidum* as a result of the hematogenous spread from an infected mother, although transmission may also occur from direct contact with the infectious genitalia of the mother. Since the primary stage of syphilis is characterized by spirochetemia, infectious rates of the fetus are nearly 100% if the mother has primary syphilis.[20,21]

Diagnostic procedures include dark-field microscopy, nontreponemal exams[9,20] (ie, the Venereal Disease Laboratory [VDRL] and the rapid plasma reagin [RPR] test), and treponemal exams (ie, enzyme immunoassay, the *T. pallidum* hemagglutination test, the fluorescent treponemal antibody test, and the enzyme-linked immunosorbent assay [ELISA]).

TREATMENT

After confirming the diagnosis of syphilis, the desired outcome is a fourfold decrease in quantitative nontreponemal titers over a 6-month period and within 12 to 24 months after treatment of latent or late syphilis. An algorithm for the treatment of syphilis is shown in Figure 80–1.

With regard to neurosyphilis, a reduction in neurologic manifestations is desired, which may include seizures, paresis, meningitis, stroke, hyperreflexia, visual disturbances, hearing loss, neuropathy, or loss of bowel and bladder function. In late neurosyphilis, vascular lesions (meningovascular neurosyphilis) may also be observed; thus, a reduction in the number of

LO 6 LO 7

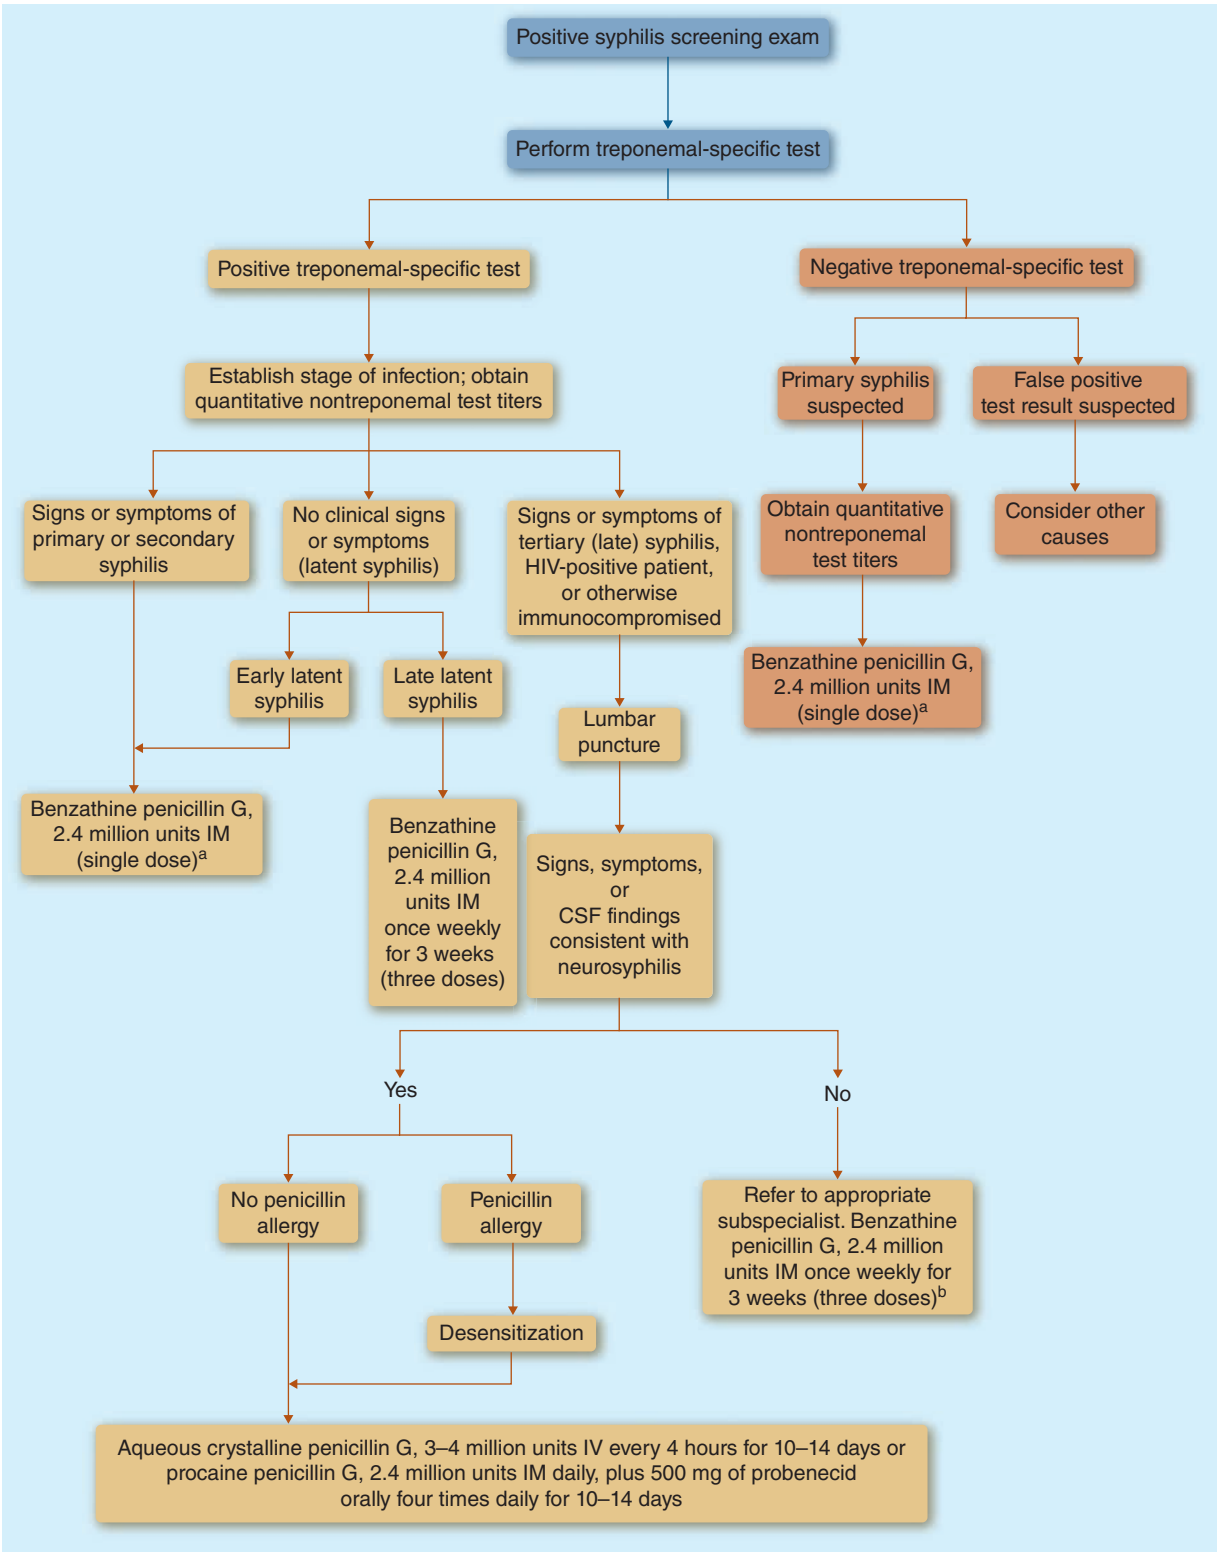

FIGURE 80–1. Treatment of syphilis. [a]Alternative treatments for nonpregnant penicillin-allergic patients: doxycycline 100 mg PO twice daily for 2 weeks, or tetracycline 500 mg four times daily for 2 weeks; limited data support ceftriaxone 1 g once daily IM or IV for 8 to 10 days; or azithromycin, 2 g PO (single dose). [b]Alternative treatments for nonpregnant penicillin-allergic patients: doxycycline, 100 mg PO twice daily for 4 weeks, or tetracycline 500 mg PO four times daily for 4 weeks. (CSF, cerebrospinal fluid; IM, intramuscularly.) Patient Encounter 2

JN is an HIV-positive man who complains of first observing the appearance of a "round sore" on his penis. He admits to disregarding the lesion; however, he is now experiencing fatigue, diffuse rash, fever, and perineal condyloma latum. He reports having unprotected sexual intercourse with one female and two male partners. He denies pain or itching at the original site of the lesion, dysuria, or frequent urination. Additionally, there appears to be no vesicles in the genital area.

What information is suggestive of syphilis?

What stage of syphilis is present?

What potential risk factors for STIs are present?

How should the diagnosis of syphilis be confirmed in this patient?

If the diagnosis of syphilis is confirmed, what therapeutic options exist for this patient?

observed lesions is warranted. A diminution in CSF white blood cell (WBC) (< $10 \times 10^3/mm^3$ [$10 \times 10^9/L$]) or protein levels (0.05 g/dL [0.5 g/L]) is also preferred.

Pharmacologic Therapy

KEY CONCEPT Parenterally administered penicillin is recommended for all stages of syphilis (Table 80–1). Although penicillin is the drug of choice, combinations of benzathine penicillin with procaine penicillin or oral penicillin preparations are not considered appropriate treatment regimens. Several reports demonstrated the misuse of the benzathine–procaine combination (Bicillin C-R) instead of the standard benzathine penicillin (Bicillin L-A) for treatment of syphilis.[20,22] Clinicians and purchasing agents should be aware of the similarities in product names to avoid errors in the prescribing and administration of these agents. Pertinent information germane to benzathine penicillin G is found in Table 80–1.

Alternative agents may be used in allergic individuals and include doxycycline, minocycline, tetracycline, or erythromycin base or stearate. Some patients (such as young children or pregnant women) may not respond favorably to alternative modalities or should not receive tetracyclines. Therefore, in patients who must be administered penicillin (ie, patients who are pregnant or have central nervous system [CNS] involvement) and are allergic, **desensitization** should be performed because penicillin as a treatment modality is far superior to alternatives.

Patients may experience fever, chills, tachycardia, and tachypnea, a condition commonly known as the Jarisch-Herxheimer reaction, an acute febrile reaction accompanied by headache, myalgia, fever, and other symptoms within the first 24 hours after the initiation of therapy. This reaction is postulated to occur secondary to spirochete lysis and proinflammatory cytokine cascades. Treatment is supportive and may include antipyretic and anti-inflammatory agents, as well as fluid resuscitation and bed rest.

▶ *Primary Syphilis*

Drug of Choice

Adults Benzathine penicillin, 2.4 million units IM as a single dose. Additional doses of benzathine penicillin or other antibiotics do not enhance efficacy, regardless of HIV status.[9]

Children Benzathine penicillin 50,000 units/kg IM, up to the adult dose of 2.4 million units in a single dose. Infants less than 1 month of age diagnosed with syphilis should have a CSF test to determine if asymptomatic neurosyphilis is present. Patient records should be reviewed to decipher whether syphilis is congenital or acquired.

Alternatives Oral doxycycline 100 mg twice daily for 2 weeks *or* tetracycline 500 mg by mouth four times daily for 2 weeks. Limited literature also supports the use of ceftriaxone 1 g IM or IV once daily for 10 days *or* oral azithromycin as a single 2 g dose.[9,21]

Table 80–1

Benzathine and Procaine Penicillin G Informational Chart

Categories	Benzathine Penicillin G	Procaine Penicillin G
Potential adverse reactions	CNS: convulsions, confusion, drowsiness, myoclonus, fever Dermatologic: rash Metabolic: electrolyte imbalance; Hematologic: positive Coombs test, hemolytic anemia Local: pain, thrombophlebitis Renal: acute interstitial nephritis Miscellaneous: anaphylaxis, hypersensitivity, Jarisch-Herxheimer reaction	CNS: seizures, confusion, drowsiness, myoclonus, CNS stimulation Cardiovascular: myocardial depression, vasodilation, conduction disturbances Hematologic: positive Coombs test, hemolytic anemia, neutropenia Local: thrombophlebitis, sterile abscess at injection site Renal: interstitial nephritis Miscellaneous: pseudoanaphylactic reactions, hypersensitivity, Jarisch-Herxheimer reaction, serum sickness
Monitoring parameters	Observe for anaphylaxis during first dose	Periodic renal and hematologic function tests with prolonged therapy; fever, mental status, WBC
Pregnancy category	B	B
Lactation	Enters breast milk	Enters breast milk
Availability	Bicillin L-A: 600,000 units/mL (1, 2, and 4 mL) Permapen isoject: 600,000 units/mL (2 mL)	Injection, suspension: 600,000 units/mL (1, 2 mL)
Combination	Bicillin C-R: (1, 2, 4 mL) Bicillin C-R: 900/300: (2 mL)	Same

CNS, central nervous system; IM, intramuscular.

LO 7

▶ *Secondary and Early Latent Syphilis*

Treatment modalities administered in primary syphilis are also effective in secondary syphilis and early latent syphilis (< 1-year duration).

Children with early latent syphilis should receive benzathine penicillin G 50,000 units/kg IM, up to the adult dose of 2.4 million units in a single dose.

LO 7

▶ *Late Latent Syphilis*

Benzathine penicillin, 7.2 million units total, administered as three doses of 2.4 million units IM each at 1-week intervals.

Children with late latent syphilis should be treated with benzathine penicillin G 50,000 units/kg IM, up to the adult dose of 2.4 million units, administered as three doses at 1-week intervals (total 150,000 units/kg up to the adult dose of 7.2 million units).

LO 7

▶ *Tertiary Syphilis*

Drug of Choice Benzathine penicillin 2.4 million units administered IM once weekly for 3 weeks. A total of 7.2 million units should be administered.

Alternatives In nonpregnant patients with a penicillin allergy, alternative regimens include doxycycline 100 mg PO two times daily for 4 weeks *or* tetracycline 500 mg PO four times daily for 4 weeks.

▶ *Gummatous and Cardiovascular Syphilis*

As long as no evidence of CNS involvement exists, antibiotic therapy for gummatous and cardiovascular syphilis is identical to that for tertiary syphilis.

LO 7

▶ *Neurosyphilis*

As an effective treatment for neurosyphilis, the Centers for Disease Control and Prevention (CDC) endorse two regimens of penicillin. Alternatively, ceftriaxone may also be prescribed.[25]

The regimens of choice are aqueous penicillin G 3 to 4 million units administered IV every 4 hours or continuous infusion for 10 to 14 days *or* procaine penicillin G 2.4 million units administered IM once daily, plus probenecid 500 mg PO four times daily, both for 10 to 14 days.

Congenital Syphilis[23–25]

The decision to treat an infant should be based on a diagnosis of syphilis in the mother and confirmation of adequacy of maternal treatment. Clinical, laboratory, or radiographic evidence of syphilis in the infant should be documented. Maternal nontreponemal titers (at delivery) should be compared with the infant's nontreponemal titers. Since diagnosis based on neonatal serologic testing is complicated by the transplacental transfer of maternal immunoglobulin G (IgG) antibodies, which can cause a positive test in the absence of infection, neonatal titers are assessed. A titer greater than four times the maternal titer would not generally result from passive transfer and diagnosis is considered confirmed or highly probable.

The following regimens are recommended for treatment of maternal syphilis: benzathine penicillin G 2.4 million units or 7.2 million units IM over 3 weeks if the duration of syphilis has been at least a year. An alternative regimen is procaine penicillin 0.6 to 0.9 million units IM for 10 to 14 days, or ceftriaxone 1 g daily IM or IV for 8 to 10 days.

In women who experience uterine cramping, pelvic pain, or fever, administer acetaminophen to combat these symptoms. Additionally, the patient should be well hydrated and rested.

Treatment of asymptomatic neonates is with 50,000 units/kg of benzathine penicillin G in a single IM dose. Symptomatic neonates should receive 50,000 units/kg of aqueous crystalline penicillin G every 12 hours IM for the first 7 days of life, then every 8 hours for 3 days *or* procaine penicillin G 50,000 IU/kg IM as a single dose daily for 10 days.

Outcome Evaluation

LO 8

The CDC has provided patient care monitoring guidelines for syphilis (Figure 80–2).[9,11,20]

Primary and Secondary Syphilis

- After 6, 12, and 24 months of treatment, reexamine the patient and recommend a follow-up quantitative nontreponemal titer. More frequent assessment might be sensible if follow-up is uncertain. If the patient is asymptomatic and a fourfold increase in nontreponemal titer or persistent or recurrent symptoms are observed, order an HIV test and a lumbar puncture; if the patient is HIV-positive, suggest an infectious disease consult.
- In patients who are both negative for HIV and the lumbar puncture, administer benzathine penicillin G 2.4 million units IM once weekly for 3 additional weeks. Perform a patient follow-up in 6 months including a clinical examination and another nontreponemal titer. In HIV-negative patients with lumbar puncture findings compatible with neurosyphilis, treat the patient accordingly for neurosyphilis.
- Six months after the original diagnosis, institute a standard clinical follow-up examination in patients who show no symptomatology and a fourfold decrease in nontreponemal titers. By testing and observing the patient for signs of remission, you may be able to initiate proper treatment or recommend a consult in a timely fashion, thereby decreasing the propensity of the patient's condition to advance to a higher stage.
- If serologic titers do not decline despite a negative CSF examination and a repeated course of therapy, it is unclear whether additional therapy or CSF examinations are needed; additional testing or repeated therapy is not generally recommended.

Early and Late Latent Syphilis

- Order nontreponemal titers 6, 12, and 24 months after instituting treatment for early or late latent syphilis. Neurosyphilis should be strongly considered in patients who show a fourfold increase in titers, patients who have an initially high titer (1:32 or greater) that fails to decline at least fourfold within 12 to 24 months of therapy, HIV-infected patients, and patients who develop signs or symptoms associated with neurosyphilis.

Neurosyphilis

- Follow-up is dependent on the CSF findings. If pleocytosis is present, reexamine the CSF every 6 months until the WBC count normalizes. Consider recommending a second

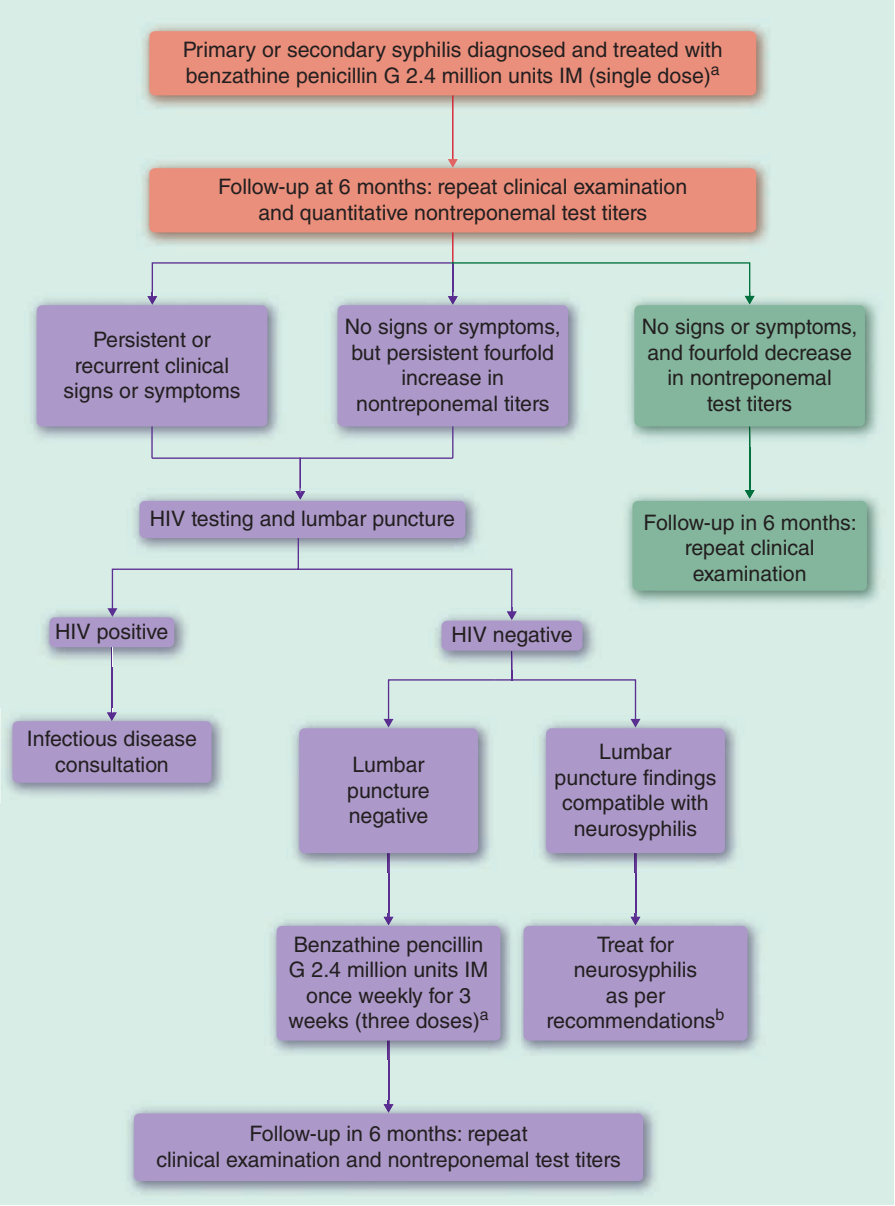

FIGURE 80–2. Patient care monitoring for syphilis. [a]See text for alternative treatment recommendations for nonpregnant penicillin-allergic patients. [b]See text for treatment recommendations for neurosyphilis. (Reprinted with permission from Diagnosis and Management of Syphilis, July 15, 2003, Vol 68, No 2, American Family Physician Copyright © 2003 American Academy of Family Physicians, All Rights Reserved.)

course of treatment if the CSF white count does not decline after 6 months or completely normalize after 2 years.[4,9,20] Failure to normalize may require retreatment; most treatment failures occur in immunocompromised patients.

Congenital Syphilis

- Observe the patient for changes in clinical features; hepatomegaly, jaundice, and bone changes will usually resolve in 3 months.
- Monitor elevated serologic markers (nontreponemal tests) for reduction in titer levels. Given effective treatment, clinical features will usually disappear after 6 months. On this basis, evaluate seropositive infants periodically for at least 6 months.[24]

TRICHOMONIASIS

LO 4

Trichomoniasis is caused by the protozoan *Trichomonas vaginalis* and is far more prevalent than *C. trachomatis* or *N. gonorrhoeae*. In the United States, approximately 5 million new cases appear annually, compared with 3 million chlamydial and 650,000 gonococcal cases annually.[26]

PATHOPHYSIOLOGY

T. vaginalis, a protozoa, may be isolated from the vagina, urethra, and Bartholin or Skene glands. After attachment to the host cells, it ignites an inflammatory response exhibited as a discharge containing elevated levels of polymorphonuclear leukocytes. The pathogen causes direct damage to the epithelium, leading to microulcerations.

CLINICAL PRESENTATION AND DIAGNOSIS

LO6 Diagnosis is usually performed with a wet mount or Papanicolaou smear. In women, symptoms are characterized by diffuse, malodorous, yellow-green vaginal discharge with vulvar irritation. Some women may be asymptomatic.

TREATMENT

The desired outcome is the complete eradication of *T. vaginalis* in both partners and elimination of the signs and symptoms observed.

Pharmacologic Therapy

KEY CONCEPT The 5-nitroimidazoles (metronidazole and tinidazole) have been the standard therapy for trichomoniasis for over 45 years. When using these agents, advise patients to avoid the consumption of alcohol.

▶ *Metronidazole*

LO7 Metronidazole may be administered PO as a single 2 g dose or 500 mg twice daily for 7 days.[9,26] Pregnant women should be prescribed the single dose of metronidazole. Cure rates are greater than 90% when metronidazole is administered as either a single 2 g dose or a 7-day regimen. Possible adverse effects include an unpleasant metallic taste, reversible neutropenia, urticaria, rash, flushing, dry mouth, darkened urine, and a disulfiram-like reaction.

▶ *Tinidazole*

Tinidazole is a second-generation nitroimidazole with protozoal and anaerobic activity.[27] As a single 2 g dose, tinidazole has an efficacy equivalent to a 2-g dose of metronidazole. Tindazole also has a longer half-life than metronidazole, 14 and 7 hours, respectively, and penetrates into male reproductive tissue better than metronidazole.

Tinidazole is effective for metronidazole-resistant trichomoniasis.[26,27] Possible side effects include an unpleasant metallic taste, dizziness, loss of coordination, seizures, severe diarrhea, darkened urine, nausea, vomiting, and a swollen or discolored tongue.

Outcome Evaluation

- Order diagnostic test for trichomoniasis. If positive, recommend antibiotics that cover *T. vaginalis*.
- Subsequent to treatment, expect the eradication of the protozoa.
- Monitoring is generally not required.

Clinical Presentation of Trichomoniasis[9,26]

General

- Asymptomatic

LO5

Signs

- Strawberry cervix (women)
- Colpitis macularis (women)
- Prostatitis or epididymitis (men)

Symptoms

- Vaginal/vulvar erythema
- Excessive yellow-green discharge
- Vulvar itching
- Vaginal odor
- Urethral discharge or irritation
- Dysuria
- Vaginal pH greater than 4.5

GENITAL WARTS

LO4 Genital warts, caused by the human papillomavirus (HPV), usually appear in the genital area as very contagious, small bumps. Responsible for various visible, keratotic, and nonkeratotic manifestations, HPV has more than 150 noted strains, some of which have been linked to squamous cell carcinoma.[28] More than 40 strains have been linked to the genital area.[29]

EPIDEMIOLOGY AND ETIOLOGY

LO3 Genital warts are caused by several strains of HPV and spread by skin-to-skin contact (ie, vaginal, anal, or oral) during sexual activity with an infected person.[30,31] HPV can be passed when an infected person has no signs or symptoms. Affecting over 79 million Americans, HPV is the most common, newly diagnosed STI in the United States, with prevalence of approximately 52%. Almost 14 million new HPV infections occur every year in the United States.[28] Nearly half of new infections occur among persons aged 15 to 24 years. Condoms offer incomplete (grade B, level II [fair research-based evidence to support the recommendation]) protection against HPV because HPV can infect areas not covered by a condom.[30,31]

The frequency of cervicovaginal HPV infection among sexually active women has been observed at 43%, with the greatest incidence noticed in men with three or more sex partners and women whose most recent regular sexual partner had two or more lifetime partners. Most people with HPV do not develop symptoms. At least half of sexually active persons will become infected at least once in their lifetime. In 90% of the cases, the body immune system clears HPV naturally within 2 years. Routine testing of HPV DNA infection is not recommended because test results would not alter clinical management of the condition. KEY CONCEPT HPV types 16 and 18 cause 99.7% of all cervical cancer while HPV types 6 and 11 are responsible for about 90% of genital warts.[30,32]

PATHOPHYSIOLOGY

HPV replicates in terminally differentiated squamous cells in the intermediate layers of the genital mucosa. Hence, these effects of the viral early region genes on DNA synthesis are critical for viral survival. Genital warts are the clinical manifestation of active viral replication and virion production at the infection site.

CLINICAL PRESENTATION AND DIAGNOSIS

LO6
- A definitive diagnosis of HPV is based on DNA, RNA, or capsid protein detection.
- Diagnosis is generally made from the clinical presentation or by visual inspection. It may be classified into several

Clinical Presentation of Genital Warts[9,32,33]

General

- Appear as rough, thick, cauliflower-like lesions

LO 6

Signs

- Black dots within warts
- Disrupted surface

Symptoms

- Anogenital pruritus
- Burning
- Vaginal discharge or bleeding
- Although rare, dyspareunia may occur with vulvovaginal condyloma

categories: classic condyloma acuminata, which are pointed or cauliform; keratotic warts with a thick, horny surface resembling common skin warts; and flat warts, which are frequently observed on the surface.

- Tissue biopsy or viral typing is only indicated if the diagnosis is uncertain and is not recommended for patients with routine or typical lesions.
- Since HPV is highly associated with cervical cancer and has more than 20 different cancer-associated HPV types, patients who are diagnosed with HPV should be tested for cervical cancer.

TREATMENT

Genital warts are usually asymptomatic but can be painful or pruritic. Approximately 40% to 60% of untreated warts will spontaneously resolve in 9 to 12 months if left untreated.[30] Treatment of benign, symptomatic genital warts is aimed at alleviation of physical symptoms and cosmetic improvement. Removal of visible warts and reduction of infectivity are the goals of treatment.

A comparison of adverse effects related to treatment options may be found in Table 80–2.[34]

Table 80–2

Comparison of Adverse Effects Seen with Treatments for Genital Warts

Treatment	Adverse Effects
Podofilox	Burning at site of application, pain, inflammation
Imiquimod	Erythema, irritation, ulceration, pain, burning, edema, pigmentary changes
Sinecatechins	Burning at site of application, erythema, pruritus, edema
Podophyllin resin	Local irritation, erythema, burning, soreness at application site; possibly oncogenic
Bichloroacetic and trichloroacetic acid	Local irritation and pain, minimal systemic effects
Cryotherapy	Pain or blisters at application site
Surgical excision	Pain, bleeding, scarring; possible burning or allergic reaction to local anesthetic
Vaporization	Pain, bleeding, scarring; risk of HPV spreading via smoke plumes
Intralesional interferon	Burning, itching, irritation at injection site, systemic myalgia, headache, fever, chills, leukopenia, elevated liver enzymes, and thrombocytopenia

HPV, human papillomavirus.

Data from Refs. 9, 28, and 31.

Patient-Applied Treatment

▶ *Podofilox*

LO 7

Available as a 0.5% gel or solution containing purified extract of the most active compound of podophyllin, podofilox inhibits the formation of the mitotic spindle, prevents cell division, and may also induce damage in blood vessels within the warts. The surface area treated must not exceed 10 cm^2, and a maximum of 0.5 mL should be used on a daily basis.

Apply podofilox twice daily for 3 consecutive days, followed by 4 consecutive days without treatment. This cycle may be repeated until there are no visible warts or for a maximum of 4 weeks. Side effects are generally local and may include erythema, swelling, and erosions. Podofilox is not recommended for use in the vagina, anus, or during pregnancy.

▶ *Imiquimod*

Imiquimod is a cell-mediated immune-response modifier, available as a topical 5% cream in single-dose application packets. There are two recommended dosage regimens:

a. Apply at bedtime, three times a week for up to 16 weeks.
b. Apply every other day for three applications.

The treatment area should be washed with soap and water 6 to 10 hours after application. Mild to moderate erythema has been noted with imiquimod use; however, this generally suggests that the drug is reaching a therapeutic range and may be clearing the lesion.[35,36]

▶ *Sinecatechins*

A green tea extract with an active product (catechins) is available as a 15% ointment. Apply a thin layer (0.5 cm) using a finger to each wart three times a day until complete clearance of warts. Do not wash off after use and all sexual contact should be avoided while ointment is on the skin. This product should not be continued for longer than 16 weeks.[9]

Physician-Applied Treatments

▶ *Podophyllin Resin*

A 10% to 25% solution of podophyllin resin in a compound tincture of benzoin has been the standard in-office treatment for genital warts. Because podophyllin is neurotoxic and systemically absorbed, only a small amount (no > 0.5 mL) should be applied. Application should be limited to less than 0.5 mL of podophyllin on an area of less than 10 cm^2 of warts per session and no open lesions or wounds should exist in the area to which treatment is administered. The affected area will likely become erythematous and painful within 48 hours of application.[36]

Topical podophyllin is applied once weekly; and the area should be allowed to dry. Immediately following treatment, the dried drug should be removed using alcohol or soap and water. Topical podophyllin is contraindicated in pregnant patients.

▶ *Bichloroacetic (BCA) and Trichloroacetic (TCA) Acids*

These caustic agents are available in 80% to 90% concentrations and are not systemically absorbed. The products are effective when used to treat a few small, moist lesions. Apply once a week until the wart is resolved. They may be applied to both keratinized epithelial and mucosal surfaces and may be used in pregnancy.

A noted reaction to these medications is transient burning; contact with surrounding epithelium may prove to be painful, producing significant local erythema and swelling. To avoid these effects, place petroleum jelly around the external lesion, including unaffected skin, and carefully apply the agent with a small applicator. If an excess amount of acid is used, talc or sodium bicarbonate (baking soda) or liquid soap preparations may be administered to neutralize unreacted acid.

▶ *Other Treatments*

Other treatments may include fluorouracil/epinephrine/bovine collagen gel, an intralesional injection that has been proven effective in clinical trials for refractory patients or an intralesional injection of interferon.[33]

Ablative Therapy

Several ablative options have been employed in the treatment of genital warts and include cryotherapy with liquid nitrogen or cryoprobe, surgical removal by excision, and vaporization.

Special Therapeutic Issues[34–37]

▶ *Large Warts*

Treat warts greater than 10 mm in diameter with surgical excision. Use imiquimod for three to four treatment cycles to reduce the number of warts and improve surgical outcomes. Fifty percent reduction in wart size after four treatment cycles warrants continued use of imiquimod until warts clear or eight cycles have been completed; less than 50% reduction warrants surgical excision or other ablative therapy.

▶ *Subclinical Warts*

Subclinical warts may be identified through colonoscopy, biopsy, acetic acid application, or laboratory serology. However, early treatment has not been linked to a favorable effect during the course of therapy in the index patient or the partner with regard to reduction of the transmission rate.

▶ *Pregnancy*

Agents contraindicated in pregnancy include podofilox, sinecatechins, fluorouracil, and podophyllin. Imiquimod is not approved for use in pregnancy, although it has been considered after signed consent has been obtained. Bichloroacetic and trichloroacetic acids have been used without problems. Ablative therapy is also a viable option.

Vaccinations

Several HPV genotypes have been linked to the development of cervical cancer. Gardasil, a quadrivalent vaccine developed to protect against HPV genotypes 6, 11, 16, and 18, was the first vaccine employed to prevent cervical cancer, precancerous genital lesions, and genital warts due to HPV. Cervarix, a bivalent vaccine, prevents cervical cancer and precancers caused by HPV types 16 and 18. Additionally, Gardasil 9, a 9-valent vaccine, protects against infection with HPV types 6, 11, 16, 18, 31, 33, 45, 52, and 58.

The CDC recommends the HPV vaccine for all 11- and 12-year-old girls and boys. Vaccination is also recommended for females aged 13 through 26 years and males 13 to 21 years old who have not been previously vaccinated or who have not completed the full series of shots.[28,38] The quadrivalent vaccine, Gardasil, is Food and Drug Administration (FDA)-approved for females and males 9 to 26 years old.[39]

In the past, inactivated vaccines were given in a series of three IM injections over a 6-month period. Second and third doses were given at 2 and 6 months (respectively) after the first dose. However, the CDC guidelines now recommend that 11–12-year olds receive two doses of the HPV vaccine rather than the previously mentioned three doses. The second dose should be given 6–12 months after the first. HPV vaccine may be given at the same time as other vaccines. Vaccines are efficacious in preventing genital warts; however, they will not clear those that are already present. Either vaccine is recommended for girls/women, whereas only one vaccine (Gardasil) is recommended for boys/men.[28]

Outcome Evaluation

LO 8

- Monitor the patient for any visible warts and relief of symptoms.
- Apply powder with talc, baking soda, or liquid soap to remove unreacted trichloracetic or bichloroacetic acid.
- Dry area before contact with normal mucosa after application of podophyllin.
- Repeat TCA, BCA, podophyllin treatment weekly if necessary.
- Administer a different agent if warts persist after one type of therapy.
- Refer all recalcitrant patients to local STI clinic, gynecologists, dermatologists, or urologists.

GENITAL HERPES

LO 4

Genital herpes (GH) is caused by herpes simplex virus (HSV) types 1 and 2. HSV is a chronic, lifelong viral infection, for which there is no cure. Once latency is established, neither competent host immunity nor therapeutic agents can eradicate the virus.[9] Currently, there is no vaccine available for HSV, and it seems that the development of one is unlikely in the near future. HSV-1 is mainly transmitted by oral to oral contact to cause oral herpes (cold sores) but can also cause GH through oral sex. HSV-2 is an STI that causes GH.[40]

EPIDEMIOLOGY AND ETIOLOGY

LO 3

Approximately 50 million Americans have GH. HSV-2 is the most common cause of recurrent GH. Roughly 1 in 6 people in the United States (16.2%) aged 14–49 is infected with HSV-2. Prevalence of HSV-2 infection has grown by approximately slightly since the late 1970s (16.4%–17.2%), and currently over 500,000 new cases of HSV-2 occur annually.[9] Many persons infected with HSV-2 have not been diagnosed; therefore most GS infections are transmitted by persons unaware of their status.[36]

PATHOPHYSIOLOGY

KEY CONCEPT Nearly all HSV-2 infections are sexually acquired.

LO 3

Since HSV is only found in humans, infection may only be transmitted from infectious secretions onto mucosal surfaces (ie, cervix or urethra) or direct contact with an active lesion

(abraded skin). The virus may survive for a limited amount of time on environmental surfaces. Most sexual transmission occurs while the source case is asymptomatic. Most patients with asymptomatic or unrecognized genital HSV infections will still shed virus intermittently in the genital tract. Patients will have small, painful blisters that are filled with fluid. The first outbreak takes 2 to 4 weeks to heal, and later attacks are less severe. Because there is no cure for this illness, treatment will only help reduce the signs, symptoms, and number of attacks.[9] Persons with GS should be tested for HIV infection because of their epidemiological synergy.[36]

CLINICAL PRESENTATION AND DIAGNOSIS

LO 6

Ulcerative or multiple vesicular lesions are absent in many infected persons. Laboratory confirmation is vital to effective treatment of HSV, especially in individuals in whom a clinical diagnosis cannot be obtained. There are several methods by which a definitive diagnosis may be acquired, and these include virologic typing, serologic diagnosis, rapid point-of-care antigen detection, ELISA, immunoblot, and DNA polymerase chain reaction.[41] Glycoprotein G-based assays may also be used to aid in the diagnosis of HSV.

TREATMENT

Management of genital HSV should address the chronic nature of the disease rather than focusing solely on treatment of acute episodes of genital lesions. The desired outcome is to curtail the number of episodic prodromes and to minimize any side effects experienced due to the antivirals. Counseling of infected persons and their partners is vital to the management of HSV.

First Episode

The first episode is a systemic illness associated with the vesicular lesions, may last up to 21 days, usually has an uncomplicated course of infection, and, in severe cases, may require hospitalization. This initial presentation occurs 4 to 7 days after sexual exposure. Several agents are effective during this period (Table 80–3).[42–44] At the cited dosages, these agents produce excellent outcomes with regard to lesion healing time, viral shedding, and reduction in pain. Common adverse effects are nausea, headache, and diarrhea. It is important to note that the first episode does not necessarily indicate recent infection and the genital symptoms may develop several years after the infection was acquired. Condom use in new or uninfected partners, particularly in the 12 months after the first attack, is recommended.

Clinical Presentation of Genital Herpes[9,41,42]

General

- Asymptomatic

LO 5

Classic Sign

- A cluster of painful vesicles on an erythematous base

Symptoms

- Itching
- Burning
- Tingling
- Groin lump
- Dysuria
- Dyspareunia
- Increased urinary frequency

Other Symptoms

- Ulcerative lesions, fissures, cervicitis

Episodic Therapy

In a patient with a previous diagnosis of GS, the appearance of new vesicular lesions is synonymous with HSV reactivation. For most patients, GS recurrence is self-limiting and short-lived, lasting approximately 6 to 7 days.

Suppressive Therapy

Suppressive therapy is effective for controlling all symptoms related to the disease and may impact troublesome complications of infection. Before beginning suppressive therapy, discuss patient expectations. Encourage patients to record any breakthrough episodes, as this may require treatment reevaluation and adjustment.

Preventive Therapy

Valacyclovir 500 mg PO once daily has been used to prevent the sexual transmission of HSV to an uninfected partner. In addition to pharmacologic therapy, counsel patients regarding safe sex practices.

Drug Resistance

All acyclovir-resistant strains are resistant to valacyclovir and the majority are resistant to famciclovir. Foscarnet, cidofovir, and trifuridine have been administered in acyclovir-resistant patients.[45] These agents are usually reserved for use after other medications have failed because of their associated toxicities.

Pregnancy

Women who are pregnant may transmit the virus to the neonate during delivery. There are two management strategies: caesarean section and antiviral therapy. Acyclovir 200 to 400 mg every 8 hours has been administered from 38 weeks' gestation until delivery. Acyclovir, famciclovir, and valcyclovir are all classified as category B (no evidence of risk in humans) for use during pregnancy. Suppressive treatment includes the use of acyclovir or valacyclovir from week 36 until delivery. The goal of therapy is to reduce the number of lesions and asymptomatic shedding at delivery.

Neonates

The risk for transmission from an infected mother to a neonate is highest among women who acquired GH near time of delivery. Women who have GH prior to pregnancy are at very low risk of transmitting HSV to their infants. HSV infections should be considered in all neonates who present with nonspecific symptoms such as fever, poor feeding, lethargy, or seizures in the first month of life. Infants suspected to have or who are diagnosed with an HSV infection should be treated parenterally. Acyclovir 20 mg/kg/day in three divided doses IV for 21 days for disseminated and CNS disease or 14 days for disease limited to skin, eyes, and mucous membranes.

Table 80–3

Comparison of Antiviral Agents Used for Herpes Simplex Infection

Agent	Dose	Side Effects
First Episode		
Acyclovir	*200 mg PO five times a day × 7–10 days* ***or*** 400 mg PO three times daily × 7–10 days	Headache, confusion, nausea, vomiting, thrombocytopenia, renal insufficiency, rash, pruritus, fever, arthralgias, myalgia, thrombotic thrombocytopenic purpura, hallucinations, somnolence, depression
Valacyclovir	*1 g PO two times daily × 7–10 days*	Refer to acyclovir
Famciclovir	250 mg PO three times daily × 7–10 days	Refer to acyclovir
Episodic		
Acyclovir	*200 mg PO five times daily × 5 days* ***or*** 400 mg PO every 8 hours × 5 days ***or*** 800 mg PO two times daily × 5 days ***or*** 800 mg PO three times daily × 2 days	Refer to acyclovir (WHO)
Valacyclovir	*500 mg PO two times daily × 3 days* ***or*** 1 g PO once daily × 5 days	Refer to acyclovir
Famciclovir	125 mg PO two times daily × 5 days ***or*** 1000 mg PO twice daily × 1 day	Refer to acyclovir
Suppressive		
Acyclovir	400 mg PO two times daily continuously ***or***	Refer to acyclovir
Valacyclovir	500 mg PO once daily continuously ***or***	Refer to acyclovir
Valacyclovir	1000 mg PO once daily continuously ***or***	Refer to acyclovir
Famciclovir	250 mg PO two times daily continuously	Refer to acyclovir
Reserved Agents		
Foscarnet	40 mg/kg IV every 8 hours until clinical resolution is attained	Renal insufficiency, metabolic disturbances, hypophosphatemia
Cidofovir	1% topical agent (gel) used daily on a compassionate basis for acyclovir-resistant herpes lesions for 5 days	Application site reactions, lesion recrudescence
Imiquimod	Topical alternative used daily on a compassionate basis for acyclovir-resistant herpes lesions for 5 days	Application site reactions, lesion recrudescence

Italicized data indicate preferred dosages.

Data from Refs. 9 and 33.

HIV Infection

Lesions caused by HSV are common among persons with HIV infection and may have prolonged episodes of GH. HSV shedding is increased in persons with HIV infection. Oral antiviral agents are effective in decreasing the clinical manifestations of HSV among people with HIV infection.[9]

Outcome Evaluation

LO 8

- Monitor for systemic symptom improvement and a decrease in viral shedding in initial HSV treatment.
- Take lukewarm baths three to four times a day to ease itching and pain. Pat dry affected areas.
- Wear loose-fitting underwear to help the sore dry.
- Avoid sexual contact until treatment is finished.
- Consider stopping suppressive therapy after 1 year to assess recurrence rate.
- Compound topical 1% cidofovir gel in acyclovir-resistant strains where IV foscarnet is not preferred.

PELVIC INFLAMMATORY DISEASE

LO 4

Pelvic inflammatory disease (PID) usually affects young, sexually active women. PID includes a spectrum of inflammatory disorders of the upper female genital tract. In the majority of cases, the pathogens responsible are *Chlamydia trachomatis* and *Neisseria gonorrhoeae*; although anaerobes, enteric gram-negative rods, and cytomegalovirus have also been implicated in the pathogenesis.[46] PID has been correlated with ectopic pregnancy, infertility, tubo-ovarian abscess, and chronic pelvic pain.[47]

EPIDEMIOLOGY AND ETIOLOGY

LO 3

PID is most common in minority women younger than 25 years of age, who have more than one sex partner. Approximately 800,000 women are diagnosed with PID each year in the United States. The estimated prevalence of self-reported lifetime PID was 4.4% in sexually experienced women of reproductive age (18–44 years). The highest rates of PID occur in

Patient Encounter 3

MB is a 21-year-old Haitian woman whose native tongue is French Creole. She confides in her physician about her profession as an escort. She comes into the clinic because of a vaginal discharge and the recurrence of small bumps in her genital area. MB explains that some of her clients pay extra money to have unprotected sex. Her boyfriend gave her a gel to apply that he received from his doctor because of a past STI in the past.

What information is suggestive of genital herpes?

What potential risk factors for STIs are present?

What additional information is required to initiate a treatment plan?

What is your opinion about the use of the Gardasil vaccine in this patient?

teenagers and first-time mothers. Up to 10% to 15% of these women may become infertile as a result of PID.[9] Since many cases of PID are asymptomatic or inadequately treated, the potential for damage to the reproductive health of women is increased. There is an elevated risk for women with past STIs and for those who have more than one partner. However, over the past decade, there is evidence suggesting of a decline in PID diagnoses in the United States.[48]

PATHOPHYSIOLOGY

PID is an infection that occurs when bacteria move upward from a woman's vagina into her reproductive organs. Normally, the cervix prevents bacteria from entering the vagina and spreading to the reproductive organs. However, when the cervix is exposed to STIs such as chlamydia and gonorrhea, bacteria are disseminated into female internal organs. Chlamydia may produce a heat-shock protein that causes tissue damage through a delayed hypersensitivity reaction. *Chlamydia trachomatis* may also possess DNA evidence of toxin-like genes that code for high-molecular-weight proteins with structures similar to *Clostridium difficile* cytotoxins, enabling inhibition of immune activation. This may explain the observation of a chronic chlamydia infection in subclinical PID.

Patient Encounter 4

TC is a 25-year-old former heroin abuser. She works long hours for little pay at a local pub as a cocktail waitress and constantly worries about not being able to pay her bills. She has four children from three different men. Her PHM includes depression, schizophrenia, and delusions. Social history includes smoking ½ pack/day of Newports and occasional drinking.

She presents at the clinic because of a stinging sensation while urination and painful blisters in the genital area.

What information is suggestive of HSV?

Identify your treatment goals for this patient.

CLINICAL PRESENTATION AND DIAGNOSIS[46,49]

LO 6

Because many women with PID have subtle or mild symptoms, delays in diagnosis and treatment may lead to inflammatory sequelae in the upper reproductive tract. All women who receive a diagnosis of acute PID should be tested for HIV, as well as gonorrhea and chlamydia. To be diagnosed with PID, patients must have uterine tenderness, cervical motion tenderness, painful urination, lower abdominal pain, painful intercourse, and adnexal tenderness with no other cause of these signs. Additional criteria include:

- Oral temperature greater than 38.3°C (101°F)
- Abnormal cervical or vaginal discharge or that has an unusual color (green or yellow)
- WBC presence on saline microscopy of vaginal secretions
- Elevated erythrocyte sedimentation rate
- Elevated C-reactive protein
- Laboratory documentation of cervical infection with *N. gonorrhoeae* or *C. trachomatis*

TREATMENT

LO 8

Presumptive treatment of PID should be initiated in young, sexually active women if they are experiencing pelvic or lower abdominal pain with one or more of the minimum clinical criteria present on the pelvic examination. KEY CONCEPT The removal of causative bacteria and reduction of any related sequelae are the desired goals of treatment. Resolution of infection (ie, *N. gonorrhoeae, C. trachomatis*, *Streptococcus* spp., and gram-negative facultative bacteria) and mitigation of sequelae should be the main goal of pharmacologic therapy. Treatment regimens for PID must provide empiric, broad-spectrum coverage of likely pathogens. Parenteral and oral regimens appear to have similar efficacy in women with PID of mild or moderate clinical severity. CDC-approved treatment regimens are shown in Table 80–4.[9,46]

Though outpatient management remains contentious, many feel that outpatient management should be limited to individuals who remain afebrile, tolerate oral nourishment, or have a WBC counts less than $11 \times 10^3/mm^3$ ($11 \times 10^9/L$), minimal evidence of peritonitis, or active bowel sounds. Nonetheless, outpatient therapy with a parenteral cephalosporin followed by doxycycline and metronidazole is recommended.

Outcome Evaluation

LO 8

- Reevaluate any patient who does not respond significantly within 72 hours of parenteral/oral treatment.
- Initiate parenteral therapy (inpatient or outpatient) for patients that do not respond to oral treatment.
- Continue parenteral therapy for 14 days; however, it may be stopped 24 hours after clinical improvement and doxycycline continued to complete 14 days of therapy.
- Hospitalization and reassessment of the antimicrobial regimen and diagnostics are recommended in women without clinical improvement.
- Repeat testing of all women who have been diagnosed with chlamydia or gonorrhea is recommended 3 to 6 months after treatment, regardless of whether their sex partners were treated.
- Inform the patient that an alteration in sexual behavior should be the first concern, as promiscuous sexual activity augments the probability of infection.

Table 80–4

Treatment Regimens for Pelvic Inflammatory Disease

LO 7

Parenteral Option A
Cefotetan 2 g IV every 12 hours
or
Cefoxitin 2 g IV every 6 hours plus doxycycline 100 mg PO or IV every 12 hours

Parenteral Option B
Clindamycin 900 mg IV every 8 hours plus gentamicin, loading dose IV or IM (2 mg/kg) followed by maintenance dose (1.5 mg/kg) every 8 hours. A single daily dose of gentamicin (3–5 mg/kg) may be used

Alternative Parenteral treatment
Ampicillin-sulbactam 3 g IV every 6 hours plus doxycycline 100 mg PO or IV every 12 hours

Oral
Ceftriaxone 250 mg intramuscular single dose plus doxycycline 100 mg PO twice daily for 14 days with or without metronidazole 500 mg PO twice daily for 14 days
or
Cefoxitin 2 g intramuscular single dose and probenecid 1 g single dose, plus doxycycline 100 mg PO twice daily for 14 days with or without metronidazole 500 mg PO twice daily for 14 days
or
Third-generation cephalosporin (ceftizoxime or cefotaxime) plus doxycycline 100 mg PO twice daily for 14 days with or without metronidazole 500 mg PO twice daily for 14 days

Data from Refs. 9, 45, and 46.

Abstinence is the best course of action, especially in patients with herpes during lesional episodes. However, compliance in some may be minimal, in which case, appropriate condom use should always be recommended. To alleviate any possible misconceptions about condom application, either demonstrate how to apply a condom or ask the patient to demonstrate. During the demonstration, explicitly educate the patient with regard to application, storage, and the use of lubricants.[49] Additionally, a woman's sexual partner(s) should be treated to decrease the risk of reinfection, even if the partner(s) has no symptoms.

Clinical Presentation of Pelvic Inflammatory Disease[9,49]

General

- Signs and symptoms may vary from mild to severe.

LO 5

Signs

- Vague

Symptoms

- Lower abdominal or pelvic pain
- Malodorous vaginal discharge
- Abnormal uterine bleeding
- Dyspareunia
- Dysuria
- Nausea and/or vomiting
- Fever

Patient Care Process

Collect Information:

- Review current and past medications.
- Verify sexual history and identify lifestyle habits.
- Review all medical conditions.
- Document allergies and adverse drug reactions to medications.

Assess the Information:

- Test for pregnancy, complete blood count, gonorrhea, chlamydia, and bacterial vaginosis.
- Based on a physical examination that includes a pelvic examination, determine if the patient is experiencing any pain in the lower belly or back, vagina discharge with or without color, painful sex, fever, or burning during urination.
- Determine if any current drug–drug interactions will affect efficacy of treatment therapy.
- Identify comorbidities that may exacerbate current condition.

Develop a Care Plan:

LO 8

- Optimal management of STI should be individualized based on clinical setting and patient characteristics but will typically involve antibiotic therapy.
- For some patients, hospitalizations, IV antibiotics, and surgical treatment of complications may be needed.

Implement the Care Plan:

- If no clinical improvement has occurred after parenteral or outpatient oral therapy, perform further assessment.
- Educate the patient about the goals of monitoring patients which include both short- and long-term outcomes.
- Partners should be counseled and depending on the STI treated simultaneously.

Follow-up: Monitor and Evaluate:

- Advise a combination of prevention efforts.
- The primary approach should be prevention and education of at-risk patients.

Abbreviations Introduced in This Chapter

CSF	Cerebrospinal fluid
ELISA	Enzyme-linked immunosorbent assay
GH	Genital herpes
HPV	Human papillomavirus
HSV	Herpes simplex virus
L-A	Long Acting
MSM	Men who have sex with men
PID	Pelvic inflammatory disease
RPR	Rapid plasma reagent
STI	Sexually transmitted infection
WSW	Women who have sex with women

81 Osteomyelitis

Jessica E. Burchette and David B. Cluck

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

1. List common risk factors for osteomyelitis.
2. Discuss the pathophysiology of osteomyelitis.
3. Compare and contrast the classic signs and symptoms of acute and chronic osteomyelitis.
4. Evaluate microbiology culture data and other laboratory tests and imaging studies utilized for diagnosis of osteomyelitis.
5. List the most common pathogens isolated in acute and chronic osteomyelitis.
6. Develop a treatment plan for osteomyelitis.
7. Recommend parameters to monitor antimicrobial therapy for effectiveness and toxicity.
8. Describe how principles of antimicrobial stewardship can be applied to the management of osteomyelitis.
9. Educate patients regarding lifestyle modifications that may impact disease outcomes.

INTRODUCTION

KEY CONCEPT Osteomyelitis is an infection of the bone that may be either an acute or chronic process. The inflammatory response associated with acute osteomyelitis can lead to bone necrosis and subsequent chronic infection.[1] Bacterial pathogens, such as *Staphylococcus aureus*, are most commonly responsible for both acute and chronic infections.[1–8] Diagnosis and treatment present significant challenges to clinicians due to the complex nature of osteomyelitis.[1,2] Medical management is considered the cornerstone of treatment for acute infections; however, surgical intervention in addition to antimicrobial therapy is necessary to achieve cure for chronic infections.[1,2]

KEY CONCEPT Osteomyelitis is most often classified by duration of disease and route of infection.[1,2,9]

Two major osteomyelitis classification schemes exist. The Cierny-Mader classification focuses on the affected portion of bone, physiologic status of the patient, and factors impacting local vascularity.[1] In contrast, the Waldvogel classification scheme categorizes disease based on route of infection (**hematogenous** or **contiguous**) and duration of disease (acute versus chronic).[9] Using this classification scheme, osteomyelitis secondary to a contiguous focus can be further subdivided into infections with or without vascular insufficiency. Typical bone involvement in osteomyelitis depends on the route of infection.

- Hematogenous: long bones (femur, tibia) in children and vertebra in the elderly[2–5,10]
- Contiguous with vascular insufficiency: lower extremities[2,11,12]
- Contiguous without vascular insufficiency: bones affected by trauma, surgery, or adjacent soft-tissue infection[1,5]

A single pathogen is most often isolated in hematogenous osteomyelitis, whereas multiple organisms are often isolated in contiguous infections.[7,10,11,13]

While there are no validated definitions delineating acute versus chronic infection,[1,9,10] acute infection is often defined as the first episode or onset of symptoms within 2 weeks.[2,9–11] In comparison, chronic osteomyelitis is generally defined as disease relapse or symptoms persisting beyond 2 months.[2,9] Because there is no abrupt temporal demarcation, but rather a gradual shift from acute to chronic infection, many describe chronic osteomyelitis as the presence of necrotic bone.[1,2,10,11]

EPIDEMIOLOGY AND ETIOLOGY

The most common origin of osteomyelitis is dependent on the age of the patient. Children are more likely to suffer from hematogenous disease while adults are more likely to develop osteomyelitis due to contiguous spread.[1–4,6] However, hematogenous osteomyelitis can also be seen in older adults and in patients with a history of intravenous (IV) drug abuse, with the spine (vertebral osteomyelitis) being the most common site of infection.[1,2,5]

KEY CONCEPT *S. aureus* is the predominant pathogen seen in all types of osteomyelitis, with methicillin-resistant *S. aureus* (MRSA) being increasingly reported.[1–4,6,10] Patient-specific risk factors have the greatest impact on the potential pathogens including the following:

LO 1

- Uncontrolled diabetes and/or peripheral vascular disease (polymicrobial including MRSA, Enterobacteriaceae, and *Pseudomonas aeruginosa*).[11,14]
- Sickle cell patients (*Salmonella* spp.).[1,2,7]
- Individuals with prosthetic implants (coagulase-negative staphylococci).[7]

- Neonates (*E. coli* or group B streptococci).[2]
- Patients with pressure sores (polymicrobial).[2,7]

Regardless of patient-specific risk factors all patients with deep or extensive wounds, particularly those that are nonhealing should be evaluated for underlying osteomyelitis.[11,14]

PATHOPHYSIOLOGY

Both microbial and patient-specific factors are important determinants in the development of osteomyelitis.[1] Healthy bone tissue is normally resistant to infection but may become susceptible under certain conditions.[1,2] Bone can become infected: (a) via the presence of bacteria in the bloodstream (hematogenous), (b) by direct inoculation from trauma or surgery, and (c) by spread from an adjacent site (eg, soft-tissue infection) (contiguous).[1] The latter is particularly problematic in patients with implantable devices (eg, hip replacement), vascular insufficiency, and chronic skin ulcers.[1,11] LO 2

Staphylococcus species possess bacterial adhesins, which promote their attachment to tissues and prosthetic material.[1] Microbial adherence to bone elicits an inflammatory response.[1] The subsequent release of leukocytes and cytokines leads to local edema and **ischemia** facilitating bone necrosis.[1] Pieces of dead bone may become separated, forming **sequestra**.[1] The presence of sequestra is often indicative of chronic disease. These areas typically cannot be penetrated by antimicrobials or phagocytic cells due to poor blood supply and thus require surgical intervention to eradicate the bacterial **nidus**.[1,11] LO 2

CLINICAL PRESENTATION AND DIAGNOSIS

General

The clinical presentations of osteomyelitis may vary depending on route and duration of infection, as well as patient-specific factors such as infection site, age, and comorbidities.[1–4,7,11,14]

KEY CONCEPT Bone biopsy is the gold standard for confirmatory diagnosis of osteomyelitis. A bone biopsy allows for isolation of microorganism(s) from culture in addition to the presence of inflammatory cells and osteonecrosis on histologic exam.[1,2,11–14] Due to the invasive nature of the bone biopsy, the diagnosis of osteomyelitis is often based on clinical findings, laboratory tests, and imaging studies.[1,12,13]

KEY CONCEPT Typical signs and symptoms of osteomyelitis include local pain and tenderness over the affected bone, as well as inflammation, erythema, edema, and decreased range of motion.[1,3,4,6,9] Patients with acute hematogenous osteomyelitis may also present with systemic symptoms such as fever, chills, and/or malaise.[1,3,4,9] A cardinal sign of chronic osteomyelitis is the formation of a sinus tract (a channel from the infected site to the skin) with purulent drainage.[1] LO 3

Laboratory Tests

LO 4

Though no single noninvasive laboratory test is currently available for the diagnosis of osteomyelitis, several nonspecific tests are commonly used to aid in the diagnosis and to monitor response to therapy.

Nonspecific inflammatory markers for infection include:[1,2,4–6]

- White blood cell (WBC) count
- Erythrocyte sedimentation rate (ESR)
- C-reactive protein (CRP)
- Procalcitonin

WBC, ESR, and CRP are often elevated, but may also be within normal limits. An elevated WBC is mostly seen in patients with acute osteomyelitis.[1,3,6,9] CRP rises faster than ESR during early stages of infection and also returns to normal levels more quickly than ESR. This makes CRP a more useful tool for both diagnosis and monitoring of therapeutic response.[4–6] Similar to CRP, procalcitonin may be useful for both diagnosis and monitoring of therapeutic response; however, it is often more expensive and may not be as readily available.[4]

Microbiologic Evaluation

LO 4

Isolation of a causative pathogen from bone biopsy samples is essential for definitive antimicrobial therapy.[1–3,5,7,11,12] If bone biopsy cannot be performed, quality specimens (eg, two consecutive samples with bone contact [deep samples] in patients with contiguous osteomyelitis[12,15] or blood cultures in patients with acute hematogenous osteomyelitis)[1,3,5] may assist in pathogen identification. Superficial swabs often represent colonization rather than infecting organism(s) and thus have little value in selecting therapy.[1,7,12,14]

Imaging Studies

LO 4

Various imaging studies are used to assist in the diagnosis of osteomyelitis.[1,3,12,14,16,17]

- Magnetic resonance imaging (MRI) is considered the gold standard imaging modality for diagnosing of osteomyelitis.[1,3,4,11,13,14,16,17] Advantages include early detection (3–5 days after onset of symptoms), no radiation exposure, and high resolution.[1,6,16,17] Disadvantages include expense, inconvenience to patients (long examination time), movement artifacts, and the limitations to scanning patients with pacemakers and other implantable metal devices.[3,17]
- Plain film radiographs (x-rays) are the initial imaging study of choice for skeletal infections.[1,5,6,12,16] Although changes in soft tissue may appear within 3 days of infection, bone lesions may not be visible for 10 to 21 days.[1,4,6,11,12,16] Advantages of radiographs are accessibility, cost, low radiation exposure, and they are easily repeatable.[5,16] A disadvantage is the inability to detect early bone infections.[1,3,4,6,11,16]
- Computed tomography (CT) scans have high resolution and reproducibility.[17] CT scans have reduced sensitivity compared to MRI and should not be routinely used to diagnose osteomyelitis.[1,5,16] Advantages are that it is useful for the identification of sequestra, and it is less expensive than MRI.[3,16,17] Disadvantages include patient exposure to radiation and inability to use contrast medium to enhance images in patients with impaired renal function or previous allergic reactions.[3,4,17]
- Radionuclide imaging is also used for the early diagnosis of bone infections.[16] The most widely used nuclear medicine test is the three-phase bone scan.[16,17] An advantage is early detection within 24 to 48 hours after onset of symptoms.[5,6,16] Disadvantages include low specificity (increased risk of false positives) in patients with recent trauma, surgery, orthopedic prosthesis, diabetes, and ischemia, and high radiation dose required.[1,16] Using a labeled WBC scan in combination with the three-phase bone scan can increase sensitivity and specificity.[14,16]

TREATMENT

KEY CONCEPT The treatment goals for osteomyelitis are to eradicate the infection and prevent recurrence.[6–8,14,18]

Patient Encounter Part 1

A 42-year-old man limps into the emergency department complaining of pain and swelling in his left lower leg. He states that he also has a fever and feels tired. After questioning him, you discover that he was discharged from the hospital approximately 1 week ago following surgery for an open fracture of his left tibia. He had undergone debridement and irrigation, followed by internal fixation and treatment with IV vancomycin. He was discharged home on oral ciprofloxacin due to a history of reported penicillin allergy. On physical examination, the area above the fracture is red and swollen (erythematous and inflamed).

What information is suggestive of osteomyelitis?

What risk factors, if any, does he have for osteomyelitis?

General Approach to Treatment

KEY CONCEPT Antimicrobial therapy alone is the mainstay of treatment for acute osteomyelitis.[3–5,7] In comparison, treatment for chronic osteomyelitis typically requires a combination of antimicrobial therapy and surgical intervention.[7,11,14] If the patient is not a candidate for surgical intervention, prolonged antimicrobial therapy is generally necessary.[11–14]

▶ *Nonpharmacologic Therapy*

LO 9

In addition to medical and surgical management, nonpharmacologic interventions for health promotion such as smoking cessation, weight-control, and good nutrition should be emphasized to the patient. Additionally, patients with diabetes should be counseled regarding the importance of frequent blood glucose monitoring and control, routine care and self-examination of lower extremities, and aggressive wound care.[14] Patients with chronic immobility should be counseled on skin care and techniques to prevent the development of pressure ulcers.[7]

▶ *Pharmacologic Therapy*

KEY CONCEPT Empiric antimicrobial therapy should target common pathogen(s) based on patient-specific risk factors and route of infection.[6] Empiric antimicrobial coverage against *S. aureus*, including MRSA, should be considered for all classifications of osteomyelitis.[1,2,6,7,19,20] In addition to MRSA coverage, patients with contiguous osteomyelitis with vascular insufficiency (eg, diabetic) should also receive empiric coverage for Enterobacteriaceae, *P. aeruginosa,* and anaerobes.[11,14] Specific recommendations may vary based on factors such as patient allergies, potential for harboring resistant organisms, institution formulary, and cost considerations.[2,3,11]

LO 5

Patient Encounter Part 2

The medical team suspected osteomyelitis and ordered laboratory tests and imaging studies and consulted orthopedic surgery service.

How would you classify the infection in this patient?

What laboratory test(s) should be ordered for this patient?

What imaging study(s) should be ordered for this patient?

LO 6

Antimicrobial therapy should be guided by culture and susceptibility data of appropriately collected specimens when available (Table 81–1).[4,6,11,14] If MRSA is isolated, vancomycin is considered first-line therapy with desired troughs between 15 and 20 mcg/mL. However, if the minimum inhibitory concentration is greater than 2 mcg/mL (2 mg/L), alternative agents should be considered.[10,21,22] Alternative agents include daptomycin, linezolid, trimethoprim-sulfamethoxazole in combination with oral rifampin, or clindamycin.[21] Other MRSA active agents (tigecycline, telavancin, ceftaroline, dalbavancin, tedizolid, oritavancin) lack robust clinical data to support their routine use in osteomyelitis.[10,23] Clindamycin is commonly used in pediatric patients.[3,4,8,21] However, microbiology laboratories must screen with a disk diffusion test (D-test) for inducible resistance via the macrolide-lincosamide-streptogramin gene, as clindamycin failures have been associated with infections caused by isolates that are D-test positive.[3,24] If methicillin-sensitive *S. aureus* (MSSA) is isolated and the patient has no β-lactam allergy, therapy should be changed to nafcillin/oxacillin or cefazolin.[1,2,5–7]

In comparison to acute hematogenous osteomyelitis, chronic osteomyelitis is associated with higher failure rates, largely due to the presence of necrotic bone.[1,8,14,25] These patients typically require surgical intervention to remove the necrotic bone and tissue, and if applicable, to replace infected hardware.[7] Comorbidities such as vascular insufficiency can further contribute to poor treatment outcomes seen with chronic osteomyelitis.[1,7] Due to the high failure rates, treatment in this patient population may require prolonged courses of therapy, with the primary goal of preventing amputation of infected area(s).[1,11,14]

KEY CONCEPT Treatment is initiated with IV antimicrobials in the inpatient or outpatient setting to optimize drug concentrations in bone.[7,14,16] Following initial IV therapy, a switch to oral antibiotics may be considered in patients with good clinical response, strict adherence, and reliable outpatient follow-up.[3,4,6,8,11,14,21] Ideally, oral agents should possess characteristics such as high bioavailability, good bone penetration, and long half-life (eg, extended dosing interval).[1,3,5–7,10,11,21,25] Commonly used oral antimicrobials include fluoroquinolones, clindamycin, linezolid, and trimethoprim-sulfamethoxazole.[1,6,7,19,21] Additionally, oral rifampin may be used in combination with another antibiotic in patients with osteomyelitis associated with prosthetic material or as part of step-down therapy for MRSA osteomyelitis in combination with trimethoprim-sulfamethoxazole.[1,7,11,21,25] For chronic osteomyelitis, some clinicians recommend placement of antibiotic impregnated beads or cement.[3,7,11,14] This enables antibiotics such as aminoglycosides and vancomycin to be delivered in high concentrations at the site of infection.[3,7]

KEY CONCEPT The duration of treatment is typically 4 to 8 weeks for acute and chronic osteomyelitis.[1–5,8,14,21] Shorter regimens (3 weeks) are often recommended for uncomplicated acute hematogenous infections due to *S. aureus* in children greater than 3 months of age.[4,6,8] Infectious Diseases Society of America (IDSA) MRSA guidelines recommend a minimum of 8 weeks for treatment of MRSA osteomyelitis in adults.[21] Suppressive therapy (> 3 months) may be necessary for certain populations such as patients with vascular insufficiency or patients with recalcitrant infections that do not respond to 4 to 8 weeks of therapy.[1,5,11,14,21]

Antimicrobial Stewardship Implications in the Management of Osteomyelitis

Stewardship programs have become increasingly common in an attempt to ensure appropriate antimicrobial use as well

Table 81–1

Pathogen-Targeted Antimicrobial Therapy and Dosing Recommendations in Adults and Pediatrics

Microorganism	Antimicrobial Agent	Adult Dose	Pediatric Dose[a]
S. aureus			
MRSA	Vancomycin[b]	15–20 mg/kg IV every 8–12 hours	15 mg/kg IV every 6 hours
	Daptomycin[b]	6 mg/kg IV every 24 hours	6–10 mg/kg IV every 24 hours
	Linezolid	600 mg IV/oral every 12 hours	10 mg/kg IV/oral every 8 hours (< 12 years old)
	Clindamycin[c]	600 mg IV/oral every 8 hours	10–13 mg/kg/dose IV/oral every 6–8 hours
	Trimethoprim-sulfamethoxazole[b] (+ rifampin[c] 600 mg oral daily)	3.5–4.0 mg/kg of trimethoprim component IV/oral every 8–12 hours (trimethoprim-sulfamethoxazole single strength tablet is 80 mg/400 mg; double strength tablet is 160 mg/800 mg)	—
MSSA	Nafcillin[d]/oxacillin[b]	1–2 g IV every 4–6 hours	100–200 mg/kg/day IV in divided doses every 4–6 hours
	Cefazolin[b]	1–2 g IV every 6–8 hours	50–100 mg/kg/day IV in divided doses every 6–8 hours
***Enterococcus* spp.**			
Ampicillin-sensitive	Ampicillin[b]	2 g IV every 4–6 hours	100–400 mg/kg/day IV in divided doses every 6 hours
Ampicillin-resistant Vancomycin-resistant	Vancomycin[b]	15–20 mg/kg IV every 8–12 hours	15 mg/kg IV every 6 hours
	Daptomycin[b]	6 mg/kg IV every 24 hours	—
	Linezolid	600 mg IV/oral every 12 hours	10 mg/kg IV/oral every 8 hours (< 12 years old)
***Streptococcus* spp.**	Penicillin G[b]	2–4 million units IV every 4–6 hours	250,000–400,000 units/kg/day IV in divided doses every 4–6 hours
	Ceftriaxone[d]	1–2 g IV every 24 hours	50–100 mg/kg/day IV in divided dose every 12–24 hours
P. aeruginosa			
	Doripenem[b]	500 mg IV every 8 hours	—
	Imipenem/cilastatin[b]	500 mg IV every 6 hours	25 mg/kg IV every 6 hours
	Meropenem[b]	1 g IV every 8 hours	10–20 mg/kg IV every 8 hours
	Ceftazidime[b]	2 g IV every 8 hours	50 mg/kg IV every 8 hours
	Cefepime[b]	2 g IV every 12 hours	50 mg/kg IV every 8–12 hours
	Piperacillin/tazobactam[b]	4.5 g IV every 6 hours	100 mg/kg IV piperacillin component every 8 hours
	Ciprofloxacin[b,e]	400 mg IV every 8–12 hours; 750 mg oral every 12 hours	—
	Levofloxacin[b,e]	750 mg IV/oral every 24 hours	—
Enterobacteriaceae (in addition to antipseudomonal agents listed above)	Ceftriaxone[d]	1–2 g IV every 24 hours	50–100 mg/kg/day IV in divided doses every 12–24 hours
	Cefotaxime[b,d]	1–2 g IV every 8 hours	50–200 mg/kg/day IV in divided doses every 6–8 hours
	Ertapenem[b]	1 g IV every 24 hours	—
	Moxifloxacin[c,e]	400 mg IV/oral every 24 hours	—
Anaerobes[f]	Clindamycin[c]	600–900 mg IV every 8 hours; 300–450 mg oral every 6–8 hours	25–40 mg/kg/day IV in divided doses every 6–8 hours
	Metronidazole[b,c]	500 mg IV/oral every 6–8 hours	30 mg/kg/day IV/oral in divided doses every 6–8 hours

[a]Refer to specialized pediatric reference for maximum neonatal and pediatric dosing recommendations.

[b]Dosage adjustment necessary in renal dysfunction.

[c]Dosage adjustment necessary in severe hepatic dysfunction.

[d]Dosage adjustment necessary in patients with concomitant renal and hepatic dysfunction.

[e]Fluoroquinolones: Not approved by the US FDA for use in children except for anthrax (ciprofloxacin, levofloxacin) and complicated UTI and pyelonephritis (ciprofloxacin).

[f]May consider β-lactam/β-lactamase inhibitor or carbapenem for broad-spectrum activity including anaerobes.

Data from Refs. 1, 3, 4, 7, 8, 10, 11, 19, and 21–26.

LO 8 as to combat emerging resistance. Patients with osteomyelitis are typically subject to prolonged durations of therapy and thus much of the stewardship focus should be on appropriate de-escalation of empiric therapy and duration without sacrificing successful outcomes. As mentioned above, compliant patients with an identified organism may be switched to oral therapy and those who require IV therapy should receive an agent with the narrowest spectrum. Stewardship opportunities may arise throughout the treatment course and thus opportunities to optimize patient care should be continually evaluated.

OUTCOME EVALUATION

LO 7 Therapeutic success is measured by the extent to which the care plan (a) resolves signs and symptoms, (b) eradicates the microorganism(s), (c) prevents relapses, and (d) prevents complications such as amputation.[8,11,14] Patients should be evaluated for resolution of clinical signs and symptoms and normalization of laboratory tests (WBC, CRP, ESR, procalcitonin, and cultures).[3–6,8,10,14] Improvement in clinical manifestations may be seen within 2 to 4 days of initiation of IV antimicrobial therapy in patients with acute osteomyelitis.[4,8] A reduction in CRP should be seen within 1 week of therapy and should be monitored weekly throughout therapy for a continued downward trend.[3,4,6] ESR can also be monitored weekly, although normalization will be slower than for CRP.[3,6] Patients should also be monitored for antimicrobial tolerability and toxicity[2] (Table 81–2). If poor response is noted, the following should be evaluated: (a) patient adherence, (b) significant drug–drug or drug–food interactions, (c) appropriate dosage to achieve therapeutic concentrations, (d) development of antimicrobial resistance necessitating a change in the treatment regimen, (e) need for additional imaging studies, and (f) diagnostic reevaluation.[8,14] Treatment is considered successful if all clinical signs and symptoms are resolved and

Patient Encounter Part 3: The Medical History, Physical Examination, and Diagnostic Tests

PMH: Type 2 diabetes mellitus, dyslipidemia, depression/generalized anxiety disorder

SH: Tobacco smoker (one pack per day for 10 years), two to three cans of beer daily. Employed as mechanic

Allergies: Penicillins (hives)

Meds: Ciprofloxacin 500 mg orally two times a day; rosuvastatin 20 mg orally at bedtime; glargine 10 units subcutaneously at bedtime; fluoxetine 20 mg orally daily; OTC ibuprofen 200 mg orally every 4 hours

PE:

Gen: Moderate distress with pain and tenderness in lower left leg; limps

Skin: Erythema and inflammation

VS: BP 150/70 mm Hg, P 95 beats/min, RR 20 breaths/min, T 38.4°C (101.2°F), Ht 5′ 7″ (170 cm), Wt 73 kg (161 lb)

Labs: WBC 16.4 × 10^3/mm^3 (16.4 × 10^9/L), hemoglobin 13.0 g/dL (130g/L; 8.07 mmol/L), hematocrit 37.0% (0.37), platelets 220 × 10^3/uL (220 × 10^9/L), BUN 23 mg/dL (8.2 mmol/L), serum creatinine (Scr) 1.3 mg/dL (115 µmol/L), total bilirubin 1.1 mg/dL (18.8 µmol/L), alkaline phosphatase 82 U/L (1.37 µkat/L), AST 28U/L (0.47 µkat/L), ALT 13 U/L (0.22 µkat/L), albumin 3.7 g/dL (37 g/L), fasting blood glucose 210 mg/dL (11.6 mmol/L), ESR 110 mm/h, CRP 24 mg/dL (240 mg/L)

Microbiology: Culture from bone aspirate is pending

Based on the information presented, create a care plan for this patient's osteomyelitis. Your plan should include: (a) goals of therapy, (b) patient-specific detailed therapeutic plan, (c) nonpharmacologic interventions, and (d) follow-up plan to determine whether outcomes have been achieved.

Table 81–2

Monitoring Considerations for Select Antistaphylococcal Agents

Antimicrobial	Monitoring Considerations
Daptomycin	Muscle pain or weakness particularly of the distal extremities; monitor CPK weekly with more frequent monitoring in patients with renal insufficiency or receiving (or recent discontinuation) of HMG-CoA reductase inhibitors; consider temporarily discontinuing HMG-CoA reductase inhibitors while patient receiving daptomycin. Peripheral neuropathy: Monitor for neuropathy. Decreased efficacy was observed in patients with moderate baseline renal impairment.
